1.7 SysConfig and PinMUX Tool.....	75
<b>2 C28x Processor</b> .....	76
2.1 Introduction.....	77
2.2 C28X Related Collateral.....	77
2.3 Features.....	77
2.4 Floating-Point Unit.....	78
2.5 Trigonometric Math Unit (TMU).....	78
2.6 Viterbi, Complex Math, and CRC Unit (VCU).....	79
<b>3 System Control and Interrupts</b> .....	81
3.1 Introduction.....	82
3.1.1 SYSCTL Related Collateral.....	82
3.2 Power Management.....	83
3.2.1 Internal 1.2-V Switching Regulator (DC-DC).....	83
3.3 Device Identification and Configuration Registers.....	83
3.4 Resets.....	84
3.4.1 Reset Sources.....	84
3.4.2 External Reset ( $\overline{XRS}$ ).....	84
3.4.3 Power-On Reset (POR).....	85
3.4.4 Debugger Reset (SYSRS).....	85
3.4.5 Watchdog Reset (WDRS).....	85
3.4.6 NMI Watchdog Reset ( $\overline{NMIWDRS}$ ).....	85
3.4.7 DCSM Safe Code Copy Reset ( $\overline{SCCRESET}$ ).....	85
3.5 Peripheral Interrupts.....	86
3.5.1 Interrupt Concepts.....	86
3.5.2 Interrupt Architecture.....	86
3.5.3 Interrupt Entry Sequence.....	87
3.5.4 Configuring and Using Interrupts.....	88
3.5.5 PIE Channel Mapping.....	90
3.5.6 Vector Tables.....	92
3.6 Exceptions and Non-Maskable Interrupts.....	98
3.6.1 Configuring and Using NMIs.....	98
3.6.2 Emulation Considerations.....	98
3.6.3 NMI Sources.....	98
3.6.4 Illegal Instruction Trap (ITRAP).....	99
3.6.5 Error Pin.....	99
3.7 Clocking.....	100

3.7.1 Clock Sources.....	101
3.7.2 Derived Clocks.....	103
3.7.3 Device Clock Domains.....	104
3.7.4 XCLKOUT.....	105
3.7.5 Clock Connectivity.....	105
3.7.6 Clock Source and PLL Setup.....	106
3.7.7 Using an External Crystal or Resonator.....	107
3.7.8 Using an External Oscillator.....	107
3.7.9 Choosing PLL Settings.....	107
3.7.10 System Clock Setup.....	108
3.7.11 Clock Configuration Examples.....	108
3.7.12 Missing Clock Detection.....	109
3.8 32-Bit CPU Timers 0/1/2.....	110
3.9 Watchdog Timer.....	111
3.9.1 Servicing the Watchdog Timer.....	112
3.9.2 Minimum Window Check.....	112
3.9.3 Watchdog Reset or Watchdog Interrupt Mode.....	113
3.9.4 Watchdog Operation in Low-Power Modes.....	113
3.9.5 Emulation Considerations.....	113
3.10 Low-Power Modes.....	114
3.10.1 IDLE.....	114
3.10.2 Guidelines on Software Emulation of STANDBY Mode.....	114
3.10.3 HALT.....	115
3.10.4 Flash Power-down Considerations.....	116
3.11 Memory Controller Module.....	117
3.11.1 Functional Description.....	117
3.12 Flash and OTP Memory.....	124
3.12.1 Features.....	124
3.12.2 Flash Tools.....	124
3.12.3 Default Flash Configuration.....	125
3.12.4 Flash Bank, OTP and Pump.....	125
3.12.5 Flash Module Controller (FMC).....	125
3.12.6 Flash and OTP and Wakeup Power-Down Modes.....	126
3.12.7 Flash and OTP Performance.....	127
3.12.8 Flash Access Interface.....	128
3.12.9 Erase/Program Flash.....	130
3.12.10 Error Correction Code (ECC) Protection.....	131
3.12.11 Reserved Locations Within Flash and OTP.....	135
3.12.12 Procedure to Change the Flash Control Registers.....	135
3.12.13 Simple Procedure to Modify an Application from RAM Configuration to Flash Configuration.....	135
3.13 Dual Code Security Module (DCSM).....	136
3.13.1 Functional Description.....	136
3.13.2 C Code Example to Get Zone Select Block Addr for Zone1 in BANK0.....	144
3.13.3 Flash and OTP Erase/Program.....	144
3.13.4 Safe Copy Code.....	144
3.13.5 SafeCRC.....	145
3.13.6 CSM Impact on Other On-Chip Resources.....	145
3.13.7 Incorporating Code Security in User Applications.....	147
3.14 System Control Register Configuration Restrictions.....	152
3.15 System Control Registers.....	153
3.15.1 System Control Base Address Table.....	153
3.15.2 CPUTIMER_REGS Registers.....	154
3.15.3 PIE_CTRL_REGS Registers.....	161
3.15.4 WD_REGS Registers.....	213
3.15.5 NMI_INTRUPT_REGS Registers.....	220
3.15.6 XINT_REGS Registers.....	229
3.15.7 DMA_CLA_SRC_SEL_REGS Registers.....	238
3.15.8 DEV_CFG_REGS Registers.....	245
3.15.9 CLK_CFG_REGS Registers.....	273
3.15.10 CPU_SYS_REGS Registers.....	289
3.15.11 PERIPH_AC_REGS Registers.....	326

3.15.12 DCSM_BANK0_Z1_REGS Registers.....	380
3.15.13 DCSM_BANK0_Z2_REGS Registers.....	404
3.15.14 DCSM_COMMON_REGS Registers.....	424
3.15.15 DCSM_BANK1_Z1_REGS Registers.....	437
3.15.16 DCSM_BANK1_Z2_REGS Registers.....	447
3.15.17 MEM_CFG_REGS Registers.....	457
3.15.18 ACCESS_PROTECTION_REGS Registers.....	503
3.15.19 MEMORY_ERROR_REGS Registers.....	526
3.15.20 FLASH_CTRL_REGS Registers.....	543
3.15.21 FLASH_ECC_REGS Registers.....	553
3.15.22 UID_REGS Registers.....	576
3.15.23 DCSM_BANK0_Z1_OTP Registers.....	585
3.15.24 DCSM_BANK0_Z2_OTP Registers.....	596
3.15.25 DCSM_BANK1_Z1_OTP Registers.....	603
3.15.26 DCSM_BANK1_Z2_OTP Registers.....	607
3.15.27 Register to Driverlib Function Mapping.....	611
<b>4 ROM Code and Peripheral Booting.....</b>	<b>630</b>
4.1 Introduction.....	631
4.2 Device Boot Sequence.....	631
4.3 Device Boot Modes.....	632
4.3.1 Configuring Alternate Boot Mode Pins.....	633
4.3.2 Configuring Alternate Boot Mode Options.....	634
4.3.3 Boot Mode Example Use Cases.....	634
4.4 Device Boot Flow Diagrams.....	635
4.4.1 Emulation Boot Flow Diagram.....	637
4.4.2 Standalone Boot Flow Diagram.....	638
4.5 Device Reset and Exception Handling.....	639
4.5.1 Reset Causes and Handling.....	639
4.5.2 Exceptions and Interrupts Handling.....	639
4.6 Boot ROM Description.....	640
4.6.1 Boot ROM Registers.....	640
4.6.2 Boot ROM User OTP.....	640
4.6.3 Entry Points.....	641
4.6.4 Wait Points.....	641
4.6.5 Memory Maps.....	642
4.6.6 ROM Tables.....	644
4.6.7 Boot Modes.....	646
4.6.8 Boot Data Stream Structure.....	659
4.6.9 GPIO Assignments.....	661
4.6.10 Secure ROM Function APIs.....	664
4.6.11 DCSM Usage.....	665
4.6.12 Clock Initialization.....	665
4.6.13 Boot Status Information.....	666
4.6.14 ROM Version.....	667
4.7 The C2000 Hex Utility.....	667
Example 4-2. HEX2000.exe Command Syntax.....	668
<b>5 Control Law Accelerator (CLA).....</b>	<b>669</b>
5.1 Introduction.....	670
5.1.1 Features.....	670
5.1.2 CLA Related Collateral.....	670
5.1.3 Block Diagram.....	671
5.2 CLA Interface.....	672
5.2.1 CLA Memory.....	672
5.2.2 CLA Memory Bus.....	673
5.2.3 Shared Peripherals and EALLOW Protection.....	674
5.2.4 CLA Tasks and Interrupt Vectors.....	674
5.2.5 CLA Software Interrupt to CPU.....	678
5.3 CLA, DMA, and CPU Arbitration.....	678
5.3.1 CLA Message RAM.....	678
5.3.2 CLA Program Memory.....	679
5.3.3 CLA Data Memory.....	680

5.3.4 Peripheral Registers (ePWM, HRPWM, Comparator).....	680
5.4 CLA Configuration and Debug.....	681
5.4.1 Building a CLA Application.....	681
5.4.2 Typical CLA Initialization Sequence.....	681
5.4.3 Debugging CLA Code.....	682
5.4.4 CLA Illegal Opcode Behavior.....	684
5.4.5 Resetting the CLA.....	685
5.5 Pipeline.....	685
5.5.1 Pipeline Overview.....	685
5.5.2 CLA Pipeline Alignment.....	686
5.5.3 Parallel Instructions.....	691
5.5.4 CLA Task Execution Latency.....	691
5.6 Software.....	692
5.6.1 CLA Examples.....	692
5.7 Instruction Set.....	696
5.7.1 Instruction Descriptions.....	696
5.7.2 Addressing Modes and Encoding.....	697
5.7.3 Instructions.....	700
5.8 CLA Registers.....	830
5.8.1 CLA Base Address Table.....	830
5.8.2 CLA_ONLY_REGS Registers.....	831
5.8.3 CLA_SOFTINT_REGS Registers.....	840
5.8.4 CLA_REGS Registers.....	844
5.8.5 CLA Registers to Driverlib Functions.....	892
<b>6 Dual-Clock Comparator (DCC).....</b>	<b>895</b>
6.1 Introduction.....	896
6.1.1 Features.....	896
6.1.2 Block Diagram.....	896
6.2 Module Operation.....	897
6.2.1 Configuring DCC Counters.....	898
6.2.2 Single-Shot Measurement Mode.....	899
6.3 Interrupts.....	899
6.4 Software.....	900
6.4.1 DCC Examples.....	900
6.5 DCC Registers.....	902
6.5.1 DCC Base Address Table.....	902
6.5.2 DCC_REGS Registers.....	903
6.5.3 DCC Registers to Driverlib Functions.....	914
<b>7 CLA Program ROM CRC (CLAPROMCRC).....</b>	<b>916</b>
7.1 Overview.....	917
7.2 Functional Description.....	917
7.2.1 Start Address.....	917
7.2.2 Seed.....	917
7.2.3 Halt.....	918
7.2.4 Result and Comparison.....	918
7.3 Software.....	919
7.3.1 CLAPROMCRC Examples.....	919
7.4 CLAPROM Registers.....	919
7.4.1 CLA PROM CRC Base Address Table.....	919
7.4.2 CLA_PROM_CRC32_REGS Registers.....	920
7.4.3 CLAPROMCRC Registers to Driverlib Functions.....	931
<b>8 General-Purpose Input/Output (GPIO).....</b>	<b>933</b>
8.1 Introduction.....	934
8.1.1 GPIO Related Collateral.....	935
8.2 Configuration Overview.....	936
8.3 Digital Inputs on ADC Pins (AIOs).....	936
8.4 Digital General-Purpose I/O Control.....	937
8.5 Input Qualification.....	938
8.5.1 No Synchronization (Asynchronous Input).....	938
8.5.2 Synchronization to SYSCLKOUT Only.....	938
8.5.3 Qualification Using a Sampling Window.....	939

8.6 GPIO and Peripheral Muxing.....	942
8.6.1 GPIO Muxing.....	942
8.6.2 Peripheral Muxing.....	945
8.7 Internal Pullup Configuration Requirements.....	947
8.8 Software.....	948
8.8.1 GPIO Examples.....	948
8.8.2 LED Examples.....	949
8.9 GPIO Registers.....	949
8.9.1 GPIO Base Address Table.....	949
8.9.2 GPIO_CTRL_REGS Registers.....	950
8.9.3 GPIO_DATA_REGS Registers.....	1022
8.9.4 GPIO Registers to Driverlib Functions.....	1040
<b>9 Crossbar (X-BAR).....</b>	<b>1044</b>
9.1 Input X-BAR.....	1045
9.2 ePWM, CLB, and GPIO Output X-BAR.....	1048
9.2.1 ePWM X-BAR.....	1048
9.2.2 CLB X-BAR.....	1050
9.2.3 GPIO Output X-BAR.....	1053
9.2.4 X-BAR Flags.....	1055
9.3 XBAR Registers.....	1056
9.3.1 XBAR Base Address Table.....	1056
9.3.2 INPUT_XBAR_REGS Registers.....	1057
9.3.3 XBAR_REGS Registers.....	1076
9.3.4 EPWM_XBAR_REGS Registers.....	1108
9.3.5 CLB_XBAR_REGS Registers.....	1201
9.3.6 OUTPUT_XBAR_REGS Registers.....	1294
9.3.7 Register to Driverlib Function Mapping.....	1395
<b>10 Direct Memory Access (DMA).....</b>	<b>1401</b>
10.1 Introduction.....	1402
10.1.1 Features.....	1402
10.1.2 Block Diagram.....	1403
10.2 Architecture.....	1404
10.2.1 Peripheral Interrupt Event Trigger Sources.....	1404
10.2.2 DMA Bus.....	1408
10.3 Address Pointer and Transfer Control.....	1408
10.4 Pipeline Timing and Throughput.....	1414
10.5 CPU and CLA Arbitration.....	1415
10.6 Channel Priority.....	1416
10.6.1 Round-Robin Mode.....	1416
10.6.2 Channel 1 High-Priority Mode.....	1417
10.7 Overrun Detection Feature.....	1417
10.8 Software.....	1418
10.8.1 DMA Examples.....	1418
10.9 DMA Registers.....	1418
10.9.1 DMA Base Address Table.....	1418
10.9.2 DMA_REGS Registers.....	1419
10.9.3 DMA_CH_REGS Registers.....	1424
10.9.4 DMA_CLA_SRC_SEL_REGS Registers.....	1451
10.9.5 DMA Registers to Driverlib Functions.....	1457
<b>11 Embedded Real-time Analysis and Diagnostic (ERAD).....</b>	<b>1460</b>
11.1 Introduction.....	1461
11.1.1 ERAD Related Collateral.....	1461
11.2 Enhanced Bus Comparator Unit.....	1462
11.2.1 Enhanced Bus Comparator Unit Operations.....	1462
11.3 System Event Counter Unit.....	1463
11.3.1 System Event Counter Modes.....	1463
11.3.2 Reset on Event.....	1466
11.3.3 Operation Conditions.....	1466
11.4 ERAD Ownership, Initialization and Reset.....	1466
11.5 ERAD Programming Sequence.....	1467
11.5.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence.....	1467

11.5.2 Timer and Counter Programming Sequence.....	1468
11.6 Software.....	1469
11.6.1 ERAD Examples.....	1469
11.7 ERAD Registers.....	1477
11.7.1 ERAD Base Address Table.....	1477
11.7.2 ERAD_GLOBAL_REGS Registers.....	1478
11.7.3 ERAD_HWBP_REGS Registers.....	1487
11.7.4 ERAD_COUNTER_REGS Registers.....	1494
11.7.5 ERAD Registers to Driverlib Functions.....	1502
<b>12 Analog Subsystem.....</b>	<b>1504</b>
12.1 Introduction.....	1505
12.1.1 Features.....	1505
12.1.2 Block Diagram.....	1505
12.2 Optimizing Power-Up Time.....	1510
12.3 Digital Inputs on ADC Pins (AIOs).....	1510
12.4 Digital Inputs and Outputs on ADC Pins (AGPIOs).....	1510
12.5 Analog Pins and Internal Connections.....	1511
12.6 Analog Subsystem Registers.....	1514
12.6.1 Analog Subsystem Base Address Table.....	1514
12.6.2 ANALOG_SUBSYS_REGS Registers.....	1515
<b>13 Analog-to-Digital Converter (ADC).....</b>	<b>1532</b>
13.1 Introduction.....	1533
13.1.1 ADC Related Collateral.....	1533
13.1.2 Features.....	1534
13.1.3 Block Diagram.....	1535
13.2 ADC Configurability.....	1536
13.2.1 Clock Configuration.....	1536
13.2.2 Resolution.....	1536
13.2.3 Voltage Reference.....	1537
13.2.4 Signal Mode.....	1538
13.2.5 Expected Conversion Results.....	1538
13.2.6 Interpreting Conversion Results.....	1538
13.3 SOC Principle of Operation.....	1539
13.3.1 SOC Configuration.....	1540
13.3.2 Trigger Operation.....	1540
13.3.3 ADC Acquisition (Sample and Hold) Window.....	1540
13.3.4 ADC Input Models.....	1540
13.3.5 Channel Selection.....	1541
13.4 SOC Configuration Examples.....	1542
13.4.1 Single Conversion from ePWM Trigger.....	1542
13.4.2 Oversampled Conversion from ePWM Trigger.....	1542
13.4.3 Multiple Conversions from CPU Timer Trigger.....	1543
13.4.4 Software Triggering of SOCs.....	1544
13.5 ADC Conversion Priority.....	1544
13.6 Burst Mode.....	1547
13.6.1 Burst Mode Example.....	1547
13.6.2 Burst Mode Priority Example.....	1548
13.7 EOC and Interrupt Operation.....	1549
13.7.1 Interrupt Overflow.....	1550
13.7.2 Continue to Interrupt Mode.....	1550
13.7.3 Early Interrupt Configuration Mode.....	1550
13.8 Post-Processing Blocks.....	1551
13.8.1 PPB Offset Correction.....	1552
13.8.2 PPB Error Calculation.....	1552
13.8.3 PPB Limit Detection and Zero-Crossing Detection.....	1552
13.8.4 PPB Sample Delay Capture.....	1554
13.9 Opens/Shorts Detection Circuit (OSDETECT).....	1555
13.9.1 Implementation.....	1556
13.9.2 Detecting an Open Input Pin.....	1556
13.9.3 Detecting a Shorted Input Pin.....	1556
13.10 Power-Up Sequence.....	1557

13.11 ADC Calibration.....	1557
13.11.1 ADC Zero Offset Calibration.....	1557
13.12 ADC Timings.....	1558
13.12.1 ADC Timing Diagrams.....	1558
13.13 Additional Information.....	1561
13.13.1 Ensuring Synchronous Operation.....	1561
13.13.2 Choosing an Acquisition Window Duration.....	1564
13.13.3 Achieving Simultaneous Sampling.....	1566
13.13.4 Result Register Mapping.....	1566
13.13.5 Internal Temperature Sensor.....	1566
13.13.6 Designing an External Reference Circuit.....	1566
13.13.7 ADC-DAC Loopback Testing.....	1569
13.13.8 Internal Test Mode.....	1570
13.13.9 ADC Gain and Offset Calibration.....	1570
13.14 Software.....	1571
13.14.1 ADC Examples.....	1571
13.15 ADC Registers.....	1576
13.15.1 ADC Base Address Table.....	1576
13.15.2 ADC_RESULT_REGS Registers.....	1577
13.15.3 ADC_REGS Registers.....	1598
13.15.4 ADC Registers to Driverlib Functions.....	1711
<b>14 Programmable Gain Amplifier (PGA).....</b>	<b>1716</b>
14.1 Programmable Gain Amplifier (PGA) Overview.....	1717
14.1.1 Features.....	1717
14.1.2 Block Diagram.....	1717
14.2 Linear Output Range.....	1718
14.3 Gain Modes.....	1718
14.4 External Filtering.....	1718
14.5 Error Calibration.....	1719
14.5.1 Offset Error.....	1719
14.5.2 Gain Error.....	1720
14.6 Ground Routing.....	1720
14.7 Enabling and Disabling the PGA Clock.....	1721
14.8 Lock Register.....	1721
14.9 Examples.....	1721
14.9.1 Direct Amplifier.....	1721
14.9.2 RC Filter.....	1722
14.10 Analog Front End Integration.....	1722
14.10.1 ADC.....	1722
14.10.2 CMPSS.....	1723
14.10.3 Buffered DAC.....	1723
14.10.4 Alternate Functions.....	1724
14.11 Software.....	1725
14.11.1 PGA Examples.....	1725
14.12 PGA Registers.....	1726
14.12.1 PGA Base Address Table.....	1726
14.12.2 PGA_REGS Registers.....	1727
14.12.3 PGA Registers to Driverlib Functions.....	1734
<b>15 Buffered Digital-to-Analog Converter (DAC).....</b>	<b>1735</b>
15.1 Introduction.....	1736
15.1.1 DAC Related Collateral.....	1736
15.1.2 Features.....	1736
15.1.3 Block Diagram.....	1736
15.2 Using the DAC.....	1737
15.2.1 Initialization Sequence.....	1737
15.2.2 DAC Offset Adjustment.....	1738
15.2.3 EPWMSYNCPER Signal.....	1738
15.3 Lock Registers.....	1738
15.4 Software.....	1739
15.4.1 DAC Examples.....	1739
15.5 DAC Registers.....	1739

15.5.1 DAC Base Address Table.....	1739
15.5.2 DAC_REGS Registers.....	1740
15.5.3 DAC Registers to Driverlib Functions.....	1747
<b>16 Comparator Subsystem (CMPSS)</b> .....	<b>1749</b>
16.1 Introduction.....	1750
16.1.1 CMPSS Related Collateral.....	1750
16.1.2 Features.....	1750
16.1.3 Block Diagram.....	1751
16.2 Comparator.....	1751
16.3 Reference DAC.....	1752
16.4 Ramp Generator.....	1753
16.4.1 Ramp Generator Overview.....	1753
16.4.2 Ramp Generator Behavior.....	1754
16.4.3 Ramp Generator Behavior at Corner Cases.....	1755
16.5 Digital Filter.....	1756
16.5.1 Filter Initialization Sequence.....	1757
16.6 Using the CMPSS.....	1757
16.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals.....	1757
16.6.2 Synchronizer, Digital Filter, and Latch Delays.....	1757
16.6.3 Calibrating the CMPSS.....	1758
16.6.4 Enabling and Disabling the CMPSS Clock.....	1758
16.7 Software.....	1759
16.7.1 CMPSS Examples.....	1759
16.8 CMPSS Registers.....	1760
16.8.1 CMPSS Base Address Table.....	1760
16.8.2 CMPSS_REGS Registers.....	1761
16.8.3 CMPSS Registers to Driverlib Functions.....	1785
<b>17 Sigma Delta Filter Module (SDFM)</b> .....	<b>1788</b>
17.1 Introduction.....	1789
17.1.1 SDFM Related Collateral.....	1789
17.1.2 Features.....	1790
17.1.3 Block Diagram.....	1791
17.2 Configuring Device Pins.....	1793
17.3 Input Control Unit.....	1794
17.4 Sinc Filter.....	1795
17.4.1 Data Rate and Latency of the Sinc Filter.....	1797
17.5 Data (Primary) Filter Unit.....	1798
17.5.1 32-bit or 16-bit Data Filter Output Representation.....	1799
17.5.2 Data FIFO.....	1799
17.5.3 SDSYNC Event.....	1801
17.6 Comparator (Secondary) Filter Unit.....	1803
17.6.1 Higher Threshold (HLT) Comparators.....	1805
17.6.2 Lower Threshold (LLT) Comparators.....	1805
17.7 Theoretical SDFM Filter Output.....	1806
17.8 Interrupt Unit.....	1808
17.8.1 SDFM (SDyERR) Interrupt Sources.....	1808
17.8.2 Data Ready (DRINT) Interrupt Sources.....	1809
17.9 Software.....	1811
17.9.1 SDFM Examples.....	1811
17.10 SDFM Registers.....	1814
17.10.1 SDFM Base Address Table.....	1814
17.10.2 SDFM_REGS Registers.....	1815
17.10.3 SDFM Registers to Driverlib Functions.....	1872
<b>18 Enhanced Pulse Width Modulator (ePWM)</b> .....	<b>1877</b>
18.1 Introduction.....	1878
18.1.1 EPWM Related Collateral.....	1879
18.1.2 Submodule Overview.....	1880
18.2 Configuring Device Pins.....	1885
18.3 ePWM Modules Overview.....	1885
18.4 Time-Base (TB) Submodule.....	1887
18.4.1 Purpose of the Time-Base Submodule.....	1887

18.4.2 Controlling and Monitoring the Time-Base Submodule.....	1888
18.4.3 Calculating PWM Period and Frequency.....	1890
18.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....	1893
18.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules.....	1893
18.4.6 Time-Base Counter Modes and Timing Waveforms.....	1894
18.4.7 Global Load.....	1898
18.5 Counter-Compare (CC) Submodule.....	1900
18.5.1 Purpose of the Counter-Compare Submodule.....	1900
18.5.2 Controlling and Monitoring the Counter-Compare Submodule.....	1901
18.5.3 Operational Highlights for the Counter-Compare Submodule.....	1902
18.5.4 Count Mode Timing Waveforms.....	1903
18.6 Action-Qualifier (AQ) Submodule.....	1906
18.6.1 Purpose of the Action-Qualifier Submodule.....	1906
18.6.2 Action-Qualifier Submodule Control and Status Register Definitions.....	1907
18.6.3 Action-Qualifier Event Priority.....	1909
18.6.4 AQCTLA and AQCTLB Shadow Mode Operations.....	1910
18.6.5 Configuration Requirements for Common Waveforms.....	1912
18.7 Dead-Band Generator (DB) Submodule.....	1919
18.7.1 Purpose of the Dead-Band Submodule.....	1919
18.7.2 Dead-band Submodule Additional Operating Modes.....	1920
18.7.3 Operational Highlights for the Dead-Band Submodule.....	1922
18.8 PWM Chopper (PC) Submodule.....	1926
18.8.1 Purpose of the PWM Chopper Submodule.....	1926
18.8.2 Operational Highlights for the PWM Chopper Submodule.....	1926
18.8.3 Waveforms.....	1927
18.9 Trip-Zone (TZ) Submodule.....	1930
18.9.1 Purpose of the Trip-Zone Submodule.....	1930
18.9.2 Operational Highlights for the Trip-Zone Submodule.....	1931
18.9.3 Generating Trip Event Interrupts.....	1934
18.10 Event-Trigger (ET) Submodule.....	1936
18.10.1 Operational Overview of the ePWM Event-Trigger Submodule.....	1937
18.11 Digital Compare (DC) Submodule.....	1941
18.11.1 Purpose of the Digital Compare Submodule.....	1943
18.11.2 Enhanced Trip Action Using CMPSS.....	1943
18.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis.....	1943
18.11.4 Operation Highlights of the Digital Compare Submodule.....	1944
18.12 ePWM Crossbar (X-BAR).....	1951
18.13 Applications to Power Topologies.....	1953
18.13.1 Overview of Multiple Modules.....	1953
18.13.2 Key Configuration Capabilities.....	1954
18.13.3 Controlling Multiple Buck Converters With Independent Frequencies.....	1955
18.13.4 Controlling Multiple Buck Converters With Same Frequencies.....	1957
18.13.5 Controlling Multiple Half H-Bridge (HHB) Converters.....	1959
18.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM).....	1961
18.13.7 Practical Applications Using Phase Control Between PWM Modules.....	1963
18.13.8 Controlling a 3-Phase Interleaved DC/DC Converter.....	1964
18.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter.....	1967
18.13.10 Controlling a Peak Current Mode Controlled Buck Module.....	1969
18.13.11 Controlling H-Bridge LLC Resonant Converter.....	1970
18.14 Register Lock Protection.....	1971
18.15 High-Resolution Pulse Width Modulator (HRPWM).....	1972
18.15.1 Operational Description of HRPWM.....	1974
18.15.2 SFO Library Software - SFO_TI_Build_V8.lib.....	1995
18.16 Software.....	1998
18.16.1 EPWM Examples.....	1998
18.16.2 HRPWM Examples.....	2002
18.17 ePWM Registers.....	2004
18.17.1 ePWM Base Address Table.....	2004
18.17.2 EPWM_REGS Registers.....	2005
18.17.3 SYNC_SOC_REGS Registers.....	2127

## About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

## Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

## Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at <http://www.ti.com>. Additionally, the [TMS320C28x CPU and Instruction Set Reference Guide](#) and the [TMS320C28x Floating Point Unit and Instruction Set Reference Guide](#) must be used in conjunction with this TRM.

## Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

Chapter 1

# C2000™ Microcontrollers Software Support

---

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

1.1 Introduction.....	74
1.2 C2000Ware Structure.....	74
1.3 Documentation.....	74
1.4 Devices.....	74
1.5 Libraries.....	74
1.6 Code Composer Studio™ Integrated Development Environment (IDE).....	74
1.7 SysConfig and PinMUX Tool.....	75

## 1.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

## 1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in [Table 1-1](#).

**Table 1-1. C2000Ware Root Directories**

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

## 1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

## 1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: [www.ti.com/c2000](http://www.ti.com/c2000).

## 1.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

## 1.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: [www.ti.com/ccstudio](http://www.ti.com/ccstudio)

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

## 1.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: [dev.ti.com](https://dev.ti.com)

This chapter contains a short description of the C28x processor and extended instruction sets.

## 2.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

## 2.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

## 2.4 Floating-Point Unit

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 2-1](#).

**Table 2-1. TMU Supported Instructions**

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32 RaH,RbH	$a = b * 2\pi$	2/3
DIV2PIF32 RaH,RbH	$a = b / 2\pi$	2/3
DIVF32 RaH,RbH,RcH	$a = b/c$	5
SQRTF32 RaH,RbH	$a = \text{sqrt}(b)$	5
SINPUF32 RaH,RbH	$a = \sin(b*2\pi)$	4
COSPUF32 RaH,RbH	$a = \cos(b*2\pi)$	4
ATANPUF32 RaH,RbH	$a = \text{atan}(b)/2\pi$	4
QUADF32 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

No changes have been made to existing instructions, pipeline, or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out the operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.6 Viterbi, Complex Math, and CRC Unit (VCU)

The C28x device with VCU (C28x+VCU) processor extends the capabilities of the C28x fixed-point or floating-point CPU by adding registers and instructions to support the following algorithm types:

- **Viterbi Decoding**

Viterbi decoding is commonly used in baseband communications applications. The viterbi decode algorithm consists of three main parts: branch metric calculations, compare-select (viterbi butterfly), and a traceback operation. [Table 2-2](#) shows a summary of the VCU performance for each of these operations.

**Table 2-2. Viterbi Decode Performance**

Viterbi Operation	VCU Cycles
Branch Metric Calculation (code rate = 1/2)	1
Branch Metric Calculation (code rate = 1/3)	2p
Viterbi Butterfly (add-compare-select)	2 <sup>(1)</sup>
Traceback per Stage	3 <sup>(2)</sup>

(1) C28x CPU takes 15 cycles per butterfly.

(2) C28x CPU takes 22 cycles per stage.

- **Cyclic Redundancy Check (CRC)**

CRC algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCU can perform 8-, 16-, and 32-bit CRCs. For example, the VCU can compute the CRC for a block length of 10 bytes in 10 cycles. A CRC result register contains the current CRC which is updated whenever a CRC instruction is executed.

- **Complex Math**

Complex math is used in many applications; a few are:

- Fast Fourier transform (FFT)

The complex FFT is used in spread spectrum communications, as well as many signal processing algorithms.

- Complex filters

Complex filters improve data reliability, transmission distance, and power efficiency. The C28x+VCU can perform a complex I and Q multiply with coefficients (four multiplies) in a single cycle. In addition, the C28x+VCU can read/write the real and imaginary parts of 16-bit complex data to memory in a single cycle.

[Table 2-3](#) shows a summary of a few complex math operations enabled by the VCU.

**Table 2-3. Complex Math Performance**

Complex Math Operation	VCU Cycles	Notes
Add or Subtract	1	32 +/- 32 = 32-bit (Useful for filters)
Add or Subtract	1	16 +/- 32 = 15-bit (Useful for FFT)
Multiply	2p	16 x 16 = 32-bit
Multiply and Accumulate (MAC)	2p	32 + 32 = 32-bit, 16 x 16 = 32-bit
Repeat Multiply and Accumulate (MAC)	2p+N	Repeat MAC. Single cycle after the first operation.

Throughout this chapter the following notations are used:

- C28x refers to the C28x fixed-point CPU.
- C28x plus Floating-Point and C28x+FPU both refer to the C28x CPU with enhancements to support IEEE single-precision floating-point operations.
- C28x plus VCU and C28x+VCU both refer to the C28x CPU with enhancements to support viterbi decode, complex math and CRC.
- Some devices have both the FPU and the VCU. These are referred to as C28x+FPU+VCU.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## Chapter 3 System Control and Interrupts

The system-level functionality of this microcontroller configures the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

Further information about this device can be found in the following documents:

### 3.1 Introduction

System-level configuration is controlled by a group of submodules which are collectively referred to as the system control module. The system control module provides the following capabilities:

- System-level resets, including power-on and brownout resets
- Clock source selection and PLL configuration
- Missing clock detection
- Clock-gating low-power modes
- Peripheral interrupt handling
- Non-maskable interrupts for certain fault conditions
- Three 32-bit timers
- Windowed watchdog timer, which can generate an interrupt or a reset
- RAM initialization, write protection, and control
- Flash memory ECC, wait state, and cache configuration
- Dual-zone code security module

Some registers in the system are protected from spurious CPU writes by the EALLOW protection mechanism. This uses the special CPU instructions EALLOW and EDIS to enable and disable access to protected registers. The current protection state is given by the EALLOW bit in the CPU ST1 register, see [Table 3-1](#).

**Table 3-1. Access to EALLOW-Protected Registers**

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed	Allowed <sup>(1)</sup>	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden using the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio™ IDE interface.

Register protection is enabled by default at startup. While protected, all writes to protected registers by the CPU are ignored. Only CPU reads, JTAG reads, and JTAG writes are allowed. If protection is disabled by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

Writes to the clock configuration and peripheral clock enable registers can be disabled until the next reset by writing to special lock registers.

## 3.2 Power Management

### 3.2.1 Internal 1.2-V Switching Regulator (DC-DC)

The internal DC-DC regulator is disabled by default. To use this supply, the TMS320F28004x MCU core must power up initially with the internal LDO (VREG) and then transition to the internal DC-DC regulator by way of the application software. Note that VREGENZ low is required for both the internal LDO and the internal DC-DC to function. Perform the following procedure to enable the internal DC-DC regulator:

1. Set EALLOW bit.
2. Set the DCDCCTL.DCDCEN bit.
3. Wait for DCDCSTS.SWSEQDON to equal 0x1.
  - If this bit did not get set then the transition from VREG to DC-DC was not successful (check the hardware connections on the application board). See the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for schematic details.
4. Check if DCDCSTS.INNDETECT is equal to 0x1.
  - If this bit did not get set, then the inductor is not detected on the VSW pin.
5. If the inductor is detected, delay 80µs to allow the DC-DC regulator output to settle.
6. EDIS

---

#### Note

The procedure to enable the internal DC-DC regulator must be completed prior to all other initialization functions and application code; this is to make sure that the DC-DC switchover happens during low-current state.

---

The application can switch back to the internal LDO at any time. This can be accomplished by clearing the DCDCCTL.DCDCEN bit and waiting 80µs for the internal LDO to power up.

---

#### Note

Setting DCDCEN to 1 automatically places GPIO22 and GPIO23 in analog mode; hence, configuring AMSEL for GPIO22 and GPIO23 when turning on the DCDC is not required.

---

## 3.3 Device Identification and Configuration Registers

The device identification registers and configuration registers provide information on the part number, product family, revision, pin count, qualification status, and feature availability of the device.

All of the device information is part of the DEV\_CFG\_REGS space. The identification registers are PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID\_REGS. The 256 bits are separated into these registers:

- UID\_PSRAND0-5: 192 bits of pseudo-random data
- UID\_UNIQUE: 32-bit unique data, the value in this register will be unique across all devices with the same PARTIDH
- UID\_CHECKSUM: 32-bit fletcher checksum of UID\_PSRAND0-5 and UID\_UNIQUE and calculated as either little- or big-endian during factory testing

## 3.4 Resets

This section explains the types and effects of the different resets on this device.

### 3.4.1 Reset Sources

Table 3-2 summarizes the various reset signals and their effect on the device.

**Table 3-2. Reset Signals**

Reset Source	CPU Core Reset (C28x, FPU, VCU)	Peripherals Reset	JTAG / Debug Logic Reset	IOs	XRS Output
POR	Yes	Yes	Yes	Hi-Z	Yes
$\overline{\text{XRS}}$ Pin	Yes	Yes	No	Hi-Z	-
$\overline{\text{WDRS}}$	Yes	Yes	No	Hi-Z	Yes
$\overline{\text{NMIWDRS}}$	Yes	Yes	No	Hi-Z	Yes
$\overline{\text{SYSRS}}$ (Debugger Reset)	Yes	Yes	No	Hi-Z	No
$\overline{\text{SCCRESET}}$	Yes	Yes	No	Hi-Z	No

The resets can be divided into two groups:

- Chip-level resets ( $\overline{\text{XRS}}$ , POR, BOR,  $\overline{\text{WDRS}}$ , and  $\overline{\text{NMIWDRS}}$ ), which reset all or almost all of the device.
- System resets ( $\overline{\text{SYSRS}}$  and  $\overline{\text{SCCRESET}}$ ), which reset a large subset of the device but maintain some system-level configuration.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. The bits can only be cleared by a power-on reset (POR) or by writing ones to the RESCCLR register. Some are cleared by the boot ROM as part of the start-up routines.

Many peripheral modules have individual resets accessible through the SOFTPRESx registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After any reset, the CPU begins execution from address 0x3FFFC0 (the reset vector), which is in the boot ROM. After running the boot ROM code, the CPU typically branches to the start of the Flash memory at address 0x80000. For more information on controlling the boot process, see [Chapter 4](#).

#### Note

After a POR, the boot ROMs clear the M0, M1, LSx, GSx, and message RAMs to make sure they contain valid ECC or parity.

### 3.4.2 External Reset ( $\overline{\text{XRS}}$ )

The external reset ( $\overline{\text{XRS}}$ ) is the main chip-level reset for the device. It resets the CPU, all peripherals and I/O pin configurations, and most of the system control registers. There is a dedicated open-drain pin for XRS. This pin may be used to drive reset pins for other ICs in the application, and may itself be driven by an external source. The XRS is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register will be set whenever  $\overline{\text{XRS}}$  is driven low for any reason. This bit is then cleared by the boot ROM.

### 3.4.3 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The  $\overline{XRS}$  pin is held low for the duration of the POR. In most applications,  $\overline{XRS}$  is held low long enough to reset other system ICs, but some applications require a longer pulse. In these cases, the  $\overline{XRS}$  pin can be driven low externally to provide the correct reset duration. A POR resets everything that  $\overline{XRS}$  does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), and the X1 clock counter register (X1CNT). A POR also resets the debug logic used by the JTAG port.

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

### 3.4.4 Debugger Reset ( $\overline{SYSRS}$ )

During development, it is sometimes necessary to reset the CPU and its peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, the CPU has its own subsystem reset, which can be triggered by a debugger using Code Composer Studio™ IDE. This reset ( $\overline{SYSRS}$ ) resets the CPU, its peripherals, many system control registers (including its clock gating and LPM configuration), and all I/O pin configurations.

The  $\overline{SYSRS}$  does not reset the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.4.3](#)).

### 3.4.5 Watchdog Reset ( $\overline{WDRS}$ )

The device has a watchdog timer that can optionally trigger a reset if the watchdog timer is not serviced by the CPU within a user-specified amount of time. This watchdog reset ( $\overline{WDRS}$ ) produces an  $\overline{XRS}$  that lasts for 512 INTOSC1 cycles.

After a watchdog reset, the WDRSn bit in RESC is set. If both the XRSn and WDRSn bits are set in RESC, then the reset was initiated by the watchdog. If only the XRSn bit is set in RESC, then the watchdog is a reset from XRSn.

### 3.4.6 NMI Watchdog Reset ( $\overline{NMIWDRS}$ )

The device has a non-maskable interrupt (NMI) module that detects hardware errors in the system. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This NMI watchdog reset ( $\overline{NMIWDRS}$ ) produces an  $\overline{XRS}$  that lasts for 512 INTOSC1 cycles.

After an NMI watchdog reset, the NMIWDRSn bit in RESC is set.

### 3.4.7 DCSM Safe Code Copy Reset ( $\overline{SCCRESET}$ )

The device has a dual-zone code security module (DCSM) that blocks read access to certain areas of the Flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. This security reset ( $\overline{SCCRESET}$ ) is similar to a  $\overline{SYSRS}$ . However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

## 3.5 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.6](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

### 3.5.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

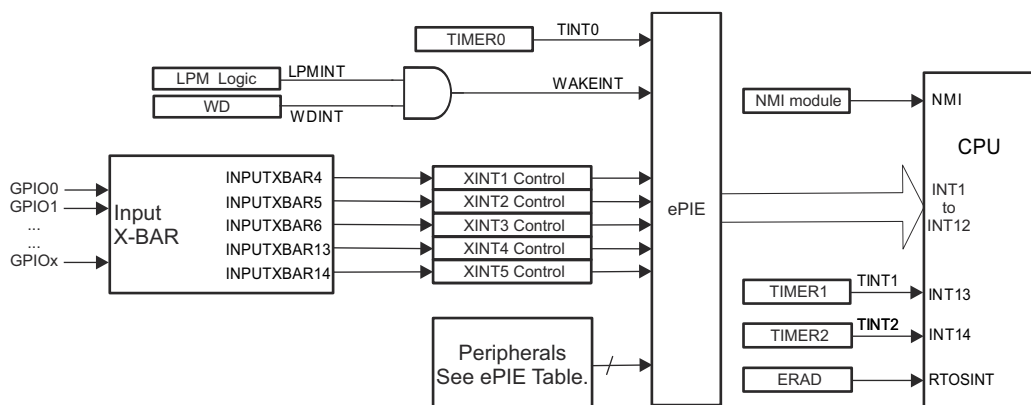

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

### 3.5.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line and also expands the vector table to allow each interrupt to have their own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has their own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

**Figure 3-1. Device Interrupt Architecture**

#### 3.5.2.1 Peripheral Stage

Each peripheral has its own unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral might use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt will be generated.

### 3.5.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, the CPU fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition does not happen unless software changes the state of the PIE while an interrupt is propagating. Section 3.5.4 contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

### 3.5.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of its interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC and CLRC instructions. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is set, the next instruction in the pipeline will run with interrupts disabled. No software delays are needed.

### 3.5.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), it triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves its context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories will add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

### 3.5.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

#### 3.5.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in [Section 3.5.6](#). Note that the vector table is EALLOW-protected.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be found in [Section 3.5.6](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

#### 3.5.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler, if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU will not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

### 3.5.4.3 Disabling Interrupts

To disable all interrupts, set the CPU global interrupt mask using DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction executes with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, the interrupt signal can reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation can cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR can only contain a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to the original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

### 3.5.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts using a software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at the "C28x Interrupt Nesting" page linked in [Section 3.1.1](#).

### 3.5.4.5 Vector Address Validity Check

There are two copies of the ePIE vector table. The primary vector table is located at addresses 0xD00 - 0xEFF. The redundant vector table is located at addresses 0x0100 0D00 to 0x0100 0EFF. A write to a primary vector address writes to both tables, while a write to a redundant vector address only writes to the redundant table. Both tables are read independently.

During a vector fetch, the ePIE performs a hardware comparison of both vector table outputs. If there is a mismatch between the two vector tables, the CPU branches to the address in the PIEVERRADDR register and the ePIE sends trip signals to the PWMs. If the PIEVERRADDR register value has not been set, the default boot ROM handler at address 0x003F FFBE is used.

### 3.5.5 PIE Channel Mapping

Table 3-3 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel is the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

**Note**

Cells marked "-" are Reserved

### 3.5.5.1 PIE Interrupt Priority

#### 3.5.5.1.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 will be serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 will be serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, in order for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 which is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU will service channel 1.2 and channel 1.3 will still be left pending. Using the steps from the Interrupt Entry Sequence ([Section 3.5.3](#)), channel 1.2 interrupt can happen as late as step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and it will still be serviced ahead of channel 1.3.

#### 3.5.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in their respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 will be serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence ([Section 3.5.3](#)).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence ([Section 3.5.3](#)).

1. As the CPU reaches step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 will be serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 will be serviced ahead of 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only guaranteed if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence ([Section 3.5.3](#)) is not executing.

### 3.5.6 Vector Tables

Table 3-4 shows the CPU interrupt vector table. The vectors for INT1 – INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table. All vectors are EALLOW-protected.

Table 3-5 shows the pie vector table.

**Table 3-4. CPU Interrupt Vectors**

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority

## 3.6 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

### 3.6.1 Configuring and Using NMIs

An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value in the NMIWDPRD register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register may also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

### 3.6.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended:	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode:	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

### 3.6.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

#### 3.6.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and an NMI is fired to the CPU. For more information on missing clock detection, see [Section 3.7.12](#).

#### 3.6.3.2 RAM Uncorrectable ECC Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read will trigger an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.11.1.7](#).

#### 3.6.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on Flash error detection, see [Section 3.12.10.2](#).

#### 3.6.3.4 Software-Forced Error

There is a special NMI source that can only be triggered by writing to the SWERR bit in the NMIFLGFRM register. Since the SWERR flag is never set by a real hardware fail, it can be used to implement a self-test mode for the NMI subsystem.

### 3.6.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, it generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has its own vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

---

#### Note

A RAM fetch access violation will trigger an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU will handle the ITRAP first.

---

### 3.6.5 Error Pin

A signal called ERRORSTS can be output to GPIO24, GPIO28, or GPIO29. This signal goes low when any bit is set in the NMI shadow flag register (NMISHDFLG). The signal can be used to alert an external system to a problem in the microcontroller. Since the state of ERRORSTS is based on the shadow flags, ERRORSTS remains low until the flags are cleared by the CPU or a power-on reset occurs.

All GPIO pins are inputs on power-up. If you want an error-state to be asserted during power-up or during a fault with the ERRORSTS signal, an external pull-down resistor can be used. A pull-up resistor can be used if you do not want an error-state asserted for the conditions mentioned.

### 3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-3 and Figure 3-4 provide an overview of the device's clocking system.

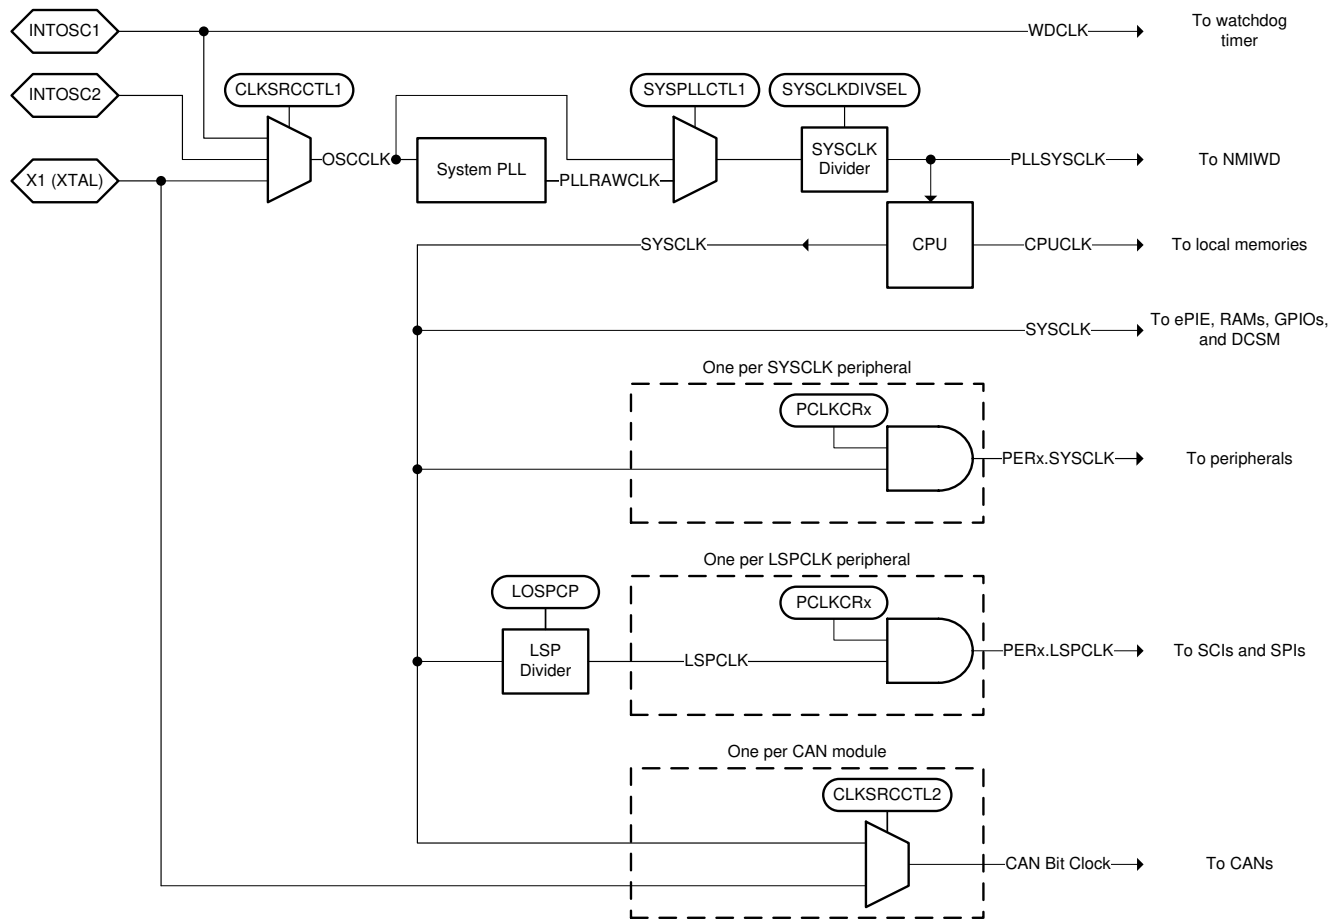

Figure 3-3. Clocking System

Figure 3-4. System PLL

### 3.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

#### 3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. INTOSC2 is used to run the boot ROM and can be used as the system clock source for the application. Note that the INTOSC2 frequency tolerance is too loose to meet the timing requirements for CAN. Use of the CAN modules requires an external oscillator. When INTOSC2 is used as the system clock source, GPIO18 (X2) is available for use as a GPIO. A 1k pull-down resistor must be connected to X1. GPIO18 has different electrical characteristics from the other GPIOs due to interaction with the oscillator circuit. For more information, see the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#).

**Figure 3-5. Using GPIO18 when INTOSC2 is the SYSCLK Source**

#### 3.7.1.2 Backup Internal Oscillator (INTOSC1)

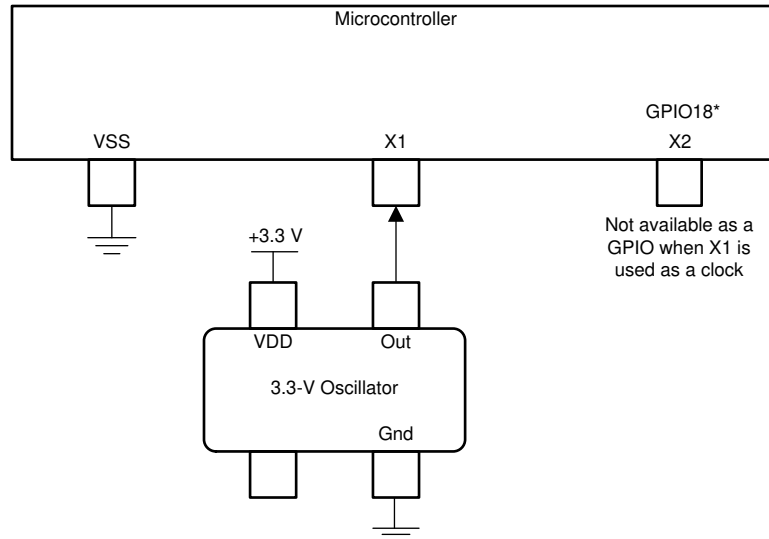

The device also includes a redundant on-chip 10MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 can also be manually selected as the system clock source for debug purposes.

#### 3.7.1.3 External Oscillator (XTAL)

The device supports an external clock source (XTAL), which can be used as the main system and CAN bit clock source. Frequency limits and timing requirements can be found in the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#). External clock sources use the X1 and X2/GPIO18 pins. After power-up, the X1 and X2 pin functionality can be enabled by following the procedure in [Section 3.7.6](#).

Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal is connected to X1, as shown in [Figure 3-6](#). X2/GPIO18 is not available as a GPIO.

**Figure 3-6. Single-ended 3.3V External Clock**

- An external crystal. The crystal is connected across X1 and X2 with the load capacitors connected to VSS as shown in [Figure 3-7](#).

**Figure 3-7. External Crystal**

- An external resonator. The resonator is connected across X1 and X2 with the ground connected to VSS as shown in Figure 3-8.

Figure 3-8. External Resonator

Table 3-6. ALT Modes

XTALCR Bit <sup>(1)</sup>		Operating Mode	GPIO18 Available on X2?
OSCOFF	SE		
0	0	Crystal Mode: Quartz crystal connected to X1/X2	No
0	1	Single-Ended Mode: External clock on X1	No
1	0	Oscillator off	Yes <sup>(2)</sup>
1	1	Single-Ended Mode: External clock on X1 <sup>(3)</sup>	No

(1) OSCOFF and SE determine the ALT mode of GPIO18.

(2) A 1K ohm pull-down is required on X1 when using GPIO18.

(3) There is an approximately 1K ohm pull-down on X1 in this mode, external single-ended clock must be able to drive this load.

### 3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using the PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

#### 3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

#### 3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at its maximum rated operating frequency, and in most applications will generate the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier. PLLRAWCLK is the output of the PLL's voltage-controlled oscillator (VCO). For configuration instructions, see Section 3.7.6.

### 3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

#### 3.7.3.1 System Clock (PLLSYSCLK)

The NMI watchdog timer has their own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

#### 3.7.3.2 CPU Clock (CPUCLK)

The CPU has a clock (CPUCLK) that is used to clock the CPU, the coprocessors, the private RAMs (M0 and M1), and the boot ROM and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or HALT mode.

#### 3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

The CPU provides a clock (SYSCLK) to the CLA, DMA, and most peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters HALT mode.

Each peripheral clock has its own independent clock gating that is controlled by the PCLKCRx registers.

---

#### Note

When using PCLKCRx, the application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals.

---

#### 3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI and SPI modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed using the LOSPCP register. Each SCI and SPI module's clock (PERx.LSPCLK) can be gated independently using the PCLKCRx registers.

#### 3.7.3.5 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) can not be precise enough, the bit clock can also be connected to XTAL using the CLKSRCCTL2 register. There is an independent selection for each CAN module.

To maintain correct operation, the frequency of the CAN bit clock must be less than or equal to the SYSCLK frequency.

#### 3.7.3.6 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but can also be connected to INTOSC1, INTOSC2, or XTAL using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a non-SYSCLK source is used, the source must be divided down to no more than half the SYSCLK frequency.

The main reason to use a non-SYSCLK source can be for internal frequency measurement. In most applications, timer 2 runs off of SYSCLK.

### 3.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, which can be GPIO16 or GPIO18. The available clock sources are PLLSYSCLK, PLLRAWCLK, SYSCLK, INTOSC1, INTOSC2, and XTAL.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect GPIO16 or GPIO18 to mux channel 11 using the GPIO configuration registers.

### 3.7.5 Clock Connectivity

[Table 3-7](#) shows the clock connections sorted by the clock domain and [Table 3-8](#) shows the clock connections sorted by the module name.

**Table 3-7. Clock Connections Sorted by Clock Domain**

Clock Domain	Module Name
CPUCLK	CPU FPU TMU VCU Flash M0 - M1 RAMs Boot ROM

VCU	CPUCLK
Watchdog Timer	WDCLK (INTOSC1)

### 3.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but they should provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. What types of external oscillators or clock sources are available?

If CAN is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, it may be possible to use only INTOSC2 and avoid the need for more external components.

### 3.7.7 Using an External Crystal or Resonator

The X2 pin doubles as GPIO18. At power-up, GPIO mode is enabled and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pin to X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. 1ms is the typical wait time but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 1023 (0x3FF).
4. Wait for the X1 counter value in the X1CNT register to reach 1023 (0x3FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDPCR register. If set, the oscillator has not finished powering up and more time is required:
  - a. Clear the missing clock status by writing a 1 to MCDPCR.MCLKCLR.
  - b. Repeat steps 2-7. Do not reset the device. Doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
  - c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
8. If MCDPCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

### 3.7.8 Using an External Oscillator

The procedure for using an external oscillator connected to the X1 pin is similar to the procedure for using a crystal or resonator:

1. Clear the XTALCR.OSCOFF bit.
2. Set the XTALCR.SE bit to enable single-ended mode.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 1023 (0x3FF).
4. Wait for the X1 counter value in the X1CNT register to reach 1023 (0x3FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDPCR register. If set, either the external oscillator or the device has failed.
8. If MCLKSTS is clear, the switch to the external clock is a success. The system clock is now derived from XTAL.

### 3.7.9 Choosing PLL Settings

There are two settings to configure for the PLL – a multiplier and a divider. The settings obey the formula:

$$f_{\text{PLLSYSCLK}} = f_{\text{OSCCLK}} * (\text{SYSPLLMULT.IMULT} + \text{SYSPLLMULT.FMULT}) / (\text{SYSPLLMULT.ODIV} * \text{SYSCLKDIVSEL.PLLSYSCLKDIV})$$

where  $f_{\text{OSCCLK}}$  is the system oscillator clock frequency, IMULT and FMULT are the integral and fractional parts of the multipliers, ODIV is the PLL output divider, and PLLSYSCLKDIV is the system clock divider. For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data manual  $f_{\text{VCO}}$  parameter. The VCO frequency divided by the output divider (known as the PLL output frequency) must be in the range specified by the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#)  $f_{\text{PLLRWCLK}}$  parameter. The following examples use 120MHz to 200MHz for this parameter.

---

**Note**

The system clock frequency (PLLSYSCLK) can not exceed the limits specified in the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#)  $f_{(SYSCLK)}$  parameter. These limits do not allow for oscillator tolerance.

---

### 3.7.10 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

1. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. To enable XTAL, follow the instructions in the previous sections.
2. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. Allow at least 300 NOP instructions for this to take effect.
3. Set up the system PLL if desired. TI recommends using the C2000Ware SysCtl:setClock() function for proper configuration of the PLL clock.
4. Select the LSPCLK divider by writing to LOSPCP.
5. If an alternate CAN bit clock is needed, select it by writing to CLKSRCCTL2.CANABCLKSEL and CLKSRCCTL2.CANBBCLKSEL.
6. Enable the desired peripheral clocks by writing to the PCLKCRx registers.

The system clock configuration can be changed at run time. Changing the OSCCLK source will automatically bypass the PLL and set the multiplier to zero. Changing the multiplier from one non-zero value to another will temporarily bypass the PLL until it re-locks.

---

**Note**

At least a 300 CPU clock cycles delay is needed after OSSCLK source is changed.

---

### 3.7.11 Clock Configuration Examples

**Example 1:** Using INTOSC2 (10MHz) as a reference, generate a CPU frequency of 100MHz - 3%:

```

CLKSRCCTL1.OSCCLKSRCSEL = 0x0
SYSPLLMULT = 0x00113
SYSCLKDIVSEL.PLLSYSCLKDIV = 2 (0x1)
SYSPLLCTL1.PLLCLKEN = 1
IMULT = 19 (0x13), FMULT = 0.25 (0x1), ODIV = 1 (0x0)
    
```

This gives a PLLRAWCLK of 192.5MHz, which is within the acceptable range of 150 to 200MHz. The CPU frequency is 96.25MHz with a 3% tolerance due to variation in the internal oscillator.

**Example 2:** Using a crystal (20MHz) as a reference, generate a CPU frequency of 85MHz:

```

XTALCR.OSCOFF = 0
XTALCR.X1CNT.CLR = 1
(wait for X1CNT to reach 0x3ff)
CLKSRCCTL1.OSCCLKSRCSEL = 0x1
(check MCDPCR.MCLKSTS and repeat the above if necessary)
SYSPLLMULT = 0x00208
IMULT = 8 (0x08), FMULT = .50 (0x2), ODIV = 1
(0x0)

SYSCLKDIVSEL.PLLSYSCLKDIV = 2 (0x1)
SYSPLLCTL1.PLLCLKEN = 1

```

This gives a PLLRAWCLK of 170MHz, which is in the acceptable range. The CPU frequency is exactly 85MHz.

#### Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 60 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN = 0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLEN = 0.
4. At least 60 CPU clock cycles delay is needed after OSSCLK source is changed.

### 3.7.12 Missing Clock Detection

The missing clock detection (MCD) subsystem detects OSCCLK failure using INTOSC1 as a reference clock. This subsystem only detects complete loss of OSCCLK. Frequency drift is not detected.

OSCCLK is connected to a 7-bit counter (MCDPCNT). INTOSC1 is connected to a 13-bit counter (MCDSCNT). When MCDPCNT overflows, MCDSCNT is reset. Thus, if OSCCLK is present and the frequency is greater than 1/64 of the INTOSC1 frequency, MCDSCNT never overflows. If OSCCLK stops for any reason, MCDSCNT overflows and a missing clock condition is detected. Missing clock detection time is 8192 INTOSC1 cycles (819.2µs assuming INTOSC1 = 10MHz).

When the MCD subsystem detects that OSCCLK is missing, the following occurs:

- The PLL is bypassed and OSCCLK is connected to INTOSC1 (after the PLLSYSCLK divider). PLLMULT is zeroed out automatically.
- The MCDPCR.MCDSTS flag is set. While this flag is set, the OSCCLKSRCSEL bits have no effect.
- The CLOCKFAIL signal goes high, which generates trip events to the PWM modules and triggers an NMI.
- The MCDSCNT counter is frozen to prevent further missing clock detection.

To clear a missing clock condition, write a 1 to the MCDPCR.MCLKCLR bit. This restores the functionality of the OSCCLKSRCSEL bits and resets the MCD counters. The user can also write to the PLL registers to re-lock the PLL. Under this situation, the missing clock detect circuit is automatically re-enabled (PLLSTS[MCLKSTS] bit is automatically cleared).

Missing clock detection is enabled at startup.

### 3.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU timers (TIMER0/1/2) shown in Figure 3-9.

Timer0 and Timer1 can be used in user applications. Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then Timer2 can be used in the application. timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-10.

Figure 3-9. CPU Timers

- A. The timer registers are connected to the memory bus of the C28x processor.
- B. The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-10. CPU Timer Interrupt Signals and Output Signal

The general operation of a CPU timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every  $(TPR[TDDR:H:TDDR]+1)$  SYSCLK cycles, where TDDR:H:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.15 are used to configure the timers.

### 3.9 Watchdog Timer

The watchdog module consists of an 8-bit counter fed by a prescaled clock (WDCLK, which is connected to INTOSC1). When the counter reaches its maximum value, the module generates an output pulse 512 WDCLKs wide. This pulse can generate an interrupt or a reset. The CPU must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled.

The counter's clock is divided down from WDCLK by two dividers. The prescaler is adjustable from /1 to /64 in powers of two. The pre-divider defaults to /512 for backwards compatibility, but is adjustable from /2 to /4096 in powers of two. This allows a wide range of timeout values for safety-critical applications.

Figure 3-11 shows the various functional blocks within the watchdog module.

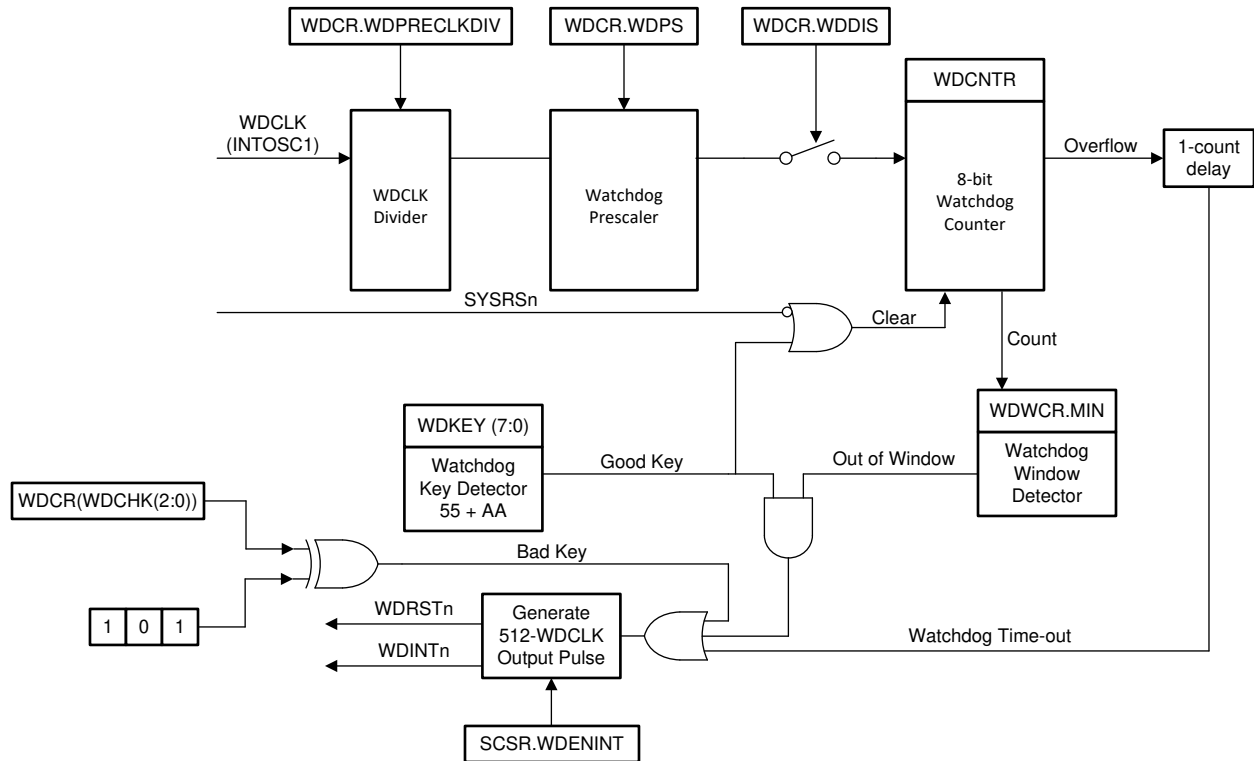

Figure 3-11. Watchdog Timer Module

### 3.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR. An example watchdog key sequence is shown in [Table 3-9](#).

The first action that enables the WDCNTR to be reset is shown in Step 3 in [Table 3-9](#). The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and set the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset is caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

**Table 3-9. Example Watchdog Key Sequences**

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

### 3.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value will take effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR will trigger a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

### 3.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ( $\overline{\text{WDRST}}$ ) or assert an interrupt ( $\overline{\text{WDINT}}$ ) if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the  $\overline{\text{WDRST}}$  signal pulls the device reset ( $\overline{\text{XRS}}$ ) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the counter asserts an interrupt by driving the  $\overline{\text{WDINT}}$  signal low for 512 INTOSC1 cycles. The falling edge of  $\overline{\text{WDINT}}$  triggers a WAKEINT interrupt in the PIE if enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while  $\overline{\text{WDINT}}$  is active does not produce a duplicate interrupt.

To avoid unexpected behavior, software must not change the configuration of the watchdog while  $\overline{\text{WDINT}}$  is active. For example, changing from interrupt mode to reset mode while  $\overline{\text{WDINT}}$  is active immediately resets the device. Disabling the watchdog while  $\overline{\text{WDINT}}$  is active causes a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while  $\overline{\text{WDINT}}$  is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of  $\overline{\text{WDINT}}$ .

### 3.9.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt ( $\overline{\text{WDINT}}$ ) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt can trigger a WAKE interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

If the watchdog interrupt is used to wake-up from an IDLE low-power mode condition, software must make sure that the  $\overline{\text{WDINT}}$  signal goes back high before attempting to reenter the IDLE mode. The  $\overline{\text{WDINT}}$  signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of  $\overline{\text{WDINT}}$  can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of  $\overline{\text{WDINT}}$  by two SYSCLKOUT cycles.

In HALT mode, the internal oscillators and watchdog timer are kept active, if CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

### 3.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

### 3.10 Low-Power Modes

All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes can not be entered into while a Flash program or erase operation is ongoing. Entering HALT stops all CPU and peripheral activities. This includes active transmissions and control algorithms. When preparing to enter the HALT mode, the application can make sure that the system is prepared to enter a period of inactivity.

Before entering the HALT mode, check the value of the GPIODAT register of the pin selected for HALT wake-up (GPIOLPMSEL0/1) prior to entering the low-power mode to make sure that the wake event has not already been asserted.

#### 3.10.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events.

Any enabled interrupt will wake the CPU up from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

The CPU will resume normal operations upon any enabled interrupt event.

#### 3.10.2 Guidelines on Software Emulation of STANDBY Mode

STANDBY is not supported on this device, but can be emulated using the following steps to conserve power:

1. Switch SYSCLK source from PLLCLK to OSCCLK by configuring SYSPLLCTL1.PLLCLKEN=0
2. Disable peripheral clocks through PCLKCRx registers
3. Enter IDLE mode using the instructions defined in [Section 3.10.1](#).

[Table 3-10](#) lists the key differences between Software Emulated STANDBY versus STANDBY mode.

**Table 3-10. Software Emulated STANDBY versus STANDBY Mode**

Software Emulated STANDBY	STANDBY (Not Supported)
Peripheral clocks needs to be disabled prior to entering IDLE mode.	Peripheral clocks are automatically disabled.
Wakeup source is XINT or WDINT.	Wakeup source is WAKEINT or WDINT.
Peripheral Interrupts can be disabled prior to entering IDLE mode, since any interrupt going into the PIE wakes up the system.	System can only wake up externally through WAKENIT (dedicated LPM Interrupt).
Any GPIO can be routed through INPUT XBAR to XINT as a wake up source. Qualification of the GPIO is through GPxQSEL.	GPIO has to be configured as LPM interrupt through GPIOLPMSELx to trigger WAKEINT. Qualification of the GPIO is through dedicated Low Power Mode register.
On wakeup, the CPU enters XINT ISR.	On wakeup, the CPU enters WAKEINT ISR.
Any peripheral clocks and Interrupts disabled prior to entering IDLE mode can be re-enabled by software on Wakeup.	System resumes normal operation on wake up. No extra steps needed.
If SYSCLK is switched from PLLCLK to OSCCLK prior to entering IDLE mode, SYSCLK has to be switched back by configuring SYSPLLCTL1.PLLCLKEN=1 to resume normal operation.	System resumes normal operation on wake up. No extra steps needed.

### 3.10.3 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks.

Unlike on other C2000™ devices, HALT mode will not automatically power down the XTAL upon HALT entry. Additionally, if the XTAL is not powered on, waking up from HALT mode will not automatically power on the XTAL. The XTALCR.OSCOFF bit has been added to power on and off the XTAL circuitry when not needed through application software.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

GPIO0-63 can be configured to wake up the system from HALT. No other wakeup option is available. However, the watchdog timer may still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, the CPU receives a WAKEINT interrupt.

#### To enter HALT mode:

1. Enable the WAKEINT interrupt in the PIE .
2. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
3. Set CLKSRCCTL1.WDHALTI to 1 to keep the watchdog timer active and INTOSC1 and INTOSC2 powered up in HALT.
4. Set CLKSRCCTL1.WDHALTI to 0 to disable the watchdog timer and power down INTOSC1 and INTOSC2 in HALT.
5. Execute the IDLE instruction to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system will begin executing the WAKEINT ISR. After HALT wakeup, ISR execution will resume where it left off.

---

#### Note

Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), it must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device will never wake up.

---

#### To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5us. This will activate the WAKEINT PIE interrupt.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL
3. Wait 16  $\mu$ s plus 1024 OSCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

### 3.10.4 Flash Power-down Considerations

The Flash module on this device can be powered down at any time during an application. There are some considerations that must be made when powering down the Flash.

When the application software powers down the Flash, the application must make sure that the function that puts the Flash to sleep is executed from RAM. Note that there can not be any access to Flash after the Flash is put to sleep to realize the power savings. If there is an access to Flash, the Flash wakeup process (wakeup time depends on PSLEEP and RWAIT as mentioned in [Section 3.12.6.1](#)) gets initialized and the application does not realize Flash power savings. For example, if the application has to execute any code after putting the Flash to sleep and before putting the device in to low-power mode, the application must execute that code from RAM and not from Flash.

As mentioned in [Section 3.12.6.1](#), PSLEEP and RWAIT can be optimized to reduce the Flash wakeup time for a given SYSCLK frequency. BootROM configures the best possible PSLEEP value for the 100MHz operation. However, the application software can decrease the PSLEEP value to reduce the Flash wakeup time if the application SYSCLK is less than 100MHz. This is applicable in the context of an application entering the Halt mode since PLL must be disabled before entering the Halt mode. In this case, the PSLEEP value can be decreased to get a faster Flash wakeup upon exit from LPM.

If the Wake ISR is in Flash, optimize the PSLEEP and RWAIT values before entering the LPM, and after the Flash is in sleep, since the application does not get a chance to modify these before Flash is awake after exiting from LPM. However, after the LPM exit and once the Flash is awake, the application must branch to RAM to restore RWAIT and PSLEEP (as per the application SYSCLK to which PLL is locked for) and then proceed with Flash execution to lock the PLL.

If the Wake ISR is in RAM, application can optimize the PSLEEP and RWAIT values in the Wake ISR and then do a dummy Flash access to initiate the Flash wakeup process. While the Flash is waking up, application can initialize the PLL lock process. Once the Flash is awake, application can put the PLL in clock path. If the user does not want to lock the PLL from RAM, PLL can be locked from Flash (this means Flash wakeup and PLL lock are not done in parallel), but in any case make sure to restore the RWAIT and PSLEEP (as per the application SYSCLK to which PLL is locked for) in Wake ISR before proceeding to Flash execution.

The Flash fallback mode is not automatically configured as active mode upon Flash wakeup in F28004x and instead the device stays as configured before entering the Flash low-power mode. Hence, the BootROM code and the Flash initialization routine in C2000Ware configure the Flash fallback mode to active mode to avoid Flash falling back to low-power mode after the grace period expiration. Similarly, in the context of the device LPM, the application software must change the Flash Fallback mode to the Active state in the Wake ISR if required. If not, Flash enters the configured fallback power mode when the grace period expires as mentioned in [Section 3.12.6.1](#). This applies to all low-power modes on this device.

### 3.11 Memory Controller Module

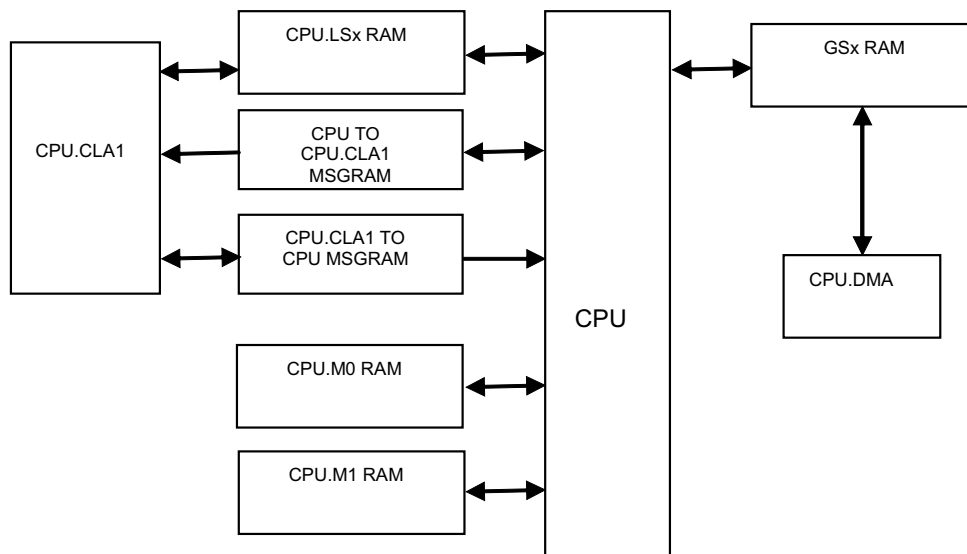

For these devices, the RAMs have different characteristics. Some are:

- dedicated to the CPU (M0 and M1)
- shared between the CPU and CLA (LSx RAM)
- shared between the CPU and DMA (GSx RAM)
- used to send and receive messages between processors (MSGRAM)

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. All dedicated RAMs are enabled with the ECC feature (both data and address) and shared RAMs, are enabled with the parity (both data and address) feature. Some of the dedicated memories are secure memory as well. Refer to [Section 3.13](#) for more details. Each RAM has a controller that takes care of the access protection/ security related checks and ECC/Parity features for that RAM. [Figure 3-12](#) shows the configuration of these RAMs.

**Note**

All RAMs on these devices are SRAMs.

**Figure 3-12. Memory Architecture**

#### 3.11.1 Functional Description

This section further defines and discusses the dedicated RAMs, shared RAMs, and MSG RAMs on this device.

##### 3.11.1.1 Dedicated RAM (Mx RAM)

This device has two dedicated RAM blocks: M0 and M1. M0 and M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (including DMA) have any access to these memories.

All dedicated RAMs have the ECC feature.

### 3.11.1.2 Local Shared RAM (LSx RAM)

RAM blocks which are accessible to the CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the parity feature. By default, these memories are dedicated to the CPU only, and the user could choose to share these memories with the CLA by appropriately configuring the MSEL\_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user could choose to use these memories as CLA program memory by configuring the CLAPGM\_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks which are programmed as CLA program memory are blocked.

All these RAMs have the access protection (CPU write/CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers. [Table 3-11](#) shows the LSx RAM features.

**Table 3-11. Local Shared RAM**

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write Emulation Data Read Emulation Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Program Read Emulation Program Write	LSx memory is CLA1 program memory

### 3.11.1.3 Global Shared RAM (GSx RAM)

RAM blocks which are accessible from the CPU and DMA are called global shared RAMs (GSx RAMs). [Table 3-12](#) shows the features of the GSx RAM.

**Table 3-12. Global Shared RAM**

CPU (Fetch)	CPU (Read)	CPU (Write)	CPU.DMA (Read)	CPU.DMA (Write)
Yes	Yes	Yes	Yes	Yes

Like other shared RAM, these RAMs also have different levels of access protection which can be enabled or disabled by configuring specific bits in the GSxACCPROT registers.

Master select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once a configuration is committed for a particular GSx RAM block, the configuration can not be changed further until CPU SYSRS is issued.

### 3.11.1.4 Message RAM (CLA MSGRAM)

These RAM blocks are used to share data between the CPU and CLA. The CLA has read and write access to the CLA to CPU MSGRAM. The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

### 3.11.1.5 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time.

The following is the order of fixed priority for CPU accesses:

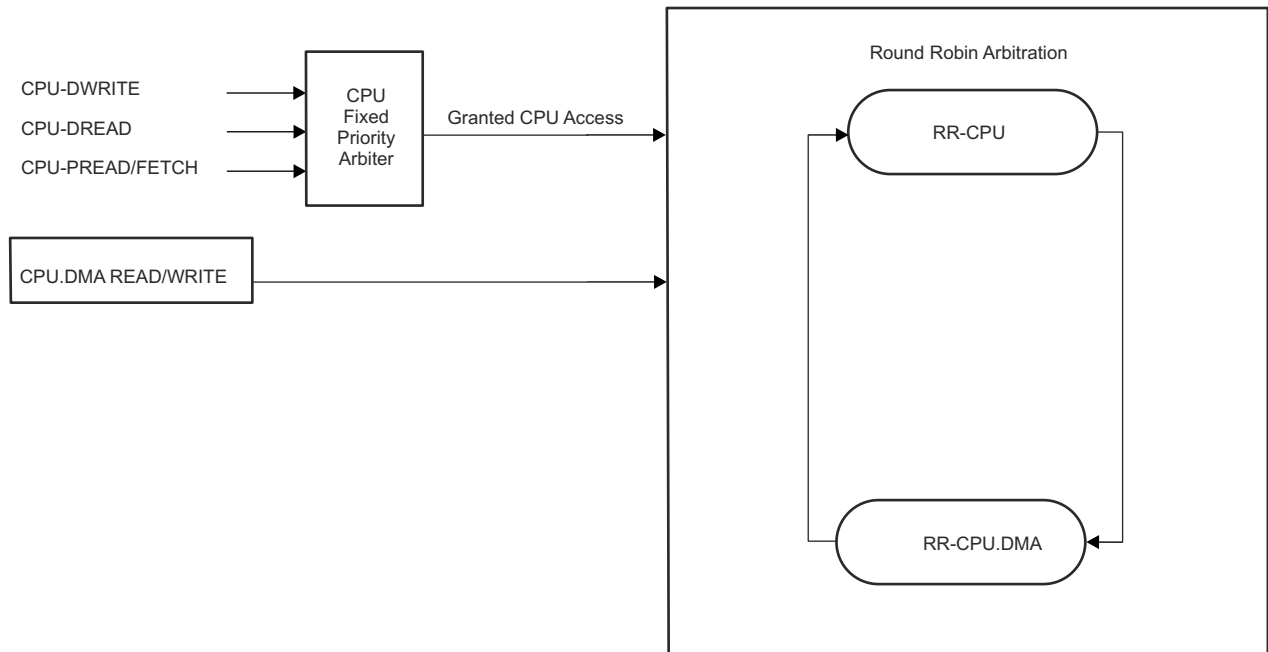

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

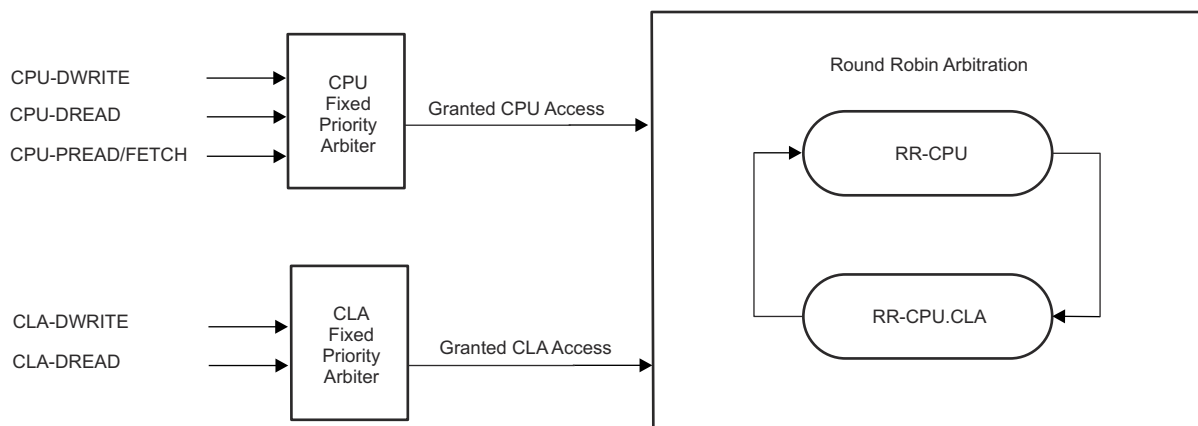

1. Data Write
2. Data Read/Program Fetch

Figure 3-13 represents the arbitration scheme on global shared memories.

Figure 3-14 represents arbitration scheme on local shared memories.

**Figure 3-13. Arbitration Scheme on Global Shared Memories**

**Figure 3-14. Arbitration Scheme on Local Shared Memories**

### 3.11.1.6 Access Protection

All RAM blocks except for M0/M1 have different levels of protection. This feature enables or disables specific access to individual RAM blocks from individual masters. There is no protection for read accesses; hence, reads are always allowed from all the masters that have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

---

**Note**

For debug accesses, all the protections are disabled.

---

#### 3.11.1.6.1 CPU Fetch Protection

Fetch accesses from the CPU can be protected by setting the FETCHPROTx bit of the specific register to 1. If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

If a fetch protection violation occurs, the violation results in an ITRAP for CPU. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU fetch access violation address register.

#### 3.11.1.6.2 CPU Write Protection

Write accesses from the CPU can be protected by setting the CPUWRPROTx bit of the specific register to 1. If a write access is done by a CPU to memory where the memory is protected, a write protection violation occurs.

If a write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

#### 3.11.1.6.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the accesses from the CPU, including a read, will be blocked and the violation will be considered a non-master access violation.

If a read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

#### 3.11.1.6.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, it results in a MSTOP. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

### 3.11.1.6.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the CPU if enabled in the interrupt enable register.

### 3.11.1.6.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

### 3.11.1.6.7 DMA Write Protection

Write accesses from the DMA can be protected by setting the DMAWRPROTx bit of a specific register to 1. If a write access is done by the DMA to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master DMA, the write is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to 1 for that memory, the write is called a master DMA write protection violation.

A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

- Note 1:** All access protections are ignored during debug accesses. Write access to a protected memory go through when the write is done by way of the debugger, irrespective of the write protection configuration for that memory.
- Note 2:** Access protection is not implemented for M0 and M1 memories.
- Note 3:** In the case of local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the accesses from the CPU (including read) and data accesses from the CLA are blocked, and the violation is considered a non-master access violation. If the memory is configured as dedicated to the CPU, all accesses from the CLA are blocked and the violation is considered a non-master access violation.

### 3.11.1.7 Memory Error Detection, Correction and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs support error correction code (ECC) protection and the shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit of data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

### 3.11.1.7.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent a double-bit error due to another single-bit error at the same memory address.

### 3.11.1.7.2 Error Handling

For each correctable error, the count in the correctable error count register will increment by one. When the value in this count register becomes equal to the value configured in the correctable error threshold register, an interrupt is generated to the CPU, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into a register and a flag also gets set in a status register.

If there are uncorrectable errors, an NMI gets generated for the CPU. In this case also, the address for which the error occurred gets latched into a register, and a flag gets set in a status register.

[Table 3-13](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

**Table 3-13. Error Handling in Different Scenarios**

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes -CPU/CPU.DMA/CPU.CLA1 CPU/DMA/CLA Read Error Address Register Data returned to CPU/ CPU.DMA/CPU.CLA1 is incorrect	NMI for CPU access NMI for CPU.DMA access NMI to CPU for CPU.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPU/CPU.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPU/CPU.DMA/CPU.CLA1 CPU/DMA/CLA Read Address Error Register Data returned to CPU/ CPU.DMA/CPU.CLA1 is incorrect	NMI to CPU for CPU access NMI to CPU for CPU.DMA access NMI to CPU for CPU.CLA1 access

#### Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

### 3.11.1.8 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error could be injected into data.

---

#### Note

The memory map for ECC/Parity bits and data bits are the same. The user must choose a different test mode to access ECC/Parity bits. In test mode, all access to memories (data as well as ECC/Parity) should be done as 32-bit access only.

---

Table 3-14 and Table 3-15 shows the bit mapping for the ECC/Parity bits when they are read in RAMTEST mode using their respective addresses.

**Table 3-14. Mapping of ECC Bits in Read Data from ECC/Parity Address Map**

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

**Table 3-15. Mapping of Parity Bits in Read Data from ECC/Parity Address Map**

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

### 3.11.1.9 RAM Initialization

To make sure that read and fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM\_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to 1 for the specific RAM block in INIT registers. To check the status of RAM initialization, software can poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access can be made to that RAM memory block.

---

#### Note

None of the masters can access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization does not happen correctly.

---

## 3.12 Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of Flash. This section also includes information on Flash and OTP power modes, how to improve Flash performance by enabling the Flash prefetch/cache mode, and the SECEDED safety feature.

### 3.12.1 Features

Features of Flash memory include:

- Up to two Flash banks (Bank0 and Bank1) (refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for the number and size of the Flash banks)
- One FMC controlling up to two Flash banks
- 128 bits (bank width) can be programmed at a time along with ECC
- Multiple sectors providing the option of leaving some sectors programmed and only erasing specific sectors
- User-programmable OTP locations (in user-configurable DCSM OTP, also called USER OTP) for configuring security, OTP boot-mode and boot-mode select pins (if unable to use the factory-default boot-mode select pins)
- Flash pump shared by the two banks
- Enhanced performance using the code-prefetch mechanism and data cache in FMC
- Configurable wait states to give the best performance for a given execution speed
- Safety Features:
  - SECEDED-single error correction and double error detection is supported in the FMC
  - Address bits are included in ECC
  - Test mode to check the health of ECC logic
- Supports low-power modes for Flash bank and pump for power savings
- Built-in power mode control logic
- Integrated Flash program/erase state machine (FSM) in the FMC
  - Simple Flash API algorithms
  - Fast erase and program times (refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for details)
- Dual Code Security Module (DCSM) to prevent access to the Flash by unauthorized persons (refer to [Section 3.13](#) for details)

### 3.12.2 Flash Tools

Texas Instruments provides the following tools for Flash memory:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin
- F021 Flash API Library - a set of software peripheral functions to erase/program Flash. Refer to the [TMS320F28004x Flash API Reference Guide](#) for more information.
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS IDE is required.
- Linker ECC generation - to generate the Flash ECC from the Flash data and to introduce errors in Flash/ECC space. Refer to the [TMS320C28x Assembly Language Tools User's Guide](#) for more information.
- CCS On-Chip Flash Plugin and UniFlash tools are developed for a fully Flash-embedded application, which can be a standalone program that has all the initialized sections linked to Flash. Any code that needs to be executed from RAM can be copied from Flash at run time.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

### 3.12.3 Default Flash Configuration

The following are Flash module configuration settings at power-up:

- Flash banks are in sleep power mode (BNKPWR bit field in the FBFALLBAC register)
- Shared pump is in sleep power mode (PMPPWR bit field in the FPAC1 register)
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled in the FMC
- Bank and pump active grace periods are set to 0x0 (refer to the BAGP field in the FBAC register and PAGP bit field in the FPAC2 register)

Note that boot ROM changes the BNKPWR and PMPPWR bit fields to active mode.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD\_INTF\_CTRL register, to achieve optimum system performance. Software that configures Flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from Flash memory.

---

#### Note

Before initializing wait-states, turn off the pre-fetch and data caching in the FRD\_INTF\_CTRL register.

---

### 3.12.4 Flash Bank, OTP and Pump

There are two Flash banks, Bank0 and Bank1 (refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for the number of banks available). Also, there is a one-time programmable (OTP) memory called USER OTP, which the user can program only once and cannot erase. Flash and OTP are uniformly mapped in both program and data memory space.

There is also a TI-OTP that contains manufacturing information like settings used by the Flash state machine for erase and program operations, and so on. Users can read TI-OTP, but TI-OTP cannot be programmed or erased. For memory map and size information of the banks, TI-OTP, USER OTP, and corresponding ECC locations, refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#).

Bank0 and Bank1 share a common Flash pump; therefore, only one bank can be programmed or erased at a time. Execution or reads from one bank, while erase or program is in progress on the other bank, is supported.

[Figure 3-19](#) shows the user-programmable OTP locations in USER-OTP. For more information on the functionality of these fields, refer to [Section 3.13](#) and [Chapter 4](#).

### 3.12.5 Flash Module Controller (FMC)

A single FMC controls both Bank0 and Bank1, see [Figure 3-15](#). The CPU interfaces with the FMC, which in turn interfaces with Bank0 and Bank1 and the shared pump, to perform erase or program operations, to read data, and execute code from these Flash banks.

There is a state machine in FMC that generates the erase/program sequences in hardware. This simplifies the Flash API software that configures control registers in the FMC to perform Flash erase and program operations. Refer to the [TMS320F28004x Flash API Reference Guide](#) for more information for details on Flash API.

[Section 3.12.6](#) through [Section 3.12.10](#) describe FMC in detail.

**Figure 3-15. FMC Interface with Core, Bank and Pump**

### 3.12.6 Flash and OTP and Wakeup Power-Down Modes

The Flash banks and pump consume a significant amount of power when active. The Flash module provides a mechanism to power-down Flash banks and pump. Special timers automatically sequence the power-up and power-down of Bank0 and Bank1 independently of each other. The shared charge pump module has independent power-up and power-down timers as well.

#### 3.12.6.1 Flash/OTP and Pump Power Modes and Wakeup

The Flash banks and OTP operate in three power modes:

- **Sleep State (lowest power):** This is the state after a device reset. In this state, a CPU data read or opcode fetch automatically initiates a change in power mode to the standby state and then to the active state. During this transition time to the active state, the CPU is automatically stalled.
- **Standby State:** This state uses more power than the sleep state, but takes a shorter time to transition to the active or read state. In this state, a CPU data read or opcode fetch automatically initiates a change in power mode to the active state. During this transition time to the active state, the CPU is automatically stalled. Once the Flash/OTP has reached the active state, the CPU access completes as normal.
- **Active State (highest power):** In this state, the bank and pump are in active power mode state.

The charge pump operates in two power modes:

- Sleep (lowest power)
- Active (highest power)

Any access to any Flash bank/OTP causes the charge pump to go into active mode, if the charge pump is in sleep mode. Also, any erase or program command causes the charge pump and bank to become active. If any bank is active or in standby mode, the charge pump is in active mode, independent of the charge pump power mode control configuration (refer to the PMPPWR bit field in the FPAC1 register). While the pump is in sleep state, a charge pump sleep down counter holds a user-configurable value (PSLEEP bit field in the FPAC1 register) and when the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles (prescaled clock is SYSCLK/2) before putting the charge pump into active power mode. Note that the configured PPSLEEP value can yield at least a delay of 20  $\mu$ s for the pump to go to active mode. Refer to [Section 3.15](#) for detailed information.

Following are the number of cycles for the bank and pump to wake up from low-power modes.

1. Pump sleep to active = PSLEEP \* (SYSCLK/2) cycles
2. Bank sleep to standby = 254 Flash clock cycles
3. Bank standby to active = 55 Flash clock cycles

Where Flash clock = SYSCLK/(RWAIT + 1)

### 3.12.6.2 Active Grace Period

The active grace period (AGP) can be used to optimize the Flash module power consumption versus access time. Faster access times are associated with higher-power modes of operation. At one extreme, the power control logic can attempt to reduce power consumption by putting the bank and charge pump into a low-power mode immediately at the end of every Flash access. However, if accesses are only a few cycles apart, this can actually increase power consumption versus leaving the Flash powered, because the bank and charge pump consume more power during Flash startup and access.

The active grace periods (supported for Bank0 and Bank1 together, in addition to the charge pump module) allow the banks and/or charge pump to be maintained in active mode for a specified period following an access. This is done in anticipation of another read within the AGP time, to allow the subsequent read to have a faster access and spend less time dissipating power, than if the bank went into one of the low power modes immediately. If the next access does not occur within the AGP time, the power control logic can automatically put the bank and/or charge pump into a low-power mode to reduce power consumption during long periods of inactivity.

The AGP value is programmed by a set of programmable counters (FBAC and FPAC2) that keep the Flash bank or charge pump in active mode until the counter expires, at which time the bank or charge pump reverts to the fallback power mode as defined in the FBFALLBACK and FPAC1 (refer to PMPPWR bit-field) registers. The application software can configure the fallback power mode to reduce power consumption, or configure the fallback power mode to be in active mode to keep the bank active regardless of counter settings (default is SLEEP). The charge pump AGP counter remains in the initialized state when the bank is active, including the AGP counter of the bank. The charge pump AGP counter begins counting when the bank has become inactive.

The application software can check the current power mode of Flash bank and charge pump by reading the FBPRDY register. Refer to [Section 3.15](#) for detailed information.

### 3.12.7 Flash and OTP Performance

Once the Flash bank and pump are in the active power state, a read or fetch access can be classified as a Flash access (access to an address location in Flash) or an OTP access (access to an address location in OTP). Once the CPU throws an access to a Flash memory address, data is returned after RWAIT + 1 number of SYSCLK cycles. For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait-states and is configurable using the RWAIT bit-field in the FRDCNTL register. At reset, the RWAIT bit-field defaults to a worst-case wait-state count (15), and therefore needs to be initialized for the appropriate number of wait states to improve performance, based on the CPU clock rate and the access time of the Flash.

For a given system clock frequency, RWAIT has to be configured using the formula:

$$\text{RWAIT} = \text{ceiling}[(\text{SYSCLK}/\text{FCLK}) - 1]$$

where:

SYSCLK is the system operating frequency

FCLK is the Flash clock frequency. FCLK can be  $\leq \text{FCLK}_{\text{max}}$ , the allowed maximum Flash clock frequency at RWAIT = 0.

If RWAIT results in a fractional value when calculated using the above formula, RWAIT has to be rounded up to the nearest integer. See the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for the RWAIT configuration details.

### 3.12.8 Flash Access Interface

This section provides details about the modes to access Flash/OTP and the configuration registers which control the read interface. In addition to a standard read mode, the FMC has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

#### 3.12.8.1 Standard Access Mode

Standard access mode is defined as the access mode in effect when the code prefetch-mechanism and data cache are disabled. Standard access mode is also the default mode after reset. During this mode, each access to Flash is decoded by the Flash wrapper to read/fetch the data/code from the addressed location and the data/code is returned after the RWAIT+1 number of cycles.

The prefetch buffer associated with the prefetch mechanism and data cache is bypassed in standard access mode; therefore, every access to the Flash/OTP is used by the CPU immediately, and every access creates a unique Flash bank access.

Standard access mode is the recommended mode for lower system-frequency operation in which RWAIT can be set to zero to provide single-cycle access operation. The FMC can operate at higher frequencies using standard access mode at the expense of adding wait states. At higher system-frequencies, enable cache and prefetch mechanisms to improve performance. Refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) to determine the maximum Flash frequency allowed in standard access mode (that is, the maximum Flash clock frequency with RWAIT = 0,  $FCLK_{max}$ ).

#### 3.12.8.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from sequential memory addresses, except when a discontinuity occurs. Usually the portion of the code that resides in sequential addresses makes up the majority of the application code and is referred to as linear code. To improve the performance of linear code execution, a Flash prefetch-mechanism has been implemented in the FMC. [Figure 3-16](#) illustrates how this mode functions.

This prefetch mechanism does a look-ahead prefetch on linear address increments starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. Setting the PREFETCH\_EN bit in the FRD\_INTF\_CTRL register enables this prefetch mode.

An instruction fetch from the Flash or OTP reads out 128 bits per access. The starting address of the access from Flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. With the Flash prefetch mode enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the Flash bank, there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time to process these instructions, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 128 bits. In this manner, the Flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash or OTP is improved significantly.

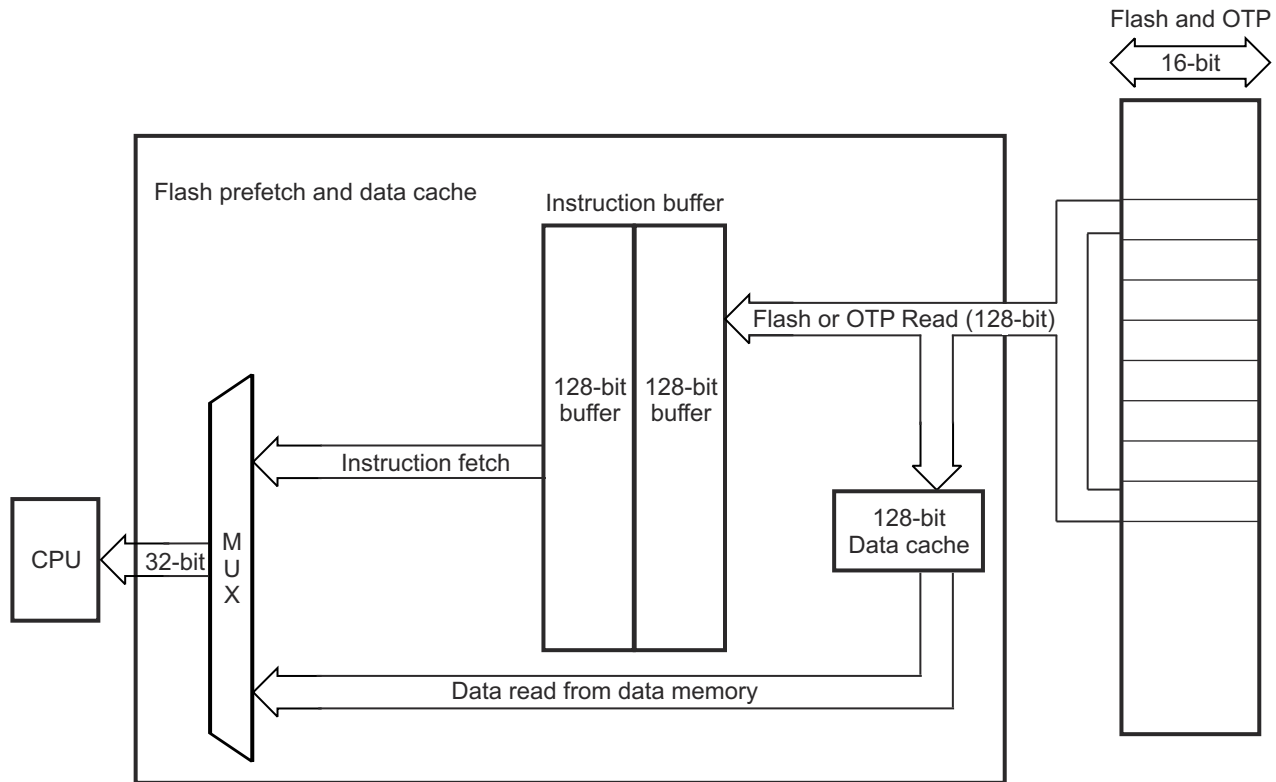

---

#### Note

If the prefetch mechanism is enabled, then the last two rows (16 16-bit words, that is, 256 bits) of the bank that do not have a valid address beyond the boundary can not be used, because the prefetch logic that does a look-ahead prefetch tries to fetch from outside the bank and can result in an ECC error.

---

**Figure 3-16. Flash Prefetch Mode**

The Flash prefetch is aborted only on a PC discontinuity caused by executing an instruction such as a branch, BANZ, call, or loop. When this occurs, the prefetch mechanism is aborted and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the Flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the Flash and OTP, the prefetch is aborted and begins again only when a branch is made back into the Flash or OTP. The Flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch buffer capability and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When this read happens, the prefetch buffer is bypassed but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read is stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

### 3.12.8.3 Data Cache

Along with the prefetch mechanism, a data cache of 128-bits wide is also implemented to improve data-space read and program-space read performance. This data cache is not filled by the prefetch mechanism. When any kind of data-space read or program-space read is made by the CPU from an address in the bank, and if the data corresponding to the requested address is not in the data cache, then 128 bits of data are read from the bank and loaded in the data cache. This data is eventually sent to the CPU for processing. The starting address of the access from Flash is automatically aligned to a 128-bit boundary such that the requested address location is within the 128 bits to be read from the bank. By default, this data cache is disabled and can be enabled by setting DATA\_CACHE\_EN bit in the FRD\_INTF\_CTRL register. Note that the data cache gets bypassed when RWAIT is configured as zero.

Some other points to keep in mind when working with Flash/ OTP:

- Reads of the USER OTP locations are hardwired for 10 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to the Flash or OTP memory-mapped areas are ignored. The writes complete in a single cycle.
- If a security zone is in the locked state and the respective password lock bits are not all 1s, then,
  - Data reads to Zx-CSMPSWD return 0
  - Program space reads to Zx-CSMPSWD return 0
  - Program fetches to Zx-CSMPSWD return 0
- When the Dual Code Security Module (DCSM) is secured, reads to the Flash/OTP memory map area from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns a zero.
- The arbitration scheme in FMC prioritizes CPU accesses in the fixed priority order of data read (highest priority), program space read and program fetches/program prefetches (lowest priority).
- When FSM interface is active for erase and program operations, data in the prefetch buffers and data cache in FMC is flushed.

When the data cache is enabled, the debugger memory window open to Flash and OTP space invokes data caching. Therefore, the debugger memory window can not be left open for Flash and OTP space when benchmarking the code for performance.

---

#### Note

Flash contents are verified for ECC correctness before the contents enter the prefetch buffer or data cache and not inside the prefetch buffer or data cache.

---

### 3.12.9 Erase/Program Flash

Flash memory can be programmed either by using the CCS Flash plugin or by using Uniflash. If these methods are not feasible in an application, the API can be used. The Flash memory can be programmed, erased, and verified only by using the F021 Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations. This section only provides a high-level description for these operations; for more information, refer to the [TMS320F28004x Flash API Reference Guide](#).

Note that Flash API execution is interruptible. However, there can not be any read and fetch access from the Flash bank on which an erase and program operation is in progress. In single-bank devices, Flash API must be executed from RAM. In dual-bank devices, Flash API can execute from one bank to perform erase and program operations on another bank. If prefetch is enabled, note that the last 128 bits of Bank0 can not be accessed when erasing and programming Bank1 since accessing them causes a prefetch access to Bank1.

A typical flow to program Flash is:

Erase → Program → Verify

Always refer to the device-specific support folder in C2000Ware for the latest Flash API library.

#### 3.12.9.1 Erase

When the target Flash is erased, the Flash reads as all 1's. This state is called 'blank.' The erase function must be executed before programming. Can not skip erase on sectors that read as 'blank' because these sectors can require additional erasing due to marginally erased bits columns. The FSM provides an "Erase Sector" command to erase the target sector. The erase function erases the data and the ECC together. This command is implemented by the following Flash API function: `Fapi_issueAsyncCommandWithAddress();`

The Flash API provides the following function to determine if the Flash bank is 'blank': `Fapi_doBlankCheck();`

### 3.12.9.2 Program

The FSM provides a command to program the USER OTP and Flash. This command is also used to program ECC check bits.

This command is implemented by the following Flash API function:

```
Fapi_issueProgrammingCommand();
```

The Program function provides the options to program data without ECC, data with user-provided ECC data with ECC calculated by API software, and to program ECC only.

---

#### Note

The main array Flash programming must be aligned to 64-bit address boundaries and each 64-bit word can only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128-bit address boundaries and each 128-bit word can only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP must be programmed together, and can be programmed one bit at a time as required by the DCSM operation.
  - The DCSM Zx-LINKPOINTER3 values in the DCSM OTP can be programmed one bit at a time on a 64-bit boundary to separate it from Zx-PSWDLOCK, which must only be programmed once.
- 

### 3.12.9.3 Verify

After programming, the user can verify the programmed contents using API function Fapi\_doVerify(). This function verifies the Flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default) catches single-bit errors, double-bit errors, and address errors whenever the CPU reads or fetches from a Flash address.

### 3.12.10 Error Correction Code (ECC) Protection

FMC contains an embedded single-error correction and double-error detection (SECCDED) module. SECCDED, when enabled, provides the capability to screen out memory faults. SECCDED can detect and correct single-bit data errors and detect address errors/double-bit data errors. For every 64 bits of Flash/OTP data (aligned on a 64-bit memory boundary) that is programmed, eight ECC check bits have to be calculated and programmed in ECC memory space. Refer to the [TMS320F28004x Real-Time Microcontrollers Data Sheet](#) for the Flash/OTP ECC memory map. ECC memory space in Flash can not be used to program code or data; ECC memory space is used only for error correction and detection. SECCDED works with a total of eight user-calculated error correction code (ECC) check bits associated with each 64-bit wide data word and the corresponding 128-bit memory-aligned address. Program ECC check bits along with Flash. TI recommends using the AutoEccGeneration option available in Plugin/API to program ECC. Use the F021 Flash API to calculate and program ECC data along with Flash data. Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with Code Composer Studio IDE, uses Flash API to generate and program ECC data. Alternatively, use the linker-supported ECC generation option to generate and place ECC in separate sections through the linker command file. Refer to the [TMS320C28x Assembly Language Tools User's Guide](#) for more information on using the linker-supported ECC generation method.

Figure 3-17 illustrates the ECC logic inputs and outputs.

**Figure 3-17. ECC Logic Inputs and Outputs**

During an instruction fetch or a data read operation, the 19 most-significant address bits (three least-significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of Flash banks/ECC memory-map area, pass through the SECDDED logic and the eight check bits are produced in FMC. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the SECDDED module to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- An uncorrectable error (double-bit data error or address error) occurred

If the SECDDED logic finds a single-bit error in the address field, then the single-bit error is considered to be an uncorrectable error.

#### Note

Since ECC is calculated for an entire 64-bit data, a non 64-bit read such as a byte read or a half-word read still forces the entire 64-bit data to be read and calculated, but only the byte or half-word is actually used by the CPU.

This ECC (SECDDED) feature is enabled at reset. The ECC\_ENABLE register can be used to configure (enable/disable) the ECC feature. The ECC for the application code must be programmed. There are two SECDDED modules in each FMC. Out of the 128-bit data (aligned on a 128-bit memory boundary) read from the bank/OTP address, the lower 64-bits of data and corresponding 8 ECC bits (read from user programmable ECC memory area) are supplied as inputs to one SECDDED module along with 128-bit aligned 19-bit address from where data has been read. The upper 64-bits of data and corresponding 8 ECC bits are supplied as inputs to another SECDDED module in parallel, along with 128-bit aligned 19-bit address. Each of the SECDDED modules evaluate the inputs and determine if there is any single-bit data error or double-bit data error/address error.

ECC logic is bypassed when the 64 data bits and the associated ECC bits fetched from the bank are either all ones or zeros.

### 3.12.10.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in Flash data or in ECC data, then the error is considered as a single-bit data error. The SECDED module detects and corrects single-bit errors, if any, in the 64-bit Flash data or eight ECC check bits read from the Flash/ECC memory map before the read data is provided to the CPU.

When SECDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the single-bit error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address is captured in the SINGLE\_ERR\_ADDR\_LOW register. If the single-bit error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address is captured in the SINGLE\_ERR\_ADDR\_HIGH register.
- Whether the error occurred in data bits or ECC bits – the ERR\_TYPE\_L and ERR\_TYPE\_H bit fields in the ERR\_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64-bits, or the upper 64-bits respectively, of a 128-bit memory-aligned data.
- Bit position at which error occurred – the ERR\_POS\_L and ERR\_POS\_H bit fields in the ERR\_POS register indicate the bit position of the error in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned data.
- Whether the corrected value is 0 (FAIL\_0\_L, FAIL\_0\_H flags in ERR\_STATUS register)
- Whether the corrected value is 1 (FAIL\_1\_L, FAIL\_1\_H flags in ERR\_STATUS register)
- A single bit error counter that increments on every single bit error occurrence (ERR\_CNT register) until a user-configurable threshold (see ERR\_THRESHOLD) is met
- A flag that gets set when one or more single-bit errors occurs after ERR\_CNT equals ERR\_THRESHOLD (SINGLE\_ERR\_INT\_FLG flag in the ERR\_INTFLG register)

When the ERR\_CNT value equals THRESHOLD+1 value and a single-bit error occurs, the SINGLE\_ERR\_INT flag is set, and an interrupt (FLASH\_CORRECTABLE\_ERR on C28x PIE has to be enabled for interrupt, if needed) is fired. The SINGLE\_ERR interrupt is not fired again until the SINGLE\_ERR\_INTFLG is cleared. If the single-error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, the error interrupt does not come again, as this is an edge-based interrupt.

When multiple single-bit errors get caught by ECC logic, the Flash ECC error registers hold the information related to the latest ECC error. Although ECC is calculated on a 64-bit basis, a read of any address location within a 128-bit aligned Flash memory causes the single-bit error flag to get set when there is a single-bit error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 3.12.10.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data/ECC. When SECDED finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the uncorrectable error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_LOW register. If the uncorrectable error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC\_ERR\_L and UNC\_ERR\_H flags in the ERR\_STATUS register indicate the uncorrectable error occurrence in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned data.
- A flag is set indicating that an uncorrectable error interrupt is fired (UNC\_ERR\_INTFLG in ERR\_INTFLG register)

When an uncorrectable error occurs, the UNC\_ERR\_INTFLG bit is set and an uncorrectable error interrupt is fired. This uncorrectable error interrupt generates an NMI, if enabled. If an uncorrectable error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, an error interrupt will not come again, as this is an edge based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the uncorrectable error flag to get set when there is an uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data. NMI will occur on the CPU for a read of any address location within a 128-bit aligned Flash memory, when there is an uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 3.12.10.3 SECEDED Logic Correctness Check

Since error detection and correction logic are part of safety-critical logic, safety applications need to make sure that the SECEDED logic is always working properly. For these safety concerns and to make sure the correctness of the SECEDED logic, an ECC test mode is provided to test the correctness of ECC logic periodically. In ECC test mode, Data/ECC and address inputs to the ECC logic are controlled by the ECC test mode registers FDATAH\_TEST, FDATAL\_TEST, FECC\_TEST, and FADDR\_TEST, respectively. Using this test mode, introduce single-bit errors, double-bit errors, or address errors and check whether or not SECEDED logic is catching those errors. Check if SECEDED logic is reporting any false errors when no errors are introduced.

This ECC test mode can be enabled by setting the ECC\_TEST\_EN bit in the FECC\_CTRL register. When ECC test mode is enabled, the CPU cannot read the data from Flash and instead the CPU gets data from the ECC test mode registers (FDATAH\_TEST/FDATAL\_TEST). This is because ECC test mode registers (FDATAH\_TEST, FDATAL\_TEST, FECC\_TEST) are multiplexed with data from the Flash. Hence, the CPU can not read and fetch from Flash when ECC test mode is enabled. For this reason, ECC test mode code can be executed from RAM and not from Flash.

Only one of the SECEDED modules (out of the two SECEDED modules that work on lower 64 bits and upper 64 bits of a read 128-bit data) at a time can be tested. The ECC\_SELECT bit in the FECC\_CTRL register can be configured by users to select one of the SECEDED modules for test. To test the ECC logic using ECC test mode, perform the following steps:

1. Obtain the ECC for a given Flash address (128-bit aligned) and 64-bit data by using Auto ECC generation option provided in Flash API or by using the linker ECC generation method.
2. Develop an application to test ECC logic using the above data. In this application
  - Write the 128-bit aligned 19-bit Flash address in FADDR\_TEST
  - Write 64-bit data in FDATAH\_TEST (upper 32 bits) and FDATAL\_TEST (lower 32 bits) registers
  - Write the corresponding 8-bit ECC in the FECC\_TEST register
  - In any of the above three steps, insert errors (single-bit data error or double-bit data error, address error, or single-bit ECC error or double-bit ECC error) to check if the ECC logic is able to catch the errors
  - Select the ECC logic block (lower 64-bits or upper 64-bits) that needs to be tested using the ECC\_SELECT bit in the FECC\_CTRL register
  - Enable ECC test mode using the ECC\_TEST\_EN bit in FECC\_CTRL register
  - Write a value of 1 in the DO\_ECC\_CALC bit in FECC\_CTRL register to enable ECC test logic for a single cycle to evaluate the address, data, ECC in FADDR\_TEST, FDATAH\_TEST and FECC\_TEST registers for ECC errors

Once the above ECC test mode registers are written:

- The FECC\_OUTH register holds the data output bits 63:32 from the SECEDED block under test
- The FECC\_OUTL register holds the data output bits 31:0 from the SECEDED block under test
- The FECC\_STATUS register holds the status of single-bit error occurrence, uncorrectable error occurrence, and error position of single-bit error in data/check bits

### 3.12.10.4 Reading ECC Memory From a Higher Address Space

In these devices, ECC memory for Flash and OTP is allocated at a higher address space (address width more than 22 bits). C2000 Codegen tools (6.2 and onwards) are updated to include the below intrinsics to read ECC space.

For 16-bit read: unsigned int variable = \_\_addr32\_read\_uint16(unsigned long address);

For 32-bit read: unsigned long variable = \_\_addr32\_read\_uint32(unsigned long address);

### 3.12.11 Reserved Locations Within Flash and OTP

When allocating code and data to Flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, refer to [Section 3.13](#) and [Chapter 4](#).
- Refer to [Chapter 4](#) for reserved locations in Flash for real-time operating system usage and a boot-to-Flash entry point. A boot-to-Flash entry point is reserved for an entry-into-Flash branch instruction. When the boot-to-Flash boot option is used, the boot ROM jumps to this address in Flash. If programming a branch instruction here, that then redirects code execution to the entry point of the application.

### 3.12.12 Procedure to Change the Flash Control Registers

During Flash configuration, no accesses to the Flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown for any code that modifies the Flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the Flash configuration code (that writes to Flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the Flash configuration cannot execute from the Flash or OTP and must reside in RAM.
3. Execute the Flash configuration code (can be located in RAM) that writes to Flash control registers like FRDCNTL, FRD\_INTF\_CTRL, and so on.
4. At the end of the Flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function that can reside in RAM or Flash/OTP and continue execution.

### 3.12.13 Simple Procedure to Modify an Application from RAM Configuration to Flash Configuration

All of the C2000Ware example projects are provided with both RAM and Flash build configurations. To change the build configuration from RAM to Flash, import the project in to the CCS IDE and right click on the project and select 'Build Configurations' -> 'Set Active' -> 'Flash'. By selecting this, notice that:

1. `_FLASH` symbol is defined in the "Predefined symbols" section under Project Build settings. This is used to define and execute any Flash-build specific code.
2. Flash-based linker command file is chosen for the application instead of a RAM-based linker command file. Flash-based linker command files are provided in the C2000Ware for reference (for example: `XXX_FLASH_Ink_cpu1.cmd` at `C2000Ware_x_xx_xx_xx\device_support\XXX\common\cmd`). Flash-based linker command files have `codestart` mapped to a Flash entry point address.
3. All of the initialized sections are mapped to Flash memory in the Flash-based linker command file.
4. All of the functions that need to execute from RAM (for initialization or 0-wait performance purpose) are assigned to the `.TI.ramfunc` section in the code. For example, `Flash_initModule()` is assigned to `.TI.ramfunc` section.
5. `.TI.ramfunc` section is mapped to a Flash address for "Load" and a RAM address for "RUN" in the Flash-based linker command file.
6. All of the sections mapped to Flash are aligned on a 128-bit boundary using the `ALIGN()` directive in the Flash-based linker command file.
7. `memcpy()` function is called in the application to copy the `.TI.ramfunc` content from Flash to RAM. The `memcpy()` is called before executing any code that is assigned to `.TI.ramfunc` section.
8. For EABI type executable: All uninitialized sections mapped to RAM are defined as `NOINIT` sections (using the directive "type=NOINIT") in the linker cmd file.

### 3.13 Dual Code Security Module (DCSM)

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) to unauthorized persons. It also prevents duplication and reverse engineering of proprietary code. The term “secure” implies that access to on-chip secure memories and resources are blocked. The term “unsecure” implies that access is allowed (the contents of the memory could be read by any means); for example, through a debugging tool such as the Code Composer Studio™ IDE.

The CSM has dual-zone security; zone1 and zone2.

#### 3.13.1 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone 1 (Z1) and Zone 2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF). This device has two Flash banks (Bank0 and Bank1) and each bank has its own USER OTP. Both banks' USER OTP are secure and partitioned between Zone1 and Zone2.
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM location in the Bank0 USER OTP.
- **Flash Sectors:** Flash sectors of both the banks (Bank0 and Bank1) can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT location in the respective bank's USER OTP.
- **Secure ROM:** This device also has secure ROM which is EXEONLY-protected. This ROM contains specific function for the user, provided by TI.

Table 3-16 shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

**Table 3-16. RAM/Flash Status**

Zone 1 GRAMRAMx/GRABSECTx Bits	Zone 2 GRAMRAMx/GRABSECT	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11 <sup>(2)</sup>	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11 <sup>(1)</sup>	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure

- (1) Zone1 must be unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user hence Zone1 will always be unsecure.
- (2) Zone2 must be unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user hence Zone2 will always be unsecure.

#### Note

The user should never program any other values in these fields. Failing any these conditions for a RAM block/Flash sector will make that RAM block/Flash sector inaccessible.

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in Bank0 USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 3.13.7.4](#).

There are three types of accesses:

- **Data/program reads:** Data reads to a secure memory are always blocked unless the program is executing from a memory that belongs to the same zone. Data reads to unsecure memory are always allowed. [Table 3-17](#) shows the levels of security.
- **JTAG access:** JTAG accesses are always blocked when a memory is secure.
- **Instruction fetches (calls, jumps, code executions, ISRs):** Instruction fetches are never blocked.

**Table 3-17. Security Levels**

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

### 3.13.1.1 CSM Passwords

Unlike earlier C2000™ devices, on this device an ALL\_1 value (0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL\_1 from USER OTP, the device is in a BLOCKED state. Due to this reason, TI programs a few bits in the second 32-bit password value (ZxOTP\_CSMPSWD1) in every zone select block of each zone with a value of 0. The default value for this password location is chosen in a manner that the respective ECC value remains ALL\_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See [Table 3-18](#) for ZxOTP\_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, change this value by flipping the bits that are 1 to 0 but leaving the bits that are already programmed by TI as 0. The BOOTROM code writes the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL\_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers which means the zone cannot be unlocked using PMF, the password match flow described in [Section 3.13.7.4](#). Therefore, never use an ALL\_0 as password. A password of ALL\_0 prevents debugging of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Default value of other fields in USER OTP are also not ALL\_1. While programming these setting in USER OTP, keep already programmed bits 0 only; else, programming operation does not work.

Default value for all the LINKPOINTER location in USER OTP is 0x1FFF FFFF.

**Table 3-18. Default Value of ZxOTP\_CSMPSWD1 and Other Fields (programmed by TI)**

Zone Select Block	Zone1		Zone2	
	Address	Value	Address	Value
PSWDLOCK (LSW)	0x0007 8010	0xFB7F FFFF	0x0007 8210	0xBF7F FFFF

### 3.13.1.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected trips the ECSL and breaks the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This write disables the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU starts running and can execute an instruction that performs an access to a protected ECSL area. If the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL trips and causes the emulator connection to be broken.

An answer to this problem is:

- Use the Wait Boot Mode boot option. In this mode, the CPU is in a loop and does not jump to the user application code. Using this BOOTMODE, connect to CCS IDE and debug the code.

### 3.13.1.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

### 3.13.1.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

### 3.13.1.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone's PSWDLOCK field with any value other than 1111 (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations are not secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a new device, the value for password lock fields for all zones at the PSWDLOCK location in OTP is 1111, which means the password for all zones is unlocked.

---

#### Note

Password unlock only makes password locations non-secure. All other secure memories and other locations of Flash sectors, which contain a password, remain secure as per security settings. But since passwords are non-secure, anyone can read the password and make the zone non-secure by running through PMF.

---

### 3.13.1.6 JTAG Lock

The JTAG lock feature can be used to *permanently* disable any access to the device using the JTAG port. For example, access by the Code Composer Studio™ IDE debugger or Flash programming tools are blocked. This feature is enabled by programming the Z1OTP\_JTAGLOCK location in user OTP memory with any value other than 1111 (0xF). Values of CRCLOCK, JTAGLOCK, and PSWDLOCK locations in the OTP memory are copied in the Z1\_OTPSECLOCK register by the boot-ROM code.

**CAUTION**

If the JTAG lock feature is enabled, all future debug of the device through JTAG is disabled. This specifically impairs TI's ability to analyze devices returned to TI for failure analysis. If the JTAG lock feature is enabled, TI rejects any return analysis requests.

**3.13.1.7 Link Pointer and Zone Select**

For each of the two security zones, a dedicated OTP block exists in both the banks that holds the configuration related to the zone's security. The following are the available programmed configurations:

**BANK0 USER OTP**

- B0\_ZxOTP\_LINKPOINTER1
- B0\_ZxOTP\_LINKPOINTER2
- B0\_ZxOTP\_LINKPOINTER3
- Z1OTP\_GPREG1
- Z1OTP\_GPREG2
- ZxOTP\_PSWDLOCK
- ZxOTP\_CRCLOCK
- Zx\_JTAGLOCK
- Z1OTP\_GPREG3
- Z1OTP\_BOOTCTRL
- ZxOTP\_EXEONLYRAM
- B0\_ZxOTP\_EXEONLYSECT
- ZxOTP\_GRABRAM
- B0\_ZxOTP\_GRABSECT
- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1
- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3

**BANK1 USER OTP**

- B1\_ZxOTP\_LINKPOINTER1
- B1\_ZxOTP\_LINKPOINTER2
- B1\_ZxOTP\_LINKPOINTER3
- Zx\_JTAGLOCK
- B1\_ZxOTP\_EXEONLYSECT
- B1\_ZxOTP\_GRABSECT

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks.

- ZxOTP\_EXEONLYRAM
- B0\_ZxOTP\_EXEONLYSECT
- ZxOTP\_GRABRAM
- B0\_ZxOTP\_GRABSECT
- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1
- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3
- B1\_ZxOTP\_EXEONLYSECT
- B1\_ZxOTP\_GRABSECT

The location of the zone select block in OTP is decided based on the value of three 29-bit link pointers (Bx-Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointer locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware when a dummy read is done to all the link pointers by comparing all the three values (bit-wise voting logic). Since in OTP, a 1 can be flipped by the user to 0, but 0 can not be flipped to 1 (no erase operation for OTP), the most-significant bit position in the resolved link pointer that is 0, defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in Figure 3-18, the final link pointer value becomes All\_1 (0xFFFF\_FFFF) which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Addr Offset Of Zone-Select Block
32'b00011111111111111111111111111111	0x20

Figure 3-18. Storage of Zone-Select Bits in OTP

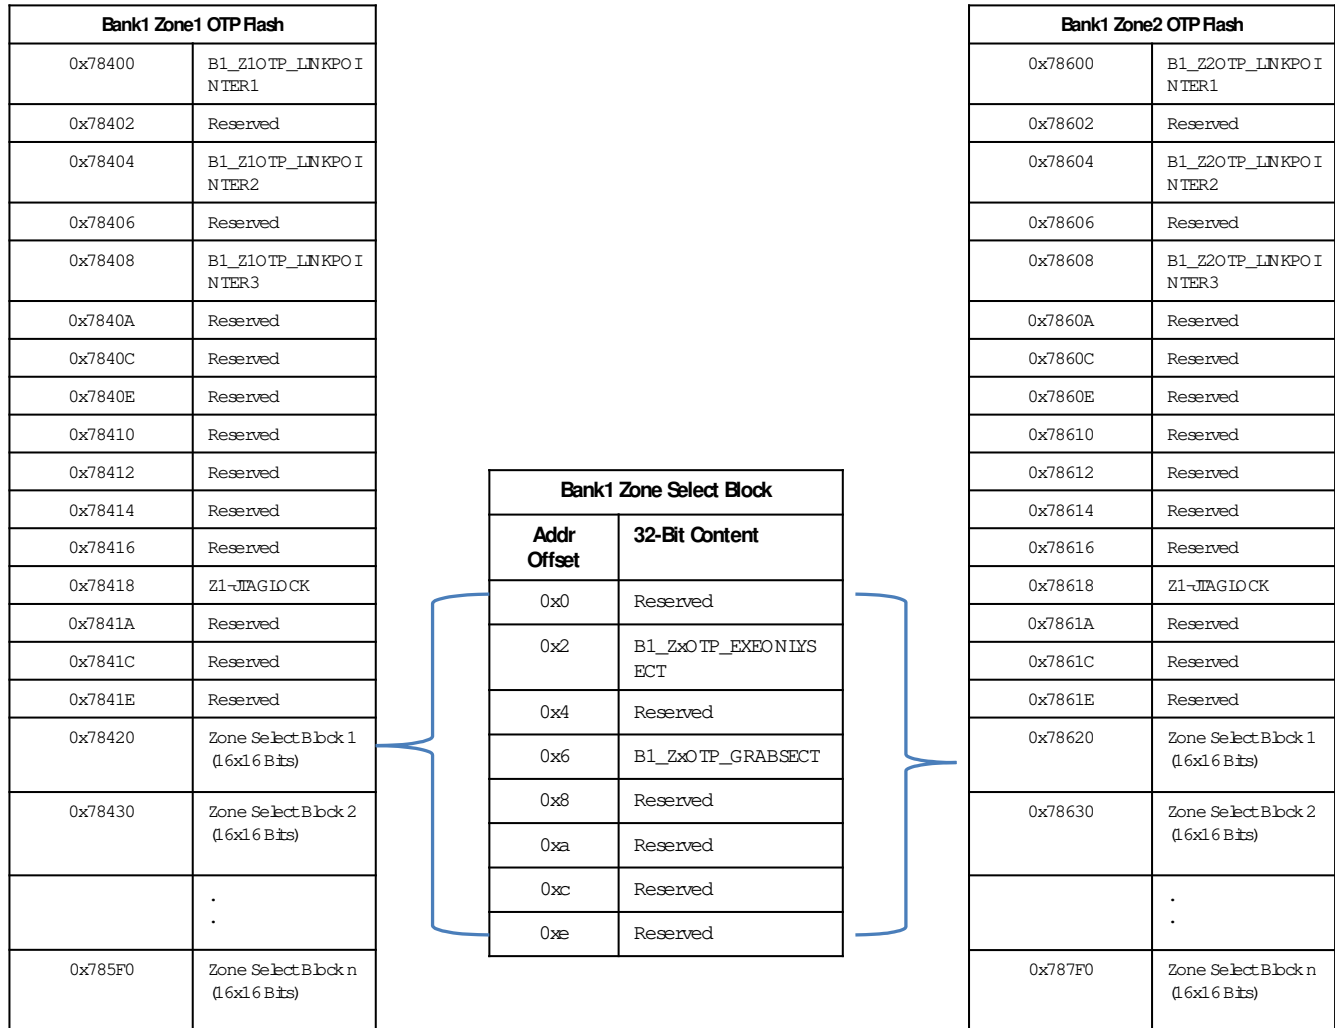

**Note**

Address locations for other security settings (PSWDLCK/CRCLOCK) that are not part of Zone Select blocks can be programmed only once; therefore, program the address locations toward the end of the development cycle.

Zone select blocks in BANK1 only have Zx-EXEONLYSECT and Zx-GRABSECT as valid configurations. Other locations in zone select block of BANK1 are reserved.

**Figure 3-19. Location of Zone-Select Block Based on Link-Pointer for Bank0**

**Figure 3-20. Location of Zone-Select Block Based on Link-Pointer for Bank1**

**CAUTION**

USER OTP is ECC protected. Program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value can cause the device to be blocked permanently and require replacing the device.

### 3.13.2 C Code Example to Get Zone Select Block Addr for Zone1 in BANK0

```

unsigned long LinkPointer;
unsigned long *ZoneSelBlockPtr;
int Bitpos = 28;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 30 and 29 as most-significant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 3;
while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        ZoneSelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 3)*16));
    }
    Else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    ZoneSelBlockPtr = (unsigned long *)0x78020;
}

```

#### 3.13.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has their own dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECT location in OTP of both the banks. Each zone has their own CSM passwords; read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Zone 2 and conversely. Before programming any secure Flash sector, either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory that belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

The Flash wrapper registers through which any Flash or OTP program/erase operations are performed are common resources shared by the two security zones. A semaphore mechanism is provided to avoid the conflict between Zone1 and Zone2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

#### 3.13.4 Safe Copy Code

In some applications, copy the code from secure Flash to secure RAM for better performance. Do not do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Safe Copy Code” library functions for each zone to enable copying content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

### 3.13.5 SafeCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC for content in EXEONLY memories using the VCU. But in some safety-critical applications, the user may have to calculate the CRC on these memories as well. To enable this without compromising on security, TI provides specific “SafeCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length\_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

---

#### Note

The user must disable all the interrupts before calling the safe copy code and the safeCRC function. If there is a vector fetch during copy code operation, the CPU gets reset immediately.

---

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

### 3.13.6 CSM Impact on Other On-Chip Resources

On this device, M0/M1 and GSx memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT\_ROM and OTP is accessible to the user.

The following steps are required after reset (any type of reset) to initialize the security on each CPU subsystem.

#### Security Initialization

- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER1 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER2 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER3 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER1 in Z2 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER2 in Z2 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER3 in Z2 OTP of Bank0
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER1 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER2 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER3 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER1 in Z2 OTP of Bank1
- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER2 in Z2 OTP of Bank1
- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER3 in Z2 OTP of Bank1
- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP\_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_CRCLOCK in Z1 OTP

- Dummy Read to address location of Z1-JTAGLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_GPREG1, Z1OTP\_GPREG2, Z1OTP\_GPREG3 in Z1 OTP of Bank0
- Dummy Read to address location of Z1OTP\_BOOTCTRL in Z1 OTP
- Dummy Read to address location of Z2OTP\_PSWDLOCK in Z2 OTP of Bank0
- Dummy Read to address location of Z2OTP\_CRCLOCK in Z2 OTP of Bank0
- Dummy Read to address location of Z2-JTAGLOCK in Z2 OTP of Bank0
- Read to memory-map register of B0\_Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP\_EXEONLYRAM in Z1 OTP of Bank0
- Dummy read to address location of B0\_Z1OTP\_EXEONLYSECT in Z1 OTP of Bank0
- Dummy read to address location of Z1OTP\_GRABRAM in Z1 OTP of Bank0
- Dummy read to address location of B0\_Z1OTP\_GRABSECT in Z1 OTP of Bank0
- Read to memory-map register of B0\_Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP\_EXEONLYRAM in Z2 OTP of Bank0
- Dummy read to address location of B0\_Z2OTP\_EXEONLYSECT in Z2 OTP of Bank0
- Dummy read to address location of Z2OTP\_GRABRAM in Z2 OTP of Bank0
- Dummy read to address location of B0\_Z2OTP\_GRABSECT in Z2 OTP of Bank0
- Read to memory-map register of B1\_Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of B1\_Z1OTP\_EXEONLYSECT in Z1 OTP of Bank1
- Dummy read to address location of B1\_Z1OTP\_GRABSECT in Z1 OTP of Bank1
- Read to memory-map register of B1\_Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of B1\_Z2OTP\_EXEONLYSECT in Z2 OTP of Bank1
- Dummy read to address location of B1\_Z2OTP\_GRABSECT in Z2 OTP of Bank1

#### **CAUTION**

Security Initialization is done by BOOTROM code on all the resets (as part of device initialization). This is not be part of user application code

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS IDE), the security initialization can occur in an incorrect order, locking the device down. To avoid this, do not keep a memory window with the USER OTP address opened in the debugger (CCS IDE) when performing a reset.

### 3.13.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password can be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx\_CR.15) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (using JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

#### 3.13.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring can be required:

- Code development using debuggers (such as Code Composer Studio™ IDE). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio™ On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the necessary password is supplied, the Flash utilities disable the security logic before attempting to program the Flash. The Flash utilities can disable the code security logic in new devices without any authorization, since new devices come with an erased Flash. However, reprogramming devices that already contain a custom password require the password to be supplied to the Flash utilities to unlock the device to enable programming. In custom programming that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application. In addition to the above, access to secure memory contents can be required in situations such as:
  - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
  - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code can compromise code security.

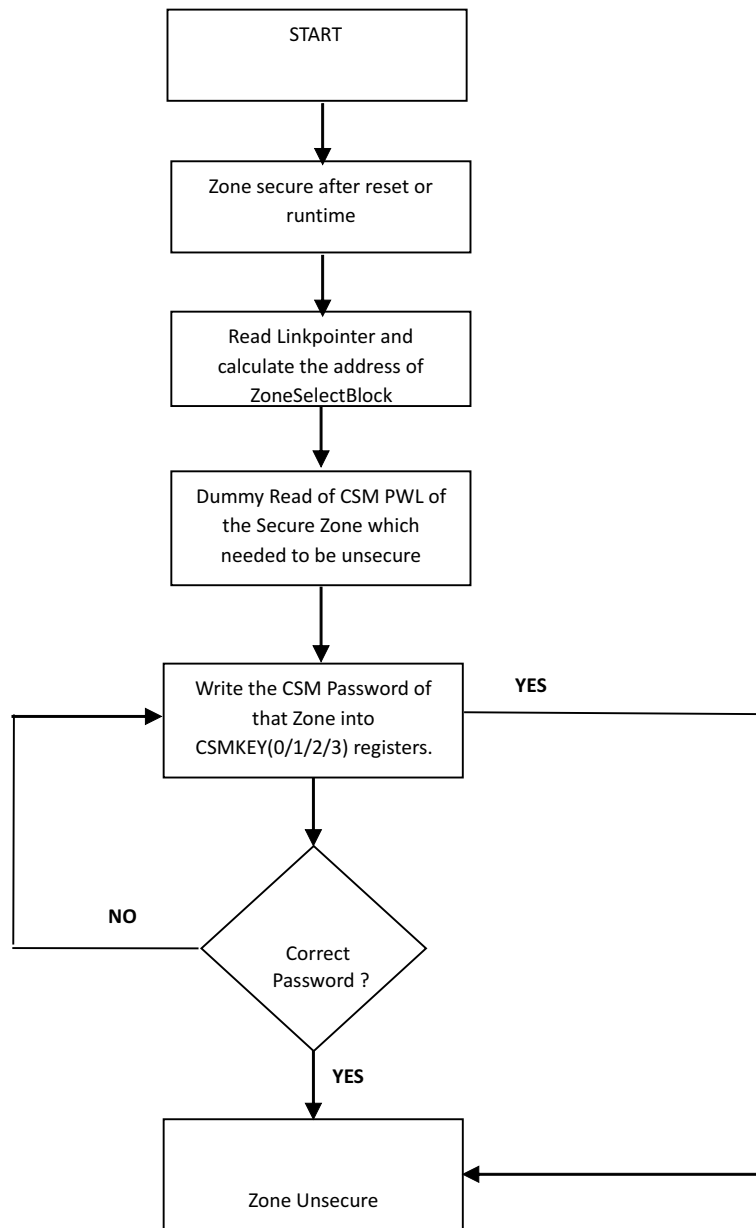

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 3-21](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

### 3.13.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to the CSMKEY(0/1/2/3) registers. [Figure 3-21](#) shows how PMF helps to initialize the security logic registers and disable security logic.

#### Note

User must disable the data cache by configuring DATA\_CACHE\_EN bit in the FRD\_INTF\_CTRL register to 0 before running CSM password match flow (PMF) in application.

**Figure 3-21. CSM Password Match Flow (PMF)**

### 3.13.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)0x5F010; //CSM register file
volatile long int *CSMPWL = (volatile long int *)0x78028; //CSM Password location (assuming default
// Zone select block)

volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// If the password locations (CSMPWL) are all = ones (0xFFFF),
// then the zone will now be unsecure. If the password
// is not all ones (0xFFFF), then the code below is required
// to unsecure the CSM.
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F014
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F016
```

### 3.13.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

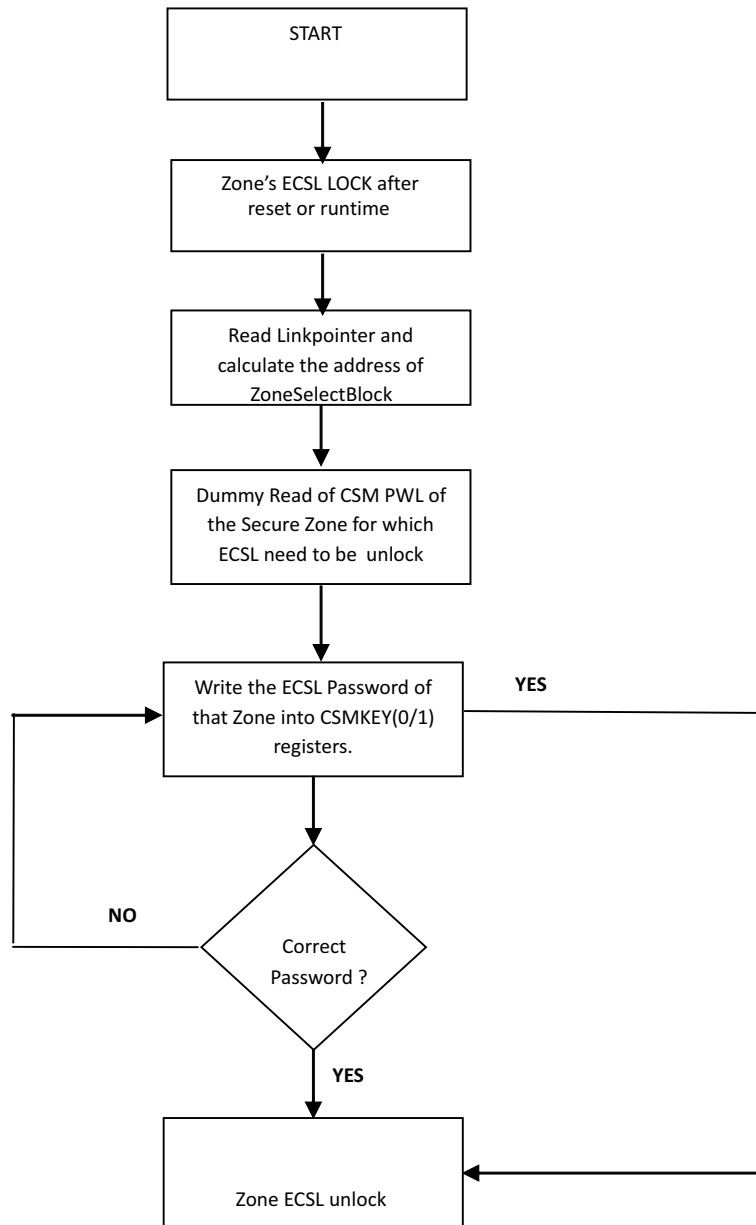

### 3.13.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and can halt while the main IP code is running. If ECSL is not unlocked, then Code Composer Studio IDE connections gets disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of CCS (JTAG).

### 3.13.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. Figure 3-22 shows how the PMF helps to initialize the security logic registers and disable security logic.

**Figure 3-22. ECSL Password Match Flow (PMF)**

### 3.13.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

#### 3.13.7.7.1 C Code Example to Disable ECSL for C28x-Zone1

```
volatile long int *ECSL = (volatile int *)0x5F000; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
                                                    Zone select block)

volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL)
.
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// If the ECSL password locations (ECSLPWL) are all = ones (0xFFFF),
// then the ECSL will now be disable. If the password
// is not all ones (0xFFFF), then the code below is required
// to disable the ECSL.
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMKEY then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
```

### 3.13.7.8 Device Unique ID

Bank 0 OTP contains a 256-bit value that is made up of both pseudo-random and sequential parts. This value may be used as a seed for code encryption. The starting address of the value is 0x703C0. The first 192 bits are pseudo-random, the next 32 bits are sequential, and the last 32 bits are a checksum value. The degree of randomness is not guaranteed.

### 3.14 System Control Register Configuration Restrictions

Memory-mapped registers in the System Control operate on INTOSC1 clock domain; hence, any CPU writes to these registers requires a delay between subsequent writes otherwise a second write can be lost. The application needs to take this into consideration and add a delay in terms of the number of NOP instructions after every write to these registers that are mentioned in [Table 3-19](#). The formula to compute delay between subsequent writes:

$$\text{Delay (in SYSCLK cycles)} = 3 \times (F_{\text{SYSCLK}} \div F_{\text{INTOSC1}}) + 9$$

For Example - For SYSCLK = 100MHz

$$\text{Delay (in SYSCLK cycles)} = 3 \times (100\text{MHz} \div 10\text{MHz}) + 9 = 39 \text{ SYSCLK cycles}$$

**Table 3-19. System Control Registers Impacted**

Registers requiring delay after every write
CLBCLKCTL

### 3.15.2 CPUTIMER\_REGS Registers

Table 3-21 lists the memory-mapped registers for the CPUTIMER\_REGS registers. All register offset addresses not listed in Table 3-21 should be considered as reserved locations and the register contents should not be modified.

**Table 3-21. CPUTIMER\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		<a href="#">Go</a>
2h	PRD	CPU-Timer, Period Register		<a href="#">Go</a>
4h	TCR	CPU-Timer, Control Register		<a href="#">Go</a>
6h	TPR	CPU-Timer, Prescale Register		<a href="#">Go</a>
7h	TPRH	CPU-Timer, Prescale Register High		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-22 shows the codes that are used for access types in this section.

**Table 3-22. CPUTIMER\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

### 3.15.2.1 TIM Register (Offset = 0h) [Reset = 0000FFFFh]

TIM is shown in [Figure 3-23](#) and described in [Table 3-23](#).

Return to the [Summary Table](#).

CPU-Timer, Counter Register

**Figure 3-23. TIM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

**Table 3-23. TIM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

### 3.15.2.2 PRD Register (Offset = 2h) [Reset = 0000FFFFh]

PRD is shown in [Figure 3-24](#) and described in [Table 3-24](#).

Return to the [Summary Table](#).

CPU-Timer, Period Register

**Figure 3-24. PRD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

**Table 3-24. PRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

### 3.15.2.3 TCR Register (Offset = 4h) [Reset = 0001h]

TCR is shown in [Figure 3-25](#) and described in [Table 3-25](#).

Return to the [Summary Table](#).

CPU-Timer, Control Register

**Figure 3-25. TCR Register**

15		14		13		12		11		10		9		8	
TIF		TIE		RESERVED				FREE		SOFT		RESERVED			
R/W1C-0h		R/W-0h		R-0h				R/W-0h		R/W-0h		R-0h			
7		6		5		4		3		2		1		0	
RESERVED				TRB		TSS		RESERVED							
R-0h				R/W-0h		R/W-0h		R-1h							

**Table 3-25. TCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

**Table 3-25. TCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDR:H:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

### 3.15.2.4 TPR Register (Offset = 6h) [Reset = 0000h]

TPR is shown in [Figure 3-26](#) and described in [Table 3-26](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register

**Figure 3-26. TPR Register**

TDDR							
R/W-0h							

**Table 3-26. TPR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	<p>CPU-Timer Prescale Counter.</p> <p>These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0.</p> <p>Reset type: SYSRSn</p>
7-0	TDDR	R/W	0h	<p>CPU-Timer Divide-Down.</p> <p>Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software.</p> <p>Reset type: SYSRSn</p>

### 3.15.2.5 TPRH Register (Offset = 7h) [Reset = 0000h]

TPRH is shown in [Figure 3-27](#) and described in [Table 3-27](#).

Return to the [Summary Table](#).

**Table 3-30. PIECTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

### 3.15.3.2 PIEACK Register (Offset = 1h) [Reset = 0000h]

PIEACK is shown in [Figure 3-29](#) and described in [Table 3-31](#).

Return to the [Summary Table](#).

#### Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.

Writes of 0 are ignored.

**Figure 3-29. PIEACK Register**

### 3.15.3.3 PIEIER1 Register (Offset = 2h) [Reset = 0000h]

PIEIER1 is shown in [Figure 3-30](#) and described in [Table 3-32](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

0	INTx1	R/W	0h	Enable for Interrupt 1.1 Reset type: SYSRSn

### 3.15.3.4 PIEIFR1 Register (Offset = 3h) [Reset = 0000h]

PIEIFR1 is shown in [Figure 3-31](#) and described in [Table 3-33](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-31. PIEIFR1 Register**

### 3.15.3.8 PIEIFR3 Register (Offset = 7h) [Reset = 0000h]

PIEIFR3 is shown in [Figure 3-35](#) and described in [Table 3-37](#).

Return to the [Summary Table](#).

#### Interrupt Group 3 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.15.3.16 PIEIFR7 Register (Offset = Fh) [Reset = 0000h]

PIEIFR7 is shown in [Figure 3-43](#) and described in [Table 3-45](#).

Return to the [Summary Table](#).

#### Interrupt Group 7 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.15.3.17 PIEIER8 Register (Offset = 10h) [Reset = 0000h]

PIEIER8 is shown in [Figure 3-44](#) and described in [Table 3-46](#).

Return to the [Summary Table](#).

#### Interrupt Group 8 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

### 3.15.3.24 PIEIFR11 Register (Offset = 17h) [Reset = 0000h]

PIEIFR11 is shown in [Figure 3-51](#) and described in [Table 3-53](#).

Return to the [Summary Table](#).

#### Interrupt Group 11 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.15.3.25 PIEIER12 Register (Offset = 18h) [Reset = 0000h]

PIEIER12 is shown in [Figure 3-52](#) and described in [Table 3-54](#).

Return to the [Summary Table](#).

#### Interrupt Group 12 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-52. PIEIER12 Register**

### 3.15.3.26 PIEIFR12 Register (Offset = 19h) [Reset = 0000h]

PIEIFR12 is shown in [Figure 3-53](#) and described in [Table 3-55](#).

Return to the [Summary Table](#).

#### Interrupt Group 12 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.15.4 WD\_REGS Registers

Table 3-56 lists the memory-mapped registers for the WD\_REGS registers. All register offset addresses not listed in Table 3-56 should be considered as reserved locations and the register contents should not be modified.

**Table 3-56. WD\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	<a href="#">Go</a>
23h	WDCNTR	Watchdog Counter Register	EALLOW	<a href="#">Go</a>
25h	WDKEY	Watchdog Reset Key Register	EALLOW	<a href="#">Go</a>
29h	WDCR	Watchdog Control Register	EALLOW	<a href="#">Go</a>
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-57 shows the codes that are used for access types in this section.

**Table 3-57. WD\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.4.1 SCSR Register (Offset = 22h) [Reset = 5h]

SCSR is shown in [Figure 3-54](#) and described in [Table 3-58](#).

Return to the [Summary Table](#).

#### System Control & Status Register

It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

**Figure 3-54. SCSR Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
RESERVED					WDINTS	WDENINT	WDOVERRIDE
R-0-0h					R-1h	R/W-0h	R/W1C-1h

**Table 3-58. SCSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	<p>Watchdog Interrupt Status</p> <p>This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The watchdog interrupt signal is active.</p> <p>1h (R/W) = The watchdog interrupt signal is inactive.</p>
1	WDENINT	R/W	0h	<p>Watchdog Interrupt Enable/Reset Disable</p> <p>This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Counter expiration triggers a reset. This is the default state on power-up and after any system reset.</p> <p>1h (R/W) = Counter expiration triggers an interrupt.</p>
0	WDOVERRIDE	R/W1C	1h	<p>If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user.</p> <p>Reset type: SYSRSn</p>

### 3.15.4.2 WDCNTR Register (Offset = 23h) [Reset = 0h]

WDCNTR is shown in [Figure 3-55](#) and described in [Table 3-59](#).

Return to the [Summary Table](#).

Watchdog Counter Register

**Figure 3-55. WDCNTR Register**

RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
WDCNTR							
R-0h							

**Table 3-59. WDCNTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDCNTR	R	0h	Watchdog Counter These bits contain the current value of the watchdog counter. This counter increments with each WDCLK (INTOSC1) cycle. If the counter overflows, either an interrupt or a reset is generated based on the value of the WDINTEN bit in the SCSR register. If the correct value is written to the WDKEY register, this counter is reset to zero. Reset type: IORSn

### 3.15.4.3 WDKEY Register (Offset = 25h) [Reset = 0h]

WDKEY is shown in [Figure 3-56](#) and described in [Table 3-60](#).

Return to the [Summary Table](#).

Watchdog Reset Key Register

**Figure 3-56. WDKEY Register**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDKEY	R/W	0h	Watchdog Counter Reset Writing 0x55 followed by 0xAA will cause the watchdog counter to reset to zero, preventing an overflow. Writing other values has no effect. Reads of this register return the value of the WDCR register. Reset type: IORSn

### 3.15.4.4 WDCR Register (Offset = 29h) [Reset = 0h]

WDCR is shown in [Figure 3-57](#) and described in [Table 3-61](#).

Return to the [Summary Table](#).

#### Watchdog Control Register

This memory mapped register requires a delay between subsequent writes to the register, otherwise a second write can be lost. The required delay is 69 SYSCLK cycles for a 200 MHz device, 45 SYSCLK cycles for a 120 MHz device, and 39 SYSCLK cycles for a 100 MHz device. This delay can be realized by adding NOP instructions corresponding to the required delay cycles.

**Figure 3-57. WDCR Register**

R/W1S-0h		R/W-0h		R-0/W-0h				R/W-0h							

**Table 3-61. WDCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ Reset type: IORSn 0h (R/W) = $PREDIVCLK = INTOSC1 / 512$ 1h (R/W) = $PREDIVCLK = INTOSC1 / 1024$ 2h (R/W) = $PREDIVCLK = INTOSC1 / 2048$ 3h (R/W) = $PREDIVCLK = INTOSC1 / 4096$ 4h (R/W) = Reserved 5h (R/W) = Reserved 6h (R/W) = Reserved 7h (R/W) = Reserved 8h (R/W) = $PREDIVCLK = INTOSC1 / 2$ 9h (R/W) = $PREDIVCLK = INTOSC1 / 4$ Ah (R/W) = $PREDIVCLK = INTOSC1 / 8$ Bh (R/W) = $PREDIVCLK = INTOSC1 / 16$ Ch (R/W) = $PREDIVCLK = INTOSC1 / 32$ Dh (R/W) = $PREDIVCLK = INTOSC1 / 64$ Eh (R/W) = $PREDIVCLK = INTOSC1 / 128$ Fh (R/W) = $PREDIVCLK = INTOSC1 / 256$
7	WDFLG	R/W1S	0h	Watchdog reset status flag bit. This bit, if set, indicates a watchdog reset (WDRSTn) generated the reset condition. If 0, then it was an external device or power-up reset condition. This bit remains latched until the user writes a 1 to clear the condition. Writes of 0 will be ignored. Reset type: IORSn
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn

**Table 3-61. WDCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn 0h (R/W) = $WDCLK = PREDIVCLK / 1$ 1h (R/W) = $WDCLK = PREDIVCLK / 1$ 2h (R/W) = $WDCLK = PREDIVCLK / 2$ 3h (R/W) = $WDCLK = PREDIVCLK / 4$ 4h (R/W) = $WDCLK = PREDIVCLK / 8$ 5h (R/W) = $WDCLK = PREDIVCLK / 16$ 6h (R/W) = $WDCLK = PREDIVCLK / 32$ 7h (R/W) = $WDCLK = PREDIVCLK / 64$

### 3.15.4.5 WDWCR Register (Offset = 2Ah) [Reset = 0h]

WDWCR is shown in [Figure 3-58](#) and described in [Table 3-62](#).

Return to the [Summary Table](#).

Watchdog Windowed Control Register

It can be cleared by a system reset or by writing to the corresponding bit in the NMIFLGCLR register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No uncorrectable error detected</p> <p>1h (R/W) = Uncorrectable error detected</p>
1	CLOCKFAIL	R	0h	<p>Clock Fail NMI Flag</p> <p>This bit indicates whether a clock fail condition has been detected. It can be cleared by a system reset or by writing to the corresponding bit in the NMIFLGCLR register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No clock fail detected</p> <p>1h (R/W) = Clock fail detected</p>
0	NMIINT	R	0h	<p>Global NMI Flag</p> <p>This bit indicates whether an NMI has been generated. It can be cleared by a system reset or by writing to the corresponding bit in the NMIFLGCLR register. No further NMIs are generated until this flag is cleared.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No NMI generated</p> <p>1h (R/W) = NMI generated</p>

### 3.15.5.3 NMIFLGCLR Register (Offset = 2h) [Reset = 0000h]

NMIFLGCLR is shown in [Figure 3-61](#) and described in [Table 3-67](#).

Return to the [Summary Table](#).

Writing a 1 to one of these bits clears the corresponding bit in the NMIFLG register. Writes of 0 are ignored, and these bits always read 0. If an NMI arrives on the same cycle that this register is written, the NMI is latched. All other NMI flags must be cleared before the NMIINT flag is cleared, otherwise NMIINT will be set again.

0	NMIINT	R-0/W1S	0h	Clear the NMIINT flag. This flag should only be cleared after all other active flags have been cleared. Reset type: SYSRSn

### 3.15.5.4 NMIFLGFRFC Register (Offset = 3h) [Reset = 0000h]

NMIFLGFRFC is shown in [Figure 3-62](#) and described in [Table 3-68](#).

Return to the [Summary Table](#).

Writing a 1 to one of these bits sets the corresponding bit in the NMIFLG register. Writes of 0 are ignored, and these bits always read 0. This register can be used to test the NMI functionality.

**Figure 3-62. NMIFLGFRFC Register**

### 3.15.5.5 NMIWDCNT Register (Offset = 4h) [Reset = 0000h]

NMIWDCNT is shown in [Figure 3-63](#) and described in [Table 3-69](#).

Return to the [Summary Table](#).

NMI Watchdog Counter Register

**Figure 3-63. NMIWDCNT Register**

15	14	13	12	11	10	9	8
NMIWDCNT							
R-0h							
7	6	5	4	3	2	1	0
NMIWDCNT							
R-0h							

**Table 3-69. NMIWDCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter This 16-bit counter increments once per SYSCLK cycle whenever any of the NMIFLG bits are set. If the counter reaches the period value in the NMIWDPRD register, the NMI module generates a reset (NMIWDRS). After this reset, the counter resets to zero and stops counting. If all NMI flags are cleared, the counter will reset to zero and stop counting until another NMI flag is set. Reset type: SYSRSn

### 3.15.5.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in [Figure 3-64](#) and described in [Table 3-70](#).

Return to the [Summary Table](#).

NMI Watchdog Period Register

**Table 3-70. NMIWDPRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	NMIWDPRD	R/W	FFFFh	NMI Watchdog Period These bits specify the period of the NMI watchdog timer in SYSCLK cycles. Writing a period value that is smaller than the current counter value will immediately force a reset (NMIWDRS). Reset type: SYSRSn

### 3.15.5.7 NMISHDFLG Register (Offset = 6h) [Reset = 0000h]

NMISHDFLG is shown in [Figure 3-65](#) and described in [Table 3-71](#).

Return to the [Summary Table](#).

These shadow flag bits are set whenever the corresponding bits in the NMIFLG register are set. The shadow flags are only reset by a power-on reset (POR), but any system or external reset will reset the normal flags. The shadow flags allow NMIs to be tracked across resets.

### 3.15.6 XINT\_REGS Registers

Table 3-72 lists the memory-mapped registers for the XINT\_REGS registers. All register offset addresses not listed in Table 3-72 should be considered as reserved locations and the register contents should not be modified.

**Table 3-72. XINT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	XINT1CR	XINT1 configuration register		<a href="#">Go</a>
1h	XINT2CR	XINT2 configuration register		<a href="#">Go</a>
2h	XINT3CR	XINT3 configuration register		<a href="#">Go</a>
3h	XINT4CR	XINT4 configuration register		<a href="#">Go</a>
4h	XINT5CR	XINT5 configuration register		<a href="#">Go</a>
8h	XINT1CTR	XINT1 counter register		<a href="#">Go</a>
9h	XINT2CTR	XINT2 counter register		<a href="#">Go</a>
Ah	XINT3CTR	XINT3 counter register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-73 shows the codes that are used for access types in this section.

**Table 3-73. XINT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.6.1 XINT1CR Register (Offset = 0h) [Reset = 0000h]

XINT1CR is shown in [Figure 3-66](#) and described in [Table 3-74](#).

Return to the [Summary Table](#).

INTCTR							
R-0h							

**Table 3-79. XINT1CTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

### 3.15.6.7 XINT2CTR Register (Offset = 9h) [Reset = 0000h]

XINT2CTR is shown in [Figure 3-72](#) and described in [Table 3-80](#).

Return to the [Summary Table](#).

Reads to the registers which have LOCK protection are always allowed Reset type: SYSRSn
0	DMACHSRCSEL1	R/WSoOnce	0h	DMACHSRCSEL1 Register Lock bit: 0: Respective register is not locked 1: Respective register is locked. Notes: [1] Any SOnce bit in this register, once set can only be cleared through a SYSRSn. Write of 0 to any bit of this register has no effect [2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed Reset type: SYSRSn

### 3.15.7.3 CLA1TASKSRCSEL1 Register (Offset = 6h) [Reset = 0000000h]

CLA1TASKSRCSEL1 is shown in [Figure 3-76](#) and described in [Table 3-86](#).

Return to the [Summary Table](#).

CLA1 Task Trigger Source Select Register-1

**Figure 3-76. CLA1TASKSRCSEL1 Register**

130h	TAP_STATUS	Status of JTAG State machine & Debugger Connect		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-91 shows the codes that are used for access types in this section.

**Table 3-91. DEV\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set

**Table 3-91. DEV\_CFG\_REGS Access Type Codes (continued)**

Access Type	Code	Description
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.8.1 PARTIDL Register (Offset = 8h) [Reset = 00XXXX0h]

PARTIDL is shown in [Figure 3-80](#) and described in [Table 3-92](#).

Return to the [Summary Table](#).

### 3.15.8.11 SOFTPRES7 Register (Offset = 90h) [Reset = 0000000h]

SOFTPRES7 is shown in [Figure 3-90](#) and described in [Table 3-102](#).

Return to the [Summary Table](#).

Peripheral Software Reset register

When bits in this register are set, the respective peripheral is in reset. All data is lost and the peripheral registers are returned to their reset states. Bits must be manually cleared after being set.

RESERVED												JTAG_nTRST			
R-0-0h												R/W-0h			

**Table 3-115. SOFTPRES40 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	JTAG_nTRST_Key	R-0/W	0h	0xDCAF : Writing this '0xDCAF' key value along with 0xA in JTAG_nTRST field causes a JTAG nTRST pulse to be sent to the JTAG state machine. Any other write does not have impact on the JTAG state machine, bits are self clearing. Reset type: SYSRSn, TRSTn
15-4	RESERVED	R-0	0h	Reserved
3-0	JTAG_nTRST	R/W	0h	1010: Writing '1010' (along with valid key in JTAG_nTRST_Key) takes JTAG TAP to the Test Logic Reset (TLR) state. This can be used to clear unwanted JTAG state transitions due to system noise or pin transitions during power up on TCK and TMS. Writing this field will reset the CCS debugger connection. See the TAP_STATUS register for additional debug information on the JTAG state. Writing any other value or mismatched key does not have any effect on the JTAG TAP reset behavior. Once reset to JTAG is asserted then this field is cleared back to 0 (JTAG is only temporarily reset, not held in reset). Reset type: SYSRSn, TRSTn

### 3.15.8.25 TAP\_STATUS Register (Offset = 130h) [Reset = 0000000h]

TAP\_STATUS is shown in [Figure 3-104](#) and described in [Table 3-116](#).

Return to the [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. Table 3-118 shows the codes that are used for access types in this section.

**Table 3-118. CLK\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.9.1 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 0000000h]

CLKCFGLOCK1 is shown in [Figure 3-105](#) and described in [Table 3-119](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

**Table 3-120. CLKSRCCTL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	WDHALTI	R/W	0h	Watchdog HALT Mode Ignore Bit: This bit determines if WD is functional in the HALT mode or not. 0 = WD is not functional in the HALT mode. Clock to WD is gated when system enters HALT mode. Additionally, INTOSC1 and INTOSC2 are powered-down when system enters HALT mode 1 = WD is functional in the HALT mode. Clock to WD is not gated and INTOSC1/2 are not powered-down when system enters HALT mode Reset type: XRSn
4	RESERVED	R/W	0h	Reserved
3	INTOSC2OFF	R/W	0h	Internal Oscillator 2 Off Bit: This bit turns oscillator 2 off: 0 = Internal Oscillator 2 On (default on reset) 1 = Internal Oscillator 2 Off This bit could be used by the user to turn off the internal oscillator 2 if it is not used. NOTE: Ensure no resources are using a clock source prior to disabling it. For example OSCCLKSRCSEL (SYSPLL), AUXOSCCLKSRCSEL (AUXPLL), TMR2CLKSRCSEL (CPUTIMER2) and XCLOCKOUT (XCLKOUT). Reset type: XRSn
2	RESERVED	R-0	0h	Reserved

**Table 3-120. CLKSRCCTL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	<p>Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK.</p> <p>00 = INTOSC2 (default on reset)            01 = External Oscillator (XTAL)            10 = INTOSC1            11 = reserved (default to INTOSC1)</p> <p>At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier.</p> <p>The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete..</p> <p>Notes:            [1] Reserved selection defaults to 00 configuration            [2] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL.</p> <p>Reset type: XRSn</p>

### 3.15.9.3 CLKSRCCTL2 Register (Offset = Ah) [Reset = 0000000h]

CLKSRCCTL2 is shown in [Figure 3-107](#) and described in [Table 3-121](#).

Return to the [Summary Table](#).

Clock Source Control register-2

This memory mapped register requires a delay of 39 SYSCCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 39 NOP instructions.

2	RESERVED	R/W	1h	Reserved
1	SE	R/W	0h	Configures XTAL oscillator in single-ended or Crystal mode when XTAL oscillator is powered up (i.e. OSCOFF = 0) 0 XTAL oscillator in Crystal mode 1 XTAL oscillator in single-ended mode (through X1) Reset type: XRSn
0	OSCOFF	R/W	1h	This bit if '1', powers-down the XTAL oscillator macro and hence doesn't let X2 to be driven by the XTAL oscillator. If a crystal is connected to X1/X2, user needs to first clear this bit, wait for the oscillator to power up (using X1CNT) and then only switch the clock source to X1/X2 Reset type: XRSn

### 3.15.10 CPU\_SYS\_REGS Registers

Table 3-132 lists the memory-mapped registers for the CPU\_SYS\_REGS registers. All register offset addresses not listed in Table 3-132 should be considered as reserved locations and the register contents should not be modified.

**Table 3-132. CPU\_SYS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CPUSYSLOCK1	Lock bit for CPUSYS registers	EALLOW	<a href="#">Go</a>
Ah	PIEVERRADDR	PIE Vector Fetch Error Address register	EALLOW	<a href="#">Go</a>
22h	PCLKCR0	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
26h	PCLKCR2	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
28h	PCLKCR3	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
2Ah	PCLKCR4	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
2Eh	PCLKCR6	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
30h	PCLKCR7	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
32h	PCLKCR8	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
34h	PCLKCR9	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
36h	PCLKCR10	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
3Ch	PCLKCR13	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
3Eh	PCLKCR14	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
40h	PCLKCR15	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
42h	PCLKCR16	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
44h	PCLKCR17	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
46h	PCLKCR18	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
48h	PCLKCR19	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
4Ah	PCLKCR20	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
4Ch	PCLKCR21	Peripheral Clock Gating Registers	EALLOW	<a href="#">Go</a>
76h	LPMCR	LPM Control Register	EALLOW	<a href="#">Go</a>
78h	GPIOLPMSEL0	GPIO LPM Wakeup select registers	EALLOW	<a href="#">Go</a>
7Ah	GPIOLPMSEL1	GPIO LPM Wakeup select registers	EALLOW	<a href="#">Go</a>
7Ch	TMR2CLKCTL	Timer2 Clock Measurement functionality control register	EALLOW	<a href="#">Go</a>
7Eh	RESCCLR	Reset Cause Clear Register		<a href="#">Go</a>
80h	RESC	Reset Cause register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-133 shows the codes that are used for access types in this section.

**Table 3-133. CPU\_SYS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once

**Table 3-133. CPU\_SYS\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.10.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0000000h]

CPUSYSLOCK1 is shown in [Figure 3-118](#) and described in [Table 3-134](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.15.10.23 GPIO\_LPMSEL1 Register (Offset = 7Ah) [Reset = 0000000h]

GPIO\_LPMSEL1 is shown in [Figure 3-140](#) and described in [Table 3-156](#).

Return to the [Summary Table](#).

GPIO LPM Wakeup select registers

Connects the selected pin to the LPM circuit. Refer to LPM section of the TRM for the wakeup capabilities of the selected pin.

### 3.15.10.24 TMR2CLKCTL Register (Offset = 7Ch) [Reset = 0000000h]

TMR2CLKCTL is shown in [Figure 3-141](#) and described in [Table 3-157](#).

Return to the [Summary Table](#).

Timer2 Clock Measurement functionality control register

This memory mapped register requires a delay of 39 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 39 NOP instructions.

Complex bit access types are encoded to fit into small table cells. [Table 3-161](#) shows the codes that are used for access types in this section.

**Table 3-161. PERIPH\_AC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.11.1 ADCA\_AC Register (Offset = 0h) [Reset = 000003Fh]

ADCA\_AC is shown in [Figure 3-144](#) and described in [Table 3-162](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

31-6	RESERVED	R-0	0h	Reserved
5-4	DMA1_ACC	R/W	3h	Defines Access control definition for the DMA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPU1_ACC	R/W	3h	Defines Access control definition for the CPU1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.15.11.4 CMPSS1\_AC Register (Offset = 10h) [Reset = 0000003Fh]

CMPSS1\_AC is shown in [Figure 3-147](#) and described in [Table 3-165](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPU1_ACC	R/W	3h	Defines Access control definition for the CPU1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.15.11.17 PGA5\_AC Register (Offset = 40h) [Reset = 000003Fh]

PGA5\_AC is shown in [Figure 3-160](#) and described in [Table 3-178](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

0	LOCK_AC_WR	R/WOnce	0h	Defines Access control definition for the CPU1 as: 1: Access Control registers are Read Only 0: Read/Write Access allowed to Access Control registers. Writing '1' sets the bit, writing '0' has no effect. Reset type: SYSRSn

### 3.15.12 DCSM\_BANK0\_Z1\_REGS Registers

Table 3-214 lists the memory-mapped registers for the DCSM\_BANK0\_Z1\_REGS registers. All register offset addresses not listed in Table 3-214 should be considered as reserved locations and the register contents should not be modified.

**Table 3-214. DCSM\_BANK0\_Z1\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B0_Z1_LINKPOINTER	Zone 1 Link Pointer for flash BANK0		<a href="#">Go</a>
2h	Z1_OTPSECLOCK	Zone 1 OTP Secure JTAG lock		<a href="#">Go</a>
4h	Z1_BOOTDEF_HIGH	Boot definition (high 32bit)		<a href="#">Go</a>
6h	B0_Z1_LINKPOINTERERR	Link Pointer Error for flash BANK0		<a href="#">Go</a>
8h	Z1_BOOTPIN_CONFIG	Boot Pin Configuration		<a href="#">Go</a>
Ah	Z1_GPREG2	Zone1 General Purpose Register-2		<a href="#">Go</a>
Ch	Z1_BOOTDEF_LOW	Boot definition (low 32bit)		<a href="#">Go</a>
10h	Z1_CSMKEY0	Zone 1 CSM Key 0		<a href="#">Go</a>
12h	Z1_CSMKEY1	Zone 1 CSM Key 1		<a href="#">Go</a>
14h	Z1_CSMKEY2	Zone 1 CSM Key 2		<a href="#">Go</a>
16h	Z1_CSMKEY3	Zone 1 CSM Key 3		<a href="#">Go</a>
19h	Z1_CR	Zone 1 CSM Control Register		<a href="#">Go</a>
1Ah	B0_Z1_GRABSECTR	Zone 1 Grab Flash BANK0 Sectors Register		<a href="#">Go</a>
1Ch	Z1_GRABRAMR	Zone 1 Grab RAM Blocks Register		<a href="#">Go</a>
1Eh	B0_Z1_EXEONLYSECTR	Zone 1 Flash BANK0 Execute_Only Sector Register		<a href="#">Go</a>
20h	Z1_EXEONLYRAMR	Zone 1 RAM Execute_Only Block Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-215 shows the codes that are used for access types in this section.

**Table 3-215. DCSM\_BANK0\_Z1\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.12.1 B0\_Z1\_LINKPOINTER Register (Offset = 0h) [Reset = E000000h]

B0\_Z1\_LINKPOINTER is shown in [Figure 3-196](#) and described in [Table 3-216](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer for flash BANK0

### 3.15.13 DCSM\_BANK0\_Z2\_REGS Registers

Table 3-232 lists the memory-mapped registers for the DCSM\_BANK0\_Z2\_REGS registers. All register offset addresses not listed in Table 3-232 should be considered as reserved locations and the register contents should not be modified.

**Table 3-232. DCSM\_BANK0\_Z2\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B0_Z2_LINKPOINTER	Zone 2 Link Pointer for flash BANK0		<a href="#">Go</a>
2h	Z2_OTPSECLOCK	Zone 2 OTP Secure JTAG lock		<a href="#">Go</a>
6h	B0_Z2_LINKPOINTERERR	Link Pointer Error for flash BANK0		<a href="#">Go</a>
10h	Z2_CSMKEY0	Zone 2 CSM Key 0		<a href="#">Go</a>
12h	Z2_CSMKEY1	Zone 2 CSM Key 1		<a href="#">Go</a>
14h	Z2_CSMKEY2	Zone 2 CSM Key 2		<a href="#">Go</a>
16h	Z2_CSMKEY3	Zone 2 CSM Key 3		<a href="#">Go</a>
19h	Z2_CR	Zone 2 CSM Control Register		<a href="#">Go</a>
1Ah	B0_Z2_GRABSECTR	Zone 2 Grab Flash BANK0 Sectors Register		<a href="#">Go</a>
1Ch	Z2_GRABRAMR	Zone 2 Grab RAM Blocks Register		<a href="#">Go</a>
1Eh	B0_Z2_EXEONLYSECTR	Zone 2 Flash BANK0 Execute_Only Sector Register		<a href="#">Go</a>
20h	Z2_EXEONLYRAMR	Zone 2 RAM Execute_Only Block Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-233 shows the codes that are used for access types in this section.

**Table 3-233. DCSM\_BANK0\_Z2\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.13.1 B0\_Z2\_LINKPOINTER Register (Offset = 0h) [Reset = E000000h]

B0\_Z2\_LINKPOINTER is shown in [Figure 3-212](#) and described in [Table 3-234](#).

Return to the [Summary Table](#).

Zone 2 Link Pointer for flash BANK0

**Figure 3-212. B0\_Z2\_LINKPOINTER Register**

### 3.15.14 DCSM\_COMMON\_REGS Registers

Table 3-246 lists the memory-mapped registers for the DCSM\_COMMON\_REGS registers. All register offset addresses not listed in Table 3-246 should be considered as reserved locations and the register contents should not be modified.

**Table 3-246. DCSM\_COMMON\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	<a href="#">Go</a>
2h	B0_SECTSTAT	Flash BANK0 Sectors Status Register		<a href="#">Go</a>
4h	RAMSTAT	RAM Status Register		<a href="#">Go</a>
8h	B1_SECTSTAT	Flash BANK1 Sectors Status Register		<a href="#">Go</a>
Ah	SECERRSTAT	Security Error Status Register		<a href="#">Go</a>
Ch	SECERRCLR	Security Error Clear Register		<a href="#">Go</a>
Eh	SECERRFRC	Security Error Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-247 shows the codes that are used for access types in this section.

**Table 3-247. DCSM\_COMMON\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.14.1 FLSEM Register (Offset = 0h) [Reset = 0000000h]

FLSEM is shown in [Figure 3-224](#) and described in [Table 3-248](#).

Return to the [Summary Table](#).

**Table 3-254. SECERRFRC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R-0	0h	Reserved
0	ERR	R-0/W1S	0h	A write of '1' sets the SECERRSTST.ERR bit. Write of '0' is ignored. This bit always reads back '0'. Reset type: N/A

### 3.15.15 DCSM\_BANK1\_Z1\_REGS Registers

Table 3-255 lists the memory-mapped registers for the DCSM\_BANK1\_Z1\_REGS registers. All register offset addresses not listed in Table 3-255 should be considered as reserved locations and the register contents should not be modified.

**Table 3-255. DCSM\_BANK1\_Z1\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B1_Z1_LINKPOINTER	Zone 1 Link Pointer for flash BANK1		<a href="#">Go</a>
6h	B1_Z1_LINKPOINTERERR	Link Pointer Error for flash BANK1		<a href="#">Go</a>
1Ah	B1_Z1_GRABSECTR	Zone 1 Grab Flash BANK1 Sectors Register		<a href="#">Go</a>
1Eh	B1_Z1_EXEONLYSECTR	Zone 1 Flash BANK1 Execute_Only Sector Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-256 shows the codes that are used for access types in this section.

**Table 3-256. DCSM\_BANK1\_Z1\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.15.1 B1\_Z1\_LINKPOINTER Register (Offset = 0h) [Reset = E000000h]

B1\_Z1\_LINKPOINTER is shown in [Figure 3-231](#) and described in [Table 3-257](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer for flash BANK1

**Figure 3-231. B1\_Z1\_LINKPOINTER Register**

### 3.15.16 DCSM\_BANK1\_Z2\_REGS Registers

Table 3-261 lists the memory-mapped registers for the DCSM\_BANK1\_Z2\_REGS registers. All register offset addresses not listed in Table 3-261 should be considered as reserved locations and the register contents should not be modified.

**Table 3-261. DCSM\_BANK1\_Z2\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B1_Z2_LINKPOINTER	Zone 2 Link Pointer for flash BANK1		<a href="#">Go</a>
6h	B1_Z2_LINKPOINTERERR	Link Pointer Error for flash BANK1		<a href="#">Go</a>
1Ah	B1_Z2_GRABSECTR	Zone 2 Grab Flash BANK1 Sectors Register		<a href="#">Go</a>
1Eh	B1_Z2_EXEONLYSECTR	Zone 2 Flash BANK1 Execute_Only Sector Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-262 shows the codes that are used for access types in this section.

**Table 3-262. DCSM\_BANK1\_Z2\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.16.1 B1\_Z2\_LINKPOINTER Register (Offset = 0h) [Reset = E000000h]

B1\_Z2\_LINKPOINTER is shown in [Figure 3-235](#) and described in [Table 3-263](#).

Return to the [Summary Table](#).

Zone 2 Link Pointer for flash BANK1

**Figure 3-235. B1\_Z2\_LINKPOINTER Register**

50h	GSxTEST	Global Shared RAM TEST Register	EALLOW	<a href="#">Go</a>
52h	GSxINIT	Global Shared RAM Init Register	EALLOW	<a href="#">Go</a>
54h	GSxINITDONE	Global Shared RAM InitDone Status Register		<a href="#">Go</a>
60h	MSGxLOCK	Message RAM Config Lock Register		<a href="#">Go</a>
62h	MSGxCOMMIT	Message RAM Config Lock Commit Register		<a href="#">Go</a>
70h	MSGxTEST	Message RAM TEST Register	EALLOW	<a href="#">Go</a>
72h	MSGxINIT	Message RAM Init Register	EALLOW	<a href="#">Go</a>
74h	MSGxINITDONE	Message RAM InitDone Status Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-268 shows the codes that are used for access types in this section.

**Table 3-268. MEM\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write

**Table 3-268. MEM\_CFG\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.17.1 DxLOCK Register (Offset = 0h) [Reset = 0000000h]

DxLOCK is shown in [Figure 3-239](#) and described in [Table 3-269](#).

Return to the [Summary Table](#).

### 3.15.18 ACCESS\_PROTECTION\_REGS Registers

Table 3-298 lists the memory-mapped registers for the ACCESS\_PROTECTION\_REGS registers. All register offset addresses not listed in Table 3-298 should be considered as reserved locations and the register contents should not be modified.

**Table 3-298. ACCESS\_PROTECTION\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	NMAVFLG	Non-Master Access Violation Flag Register		<a href="#">Go</a>
2h	NMAVSET	Non-Master Access Violation Flag Set Register	EALLOW	<a href="#">Go</a>
4h	NMAVCLR	Non-Master Access Violation Flag Clear Register	EALLOW	<a href="#">Go</a>
6h	NMAVINTEN	Non-Master Access Violation Interrupt Enable Register	EALLOW	<a href="#">Go</a>
8h	NMCPURDAVADDR	Non-Master CPU Read Access Violation Address		<a href="#">Go</a>
Ah	NMCPUWRAVADDR	Non-Master CPU Write Access Violation Address		<a href="#">Go</a>
Ch	NMCPUFAVADDR	Non-Master CPU Fetch Access Violation Address		<a href="#">Go</a>
Eh	NMDMAWRAVADDR	Non-Master DMA Write Access Violation Address		<a href="#">Go</a>
10h	NMCLA1RDAVADDR	Non-Master CLA1 Read Access Violation Address		<a href="#">Go</a>
12h	NMCLA1WRAVADDR	Non-Master CLA1 Write Access Violation Address		<a href="#">Go</a>
14h	NMCLA1FAVADDR	Non-Master CLA1 Fetch Access Violation Address		<a href="#">Go</a>
20h	MAVFLG	Master Access Violation Flag Register		<a href="#">Go</a>
22h	MAVSET	Master Access Violation Flag Set Register	EALLOW	<a href="#">Go</a>
24h	MAVCLR	Master Access Violation Flag Clear Register	EALLOW	<a href="#">Go</a>
26h	MAVINTEN	Master Access Violation Interrupt Enable Register	EALLOW	<a href="#">Go</a>
28h	MCPUFAVADDR	Master CPU Fetch Access Violation Address		<a href="#">Go</a>
2Ah	MCPUWRAVADDR	Master CPU Write Access Violation Address		<a href="#">Go</a>
2Ch	MDMAWRAVADDR	Master DMA Write Access Violation Address		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-299 shows the codes that are used for access types in this section.

**Table 3-299. ACCESS\_PROTECTION\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

**Table 3-299. ACCESS\_PROTECTION\_REGS Access Type Codes (continued)**

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.18.1 NMAVFLG Register (Offset = 0h) [Reset = 0000000h]

NMAVFLG is shown in [Figure 3-268](#) and described in [Table 3-300](#).

Return to the [Summary Table](#).

### 3.15.19 MEMORY\_ERROR\_REGS Registers

Table 3-318 lists the memory-mapped registers for the MEMORY\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-318 should be considered as reserved locations and the register contents should not be modified.

**Table 3-318. MEMORY\_ERROR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	UCERRFLG	Uncorrectable Error Flag Register		<a href="#">Go</a>
2h	UCERRSET	Uncorrectable Error Flag Set Register	EALLOW	<a href="#">Go</a>
4h	UCERRCLR	Uncorrectable Error Flag Clear Register	EALLOW	<a href="#">Go</a>
6h	UCCPUREADDR	Uncorrectable CPU Read Error Address		<a href="#">Go</a>
8h	UCDMAREADDR	Uncorrectable DMA Read Error Address		<a href="#">Go</a>
Ah	UCCLA1READDR	Uncorrectable CLA1 Read Error Address		<a href="#">Go</a>
20h	CERRFLG	Correctable Error Flag Register		<a href="#">Go</a>
22h	CERRSET	Correctable Error Flag Set Register	EALLOW	<a href="#">Go</a>
24h	CERRCLR	Correctable Error Flag Clear Register	EALLOW	<a href="#">Go</a>
26h	CCPUREADDR	Correctable CPU Read Error Address		<a href="#">Go</a>
2Eh	CERRCNT	Correctable Error Count Register		<a href="#">Go</a>
30h	CERRTHRES	Correctable Error Threshold Value Register	EALLOW	<a href="#">Go</a>
32h	CEINTFLG	Correctable Error Interrupt Flag Status Register		<a href="#">Go</a>
34h	CEINTCLR	Correctable Error Interrupt Flag Clear Register	EALLOW	<a href="#">Go</a>
36h	CEINTSET	Correctable Error Interrupt Flag Set Register	EALLOW	<a href="#">Go</a>
38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-319 shows the codes that are used for access types in this section.

**Table 3-319. MEMORY\_ERROR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.19.1 UCERRFLG Register (Offset = 0h) [Reset = 0000000h]

UCERRFLG is shown in [Figure 3-286](#) and described in [Table 3-320](#).

Return to the [Summary Table](#).

31-0	CCPUREADDR	R	0h	This register captures the address location for which CPU read/fetch access resulted in correctable ECC error. Reset type: SYSRSn

### 3.15.19.11 CERRCNT Register (Offset = 2Eh) [Reset = 0000000h]

CERRCNT is shown in [Figure 3-296](#) and described in [Table 3-330](#).

Return to the [Summary Table](#).

Correctable Error Count Register

**Figure 3-296. CERRCNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CERRCNT																															
R-0h																															

**Table 3-330. CERRCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CERRCNT	R	0h	This register holds the count of how many times correctable error occurred. Reset type: SYSRSn

### 3.15.19.12 CERRTHRES Register (Offset = 30h) [Reset = 0000000h]

CERRTHRES is shown in [Figure 3-297](#) and described in [Table 3-331](#).

Return to the [Summary Table](#).

Correctable Error Threshold Value Register

**Figure 3-297. CERRTHRES Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CERRTHRES																															
R/W-0h																															

**Table 3-331. CERRTHRES Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CERRTHRES	R/W	0h	When value in CERRCNT register is greater than value configured in this register, correctable interrupt gets generated, if enabled. Reset type: SYSRSn

### 3.15.19.13 CEINTFLG Register (Offset = 32h) [Reset = 0000000h]

CEINTFLG is shown in [Figure 3-298](#) and described in [Table 3-332](#).

Return to the [Summary Table](#).

Correctable Error Interrupt Flag Status Register

**Figure 3-298. CEINTFLG Register**

0	CEINTEN	R/W	0h	0: Correctable Error Interrupt is disabled. 1: Correctable Error Interrupt is enabled. Reset type: SYSRSn

### 3.15.20 FLASH\_CTRL\_REGS Registers

Table 3-336 lists the memory-mapped registers for the FLASH\_CTRL\_REGS registers. All register offset addresses not listed in Table 3-336 should be considered as reserved locations and the register contents should not be modified.

**Table 3-336. FLASH\_CTRL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	FRDCNTL	Flash Read Control Register	EALLOW	<a href="#">Go</a>
1Eh	FBAC	Flash Bank Access Control Register	EALLOW	<a href="#">Go</a>
20h	FBFALLBACK	Flash Bank Fallback Power Register	EALLOW	<a href="#">Go</a>
22h	FBPRDY	Flash Bank Pump Ready Register	EALLOW	<a href="#">Go</a>
24h	FPAC1	Flash Pump Access Control Register 1	EALLOW	<a href="#">Go</a>
26h	FPAC2	Flash Pump Access Control Register 2	EALLOW	<a href="#">Go</a>
2Ah	FMSTAT	Flash Module Status Register	EALLOW	<a href="#">Go</a>
180h	FRD_INTF_CTRL	Flash Read Interface Control Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-337 shows the codes that are used for access types in this section.

**Table 3-337. FLASH\_CTRL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.20.1 FRDCNTL Register (Offset = 0h) [Reset = F00h]

FRDCNTL is shown in [Figure 3-302](#) and described in [Table 3-338](#).

Return to the [Summary Table](#).

Flash Read Control Register

**Figure 3-302. FRDCNTL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED

RESERVED				RWAIT				RESERVED							
R-0h				R/W-Fh				R-0h							

**Table 3-338. FRDCNTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-12	RESERVED	R	0h	Reserved
11-8	RWAIT	R/W	Fh	Random read waitstate These bits indicate how many waitstates are added to a flash read/ fetch access. The RWAIT value can be set anywhere from 0 to 0xF. For a flash access, data is returned in RWAIT+1 SYSCLK cycles. Note: The required wait states for each SYSCLK frequency can be found in the device data manual. Reset type: SYSRSn
7-0	RESERVED	R	0h	Reserved

### 3.15.20.2 FBAC Register (Offset = 1Eh) [Reset = Fh]

FBAC is shown in [Figure 3-303](#) and described in [Table 3-339](#).

Return to the [Summary Table](#).

Flash Bank Access Control Register

**Figure 3-303. FBAC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																BAGP						RESERVED									
R-0h																R/W-0h						R/W-Fh									

**Table 3-339. FBAC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-8	BAGP	R/W	0h	Bank Active Grace Period. These bits contain the starting count value for the BAGP down counter. Any access to a given bank causes its BAGP counter to reload the BAGP value for that bank. After the last access to this flash bank, the down counter delays from 0 to 255 prescaled SYSCLK clock cycles before putting the bank into one of the fallback power modes as determined by the FBFALLBACK register. This value must be greater than 1 when the fallback mode is not ACTIVE. Note: The prescaled clock used for the BAGP down counter is a clock divided by 16 from input SYSCLK. Reset type: SYSRSn
7-0	RESERVED	R/W	Fh	Reserved

### 3.15.20.3 FBFALLBACK Register (Offset = 20h) [Reset = 0h]

FBFALLBACK is shown in [Figure 3-304](#) and described in [Table 3-340](#).

Return to the [Summary Table](#).

Flash Bank Fallback Power Register

**Table 3-341. FBPRDY Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15	PUMPRDY	R	0h	Pump Ready. This is a read-only bit which allows software to determine if the pump is ready for flash access before attempting the actual access. If an access is made to a bank when the pump is not ready, wait states are asserted until it becomes ready. 0 Pump is not ready. 1 Pump is ready, in active power state. Reset type: SYSRSn
14-2	RESERVED	R	0h	Reserved
1	BANK1RDY	R	0h	Bank 1 Ready. This is a read-only register which allows software to determine if the Bank 1 is ready for Flash access before the access is attempted. Note: The user should wait for both the pump and the bank to be ready before attempting an access. 0 Bank 1 is not ready. 1 Bank 1 is in active power mode and is ready for access. Reset type: SYSRSn
0	BANK0RDY	R	0h	Bank 0 Ready. This is a read-only register which allows software to determine if the Bank 0 is ready for Flash access before the access is attempted. Note: The user should wait for both the pump and the bank to be ready before attempting an access. 0 Bank 0 is not ready. 1 Bank 0 is in active power mode and is ready for access. Reset type: SYSRSn

### 3.15.20.5 FPAC1 Register (Offset = 24h) [Reset = 00A00000h]

FPAC1 is shown in [Figure 3-306](#) and described in [Table 3-342](#).

Return to the [Summary Table](#).

Flash Pump Access Control Register 1

**Figure 3-306. FPAC1 Register**

31	30	29	28	27	26	25	24
RESERVED				PSLEEP			
R-0h				R/W-A0h			
23	22	21	20	19	18	17	16

7	6	5	4	3	2	1	0
RESERVED						PMPPWR	
R-0h						R/W-0h	

**Table 3-342. FPAC1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	Reserved
27-16	PSLEEP	R/W	A0h	Pump sleep. These bits contain the starting count value for the charge pump sleep down counter. While the charge pump is in sleep mode, the power mode management logic holds the charge pump sleep counter at this value. When the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles before putting the charge pump into active power mode. Note: The pump sleep down counter uses the same prescaled clock as Bank sleep down counter which is divided by 2 of input SYSCLK. Note: BootROM configures the PSLEEP value as 0x3E8 for 100 MHz operation. Users can modify the PSLEEP value based on their application requirements if needed. Reset type: SYSRSn
15-1	RESERVED	R	0h	Reserved
0	PMPPWR	R/W	0h	Flash Charge Pump Fallback Power Mode. This bit selects what power mode the charge pump enters after the pump active grace period (PAGP) counter has timed out. 0 Sleep (all pump circuits disabled) 1 Active (all pump circuits active) Note for devices with multiple flash banks: As the pump is shared between flash banks, if an access is made either bank, the value of this bit changes to 1 (active). Reset type: SYSRSn

### 3.15.20.6 FPAC2 Register (Offset = 26h) [Reset = 0h]

FPAC2 is shown in [Figure 3-307](#) and described in [Table 3-343](#).

Return to the [Summary Table](#).

Flash Pump Access Control Register 2

**Figure 3-307. FPAC2 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																PAGP															
R-0h																R/W-0h															

**Table 3-343. FPAC2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	PAGP	R/W	0h	Pump Active Grace Period. This register contains the starting count value for the PAGP mode down counter. Any access to flash memory causes the counter to reload with the PAGP value. After the last access to flash memory, the down counter delays from 0 to 65535 prescaled SYSCLK clock cycles before entering one of the charge pump fallback power modes as determined by PUMPPWR in the FPAC1 register. Note: The PAGP down counter is clocked by the same prescaled clock as the BAGP down counter which is divided by 16 of input SYSCLK. Reset type: SYSRSn

### 3.15.20.7 FMSTAT Register (Offset = 2Ah) [Reset = 0h]

FMSTAT is shown in [Figure 3-308](#) and described in [Table 3-344](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18	UNC_ERR_H_CLR	R-0/W1S	0h	Uncorrectable error clear. Writing a 1 to this bit will clear the UNC_ERR_H bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn
17	FAIL_1_H_CLR	R-0/W1S	0h	Fail on 1 clear. Writing a 1 to this bit will clear the FAIL_1_H bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn
16	FAIL_0_H_CLR	R-0/W1S	0h	Fail on 0 clear. Writing a 1 to this bit will clear the FAIL_0_H bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn
15-3	RESERVED	R	0h	Reserved
2	UNC_ERR_L_CLR	R-0/W1S	0h	Uncorrectable error clear. Writing a 1 to this bit will clear the UNC_ERR_L bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn
1	FAIL_1_L_CLR	R-0/W1S	0h	Fail on 1 clear. Writing a 1 to this bit will clear the FAIL_1_L bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn
0	FAIL_0_L_CLR	R-0/W1S	0h	Fail on 0 clear. Writing a 1 to this bit will clear the FAIL_0_L bit of ERR_STATUS register. Writes of 0 have no effect. Read returns 0. Reset type: SYSRSn

### 3.15.21.9 ERR\_CNT Register (Offset = 10h) [Reset = 0000000h]

ERR\_CNT is shown in [Figure 3-318](#) and described in [Table 3-356](#).

Return to the [Summary Table](#).

Error Control

**Figure 3-318. ERR\_CNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ERR_CNT															
R-0h																R/W-0h															

**Table 3-356. ERR\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	ERR_CNT	R/W	0h	Single bit error count. This counter increments with every single bit ECC error occurrence. Upon reaching the threshold value counter stops counting on single bit errors. ERR_CNT can be cleared (irrespective of whether threshold is met or not) using 'Single Err Int Clear' bit. This is applicable for ECC logic test mode and normal operational mode. Reset type: SYSRSn

### 3.15.21.10 ERR\_THRESHOLD Register (Offset = 12h) [Reset = 0000000h]

ERR\_THRESHOLD is shown in [Figure 3-319](#) and described in [Table 3-357](#).

Return to the [Summary Table](#).

Error Threshold

**Figure 3-319. ERR\_THRESHOLD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ERR_THRESHOLD															
R-0h																R/W-0h															

**Table 3-357. ERR\_THRESHOLD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	ERR_THRESHOLD	R/W	0h	Single bit error threshold. Sets the threshold for single bit errors. When the ERR_CNT value equals the THRESHOLD value and a single bit error occurs, SINGLE_ERR_INT flag is set, and an interrupt is fired. Reset type: SYSRSn

### 3.15.21.11 ERR\_INTFLG Register (Offset = 14h) [Reset = 0000000h]

ERR\_INTFLG is shown in [Figure 3-320](#) and described in [Table 3-358](#).

Return to the [Summary Table](#).

RESERVED							ERR_TYPE
R-0h							R-0h
7	6	5	4	3	2	1	0
DATA_ERR_POS						UNC_ERR	SINGLE_ERR
R-0h						R-0h	R-0h

**Table 3-367. FECC\_STATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-9	RESERVED	R	0h	Reserved
8	ERR_TYPE	R	0h	Test mode ECC single bit error indicator. When 1, indicates that the single bit error is in check bits. When 0, indicates that the single bit error is in data bits (If SINGLE_ERR field is also set). Reset type: SYSRSn
7-2	DATA_ERR_POS	R	0h	Test mode single bit error position. Holds the bit position where the single bit error occurred. The position is interpreted depending on whether the CHK_ERR bit indicates a check bit or a data bit. If CHK_ERR indicates a check bit error, the error position could range from 0 to 7, or it could range from 0 to 63. Reset type: SYSRSn
1	UNC_ERR	R	0h	Test mode ECC double bit error. When 1 indicates that the ECC test resulted in an uncorrectable bit error. Reset type: SYSRSn
0	SINGLE_ERR	R	0h	Test mode ECC single bit error. When 1 indicates that the ECC test resulted in a single bit error. Reset type: SYSRSn

### 3.15.22 UID\_REGS Registers

Table 3-368 lists the memory-mapped registers for the UID\_REGS registers. All register offset addresses not listed in Table 3-368 should be considered as reserved locations and the register contents should not be modified.

**Table 3-368. UID\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	UID_PSRAND0	UID Psuedo-random 192 bit number		<a href="#">Go</a>
2h	UID_PSRAND1	UID Psuedo-random 192 bit number		<a href="#">Go</a>
4h	UID_PSRAND2	UID Psuedo-random 192 bit number		<a href="#">Go</a>
6h	UID_PSRAND3	UID Psuedo-random 192 bit number		<a href="#">Go</a>
8h	UID_PSRAND4	UID Psuedo-random 192 bit number		<a href="#">Go</a>
Ah	UID_PSRAND5	UID Psuedo-random 192 bit number		<a href="#">Go</a>
Ch	UID_UNIQUE	UID Unique 32 bit number		<a href="#">Go</a>
Eh	UID_CHECKSUM	UID Checksum		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-369 shows the codes that are used for access types in this section.

**Table 3-369. UID\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value

### 3.15.22.1 UID\_PSRAND0 Register (Offset = 0h) [Reset = 00000000h]

UID\_PSRAND0 is shown in [Figure 3-330](#) and described in [Table 3-370](#).

Return to the [Summary Table](#).

UID Psuedo-random 192 bit number

Bit	Field	Type	Reset	Description
31-0	Checksum	R	0h	Fletcher checksum of UID_PSRANDx and UID_UNIQUE Reset type: N/A

### 3.15.23 DCSM\_BANK0\_Z1\_OTP Registers

Table 3-378 lists the memory-mapped registers for the DCSM\_BANK0\_Z1\_OTP registers. All register offset addresses not listed in Table 3-378 should be considered as reserved locations and the register contents should not be modified.

**Table 3-378. DCSM\_BANK0\_Z1\_OTP Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B0_Z1OTP_LINKPOINTER1	Zone 1 Link Pointer1 in Z1 OTP for flash BANK0		<a href="#">Go</a>
4h	B0_Z1OTP_LINKPOINTER2	Zone 1 Link Pointer2 in Z1 OTP for flash BANK0		<a href="#">Go</a>
8h	B0_Z1OTP_LINKPOINTER3	Zone 1 Link Pointer3 in Z1 OTP for flash BANK0		<a href="#">Go</a>
Ch	Z1OTP_BOOTPIN_CONFIG	Boot Pin Configuration		<a href="#">Go</a>
Eh	Z1OTP_GPREG2	Zone-1 General Purpose Register-2 content		<a href="#">Go</a>
10h	Z1OTP_PSWDLOCK	Secure Password Lock in Z1 OTP		<a href="#">Go</a>
14h	Z1OTP_CRCLOCK	Secure CRC Lock in Z1 OTP		<a href="#">Go</a>
18h	Z1OTP_JTAGLOCK	Secure JTAG Lock in Z1 OTP		<a href="#">Go</a>
1Ch	Z1OTP_BOOTDEF_LOW	Boot definition (low 32bit)		<a href="#">Go</a>
1Eh	Z1OTP_BOOTDEF_HIGH	Boot definition (high 32bit)		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-379 shows the codes that are used for access types in this section.

**Table 3-379. DCSM\_BANK0\_Z1\_OTP Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.23.1 B0\_Z1OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

B0\_Z1OTP\_LINKPOINTER1 is shown in [Figure 3-338](#) and described in [Table 3-380](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer1 in Z1 OTP for flash BANK0

### 3.15.24 DCSM\_BANK0\_Z2\_OTP Registers

Table 3-390 lists the memory-mapped registers for the DCSM\_BANK0\_Z2\_OTP registers. All register offset addresses not listed in Table 3-390 should be considered as reserved locations and the register contents should not be modified.

**Table 3-390. DCSM\_BANK0\_Z2\_OTP Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B0_Z2OTP_LINKPOINTER1	Zone 2Link Pointer1 in Z2 OTP for flash BANK0		<a href="#">Go</a>
4h	B0_Z2OTP_LINKPOINTER2	Zone 2 Link Pointer2 in Z2 OTP for flash BANK0		<a href="#">Go</a>
8h	B0_Z2OTP_LINKPOINTER3	Zone 12Link Pointer3 in Z2 OTP for flash BANK0		<a href="#">Go</a>
10h	Z2OTP_PSWDLOCK	Secure Password Lock in Z2 OTP		<a href="#">Go</a>
14h	Z2OTP_CRCLOCK	Secure CRC Lock in Z2 OTP		<a href="#">Go</a>
18h	Z2OTP_JTAGLOCK	Secure JTAG Lock in Z2 OTP		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-391 shows the codes that are used for access types in this section.

**Table 3-391. DCSM\_BANK0\_Z2\_OTP Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.24.1 B0\_Z2OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

B0\_Z2OTP\_LINKPOINTER1 is shown in [Figure 3-348](#) and described in [Table 3-392](#).

Return to the [Summary Table](#).

Zone 2Link Pointer1 in Z2 OTP for flash BANK0

### 3.15.25 DCSM\_BANK1\_Z1\_OTP Registers

Table 3-398 lists the memory-mapped registers for the DCSM\_BANK1\_Z1\_OTP registers. All register offset addresses not listed in Table 3-398 should be considered as reserved locations and the register contents should not be modified.

**Table 3-398. DCSM\_BANK1\_Z1\_OTP Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	B1_Z1OTP_LINKPOINTER1	Zone 1 Link Pointer1 in Z1 OTP for flash BANK1		<a href="#">Go</a>
4h	B1_Z1OTP_LINKPOINTER2	Zone 1 Link Pointer2 in Z1 OTP for flash BANK1		<a href="#">Go</a>
8h	B1_Z1OTP_LINKPOINTER3	Zone 1 Link Pointer3 in Z1 OTP for flash BANK1		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-399 shows the codes that are used for access types in this section.

**Table 3-399. DCSM\_BANK1\_Z1\_OTP Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.15.25.1 B1\_Z1OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

B1\_Z1OTP\_LINKPOINTER1 is shown in [Figure 3-354](#) and described in [Table 3-400](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer1 in Z1 OTP for flash BANK1

## Chapter 4 ROM Code and Peripheral Booting

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

Further information about the boot-loading process can be found in the [TMS320F28004x Boot Features and Configurations Application Report](#).

<b>4.1 Introduction</b> .....	<b>631</b>
<b>4.2 Device Boot Sequence</b> .....	<b>631</b>
<b>4.3 Device Boot Modes</b> .....	<b>632</b>
<b>4.4 Device Boot Flow Diagrams</b> .....	<b>635</b>
<b>4.5 Device Reset and Exception Handling</b> .....	<b>639</b>
<b>4.6 Boot ROM Description</b> .....	<b>640</b>
<b>4.7 The C2000 Hex Utility</b> .....	<b>667</b>

## 4.1 Introduction

The purpose of this chapter is to explain the boot ROM code functionality including the boot procedure when executed, the functions and features of the boot ROM code, and to detail the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run application code. The boot ROM also contains peripheral bootloaders that can be used to load an application into RAM.

**Table 4-1. ROM Memory**

ROM	Size
Unsecure boot ROM	128KB
Secure ROM	64KB
CLA Data ROM	8KB

## 4.2 Device Boot Sequence

The boot sequence ([Table 4-2](#)) describes the general boot ROM procedure each time the CPU core is reset. During booting, the boot ROM code updates a boot status location in RAM that details the actions taken during this process.

Refer to [Section 4.6.13](#) for more details on the boot status information.

**Table 4-2. Boot ROM Sequence**

Step	Action
1	After reset, the FUSE error register is checked for any errors and are handled accordingly.
2	Clock and Flash configuration.
3	Device configuration registers are programmed from OTP.
4	On power-on reset (POR), all CPU RAMs are initialized. RAM initialization includes the following RAMs: <ul style="list-style-type: none"> <li>• M0, M1</li> <li>• LS0 to LS7</li> <li>• GS0 to GS3</li> <li>• CLA1TOCPUMSGRAM, CPUCLA1MSGGRAM</li> </ul>
5	Any pending NMI is handled by the code.
6	The DCSM sequences are executed. (Refer to <a href="#">Section 4.6.11</a> for details on how boot ROM interprets the OTP data after initialization)
7	Device calibration is performed, trimming the specified peripherals with set OTP values.
8	The boot mode GPIO pins are polled to determine whether to boot from SRAM, Flash, or peripherals.
9	Based on the boot mode and options, the appropriate boot sequence is executed. Refer to <a href="#">Section 4.4</a> for a flow diagram of the device boot sequence and the emulation and standalone boot modes.

### 4.3 Device Boot Modes

This section explains the boot modes supported on this device. The boot ROM uses the boot control GPIO pins to determine the boot mode configuration. The device can be configured to boot to RAM, boot to Flash, execute a bootloader, or hold in a wait mode.

[Table 4-3](#) shows the default boot mode options. Users have the option to customize the boot modes supported as well as the boot mode select pins.

**Table 4-3. Device Default Boot Modes**

Boot Mode	GPIO24 (Default boot mode select pin 1)	GPIO32 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait boot	0	1
CAN	1	0
Flash	1	1

**Table 4-4. All Available Boot Modes**

Boot Mode Number	Boot Mode
0	Parallel IO
1	SCI / Wait boot
2	CAN
3	Flash
4	Wait
5	RAM
6	SPI Master
7	I2C Master

#### Note

All the peripheral boot modes supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, the mode is actually referring to the first module instance, meaning SCI boot on the SCIA port. The same applies to the other peripheral boots.

### 4.3.1 Configuring Alternate Boot Mode Pins

This section explains how the boot mode select pins can be customized by programming the BOOTPIN\_CONFIG location in the user-configurable DCSM OTP. The location in the DCSM OTP is Z1-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use 0, 1, 2, or 3 boot mode select pins as needed.

**Table 4-5. BOOTPIN\_CONFIG Bit Fields**

Bit	Name	Description
31-24	Key	Write 0x5A to these 8-bits to indicate to the boot ROM code that the bits in this register are valid
23-16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description except for BMSP2
15-8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description except for BMSP1
7-0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x00 = GPIO0 0x01 = GPIO1 ... 0xFF is invalid and selects the factory default chosen BMSP0, if all other BMSPs are also set to 0xFF. If any other BMSPs are not set to 0xFF, then setting a BMSP to 0xFF disables that particular BMSP.

#### Note

The following GPIOs cannot be used as a BMSP. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIO (the factory default for BMSP2 is 0xFF, which disables the BMSP).

- GPIO 20 to 23
- GPIO 36
- GPIO 38
- GPIO 60 to 223

**Table 4-6. Standalone Boot Mode Select Pin Decoding**

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
≠ 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs (GPIO24, GPIO32)
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2

### 4.3.2 Configuring Alternate Boot Mode Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options. The 64-bit location is located in the user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins are being used. Refer to [Section 4.3.3](#) for examples on how to use the BOOTPIN\_CONFIG and BOOTDEF values.

**Table 4-7. BOOTDEF Bit Fields**

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7-0	BOOT_DEF0 Mode/Options	Set the boot mode and boot mode options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Any unsupported boot mode causes the device to reset. Refer to <a href="#">Section 4.6.9</a> for valid BOOTDEF values.
BOOT_DEF1	15-8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description
BOOT_DEF2	23-16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31-24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39-32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47-40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55-48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63-56	BOOT_DEF7 Mode/Options	

### 4.3.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins.

#### 4.3.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table.
  - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash with a boot mode value of 0
  - Optionally: Set BOOTDEF.BOOT\_DEF0\_ALT\_OPTIONS to a different value to switch to one of the available Flash entry point alternatives.

**Table 4-8. Zero Boot Pin Boot Table Result**

Boot Mode Number	Boot Mode
0	Flash Boot (0x03)

Refer to [Section 4.6.3](#) for the available alternative entry point addresses.

#### 4.3.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table.
  - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting with a boot mode value of 0
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash with a boot mode value of 1
  - Optionally: Set BOOTDEF.BOOT\_DEF1\_ALT\_OPTIONS to a different value to switch to one of the available Flash entry point alternatives.

**Table 4-9. One Boot Pin Boot Table Result**

Boot Mode Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

Refer to [Section 4.6.3](#) for the available alternative entry point addresses.

## 4.4 Device Boot Flow Diagrams

[Figure 4-1](#) shows the device boot flow detailing the actions executed by boot ROM after a reset.

Figure 4-1. Device Boot Flow

### 4.4.1 Emulation Boot Flow Diagram

Figure 4-2 shows the device boot flow when running the device in emulation mode.

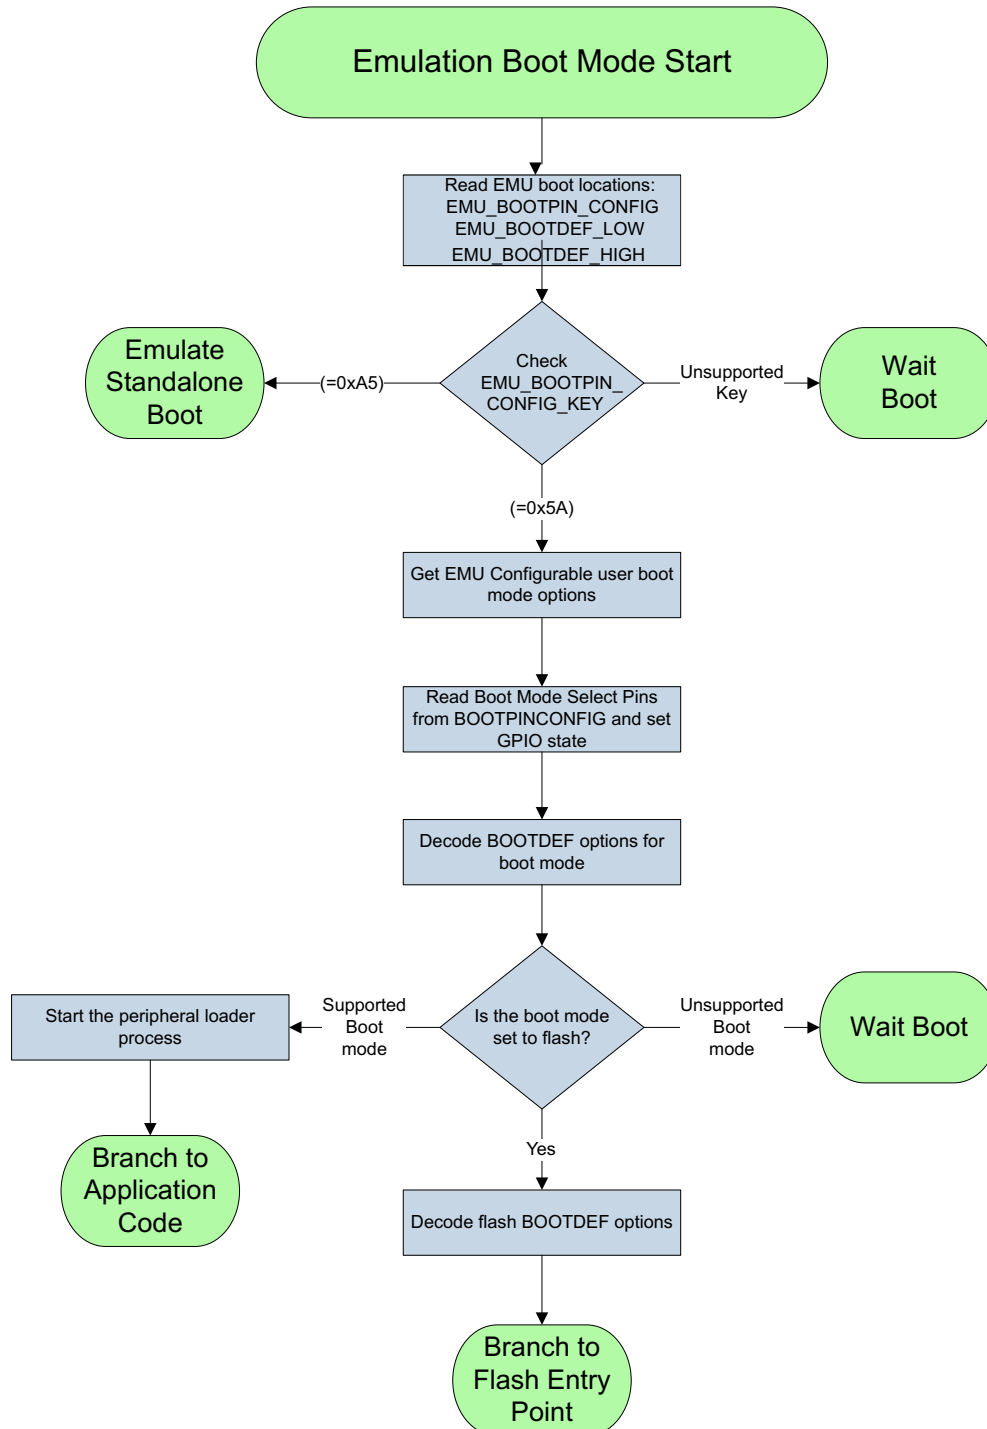

Figure 4-2. Emulation Boot Flow

### 4.4.2 Standalone Boot Flow Diagram

Figure 4-3 shows the device boot flow when running the device in standalone boot mode.

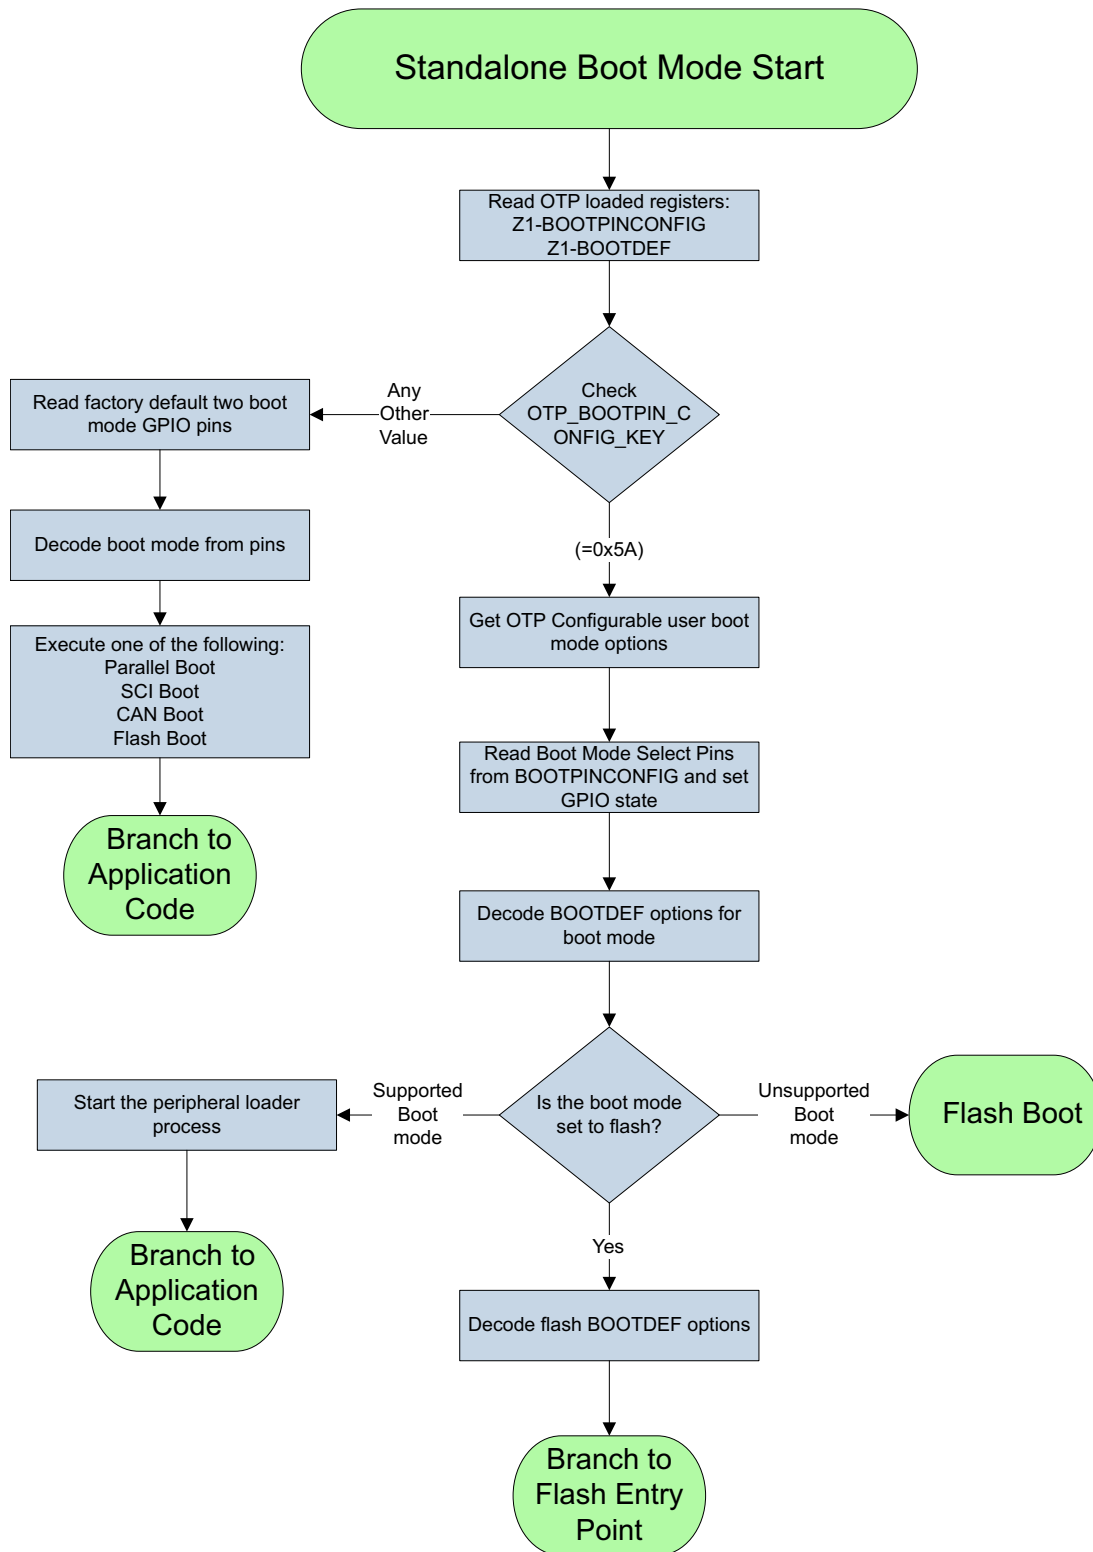

Figure 4-3. Standalone Boot Flow

## 4.5 Device Reset and Exception Handling

### 4.5.1 Reset Causes and Handling

Table 4-10 explains the actions boot ROM performs upon reset after checking the reset cause.

**Table 4-10. Boot ROM Reset Causes and Actions**

Reset Source	Boot ROM Actions
POR	<ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. RAM initialization</li> <li>4. Continue default boot flow</li> </ol>
XRS	<ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>
WDRS	<ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>
NMIWDRS	<ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>
SCCRESET	<ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>
Debugger Reset	<ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>

### 4.5.2 Exceptions and Interrupts Handling

Table 4-11 explains the actions boot ROM performs if any exceptions that can occur during boot.

**Table 4-11. Boot ROM Exceptions and Actions**

Exception Event Source	Boot ROM Action	Event Logged
Single-bit error in FUSEERR	Ignore and continue to boot	No
Multi-bit error in FUSEERR	Reset the device	No
Clock fail condition detected	Clear NMI, log, and continue to boot	Yes
Double-bit ECC error from RAM	Reset the device	Yes
Double-bit error from Flash	Reset the device	Yes
Software NMI error	Let the device reset	Yes
ITRAP Exception	Give the ROM location where boot ROM loops	Yes

#### Note

The above NMI errors are logged into a RAM variable for an application to read it when it starts. Refer to [Section 4.6.13](#) for more details on the boot status information.

## 4.6 Boot ROM Description

This section explains the details regarding the device boot ROM.

### 4.6.1 Boot ROM Registers

The boot ROM code accesses several memory addresses and registers during execution. There are two sets of addresses, one for emulation and one for standalone boot flow. The emulation locations emulate OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and thus can only be written once. [Table 4-12](#) details these locations.

**Table 4-12. Boot ROM Registers**

Boot Flow	DCSM Name	Boot ROM Name	Address
Emulation	Z1-GPREG1	EMU-BOOTPIN-CONFIG	0x0000 0D00
	Z1-GPREG3	EMU-BOOTDEF-LOW	0x0000 0D04
	Z1-BOOTCTRL	EMU-BOOTDEF-HIGH	0x0000 0D06
Standalone	Z1-GPREG1	Z1-OTP-BOOTPIN-CONFIG	0x0005 F008
	Z1-GPREG2	Z1-OTP-BOOT-GPREG2	0x0005 F00A
	Z1-GPREG3	Z1-OTP-BOOTDEF-LOW	0x0005 F00C
	Z1-BOOTCTRL	Z1-OTP-BOOTDEF-HIGH	0x0005 F004

### 4.6.2 Boot ROM User OTP

The boot ROM user-configurable DCSM OTP field descriptions and memory addresses are detailed in [Table 4-13](#).

**Table 4-13. User-Configurable DCSM OTP Fields**

Field Name	Description	Bank 0 USER OTP Address
GPREG1[0:15]	BOOTPIN_CONFIG [0:15]	0x7800C
GPREG1[16:31]	BOOTPIN_CONFIG [16:31]	0x7800D
GPREG2[0:15]	GPREG2[0:15]	0x7800E
GPREG2[16:31]	GPREG2[16:31]	0x7800F
GPREG3[0:15]	BOOTDEF_CONFIG[0:15]	0x7801C
GPREG3[16:31]	BOOTDEF_CONFIG[16:31]	0x7801D
BOOTCTRL[0:15]	BOOTDEF_CONFIG[32:47]	0x7801E
BOOTCTRL[16:31]	BOOTDEF_CONFIG[48:63]	0x7801F

### 4.6.3 Entry Points

[Table 4-14](#) gives details about the entry point addresses for various boot modes. These entry points tell the boot ROM where to branch to at the end of booting as per the selected boot mode.

**Table 4-14. Entry Point Addresses**

Entry Point	Address
RAM	0x0000 0000
Flash (Option 1 – Default)	0x0008 0000
Flash (Option 2)	0x0008 EFF0
Flash (Option 3) <sup>(1)</sup>	0x0009 0000
Flash (Option 4) <sup>(1)</sup>	0x0009 EFF0

(1) This option is not supported on device part numbers that do not have Flash bank 1. Refer to the data sheet for the part numbers.

### 4.6.4 Wait Points

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons. [Table 4-15](#) details the address ranges that the CPU PC register value falls within, if the CPU PC register enters one of these instances.

**Table 4-15. Wait Point Addresses**

Address Range	Description
0x003FAD74 – 0x003FB0CD	In Wait Boot
0x000706DC – 0x000706DF	In SCI Boot
0x003FBCD1 – 0x003FBD67	In NMI Handler
0x003FBD67 – 0x003FBDD5	In ITRAP ISR

## 4.6.5 Memory Maps

This section details the ROM memory maps.

### 4.6.5.1 Boot ROM Memory Map

**Table 4-16. Boot ROM Memory Map (Silicon Revision 0, A)**

Memory	Start Address	End Address	Length
ROM Signature	0x003F 0000	0x003F 0001	0x0002
TI-RTOS (ROM)	0x003F 7200	0x003F 91FF	0x2000
FPU32 Table	0x003F 9200	0x003F A9FF	0x1800

Version	0x003F FF7A	0x003F FF7B	0x0002
Vectors	0x003F FFBE	0x003F FFFF	0x0042
TI-RTOS (Flash)	0x0008 1010	0x0008 13EE	0x03DF

(1) Check the data sheet to determine if these are available for your device part number. If not available, treat these sections as reserved.

#### 4.6.5.2 CLA Data ROM Memory Map

**Table 4-18. CLA Data ROM Memory Map**

Memory	Start Address	End Address	Length
FFT Tables (Load)	0x0100 1070	0x0100 186F	0x0800
Data (Load)	0x0100 1870	0x0100 1FF9	0x078A
Version (Load)	0x0100 1FFA	0x0100 1FFF	0x0006
FFT Tables (Run)	0x0000 F070	0x0000 F86F	0x0800
Data (Run)	0x0000 F870	0x0000 FFF9	0x078A
FFT Tables (Run)	0x0000 FFFA	0x0000 FFFF	0x0006

#### Note

**Load** refers to the memory addresses where the C28x CPU can view the data. **Run** refers to the CLA memory addresses that the CLA uses to access the data.

#### 4.6.5.3 Reserved RAM and Flash Memory Map

This section details memory usage in RAM and Flash that is reserved for boot ROM to use. These memory sections can be reserved in your application.

**Table 4-19. Reserved RAM and Flash Memory Map (Silicon revision A)**

Memory	Description	Start Address	End Address	Length
RAM	Boot ROM	0x0000 0002	0x0000 00F4	0x00F3
	TI-RTOS <sup>(1)</sup>	0x0000 0780	0x0000 07FF	0x0080
Flash	TI-RTOS <sup>(1) (2)</sup>	0x0008 1010	0x0008 13EE	0x03DF

- (1) If the user is not planning on using TI-RTOS in ROM, then these memory locations are free to be used by the application.
- (2) For using the TI-RTOS in Flash sector A, TI recommends that this sector be made unsecure, or at minimum, the sector be verified that there is no secure zone claiming this sector.

**Table 4-20. Reserved RAM and Flash Memory Map (Silicon revision B)**

Memory	Description	Start Address	End Address	Length
RAM	Boot ROM	0x0000 0002	0x0000 00F4	0x00F3
	Flash API Library <sup>(1)</sup>	0x0000 0760	0x0000 077F	0x0020
	TI-RTOS <sup>(1)</sup>	0x0000 0780	0x0000 07FF	0x0080
Flash	TI-RTOS <sup>(2)</sup>	0x0008 1010	0x0008 13EE	0x03DF

- (1) If the user is not planning on using Flash API or TI-RTOS in ROM, then these memory locations are free to be used by the application.
- (2) For using the TI-RTOS in Flash sector A, TI recommends that this sector be made unsecure, or at minimum, the sector be verified that there is no secure zone claiming this sector.

## 4.6.6 ROM Tables

This section details the boot ROM and CLA ROM symbol tables.

### 4.6.6.1 Boot ROM Tables

Table 4-21 details the boot ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

**Table 4-21. ROM Symbol Tables**

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F28004xbootROM_Symbols	Under <code>/libraries/boot_rom</code> in <a href="#">C2000Ware</a>
CLA Data ROM Tables	F28004x_CLADATROM_Symbols	
AES Tables	F28004x_brom_aes_BootROMSymbols	
Flash API	F021_API_F28004x_FPU32_ROM	
Safe Zone APIs	F28004x_SafeZoneCodeSymbols	

### 4.6.6.2 CLA ROM Tables

Table 4-22 lists the symbol tables included in ROM for the CLA and the addresses.

**Table 4-22. CLA ROM Tables**

Table	Address
_cla_twiddleFactors	0x0000 F070
_cla_bitReversalTable	0x0000 F470

## 4.6.7 Boot Modes

The available boot modes supported on this device are detailed in this section. Each boot mode allows for various options, providing configurations with different IOs to be used depending on the application.

### 4.6.7.1 Wait Boot Mode

The wait boot mode puts the CPU in a loop and does not branch to the user application code. The device can enter wait boot mode either manually or because an error occurred during boot up. TI recommends using wait boot when using a debugger to avoid any JTAG complications.

Actions resulting in entering wait boot mode:

- Wait boot is set by the user as the boot mode
- The boot mode is unrecognized and a debugger is connected to the device
- The emulation BOOTPIN\_CONFIG key is not equal to 0xA5 or 0x5A
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode

### 4.6.7.2 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as outlined in [Example 4-1](#).

**Figure 4-4. Overview of SCI Bootloader Operation**

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason, the SCI loader is very flexible and uses a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echos back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by the transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

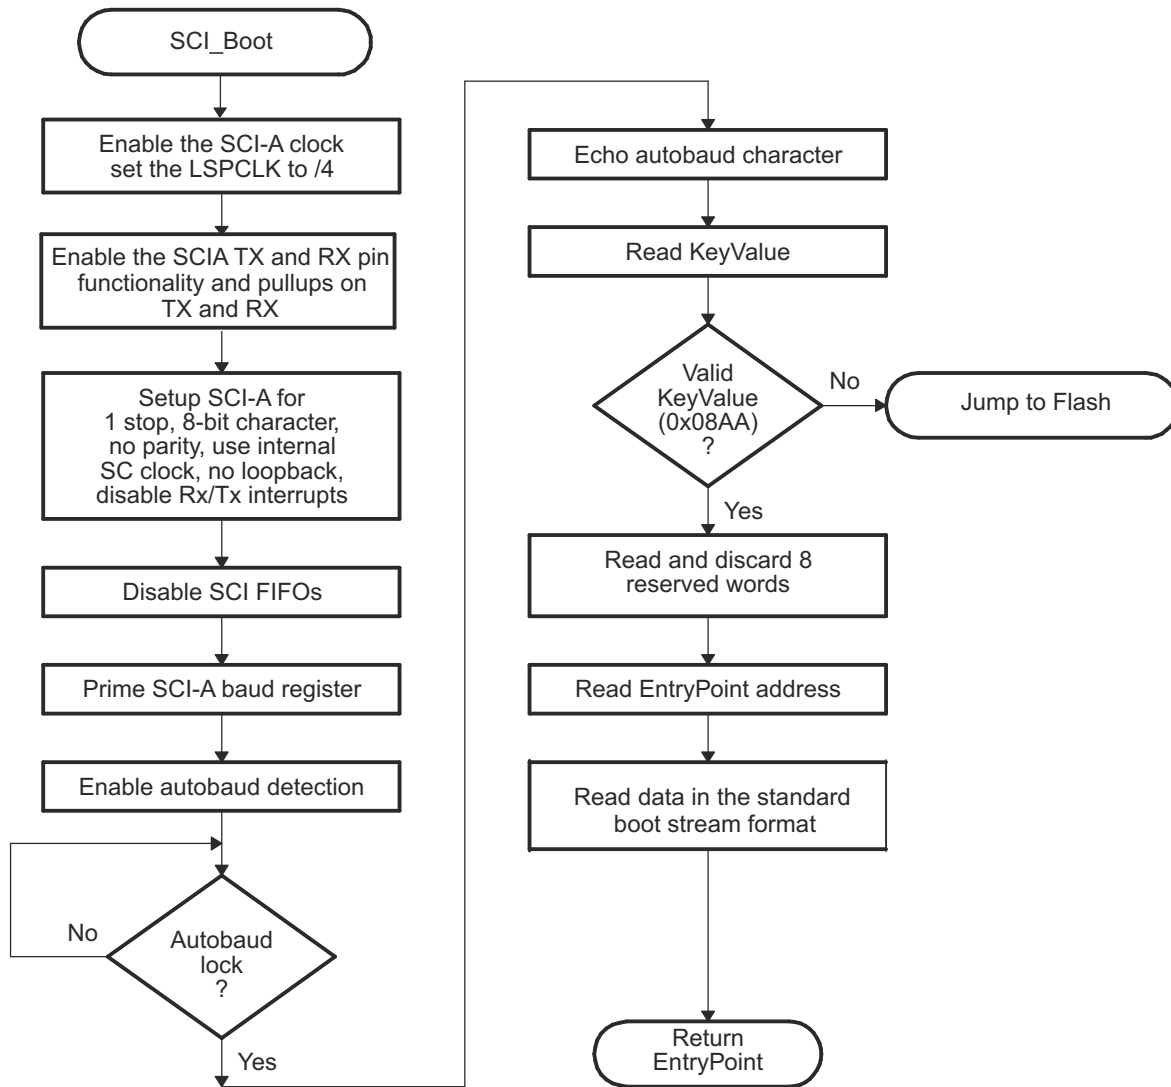

Figure 4-5. Overview of SCI Boot Function

#### 4.6.7.3 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as indicated in Figure 4-6. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

Figure 4-6. SPI Loader

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be setup to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI\_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, specify a change in baud rate or low-speed peripheral clock. [Table 4-23](#) shows the 8-bit data stream used by the SPI.

**Table 4-23. SPI 8-Bit Data Stream**

Byte	Contents
1	LSB: AA (KeyValue for memory width = 8 bits)

...	...
...	Data for this section.
...	...
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

1. The SPI-A port is initialized
2. The SPISTE pin is used as a chip-select for the serial SPI EEPROM or Flash
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next 2 bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next 7 words are reserved for future enhancements. The SPI bootloader reads these 7 words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

**Figure 4-7. Data Transfer from EEPROM Flow**

#### 4.6.7.4 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as indicated in [Figure 4-8](#). The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

**Figure 4-8. EEPROM Device at Address 0x50**

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that the application is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C\_Get Word). If a non acknowledgment is received during the data read messages, the I2C bus hangs. [Table 4-24](#) shows the 8-bit data stream used by the I2C.

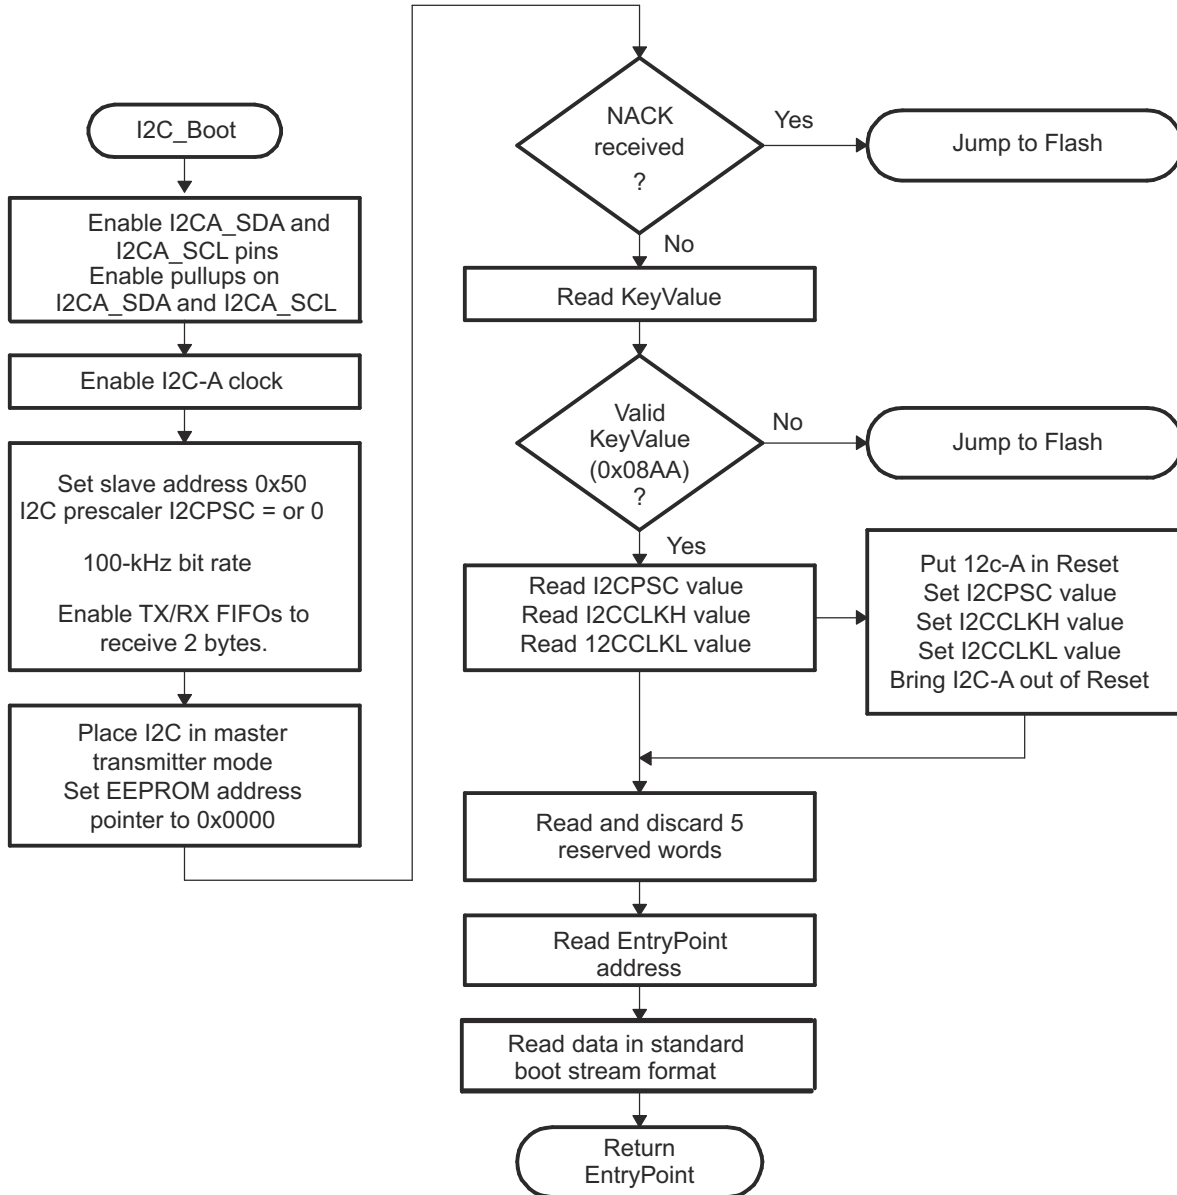

Figure 4-9. Overview of I2C Boot Function

n+1	MSB: 00h - indicates the end of the source

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 4-10](#) and [Figure 4-11](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in [Figure 4-10](#). All subsequent reads are shown in [Figure 4-11](#) and are read two bytes at a time.

**Figure 4-10. Random Read**

**Figure 4-11. Sequential Read**

4.6.7.5 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from GPIO0 to GPIO7 internal memory. Each value is 8-bits long and follows the same data flow as outlined in Figure 4-12.

Figure 4-12. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the GPIO16 and GPIO11 lines. The handshake protocol shown in Figure 4-13 must be used to successfully transfer each word using GPIO[0-7]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The most-significant byte (MSB) is read first followed by the least-significant byte (LSB). In this case, data is read from GPIO[0-7].

The 8-bit data stream is shown in Table 4-25.

Table 4-25. Parallel GPIO Boot 8-Bit Data Stream

Bytes		GPIO[ 7:0]		Description
		(Byte 1 of 2)	(Byte 2 of 2)	
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	00	00	8 reserved words (words 2 - 9)
...	...	...	...	...
17	18	00	00	Last reserved word
19	20	BB	00	Entry point PC[22:16]
21	22	DD	CC	Entry point PC[15:0] (PC = 0x00BB CCDD)
23	24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25	26	BB	AA	Destination address of first block Addr[31:16]
27	28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABB CCDD)
29	30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...				...
...				Data for this section.
...				...
.		BB	AA	Last word of the first block of the source being loaded = 0xAABB
.		NN	MM	Block size of the 2nd block to load = 0xMMNN words
.		BB	AA	Destination address of second block Addr[31:16]
.		DD	CC	Destination address of second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
.				...
n	n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that the device is ready to begin data transfer by pulling the GPIO16 pin low. The host load then initiates the data transfer by pulling the GPIO11 pin low. The complete protocol is shown in Figure 4-13.

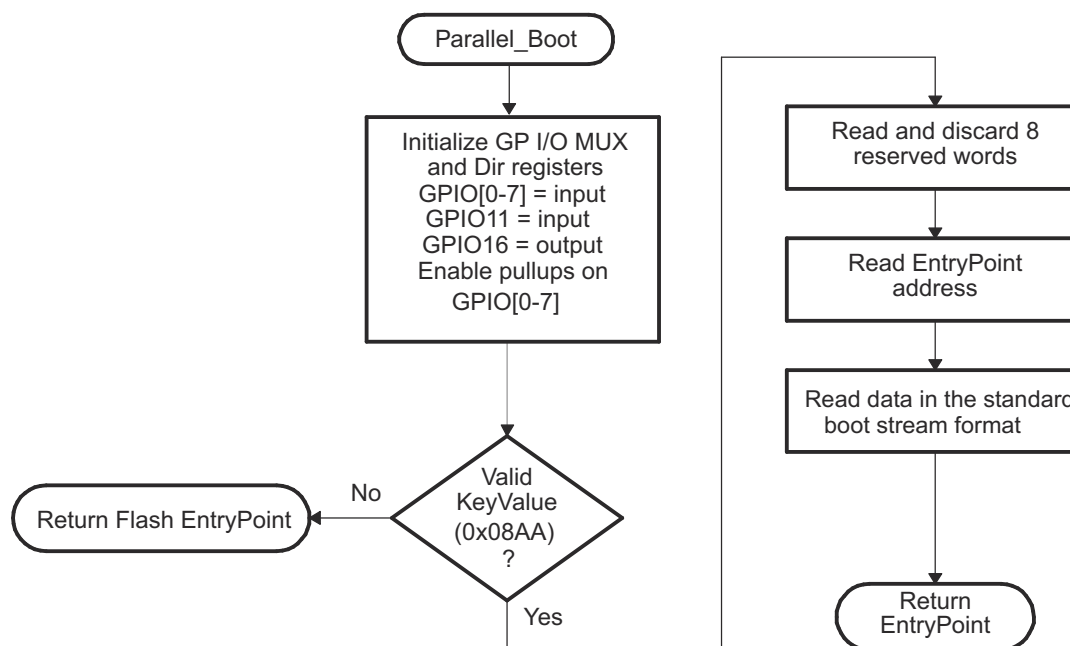

**Figure 4-13. Parallel GPIO Bootloader Handshake Protocol**

1. The device indicates the device is ready to start receiving data by pulling the GPIO16 pin low.
2. The bootloader waits until the host puts data on GPIO[0-7]. The host signals to the device that data is ready by pulling the GPIO11 pin low.
3. The device reads the data and signals the host that the read is complete by pulling GPIO16 high.
4. The bootloader waits until the host acknowledges the device by pulling GPIO11 high.
5. The device again indicates the device is ready for more data by pulling the GPIO16 pin low.

This process is repeated for each data value to be sent.

Figure 4-14 shows an overview of the Parallel GPIO bootloader flow.

**Figure 4-14. Parallel GPIO Mode Overview**

Figure 4-15 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode, as the host waits for the device and the device, in turn, waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

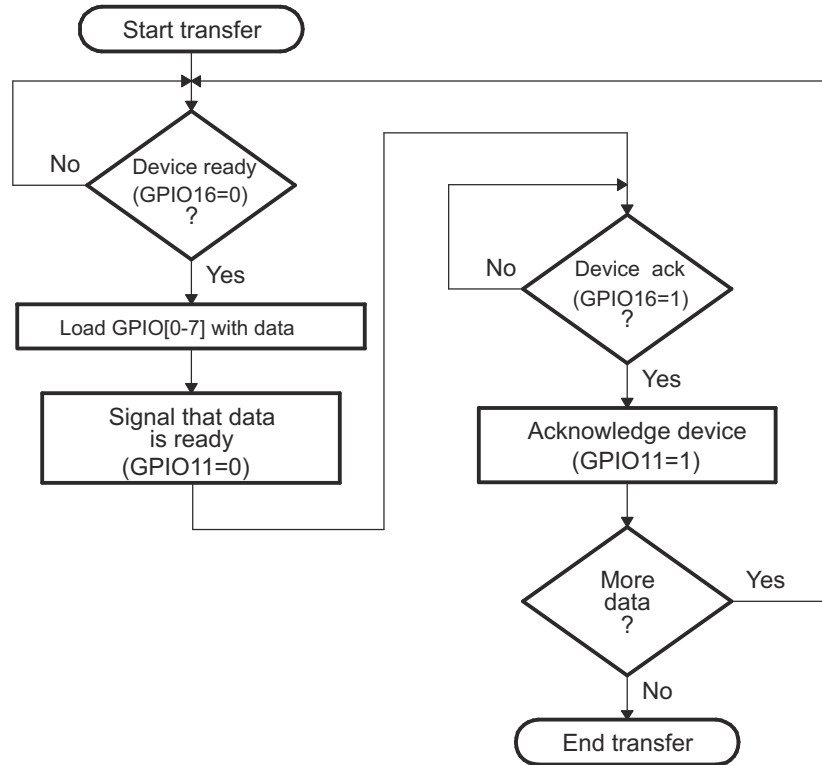

Figure 4-15. Parallel GPIO Mode - Host Transfer Flow

Figure 4-16 shows the flow used to read a single word of data from the parallel port.

- 8-bit data stream:** The 8-bit routine, shown in Figure 4-16, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with GPIO7 in bit position 7 and GPIO6 in bit position 6 as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

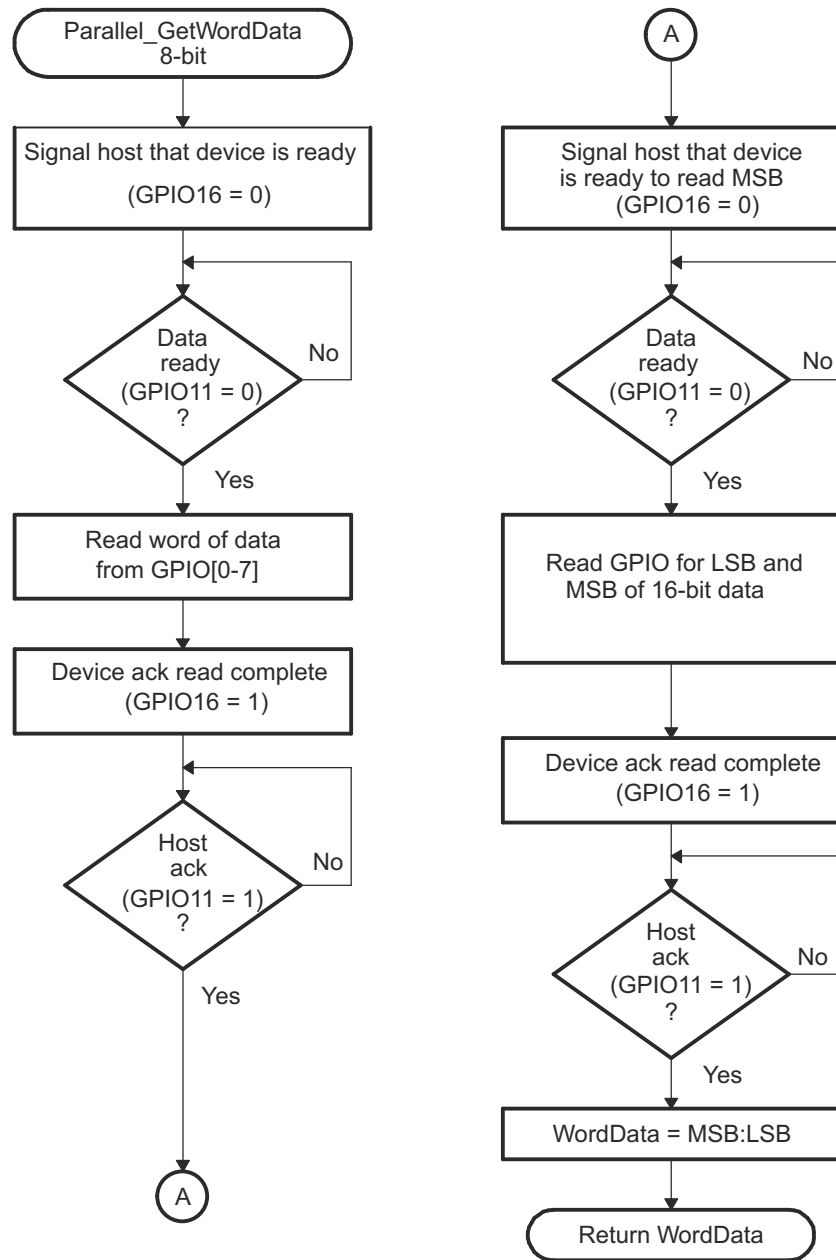

Figure 4-16. 8-Bit Parallel GetWord Function

4.6.7.6 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

Figure 4-17. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in Table 4-26.

Table 4-26. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCCLK	Bit Rate
20MHz	10MHz	100kbps

The SYSCCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host must transmit only 2 bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN boot-loader is identical to the SCI boot-loader. The data sequence for the CAN boot-loader is shown in Table 4-27.

**Table 4-27. CAN 8-Bit Data Stream**

Bytes	Byte 1 of 2	Byte 2 of 2	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3 4	00	00	reserved
5 6	00	00	reserved
7 8	00	00	reserved
9 10	00	00	reserved
11 12	00	00	reserved
13 14	00	00	reserved
15 16	00	00	reserved
17 18	00	00	reserved
19 20	BB	AA	Entry point PC[22:16]
21 22	DD	CC	Entry point PC[15:0] (PC = 0xAABB CCDD)
23 24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25 26	BB	AA	Destination address of first block Addr[31:16]
27 28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABB CCDD)
29 30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...			....
...			Data for this section.
...			...
.	BB	AA	Last word of the first block of the source being loaded = 0xAABB
.	NN	MM	Block size of the 2nd block to load = 0xMMNN words
.	BB	AA	Destination address of second block Addr[31:16]
.	DD	CC	Destination address of second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

The CAN bootloader provides an option to increase the default bit-rate. By default, the CAN bit-timing register (CAN\_BTR) is programmed for 100kbps bitrate with a 20MHz external oscillator. If a faster bit-rate is desired, the host can supply certain parameters as part of the bit-stream. These parameters are then used to modify the CANBTR register and hence the bit-rate. CAN\_BTR determines the current bit-rate, represented by a 32-bit value. For the generated application hex file on the host side, the 8-bit data-stream has the following sequence of bytes: AA, 08, 00, 00, .. ... , 00 (16 reserved bytes). The *KeyValue* is the first two bytes (0x08AA), ordered in LSB-MSB format. Through usage of a host programmer, after the *KeyValue* has been recognized and the reserved words parsed by the bootloader, the value of the CAN\_BTR register can be changed with new (non-zero) bit-timing register values. For example, suppose an application wants to increase the bit-rate to 1Mbps. A value of 0x7AC0 written to CAN\_BTR can achieve this (note that a given bit-rate can be achieved with different combinations of TSEG1 and TSEG2 values; 0x7AC0 is just shown as an example). The generated application text file needs to be modified as follows to achieve this: AA, 08, C0, 7A, ..., 00 to choose the new bit-rate (100kbps to 1Mbps). Additionally, the host programmer can modify the bit-rate to continue communicating with the boot-loader at the new bitrate.

### 4.6.8 Boot Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on the C2000™ devices.

#### 4.6.8.1 Bootloader Data Stream Structure

[Table 4-28](#) and [Example 4-1](#) show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex.

The first 16-bit word in the data stream is known as the key value. The key value is used to indicate to the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8- and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to it. If a bootloader does not use these values then they are reserved for future use and the bootloader simply reads the value and then discards it. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size can be 0x000A to indicate 10 16-bit words.

The next two words indicate to the loader the destination address of the block of data. Following the size and address is the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine that cleans up and exits. Execution then continues at the entry point address as determined by the input data stream contents.

**Table 4-28. LSB/MSB Loading Sequence in 8-Bit Data Stream**

Byte		Contents	
		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program. Otherwise another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

### Example 4-1. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8-bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 - First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 - First block is loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - 2nd block consists of 2 16-bit words
3F 00 00 80 ; 0x003F8000 - 2nd block is loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 - size of 0 indicates end of data stream
After load has completed, the following memory values are initialized as follows:
Location  Value
0x3F9010  0x0001
0x3F9011  0x0002
0x3F9012  0x0003
0x3F9013  0x0004
0x3F9014  0x0005
0x3F8000  0x7700
0x3F8001  0x7625
PC Begins execution at 0x3F8000

```

#### 4.6.9 GPIO Assignments

This section details the GPIOs and boot options used for each boot mode set in BOOT\_DEFx located at Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH. Refer to [Section 4.3.1](#) on how to manipulate BOOT\_DEFx. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

**Table 4-29. SCI Boot Options**

Option	BOOTDEFx Value	SCIATX GPIO	SCIARX GPIO
0 (default)	0x01	GPIO29	GPIO28
1	0x21	GPIO16	GPIO17
2	0x41	GPIO8	GPIO9
4	0x81	GPIO24	GPIO25

#### Note

Pull-ups are enabled on the SCIATX and SCIARX pins.

**Table 4-30. CAN Boot Options**

Option	BOOTDEFx Value	CANTXA GPIO	CANRXA GPIO
0 (default)	0x02	GPIO32	GPIO33
1	0x22	GPIO4	GPIO5
2	0x42	GPIO31	GPIO30
3	0x62	GPIO37	GPIO35

**Note**

Pull-ups are enabled on the CANTXA and CANRXA pins.

**Table 4-31. Flash Boot Options**

Option	BOOTDEFx Value	Flash Entry Point (Address)	Flash Bank, Sector
0 (default)	0x03	Flash – Default Option 1 (0x0008 0000)	Bank 0, Sector 0
1	0x23	Flash – Option 2 (0x0008 EFF0)	Bank 0, Sector 14
2	0x43	Flash – Option 3 (0x0009 0000)	Bank 1, Sector 0
3	0x63	Flash – Option 4 (0x0009 EFF0)	Bank 1, Sector 14

**Table 4-32. Wait Boot Options**

Option	BOOTDEFx Value	Watchdog Status
0	0x04	Enabled
1	0x24	Disabled

**Table 4-33. SPI Boot Options**

Option	BOOTDEFx Value	SPIA_SIMO	SPIA_SOMI	SPIA_CLK	SPIA_STE
1	0x26	GPIO8	GPIO10	GPIO9	GPIO11
2	0x46	GPIO54	GPIO55	GPIO56	GPIO57
3	0x66	GPIO16	GPIO17	GPIO56	GPIO57
4	0x86	GPIO8	GPIO17	GPIO9	GPIO11

**Note**

Pull-ups are enabled on the SPIA\_SIMO, SPIA\_SOMI, SPIA\_CLK, and SPIA\_STE pins.

**Table 4-34. I2C Boot Options**

Option	BOOTDEFx Value	SDAA GPIO	SCLA GPIO
0	0x07	GPIO32	GPIO33
1	0x47	GPIO26	GPIO27
2	0x67	GPIO42	GPIO43

---

**Note**

Pull-ups are enabled on the SDAA and SCLA pins.

---

**Table 4-35. Parallel Boot Options**

Option	BOOTDEFx Value	D0-D7 GPIO	DSP Control GPIO	Host Control GPIO
0 (default)	0x00	GPIO0-GPIO7	GPIO16	GPIO11

---

**Note**

Pull-ups are enabled on GPIO0 to GPIO7.

---

**Table 4-36. RAM Boot Options**

Option	BOOTDEFx Value	RAM Entry Point (Address)
0	0x05	0x0000 0000

#### 4.6.10 Secure ROM Function APIs

Within secure ROM, functions are available to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

#### Note

The application can disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU while the program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset fires. The consequence of this is if an NMI or ITRAP occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP cannot be serviced because a reset is fired to that subsystem.

The **secure copy code zone 1 and zone 2 functions** (Table 4-37) allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

**Table 4-37. Secure Copy Code Function**

Function Prototype	Function Parameters	Function Return Value
<b>Uint16 SafeCopyCodeZ1</b> (Uin32 size, Uin16 *dst, Uin16 *src)	<i>size</i> : The number of 16-bit words to copy  <i>dst</i> : The destination memory address in EXEONLY RAM	0xFFFF : Returns the number of 16-bit words copied  0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash and/or RAM are not set to EXEONLY; Error occurred during data copy
<b>Uin16 SafeCopyCodeZ2</b> (Uin32 size, Uin16 *dst, Uin16 *src)	<i>src</i> : The source memory address in EXEONLY Flash	(Same as above)

The **secure CRC calculation zone 1 and zone 2 functions** (Table 4-38) allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

**Table 4-38. Secure CRC Calculation Function**

Function Prototype	Function Parameters	Function Return Value
<b>Uin16 SafeCRCCalcZ1</b> (Uin16 len_id, Uin16 *dst, Uin16 *src)	<i>len_id</i> : A number from 1 to 8 which corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words  <i>dst</i> : The destination memory address for resulting CRC	0xFFFF : Returns the number of 16-bit words CRC'd  0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone
<b>Uin16 SafeCRCCalcZ2</b> (Uin16 size, Uin16 *dst, Uin16 *src)	<i>src</i> : The source memory address to begin CRC calculation	(Same as above)

#### 4.6.11 DCSM Usage

Table 4-39 explains how the bit field values from the user-configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2, are decoded by the boot ROM after DCSM initialization is complete.

**Table 4-39. DCSM Z1-OTP-BOOT-GPREG2 Bit Fields**

Bit	Name	Description	Boot ROM Action
31-24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.	If user set to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores the values in this register.
23-6	Reserved	Reserved	No action
5-4	Error Status Pin	Sets the GPIO pin to be used as the ERRORSTS 0x0 – GPIO24 0x1 – GPIO28 0x2 – GPIO29 0x3 – ERRORSTS disabled (Default)	Boot ROM configures the appropriate mux for the selected GPIO pin.
3-0	Reserved	Reserved	No action

#### Note

Program DCSM OTP locations Z1-OTP-BOOT-GPREG2 and Z1-OTP-BOOTPIN-CONFIG at the same time, because the locations share ECC.

#### 4.6.12 Clock Initialization

During boot up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR or XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

**Table 4-40. Boot Clock Sources**

Source	Frequency	Description
INTOSC2	10MHz	Default clock source
INTOSC1	10MHz	Set as clock source if missing clock is detected at power up or right after device reset

**Table 4-41. Clock State after Boot ROM**

Reset Source	Clock State
POR/XRS	Bypassed PLL. PLL multiplier is set to 0x0. Clock divider is set to /1.
All other Resets	Maintain clocks setup before device reset.

#### Note

When the PLL is used by the bootloader, the PLL is bypassed by the boot ROM code before branching to the user application.

### 4.6.13 Boot Status Information

Boot ROM keeps a record of the different events that can occur during boot ROM execution. This is because NMI and other exceptions are enabled by default in the device, and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can look at this boot status and take the necessary actions per the application's needs to handle these events.

#### 4.6.13.1 Booting Status

[Table 4-42](#) and [Table 4-43](#) detail the boot status RAM location and its bit field definitions. When the specific bit field is set, the described event or action has occurred.

**Table 4-42. Boot Status Address**

Description	Address
BROM_STATUS	0x0000 0002

**Table 4-43. Boot Status Bit Fields**

Bit	Description
22	Boot ROM detected a missing clock NMI
21	Boot ROM detected a RAM bit error NMI
20	Boot ROM detected a Flash bit error NMI
17	Boot ROM detected a PIE mismatch
16	Boot ROM detected an ITRAP
15	Boot ROM has completed running
13	Boot ROM handled POR
12	Boot ROM handled XRS
11	Boot ROM handled all the resets
10	POR memory test has completed
9	DCSM initialization has completed
7	CAN boot has started
6	I2C boot has started
5	SPI boot has started
4	SCI boot has started
3	RAM boot has started
2	Parallel boot has started
1	Flash boot has started
0	Boot ROM has started running

#### 4.6.13.2 Flash Single-Bit Error Status

After DCSM is initialized during a reset by the boot ROM, the Flash single-bit error status is stored at the high and low RAM location detailed in [Table 4-44](#). Both the high and low status are 32-bits wide.

**Table 4-44. Flash Single-Bit Error Status Addresses**

Description	Address
Flash Single-Bit Error (Low)	0x0000 0004
Flash Single-Bit Error (High)	0x0000 0006

#### 4.6.14 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in [Table 4-45](#).

**Table 4-45. Boot ROM Version Information**

Start Address	End Address	Contents
0x003F FF7A	0x003F FF7A	Revision Number
0x003F FF7B	0x003F FF7B	Revision Date

Interpreting the contents:

- Reading a revision number value of “0x100” represents version “1.0”.
- Reading a revision date value of “0x0715” represents “07/15” or “July 2015”.

#### 4.7 The C2000 Hex Utility

To use the features of the bootloader, generate a data stream and boot table as described in [Section 4.6.8.1](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 4-2](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex) differs from one specific application to another and some additional conversion is required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.** This creates the object files that is then used by the linker to create a single output file.
2. **Link the file.** The linker combines all of the object files into a single output file in common object file format (COFF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the COFF file. Uninitialized sections are not converted by the hex conversion utility. The following options are useful:

The linker `-m` option can be used to generate a map file. This map file shows all of the sections that were created, the location in memory, and the length. The map file is useful to check this file to make sure that the initialized sections are where the user expects the sections to be.

The linker `-w` option configures the linker to show if the linker assigned a section to a memory region automatically. For example, if there is a section in the code called `ramfuncs`.

3. **Run the hex conversion utility.** Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the COFF file produced by the linker to a boot table.

See the [TMS320C28x Assembly Language Tools User's Guide](#) and the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) for more information on the compiling and linking process.

[Table 4-46](#) summarizes the hex conversion utility options available for the bootloader. See the [TMS320C28x Assembly Language Tools User's Guide](#) for a detailed description of the hex2000 operations used to generate a boot table. Updates are made to support the I2C boot. See the Codegen release notes for the latest information.

**Table 4-46. Boot Loader Options**

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally <code>_c_int00</code> unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the 8 least-significant bits and can be set to maintain an I2C module clock of 7 to 12MHz.
-i2cclkh value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cckl value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

**Example 4-2. HEX2000.exe Command Syntax**

```

C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN
        uses the same data format as the GPIO in 8-bit mode.
- a Select ASCII-Hex as the output format.
    
```

## Chapter 5 Control Law Accelerator (CLA)

---

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

<b>5.1 Introduction</b> .....	<b>670</b>

## 5.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

### 5.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating-point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines, or seven tasks and a main background task.
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.
  - The Type-2 CLA can have a main task that runs continuously in the background, while other high priority events trigger a foreground task.
- Task trigger mechanisms:
  - C28x CPU using the IACK instruction
  - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
  - Task8 can be set to be the background task, while Tasks 1 through 7 take peripheral triggers.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - Two dedicated message RAMs for communication between the CLA and the DMA.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

**Figure 5-1. CLA Block Diagram**

## 5.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

### 5.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* section of the *System Control and Interrupts* chapter for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT<sub>x</sub> registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
- **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

### 5.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and can be described in the data sheet.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

### 5.2.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CPU, CLA, and DMA can share access to some peripherals. There is a 3-way arbitration among the different master's that is described in [Section 5.3](#). Each peripheral has an access control register with two bit fields, CPU<sub>n</sub>AC, CLAnAC, and DMA<sub>n</sub>AC (n being the instance) that determine what kind of access is given to that particular master.

---

#### Note

The CLA read access time to the bus is 2-wait states while write access is 0-wait.

---

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 5.5](#).

### 5.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain the priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 5-1](#).

For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

**Table 5-1. Configuration Options**

130	CLB4_INT

**Table 5-1. Configuration Options (continued)**

Select Value	CLA Trigger Source
131-255	Reserved

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has a fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

### 5.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. See [Section 5.8](#) for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt is not issued to the C28x CPU when that task completes.

## 5.3 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA, DMA, or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure occurs. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

### 5.3.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU or CLA and DMA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
  - The following accesses are allowed:
    - CPU reads
    - CLA data reads and writes
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CPU writes
- CPU to CLA Message RAM:
  - The following accesses are allowed:
    - CPU reads and writes
    - CLA reads
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CLA writes

### 5.3.2 CLA Program Memory

The behavior of the program memory depends on the state of the MMEMCFG[PROGE] bit. This bit controls whether the memory is mapped to CLA space or CPU space.

- **MMEMCFG[PROGE] == 0**

In this case, the memory is mapped to the CPU. The CLA is halted and no tasks can be incoming.

- Any CLA fetch is treated as an illegal opcode condition as described in [Section 5.4.4](#). This condition does not occur, if the proper procedure is followed to map the program memory.
- CLA reads and writes cannot occur
- The memory block behaves as any normal RAM block mapped to CPU memory space.

Priority of accesses are (highest priority first):

1. CPU data write, program write, debug write
2. CPU data read, program read, debug read
3. CPU fetch, program read

- **MMEMCFG[PROGE] == 1**

In this case, the memory block is mapped to CLA space. The CPU can only make debug accesses.

- CLA reads and writes cannot occur
- CLA fetches are allowed
- CPU fetches return 0 that is an illegal opcode and causes an ITRAP interrupt.
- CPU data reads and program reads return 0
- CPU data writes and program writes are ignored

Priority of accesses are (highest priority first):

1. CLA fetch
2. CPU debug write
3. CPU debug read

---

#### Note

Because the CLA fetch has higher priority than CPU debug reads, there is a possibility for the CLA to permanently block debug accesses if the CLA is executing in a loop. This can occur when initially developing CLA code due to a bug. To avoid this issue, the program memory returns all 0x0000 for CPU debug reads (ignore writes) when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access can be performed.

---

### 5.3.3 CLA Data Memory

There are independent data memory blocks. The behavior of the data memory depends on the state of the MMEMCFG[RAM0E] MMEMCFG[RAM1E] bits. These bits determine whether the memory blocks are mapped to CLA space or CPU space.

- **MMEMCFG[RAMxE] == 0**

In this case the memory block is mapped to the CPU.

- CLA fetches cannot occur to this block.
- CLA reads return 0.
- CLA writes are ignored.
- The memory block behaves as any normal RAM block mapped to the CPU memory space.

Priority of accesses are (highest priority first):

1. CPU data write/program write/debug access write
2. CPU data read/debug access read
3. CPU fetch/program read

- **MMEMCFG[RAMxE] == 1**

In this case the memory block is mapped to CLA space. The CPU can make only debug accesses.

- CLA fetches cannot occur to this block.
- CLA read and CLA writes are allowed.
- CPU fetches return 0
- CPU data reads and program reads return 0.
- CPU data writes and program writes are ignored.

Priority of accesses are (highest priority first):

1. CLA data write
2. CPU debug write
3. CPU debug read
4. CLA read

### 5.3.4 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

## 5.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

### 5.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 5.7](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

The CLA Type 2 requires Codegen V16.9.1.LTS or later with the compiler switch: `--cla_support=cla2`.

### 5.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. **Copy CLA code into the CLA program RAM:** The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
2. **Initialize CLA data RAM, if necessary:** Populate the CLA data RAM with any required data coefficients or constants.
3. **Configure the CLA registers:** Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
  - **Enable the CLA peripheral clock using the assigned PCLKCRn register:** The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
  - **Populate the CLA task interrupt vectors:**
    - MVECT1 to MVECT8
 

Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.
    - MVECT1 to MVECT7, and MVECTBGRND
 

When using the background task, the vector (MVECTBGRND) must be loaded with the start address of the task in lower 64K of memory. Note that Task 8 is ignored when the background task is enabled.
  - **Select the task interrupt sources:** For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt. Since the background task takes the place of Task 8, the task uses the same peripheral trigger source as task 8.
  - **Enable IACK to start a task from software, if desired:** To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit. If the background task is enabled, the IACK bit for task 8 is ignored; the user must, instead, write to the BGSTART bit of the MCTLBGRND register to start the background task (TRIGEN can be 0 to avoid a peripheral trigger from causing an overflow, for example, MSTSBGRND.BGOVF is set to 1).
  - **Map CLA data RAM to CLA space, if necessary:** Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit, and then specifying the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT<sub>x</sub> registers.

- **Map CLA program RAM to CLA space:** Map the CLA program RAM to CLA space by first assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit, and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles in which the CLA is not fetching a new instruction.
4. **Initialize the PIE vector table and registers:** When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
  5. **Enable CLA tasks/interrupts:** Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
  6. **Initialize other peripherals:** Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

### 5.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

#### 5.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction flushes all the instructions that have already been fetched; on a single-step or run-free command, the CLA refetches the same instruction that it replaced. [Table 5-2](#) illustrates the pipeline behavior.

**Table 5-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction**

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
1	i1								
2	i2	i1							
3	i3	i2	i1						
4	i4	i3	i2	i1					
5	MDEBUG STOP1	i4	i3	i2	i1				
6	i6	MDEBUG STOP1	i4	i3	i2	i1			
7	i7	i6	MDEBUG STOP1	i4	i3	i2	i1		
9	i8	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	i1	CLA halted
10	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	CLA step/run
11	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	CLA step/run
12	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	CLA step/run

**Table 5-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction (continued)**

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
13	i8	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	CLA step/run

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. It takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

#### 5.4.3.2 Legacy Breakpoint Support (MDEBUGSTOP)

##### 1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUGSTOP instruction as needed.

If CLA breakpoints are not enabled, then the MDEBUGSTOP instruction is ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUGSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

##### 2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

##### 3. Start the task

There are three ways to start the task:

- The peripheral can assert an interrupt,
- The main CPU can execute an IACK instruction, or
- The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA executes instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUGSTOP instruction.

#### 4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

---

#### Note

A CLA fetch has higher priority than CPU debug reads. For this reason, the CLA to permanently block CPU debug accesses if the CLA is executing in a loop is possible. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

---

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

#### 5. Disable CLA breakpoints, if desired

In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

##### 5.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, the CLA behaves as follows:

- The CLA halts with the illegal opcode in the D2 phase of the pipeline as if a breakpoint. This occurs whether CLA breakpoints are enabled or not.
- The CLA issues the task-specific interrupt to the PIE.
- The MIRUN bit for the task remains set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 5.4.5](#).

### 5.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using  $\overline{\text{XRS}}$  or the debugger). In this case, all CLA configuration and execution registers can be set to the default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start. In addition, the background task start bit (MCTLBGRN.BGSTART) and trigger enable bit (MCTLBGRND.TRIGEN) are reset. The MVECTBGRNACTIVE is set to the value of MVECTBGRND, and the status register (MSTSBGRND) is also reset.

## 5.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

### 5.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage is stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage is stalled.

### 5.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in [Table 5-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in [Table 5-4](#).

This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

**Table 5-3. Write Followed by Read - Read Occurs First**

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

**Table 5-4. Write Followed by Read - Write Occurs First**

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	I1
						I5	I4	I1
							I5	I1

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

Referring to [Example 5-1](#), the following applies to delayed conditional instructions:

- **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
- **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

For a more detailed description, refer to the description for [MBCNDD](#), [MCCNDD](#), and [MRCNDD](#).

**Example 5-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD**

```

<Instruction 1>      ; I1 Last instruction that can affect flags for
                   ;   the branch, call or return operation
<Instruction 2>      ; I2 Cannot be stop, branch, call or return
<Instruction 3>      ; I3 Cannot be stop, branch, call or return
<Instruction 4>      ; I4 Cannot be stop, branch, call or return
<branch/call/ret>   ; MBCNDD, MCCNDD or MRCNDD
                   ; I5-I7: Three instructions after are always
                   ;   executed whether the branch/call or return is
                   ;   taken or not
<Instruction 5>      ; I5 Cannot be stop, branch, call or return
<Instruction 6>      ; I6 Cannot be stop, branch, call or return
<Instruction 7>      ; I7 Cannot be stop, branch, call or return
<Instruction 8>      ; I8
<Instruction 9>      ; I9
....

```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to [Example 5-1](#). To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

### • Loading MAR0 or MAR1

A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to [Example 5-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2:** The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
- **I3:** Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #\_X.
- **I4:** Starting with the 4th instruction MAR0 or MAR1 has the new value.

#### **Example 5-2. Code Fragment for Loading MAR0 or MAR1**

```

; Assume MAR0 is 50 and #_X is 20

MMOV16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1> ; I1 uses the old value of MAR0 (50)
<Instruction 2> ; I2 uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 uses the new value of MAR0 (20)
<Instruction 5> ; I5 uses the new value of MAR0 (20)
....

```

### • Background Task Interrupted Close to a Branch

When the background task is running, if another task request happens (and MSTSBGRND.BGINTM is not set), then the following sequence of operations happen.

- A check is made to determine if the following instructions are not in the pipeline (D2 – R2).
  - MBCNDD
  - MCCNDD
  - MRCNDD

If any of the above instructions are present in the pipeline, the back ground task continues to execute until such time when the condition is satisfied. Once the condition is satisfied, the following actions are performed:

- The MPC value of the D1 phase instruction is saved to the MVECTBGRNDACTIVE register.
- The run status bit of the background task (MSTSBGRND.RUNSTS) is cleared.
- An MSTOP instruction is forced into the D2 phase of the pipeline; causing the background task to terminate.

When the background task terminates, the CLA picks the next highest pending task and begins execution. Note that while the background task is pending, the background task has the lowest priority and, therefore, yields to any other pending task. Once all pending non-background tasks have completed execution, the CLA restores the program counter (MPC), that is, loads the address from the MVECTBGRNDACTIVE register to the MPC, sets the background status to RUN (MSTSBGRND.RUN = 1), and continues execution from that point.

- **MSTOP in the Background Task**

If an MSTOP instruction occurs in the D1 phase while the background task is running, the following sequence of operations happens:

- The RUN bit (MSTSBGRND.RUN) is cleared.
- The address stored in MVECTBGRND is copied over to MVECTBGRNDACTIVE.
- An interrupt, signaling the background task has completed execution, is generated. This interrupt signal is ANDed with the interrupt from Task 8 and fed to the PIE. Note that if an illegal instruction occurs inside the background task, the interrupt for task 8 is fired.
- When the background task terminates, the CLA resumes arbitration among the pending tasks.

### 5.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

For example, if using the 12-bit ADC with ADCCLK at SYSCLK / 4, the ADC can take  $10.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 42 \text{ SYSCLK}$  cycles to complete a conversion.

From a CLA perspective, the pipeline activity is shown in [Table 5-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

**Table 5-5. ADC to CLA Early Interrupt Response**

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
Conversion <sub>(Cycle 1)</sub>	Interrupt Received

Conversion <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>	I <sub>(Cycle N-9)</sub>	I <sub>(Cycle N-10)</sub>	I <sub>(Cycle N-11)</sub>		
Conversion <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>	I <sub>(Cycle N-9)</sub>	I <sub>(Cycle N-10)</sub>		
Conversion <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>	I <sub>(Cycle N-9)</sub>		
Conversion <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>		
Conversion <sub>(Cycle N-2)</sub>	<b>Read RESULT</b>	<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>		
Conversion <sub>(Cycle N-1)</sub>			<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>		
Conversion <sub>(Cycle N-0)</sub>				<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>		
Conversion Complete					<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>		
RESULT Latched						<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>		
<b>RESULT Available</b>							<b>Read RESULT</b>		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is  $(N-2) - 4 = N-6$ .

### 5.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

#### Example 5-3. Math Operation with Parallel Load

```

; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
; MADDF32 MR0, MR1, #2 ; MR0 = MR1 + 2,
|| MMOV32 MR1, @val ; MR1 gets the contents of val
; <-- MMOV32 completes here (MR1 is valid)
; <-- DDF32 completes here (MR0 is valid)
MMPYF32 MR0, MR0, MR1 ; Any instruction, can use MR1 and/or MR0

```

#### Example 5-4. Multiply with Parallel Add

```

; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
; MMPYF32 MR0, MR1, MR3 ; MR0 = MR1 * MR3
|| MADDF32 MR1, MR2, MR0 ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
MMPYF32 MR1, MR1, MR0 ; Any instruction, can use MR1 and/or MR0

```

### 5.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

#### Note

If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

#### Note

If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

## 5.6 Software

### 5.6.1 CLA Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/cla

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 5.6.1.1 CLA arcsine(x) using a lookup table (cla\_asin\_cpu01)

FILE: cla\_ex1\_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

##### *Memory Allocation*

- CLA1 Math Tables (RAMLS1)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

##### *Watch Variables*

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

#### 5.6.1.2 CLA arctangent(x) using a lookup table (cla\_atan\_cpu01)

FILE: cla\_ex2\_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

##### *Memory Allocation*

- CLA1 Math Tables (RAMLS1)
  - CLAatan2Table - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fNum - Numerator of sample input
  - fDen - Denominator of sample input

##### *Watch Variables*

- fVal - Argument to task 1
- fResult - Result of arctan(fVal)

#### 5.6.1.3 CLA background nesting task

FILE: cla\_ex3\_background\_nesting\_task.c

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the

start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag `cla_background_task` is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

#### *External Connections*

### **5.6.1.4 Controlling PWM output using CLA**

FILE: `cla_ex4_pwm_control.c`

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

#### *External Connections*

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

#### *Watch Variables*

- duty

### **5.6.1.5 Just-in-time ADC sampling with CLA**

FILE: `cla_ex5_adc_just_in_time.c`

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched. The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :-  
 -ADC acquisition cycles programmed = 10 SYSCLKS  
 -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCLKS  
 -CLA task trigger to first instruction in Fetch delay = 4  
 -Let the interrupt offset value be 'x'  
 -The code inside CLA control task before ADC read takes below cycles :  
 Setting up profiling gpio : 3 cycles  
 Pre-processing : 13 cycles  
 Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. :  $x + 4 + 16 = 40$  :  $x = 20$

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality, observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (440 ns) based on the above calculation.

#### *External Connections*

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1  
3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto  $f_s / 10 = 100$  KHz for observing continuous duty variations
- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

#### *Watch Variables*

- None

#### **5.6.1.6 Optimal offloading of control algorithms to CLA**

FILE: cla\_ex6\_cpu\_offloading.c

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system\_OFF" is set to 1. The system gets enabled again once "system\_OFF" is restored back to 0. By default system\_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops. User-configurable pre-defined symbol "run\_loop1\_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For run\_loop1\_cla == 0 i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For run\_loop1\_cla == 1 i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU) = ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intuitive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be  $1.0(0.2 + 0.8)$  but will get saturated to 0.9(the maximum value defined). Similarly

if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

#### *External Connections*

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V 0.8 3.3V 3.3V 0.1 Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

#### **5.6.1.7 Handling shared resources across C28x and CLA**

FILE: `cla_ex7_shared_resource_handling.c`

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100KHz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA do read-modify -write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase\_shift\_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase\_shift\_ON" is set to 1.

#### *External Connections*

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

## 5.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

### 5.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction presents the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x instructions; the source operands are always on the right and the destination operands are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the CLA are given in [Table 5-6](#).

**Table 5-6. Operand Nomenclature**

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	Auxiliary register 0
MAR1	Auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

**Table 5-7. INSTRUCTION dest, source1, source2 Short Description**

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in <a href="#">Section 5.5</a>
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed the CLA data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

### 5.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 5-8](#).

**Table 5-8. Addressing Modes**

Addressing Mode	'addr' Opcode Field Encode <sup>(1)</sup>	Description
<b>@dir</b>	<b>0000</b>	<p><b>Direct Addressing Mode</b></p> <p>Example 1: <code>MMOV32 MR1, @_VarA</code></p> <p>Example 2: <code>MMOV32 MR1, @_EPwm1Regs.CMPA.all</code></p> <p>In this case, the 'mmmm mmmm mmmm mmmm' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU.</p> <p>For example, <code>@_VarA</code> populates the address of the variable <code>VarA</code>. and <code>@_EPwm1Regs.CMPA.all</code> populates the address of the <code>CMPA</code> register.</p>
<b>*MAR0[#imm16]++</b>	<b>0001</b>	<p><b>MAR0 Indirect Addressing with 16-bit Immediate Post Increment</b></p> <p><b>MAR1 Indirect Addressing with 16-bit Immediate Post Increment</b></p> <p><code>addr = MAR0 (or MAR1)</code> Access memory using the address stored in <code>MAR0 (or MAR1)</code>.  <code>MAR0 (or MAR1) += #imm16</code> Then post increment <code>MAR0 (or MAR1)</code> by <code>#imm16</code>.</p> <p>Example 1: <code>MMOV32 MR0, *MAR0[2]++</code></p> <p>Example 2: <code>MMOV32 MR1, *MAR1[-2]++</code></p> <p>For a post increment of 0, the assembler accepts both <code>*MAR0</code> and <code>*MAR0[0]++</code>.</p> <p>The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if <code>#imm16</code> is 2, then the opcode field is <code>0x0002</code>. Likewise, if <code>#imm16</code> is -2, then the opcode field is <code>0xFFFFE</code>.</p> <p>If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.</p>
<b>*MAR1[#imm16]++</b>	<b>0010</b>	
<b>*MAR0+[#imm16]</b>	<b>0101</b>	<p><b>MAR0 Offset Addressing with 16-bit Immediate Offset</b></p> <p><b>MAR1 Offset Addressing with 16-bit Immediate Offset</b></p> <p><code>addr = MAR0 (or MAR1) + #imm16</code> Add the offset <code>#imm16</code> to the address stored in <code>MAR0(MAR1)</code> to access the desired memory location.</p> <p>Example 1: <code>MMOV32 MR0, *MAR0+[2]</code></p> <p>Example 1: <code>MMOV32 MR1, *MAR1+[-2]</code></p> <p>The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if <code>#imm16</code> is 2, then the opcode field is <code>0x0002</code>. Likewise, if <code>#imm16</code> is -2, then the opcode field is <code>0xFFFFE</code>.</p> <p>If the addition of the 16-bit immediate causes overflow, the value wraps around on a 16-bit boundary.</p>
<b>*MAR1+[#imm16]</b>	<b>0110</b>	

(1) Values not shown are reserved.

Encoding for the shift fields in the `MASR32`, `MLSR32` and `MLSL32` instructions is shown in [Table 5-9](#).

**Table 5-9. Shift Field Encoding**

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	....
32	1111

For instructions that use MRx (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to [Table 5-10](#).

**Table 5-10. Operand Encoding**

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

[Table 5-11](#) shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

**Table 5-11. Condition Field Encoding**

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

### 5.7.3 Instructions

The instructions are listed alphabetically.

#### Instruction Set Summary

<b>MABSF32 MRa, MRb</b> — 32-Bit Floating-Point Absolute Value.....	702
<b>MADD32 MRa, MRb, MRc</b> — 32-Bit Integer Add.....	703
<b>MADDF32 MRa, #16FHi, MRb</b> — 32-Bit Floating-Point Addition.....	704
<b>MADDF32 MRa, MRb, #16FHi</b> — 32-Bit Floating-Point Addition.....	706
<b>MADDF32 MRa, MRb, MRc</b> — 32-Bit Floating-Point Addition.....	708
<b>MADDF32 MRd, MRe, MRf   MMOV32 mem32, MRa</b> — 32-Bit Floating-Point Addition with Parallel Move.....	709
<b>MADDF32 MRd, MRe, MRf   MMOV32 MRa, mem32</b> — 32-Bit Floating-Point Addition with Parallel Move.....	710
<b>MAND32 MRa, MRb, MRc</b> — Bitwise AND.....	712
<b>MASR32 MRa, #SHIFT</b> — Arithmetic Shift Right.....	713
<b>MBCNDD 16BitDest {, CNDF}</b> — Branch Conditional Delayed.....	715
<b>MCCNDD 16BitDest {, CNDF}</b> — Call Conditional Delayed.....	720
<b>MCLRC BGINTM</b> — Clear Background Task Interrupt Mask.....	724
<b>MCMP32 MRa, MRb</b> — 32-Bit Integer Compare for Equal, Less Than or Greater Than.....	725
<b>MCMPF32 MRa, MRb</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	727
<b>MCMPF32 MRa, #16FHi</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	728
<b>MDEBUGSTOP</b> — Debug Stop Task.....	730
<b>MDEBUGSTOP1</b> — Software Breakpoint.....	731
<b>MEALLOW</b> — Enable CLA Write Access to EALLOW Protected Registers.....	732
<b>MEDIS</b> — Disable CLA Write Access to EALLOW Protected Registers.....	733
<b>MEINVF32 MRa, MRb</b> — 32-Bit Floating-Point Reciprocal Approximation.....	734
<b>MEISQRTF32 MRa, MRb</b> — 32-Bit Floating-Point Square-Root Reciprocal Approximation.....	736
<b>MF32TOI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer.....	738
<b>MF32TOI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round.....	739
<b>MF32TOI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Integer.....	740
<b>MF32TOUI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer .....	742
<b>MF32TOUI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round.....	743
<b>MF32TOUI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer .....	744
<b>MFRACF32 MRa, MRb</b> — Fractional Portion of a 32-Bit Floating-Point Value.....	745
<b>MI16TOF32 MRa, MRb</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....	746
<b>MI16TOF32 MRa, mem16</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....	747
<b>MI32TOF32 MRa, mem32</b> — Convert 32-Bit Integer to 32-Bit Floating-Point Value .....	748
<b>MI32TOF32 MRa, MRb</b> — Convert 32-Bit Integer to 32-Bit Floating-Point Value .....	749
<b>MLSL32 MRa, #SHIFT</b> — Logical Shift Left.....	750
<b>MLSR32 MRa, #SHIFT</b> — Logical Shift Right.....	752
<b>MMACF32 MR3, MR2, MRd, MRe, MRf   MMOV32 MRa, mem32</b> — 32-Bit Floating-Point Multiply and Accumulate with Parallel Move.....	753
<b>MMAXF32 MRa, MRb</b> — 32-Bit Floating-Point Maximum.....	756
<b>MMAXF32 MRa, #16FHi</b> — 32-Bit Floating-Point Maximum.....	758
<b>MMINF32 MRa, MRb</b> — 32-Bit Floating-Point Minimum.....	760
<b>MMINF32 MRa, #16FHi</b> — 32-Bit Floating-Point Minimum.....	762
<b>MMOV16 MARx, MRa, #16I</b> — Load the Auxiliary Register with MRa + 16-bit Immediate Value.....	764
<b>MMOV16 MARx, mem16</b> — Load MAR1 with 16-bit Value.....	767
<b>MMOV16 mem16, MARx</b> — Move 16-Bit Auxiliary Register Contents to Memory.....	770
<b>MMOV16 mem16, MRa</b> — Move 16-Bit Floating-Point Register Contents to Memory.....	771
<b>MMOV32 mem32, MRa</b> — Move 32-Bit Floating-Point Register Contents to Memory .....	773
<b>MMOV32 mem32, MSTF</b> — Move 32-Bit MSTF Register to Memory.....	775
<b>MMOV32 MRa, mem32 {, CNDF}</b> — Conditional 32-Bit Move.....	776
<b>MMOV32 MRa, MRb {, CNDF}</b> — Conditional 32-Bit Move.....	778
<b>MMOV32 MSTF, mem32</b> — Move 32-Bit Value from Memory to the MSTF Register.....	780

<b>MMOVED32 MRa, mem32</b> — Move 32-Bit Value from Memory with Data Copy.....	781
<b>MMOVF32 MRa, #32F</b> — Load the 32-Bits of a 32-Bit Floating-Point Register.....	783
<b>MMOV16 MARx, #16I</b> — Load the Auxiliary Register with the 16-Bit Immediate Value.....	785

**MBSF32 MRa, MRb****32-Bit Floating-Point Absolute Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

**Description**

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MBSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MBSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MBSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MBSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

## MADD32 MRa, MRb, MRc

### 32-Bit Integer Add

#### Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

#### Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

#### Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

#### Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

**MADDF32 MRa, #16FHi, MRb****32-Bit Floating-Point Addition****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

**Description**

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1 ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3 ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

**MADDF32 MRa, MRb, MRc****32-Bit Floating-Point Addition****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

**Description**

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
;
_Cla1Task1:
  MMOV32 MR0,@M1      ; Load MR0 with M1
  MMOV32 MR1,@X1      ; Load MR1 with X1
  MMPYF32 MR1,MR1,MR0 ; Multiply M1*X1
  || MMOV32 MR0,@B1    ; and in parallel load MR0 with B1
  MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
  MMOV32 @Y1,MR1      ; Store the result

**32-Bit Floating-Point Addition with Parallel Move**
**Operands**

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

Both MADDF32 and MMOV32 complete in a single cycle.

**Example**

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_Cla1Task2:
  MMOV32  MR0, @_A      ; Load MR0 with A
  MMOV32  MR1, @_B      ; Load MR1 with B
  MMPYF32 MR1, MR1, MR0 ; Multiply A*B
  || MMOV32 MR0, @_C      ; and in parallel load MR0 with C
  MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
  || MMOV32 @_Y2, MR1    ; and in parallel store A*B
  MMOV32  @_Y3, MR1    ; Store the A*B + C
  MSTOP                ; end of task
```

[MADDF32 MRd, MRe, MRf || MMOV32 MRa, mem32](#)

**MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32**
**32-Bit Floating-Point Addition with Parallel Move**
**Operands**

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

**Pipeline**

The MADDF32 and the MMOV32 both complete in a single cycle.

MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

### 32-Bit Floating-Point Addition with Parallel Move

#### Example 1

```

; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y1 = A + 4B
;           Y2 = A + C
;
;
;_Cla1Task1:

**MASR32 MRa, #SHIFT****Arithmetic Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000
```

**Description**

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate
; m2 = m2/2
; x2 = x2/4
; b2 = b2/8
;
_Cla1Task2:
  MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
  MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
  MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFFFFF80)
  MASR32 MR0, #1 ; MR0 = 16 (0x00000010)
  MASR32 MR1, #2 ; MR1 = 16 (0x00000010)
  MASR32 MR2, #3 ; MR2 = -16 (0xFFFFFFFFF0)
  MMOV32 @_m2, MR0 ; store results
  MMOV32 @_x2, MR1
  MMOV32 @_b2, MR2
  MSTOP ; end of task
```

**MBCNDD 16BitDest {, CNDF}**
**Branch Conditional Delayed**
**Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

**Opcode**

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

**Description**

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Restrictions**

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**MBCNDD 16BitDest {, CNDF} (continued)**
***Branch Conditional Delayed***
**Pipeline**

The MBCNDD instruction alone is a single-cycle instruction. As shown in [Table 5-12](#), 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to [Table 5-12](#) and [Table 5-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```

<Instruction 1> ; I1 Last instruction that can affect flags for
                ; the MBCNDD operation
<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return
MBCNDD _Skip, NEQ ; Branch to Skip if not equal to zero
                ; Three instructions after MBCNDD are always
                ; executed whether the branch is taken or not

[MCCNDD 16BitDest, CNDF](#)  
[MRCNDD CNDF](#)

**MCCNDD 16BitDest {, CNDF}****Call Conditional Delayed****Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

**Opcode**

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

**Description**

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Restrictions**

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

**Flags**

This instruction does not modify flags in the MSTF register.

**MCCNDD 16BitDest {, CNDF} (continued)**
**Call Conditional Delayed**

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

The MCCNDD instruction alone is a single-cycle instruction. As shown in [Table 5-14](#), 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 5-14](#) and [Table 5-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

**MCLRC BGINTM*****Clear Background Task Interrupt Mask*****Operands**

---

None      This instruction does not have any operands

---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0111 0000

**Description**

This instruction clears the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, allowing any code thereafter to be interrupted by a higher priority task. This instruction clears the BGINTM bit at the end of the D2 phase.

**Note**

---

This instruction does not require the MEALLOW bit to be asserted before or deasserted after clearing BGINTM.

---

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

MCLRC BGINTM	;	Allow the background task to be
	;	interrupted by clearing the
	;	MSTSBGRND.BGINTM bit

**See also**

## MCMP32 MRa, MRb

### 32-Bit Integer Compare for Equal, Less Than or Greater Than

#### Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

#### Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

#### Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to [MCMPF32](#).

#### Note

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag `--cla_signed_compare_workaround` enables this workaround.

#### Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

```

#### Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

#### Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

#### Pipeline

This is a single-cycle instruction.

#### Example

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xc0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0
MCMPF32 MR0, MR0 ; ZF = 1, NF = 0
```

**MCMPF32 MRa, #16FHi****32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

**Description**

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

**Pipeline**

This is a single-cycle instruction

**Example 1**

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32 MR0, #6.5 ; ZF = 0, NF = 1
MCMPF32 MR0, #5.0 ; ZF = 1, NF = 0
```

**MCMPF32 MRa, #16FHi (continued)**

**MDEBUGSTOP*****Debug Stop Task*****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000

**Description**

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

**Restrictions**

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**See also**

[MSTOP](#) , [MDEBUGSTOP1](#)

**MDEBUGSTOP1****Software Breakpoint****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0011 0000

**Description**

The instruction at which a software breakpoint is placed is replaced by the MDEBUGSTOP1 instruction. The instruction halts execution once the instruction reaches the D2 phase in the pipeline; at that point, the subsequent instructions that were fetched, after the halt, are flushed from the pipeline. The replace instruction is re-fetched after this and execution continues normally (either in run or step mode).

See [Section 5.4.3](#) for a detailed explanation of the operation.

**Restrictions**

The MDEBUGSTOP1 instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**MEALLOW****Enable CLA Write Access to EALLOW Protected Registers****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000

**Description**

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP

```

**See also**

[MEDIS](#)

**MEDIS*****Disable CLA Write Access to EALLOW Protected Registers*****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000

**Description**

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP

```

**MEINVF32 MRa, MRb****32-Bit Floating-Point Reciprocal Approximation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

**Description**

This operation generates an estimate of  $1/X$  in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**MEINVF32 MRa, MRb (continued)**
**32-Bit Floating-Point Reciprocal Approximation**
**Example**

```

; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
;
;_Cla1Task1:
  MMOV32 MR1, @_Den      ; MR1 = Den

**MEISQRTF32 MRa, MRb****32-Bit Floating-Point Square-Root Reciprocal Approximation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

**Description**

This operation generates an estimate of  $1/\sqrt{X}$  in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**MF32TOUI16 MRa, MRb****Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1010 0000
```

**Description**

Convert the 32-bit floating point value in MRb to an unsigned 16-bit integer value and truncate to zero. The result is stored in MRa. To instead round the integer to the nearest even value, use the MF32TOUI16R instruction.

```
MRa(15:0) = F32TOUI16(MRb);
MRa(31:16) = 0x0000;
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ    MR0, #9.0      ; MR0 = 9.0 (0x41100000)
MF32TOUI16 MR1, MR0      ; MR1(15:0) = MF32TOUI16(MR0) = 9 (0x0009)
              ; MR1(31:16) = 0x0000
MMOVIZ    MR2, #-9.0     ; MR2 = -9.0 (0xc1100000)
MF32TOUI16 MR3, MR2      ; MR3(15:0) = MF32TOUI16(MR2) = 0 (0x0000)
              ; MR3(31:16) = 0x0000
```

**MF32TOUI16R MRa, MRb**
**Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1100 0000
```

**Description**

Convert the 32-bit floating-point value in MRb to an unsigned 16-bit integer and round to the closest even value. The result is stored in MRa. To instead truncate the converted value, use the MF32TOUI16 instruction.

```
MRa(15:0) = MF32TOUI16round(MRb);
MRa(31:16) = 0x0000;
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ      MR0, #0x412C    ; MR0 = 0x412C
MMOVXI      MR0, #0xCCCCD   ; MR0 = 0xCCCCD ; MR0 = 10.8 (0x412CCCCD)
MF32TOUI16R MR1, MR0        ; MR1(15:0) = MF32TOUI16round(MR0) = 11 (0x000B)
                ; MR1(31:16) = 0x0000
MMOVF32     MR2, #-10.8     ; MR2 = -10.8 (0x0xC12CCCCD)
MF32TOUI16R MR3, MR2        ; MR3(15:0) = MF32TOUI16round(MR2) = 0 (0x0000)
                ; MR3(31:16) = 0x0000
```

**MFRACF32 MRa, MRb**
***Fractional Portion of a 32-Bit Floating-Point Value***
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0000 0000
```

**Description**

Returns in MRa the fractional portion of the 32-bit floating-point value in MRb

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR2, #19.625 ; MR2 = 19.625 (0x419D0000)
MFRACF32 MR3, MR2 ; MR3 = MFRACF32(MR2) = 0.625 (0x3F200000)0
```

**MI16TOF32 MRa, MRb****Convert 16-Bit Integer to 32-Bit Floating-Point Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1000 0000
```

**Description**

Convert the 16-bit signed integer in MRb to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32(MRb);
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ    MR0, #0x0000    ; MR0(31:16) = 0.0 (0x0000)
MMOVXI    MR0, #0x0004    ; MR0(15:0) = 4.0 (0x0004)
MI16TOF32 MR1, MR0        ; MR1 = MI16TOF32 (MR0) = 4.0 (0x40800000)

**MLSL32 MRa, #SHIFT****Logical Shift Left****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

**Description**

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate:
; m2 = m2*2
; x2 = x2*4
; b2 = b2*8
;
_Cla1Task3:
  MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
  MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
  MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
  MLSL32 MR0, #1 ; MR0 = 64 (0x00000040)
  MLSL32 MR1, #2 ; MR1 = 256 (0x00000100)
  MLSL32 MR2, #3 ; MR2 = -1024 (0xFFFFFC00)
  MMOV32 @_m2, MR0 ; Store results
  MMOV32 @_x2, MR1
  MMOV32 @_b2, MR2
  MSTOP ; end of task
```

MLSL32 MRa, #SHIFT (continued)

***Logical Shift Left***

**MLSR32 MRa, #SHIFT****Logical Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

**Description**

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0 ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0 ; MR2 = 0xAAAA5555
MASR32 MR1, #1 ; MR1 = 0xD5552AAA
MLSR32 MR2, #1 ; MR2 = 0x55552AAA
MASR32 MR1, #1 ; MR1 = 0xEAAA9555
MLSR32 MR2, #1 ; MR2 = 0x2AAA9555
MASR32 MR1, #6 ; MR1 = 0xFFAAA555
MLSR32 MR2, #6 ; MR2 = 0x00AAA555
```

**MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32**
**32-Bit Floating-Point Multiply and Accumulate with Parallel Move**
**Operands**

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

**Description**

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

**Restrictions**

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

**Pipeline**

MMACF32 and MMOV32 complete in a single cycle.

**MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)**
**32-Bit Floating-Point Multiply and Accumulate with Parallel Move**
**Example 1**

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E
;
_Cla1Task1:

**MMAXF32 MRa, MRb****32-Bit Floating-Point Maximum****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

**Description**

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example 1**

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)

**MMAXF32 MRa, #16FHi****32-Bit Floating-Point Maximum****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

**Description**

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR0, #5.5 ; MR0 = 5.5, ZF = 0, NF = 1
MMAXF32 MR1, #2.5 ; MR1 = 4.0, ZF = 0, NF = 0
MMAXF32 MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

**MMOV16 MARx, MRa, #16I****Load the Auxiliary Register with MRa + 16-bit Immediate Value****Operands**

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

**Description**

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARX = MRa(15:0) + #16I;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #\_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
MMOV16 MAR0, MR0, #_X ; Load MAR0 with address of x (20) + MR0 (10)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (30)
<Instruction 5> ; I5
```

```

**See also**
[MMOV32 mem32, MSTF](#)

**MMOV32 mem32, MSTF*****Move 32-Bit MSTF Register to Memory*****Operands**

MSTF	Floating-point status register
mem32	32-bit destination memory

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr
```

**Description**

Copy the CLA floating-point status register, MSTF, to memory.

```
[mem32] = MSTF;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

**Example**

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
MMOV32 @_temp, MSTF ; D2 | |
MNOP                ; R1 | F1 | MCCNDD is fetched
MNOP                ; R2 | F2 |
MNOP                ; E  | D1 |
MCCNDD _bar, UNC    ; W  | D2 | old RPC written to memory,
                   ;   |   | RPC updated with MPC+1
MNOP                ;   | R1 |
MNOP                ;   | R2 |
MNOP                ;   | E  | execution branches to _bar
```

[MMOV32 mem32, MRa](#)

**MMOV32 MRa, mem32 {, CNDF}****Conditional 32-Bit Move****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

**Description**

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31);
  ZF = 0;
  if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
else No flags modified;
```

**MMOV32 MRa, mem32 {, CNDF}** (continued)

### **Conditional 32-Bit Move**

---

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A != B) calculate Y = X*M2
;
_Cla1Task5:
  MMOV32   MR0, @_A
  MMOV32   MR1, @_B
  MCMPF32  MR0, MR1
  MMOV32   MR2, @_M1, EQ ; if A == B, MR2 = M1
                        ; Y = M1*X
  MMOV32   MR2, @_M2, NEQ ; if A != B, MR2 = M2
                        ; Y = M2*X

  MMOV32   MR3, @_X
  MMPYF32  MR3, MR2, MR3 ; Calculate Y
  MMOV32   @_Y, MR3      ; Store Y
  MSTOP
; end of task

CNDF	Optional condition

**Opcode**

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000
```

**Description**

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = MRb;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31); ZF = 0;
  if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

**MMOV32 MRa, MRb {, CNDF}** (continued)

**Conditional 32-Bit Move**

---

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; Given: X = 8.0
;         Y = 7.0
;         A = 2.0
;         B = 5.0
; _ClaTask1

LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

**Description**

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating-point format), use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

**Example**

```
MMOVF32 MR1, #3.0 ; MR1 = 3.0 (0x40400000)
                  ; Assembler converts this instruction as
                  ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0 ; MR2 = 0.0 (0x00000000)
                  ; Assembler converts this instruction as
                  ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265 ; MR3 = 12.625 (0x41443D71)
                    ; Assembler converts this instruction as
                    ; MMOVIZ MR3, #0x4144
                    ; MMOVXI MR3, #0x3D71
```

**MMOVF32 MRa, #32F** (continued)

**MMOVI16 MARx, #16I****Load the Auxiliary Register with the 16-Bit Immediate Value****Operands**

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000
```

**Description**

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = #16I;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #\_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```
; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X          ; Load MAR0 with address of X (20)
<Instruction 1>             ; I1 Uses the old value of MAR0 (50)
<Instruction 2>             ; I2 Uses the old value of MAR0 (50)
<Instruction 3>             ; I3 Cannot use MAR0
<Instruction 4>             ; I4 Uses the new value of MAR0 (20)
<Instruction 5>             ; I5
....
```

**MMOVI16 MARx, #16I (continued)**
***Load the Auxiliary Register with the 16-Bit Immediate Value***

I6	I6	I5	I4	I3	I2	I1	MMOVI16	

**MMOVI32 MRa, #32FHex**
**Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate**
**Operands**

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

**Description**

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOV32 to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOV32 to MMOVIZ and MMOVXI instructions.

**MMOVI32 MRa, #32FHex (continued)**
**Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate**
**Example**

```

MOVI32  MR1, #0x40400000 ; MR1 = 0x40400000
                                ; Assembler converts this instruction as
                                ; MMOVIZ MR1, #0x4040
MOVI32  MR2, #0x00000000 ; MR2 = 0x00000000
                                ; Assembler converts this instruction as
                                ; MMOVIZ MR2, #0x0
MOVI32  MR3, #0x40004001 ; MR3 = 0x40004001
                                ; Assembler converts this instruction as
                                ; MMOVIZ MR3, #0x4000
                                ; MMOVXI MR3, #0x4001
MOVI32  MR0, #0x00004040 ; MR0 = 0x00004040
                                ; Assembler converts this instruction as
                                ; MMOVIZ MR0, #0x0000
                                ; MMOVXI MR0, #0x4040
    
```

**MMOVIZ MRa, #16FHi****Load the Upper 16-Bits of a 32-Bit Floating-Point Register****Operands**

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

**Description**

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0) = 0;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
MMOVIZ MR0, #0xBFC0 ; MR0 = 0xBFC00000 (1.5)
MMOVIZ MR1, #-1.5 ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
MMOVIZ MR2, #0x4049 ; MR2 = 0x40490000
MMOVXI MR2, #0x0FDB ; MR2 = 0x40490FDB
```

**MMOVZ16 MRa, mem16****Load MRx with 16-Bit Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

**Description**

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**MMOVXI MRa, #16FLoHex**
***Move Immediate Value to the Lower 16-Bits of a Floating-Point Register***
**Operands**

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

**Description**

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

**Flags**

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
MMOVIZ   MR0,#0x4049   ; MR0 = 0x40490000
MMOVXI   MR0,#0x0FDB   ; MR0 = 0x40490FDB
```

**MMPYF32 MRa, MRb, MRc||MADDF32 MRd, MRe, MRf**
**32-Bit Floating-Point Multiply with Parallel Add**
**Operands**

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRC	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MADDF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

**Opcode**

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

**Description**

Multiply the contents of two floating-point registers with parallel addition of two registers.

```
MRa = MRb * MRC;
MRd = MRe + MRf;
```

**Restrictions**

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

**Pipeline**

Both MMPYF32 and MADDF32 complete in a single cycle.

**MNEGF32 MRa, MRb{, CNDF}****Conditional Negation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Condition tested

**Opcode**

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000
```

**Description**

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

**Pipeline**

This is a single-cycle instruction.

**MRCNDD {CNDF}*****Return Conditional Delayed*****Operands**

CNDF	Optional condition
------	--------------------

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf

**Description**

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

<code>if (CNDF == TRUE) MPC = RPC;</code>
---

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

The MRCNDD instruction is a single-cycle instruction. As shown in [Table 5-19](#), 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled.

**MRCNDD {CNDF} (continued)**
***Return Conditional Delayed***

The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 5-19](#) and [Table 5-20](#), the instructions before and after MRCNDD have the following properties:

```

;
;
<Instruction 1> ; I1 Last instruction that can affect flags for
; the MCCNDD operation
<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ ; Call to func if not equal to zero
; Three instructions after MCCNDD are always
; executed whether the call is taken or not
<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return
<Instruction 8> ; I8 The address of this instruction is saved
; in the RPC field of the MSTF register.
; Upon return this value is loaded into MPC
; and fetching continues from this point.
<Instruction 9> ; I9
<Instruction 10> ; I10
....
....
_func:
<Destination 1> ; d1 Can be any instruction
<Destination 2> ; d2
<Destination 3> ; d3
<Destination 4> ; d4 Last instruction that can affect flags for
; the MRCNDD operation

....
....
MSTOP
....

```

- **d4**
  - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
  - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
  - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.

## MRCNDD {CNDF} (continued)

**Return Conditional Delayed**

- These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

**Table 5-19. Pipeline Activity for MRCNDD, Return Not Taken**

**MSETC BGINTM*****Set Background Task Interrupt Mask*****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0101 0000

**Description**

This instruction sets the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, making any code thereafter uninterruptible. No other higher priority task is able to interrupt the background task until the BGINTM is cleared. This instruction sets the BGINTM bit at the end of the D2 phase.

This instruction does not require the MEALLOW bit to be asserted before, or de-asserted after, setting BGINTM.

**Flags**

This instruction does not modify the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

MSETC BGINTM	;	Set the MSTSBGRND.BGINTM bit
	;	to prevent any other tasks from
	;	interrupting the background task

**See also**

[MCLRC BGINTM](#)

**MSETFLG FLAG, VALUE*****Set or Clear Selected Floating-Point Status Flags*****Operands**

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

**Opcode**

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

**Description**

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF 32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

**Pipeline**

This is a single-cycle instruction.

**Example**

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSETFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

## MSTOP

### Stop Task

#### Operands

none	This instruction does not have any operands
------	---

#### Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000

#### Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

#### Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

#### Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**MSTOP** (continued)**Stop Task****Pipeline**

This is a single-cycle instruction. [Table 5-21](#) shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

**Table 5-21. Pipeline Activity for MSTOP**

**MSUB32 MRa, MRb, MRc****32-Bit Integer Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

**Description**

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRC(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given A = (int32)1
;         B = (int32)2
;         C = (int32)-7
;
;
; Calculate Y2 = A - B - C
;

**MSUBF32 MRa, MRb, MRc****32-Bit Floating-Point Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

**Description**

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
;
_Cla1Task5:
  MMOV32  MR0, @_A      ; Load MR0 with A

**MSUBF32 MRa, #16FHi, MRb**
**32-Bit Floating-Point Subtraction**
**Operands**

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

**Description**

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**MSUBF32 MRa, #16FHi, MRb (continued)**
**32-Bit Floating-Point Subtraction**
**Example**

```

; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
  MMOV32      MR0, @_x          ; MR0 = X
  MEISQRTF32 MR1, MR0          ; MR1 = Ye = Estimate(1/sqrt(X))
  MMOV32      MR1, @_x, EQ      ; if(X == 0.0) Ye = 0.0
  MMPYF32     MR3, MR0, #0.5    ; MR3 = X*0.5
  MMPYF32     MR2, MR1, MR3     ; MR2 = Ye*X*0.5
  MMPYF32     MR2, MR1, MR2     ; MR2 = Ye*Ye*X*0.5
  MSUBF32     MR2, #1.5, MR2    ; MR2 = 1.5 - Ye*Ye*X*0.5
  MMPYF32     MR1, MR1, MR2     ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
  MMPYF32     MR2, MR1, MR3     ; MR2 = Ye*X*0.5
  MMPYF32     MR2, MR1, MR2     ; MR2 = Ye*Ye*X*0.5
  MSUBF32     MR2, #1.5, MR2    ; MR2 = 1.5 - Ye*Ye*X*0.5
  MMPYF32     MR1, MR1, MR2     ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
  MMPYF32     MR0, MR1, MR0     ; MR0 = Y = Ye*X
  MMOV32      @_y, MR0         ; Store Y = sqrt(X)

**MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32**
**32-Bit Floating-Point Subtraction with Parallel Move**
**Operands**

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

**Description**

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

**Pipeline**

Both MSUBF32 and MMOV32 complete in a single cycle.

**Example**

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

**MSWAPF MRa, MRb {, CNDF}**
**Conditional Swap**
**Operands**

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

**Opcode**

```
LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000
```

**Description**

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

**Pipeline**

This is a single-cycle instruction.

**MSWAPF MRa, MRb {, CNDF} (continued)**

  MSTOP     ; End of task

```

## MTESTTF CNDF

### Test MSTF Register Flag Condition

#### Operands

CNDF	Condition to test based on MSTF flags
------	---------------------------------------

#### Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

#### Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

#### Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

#### Pipeline

This is a single-cycle instruction.

## MTESTTF CNDF (continued)

**Test MSTF Register Flag Condition**
**Example**

```

; if (State == 0.1)
;   RampState = RampState || RAMPMASK
; else if (State == 0.01)
;   CoastState = CoastState || COASTMASK
; else
;   SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:
  MMOV32   MR0, @_State
  MCMPF32  MR0, #0.1           ; Affects flags for 1st MBCNDD (A)
  MCMPF32  MR0, #0.01         ; Check used by 2nd MBCNDD (B)
  MTESTTF  EQ                 ; Store EQ flag in TF for 2nd MBCNDD (B)
  MNOP
  MBCNDD   _Skip1, NEQ        ; (A) If State != 0.1, go to Skip1
  MMOV32   MR1, @_RampState   ; Always executed
  MMOVXI   MR2, #RAMPMASK     ; Always executed
  MOR32    MR1, MR2           ; Always executed
  MMOV32   @_RampState, MR1   ; Execute if (A) branch not taken
  MSTOP    ; end of task if (A) branch not taken
_Skip1:
  MMOV32   MR3, @_SteadyState
  MMOVXI   MR2, #STEADYMASK
  MOR32    MR3, MR2
  MBCNDD   _Skip2, NTF        ; (B) if State != .01, go to Skip2
  MMOV32   MR1, @_CoastState  ; Always executed
  MMOVXI   MR2, #COASTMASK    ; Always executed
  MOR32    MR1, MR2           ; Always executed
  MMOV32   @_CoastState, MR1  ; Execute if (B) branch not taken
  MSTOP    ; end of task if (B) branch not taken
_Skip2:
  MMOV32   @_SteadyState, MR3  ; Executed if (B) branch taken
  MSTOP

```

**MUI16TOF32 MRa, mem16**
***Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value***
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

**Description**

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**MXOR32 MRa, MRb, MRc**
**Bitwise Exclusive Or**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000
```

**Description**

Bitwise XOR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) XOR MRC(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 XOR 0101 = 0000 (0)
; 0101 XOR 0100 = 0001 (1)
; 0101 XOR 0011 = 0110 (6)
; 0101 XOR 0010 = 0111 (7)
; 1010 XOR 1111 = 0101 (5)
; 1010 XOR 1110 = 0100 (4)
; 1010 XOR 1101 = 0111 (7)
; 1010 XOR 1100 = 0110 (6)
MXOR32 MR2, MR1, MR0 ; MR3 = 0x01675476
```

## 5.8 CLA Registers

This section describes the Control Law Accelerator registers.

### 5.8.1 CLA Base Address Table

**Table 5-22. CLA Base Address Table**

Device Registers	Register Name	Start Address	End Address
Cla1OnlyRegs	CLA_ONLY_REGS	0x0000_0C00	0x0000_0CFF
Cla1SoftIntRegs	CLA_SOFTINT_REGS	0x0000_0CE0	0x0000_0CFF
Cla1Regs	CLA_REGS	0x0000_1400	0x0000_147F

### 5.8.2 CLA\_ONLY\_REGS Registers

Table 5-23 lists the memory-mapped registers for the CLA\_ONLY\_REGS registers. All register offset addresses not listed in Table 5-23 should be considered as reserved locations and the register contents should not be modified.

**Table 5-23. CLA\_ONLY\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	<a href="#">Go</a>
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	<a href="#">Go</a>
C2h	_MPSA1	CLA PSA1 Register	EALLOW	<a href="#">Go</a>
C4h	_MPSA2	CLA PSA2 Register	EALLOW	<a href="#">Go</a>
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		<a href="#">Go</a>
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-24 shows the codes that are used for access types in this section.

**Table 5-24. CLA\_ONLY\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 5.8.2.1 \_MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0000h]

\_MVECTBGRNDACTIVE is shown in [Figure 5-2](#) and described in [Table 5-25](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

**Figure 5-2. \_MVECTBGRNDACTIVE Register**

15	14	13	12	11	10	9	8

4	TASK5	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
3	TASK4	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
2	TASK3	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
1	TASK2	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
0	TASK1	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn

### 5.8.3 CLA\_SOFTINT\_REGS Registers

Table 5-31 lists the memory-mapped registers for the CLA\_SOFTINT\_REGS registers. All register offset addresses not listed in Table 5-31 should be considered as reserved locations and the register contents should not be modified.

**Table 5-31. CLA\_SOFTINT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		<a href="#">Go</a>
2h	SOFTINTFRC	CLA Software Interrupt Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-32 shows the codes that are used for access types in this section.

**Table 5-32. CLA\_SOFTINT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 5.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0000h]

SOFTINTEN is shown in [Figure 5-8](#) and described in [Table 5-33](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

**Figure 5-8. SOFTINTEN Register**

**Table 5-33. SOFTINTEN Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R/W	0h	Reserved
7	TASK8	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
6	TASK7	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
5	TASK6	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
4	TASK5	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
3	TASK4	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
2	TASK3	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
1	TASK2	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn

**Table 5-33. SOFTINTEN Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	TASK1	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn

### 5.8.3.2 SOFTINTFRC Register (Offset = 2h) [Reset = 0000h]

SOFTINTFRC is shown in [Figure 5-9](#) and described in [Table 5-34](#).

Return to the [Summary Table](#).

Writing a value of 1 in a bit will generate the corresponding task interrupt. This register is only accessible by the CLA (not the CPU).

42h	_MPSACTL	CLA PSA Control Register	EALLOW	<a href="#">Go</a>
44h	_MPSA1	CLA PSA1 Register	EALLOW	<a href="#">Go</a>
46h	_MPSA2	CLA PSA2 Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-36 shows the codes that are used for access types in this section.

**Table 5-36. CLA\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		

**Table 5-36. CLA\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 5.8.4.1 MVECT1 Register (Offset = 0h) [Reset = 0000h]

MVECT1 is shown in [Figure 5-10](#) and described in [Table 5-37](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-10. MVECT1 Register**

15-0	MVECT	R/W	0h	<p>MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

### 5.8.4.2 MVECT2 Register (Offset = 1h) [Reset = 0000h]

MVECT2 is shown in [Figure 5-11](#) and described in [Table 5-38](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-11. MVECT2 Register**

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

### 5.8.4.3 MVECT3 Register (Offset = 2h) [Reset = 0000h]

MVECT3 is shown in [Figure 5-12](#) and described in [Table 5-39](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-12. MVECT3 Register**

The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

#### 5.8.4.4 MVECT4 Register (Offset = 3h) [Reset = 0000h]

MVECT4 is shown in [Figure 5-13](#) and described in [Table 5-40](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-13. MVECT4 Register**

The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

#### 5.8.4.5 MVECT5 Register (Offset = 4h) [Reset = 0000h]

MVECT5 is shown in [Figure 5-14](#) and described in [Table 5-41](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-14. MVECT5 Register**

The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

#### 5.8.4.6 MVECT6 Register (Offset = 5h) [Reset = 0000h]

MVECT6 is shown in [Figure 5-15](#) and described in [Table 5-42](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-15. MVECT6 Register**

Bit	Field	Type	Reset	Description
15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

### 5.8.4.7 MVECT7 Register (Offset = 6h) [Reset = 0000h]

MVECT7 is shown in [Figure 5-16](#) and described in [Table 5-43](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-16. MVECT7 Register**

The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

#### 5.8.4.8 MVECT8 Register (Offset = 7h) [Reset = 0000h]

MVECT8 is shown in [Figure 5-17](#) and described in [Table 5-44](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 5-17. MVECT8 Register**

15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

### 5.8.4.9 MCTL Register (Offset = 10h) [Reset = 0000h]

MCTL is shown in [Figure 5-18](#) and described in [Table 5-45](#).

Return to the [Summary Table](#).

Control Register

**Figure 5-18. MCTL Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R-0/W1S-0h	R-0/W1S-0h

**Table 5-45. MCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	<p>IACK Operation Enable Bit: Writing a '1' to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of '1' will set respective MIFR bit). At reset, this feature is disabled.</p> <p>This feature enables the C28 CPU to efficiently trigger a task.</p> <p>Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The CLA ignores the IACK instruction. (default)</p> <p>1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software.</p> <p>Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1</p> <p>IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2</p>
1	SOFTRESET	R-0/W1S	0h	<p>Soft Reset Bit: Writing a '1' to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of '0' are ignored and reads always return a '0'.</p> <p>Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.</p>
0	HARDRESET	R-0/W1S	0h	<p>Hard Reset Bit: Writing a '1' to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of '0' are ignored and reads always return a '0'.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.</p>

#### 5.8.4.10 \_MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0000h]

\_MVECTBGRNDACTIVE is shown in [Figure 5-19](#) and described in [Table 5-46](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

**Figure 5-19. \_MVECTBGRNDACTIVE Register**

15	14	13	12	11	10	9	8
i16

R-0h							

**Table 5-46. \_MVECTBGRNDACTIVE Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	i16	R	0h	Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0. Reset type: SYSRSn

### 5.8.4.11 SOFTINTEN Register (Offset = 1Ch) [Reset = 0000h]

SOFTINTEN is shown in [Figure 5-20](#) and described in [Table 5-47](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA. Only reads are allowed from CPU. Writes are not allowed from CPU.

**Figure 5-20. SOFTINTEN Register**

### 5.8.4.15 MIFR Register (Offset = 20h) [Reset = 0000h]

MIFR is shown in [Figure 5-24](#) and described in [Table 5-51](#).

Return to the [Summary Table](#).

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.

The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

### 5.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0000h]

MIOVF is shown in [Figure 5-25](#) and described in [Table 5-52](#).

Return to the [Summary Table](#).

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

### 5.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0000h]

MIFRC is shown in [Figure 5-26](#) and described in [Table 5-53](#).

Return to the [Summary Table](#).

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

### 5.8.4.18 MICLR Register (Offset = 23h) [Reset = 0000h]

MICLR is shown in [Figure 5-27](#) and described in [Table 5-54](#).

Return to the [Summary Table](#).

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

### 5.8.4.19 MICLROVF Register (Offset = 24h) [Reset = 0000h]

MICLROVF is shown in [Figure 5-28](#) and described in [Table 5-55](#).

Return to the [Summary Table](#).

Overflow flag bits in the MIOVF register are latched until manually cleared using the MICLROVF register. Writing a 1 to a MICLROVF bit will clear the corresponding bit in the MIOVF register. Writes of 0 are ignored and reads always return 0.

#### 5.8.4.20 MIER Register (Offset = 25h) [Reset = 0000h]

MIER is shown in [Figure 5-29](#) and described in [Table 5-56](#).

Return to the [Summary Table](#).

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

### 5.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0000h]

MIRUN is shown in [Figure 5-30](#) and described in [Table 5-57](#).

Return to the [Summary Table](#).

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task completes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

### 5.8.4.25 \_MSTF Register (Offset = 2Eh) [Reset = 0000000h]

\_MSTF is shown in [Figure 5-34](#) and described in [Table 5-61](#).

Return to the [Summary Table](#).

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:

- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLSR32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

Chapter 6  
**Dual-Clock Comparator (DCC)**

---

This chapter describes the Dual-Clock Comparator (DCC) module.

<b>6.1 Introduction</b> .....	<b>896</b>
<b>6.2 Module Operation</b> .....	<b>897</b>
<b>6.3 Interrupts</b> .....	<b>899</b>
<b>6.4 Software</b> .....	<b>900</b>
<b>6.5 DCC Registers</b> .....	<b>902</b>

## 6.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

### 6.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

### 6.1.2 Block Diagram

Figure 6-1 shows how the DCC connects to the rest of the system. Figure 6-2 shows the main concept of the DCC module.

**Figure 6-1. DCC Module Overview**

Figure 6-2. DCC Operation

## 6.2 Module Operation

As shown in Figure 6-2, DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with the user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

### 6.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 ( $F_{clk1} \times \text{Counter0} = F_{clk0} \times \text{Counter1}$ ). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
  - If  $F_{clk1} > F_{clk0}$ , then Async. Error (in Clock0 cycles) =  $2 + 2 \times (F_{sysclk} / F_{clk0})$
  - If  $F_{clk1} < F_{clk0}$ , then Async. Error (in Clock0 cycles) =  $2 \times (F_{clk0} / F_{clk1}) + 2 \times (F_{sysclk} / F_{clk0})$
  - If  $F_{clk1}$  is unknown, then Async. Error (in Clock0 cycles) =  $2 + 2 \times (F_{sysclk} / F_{clk0})$
- Digitization Error = 8 Clock0 cycles

#### DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

#### Window (in Clock0 Cycles) = (DCC Error) / (0.01 × Tolerance)

For example, if DCC Error is 10 and the tolerance desired is +/-0.1%, then:

$$\text{Window (in Clock0 Cycles)} = 10 / (0.01 \times 0.1) = 10000$$

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example, +/-1%) can be accounted for and factored into the counter configuration. The formula is:

$$\text{Frequency Error Allowed (in Clock0 Cycles)} = \text{Window} \times (\text{Allowable Frequency Tolerance (in \%)} / 100)$$

$$\text{Total Error (in Clock0 Cycles)} = \text{DCC Error} + \text{Frequency Error Allowed}$$

The following equations are used to configure counter values:

$$\text{Counter0 (DCCNTSEED0)} = \text{Window} - \text{Total Error}$$

$$\text{Valid0 (DCCVALIDSEED0)} = 2 \times \text{Total Error}$$

$$\text{Counter1 (DCCNTSEED1)} = \text{Window} \times (F_{clk1} / F_{clk0})$$

#### Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

$$\text{Tolerance (\%)} = (100 \times \text{DCC Error} \times (F_{clk1} / F_{clk0})) / 1048575$$

## 6.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

### Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10MHz, PLL output frequency is 100MHz, SYSCLK is 100MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in [Section 6.2.1](#), calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the PIE. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the PIE whenever this DCC error is indicated. Refer to the PIE Channel Mapping table in the *System Control and Interrupts* chapter to determine the channel mapping of the DCC Interrupt.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

### Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

## 6.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided DCCGCTRL.DONENA=1.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided DCCGCTRL.ERRENA=1.

Interrupts generated by DONE or ERROR events are ORed and flagged as a DCC interrupt, which goes to INT7.16 in the PIE Channel Mapping table in the *System Control and Interrupts* chapter. The application interrupt service routine needs to check the status flag inside the DCCSTATUS register to determine whether the interrupt is due to ERROR or DONE.

## 6.4 Software

### 6.4.1 DCC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/dcc

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 6.4.1.1 DCC Single shot Clock verification

FILE: dcc\_ex1\_single\_shot\_verification.c

This program uses the XTAL clock as a reference clock to verify the frequency of the PLLRAW clock.

The Dual-Clock Comparator Module 0 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

#### *External Connections*

- None

#### *Watch Variables*

- *status/result* - Status of the PLLRAW clock verification

#### 6.4.1.2 DCC Single shot Clock measurement

FILE: dcc\_ex2\_single\_shot\_measurement.c

This program demonstrates Single Shot measurement of the INTOSC2 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 0 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of the clock1 needs to be measured an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

#### *External Connections*

- None

#### *Watch Variables*

- *result* - Status if the INTOSC2 clock measurement completed successfully.
- *meas\_freq1* - measured clock frequency, in this case for INTOSC2.

#### 6.4.1.3 DCC Continuous clock monitoring

FILE: dcc\_ex3\_continuous\_monitoring\_of\_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). The clock0 and clock1 seed are set to achieve a window of 300us. Seed is the value that gets loaded into the Counter. For the sake of demo a slight variance is given to clock1 seed value to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

#### *External Connections*

- None

#### Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

#### 6.4.1.4 DCC Continuous clock monitoring

FILE: dcc\_ex3\_continuous\_monitoring\_of\_clock\_syscfg.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 100Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

#### External Connections

- None

#### Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

#### 6.4.1.5 DCC Detection of clock failure

FILE: dcc\_ex4\_clock\_fail\_detect.c

This program demonstrates clock failure detection on continuous monitoring of the PLL Clock in the system using XTAL as the osc clock source. Once the oscillator clock fails, it would trigger a DCC error interrupt, causing the decrement/ reload of counters to stop. In this examples, the clock failure is simulated by turning off the XTAL oscillator. Once the ISR is serviced, the osc source is changed to INTOSC1 and the PLL is turned off.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

In the current example, the XTAL is expected to be a Resonator running in Crystal mode which is later switched off to simulate the clock failure. If an SE Crystal is used, you will need to physically disconnect the clock on the board. Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

#### External Connections

- None

#### Watch Variables

- *status/result* - Status of the clock failure detection

## 6.5 DCC Registers

This section describes the Dual Clock Comparator Registers.

### 6.5.1 DCC Base Address Table

**Table 6-1. DCC Base Address Table**

Device Registers	Register Name	Start Address	End Address
DCC0Regs	DCC_REGS	0x0005_E700	0x0005_E71C

### 6.5.2 DCC\_REGS Registers

Table 6-2 lists the memory-mapped registers for the DCC\_REGS registers. All register offset addresses not listed in Table 6-2 should be considered as reserved locations and the register contents should not be modified.

**Table 6-2. DCC\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	DCCGCTRL	Global Control Register		<a href="#">Go</a>
4h	DCCREV	DCC Revision Register		<a href="#">Go</a>
8h	DCCNTSEED0	Counter 0 Seed Value		<a href="#">Go</a>
Ch	DCCVALIDSEED0	Valid 0 Seed Value		<a href="#">Go</a>
10h	DCCNTSEED1	Counter 1 Seed Value		<a href="#">Go</a>
14h	DCCSTATUS	DCC Status		<a href="#">Go</a>
18h	DCCNT0	Counter 0 Value		<a href="#">Go</a>
1Ch	DCCVALID0	Valid Value 0		<a href="#">Go</a>
20h	DCCNT1	Counter 1 Value		<a href="#">Go</a>
24h	DCCCLKSRC1	Clock Source 1		<a href="#">Go</a>
28h	DCCCLKSRC0	Clock Source 0		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 6-3 shows the codes that are used for access types in this section.

**Table 6-3. DCC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 6.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 00005555h]

DCCGCTRL is shown in [Figure 6-3](#) and described in [Table 6-4](#).

Return to the [Summary Table](#).

Starts / stops the counters. Clears the error signal.

**Figure 6-3. DCCGCTRL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15-11	RESERVED	R	2h	Reserved
10-8	MAJOR	R	0h	Major Revision Number Represents major changes to the module (e.g. entirely new features are added/changed). The major revision number for this module. Reset type: SYSRSn
7-6	RESERVED	R	0h	Reserved
5-0	MINOR	R	3h	Minor Revision Number Represents minor changes to the module (e.g. enhancements to existing features). The minor revision number for this module. Reset type: SYSRSn

### 6.5.2.3 DCCNTSEED0 Register (Offset = 8h) [Reset = 0000000h]

DCCNTSEED0 is shown in [Figure 6-5](#) and described in [Table 6-6](#).

Return to the [Summary Table](#).

Seed value for the counter attached to Clock Source 0.

**Figure 6-5. DCCNTSEED0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**CLA Program ROM CRC (CLAPROMCRC)**

The CLA Program ROM CRC (CLAPROMCRC) is a feature that calculates a CRC-32 value of a configurable block of data in the Control Law Accelerator (CLA) program ROM space.

<b>7.1 Overview</b> .....	<b>917</b>
<b>7.2 Functional Description</b> .....	<b>917</b>
<b>7.3 Software</b> .....	<b>919</b>
<b>7.4 CLAPROM Registers</b> .....	<b>919</b>

## 7.1 Overview

The CLAPROMCRC is a feature which calculates a CRC-32 on a configurable block of memory in the CLA program ROM space. Neither the C28x nor the CLA have the capability to compute a CRC on the CLA program ROM. The CLAPROMCRC solves this problem by calculating a CRC-32 in a non-intrusive manner. It is a hardware CRC-32 module which fetches the CLA program ROM during idle cycles (when the CLA is not accessing the ROM on the CLA program bus), and calculates the CRC-32 in order to perform a code integrity check. It then compares the result with a golden CRC-32 value and indicates a pass or fail condition.

## 7.2 Functional Description

The CLAPROMCRC module can be configured and initiated by either the C28x or the CLA. Once the CLAPROMCRC is initiated, the processing core can switch back to the application and service the CLAPROMCRC by way of an interrupt. An interrupt can trigger the C28x and CLA and signal that the CRC-32 calculation and comparison has completed (CRCDONE). The CLAPROMCRC module waits for CLA program bus idle cycles to access the CLA program ROM. This makes sure that the CRC-32 hardware calculation does not affect code execution and performance on the CLA.

Figure 7-1 is a functional diagram of the CLAPROMCRC module.

Figure 7-1. CLAPROMCRC Functional Diagram

Once the CLAPROMCRC is initiated by the C28x or CLA, the module snoops for idle cycles to fetch program memory and calculate the CRC-32. The module begins fetching from the `START_ADDRESS` and stops after the CRC-32 has been calculated for the required number of bytes specified by `BLOCK_SIZE`. The CRC-32 can be calculated on as little as 1KB of data up to the size of the CLA program ROM in increments of 1KB.

The CLAPROMCRC module fetches 32 bits of program data on every fetch and takes 4 cycles to calculate the CRC-32 value for each fetch. For example, to calculate a CRC-32 on 1KB of program data, the module requires 256 idle cycles if each fetch access is spaced 4 cycles apart. Therefore, to calculate the CRC-32 on a 1KB block of program data requires a minimum of 1024 cycles. The CRC polynomial used in the hardware calculation is 0x04C11DB7.

### 7.2.1 Start Address

The start address must be aligned to a 1KB boundary (512 word boundary). If a non-aligned address is programmed, then the 9 least significant bits are ignored to align the address. The start address written to the `CRC32_STARTADDRESS` register must be the memory address corresponding to the CLA memory map.

#### Note

If the start address is not within the CLA program ROM space of the CLA memory map, then the calculation will not be initiated.

### 7.2.2 Seed

The seed is the initial value used for the CRC-32 calculation. Therefore, the result will vary with the initial seed. The seed can be written into the `CRC32_SEED` register.

### 7.2.3 Halt

Once the CRC calculation is triggered, it can be halted by setting the HALT bit in the configuration register (CRC32\_CONTROLREG). When this bit is cleared, the CRC calculation will resume from the current address.

### 7.2.4 Result and Comparison

To protect the contents of the CLA program ROM, which includes TI proprietary code, the result of the CRC-32 must be protected. To protect the result, the actual CRC-32 value as it is calculated cycle by cycle is not made visible. However, the final result of the block is populated in the CRC32\_CRCRESULT register. This is the reason for the block size requirements which must specifically be a minimum of 1KB and an increment of 1KB.

To check the correctness of the CRC-32 result, a golden CRC value should be written in the CRC32\_GOLDENCRC register. After the CRC-32 calculation is completed by the module for the configured block size, the golden CRC will be compared with the final result and the module will then set a pass or fail bit accordingly in the status register (CRC32\_STATUSREG).

## 7.3 Software

### 7.3.1 CLAPROMCRC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/clapromcrc

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 7.3.1.1 CLAPROMCRC CPU Interrupt Example

FILE: clapromcrc\_ex1\_cpuinterrupt.c

This example demonstrates how to configure and run the CLAPROMCRC from the CPU. This uses the golden CRC values in 'clapromcrc\_ex1\_crctable.h' The CRC calculation uses the 32-bit polynomial 0x04C11DB7.

#### External Connections

- None.

#### Watch Variables

- None.

## 7.4 CLAPROM Registers

### 7.4.1 CLA PROM CRC Base Address Table

**Table 7-1. CLA PROM CRC Base Address Table**

Device Registers	Register Name	Start Address	End Address
ClaPromCrc32Regs	CLA_PROM_CRC32_REGS	0x000061C0	0x000061DF

## 7.4.2 CLA\_PROM\_CRC32\_REGS Registers

Table 7-2 lists the memory-mapped registers for the CLA\_PROM\_CRC32\_REGS registers. All register offset addresses not listed in Table 7-2 should be considered as reserved locations and the register contents should not be modified.

**Table 7-2. CLA\_PROM\_CRC32\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CRC32_CONTROLREG	CRC32-Control Register	EALLOW	<a href="#">Go</a>
2h	CRC32_STARTADDRESS	CRC32-Start address register	EALLOW	<a href="#">Go</a>
4h	CRC32_SEED	CRC32-Seed Register	EALLOW	<a href="#">Go</a>
6h	CRC32_STATUSREG	CRC32-Status Register		<a href="#">Go</a>
8h	CRC32_CRCRESULT	CRC32-CRC result Register		<a href="#">Go</a>
Ah	CRC32_GOLDENCRC	CRC32-Golden CRC register		<a href="#">Go</a>
18h	CRC32_INTEN	CRC32-Interrupt enable register	EALLOW	<a href="#">Go</a>
1Ah	CRC32_FLG	CRC32-Interrupt Flag Register		<a href="#">Go</a>
1Ch	CRC32_CLR	CRC32-Interrupt Clear Register		<a href="#">Go</a>
1Eh	CRC32_FRC	CRC32-Interrupt Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 7-3 shows the codes that are used for access types in this section.

**Table 7-3. CLA\_PROM\_CRC32\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 7.4.2.1 CRC32\_CONTROLREG Register (Offset = 0h) [Reset = 0000000h]

CRC32\_CONTROLREG is shown in [Figure 7-2](#) and described in [Table 7-4](#).

Return to the [Summary Table](#).

CRC32-Control Register

**General-Purpose Input/Output (GPIO)**

The GPIO module controls the device's digital and analog I/O multiplexing, which uses shared pins to maximize application flexibility. The pins are named by the general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. The input signals can be qualified to remove unwanted noise.

## 8.1 Introduction

Up to twelve independent peripheral signals are multiplexed on a single GPIO-enabled pin in addition to the CPU-controlled I/O capability. Each pin output can be controlled by either a peripheral or one of the two CPU masters.

- CPU1
- CPU1.CLA

There are up to 8 possible I/O ports:

- Port A consists of GPIO0-GPIO31
- Port B consists of GPIO32-GPIO63
- Port C consists of GPIO64-GPIO95
- Port D consists of GPIO96-GPIO127
- Port E consists of GPIO128-GPIO159
- Port F consists of GPIO160-GPIO191
- Port G consists of GPIO192-GPIO223
- Port H consists of GPIO224-GPIO255

---

### Note

Some GPIO and I/O ports can be unavailable on particular devices. See the *GPIO Registers* section for available GPIO and I/O ports.

---

The analog signals on this device are multiplexed with digital inputs. These analog IO (AIO) pins do not have digital output capability. The analog IO (AIO) pins are assigned to a single port:

- Port H consists of GPIO224-GPIO247

Figure 8-1 shows the GPIO logic for a single pin.

There are two key features to note in Figure 8-1. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, for both CPUs and CLAs to read the physical state of the pin independent of CPU mastering and peripheral muxing is possible. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all masters and peripherals. However, the peripheral muxing, CPU muxing, and pin options can only be configured by CPU1.

---

### Note

JTAG uses a different signal path that does not support inversion or qualification.

GPIO22 and GPIO23 are in a special analog mode at reset, and must be reconfigured for GPIO use by disabling DC-DC and clearing the bits in GPAAMSEL. GPIO23 maximum toggle frequency is limited. This is estimated to be 12MHz.

GPIO18/X2 has different timings due to the load placed on GPIO18/X2 by the oscillator circuit. For information on using GPIO18/X2 as a GPIO, see the data sheet and the *Clocking* section of this document.

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

---

## 8.2 Configuration Overview

I/O pin configuration consists of several steps:

1. **Plan the device pin-out:** Make a list of all required peripherals for the application. Using the peripheral mux information in the device data sheet, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU and CLA.

Once the peripheral muxing has been chosen, implement the mux by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals.

2. **(Optional) Enable internal pullup resistors:** To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. Pullups can be used to keep input pins in a known state when there is no external signal driving them.
3. **Select input qualification:** If the pin is used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK. For an explanation of input qualification, see [Section 8.5](#).
4. **Select the direction of any general-purpose I/O pins:** For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.
5. **Select low-power mode wake-up sources:** GPIOs 0-63 can be used to wake the system up from low power modes. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. For more information on low-power modes and GPIO wake-up, see the Low-Power Modes section in the *System Control and Interrupts* chapter.
6. **Select external interrupt sources:** Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and the polarity must be configured using the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *Crossbar (X-BAR)* chapter.

## 8.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

---

### Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

---

## 8.4 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using the following registers.

- **GPyDAT Registers**

Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general-purpose output (GPIO output), the pin is also driven either low or high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin.

When using the GPyDAT register to change the level of an output pin, be cautious to not accidentally change the level of another pin. For example, to change the output latch level of GPIOA1 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This can pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) reads the old value and writes the value back.

```

GpioDataRegs.GPADAT.bit.GPIO1 = 1; //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1; //I2 also a read-modify-write of GPADAT
                                     //GPADAT gets the old value of GPIO1 due to the delay

```

The second instruction waits for the first to finish the write due to the write-followed-by-read protection on this peripheral frame. There is some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction reads the old value of GPIO1 (0) and writes the value back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

One answer is to put some NOPs between instructions. A better answer is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bits that are currently in the process of changing.

- **GPySET Registers**

The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register sets the output latch high and the corresponding pin is driven high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPyCLEAR Registers**

The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general-purpose output, then writing a 1 to the corresponding bit in the clear register clears the output latch and the pin is driven low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPYTOGGLE Registers**

The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register pulls the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register pulls the pin low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

## 8.5 Input Qualification

The input qualification scheme has been designed to be very flexible. Select the type of input qualification for each GPIO pin by configuring the GPyQSEL1 and GPyQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronized to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

### 8.5.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I<sup>2</sup>C. In addition, the ePWM trip zone ( $\overline{TZn}$ ) signals can function independent of the presence of SYSCLKOUT.

---

#### Note

Using input synchronization when the peripheral performs the synchronization can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

---

### 8.5.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, a SYSCLKOUT period of delay is needed for the input to the device to be changed. No further qualification is performed on the signal.

### 8.5.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. Figure 8-2 and Figure 8-3 show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

Figure 8-2. Input Qualification Using a Sampling Window

#### Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal is sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register. The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPxCTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPxCTRL[QUALPRD1]. Table 8-1 and Table 8-2 show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 8-1. Sampling Period

Sampling Period	
If GPxCTRL[QUALPRDn] = 0	$1 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] ≠ 0	$2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

Table 8-2. Sampling Frequency

Sampling Frequency	
If GPxCTRL[QUALPRDn] = 0	$f_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] ≠ 0	$f_{\text{SYSCLKOUT}} \times 1 + (2 \times \text{GPxCTRL[QUALPRDn]})$
Where $f_{\text{SYSCLKOUT}}$ is the frequency of SYSCLKOUT	

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

**Example: Maximum Sampling Frequency:**

If GPxCTRL[QUALPRDn] = 0

then the sampling frequency is  $f_{\text{SYSCLKOUT}}$

If, for example,  $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at 60MHz or one sample every 16.67ns.

**Example: Minimum Sampling Frequency:**

If GPxCTRL[QUALPRDn] = 0xFF (255)

then the sampling frequency is  $f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$

If, for example,  $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at  $60\text{MHz} \times 1 \div (2 \times 255)$  (117.647kHz) or one sample every 8.5 $\mu\text{s}$ .

**Number of samples:**

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPAQSEL1, GPAQSEL2, GPBQSEL1, and GPBQSEL2) registers. When three or six consecutive cycles are the same, then the input change is passed through to the device.

**Total Sampling-Window Width:**

The sampling window is the time during which the input signal is sampled as shown in [Figure 8-3](#). By using the equation for the sampling period, along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling-window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling-window width is two sampling-periods wide where the sampling period is defined in [Table 8-1](#). Likewise, for a six-sample window, the sampling-window width is five sampling-periods wide. [Table 8-3](#) and [Table 8-4](#) show the calculations used to determine the total sampling-window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

**Table 8-3. Case 1: Three-Sample Sampling-Window Width**

Total Sampling-Window Width	
If GPxCTRL[QUALPRDn] = 0	$2 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$2 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

**Table 8-4. Case 2: Six-Sample Sampling-Window Width**

Total Sampling-Window Width	
If GPxCTRL[QUALPRDn] = 0	$5 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$5 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

**Note**

The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input must be held stable for a time greater than the sampling-window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period + T<sub>SYSCLKOUT</sub>.

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the data sheet.

**Example Qualification Window:**

For the example shown in Figure 8-3, the input qualification has been configured as follows:

- GPxQSEL1/2 = 1,0. This indicates a six-sample qualification.
- GPxCTRL[QUALPRDn] = 1. The sampling period is  $t_w(SP) = 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 2 \times T_{SYSCLKOUT}$ .

This configuration results in the following:

- The width of the sampling window is:

$$t_w(IQSW) = 5 \times t_w(SP) = 5 \times 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 5 \times 2 \times T_{SYSCLKOUT}$$

- If, for example, T<sub>SYSCLKOUT</sub> = 16.67ns, then the duration of the sampling window is:

$$\text{Sampling period, } t_w(SP) = 2 \times T_{SYSCLKOUT} = 2 \times 16.67\text{ns} = 33.3\text{ns}$$

$$\text{Sampling window, } t_w(IQSW) = 5 \times t_w(SP) = 5 \times 33.3\text{ns} = 166.7\text{ns}$$

- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to a single additional sampling period and SYSCLK period is required to detect a change in the input signal. For this example:

$$t_w(IQSW) + t_w(SP) + T_{SYSCLKOUT} = 166.7\text{ns} + 33.3\text{ns} + 16.67\text{ns} = 216.7\text{ns}$$

- In Figure 8-3, the glitch (A) is shorter than the qualification window and is ignored by the input qualifier.

A. This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value "n", the qualification sampling period in 2n SYSCLKOUT cycles (i.e., at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).  
 B. The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.  
 C. The qualification block can take either three or six samples. The QUAL\_SEL Register selects which sample mode is used.  
 D. In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles or greater. In other words, the inputs should be stable for (5 x QUALPRD x 2) SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, an 13-SYSCLKOUT-wide pulse ensures reliable recognition.

**Figure 8-3. Input Qualifier Clock Cycles**

## 8.6 GPIO and Peripheral Muxing

### 8.6.1 GPIO Muxing

Up to twelve different peripheral functions are multiplexed to each pin along with a general-purpose input/output (GPIO) function. This allows you to choose the peripheral mix and pinout that works best for your particular application. Refer to [Table 8-5](#) for muxing combinations and definitions.

**Table 8-5. GPIO Muxed Pins**

0, 4, 8, 12	1	2	3	5	6	7	9	10	11	13	14	15

### 8.6.2 Peripheral Muxing

For example, multiplexing for the GPIO6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO6 is configured as either a general-purpose digital I/O or one of several different peripheral functions. An example of GPyGMUX and GPyMUX selection and options for a single GPIO are shown in [Table 8-6](#).

#### Note

The following table is for example only. Refer to the device data sheet to check the availability of GPIO6 on this device. If GPIO6 is available, the functions mentioned in the table may not match the actual functions available. See [Section 8.6.1](#) for correct list of GPIOs and corresponding mux options for this device.

**Table 8-6. GPIO and Peripheral Muxing**

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin Functionality
00	00	GPIO6
00	01	Peripheral 1
00	10	Peripheral 2
00	11	Peripheral 3
01	00	GPIO6
01	01	Peripheral 4
01	10	Peripheral 5
01	11	
10	00	GPIO6
10	01	
10	10	Peripheral 6
10	11	Peripheral 7
11	00	GPIO6
11	01	Peripheral 8
11	10	Peripheral 9
11	11	Peripheral 10

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and must not be used.

#### CAUTION

If a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode is selected, the state of the pin is undefined and the pin is driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see the data sheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin by way of the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs p, q, or r (where p, q, and r are example GPIO numbers), depending on individual system requirements. An example of this is shown in [Table 8-7](#).

#### Note

The following table is for example only. Bit ranges cannot correspond to OUTPUTXBAR1 on this device. See [Section 8.6.1](#) for correct list of GPIOs and corresponding mux options for this device.

If none or more than one of the GPIO pins is configured as peripheral input pins, then that GPIO is set to a hard-wired default value.

**Table 8-7. Peripheral Muxing (Multiple Pins Assigned)**

GMUX Configuration	MUX Configuration	
Choice 1: GPIOp	GPyGMUX1[5:4]=01	GPyMUX1[5:4]=01
or Choice 2: GPIOq	GPyGMUX2[17:16]=00	GPyMUX2[17:16]=01
or Choice 3: GPIOr	GPyGMUX1[7:6]=01	GPyMUX1[7:6]=01

## 8.7 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user must always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above  $V_{ih}$  or below  $V_{il}$
- Input mode with GPIO internal pullup enabled
- Output mode

On devices with lesser pin count packages, pull-ups on unbonded GPIOs are by default enabled to prevent floating inputs. The user must take care to avoid disabling these pullups in the application code.

On devices with larger pin count packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE/C2000Ware that users can call to enable the pullup on any unbonded GPIO for the package in use. This function, `GPIO_EnabledUnbondedIOPullups()`, resides in the `(Device)_Sysctrl.c` file and is called by default from `InitSysCtrl()`. The user must take care to avoid disabling these pullups in the application code.

## 8.8 Software

### 8.8.1 GPIO Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/gpio

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 8.8.1.1 Device GPIO Setup

FILE: gpio\_ex1\_setup.c

Configures the device GPIO into two different configurations This code is verbose to illustrate how the GPIO could be setup. In a real application, lines of code can be combined for improved code size and efficiency.

This example only sets-up the GPIO. Nothing is actually done with the pins after setup.

*In general:*

- All pullup resistors are enabled. For ePWMs this may not be desired.
- Input qual for communication ports (CAN, SPI, SCI, I2C) is asynchronous
- Input qual for Trip pins (TZ) is asynchronous
- Input qual for eCAP and eQEP signals is synch to SYSCLKOUT
- Input qual for some I/O's and \_\_interrupts may have a sampling window

#### 8.8.1.2 Device GPIO Toggle

FILE: gpio\_ex2\_toggle.c

Configures the device GPIO through the sysconfig file. The GPIO pin is toggled in the infinite loop. In order to migrate the project within syscfg to any device, click the switch button under the device view and select your corresponding device to migrate, saving the project will auto-migrate your project settings.

: This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example.

#### 8.8.1.3 Device GPIO Interrupt

FILE: gpio\_ex3\_interrupt.c

Configures the device GPIOs through the sysconfig file. One GPIO output pin, and one GPIO input pin is configured. The example then configures the GPIO input pin to be the source of an external interrupt which toggles the GPIO output pin.

#### 8.8.1.4 External Interrupt (XINT)

FILE: gpio\_ex4\_aio\_external\_interrupt.c

In this example AIO pins are configured as digital inputs. Two other GPIO signals (connected externally to AIO pins) are toggled in software to trigger external interrupt through AIO224 and AIO225 (AIO224 assigned to XINT1 and AIO225 assigned to XINT2). The user is required to externally connect these signals for the program to work properly. Each interrupt is fired in sequence: XINT1 first and then XINT2.

GPIO34 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope.

*ExternalConnections*

- Connect GPIO30 to AIO224. AIO224 will be assigned to XINT1
- Connect GPIO31 to AIO225. AIO225 will be assigned to XINT2
- GPIO34 can be monitored on an oscilloscope

*Watch Variables*

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

### 8.8.2 LED Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/led

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 8.8.2.1 LED Blinky Example with DCSM

FILE: led\_ex2\_blinky\_dcs.c

This example demonstrates how to blink a LED and program the DCSM OTP.

##### *External Connections*

- None.

##### *Watch Variables*

- None.

## 8.9 GPIO Registers

This section describes the General-Purpose Input/Output Registers.

### 8.9.1 GPIO Base Address Table

**Table 8-8. GPIO Base Address Table**

Device Registers	Register Name	Start Address	End Address
GpioCtrlRegs	GPIO_CTRL_REGS	0x0000_7C00	0x0000_7EFF
GpioDataRegs	GPIO_DATA_REGS	0x0000_7F00	0x0000_7FFF

## 8.9.2 GPIO\_CTRL\_REGS Registers

Table 8-9 lists the memory-mapped registers for the GPIO\_CTRL\_REGS registers. All register offset addresses not listed in Table 8-9 should be considered as reserved locations and the register contents should not be modified.

**Table 8-9. GPIO\_CTRL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GPACTRL	GPIO A Qualification Sampling Period (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
2h	GPAQSEL1	GPIO A Qualification Type (GPIO0 to GPIO15)	EALLOW	<a href="#">Go</a>
4h	GPAQSEL2	GPIO A Qualification Type (GPIO16 to GPIO31)	EALLOW	<a href="#">Go</a>
6h	GPAMUX1	GPIO A Peripheral Mux (GPIO0 to GPIO15)	EALLOW	<a href="#">Go</a>
8h	GPAMUX2	GPIO A Peripheral Mux (GPIO16 to GPIO31)	EALLOW	<a href="#">Go</a>
Ah	GPADIR	GPIO A Direction (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
Ch	GPAPUD	GPIO A Pull-Up Disable (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
10h	GPAINV	GPIO A Input Inversion (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
12h	GPAODR	GPIO A Open Drain Output Mode (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
14h	GPAAMSEL	GPIO A Analog Mode Select (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
20h	GPAGMUX1	GPIO A Peripheral Group Mux (GPIO0 to GPIO15)	EALLOW	<a href="#">Go</a>
22h	GPAGMUX2	GPIO A Peripheral Group Mux (GPIO16 to GPIO31)	EALLOW	<a href="#">Go</a>
28h	GPACSEL1	GPIO A Master Core Select (GPIO0 to GPIO7)	EALLOW	<a href="#">Go</a>
2Ah	GPACSEL2	GPIO A Master Core Select (GPIO8 to GPIO15)	EALLOW	<a href="#">Go</a>
2Ch	GPACSEL3	GPIO A Master Core Select (GPIO16 to GPIO23)	EALLOW	<a href="#">Go</a>
2Eh	GPACSEL4	GPIO A Master Core Select (GPIO24 to GPIO31)	EALLOW	<a href="#">Go</a>
3Ch	GPALOCK	GPIO A Lock Register (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
3Eh	GPACR	GPIO A Lock Commit Register (GPIO0 to GPIO31)	EALLOW	<a href="#">Go</a>
40h	GPBCTRL	GPIO B Qualification Sampling Period (GPIO32 to GPIO63)	EALLOW	<a href="#">Go</a>
42h	GPBQSEL1	GPIO B Qualification Type (GPIO32 to GPIO47)	EALLOW	<a href="#">Go</a>
44h	GPBQSEL2	GPIO B Qualification Type (GPIO48 to GPIO63)	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 8-10](#) shows the codes that are used for access types in this section.

**Table 8-10. GPIO\_CTRL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 8.9.2.1 GPECTRL Register (Offset = 0h) [Reset = 0000000h]

GPECTRL is shown in [Figure 8-4](#) and described in [Table 8-11](#).

Return to the [Summary Table](#).

GPIO A Qualification Sampling Period (GPIO0 to GPIO31)

Each field in this register selects the qualification sampling period in SYSCLK cycles for eight GPIOs. The period is equal to 2 times the register field value.

0x00: Period = 0 SYSCLK cycles

0x01: Period = 2 SYSCLK cycles

0x02: Period = 4 SYSCLK cycles

...

0xFF: Period = 510 SYSCLK cycles

15-8	QUALPRD1	R/W	0h	Qualification sampling period for GPIO8 to GPIO15 Reset type: SYSRSn
7-0	QUALPRD0	R/W	0h	Qualification sampling period for GPIO0 to GPIO7 Reset type: SYSRSn

### 8.9.2.2 GPAQSEL1 Register (Offset = 2h) [Reset = 0000000h]

GPAQSEL1 is shown in [Figure 8-5](#) and described in [Table 8-12](#).

Return to the [Summary Table](#).

GPIO A Qualification Type (GPIO0 to GPIO15)

Each field in this register selects the input qualification type for one IO pin. The available types are:

- 0: Synchronous
- 1: 3-sample qualification
- 2: 6-sample qualification
- 3: Asynchronous

**Figure 8-5. GPAQSEL1 Register**

### 8.9.2.4 GPAMUX1 Register (Offset = 6h) [Reset = 0000000h]

GPAMUX1 is shown in [Figure 8-7](#) and described in [Table 8-14](#).

Return to the [Summary Table](#).

GPIO A Peripheral Mux (GPIO0 to GPIO15)

Each field in this register determines part of the GPIO mux configuration for one IO pin. A value of 0x0, 0x4, 0x8, or 0xC configures the pin as a general-purpose IO. All other values select a peripheral to control the pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using this register before changing the corresponding field in the GPAGMUX1 register.

**Figure 8-7. GPAMUX1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3-2	GPIO1	R/W	0h	Lower 2 bits of peripheral mux configuration for GPIO1 Reset type: SYSRSn

**Table 8-14. GPAMUX1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	GPIO0	R/W	0h	Lower 2 bits of peripheral mux configuration for GPIO0 Reset type: SYSRSn

### 8.9.2.5 GPAMUX2 Register (Offset = 8h) [Reset = 0000000h]

GPAMUX2 is shown in [Figure 8-8](#) and described in [Table 8-15](#).

Return to the [Summary Table](#).

GPIO A Peripheral Mux (GPIO16 to GPIO31)

Each field in this register determines part of the GPIO mux configuration for one IO pin. A value of 0x0, 0x4, 0x8, or 0xC configures the pin as a general-purpose IO. All other values select a peripheral to control the pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using this register before changing the corresponding field in the GPAGMUX2 register.

**Figure 8-8. GPAMUX2 Register**

### 8.9.2.6 GPADIR Register (Offset = Ah) [Reset = 0000000h]

GPADIR is shown in [Figure 8-9](#) and described in [Table 8-16](#).

Return to the [Summary Table](#).

#### GPIO A Direction (GPIO0 to GPIO31)

Each field in this register selects the direction of one IO pin in GPIO mode. If the pin is not configured as a general-purpose IO, this register has no effect.

0: The pin is an input

1: The pin is an output

**Figure 8-9. GPADIR Register**

31	30	29	28	27	26	25	24

### 8.9.2.7 GPAPUD Register (Offset = Ch) [Reset = FFFFFFFFh]

GPAPUD is shown in [Figure 8-10](#) and described in [Table 8-17](#).

Return to the [Summary Table](#).

GPIO A Pull-Up Disable (GPIO0 to GPIO31)

Each field in this register selects the state of the internal pull-up resistor for a single IO pin.

0: Pull-up enabled

1: Pull-up disabled

**Figure 8-10. GPAPUD Register**

### 8.9.2.8 GPAINV Register (Offset = 10h) [Reset = 0000000h]

GPAINV is shown in [Figure 8-11](#) and described in [Table 8-18](#).

Return to the [Summary Table](#).

GPIO A Input Inversion (GPIO0 to GPIO31)

Each field in this register selects whether the input value of one IO pin passes through an inverter.

0: The input is not inverted

1: The input is inverted

**Figure 8-11. GPAINV Register**

### 8.9.2.9 GPAODR Register (Offset = 12h) [Reset = 0000000h]

GPAODR is shown in [Figure 8-12](#) and described in [Table 8-19](#).

Return to the [Summary Table](#).

#### GPIO A Open Drain Output Mode (GPIO0 to GPIO31)

Each field in this register selects between push-pull mode and open-drain mode for one general-purpose output pin. In both modes, writing a 0 to the output data latch drives the pin low. In push-pull mode, writing a 1 to the output data latch drives the pin high. In open-drain mode, it tri-states the output buffer.

0: Push-pull output

1: Open-drain output

### 8.9.2.13 GPACSEL1 Register (Offset = 28h) [Reset = 0000000h]

GPACSEL1 is shown in [Figure 8-16](#) and described in [Table 8-23](#).

Return to the [Summary Table](#).

GPIO A Master Core Select (GPIO0 to GPIO7)

Each field in this register selects the master for one IO pin. The master controls the pin in GPIO mode via its GPADAT, GPASET, GPACLEAR, and GPATOGGLE registers. GPADAT (read) always goes to both CPUs.

0x0: CPU is the master

0x1: CLA is the master

0x2 - 0xF: Reserved

**Figure 8-16. GPACSEL1 Register**

### 8.9.2.14 GPACSEL2 Register (Offset = 2Ah) [Reset = 0000000h]

GPACSEL2 is shown in [Figure 8-17](#) and described in [Table 8-24](#).

Return to the [Summary Table](#).

GPIO A Master Core Select (GPIO8 to GPIO15)

Each field in this register selects the master for one IO pin. The master controls the pin in GPIO mode via its GPADAT, GPASET, GPACLEAR, and GPATOGGLE registers. GPADAT (read) always goes to both CPUs.

0x0: CPU is the master

0x1: CLA is the master

0x2 - 0xF: Reserved

### 8.9.2.17 GPALOCK Register (Offset = 3Ch) [Reset = 0000000h]

GPALOCK is shown in [Figure 8-20](#) and described in [Table 8-27](#).

Return to the [Summary Table](#).

GPIO A Lock Register (GPIO0 to GPIO31)

Each field in this register locks one IO pin's configuration. This blocks writes to the corresponding bits in the GPAMUXn, GPAIDR, GPAINV, GPAODR, GPAGMUXn, and GPACSELn registers.

0: Pin configuration is unlocked

1: Pin configuration is locked

### 8.9.2.18 GPACR Register (Offset = 3Eh) [Reset = 0000000h]

GPACR is shown in [Figure 8-21](#) and described in [Table 8-28](#).

Return to the [Summary Table](#).

GPIO A Lock Commit Register (GPIO0 to GPIO31)

Each field in this register blocks writes to one IO pin's GPALOCK bit. Once set, a lock commit can only be cleared by a reset.

0: Pin configuration lock is unlocked

1: Pin configuration lock is locked

**Figure 8-21. GPACR Register**

### 8.9.2.19 GPBCTRL Register (Offset = 40h) [Reset = 0000000h]

GPBCTRL is shown in [Figure 8-22](#) and described in [Table 8-29](#).

Return to the [Summary Table](#).

GPIO B Qualification Sampling Period (GPIO32 to GPIO63)

Each field in this register selects the qualification sampling period in SYSCLK cycles for eight GPIOs. The period is equal to 2 times the register field value.

0x00: Period = 0 SYSCLK cycles

0x01: Period = 2 SYSCLK cycles

0x02: Period = 4 SYSCLK cycles

...

0xFF: Period = 510 SYSCLK cycles

**Figure 8-22. GPBCTRL Register**

### 8.9.2.21 GPBQSEL2 Register (Offset = 44h) [Reset = 0000000h]

GPBQSEL2 is shown in [Figure 8-24](#) and described in [Table 8-31](#).

Return to the [Summary Table](#).

GPIO B Qualification Type (GPIO48 to GPIO63)

Each field in this register determines the input qualification type for one IO pin. The available types are:

- 0: Synchronous
- 1: 3-sample qualification
- 2: 6-sample qualification
- 3: Asynchronous

**Figure 8-24. GPBQSEL2 Register**

### 8.9.2.22 GPBMUX1 Register (Offset = 46h) [Reset = 0000CC0h]

GPBMUX1 is shown in [Figure 8-25](#) and described in [Table 8-32](#).

Return to the [Summary Table](#).

GPIO B Peripheral Mux (GPIO32 to GPIO47)

Each field in this register determines part of the GPIO mux configuration for one IO pin. A value of 0x0, 0x4, 0x8, or 0xC configures the pin as a general-purpose IO. All other values select a peripheral to control the pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using this register before changing the corresponding field in the GPBGMUX1 register.

### 8.9.2.23 GPBMUX2 Register (Offset = 48h) [Reset = 0000000h]

GPBMUX2 is shown in [Figure 8-26](#) and described in [Table 8-33](#).

Return to the [Summary Table](#).

#### GPIO B Peripheral Mux (GPIO48 to GPIO63)

Each field in this register determines part of the GPIO mux configuration for one IO pin. A value of 0x0, 0x4, 0x8, or 0xC configures the pin as a general-purpose IO. All other values select a peripheral to control the pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using this register before changing the corresponding field in the GPBGMUX2 register.

### 8.9.2.24 GPBDIR Register (Offset = 4Ah) [Reset = 0000000h]

GPBDIR is shown in [Figure 8-27](#) and described in [Table 8-34](#).

Return to the [Summary Table](#).

GPIO B Direction (GPIO32 to GPIO63)

Each field in this register selects the direction of one IO pin in GPIO mode. If the pin is not configured as a general-purpose IO, this register has no effect.

0: The pin is an input

1: The pin is an output

### 8.9.2.27 GPBODR Register (Offset = 52h) [Reset = 0000000h]

GPBODR is shown in [Figure 8-30](#) and described in [Table 8-37](#).

Return to the [Summary Table](#).

#### GPIO B Open Drain Output Mode (GPIO32 to GPIO63)

Each field in this register selects between push-pull mode and open-drain mode for one general-purpose output pin. In both modes, writing a 0 to the output data latch drives the pin low. In push-pull mode, writing a 1 to the output data latch drives the pin high. In open-drain mode, it tri-states the output buffer.

0: Push-pull output

1: Open-drain output

### 8.9.2.28 GPBGMUX1 Register (Offset = 60h) [Reset = 0000CC0h]

GPBGMUX1 is shown in [Figure 8-31](#) and described in [Table 8-38](#).

Return to the [Summary Table](#).

GPIO B Peripheral Group Mux (GPIO32 to GPIO47)

Each field in this register determines part of the GPIO mux configuration for one IO pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using the GPBMUX1 register before changing their configuration in this register.

**Figure 8-31. GPBGMUX1 Register**

### 8.9.2.29 GPBGMUX2 Register (Offset = 62h) [Reset = 0000000h]

GPBGMUX2 is shown in [Figure 8-32](#) and described in [Table 8-39](#).

Return to the [Summary Table](#).

GPIO B Peripheral Group Mux (GPIO48 to GPIO63)

Each field in this register determines part of the GPIO mux configuration for a single IO pin. See the device datasheet for a table of peripheral mux options. Pins must be set to GPIO mode using the GPBMUX2 register before changing their configuration in this register.

**Figure 8-32. GPBGMUX2 Register**

### 8.9.2.30 GPBCSEL1 Register (Offset = 68h) [Reset = 0000000h]

GPBCSEL1 is shown in [Figure 8-33](#) and described in [Table 8-40](#).

Return to the [Summary Table](#).

GPIO B Master Core Select (GPIO32 to GPIO39)

Each field in this register selects the master for one IO pin. The master controls the pin in GPIO mode via its GPBDAT, GPBSET, GPBCLEAR, and GPBTOGGLE registers. GPBDAT (read) always goes to both CPUs.

0x0: CPU is the master

0x1: CLA is the master

0x2 - 0xF: Reserved

### 8.9.2.34 GPBLOCK Register (Offset = 7Ch) [Reset = 0000000h]

GPBLOCK is shown in [Figure 8-37](#) and described in [Table 8-44](#).

Return to the [Summary Table](#).

GPIO B Lock Register (GPIO32 to GPIO63)

Each field in this register locks one IO pin's configuration. This blocks writes to the corresponding bits in the GPBMUXn, GPBIDR, GPBINV, GPBODR, GPBGMUXn, and GPBCSELn registers.

0: Pin configuration is unlocked

1: Pin configuration is locked

### 8.9.2.36 GPHCTRL Register (Offset = 1C0h) [Reset = 0000000h]

GPHCTRL is shown in [Figure 8-39](#) and described in [Table 8-46](#).

Return to the [Summary Table](#).

GPIO H Qualification Sampling Period (GPIO224 to GPIO255)

Each field in this register selects the qualification sampling period in SYSCLK cycles for eight GPIOs. The period is equal to 2 times the register field value.

0x00: Period = 0 SYSCLK cycles

0x01: Period = 2 SYSCLK cycles

0x02: Period = 4 SYSCLK cycles

...

0xFF: Period = 510 SYSCLK cycles

7-0	QUALPRD0	R/W	0h	Qualification sampling period for GPIO224 to GPIO231 Reset type: SYSRSn

### 8.9.2.37 GPHQSEL1 Register (Offset = 1C2h) [Reset = 0000000h]

GPHQSEL1 is shown in [Figure 8-40](#) and described in [Table 8-47](#).

Return to the [Summary Table](#).

GPIO H Qualification Type (GPIO224 to GPIO239)

Each field in this register selects the input qualification type for one IO pin. The available types are:

- 0: Synchronous
- 1: 3-sample qualification
- 2: 6-sample qualification
- 3: Asynchronous

**Figure 8-40. GPHQSEL1 Register**

### 8.9.2.38 GPHQSEL2 Register (Offset = 1C4h) [Reset = 0000000h]

GPHQSEL2 is shown in [Figure 8-41](#) and described in [Table 8-48](#).

Return to the [Summary Table](#).

GPIO H Qualification Type (GPIO240 to GPIO255)

Each field in this register determines the input qualification type for one IO pin. The available types are:

- 0: Synchronous
- 1: 3-sample qualification
- 2: 6-sample qualification
- 3: Asynchronous

**Figure 8-41. GPHQSEL2 Register**

### 8.9.2.40 GPHINV Register (Offset = 1D0h) [Reset = 0000000h]

GPHINV is shown in [Figure 8-43](#) and described in [Table 8-50](#).

Return to the [Summary Table](#).

GPIO H Input Inversion (GPIO224 to GPIO255)

Each field in this register selects whether the input value of one IO pin passes through an inverter.

0: The input is not inverted

1: The input is inverted

### 8.9.2.43 GPHCR Register (Offset = 1FEh) [Reset = 0000000h]

GPHCR is shown in [Figure 8-46](#) and described in [Table 8-53](#).

Return to the [Summary Table](#).

GPIO H Lock Commit Register (GPIO224 to GPIO255)

Each field in this register blocks writes to one IO pin's GPHLOCK bit. Once set, a lock commit can only be cleared by a reset.

0: Pin configuration lock is unlocked

1: Pin configuration lock is locked

### 8.9.3 GPIO\_DATA\_REGS Registers

Table 8-54 lists the memory-mapped registers for the GPIO\_DATA\_REGS registers. All register offset addresses not listed in Table 8-54 should be considered as reserved locations and the register contents should not be modified.

**Table 8-54. GPIO\_DATA\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT	GPIO A Data Register (GPIO0 to GPIO31)		<a href="#">Go</a>
2h	GPASET	GPIO A Output Set (GPIO0 to GPIO31)		<a href="#">Go</a>
4h	GPACLEAR	GPIO A Output Clear (GPIO0 to GPIO31)		<a href="#">Go</a>
6h	GPATOGGLE	GPIO A Output Toggle (GPIO0 to GPIO31)		<a href="#">Go</a>
8h	GPBDAT	GPIO B Data Register (GPIO32 to GPIO64)		<a href="#">Go</a>
Ah	GPBSET	GPIO B Output Set (GPIO32 to GPIO64)		<a href="#">Go</a>
Ch	GPBCLEAR	GPIO B Output Clear (GPIO32 to GPIO64)		<a href="#">Go</a>
Eh	GPBTOGGLE	GPIO B Output Toggle (GPIO32 to GPIO64)		<a href="#">Go</a>
38h	GPHDAT	GPIO H Data Register (GPIO0 to GPIO255)		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 8-55 shows the codes that are used for access types in this section.

**Table 8-55. GPIO\_DATA\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 8.9.3.1 GPADAT Register (Offset = 0h) [Reset = 0000000h]

GPADAT is shown in [Figure 8-47](#) and described in [Table 8-56](#).

Return to the [Summary Table](#).

#### GPIO A Data (GPIO0 to GPIO31)

Reading a field in this register returns the input level of the corresponding IO pin after qualification and (optionally) inversion. The input value is always readable even when the pin is configured as a GPIO output or peripheral signal.

Writing to a field in this register selects the value of the output data latch for the corresponding IO pin. If the pin is configured as a GPIO output, this value will be driven onto the pin. Otherwise, the value will be latched and ignored unless the pin is reconfigured to be an output. A system reset will clear all output latches.

Due to the difference between the read and write values, sequential read-modify-write operations on this register may corrupt the state of the output latches. The GPASET, GPACLEAR, and GPATOGGLE registers should be used to safely control the output latches.

**Figure 8-47. GPADAT Register**

### 8.9.3.2 GPASET Register (Offset = 2h) [Reset = 0000000h]

GPASET is shown in [Figure 8-48](#) and described in [Table 8-57](#).

Return to the [Summary Table](#).

GPIO Output Set (GPIO0 to GPIO31)

Writing a 1 to a field in this register sets the output data latch for the corresponding IO pin. Writes of 0 are ignored. Reads of this register always return 0.

### 8.9.3.3 GPACLEAR Register (Offset = 4h) [Reset = 0000000h]

GPACLEAR is shown in [Figure 8-49](#) and described in [Table 8-58](#).

Return to the [Summary Table](#).

#### GPIO Output Clear (GPIO0 to GPIO31)

Writing a 1 to a field in this register clears the output data latch for the corresponding IO pin. Writes of 0 are ignored. Reads of this register always return 0.

**Figure 8-49. GPACLEAR Register**

### 8.9.3.5 GPBDAT Register (Offset = 8h) [Reset = 0000000h]

GPBDAT is shown in [Figure 8-51](#) and described in [Table 8-60](#).

Return to the [Summary Table](#).

#### GPIO B Data (GPIO32 to GPIO64)

Reading a field in this register returns the input level of the corresponding IO pin after qualification and (optionally) inversion. The input value is always readable even when the pin is configured as a GPIO output or peripheral signal.

Writing to a field in this register selects the value of the output data latch for the corresponding IO pin. If the pin is configured as a GPIO output, this value will be driven onto the pin. Otherwise, the value will be latched and ignored unless the pin is reconfigured to be an output. A system reset will clear all output latches.

Due to the difference between the read and write values, sequential read-modify-write operations on this register may corrupt the state of the output latches. The GPBSET, GPBCLEAR, and GPBTOGGLE registers should be used to safely control the output latches.

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of four X-BARs:

- Input X-BAR
- Output X-BAR
- CLB X-BAR
- ePWM X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR brings external signals “in” to the device. The Output X-BAR takes internal signals “out” of the device to a GPIO. The CLB X-BAR and ePWM X-BAR take signals to the CLB and ePWM modules, respectively.

<b>9.1 Input X-BAR</b> .....	<a href="#">1045</a>
<b>9.2 ePWM, CLB, and GPIO Output X-BAR</b> .....	<a href="#">1048</a>
<b>9.3 XBAR Registers</b> .....	<a href="#">1056</a>

## 9.1 Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in [Figure 9-1](#) and [Table 9-1](#). For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT\_XBAR\_REGS register definitions in the *XBAR Registers* section.

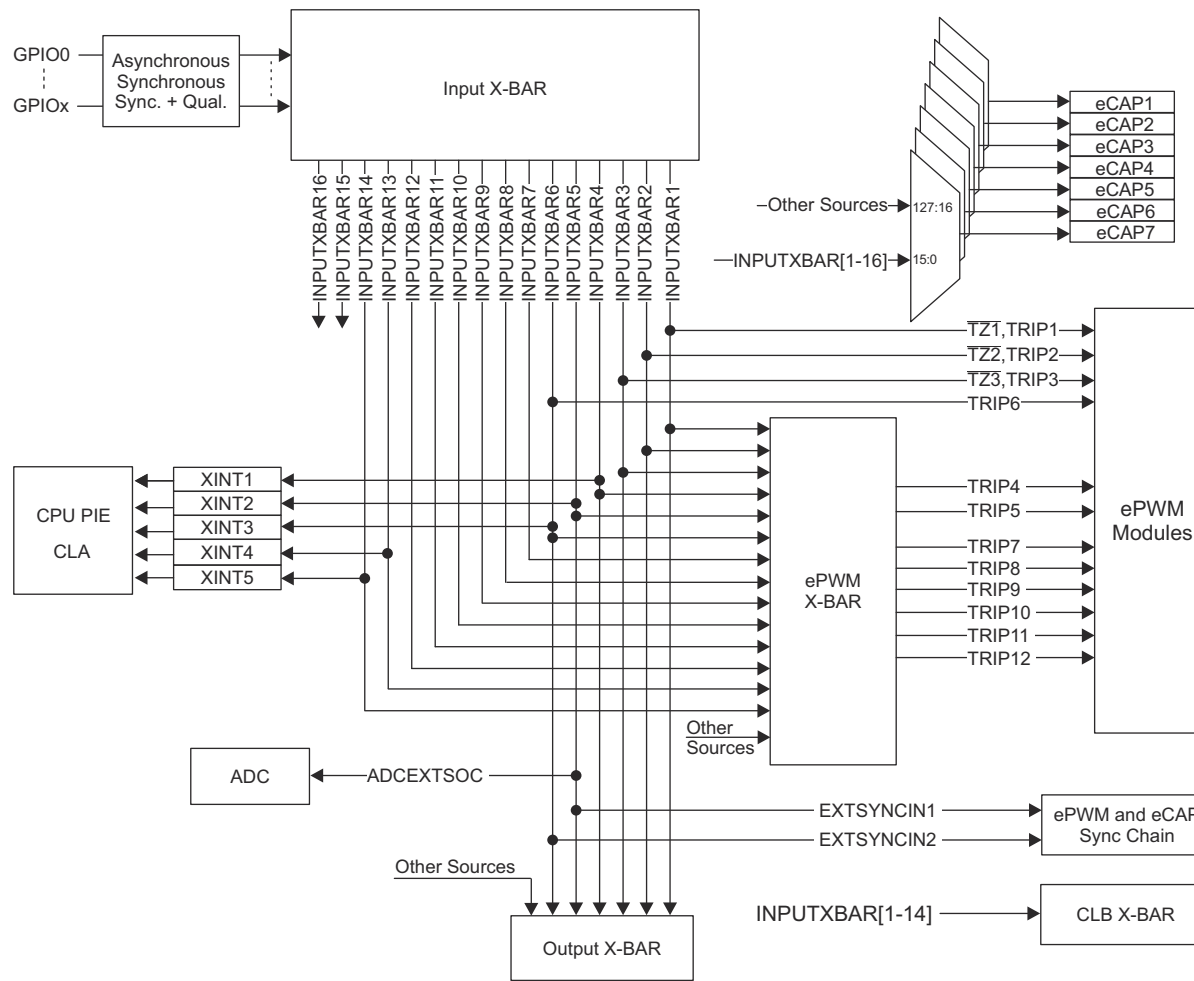

Figure 9-1. Input X-BAR

**Note**

INPUTXBARx, INPUTXBAR\_INPUTx, and INPUTx (when referenced in the context of Input X-BAR) are equivalent in all C2000 software and documentation.

**Table 9-1. Input X-BAR Destinations**

## 9.2 ePWM, CLB, and GPIO Output X-BAR

This section describes the ePWM, CLB, and GPIO Output X-BAR. .

### 9.2.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 9-2 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

#### 9.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. Figure 9-2 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 9-2. Select up to one signal per mux for each TRIPx output. Select the inputs to ePWM X-BAR using the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. To pass any signal through to the ePWM, enable the signal using the TRIPxMUXENABLE register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the TRIPOUTINV register.

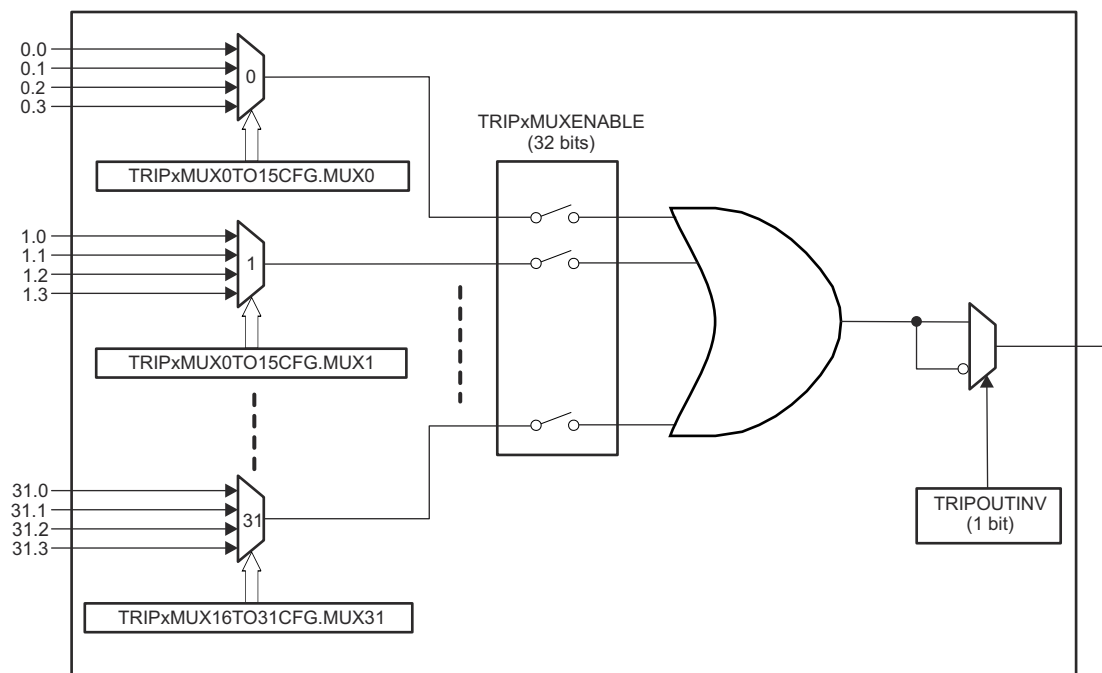

Figure 9-2. ePWM X-BAR Architecture - Single Output

**Note**

Do not use "Reserved" signals in your application.

**Table 9-2. EPWM X-BAR Mux Configuration Table**

## 9.2.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. [Figure 9-3](#) shows the architecture of the CLB X-BAR. Note that the architecture of the CLB X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

### 9.2.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. [Figure 9-3](#) represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing [Table 9-3](#). Select up to one signal per mux (31 total muxes) for each AUXSIGx output. Select the inputs to each mux using the AUXSIGxMUX0TO15CFG and AUXSIGxMUX16TO31CFG registers. To pass any signal through to the CLB, enable the mux in the AUXSIGxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective AUXSIGx signal on the CLB. To optionally invert the signal, use the AUXSIGOUTINV register.

### 9.2.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 9-5 shows the architecture of the GPIO Output X-BAR. The X-BAR contains eight outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single input or a logical-OR of many inputs.

#### 9.2.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has eight outputs that are routed to the GPIO module. Figure 9-5 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs. Note that the architecture of the Output X-BAR (with the exception of the output latch) is similar to the architecture of the ePWM X-BAR.

First, determine the signals that can be passed to the GPIO by referencing Table 9-4. Select up to one signal per mux (32 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux using the OUTPUTxMUX0TO15CFG and OUTPUTxMUX16TO31CFG registers. To pass any signal through to the GPIO, enable the mux in the OUTPUTxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective OUTPUTx signal on the GPIO module. To optionally invert the signal, use the OUTPUTINV register. The final output is only recognized on the GPIO if the proper OUTPUTx muxing options are selected using the GPIO registers.

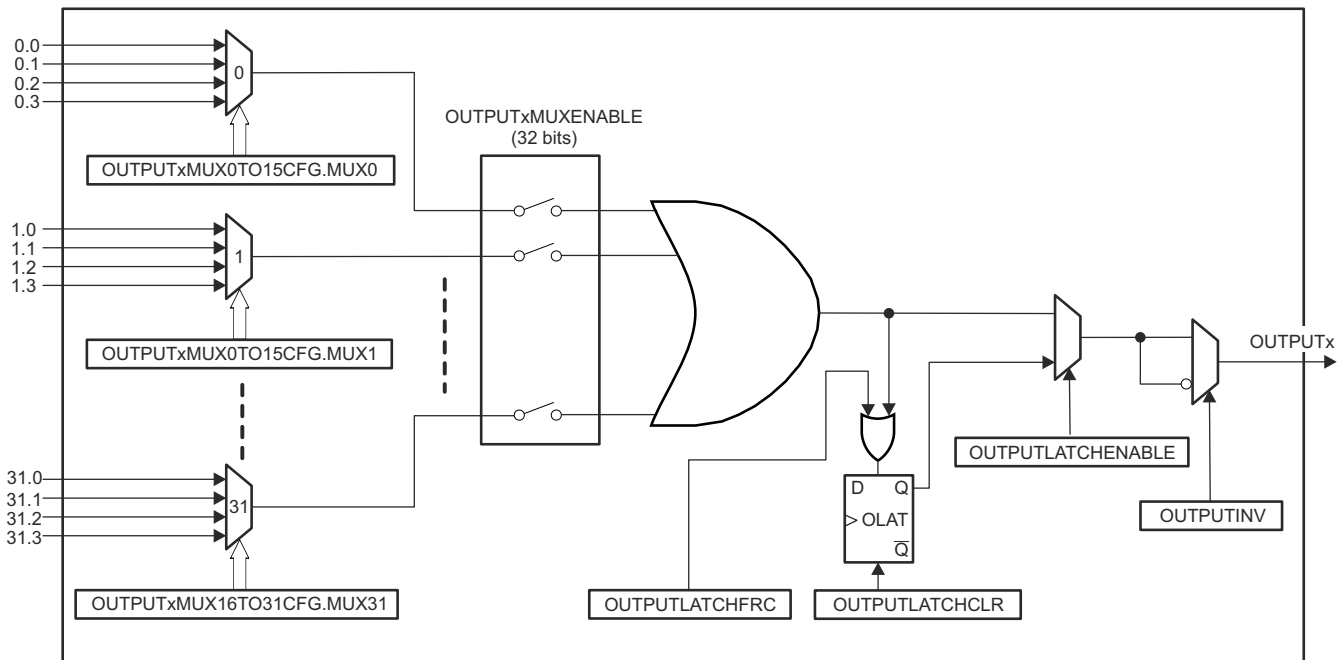

Figure 9-5. GPIO Output X-BAR Architecture

**Note**

Do not use "Reserved" signals in your application.

All unused and reserved positions are tied to 0.

**Table 9-4. Output X-BAR Mux Configuration Table**

### 9.2.4 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See Figure 9-6 for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLRx register.

**Note**

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

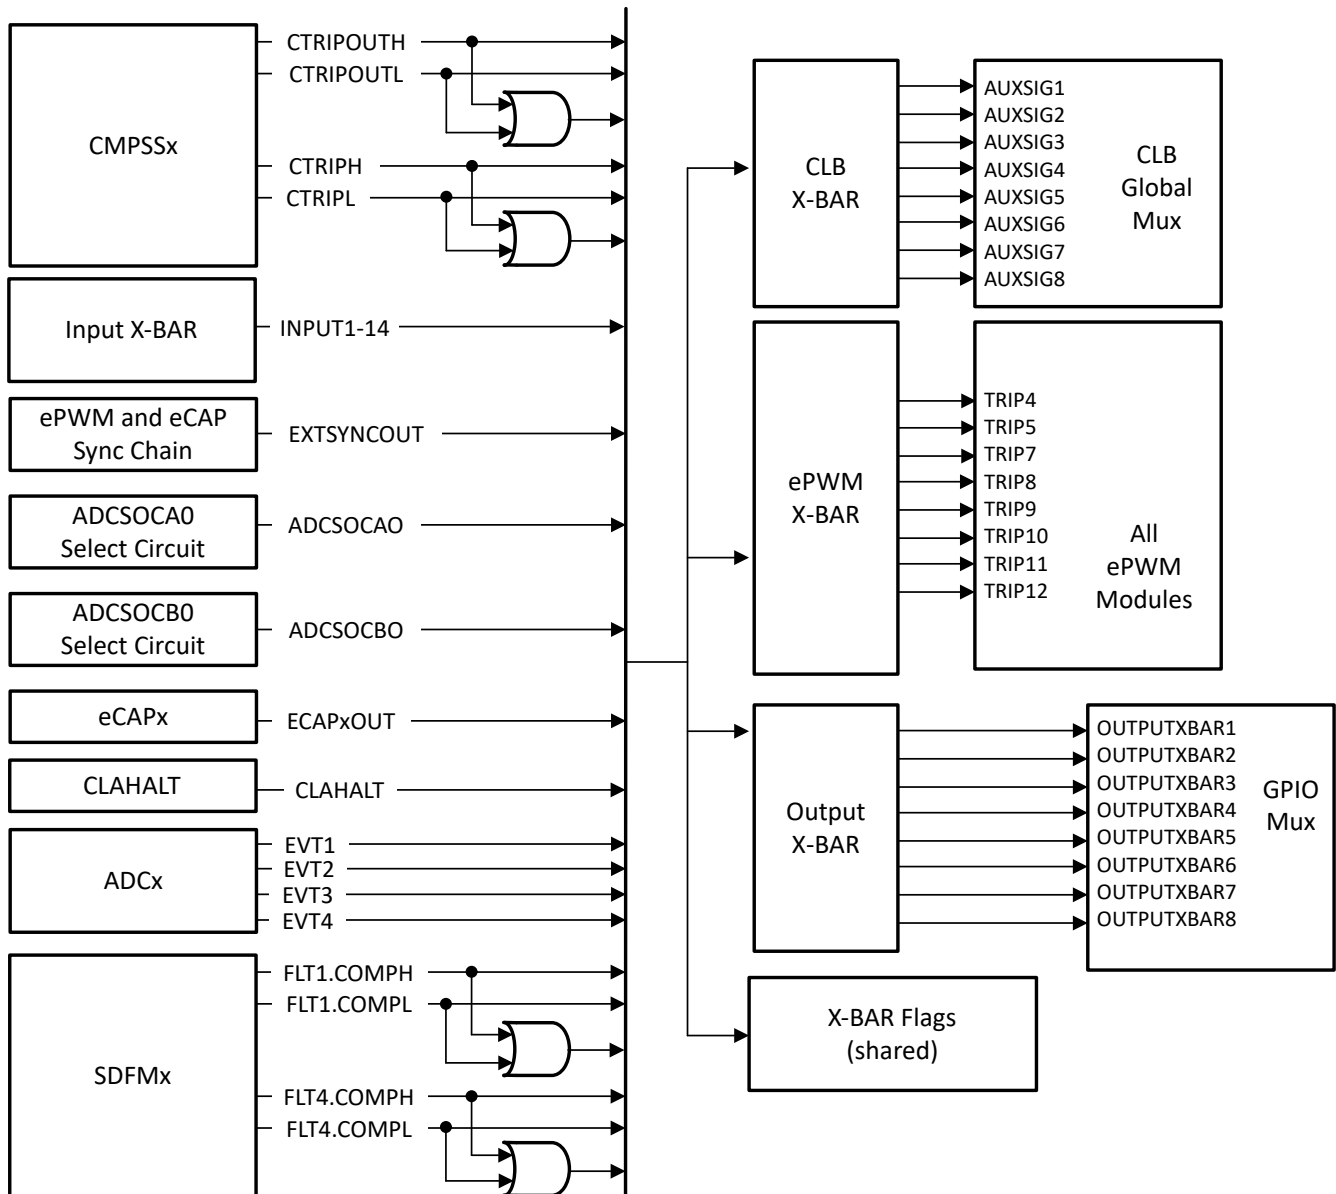

Figure 9-6. X-BAR Input Sources

## 9.3 XBAR Registers

This section describes the Crossbar registers.

### 9.3.1 XBAR Base Address Table

**Table 9-5. XBAR Base Address Table**

Device Registers	Register Name	Start Address	End Address
InputXbarRegs	INPUT_XBAR_REGS	0x0000_7900	0x0000_791F
XbarRegs	XBAR_REGS	0x0000_7920	0x0000_793F
EpwmXbarRegs	EPWM_XBAR_REGS	0x0000_7A00	0x0000_7A3F
ClbXbarRegs	CLB_XBAR_REGS	0x0000_7A40	0x0000_7A7F
OutputXbarRegs	OUTPUT_XBAR_REGS	0x0000_7A80	0x0000_7ABF

### 9.3.2 INPUT\_XBAR\_REGS Registers

Table 9-6 lists the memory-mapped registers for the INPUT\_XBAR\_REGS registers. All register offset addresses not listed in Table 9-6 should be considered as reserved locations and the register contents should not be modified.

**Table 9-6. INPUT\_XBAR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	INPUT1SELECT	INPUT1 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
1h	INPUT2SELECT	INPUT2 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
2h	INPUT3SELECT	INPUT3 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
3h	INPUT4SELECT	INPUT4 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
4h	INPUT5SELECT	INPUT5 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
5h	INPUT6SELECT	INPUT6 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>

7h	INPUT8SELECT	INPUT8 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
8h	INPUT9SELECT	INPUT9 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
9h	INPUT10SELECT	INPUT10 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Ah	INPUT11SELECT	INPUT11 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Bh	INPUT12SELECT	INPUT12 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Ch	INPUT13SELECT	INPUT13 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Dh	INPUT14SELECT	INPUT14 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Eh	INPUT15SELECT	INPUT15 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
Fh	INPUT16SELECT	INPUT16 Input Select Register (GPIO0 to x)	EALLOW	<a href="#">Go</a>
1Eh	INPUTSELECTLOCK	Input Select Lock Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 9-7 shows the codes that are used for access types in this section.

**Table 9-7. INPUT\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 9.3.2.1 INPUT1SELECT Register (Offset = 0h) [Reset = FFFEh]

INPUT1SELECT is shown in [Figure 9-7](#) and described in [Table 9-8](#).

Return to the [Summary Table](#).

INPUT1 Input Select Register (GPIO0 to x)

Reset type: CPU1.SYSRSn

### 9.3.2.17 INPUTSELECTLOCK Register (Offset = 1Eh) [Reset = 0000000h]

INPUTSELECTLOCK is shown in [Figure 9-23](#) and described in [Table 9-24](#).

Return to the [Summary Table](#).

Input Select Lock Register.

Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

### 9.3.3 XBAR\_REGS Registers

Table 9-25 lists the memory-mapped registers for the XBAR\_REGS registers. All register offset addresses not listed in Table 9-25 should be considered as reserved locations and the register contents should not be modified.

**Table 9-25. XBAR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	XBARFLG1	X-Bar Input Flag Register 1		<a href="#">Go</a>
2h	XBARFLG2	X-Bar Input Flag Register 2		<a href="#">Go</a>
4h	XBARFLG3	X-Bar Input Flag Register 3		<a href="#">Go</a>
6h	XBARFLG4	X-Bar Input Flag Register 4		<a href="#">Go</a>
8h	XBARCLR1	X-Bar Input Flag Clear Register 1		<a href="#">Go</a>
Ah	XBARCLR2	X-Bar Input Flag Clear Register 2		<a href="#">Go</a>
Ch	XBARCLR3	X-Bar Input Flag Clear Register 3		<a href="#">Go</a>
Eh	XBARCLR4	X-Bar Input Flag Clear Register 4		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 9-26 shows the codes that are used for access types in this section.

**Table 9-26. XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 9.3.3.1 XBARFLG1 Register (Offset = 0h) [Reset = 0000000h]

XBARFLG1 is shown in [Figure 9-24](#) and described in [Table 9-27](#).

Return to the [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

1: Corresponding Input was triggered

0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
4	CMPSS3_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CMPSS3_CTRIPL input was triggered 0: CMPSS3_CTRIPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	CMPSS2_CTRIPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CMPSS2_CTRIPH input was triggered 0: CMPSS2_CTRIPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	CMPSS2_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CMPSS2_CTRIPL input was triggered 0: CMPSS2_CTRIPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	CMPSS1_CTRIPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CMPSS1_CTRIPH input was triggered 0: CMPSS1_CTRIPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	CMPSS1_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CMPSS1_CTRIPL input was triggered 0: CMPSS1_CTRIPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

### 9.3.3.2 XBARFLG2 Register (Offset = 2h) [Reset = 0000000h]

XBARFLG2 is shown in [Figure 9-25](#) and described in [Table 9-28](#).

Return to the [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

1: Corresponding Input was triggered

0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
31	ADCCEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT1 input was triggered 0: ADCCEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
30	ADCBEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT4 input was triggered 0: ADCBEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
29	ADCBEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT3 input was triggered 0: ADCBEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
28	ADCBEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT2 input was triggered 0: ADCBEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

**Table 9-28. XBARFLG2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	ADCB EVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT1 input was triggered 0: ADCBEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	ADCAEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCAEVT4 input was triggered 0: ADCAEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	ADCAEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCAEVT3 input was triggered 0: ADCAEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	ADCAEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCAEVT2 input was triggered 0: ADCAEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	ADCAEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCAEVT1 input was triggered 0: ADCAEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	EXTSYNCOU	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EXTSYNCOU input was triggered 0: EXTSYNCOU Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	ECAP6_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP6_OUT input was triggered 0: ECAP6_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
20	ECAP5_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP5_OUT input was triggered 0: ECAP5_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

**Table 9-28. XBARFLG2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	ECAP4_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP4_OUT input was triggered 0: ECAP4_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	ECAP3_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP3_OUT input was triggered 0: ECAP3_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	ECAP2_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP2_OUT input was triggered 0: ECAP2_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	ECAP1_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ECAP1_OUT input was triggered 0: ECAP1_OUT Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	INPUT14	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT14 input was triggered 0: INPUT14 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	INPUT13	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT13 input was triggered 0: INPUT13 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	INPUT12	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT12 input was triggered 0: INPUT12 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	INPUT11	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT11 input was triggered 0: INPUT11 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

**Table 9-28. XBARFLG2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	INPUT10	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT10 input was triggered 0: INPUT10 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	INPUT9	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT9 input was triggered 0: INPUT9 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	INPUT8	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT8 input was triggered 0: INPUT8 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	INPUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT7 input was triggered 0: INPUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	ADCSOCB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCSOCB input was triggered 0: ADCSOCB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	ADCSOCA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCSOCA input was triggered 0: ADCSOCA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	INPUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT6 input was triggered 0: INPUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	INPUT5	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT5 input was triggered 0: INPUT5 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

**Table 9-28. XBARFLG2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	INPUT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT4 input was triggered 0: INPUT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	INPUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT3 input was triggered 0: INPUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	INPUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT2 input was triggered 0: INPUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	INPUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT1 input was triggered 0: INPUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

### 9.3.3.3 XBARFLG3 Register (Offset = 4h) [Reset = 0000000h]

XBARFLG3 is shown in [Figure 9-26](#) and described in [Table 9-29](#).

Return to the [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

1: Corresponding Input was triggered

0: Corresponding Input was not triggered

**Table 9-29. XBARFLG3 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	ADCCEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT3 input was triggered 0: ADCCEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	ADCCEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT2 input was triggered 0: ADCCEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

### 9.3.3.4 XBARFLG4 Register (Offset = 6h) [Reset = 0000000h]

XBARFLG4 is shown in [Figure 9-27](#) and described in [Table 9-30](#).

Return to the [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

1: Corresponding Input was triggered

0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
31	CMPSS8_CTRLIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS8_CTRLIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
30	CMPSS8_CTRLIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS8_CTRLIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
29	CMPSS7_CTRLIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS7_CTRLIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
28	CMPSS7_CTRLIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS7_CTRLIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
27	CMPSS6_CTRLIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS6_CTRLIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
26	CMPSS6_CTRLIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS6_CTRLIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

**Table 9-31. XBARCLR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
25	CMPSS5_CTRIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS5_CTRIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
24	CMPSS5_CTRIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS5_CTRIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
23	CMPSS4_CTRIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS4_CTRIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
22	CMPSS4_CTRIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS4_CTRIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
21	CMPSS3_CTRIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS3_CTRIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
20	CMPSS3_CTRIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS3_CTRIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
19	CMPSS2_CTRIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS2_CTRIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
18	CMPSS2_CTRIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS2_CTRIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
17	CMPSS1_CTRIPOUTH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPOUTH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
16	CMPSS1_CTRIPOUTL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPOUTL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
15	CMPSS8_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS8_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
14	CMPSS8_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS8_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
13	CMPSS7_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS7_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
12	CMPSS7_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS7_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

**Table 9-31. XBARCLR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	CMPSS6_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS6_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
10	CMPSS6_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS6_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
9	CMPSS5_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS5_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
8	CMPSS5_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS5_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
7	CMPSS4_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS4_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
6	CMPSS4_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS4_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
5	CMPSS3_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS3_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
4	CMPSS3_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS3_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
3	CMPSS2_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS2_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
2	CMPSS2_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS2_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
1	CMPSS1_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	CMPSS1_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

### 9.3.3.6 XBARCLR2 Register (Offset = Ah) [Reset = 0000000h]

XBARCLR2 is shown in [Figure 9-29](#) and described in [Table 9-32](#).

Return to the [Summary Table](#).

This register is used to clear the flag(s) in the XBARFLG2 register.

1: Clears the corresponding bit in the XBARFLG2 register.

0: Writing 0 has no effect

Bit	Field	Type	Reset	Description
31	ADCCEVT1	R-0/W1S	0h	Writing 1 to this bit clears the ADCCEVT1 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
30	ADCBEVT4	R-0/W1S	0h	Writing 1 to this bit clears the ADCBEVT4 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
29	ADCBEVT3	R-0/W1S	0h	Writing 1 to this bit clears the ADCBEVT3 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
28	ADCBEVT2	R-0/W1S	0h	Writing 1 to this bit clears the ADCBEVT2 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
27	ADCBEVT1	R-0/W1S	0h	Writing 1 to this bit clears the ADCBEVT1 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
26	ADCAEVT4	R-0/W1S	0h	Writing 1 to this bit clears the ADCAEVT4 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
25	ADCAEVT3	R-0/W1S	0h	Writing 1 to this bit clears the ADCAEVT3 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

**Table 9-32. XBARCLR2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
24	ADCAEVT2	R-0/W1S	0h	Writing 1 to this bit clears the ADCAEVT2 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
23	ADCAEVT1	R-0/W1S	0h	Writing 1 to this bit clears the ADCAEVT1 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
22	EXTSYNCOUT	R-0/W1S	0h	Writing 1 to this bit clears the EXTSYNCOUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
21	ECAP6_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP6_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
20	ECAP5_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP5_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
19	ECAP4_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP4_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
18	ECAP3_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP3_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
17	ECAP2_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP2_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
16	ECAP1_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP1_OUT bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
15	INPUT14	R-0/W1S	0h	Writing 1 to this bit clears the INPUT14 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
14	INPUT13	R-0/W1S	0h	Writing 1 to this bit clears the INPUT13 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
13	INPUT12	R-0/W1S	0h	Writing 1 to this bit clears the INPUT12 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
12	INPUT11	R-0/W1S	0h	Writing 1 to this bit clears the INPUT11 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
11	INPUT10	R-0/W1S	0h	Writing 1 to this bit clears the INPUT10 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
10	INPUT9	R-0/W1S	0h	Writing 1 to this bit clears the INPUT9 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

**Table 9-32. XBARCLR2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9	INPUT8	R-0/W1S	0h	Writing 1 to this bit clears the INPUT8 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
8	INPUT7	R-0/W1S	0h	Writing 1 to this bit clears the INPUT7 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
7	ADCSOCB	R-0/W1S	0h	Writing 1 to this bit clears the ADCSOCB bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
6	ADCSOCA	R-0/W1S	0h	Writing 1 to this bit clears the ADCSOCA bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
5	INPUT6	R-0/W1S	0h	Writing 1 to this bit clears the INPUT6 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
4	INPUT5	R-0/W1S	0h	Writing 1 to this bit clears the INPUT5 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
3	INPUT4	R-0/W1S	0h	Writing 1 to this bit clears the INPUT4 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
2	INPUT3	R-0/W1S	0h	Writing 1 to this bit clears the INPUT3 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
1	INPUT2	R-0/W1S	0h	Writing 1 to this bit clears the INPUT2 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	INPUT1	R-0/W1S	0h	Writing 1 to this bit clears the INPUT1 bit in the XBARFLG2 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

### 9.3.3.7 XBARCLR3 Register (Offset = Ch) [Reset = 0000000h]

XBARCLR3 is shown in [Figure 9-30](#) and described in [Table 9-33](#).

Return to the [Summary Table](#).

This register is used to clear the flag(s) in the XBARFLG3 register.

1: Clears the corresponding bit in the XBARFLG3 register.

0: Writing 0 has no effect

### 9.3.3.8 XBARCLR4 Register (Offset = Eh) [Reset = 0000000h]

XBARCLR4 is shown in [Figure 9-31](#) and described in [Table 9-34](#).

Return to the [Summary Table](#).

This register is used to clear the flag(s) in the XBARFLG4 register.

1: Clears the corresponding bit in the XBARFLG4 register.

0: Writing 0 has no effect

3Eh	TRIPLOCK	ePWM XBAR Configuration Lock register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 9-36 shows the codes that are used for access types in this section.

**Table 9-36. EPWM\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

**Table 9-36. EPWM\_XBAR\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 9.3.4.1 TRIP4MUX0TO15CFG Register (Offset = 0h) [Reset = 0000000h]

TRIP4MUX0TO15CFG is shown in [Figure 9-32](#) and described in [Table 9-37](#).

Return to the [Summary Table](#).

Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-53. TRIP4MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of Mux0 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 9.3.4.18 TRIP5MUXENABLE Register (Offset = 22h) [Reset = 0000000h]

TRIP5MUXENABLE is shown in [Figure 9-49](#) and described in [Table 9-54](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for TRIP5

**Figure 9-49. TRIP5MUXENABLE Register**

31	30	29	28	27	26	25	24

**Table 9-54. TRIP5MUXENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-54. TRIP5MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-54. TRIP5MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-54. TRIP5MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-54. TRIP5MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 9.3.4.19 TRIP7MUXENABLE Register (Offset = 24h) [Reset = 0000000h]

TRIP7MUXENABLE is shown in [Figure 9-50](#) and described in [Table 9-55](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for TRIP7

**Figure 9-50. TRIP7MUXENABLE Register**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-55. TRIP7MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-55. TRIP7MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-55. TRIP7MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-55. TRIP7MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 9.3.4.20 TRIP8MUXENABLE Register (Offset = 26h) [Reset = 0000000h]

TRIP8MUXENABLE is shown in [Figure 9-51](#) and described in [Table 9-56](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for TRIP8

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-56. TRIP8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-56. TRIP8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-56. TRIP8MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-56. TRIP8MUXENABLE Register Field Descriptions (continued)**

11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-57. TRIP9MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 9.3.4.22 TRIP10MUXENABLE Register (Offset = 2Ah) [Reset = 0000000h]

TRIP10MUXENABLE is shown in [Figure 9-53](#) and described in [Table 9-58](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for TRIP10

**Table 9-58. TRIP10MUXENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-58. TRIP10MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-58. TRIP10MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-58. TRIP10MUXENABLE Register Field Descriptions (continued)**

Complex bit access types are encoded to fit into small table cells. Table 9-64 shows the codes that are used for access types in this section.

**Table 9-64. CLB\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

**Table 9-64. CLB\_XBAR\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 9.3.5.1 AUXSIG0MUX0TO15CFG Register (Offset = 0h) [Reset = 0000000h]

AUXSIG0MUX0TO15CFG is shown in [Figure 9-58](#) and described in [Table 9-65](#).

Return to the [Summary Table](#).

**Table 9-71. AUXSIG3MUX0TO15CFG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	MUX15	R/W	0h	Group Select Bits for MUX15: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX15 01 : Select .1 input for MUX15 10 : Select .2 input for MUX15 11 : Select .3 input for MUX15 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29-28	MUX14	R/W	0h	Group Select Bits for MUX14: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX14 01 : Select .1 input for MUX14 10 : Select .2 input for MUX14 11 : Select .3 input for MUX14 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27-26	MUX13	R/W	0h	Group Select Bits for MUX13: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX13 01 : Select .1 input for MUX13 10 : Select .2 input for MUX13 11 : Select .3 input for MUX13 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25-24	MUX12	R/W	0h	Group Select Bits for MUX12: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX12 01 : Select .1 input for MUX12 10 : Select .2 input for MUX12 11 : Select .3 input for MUX12 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23-22	MUX11	R/W	0h	Group Select Bits for MUX11: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX11 01 : Select .1 input for MUX11 10 : Select .2 input for MUX11 11 : Select .3 input for MUX11 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-71. AUXSIG3MUX0TO15CFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
21-20	MUX10	R/W	0h	Group Select Bits for MUX10: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX10 01 : Select .1 input for MUX10 10 : Select .2 input for MUX10 11 : Select .3 input for MUX10 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19-18	MUX9	R/W	0h	Group Select Bits for MUX9: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX9 01 : Select .1 input for MUX9 10 : Select .2 input for MUX9 11 : Select .3 input for MUX9 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17-16	MUX8	R/W	0h	Group Select Bits for MUX8: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX8 01 : Select .1 input for MUX8 10 : Select .2 input for MUX8 11 : Select .3 input for MUX8 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15-14	MUX7	R/W	0h	Group Select Bits for MUX7: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX7 01 : Select .1 input for MUX7 10 : Select .2 input for MUX7 11 : Select .3 input for MUX7 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13-12	MUX6	R/W	0h	Group Select Bits for MUX6: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX6 01 : Select .1 input for MUX6 10 : Select .2 input for MUX6 11 : Select .3 input for MUX6 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11-10	MUX5	R/W	0h	Group Select Bits for MUX5: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX5 01 : Select .1 input for MUX5 10 : Select .2 input for MUX5 11 : Select .3 input for MUX5 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX4	R/W	0h	Group Select Bits for MUX4: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX4 01 : Select .1 input for MUX4 10 : Select .2 input for MUX4 11 : Select .3 input for MUX4 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 9-71. AUXSIG3MUX0TO15CFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-6	MUX3	R/W	0h	Group Select Bits for MUX3: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX3 01 : Select .1 input for MUX3 10 : Select .2 input for MUX3 11 : Select .3 input for MUX3 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX2	R/W	0h	Group Select Bits for MUX2: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX2 01 : Select .1 input for MUX2 10 : Select .2 input for MUX2 11 : Select .3 input for MUX2 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3-2	MUX1	R/W	0h	Group Select Bits for MUX1: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX1 01 : Select .1 input for MUX1 10 : Select .2 input for MUX1 11 : Select .3 input for MUX1 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX0	R/W	0h	Group Select Bits for MUX0: Selects 4X1 group output for AUXSIG3 of CLB-XBAR 00 : Select .0 input for MUX0 01 : Select .1 input for MUX0 10 : Select .2 input for MUX0 11 : Select .3 input for MUX0 Refer to the CLB X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 9.3.5.8 AUXSIG3MUX16TO31CFG Register (Offset = Eh) [Reset = 0000000h]

AUXSIG3MUX16TO31CFG is shown in [Figure 9-65](#) and described in [Table 9-72](#).

Return to the [Summary Table](#).
