1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

12.6.1.1.109 EDMA_TPCC_QER_RN Register (Offset = 2080h) [reset = 0h]

EDMA_TPCC_QER_RN is shown in Figure 12-134 and described in Table 12-127.

Return to Summary Table.

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

Figure 12-134. EDMA_TPCC_QER_RN Register

Table 12-134. EDMA_TPCC_OPT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PRIV	R	0h	Privilege level: privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus. PRIV = 0 : User level privilege PRIV = 1 : Supervisor level privilege
30-28	RES83	R	0h	RESERVE FIELD
27-24	PRIVID	R	0h	Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus.
23	ITCCHEN	R/W	0h	Intermediate transfer completion chaining enable: 0: Intermediate transfer complete chaining is disabled. 1: Intermediate transfer complete chaining is enabled.
22	TCCHEN	R/W	0h	Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.
21	ITCINTEN	R/W	0h	Intermediate transfer completion interrupt enable: 0: Intermediate transfer complete interrupt is disabled. 1: Intermediate transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
20	TCINTEN	R/W	0h	Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)
19	WIMODE	R/W	0h	Backward compatibility mode: 0: Normal operation 1 : WI Backwards Compatibility mode forces BCNT to be adjusted by '1' upon TR submission (0 means 1 1 means 2 ...) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)
18	RES84	R	0h	RESERVE FIELD
17-12	TCC	R/W	0h	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER (bit CER[TCC]) for chaining or in IER (bit IER[TCC]) for interrupts.

Table 12-134. EDMA_TPCC_OPT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	TCCMODE	R/W	0h	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .
10-8	FWID	R/W	0h	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.
7-4	RES85	R	0h	RESERVE FIELD
3	STATIC	R/W	0h	Static Entry: 0: Entry is updated as normal 1: Entry is static Count and Address updates are not updated after TRP is submitted. Linking is not performed.
2	SYNCDIM	R/W	0h	Transfer Synchronization Dimension: 0: A-Sync Each event triggers the transfer of ACNT elements. 1: AB-Sync Each event triggers the transfer of BCNT arrays of ACNT elements
1	DAM	R/W	0h	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO Dst addressing within an array wraps around upon reaching FIFO width.
0	SAM	R/W	0h	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR Src addressing within an array increments. Source is not a FIFO. 1: FIFO Src addressing within an array wraps around upon reaching FIFO width.

12.6.1.1.117 EDMA_TPCC_SRC Register (Offset = 4004h) [reset = 0h]

EDMA_TPCC_SRC is shown in Figure 12-142 and described in Table 12-135.

Return to Summary Table.

Table 12-136. EDMA_TPCC_ABCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNT	R/W	0h	BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation valid values for BCNT can be anywhere between 1 and 65535. Therefore the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame and BCNT=0 means 0 arrays in the frame. In normal mode a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the programmed BCNT value will be incremented by '1' before submission to TC. I.e. 0 means 1 1 means 2 2 means 3 ...
15-0	ACNT	R/W	0h	ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0 it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition the ACNT definition will disregard the 2 msbits. I.e. a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer resulting in null or dummy operation dependent on the state of BCNT and CCNT.

12.6.1.1.119 EDMA_TPCC_DST Register (Offset = 400Ch) [reset = 0h]

EDMA_TPCC_DST is shown in Figure 12-144 and described in Table 12-137.

Return to Summary Table.

Destination Address

Figure 12-144. EDMA_TPCC_DST Register

Table 12-138. EDMA_TPCC_BIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DBIDX	R/W	0h	Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2's complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.
15-0	SBIDX	R/W	0h	Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2's complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.

12.6.1.1.121 EDMA_TPCC_LNK Register (Offset = 4014h) [reset = 0h]

EDMA_TPCC_LNK is shown in Figure 12-146 and described in Table 12-139.

Return to Summary Table.

Link and Reload parameters

Figure 12-146. EDMA_TPCC_LNK Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 12-139. EDMA_TPCC_LNK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNTRLD	R/W	0h	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT not thus BCNTRLD is a don't care field.
15-0	LINK	R/W	0h	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e. after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore if the user uses the literal address with a range from 0x4000 to 0x7FFF it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000 thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs) behavior is undefined for the user (i.e. don't have to test it). In the former case (2 msbs) user should be able to take advantage of this feature (i.e. do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM then the Link will be treated as a Null Linkand all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid/Secure state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e. a value of 0x3FFE is a non-NULL PaRAM link field.

12.6.1.1.122 EDMA_TPCC_CIDX Register (Offset = 4018h) [reset = 0h]

EDMA_TPCC_CIDX is shown in Figure 12-147 and described in Table 12-140.

Return to Summary Table.

Register description is not available

Figure 12-147. EDMA_TPCC_CIDX Register

Table 12-140. EDMA_TPCC_CIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DCIDX	R/W	0h	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a ABsync transfer is the first array in the frame.
15-0	SCIDX	R/W	0h	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied the current array in an A-sync transfer is the last array in the frame while the current array in a AB-sync transfer is the first array in the frame.

12.6.1.1.123 EDMA_TPCC_CCNT Register (Offset = 401Ch) [reset = 0h]

EDMA_TPCC_CCNT is shown in Figure 12-148 and described in Table 12-141.

Return to Summary Table.

C byte count

Figure 12-148. EDMA_TPCC_CCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12-141. EDMA_TPCC_CCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RES86	R	0h	RESERVE FIELD
15-0	CCNT	R/W	0h	CCNT : Count for 3rd Dimension: CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT can be anywhere between 1 and 65535. Therefore the maximum number of frames in a block is 65535 (64K-1 frames). CCNT of '1' means '1' frame in the block and CCNT of '0' means '0' frames in the block. A CCNT value of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. WIMODE has no affect on CCNT operation.

12.6.1.2 EDMA_TPTC Registers

Table 12-142 lists the memory-mapped registers for the EDMA_TPTC. All register offset addresses not listed in Table 12-142 should be considered as reserved locations and the register contents should not be modified.

Bit	Field	Type	Reset	Description
31-18	RES19	R	0h	RESERVE FIELD
17	TCCHEN	R	0h	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.
16	TCINTEN	R	0h	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.
15-14	RES20	R	0h	RESERVE FIELD
13-8	TCC	R	0h	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.
7-4	RES21	R	0h	RESERVE FIELD
3-0	STAT	R	0h	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0h = No error 1h - 7h = Read error 8h - Fh = Write error

12.6.1.2.12 EDMA_TPTC_ERRCMD Register (Offset = 130h) [reset = 0h]

EDMA_TPTC_ERRCMD is shown in Figure 12-160 and described in Table 12-154.

Return to Summary Table.

The SECURE value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The secure attribute is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection and security checks based on the SECURE level of the external host that sets up the DMA transaction.
8	PRIV	R	0h	Privilege Level: PRIV = 0 : User level privilege PRIV = 1 : Supervisor level privilege DFMPPRXY0.PRIV is always updated with the value from the configuration bus privilege field on any/every write to Program Set BIDX Register (trigger register). The PRIV value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the PRIV of the external host that sets up the DMA transaction.
7-4	RES49	R	0h	RESERVE FIELD
3-0	PRIVID	R	0h	Privilege ID: DFMPPRXY0.PRIVID is always updated with the value from configuration bus privilege ID field on any/every write to Program Set BIDX Register (trigger register). The PRIVID value for the SA Set and DF Set are copied from the value in the Program set along with the remainder of the parameter values. The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform memory protection checks based on the privid of the external host that sets up the DMA transaction.

ADC Buffer

The ADC buffer is on-chip memory arranged as a ping-pong buffer, with ECC support for each ping and pong memory. The raw ADC output data from RADAR-SS is stored on this memory, to be consumed by the DSP with the 16xx/18xx, or by the hardware FFT accelerator with the 14xx, or by the DSP or hardware FFT accelerator with the 68xx for the post processing. The buffer size details are:

Device	14xx	16xx/68xx/18xx
Size in KB	16	32

For the application software, the ADC buffer (either ping or pong) is seen as a single memory at the base address, as specified in , and size as mentioned above. For the register details, refer to .

Topic **Page**

13.1 Functional Description **1846**

13.1 Functional Description

Figure 13-2 shows the block diagram of the ADC buffer scheme. The three data input sources to the ADC buffer are:

- Supported in the 14xx and 16xx/18xx/68xx:
  - Raw ADC output data from the digital front end (DFE)
  - Ramp pattern data from the test pattern generator
- Supported in the 16xx/18xx/68xx only:
  - HIL data from the DMM interface, as shown in Figure 13-1 and Figure 13-2.

Figure 13-1. ADC Buffer Block Diagram for the 14xx

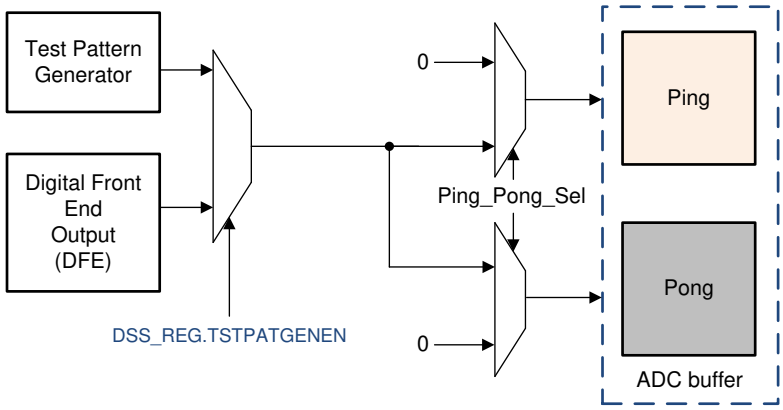

Figure 13-2. ADC Buffer Block Diagram for the 16xx/18xx/68xx

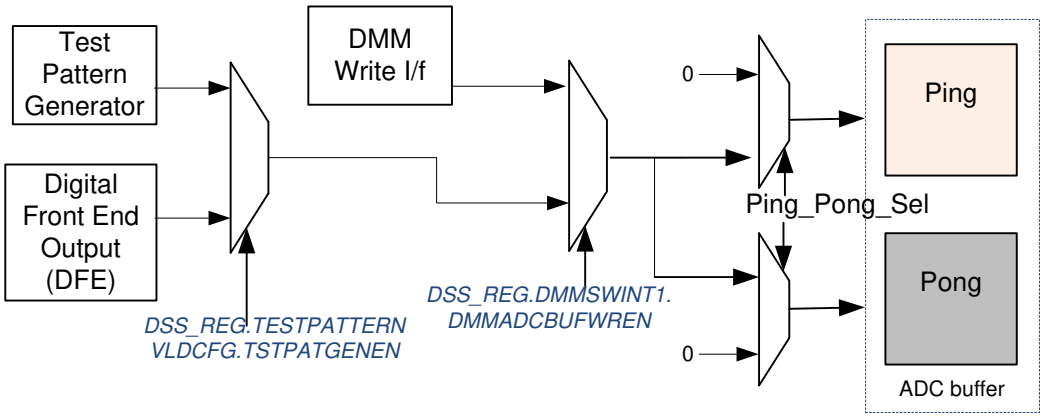


13.1.1 DFE Data Write Operation

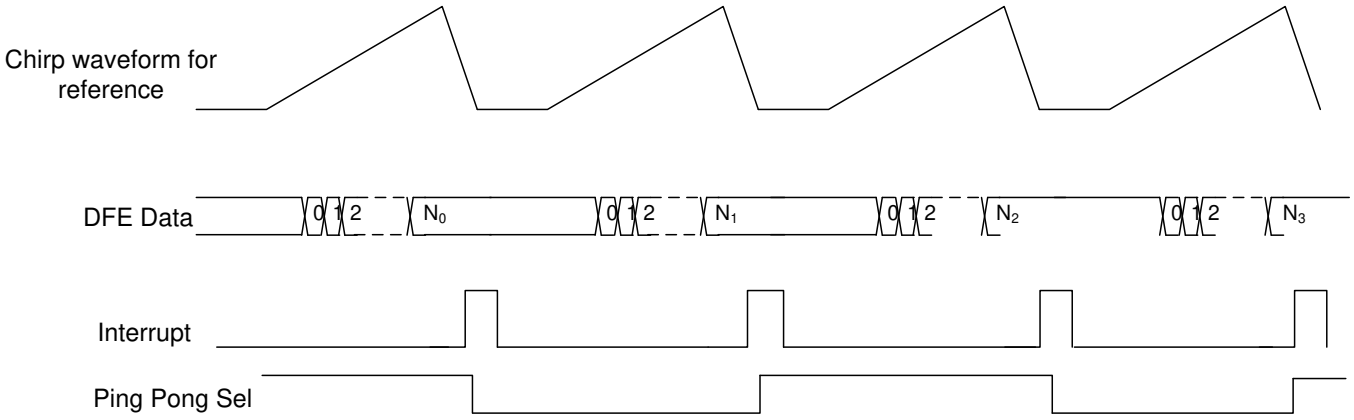
The ADC buffer can be written from DFE in any of the three modes by configuring the control registers ADCBUFCFG1, ADCBUFCFG2, ADCBUFCFG3, and ADCBUFCFG4 in DSS_REG address space:

1. Single-chirp mode
2. Multi-chirp mode
3. Continuous mode

The DFE data from the four Rx channels can be independently enabled by programming the register ADCBUFCFG1.

In single-chirp mode, the FMCW chirp data from the DFE is written to the ADC buffer on a per chirp basis, and a chirp available interrupt is generated on the completion of the write data operation at the end of the chirp, as shown in Figure 13-3. ADC buffer control logic generates the Ping_Pong_Sel signal, as shown in Figure 13-3, which controls whether the data is written into either ping or pong buffer. Data write can start from either the ping or pong buffer.

Figure 13-3. Single-Chirp Mode



In multi-chirp mode, ADC samples for N chirps are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The number of chirps stored in the ping buffer is configured in the register field ADCBUFNUMCHRPPING, and the number of chirps to be stored in the pong buffer is configured in the register field ADCBUFNUMCHRPPONG.

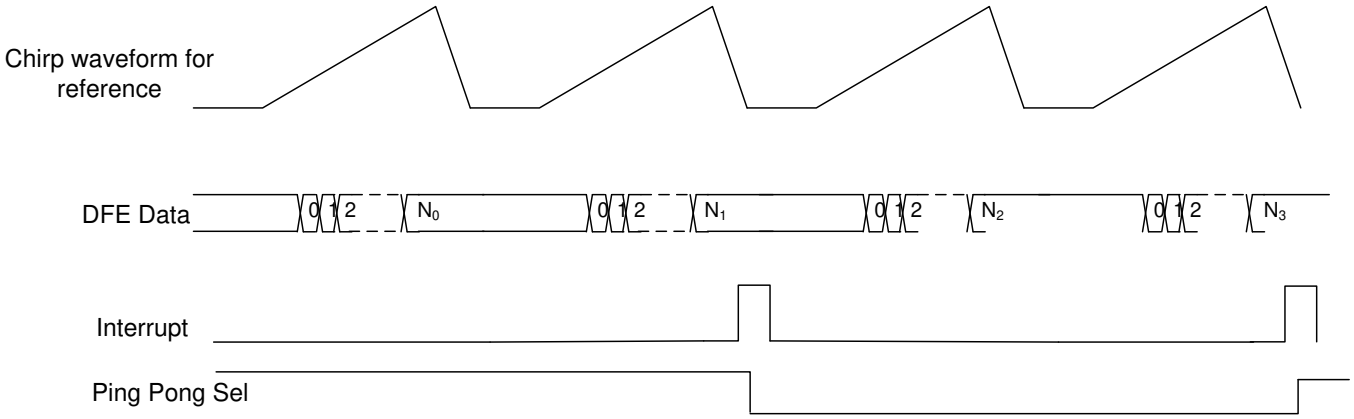
Table 13-1 shows the programming sequence for the ADC buffer single-chirp and multi-chirp modes.

NOTE: Registers for ping and pong must be programmed with the same value for correct functionality.

Table 13-1. ADC Buffer Single-Chirp and Multi-Chirp Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
	ADCBUFCFG1.RX3EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE
Configure whether real or complex samples are to be stored in the ADC buffer	ADCBUFCFG1.ADCBUFREALONLYMODE
For complex samples. Configure if I or Q sample is stored in the LSB	ADCBUFCFG1.ADCBUFIQSWAP
Configure the number of samples to be stored in each ping/pong buffer as N	ADCBUFCFG4.ADCBUFNUMCHRPPONG
	ADCBUFCFG4.ADCBUFNUMCHRPP1NG

Figure 13-4. Multi-Chirp Mode



In continuous mode, where the FMCW transceiver is configured to output a single frequency tone in the range of 76-81 GHz, 'N' ADC samples are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The value N is configured in the field DSS_REG.ADCBUFCFG4.ADCBUFSAMPCNT. In real mode, this value N refers to the number of real samples per channel, and in complex mode, this refers to the number of complex samples per channel. This counter increments once for every new sample (as long as 1 or more Rx channels are enabled). Continous mode is expected to be only used for CZ and ADC buffer testpattern mode.

Table 13-2 shows the programming sequence for ADC buffer continuous mode.

Table 13-2. ADC Buffer Continuous Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
	ADCBUFCFG1.RX3EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE
Configure whether real or complex samples are to be stored in the ADC buffer	ADCBUFCFG1.ADCBUFREALONLYMODE
For complex samples. Configure if I or Q sample is stored in the LSB	ADCBUFCFG1.ADCBUFIQSWAP
Configure the number of samples to be store in each ping/pong buffer	ADCBUFCFG4.ADCBUFSAMPCNT
Enable the ADC buffer in continuous mode	ADCBUFCFG1.ADCBUFCONTMODEEN
To start the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTRTPL
To stop the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTOPPL

13.1.2 Support for Hardware in Loop (HIL)

In hardware in loop mode (supported only in the 16xx/18xx/68xx), the ADC data write from DFE can be bypassed by writing the data from the DMM module. Enable this path by writing to the field DSS_REG.DMMSWINT1.DMMADCBUFWREN. The DMM can now access the DSS_ADCBUF memory through the DSS_ADCBUF_WRITE address space. To toggle the ping/pong buffer, toggle DSS_REG.DMMSWINT1.DMMADCBUFPINPONSEL.

13.1.3 Test Pattern Generator Support

An internal test pattern generator which outputs a ramp pattern helps during the initial software development and debug. The output of this module is muxed with the DFE data before sending it to the ADC buffers, as shown in Figure 13-2. Because this is meant for testing the path from the ADC buffer until the final output through LVDS, the ADC buffer configurations must be set to continuous streaming mode, in which the ping-pong switch is based on the number of samples. The test pattern generator can be configured by programming the register TESTPATTERNVLDCFG in the DSS_REG address space. Additional configurable registers are provided for configuring the ramp pattern output from the test pattern generator, such as offset at the start of ramp, step size, and so forth. Refer to the DSS_REG address space and test pattern generator-related registers for further information.

13.1.4 ADC Buffer Data Formats

The data is written in the following formats to the ADC buffer:

- Interleaved data format (supported only in the 14xx)
- Non-interleaved data format (supported in 14xx and 16xx/18xx/68xx)

13.1.4.1 Interleaved Data Format

In interleaved format of data storage, Sample 0 of all the enabled channels, followed by Sample1 of all the enabled channels, and so forth, are written to the buffer as illustrated below for real/complex data, with different configurations of RX channels enabled.

For 4-channels-Rx channels 0,1, 2, and 3 enabled, complex:

RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 4-channels Rx channels 0,1, 2, and 3 enabled, Real Only:

RX3_I(1)	RX2_I(1)	RX1_I(1)	RX0_I(1)	RX3_I(0)	RX2_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0,1, and 2 enabled, Complex:

NA	NA	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 0,1, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 0, 2, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX0_Q(0)	RX0_I(0)

For 3-channels Rx channels 1, 2, and 3 enabled, Complex:

NA	NA	RX3_Q(0)	RX3_I(0)	RX2_Q(0)	RX2_I(0)	RX1_Q(0)	RX1_I(0)

For 3-channels-Rx channels 0, 1, and 2 enabled, Real only:

NA	NA	RX2_I(1)	RX1_I(1)	RX0_I(1)	RX2_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0, 1, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX1_I(1)	RX0_I(1)	RX3_I(0)	RX1_I(0)	RX0_I(0)

For 3-channels Rx channels 0, 2, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX2_I(1)	RX0_I(1)	RX3_I(0)	RX2_I(0)	RX0_I(0)

For 3-channels Rx channels 1, 2, and 3 enabled, Real only:

NA	NA	RX3_I(1)	RX2_I(1)	RX1_I(1)	RX3_I(0)	RX2_I(0)	RX1_I(0)

For 2-channels Rx channels 0, 1 enabled, Complex:

RX1_Q(1)	RX1_I(1)	RX0_Q(1)	RX0_I(1)	RX1_Q(0)	RX1_I(0)	RX0_Q(0)	RX0_I(0)

For 2-channels Rx channels 0, 1 enabled, Real only:

RX1_I(3)	RX0_I(3)	RX1_I(2)	RX0_I(2)	RX1_I(1)	RX0_I(1)	RX1_I(0)	RX0_I(0)

For 1-channels Rx channels 0 enabled, Complex:

RX0_Q(3)	RX0_I(3)	RX0_Q(2)	RX0_I(2)	RX0_Q(1)	RX0_I(1)	RX0_Q(0)	RX0_I(0)

For 1-channels Rx channels 0 enabled, Real:

RX0_I(7)	RX0_I(6)	RX0_I(5)	RX0_I(4)	RX0_I(3)	RX0_I(2)	RX0_I(1)	RX0_I(0)

Where RXn_I/Q(m) stands for the ‘m’th sample I/Q of ‘n’th RX channel.

13.1.4.2 Non-Interleaved Data Format

In non-interleaved mode storage, each channel data is stored in different memory locations, as shown in Table 13-3.

Table 13-3. Non-Interleaved Data Format

RX0(3)	RX0(2)	RX0(1)	RX0(0)
RX0(7)	RX0(6)	RX0(5)	RX0(4)
RX1(3)	RX1(2)	RX1(1)	RX1(0)
RX1(7)	RX1(6)	RX1(5)	RX1(4)
RX2(3)	RX2(2)	RX2(1)	RX2(0)
RX2(7)	RX2(6)	RX2(5)	RX2(4)
RX3(3)	RX3(2)	RX3(1)	RX3(0)
RX3(7)	RX3(6)	RX3(5)	RX3(4)

High-Speed Interface (HSI)

Topic **Page**

14.1 Overview **1852**
14.2 CBUFF **1852**
14.3 LVDS **1859**
14.4 CSI2 ..... **1998**

14.1 Overview

High-speed interfaces available on the device are mentioned in the HSI integration chapter specific to the device. System data, such as the ADC buffer raw data, chirp profile data, chirp quality data, safety monitoring data, and software variables may be sent out over the high-speed interface.

All data from the system which must be transmitted over CSI2 or LVDs is first sent to the CBUFF controller (Common Buffer Controller). In its simplest form, the CBUFF is an intermediate buffer between the system and the high-speed interfaces, and sits as a slave port on the DSS interconnect.

The CBUFF controller can directly trigger the EDMAs on selected hardware events to request data and initiate an HSI transmission without processor intervention. Alternatively, the CBUFF can also be triggered from software. An EDMA is always used to send data to the CBUFF. This ensures proper synchronization and throughput. The EDMA reads data from any of the data sources and writes to the CBUFF slave port. The CBUFF uses bus flow control mechanisms to handle the differences between EDMA writes and high-speed bandwidth.

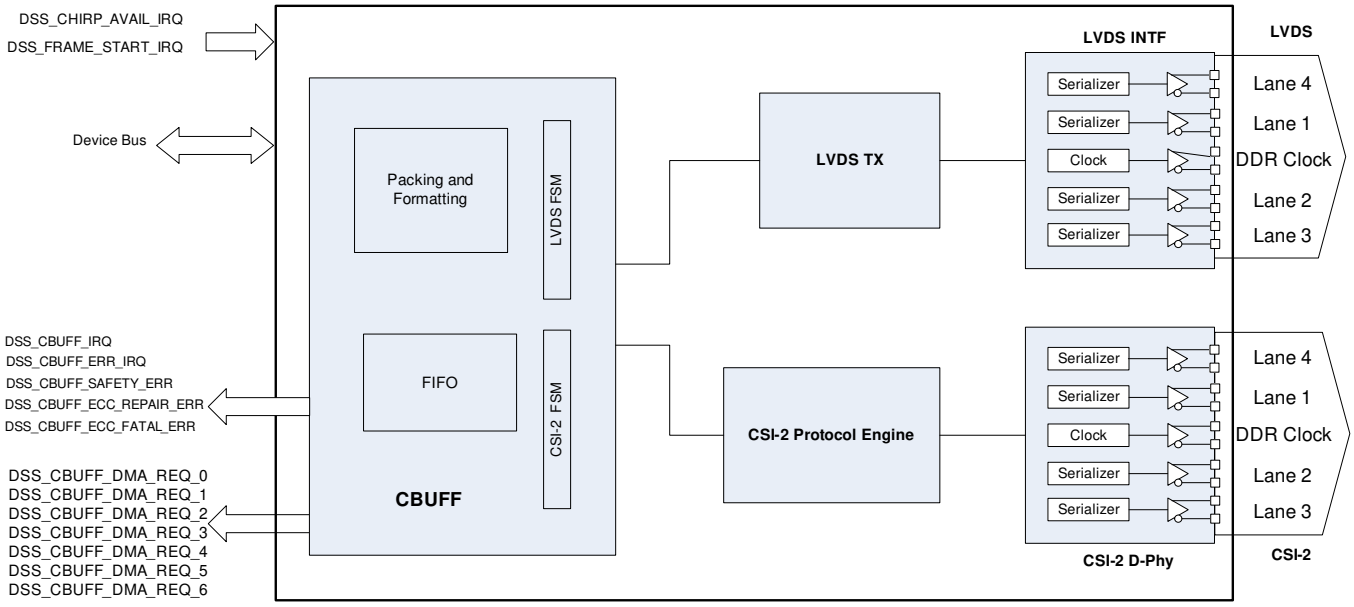
The data from the various sources, such as ADC buffer, CQ memory, and so forth may need to be packed into the correct format before being sent over LVDS and CSI2. Data from multiple sources may also be needed to be combined and sent as part of a single LVDS frame or CSI2 packet. The data may need to be sent between markers such as CSI2 sync packets. All this is done within the CBUFF.

For CSI2, the CBUFF sends the data to the CSI2 protocol engine, which is configured in command mode – OCP mode. The CSI2 protocol engine then sends the data to the CSI2 D-Phy transmitter.

For LVDS, the LVDS TX IP is closely integrated with the configuration of CBUFF, and does not need to be configured separately.

Figure 14-1 illustrates the integration scheme, which shows all the components for HSI data transfer.

Figure 14-1. HSI Overview



NOTE: High-speed interfaces available on the device are mentioned in the HSI integration chapter specific to the device.

14.2 CBUFF

14.2.1 CBUFF Overview

- 128-bit Slave write-only interface over the EDMA writes the data from different sources, such as ADC buffer, chip quality, chirp parameters, safety data, and so forth, to be sent over the high-speed

interfaces. Minimum packet size is 64 bytes.

- Data can be transmitted over any one of the following high-speed interfaces:
  - CSI-2
  - LVDS

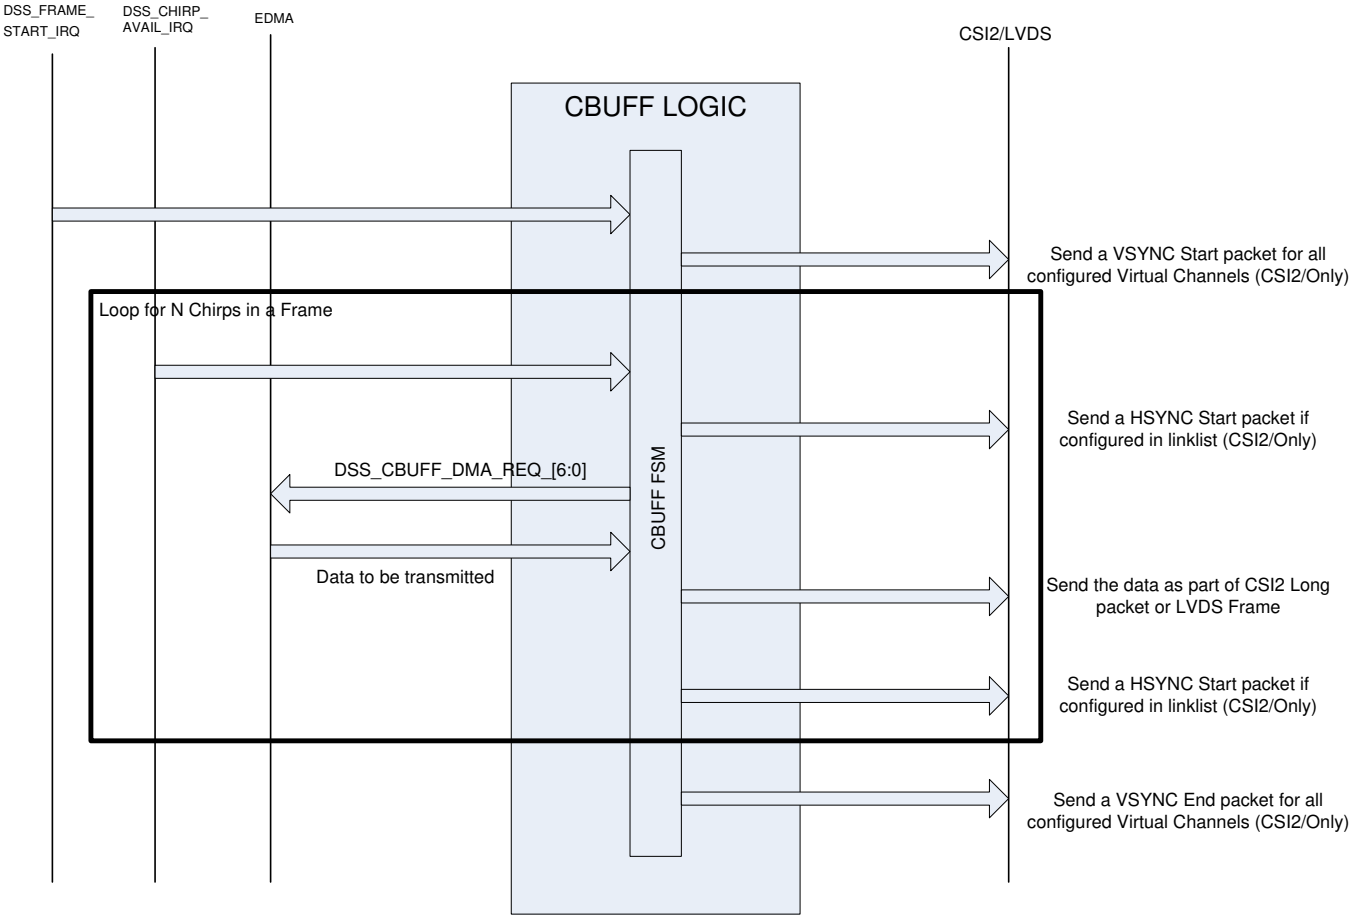
    The CBUFF supports sending the data over up to 4 lanes.
- The data written by the EDMA is stored in a 128-bit internal FIFO. The CBUFF has flow control mechanisms to stall the DMA writes until there is sufficient space in the FIFO to manage bandwidth differences in EDMA and the high-speed interface.
- CBUFF always handles external data at a 16-bit boundary. This is a CBUFF unit: 1 CBUFF UNIT == 16 bits of data
- Minimum size of the LVDS or CSI2 packet is 64 bytes.
- CBUFF supports the following formats:
  - DATA16 : Entire CBUFF unit is sent over CSI/LVDS
  - DATA14 : 14 bits of 1 CBUFF unit is sent over CSI/LVDS
  - DATA12 : 12 bits of 1 CBUFF unit is sent over CSI/LVDS
- Supports packing data from different sources and transmitting as a single LVDS/CSI2 packet through link-list configuration
- CSI2 features:
  - Packing of data into RAW12/RAW14/RAW8 to send data formats DATA12/DATA14/DATA16, respectively
  - Supports virtual channels
  - Supports sending Vsync and Hsync packets
- LVDS features:
  - SDR and DDR clocking modes
  - CRC with the LVDS frame
- Safety features:
  - CRC check on the data transfer between the ADC buffer and CBUFF
  - ECC with single-bit correction and double-bit detection on the CBUFF FIFO
  - Detection of erroneous incomplete transfer when the trigger for the next transfer is received

14.2.2 CBUFF Sequencing

The CBUFF can transmit data over either CSI2 or LVDS. This is selected by configuring the field CONFIG_REG_0.CFG_1LVDS_0CSI.

The CBUFF has an internal state machine that can sequence the transmission of high-speed data without processor intervention. The hardware system events Frame Start (DSS_FRAME_START_IRQ) and Chirp Available (DSS_CHIRP_AVAIL_IRQ) can be used to trigger the data transmission.

Figure 14-2. CBUFF Sequencing



14.2.2.1 LVDS Transmission Sequence

1. CBUFF is programmed and enabled.
2. On Frame Start, CBUFF moves to the next state to wait for the Chirp Available trigger.
3. On Chirp Available, CBUFF generates an EDMA hardware request. The EDMA sends the data to be sent over HSI to CBUFF, and CBUFF transfers the data over LVDS. On completion, it sends a Chirp Done interrupt.
4. If this is the last Chirp configured in the CBUFF, it generates a Frame Done interrupt and waits for the next Frame Sync (Step 2). Else, it waits for the next Chirp available (Step 3).

14.2.2.2 CSI2 Transmission Sequencing

1. CBUFF is programmed and enabled.
2. On Frame Start, CBUFF sends a Vertical Start Sync Short packet command to the CSI protocol engine, and waits for a Packet Sent signal from the CSI protocol engine.
3. On Chirp Available, it generates a DMA request signal and sends a Horizontal Start Short Packet command to the CSI protocol engine, which is configured in Command Mode-OCP, then waits for the Packet Sent signal from the CSI protocol engine. The DMA begins to send the data to be transferred over HSI to the CBUFF.
4. CBUFF sends a Long Packet Header command to the CSI protocol engine.
5. CBUFF writes the data to be transferred, filled in its FIFO to the Long Packet Payload register.
6. CBUFF waits for Packet Sent, then sends the Horizontal End Sync Packet command to the CSI PE, and waits for the Packet Sent signal from the CSI PE before sending a Chirp Done interrupt.

7. If this is the last Chirp configured in the CBUFF, it sends a Vertical End Sync Short packet command to CSI PE, waits for the Packet Sent signal from the CSI PE, sends a Frame Done Interrupt, then waits for the next Frame Sync (Step 2). Else, it waits for the next Chirp available (Step 3).

14.2.3 Sequence-Related CBUFF Configuration Fields

14.2.3.1 Software Triggering Option

CBUFF has the option to be triggered by software, by configuring the fields CONFIG_REG_0.CFG_SW_TRIG_EN and CONFIG_REG_0.CFTRIGEN. If these fields are configured for the software trigger, then the CBUFF can be triggered by writing into the field CONFIG_REG_0.CFG_FRAME_START_TRIG to generate a Frame Start trigger and CONFIG_REG_0. CFG_CHIRP_AVAIL_TRIG to generate a Chirp Available trigger to the CBUFF.

14.2.3.2 Configuration for CSI2 VSYNC Packet Transmission (CSI2 Only)

CBUFF can be configured to send out VSYNC Start and End packets on any of the four CSI2 virtual channel IDs. Configure CONFIG_REG_0.CVC0EN for VSYNC packets on Virtual Channel 0; configure CONFIG_REG_0.CVC1EN for VSYNC packets on Virtual Channel 1, and so forth.

14.2.3.3 Number of Chirps per Frame

The register CFG_CHIRPS_PER_FRAME determines the number of times the CBUFF state machine loops as shown in Figure 14-2.

14.2.3.4 Configuring the Short Packet Details

The CSI2 sync packets codes and the CSI2 Protocol Engine Register mapping are driven from registers, and must be configured before transmission. Though there are no sync packets in LVDS, these registers (CFG_SPHDR_ADDRESS, CFG_CMD_HSVAL, CFG_CMD_HEVAL, CFG_CMD_VSVAL, CFG_CMD_VEVAL, CFG_LPHDR_ADDRESS, and CFG_LPPYLD_ADDRESS) must be configured appropriately as per details provided in their descriptions.

14.2.4 CBUFF Linklist Concept

Figure 14-3. CBUFF Linklist Concept

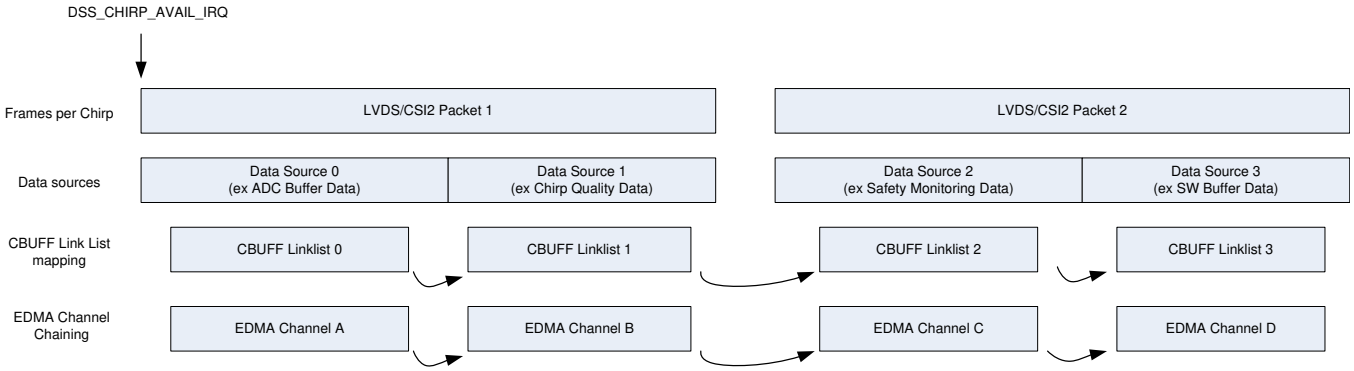


Figure 14-3 shows how data to be sent out within a Chirp is broken down in the system and spilt into configurations for the different IPs involved in the data transmission.

Each of the data sources has a separate CBUFF linklist entry in the CBUFF.

The following sections list the configurable parameters available for each linklist. For more details, refer to the *AWR1xxx Data Path Programmer's Guide* API document.

14.2.4.1 VALID

The field CFG_DATA_LL[X].LL[X]_VALID determines if the linklist entry is valid. Once the CBUFF is triggered for data transmission, the CBUFF linklist is parsed from Linklist 0 to Linklist 31 until an invalid Linklist entry is found. When an invalid linklist is found, there should not be any further valid entries.

14.2.4.2 HSYNC Start and HSYNC End

For CSI2 transmission, the field CFG_DATA_LL[X]. LL[X]_HS determines if a HSYNC start packet is sent out before the transmission of Linklist data. This field can be set to 0x1 only of the linklist is the start of a new CSI2 packet.

For CSI2 transmission, the field CFG_DATA_LL[X]. LL[X]_HE determines if a HSYNC end packet is sent out after the transmission of data for CSI2. This field can be set to 0x1 only of the linklist is the end of a CSI2 packet.

14.2.4.3 Virtual Channel Number

For CSI2 transmission, the field CFG_DATA_LL[X]. LL[X]_VCNUM is used as the virtual channel number for the HSYNC packet related to the linklist.

14.2.4.4 CRC Enable

The field CFG_DATA_LL[X].LL[X]_CRC_EN is related to the safety feature on data from the ADC buffer. CBUFF can perform a CRC check on the data being sent from the ADC buffer. If the ADC buffer is stored in interleaved format, the entire ADC buffer data should be mapped to a single CBUFF linklist entry. If the ADC buffer is stored in non-interleaved format, each Rx channel should be mapped to a separate CBUFF linklist entry with the field set in each of the linklists. Also, Rx[n] channel data sent out before Rx[m] channel data. Where n < m.

14.2.4.5 Format

CBUFF always handles external data at 16-bit boundary. This is a CBUFF unit:

1 CBUFF UNIT == 16 bits of data

CBUFF supports the following formats:

- DATA16 : Entire CBUFF unit is sent over CSI/LVDS
- DATA14 : 14 bits of 1 CBUFF unit is sent over CSI/LVDS
- DATA12 : 12 bits of 1 CBUFF unit is sent over CSI/LVDS

If fewer than 16 bits of data are sent out, the LSB bits of the CBUFF unit are sent out. The format is determined by the field CFG_DATA_LL[X].LL[X]_FMT. The format for all linklist within a CSI packet/ LVDS frame remains the same.

14.2.4.6 LVDS Format Mapping

The linklist-independent registers CFG_LVDS_MAPPING_LANEx_FMT_0 and CFG_LVDS_MAPPING_LANEx_FMT_1 are used to configure the mapping of each CBUFF unit (16-bit data) within the 128-bit CBUFF FIFO line to a specific LVDS lane. The field LL[X]_FMT_MAP in each CFG_DATA_LL[X] register selects whether FMT0 or FMT1 should be used for that linklist entry. All linklist entries must use the same format (0 or 1).

Consider the configuration for CFG_LVDS_MAPPING_LANEx_FMT_0. There are 4 such registers for each of the LVDS lanes:

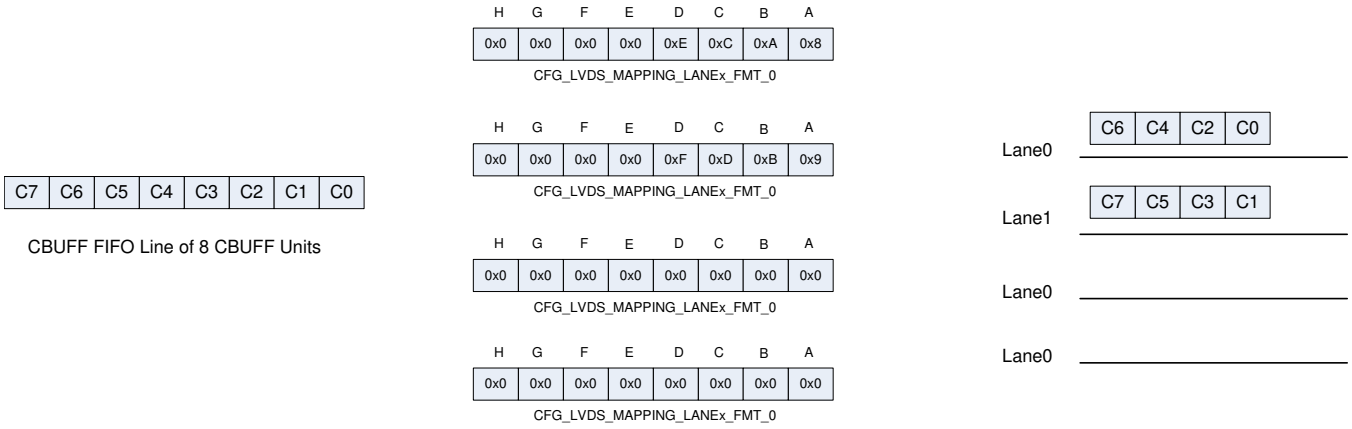
- CFG_LVDS_MAPPING_LANE0_FMT_0
- CFG_LVDS_MAPPING_LANE1_FMT_0
- CFG_LVDS_MAPPING_LANE2_FMT_0
- CFG_LVDS_MAPPING_LANE3_FMT_0

Consider the register for a LVDS Lane 0, CFG_LVDS_MAPPING_LANE0_FMT_0. It has 8 fields, CFG_LVDS_MAPPING_LANE0_FMT_1_A to CFG_LVDS_MAPPING_LANE3_FMT_1_H.

For each of the 4-bit fields, Bits [2:0] selects 1 of the 8 CBUFF units in a CBUFF FIFO line, which is mapped to this lane. Bit[3] is set to 0x1 to indicate it is a valid mapping.

Figure 14-4 is an example of the default use case for the 16xx/18xx/68xx device, where data is sent over 2 LVDS lanes. For more details, refer to the *AWR1xxx Data Path Programmer's Guide* API document.

Figure 14-4. Default Use Case



Where x is 0-3.

14.2.4.7 Input Data Format

The field CFG_DATA_LL[X].LL[X]_FMT_IN allows user to configure if all 128 bits in a CBUFF FIFO line are sent out over the interface, or if only the lower 96 bits in a 128-bit CBUFF FIFO line are send out over HSI and the rest are discarded. This is useful for 3-channel data stored in interleaved mode. For more details, refer to the *AWR1xxx Data Path Programmer's Guide* API document.

14.2.4.8 Size

The field CFG_DATA_LL[X].LL[X]_SIZE determines the size of the data for the given linklist. The value configured is the number of CBUFF units of data for the given linklist.

The minimum size of a link list is 2 CBUFF units. The maximum size is [16K -1] CBUFF units.

14.2.4.9 Long Packet Header

If the linklist is the start of a CSI2 packet, the field CFG_DATA_LL[X]_LPHDR_EN should be set to 0x1. When this field is set, the data in the register CFG_DATA_LL[X]_LPHDR_VAL is sent as the long packet header for the CSI2 packet. The long packet 32-bit header should be calculated as in Equation 2.

0xEC << 24 | [CSI2 packet size in bytes] << 8) | CSI2 Data Packet ID (2)

For more details, refer to the *AWR1xxx Data Path Programmer's Guide* API document.

14.2.4.10 EDMA Request Number

For Linklist 0, then CBUFF generates a DMA request to trigger the DMA transfer to trigger the transfer of data to be transmitted out for the chirp. The DMA request number to the EDMA can be configured in CFG_DATA_LL0_THRESHOLD.LL0DMAN.

14.2.5 CBUFF Interrupts

14.2.5.1 CBUFF Interrupt (DSS_CBUFF_IRQ)

The CBUFF interrupt can be generated on completion of data transmission for a chirp. To enable this interrupt generation from CBUFF, the field CFG_MASK_REG0[11] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_CBUFF_REG0.S_CHIRP_DONE interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_CBUFF_REG0.C_CHIRP_DONE field.

The CBUFF interrupt can be generated on completion of data transmission for a frame. To enable this interrupt generation from CBUFF, the field CFG_MASK_REG0[12] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_CBUFF_REG0.S_FRAME_DONE interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_CBUFF_REG0.C_FRAME_DONE field.

14.2.5.2 CBUFF Error Interrupt (DSS_CBUFF_ERR_IRQ)

The CBUFF Error interrupt can be generated if the CBUFF receives another Chirp Available hardware event trigger before completion of data transmission for the previous chirp. To enable this interrupt generation from CBUFF, the field CFG_MASK_REG1[16] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_CBUFF_REG1.S_CHIRP_ERR interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_CBUFF_REG1[16] field.

The CBUFF Error interrupt can be generated if the CBUFF receives another Frame Start hardware event trigger before completion of data transmission for the previous frame. To enable this interrupt generation from CBUFF, the field CFG_MASK_REG1[17] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_CBUFF_REG1.S_FRAME_ERR interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_CBUFF_REG1[17] field.

14.2.5.3 CBUFF Safety Interrupt (DSS_CBUFF_SAFETY_ERR)

The CBUFF Safety interrupt can be generated if the CBUFF receives another Chirp Available hardware event trigger before completion of data transmission for the previous chirp. To enable this interrupt generation from CBUFF, the field MASK_SAFETY[8] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_SAFETY.SAF_CHIRP_ERR interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_SAFETY[8] field.

The CBUFF Safety interrupt can be generated if the CBUFF detects a CRC error on the data from ADC buffer. To enable this interrupt generation from CBUFF, the field MASK_SAFETY[7:0] must be unmasked by clearing it. On an interrupt, the processor must read the STAT_SAFETY.SAF_CRC interrupt to confirm the event occurred. The processor should then clear the interrupt by writing 0x1 into the CLR_SAFETY[7:0] bits.

14.2.5.4 CBUFF ECC Interrupts (DSS_CBUFF_ECC_REPAIR_ERR and DSS_CBUFF_ECC_FATAL_ERR)

CBUFF can be enabled with ECC on its internal 128-bit wide FIFO by configuring the CONFIG_REG_0.CFG_ECC_EN field. To enable the interrupts to ESM for Single Bit Error (SBE) correction and Double Bit Error (DBE) detection, the interrupts should be unmasked by clearing the fields MASK_CBUFF_ECC_REG.MECCSBE and MASK_CBUFF_ECC_REG.MECCDBE. On an interrupt, processor must read the fields STAT_CBUFF_ECC_REG.SECCSBE and STAT_CBUFF_ECC_REG.SECCDBE to confirm an error was generated. If a status bit is set, then the field STAT_CBUFF_ECC_REG.SECCADD provides the FIFO address where the error occurred. The processor must then clear the status by writing to the register CLR_CBUFF_ECC_REG.CECCSBE and CLR_CBUFF_ECC_REG.CECCDBE and CLR_CBUFF_ECC_REG.CECCADD fields.

CBUFF programming: see the relevant CBUFF register programming in CSI2 and LVDS programming sections.

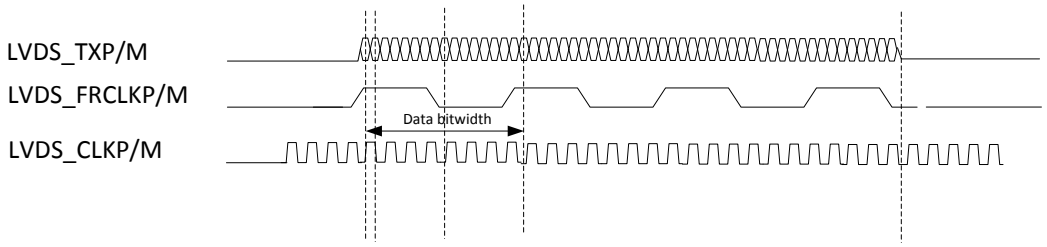
14.3 LVDS

14.3.1 LVDS Overview

The LVDS interface includes the following signals:

- LVDS bit clock
- LVDS data lanes (the HSI integration chapter specific to the device lists the number of available lanes specific to the device)
- LVDS frame clock
- LVDS data_valid signal (not supported in the 16xx/18xx/68xx)

Figure 14-5. LVDS Interface Timings



The LVDS interface supports the following data rates:

- 900 Mbps (450-MHz DDR Clock)
- 600 Mbps (300-MHz DDR Clock)
- 450 Mbps (225-MHz DDR Clock)
- 400 Mbps (200-MHz DDR Clock)
- 300 Mbps (150-MHz DDR Clock)
- 225 Mbps (112.5-MHz DDR Clock)
- 150 Mbps (75-MHz DDR Clock)

Refer to the device data sheet for more details.

14.3.2 LVDS Programming Sequence

The following sections show the programming sequence needed before the hardware triggers are generated to initiate the high-speed LVDS data transmission.

14.3.2.1 LVDS Global Initialization

Table 14-1. Main Sequence – PRCM and Global Configuration

Steps	Register/Bit Field/Programming	Value
Power on the LVDS I/Os	MSS_TOP_RCM. LVDSPADCTL0 MSS_TOP_RCM. LVDSPADCTL1	0x0 0x0
Power off the LVDS I/Os	MSS_TOP_RCM. LVDSPADCTL0 MSS_TOP_RCM. LVDSPADCTL1	0x01010101 0x010101
Power on the LVDS I/Os	MSS_TOP_RCM. LVDSPADCTL0 MSS_TOP_RCM. LVDSPADCTL1	0x0 0x0

14.3.2.2 CBUFF Configuration

Table 14-2. Main Sequence – CBUFF LVDS Static Configuration

Steps	Register/Bit Field/Programming	Value
Assert the CBUFF soft reset	CONFIG_REG_0.CSWCRST	0x1
Configure CBUFF for LVDS data transfer	CONFIG_REG_0.CFG_1LVDS_0CSI__POS	0x1
Configure static values for LVDS	CONFIG_REG_0.CVC0EN	
	CFG_SPHDR_ADDRESS	0x3
	CFG_CMD_VSVAL	0x55555555
	CFG_CMD_VEVAL	0xAAAAAAAA
	CFG_LPHDR_ADDRESS	0xAAAAAAAA
	CFG_LVDS_GEN_0.CCSMEN	0x1
Configure the number of chirps in a frame	CFG_CHIRPS_PER_FRAME	X
Configure static values for LVDS based on LVDS CRC enabled or disabled	CFG_LVDS_GEN_0.CBCRCEN CFG_CMD_HEVAL CFG_CMD_HSVAL	X
Enable the LVDS lanes	CFG_LVDS_GEN_0.CFG_LVDS_LANE[X]_EN	0x1
Set the SDR or DDR mode	CFG_LVDS_GEN_0.CFG_BIT_CLK_MODE	0x-
Set the SDR or DDR mode clock mux	CFG_LVDS_GEN_0.CCLKSEL1	0x-
Configure the alignment for start of samples	CFG_LVDS_GEN_0.CPOSSEL	0x-
Configure the LVDS FIFO initial threshold	CFG_LVDS_GEN_0.CFDLY	0x8
Set the 3C3L mode if the system configuration is interleaved 3 channel – 3 lane	CFG_LVDS_GEN_1.C3C3L	0x-
Configure the lane-mapping format registers	CFG_LVDS_MAPPING_LANE[X]_FMT_0 CFG_LVDS_MAPPING_LANE[X]_FMT_1	X
Release the CBUFF from soft reset	CONFIG_REG_0.CSWCRST	0x0

The configuration in Table 14-3 should be performed for each linklist entry required to transmit the LVDS packet.

Table 14-3. Main Sequence – CBUFF Linklist

Steps	Register/Bit Field/Programming	Value
Set the valid for the linklist	CFG_DATA_LL[X].LL[X]_VALID	0x1
If the linklist is the start of a new LVDS packet	CFG_DATA_LL[X].LL[X]_LPHDR_EN CFG_DATA_LL[X].LL[X]_HS	0x-
Configure the long packet header to static value for LVDS	CFG_DATA_LL[X]_LPHDR_VAL	0xBBBBBBBB
If the linklist is the end of a LVDS packet	CFG_DATA_LL[X].LL[X]_HE	0x-
Configure the size in CBUFF units	CFG_DATA_LL[X].LL[X]_SIZE	X
Configure the format of the CSI2 packet to which the linklist belongs	CFG_DATA_LL[X].LL[X]_FMT	X
Select the LVDS format-mapping register for the LVDS packet	CFG_DATA_LL[X].LL[X]_FMT_MAP	0x-
Set the input format	CFG_DATA_LL[X].LL[X]_FMT_IN	X
Set the Linklist write threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_WR_THRESHOLD	X

Table 14-3. Main Sequence – CBUFF Linklist (continued)

Steps	Register/Bit Field/Programming	Value
Set the Linklist read threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_WR_THRESHOLD	X

14.3.3 CBUFF and LVDS Registers

14.3.3.1 DSS_CBUFF Registers

Table 14-4 lists the memory-mapped registers for the DSS_CBUFF. All register offset addresses not listed in Table 14-4 should be considered as reserved locations and the register contents should not be modified.

Table 14-4. DSS_CBUFF Registers

Offset	Acronym	Register Name	Section
0h	CONFIG_REG_0	CONFIG_REG_0	Section 14.3.3.1.1
4h	CFG_SPHDR_ADDRESS	CFG_SPHDR_ADDRESS	Section 14.3.3.1.2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU2	LL31_WR_THRESHOLD							NU1	LL31_RD_THRESHOLD						
R-0h	R/W-3Fh							R-0h	R/W-0h						

Table 14-111. CFG_DATA_LL31_THRESHOLD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	NU3	R	0h	
18-16	ll31dman	R/W	0h	If the long Packet Header is enabled, CBUFF can generate a DMA request to trigger the DMA trasnfer for the new packet 0 : Send a Request on DMA HW Req output line 0 1 : Send a Request on DMA HW Req output line 1 2 : Send a Request on DMA HW Req output line 2 3 : Send a Request on DMA HW Req output line 3 4 : Send a Request on DMA HW Req output line 4 5 : Send a Request on DMA HW Req output line 5 6 : Send a Request on DMA HW Req output line 6 7 : Do not generate dma trigger
15	NU2	R	0h	
14-8	LL31_WR_THRESHOLD	R/W	3Fh	Configure the CBUFF FIFO Write threshold over which CBUFF will stall the DMA write to the CBUFF. Static configuration. This can be programmed to fixed value mentioned in the Programming Model
7	NU1	R	0h	
6-0	LL31_RD_THRESHOLD	R/W	0h	Configure the CBUFF Read threshold to be Reached before sending the data over CSI2/LVDS and start draining the CBUFF FIFO. Static configuration. This can be programmed to fixed value mentioned in the Programming Model

14.3.3.1.107 CFG_LVDS_MAPPING_LANE0_FMT_0 Register (Offset = 1B0h) [reset = 0h]

CFG_LVDS_MAPPING_LANE0_FMT_0 is shown in Figure 14-112 and described in Table 14-112.

Return to Summary Table.

14.4 CSI2

14.4.1 CSI2 Overview

The CSI-2 Specification defines standard data transmission and control interfaces between transmitter and receiver. The data transmission interface (referred as CSI-2) is a unidirectional differential serial interface with data and clock signals; the physical layer of this interface is the MIPI Alliance Specification for D-PHY.

The physical layer for a CSI-2 implementation is composed of four unidirectional data lanes and one clock lane.

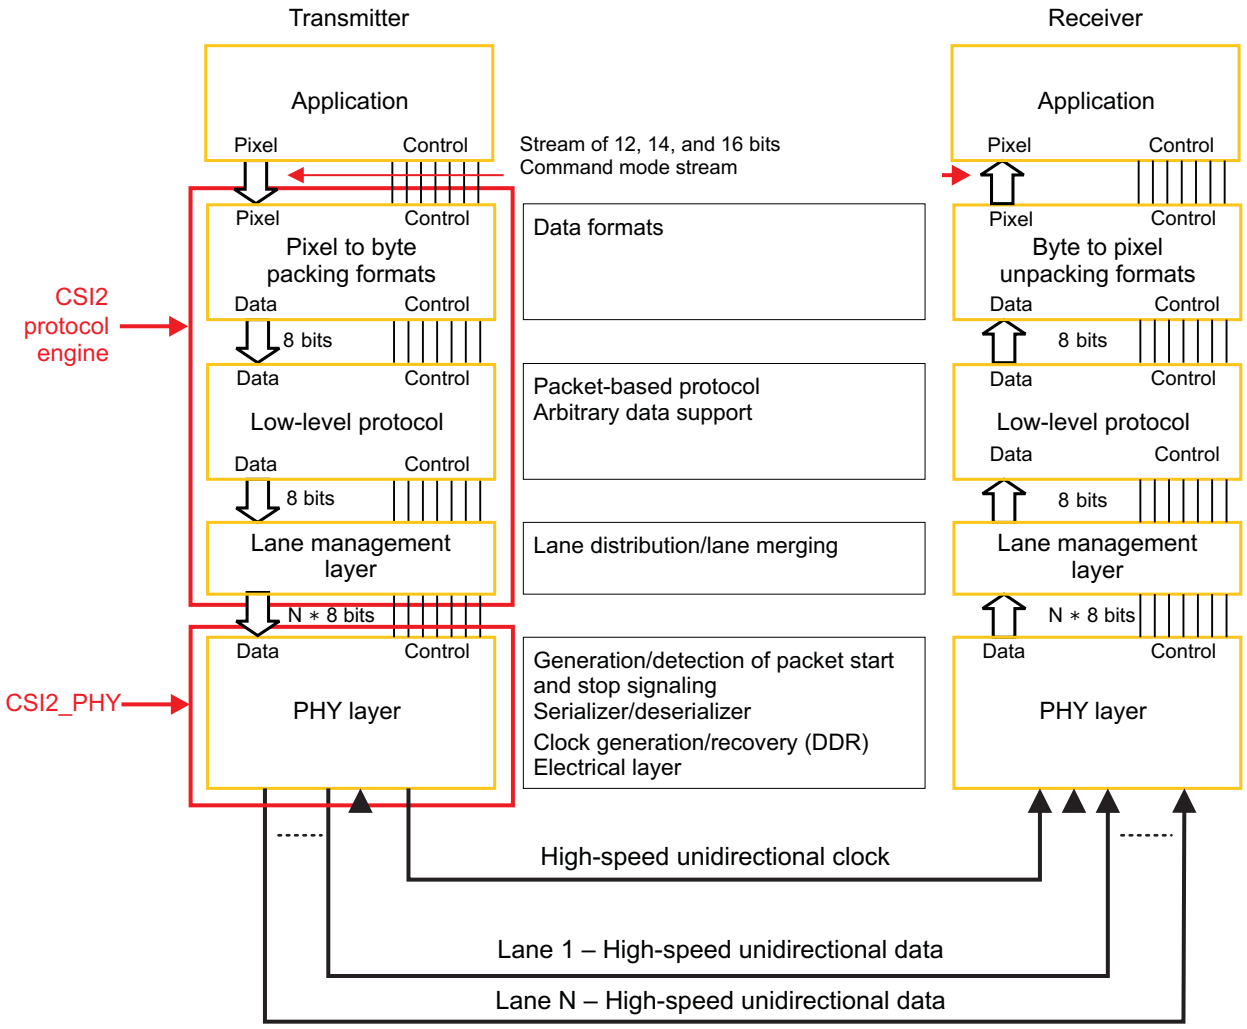
Main features:

- Supports MIPI-CSI2 (up to four data lanes and one clock lane)
- Supports command mode only
- RAW8, RAW12, and RAW14 formats are supported for command mode
- Supports up to four data-configurable lanes, in addition to the clock signaling
- Maximum data rate of 600 Mbps per data pair for four-data lane configuration, and 900 Mbps for up to three-data lane configuration
- Data splitter for 2-data, 3-data, and 4-data lane configurations
- Connection to the CSI2_PHY complex I/O through PPI
- Error-correction code (ECC) and checksum generation

14.4.1.1 CSI2 Environment

Figure 14-138 shows the high-level data flow of the CSI2 transmitter/receiver.

Figure 14-138. CSI2 Transmitter/Receiver Data Flow



14.4.1.1.1 CSI2 PHY

Table 14-138 lists the CSI2 I/Os.

Table 14-138. I/O Description of CSI2

Signal Name		I/O[1]	Description	Value at Reset
CSI2_dx0 CSI2_dy0	lane 1	I/O	Serial data/clock lane	N/A
CSI2_dx1 CSI2_dy1	lane 2	I/O	Serial data/clock lane	N/A
CSI2_dx2 CSI2_dy2	lane 3	I/O	Serial data/clock lane	N/A
CSI2_dx3 CSI2_dy3	lane 4	I/O	Serial data/clock lane	N/A
CSI2_dx4 CSI2_dy4	lane 5	I/O	Serial data lane only	N/A

(1) I = Input; O = Output; I/O = Bidirectional

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- Off mode: Lane is off.

NOTE: The DSS_REG:CSI_CFG1 register in the DSS_REG of the device provides the following control over the CSI2 lanes:

- Enable and disable each lane
- Pulldown enable and disable on each lane

14.4.1.1.1.1 Data/Clock Configuration

Data-clock signaling consists of one to four data pairs and one clock pair. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit serial data. The CSI2 transmitter in the host sends the data in-quadrature with the dual data rate (DDR) clock in HS mode. The data is transmitted byte-wise LSB first.
- The clock signal carries the DDR clock signal in HS transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each CSI2_PHY into bytes.

Table 14-139 lists some of the CSI2 lane configurations.

NOTE: All combinations for the order of the clock and data lanes are supported (except clock cannot be on lane 5) but not explicitly described in Table 14-139.

Table 14-139. CSI2 Lane Configuration

CSI2_PHY Lane Configuration	Data/Clock Lane Position					Description
	1	2	3	4	5	
Mode CLK + DATA1						Single data lane

14.4.1.1.2 Low Level Protocol

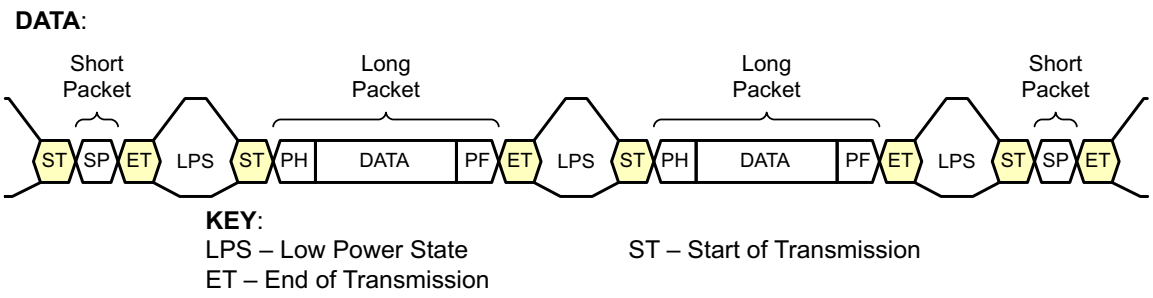
The Low Level Protocol (LLP) is a byte orientated, packet-based protocol that supports the transport of arbitrary data using short and long packet formats. For simplicity, all examples in this section are single lane configurations.

Low level protocol features:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 14-139 shows the protocol layer with short and long packets.

Figure 14-139. Low Level Protocol Packet Overview



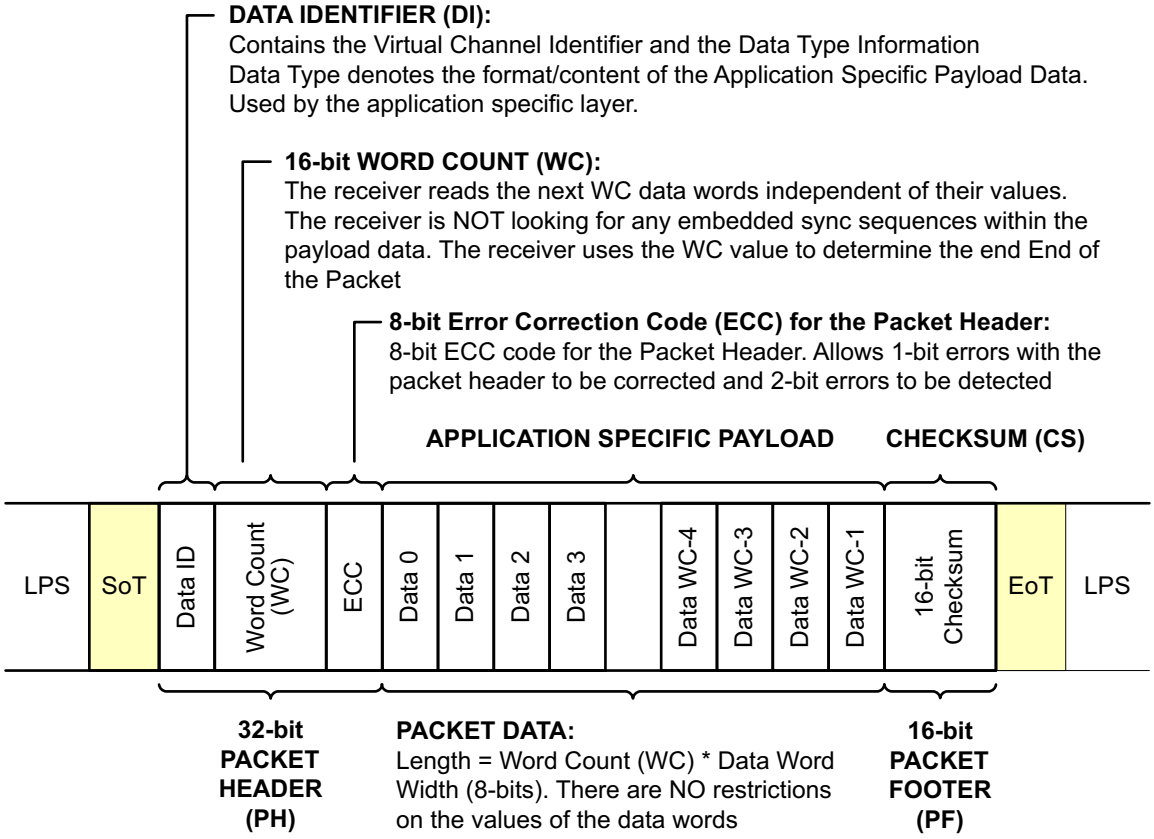
14.4.1.1.2.1 Low-Level Protocol Packet Format

Two packet structures are defined for low-level protocol communication: long packets and short packets. For each packet structure exit from the low-power state, the start of transmission (SoT) sequence indicates the start of the packet. The end of transmission (EoT) sequence, followed by the low-power state, indicates the end of the packet.

14.4.1.1.2.1.1 Low-Level Protocol Long Packet Format

Figure 14-140 shows the structure of the low level protocol long packet. A long packet is identified by data types 0x10 to 0x37. See Table 14-140 for a description of the data types. A long packet consists of three elements: a 32-bit packet header (PH), an application-specific data payload with a variable number of 8-bit data words, and a 16-bit packet footer (PF). The packet header is further composed of three elements: an 8-bit data identifier, a 16-bit word count field, and an 8-bit ECC. The packet footer has one element, a 16-bit checksum. See Section 14.4.1.1.2.2 through Section 14.4.1.1.2.3.2 for further descriptions of the packet elements.

Figure 14-140. Long Packet Structure



The data identifier defines the virtual channel for the data and the data type for the application-specific payload data.

The word count defines the number of 8-bit data words in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer shall be included in the word count.

The error correction code (ECC) byte allows single-bit errors to be corrected, and 2-bit errors to be detected in the packet header. This includes both the data identifier value and the word count value.

After the end of the packet header, the receiver reads the next word count 8-bit data words of the data payload. While reading the data payload, the receiver does not look for any embedded sync codes. Therefore, there are no limitations on the value of a data word.

When the receiver has read the data payload, it reads the checksum in the packet footer. In the generic case, the length of the data payload is a multiple of 8-bit data words. In addition, each data format may impose additional restrictions on the length of the payload data, such as a multiple of four bytes.

Each byte is transmitted least significant bit first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multi-byte elements such as word count, checksum, and the short packet 16-bit data field are transmitted least significant byte first.

After the EoT sequence, the receiver begins looking for the next SoT sequence.

14.4.1.1.2.2 Short Packet

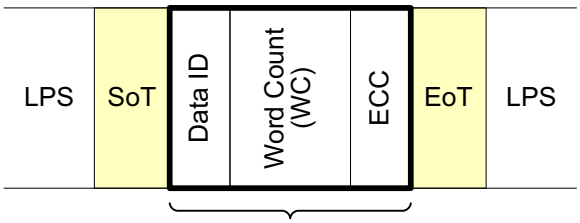
Figure 14-141 shows the structure of the low level protocol short packet. A short packet is identified by data types 0x00 to 0x0F. See Table 14-140 for a description of the data types. A short packet contains only a packet header; a packet footer is not present. The word count field in the packet header is replaced by a short packet data field.

For frame synchronization data types, the short packet data field is the frame number. For line synchronization data types, the short packet data field is the line number.

For generic short packet data types, the content of the short packet data field is user-defined.

The error correction code (ECC) byte allows single-bit errors to be corrected, and 2-bit errors to be detected in the short packet.

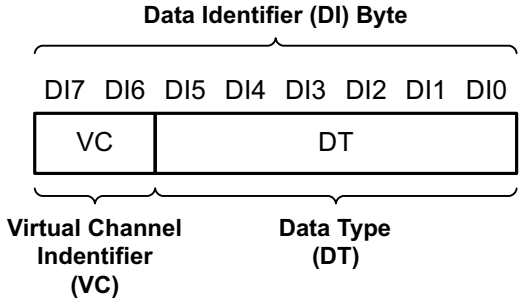
Figure 14-141. Short Packet Structure



14.4.1.1.2.3 Data Identifier (DI)

The data identifier byte contains the virtual channel identifier (VC) value and the data type (DT) value, as shown in Figure 14-142. The virtual channel identifier is contained in the 2 MS bits of the data identifier byte The data type value is contained in the six LS bits of the data identifier byte.

Figure 14-142. Data Identifier Byte



14.4.1.1.2.3.1 Virtual Channel Identifier

The purpose of the virtual channel identifier is to provide separate channels for different data flows interleaved in the data stream.

The virtual channel identifier number is in the top two bits of the data identifier byte. The receiver monitors the virtual channel identifier and de-multiplexes the interleaved video streams to their appropriate channel. A maximum of four data streams is supported; valid channel identifiers are 0 to 3. The virtual channel identifiers in the peripherals should be programmable, to allow the host processor to control how the data streams are de-multiplexed. The principle of logical channels is presented in Figure 14-143.

Figure 14-143. Logical Channel Block Diagram (Receiver)

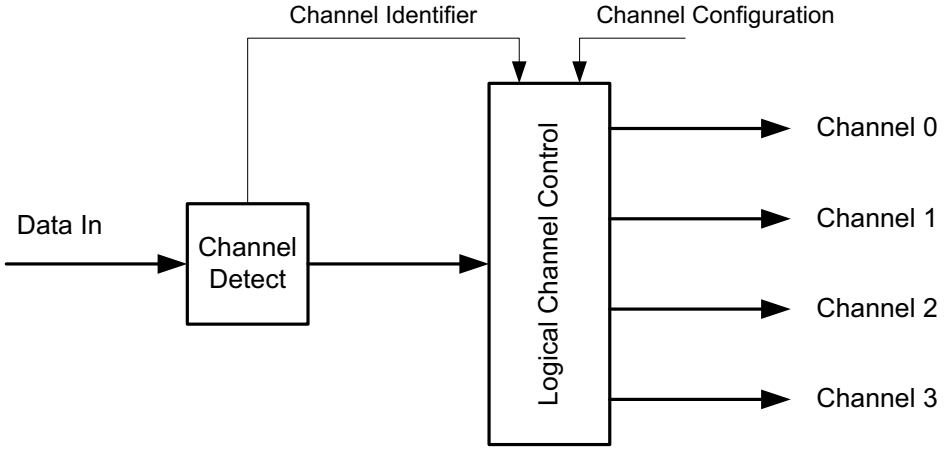


Figure 14-144 illustrates an example of data streams utilizing virtual channel support.

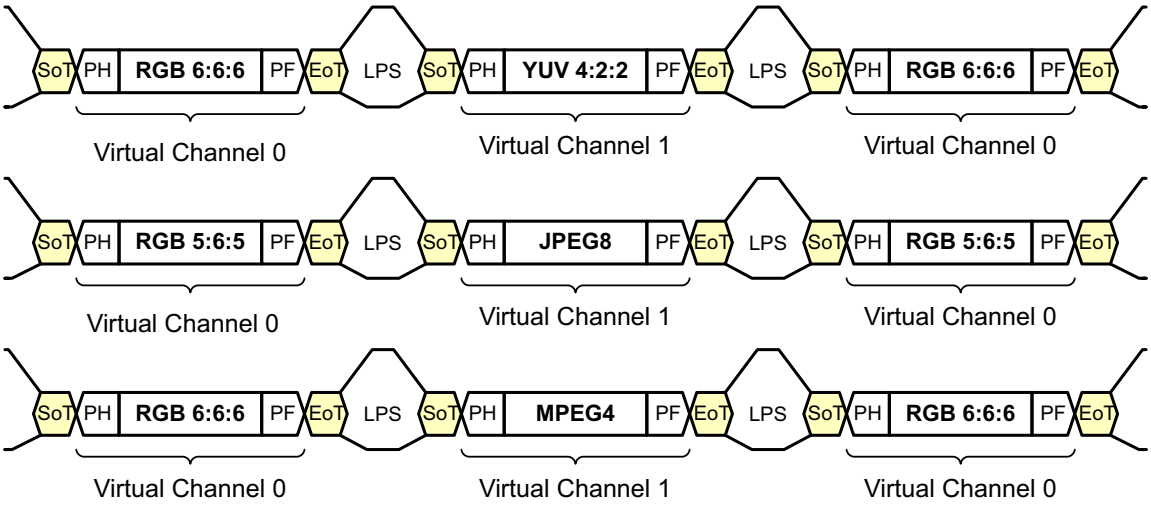
Figure 14-144. Interleaved Video Data Streams Examples



KEY:
LPS – Low Power State
SoT – Start of Transmission
EoT – End of Transmission
PH – Packet Header
PF – Packet Footer

14.4.1.1.2.3.2 Data Type (DT)

The data type value specifies the format and content of the payload data. A maximum of sixty-four data types are supported.

There are eight different data type classes, as shown in Table 14-140. Within each class, there are up to eight different data type definitions. The first two classes denote short packet data types. The remaining six classes denote long packet data types.

Table 14-140. Data Type Classes

Data Type	Description
0x00 to 0x07	Synchronization short packet data types
0x08 to 0x0F	Generic short packet data types
0x10 to 0x17	Generic long packet data types
0x18 to 0x1F	YUV data
0x20 to 0x27	RGB data
0x28 to 0x2F	RAW data
0x30 to 0x37	User-defined byte-based data
0x38 to 0x3F	Reserved

14.4.1.1.3 CSI2 Multilane Layer

A layer consists of lane splitter logic to split the incoming byte stream into a serial stream. The bits are sent with the LSB first. The number of active lanes is configurable through a register. The order of the lanes is configurable. The number of lanes can be changed only in ULPS or when all data lanes are in STOP state.

14.4.1.1.3.1 SoT and EoT in Multilane Configurations

Because a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its valid data signal into lanes for which there is no further data. Although all lanes start simultaneously with parallel start-of-transmissions (SoTs), each lane operates independently and may complete the HS transmission before the other lanes, sending an end-of-transmission (EoT) one cycle (byte) earlier.

14.4.1.1.3.2 Lane Splitter

The lane splitter can split the byte stream into two, three, or four lanes (for one lane, the splitter is bypassed). Figure 14-145 through Figure 14-148 show the byte position in each serial link for one-, two-, three-, and four-data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is used only when packets are sent using HS mode. In LS mode, only data lane 1 is used.

Figure 14-145. Four-Data Lane Configuration

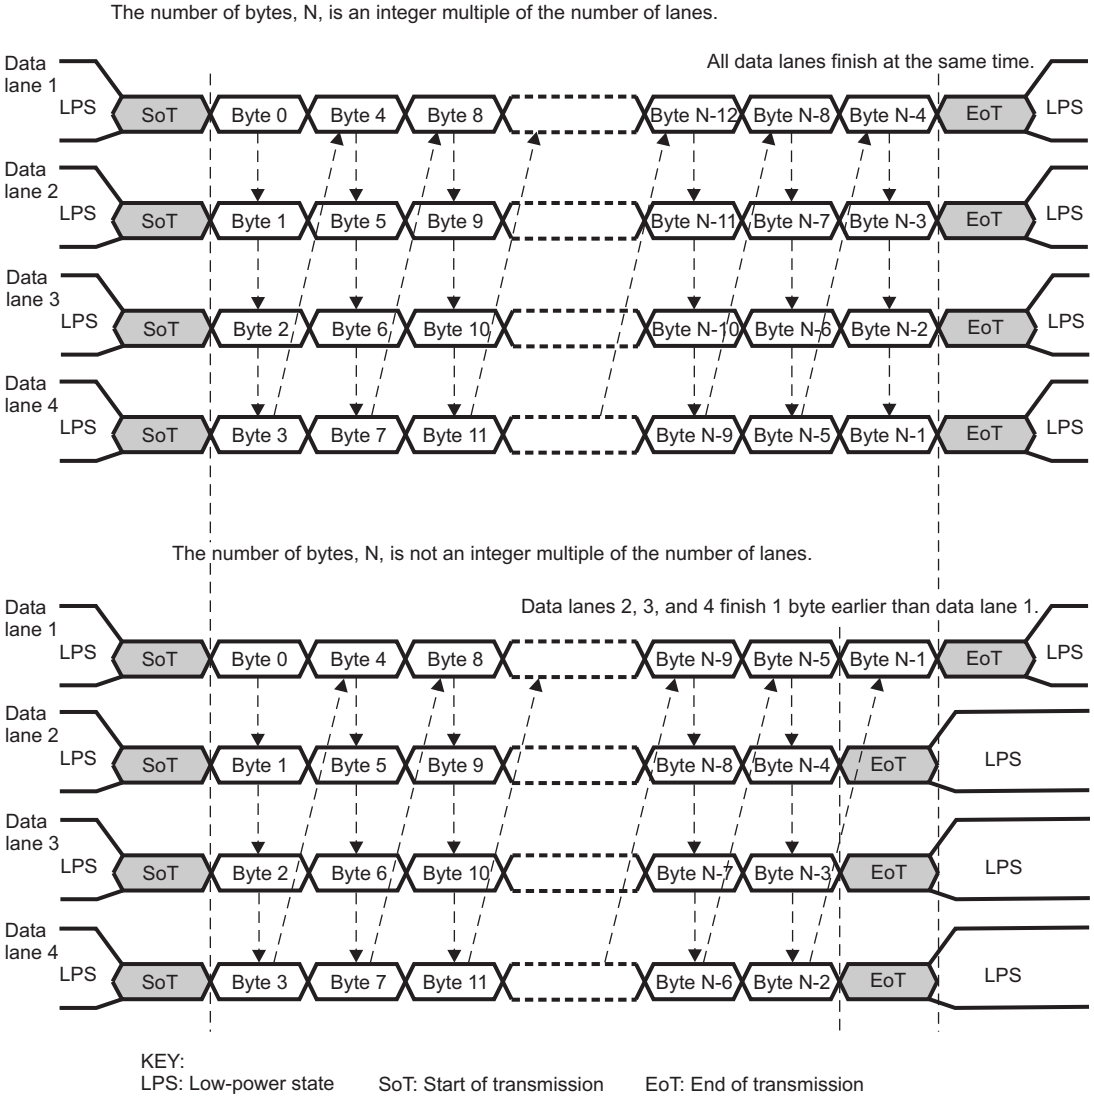


Figure 14-146. Three-Data Lane Configuration

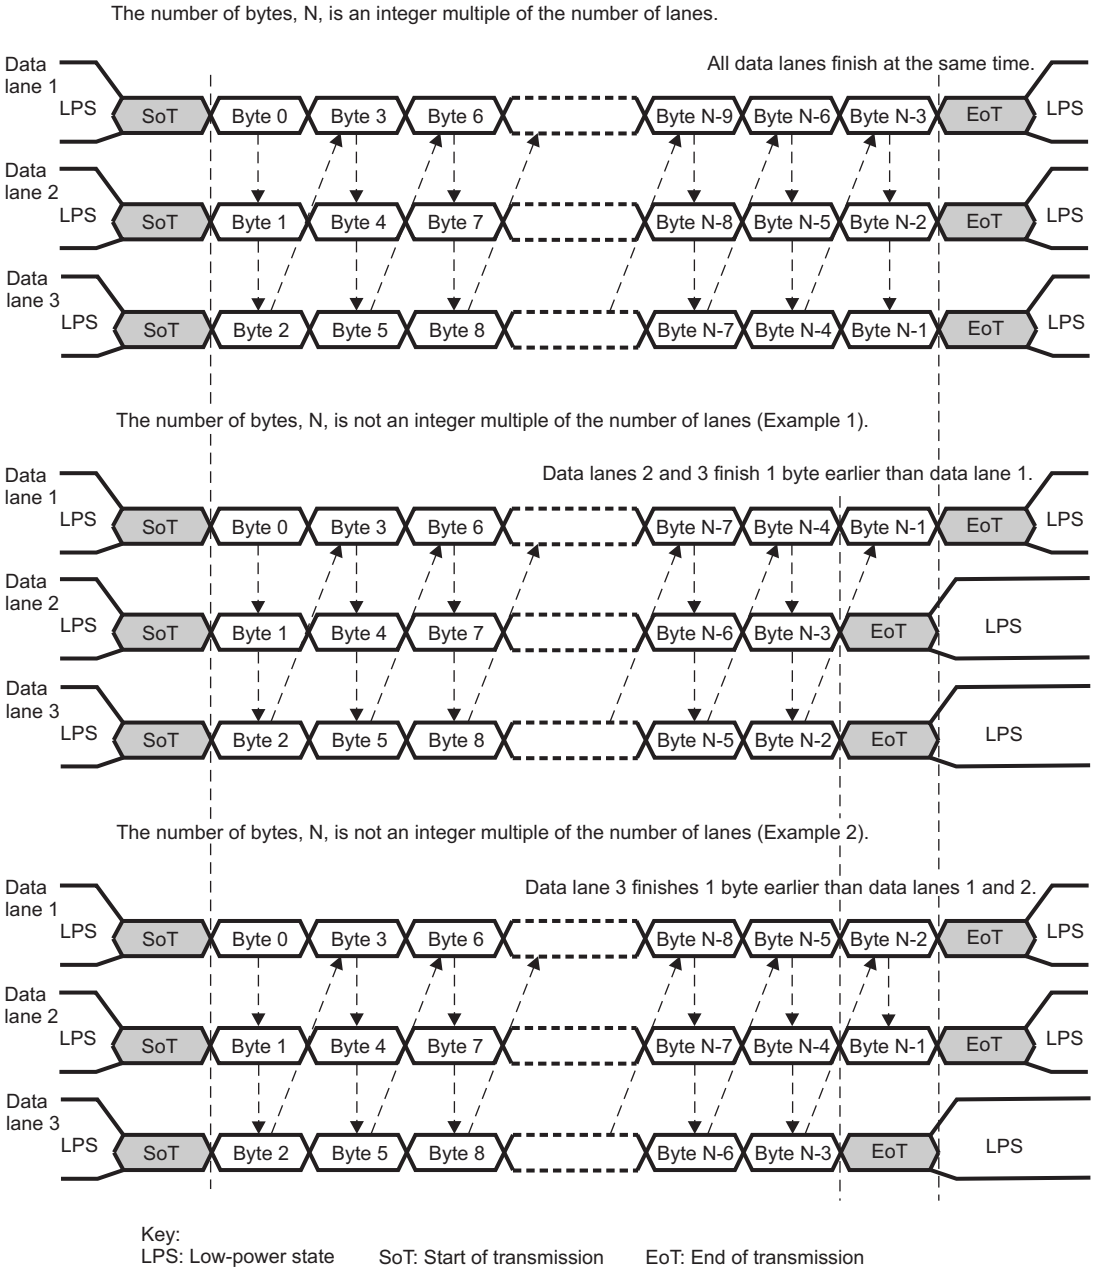

Figure 14-147. Two-Data Lane Configuration

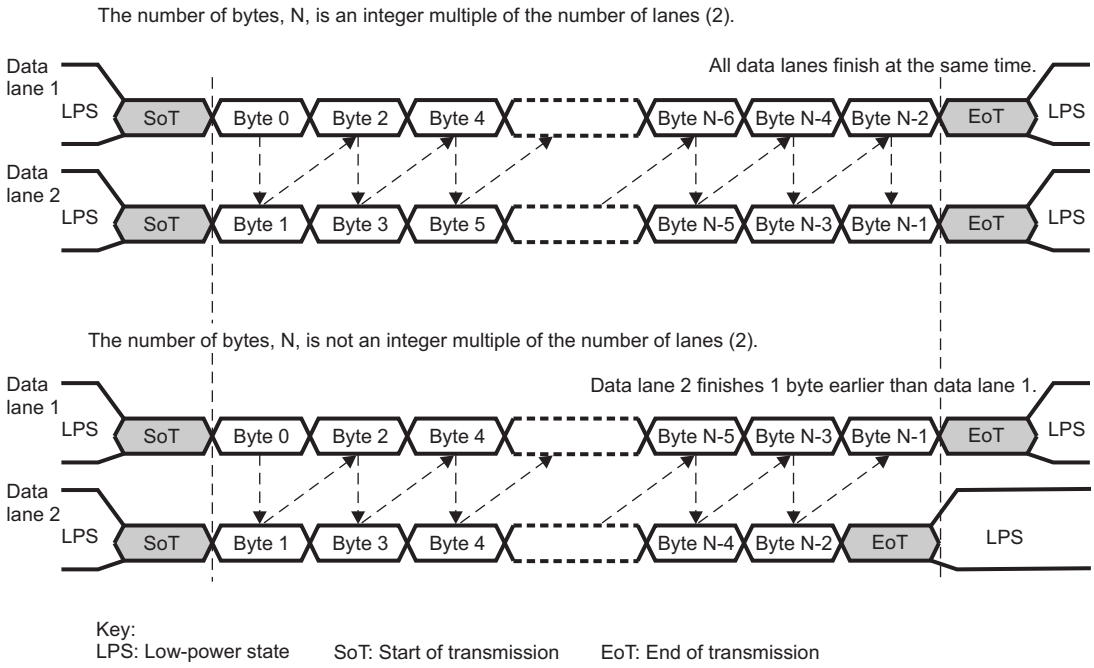

Figure 14-148. One-Data Lane Configuration

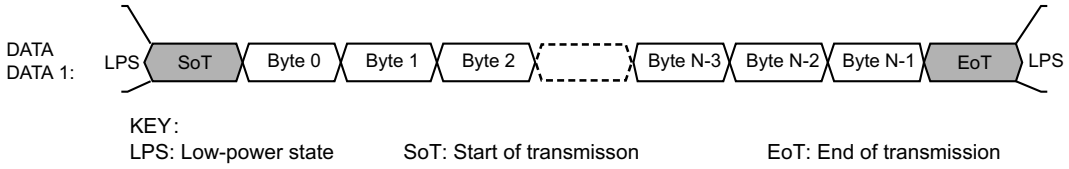


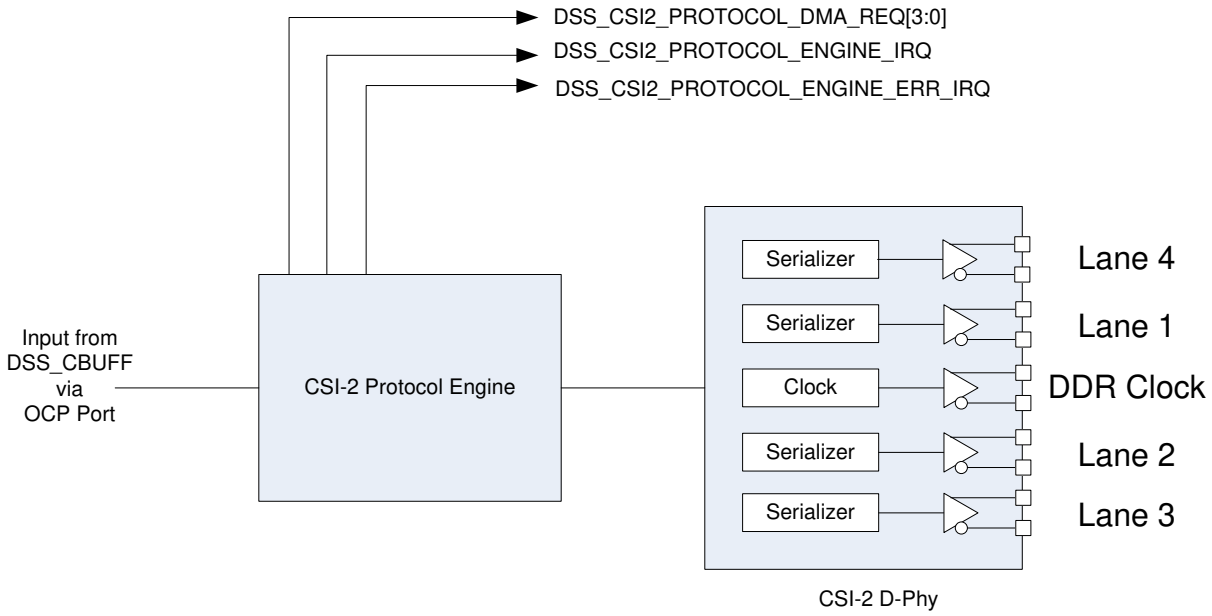
14.4.2 CSI2 Protocol Engine and Phy

This section describes the functions of the CSI2 module.

14.4.2.1 CSI2 Protocol Overview

The CSI2 protocol engine receives data from the common buffer, generates the ECC and checksum, and splits the data into byte streams to the CSI2_PHY to be sent using HS protocol.

Figure 14-149. CSI2 Protocol Engine



14.4.2.2 CSI2 Global Register Controls

Before receiving data from the CSI2 complex I/O, the CSI2_PHY SCP registers in the CSI2 complex I/O must be configured. Table 14-141 lists the register access width limitations for all the CSI2 modules.

Table 14-141. Register Access Width Limitations

Register Name	Register Access Width
All CSI2 complex I/O registers (CSI2_PHY SCP)	32-bit only
CSI2_VC_LONG_PACKET_HEADER_i	32-bit only
CSI2_VC_SHORT_PACKET_HEADER_i	32-bit only
CSI2_VC_LONG_PACKET_PAYLOAD_i	16- and 32-bit
All other CSI2 protocol engine registers	8-, 16-, and 32-bit

The CSI2 protocol engine is globally controlled by the CSI2_CTRL register. The interface to the complex I/O is enabled by setting the CSI2_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the CSI2_CTRL[0] IF_EN bit is set to 1, the pending packets are sent to the CSI2 complex I/O.

14.4.2.3 CSI2 Transfer Modes

14.4.2.3.1 Command Mode

The CSI2_VC_LONG_PACKET_HEADER registers are used for the header of long packets; the CSI2_VC_SHORT_PACKET_HEADER registers are used for the short packets.

For the payload, the CSI2_VC_LONG_PACKET_PAYLOAD register is used. Each 32-bit payload data is written to the CSI2_VC_LONG_PACKET_PAYLOAD register from the CBUFF.

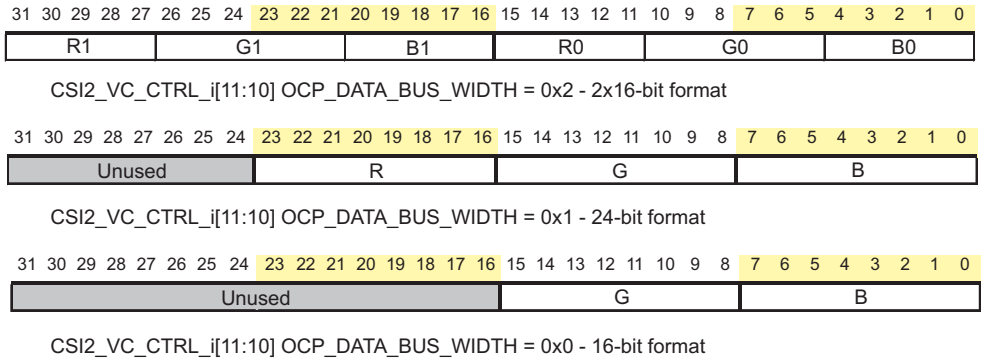
The CSI2_VC_CTRL_i[11:10] OCP_DATA_BUS_WIDTH bit field is used to define the size of the data on the slave port for the write access:

- 0x0: 16-bit data width (LSB of the 32-bit interface port data bus)
- 0x1: 24-bit data width (LSB of the 32-bit interface port data bus)
- 0x2: 2x16-bit data width (first pixel on the LSB of the 32-bit Interface port data bus and second pixel on the MSB of the 32-bit interface port data bus for the same interface access)
- 0x3: 32-bit data width (no bit, no byte, no pixel manipulation)

The device only uses the mode with 0x3.

Figure 14-150 shows the different data width configurations of the L3 interconnect slave port.

Figure 14-150. Interface Data Configuration



The write into the CSI2_VC_LONG_PACKET_HEADER_i register is required before accessing the CSI2_VC_LONG_PACKET_PAYLOAD_i register. The CSI2 protocol engine must extract the length of the payload and discard the extra data sent using the CSI2_VC_LONG_PACKET_PAYLOAD_i register. Writes into the CSI2_VC_LONG_PACKET_HEADER_i register are valid only if the VC is enabled; otherwise, the write is ignored.

The device always uses the VC_0 FIFO and the registers in the protocol engine. VC management is within the CBUFF.

14.4.2.4 Clock Requirements

The serial clock generated by the CSI2 host must be a continuous clock. It is software-programmed through the CSI2_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit: This bit can be programmed only when the interface is disabled (the CSI2_CTRL[0] IF_EN bit set to 0).

The CSI2_CLK_CTRL[20] LP_CLK_ENABLE bit is used to enable or disable the clock. When disabled, the value of the CSI2_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field is ignored and does not have to be programmed by software users.

14.4.2.4.1 Timing Parameters for an LP to HS Transaction

Figure 14-151 shows the timing requirement when switching the data and clock lane state from LP to HS.

lists the LP to HS timing parameters.

Figure 14-151. LP to HS Timing

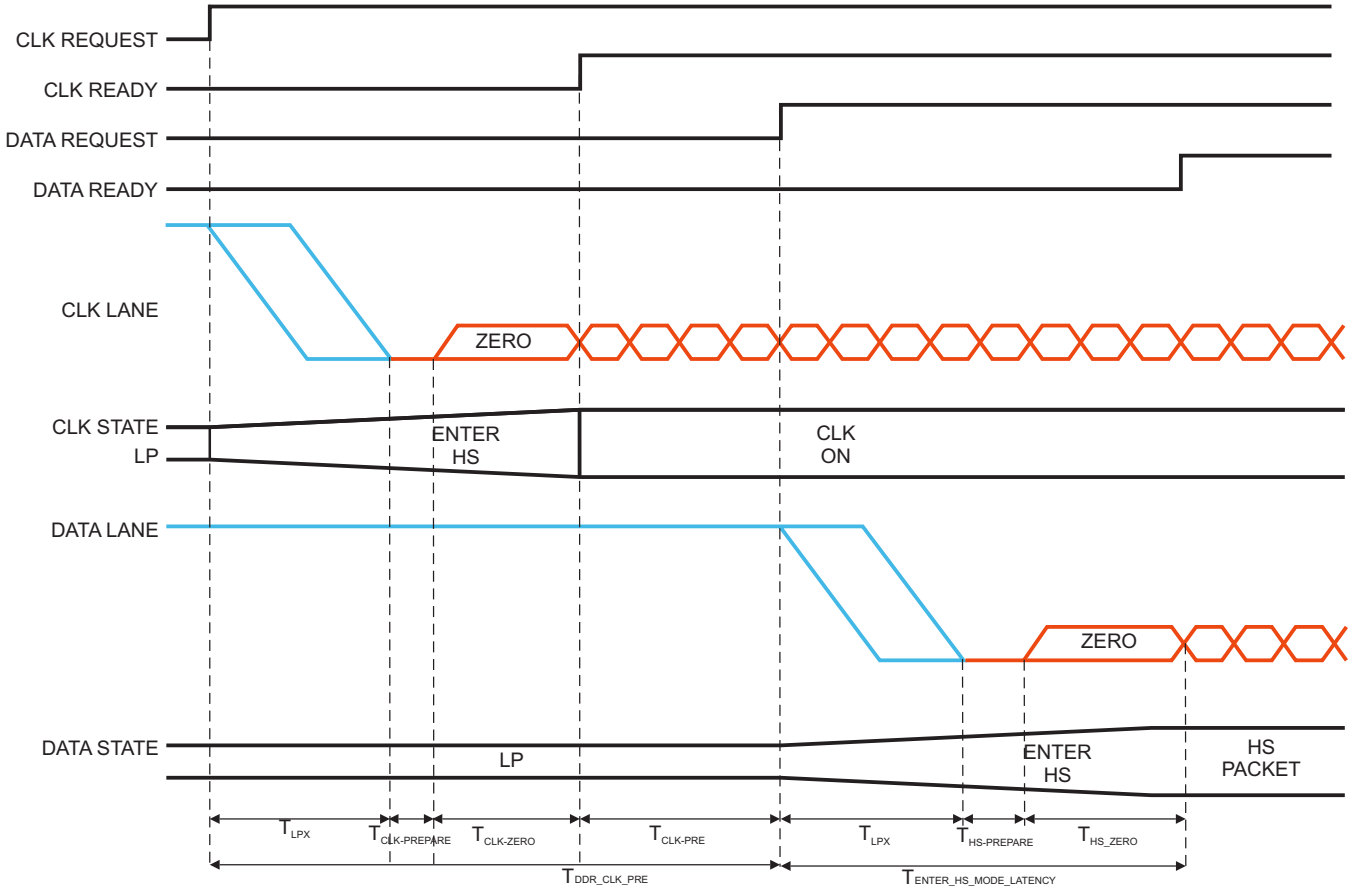


Table 14-142. LP to HS Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{LPX}	Length of any low-power state period	CSI2_PHY_REGISTER1[20:16] REG_TLPXBY2 The value set in this bit field is half of the T_{LPX}	CEIL (25 ns / DDR_Clock_Period)	CEIL (2 * REG_TLPXBY2/4) * 4 * DDR_Clock_Period
$T_{CLK-PREPARE}$	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	CSI2_PHY_REGISTER2[7:0] REG_TCLKPREPARE	CEIL (65 ns / DDR_Clock_Period)	REG_TCLKPREPARE * DDR_Clock_Period + (~– 25 ns – +5 ns)
$T_{CLK-ZERO}$	Time to drive the CLK lane to HS-0 state, before starting the clock	CSI2_PHY_REGISTER1[7:0] REG_TCLKZERO	CEIL (265 ns / DDR_Clock_Period)	{CEIL [(REG_TCLKZERO + 3)/4] * 4 + CEIL (REG_TCLKPREPARE/4) * 4 – REG_TCLKPREPARE + 2} * DDR_Clock_Period + (~ 0 ns – +5 ns)
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode	N/A	N/A	DDR_CLK_PRE - T_{LPX} - $T_{CLK-PREPARE}$ - $T_{CLK-ZERO}$
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	CSI2_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL (70 ns / DDR_Clock_Period) + 2	REG_THSPREPARE * DDR_Clock_Period + (–26.5 ns – + 4 ns)
$T_{HS-ZERO}$ + $T_{HS-PREPARE}$	$T_{HS-ZERO}$: Time to drive the data lane to HS-0 state before the synchronous sequence.	CSI2_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	CEIL (175 ns / DDR_Clock_Period) + 2	{CEIL [(N + 3)/4] * 4 + CEIL (M/4) * 4 + 3} * DDR_Clock_Period + (~ – 29 ns – 0 ns). Where N = REG_THSPREPARE_THSZERO – REG_THSPREPARE M = REG_THSPREPARE
$T_{DDR\_CLK\_PRE}$	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	CSI2_CLK_TIMING[15:8] DDR_CLK_PRE	CEIL [(T_{LPX} + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$) / $T_{TXBYTECLKHS}$] (1)(2)	
$T_{ENTER\_HS\_MODE\_LATENCY}$ (3)	Time to enter data lane into HS mode.	CSI2_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	CEIL [(T_{LPX} + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$) / $T_{TXBYTECLKHS}$] (1)	

(1) The timings seen on the line should be used to determine the register value.
(2) See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.
(3) ENTER_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 14-143, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz.

Table 14-143. LP to HS Timing Parameters Example for 400-MHz DDR Clock

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line
T_{LPX}	CSI2_PHY_REGISTER1[20:16] REG_TLPXBY2	10	50 ns
$T_{CLK-PREPARE}$	CSI2_PHY_REGISTER2[7:0] REG_TCLKPREPARE	26	40–70 ns
$T_{CLK-ZERO}$	CSI2_PHY_REGISTER1[7:0] REG_TCLKZERO	106	280–285 ns

Table 14-143. LP to HS Timing Parameters Example for 400-MHz DDR Clock (continued)

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line
$T_{CLK-PRE}$ (1)	N/A	N/A	80 ns
$T_{HS-PREPARE}$	CSI2_PHY_REGISTER0[31:24] REG_THSPREPARE	30	48.5–79 ns
$T_{HS-ZERO}$	CSI2_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	72	178.5–207.5 ns
$T_{DDR\_CLK\_PRE}$	CSI2_CLK_TIMING[15:8] DDR_CLK_PRE	45–49 (2)	450–490 ns
$T_{ENTER\_HS\_MODE\_LATENCY}$	CSI2_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	24 * $T_{TXBYTECLKHS}$ or 96 * DDR_CLOCK 34 * $T_{TXBYTECLKHS}$ or 136 * DDR_CLOCK (2)	277–336.5 ns

(1) See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.
(2) Register setting calculated based on the values in the Timing Seen on the Line column.

14.4.2.4.2 Timing Parameters for an HS to LP Transaction

Figure 14-152 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. lists the HS to LP timing parameters.

Figure 14-152. HS to LP Timing

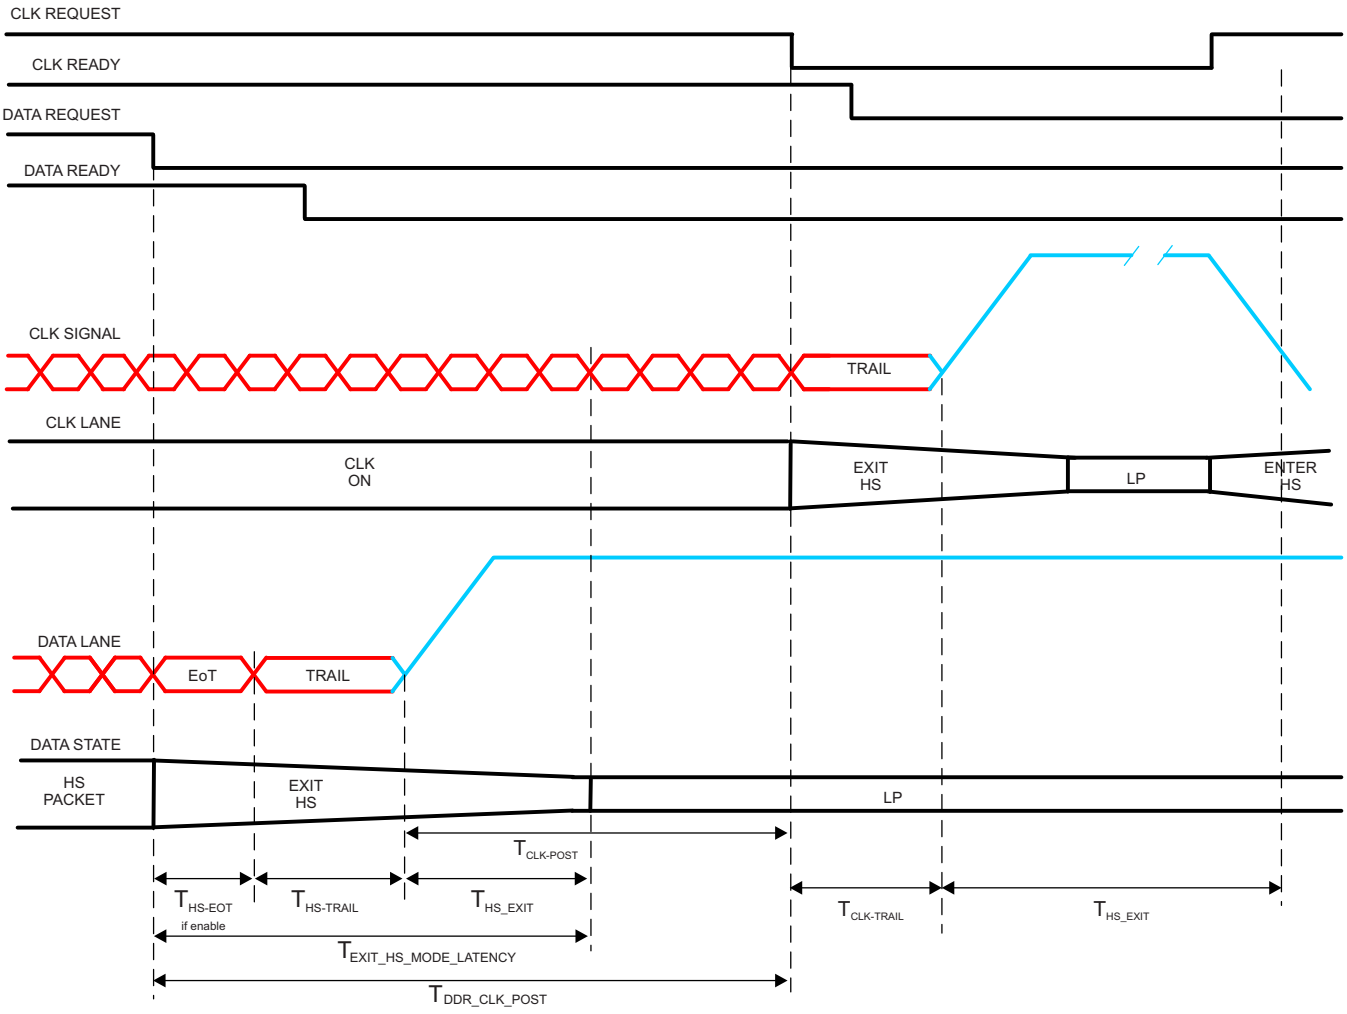

Table 14-144. HS to LP Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{HS-EOT}	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes.	N/A	N/A	DIVROUNDUP (4, NB_DATA_LANES) Thus: One data lane = Four DDR clocks Two data lanes = Two DDR clocks
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of an HS transmission burst	CSI2_PHY_REGISTER0[15:8] REG_THSTRAIL	CEIL (60 ns / DDR_Clock_Period) + 5	{CEIL [(REG_THSTRAIL + 3)/4] * 4 – 2.75} * DDR_Clock_Period + (~ 0 ns – 5 ns)
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	CSI2_PHY_REGISTER0[7:0] REG_THSEXIT	CEIL (145 ns / DDR_Clock_Period)	[CEIL (REG_THSEXIT/4) * 4] * DDR_Clock_Period – (~ 3 ns – 45 ns)
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	N/A	N/A	DDR_CLK_POST - T_{HS-EOT} [(1)] - $T_{HS-TRAIL}$
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of an HS transmission burst	CSI2_PHY_REGISTER1[15:8] REG_TCLKTRAIL	CEIL (60 ns / DDR_Clock_Period) + 2	{CEIL [(REG_TCLKTRAIL + 3)/4] * 4 – 1.5} * DDR_Clock_Period + (~ 0 ns – 5 ns)
$T_{DDR\_CLK\_POST}$	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $T_{DDR\_CLK\_POST} \geq T_{HS-TRAIL} + T_{HS-EOT} + T_{CLK-POST}$	CSI2_CLK_TIMING[7:0] DDR_CLK_POST	CEIL [($T_{HS-TRAIL}$ + T_{HS-EOT} [(1)] + $T_{CLK-POST}$) / $T_{TXBYTECLKHS}$] [(2)] [(3)]	
$T_{EXIT\_HS\_MODE\_LATENCY}$ [(4)]	Time to exit HS mode	CSI2_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	CEIL [($T_{HS-TRAIL}$ + $T_{HS-EXIT}$ + T_{HS-EOT} [(1)]) / $T_{TXBYTECLKHS}$] [(2)]	

(1) If T_{HS-EOT} is enabled
(2) The timings seen on the line should be used to determine the register value.
(3) See the MIPI D-PHY specification for the$T_{CLK-POST}$ value.
(4) EXIT_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 14-145, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz; two data lanes.

Table 14-145. HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
T_{HS-EOT}	N/A	N/A	5 ns	N/A
$T_{HS-TRAIL}$	CSI2_PHY_REGISTER0 [15:8] REG_THSTRAIL	29	73.125–78.125 ns	73.125–78.125 ns
$T_{HS-EXIT}$	CSI2_PHY_REGISTER0 [7:0] REG_THSEXIT	58	105–147 ns	105–147 ns
$T_{CLK-POST}$ [(1)]	N/A	N/A	585 ns	580 ns

(1) See the MIPI D-PHY specification.

Table 14-145. HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes (continued)

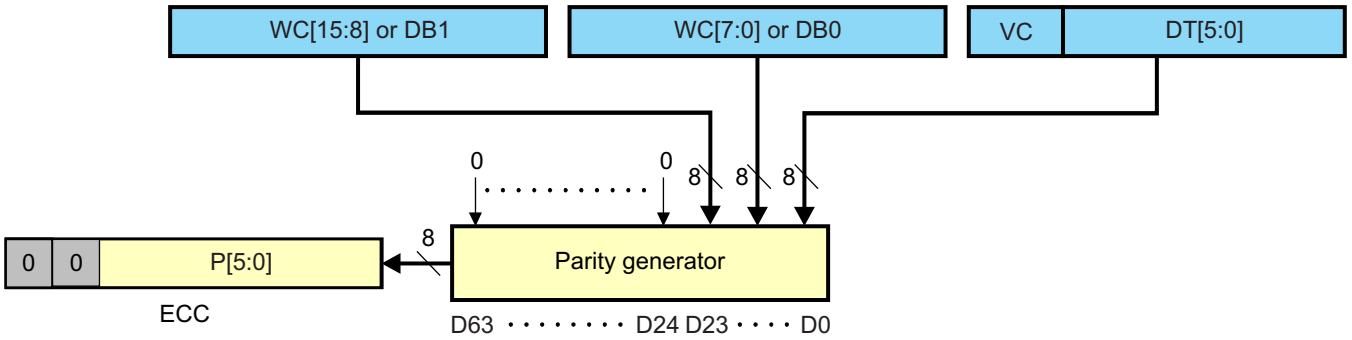
Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
$T_{CLK-TRAIL}$	CSI2_PHY_REGISTER1 [15:8] REG_TCLKTRAIL	26	76.25–81.25 ns	76.25–81.25 ns
DDR_CLK_POST	CSI2_CLK_TIMING[7:0] DDR_CLK_POST	66 * TxByteClkHS or 264 * DDR_CLOCK	658.125–663.125 ns	653.125–658.125 ns
		67 * TxByteClkHS or 268 * DDR_CLOCK (2)		
EXIT_HS_MODE_LATENCY	CSI2_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	19 * TxByteClkHS or 76 * DDR_CLOCK	183.125–230.125 ns	178.125–225.125 ns
		24 * TxByteClkHS or 96 * DDR_CLOCK (2)		

(2) Register setting calculated based on the values in Timing Seen on the Line (T_{HS-EOT} Enabled) column.

14.4.2.5 ECC Generation

The CSI2 protocol uses a 4-byte PH. Because ECC generation requires a fixed word length of 64-bits, the packet headers must be padded with additional bits to form a full 8-byte value for ECC generation and checking. The PH minus the ECC byte should occupy bits D[23:0], and the pad bits should occupy bits D[63:24]. All padding bits must be 0 to generate the ECC byte. ECC can be generated using a parallel approach, as shown in Figure 14-153.

Figure 14-153. 64-Bit ECC Generation on TX Side



The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The CSI2_VC_CTRL_i[8] ECC_TX_EN bit enables and disables ECC generation.

The ECC can be provided while writing the ECC value directly into the CSI2_VC_LONG_PACKET_HEADER_i and CSI2_VC_SHORT_PACKET_HEADER_i registers. The CSI2_VC_CTRL_i[8] ECC_TX_EN bit indicates whether the ECC value will be calculated or whether the value written in the register will be used instead.

14.4.2.6 Checksum Generation for Long Packet Payloads

Long packets are comprised of a PH protected by an ECC byte and a payload of 0 to 2^{16} - 1 bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. For the special case of a 0-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional CSI2 implementations, because the peripheral has no way to report errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets

to peripherals; it is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation must transmit 2 bytes with a value of 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor must disable checksum checking for received long packets from peripherals that do not support checksum generation.

Checksum must be realized as a 16-bit CRC with a generator polynomial of $x^{16}+x^{12}+x^5+x^0$. The LSByte is sent first, followed by the MSByte. Within the byte, the LSB is sent first.

Figure 14-154 shows the checksum transmission.

Figure 14-154. Checksum Transmission

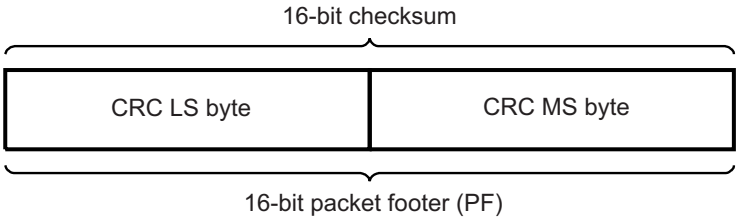


Figure 14-155 shows the CRC implementation. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the PH then enters as a bitwise data stream from the left, LSB first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the MSB of the checksum, and C0 contains the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

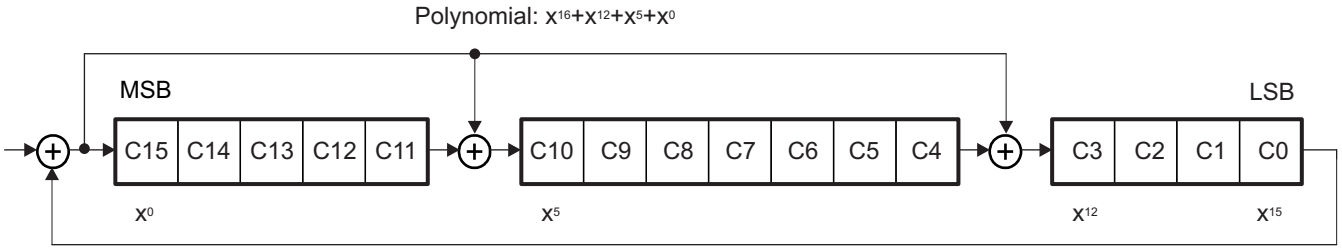
Figure 14-155. 16 Bit CRC Generation Using a Shift Register



Checksum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The CSI2_CTRL[1] CS_RX_EN bit enables and disables checksum generation.
- The CSI2_VC_CTRL_i[7] CS_TX_EN bit enables and disables checksum generation.

14.4.2.7 Software Reset

The CSI2 protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The CSI2 protocol engine can be reset by setting the CSI2_SYSCONFIG[1] SOFT_RESET bit to 1. Software can monitor the CSI2_SYSSTATUS[0] RESET_DONE status bit to wait for the reset to complete. If after five reads the CSI2_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional because a hardware reset is always performed on the CSI2 protocol engine at device reset.

14.4.2.8 Power Management

The power-management behavior of the CSI2 protocol engine is controlled by the CSI2_SYSCONFIG register. This register controls the way the module interacts with the PRCM module. The CSI2_SYSCONFIG[0] AUTO_IDLE bit must be set to 1 (default value) to enable automatic clock gating in the module.

The CSI2 protocol engine implements a handshake protocol on the interconnect slave port with the PRCM module. The protocol engine provides control signal CIO_CLK_ICG to gate the SCPClk (MSS_VCLK/4). It allows reduction of the power consumption of the complex I/O while the CSI2 link is not in use (CSI2_CLK_CTRL[14] CIO_CLK_ICG).

14.4.2.9 Power Control of CSI2 PHY Complex I/O

The CSI2 protocol engine can control and send power commands for the CSI2 complex I/O module.

14.4.2.9.1 Complex I/O Power Control Commands

14.4.2.9.1.1 Complex I/O Power Control Commands

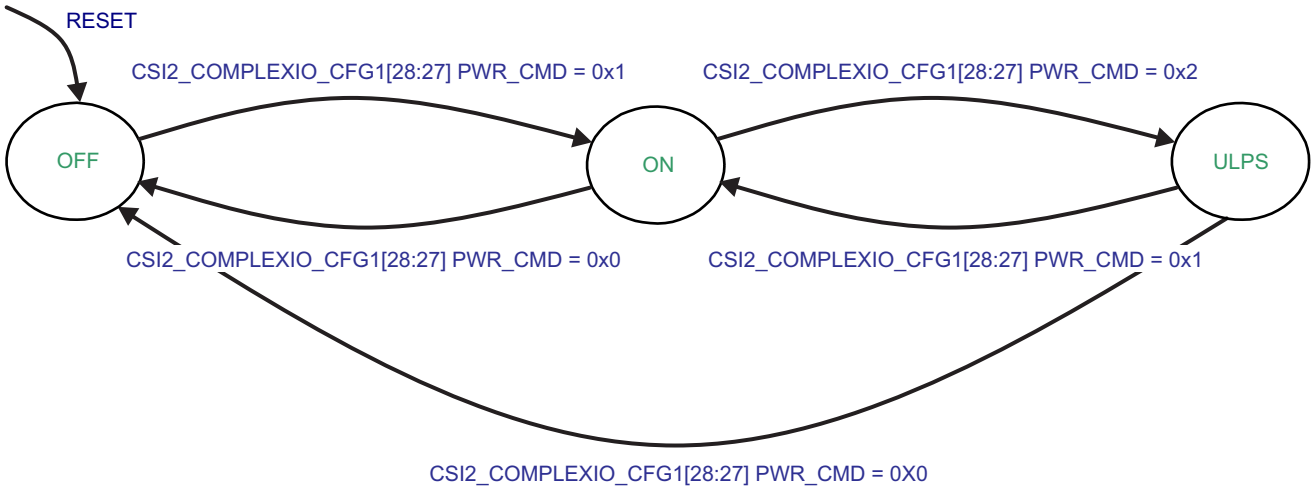
The CSI2 complex I/O can be set in three modes:

- OFF: In this power state, the complete CSI2_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete CSI2_PHY circuit is powered on and functional.
- ULPS: Mode not supported by this module.

14.4.2.9.1.2 Complex I/O Power FSM

Figure 14-156 shows the FSM to control the power state of the complex I/O.

Figure 14-156. Complex I/O Power FSM



The PwrCmdOff, PwrCmdUlp, and PwrCmdOn commands control the state transition of the CSI2 complex I/O. The CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD bit field allows the state to be modified. The allowed transitions are: OFF - ON, and ON - ULPS, and ULPS - OFF. The CSI2_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the CSI2 complex I/O.

CAUTION

- In automatic mode, software must ensure that the CSI2 complex I/O is in ON state (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state that is the current one (acknowledge has been received), the command is ignored (nothing is sent to the CSI2 complex I/O).

14.4.2.10 CSI2 Complex I/O

14.4.2.10.1 CSI2 Complex I/O Overview

CSI2_PHY is a complex I/O with five unidirectional (HS) lane modules. This includes four data lane modules and one clock lane module. Each lane module has two data pads (DX, DY). These data pads are connected with a complementary lane module on the CSI2 receiver device using a point-to-point interconnect.

Lane modules support HS burst mode.

The maximum data rate supported in HS mode is 600 Mbps for four data lanes, and 900 Mbps for up to three data lanes. The lane module function and position are configurable; that is, any lane module can be chosen as a clock lane module, and the DX/DY data pad for each lane module can be configured as a DP or DN pin defined by the D-PHY specification.

CSI2_PHY interacts with the higher layers of the CSI2 link through the PPI. CSI2_PHY does not include a PLL; a high-frequency clock input is expected in HS mode (CLKIN4DDR). CSI2_PHY also supports the SCP interface to set various configuration and control registers.

14.4.2.10.2 Software Reset

The clock domain using the TXBYTECLKHS byte clock from the CSI2 complex I/O has dedicated reset-done information in the CSI2_COMPLEXIO_CFG1[29] RESET_DONE bit. The CSI2_SYSCONFIG[1] SOFT_RESET bit is used to reset the byte clock power domain. A dummy read using the SCP interface to any CSI2_PHY register is required after CSI2_PHY reset to complete the reset of the CSI2 complex I/O.

14.4.2.10.3 Pad Configuration

The number of lanes is configurable through the CSI2_COMPLEXIO_CFG1 register.

It is not allowed to change on the fly the position (by modifying the DATAx_POSITION, where x = 1 through 4, and CLOCK_POSITION fields), the P/N order (positive/negative order of the differential pair by modifying the DATAy_POL, where y = 1 through 4, and CLOCK_POL), or the number of active data lanes (by modifying the CSI2_COMPLEXIO_CFG1[10:8] DATA2_POSITION, CSI2_COMPLEXIO_CFG1[14:12] DATA3_POSITION, and CSI2_COMPLEXIO_CFG1[18:16] DATA4_POSITION bit fields). To add or remove lanes 2, 3, or 4, it is required to be in OFF mode for the CSI2 complex I/O.

The configuration of the CSI2 complex I/O (number of data lanes, position, differential order) must not be changed while the CSI2_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For hardware to recognize a new configuration of the complex I/O (done in the CSI2_COMPLEXIO_CFG1 register), the following sequence shall be followed:

1. Set the CSI2_CTRL[0] IF_EN bit to 1.
2. Reset the CSI2_CTRL[0] IF_EN bit to 0.
3. Set CSI2_CLK_CTRL[20] LP_CLK_ENABLE bit to 1.
4. Set again the CSI2_CTRL[0] IF_EN bit to 1.

If the sequence is not followed, the CSI2 complex I/O configuration is undetermined.

The minimum requirement for the number of lanes is one clock lane and one data lane. By default, data lanes 2, 3, and 4 are not connected (the reset value of the DATAx_POSITION bit fields is 0).

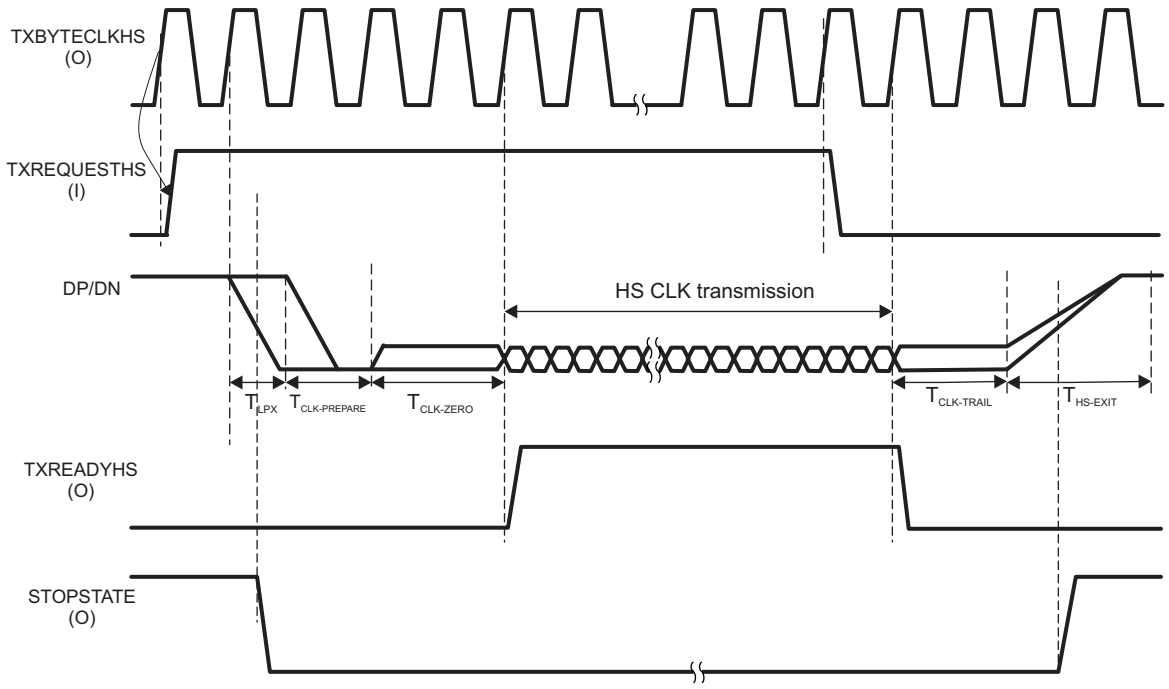
14.4.2.10.4 Display Timing Configuration

Depending on the CLKIN4DDR clock frequency settings programmed with the PRCM module, software users must program accordingly the timing parameters in the CSI2 complex I/O registers.

14.4.2.10.4.1 High-Speed Clock Transmission

Figure 14-157 shows an example of HS clock transmission.

Figure 14-157. HS Clock Transmission



TXBYTECLKHS is an output clock that is derived by dividing CLKIN4DDR by 16.
The TXBYTECLKHS clock is driven by CSI2_PHY when:

- The CLKIN4DDR is running and CSI2_PLL_CONFIGURATION2[14] PHY_CLKINEN bit is set to '1'.
- CSI2_PHY is in ON power state (CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD bit = 1) and at least one lane is enabled.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXBYTECLKHS. The PHY detects this signal on the next rising edge, after which it initiates the LP SoT procedure.

During an HS clock transmission, these parameters are defined in multiples of CLKIN4DDR and are programmed by the following bit fields:

- TLPX timing is programmed by CSI2_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE timing is programmed by CSI2_PHY_REGISTER0[31:24] THSPREPARE.
- TCLK-ZERO timing is programmed by CSI2_PHY_REGISTER1[7:0] TCLKZERO.

TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The CSI2_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The CSI2_PHY then goes through the LP EoT procedure. The TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and are programmed by the following bit fields:

- TCLK-TRAIL timing is programmed by CSI2_PHY_REGISTER1[15:8] TCLKTRAIL.
- THS-EXIT timing is programmed by CSI2_PHY_REGISTER0[7:0] THSEXIT.

The CSI2_PHY completes the SoT and EoT procedures, once begun, regardless of any change in the PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

The HS clock must be present for a period of time before (TCLK-PRE) and after (TCLK-POST) HS data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

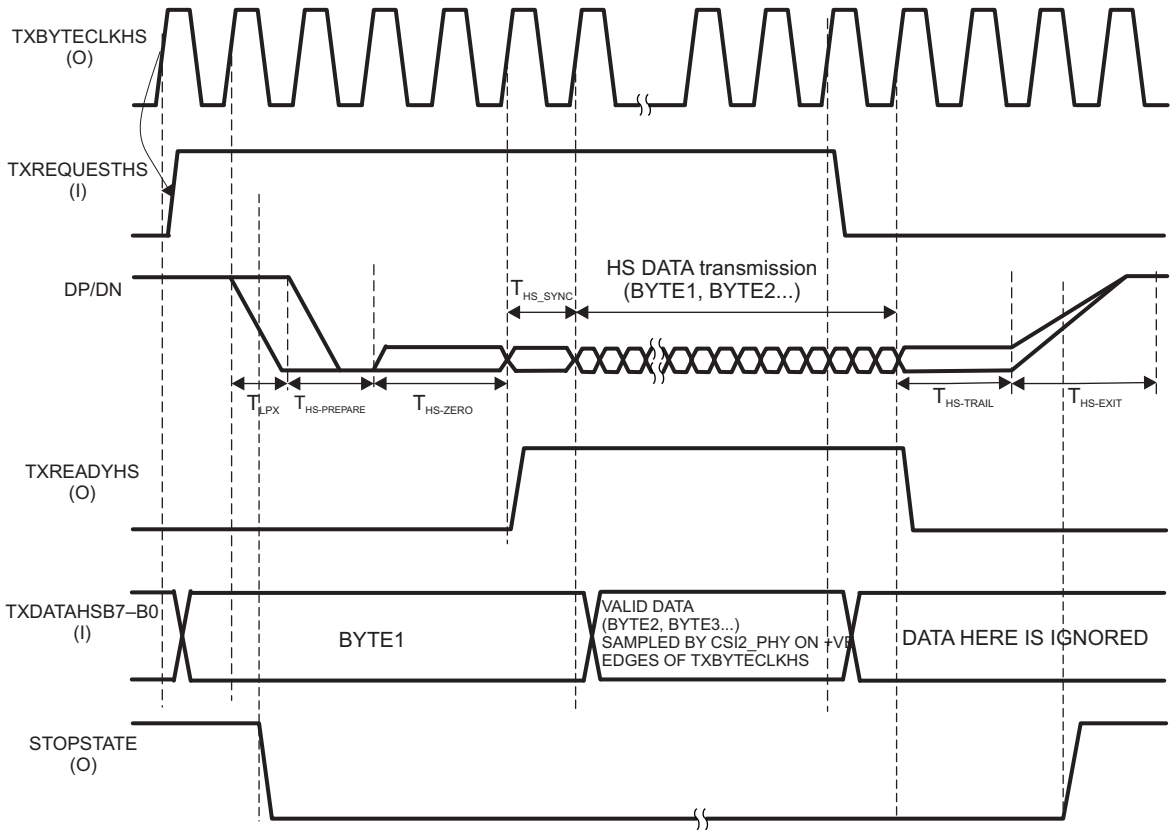
The PHY ensures that the clock signal has a quadrature phase with respect to a toggling bit sequence on any data lane, and a rising edge in the center of the first transmitted bit of each data byte. These relations are not described in the timing diagram.

CLKIN4DDR can be shut off 300 ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after the TxRequestHS falling edge is received by CSI2_PHY.

14.4.2.10.4.2 High-Speed Data Transmission

Figure 14-158 shows an example of HS data transmission.

Figure 14-158. HS Data Transmission



To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXBYTECLKHS. It also makes TXREQUESTHS high on the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXBYTECLKHS, following which it initiates the LP SoT procedure.

During an HS data transmission, these timings are multiples of CLKIN4DDR and are programmed by the following bit fields:

- TLPX timing is programmed by CSI2_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE + THS-ZERO timing is programmed by CSI2_PHY_REGISTER0[23:16] THSPRPR_THSZERO.

THS-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles. THS-SYNC corresponds to the length of the sync pattern (8 HS bits), and can be configured through the CSI2_PHY_REGISTER2[31:24] HSSYNCPATTERN bit field.

Toward the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXBYTECLKHS and then starts accepting data from TXDATAHS from the next positive edge onward. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXBYTECLKHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS data transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP EoT procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and are programmed by the following bit fields:

- THS-TRAIL timing is programmed by CSI2_PHY_REGISTER0[15:8] THSTRAIL.
- THS-EXIT timing is programmed by CSI2_PHY_REGISTER0[7:0] THSEXIT.

The PHY completes the SoT and EoT procedures, once begun, regardless of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

14.4.3 CSI2 Programming Sequence

The following sections list the programming sequence needed before the hardware triggers are generated to initiate the high-speed CSI2 data transmission.

14.4.3.1 CSI2 Global Initialization

Table 14-146. Main Sequence – PRCM and Global Configuration

Steps	Register/Bit Field/Programming	Value
Ensure the LVDS I/Os are powered off and tri-stated before CSI2 transmission	MSS_TOP_RCM. LVDSPADCTL0 MSS_TOP_RCM. LVDSPADCTL1	0x61616161 0x616161
Bring the CSI2 PE out of Idle	DSS_REG.CSICFG1.CSIMIDLEREQ	0x0
Poll to ensure the protocol engine is out of IDLE	DSS_REG.CSICFG1.CSISIDLEACK	=0x0
Enable the respective CSI2 lanes	DSS_REG.CSICFG1.CSILANEENABLE	0x-

14.4.3.2 CSI2 Protocol Engine and PHY Configuration

Table 14-147. Main Sequence – Configure CSI2 Clock Configuration

Steps	Register/Bit Field/Programming	Value
Set the ratio for the LP clock	CSI2_CLK_CTRL.LP_CLK_DIVISOR	0XA
Enable the LP clock	CSI2_CLK_CTRL.LP_CLK_ENABLE	0x1
Enable or disable clock gating to CSI2_PHY module	CSI2_CLK_CTRL.CIO_CLK_ICG	0x1
Configure if the DDR clock is also sent when no HS packets are sent to the peripheral	CSI2_CLK_CTRL.DDR_CLK_ALWAYS_ON	0x1
Enable or disable the automatic assertion and deassertion of CSI2StopClk	CSI2_CLK_CTRL.HS_AUTO_STOP_ENABLE	0x1
Configure the CSI2 functional clock synchronization and clock speed.	CSI2_CLK_CTRL.LP_RX_SYNCHRO_ENABLE	0x1
Turn ON/OFF PLL and HSDIVIDER	CSI2_CLK_CTRL.PLL_PWR_CMD	0x2

Table 14-148 summarizes the CSI2_PHY timing settings. For more information about timing calculation, see Section 14.4.2.

Table 14-148. Main Sequence – Configure CSI2_PHY

Steps	Register/Bit Field/Programming	Value
Settings of the CSI2 protocol timing. For a complete description of timing specifications see Section 14.4.2.4	CSI2_PHY_REGISTER0[31:24] REG_THSPREPARE	ceil(70ns/DDR clock period) + 2
	CSI2_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175ns/DDR clock period) + 2
	CSI2_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145ns/DDR clock period)
	CSI2_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60ns/DDR clock period) + 5
	CSI2_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65ns/DDR clock period)
	CSI2_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265ns/DDR clock period)
	CSI2_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60ns/DDR clock period) + 2
	CSI2_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25ns/DDR clock period)

Table 14-149. Main Sequence – CSI2 Complex IO Configuration

Steps	Register/Bit Field/Programming	Value
Set the complex I/O power state	CSI2_COMPLEXIO_CFG1.PWR_CMD	0x1
Set the position of data lane 1	CSI2_COMPLEXIO_CFG1.DATA1_POSITION	X
Set the position of data lane 2	CSI2_COMPLEXIO_CFG1.DATA2_POSITION	X
Set the position of data lane 3	CSI2_COMPLEXIO_CFG1.DATA3_POSITION	X
Set the position of data lane 4	CSI2_COMPLEXIO_CFG1.DATA4_POSITION	X
Set the position of the clock lane	CSI2_COMPLEXIO_CFG1.CLOCK_POSITION	X
Wait until power control is ON	CSI2_COMPLEXIO_CFG1.PWR_STATUS	=0x1
Enable the CSI protocol engine	CSI2_CTRL.IF_EN	0x1
Disable the CSI protocol engine	CSI2_CTRL.IF_EN	0x0
Wait until the interface is disabled	CSI2_CTRL.IF_EN	=0x0

Table 14-150. Main Sequence – VC and OCP Configuration

Steps	Register/Bit Field/Programming	Value
Set size of the TX FIFO allocated for used VC0	CSI2_TX_FIFO_VC_SIZE	X
Set the slave interface power management mode	CSI2_SYSCONFIG.SIDLEMODE	0x1
Set the wake-up mode enable	CSI2_SYSCONFIG.ENWAKEUP	0x1
Set the OCP clock to be free-running	CSI2_SYSCONFIG.AUTO_IDLE	0x0
Set the OCP data bus width	CSI2_VC_CTRL.OCP_DATA_BUS_WIDTH	0x3
Set the trigger reset mode	CSI2_CTRL.TRIGGER_RESET_MODE	0x1
Select source of data to be OCP	CSI2_VC_CTRL.SOURCE	0x0
Configure the mode to command mode	CSI2_VC_CTRL.MODE	0x0
Enable the checksum generation for the transmit payload	CSI2_VC_CTRL.CS_TX_EN	0x1
Enable or disable the ECC generation for the transmit header	CSI2_VC_CTRL.ECC_TX_EN	0x1
Set the number of TXBYTECLKHS clock cycles	CSI2_CLK_TIMING.DDR_CLK_PRE CSI2_CLK_TIMING.DDR_CLK_POST	X
Disable the multiplication factor for the number of CSI2_CLK functional clock cycles defined in STOP_STATE_COUNTER_IO bit-field	CSI2_TIMING1.STOP_STATE_X16_IO CSI2_TIMING1.STOP_STATE_X4_IO	0x0
Force TX stop mode	CSI2_TIMING1.FORCE_TX_STOP_MODE_IO	0x1
Enable used VC	CSI2_VC_CTRL.VC_EN	0x1
Enable the CSI protocol engine	CSI2_CTRL.IF_EN	0x1
Wait until the end of TX stop mode assertion	CSI2_TIMING1.FORCE_TX_STOP_MODE_IO	=0x1

CSI2 protocol engine VC0 FIFO size configuration requirements: because the CSI2 protocol engine has certain conditions on which it triggers the HSI transfer when data in the FIFO, the FIFO size is dependent on the CSI2 packet size.

- Case 1: If the packets to be transferred are larger than 128 bytes, configure the FIFO size to 32 entries (default configuration). By default, the FIFO size should be configured to 32 entries.
- Case 2: Single packet transferred per chirp. If the packet size is less than 128 byes, configure the FIFO size to 64 entries.
- Case 3: 2 packets sent per chirp. If the packet size is less than 128 bytes, configure the FIFO size to 64. If the second packet is less than 256 bytes, configure the FIFO size to 96.

14.4.3.3 CBUFF Configuration

Table 14-151. Main Sequence – CBUFF CSI2 Static Configuration

Steps	Register/Bit Field/Programming	Value
Set address of the CSI2 protocol engine short packet header address	CFG_SPHDR_ADDRESS	DSS_CSI2_PROTOCOL_ENGINE_U_BASE + CSI2_VC_SHORT_PACKET_HEADER
Set address of the CSI2 protocol engine long packet header address	CFG_LPHDR_ADDRESS	DSS_CSI2_PROTOCOL_ENGINE_U_BASE + CSI2_VC_LONG_PACKET_HEADER

Table 14-151. Main Sequence – CBUFF CSI2 Static Configuration (continued)

Steps	Register/Bit Field/Programming	Value
Set address of the CSI2 protocol engine long packet payload address	CFG_LPPYLD_ADDRESS	DSS_CSI2_PROTOCOL_ENGINE_U_BASE + CSI2_VC_LONG_PACKET_PAYLOAD
Configure the FIFO free threshold	CFG_FIFO_FREE_THRESHOLD	0x8
Configure the CSI2 VSYNC start code	CFG_CMD_VEVAL	0xEC000000
Configure the CSI2 VSYNC end code	CFG_CMD_VEVAL	0xEC000001
Configure the CSI2 HSYNC start code	CFG_CMD_VSVAL	0xEC000002
Configure the CSI2 HSYNC end code	CFG_CMD_VEVAL	0xEC000003
Configure the Number of chirps in a frame	CFG_CHIRPS_PER_FRAME	X
Configure the VSYNC start and end packets to be sent	CONFIG_REG_0.CVC0EN CONFIG_REG_0.CVC1EN CONFIG_REG_0.CVC2EN CONFIG_REG_0.CVC3EN	X

The configuration in Table 14-152 should be performed for each linklist entry required to transmit the CSI2 packet.

Table 14-152. Main Sequence – CBUFF Linklist

Steps	Register/Bit Field/Programming	Value
Set the valid for the linklist	CFG_DATA_LL[X].LL[X]_VALID	0x1
If linklist is the start of a new CSI2 packet, enable the long packet header	CFG_DATA_LL[X].LL[X]_LPHDR_EN	0x-
If linklist is the start of a new CSI2 packet, configure the long packet header	CFG_DATA_LL[X]_LPHDR_VAL	X
If a HSYNC start packet should be sent out before this linklist data	CFG_DATA_LL[X].LL[X]_HS	0x-
If a HSYNC end packet should be sent out at the end of this linklist data	CFG_DATA_LL[X].LL[X]_HE	0x-
Set the virtual channel number for the CSI2 packet to which the linklist belongs	CFG_DATA_LL[X].LL[X]_VCNUM	X
Configure the size in CBUFF units	CFG_DATA_LL[X].LL[X]_SIZE	X
Configure the format of the CSI2 packet to which the linklist belongs	CFG_DATA_LL[X].LL[X]_FMT	X
Set the linklist write threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_WR_THRESHOLD	X
Set the linklist read threshold	CFG_DATA_LL[X]_THRESHOLD.LL[X]_WR_THRESHOLD	X
Set the input format	CFG_DATA_LL[X].LL[X]_FMT_IN	X

14.4.4 CSI2_PROTOCOL_ENGINE Registers

Table 14-153 lists the memory-mapped registers for the CSI2_PROTOCOL_ENGINE. All register offset addresses not listed in Table 14-153 should be considered as reserved locations and the register contents should not be modified.

Table 14-153. CSI2_PROTOCOL_ENGINE Registers

Offset	Acronym	Register Name	Section
0h	CSI2_REVISION	MODULE REVISION This register contains the IP revision code in binary coded digital. For example, we have: 0x01 = revision 0.1 and 0x21 = revision 2.1	Section 14.4.4.1
10h	CSI2_SYSCONFIG	SYSTEM CONFIGURATION REGISTER This register is the OCP-socket system configuration register.	Section 14.4.4.2
14h	CSI2_SYSSTATUS	SYSTEM STATUS REGISTER This register provides status information about the module, excluding the interrupt status register.	Section 14.4.4.3
18h	CSI2_IRQSTATUS	INTERRUPT STATUS REGISTER - All virtual channels + Complex IO + PLL This register associates one bit for each virtual channel in order to determine which virtual channel has generated the interrupt. The virtual channel shall be enabled for events to be generated on that virtual channel. If the virtual channel is disabled, the interrupt is not generated.	Section 14.4.4.4
1Ch	CSI2_IRQENABLE	INTERRUPT ENABLE REGISTER - This register associates one bit for each virtual channel in order to enable/disable each virtual channel individually.	Section 14.4.4.5
40h	CSI2_CTRL	GLOBAL CONTROL REGISTER This register controls the CSI2 Protocol Engine module. This register shall not be modified dynamically (except IF_EN bit fields).	Section 14.4.4.6
44h	CSI2_GNQ	GENERIC PARAMETER REGISTER This register provide a way to read the generic parameters used in the design.	Section 14.4.4.7
48h	CSI2_COMPLEXIO_CFG1	COMPLEXIO CONFIGURATION REGISTER for the complex IO This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.	Section 14.4.4.8
4Ch	CSI2_COMPLEXIO_IRQSTATUS	INTERRUPT STATUS REGISTER - All errors from complex IO	Section 14.4.4.9
50h	CSI2_COMPLEXIO_IRQENABLE	INTERRUPT ENABLE REGISTER - All errors from complex IO	Section 14.4.4.10
54h	CSI2_CLK_CTRL	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.	Section 14.4.4.11
58h	CSI2_TIMING1	TIMING1 REGISTER This register controls the CSI2 Protocol Engine module timers. Any bit-field can be modified while CSI2_CTRL.IF_EN is set to '1'. It is used to indicate the number of CSI2_CLK functional clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER	Section 14.4.4.12
5Ch	CSI2_TIMING2	TIMING2 REGISTER This register controls the CSI2 Protocol Engine module timers. Any bit-field can be modified while CSI2_CTRL.IF_EN is set to '1'. It is used to indicate the number of CSI2_CLK functional clock cycles for the timers HS_TX_TIMER and LP_RX_TIMER	Section 14.4.4.13
60h	CSI2_VM_TIMING1	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.14

Table 14-153. CSI2_PROTOCOL_ENGINE Registers (continued)

Offset	Acronym	Register Name	Section
64h	CSI2_VM_TIMING2	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.15
68h	CSI2_VM_TIMING3	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.16
6Ch	CSI2_CLK_TIMING	CLOCK TIMING REGISTER This register controls the CSI2 Protocol Engine module timers. This register shall not be modified while CSI2_CTRL.IF_EN is set to '1'.	Section 14.4.4.17
70h	CSI2_TX_FIFO_VC_SIZE	Defines the corresponding memory entries allocated for each virtual channel. The virtual channel shall be disabled in order to allocate/un-allocate some entries in the TX FIFO.	Section 14.4.4.18
74h	CSI2_RX_FIFO_VC_SIZE	Defines the corresponding memory entries allocated for each virtual channel and the addresses. The virtual channel shall be disabled in order to allocate/un-allocate some entries in the RX FIFO.	Section 14.4.4.19
78h	CSI2_COMPLEXIO_CFG2	COMPLEXIO CONFIGURATION REGISTER for the complex IO This register contains the lane configuration for the ULPS for each lane.	Section 14.4.4.20
7Ch	CSI2_RX_FIFO_VC_FULLNESS	Defines the fullness of each space allocated for each virtual channel.	Section 14.4.4.21
80h	CSI2_VM_TIMING4	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.22
84h	CSI2_TX_FIFO_VC_EMPTINESS	Defines the emptiness of each space allocated for each virtual channel.	Section 14.4.4.23
88h	CSI2_VM_TIMING5	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.24
8Ch	CSI2_VM_TIMING6	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.25
90h	CSI2_VM_TIMING7	Defines the minimum number of HS bytes clock cycles that are required to allow for the delays in entering and exiting HS mode. The supported values are from 0 to 65535	Section 14.4.4.26
94h	CSI2_STOPCLK_TIMING	Number of functional clock cycles to wait for TxByteClkHS to stop/start after change in CSI2StopClk signal	Section 14.4.4.27
98h	CSI2_CTRL2	Additional control bits for use with Video Port 2	Section 14.4.4.28
9Ch	CSI2_VM_TIMING8	VIDEO MODE TIMING REGISTER This register defines the video mode timing.	Section 14.4.4.29
A0h	CSI2_TE_HSYNC_WIDTH_0	The register configures the TE HSYNC minimum pulse width for TE0 and TE1 CMOS signals The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.30
A4h	CSI2_TE_VSYNC_WIDTH_0	The register configures the TE VSYNC minimum pulse width for TE0 and TE1 CMOS signals The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.31
A8h	CSI2_TE_HSYNC_NUMBER_0	The register configures the number of HSYNC to synchronize the beginning of the transfer on CSI2 link based on the number of HSYNC pulse received on the TE line. The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.32
A6h	CSI2_TE_HSYNC_WIDTH_1	The register configures the TE HSYNC minimum pulse width for TE0 and TE1 CMOS signals The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.30

Table 14-153. CSI2_PROTOCOL_ENGINE Registers (continued)

Offset	Acronym	Register Name	Section
AAh	CSI2_TE_VSYNC_WIDTH_1	The register configures the TE VSYNC minimum pulse width for TE0 and TE1 CMOS signals The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.31
AEh	CSI2_TE_HSYNC_NUMBER_1	The register configures the number of HSYNC to synchronize the beginning of the transfer on CSI2 link based on the number of HSYNC pulse received on the TE line. The input TE signal is asynchronous and needs to be re-synchronizred to CSI2_CLK clock domain.	Section 14.4.4.32
100h	CSI2_VC_CTRL_0	CONTROL REGISTER - Virtual channel This register controls the virtual channel.	Section 14.4.4.33
104h	CSI2_VC_TE_0	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.	Section 14.4.4.34
108h	CSI2_VC_LONG_PACKET_HEADER_0	LONG PACKET HEADER INFORMATION -Virtual channel This register sets the 32-bit DATA_ID + Word count + ECC (the virtual channel id can be different than VC). The ECC will be computed if ECC_TX_EN is set to 1. DATA_ID is located at bit[7:0] WC is located at bit[23:8] ECC is located at bit[31:24] (Least significant byte first and least significant bit first)	Section 14.4.4.35
10Ch	CSI2_VC_LONG_PACKET_PAYLOAD_0	LONG PACKET PAYLOAD INFORMATION -Virtual channel This register sets the payload information (excluding Check-sum). The HW shall capture the word count in the packet header (in CSI2_VC_LONG_PACKET_HEADER) in order to determine the last valid data. (the virtual channel id can be different than VC). Byte1 is bit[7:0] Byte2 is bit[15:8] Byte3 is bit[23:16] Byte4 is bit[31:24] Byten is sent before Byten+1 (Least significant byte first and least significant bit first)	Section 14.4.4.36
110h	CSI2_VC_SHORT_PACKET_HEADER_0	SHORT PACKET HEADER INFORMATION -Virtual channel This register sets the 24-bit DATA_ID + Short Packet Data Field + ECC (the virtual channel id can be different than VC). The ECC will be computed if ECC_TX_EN is set to 1. DATA_ID is located at bit[7:0] Short Packet Data field is located at bit[23:8] ECC is located at bit[31:24] (Least significant byte first and least significant bit first)	Section 14.4.4.37

Table 14-160. CSI2_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R-0	0h	
24	DISPC_UPDATE_SYNC	R/W	0h	Determines if the Dispc_Update_Sync signal from the display controller is used. 0h (R/W) = Dispc_Update_Sync signal is not used. 1h (R/W) = Dispc_Update_Sync signal is used.
23	HSA_BLANKING_MODE	R/W	0h	Blanking mode 0h (R/W) = Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 1h (R/W) = LONG BLANKING PACKETS only are used during HSA blanking period of video mode.
22	HBP_BLANKING_MODE	R/W	0h	Blanking mode 0h (R/W) = Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 1h (R/W) = LONG BLANKING PACKETS only are used during HBP blanking period of video mode.
21	HFP_BLANKING_MODE	R/W	0h	Blanking mode 0h (R/W) = Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 1h (R/W) = LONG BLANKING PACKETS only are used during HFP blanking period of video mode.

Table 14-160. CSI2_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	BLANKING_MODE	R/W	0h	Blanking mode 0h (R/W) = LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE AND HFP_BLANKING_MODE respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 1h (R/W) = LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE AND HFP_BLANKING_MODE respectively) regardless of the packets present in the TX FIFO ready to be sent
19	EOT_ENABLE	R/W	0h	Enable EOT packets at the end of HS transmission. 0h (R/W) = No EOT packets 1h (R/W) = EOT packet is sent at all HS to LP transitions.
18	VP_HSYNC_END	R/W	0h	HSYNC end pulse. 0h (R/W) = Disabled. No HSYNC END short packet is generated. 1h (R/W) = Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.
17	VP_HSYNC_START	R/W	0h	HSYNC start pulse. 0h (R/W) = Disabled. No HSYNC START short packet is generated. 1h (R/W) = Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.
16	VP_VSYNC_END	R/W	0h	VSYNC end pulse. 0h (R/W) = Disabled. No VSYNC END short packet is generated. 1h (R/W) = Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.
15	VP_VSYNC_START	R/W	0h	VSYNC start pulse. 0h (R/W) = Disabled. No VSYNC START short packet is generated. 1h (R/W) = Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.
14	TRIGGER_RESET_MODE	R/W	0h	Selection of the trigger reset mode 0h (R/W) = Synchronized: the mode is only valid if there is virtual channel using the video mode and it is active. The principal is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 1h (R/W) = Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on CSI2 link and already scheduled ones are transmitted. All the other transfers are discarded.
13-12	LINE_BUFFER	R/W	0h	Number of line buffers to be used while receiving data on the video port. The valid values are from 0 to CSI2_GNQ.VP1_NB_LINE_BUFFER. 0h (R/W) = No line buffer 1h (R/W) = 1 line buffer 2h (R/W) = 2 line buffers
11	VP_VSYNC_POL	R/W	0h	VP vertical synchronization signal polarity 0h (R/W) = VSYNC signal on the video port is active low. 1h (R/W) = VSYNC signal on the video port is active high.
10	VP_HSYNC_POL	R/W	0h	VP horizontal synchronization signal polarity 0h (R/W) = HSYNC signal on the video port is active low. 1h (R/W) = HSYNC signal on the video port is active high.
9	VP_DE_POL	R/W	0h	VP data enable signal polarity 0h (R/W) = DE signal on the video port is active low. 1h (R/W) = DE signal on the video port is active high.

Table 14-160. CSI2_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	VP_CLK_POL	R/W	1h	VP clock polarity 0h (R/W) = The CSI2 Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP shall drive the data on the pixel clock rising edge. 1h (R/W) = The CSI2 Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP shall drive the data on the pixel clock falling edge.
7-6	VP_DATA_BUS_WIDTH	R/W	0h	Defines the size of the video port data bus 0h (R/W) = 16-bits data width (LSB of the 24-bit video port data bus) 1h (R/W) = 18-bits data width (LSB of the 24-bit video port data bus) 2h (R/W) = 24-bits data width (LSB of the 24-bit video port data bus)
5	TRIGGER_RESET	R/W	0h	Send the reset trigger to the peripheral. 0h (R/W) = READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 1h (R/W) = READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.
4	VP_CLK_RATIO	R/W	0h	The field indicates the clock ratio between VP.CLK and VP.PCLK. The clock VP.PCLK is generated from VP.CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0h (R/W) = The clock VP.PCLK is the clock VP.CLK divided by 2. The duty cycle of VP.PCLK is 50/50. 1h (R/W) = The clock VP.PCLK is the clock VP.CLK divided by 3 or more. The duty cycle of VP.PCLK is not 50/50 for odd ratio numbers (3,5,7,...).
3	TX_FIFO_ARBITRATION	R/W	0h	Defines the arbitration scheme for granting the virtual channel pending ready requests in the TX FIFO 0h (R/W) = Round-Robin Scheme is used 1h (R/W) = Sequential Scheme is used
2	ECC_RX_EN	R/W	0h	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0h (R/W) = Disabled 1h (R/W) = Enabled
1	CS_RX_EN	R/W	0h	Enables the checksum check for the received payload (long packet only for all virtual channel ids). 0h (R/W) = Disabled 1h (R/W) = Enabled
0	IF_EN	R/W	0h	Enables the module. When the module is disabled the signals from the complex IO are gated (no updates of the interrupt status register). It is not possible to change the bit-fields in the register CSI2_CTRL except IF_EN when it is enabled. All the other registers can be changed except the ones that require CSI2_VC_CTRL.VC_EN to be equal to 0 to be modified. 0h (R/W) = The interface is disabled. If one of the virtual channel uses the video mode with the video port to receive the data, the CSI2 protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other virtual channels in command mode are sent to the peripherals (if BTA_EN is enabled, the CSI2 protocol needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested). 1h (R/W) = The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).

14.4.4.7 CSI2_GNQ Register (Offset = 44h) [reset = 00926936h]

CSI2_GNQ is shown in Figure 14-165 and described in Table 14-161.

Return to Summary Table.

GENERIC PARAMETER REGISTER This register provide a way to read the generic parameters used in the design.

Table 14-162. CSI2_COMPLEXIO_CFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SHADOWING	R/W	0h	Shadowing configuration. 0h (R/W) = Disabled. The writes to the first 3 registers of the complex IO address map is done like the other SCP registers. 1h (R/W) = Enabled. The writes to the first 3 registers of the complex IO address map is done only when the GObit is set and when the signal DISPCUpdataSync from the display controller module is active.
30	GOBIT	R/W	0h	Allows the synchronized update of the shadow registers when the signal DISPCUpdateSync is active. 0h (R/W) = Resets the GOBIT. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The SW can reset the bit in case the user decides to abort it. There is no guarantee that the SW reset is done before the transfer of the values to the complex IO. 1h (R/W) = Set the GOBIT. Only when the transfer of the new values for the three first registers is completed (3, 2, 1, or 0 transfers are performed based on the number of registers to update), the GOBIT is reset. The DISPCUpdateSync signal is used to synchronize the update. The bit shall be set only when it is in reset state.
29	RESET_DONE	R	1h	Internal reset monitoring of the power domain using the PPI byte clock from the complex IO 0h (R) = Internal module reset is on going. 1h (R) = Reset completed.
28-27	PWR_CMD	R/W	0h	Command for power control of the complex IO 0h (R/W) = Command to change to OFF state 1h (R/W) = Command to change to ON state 2h (R/W) = Command to change to Ultra Low Power state

Table 14-162. CSI2_COMPLEXIO_CFG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26-25	PWR_STATUS	R	0h	Status of the power control of the complex IO 0h (R) = Complex IO in OFF state 1h (R) = Complex IO in ON state 2h (R) = Complex IO in Ultra Low Power state
24-22	RESERVED	R-0	0h	
21	LDO_POWER_GOOD_STATE	R	0h	Indicates the state of the signal LDOPWRGOOD. VDDALDOCSI2PLL: 1.2V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the CSI2PHY. 0h (R) = VDDALDOCSI2PLL power supply is down 1h (R) = VDDALDOCSI2PLL power supply is up
20	USE_LDO_EXTERNAL	R/W	0h	Select the external LDO for the CSI2PHY. 0h (R/W) = CSI2PHY internal LDO is used. 1h (R/W) = External LDO is used. CSI2PHY LDO is tri-stated.
19	RESERVED	R-0	0h	
19	DATA4_POL	R/W	0h	+/- differential pin order of DATA lane 4. 0h (R/W) = +/- pin order (CSI2.DX=+ and CSI2.DY=-) 1h (R/W) = -/+ pin order (CSI2.DX=- and CSI2.DY=+)
16	RESERVED	R-0	0h	
16	DATA4_POSITION	R/W	0h	Position and order of the DATA lane 4. 0h (R/W) = Not used/connected 1h (R/W) = Data lane 4 is at the position 1. 2h (R/W) = Data lane 4 is at the position 2. 3h (R/W) = Data lane 4 is at the position 3. 4h (R/W) = Data lane 4 is at the position 4. 5h (R/W) = Data lane 4 is at the position 5.
15	RESERVED	R-0	0h	
15	DATA3_POL	R/W	0h	+/- differential pin order of DATA lane 3. 0h (R/W) = +/- pin order (CSI2.DX=+ and CSI2.DY=-) 1h (R/W) = -/+ pin order (CSI2.DX=- and CSI2.DY=+)
12	RESERVED	R-0	0h

Table 14-165. CSI2_CLK_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	PLL_PWR_CMD	R/W	0h	Command for power control of the CSI2 PLL Control module 0h (R/W) = Command to change to OFF state 1h (R/W) = Command to change to ON state for PLL only (HSDIVISER is OFF) 2h (R/W) = Command to change to ON state for both PLL and HSDIVISER 3h (R/W) = Command to change to ON state for both PLL and HSDIVISER (no clock output to the CSI2 complex IO)
29-28	PLL_PWR_STATUS	R	0h	Status of the power control of the CSI2 PLL Control module 0h (R) = CSI2 PLL Control module in OFF state 1h (R) = CSI2 PLL Control module in ON state for PLL only (HSDIVISER is OFF) 2h (R) = CSI2 PLL Control module in ON state for both PLL and HSDIVISER 3h (R) = CSI2 PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the CSI2 complex IO)
27-22	RESERVED	R-0	0h	
21	LP_RX_SYNCHRO_ENABLE	R/W	0h	Defines if the functional is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0h (R/W) = The CSI2 functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 1h (R/W) = The CSI2 functional clock is higher than 30 MHz. The synchronization is rising/rising.
20	LP_CLK_ENABLE	R/W	0h	Controls the gating of the TXCLKESC clock. 0h (R/W) = Disabled. The clock is not generated. The value of LP_CLK_DIVISOR is not used and does not need to be programmed. 1h (R/W) = Enabled. The clock is generated. The value of LP_CLK_DIVISOR is used and needs to be programmed.

Table 14-165. CSI2_CLK_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	HS_MANUAL_STOP_CTRL	R/W	0h	In case HS_AUTO_STOP_ENABLE=0, the bit-field allows manual control of the assertion/de-assertion of the signal CSI2StopClk by the user. 0h (R/W) = CSI2StopClk de-assertion unconditionally. 1h (R/W) = CSI2StopClk assertion unconditionally.
18	HS_AUTO_STOP_ENABLE	R/W	0h	Enables the automatic assertion/de-assertion of CSI2StopClk signal. 0h (R/W) = Auto mode disabled. 1h (R/W) = Auto mode enabled.
17-16	LP_CLK_NULL_PACKET_SIZE	R/W	0h	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.
15	LP_CLK_NULL_PACKET_ENABLE	R/W	0h	Enables the generation of NULL packet in low speed. 0h (R/W) = Disabled. The NULL packet is not sent in LP mode after the last LP packet. 1h (R/W) = Enabled. The NULL packet is sent in LP mode after the last LP packet.
14	CIO_CLK_ICG	R/W	0h	Gates SCPClk clock provided to CSI2-PHY and PLL-CTRL module. 0h (R/W) = Disabled. SCPClk is not generated. It remains at 0. 1h (R/W) = Enabled. SCPClk is generated (OCP_CLK/4)
13	DDR_CLK_ALWAYS_ON	R/W	0h	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted. 0h (R/W) = Disabled. The DDR clock is only provided when HS packets are sent. 1h (R/W) = Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LS mode).
12-0	LP_CLK_DIVISOR	R/W	1h	Defines the ratio to be used for the generation of the Low Power mode clock from CSI2 functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency shall be in the range between 20 MHz and 32 kHz.

14.4.4.12 CSI2_TIMING1 Register (Offset = 58h) [reset = 7FFF7FFFh]

CSI2_TIMING1 is shown in Figure 14-170 and described in Table 14-166.

Return to Summary Table.

TIMING1 REGISTER This register controls the CSI2 Protocol Engine module timers. Any bit-field can be modified while CSI2_CTRL.IF_EN is set to '1'. It is used to indicate the number of CSI2_CLK functional clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER

Figure 14-170. CSI2_TIMING1 Register

7	6	5	4	3	2	1	0
STOP_STATE_COUNTER_IO							
R/W-1FFFh							

Table 14-166. CSI2_TIMING1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TA_TO	R/W	0h	Enables the turn-around timer 0h (R/W) = Turn-around counter is disabled. 1h (R/W) = Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).
30	TA_TO_X16	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER bit-field 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 16x
29	TA_TO_X8	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER bit-field 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 8x
28-16	TA_TO_COUNTER	R/W	1FFFh	Turn around counter. It indicates the number of CSI2_CLK function clock to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.
15	FORCE_TX_STOP_MODE_IO	R/W	0h	Control of ForceTxStopMode signal 0h (R/W) = De-assertion of ForceTxStopMode. The HW reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit in order to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 1h (R/W) = Assertion of ForceTxStopMode

Table 14-166. CSI2_TIMING1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	STOP_STATE_X16_IO	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in STOP_STATE_COUNTER_IO bit-field 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 16x
13	STOP_STATE_X4_IO	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in STOP_STATE_COUNTER_IO bit-field 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in STOP_STATE _COUNTER is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 4x
12-0	STOP_STATE_COUNTER_IO	R/W	1FFFh	Stop state counter. It indicates the number of CSI2_CLK function clock to assert ForceTXStopMode signal. The value is from 0 to 8191.

14.4.4.13 CSI2_TIMING2 Register (Offset = 5Ch) [reset = 7FFF7FFFh]

CSI2_TIMING2 is shown in Figure 14-171 and described in Table 14-167.

Return to Summary Table.

TIMING2 REGISTER This register controls the CSI2 Protocol Engine module timers. Any bit-field can be modified while CSI2_CTRL.IF_EN is set to '1'. It is used to indicate the number of CSI2_CLK functional clock cycles for the timers HS_TX_TIMER and LP_RX_TIMER

Figure 14-171. CSI2_TIMING2 Register

Table 14-167. CSI2_TIMING2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	HS_TX_TO	R/W	0h	Enables the HS TX timer. 0h (R/W) = Time-out counter is disabled. 1h (R/W) = Time-out counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).
30	HS_TX_TO_X64	R/W	1h	Multiplication factor for the number of BYTE_CLK functional clock cycles defined in HS_TX_COUNTER bit-field 0h (R/W) = The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 64x
29	HS_TX_TO_X16	R/W	1h	Multiplication factor for the number of BYTE_CLK functional clock cycles defined in HS_TX_COUNTER bit 0h (R/W) = The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x
28-16	HS_TX_TO_COUNTER	R/W	1FFFh	HS_TX_TIMER counter. It indicates the number of BYTE_CLK function clock for the HS TX timer. The value is from 0 to 8191.
15	LP_RX_TO	R/W	0h	Enables the LP RX timer. 0h (R/W) = Turn-around counter is disabled. 1h (R/W) = Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).
14	LP_RX_TO_X16	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in LP_RX_COUNTER bit-field 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x

Table 14-167. CSI2_TIMING2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	LP_RX_TO_X4	R/W	1h	Multiplication factor for the number of CSI2_CLK functional clock cycles defined in LP_RX_COUNTER bit 0h (R/W) = The number of CSI2_CLK functional clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 1h (R/W) = The number of CSI2_CLK functional clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x
12-0	LP_RX_TO_COUNTER	R/W	1FFFh	LP_RX_TIMER counter. It indicates the number of CSI2_CLK function clock for the LP RX timer. The value is from 0 to 8191.

14.4.4.14 CSI2_VM_TIMING1 Register (Offset = 60h) [reset = 0h]

CSI2_VM_TIMING1 is shown in Figure 14-172 and described in Table 14-168.

Return to Summary Table.

VIDEO MODE TIMING REGISTER This register defines the video mode timing.

Figure 14-172. CSI2_VM_TIMING1 Register

Table 14-169. CSI2_VM_TIMING2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R-0	0h	
27-24	WINDOW_SYNC	R/W	0h	Number of BYTE clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchornization on video port is not inside the window. CSI2 does not change its own timings if the synch is inside the window. The valid values are from 4 to 15.
23-16	VSA	R/W	0h	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.
15-8	VFP	R/W	0h	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255
7-0	VBP	R/W	0h	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255

14.4.4.16 CSI2_VM_TIMING3 Register (Offset = 68h) [reset = 0h]

CSI2_VM_TIMING3 is shown in Figure 14-174 and described in Table 14-170.

Return to Summary Table.

VIDEO MODE TIMING REGISTER This register defines the video mode timing.

Figure 14-174. CSI2_VM_TIMING3 Register

Table 14-171. CSI2_CLK_TIMING Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R-0	0h	
15-8	DDR_CLK_PRE	R/W	1h	Indicates the number of PPI Byte clock cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if CSI2_CLK_CTRL.DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.
7-0	DDR_CLK_POST	R/W	1h	Indicates the number of PPI Byte clock cycles after the de-assertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if CSI2_CLK_CTRL.DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.

14.4.4.18 CSI2_TX_FIFO_VC_SIZE Register (Offset = 70h) [reset = 0h]

CSI2_TX_FIFO_VC_SIZE is shown in Figure 14-176 and described in Table 14-172.

Return to Summary Table.

Defines the corresponding memory entries allocated for each virtual channel. The virtual channel shall be disabled in order to allocate/un-allocate some entries in the TX FIFO.

2	LANE3_ULPS_SIG1	R/W	0h	Enables the ULPS for the lane #3. The HW shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the CSI2 protocol engine and the CSI2 protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0h (R/W) = READ: Inactive state effective. WRITE: Request to change to inactive state 1h (R/W) = READ:Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc
1	LANE2_ULPS_SIG1	R/W	0h	Enables the ULPS for the lane #2. The HW shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the CSI2 protocol engine and the CSI2 protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane #2 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0h (R/W) = READ: Inactive state effective. WRITE: Request to change to inactive state 1h (R/W) = READ:Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc
0	LANE1_ULPS_SIG1	R/W	0h	Enables the ULPS for the lane #1. The HW shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the CSI2 protocol engine and the CSI2 protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane #1 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0h (R/W) = READ:Inactive state effective. WRITE: Request to change to inactive state 1h (R/W) = READ:Active state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc

14.4.4.21 CSI2_RX_FIFO_VC_FULLNESS Register (Offset = 7Ch) [reset = 0h]

CSI2_RX_FIFO_VC_FULLNESS is shown in Figure 14-179 and described in Table 14-175.

Return to Summary Table.

Defines the fullness of each space allocated for each virtual channel.

Figure 14-179. CSI2_RX_FIFO_VC_FULLNESS Register

Table 14-180. CSI2_VM_TIMING7 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ENTER_HS_MODE_LATENCY	R/W	0h	Defines the number of HS byte clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .
15-0	EXIT_HS_MODE_LATENCY	R/W	0h	Defines the number of HS byte clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of HS byte clock from de-assertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535

14.4.4.27 CSI2_STOPCLK_TIMING Register (Offset = 94h) [reset = 80h]

CSI2_STOPCLK_TIMING is shown in Figure 14-185 and described in Table 14-181.

Return to Summary Table.

Number of functional clock cycles to wait for TxByteClkHS to stop/start after change in CSI2StopClk signal

Figure 14-185. CSI2_STOPCLK_TIMING Register

31	DCS_CMD_CODE	R/W	0h	DCS command code value to insert between header and video port or OCP slave data when enabled by DCS_CMD_ENABLE (only when TE mechanism is not used otherwise the bit-field DCS_CMD_CODE is ignored by CSI2 protocol engine). 0h (R/W) = DCS write memory continue code is inserted. 1h (R/W) = DCS write memory start code is inserted.
30	DCS_CMD_ENABLE	R/W	0h	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0h (R/W) = DCS command code is NOT inserted when command mode traffic is coming from the Video Port or OCP slave port. 1h (R/W) = DCS command code is inserted automatically when command mode traffic is coming from the Video Port or OCP slave port.
29-27	DMA_RX_REQ_NB	R/W	0h	Selection of the use of the DMA request (associated to the RX FIFO) 0h (R/W) = DMA_req0 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 0) 1h (R/W) = DMA_req1 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 1) 2h (R/W) = DMA_req2 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 2) 3h (R/W) = DMA_req3 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is equal to 3) 4h (R/W) = No DMA req selected

Table 14-187. CSI2_VC_CTRL_0 to CSI2_VC_CTRL_3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26-24	DMA_RX_THRESHOLD	R/W	0h	Defines the threshold value for the DMA request (associated to the RX FIFO) 0h (R/W) = 1x 32 bits 1h (R/W) = 2 x 32 bits 2h (R/W) = 4 x 32 bits 3h (R/W) = 8 x 32 bits 4h (R/W) = 16 x 32 bits 5h (R/W) = 32 x 32 bits
23-21	DMA_TX_REQ_NB	R/W	0h	Selection of the use of the DMA request (associated to the TX FIFO) 0h (R/W) = DMA_req0 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 0) 1h (R/W) = DMA_req1 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 1) 2h (R/W) = DMA_req2 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is greater than 2) 3h (R/W) = DMA_req3 is selected (valid only if CSI2_GNQ.NB_DMA_REQUEST is equal to 3) 4h (R/W) = No DMA req selected
20	RX_FIFO_NOT_EMPTY	R	0h	FIFO status 0h (R) = The RX FIFO is empty (the FIFO does not contain any data for the virtual channel) 1h (R) = The RX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)
19-17	DMA_TX_THRESHOLD	R/W	0h	Defines the threshold value for the DMA request (associated to the TX FIFO) 0h (R/W) = 1x 32 bits 1h (R/W) = 2 x 32 bits 2h (R/W) = 4 x 32 bits 3h (R/W) = 8 x 32 bits 4h (R/W) = 16 x 32 bits 5h (R/W) = 32 x 32 bits
16	TX_FIFO_FULL	R	0h	FIFO status 0h (R) = The TX FIFO is not full (the FIFO can accept at least one more 32-bit valuel) 1h (R) = The TX FIFO is full
15	VC_BUSY	R	0h	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0h (R) = No pending operations for this VC 1h (R) = Pending operations for this VC
14	PP_BUSY	R	0h	Ping-pong buffer busy status. 0h (R) = Software is permitted to write a new header for VP command mode traffic. 1h (R) = Software is NOT permitted to write a new header for VP command mode traffic.
13	VP_SOURCE	R/W	0h	Selection between video port 1 and video port 2. If CSI2_GNQ.NB_VIDEO_PORTS=0, the bit-field is ignored since only video port 1 is present. 0h (R/W) = The video port 1 is selected. 1h (R/W) = The video port 2 is selected.
12	RGB565_ORDER	R/W	0h	Byte order for RBG565 0h (R/W) = Byte order as documented in the MIPI DBI-2 spec 1h (R/W) = Byte order as for video mode

Table 14-187. CSI2_VC_CTRL_0 to CSI2_VC_CTRL_3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	OCP_DATA_BUS_WIDTH	R/W	0h	Defines the size of the OCP data bus 0h (R/W) = 16-bits data width (LSB of the 32-bit OCP port data bus) 1h (R/W) = 24-bits data width (LSB of the 32-bit OCP port data bus) 2h (R/W) = 2x16-bits data width (first pixel on the LSB of the 32-bit OCP port data bus and second pixel on the MSB of the 32-bit OCP port data bus for the same OCP access) 3h (R/W) = 32-bits data width
9	MODE_SPEED	R/W	0h	Selection of the mode. The information is used by HW only if MODE=COMMAND_MODE otherwise it is ignored. 0h (R/W) = Low power mode (CMOS) is used to send short and long packets to the peripheral. 1h (R/W) = High Speed mode (SLVS) is used to send short and long packets to the peripheral.
8	ECC_TX_EN	R/W	0h	Enables the Error Correction Code generation for the transmit header (short and long packets). 0h (R/W) = Disabled 1h (R/W) = Enabled
7	CS_TX_EN	R/W	0h	Enables the checksum generation for the transmit payload (long packet only). 0h (R/W) = Disabled. The value 0x00 is used. 1h (R/W) = Enabled. The Check-sum value is calculated by HW.
6	BTA_EN	R/W	0h	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode is used to allow the user to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0h (R/W) = READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, shall not be used). 1h (R/W) = READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.
5	TX_FIFO_NOT_EMPTY	R	0h	FIFO status 0h (R) = The TX FIFO is empty (the FIFO does not contain any data for the virtual channel) 1h (R) = The TX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)
4	MODE	R/W	0h	Selection of the mode 0h (R/W) = Command mode. 1h (R/W) = Video mode. The bit-fields MODE_SPEED and SOURCE are not used by HW. The bit-field VP_SOURCE is used to select between video port 1 and video port 2 when two video ports are present.
3	BTA_LONG_EN	R/W	0h	Enables the automatic bus turn-around after completion of each long packet transmission. 0h (R/W) = Disabled 1h (R/W) = Enabled
2	BTA_SHORT_EN	R/W	0h	Enables the automatic bus turn-around after completion of each short packet transmission. 0h (R/W) = Disabled 1h (R/W) = Enabled

Table 14-187. CSI2_VC_CTRL_0 to CSI2_VC_CTRL_3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SOURCE	R/W	0h	Selection of the source between OCP and the Video port(s) (used by the HW only if MODE=COMMAND MODE (0x0) otherwise it is ignored). The number of available video ports is defined in CSI2_GNQ.NB_VIDEO_PORTS. 0h (R/W) = All the data are provided by the slave port. Any transfer on the video port is ignored for this virtual channel. 1h (R/W) = If MODE=VIDEO_MODE. the data received on the video port 1 or video port 2, selected using VP_SOURCE (pixels and enabled synchronization events using CSI2_CTRL1.VP_HSYNC_START, CSI2_CTRL1.VP_HSYNC_END, CSI2_CTRL1.VP_VSYNC_START, CSI2_CTRL1.VP_VSYNC_END for video port 1 and CSI2_CTRL2.VP_HSYNC_START, CSI2_CTRL2.VP_HSYNC_END, CSI2_CTRL2.VP_VSYNC_START, CSI2_CTRL2.VP_VSYNC_END for video port 2) are sent on the virtual channel (only one virtual channel can be associated with the video port, it is the SW responsibility to ensure that no more than one virtual channel is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP.STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the OCP slave port.
0	VC_EN	R/W	0h	Enables the virtual channel. 0h (R/W) = Disabled. The virtual channel shall be disabled for any register change in the CSI2_VC_... registers the corresponding virtual channel id (except for setting the bit-fields/registers: CSI2_VC_CTRL.BTA_EN, CSI2_VC_TE.TE_SIZE, CSI2_VC_TE.TE_START, CSI2_VC_LONG_,,, CSI2_VC_SHORT_..., CSI2_VC_IRQ...). 1h (R/W) = Enabled. No change is allowed to the virtual channel registers expect resetting the VC_EN.

14.4.4.34 CSI2_VC_TE_0 to CSI2_VC_TE_3 Register (Offset = 104h + [i * 8h], where i = 0 to 3) [reset = 0h]

CSI2_VC_TE_0 to CSI2_VC_TE_3 is shown in Figure 14-192 and described in Table 14-188.

Return to Summary Table.

CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.

Figure 14-192. CSI2_VC_TE_0 to CSI2_VC_TE_3 Register

Table 14-188. CSI2_VC_TE_0 to CSI2_VC_TE_3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TE_START	R/W	0h	Manual control of the start of the transfer. The user can use the TE interrupt in order to know that the TE trigger has been received prior to set the TE_START bit-field. It is not mandatory to use the TE interrupt. 0h (R/W) = Indicates the end of the transfer. The bit can be used by user to cancel the transfer if not already started. The FIFO shall be flushed by SW to ensure there is no data remaining in it. 1h (R/W) = Starts the transfer of the data. The size is defined in TE_SIZE. The bit-field is set until the transfer is completed. It is reset by HW when the transfer is completed.
30	TE_EN	R/W	0h	Tearing Effect Control 0h (R/W) = Disables the automatic transfer. The user shall use the interruption in order to know when TE PHY trigger is received or when the TE is detected on the input CMOS signals. The HW reset the bit-field when the transfer is completed (TE_SIZE=0). 1h (R/W) = Enables the automatic transfer of the data using the TE PHY trigger or one of the TE input signals as a synchronization event. The bit-field TE_LINE defines if the CMOS signal is used or if the PHY trigger is used.
29	TE_LINE	R/W	0h	
28	TE_LINE_NB	R/W	0h	Selection between TE0 and TE1 cmos signals. 0h (R/W) = TE0 cmos input line is selected 1h (R/W) = TE1 cmos input line is selected
27-24	RESERVED	R-0	0h	
23-0	TE_SIZE	R/W	0h	Defines the number of byte (payload data excluding the check -sum) to be sent. The write into the register CSI2_VC_LONG_PACKET_HEADER shall be performed by the user before sending data from the register CSI2_VC_LONG_PACKET_PAYLOAD. The register value is decremented for every byte sent of the CSI2 link. At the end of the transfer (TE_SIZE=0), the bit-field TE_EN is reset by HW. The DMA_request shall be asserted when the trigger is received in order to receive data in the TX FIFO. It shall not be used until all data (TE_SIZE) have been received in the FIFO.

14.4.4.35 CSI2_VC_LONG_PACKET_HEADER_0 to CSI2_VC_LONG_PACKET_HEADER_3 Register (Offset = 108h + [i * 8h], where i = 0 to 3) [reset = 0h]

CSI2_VC_LONG_PACKET_HEADER_0 to CSI2_VC_LONG_PACKET_HEADER_3 is shown in Figure 14-193 and described in Table 14-189.

Return to Summary Table.

LONG PACKET HEADER INFORMATION -Virtual channel
This register sets the 32-bit DATA_ID + Word count + ECC (the virtual channel id can be different than VC).
The ECC will be computed if ECC_TX_EN is set to 1.
DATA_ID is located at bit[7:0]
WC is located at bit[23:8]
ECC is located at bit[31:24]
(Least significant byte first and least significant bit first)

Figure 14-193. CSI2_VC_LONG_PACKET_HEADER_0 to CSI2_VC_LONG_PACKET_HEADER_3 Register

14.4.4.37 CSI2_VC_SHORT_PACKET_HEADER_0 to CSI2_VC_SHORT_PACKET_HEADER_3 Register (Offset = 110h + [i * 8h], where i = 0 to 3) [reset = 0h]

CSI2_VC_SHORT_PACKET_HEADER_0 to CSI2_VC_SHORT_PACKET_HEADER_3 is shown in Figure 14-195 and described in Table 14-191.

Return to Summary Table.

SHORT PACKET HEADER INFORMATION -Virtual channel
This register sets the 24-bit DATA_ID + Short Packet Data Field + ECC (the virtual channel id can be different than VC).
The ECC will be computed if ECC_TX_EN is set to 1.
DATA_ID is located at bit[7:0]
Short Packet Data field is located at bit[23:8]
ECC is located at bit[31:24]
(Least significant byte first and least significant bit first)

R/W-1Dh								R/W-3Ah							

Table 14-196. REGISTER0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	REG_THSPREPARE	R/W	1Eh	REG_THSPREPARE timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY spec:40ns+4UI-85ns+6UI Auctual value seen on line : = REG_THSPREPARE timer + analog delay & slew on signals = REG_THSPREPARE +(-26.5ns - - +4 ns) PROGRAMMED VALUE = ceil(70 ns / DDR Clock Period) + 2 Default value is programmed for 400 MHz
23-16	REG_THSPRPR_THSZERO	R/W	48h	REG_THSPREPARE_THSZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY spec: > 145ns + 10 UI Actual value seen on line N= REG_THSPREPARE_THSZERO - REG_THSPREPARE M=REG_THSPREPARE = [ceil [(N+3)/4] * 4 + ceil [M/4] * 4 + 3] * DDR_Clock_Period+[~-29ns - 0ns] PROGRAMMED VALUE = ceil (175 ns/ DDR Clock Period) + 2 Default value is programmed for 400 MHz
15-8	REG_THSTRAIL	R/W	1Dh	REG_THSTRAIL timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY spec : > 60ns + 4UI Actual value seen on line : N = REG_THSTRAIL = [ceil [(N+3)/4] * 4 - 2.75] * DDR_Clock_period +(~ 0ns - 5ns) PROGRAMMED VALUE = ceil (60 ns / DDR Clock Period) + 5 Default value is programmed for 400 MHz
7-0	REG_THSEXIT	R/W	3Ah	REG_THSEXIT timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. D-PHy spec : > 100 ns Actual value seen on line : N = REG_THSEXIT = THSEXIT timer + analog delay & slew on LP signals = [ceil[N/4] * 4] * DDR_CLOCK_PERIOD - (~3 ns - 45 ns) PROGRAMMED VALUE = ceil (145 ns/ DDR Clock Period) Default value is programmed for 400 MHz

14.4.5.2 REGISTER1 Register (Offset = 4h) [reset = 420A1A6Ah]

REGISTER1 is shown in Figure 14-199 and described in Table 14-197.

Return to Summary Table.

Table 14-197. REGISTER1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	REG_TTAGO	R/W	2h	TTA-GO timing in terms of number of TXCLKESC clocks 000 == 2 cycles 001 == 3 cycles 010 == 4 cycles 011 == 5 cycles 100 == 6 cycles 101 == 7 cycles 110 == 8 cycles 111 == 9 cycles Default value: 4 cycles
28-27	REG_TTASURE	R/W	0h	TTA-SURE timing in terms of number of TXCLKESC clocks 00 == 2 cycles 01 == Reserved 10 == 3 cycles 11 == 4 cycles Default value: 2 cycles
26-24	REG_TTAGET	R/W	2h	TTA-GET timing in terms of number of TXCLKESC clocks 000 == 3 cycles 001 == 4 cycles 010 == 5 cycles 011 == 6 cycles 100 == 7 cycles 101 == 8 cycles 110 == 9 cycles 111 == 10 cycles Default value: 5 cycles
23-21	EMPTY	R-0	0h	Reserved
20-16	REG_TLPXBY2	R/W	Ah	(TLPX)/2 timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. PROGRAMMED VALUE = ceil (25 ns / DDR Clock Period) Default value is programmed for 400 MHz Note : TLPX is used to define the length of LP-01 state in HS start of Transmision sequences on clock and data lanes. For all other purposes TLPX is defined by the period of TXLPESC
15-8	REG_TCLKTRAIL	R/W	1Ah	REG_TCLKTRAIL timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. D-PHY spec : 60 ns PROGRAMMED VALUE = ceil (60 ns / DDR Clock Period) Actual value seen on line: N = REG_TCLKTRAIL = [ceil[(N+3)/4] *4 - 1.5] * DDR_Clock_Period + (~0 ns - 5 ns) PROGRAMMED VALUE = ceil (60 ns / DDR Clock Period) + 2 Default value is programmed for 400 MHz
7-0	REG_TCLKZERO	R/W	6Ah	REG_TCLKZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY spec :[REG_TCLKPREPARE + REG_TCLKZERO] > 300 ns Derived spec for REG_TCLKERO (Min REG_TCLKPREPARE = 38 ns) REG_TCLKZERO > 262 ns Actual value seen on line : N = REG_TCLKZERO M = REG_TCLKPREPARE = [ceil [(N+3)/4] *4 + ceil (M/4) * 4 - M + 2] * DDR_Clock_Period + [~0ns - 5ns] PROGRA MMED VALUE = ceil (265 ns / DDR Clock Period) Default value is programmed for 400 MHz

14.4.5.3 REGISTER2 Register (Offset = 8h) [reset = B800001Ah]

REGISTER2 is shown in Figure 14-200 and described in Table 14-198.

Return to Summary Table.

Hardware Accelerator

Topic **Page**

15.1 Introduction **2114**
15.2 Register Map **2114**

15.1 Introduction

The radar hardware accelerator is a hardware IP that enables offloading the burden of certain frequently used computations in FMCW radar signal processing from the main processor. FMCW radar signal processing involves the use of FFT and Log-Magnitude computations to obtain a radar image across the range, velocity, and angle dimensions. Some of the frequently used functions in FMCW radar signal processing can be done within the radar hardware accelerator, while still retaining the flexibility of implementing other proprietary algorithms in the main processor. See the *Hardware Accelerator User's Guide* (SWRU526 for part 1 and SWRU527 part 2) for a functional description and features of this module.

The following describes which Hardware Accelerator (HWA) version is present in each silicon revision of each device:

	HWA V1.0	HWA v1.05	HWA V1.1
Device	IWR1443 ES1.0, ES2.0, ES3.0	IWR6843 ES1.0	IWR6843 ES2.0

15.2 Register Map

For details on the hardware accelerator register, see the *Radar Hardware Accelerator User's Guide*.

Real Time Interrupt (RTI) and RTI With Digital Watchdog Timer (WDT)

This section describes the functionality of the real-time interrupt (RTI) module. The RTI is designed as an operating system timer to support a real time operating system (RTOS). The watchdog timer is also implemented, using another instance of the RTI module.

NOTE: This chapter describes a superset implementation of the RTI module that includes features and functionality related to DMA, and Timebase control. These features are dependent on the device-specific feature content. Consult your device-specific data sheet to determine the applicability of these features to the device being used.

Topic **Page**

16.1 Overview **2116**
16.2 Module Operation **2117**
16.3 RTI Control Registers **2124**

16.1 Overview

The real-time interrupt (RTI) module provides timer functionality for operating systems and for benchmarking code. The RTI module can incorporate several counters that define the timebases needed for scheduling in the operating system.

The timers also allow you to benchmark certain areas of code by reading the values of the counters at the beginning and the end of the desired code range and calculating the difference between the values.

16.1.1 Features

The RTI module has the following features:

- Two independent 64 bit counter blocks
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- Fast enabling/disabling of events
- Two time stamp (capture) functions for system or peripheral interrupts, one for each counter block
- Digital windowed watchdog

16.1.2 Industry Standard Compliance Statement

This module is specifically designed to fulfill the requirements for OSEK (**O**ffene **S**ysteme und deren **S**chnittstellen für die **E**lektronik im **K**raftfahrzeug, or Open Systems and the Corresponding Interfaces for Automotive Electronics) as well as OSEK/time-compliant operating systems, but is not limited to it.

16.2 Module Operation

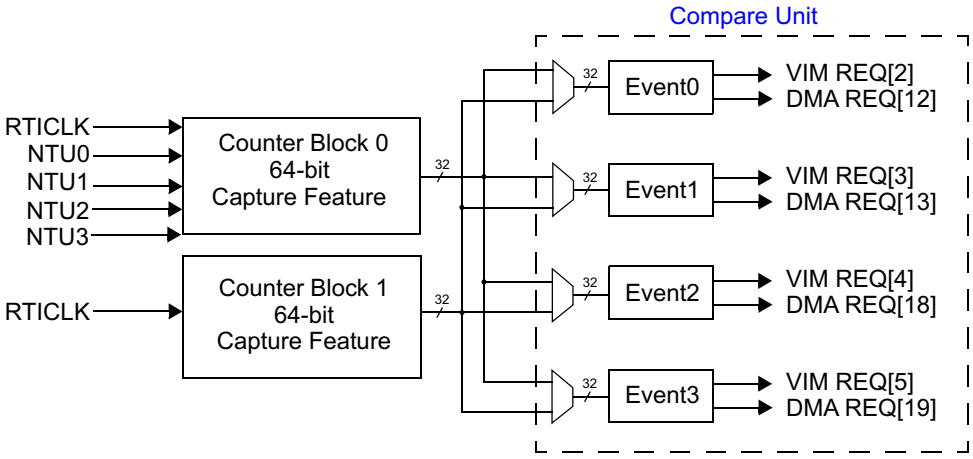
Figure 16-1 illustrates the high level block diagram of the RTI module.

The RTI module has two independent counter blocks for generating different timebases: counter block 0 and counter block 1.

A compare unit compares the counters with programmable values and generates four independent interrupt or DMA requests on compare matches. Each of the compare registers can be programmed to be compared to either counter block 0 or counter block 1.

The following sections describe the individual functions in more detail.

Figure 16-1. RTI Block Diagram



16.2.1 Counter Operation

Each counter block consists of the following (see Figure 16-2):

- One 32-bit prescale counter (RTIUC0 or RTIUC1)
- One 32-bit free running counter (RTIFRC0 or RTIFRC1)

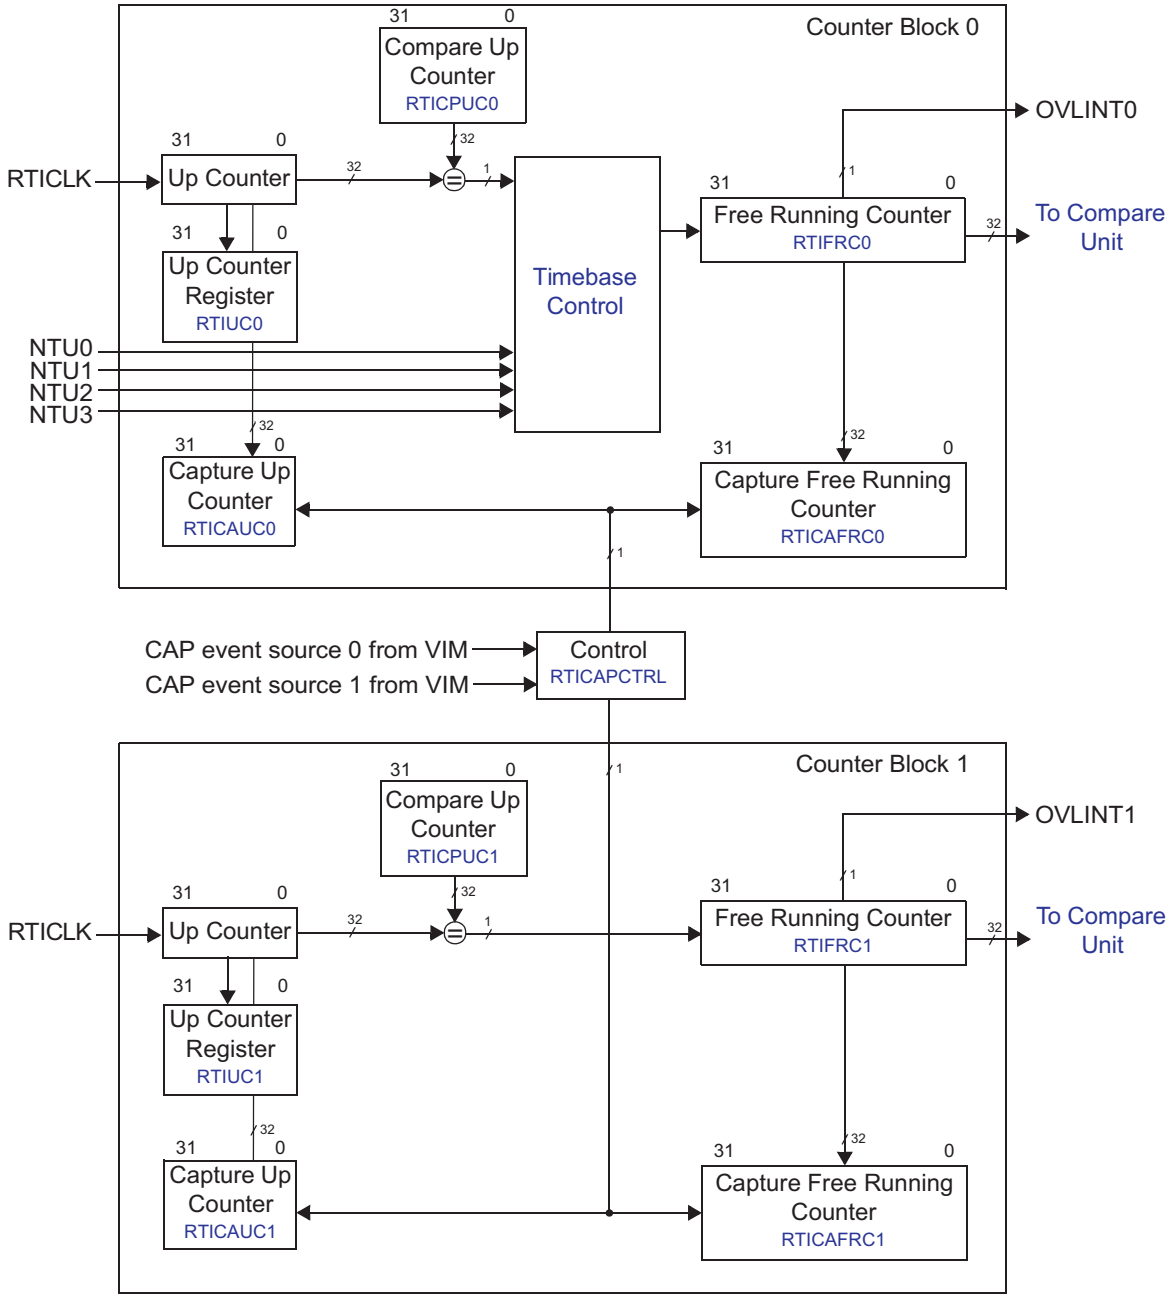
The RTIUC0/1 is driven by the RTICLK and counts up until the compare value in the compare up counter register (RTICPUC0 or RTICPUC1) is reached. When the compare matches, RTIFRC0/1 is incremented and RTIUC0/1 is reset to 0. If RTIFRC0/1 overflows, an interrupt is generated to the vectored interrupt manager (VIM). The overflow interrupt is not intended to generate the timebase for the operating system. See Section 16.2.2 for the timebase generation. The up counter together with the compare up counter value prescale the RTI clock. The resulting formula for the frequency of the free running counter (RTIFRC0/1) is:

$$f_{RTIFRCx} = \begin{cases} \dfrac{f_{RTICLK}}{RTICPUCx + 1} & \text{when RTICPUCx} \neq 0 \\ \dfrac{f_{RTICLK}}{2^{32}+1} & \text{when RTICPUCx} = 0 \end{cases} \quad (3)$$

NOTE: Setting RTICPUCx equal to zero is not recommended. Doing so will hold the Up Counter at zero for two RTICLK cycles after it overflows from 0xFFFFFFFF to zero.

The counter values can be determined by reading the respective counter registers or by generating a hardware event which captures the counter value into the respective capture register. Both functions are described in the following sections.

Figure 16-2. Counter Block Diagram



16.2.1.1 Counter and Capture Read Consistency

Portions of the device internal databus are 32-bits wide. If the application wants to read the 64-bit counters or the 64-bit capture values, a certain order of 32-bit read operations needs to be followed. This is to prevent one counter incrementing in between the two separate read operations to both counters.

Reading the Counters

The free running counter (RTIFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTIFRCx, the up counter value is stored in its counter register (RTIUCx). The second read has to access the up counter register (RTIUCx), which then holds the value which corresponds to the number of RTICLK cycles that have elapsed at the time reading the free running counter register (RTIFRCx).

NOTE: The up counters are implemented as shadow registers. Reading RTIUCx without having read RTIFRCx first will return always the same value. RTIUCx will only be updated when RTIFRCx is read.

Reading the Capture Values

The free running counter capture register (RTICAFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTICAFRCx, the up counter value is stored in its counter register (RTICAUCx). The second read has to access the up counter register (RTICAUCx), which then holds the value captured at the time when reading the capture free running counter register (RTICAFRCx).

NOTE: The capture up counter registers are implemented as shadow registers. Reading RTICAUCx without having read RTICAFRCx first will return always the same value. RTICAUCx will only be updated when RTICAFRCx is read.

16.2.1.2 Capture Feature

Both counter blocks also provide a capture feature on external events. Two capture sources can trigger the capture event. The source triggering the block is configurable (RTICAPCTRL). The sources originate from the Vectored Interrupt Manager (VIM) and allow the generation of capture events when a peripheral modules has generated an interrupt. Any of the peripheral interrupts can be selected as the capture event in the VIM.

When an event is detected, RTIUCx and RTIFRCx are stored in the capture up counter (RTICAUCx) and capture free running counter (RTICAFRCx) registers. The read order of the captured values must be the same as the read order of the actual counters (see Section 16.2.1.1).

16.2.2 Interrupt/DMA Requests

There are four compare registers (RTICOMPy) to generate interrupt requests to the VIM or DMA requests to the DMA controller. The interrupts can be used to generate different timebases for the operating system. Each of the compare registers can be configured to be compared to either RTIFRC0 or RTIFRC1. When the counter value matches the compare value, an interrupt is generated. To allow periodic interrupts, a certain value can be added to the compare value in RTICOMPy automatically. This value is stored in the update compare register (RTIUDCPy) and will be added after a compare is matched. The period of the generated interrupt/DMA request can be calculated with:

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times RTIUDCPy$$

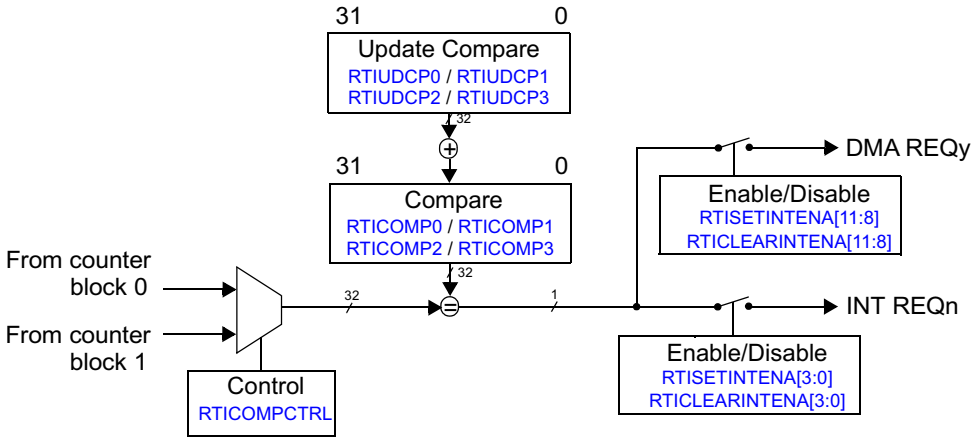
if RTICPUCy = 0,

$$t_{COMPx} = t_{RTICLK} \times (2^{32}+1) \times RTIUDCPy$$

if RTIUDCPy = 0,

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times 2^{32} \quad (4)$$

Figure 16-3. Compare Unit Block Diagram (shows only 1 of 4 blocks for simplification)



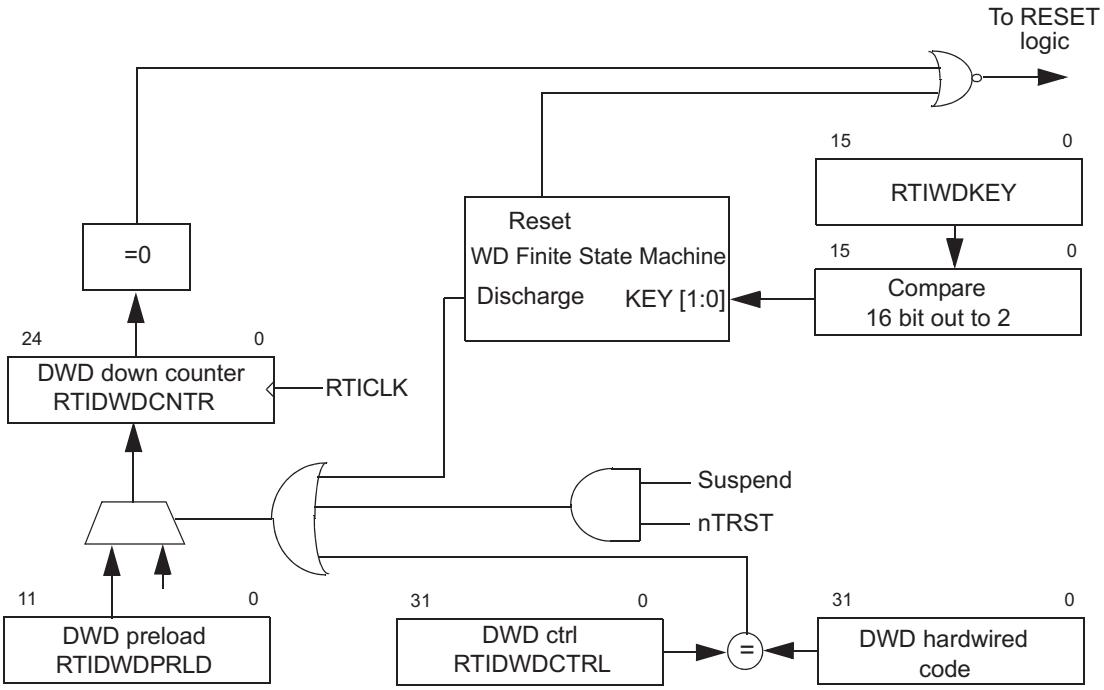
Another interrupt that can be generated is the overflow interrupt (OVLINTx) in case the RTIFRCx counter overflows.

The interrupts/DMA requests can be enabled in the RTISETINTENA register and disabled in the RTICLEARINTENA register. The RTIINTFLAG register shows the pending interrupts.

16.2.3 Digital Watchdog (DWD)

The digital watchdog (DWD) is an optional safety diagnostic which can detect a runaway CPU and generate either a reset or NMI (non-maskable interrupt) response. It generates resets or NMIs after a programmable period, or if no correct key sequence was written to the RTIWDKEY register. Figure 16-4 illustrates the DWD.

Figure 16-4. Digital Watchdog



16.2.3.1 Digital Watchdog (DWD)

The DWD is disabled by default. If it should be used, it must be enabled by writing a 32-bit value to the RTIDWDCTRL register.

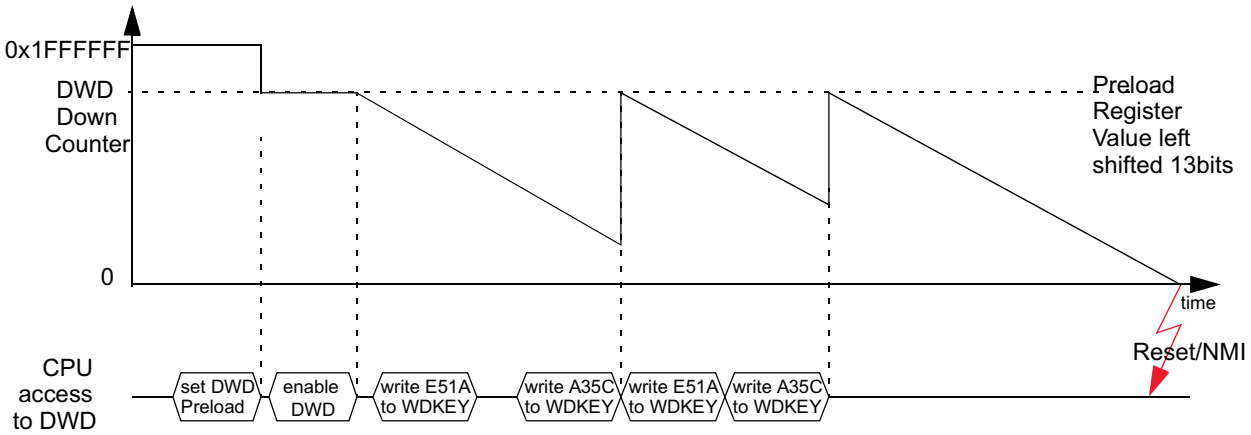
NOTE: Once the DWD is enabled, it cannot be disabled except by system reset or power on reset.

If the correct key sequence is written to the RTIWDKEY register (0xE51A followed by 0xA35C), the 25-bit DWD down counter is reloaded with the left justified 12-bit preload value stored in RTIDWDPRLD. If an incorrect value is written, a watchdog reset or NMI will occur immediately. A reset or NMI will also be generated when the DWD down counter is decremented to 0.

While the device is in suspend mode (halting debug mode), the DWD down counter keeps the value it had when entering suspend mode.

The DWD down counter will be decremented with the RTICLK frequency.

Figure 16-5. DWD Operation



The expiration time of the DWD down counter can be determined with the following equation:

$texp = (DWDPRLD + 1) \times 2^{13}/RTICLK$

where

DWDPRLD = 0...4095

NOTE: Care should be taken to ensure that the CPU write to the watchdog register is made allowing time for the write to propagate to the RTI.

16.2.3.2 Digital Windowed Watchdog (DWWD)

In addition to the time-out boundary configurable via the digital watchdog discussed in Section 16.2.3.1, for enhanced safety metrics it is desirable to check for a watchdog "pet" within a time window rather than using a single time threshold. This is enabled by the digital windowed watchdog (DWWD) feature.

- Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a NMI to the CPU. This is controlled by configuring the RTIWWDRXNCTRL register. As with the DWD, the DWWD is disabled after power on reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The NMI handler needs to clear the watchdog violation status flag(s) and then

service the watchdog by writing the correct sequence in the watchdog key register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the NMI handler does not service the watchdog in time, it could count down all the way to zero and wrap around. If the NMI Handler does not service the watchdog in time, the NMI gets generated continuously, each time the counter counts to '0'.

The DWWD uses the Digital Watchdog (DWD) preload register (RTIDWDPRLD) setting to define the end-time of the window. The start-time of the window is defined by a window size configuration register(RTIWWDSIZECTRL).

The default window size is set to 100%, which corresponds to the DWD functionality of a time-out-only watchdog. The window size can be selected (through register RTIWWDSIZECTRL) from among 100%, 50%, 25%, 12.5%, 6.25% and 3.125% as shown in Figure 16-6. The window with the respective size will be opened before the end of the DWD expiration. The user has to serve the watchdog in the window. Otherwise, a reset or NMI will generate. Figure 16-7 shows an DWWD operation example (25% window).

- Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD. This feature can be utilized to dynamically set windows of different sizes based on task execution time, adding a program sequence element to the diagnostic which can improve fault coverage.

Figure 16-6. Digital Windowed Watchdog Timing Example

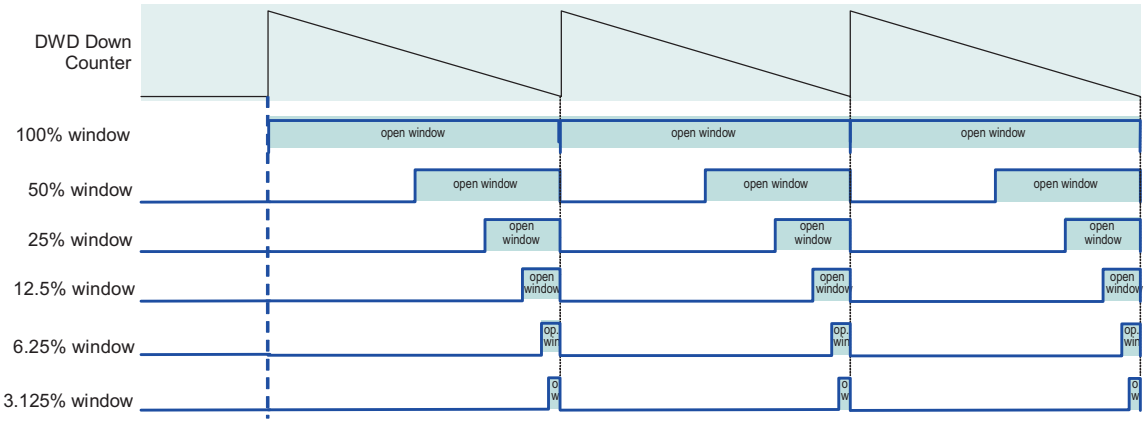


Figure 16-7. Digital Windowed Watchdog Operation Example (25% Window)

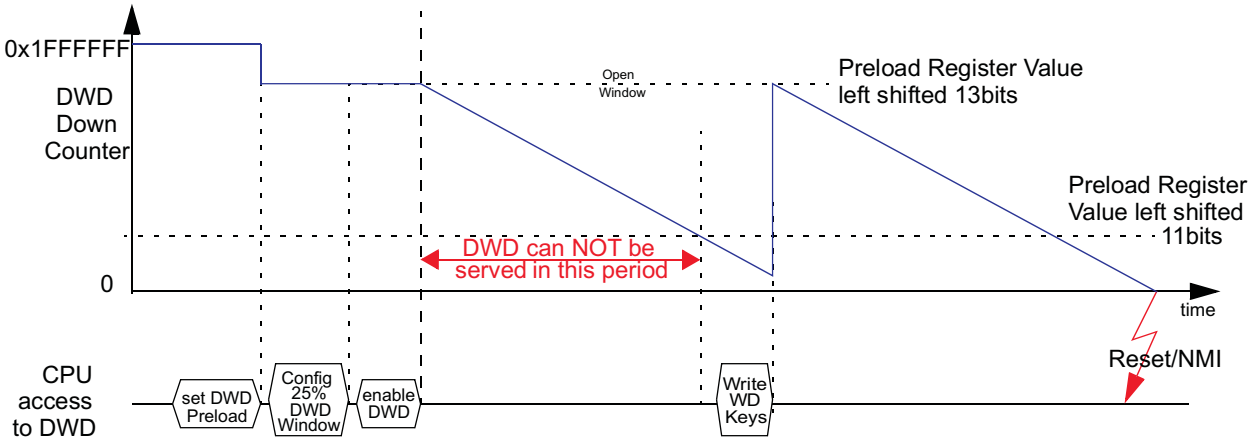

16.2.4 Halting Debug Mode Behaviour

Once the system enters halting debug mode, the behavior of the RTI depends on the COS (continue on suspend) bit. If the bit is cleared and halting debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

16.3 RTI Control Registers

Table 16-1 provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers. The subsystem contains two RTI modules, RTI1 and RTI2. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-2. RTI Global Control Register (RTIGCTRL) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	NTUSEL		Select NTU signal. These bits determine which NTU input signal is used as external timebase
		0h	NTU0
		5h	NTU1
		Ah	NTU2
		Fh	NTU3
		All other values	Tied to 0
15	COS		Continue on suspend. This bit determines if both counters are stopped when the device goes into halting debug mode or if they continue counting.
		0	Counters are stopped while in halting debug mode.
		1	Counters are running while in halting debug mode.
14-2	Reserved	0	Reads return 0. Writes have no effect.
1	CNT1EN		Counter 1 enable. This bit starts and stops counter block 1 (RTIUC1 and RTIFRC1).
		0	Counter block 1 is stopped.
		1	Counter block 1 is running.
0	CNT0EN		Counter 0 enable. This bit starts and stops counter block 0 (RTIUC0 and RTIFRC0).
		0	Counter block 0 is stopped.
		1	Counter block 0 is running.

NOTE: If the application uses the timebase circuit for synchronization between the communications controller and the operating system and the device enters halting debug mode, the synchronization may be lost depending on the COS setting in the RTI module and the halting debug mode behavior of the communications controller.

16.3.2 RTI Timebase Control Register (RTITBCTRL)

The timebase control register selects if the free running counter 0 is incremented by RTICLK or NTU. This register is shown in Figure 16-9 and described in Table 16-3.

Figure 16-9. RTI Timebase Control Register (RTITBCTRL) [offset = 04h]

Table 16-3. RTI Timebase Control Register (RTITBCTRL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	INC		Increment free running counter 0. This bit determines whether the free running counter 0 (RTIFRC0) is automatically incremented if a failing clock on the NTU signal is detected.
		0	RTIFRC0 will not be incremented on a failing external clock.
		1	RTIFRC0 will be incremented on a failing external clock.
0	TBEXT		Timebase external. This bit selects whether the free running counter 0 (RTIFRC0) is clocked by the internal up counter 0 (RTIUC0) or from the external signal NTU. Setting the TBEXT bit from 0 to 1 will not increment RTIFRC0, since RTIUC0 is reset.
			When the timebase supervisor circuit detects a missing clock edge, then the TBEXT bit is reset.
			Only the software can select whether the external signal should be used.
		0	RTIUC0 clocks RTIFRC0.
		1	NTU clocks RTIFRC0.

16.3.3 RTI Capture Control Register (RTICAPCTRL)

The capture control register controls the capture source for the counters. This register is shown in Figure 16-10 and described in Table 16-4.

Figure 16-10. RTI Capture Control Register (RTICAPCTRL) [offset = 08h]

Bit	Field	Value	Description
31-2	Reserved	0	Reads return 0. Writes have no effect.
1	CAPCNTR1		Capture counter 1. This bit determines which external interrupt source triggers a capture event of RTIUC1 and RTIFRC1.
		0	Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 0.
		1	Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 1.
0	CAPCNTR0		Capture counter 0. This bit determines which external interrupt source triggers a capture event of RTIUC0 and RTIFRC0.
		0	Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 0.
		1	Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 1.

16.3.4 RTI Compare Control Register (RTICOMPCTRL)

The compare control register controls the source for the compare registers. This register is shown in Figure 16-11 and described in Table 16-5.

Bit	Field	Value	Description
31-13	Reserved	0	Reads return 0. Writes have no effect.
12	COMPSEL3		Compare select 3. This bit determines the counter with which the compare value held in compare register 3 (RTICOMP3) is compared.
		0	Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
11-9	Reserved	0	Reads return 0. Writes have no effect.
8	COMPSEL2		Compare select 2. This bit determines the counter with which the compare value held in compare register 2 (RTICOMP2) is compared.
		0	Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
7-5	Reserved	0	Reads return 0. Writes have no effect.
4	COMPSEL1		Compare select 1. This bit determines the counter with which the compare value held in compare register 1 (RTICOMP1) is compared.
		0	Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.
3-1	Reserved	0	Reads return 0. Writes have no effect.
0	COMPSEL0		Compare select 0. This bit determines the counter with which the compare value held in compare register 0 (RTICOMP0) is compared.
		0	Value will be compared with RTIFRC0.
		1	Value will be compared with RTIFRC1.

16.3.5 RTI Free Running Counter 0 Register (RTIFRC0)

The free running counter 0 register holds the current value of free running counter 0. This register is shown in Figure 16-12 and described in Table 16-6.

Figure 16-12. RTI Free Running Counter 0 Register (RTIFRC0) [offset = 10h]

15	0
FRC0	
R/WP-0	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-6. RTI Free Running Counter 0 Register (RTIFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	FRC0	0-FFFF FFFFh	Free running counter 0. This registers holds the current value of the free running counter 0. A read of this counter returns the current value of the counter. The counter can be preset by writing (in privileged mode only) to this register. The counter increments then from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0.**

16.3.6 RTI Up Counter 0 Register (RTIUC0)

The up counter 0 register holds the current value of prescale counter. This register is shown in Figure 16-13 and described in Table 16-7.

Figure 16-13. RTI Up Counter 0 Register (RTIUC0) [offset = 14h]

31	16

Table 16-7. RTI Up Counter 0 Register (RTIUC0) Field Descriptions

Bit	Field	Value	Description
31-0	UC0	0-FFFF FFFFh	Up counter 0. This register holds the current value of the up counter 0 and prescales the RTI clock. It will be only updated by a previous read of free running counter 0 (RTIFRC0). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on up counter 0 (RTIUC0) and free running counter 0 (RTIFRC0). A read of this counter returns the value of the counter at the time RTIFRC0 was read. A write to this counter presets it with a value. The counter then increments from this written value upwards. Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0. **Note: If the preset value is bigger than the compare value stored in register RTICPUC0, then it can take a long time until a compare matches, since RTIUC0 has to count up until it overflows.**

16.3.7 RTI Compare Up Counter 0 Register (RTICPUC0)

The compare up counter 0 register holds the value to be compared with prescale counter 0 (RTIUC0). This register is shown in Figure 16-14 and described in Table 16-8.

Figure 16-14. RTI Compare Up Counter 0 Register (RTICPUC0) [offset = 18h]

31	16
CPUC0	
R/W-0	

15	0
CPUC0	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 16-8. RTI Compare Up Counter 0 Register (RTICPUC0) Field Descriptions

Bit	Field	Value	Description

31-0	CPUC0	0-FFFF FFFFh	Compare up counter 0. This register holds the value that is compared with the up counter 0. When the compare shows a match, the free running counter 0 (RTIFRC0) is incremented. RTIUC0 is set to 0 when the counter value matches the RTICPUC0 value. The value set in this register prescales the RTI clock.
			If CPUC0 = 0, then
			f_{FRC0} = RTICLK/(2^{32}+1) (Setting CPUC0 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)
			If CPUC0 ≠ 0, then
			f_{FRC0} = RTICLK/(RTICPUC0+1)
			A read of this register returns the current compare value.
			A write to this register:
			• If TBEXT = 0, the compare value is updated.
			• If TBEXT = 1, the compare value is unchanged.

16.3.8 RTI Capture Free Running Counter 0 Register (RTICAFRC0)

The capture free running counter 0 register holds the free running counter 0 on external events. This register is shown in Figure 16-15 and described in Table 16-9.

Figure 16-15. RTI Capture Free Running Counter 0 Register (RTICAFRC0) [offset = 20h]

Table 16-9. RTI Capture Free Running Counter 0 Register (RTICAFRC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAFRC0	0-FFFF FFFFh	Capture free running counter 0. This register captures the current value of the free running counter 0 (RTIFRC0) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC0 on a capture event.

16.3.9 RTI Capture Up Counter 0 Register (RTICAUC0)

The capture up counter 0 register holds the current value of prescale counter 0 on external events. This register is shown in Figure 16-16 and described in Table 16-10.

Table 16-10. RTI Capture Up Counter 0 Register (RTICAUC0) Field Descriptions

Bit	Field	Value	Description
31-0	CAUC0	0-FFFF FFFFh	Capture up counter 0. This register captures the current value of the up counter 0 (RTIUC0) when an event occurs, controlled by the external capture control block. **Note: The read sequence must be the same as with RTIUC0 and RTIFRC0. Therefore, the RTICAFRC0 register must be read before the RTICAUC0 register is read. This sequence ensures that the value of the RTICAUC0 register is the corresponding value to the RTICAFRC0 register, even if another capture event happens in between the two reads.** A read of this register returns the value of RTIUC0 on a capture event.

16.3.10 RTI Free Running Counter 1 Register (RTIFRC1)

The free running counter 1 register holds the current value of the free running counter 1. This register is shown in Figure 16-17 and described in Table 16-11.

Bit	Field	Value	Description
31-0	FRC1	0-FFFF FFFFh	Free running counter 1. This register holds the current value of the free running counter 1 and will be updated continuously. A read of this register returns the current value of the counter. A write to this register presets the counter. The counter increments then from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.**

16.3.11 RTI Up Counter 1 Register (RTIUC1)

The up counter 1 register holds the current value of the prescale counter 1. This register is shown in Figure 16-18 and described in Table 16-12.

Figure 16-18. RTI Up Counter 1 Register (RTIUC1) [offset = 34h]

Bit	Field	Value	Description
31-0	UC1	0-FFFF FFFFh	Up counter 1. This register holds the current value of the up counter 1 and prescales the RTI clock. It will be only updated by a previous read of free running counter 1 (RTIFRC1). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on RTIUC1 and RTIFRC1. A read of this register will return the value of the counter when the RTIFRC1 was read. A write to this register presets the counter. The counter then increments from this written value upwards. **Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.** **Note: If the preset value is bigger than the compare value stored in register RTICPUC1, then it can take a long time until a compare matches, since RTIUC1 has to count up until it overflows.**

16.3.12 RTI Compare Up Counter 1 Register (RTICPUC1)

The compare up counter 1 register holds the value compared with prescale counter 1. This register is shown in Figure 16-19 and described in Table 16-13.

Figure 16-19. RTI Compare Up Counter 1 Register (RTICPUC1) [offset = 38h]

Table 16-13. RTI Compare Up Counter 1 Register (RTICPUC1) Field Descriptions

Bit	Field	Value	Description

31-0	CPUC1	0-FFFF FFFFh	Compare up counter 1. This register holds the compare value, which is compared with the up counter 1. When the compare matches, the free running counter 1 (RTIFRC1) is incremented. The up counter is cleared to 0 when the counter value matches the CPUC1 value. The value set in this prescales the RTI clock according to the following formula:
			If CPUC1 = 0, then
			f_{FRC1} = RTICLK/(2^{32}+1) (Setting CPUC1 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)
			If CPUC1 ≠ 0, then
			f_{FRC1} = RTICLK/(RTICPUC1+1)
			A read of this register returns the current compare value.
			A write to this register updates the compare value.

16.3.13 RTI Capture Free Running Counter 1 Register (RTICAFRC1)

The capture free running counter 1 register holds the current value of free running counter 1 on external events. This register is shown in Figure 16-20 and described in Table 16-14.

If RTIFRC0 or RTIFRC1, depending on the counter selected, matches the compare value, an interrupt is flagged. With this register it is also possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register (in privileged mode only) will update the compare register with a new compare value.

16.3.16 RTI Update Compare 0 Register (RTIUDCP0)

The update compare 0 register holds the value to be added to the compare register 0 value on a compare match. This register is shown in Figure 16-23 and described in Table 16-17.

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-25. RTI Timebase High Compare Register (RTITBHCOMP) Field Descriptions

Bit	Field	Value	Description
31-0	TBHCOMP	0-FFFF FFFFh	Timebase high compare value. This value determines when the edge detection circuit will stop monitoring the NTU signal. It will be compared with RTIUC0. RTITBHCOMP must be less than RTICPUC0 because RTIUC0 will be reset when RTICPUC0 is reached. Example: The NTU edge detection circuit should be active ± 10 RTICLK cycles around RTICPUC0. • RTICPUC0 = 0050h • RTITBLCOMP = 0046h • RTITBHCOMP = 0009h A read of this register will return the current compare value. A write to this register has the following effects: If TBEXT = 0: The compare value is updated. If TBEXT = 1: The compare value is not changed.

16.3.25 RTI Set Interrupt Enable Register (RTISETINTENA)

This register prevents the necessity of a read-modify-write operation if a particular interrupt should be enabled. This register is shown in Figure 16-32 and described in Table 16-26.

			Write: Interrupt is disabled.

16.3.27 RTI Interrupt Flag Register (RTIINTFLAG)

The corresponding flags are set at every compare match of the RTIFRCx and RTICOMPx values, whether the interrupt is enabled or not. This register is shown in Figure 16-34 and described in Table 16-28.

Figure 16-34. RTI Interrupt Flag Register (RTIINTFLAG) [offset = 88h]

Table 16-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reads return 0. Writes have no effect.
18	OVL1INT		Free running counter 1 overflow interrupt flag. This bit determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
17	OVL0INT		Free running counter 0 overflow interrupt flag. This bit determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
16	TBINT		Timebase interrupt flag. This flag is set when the TBEXT bit is cleared by detection of a missing external clock edge. It will not be set by clearing TBEXT by software. It determines if an interrupt is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
15-4	Reserved	0	Reads return 0. Writes have no effect.
3	INT3		Interrupt flag 3. These bits determine if an interrupt due to a Compare 3 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
2	INT2		Interrupt flag 2. These bits determine if an interrupt due to a Compare 2 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.
1	INT1		Interrupt flag 1. These bits determine if an interrupt due to a Compare 1 match is pending.
		0	*Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.

Table 16-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions (continued)

Bit	Field	Value	Description
0	INT0	0	Interrupt flag 0. These bits determine if an interrupt due to a Compare 0 match is pending. *Read:* No interrupt is pending. *Write:* Bit is unchanged.
		1	*Read:* Interrupt is pending. *Write:* Bit is cleared to 0.

16.3.28 Digital Watchdog Control Register (RTIDWDCTRL)

The software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. This register is shown in Figure 16-34 and described in Table 16-28.

Figure 16-35. Digital Watchdog Control Register (RTIDWDCTRL) [offset = 90h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

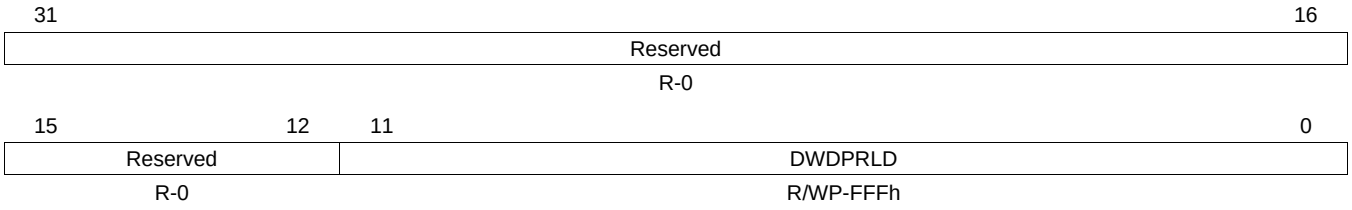
Table 16-29. Digital Watchdog Control Register (RTIDWDCTRL) Field Descriptions

Bit	Field	Value	Description
31-0	DWDCTRL	5312 ACEDh	Digital Watchdog Control. *Read:* DWD counter is disabled. *Write:* State of DWD counter is unchanged (stays enabled or disabled).
		A985 59DAh	*Read:* DWD counter is enabled. *Write:* DWD counter is enabled.
		All other values	*Read:* DWD counter state is unchanged (enabled or disabled). *Write:* State of DWD counter is unchanged (stays enabled or disabled). **Note:** Once the enable value is written, all other future writes are blocked. In other words, once DWD is enabled, it can only be disabled by system reset or power on reset. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog.

16.3.29 Digital Watchdog Preload Register (RTIDWDPRLD)

This register sets the expiration time of the DWD. This register is shown in Figure 16-34 and described in Table 16-28.

Figure 16-36. Digital Watchdog Preload Register (RTIDWDPRLD) [offset = 94h]



LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-30. Digital Watchdog Preload Register (RTIDWDPRLD) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads return 0 and writes have no effect.
11-0	DWDPRLD	0-FFFh	Digital Watchdog Preload Value. *Read:* The current preload value *Write:* Set the preload value. The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter. The expiration time of the DWD Down Counter can be determined with following equation: texp = (DWDPRLD+1) x 2^{13} / RTICLK1 where: DWDPRLD = 0...4095

16.3.30 Watchdog Status Register (RTIWDSTATUS)

This register records the status of the DWD. The values of the following status bits will not be affected by a soft reset. These bits are cleared by a power up reset, or by a write of '1'. These bits can be used for debug purposes. This register is shown in Figure 16-34 and described in Table 16-28.

Figure 16-37. Watchdog Status Register (RTIWDSTATUS) [offset = 98h]

31	8
Reserved

R-0		R/W1CP-x	R/W1CP-x	R/W1CP-x	R/W1CP-x	R/W1CP-x	R-0

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -*n* = value after reset

Table 16-31. Watchdog Status Register (RTIWDSTATUS) Field Descriptions

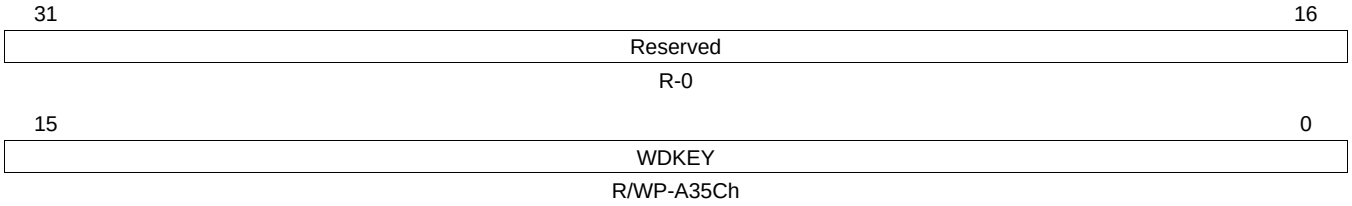
Bit	Field	Value	Description
31-6	Reserved	0	Reads return 0. Writes have no effect.
5	DWWD ST		Windowed Watchdog Status
		0	*Read:* No time-window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read:* Time-window violation has occurred. The watchdog has generated either a system reset or a non-maskable interrupt to the CPU in this case. *Write:* Bit is cleared to 0. This will also clear all other status flags in the RTIWDSTATUS register. Clearing of the status flags will deassert the non-maskable interrupt generated due to violation of the DWWD.
4	END TIME VIOL		Windowed Watchdog End Time Violation Status. This bit indicates whether the Watchdog counter expired.
		0	*Read:* No end-time window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read*: End-time defined by the windowed watchdog configuration has been violated. *Write:* Bit is cleared to 0.
3	START TIME VIOL		Windowed Watchdog Start Time Violation Status. This bit indicates whether the key is written before the watchdog window opened up.
		0	*Read:* No start-time window violation has occurred. *Write:* Leaves the current value unchanged.
		1	*Read:* Start-time defined by the windowed watchdog configuration has been violated. *Write:* Bit is cleared to 0.
2	KEY ST		Watchdog key status. This bit indicates a reset or NMI generated by a wrong key or key sequence written to the RTIWDKEY register.
		0	*Read:* No wrong key or key-sequence written. *Write:* Bit is unchanged.
		1	*Read:* Wrong key or key-sequence written to RTIWDKEY register. *Write:* Bit is cleared to 0.
1	DWD ST		DWD status. This bit is equivalent to bit END TIME VIOL.
		0	*Read:* No reset or NMI was generated. *Write:* Bit is unchanged.
		1	*Read:* Reset or NMI was generated. *Write:* Bit is cleared to 0.
0	Reserved	0	Reads return 0. Writes have no effect.

16.3.31 RTI Watchdog Key Register (RTIWDKEY)

This register must be written with the correct written key values to serve the watchdog. This register is shown in Figure 16-38 and described in Table 16-32.

NOTE: It has to be taken into account that the write to the RTIWDKEY register takes 3 VCLK cycles.

Figure 16-38. RTI Watchdog Key Register (RTIDWDKEY) [offset = 9Ch]



LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-32. RTI Watchdog Key Register (RTIDWDKEY) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reads return 0 and writes have no effect.
15-0	WDKEY	0-FFFFh	Watchdog key. These bits provide the key sequence location. Reads returns the current WDKEY value. A write of E51Ah followed by A35Ch in two separate write operations defines the key sequence and reloads the DWD. Writing any other value causes a reset or NMI, as shown in Table 16-33. Writing any other value will cause the WDKEY to reset to A35Ch.

Table 16-33. Example of a WDKEY Sequence

Step	Value Written to WDKEY	Result
1	A35Ch	No action
2	A35Ch	No action
3	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
4	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
5	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
6	A35Ch	Watchdog is reset.
7	A35Ch	No action
8	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
9	A35Ch	Watchdog is reset.
10	E51Ah	WDKEY is enabled for reset or NMI by next A35Ch.
11	2345h	System reset or NMI; incorrect value written to WDKEY.

16.3.32 RTI Digital Watchdog Down Counter (RTIDWDCNTR)

This register provides the current value of the DWD down counter. This register is shown in Figure 16-39 and described in Table 16-34.

Figure 16-39. RTI Watchdog Down Counter Register (RTIDWDCNTR) [offset = A0h]

Table 16-35. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reads return 0 and writes have no effect.
3-0	WWDRXN		The DWWD reaction
		5h	The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		Ah	The windowed watchdog will generate a non-maskable interrupt to the CPU if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
		All other values	The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.
			Note: The DWWD reaction can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDRXN is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDRXN is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

16.3.34 Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)

This register selects the DWWD window size. This register is shown in Figure 16-41 and described in Table 16-36.

Figure 16-41. Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL) [offset = A8h]

R/WP-0005h	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 16-36. Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL) Field Descriptions

Bit	Field	Value	Description
31-0	WWDSIZE	0	The DWWD window size
		0000 0005h	100% (The functionality is the same as the standard time-out digital watchdog.)
		0000 0050h	50%
		0000 0500h	25%
		0000 5000h	12.5%
		0005 0000h	6.25%
		All other values	3.125%
			Note: The DWWD window size can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDSIZE is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDSIZE is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced.

16.3.35 RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE)

When the RTI compare event is configured to generate a DMA request or triggers (all triggered by RTI compare interrupt request flag) to other peripherals, it is often desirable to clear the RTI compare flag automatically so that the requests can be generated repeatedly without any CPU intervention. This register works with the RTI compare clear registers to enable an "auto-clear" of the compare interrupt enable bit after a compare equal event. This register is shown in Figure 16-42 and described in Table 16-37.

Figure 16-42. RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE) [offset = ACh]

Bit	Field	Value	Description
31-28	Reserved	0	Reads return 0. Writes have no effect.
27-24	INTCLRENABLE3	5h	Enables the auto-clear functionality on the compare 3 interrupt. *Read:* Auto-clear for compare 3 interrupt is disabled. *Privileged Write:* Auto-clear for compare 3 interrupt becomes disabled
		All other values	*Read:* Auto-clear for compare 3 interrupt is enabled. *Privileged Write:* Auto-clear for compare 3 interrupt becomes enabled
23-20	Reserved	0	Reads return 0. Writes have no effect.
19-16	INTCLRENABLE2	5h	Enables the auto-clear functionality on the compare 2 interrupt. *Read:* Auto-clear for compare 2interrupt is disabled. *Privileged Write:* Auto-clear for compare 2 interrupt becomes disabled
		All other values	*Read:* Auto-clear for compare 2 interrupt is enabled. *Privileged Write:* Auto-clear for compare 2 interrupt becomes enabled
15-12	Reserved	0	Reads return 0. Writes have no effect.
11-8	INTCLRENABLE1	5h	Enables the auto-clear functionality on the compare 1 interrupt. *Read:* Auto-clear for compare 1 interrupt is disabled. *Privileged Write:* Auto-clear for compare 1 interrupt becomes disabled
		All other values	*Read:* Auto-clear for compare 1 interrupt is enabled. *Privileged Write:* Auto-clear for compare 1 interrupt becomes enabled
7-4	Reserved	0	Reads return 0. Writes have no effect.
3-0	INTCLRENABLE0	5h	Enables the auto-clear functionality on the compare 0 interrupt. *Read:* Auto-clear for compare 0 interrupt is disabled. *Privileged Write:* Auto-clear for compare 0 interrupt becomes disabled
		All other values	*Read:* Auto-clear for compare 0 interrupt is enabled. *Privileged Write:* Auto-clear for compare 0 interrupt becomes enabled

16.3.36 RTI Compare 0 Clear Register (RTICMP0CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 0 register Section 16.3.4. The user needs to choose the value such that the compare clear 0 event occurs before next compare 0 event. If the Free Running Counter matches the compare value, the compare 0 interrupt request flag is cleared and the value in the RTIUDCP0 register Section 16.3.16 is added to this register. This register is shown in Figure 16-43 and described in Table 16-38.

Table 16-38. RTI Compare 0 Clear Register (RTICMP0CLR) Field Descriptions

Bit	Field	Value	Description
31-0	CMP0CLR	0-FFFF FFFFh	Compare 0 clear. This registers holds a compare value. If the Free Running Counter matches the compare value, the compare 0 interrupt request flag is cleared and the value in the RTIUDCP0 register Section 16.3.16 is added to this register. Reads return the current compare clear value. A privileged write to this register updates the compare clear value.

16.3.37 RTI Compare 1 Clear Register (RTICMP1CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 1 register Section 16.3.4. The user needs to choose the value such that the compare clear 1 event occurs before next compare 1 event. If the Free Running Counter matches the compare value, the compare 1 interrupt request flag is cleared and the value in the RTIUDCP1 register Section 16.3.18 is added to this register. This register is shown in Figure 16-44 and described in Table 16-39.

Table 16-39. RTI Compare 1 Clear Register (RTICMP1CLR) Field Descriptions

Bit	Field	Value	Description
31-0	CMP0CLR	0-FFFF FFFFh	Compare 1 clear. This registers holds a compare value. If the Free Running Counter matches the compare value, the compare 1 interrupt request flag is cleared and the value in the RTIUDCP1 register Section 16.3.18 is added to this register. Reads return the current compare clear value. A privileged write to this register updates the compare clear value.

16.3.38 RTI Compare 2 Clear Register (RTICMP2CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 2 register Section 16.3.4. The user needs to choose the value such that the compare clear 2 event occurs before next compare 2 event. If the Free Running Counter matches the compare value, the compare 2 interrupt request flag is cleared and the value in the RTIUDCP2 register Section 16.3.20 is added to this register. This register is shown in Figure 16-45 and described in Table 16-40.

General Purpose I/0 (GIO)

This chapter describes the general-purpose input/output (GIO) module. The GIO module provides the family of devices with input/output (I/O) capability. The I/O pins are bidirectional and bit-programmable. The GIO module also supports external interrupt capability.

Topic **Page**

17.1 Overview **2155**
17.2 Quick Start Guide **2155**
17.3 Functional Description of GIO Module **2157**
17.4 Device Modes of Operation **2160**
17.5 MSS_GIO Registers **2161**
17.6 I/O Control Summary **2248**

17.1 Overview

The GIO module offers general-purpose input and output capability. Refer to the device data sheet for identifying the number of GIO ports supported, and the GIO terminals capable of generating an interrupt. Each terminal can be independently configured as input or output and configured as required by the application. The GIO module also supports generation of interrupts whenever a rising edge or falling edge or any toggle is detected on these GIO terminals.

The main features of the GIO module are summarized as follows:

- Allows each GIO terminal to be configured for general-purpose input or output functions
- Supports programmable pull directions on each input GIO terminal
- Supports GIO output in push/pull or open-drain modes
- Allows GIO terminals to be used for generating interrupt requests

17.2 Quick Start Guide

The GIO module comprises two separate components: an input/output (I/O) block and an interrupt generation block. Figure 17-1 and Figure 17-2 show what you should do after reset to configure the GIO module as I/O or for generating interrupts.

In GIO interrupt service routine, you shall read the GIO offset register (GIOOFF1 or GIOOFF2, depending on high-/low-level interrupt) to clear the flag and find the pending interrupt GIO channel.

Figure 17-1. I/O Function Quick Start Flow Chart

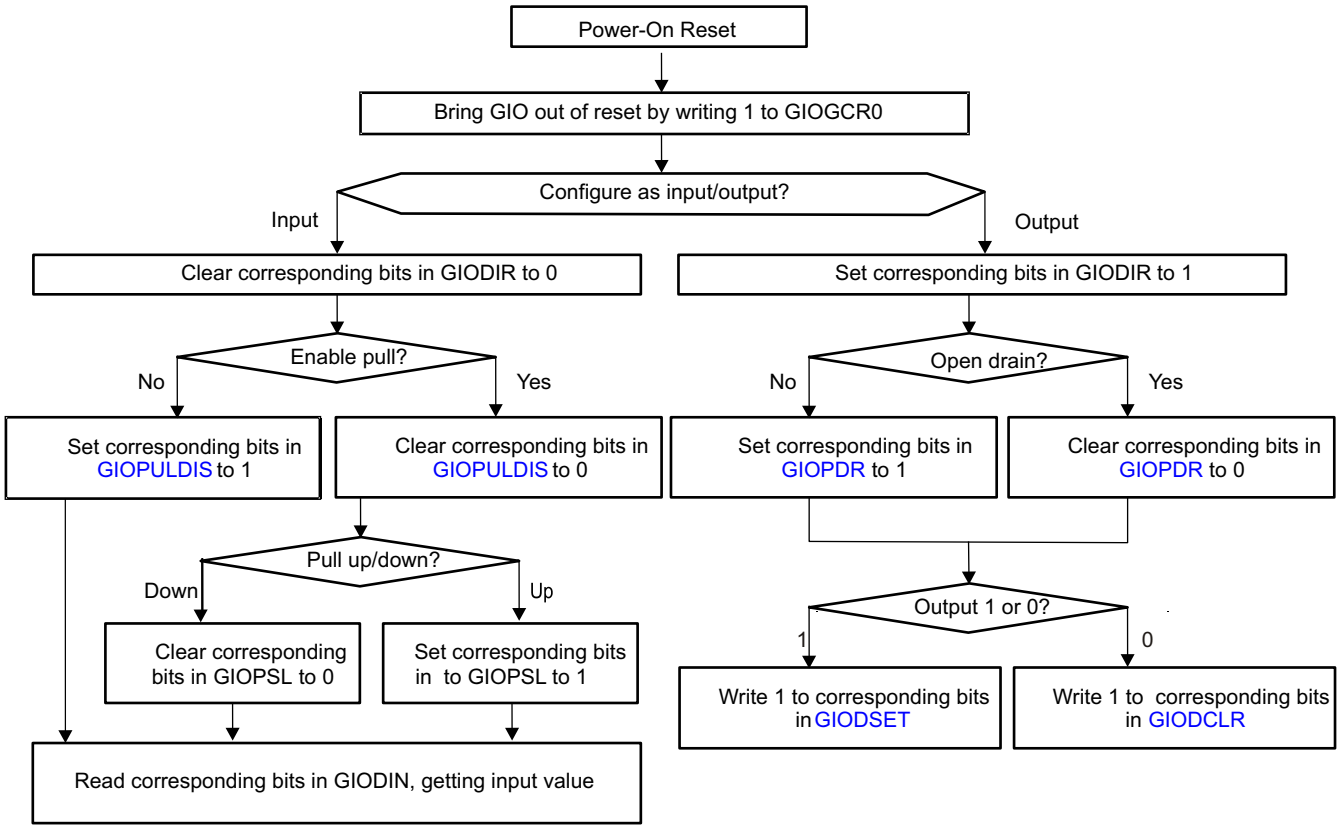

Figure 17-2. Interrupt Generation Function Quick Start Flow Chart

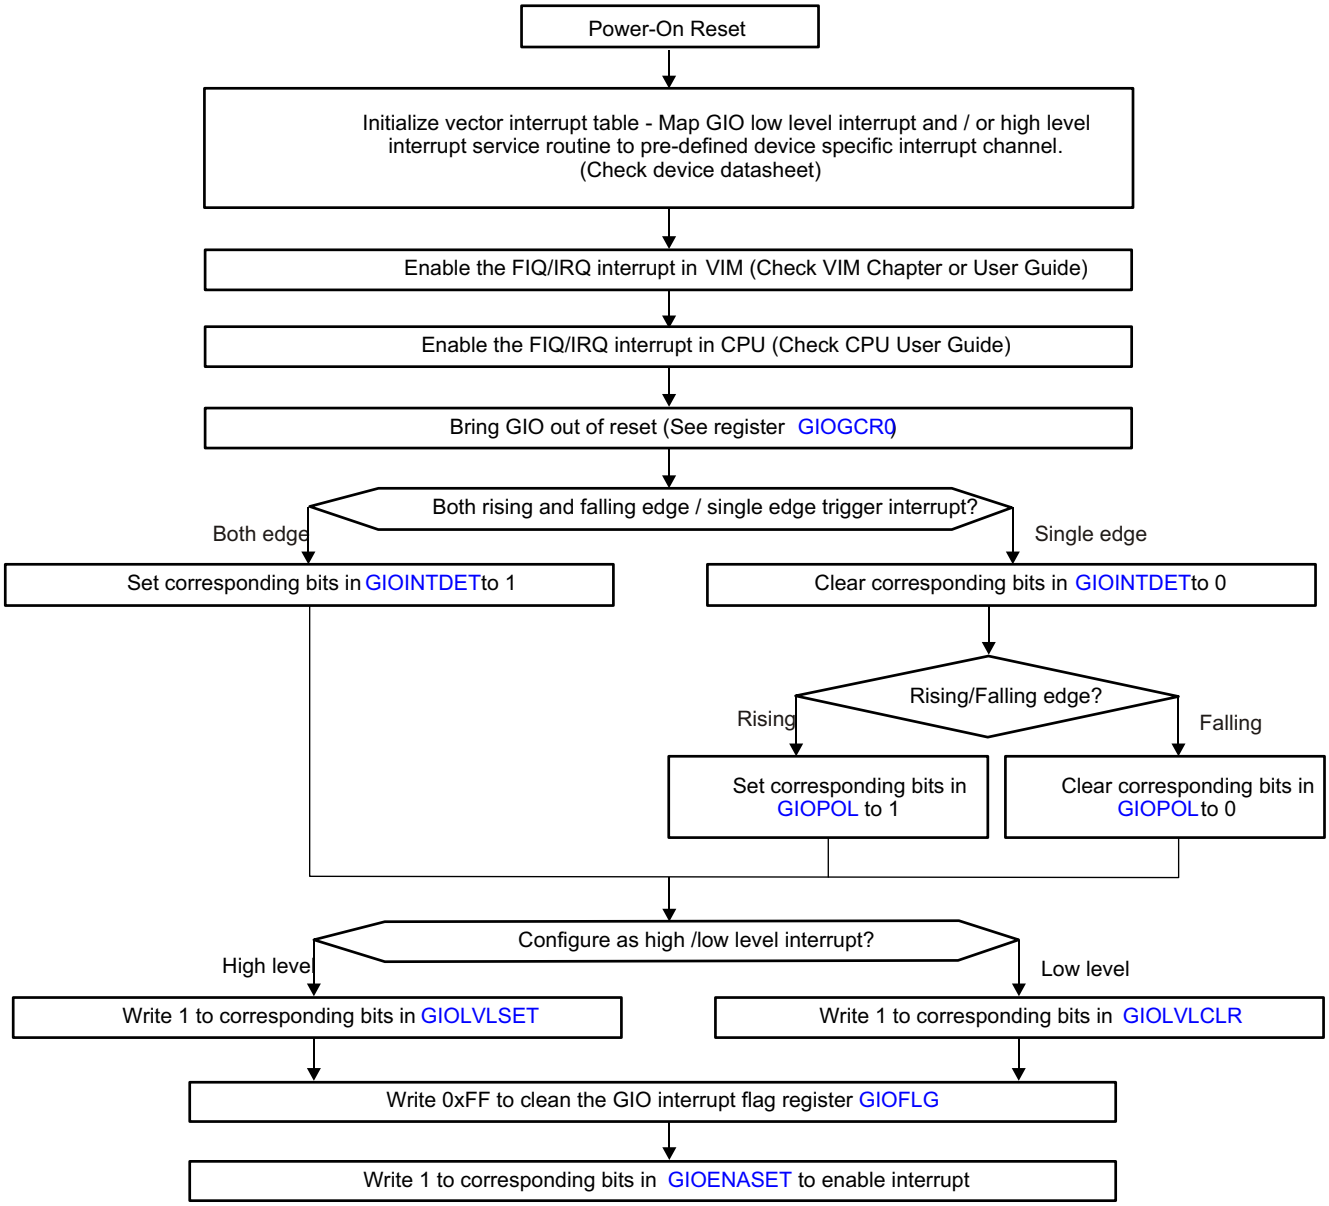
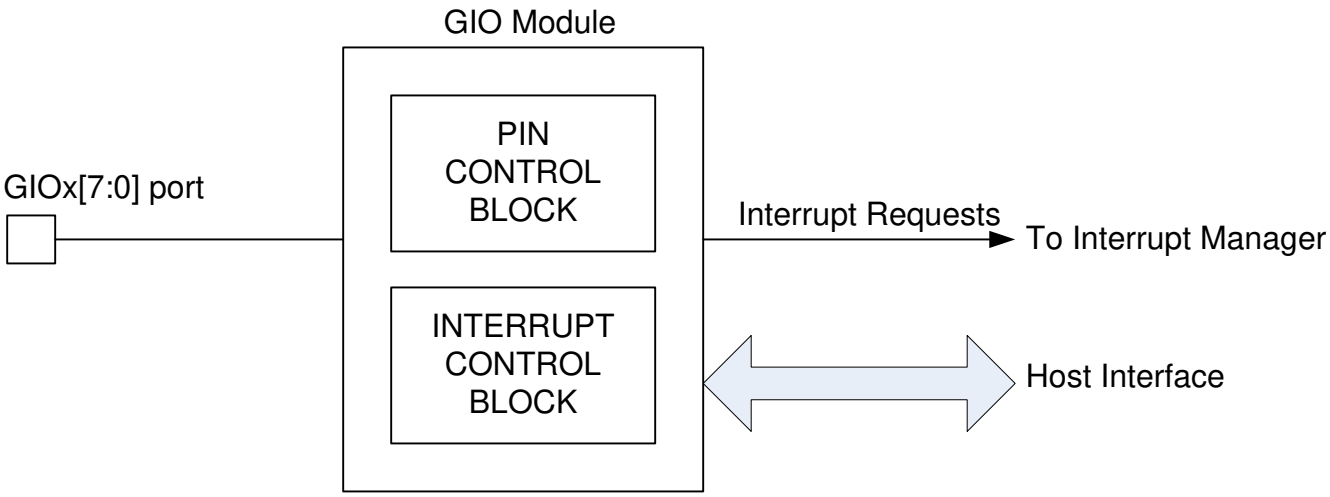


17.3 Functional Description of GIO Module

As shown in Figure 17-3, the GIO module comprises of two separate components: an input/output (I/O) block and an interrupt block.

Figure 17-3. GIO Module Diagram



17.3.1 I/O Functions

The I/O block allows each GIO terminal to be configured for use as a general-purpose input or output in the application. The GIO module supports multiple registers to control the various aspects of the input and output functions. These are described as follows.

- Data direction (GIODIR)

  Configures GIO terminal(s) as input (default) or output through the GIODIRx registers.

- Data input (GIODIN)

  Reflects the logic level on GIO terminals in the GIODINx registers. A high voltage (V_{IH} or greater) applied to the pin causes a high value (1) in the data input register (GIODIN[7:0]). When a low voltage (V_{IL} or less) is applied to the pin, the data input register reads a low value (0). The V_{IH} and V_{IL} values are device specific and can be found in the device datasheet.

- Data output (GIODOUT)

  Configures the logic level to be output on GIO terminal(s) configured as outputs. A low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower). A high value (1) written to the data output register (GIODOUTx) forces the pin to a high output voltage (V_{OH} or higher) if the open drain functionality is disabled (GIOPDRx[7:0]). If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z).

- Data set (GIODSET)

  Allows logic HIGH to be output on GIO terminal(s) configured as outputs by writing 1's to the required bits in the GIODSETx registers. If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z). The GIODSETx registers eliminate the need for the application to perform a read-modify-write operation when it needs to set one or more GIO pin(s).

- Data clear (GIODCLR)

  Allows logic LOW to be output on GIO terminal(s) configured as outputs by writing 1s to the required bits in the GIODCLRx registers. The GIODCLRx registers eliminate the need for the application to perform a read-modify-write operation when it needs to clear one or more GIO pin(s).

- Open drain (GIOPDR)

  Open drain functionality is enabled or disabled (default) using the open drain register GIOPDR[7:0] register. If open-drain mode output is enabled on a pin, a high value (1) written to the data output register (GIODOUTx[7:0]) forces the pin to a high impedance state (Z).

- Pull disable (GIOPULDIS)

  Disables the internal pull on GIO terminal(s) configured as inputs by writing to the GIOPULDISx registers.
- Pull select (GIOPSL)

  Selects internal pull down (default) or pull up on GIO terminal(s) configured as inputs by writing to the GIOPULSELx registers.

Refer to the specific device's datasheet to identify the number of GIO ports as well as the input and output functions supported. Some devices may not support the programmable pull controls. In that case, the pull disable and the pull select register controls will not work.

17.3.2 Interrupt Function

The GIO module supports terminals to be configured for generating an interrupt to the host processor through the Vectored Interrupt Manager (VIM). The main functions of the interrupt block are:

- Select the GIO pin(s) that is/are used to generate interrupt(s)

  This is done via the interrupt enable set and clear registers, GIOENASET and GIOENACLR.
- Select the edge on the selected GIO pin(s) that is/are used to generate interrupt(s): rising/falling/both

  Rising or falling edge can be selected via the GIOPOL register. If interrupt is required to be generated on both rising and falling edges, this can be configured via the GIOINTDET register.
- Select the interrupt priority

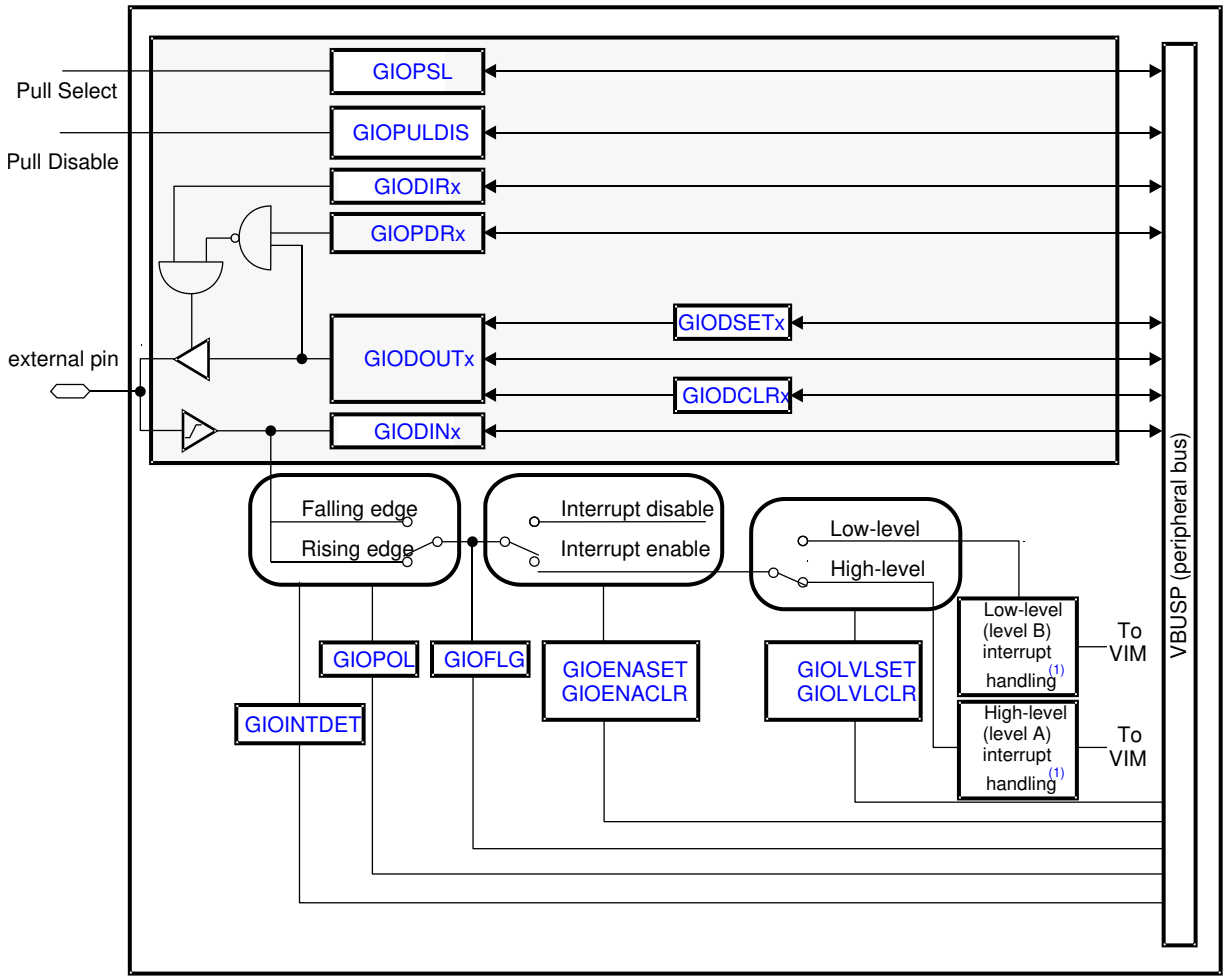
  Low- or high-level interrupt can be selected through the GIOLVLSET and GIOLVLCLR registers.
- Individual interrupt flags are set in the GIOFLG register

Interrupt-capable terminals on GIO ports can be used to handle either general I/O functions or interrupt requests. Each interrupt request can be connected to the VIM at one of two different levels – High (or A) and Low (or B), depending on the VIM channel number. The VIM has an inherent priority scheme so that a request on a lower number channel has a higher priority than a request on a higher number channel. Refer the device datasheet to identify the VIM channel numbers for the GIO level A and level B interrupt requests. Also note that the interrupt priority of level A and level B interrupt handling blocks can be re-programmed in the VIM.

17.3.3 GIO Block Diagram

The GIO block diagram (Figure 17-4) represents the flow of information through a pin. The shaded area corresponds to the I/O block; the unshaded area corresponds to the interrupt block.

Figure 17-4. GIO Block Diagram



(1) A single low-level-interrupt-handling block and a single high-level-interrupt-handling block service all of the interrupt-capable external pins, but only one pin can be serviced by an interrupt block at a time.

17.4 Device Modes of Operation

The GIO module behaves differently in different modes of operation. There are two main modes:

- Emulation mode
- Power-down mode (low-power mode)

17.4.1 Emulation Mode

Emulation mode is used by debugger tools to stop the CPU at breakpoints to read registers.

NOTE: Emulation Mode and Emulation Registers

Emulation mode is a mode of operation of the device and is separate from the GIO emulation registers (GIOEMU1 and GIOEMU2). The contents of these emulation registers are identical to the contents of GIO offset registers (GIOOFF1 and GIOOFF2). Both emulation registers and GIO offset registers are NOT cleared when they are read in emulation mode. GIO offset registers are cleared when they are read in normal mode (other than emulation mode). The emulation registers are NOT cleared when they are read in normal mode. The intention for the emulation registers is that software can use them without clearing the flags.

During emulation mode:

- External interrupts are not captured because the VIM is unable to service interrupts.
- Any register can be read without affecting the state of the system.
- A write to a register still does affect the state of the system.

17.4.2 Power-Down Mode (Low-Power Mode)

In power-down mode, the clock signal to the GIO module is disabled. Thus, there is no switching and the only current draw comes from leakage current. In power-down mode, interrupt pins become level-sensitive rather than edge-sensitive. The polarity bit changes function from falling-edge-triggered to low-level-triggered and rising-edge-triggered to high-level-triggered. A corresponding level on an interrupt pin pulls the module out of low-power mode, if the interrupt is also enabled to wake up the device out of a low-power mode.

17.4.2.1 Module-Level Power Down

The GIO module can be placed into a power down state by disabling the GIO peripheral module via the appropriate bit in the peripheral power down register.

17.4.2.2 Device-Level Power Down

The entire device can be placed in one of the pre-defined low-power modes: doze, snooze, or sleep using the clock source and clock domain disable registers in the system module.

17.5 MSS_GIO Registers

Table 22-194 lists the MSS_GIO registers. All register offset addresses not listed in Table 22-194 should be considered as reserved locations and the register contents should not be modified.

17.6 I/O Control Summary

The behavior of the output buffer and the pull control is summarized in Table 17-87.

Table 17-87. Output Buffer, and Pull Control Behavior for GIO Pins

Module under Reset?	Pin Direction (GIODIR)[1][2]	Open Drain Enable (GIOPDR)[1][3]	Pull Disable (GIOPULDIS)[1][4]	Pull Select (GIOPSL)[1][5]	Pull Control	Output Buffer[6]
Yes	X	X	X	X	Device- and module-specific	Disabled
No	0	X	0	0	Pull down	Disabled
No	0	X	0	1	Pull up	Disabled
No	0	X	1	0	Disabled	Disabled
No	0	X	1	1	Disabled	Disabled
No	1	0	X	X	Disabled	Enabled
No	1	1	X	X	Disabled	Enabled

(1) X = Don't care
(2) GIODIR = 0 for input; 1 for output
(3) See
(4) GIOPULDIS = 0 for enabling pull control; 1 for disabling pull control
(5) GIOPSL= 0 for pull-down functionality; 1 for pull-up functionality
(6) If open drain is enabled, output buffer will be disabled if a high level (1) is being output.

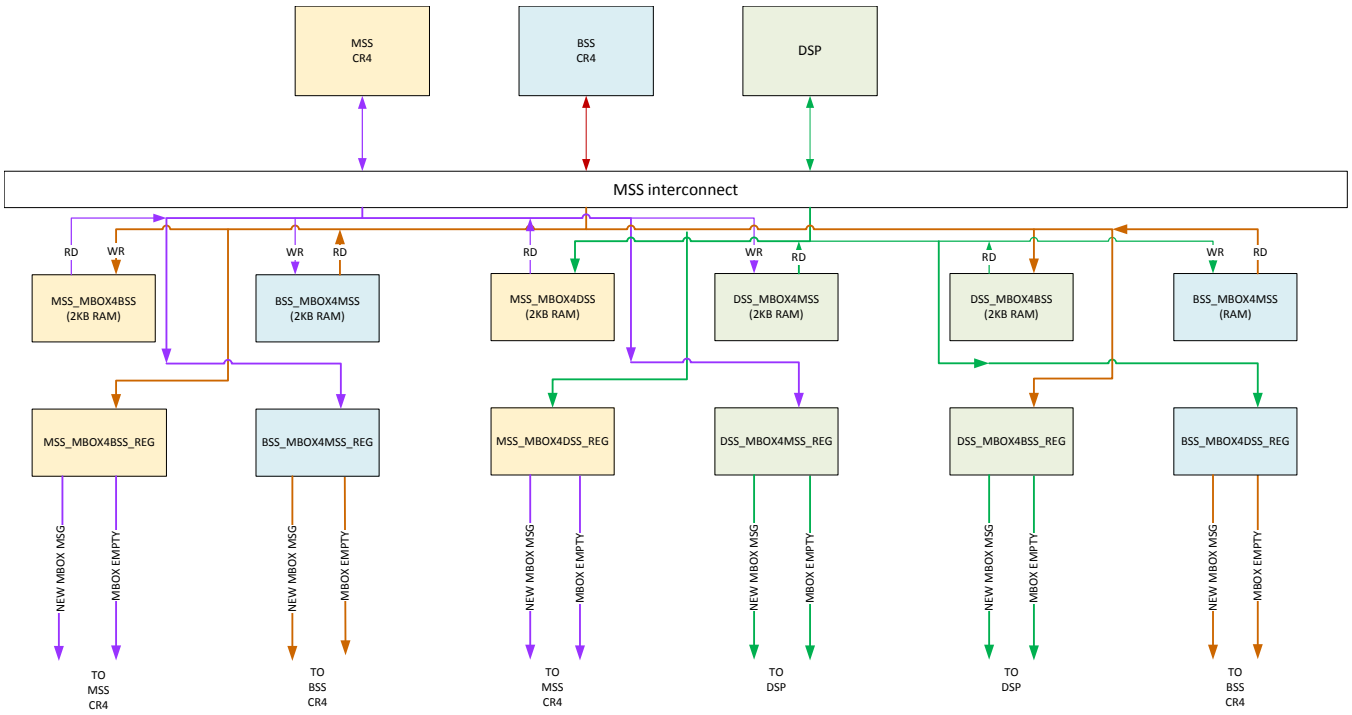
Mailbox

The device provides a mailbox mechanism to asynchronously exchange the messages between any two processors.

Each processor has a mailbox memory space, and registers designated to be used by other processor that wishes to communicate with it.

Each processor has two sets of mailbox memory space and registers, and each set is designated per other processor to communicate with it.

Figure 18-1. Mailbox Block Diagram



Topic **Page**

18.1 Maibox Message Scheme **2250**
18.2 Mailbox Registers **2251**

18.1 Maibox Message Scheme

The processor which wishes to send a message to another processor writes the message to the mailbox memory space, then interrupts the receiver processor. The receiver processor acknowledges the interrupt, then reads the message from the mailbox memory space. The receiver informs the sender that the message is read by an interrupt, which is acknowledged back by the sender. The sender must not initiate another message to the same receiver until the previously initiated mailbox interaction with the same receiver is complete.

Message from sender to receiver:

1. SENDER writes the message in the RECEIVER mailbox RECEIVER_MBOX4SENDER.
2. SENDER triggers an interrupt to RECEIVER by writing 1 to RECEIVER_MBOX4SENDER_REG__INT_TRIG[0]. This generates a mailbox-level interrupt to RECEIVER.
3. RECEIVER clears the interrupt by writing 1 to RECEIVER_MBOX4SENDER_REG__INT_ACK[0].
4. RECEIVER reads the message from the mailbox.
5. RECEIVER triggers an interrupt to SENDER indicating the mailbox is read, by writing 1 to SENDER_MBOX4RECEIVER_REG__INT_TRIG[1].
6. SENDER clears the interrupt by writing 1 to SENDER_MBOX4RECEIVER_REG__INT_ACK[1].

Mailbox message example (message from MSS to DSS):

1. MSS writes the message in the DSS mailbox (DSS_MBOX4MSS).
2. MSS triggers an interrupt to DSS by writing 1 to DSS_MBOX4MSS_REG__INT_TRIG[0]. This generates a mailbox-level interrupt to DSS.
3. DSS clears the interrupt by writing 1 to DSS_MBOX4MSS_REG__INT_ACK[0].
4. DSS reads the message from the mailbox.
5. DSS triggers an interrupt to MSS indicating the mailbox is read, by writing 1 to MSS_MBOX4DSS_REG__INT_TRIG[1].
6. MSS clears the interrupt by writing 1 to MSS_MBOX4DSS_REG__INT_ACK[1].

Mailbox message example (message from DSS to MSS):

1. DSS writes the message in the MSS mailbox (MSS_MBOX4DSS).
2. DSS triggers an interrupt to MSS by writing 1 to MSS_MBOX4DSS_REG__INT_TRIG[0]. This triggers a mailbox-level interrupt to MSS.
3. MSS clears the interrupt by writing 1 to MSS_MBOX4DSS_REG__INT_ACK[0].
4. MSS reads the message from the mailbox
5. MSS triggers an interrupt to DSS indicating the mailbox is read, by writing 1 to DSS_MBOX4MSS_REG__INT_TRIG[1].
6. DSS clears the interrupt by writing 1 to DSS_MBOX4MSS_REG__INT_ACK[1].

18.2 Mailbox Registers

Table 18-1 lists the memory-mapped registers for the Mailbox. All register offset addresses not listed in Table 18-1 should be considered as reserved locations and the register contents should not be modified.

Table 18-1. Mailbox Registers

Offset	Acronym	Register Name	Section
0h	INT_MASK	INT_MASK	Section 18.2.1
8h	INT_MASK_SET	INT_MASK_SET	Section 18.2.2
10h	INT_MASK_CLR	INT_MASK_CLR	Section 18.2.3
18h	INT_STS_CLR	INT_STS_CLR	Section 18.2.4
20h	INT_ACK	INT_ACK	Section 18.2.5
28h	INT_TRIG	INT_TRIG	Section 18.2.6
30h	INT_STS_MASKED	INT_STS_MASKED	Section 18.2.7
38h	INT_STS_RAW	INT_STS_RAW	Section 18.2.8

Complex bit access types are encoded to fit into small table cells. Table 18-2 shows the codes that are used for access types in this section.

Table 18-2. Mailbox Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

18.2.1 INT_MASK Register (Offset = 0h) [reset = 0h]

INT_MASK is shown in Figure 18-2 and described in Table 18-3.

Return to Summary Table.

Data Modification Module (DMM)

A Data Modification Module (DMM) gives the ability to write external data into the device memory.

This chapter describes the functionality of the Data Modification Module (DMM), which provides the capability to modify data in the entire 4 GB address space of the device from an external peripheral, with minimal interruption of the application. A DMM gives the ability to write external data into the device memory.

Topic **Page**

19.1 Overview **2261**
19.2 Module Operation **2262**
19.3 Control Registers **2267**

19.1 Overview

19.1.1 Features

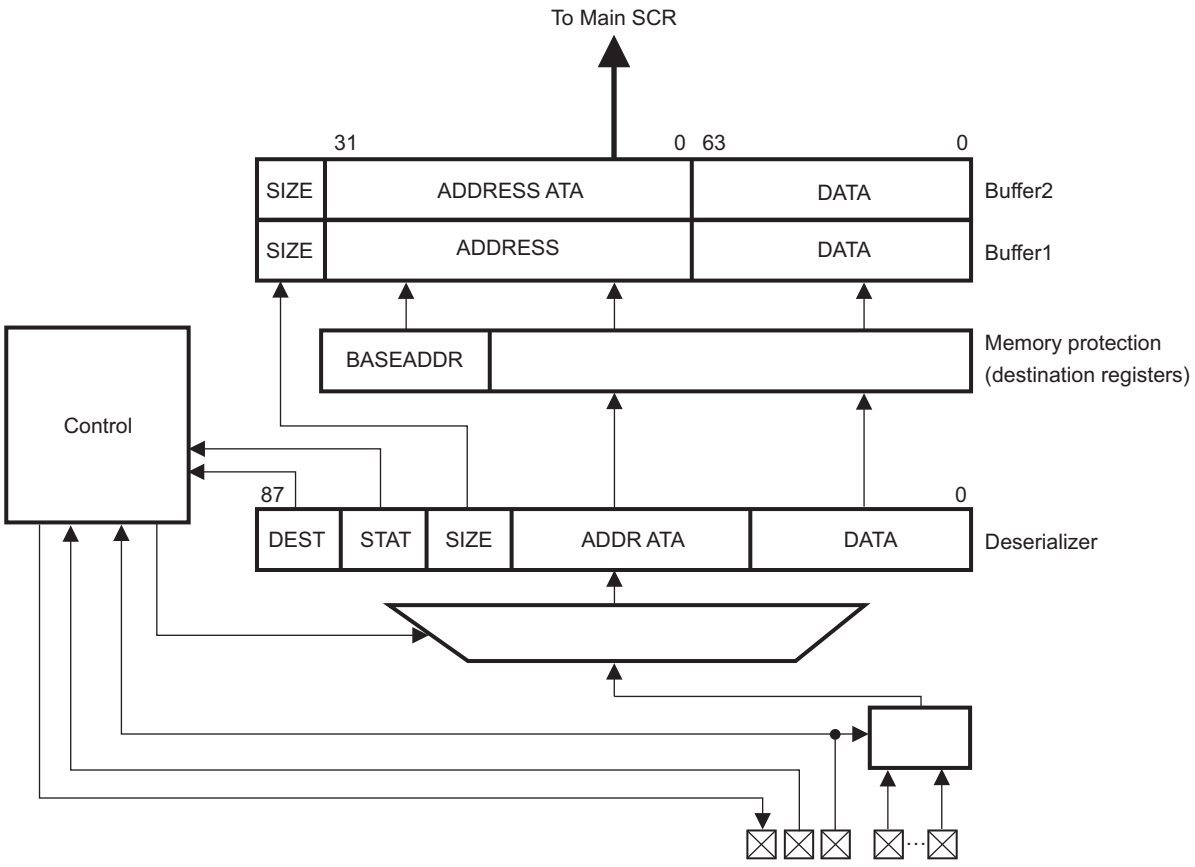
The DMM module has the following features:

- Acts as a bus master, thus enabling direct writes to the 4GB address space without CPU intervention
- Writes to memory locations specified in the received packet (leverages packets defined by trace mode of the RAM trace port (RTP) module
- Writes received data to consecutive addresses, which are specified by the DMM module (leverages packets defined by direct data mode of RTP module)
- Configurable port width (1, 2, 4, 8, 16 pins)
- Up to 65 Mbit/s pin data rate
- Unused pins configurable as GIO pins

19.1.2 Block Diagram

Figure 19-1 shows the block diagram for the DMM.

Figure 19-1. DMM Block Diagram



19.2 Module Operation

The DMM receives data over the DMM pins from external systems and writes the received data directly to the base address programmed in the module plus offset address given in the packet or into a buffer specified by start address and length. It leverages the protocol defined by the RAM Trace Port (RTP) module to have a common interface definition for external systems. It can also be used to connect an RTP and DMM module together for fast processor intercommunication.

The DMM module provides two modes of operation:

- **Trace Mode:** In this mode, the DMM writes the received data directly to an address that is calculated from the base address programmed into the destination register (Section 19.3.12; Section 19.3.14) plus the offset address contained in the received packet. An interrupt can be generated when data is written the lowest address of a programmed region. This capability enables the sender to raise an interrupt at the receiver while sending specific information.
- **Direct Data Mode:** In this mode, the DMM writes the received data into an address range of the 4GB address space. The buffer start address (Section 19.3.8) and blocksize (Section 19.3.9) is programmable in the DMM module. When the buffer reaches its end address, the buffer pointer wraps around and points to the beginning of the buffer again. The EO_BUFF flag (Section 19.3.5) will be set and if enabled, an interrupt will be generated to indicate a buffer-full condition. Another interrupt, can be configured to indicate different buffer fill levels. This can be accomplished by programming a certain fill level into the DMMINTPT register (Section 19.3.11). The PROG_BUFF flag (Section 19.3.5) indicates that this level has been reached.

Data will be captured by the input buffer and moved to the appropriate bit field in the deseralizer. When the deseralizer is completely full, the data will be moved to the output buffer register. A two-level buffer is implemented to avoid overflow conditions if the internal bus is occupied by other transactions. In addition the $\overline{\text{DMMENA}}$ signal can be used to signal the external hardware that an overflow might occur if more data is sent. The automatic generation of the $\overline{\text{DMMENA}}$ signal can be configured by setting the ENAFUNC bit (Section 19.3.16). While the $\overline{\text{DMMENA}}$ signal is active, the DMM module will not receive any new data.

The DMM is a bus master and forwards the received data to the bus system. The write operation will be minimally intrusive to the program flow, because the CPU/DMA access will only be blocked if the CPU/DMA accesses the same resource as the DMM.

To prevent an external system from overwriting critical data in the memory while configured in Trace Mode, a memory protection mechanism is implemented via a programmable start address and block size of a region. A maximum of four destinations with two regions each are supported.

For proper operation, at least DMMCLK, DMMSYNC and DMMDATA[0] need to be programmed in functional mode (Section 19.3.16). If a large amount of data should be transmitted in a short time, more data pins should be used in functional mode. The module supports 1, 2, 4, 8, or 16-pin configurations.

The module can be configured to handle a free running clock provided on DMMCLK (Section 19.3.1). Clock pulses between two DMMSYNC pulses that exceed the number of valid clock pulses for a packet will be ignored.

19.2.1 Data Format

Below is a description of the packet and frame format.

19.2.1.1 Clocking Scheme

The DMM supports both continuous and noncontinuous clocking. The clock received on DMMCLK in the continuous clocking scheme is a free-running clock. In noncontinuous clocking scheme, the clock will stop after each packet and will start with the reception of a DMMSYNC signal.

19.2.1.2 Trace Mode Packet

Figure 19-2 illustrates the trace mode packet format. One packet consists of 2 bits (DEST) denoting the destination in which the data is stored, 2 status bits (STAT), the 2-bit SIZE of the data, the 18-bit address of where the data should be written to, and a variable data field.

The DEST bits (Table 19-1) will be used to determine which destination register applies to the transmitted data and the received address determines if the packet falls into a valid region of the destination area. If the address is valid, the base address, programmed in one of the destination registers (Section 19.3.12; Section 19.3.14) of this particular region will be applied to create the complete 32-bit address for the destination. The DMM module only takes action on a "11" setting of the STAT bits (Table 19-2). This signals that an overflow in the transmitting hardware module has occurred. If this is the case the SRC_OVF flag (Section 19.3.5) will be set and the received data will be written to the address specified in the packet. The size information of the data transmitted in the packet is denoted in the SIZE bits (Table 19-3) of the packet. Depending on the SIZE information, the module expects to receive only this amount of data.

Figure 19-2. Trace Mode Packet Format

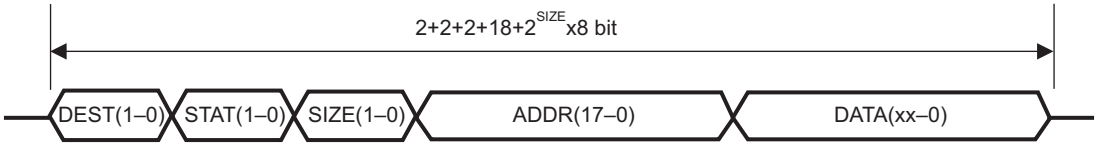


Table 19-1 through Table 19-3 illustrate the encoding of packet format in trace mode.

Table 19-1. Encoding of Destination Bits in Trace Mode Packet Format

DEST[1:0]	Destination
00	Dest 0
01	Dest 1
10	Dest 2
11	Dest 3

Table 19-2. Encoding of Status Bits in Trace Mode Packet Format

STAT[1:0]	Status
00	don't care
01	don't care
10	don't care
11	overflow

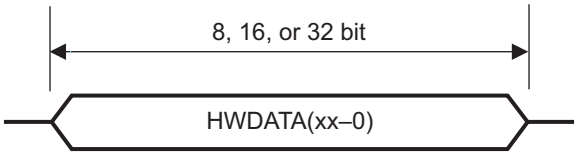
Table 19-3. Encoding of Write Size in Packet Format

SIZE[1:0]	Write Size
00	8 bit
01	16 bit
10	32 bit
11	64 bit

19.2.1.3 Direct Data Mode Packet

Figure 19-3 illustrates the direct data mode packet format.

Figure 19-3. Direct Data Mode Packet Format



The packet consists only of data bits and no header information. It can be 8-, 16- or 32-bit wide. A variable packet width is not supported because the DMM module will check the number of incoming bits (DMMCLK cycles) for error detection. The DMM will write the received data to the destination once the programmed number of bits has been received.

If the programmed word width does not correspond to the received data, the following actions will be taken:

- If the received data is greater than the programmed width, only the configured number of bits are transferred into the RAM buffer, the additional bits are discarded.
- If the received number of bits is smaller than the programmed width, no data will be written to the buffer, because a new DMMSYNC signal has been received before the expected number of bits.

19.2.2 Data Port

The packet will be received in several subpackets, depending on the width of the external data bus (DMMDATA[y:0]) and the amount of data to be transmitted. Table 19-4 illustrates the number of clock cycles required for a complete packet.

Table 19-4. Number of Clock Cycles per Packet

Port Width/ Pins	Write Size in Bits			
	8	16	32	64
1	32	40	56	88
2	16	20	28	44
4	8	10	14	22
8	4	5	7	11
16	2	3	4	6

The user can program the port width in the DMMPC0 register (Section 19.3.16). This feature allows pins that are not used for DMM functionality to be used as GIO pins. Only the pins shown in Table 19-5 can be used for a desired port width.

Table 19-5. Pins Used for Data Communication

Port Width	Pins Used
1	DMMDATA[0]
2	DMMDATA[1:0]
4	DMMDATA[3:0]
8	DMMDATA[7:0]
16	DMMDATA[15:0]

NOTE: If pins other than the ones specified in Table 19-5 are programmed as functional pins for a desired port width, the received data will be corrupted and will not be transferred to the deserializer.

NOTE: If DMMCLK or DMMSYNC are programmed as nonfunctional pins, functional operation will not occur.

19.2.2.1 Signal Description

DMMSYNC	This signal has to be provided by external hardware. It signals the start of a new packet. It has to be active (high) for one full DMMCLK cycle, starting with the rising edge of DMMCLK. If the DMMSYNC pulse is longer than a single DMMCLK cycle and two falling edges of DMMCLK see a high pulse on DMMSYNC, the module will treat the second DMMSYNC pulse as the start of a packet and will flag a PACKET_ERR_INT (Section 19.3.5).
DMMCLK	The clock is externally generated and can be suspended between two packets. For this feature, CONTCLK must be set to 0 (Section 19.3.1). If the clock is not stopped between two packets, CONTCLK must be set to 1. Data will be latched on the falling edge of the DMMCLK signal.
$\overline{\text{DMMENA}}$	This signal is pulled high if no new data should be received via the data pins, because of a potential overflow situation.
DMMDATA[15:0]	These pins receive the packet information transmitted by the external hardware. Data is latched on the falling edge of DMMCLK.

Figure 19-4 shows an example of multiple packets received during trace mode, in noncontinuous clock configuration.

Figure 19-4. Packet Sync Signal Example

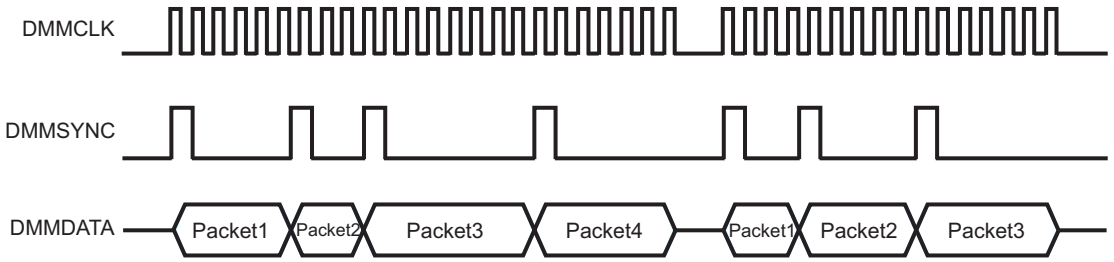


Figure 19-5 shows an example of a 4-bit data port with 8-bit receive data (A5h) to be written into DEST1 (address 0001 2345h) on a trace mode packet.

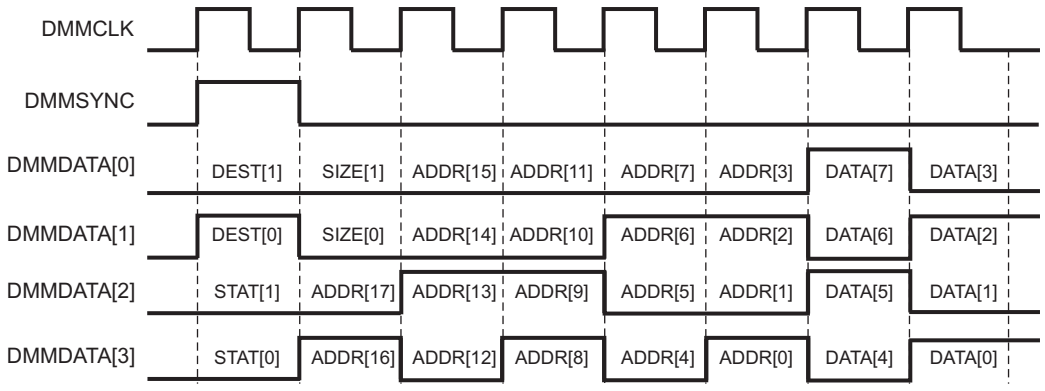
Figure 19-5. Example Single Packet Transmission



19.2.3 Error Handling

The module will generate two different kind of errors. Once an error condition is recognized, an interrupt will be generated if enabled.

19.2.3.1 Overflow Error

This error is signaled when the module has received new data before the previous data was written to the destination address. If the internal buffers are full, the DMMENA signal will go high. If the sending module does not evaluate the DMMENA signal and keeps on sending new frames, the data that was previously received might be overwritten, thus resulting in setting the BUFF_OVF flag (Section 19.3.5).

19.2.3.2 Packet Error

Noncontinuous Clock Mode

The size of the incoming packet is defined by the SIZE information of a trace mode packet or the programmed size of a direct data mode packet. If too many or less than the number of bits are received before the next sync signal, the PACKET_ERR_INT flag will be set (Section 19.3.5). In case of receiving a DMMCLK signal without a corresponding DMMSYNC signal, a packet error will also be generated.

Continuous Clock Mode

If less than the expected number of bits are received, the PACKET_ERR_INT flag will be set (Section 19.3.5) when the next DMMSYNC signal is received. Packets with more than the expected number of bits cannot be detected.

The check for packet error is done only after the detection of the first DMMSYNC signal after the DMM is turned on or comes out of suspend mode (with COS = 0; Section 19.3.1), that is, before the reception of first DMMSYNC, the toggling of DMMCLK would be ignored.

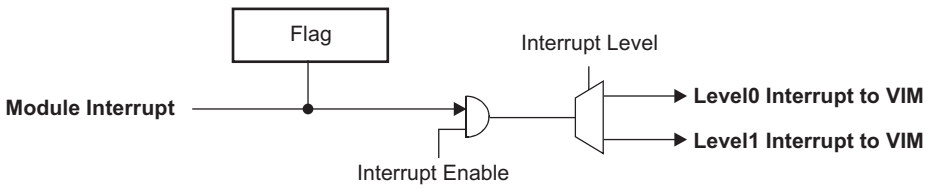
19.2.3.3 Bus Error

If an error occurs on the microcontroller internal bus system while transferring the data from the DMM to the destination, the BUSERROR flag will be set.

19.2.4 Interrupts

The module provides different interrupts. These can be programmed to different interrupt levels independently using DMMINTLVL (Section 19.3.4).

Figure 19-6. Interrupt Structure



Interrupts can be divided into error interrupts and functional interrupts. The error handling is described in Section 19.2.3. Functional interrupts depend on the mode (Trace Mode, Direct Data Mode) the DMM module is used in.

Trace Mode: An interrupt can be enabled whenever an access to the lowest address of a defined region is performed. This address is the starting address programmed in the DMMDESTxREGy register. An interrupt for each of the region can be generated by setting the individual interrupt enable bits.

Direct Data Mode: There are two interrupts that can be individually controlled. One is generated when the buffer pointer reaches the end of the defined buffer and wraps around (EO_BUFF; Section 19.3.2). The other one is generated when the buffer pointer matches the programmed interrupt threshold (PROG_BUFF; Section 19.3.2). The buffer pointer points to the next address to be written, therefor there are (interrupt threshold - 1) values stored in the buffer. The interrupt threshold can be programmed in the DMMINTPT register (Section 19.3.11).

19.3 Control Registers

This section describes the DMM registers. The registers support 8, 16, and 32-bit writes. The offset is relative to the associated peripheral select. Table 19-6 provides a summary of the registers and their bits. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 19-6. DMM Registers

Offset	Acronym	Register Description	Section

7	4	3	0
Reserved		ON/OFF	
R-0		R/WP-5h	

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

Table 19-7. DMM Global Control Register (DMMGLBCTRL) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reads returns 0. Writes have no effect.
24	BUSY		Busy indicator.
		0	The DMM does not currently receive data and has no data in its internal buffers, which needs to be transferred.
		1	The module is currently receiving data, or has data in its internal buffers
23-19	Reserved	0	Reads returns 0. Writes have no effect.
18	CONTCLK		Continuous DMMCLK input.
			User and privilege mode read, privilege mode write:
		0	DMMCLK is expected to be suspended between two packets.
		1	DMMCLK is expected to be free running between packets.
17	COS		Continue on suspend. Influences behavior of module while in debug mode. In all cases the corresponding interrupt will be set.
			User and privilege mode (read):
		0	Packets will not be received during debug mode. Before entering debug mode, the ongoing reception of a packet will be finished and the value will be written to the destination.
		1	Continue receiving packets and update destination, while in debug mode
			Privilege mode (write):
		0	Disable data reception while in debug mode
		1	Enable data reception while in debug mode
16	RESET		Reset. This bit resets the state machine and the registers to its reset value, except the RESET bit itself. It must be cleared by writing to it.
			User and privilege mode (read):
		0	No reset of DMM module
		1	Reset of DMM module
			Privilege mode (write):
		0	No reset of DMM module
		1	Reset DMM module to its reset state
15-11	Reserved	0	Reads returns 0. Writes have no effect.

Table 19-7. DMM Global Control Register (DMMGLBCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
10-9	DDM_WIDTH		Packet Width in direct data mode.
			User and privilege mode read and privilege mode write operation:
		Bit Encoding	Transfer Size
		0	8 bit
		1h	16 bit
		2h	32 bit
		3h	Reserved
8	TM_DMM		Packet Format.
			User and privilege mode (read):
		0	The DMM module assumes packets in trace mode definition
		1	The DMM module assumes packets in direct data mode definition
			Privilege mode (write):
		0	Enable trace mode
		1	Enable direct data mode
7-4	Reserved	0	Reads returns 0. Writes have no effect.
3-0	ON/OFF		Switch module on or off
			User and privilege mode (read):
		All other	The DMM module does not receive data
		Ah	The DMM module receives data and writes it to the buffer
			Privilege mode (write):
		All other	Disable receive/write operations. Packets in reception, will still be finished
		Ah	Enable receive/write operations. Packets will be received 1 HCLK cycle after enabling the module

NOTE: It is recommended to write 5h to ON/OFF to avoid having a soft error inadvertently enabling the module when a single bit flips.

NOTE: Registers that affect the operation of the module, should be only programmed when the BUSY bit is 0 and the ON/OFF bits are not Ah.

NOTE: If the module was in operation, turned off (ON/OFF = all other than Ah) and then turned on (ON/OFF = Ah) again, it is recommended to perform a reset (RESET = 1) of the module before switching it on. This avoids that the state machine is held in an unrecoverable state.

NOTE: A write to these register bits while receiving a packet will not have any effect on the received packet. The mode change will be performed after the packet is received

19.3.2 DMM Interrupt Set Register (DMMINTSET)

This register contains the interrupt set bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation.

Figure 19-8. DMM Interrupt Set Register (DMMINTSET) [offset = 04h]

Table 19-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0. Writes have no effect.
17	PROG_BUFF		**Programmable Buffer Interrupt Set.** This enables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register (Section 19.3.11). This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on pointer match.
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
16	EO_BUFF		**End of Buffer Interrupt Set.** This enables the interrupt generation in case data was written to the last entry in the buffer and the pointer wrapped around to the beginning of the buffer. This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on writing to the last entry.
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
15	DEST3REG2		**Destination 3 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 19-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
14	DEST3REG1		**Destination 3 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
13	DEST2REG2		**Destination 2 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
12	DEST2REG1		**Destination 2 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
11	DEST1REG2		**Destination 1 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 1 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
10	DEST1REG1		**Destination 1 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 1 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
9	DEST0REG2		**Destination 0 Region 2 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 0 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 19-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
8	DEST0REG1		**Destination 0 Region 1 Interrupt Set.** This enables the interrupt generation in case data was accessed at the startaddress of Destination 0 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
7	BUSERROR		Bus Error Response for errors generated when doing internal bus transfers.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
6	BUFF_OVF		**Buffer Overflow.** This enables the interrupt generation in case new data is received, while the previous data still has not been transmitted.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
5	SRC_OVF		**Source Overflow.** This enables an interrupt if the external system experienced and overflow which was signalled in the Trace Mode packet.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
4	DEST3_ERR		**Destination 3 Error.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST3REG1/DMMDEST3BL1 or DMMDEST3REG2/DMMDEST3BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

Table 19-8. DMM Interrupt Set Register (DMMINTSET) Field Descriptions (continued)

Bit	Field	Value	Description
3	DEST2_ERR		**Destination 2 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST2REG1/DMMDEST2BL1 or DMMDEST2REG2/DMMDEST2BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
2	DEST1_ERR		**Destination 1 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST1REG1/DMMDEST1BL1 or DMMDEST1REG2/DMMDEST1BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
1	DEST0_ERR		**Destination 0 Error Interrupt Set.** This enables the interrupt generation in case data should be written into a address not specified by DMMDEST0REG1/DMMDEST0BL1 or DMMDEST0REG2/DMMDEST0BL2. If both blocksizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)
0	PACKET_ERR_INT		**Packet Error.** This enables the interrupt generation in case of an error condition in the packet reception. Please refer to Section 19.2.3 for the error conditions.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated
			Privilege mode (write):
		0	No influence on bit
		1	Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL)

19.3.3 DMM Interrupt Clear Register (DMMINTCLR)

This register contains the interrupt clear bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation

Table 19-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0. Writes have no effect.
17	PROG_BUFF		**Programmable Buffer Interrupt Set.**This disables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register (Section 19.3.11). This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on pointer match.
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
16	EO_BUFF		**End of Buffer Interrupt Set.**This disables the interrupt generation in case data was written to the last entry in the buffer and the pointer wrapped around to the beginning of the buffer. This bit is only relevant in Direct Data Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on writing to the last entry.
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))

Table 19-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)

Bit	Field	Value	Description
15	DEST3REG2		**Destination 3 Region 2 Interrupt Set.**This disables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
14	DEST3REG1		**Destination 3 Region 1 Interrupt Set.**This disables the interrupt generation in case data was accessed at the startaddress of Destination 3 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
13	DEST2REG2		**Destination 2 Region 2 Interrupt Set.**This disables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 2. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):
		0	No influence on bit
		1	Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL))
12	DEST2REG1		**Destination 2 Region 1 Interrupt Set.**This disables the interrupt generation in case data was accessed at the startaddress of Destination 2 Region 1. This bit is only relevant in Trace Mode.
			User and privilege mode (read):
		0	No interrupt will be generated
		1	An interrupt will be generated on a write to the start address of this region
			Privilege mode (write):

		1	Interrupt occurred
			Privilege mode (write):
		0	No influence on bit
		1	Bit will be cleared

19.3.6 DMM Interrupt Offset 1 Register (DMMOFF1)

This register holds the offset indicating which interrupt occurred on interrupt level 0. The CPU can read this register to determine the source of the interrupt without having to test individual interrupt flags.

Figure 19-12. DMM Interrupt Offset 1 Register (DMMOFF1) [offset = 14h]

			Reading the offset will clear the corresponding flag in DMMINTFLG (Section 19.3.5).
			Privilege and user mode writes have no effect

19.3.8 DMM Direct Data Mode Destination Register (DMMDDMDEST)

This register defines the starting address of the buffer used to store the received data in Direct Data Mode. By writing to this register, the DMMDDMPT register (Section 19.3.10) will be set to 0x0000.

Figure 19-14. DMM Direct Data Mode Destination Register (DMMDDMDEST) [offset = 1Ch]

Bit	Field	Value	Description
31-15	Reserved	0	Read returns 0. Writes have no effect.
14-0	POINTER		These bits hold the pointer to the next entry to be written in the buffer. The pointer points to the byte aligned address. If in 16-bit DDM mode, bit 0 will be 0. If in 32-bit DDM mode, bit 0 and 1 will be 0. User and privilege mode (read): next data entry Privilege mode (write): writes have no effect

19.3.11 DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT)

This register can be programmed to hold a threshold to which the DMMDDMPT register (Section 19.3.10) is compared. An interrupt can be generated when both match.

Bit	Field	Value	Description
31-15	Reserved	0	Read returns 0. Writes have no effect.
14-0	INTPT		Interrupt Pointer. When the buffer pointer (Section 19.3.10) matches the programmed value in DMMINTPT and the PROG_BUF interrupt (Section 19.3.2) is set, an interrupt is generated. User and privilege mode (read): current interrupt threshold Privilege mode (write): new interrupt threshold

19.3.12 DMM Destination x Region 1 (DMMDESTxREG1)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG1 and DMMDESTxBL1, an interrupt (DESTx_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG1, DMMDEST1REG1, DMMDEST2REG1, DMMDEST3REG1.

19.3.16 DMM Pin Control 0 (DMMPC0)

This register defines if the DMM pins are used in functional or GIO mode. It should only be written when ON/OFF = 0101 and the BUSY bit = 0 (Section 19.3.1). If pins other than the pins specified in Table 19-5 are configured, or DMMCLK and DMMSYNC are programmed as non-functional pins, no operation in trace mode or direct data mode is possible.

19.3.20 DMM Pin Control 4 (DMMPC4)

This register allows to set individual pins to a logic high level without having to do a read-modify-write operation as would be the case with the DMMPC3 register (Section 19.3.19). Writing a zero to a bit will not change the state of the pin.

19.3.21 DMM Pin Control 5 (DMMPC5)

This register allows to set individual pins to a logic low level without having to do a read-modify-write operation as would be the case with the DMMPC3 register (Section 19.3.19). Writing a one to a bit will change the output to a logic low level, writing a zero will not change the state of the pin.

19.3.22 DMM Pin Control 6 (DMMPC6)

These bits configure the pins in push-pull or open-drain functionality. If configured to be open-drain, the module only drives a logic-low level on the pin. An external pull-up resistor needs to be connected to the pin to pull it high, when the pin is in high-impedance mode.

Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

Topic **Page**

20.1 Introduction **2307**
20.2 ePWM Submodules **2311**
20.3 Application Examples **2366**
20.4 MSS_ETPWM1 Registers **2381**

20.1 Introduction

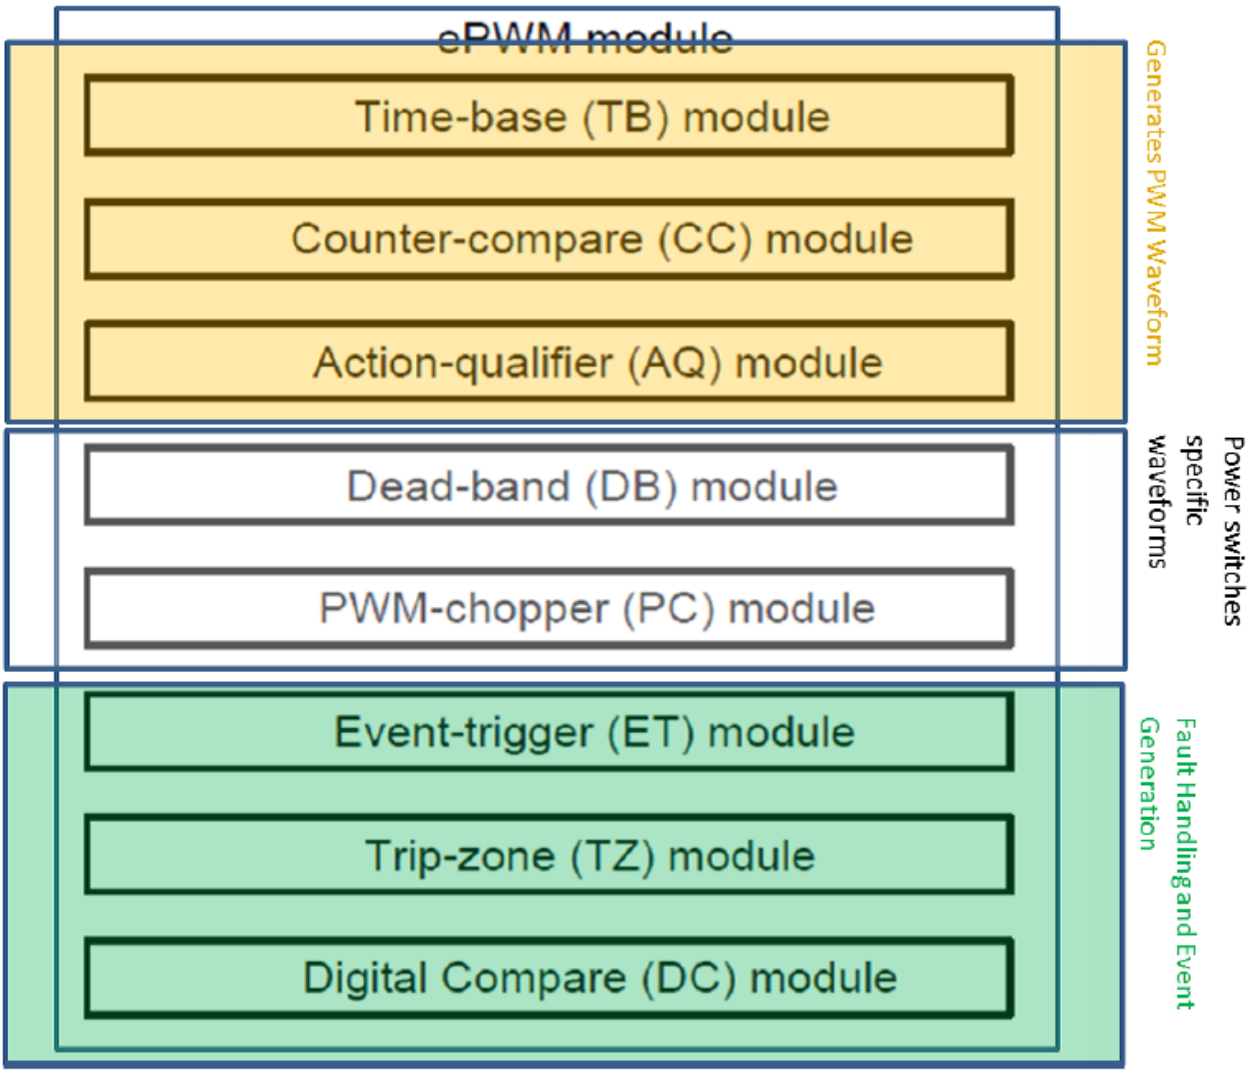
An effective PWM peripheral must be able to generate complex pulse-width waveforms with minimal CPU overhead or intervention. It is highly programmable, flexible, and easy to understand and use. The ePWM is built up from smaller single-channel modules, with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture, and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

20.1.1 Submodule Overview

In this section, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx Instance. Thus, EPWM1A and EPWM1B belong to ePWM1, and likewise EPWM3A and EPWM3B belong to PWM3.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in Figure 20-1.

Figure 20-1. ePWM Module



The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in . Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system, and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

  The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter.
- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$).**

  These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK3, or double-synchronized and filtered through a 6-VCLK3-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM. $\overline{TZ4}$ is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers. $\overline{TZ5}$ is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected. $\overline{TZ6}$ is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.
- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals**.

  The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCI of the first enhanced capture module (eCAP1).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

  Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.
- **Peripheral Bus**

  The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Each ePWM module is connected to the input/output signals shown in .

NOTE: The integration of the three ePWM modules is done such that it could be used for complex asymmetric waveforms generation for complicated power management systems, however, currently the plan is to use the three modules in a completely independent way, generating a simple symmetric waveform signal for both the PMIC device and the monitoring system input.

20.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in Table 20-1. Each register set is duplicated for each instance of the ePWM module.

Table 20-1. ePWM Module Control and Status Register Set Grouped by Submodule

Name	Address Offset[1]	Size (x16)	Shadow	Privileged Mode Write Only?	Description
Time-Base Submodule Registers

20.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

20.2.1 Overview

Table 20-2 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 20.2.3 for relevant details.

Table 20-2. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (VCLK3). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software

Table 20-2. Submodule Configuration Parameters (continued)

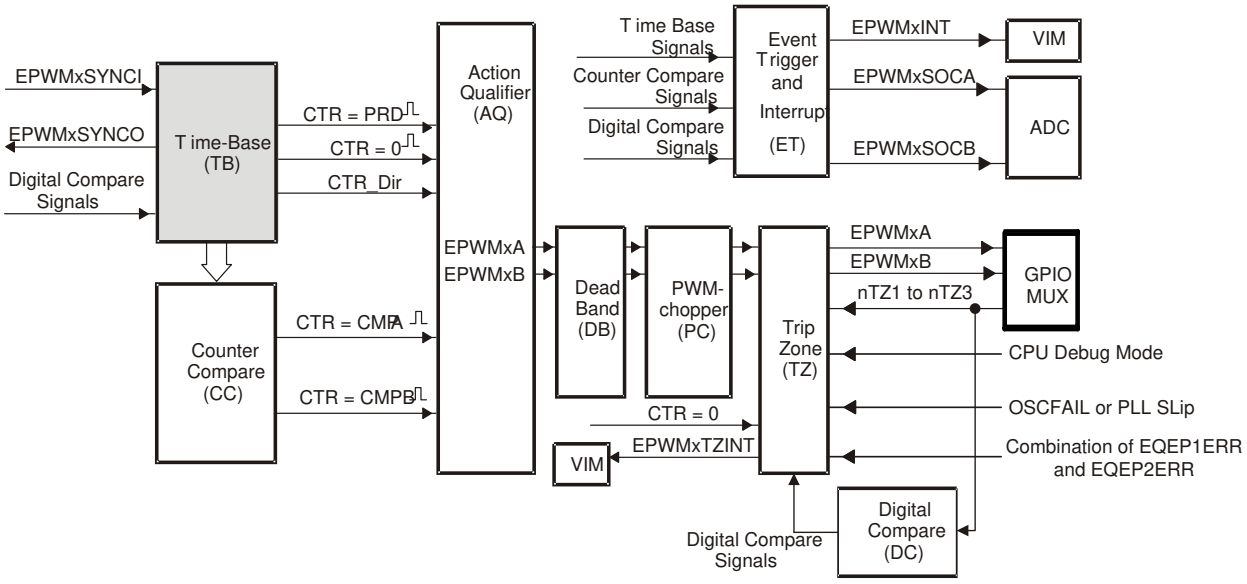
Submodule	Configuration Parameter or Option
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to each trip-zone signal: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Enable ePWM events that will trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
Digital-compare (DC)	• Enables trip zone signals to create events and filtered events • Specify event-filtering options to capture TBCTR counter or generate blanking window

Code examples are provided in this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm_defines.h* file in the device-specific header file and peripheral examples software package.

20.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 20-2 illustrates the time-base module's place within the ePWM.

Figure 20-2. Time-Base Submodule Block Diagram



20.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK3). This allows the time-base counter to increment/decrement at a slower rate.

20.2.2.2 Controlling and Monitoring the Time-Base Submodule

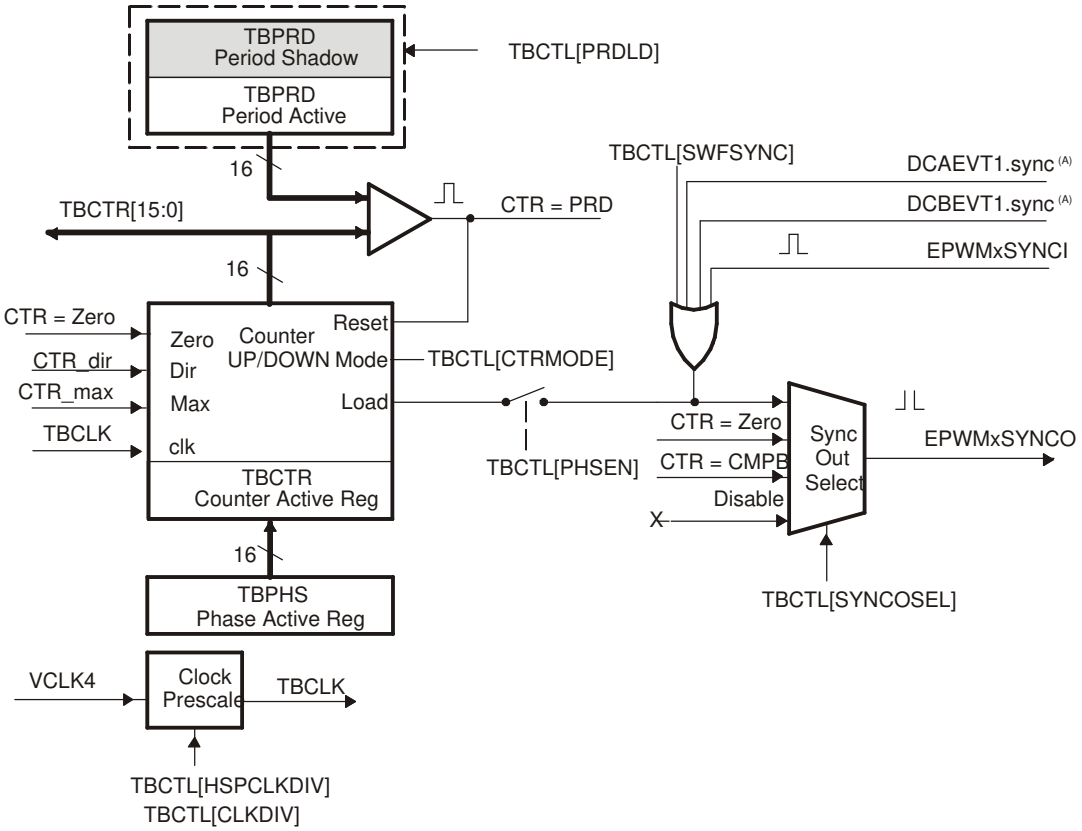
Table 20-3 shows the registers used to control and monitor the time-base submodule.

Table 20-3. Time-Base Submodule Registers

Register	Address Offset	Shadowed	Description
TBSTS		No	Time-Base Status Register
TBCTL		No	Time-Base Control Register
TBPHS		No	Time-Base Phase Register
TBPRD		Yes	Time-Base Period Register
TBCTR		No	Time-Base Counter Register

Figure 20-3 shows the critical signals and registers of the time-base submodule. Table 20-4 provides descriptions of the key signals associated with the time-base submodule.

Figure 20-3. Time-Base Submodule Signals and Registers



A. These signals are generated by the digital compare (DC) submodule.

Table 20-4. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral, EPWM3SYNCI is generated by ePWM2 and so forth. See Section 20.2.2.3.3 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000.

Table 20-4. Key Time-Base Signals (continued)

Signal	Description
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB).
	This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction.
	Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF)
	Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock.
	This is a prescaled version of the system clock (VCLK3) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

20.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 20-4 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK3).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

  In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

  In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

  In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

20.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

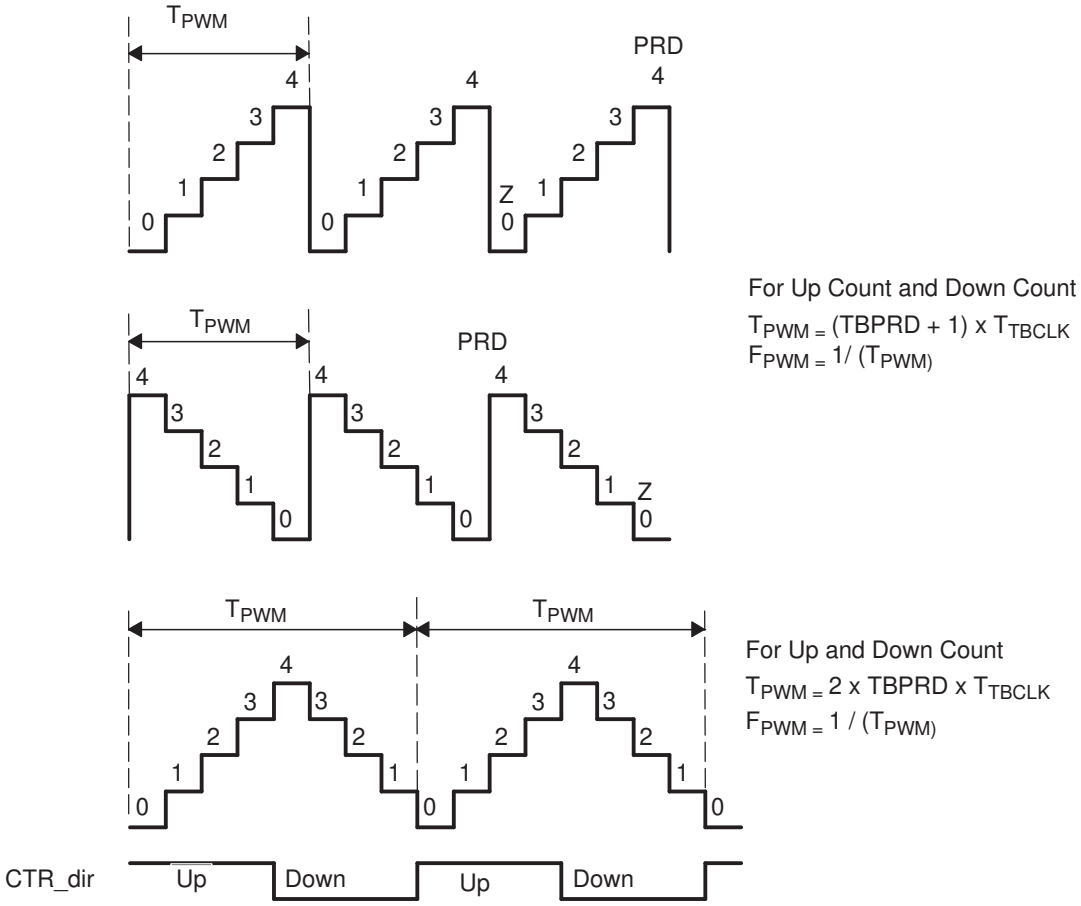
- **Active Register**

  The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

  The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

Figure 20-4. Time-Base Frequency and Period



The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

  The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:**

  If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

20.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR166 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

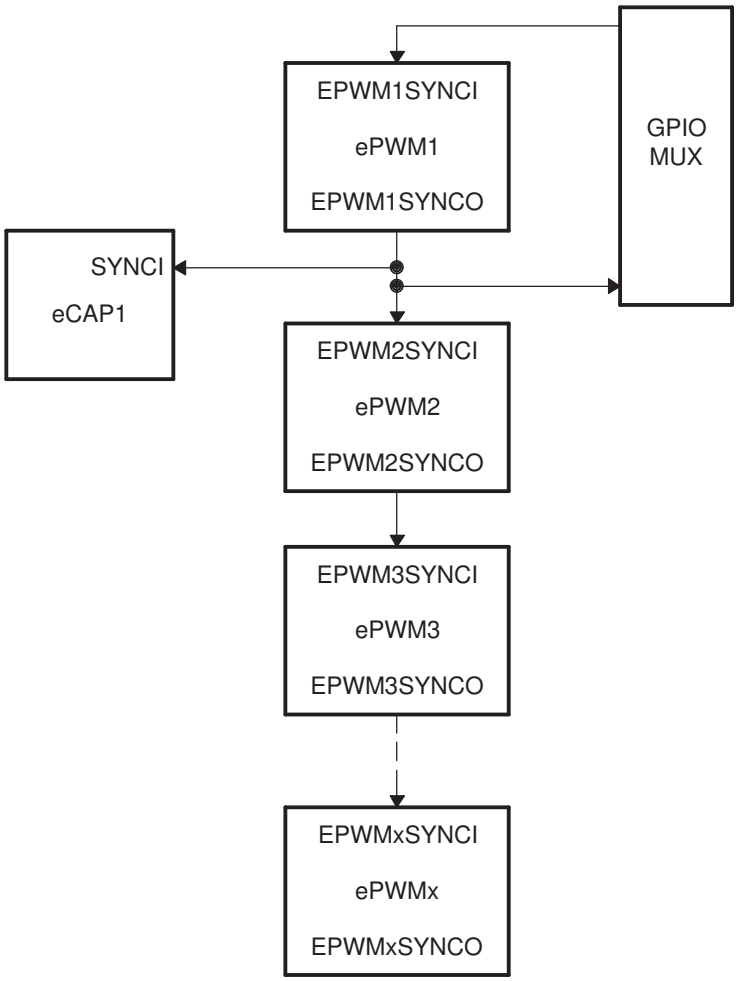
The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

20.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in Figure 20-5.

Figure 20-5. Time-Base Counter Synchronization Scheme



Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:**

  The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

  The delay from internal master module to slave modules is given by:

  – if (TBCLK = VCLK3): 2 x VCLK3
  – if (TBCLK != VCLK3): 1 TBCLK

- **Software Forced Synchronization Pulse:**

  Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

- **Digital Compare Event Synchronization Pulse:**

  DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 20-6 through Figure 20-9 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

20.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC= 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC=1.

20.2.2.5 Time-base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

Figure 20-6. Time-Base Up-Count Mode Waveforms

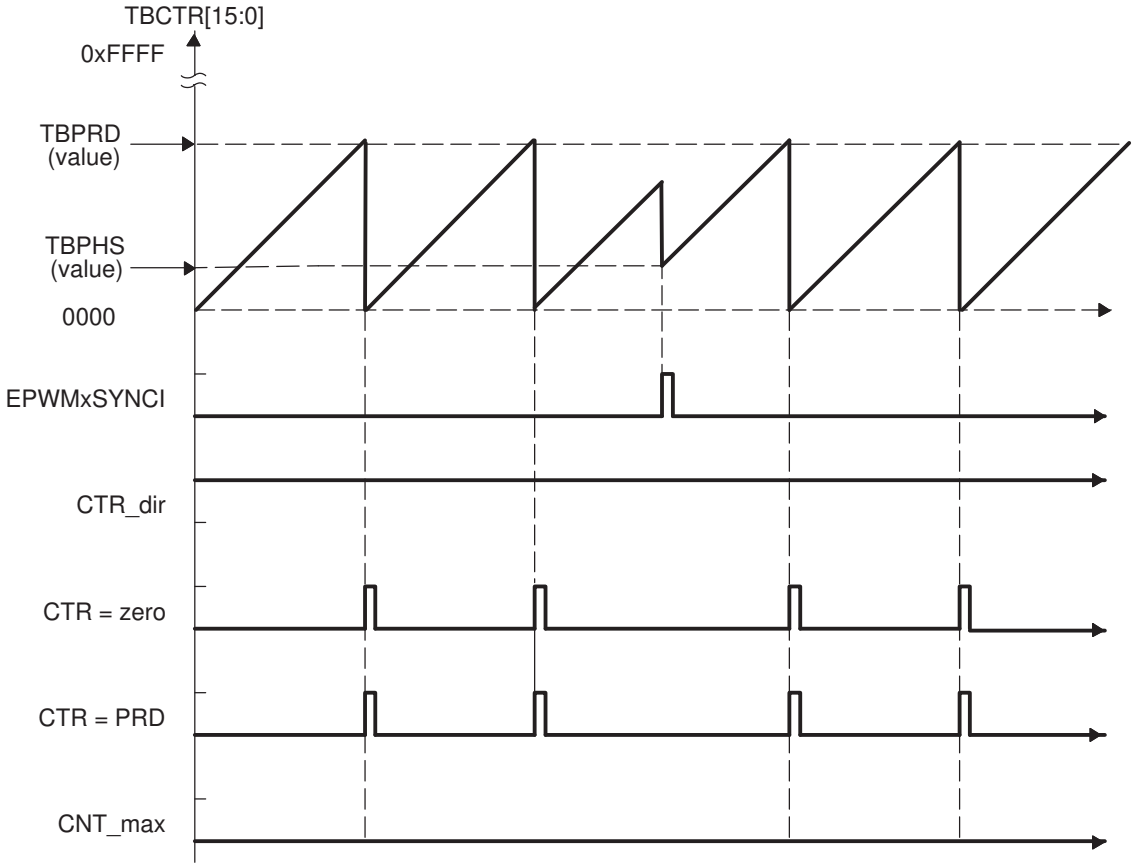


Figure 20-7. Time-Base Down-Count Mode Waveforms

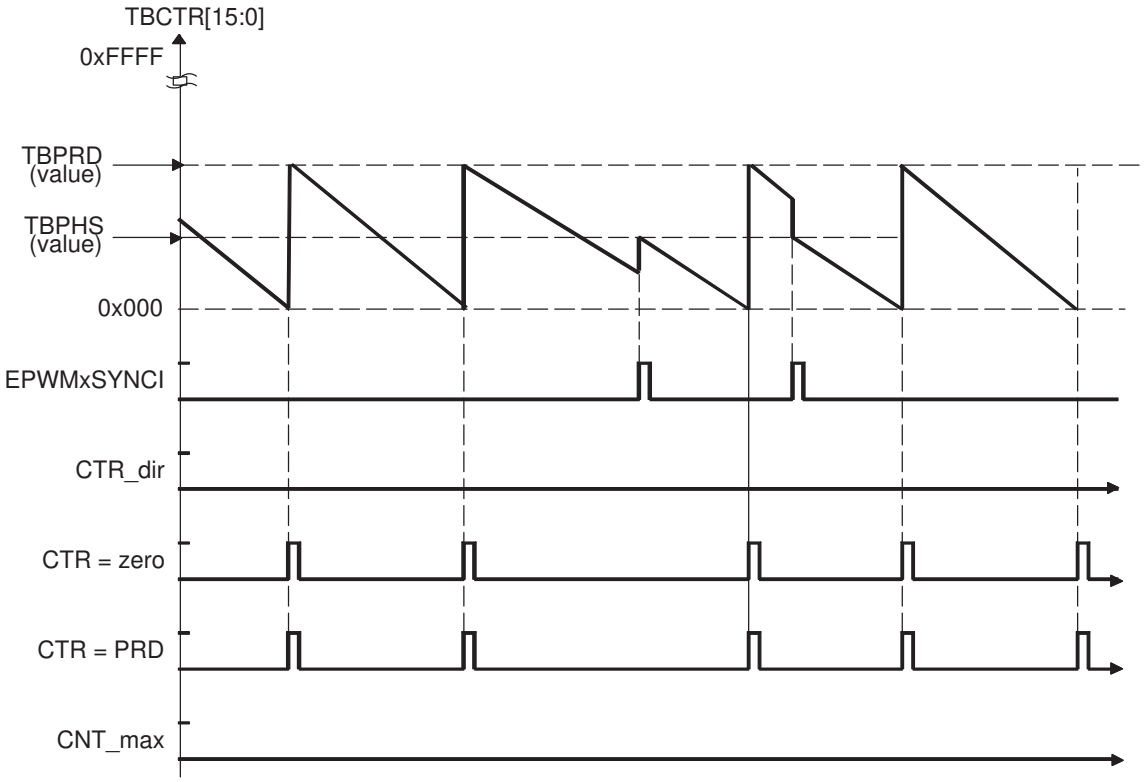

Figure 20-8. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

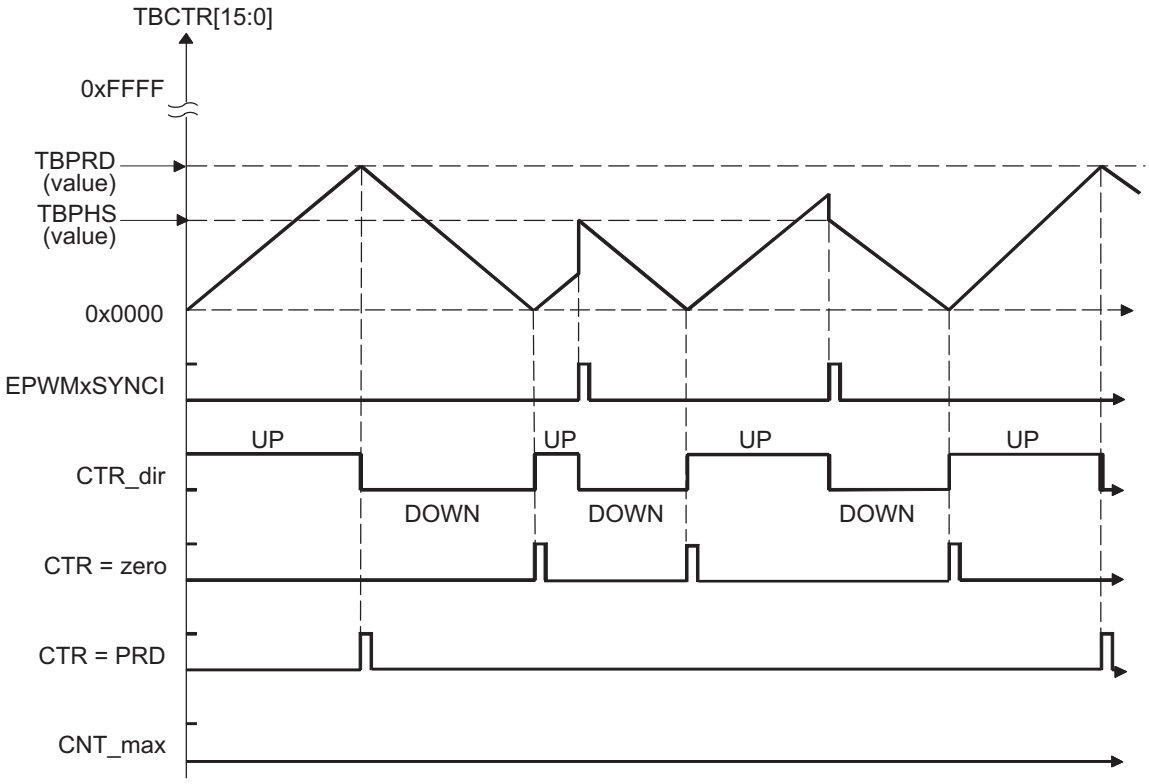

Figure 20-9. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

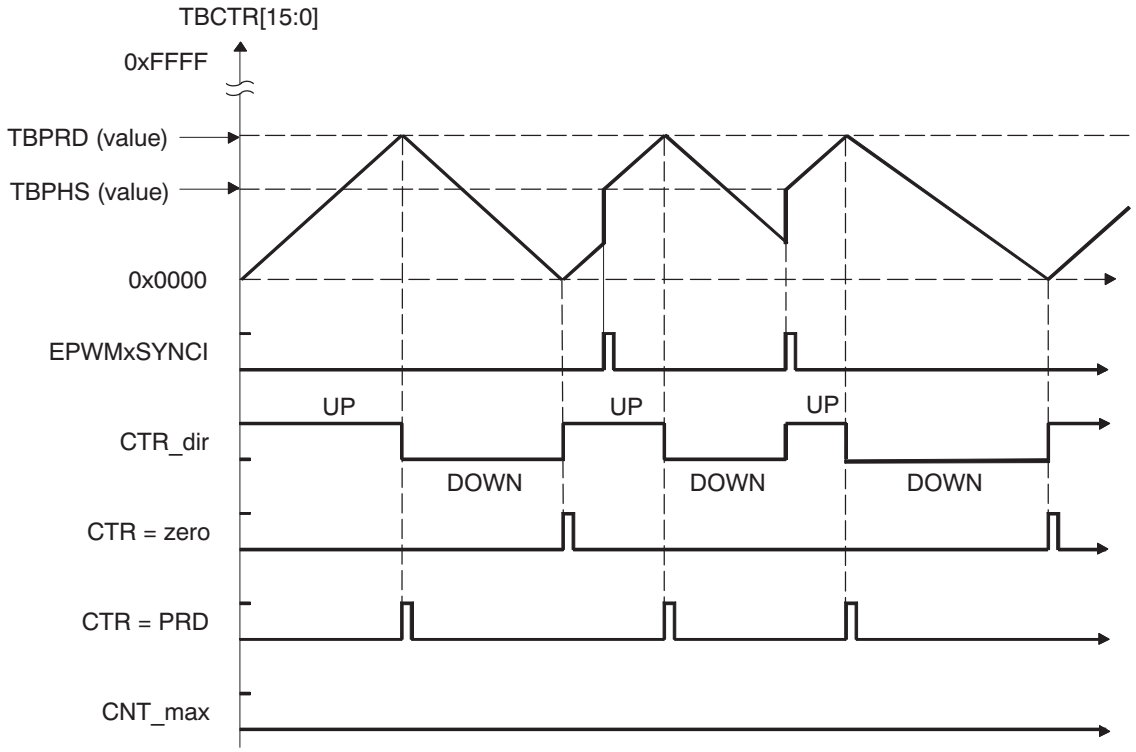

20.2.3 Counter-Compare (CC) Submodule

Figure 20-10 illustrates the counter-compare submodule within the ePWM.

Figure 20-11 shows the basic structure of the counter-compare submodule.

Figure 20-10. Counter-Compare Submodule

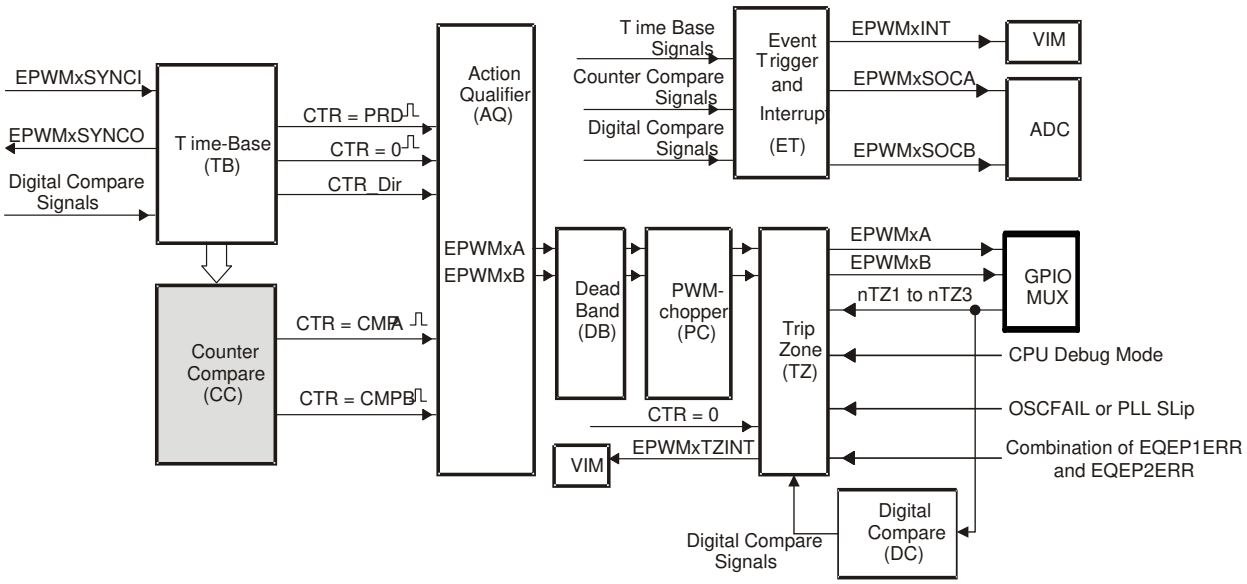

Figure 20-11. Detailed View of the Counter-Compare Submodule

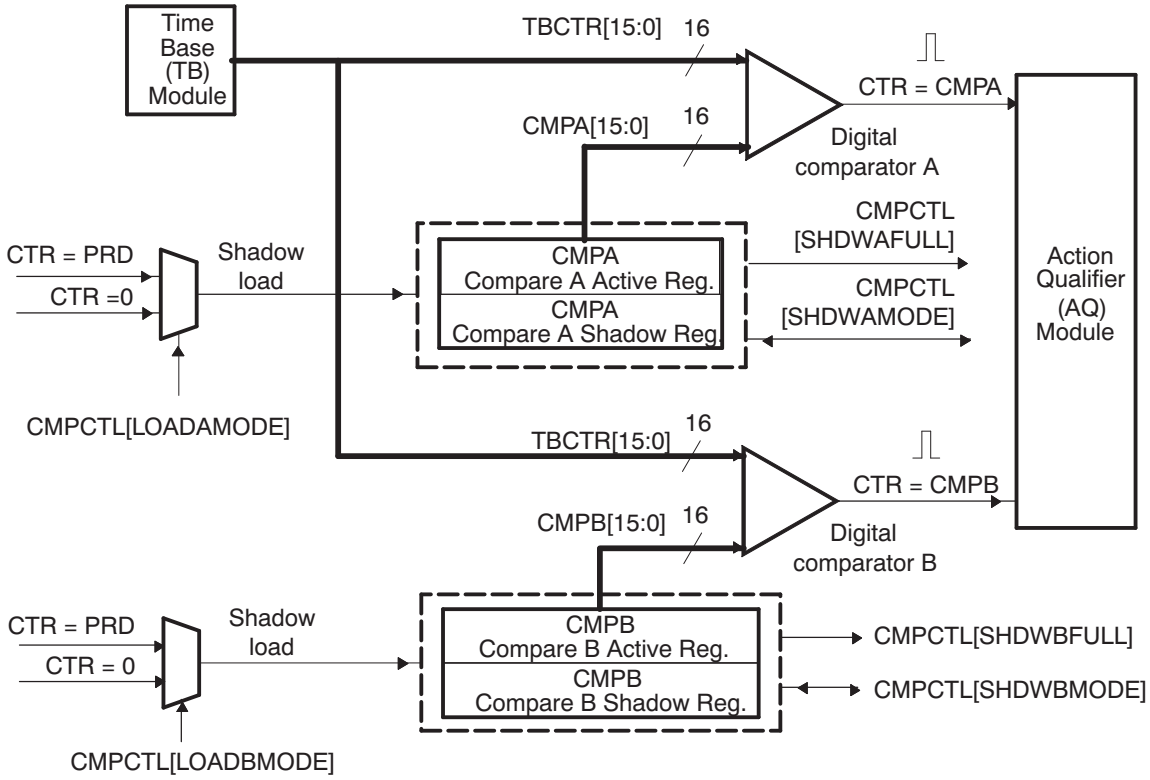


20.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

20.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers listed in Table 20-5.

The key signals associated with the counter-compare submodule are described in Table 20-6.

Table 20-5. Counter-Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
CMPCTL		No	Counter-Compare Control Register.
CMPA		Yes	Counter-Compare A Register
CMPB		Yes	Counter-Compare B Register

Table 20-6. Counter-Compare Submodule Key Signals

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCTR = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCTR = TBPRD
CTR = ZERO	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCTR = 0x0000

20.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to Section 20.2.4.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If immediate load mode is selected (TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

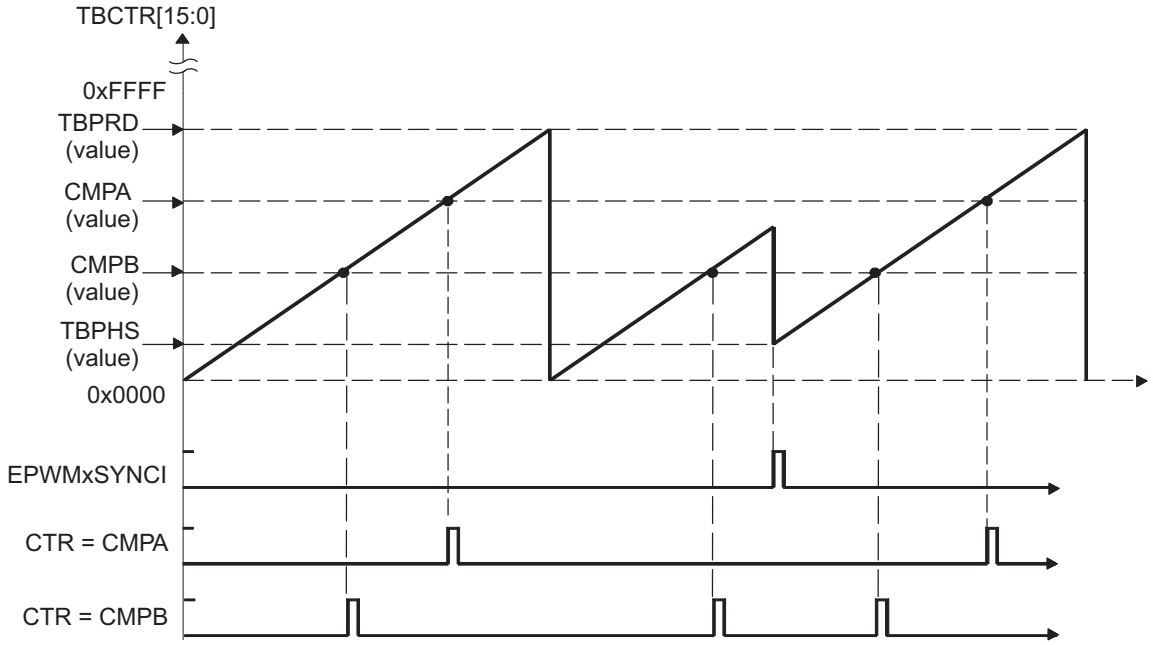
20.2.3.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To illustrate the operation of the first three modes, the timing diagrams in Figure 20-12 through Figure 20-15 show when events are generated and how the EPWMxSYNCI signal interacts.

Figure 20-12. Counter-Compare Event Waveforms in Up-Count Mode



NOTE: An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 20-13. Counter-Compare Events in Down-Count Mode

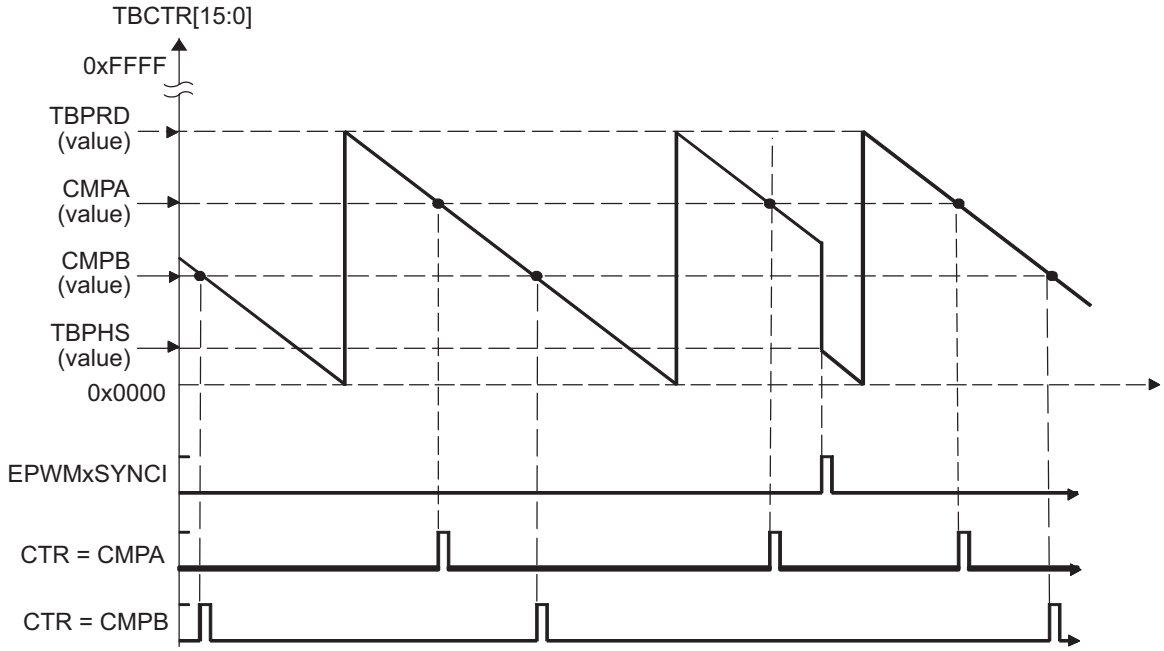


Figure 20-14. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

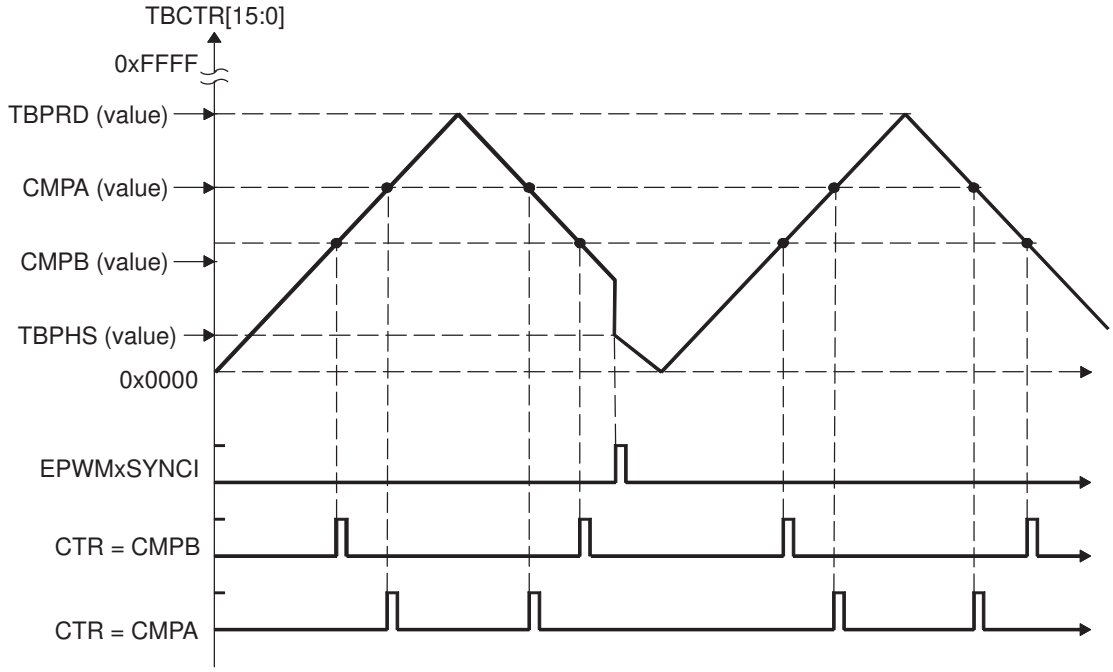

Figure 20-15. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

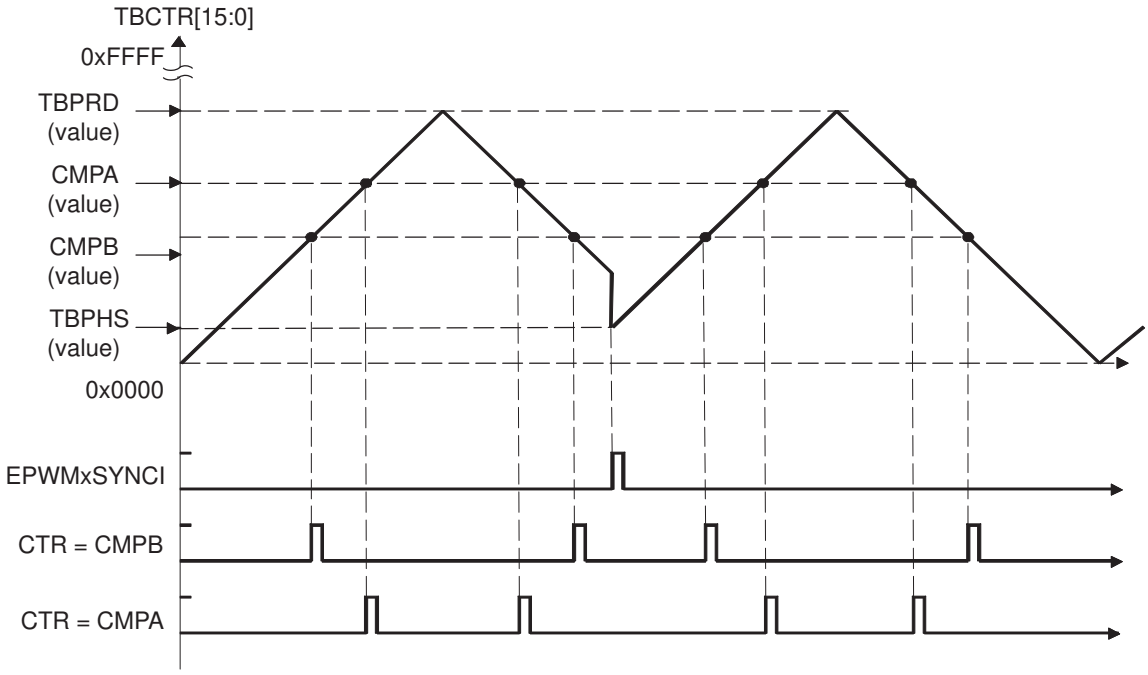
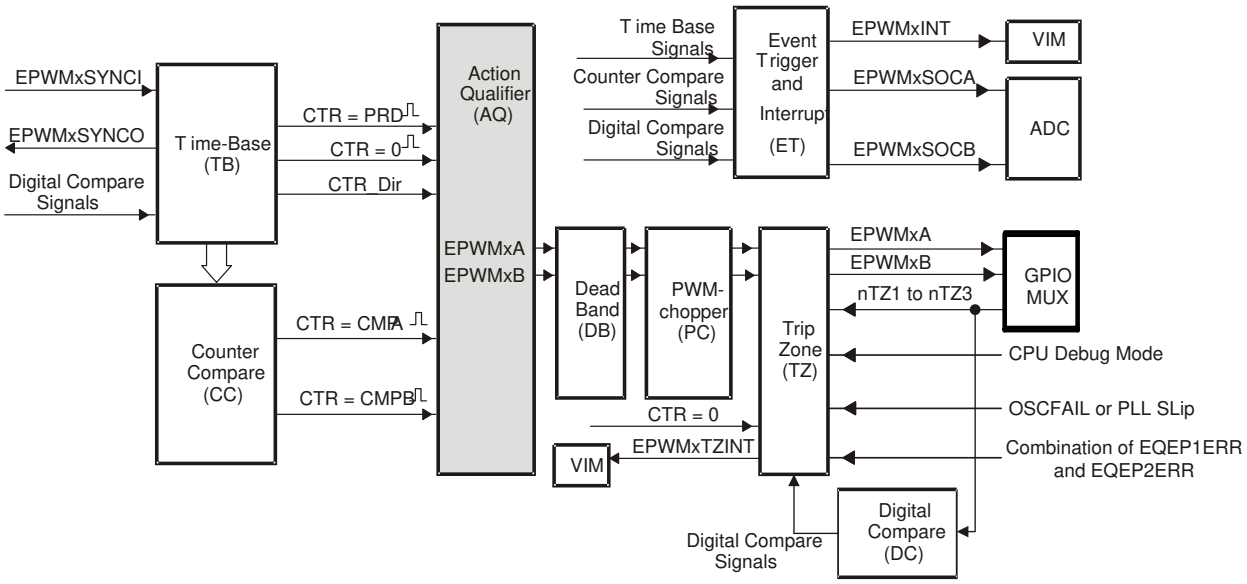


20.2.4 Action-Qualifier (AQ) Submodule

Figure 20-16 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 20-16. Action-Qualifier Submodule



20.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

20.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

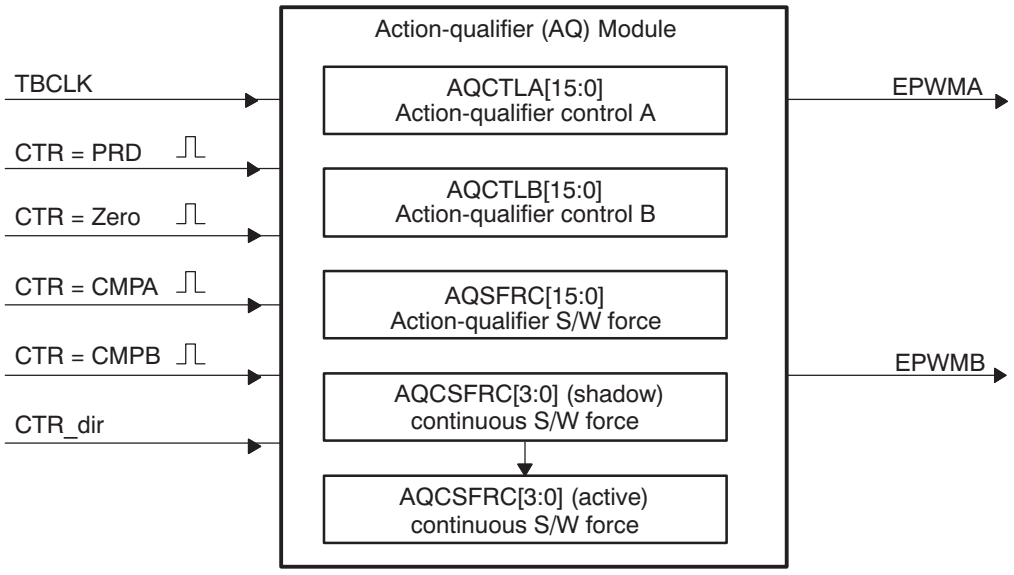
The action-qualifier submodule operation is controlled and monitored via the registers in Table 20-7.

Table 20-7. Action-Qualifier Submodule Registers

Register Name	Address Offset	Shadowed	Description
AQCTLA		No	Action-Qualifier Control Register For Output A (EPWMxA)
AQSFRC		No	Action-Qualifier Software Force Register
AQCTLB		No	Action-Qualifier Control Register For Output B (EPWMxB)
AQCSFRC		Yes	Action-Qualifier Continuous Software Force

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Table 20-7.

Figure 20-17. Action-Qualifier Submodule Inputs and Outputs



The possible input events are summarized again in Table 20-8.

Table 20-8. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to zero	TBCTR = 0x0000
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFRC and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**

  Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**

  Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**

  If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.

- **Do Nothing:**

  Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in Section 20.2.8 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in Figure 20-18. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 20-18. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW ✕	Z ✕	CA ✕	CB ✕	P ✕	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

20.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 20-9. A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 20-9. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD)	Counter equals CMPB on up-count (CBU)
6 (Lowest)	Counter equals CMPA on down-count (CAD)	Counter equals CMPA on up-count (CBU)

Table 20-10 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 20-10. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 20-11 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 20-11. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 20-12.

Table 20-12. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.

Table 20-12. Behavior if CMPA/CMPB is Greater than the Period (continued)

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCTR=TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCTR = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).

20.2.4.4 Waveforms for Common Configurations

NOTE: The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

  This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

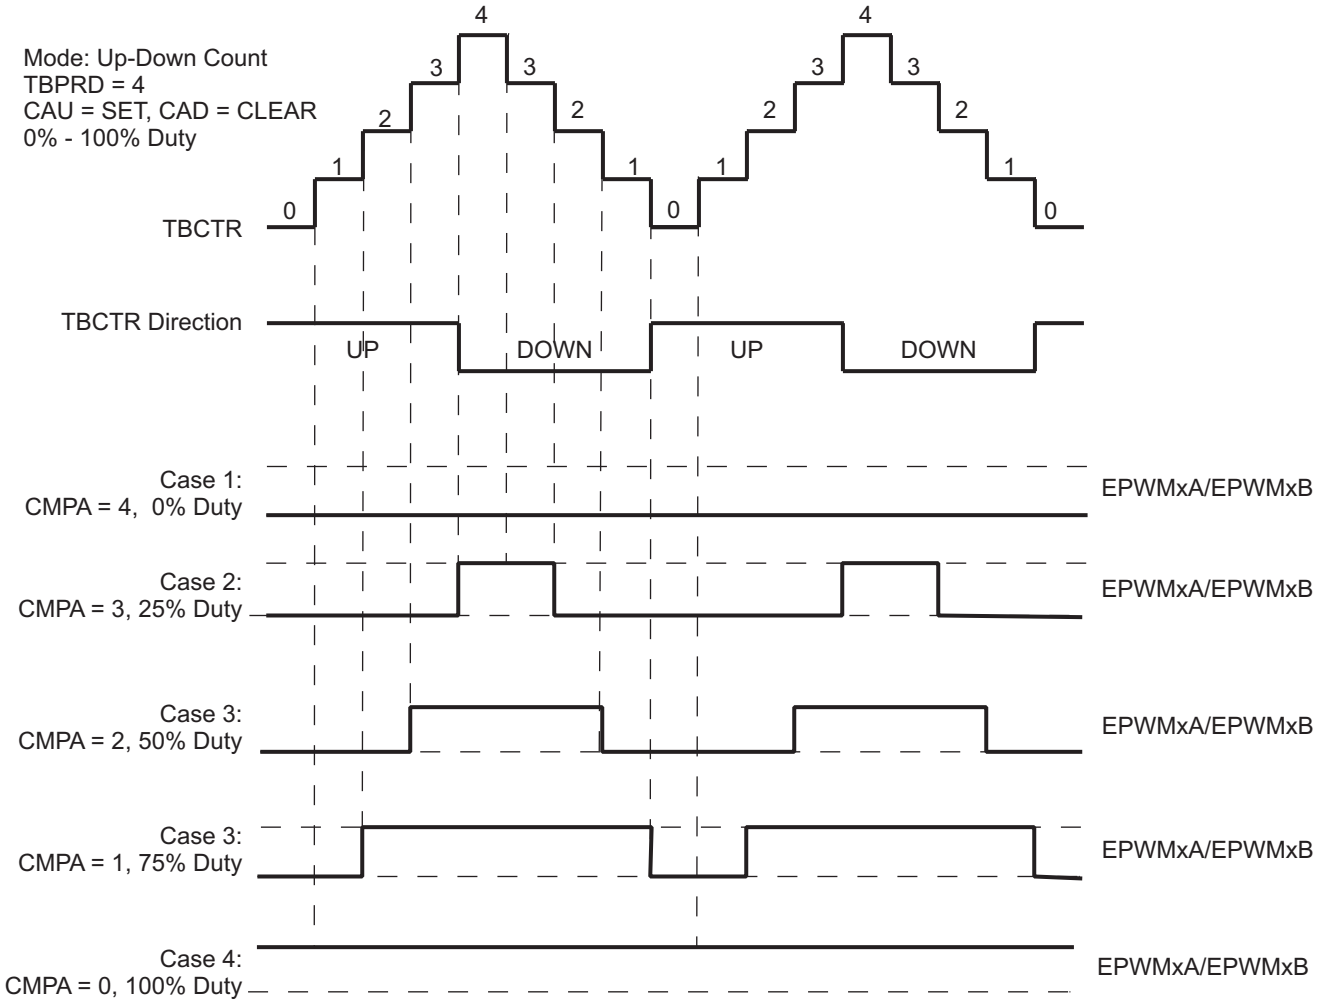
- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report (literature number SPRAAI1)

Figure 20-19 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 20-19. Up-Down-Count Mode Symmetrical Waveform

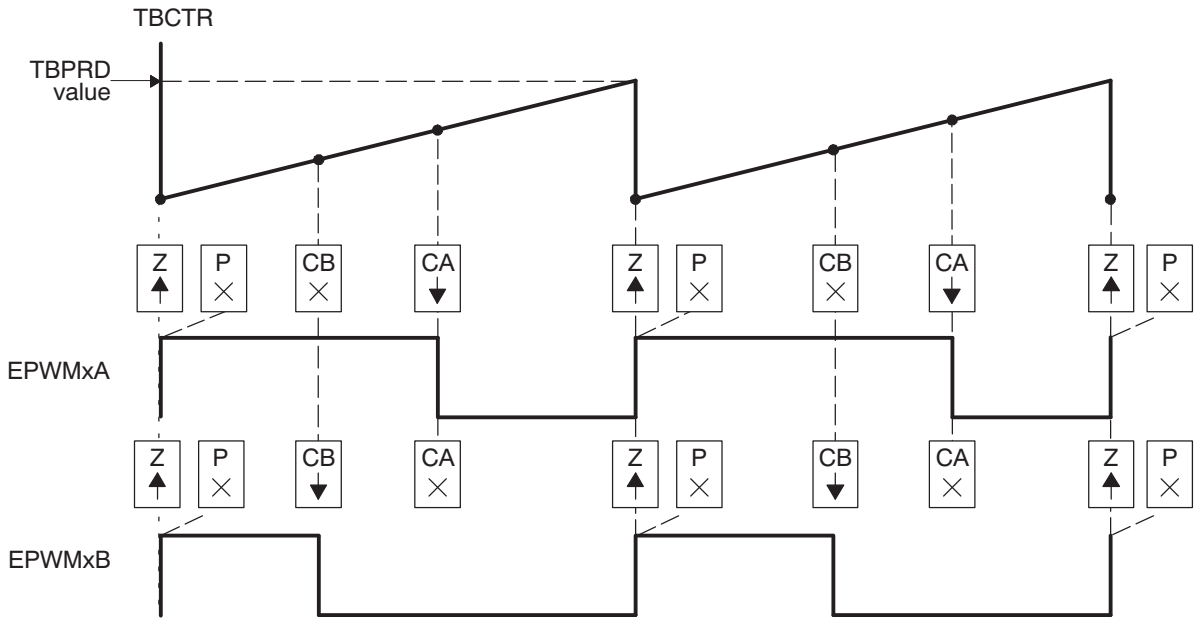


The PWM waveforms in Figure 20-20 through Figure 20-25 show some common action-qualifier configurations. The C-code samples in Example 20-1 through Example 20-6 shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Example 20-1 contains a code sample showing initialization and run time for the waveforms in Figure 20-20.

Figure 20-20. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High



A PWM period = (TBPRD + 1) × T_{TBCLK}

B Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

C Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

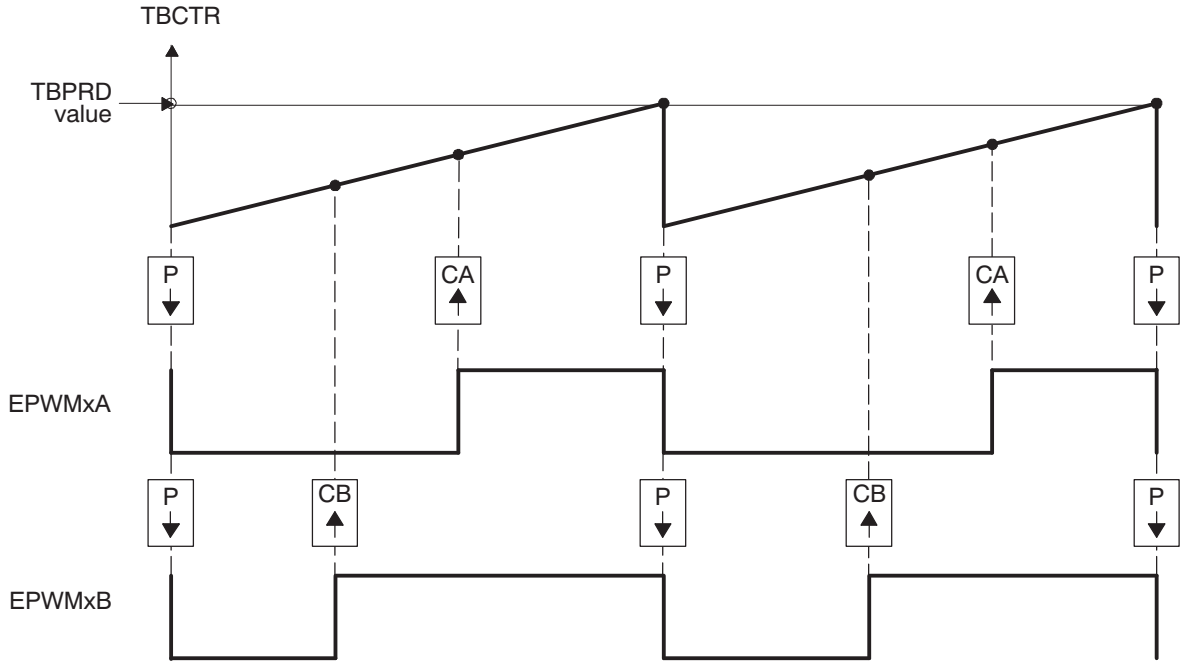
D The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.

E Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Example 20-1. Code Sample for Figure 20-20

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                        // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;               // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                         // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                          // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                          // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;       // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;      // TBCLK = SYSCLK
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;
//
// Run Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.CMPA.half.CMPA = Duty1A;            // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;                      // adjust duty for output EPWM1B
```

Figure 20-21. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low



A PWM period = (TBPRD + 1) × T_{TBCLK}

B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).

C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).

D Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Example 20-2 contains a code sample showing initialization and run time for the waveforms in Figure 20-21.

Example 20-2. Code Sample for Figure 20-21

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                          // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;                 // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                           // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                            // Set Phase register to zero

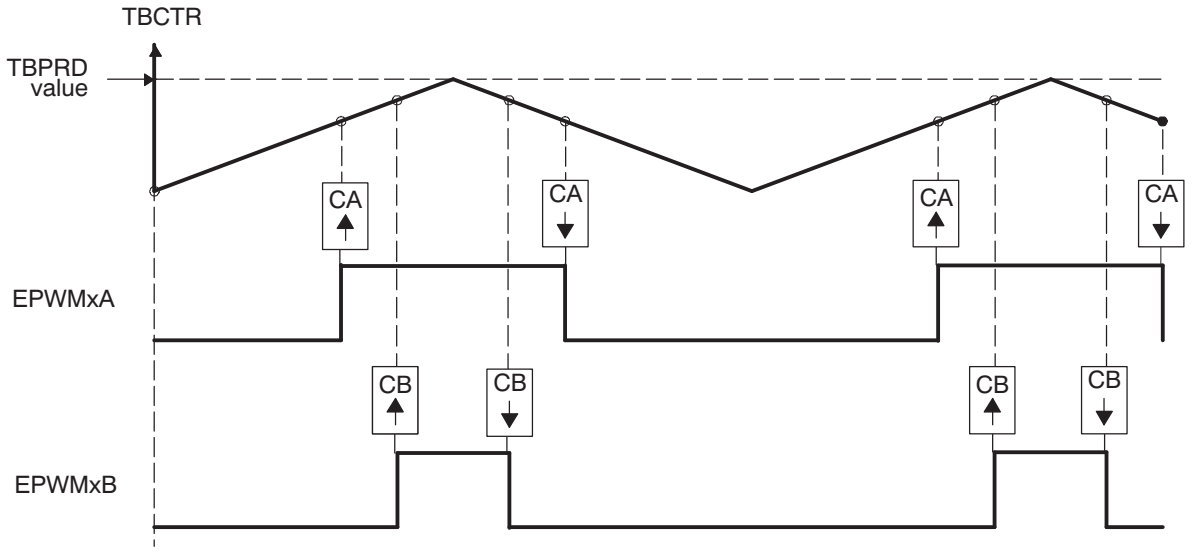
EPwm1Regs.CMPB = EdgePosB;
```

Figure 20-23. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low



A PWM period = 2 x TBPRD × T_{TBCLK}

B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).

C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).

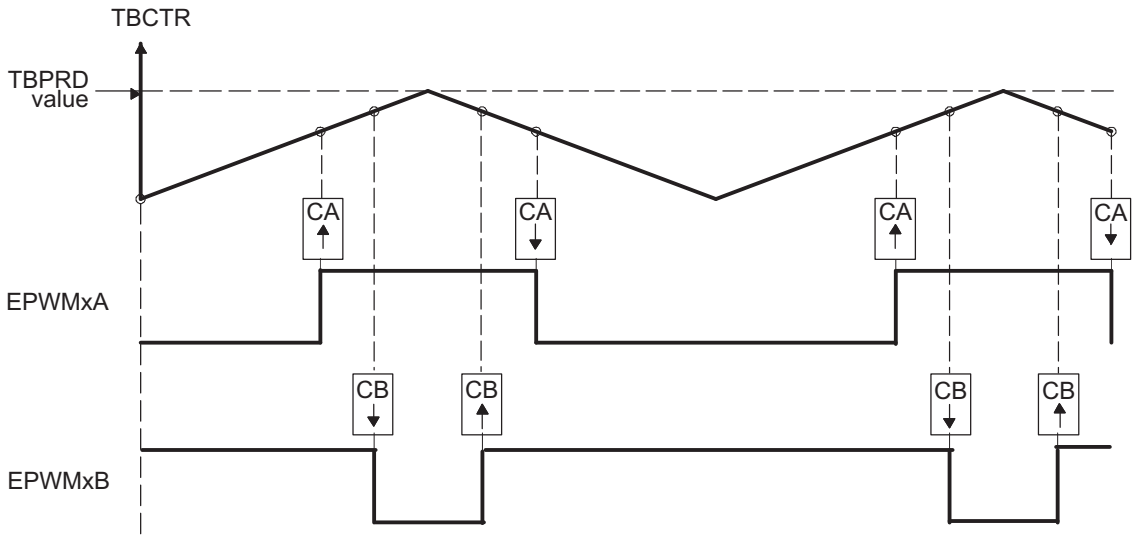
D Outputs EPWMxA and EPWMxB can drive independent power switches

Example 20-4 contains a code sample showing initialization and run time for the waveforms in Figure 20-23.

Example 20-4. Code Sample for Figure 20-23

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                          // Period = 2´600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 400;                 // Compare A = 400 TBCLK counts
EPwm1Regs.CMPB = 500;                           // Compare B = 500 TBCLK counts
EPwm1Regs.TBPHS = 0;                            // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                            // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
xEPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;       // Phase loading disabled
xEPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;       // TBCLK = VCLK3
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;
EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.CMPA.half.CMPA = Duty1A;            // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;                      // adjust duty for output EPWM1B
```

Figure 20-24. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary



A PWM period = 2 × TBPRD × T_{TBCLK}

B Duty modulation for EPWMxA is set by CMPA, and is active low, i.e., low time duty proportional to CMPA

C Duty modulation for EPWMxB is set by CMPB and is active high, i.e., high time duty proportional to CMPB

D Outputs EPWMx can drive upper/lower (complementary) power switches

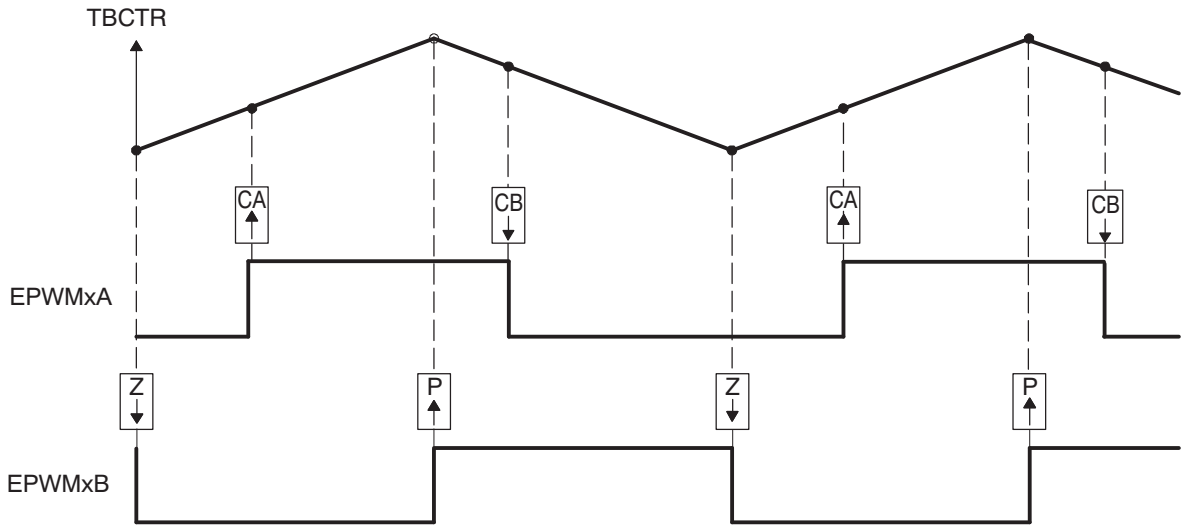
E Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

Example 20-5 contains a code sample showing initialization and run time for the waveforms in Figure 20-24.

Example 20-5. Code Sample for Figure 20-24

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.TBPRD = 600;                          // Period = 2´600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;                 // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 400;                           // Compare B = 400 TBCLK counts
EPwm1Regs.TBPHS = 0;                            // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                            // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;       // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;      // TBCLK = VCLK3
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBD = AQ_SET;
// Run Time
// = = = = = = = = = = = = = = = = = = = = = = = = =
EPwm1Regs.CMPA.half.CMPA = Duty1A;          // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;                    // adjust duty for output EPWM1B
```

Figure 20-25. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low



A PWM period = 2 × TBPRD × TBCLK

B Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.

C Duty modulation for EPWMxA is set by CMPA and CMPB.

D Low time duty for EPWMxA is proportional to (CMPA + CMPB).

E To change this example to active high, CMPA and CMPB actions need to be inverted (i.e., Set ! Clear and Clear Set).

F Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB)

Example 20-6 contains a code sample showing initialization and run time for the waveforms in Figure 20-25.

Example 20-6. Code Sample for Figure 20-25

```
// Initialization Time
// = = = = = = = = = = = = = = = = = = = = = = = = = = = = =

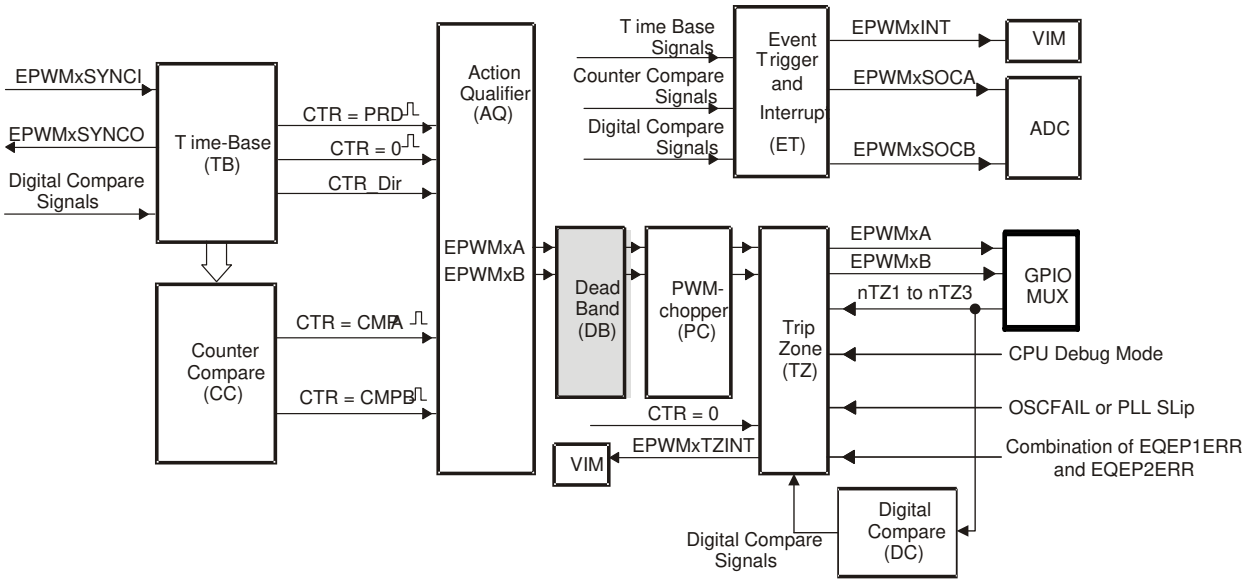
EPwm1Regs.CMPB = EdgePosB;
```

20.2.5 Dead-Band Generator (DB) Submodule

Figure 20-26 illustrates the dead-band submodule within the ePWM module.

Figure 20-26. Dead_Band Submodule



20.2.5.1 Purpose of the Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

20.2.5.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band submodule operation is controlled and monitored via the following registers:

Table 20-13. Dead-Band Generator Submodule Registers

Register Name	Address Offset	Shadowed	Description
DBCTL		No	Dead-Band Control Register
DBFED		No	Dead-Band Falling Edge Delay Count Register
DBRED		No	Dead-Band Rising Edge Delay Count Register

20.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 20-27.

- **Input Source Selection:**

  The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE) control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:

  – EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  – EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  – EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  – EPWMxB In is the source for both falling-edge and rising-edge delay.

- **Half Cycle Clocking:**

  The dead-band submodule can be clocked using half cycle clocking to double the resolution (i.e. counter clocked at 2× TBCLK)

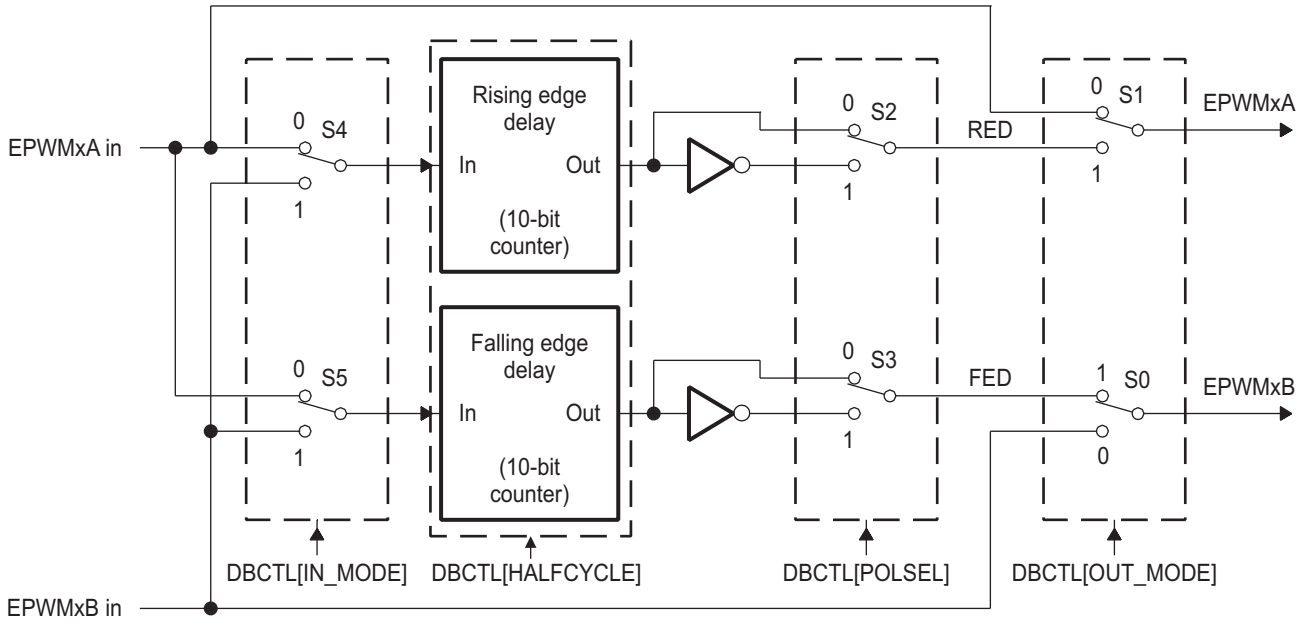
- **Output Mode Control:**

  The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.

- **Polarity Control:**

  The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 20-27. Configuration Options for the Dead-Band Submodule



Although all combinations are supported, not all are typical usage modes. Table 20-14 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 20-14 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**

  Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:**

  These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 20-28. Note that to generate equivalent waveforms to Figure 20-28, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**

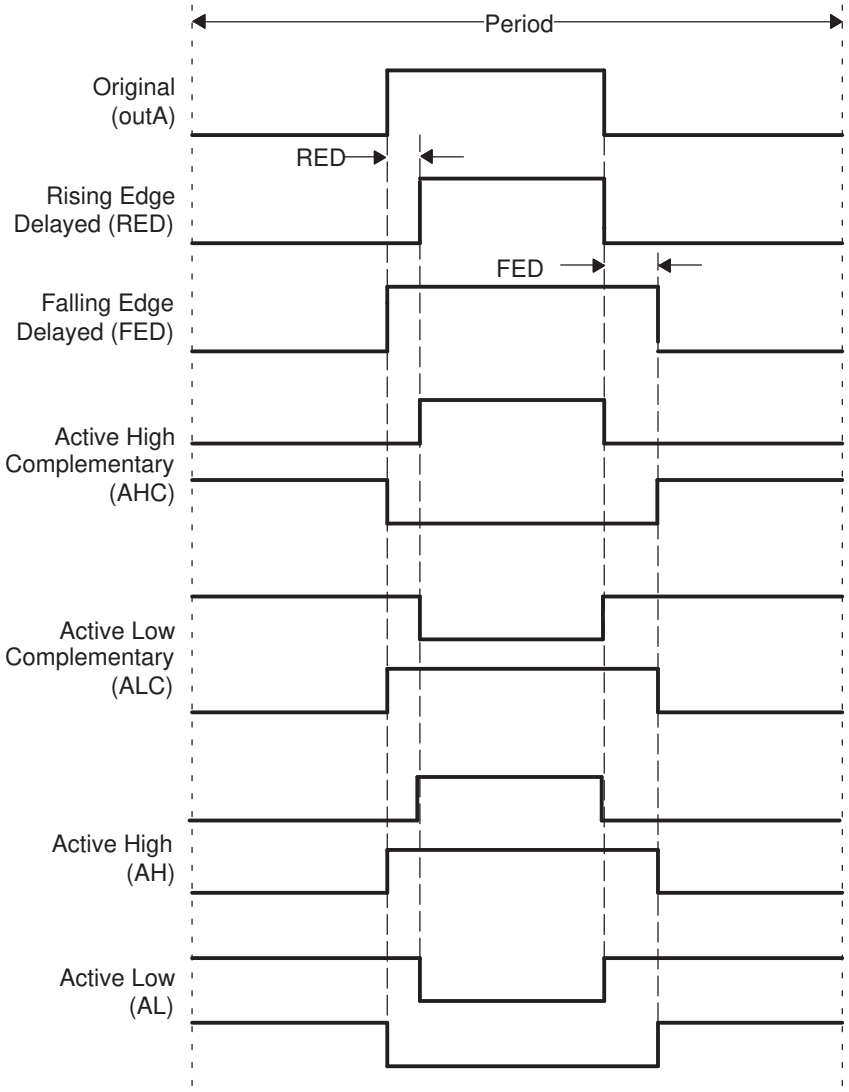
  Finally the last two entries in Table 20-14 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 20-14. Classical Dead-Band Operating Modes

		DBCTL[POLSEL]		DBCTL[OUT_MODE]	
Mode	**Mode Description**	**S3**	**S2**	**S1**	**S0**
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

Figure 20-28 shows waveforms for typical cases where 0% < duty < 100%.

Figure 20-28. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)



The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VCLK3.

For convenience, delay values for various TBCLK options are shown in Table 20-15.

Table 20-15. Dead-Band Delay Values in µS as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay in µS		
DBFED, DBRED	TBCLK = VCLK3/1	TBCLK = VCLK3 /2	TBCLK = VCLK3/4
1	0.02 µS	0.03 µS	0.07 µS
5	0.08 µS	0.17 µS	0.33 µS
10	0.17 µS	0.33 µS	0.67 µS
100	1.67 µS	3.33 µS	6.67 µS
200	3.33 µS	6.67 µS	13.33 µS
400	6.67 µS	13.33 µS	26.67 µS
500	8.33 µS	16.67 µS	33.33 µS
600	10.00 µS	20.00 µS	40.00 µS
700	11.67 µS	23.33 µS	46.67 µS
800	13.33 µS	26.67 µS	53.33 µS
900	15.00 µS	30.00 µS	60.00 µS
1000	16.67 µS	33.33 µS	66.67 µS

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$FED = DBFED \times T_{TBCLK}/2$

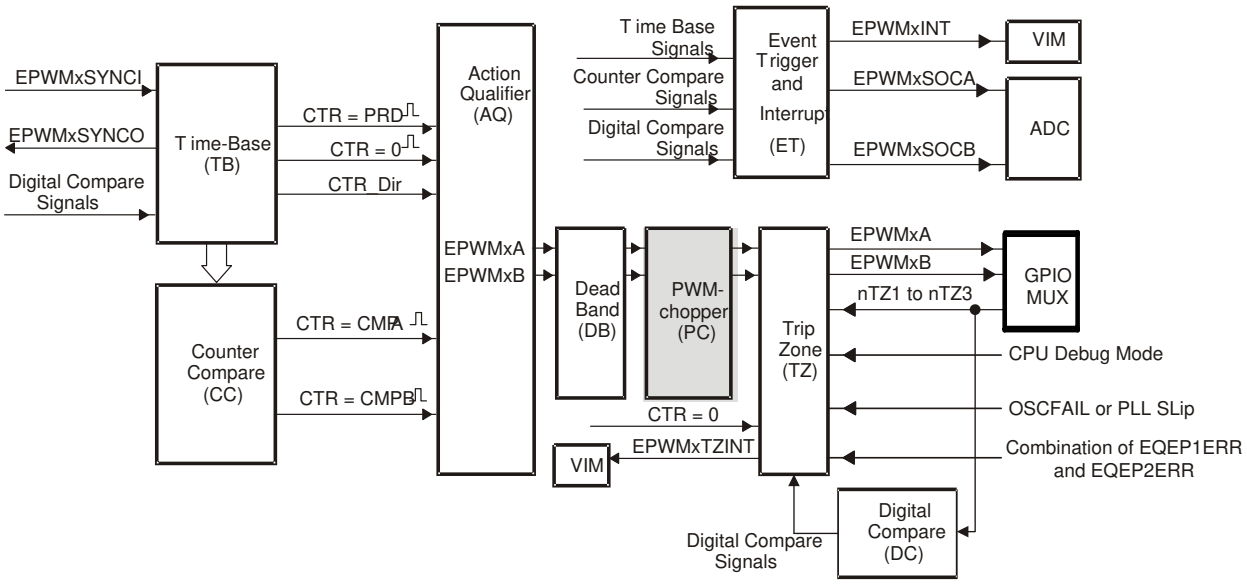
$RED = DBRED \times T_{TBCLK}/2$

20.2.6 PWM-Chopper (PC) Submodule

Figure 20-29 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 20-29. PWM-Chopper Submodule



20.2.6.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

20.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 20-16.

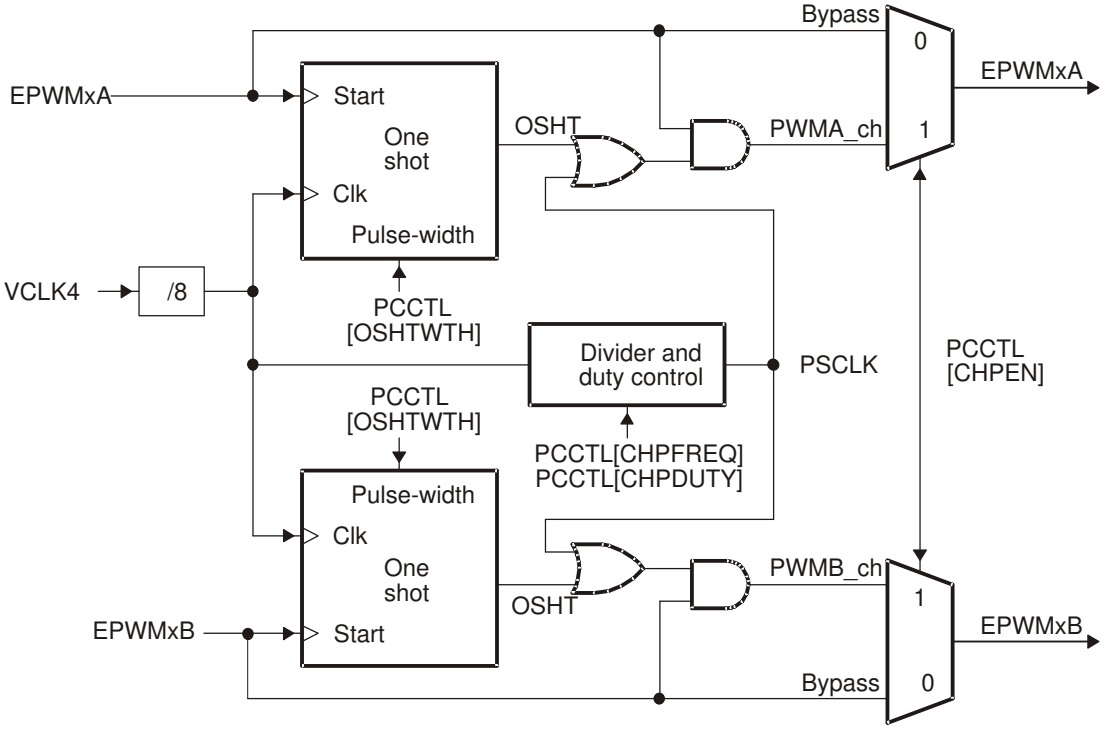
Table 20-16. PWM-Chopper Submodule Registers

Register Name	Address Offset	Shadowed	Description
PCCTL		No	PWM-chopper Control Register

20.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 20-30 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK3. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

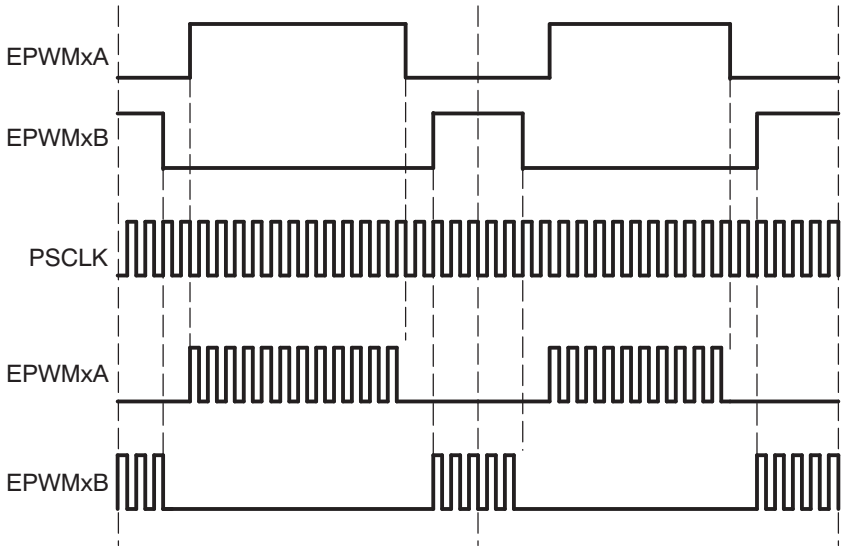
Figure 20-30. PWM-Chopper Submodule Operational Details



20.2.6.4 Waveforms

Figure 20-31 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 20-31. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only



20.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$T_{1stpulse} = T_{VCLK3} \times 8 \times OSHTWTH$

Where T_{VCLK3} is the period of the system clock (VCLK3) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 20-32 shows the first and subsequent sustaining pulses and Table 20-17 gives the possible pulse width values for a VCLK3 = 100 MHz.

Figure 20-32. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

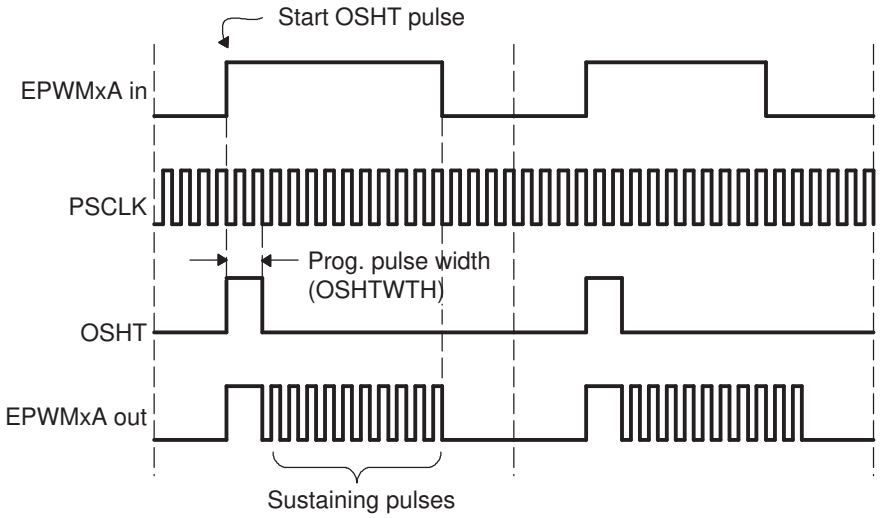


Table 20-17. Possible Pulse Width Values for VCLK3 = 100 MHz

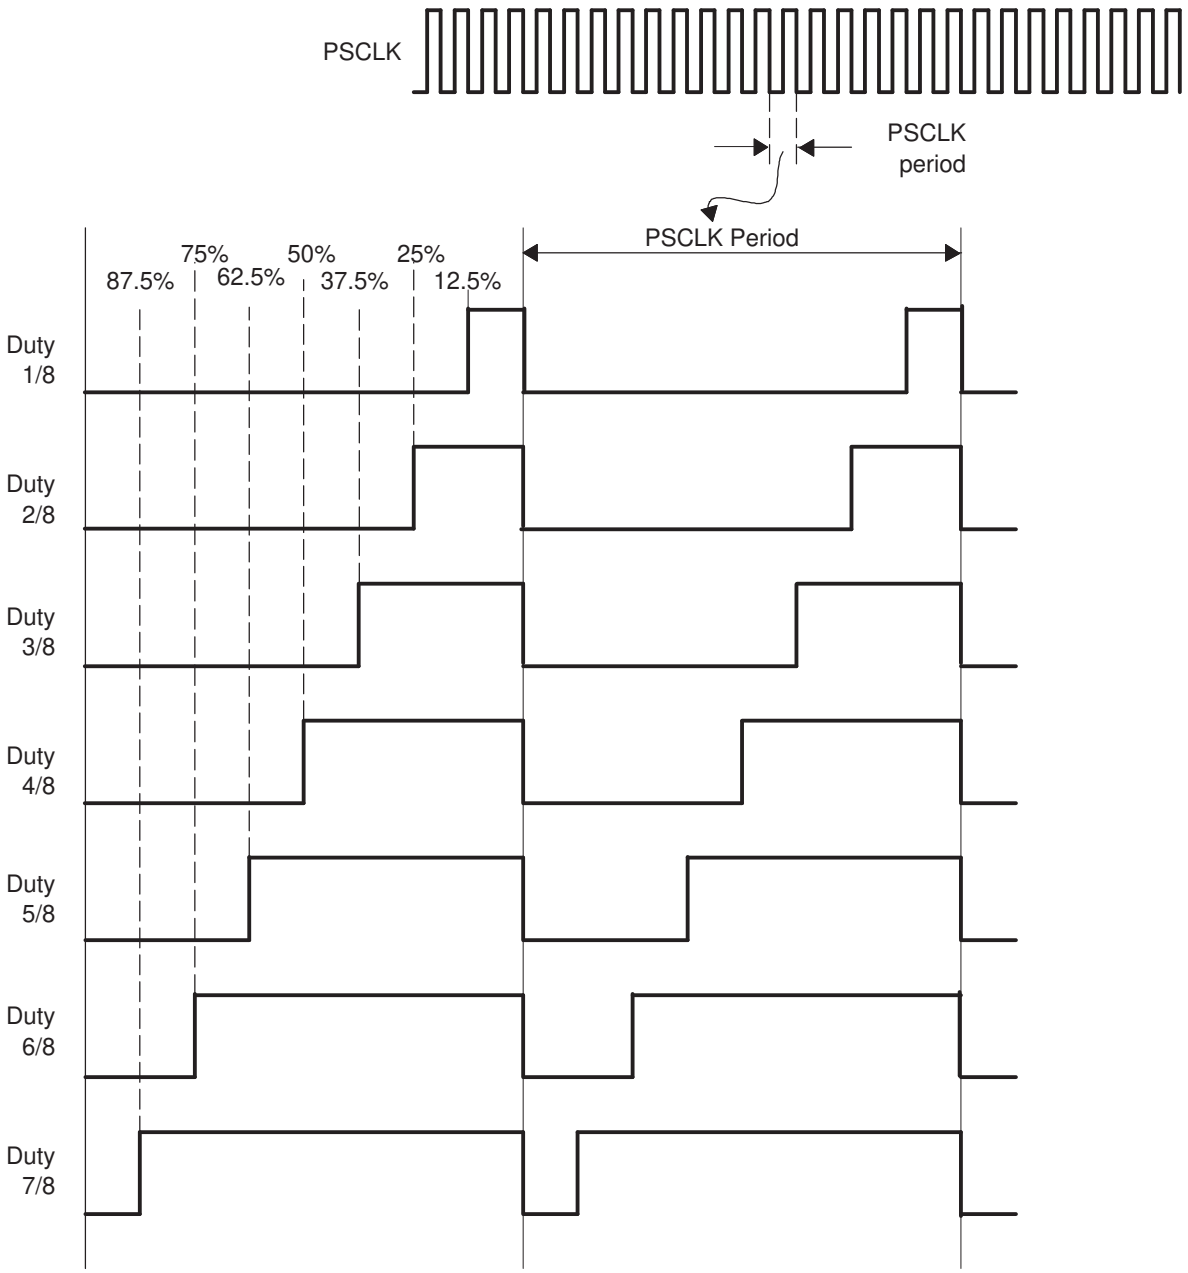
OSHTWTHz (hex)	Pulse Width (nS)
0	100
1	200
2	300
3	400
4	500
5	600
6	700
7	800
8	900
9	1000
A	1100
B	1200
C	1300
D	1400
E	1500
F	1600

20.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 20-33 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

Figure 20-33. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

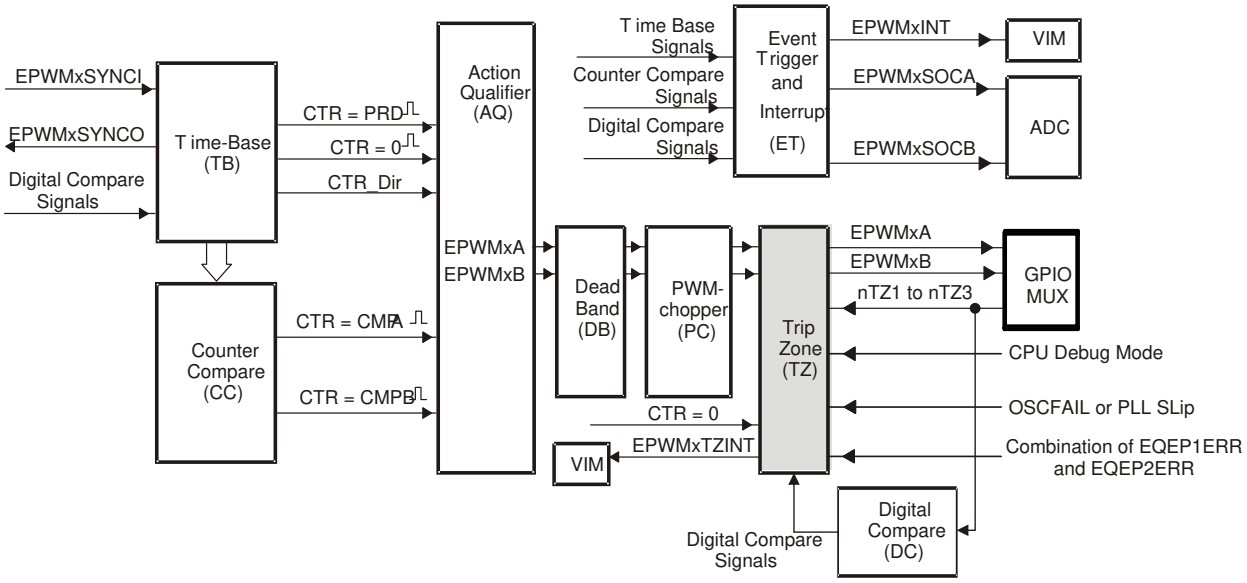


20.2.7 Trip-Zone (TZ) Submodule

Figure 20-34 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six TZn signals (TZ1 to TZ6). TZ1 to TZ3 are sourced from the GPIO mux. TZ4 is sourced from a combination of EQEP1ERR and EQEP2ERR signals. TZ5 is connected to the system oscillator or PLL clock fail logic, and TZ6 is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 20-34. Trip-Zone Submodule



20.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs TZ1 to TZ6 are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or TZ1 to TZ3 signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

20.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 20-18. Trip-Zone Submodule Registers

Register Name	Address Offset	Shadowed	Description [1]
TZDCSEL		No	Trip-zone Digital Compare Select Register [2]
TZSEL		No	Trip-Zone Select Register
TZEINT		No	Trip-Zone Enable Interrupt Register
TZCTL		No	Trip-Zone Control Register
TZCLR		No	Trip-Zone Clear Register
TZFLG		No	Trip-Zone Flag Register
TZFRC		No	Trip-Zone Force Register

(1) All trip-zone registers are writable only in privileged mode.
(2) This register is discussed in more detail in Section 20.2.9.

20.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK3) and digitally filtered within the GPIO MUX block. A minimum of 3 × TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAVET2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 20-19 lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 20-19 lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

  If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

  A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRIPSEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see Section 20.2.9.

  When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. Table 20-19 lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

  The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in Table 20-19, can be taken on a trip event.

Table 20-19. Possible Actions On a Trip Event

TZCTL Register bit-field Settings	EPWMxA and/or EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

Example 20-7. Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

20.2.7.4 Generating Trip Event Interrupts

Figure 20-35 and Figure 20-36 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 20.2.9.

Figure 20-35. Trip-Zone Submodule Mode Control Logic

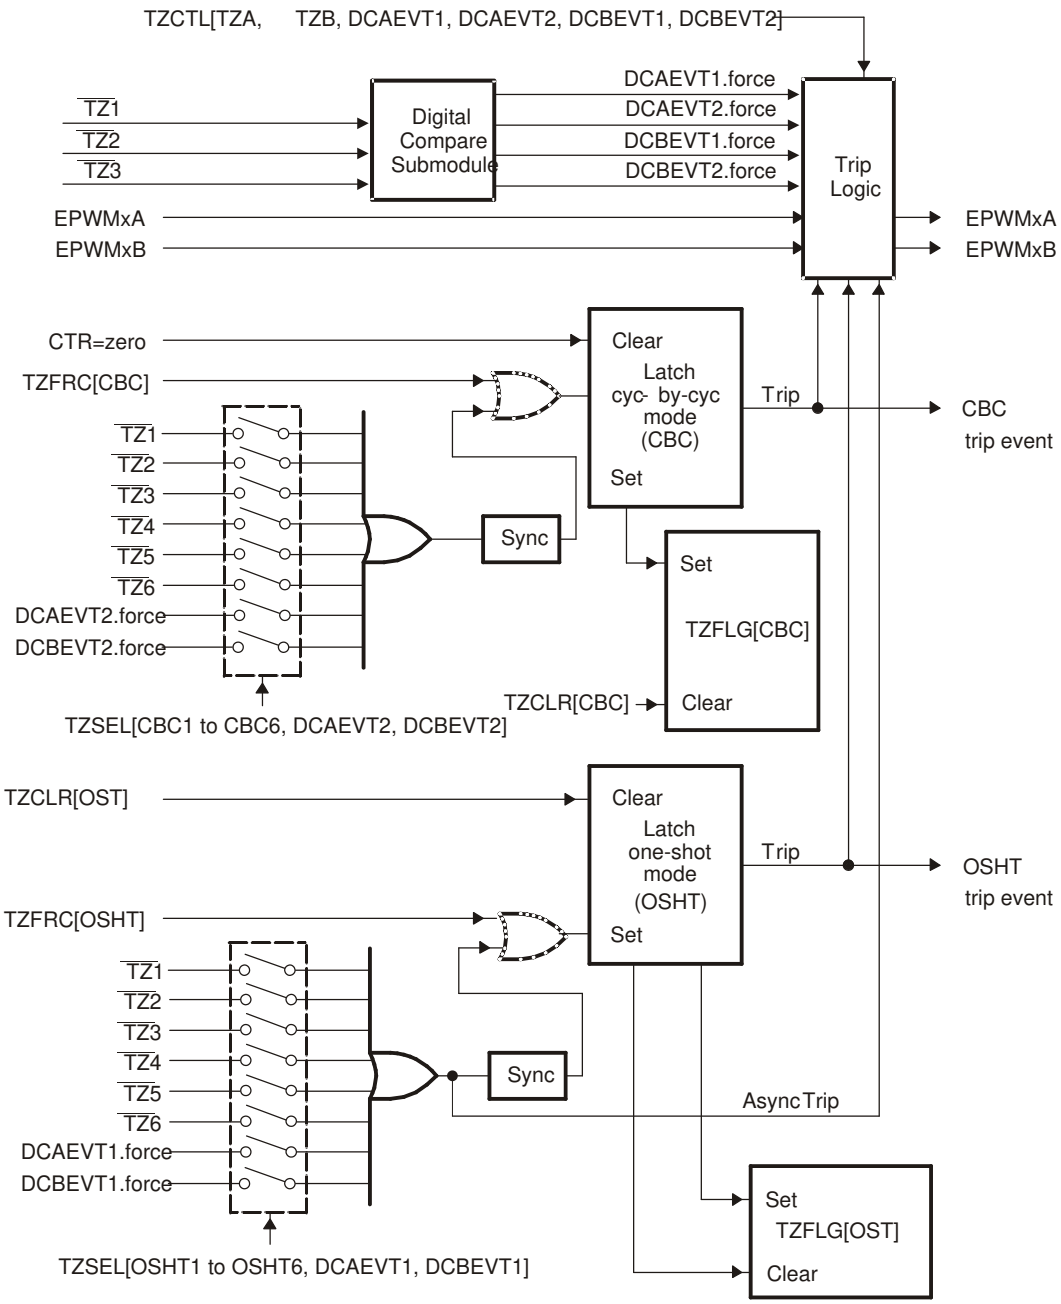


Figure 20-36. Trip-Zone Submodule Interrupt Logic

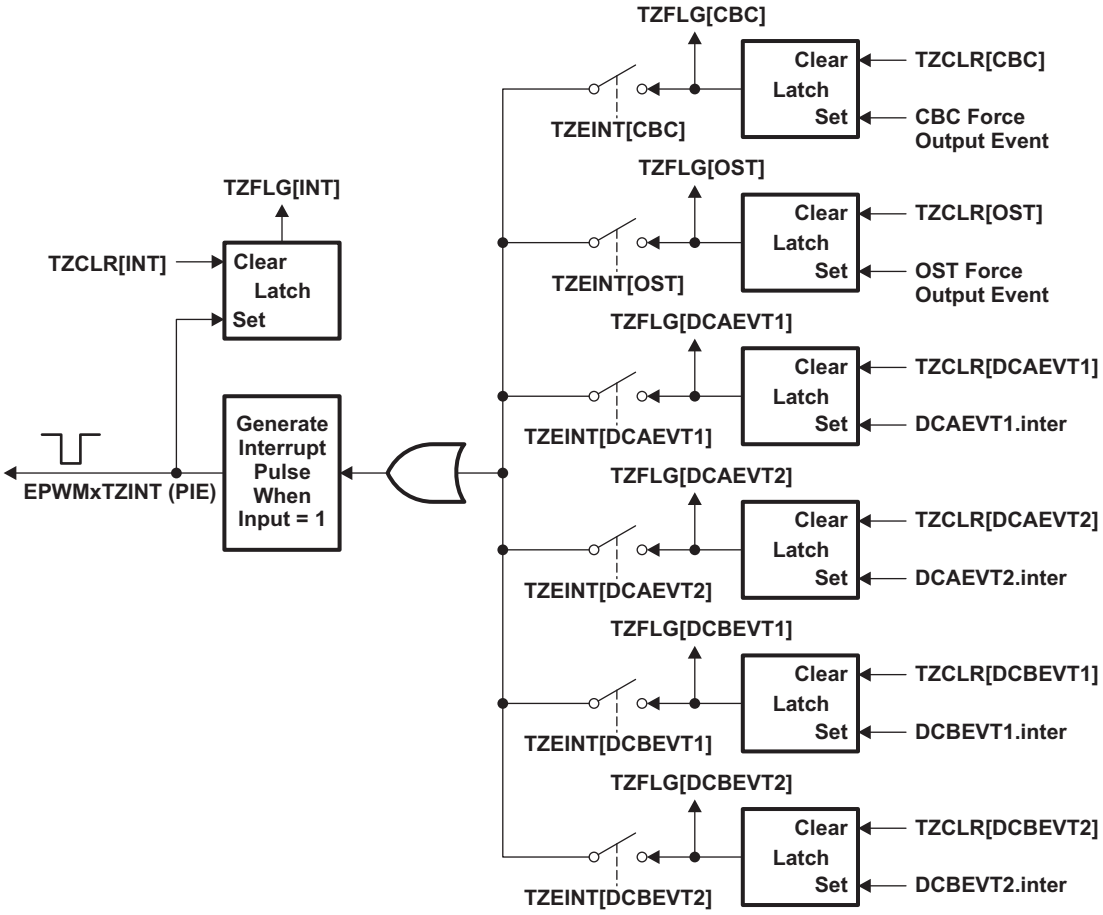


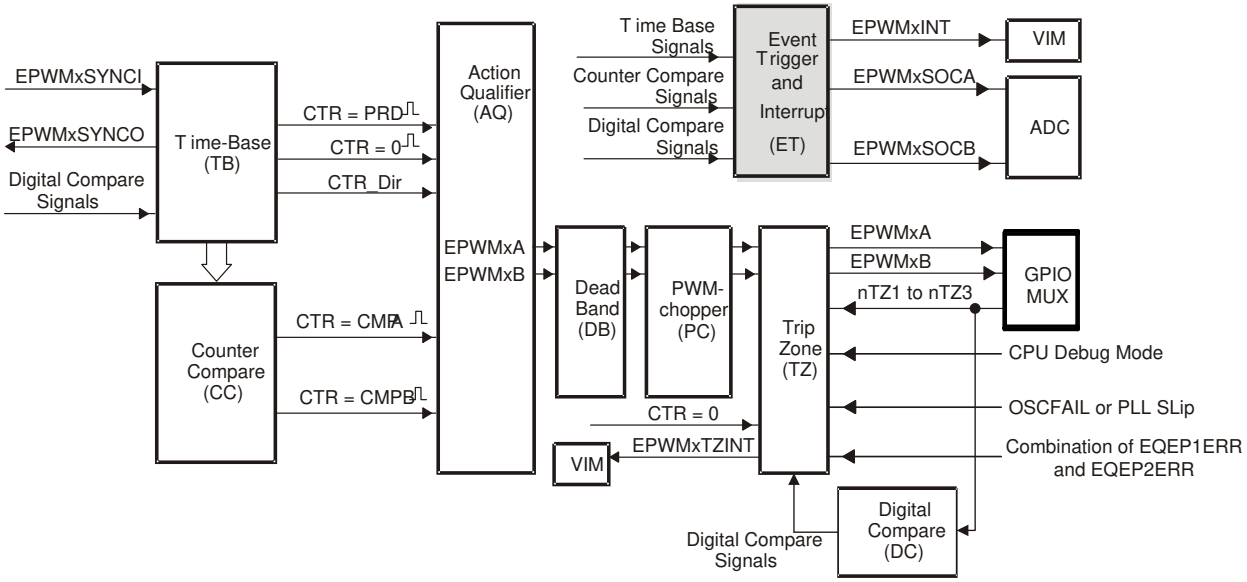
20.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. Figure 20-37 illustrates where the event-trigger submodule fits within the ePWM system.

Figure 20-37. Event-Trigger Submodule

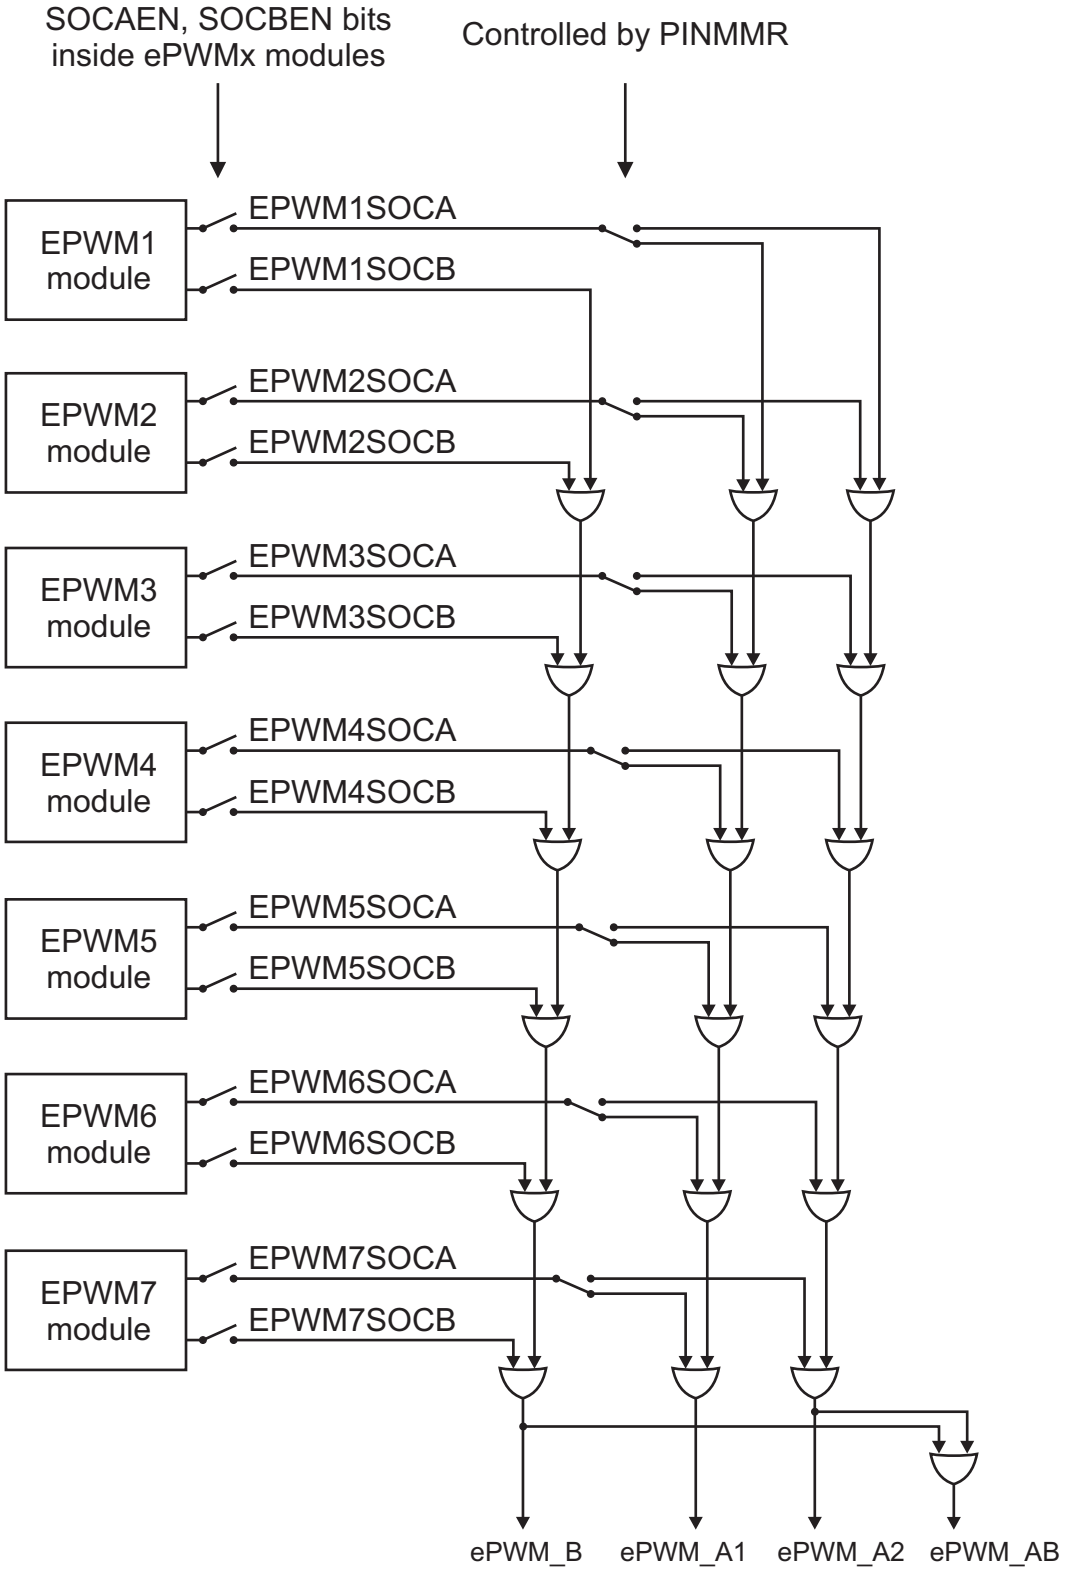


20.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in Figure 20-38, the ePWMxSOCA and ePWMxSOCB signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

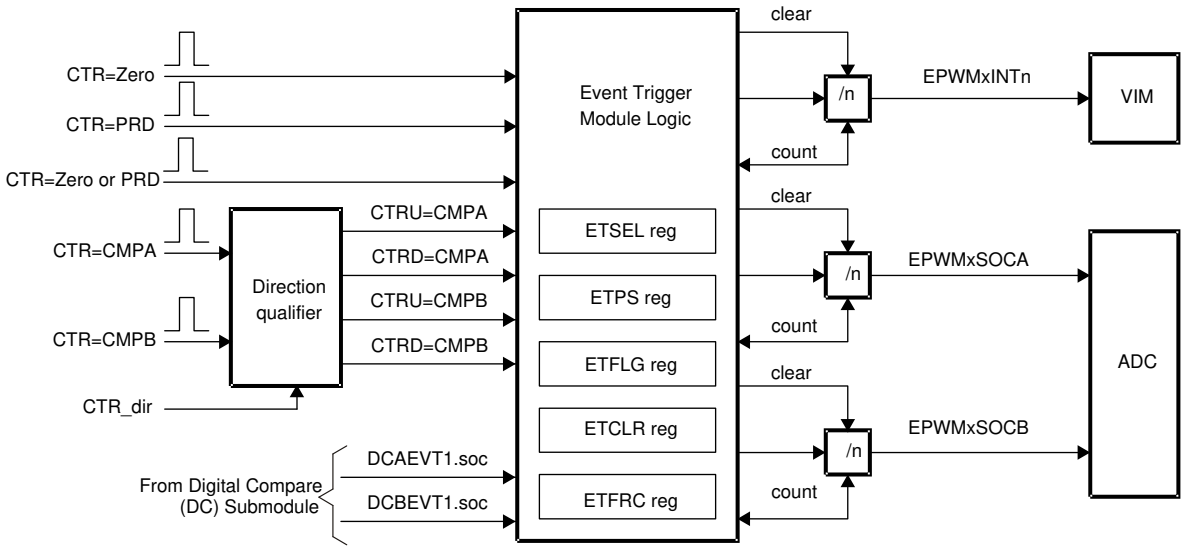
Figure 20-38. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion



The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 20-39) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

Figure 20-39. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs



The key registers used to configure the event-trigger submodule are listed in Table 20-20.

Table 20-20. Event-Trigger Submodule Registers

Register Name	Address Offset	Shadowed	Description
ETSEL		No	Event-trigger Selection Register
ETFLG		No	Event-trigger Flag Register
ETPS		No	Event-trigger Prescale Register
ETFRC		No	Event-trigger Force Register
ETCLR		No	Event-trigger Clear Register

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 20-40, Figure 20-41, and Figure 20-42.

Figure 20-40 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

Figure 20-40. Event-Trigger Interrupt Generator

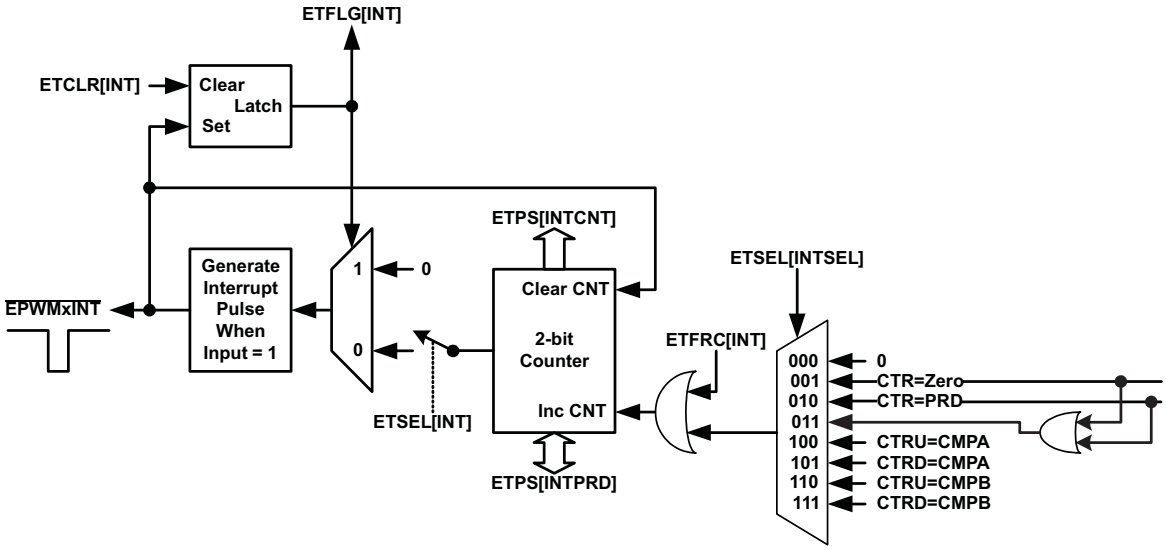


Figure 20-41 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.

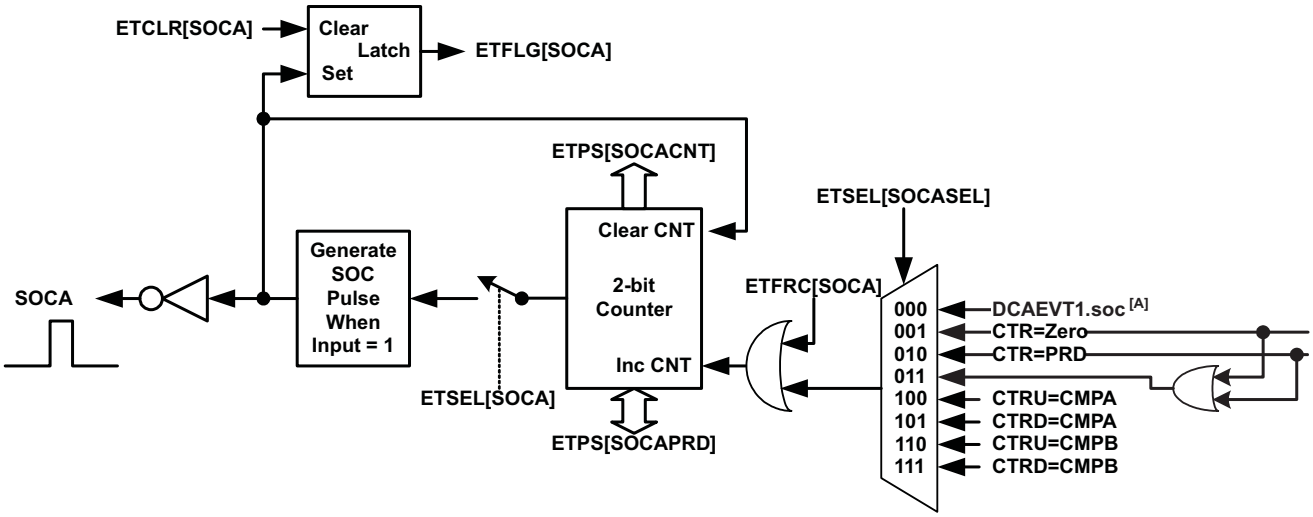
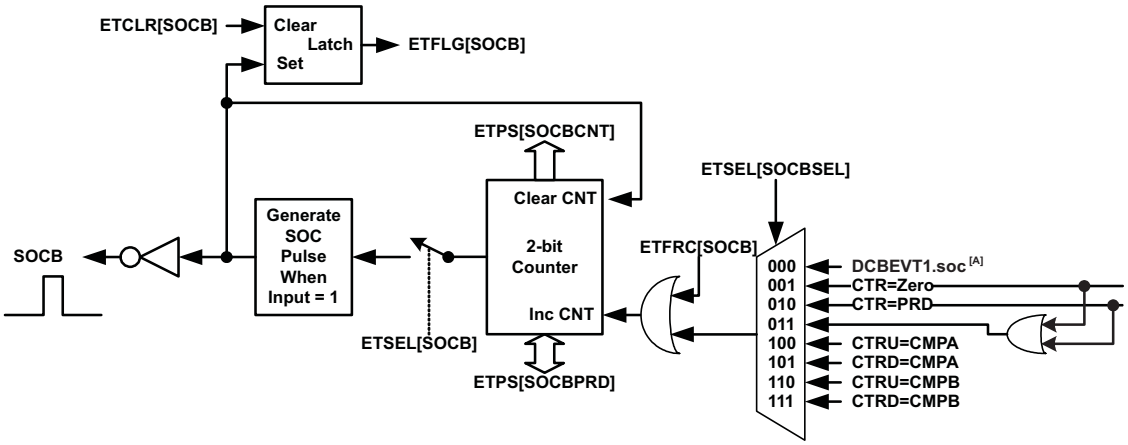
Figure 20-41. Event-Trigger SOCA Pulse Generator



A The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule, described in Section 20.2.9

Figure 20-42 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

Figure 20-42. Event-Trigger SOCB Pulse Generator



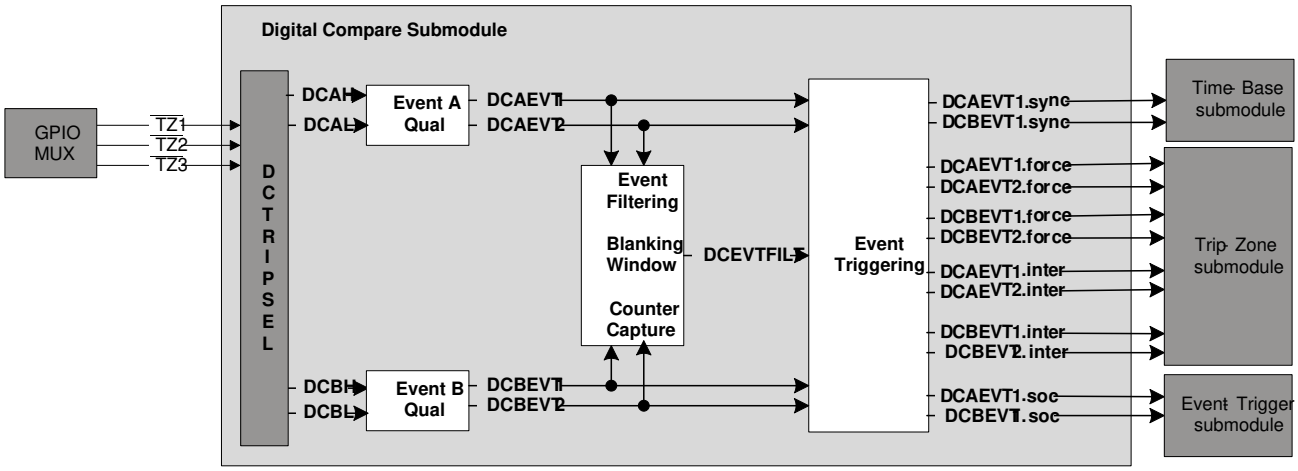
A The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule, described in Section 20.2.9

20.2.9 Digital Compare (DC) Submodule

Figure 20-43 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

Figure 20-43. Digital-Compare Submodule High-Level Block Diagram



20.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- $\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

20.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

Table 20-21. Digital Compare Submodule Registers

Register Name	Address Offset	Shadowed	Description
TZDCSEL[1] [2]		No	Trip Zone Digital Compare Select Register
DCACTL[1]		No	Digital Compare A Control Register
DCTRIPSEL[1]		No	Digital Compare Trip Select Register
DCFCTL[1]		No	Digital Compare Filter Control Register
DCBCTL[1]		No	Digital Compare B Control Register
DCFOFFSET		Writes	Digital Compare Filter Offset Register
DCCAPCTL[1]		No	Digital Compare Capture Control Register
DCFWINDOW		No	Digital Compare Filter Window Register
DCFOFFSETCNT		No	Digital Compare Filter Offset Counter Register
DCCAP		Yes	Digital Compare Counter Capture Register
DCFWINDOWCNT		No	Digital Compare Filter Window Counter Register

(1) These registers are writable only in privileged mode.

(2) The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

20.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

20.2.9.3.1 Digital Compare Events

As illustrated in Figure 20-43 earlier in this section, trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

NOTE: The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3*TBCLK sync pulse width is required. If pulse width is < 3*TBCLK sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in section 2.9.3.2. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

  DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

  Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

  Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)

- **interrupt signal:**

  DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

  The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

  The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

Figure 20-44 and Figure 20-45 show how the DCAEVT1, DCAEVT2, or DCEVTFILT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

Figure 20-44. DCAEVT1 Event Triggering

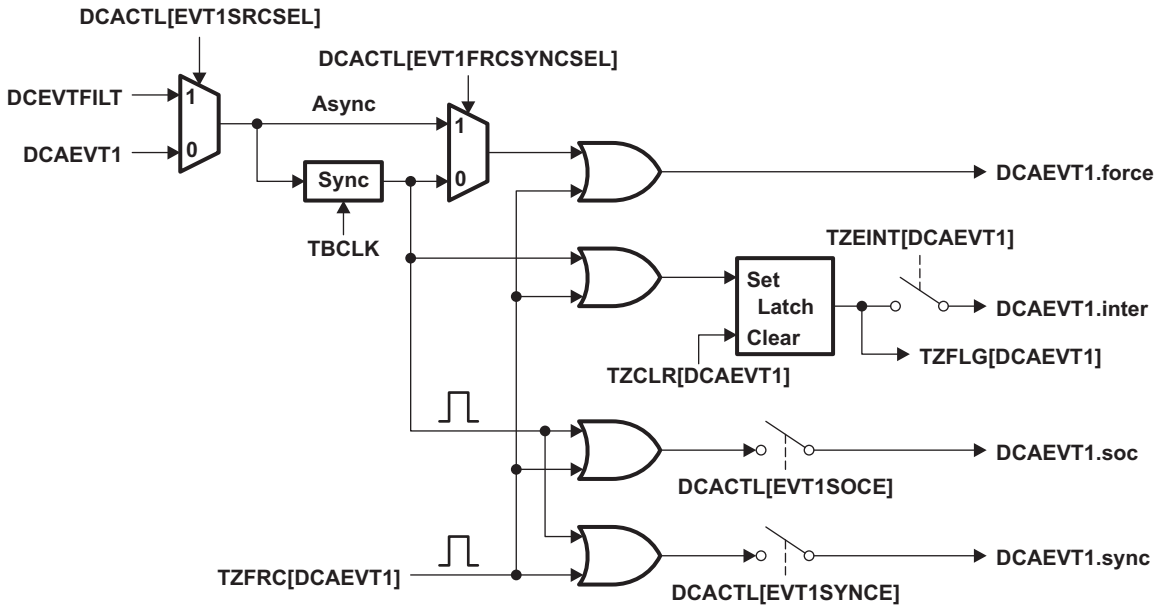


Figure 20-45. DCAEVT2 Event Triggering

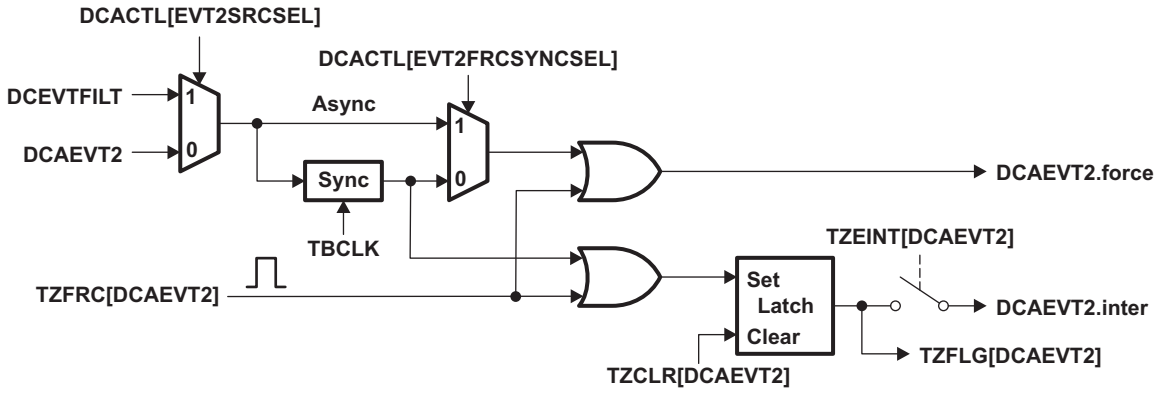

Figure 20-46 and Figure 20-47 show how the DCBEVT1, DCBEVT2, or DCEVTFILT signals are processed to generate the digital compare B event force, interrupt, soc and sync signals.

Figure 20-46. DCBEVT1 Event Triggering

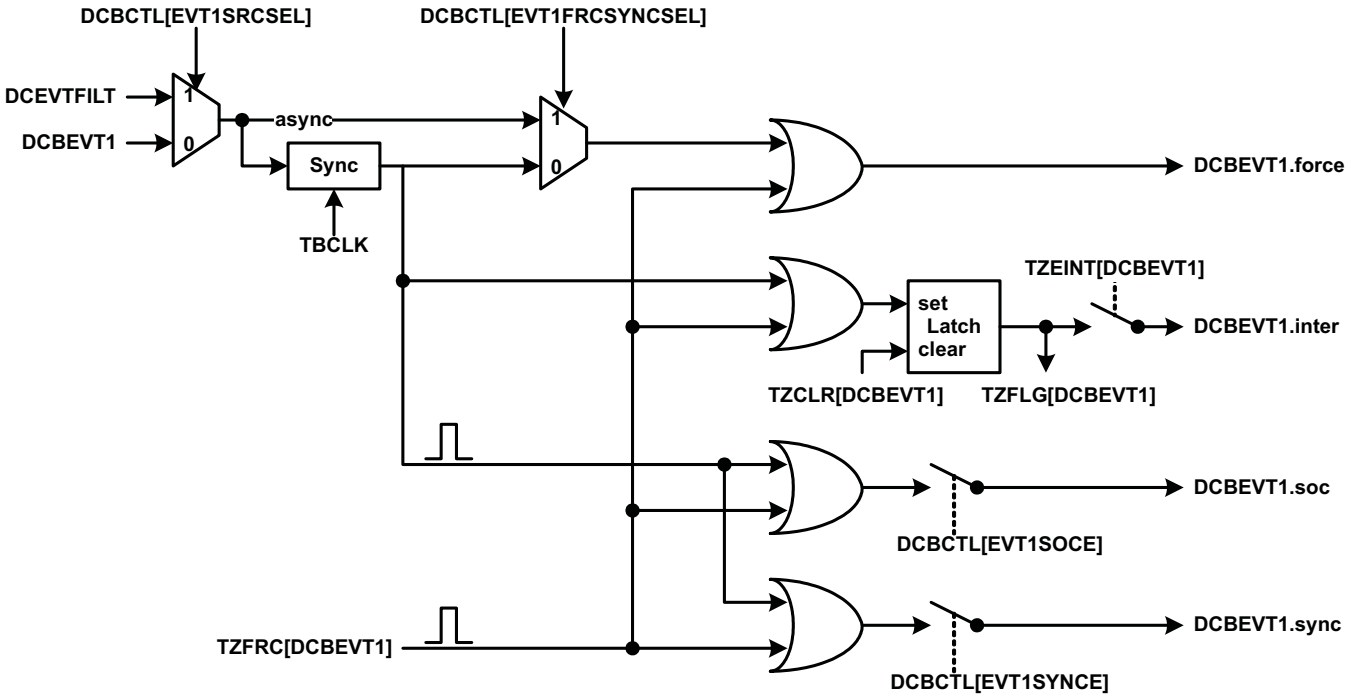

Figure 20-47. DCBEVT2 Event Triggering

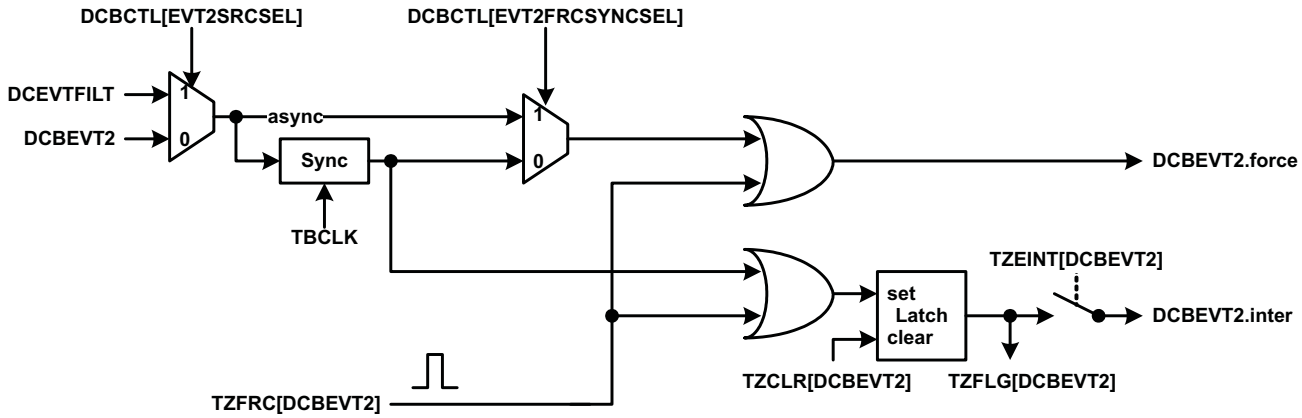
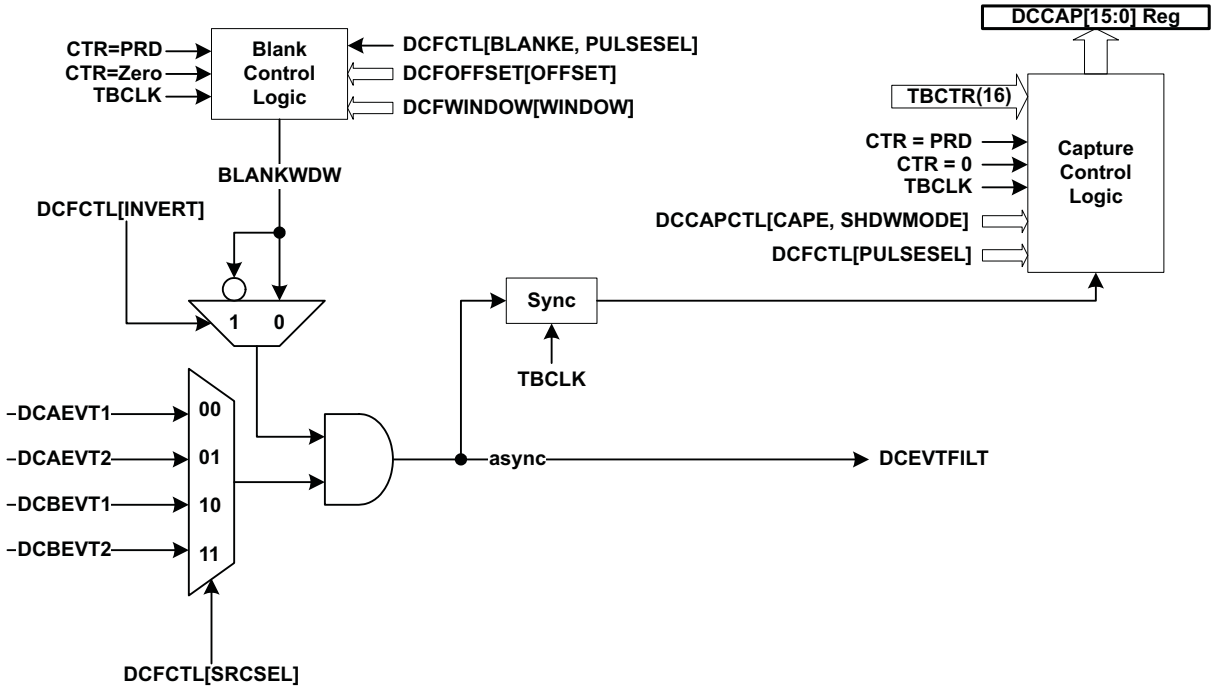


20.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 20-48 shows the details of the event filtering logic.

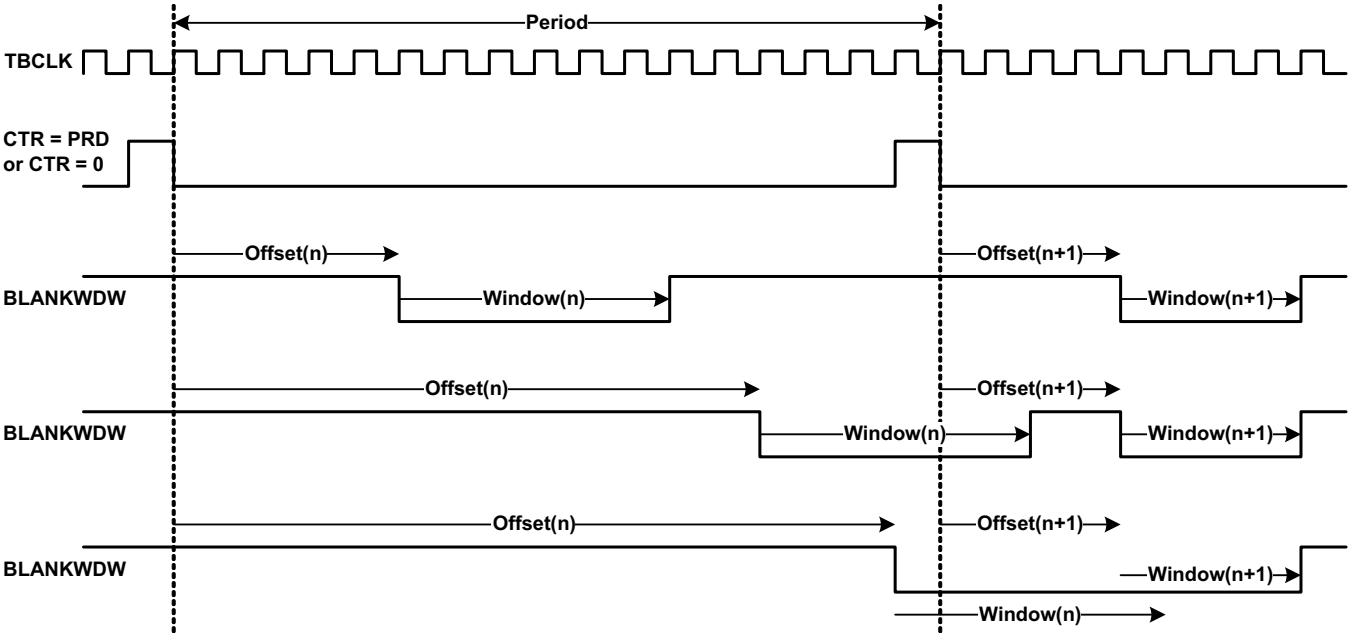
Figure 20-48. Event Filtering



If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

Figure 20-49 shows several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

Figure 20-49. Blanking Window Timing Diagram



20.2.10 Proper Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC = 0
4. Initialize peripheral registers
5. Set TBCLKSYNC = 1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

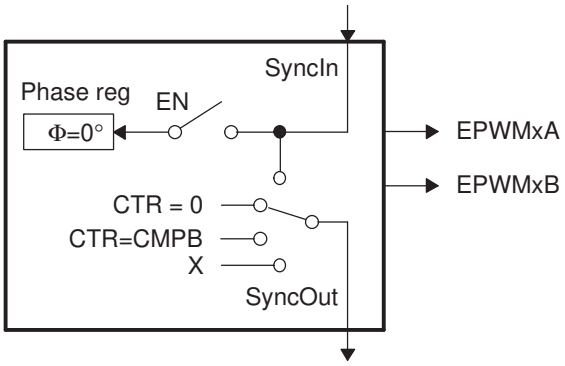
20.3 Application Examples

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

20.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 20-50. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 20-50. Simplified ePWM Module



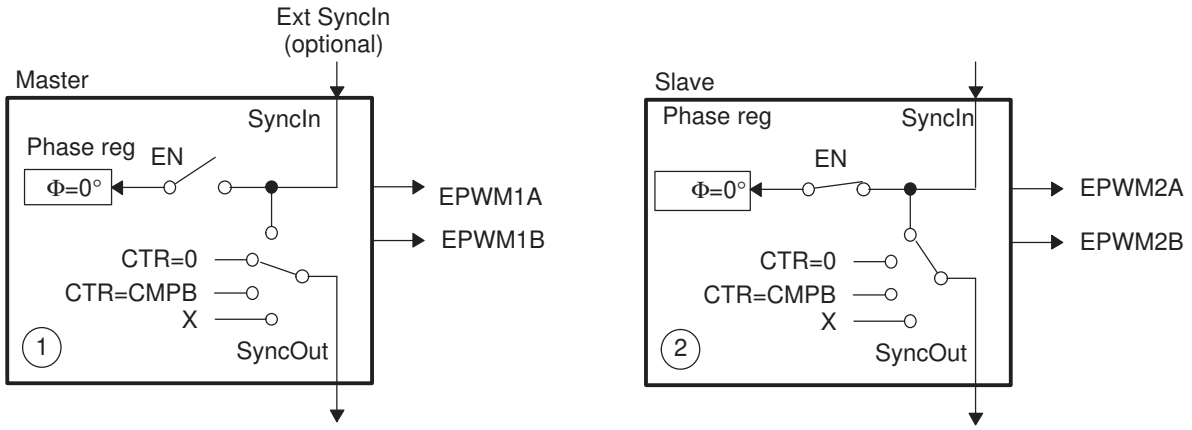
20.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, i.e., via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in Figure 20-51.

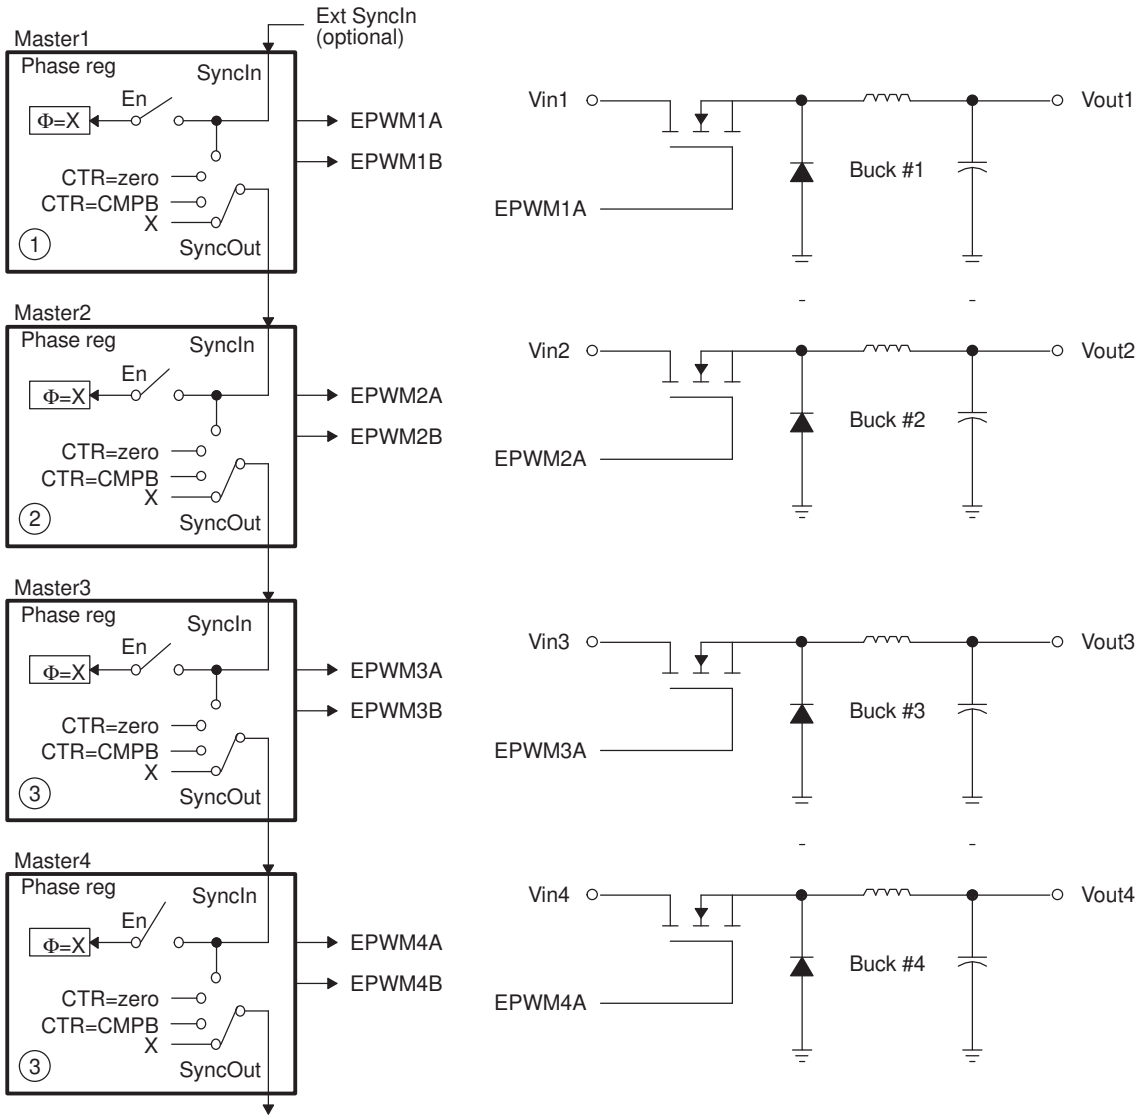
Figure 20-51. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave



20.3.3 Controlling Multiple Buck Converters With Independent Frequencies

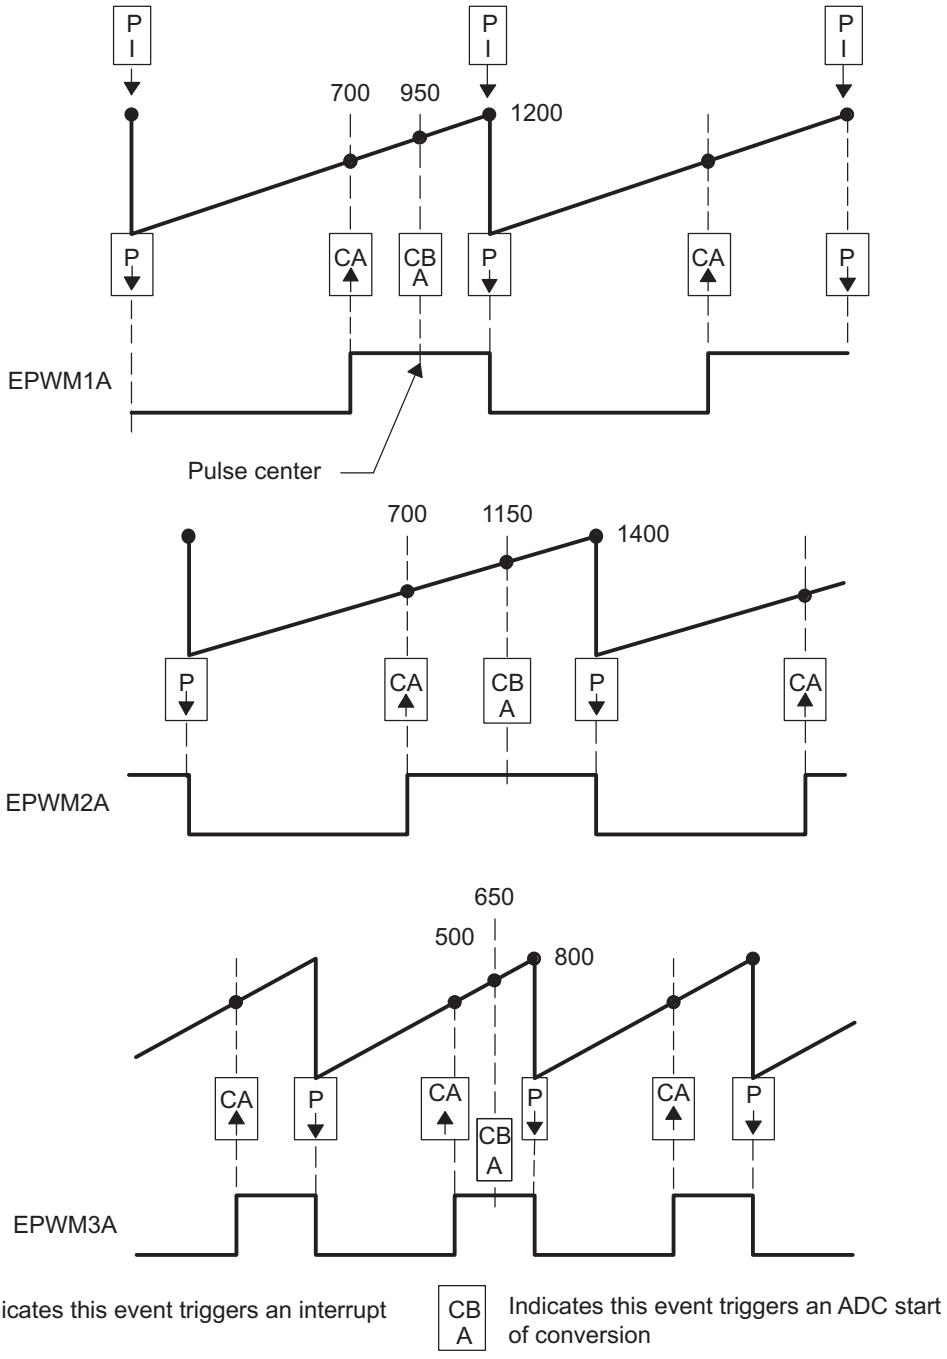
One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 20-52 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 20-53 shows the waveforms generated by the setup shown in Figure 20-52; note that only three waveforms are shown, although there are four stages.

Figure 20-52. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$



NOTE: Θ = X indicates value in phase register is a "don't care"

Figure 20-53. Buck Waveforms for Figure 20-52 (Note: Only three bucks shown here)



Example 20-8. Configuration for Example in Figure 20-53

```
//=====================================================================
// (Note: code for only 3 modules shown)

   EPwm3Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
   EPwm3Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;    // load on CTR=Zero
   EPwm3Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;    // load on CTR=Zero
   EPwm3Regs.AQCTLA.bit.PRD = AQ_CLEAR;
   EPwm3Regs.AQCTLA.bit.CAU = AQ_SET;
//
// Run Time (Note: Example execution of one run-time instant)
//=====================================================
   EPwm1Regs.CMPA.half.CMPA = 700;                  // adjust duty for output EPWM1A
   EPwm2Regs.CMPA.half.CMPA = 700;                  // adjust duty for output EPWM2A
   EPwm3Regs.CMPA.half.CMPA = 500;                  // adjust duty for output EPWM3A
```

20.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 20-54 shows such a configuration; Figure 20-55 shows the waveforms generated by the configuration.

Figure 20-54. Control of Four Buck Stages. (Note: F_{PWM2} = N x F_{PWM1})

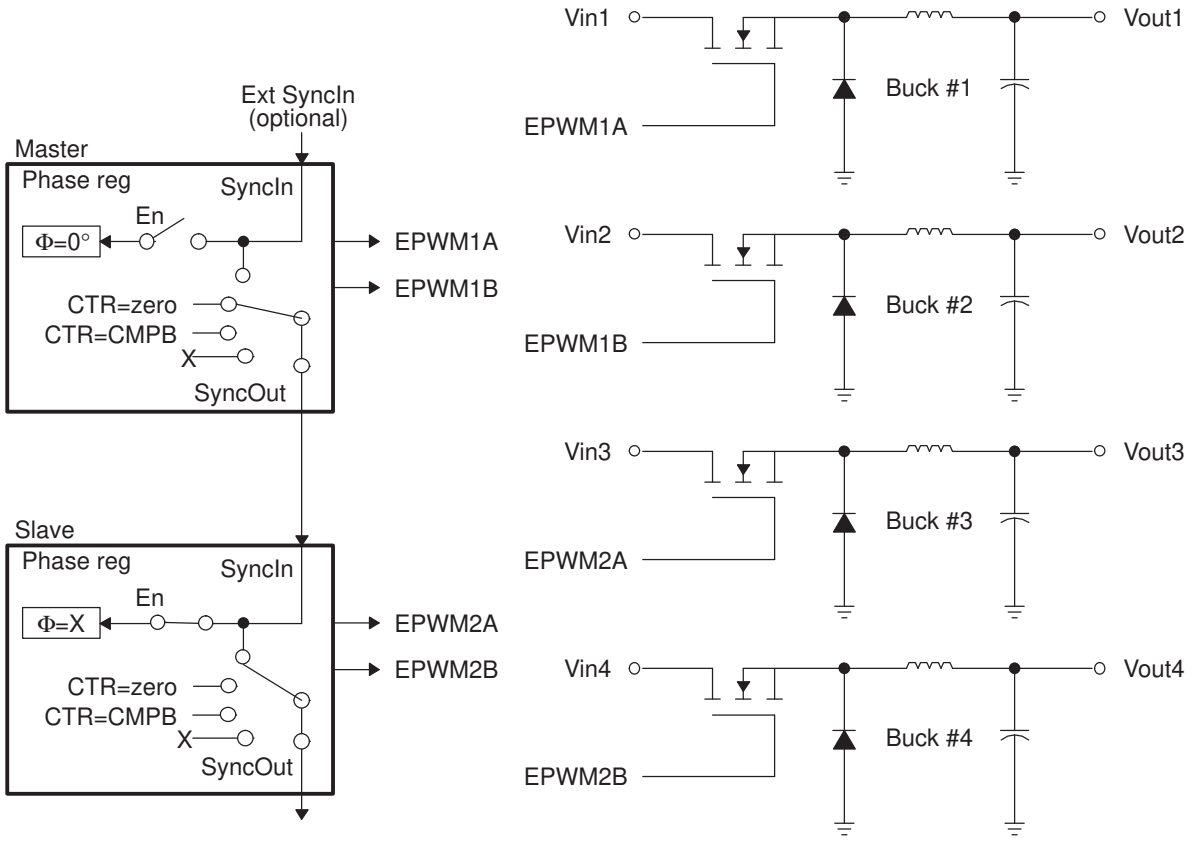

Figure 20-55. Buck Waveforms for Figure 20-54 (Note: $F_{PWM2} = F_{PWM1)}$)

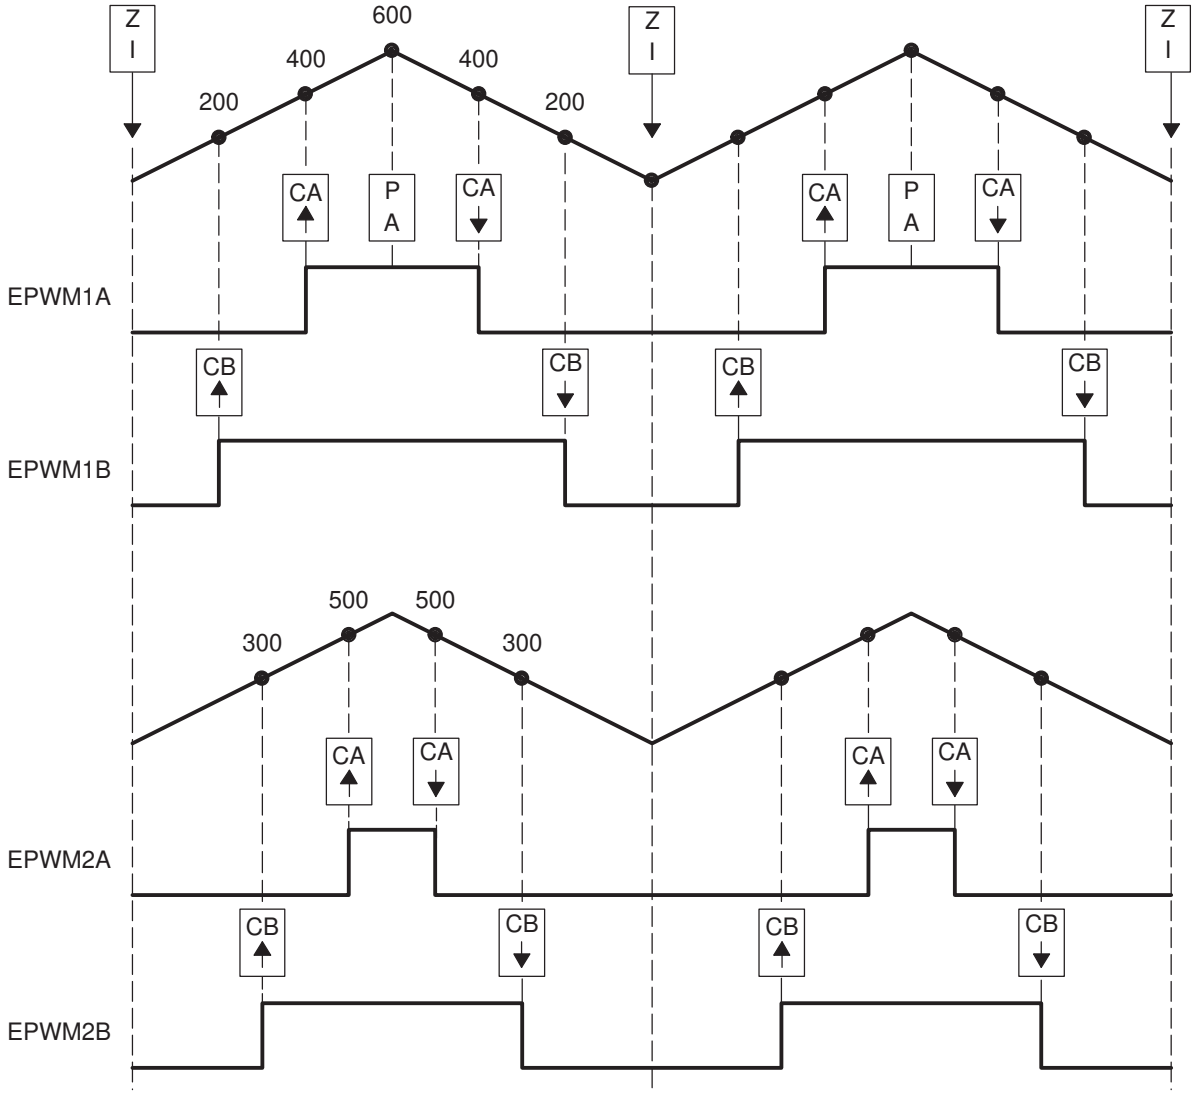

Example 20-9. Code Snippet for Configuration in Figure 20-54

```
//=======================
// EPWM Module 1 config
     EPwm1Regs.TBPRD = 600;                        // Period = 1200 TBCLK counts
     EPwm1Regs.TBPHS.half.TBPHS = 0;               // Set Phase register to zero
     EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
     EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;       // Master module
     EPwm1Regs.TBCTL.bit.PRDLD = TB_SHADOW;
     EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_CTR_ZERO;   // Sync down-stream module
     EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
     EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;            // set actions for EPWM1A
     EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
     EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;            // set actions for EPWM1B
     EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
// EPWM Module 2 config
     EPwm2Regs.TBPRD = 600;                        // Period = 1200 TBCLK counts
     EPwm2Regs.TBPHS.half.TBPHS = 0;               // Set Phase register to zero
     EPwm2Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
     EPwm2Regs.TBCTL.bit.PHSEN = TB_ENABLE;        // Slave module
     EPwm2Regs.TBCTL.bit.PRDLD = TB_SHADOW;
     EPwm2Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_IN;    // sync flow-through
     EPwm2Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.AQCTLA.bit.CAU = AQ_SET;            // set actions for EPWM2A
     EPwm2Regs.AQCTLA.bit.CAD = AQ_CLEAR;
     EPwm2Regs.AQCTLB.bit.CBU = AQ_SET;            // set actions for EPWM2B
     EPwm2Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time (Note: Example execution of one run-time instance)
//=====================================================
    EPwm1Regs.CMPA.half.CMPA = 400;               // adjust duty for output EPWM1A
    EPwm1Regs.CMPB = 200;                         // adjust duty for output EPWM1B
    EPwm2Regs.CMPA.half.CMPA = 500;               // adjust duty for output EPWM2A
    EPwm2Regs.CMPB = 300;                         // adjust duty for output EPWM2B
```

20.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 20-56 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 20-57 shows the waveforms generated by the configuration shown in Figure 20-56.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

Figure 20-56. Control of Two Half-H Bridge Stages (F_{PWM2} = N x F_{PWM1})

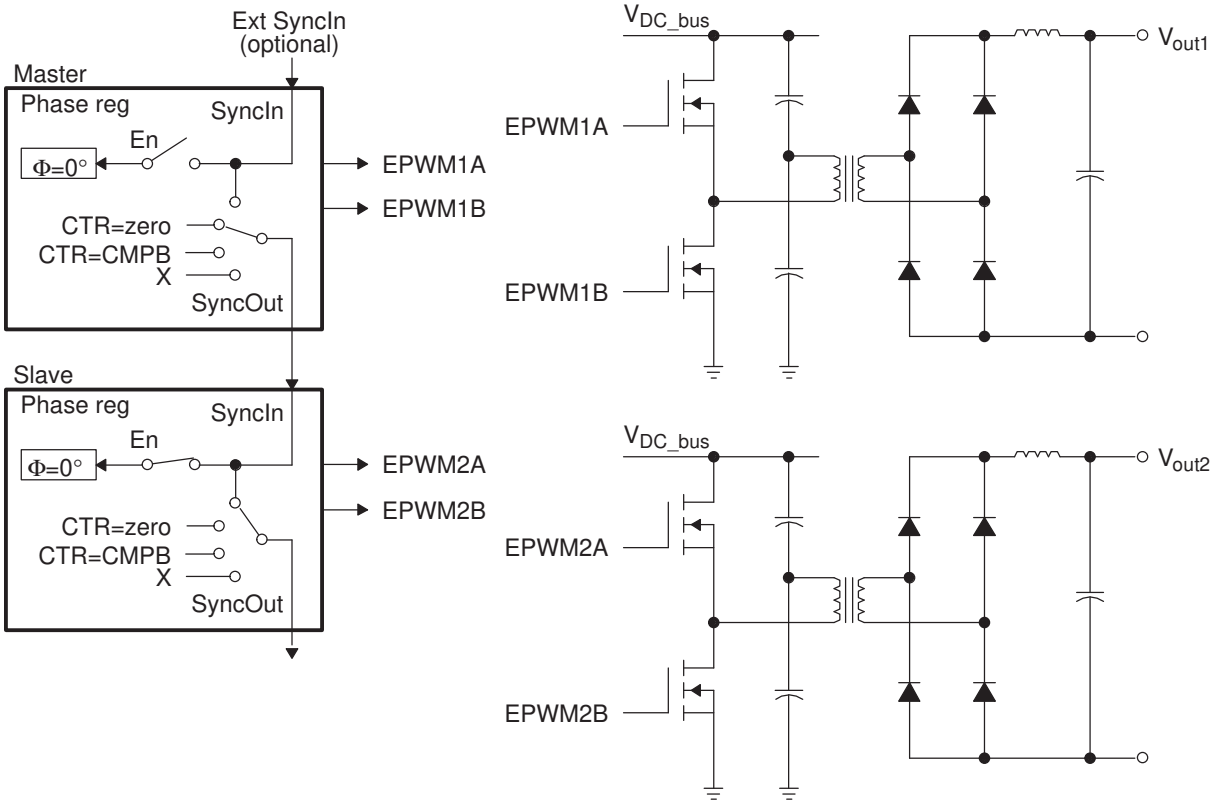

Figure 20-57. Half-H Bridge Waveforms for Figure 20-56 (Note: Here $F_{PWM2} = F_{PWM1}$)

     EPwm2Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
     EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // load on CTR=Zero
     EPwm2Regs.AQCTLA.bit.ZRO = AQ_SET;            // set actions for EPWM1A
     EPwm2Regs.AQCTLA.bit.CAU = AQ_CLEAR;
     EPwm2Regs.AQCTLB.bit.ZRO = AQ_CLEAR;          // set actions for EPWM1B
     EPwm2Regs.AQCTLB.bit.CAD = AQ_SET;
//=============================================================
     EPwm1Regs.CMPA.half.CMPA = 400;               // adjust duty for output EPWM1A & EPWM1B

     EPwm1Regs.CMPB = 200;                         // adjust point-in-time for ADCSOC trigger
     EPwm2Regs.CMPA.half.CMPA = 500;               // adjust duty for output EPWM2A & EPWM2B
     EPwm2Regs.CMPB = 250;                         // adjust point-in-time for ADCSOC trigger
```

20.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 20-58 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 20-58), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

Figure 20-58. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

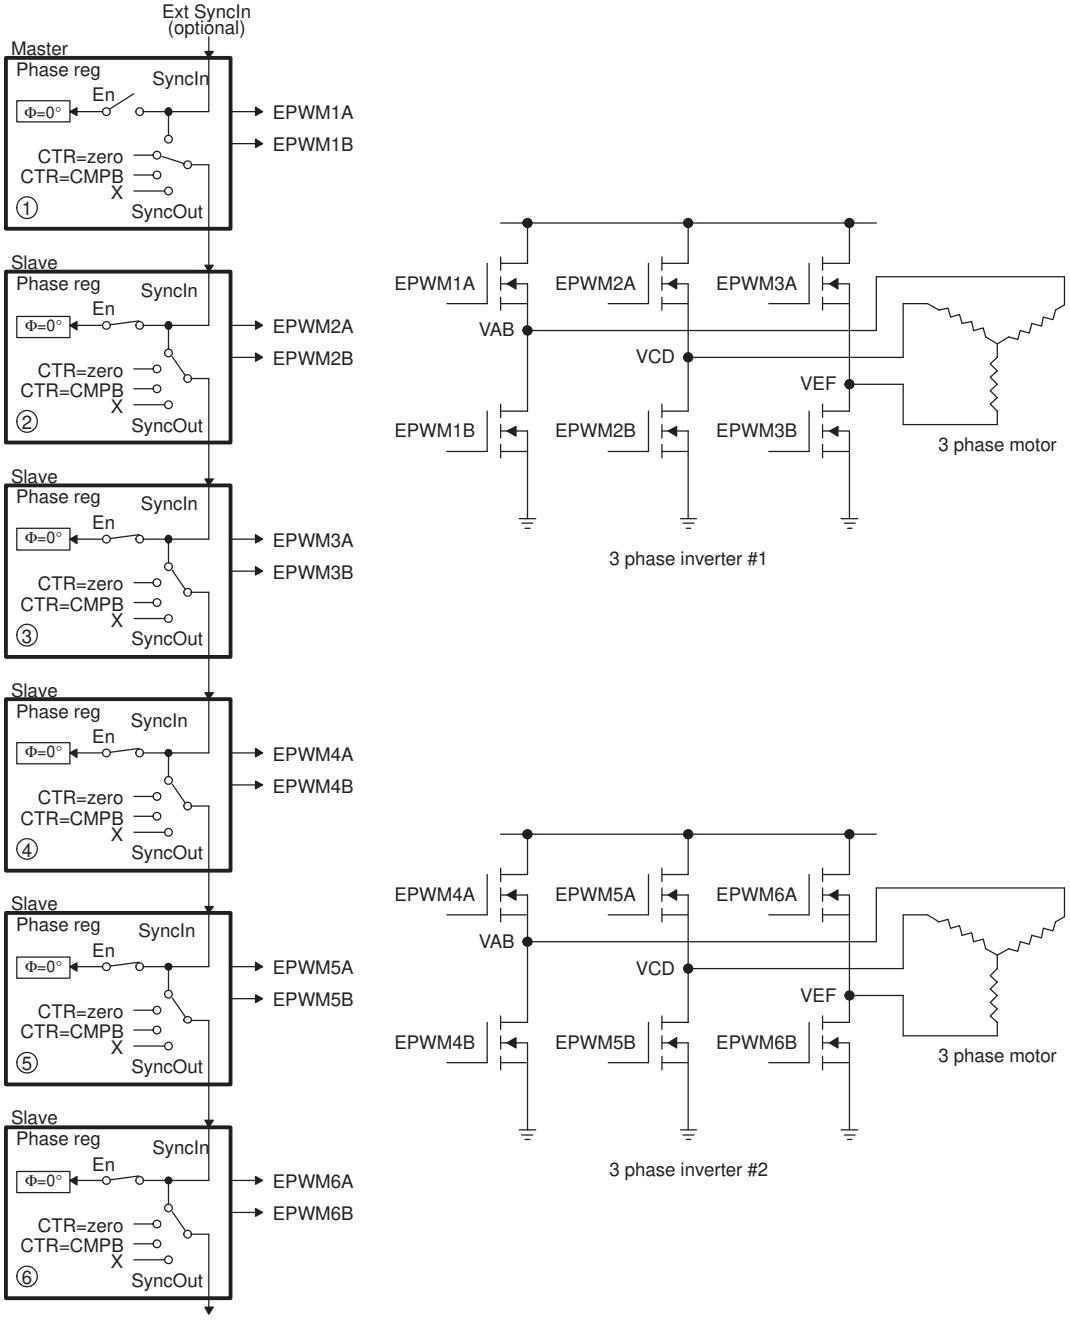

Figure 20-59. 3-Phase Inverter Waveforms for Figure 20-58 (Only One Inverter Shown)

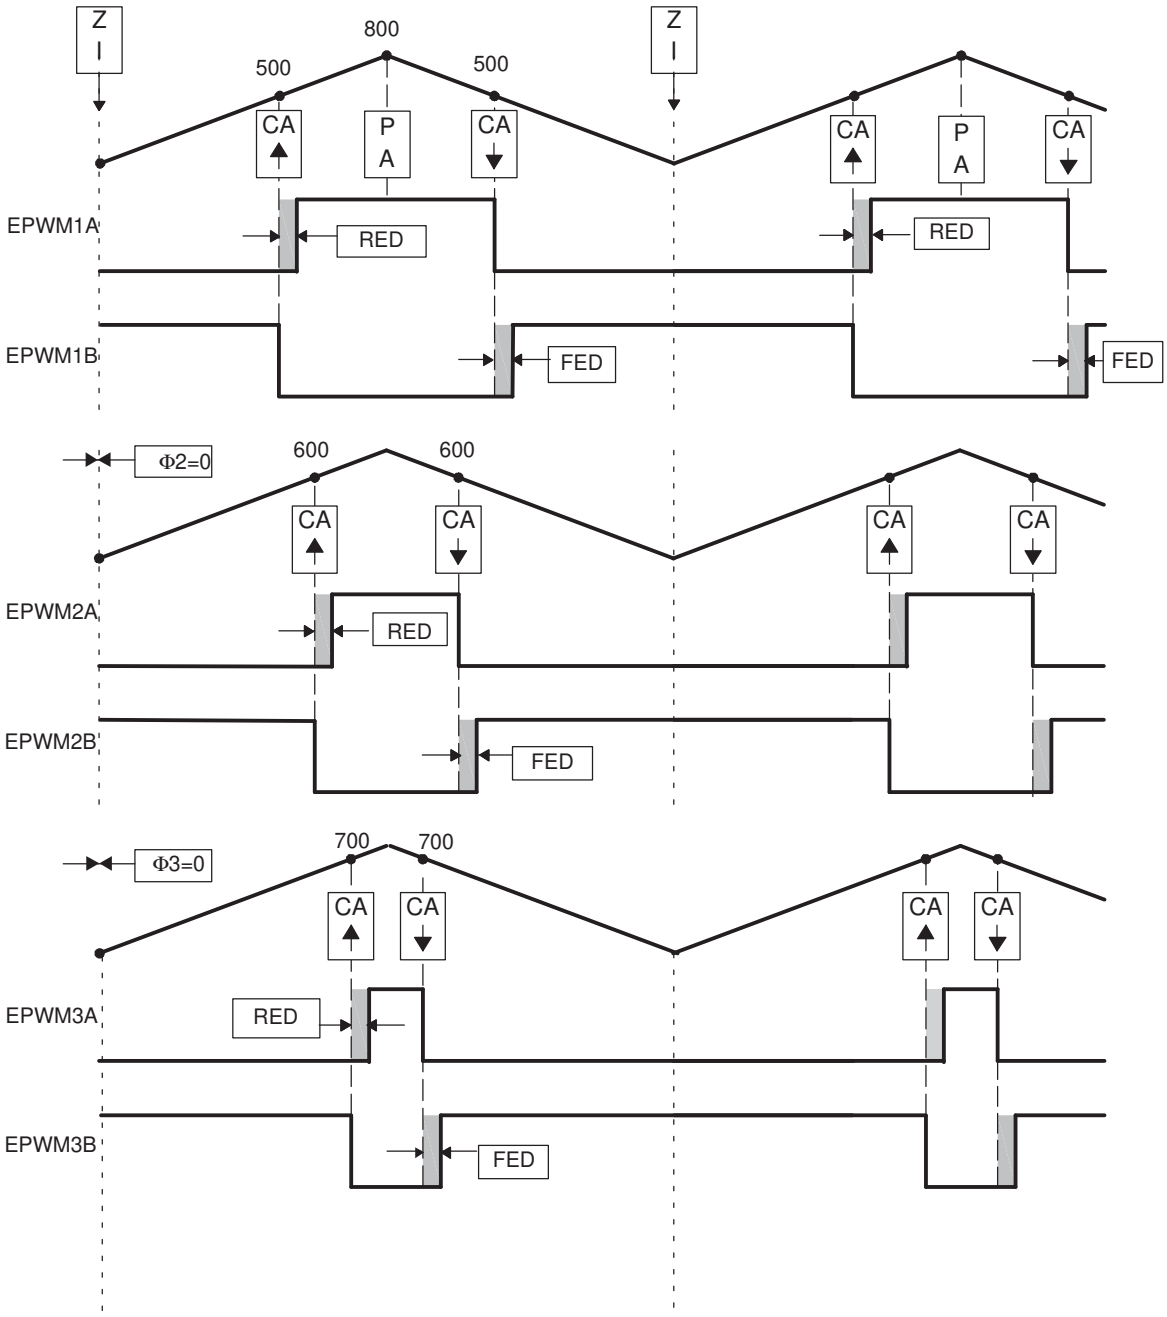

20.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 20-60 shows a master and slave module with a phase relationship of 120°, i.e., the slave leads the master.

Figure 20-60. Configuring Two PWM Modules for Phase Control

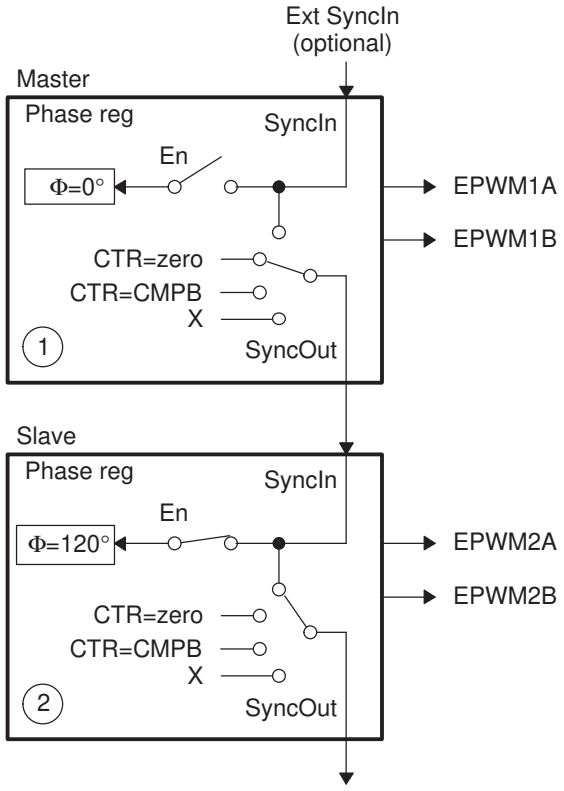

Figure 20-61 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (200/600 × 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120°.

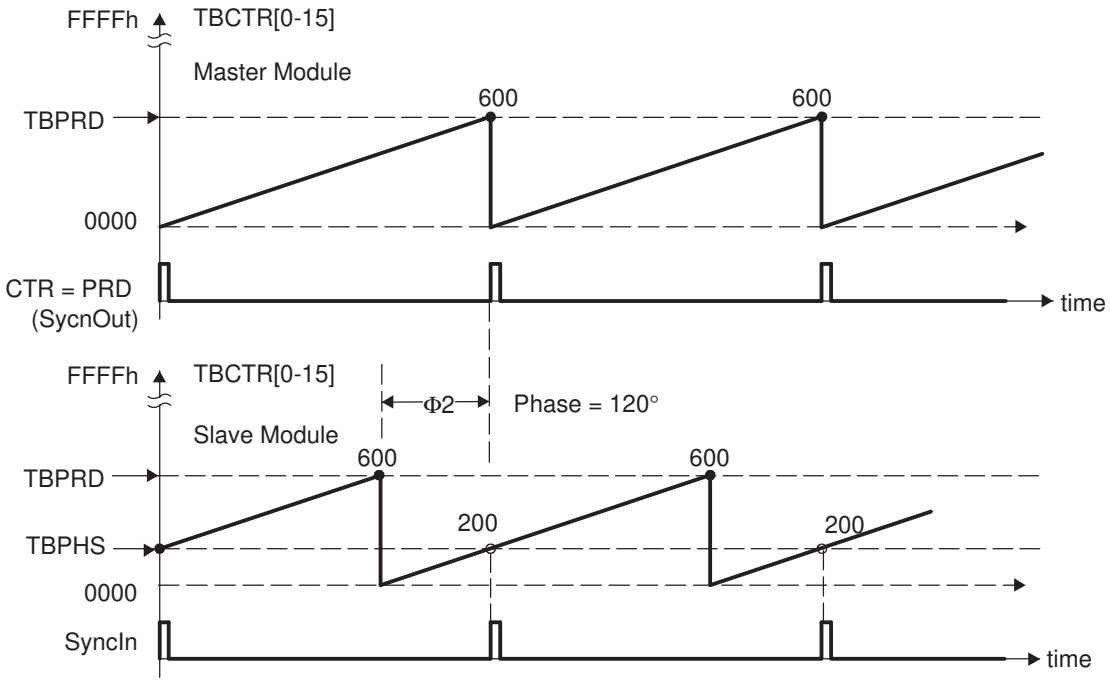
Figure 20-61. Timing Waveforms Associated With Phase Control Between 2 Modules



20.4 MSS_ETPWM1 Registers

Table 20-22 lists the memory-mapped registers for the MSS_ETPWM1. Each register set is duplicated for each instance of the ePWM module. All register offset addresses not listed in Table 20-22 should be considered as reserved locations and the register contents should not be modified.

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18	TBSTS_CTRMAX	R/W	0h	Time-Base Counter Max Latched Status Bit 0 Read: Indicates the time-base counter never reached its maximum value. Write: No effect. 1 Read: Indicates that the time-base counter reached the maximum value 0xFFFF. Write: Clears the latched event.
17	TBSTS_SYNCI	R/W	0h	Input Synchronization Latched Status Bit 0 Read: Indicates no external synchronization event has occurred. Write: No effect. 1 Read: Indicates that an external synchronization event has occurred (EPWMxSYNCI). Write: Clears the latched event.
16	TBSTS_CTRDIR	R/W	0h	Time-Base Counter Direction Status Bit. At reset, the counter is frozen; therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. 0 Time-Base Counter is currently counting down. 1 Time-Base Counter is currently counting up.
15-14	TBCTL_FREE,_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0 Stop after the next time-base counter increment or decrement 1h Stop when counter completes a whole cycle: • Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) • Down-count mode: stop when the time-base counter = 0x0000 (TBCTR = 0x0000) • Up-down-count mode: stop when the time-base counter = 0x0000 (TBCTR = 0x0000) 2h-3h Free run
13	TBCTL_PHSDIR	R/W	0h	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0 Count down after the synchronization event. 1 Count up after the synchronization event

Table 20-24. TBCTL_TBSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12-10	TBCTL_CLKDIV	R/W	0h	Time-base Clock Prescale Bits. These bits determine part of the timebase clock prescale value. TBCLK = VCLK3 / (HSPCLKDIV * CLKDIV) 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128
9-7	TBCTL_HSPCLKDIV	R/W	0h	High Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value: TBCLK = VCLK3 / (HSPCLKDIV * CLKDIV) 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14
6	TBCTL_SWFSYNC	R/W	0h	Software Forced Synchronization Pulse 0 Writing a 0 has no effect and reads always return a 0. 1 Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWMxSYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 00.
5-4	TBCTL_SYNCOSEL	R/W	0h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0 EPWMxSYNC: 1h CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000) 2h CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB) 3h Disable EPWMxSYNCO signal
3	TBCTL_PRDLD	R/W	0h	Active Period Register Load From Shadow Register Select 0 The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero. A write or read to the TBPRD register accesses the shadow register. 1 Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.
2	TBCTL_PHSEN	R/W	0h	Counter Register Load From Phase Register Enable 0 Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS) 1 Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs.
1-0	TBCTL_CTRMODE	R/W	0h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0 Up-count mode 1h Down-count mode 2h Up-down-count mode 3h Stop-freeze counter operation (default on reset)

20.4.2 TBPHS Register (Offset = 4h) [reset = 0h]

TBPHS is shown in Figure 20-63 and described in Table 20-25.

Return to Summary Table.

Time-Base Phase Register

TBPRD																TBCTR															
R/W-0h																R/W-0h															

Table 20-26. TBCTR_TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TBPRD	R/W	0h	Time-Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. • If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the timebase counter equals zero. • If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. • The active and shadow registers share the same memory map address.
15-0	TBCTR	R/W	0h	Time-Base Counter Register Reading these bits gives the current time-base counter value. Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs; the write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed.

20.4.4 CMPCTL Register (Offset = Ch) [reset = 0h]

CMPCTL is shown in Figure 20-65 and described in Table 20-27.

Return to Summary Table.

Table 20-31. AQCSFRC_DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	DBCTL_HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit: 0 Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1 Half cycle clocking enabled. The dead-band counters are clocked at TBCLK ÷ 2.
30-22	RESERVED	R	0h	Reserved
21-20	DBCTL_IN_MODE	R/W	0h	Dead Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in Figure 35-28. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 0 EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 1h EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 2h EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 3h EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.
19-18	DBCTL_POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in Figure 35-28. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes. 0 Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 1h Active low complementary (ALC) mode. EPWMxA is inverted. 2h Active high complementary (AHC). EPWMxB is inverted. 3h Active low (AL) mode. Both EPWMxA and EPWMxB are inverted

Table 20-31. AQCSFRC_DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17-16	DBCTL_OUT_MODE	R/W	0h	Dead-band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in Figure 35-28. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay. 0 Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect. 1h Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE]. 2h The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. 3h Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].
15-4	RESERVED	R	0h	Reserved
3-2	AQCSFRC_CSFB	R/W	0h	Continuous Software Force on Output B In immediate mode, a continuous force takes effect on the next TBCLK edge. In shadow mode, a continuous force takes effect on the next TBCLK edge after a shadow load into the active register. To configure shadow mode, use AQSFRC[RLDCSF]. 0 Forcing disabled, that is, has no effect 1h Forces a continuous low on output B 2h Forces a continuous high on output B 3h Software forcing is disabled and has no effect
1-0	AQCSFRC_CSFA	R/W	0h	Continuous Software Force on Output A In immediate mode, a continuous force takes effect on the next TBCLK edge. In shadow mode, a continuous force takes effect on the next TBCLK edge after a shadow load into the active register. 0 Forcing disabled, that is, has no effect 1h Forces a continuous low on output A 2h Forces a continuous high on output A 3h Software forcing is disabled and has no effect

20.4.9 DBRED_DBFED Register (Offset = 20h) [reset = 0h]

DBRED_DBFED is shown in Figure 20-70 and described in Table 20-32.

Return to Summary Table.

Dead-Band Generator Rising Edge Delay Count Register/ Dead-Band Generator Falling Edge Delay Count Register

Table 20-35. TZFLG_TZCLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22	TZCLR_DCBEVT2	R/W	0h	Clear Flag for Digital Compare Output B Event 2 0 Writing 0 has no effect. This bit always reads back 0. 1 Writing 1 clears the DCBEVT2 event trip condition.
21	TZCLR_DCBEVT1	R/W	0h	Clear Flag for Digital Compare Output B Event 1 0 Writing 0 has no effect. This bit always reads back 0. 1 Writing 1 clears the DCBEVT1 event trip condition
20	TZCLR_DCAEVT2	R/W	0h	Clear Flag for Digital Compare Output A Event 2 0 Writing 0 has no effect. This bit always reads back 0. 1 Writing 1 clears the DCAEVT2 event trip condition
19	TZCLR_DCAEVT1	R/W	0h	Clear Flag for Digital Compare Output A Event 1 0 Writing 0 has no effect. This bit always reads back 0. 1 Writing 1 clears the DCAEVT1 event trip condition.
18	TZCLR_OST	R/W	0h	Clear Flag for One-Shot Trip (OST) Latch 0 Has no effect. Always reads back a 0. 1 Clears this Trip (set) condition.
17	TZCLR_CBC	R/W	0h	Clear Flag for Cycle-By-Cycle (CBC) Trip Latch 0 Has no effect. Always reads back a 0. 1 Clears this Trip (set) condition.
16	TZCLR_INT	R/W	0h	Global Interrupt Clear Flag 0 Has no effect. Always reads back a 0. 1 Clears the trip-interrupt flag for this ePWM module (TZFLG[INT]). NOTE: No further EPWMx_TZINT VIM interrupts will be generated until the flag is cleared. If the TZFLG[INT] bit is cleared and any of the other flag bits are set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts.
15-7	RESERVED	R	0h	Reserved
6	TZFLG_DCBEVT2	R/W	0h	Latched Status Flag for Digital Compare Output B Event 2 0 Indicates no trip event has occurred on DCBEVT2 1 Indicates a trip event has occurred for the event defined for DCBEVT2
5	TZFLG_DCBEVT1	R/W	0h	Latched Status Flag for Digital Compare Output B Event 1 0 Indicates no trip event has occurred on DCBEVT1 1 Indicates a trip event has occurred for the event defined for DCBEVT1

Table 20-35. TZFLG_TZCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TZFLG_DCAEVT2	R/W	0h	Latched Status Flag for Digital Compare Output A Event 2 0 Indicates no trip event has occurred on DCAEVT2 1 Indicates a trip event has occurred for the event defined for DCAEVT2
3	TZFLG_DCAEVT1	R/W	0h	Latched Status Flag for Digital Compare Output A Event 1 0 Indicates no trip event has occurred on DCAEVT1 1 Indicates a trip event has occurred for the event defined for DCAEVT1
2	TZFLG_OST	R/W	0h	Latched Status Flag for A One-Shot Trip Event 0 No one-shot trip event has occurred. 1 Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register
1	TZFLG_CBC	R/W	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0 No cycle-by-cycle trip event has occurred. 1 Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x0000 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register
0	TZFLG_INT	R/W	0h	Latched Trip Interrupt Status Flag 0 Indicates no interrupt has been generated. 1 Indicates an EPWMx_TZINT VIM interrupt was generated because of a trip condition. No further EPWMx_TZINT VIM interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register

20.4.13 TZFRC_ETSEL Register (Offset = 30h) [reset = 0h]

TZFRC_ETSEL is shown in Figure 20-74 and described in Table 20-36.

Return to Summary Table.

R-0h				R/W-0h		R/W-0h	

Table 20-37. ETPS_ETFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	Reserved
19	ETFLG_SOCB	R/W	0h	Latched ePWM ADC Start-of-Conversion B (EPWMxSOCB) Status Flag 0 Indicates no EPWMxSOCB event occurred 1 Indicates that a start of conversion pulse was generated on EPWMxSOCB. The EPWMxSOCB output will continue to be generated even if the flag bit is set.
18	ETFLG_SOCA	R/W	0h	Latched ePWM ADC Start-of-Conversion A (EPWMxSOCA) Status Flag Unlike the ETFLG[INT] flag, the EPWMxSOCA output will continue to pulse even if the flag bit is set. 0 Indicates no event occurred 1 Indicates that a start of conversion pulse was generated on EPWMxSOCA. The EPWMxSOCA output will continue to be generated even if the flag bit is set
17	RESERVED	R	0h	Reserved
16	ETFLG_INT	R/W	0h	Latched ePWM Interrupt (EPWMx_INT) Status Flag 0 Indicates no event occurred 1 Indicates that an ePWMx interrupt (EWPMx_INT) was generated. No further interrupts will be generated until the flag bit is cleared. Up to one interrupt can be pending while the ETFLG[INT] bit is still set. If an interrupt is pending, it will not be generated until after the ETFLG[INT] bit is cleared
15-14	ETPS_SOCBCNT	R/W	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register These bits indicate how many selected ETSEL[SOCBSEL] events have occurred: 0 No events have occurred. 1h 1 event has occurred. 2h 2 events have occurred. 3h 3 events have occurred
13-12	ETPS_SOCBPRD	R/W	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared. 0 Disable the SOCB event counter. No EPWMxSOCB pulse will be generated 1h Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1 2h Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0 3h Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1

Table 20-37. ETPS_ETFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	ETPS_SOCACNT	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register These bits indicate how many selected ETSEL[SOCASEL] events have occurred: 0 No events have occurred. 1h 1 event has occurred. 2h 2 events have occurred. 3h 3 events have occurred.
9-8	ETPS_SOCAPRD	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 0 Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 1h Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 2h Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 3h Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1
7-4	RESERVED	R	0h	Reserved
3-2	ETPS_INTCNT	R/W	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 0 No events have occurred. 1h 1 event has occurred. 2h 2 events have occurred. 3h 3 events have occurred.
1-0	ETPS_INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 0 Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 1h Generate an interrupt on the first event INTCNT = 01 (first event) 2h Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 3h Generate interrupt on ETPS[INTCNT] = 1,1 (third event)

20.4.15 ETCLR_ETFRC Register (Offset = 38h) [reset = 0h]

ETCLR_ETFRC is shown in Figure 20-76 and described in Table 20-38.

Return to Summary Table.

Table 20-50. DCCAPCTL_DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DCFOFFSET_OFFSET	R/W	0h	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.
15-2	RESERVED	R	0h	Reserved
1	DCCAPCTL_SHDWMODE	R/W	0h	TBCTR Counter Capture Shadow Select Mode 0 Enable shadow mode. The DCCAP active register is copied to shadow register on a TBCTR = TBPRD or TBCTR = zero event as defined by the DCFCTL[PULSESEL] bit. CPU reads of the DCCAP register will return the shadow register contents. 1 Active Mode. In this mode the shadow register is disabled. CPU reads from the DCCAP register will always return the active register contents
0	DCCAPCTL_CAPE	R/W	0h	TBCTR Counter Capture Enable/Disable 0 Disable the time-base counter capture. 1 Enable the time-base counter capture.

20.4.28 DCFOFFSETCNT_DCFWINDOW Register (Offset = 6Ch) [reset = 0h]

DCFOFFSETCNT_DCFWINDOW is shown in Figure 20-89 and described in Table 20-51.

Return to Summary Table.

Digital Compare Filter Offset Counter Register/ Digital Compare Filter Window Register

Figure 20-89. DCFOFFSETCNT_DCFWINDOW Register

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	DCFWINDOW_WINDOW	R/W	0h	Blanking Window Width 0 No blanking window is generated. 1h-FFh Specifies the width of the blanking window in TBCLK cycles. The blanking window begins when the offset counter expires. When this occurs, the window counter is loaded and begins to count down. If the blanking window is currently active and the offset counter expires, the blanking window counter is restarted. The blanking window can cross a PWM period boundary.
15-0	DCFOFFSETCNT_OFFSETCNT	R/W	0h	Blanking Offset Counter These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCFCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by a emulation stop.

20.4.29 DCFWINDOWCNT_DCCAP Register (Offset = 70h) [reset = 0h]

DCFWINDOWCNT_DCCAP is shown in Figure 20-90 and described in Table 20-52.

Return to Summary Table.

Table 20-52. DCFWINDOWCNT_DCCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DCCAP	R/W	0h	Digital Compare Time-Base Counter Capture To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. • If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. • If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address.
15-8	RESERVED	R	0h	Reserved
7-0	DCFWINDOWCNT	R/W	0h	0-FFh Blanking Window Counter These 8 bits are read only and indicate the current value of the window counter. The counter counts down to zero and then stops until it is re-loaded when the offset counter reaches zero again.

Controller Area Network (DCAN)

This section describes the controller area network (DCAN) module.

NOTE: This section describes a superset implementation of the DCAN module. Consult your device-specific datasheet to identify the applicability of the DMA-related features, the number of instantiations of the DCAN IP, and the number of mailboxes supported on your specific device being used.

21.1 Overview

The Controller Area Network is a high-integrity, serial, multi-master communication protocol for distributed real-time applications. This CAN module is implemented according to ISO 11898-1 and is suitable for industrial, automotive and general embedded communications.

21.1.1 Features

The DCAN module provides the following features:

Protocol

- Supports CAN protocol version 2.0 part A, B

Speed

- Bit rates up to 1 MBit/s

MailBox

- Configurable Message objects
- Individual identifier masks for each message object
- Programmable FIFO mode for message objects

High Speed MailBox Access

- DMA access to Message RAM.

Power

- Global power down and wakeup support
- Local power down and wakeup support

Debug

- Suspend mode for debug support
- Programmable loop-back modes for self-test operation
- Direct access to Message RAM in test mode
- Supports Two interrupt lines - Level 0 and Level 1

Others

- Automatic Message RAM initialization
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- CAN Rx / Tx pins configurable as general purpose IO pins
- Software module reset
- Message RAM with SECDED mechanism
- Dual clock source to reduce jitter

21.1.2 Functional Description

The CAN protocol is an ISO standard (ISO 11898) for serial data communication. This protocol uses Non-Return To Zero (NRZ) with bit-stuffing. And the communication is carried over a two-wire balanced signaling scheme.

The DCAN data communication happens through the CAN_TX and CAN_RX pins. An additional transceiver hardware is required for the connection to the physical layer (CAN bus) CAN_High and CAN_Low.

The DCAN register set can be accessed directly by the CPU. These registers are used to control and configure the CAN module and the Message RAM.

Individual CAN message objects should be configured for communication over a CAN network. The message objects and identifier masks are stored in the Message RAM.

The CAN module internally handles functions such acceptance filtering, transfer of messages from and to the Message RAM, handling of transmission requests as well as the generation of interrupts or DMA requests.

21.2 CAN Blocks

The DCAN Module, shown in Figure 21-1, comprises of the following basic blocks.

21.2.1 CAN Core

The CAN Core consists of the CAN Protocol Controller and the Rx/Tx Shift Register. It handles all ISO 11898-1 protocol functions.

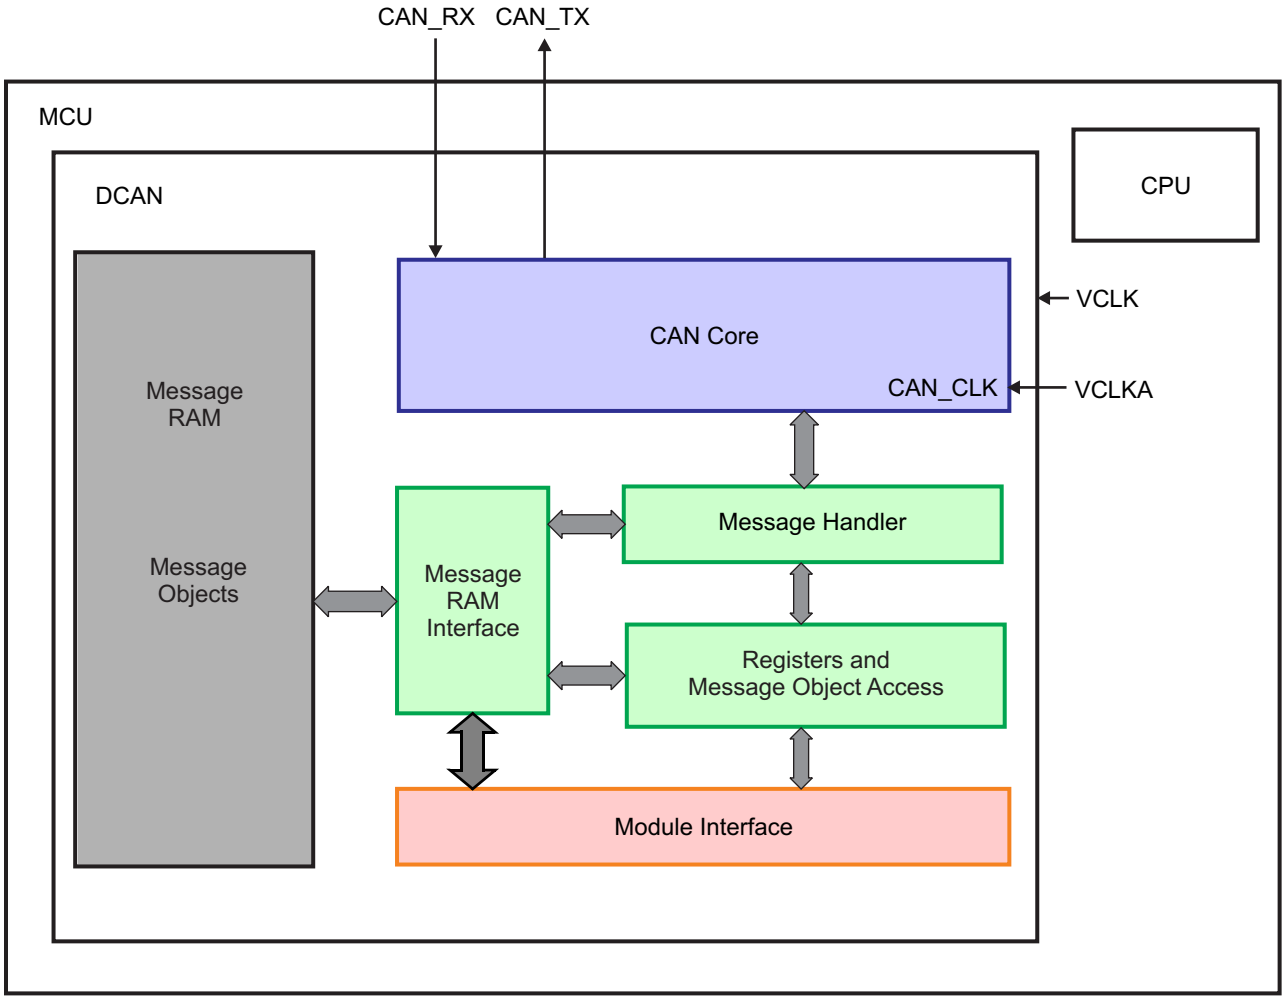
21.2.2 Message RAM

The DCAN Message RAM enables storage of CAN messages. Actual Device datasheet provides the details of the Message RAM address.

21.2.3 Message Handler

The Message Handler is a state machine that controls the data transfer between the single ported Message RAM and the CAN Core's Rx/Tx Shift Register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Figure 21-1. DCAN Block Diagram



21.2.4 Message RAM Interface

The Interface Register sets control the CPU read and write accesses to the Message RAM. There are three interface registers IF1, IF2, and IF3:

- IF1 and IF2 Interface Registers sets for read and write access.
- IF3 Interface Register set for read access only.

The Interface Registers have the same word-length as the Message RAM. Additional information can be found in Section 21.6.

21.2.5 Register and Message Object Access

During normal operation, data consistency of the message objects is guaranteed by indirectly accessing the message objects through the interface registers IF1 and IF2.

In order to be able to perform tests on the message object memory, a dedicated test mode has been implemented, that allows direct access by either the CPU or DMA. During normal operation direct access has to be avoided.

21.2.6 Dual Clock Source

Two clock domains are provided to the DCAN module:

1. VCLK - The peripheral synchronous clock domain as the general module clock source.
2. VCLKA - The peripheral asynchronous clock source domain provided to the CAN core as clock source (CAN_CLK) for generating the CAN Bit Timing.

If a frequency modulated clock output from FMPLL is used as the VCLK source, then VCLKA should be derived from an unmodulated clock source (for example, OSCIN source).

The clock source for VCLKA is selected by the Peripheral Asynchronous Clock Source Register in the system module.

Both clock domains can be derived from the same clock source (so that VCLK = VCLKA). However, if frequency modulation in the FMPLL is enabled (spread spectrum clock), then due to the high precision clocking requirements of the CAN Core, the FMPLL clock source should not be used for VCLKA. Alternatively, a separate clock without any modulation (for example, derived directly from the OSCIN clock) should be used for VCLKA.

Refer to the system module reference guide and the device datasheet for more information how to configure the relevant clock source registers in the system module.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

NOTE: If the dual clock functionality is used, then VCLK must always be higher or equal to CAN_CLK (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated VCLK has to be considered:

$$f_{0,\ VCLK} \pm \Delta f_{FM,VCLK} \geq f_{CANCLK}$$

The CAN Core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK, an oscillator frequency of 8MHz or higher has to be used.

21.3 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

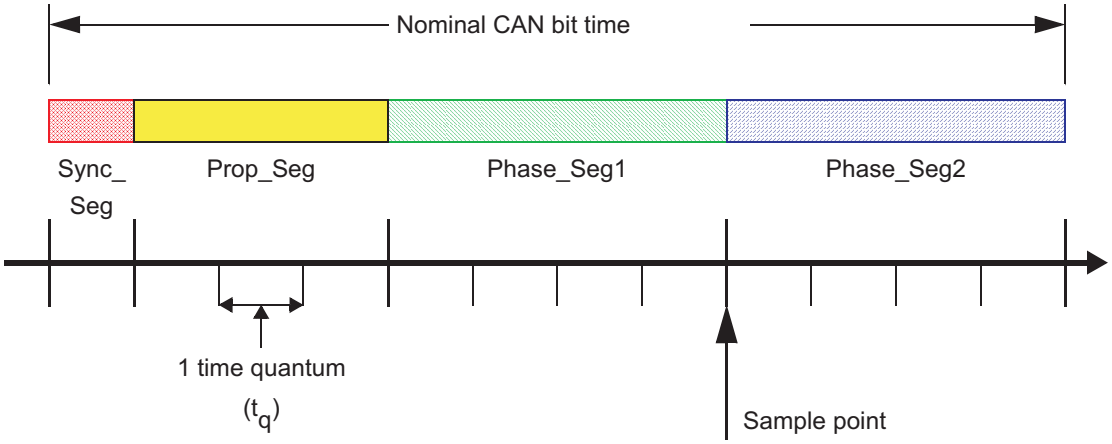
Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

21.3.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 21-2):

- Synchronization Segment (Sync_Seg)
- Propagation Time Segment (Prop_Seg)
- Phase Buffer Segment 1 (Phase_Seg1)
- Phase Buffer Segment 2 (Phase_Seg2)

Figure 21-2. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum, (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable.

Table 21-1 describes the minimum programmable ranges required by the CAN protocol. A given bit rate may be met by different Bit time configurations.

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Table 21-1. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

21.3.1.1 Synchronization Segment

The Synchronization Segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

21.3.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

21.3.1.3 Phase Buffer Segments and Synchronization

The Phase Buffer Segments (Phase_Seg1 and Phase_Seg2) and the Synchronization Jump Width (SJW) are used to compensate for the oscillator tolerance.

The Phase Buffer Segments surround the sample point. The Phase Buffer Segments may be lengthened or shortened by synchronization.

The Synchronization Jump Width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg, otherwise its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

21.3.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1-df) \times f_{nom} \leq f_{osc} \leq (1+df) \times f_{nom} \quad (5)$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \leq \frac{\min(\text{Phase\_Seg1}, \text{Phase\_Seg2})}{[2 \times (13 \times \text{bit\_time} - \text{Phase\_Seg2})]}$$

$$\text{II:} \quad df \leq \frac{\text{SJW}}{20 \times \text{bit\_time}} \quad (6)$$

It has to be considered that SJW may not be larger than the smaller of the Phase Buffer Segments and that the Propagation Time Segment limits that part of the bit time that may be used for the Phase Buffer Segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 μs) with a bus length of 40 m.

21.3.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BREP) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1… n], values in the range of [0 … n-1] are programmed. That way, SJW (functional range of [1 … 4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the Bit Timing Register (BTR) is the configuration input of the CAN protocol controller. The Baud Rate Prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

21.3.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the Baud Rate Prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0 … 2] t_q.

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and Phase_Seg1.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing Register:

Tseg2 = Phase_Seg2 - 1
Tseg1 = Phase_Seg1 + Prop_Seg - 1
SJW = SynchronizationJumpWidth - 1
BRP = Prescaler - 1

21.3.2.2 Calculation of BRP Values

If Baud and CAN_CLK(VCLK) are already known, the BRP/BRPE values need to be calculated to be programmed into the register. It is calculated using the following equation:

BRP = CAN_CLK / (BAUD)(1 + TSEG1 + TSEG2) (7)

21.3.2.3 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

t_q	100	ns	=	t_{CAN_CLK}
delay of bus driver	60	ns		
delay of receiver circuit	40	ns		
delay of bus line (40m)	220	ns		
t_{Prop}	700	ns	=	INT (2 × delays + 1) = 7 • t_q
t_{SJW}	100	ns	=	1 × t_q
t_{TSeg1}	800	ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100	ns	=	Information Processing Time + 1 • t_q
$t_{Sync\text{-}Seg}$	100	ns	=	1 × t_q
bit time	1000	ns	=	$t_{Sync\text{-}Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	1.58	%	=	$\frac{\min(TSeg1, TSeg2)}{[2 \times (13 \times bit\_time - TSeg2)]}$ (8)
			=	$\frac{0.1\mu s}{[2 \times (13 \times 1\mu s - 0.1\mu s)]}$ (9)
			=	0.38%

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$ & $(8\text{-}1)_4$ & $(1\text{-}1)_2$ & $(1\text{-}1)_6$, so the Bit Timing Register is programmed to 0000 0700h.

21.3.2.4 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	100	ns	=	$2 \times t_{CAN\_CLK}$
delay of bus driver	200	ns		
delay of receiver circuit	80	ns		
delay of bus line (40m)	220	ns		
t_{Prop}	1	µs	=	$1 \times t_q$
t_{SJW}	4	µs	=	$4 \times t_q$
t_{TSeg1}	5	µs	=	$t_{Prop} + t_{SJW}$
t_{TSeg2}	3	µs	=	Information Processing Time + $3 \times t_q$
$t_{Sync\text{-}Seg}$	1	µs	=	$1 \times t_q$
bit time	9	µs	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.43	%	=	$\frac{\min(TSeg1, TSeg2)}{[2 \times (13 \times bit\_time - TSeg2)]}$ (10)
			=	$\frac{3\mu s}{[2 \times (13 \times 9\mu s - 3\mu s)]}$ (11)
			=	1.32%

In this example, the concatenated bit time parameters are $(3\text{-}1)_3$ & $(5\text{-}1)_4$ & $(4\text{-}1)_2$ & $(2\text{-}1)_6$, so the Bit Timing Register is programmed to 0000 24C1h.

21.4 CAN Module Configuration

After a hardware reset all CAN protocol functions are disabled.The CAN module must be initialized and configured before it can participate on the CAN bus.

21.4.1 DCAN RAM Initialization Through Hardware

To start with a clean DCAN RAM ,the complete DCAN RAM has to be initialized with zeros and the ECC bits set accordingly by configuring the following registers in the system module:

1. Memory Hardware Initialization Global Control Register (MINITGCR)
2. Memory Initialization Enable Register (MSINENA)

For more details on RAM hardware initialization support, refer to the system module reference guide.

21.4.2 CAN Module Initialization

To initialize the CAN Controller, you have to set up the CAN Bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

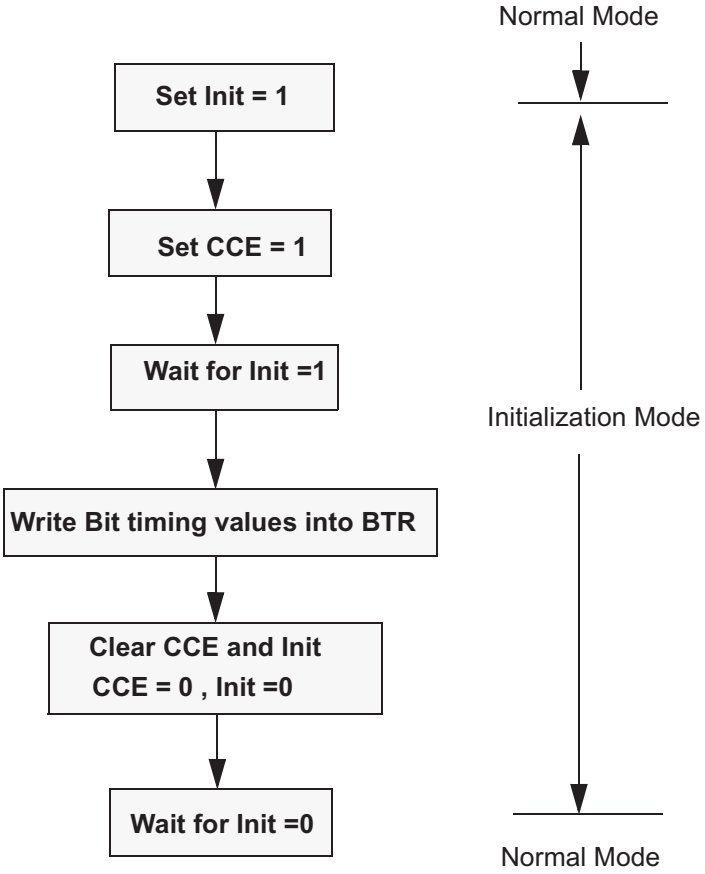
So the two critical steps are:

1. Configuration of CAN Bit Timings
2. Configuration of Message Objects

21.4.2.1 Software Configuration of CAN Bit Timings

This step involves configuring the CAN baud rate register with the calculated CAN bit timing value. The calculation procedure of CAN bit timing values for BTR register are mentioned in Section 21.3. Refer to Figure 21-3 for CAN bit timing software configuration flow.

Figure 21-3. CAN Bit-timing Configuration



Step 1: Enter “initialization mode” by setting the Init (Initialization) bit in the CAN Control Register.

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also note that the CAN module is also in initialization mode on hardware reset and during Bus-Off.

Step 2: Set the CCE (Configure Change Enable) bit in the CAN Control Register.

The access to the Bit Timing Register for the configuration of the Bit timing is enabled when both Init and CCE bits in the CAN Control Register are set.

Step 3: Wait for the Init bit to get set. This would make sure that the module has entered “Initialization mode”.

Step 4: Write the Bit-Timing values into the Bit-Timing Register (BTR).

Refer to Section 21.3.2.1 for BTR value calculation for a given bit-timing.

Step 5: Clear the CCE bit followed by Init bit.

Step 6: Wait for the Init bit to clear. This would make sure that the module has come out of “initialization mode”.

After step 6 (Init bit cleared), the module will attempt a synchronization on the CAN bus, provided that the BTR settings are meeting the CAN bus parameters.

NOTE: The module would not come out of the “initialization mode” if any incorrect BTR values are written in step 4.

21.4.2.2 Configuration of Message Objects

The whole Message RAM should be configured before putting the CAN into operation. All the message objects are deactivated by default. You should configure the message object that are to be used to a particular identifier. you can change the configuration of any message object or deactivate it when required.

The message objects can be configured only through the Interface registers (IFx) and the CPU does not have direct access to the message object (Message RAM) when DCAN is in operation.

To configure the message objects, you must know about:

1. The message object structure (Section 21.5)
2. The interface register set (IFx) (Section 21.6)

NOTE: The message objects initialization is independent of the bit-timing configuration procedure.

21.5 Message RAM

The DCAN Message RAM contains message objects and ECC bits for the message objects.

21.5.1 Structure of Message Objects

Figure 21-4 shows the structure of a message object.

The grayed fields are those parts of the message object that are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Figure 21-4. Structure of a Message Object

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 21-2. Message Object Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the Message Handler.
	1	The message object is to be used by the Message Handler.
		Note: The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN Control Register. MsgVal must also be reset if the messages object is no longer used in operation. For reconfiguration of message objects during normal operation see Section 21.7.6 and Section 21.7.7.
UMask		Use Acceptance Mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to 1, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to 1.
ID[28:0]		Message Identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier Mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Extended Identifier
	0	The 11-bit ("standard") identifier will be used for this message object.
	1	The 29-bit ("extended") identifier will be used for this message object.
MXtd		Mask Extended Identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message Direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir		Mask Message Direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.

Table 21-2. Message Object Field Descriptions (continued)

Name	Value	Description
EOB		End of Block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
NewDat		New Data
	0	No new data has been written into the data bytes of this message object by the Message Handler since the last time when this flag was cleared by the CPU.
	1	The Message Handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message Lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The Message Handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive Interrupt Enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit Interrupt Enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt Pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote Enable
	0	At the reception of a Remote Frame, TxRqst is not changed.
	1	At the reception of a Remote Frame, TxRqst is set.
TxRqst		Transmit Request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data Length Code
	0-8	Data Frame has 0-8 data bytes.
	9-15	Data Frame has 8 data bytes.
		Note: The Data Length Code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the Message Handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN Data Frame
Data 1		2nd data byte of a CAN Data Frame
Data 2		3rd data byte of a CAN Data Frame
Data 3		4th data byte of a CAN Data Frame
Data 4		5th data byte of a CAN Data Frame
Data 5		6th data byte of a CAN Data Frame
Data 6		7th data byte of a CAN Data Frame
Data 7		8th data byte of a CAN Data Frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the Message Handler stores a data frame, it will write all the eight data bytes into a message object. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

21.5.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) × 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

NOTE: 0 is not a valid message object number. At address 0x0000, message object number 64 is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

The base address for DCAN1 RAM is FF1E 0000h, DCAN2 RAM is FF1C 0000h, DCAN3 RAM is FF1A 0000h, and DCAN4 RAM base address is FF18 0000h.

Message Object number 1 has the highest priority.

Table 21-3. Message RAM Addressing in Debug/Suspend and RDA Mode

Message Object Number	Base Address Offset	Word Number	Debug/Suspend mode, see Section 21.5.3	RDA mode, see Section 21.5.4
1	0x0020	1	Reserved	Data Bytes 4-7
	0x0024	2	MXtd, MDir, Mask	Data Bytes 0-3
	0x0028	3	Xtd, Dir, ID	ID[27:0], DLC
	0x002C	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0x0030	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0x0034	6	Data Bytes 7-4	--
:	:	:	:	:
31	0x03E0	1	Reserved	Data Bytes 4-7
	0x03E4	2	MXtd, MDir, Mask	Data Bytes 0-3
	0x03E8	3	Xtd, Dir, ID	ID[27]:0, DLC
	0x03EC	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0x03F0	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0x03F4	6	Data Bytes 7-4	--
:	:	:	:	:
63	0x07E0	1	Reserved	Data Bytes 4-7
	0x07E4	2	MXtd, MDir, Mask	Data Bytes 0-3
	0x07E8	3	Xtd, Dir, ID	ID[27:0], DLC
	0x07EC	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0x07F0	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0x07F4	6	Data Bytes 7-4	--
64	0x0000	1	Reserved	Data Bytes 4-7
	0x0004	2	MXtd, MDir, Mask	Data Bytes 0-3
	0x0008	3	Xtd, Dir, ID	ID[27]:0, DLC
	0x000C	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0x0010	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0x0014	6	Data Bytes 7-4	--

21.5.3 Message RAM Representation in Debug/Suspend Mode

In Debug/Suspend mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

NOTE: During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

Figure 21-5. Message RAM Representation in Debug/Suspend Mode

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

	Data 1								Data 0							
MsgAddr + 0x14	Data 7								Data 6							
	Data 5								Data 4							

21.5.4 Message RAM Representation in Direct Access Mode

When the RDA bit in Test Register is set while the DCAN module is in Test Mode (Test bit in CAN control register is set), the CPU has direct access to the Message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM Direct Access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the Message RAM base address.

NOTE: During Direct Access Mode, the Message RAM cannot be accessed via the IFx register sets. Before entering RDA mode, it must be ensured that the Init bit is set to avoid any conflicts with the message handler accessing the message RAM.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit is not set) will be ignored.

Writes to Reserved bits have no effect.

Figure 21-6. Message RAM Representation in RAM Direct Access Mode

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

	Reserved				Reserved				MsgLst	UMask	TxIE	RxIE	RmtEn	EOB	MXtd	MDir

21.5.5 ECC RAM

On devices with SECDED implementation for the message RAM, the ECC bits are stored in a dedicated ECC RAM area that is memory-mapped as follows: The location of the ECC bits for a particular message object in RAM is: Message RAM base address + 0x1000 + (message object number) * 0x20.

NOTE: '0' is not a valid message object number. At address 0x1000, the ECC bits of the last implemented message object are located.

As shown in Figure 21-7, the ECC bits for the last implemented Message Object (here: 128) are located at offset 0x1000; the ECC bits for Message Object 1 are located at offset 0x1020, and the ECC bits for Message Object 127 are located at offset 0x1FE0. The ECC RAM is only memory mapped if SECDED diagnostic mode is enabled.

Figure 21-7. ECC RAM Representation

Bit	31 15	30 14	29 13	28 12	27 11	26 10	25 9	24 8	23 7	22 6	21 5	20 4	19 3	18 2	17 1	16 0

:																
Msg RAM base + 0x1FE0	Reserved															
	Reserved							ECC[8:0] Message Object 127								

21.6 Message Interface Register Sets

Accesses to the Message RAM are performed via the Interface Register sets:

- Interface Register 1 and 2 (IF1 and IF2)
- Interface Register 3 (IF3)

The IF3 register set can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 register set.

The Message Handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

There are two modes where the Message RAM can be directly accessed by the CPU:

1. In Debug/Suspend mode (see Section 21.5.3)
2. In RAM Direct Access (RDA) mode (see Section 21.5.4)

For the Message RAM Base address, refer to the device datasheet.

A complete message object (see Section 21.5.1) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set (see) in one single transfer.

21.6.1 Message Interface Register Sets 1 and 2

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

Table 21-4. Message Interface Register Sets 1 and 2

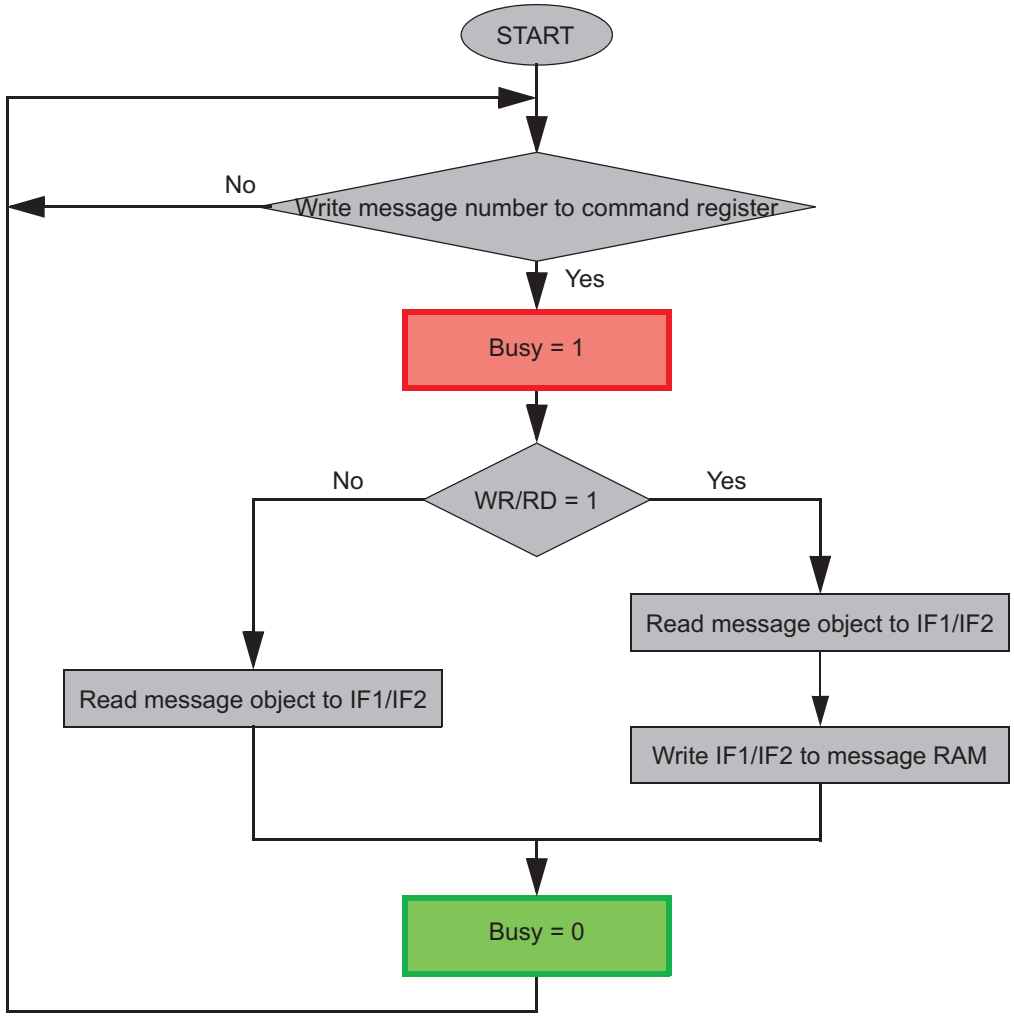
Address	IF1 Register Set		Address	IF2 Register Set	
[CAN Base +]	31 16	15 0	[CAN Base +]	31 16	15 0
0x100	IF1 Command Mask	IF1 Command Request	0x120	IF2 Command Mask	IF2 Command Request
0x104	IF1 Mask 2	IF1 Mask 1	0x124	IF2 Mask 2	IF2 Mask 1
0x108	IF1 Arbitration 2	IF1 Arbitration 1	0x128	IF2 Arbitration 2	IF2 Arbitration 1
0x10C	Rsvd	IF1 Message Control	0x12C	Rsvd	IF2 Message Control
0x110	IF1 Data A 2	IF1 Data A 1	0x130	IF2 Data A 2	IF2 Data A 1
0x114	IF1 Data B 2	IF1 Data B 1	0x134	IF2 Data B 2	IF2 Data B 1

21.6.2 Using Message Interface Register Sets 1 and 2

The Command Register addresses the desired message object in the Message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the Command Register.

When the CPU initiates a data transfer between the IF1/IF2 Registers and Message RAM, the Message Handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see Figure 21-8).

Figure 21-8. Data Transfer Between IF1 / IF2 Registers and Message RAM



21.6.3 Message Interface Register 3

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently.

Table 21-5. Message Interface Register 3

Address	IF3 Register Set	
[CAN Base +]	31 16	15 0
0x140	reserved	IF3 Observation
0x144	IF3 Mask 2	IF3 Mask 1
0x148	IF3 Arbitration 2	IF3 Arbitration 1
0x14C	reserved	IF3 Message Control
0x150	IF3 Data A 2	IF3 Data A 1
0x154	IF3 Data B 2	IF3 Data B 1
:	:	:
0x160	IF3 Update Enable 2	IF3 Update Enable 1
0x164	IF3 Update Enable 4	IF3 Update Enable 3
0x168	IF3 Update Enable 6	IF3 Update Enable 5
0x16C	IF3 Update Enable 8	IF3 Update Enable 7

The automatic update functionality can be programmed for each message object (see IF3 Update Enable Register,).

All valid message objects in Message RAM that are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN Control register. Please refer to the device datasheet to find out if this DMA source is available.

NOTE: The IF3 register set can not be used for transferring data into message objects.

21.7 Message Object Configurations

This section describes the possible message object configurations for CAN communication.

21.7.1 Configuration of a Transmit Object for Data Frames

Figure 21-9 shows how a Transmit Object can be initialized.

Figure 21-9. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The Data Registers (DLC[3:0] and Data0-7) are given by the application, TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received Remote Frame will cause the TxRqst bit to be set; the Remote Frame will autonomously be answered by a Data Frame.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = 1) to allow groups of Remote Frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 21.8.8. Identifier masking must be disabled (UMask = 0) if no Remote Frames are allowed to set the TxRqst bit (RmtEn = 0).

21.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure Transmit Objects for the transmission of Remote Frames. Setting TxRqst for a Receive Object will cause the transmission of a Remote Frame with the same identifier as the Data Frame for which this receive Object is configured.

21.7.3 Configuration of a Single Receive Object for Data Frames

Figure 21-10 shows how a Receive Object for Data Frames can be initialized.

Figure 21-10. Initialization of a Single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Data Frame with an 11-bit Identifier is received, ID[17:0] will be set to 0.

The Data Length Code (DLC[3:0]) is given by the application. When the Message Handler stores a Data Frame in the message object, it will store the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of Data Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored Data Frame.

If the RxIE bit is set, the IntPnd bit will be set when a received Data Frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a Remote Frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = 1 for acceptance filtering.

21.7.4 Configuration of a Single Receive Object for Remote Frames

Figure 21-11 shows how a Receive Object for Remote Frames can be initialized.

Figure 21-11. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

Receive Objects for Remote Frames may be used to monitor Remote Frames on the CAN bus. The Remote Frame stored in the Receive Object will not trigger the transmission of a Data Frame. Receive Objects for Remote Frames may be expanded to a FIFO buffer, see Section 21.7.5.

UMask must be set to 1. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to “must-match” or to “don’t care”, to allow groups of Remote Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 21.8.8.

The Arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received Remote Frames. If some bits of the Mask bits are set to “don’t care”, the corresponding bits of the Arbitration bits will be overwritten by the bits of the stored Remote Frame. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Remote Frame with an 11-bit Identifier is received, ID[17:0] will be set to 0.

The Data Length Code (DLC[3:0]) may be given by the application. When the Message Handler stores a Remote Frame in the message object, it will store the received Data Length Code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received Remote Frame is accepted and stored in the message object.

21.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of Receive Objects belonging to a FIFO Buffer is the same as the configuration of a single Receive Object.

To concatenate multiple message objects to a FIFO Buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO Buffer. The EoB bit of all message objects of a FIFO Buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

21.7.6 Reconfiguration of Message Objects for the Reception of Frames

A message object with Dir = ‘0’ is configured for the reception of data frames, with Dir = ‘1’ AND Umask = ‘1’ AND RmtEn = ‘0’ it is configured for the reception of remote frames.

It is neccessary to reset MsgVal to not valid before changing any of the following configuration and control bits: ID[28:0], Xtd, Dir, DLC[3:0], RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir.

These parts of a message object may be changed without clearing MsgVal: Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

21.7.7 Reconfiguration of Message Objects for the Reception of Frames

A message object with Dir = ‘1’ AND (Umask = ‘0’ OR RmtEn = ‘1’) is configured for the transmission of data frames.

It is neccessary to reset MsgVal to not valid before changing any of the following configuration and control bits: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir

These parts of a message object may be changed without clearing MsgVal: ID[28-0], Xtd, DLC[3:0], Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

21.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects.

The application has to update the data of the messages to be transmitted and enable and request their transmission. The transmission is requested automatically when a matching Remote Frame is received.

The application may read messages that are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read based on interrupts or by polling.

21.8.1 Message Handler Overview

The Message Handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data Transfer from Message RAM to CAN Core (messages to be transmitted).
- Data Transfer from CAN Core to the Message RAM (received messages).
- Data Transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The Message Handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request flags
- New Data flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting the listed status information of each message object via IFx registers separately, these Message Handler registers provides a fast and easy way to get an overview (for example, about all pending transmission requests).

All Message Handler registers are read-only.

21.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received Data Frames or Remote Frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher Message Number. The last message object may be configured to accept any Data Frame or Remote Frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

21.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx Registers and Message RAM, the d bits in the Message Valid Register and the TxRqst bits in the Transmission Request Register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the Message Handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If Automatic Retransmission mode is disabled by setting the DAR bit in the CAN Control Register, the behavior of bits TxRqst and NewDat in the Message Control Register of the Interface Register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface Register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received Remote Frames do not require a Receive Object. They will automatically trigger the transmission of a Data Frame, if in the matching Transmit Object the RmtEn bit is set.

21.8.4 Updating a Transmit Object

The CPU may update the data bytes of a Transmit Object any time via the IF1/IF2 Interface Registers, neither d nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A Register or IF1/IF2 Data B Register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data Register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command Register and then the number of the message object is written to bits [7:0] of the Command Register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 21.8.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

21.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the Transmit Objects may be managed dynamically. The CPU can write the whole message (Arbitration, Control, and Data) into the Interface Register. The bits [23:16] of the Command Register can be set to 0xB7 for the transfer of the whole message object content into the message object. Before changing the configuration of a message object, MsgVal has to be reset (see Section 21.7.7).

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the Command Register should be set to 0x87.

NOTE: After the update of the Transmit Object, the Interface Register set will contain a copy of the actual contents of the object, including the part that had not been updated.

21.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the Message Handler starts to scan of the Message RAM for a matching valid message object:

- The Acceptance Filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the Message Handler proceeds depending on the type of the frame (Data Frame or Remote Frame) received.

21.8.7 Reception of Data Frames

The Message Handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the Data Length Code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a Remote Frame, while the requested Data Frame has just been received.

21.8.8 Reception of Remote Frames

When a Remote Frame is received, three different configurations of the matching message object have to be considered:

1. Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0: The TxRqst bit of this message object is set at the reception of a matching Remote Frame. The rest of the message object remains unchanged.
2. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0: The Remote Frame is ignored, this message object remains unchanged.
3. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1: The Remote Frame is treated similar to a received Data Frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

21.8.9 Reading Received Messages

The CPU may read a received message any time via the IFx Interface Registers, the data consistency is guaranteed by the Message Handler state machine.

Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

21.8.10 Requesting New Data for a Receive Object

By means of a Remote Frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a Remote Frame with the receive object's identifier. This Remote Frame triggers the other CAN node to start the transmission of the matching Data Frame. If the matching Data Frame is received before the Remote Frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

21.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask Registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is 1.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is 0 the message object is locked for further write accesses by the Message Handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to 0, all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = 1) and therefore overwrite previous messages in this message object.

21.8.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects that are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

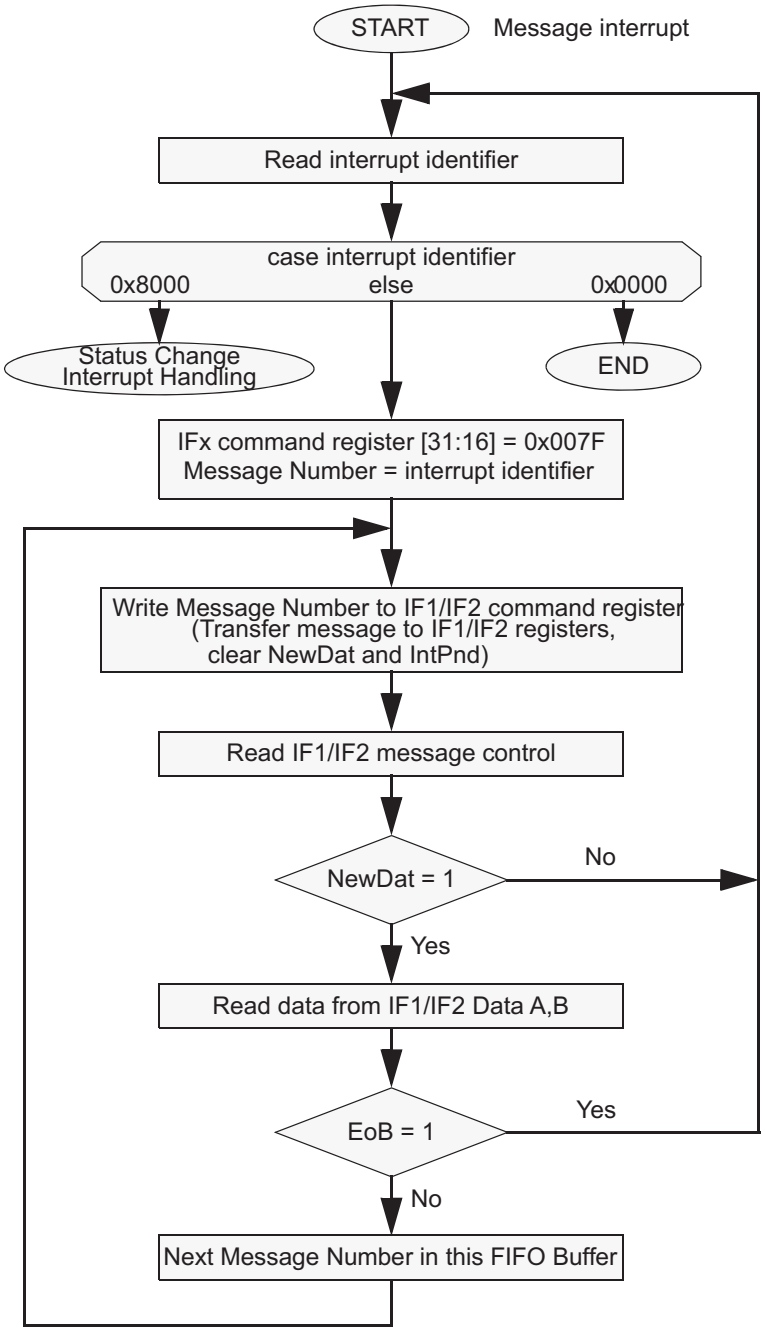
A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared.

A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 21-12.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 21-12. CPU Handling of a FIFO Buffer (Interrupt Driven)



21.9 CAN Message Transfer

Once the DCAN is initialized and Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to 1) at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes:

1. Interrupt mode
2. Polling mode.

The Interrupt Register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all Message Object's NewDat and TxRqst bits in parallel from the NewData X Registers and the Transmission Request X Registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers, all Receive Objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence, when the identifier mask is used, the arbitration bits that are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface Registers, as the Message Handler guarantees data consistency in case of concurrent accesses (for reconfiguration, see Section 21.7.6)

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending (for reconfiguration, see Section 21.7.7). However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

21.9.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to you before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit DAR (Disable Automatic Retransmission) in CAN Control Register. Further details to this mode are provided in Section 21.8.3.

21.9.2 Auto-Bus-On

Per default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature that is enabled by bit ABO in CAN Control Register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of VCLK cycles that can be defined in Auto-Bus-On Time Register.

NOTE: If the DCAN goes Bus-Off due to massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of Bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

21.10 Interrupt Functionality

Interrupts can be generated on two interrupt lines:

1. DCAN0INT line
2. DCAN1INT line

These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control Register.

The DCAN provides three groups of interrupt sources: Message Object Interrupts, Status Change Interrupts and Error Interrupts (see Figure 21-13 and Figure 21-14).

The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt Register (see). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the Interrupt Register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the Error and Status Register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt, may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 Command Register). When IntPnd is cleared, the Interrupt Register will point to the next message object with a pending interrupt.

21.10.1 Message Object Interrupts

Message Object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE, that are described in Section 21.5.1.

Message Object interrupts can be routed to either DCAN0INT or DCAN1INT line, controlled by the Interrupt Multiplexer Register (see).

21.10.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in Error and Status Register (DCAN ES) belong to the Status Change Interrupts. The Status Change Interrupt group can be enabled by bit in CAN Control Register.

If SIE is set, a Status Change Interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration.

Status Change interrupts can only be routed to interrupt line DCAN0INT that has to be enabled by setting IE0 in the CAN Control Register.

NOTE: Reading the Error and Status Register will clear the WakeUpPnd flag. If in global power down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur (additional information can be found in Section 21.11.2).

21.10.3 Error Interrupts

The events PER, BOff and EWarn (monitored in Error and Status Register, DCAN ES) belong to the Error Interrupts. The Error Interrupt group can be enabled by setting bit EIE in CAN Control Register.

Error interrupts can only be routed to interrupt line DCAN0INT that has to be enabled by setting IE0 in the CAN Control Register.

Figure 21-13. CAN Interrupt Topology 1

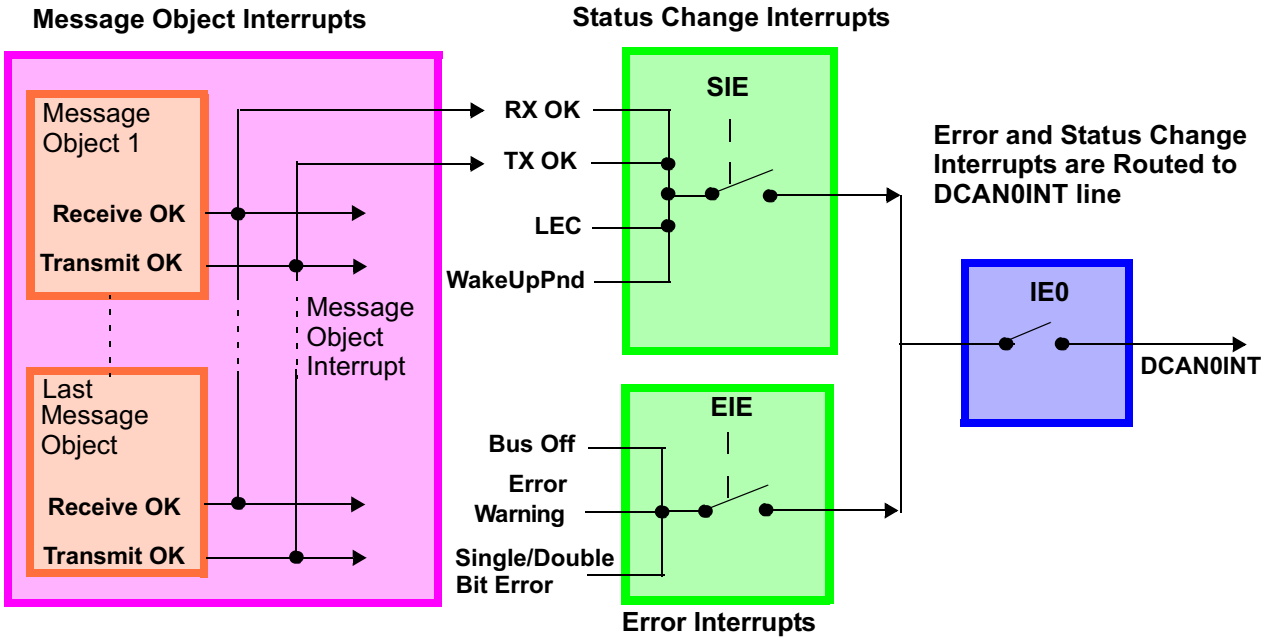


Figure 21-14. CAN Interrupt Topology 2

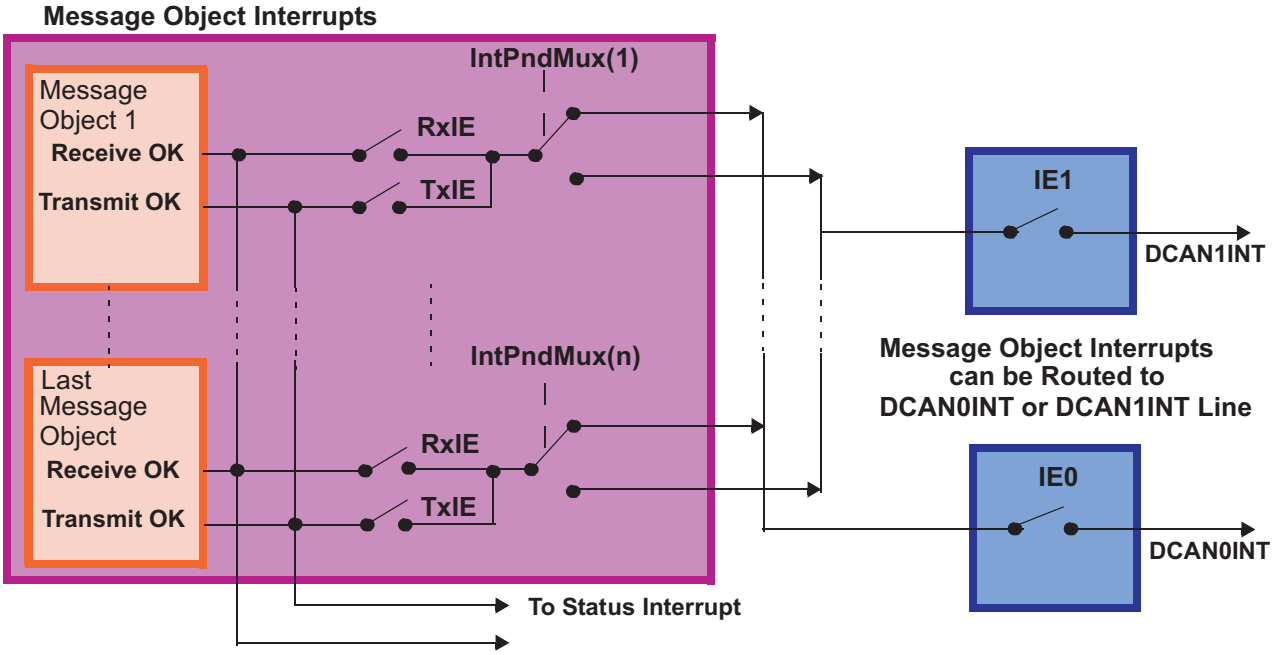


Details of Interrupt Mapping for actual device will be described in the device specific data sheet.

21.11 Global Power Down Mode

The device architecture supports a centralized global power down control over the peripheral modules through the Peripheral Central Resource (PCR) module (Additional information can be found in Platform Architecture Specification).

21.11.1 Entering Global Power Down Mode

The global power down mode for the DCAN is requested by setting the appropriate Peripheral Power Down Set bit (**PSPWRDWNSETx**) in the PCR module.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, the DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit to indicate that the global power down mode has been entered.

21.11.2 Wakeup From Global Power Down Mode

When the DCAN module is in global power down mode, a CAN bus activity detection circuit exists, which can be active, if enabled. If this circuit is active,on occurrence of a dominant CAN bus level, the DCAN will set the **WakeUpPnd** bit in Error and Status Register (DCAN ES).

If Status Interrupts are enabled, also an interrupt will be generated. This interrupt could be used by the application to wakeup the DCAN. For this, the application needs to set the appropriate Peripheral Power Down Clear bit (**PSPWRDWNCLRx**) in the PCR module, and to clear the Init bit in CAN Control Register.

After the Init bit has been cleared, the DCAN module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes Bus-Active again.

NOTE: The CAN transceiver circuit has to stay active during CAN bus activity detection. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down mode is lost.

21.12 Local Power Down Mode

Besides the centralized power down mechanism controlled by the PCR module (global power down, see Section 21.15), the DCAN supports a local power down mode that can be controlled within the DCAN control registers.

21.12.1 Entering Local Power Down Mode

The local power down mode is requested by setting the PDR bit in CAN Control Register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit in CAN Control Register to prevent any further CAN transfers, and it will also set the PDA bit in CAN Error and Status Register. With setting the PDA bits, the DCAN module indicates that the local power down mode has been entered.

During local power down mode, the internal clocks of the DCAN module are turned off, but there is a wake up logic (see Section 21.12.2) that can be active, if enabled. Also the actual contents of the control registers can be read back.

NOTE: In local low power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the Message RAM configured as to be transmitted and the application resets the init bit, these messages may be sent.

21.12.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power down mode:

1. The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control Register.
2. Alternatively, a CAN bus activity detection circuit can be activated by setting the wake up on bus activity bit (WUBA) in CAN Control Register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wake up sequence. It will clear the PDR bit in CAN Control Register and also clear the PDA bit in Error and Status Register. The WakeUpPnd bit in CAN Error and Status Register will be set. If Status Interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes Bus-Active again.

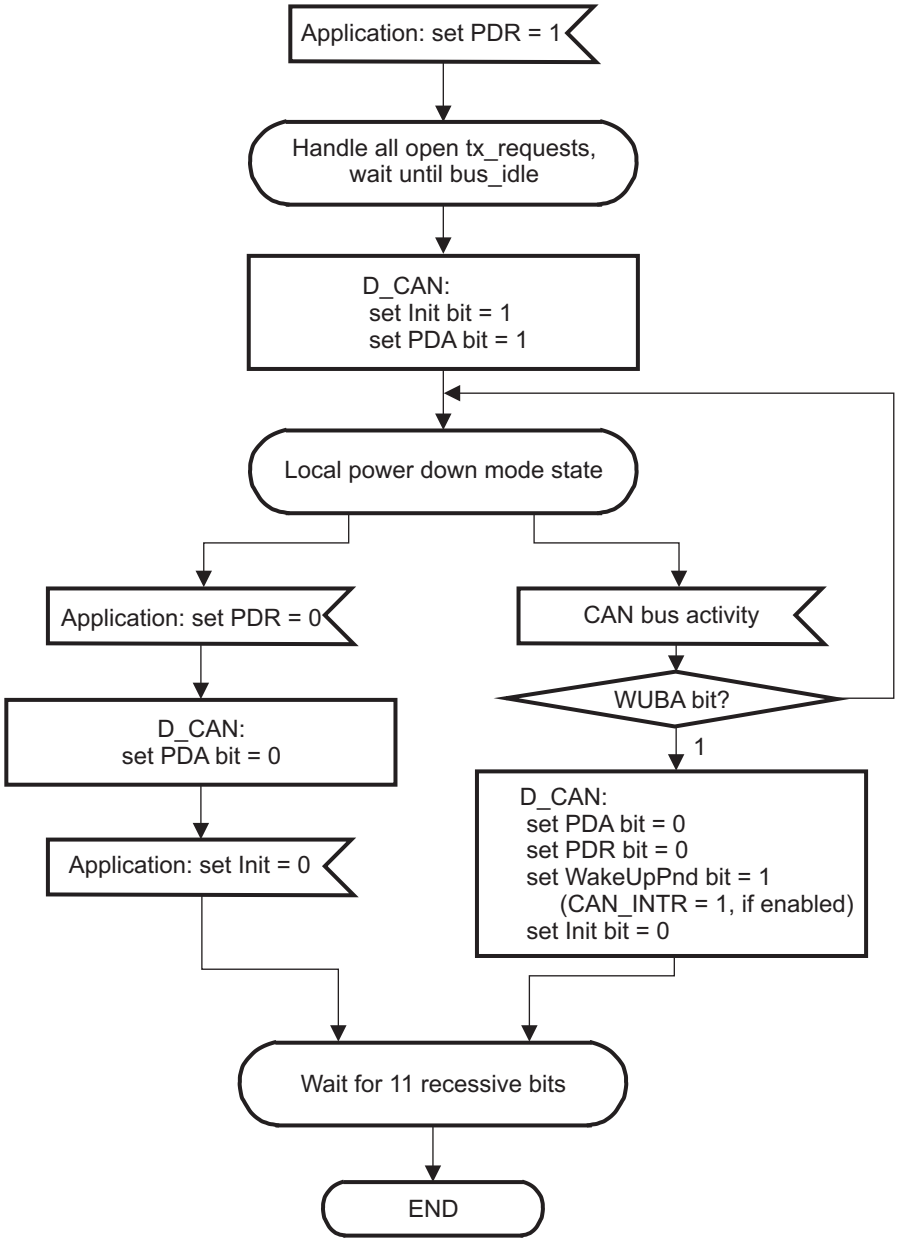
NOTE: The CAN transceiver circuit has to stay active while CAN bus observation. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, is lost.

Figure 21-15 shows a flow diagram about entering and leaving local power down mode.

21.13 GIO Support

The CAN_RX and CAN_TX pins of each DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO Control register (see) and the CAN RX IO Control register (see).

Figure 21-15. Local Power Down Mode Flow Diagram



21.14 Test Modes

The DCAN provides several test modes that are mainly intended for production tests or self test.

For all test modes, Test bit in the CAN Control Register needs to be set to one. This enables write access to the Test Register.

NOTE: When using any of the Loop Back modes, it must be ensured by software that all message transfers are finished before setting the Init bit to '1'.

21.14.1 Silent Mode

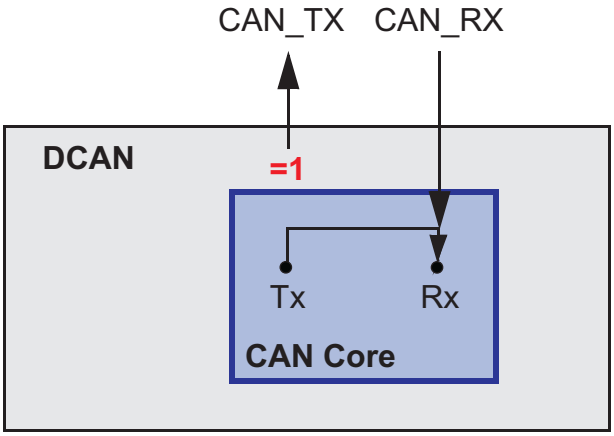
The Silent Mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN Core.

Figure 21-16 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in Silent Mode.

Silent Mode can be activated by setting the Silent bit in Test Register to 1.

In ISO 11898-1, the Silent Mode is called the Bus Monitoring Mode.

Figure 21-16. CAN Core in Silent Mode



21.14.2 Loop Back Mode

The Loop Back Mode is mainly intended for hardware self-test functions. In this mode, the CAN Core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN Core. Transmitted messages still can be monitored at the CAN_TX pin.

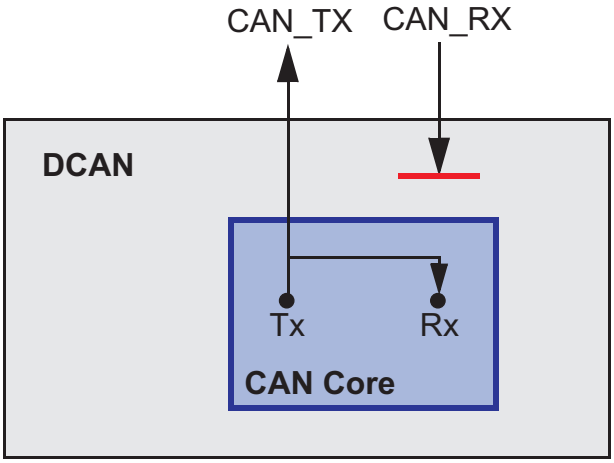
In order to be independent from external stimulation, the CAN Core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back Mode.

Figure 21-17 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in Loop Back Mode.

Loop Back Mode can be activated by setting bit LBack in Test Register to 1.

NOTE: In Loop Back mode, the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see External Loop Back mode (Section 21.14.3).

Figure 21-17. CAN Core in Loop Back Mode



21.14.3 External Loop Back Mode

The External Loop Back Mode is similar to the Loop Back Mode, however it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core. When External Loop Back Mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

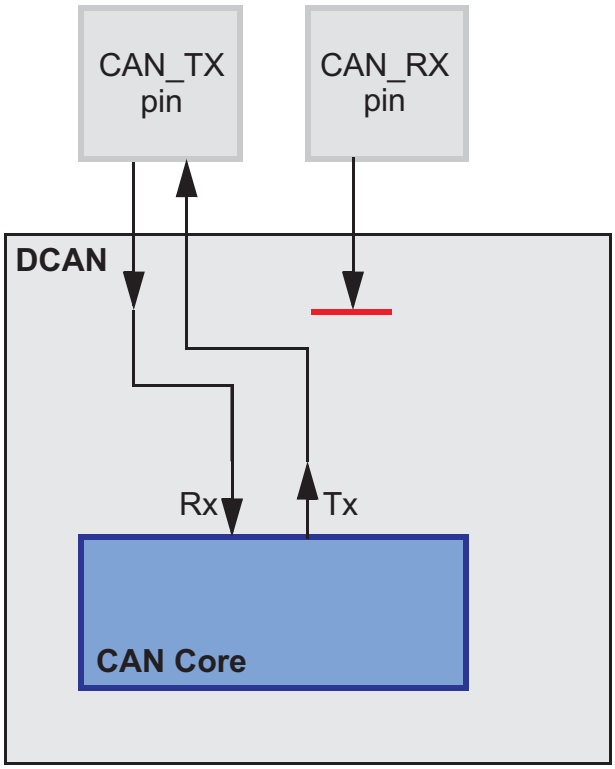
With this configuration, the Tx pin IO circuit can be tested.

External Loop Back Mode can be activated by setting bit ExL in Test Register to 1.

Figure 21-18 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in External Loop Back Mode.

NOTE: When Loop Back Mode is active (LBack bit set), the ExL bit will be ignored.

Figure 21-18. CAN Core in External Loop Back Mode

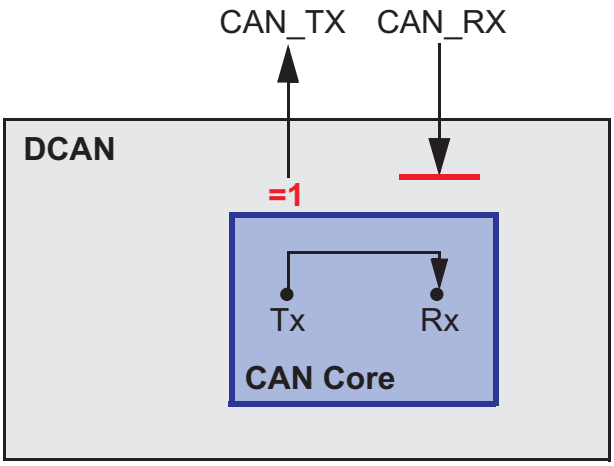


21.14.4 Loop Back Combined with Silent Mode

It is also possible to combine Loop Back Mode and Silent Mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest”, that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN_TX pin.

Figure 21-19 shows the connection of the signals CAN_TX and CAN_RX to the CAN Core in case of the combination of Loop Back Mode with Silent Mode.

Figure 21-19. CAN Core in Loop Back Combined with Silent Mode



21.14.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. Additionally to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN Sample Point signal to monitor the CAN Core’s bit timing.

Combined with the readable value of the CAN_RX pin, this can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the Test Register bits Tx[1:0] as described in .

NOTE: The software control for pin CAN_TX interferes with CAN protocol functions. For CAN message transfer or any of the test modes Loop Back Mode, External Loop Back Mode or Silent Mode, the CAN_TX pin should operate in its default functionality.

21.15 SECDED Mechanism

The DCAN module provides a single error correction and double error detection (SECDED) mechanism to ensure data integrity of Message RAM data. For each message object (136 bits) in the Message RAM, 9 ECC bits will be calculated. See Section 21.5.5.

The ECC bits are stored in a dedicated RAM. They will be generated on write accesses and will be checked on read accesses.

The SECDED functionality can be enabled or disabled by PMD bit field in CAN Control Register. If SECDED is enabled, ECC bits will be automatically generated and checked.

With the ECCMODE field in the ECC Control and Status register the single bit error correction can be enabled or disabled (default: enabled).

NOTE: During RAM initialization, no ECC check will be done, but if the PMD bit is set, the ECC bits will be generated.

21.15.1 Behavior on Single Bit Error

If a single bit error is detected with single bit error correction enabled, the correction will be done and the SEFLG in the ECC Control and Status register will be set.

If single bit error correction is disabled and a single bit error is detected then the SEFLG in the ECC Control and Status register and the the PER bit in the Error and Status register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object number where the single bit error has occurred will be indicated in the ECC Single Bit Error Code Register.

When single bit error correction is disabled the message object data can be read by the host CPU, independently of single bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the ECC Single Bit Error Code Register on single bit error interrupt.

21.15.2 Behavior on Double Bit Error

If a double bit error is detected, then the DEFLG in the ECC Control and Status register and the PER bit in Error and Status Register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset. The message object number will be indicated in the Parity Error Code Register.

The message object data can be read by the host CPU, independently of double bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on double bit error interrupt.

21.15.3 SECDED Testing

Testing of the SECDED mechanism can be implemented by using the diagnostic mode, which is enabled with the ECCDIAG register. The following procedure can be used:

1. Disable SECDED using DCAN control register. Enable diagnostic mode using the ECCDIAG register

2. Write to corrupt the data (in RDA mode) or ECC bits.

3. Enable SECDED and read data for which ECC is corrupted (either in RDA mode or via IFx registers).

4. Single bit error or double bit error flag will be set in the diagnostic status register (ECCDIAG STAT) and in the ECC Control and Status register accordingly. A double bit error or a single bit error with single bit error correction disabled also triggers the PER flag.

5. Disable diagnostic mode.

21.16 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making Message RAM content accessible via VBUSP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and Bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDS in CAN Control Register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in CAN Control Register.

During Debug/Suspend mode, all DCAN registers can be accessed. Reading reserved bits will return 0; writing to reserved bits will have no effect.

Also, the Message RAM will be memory mapped. This allows the external debug unit to read the Message RAM. For the memory organization, see Section 21.5.3).

NOTE: During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- Error and Status Register (clear of status flags by read)
- IF1/IF2 Command Registers (clear of DMAActive flag by read/write)

21.17 MSS_DCAN Registers

Table 21-6 lists the memory-mapped registers for the MSS_DCAN. All register offset addresses not listed in Table 21-6 should be considered as reserved locations and the register contents should not be modified.

Table 21-6. MSS_DCAN Registers

21.17.1 CTL Register (Offset = 0h) [reset = 1401h]

CTL is shown in Figure 21-20 and described in Table 21-8.

Return to Summary Table.

CAN Control Register The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities. When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the error and status register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

Table 21-8. CTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	
25	WUBA	R/W	0h	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0h (R/W) = No detection of a dominant CAN bus level while in local power-down mode. 1h (R/W) = Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started.
24	PDR	R/W	0h	Request for local low power-down mode 0h (R/W) = No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the Init bit has to be cleared. 1h (R/W) = Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the error and status register. The local clocks will be turned off by DCAN internal logic.
23-21	RESERVED	R	0h	
20	DE3	R/W	0h	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
19	DE2	R/W	0h	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled

Table 21-8. CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	DE1	R/W	0h	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
17	IE1	R/W	0h	Interrupt line 1 enable 0h (R/W) = Disabled - Module interrupt DCAN1INT is always low. 1h (R/W) = Enabled - interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed.
16	InitDbg	R	0h	Internal init state while debug access 0h (R/W) = Not in debug mode, or debug mode requested but not entered. 1h (R/W) = Debug mode requested and internally entered; the DCAN is ready for debug accesses.
15	SWR	R/WP	0h	SW reset enable. Note: To execute software reset, the following procedure is necessary: (a) Set Init bit to shut down CAN communication and (b) Set SWR bit additionally to Init bit. 0h (R/W) = Normal Operation 1h (R/W) = Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one OCP clock cycle.
14	RESERVED	R	0h	
13-10	PMD	R/W	5h	Parity on/off. 5 = Parity function disabled. Others = Parity function enabled.
9	ABO	R/W	0h	Auto-Bus-On enable 0h (R/W) = The Auto-Bus-On feature is disabled 1h (R/W) = The Auto-Bus-On feature is enabled
8	IDS	R/W	0h	Interruption debug support enable 0h (R/W) = When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1h (R/W) = When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	Test	R/W	0h	Test mode enable 0h (R/W) = Normal Operation 1h (R/W) = Test Mode
6	CCE	R/W	0h	Configuration change enable 0h (R/W) = The CPU has no write access to the configuration registers. 1h (R/W) = The CPU has write access to the configuration registers (when Init bit is set).
5	DAR	R/W	0h	Disable automatic retransmission 0h (R/W) = Automatic retransmission of not successful messages enabled. 1h (R/W) = Automatic retransmission disabled.
4	RESERVED	R	0h	
3	EIE	R/W	0h	Error interrupt enable 0h (R/W) = Disabled - PER, BOff and EWarn bits can not generate an interrupt. 1h (R/W) = Enabled - PER, BOff and EWarn bits can generate an interrupt at DCAN0INT line and affect the interrupt register.

Table 21-8. CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	SIE	R/W	0h	Status change interrupt enable 0h (R/W) = Disabled - WakeUpPnd, RxOk, TxOk and LEC bits can not generate an interrupt. 1h (R/W) = Enabled - WakeUpPnd, RxOk, TxOk and LEC can generate an interrupt at DCAN0INT line and affect the interrupt register.
1	IE0	R/W	0h	Interrupt line 0 enable 0h (R/W) = Disabled - Module interrupt DCAN0INT is always low. 1h (R/W) = Enabled - interrupts will assert line DCAN0INT to one; line remains active until pending interrupts are processed.
0	Init	R/W	1h	Initialization 0h (R/W) = Normal operation 1h (R/W) = Initialization mode is entered

21.17.2 ES Register (Offset = 4h) [reset = 7h]

ES is shown in Figure 21-21 and described in Table 21-9.

Return to Summary Table.

Status Register Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN control register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN control register is set). A change of bit EPass will not generate an interrupt. Reading the error and status register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the interrupt register will be replaced by the next lower priority interrupt value. The EOI for all other interrupts (DCANINT0 and DCANINT1) are automatically handled by hardware. For debug support, the auto clear functionality of error and status register (clear of status flags by read) is disabled when in debug/suspend mode.

Table 21-9. ES Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	
10	PDA	R	0h	Local power-down mode acknowledge 0h (R/W) = DCAN is not in local power-down mode. 1h (R/W) = Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.
9	WakeUp_Pnd	R	0h	Wake up pending. This bit can be used by the CPU to identify the DCAN as the source to wake up the system. This bit will be reset if error and status register is read. 0h (R/W) = No Wake Up is requested by DCAN. 1h (R/W) = DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.
8	PER_	R	0h	Parity error detected. This bit will be reset if error and status register is read. 0h (R/W) = No parity error has been detected since last read access. 1h (R/W) = The parity check mechanism has detected a parity error in the Message RAM.
7	BOff	R	0h	Bus-Off state 0h (R/W) = The CAN module is not bus-off state. 1h (R/W) = The CAN module is in bus-off state.
6	EWarn	R	0h	Warning state 0h (R/W) = Both error counters are below the error warning limit of 96. 1h (R/W) = At least one of the error counters has reached the error warning limit of 96.

Table 21-9. ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	EPass	R	0h	Error passive state 0h (R/W) = On CAN Bus error, the DCAN could send active error frames. 1h (R/W) = The CAN core is in the error passive state as defined in the CAN Specification.
4	RxOk	R	0h	Received a message successfully. This bit will be reset if error and status register is read. 0h (R/W) = No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. 1h (R/W) = A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering).
3	TxOk	R	0h	Transmitted a message successfully. This bit will be reset if error and status register is read. 0h (R/W) = No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. 1h (R/W) = A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU.
2-0	LEC	R	7h	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0h (R/W) = No error 1h (R/W) = Stuff error. More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 2h (R/W) = Form error. A fixed format part of a received frame has the wrong format. 3h (R/W) = Ack error. The message this CAN core transmitted was not acknowledged by another node. 4h (R/W) = Bit1 error. During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5h (R/W) = Bit0 error. During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6h (R/W) = CRC error. In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 7h (R/W) = No CAN bus event was detected since the last time the CPU read the error and status register. Any read access to the error and status register re-initializes the LEC to value '7.'

21.17.3 ERRC Register (Offset = 8h) [reset = 0h]

ERRC is shown in Figure 21-22 and described in Table 21-10.

Return to Summary Table.

Error Counter Register

14-8	REC	R	0h	Receive error counter. Actual state of the receive error counter (values from 0 to 255).
7-0	TEC	R	0h	Transmit error counter. Actual state of the transmit error counter (values from 0 to 255).

21.17.4 BTR Register (Offset = Ch) [reset = 2301h]

BTR is shown in Figure 21-23 and described in Table 21-11.

Return to Summary Table.

Bit Timing/BRP Extension Register This register is only writable if CCE and Init bits in the CAN control register are set. The CAN bit time may be programmed in the range of 8 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods. With a CAN_CLK of 8 MHz and BRPE = 0x00, the reset value of 0x00002301 configures the DCAN for a bit rate of 500kBit/s.

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	
19-16	BRPE	R	0h	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.
15	RESERVED	R	0h	
14-12	TSeg2	R/WP	2h	Time segment after the sample point. Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.
11-8	TSeg1	R/WP	3h	Time segment before the sample point. Valid programmed values are 1 to 15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.
7-6	SJW	R/WP	0h	Synchronization Jump Width. Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.
5-0	BRP	R/WP	1h	Baud rate prescaler. Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.

21.17.5 INT Register (Offset = 10h) [reset = 0h]

INT is shown in Figure 21-24 and described in Table 21-12.

Return to Summary Table.

Interrupt Register

Figure 21-24. INT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								Int1ID								Int0ID															
R-0h								R-0h								R-0h															

Table 21-12. INT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	
23-16	Int1ID	R	0h	Interrupt 1 Identifier (indicates the message object with the highest pending interrupt). If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared. A message interrupt is cleared by clearing the message object's IntPnd bit. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0h (R/W) = No interrupt is pending. 80h (R/W) = Number of message object which caused the interrupt.
15-0	Int0ID	R	0h	Interrupt Identifier (the number here indicates the source of the interrupt). If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0h (R/W) = Unused. 0080h (R/W) = Number of message object which caused the interrupt. 1F40h (R/W) = Error and status register value is not 0x07.

21.17.6 TEST Register (Offset = 14h) [reset = 80h]

TEST is shown in Figure 21-25 and described in Table 21-13.

Return to Summary Table.

Test Register For all test modes, the test bit in CAN control register needs to be set to one. If test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when test bit is cleared. The test register is only writable if test bit in CAN control register is set. Setting Tx[1:0] other than '00' will disturb message transfer. When the internal loop-back mode is active (bit LBack is set), bit EXL will be ignored.

21.17.8 PERR Register (Offset = 1Ch) [reset = 0h]

PERR is shown in Figure 21-27 and described in Table 21-15.

Return to Summary Table.

Parity Error Code Register If a parity error is detected, the PER flag will be set in the error and status register. This bit is not reset by the parity check mechanism; it must be reset by reading the error and status register. In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

21.17.35 TXRQ12 Register (Offset = 88h) [reset = 0h]

TXRQ12 is shown in Figure 21-54 and described in Table 21-42.

Return to Summary Table.

Transmission Request Register The TXRQ12 to TXRQ78 registers hold the TxRqst bits of the implemented message objects. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific message object can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

15-0	TxRqs_0	R	0h	Transmission request bits (for all message objects) 0h (R/W) = No transmission has been requested for this message object. 1h (R/W) = The transmission of this message object is requested and is not yet done.

21.17.39 NWDAT_X Register (Offset = 98h) [reset = 0h]

NWDAT_X is shown in Figure 21-58 and described in Table 21-46.

Return to Summary Table.

New Data X Register With the new data X register, the CPU can detect if one or more bits in the different new data registers are set. Each register bit represents a group of eight message objects. If at least on of the NewDat bits of these message objects are set, the corresponding bit in the new data X register will be set. Example 1. Bit 0 of the new data X register represents byte 0 of the new data 1 register. If one or more bits in this byte are set, bit 0 of the new data X register will be set.

21.17.55 INTMUX12 Register (Offset = D8h) [reset = 0h]

INTMUX12 is shown in Figure 21-74 and described in Table 21-62.

Return to Summary Table.

Interrupt Pending Multiplexer Register The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

Bit	Field	Type	Reset	Description
31-16	IntMux_1	R	0h	Multiplexes IntPnd value to either DCAN0INT or DCAN1INT interrupt lines (for all message objects) 0h (R/W) = DCAN0INT line is active if corresponding IntPnd flag is one. 1h (R/W) = DCAN1INT line is active if corresponding IntPnd flag is one.
15-0	IntMux_0	R	0h	Multiplexes IntPnd value to either DCAN0INT or DCAN1INT interrupt lines (for all message objects) 0h (R/W) = DCAN0INT line is active if corresponding IntPnd flag is one. 1h (R/W) = DCAN1INT line is active if corresponding IntPnd flag is one.

21.17.56 INTMUX34 Register (Offset = DCh) [reset = 0h]

INTMUX34 is shown in Figure 21-75 and described in Table 21-63.

Return to Summary Table.

Interrupt Pending Multiplexer Register The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

21.17.65 IF1CMD Register (Offset = 100h) [reset = 1h]

IF1CMD is shown in Figure 21-84 and described in Table 21-72.

Return to Summary Table.

IF1 Command Register The IF1 Command Register (IF1CMD) configures and initiates the transfer between the IF1 register sets and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both IF1 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While Busy bit is one, IF1 register sets are write protected. For debug support, the auto clear functionality of the IF1 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] of the IF1 command register, the message handler may access an implemented (valid) message object instead.

23	WR_RD	R/WP	0h	Write/Read 0h (R/W) = Direction = Read: Transfer direction is from the message object addressed by Message Number (Bits [7:0]) to the IF1 register set. 1h (R/W) = Direction = Write: Transfer direction is from the IF1 register set to the message object addressed by Message Number (Bits [7:0]).
22	Mask	R/WP	0h	Access mask bits 0h (R/W) = Mask bits will not be changed 1h (R/W) = Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF1 register set. Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1 register set to the message object addressed by Message Number (Bits [7:0]).

Table 21-72. IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	Arb	R/WP	0h	Access arbitration bits 0h (R/W) = Arbitration bits will not be changed 1h (R/W) = Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1 register set. Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1 register set to the message object addressed by Message Number (Bits [7:0]).
20	Control	R/WP	0h	Access control bits. If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF1 message control register will be ignored. 0h (R/W) = Control bits will not be changed 1h (R/W) = Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF1 register set. Direction = Write: The message control bits will be transferred from the IF1 register set to the message object addressed by message number (Bits [7:0]).
19	ClrIntPnd	R/WP	0h	Clear interrupt pending bit 0h (R/W) = IntPnd bit will not be changed 1h (R/W) = Direction = Read: Clears IntPnd bit in the message object. Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1 Registers to message RAM can only be controlled by the control flag (Bit [20]).
18	TxRqst_NewDat	R/WP	0h	Access transmission request bit. Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF1 message control Register. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1 message control register always reflect the status before resetting them. 0h (R/W) = Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit. 1h (R/W) = Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in message object.
17	Data_A	R/WP	0h	Access Data Bytes 0 to 3. 0h (R/W) = Data Bytes 0-3 will not be changed. 1h (R/W) = Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1 register set. Direction = Write: The data bytes 0-3 will be transferred from the IF1 register set to the message object addressed by the Message Number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
16	Data_B	R/WP	0h	Access Data Bytes 4 to 7. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1 register set. Direction = Write: The data bytes 4-7 will be transferred from the IF1 register set to the message object addressed by message number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	Busy	R/WP	0h	Busy flag. This bit is set to one after the message number has been written to bits 7 to 0. IF1 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF1 register set and message RAM is in progress. 1h (R/W) = Transfer between IF1 register set and message RAM is in progress.

Table 21-72. IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAactive	R/WP	0h	Activation of DMA feature for subsequent internal IF1 update. Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF1 activities. 1h (R/W) = DMA is requested after completed transfer between IF1 register set and message RAM. The DMA request remains active until the first read or write to one of the IF1 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
13-8	RESERVED	R	0h	
7-0	Message_Number	R/WP	1h	Number of message object in message RAM which is used for data transfer. 0h (R/W) = Invalid message numbers. 1h (R/W) = Valid message numbers (value 01 to 80). 50h (R/W) = Valid message number. 51h (R/W) = Invalid message numbers (value 81 to FF).

21.17.66 IF1MSK Register (Offset = 104h) [reset = FFFFFFFFh]

IF1MSK is shown in Figure 21-85 and described in Table 21-73.

Return to Summary Table.

IF1 Mask Register The bits of the IF1 mask registers mirror the mask bits of a message object. While Busy bit of IF1 command register is one, IF1 register set is write protected.

21.17.73 IF2CMD Register (Offset = 120h) [reset = 1h]

IF2CMD is shown in Figure 21-92 and described in Table 21-80.

Return to Summary Table.

IF2 Command Register The IF2 Command Register (IF1CMD) configures and initiates the transfer between the IF2 register sets and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF2 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both IF2 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While Busy bit is one, IF2 register sets are write protected. For debug support, the auto clear functionality of the IF2 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] of the IF2 command register, the message handler may access an implemented (valid) message object instead.

22	Mask	R/WP	0h	Access mask bits 0h (R/W) = Mask bits will not be changed 1h (R/W) = Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF2 register set. Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF2 register set to the message object addressed by Message Number (Bits [7:0]).

Table 21-80. IF2CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	Arb	R/WP	0h	Access arbitration bits 0h (R/W) = Arbitration bits will not be changed 1h (R/W) = Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF2 register set. Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF2 register set to the message object addressed by Message Number (Bits [7:0]).
20	Control	R/WP	0h	Access control bits. If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF2 message control register will be ignored. 0h (R/W) = Control bits will not be changed 1h (R/W) = Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF2 register set. Direction = Write: The message control bits will be transferred from the IF2 register set to the message object addressed by message number (Bits [7:0]).
19	ClrIntPnd	R/WP	0h	Clear interrupt pending bit 0h (R/W) = IntPnd bit will not be changed 1h (R/W) = Direction = Read: Clears IntPnd bit in the message object. Direction = Write: This bit is ignored. Copying of IntPnd flag from IF2 Registers to message RAM can only be controlled by the control flag (Bit [20]).
18	TxRqst_NewDat	R/WP	0h	Access transmission request bit. Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF2 message control Register. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF2 message control register always reflect the status before resetting them. 0h (R/W) = Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit. 1h (R/W) = Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in message object.
17	Data_A	R/WP	0h	Access Data Bytes 0 to 3. 0h (R/W) = Data Bytes 0-3 will not be changed. 1h (R/W) = Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF2 register set. Direction = Write: The data bytes 0-3 will be transferred from the IF2 register set to the message object addressed by the Message Number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
16	Data_B	R/WP	0h	Access Data Bytes 4 to 7. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF2 register set. Direction = Write: The data bytes 4-7 will be transferred from the IF2 register set to the message object addressed by message number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	Busy	R/WP	0h	Busy flag. This bit is set to one after the message number has been written to bits 7 to 0. IF2 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF2 register set and message RAM is in progress. 1h (R/W) = Transfer between IF2 register set and message RAM is in progress.

Table 21-80. IF2CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAactive	R/WP	0h	Activation of DMA feature for subsequent internal IF2 update. Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF2 activities. 1h (R/W) = DMA is requested after completed transfer between IF2 register set and message RAM. The DMA request remains active until the first read or write to one of the IF2 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
13-8	RESERVED	R	0h	
7-0	Message_Number	R/WP	1h	Number of message object in message RAM which is used for data transfer. 0h (R/W) = Invalid message number. 1h (R/W) = Valid message numbers (values 01 to 80). 50h (R/W) = Valid message number. 51h (R/W) = Invalid message numbers (values 81 to FF).

21.17.74 IF2MSK Register (Offset = 124h) [reset = FFFFFFFFh]

IF2MSK is shown in Figure 21-93 and described in Table 21-81.

Return to Summary Table.

IF2 Mask Register The bits of the IF2 mask registers mirror the mask bits of a message object. While Busy bit of IF2 command register is one, IF2 register set is write protected.

21.17.81 IF3OBS Register (Offset = 140h) [reset = 0h]

IF3OBS is shown in Figure 21-100 and described in Table 21-88.

Return to Summary Table.

IF3 Observation Register The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The observation flags (Bits [4:0]) in the IF3 observation register are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read. Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]). If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device-specific data sheet for the availability of this interrupt source. With this interrupt, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

0	In	R	0h	CAN_RX data in. Note: When CAN_RX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (for example, while reset of the DCAN module). 0h (R/W) = The CAN_RX pin is at logic low 1h (R/W) = The CAN_RX pin is at logic high

Modular Controller Area Network (MCAN)

This section describes the Modular Controller Area Network (MCAN).

Topic **Page**

22.1 MCAN (14xx,16xx,18xx) 2600
22.2 Modular Controller Area Network (68xx MCAN) 2733

22.1 MCAN (14xx,16xx,18xx)

22.1.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 10 Mbit/s data rate and is compliant to the CAN protocol specification 2.0 part A, B and ISO 11898-1.

22.1.1.1 Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock / Host clock)
- Parity / ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)
- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

22.1.2 MCAN Functional Description

The MCAN module performs CAN protocol communication according to the CAN protocol Specification 2.0 part A, B and ISO 11898-1. The bit rate can be programmed to values up to 10 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

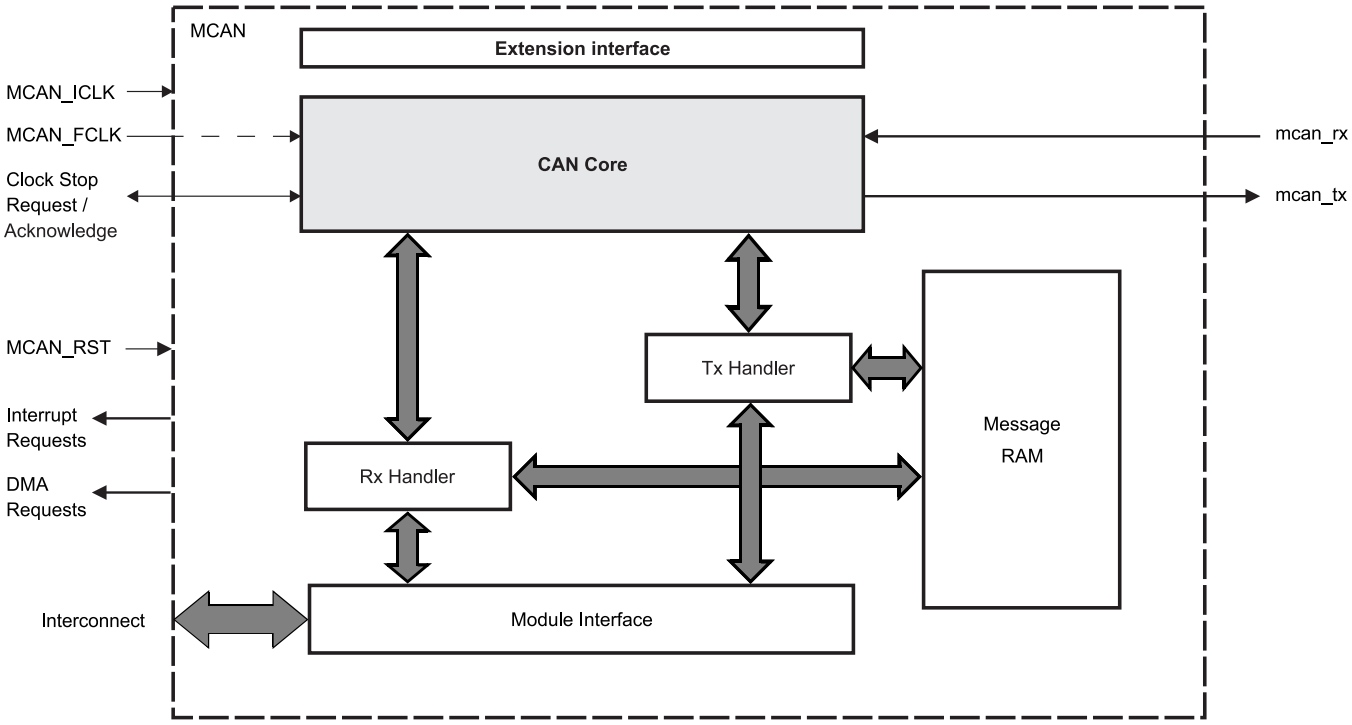
For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 22-1 shows the MCAN module block diagram.

Figure 22-1. MCAN Block Diagram



The MCAN module blocks description:

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions and supports 11-bit and 29-bit identifiers.
- **Tx Handler**: Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them.
- **Rx Handler**: Controls the transfer of received messages from the CAN Core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 22.1.2.11, *Message RAM*).
- **Module Interface**: The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.
- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).

- **Extension Interface**: All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

22.1.2.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

NOTE: MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$f_{0,\ ICLK}(OCP) \pm \Delta f_{FM,\ ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see , *PRCM* and the device data manual.

22.1.2.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see Section 22.1.2.4.8.2, *Suspend Mode*).

22.1.2.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write '1' to MCANSS_ECC_EOI[8] ECC_EOI bit (for more information, see Section 22.1.2.7.2, *ECC Aggregator*).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see Section 22.1.2.5.1, *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status (MCANSS_IES)
- End Of Interrupt (MCANSS_EOI)
- External Timestamp Prescaler (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

22.1.2.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extention Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

22.1.2.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing '1' to MCAN_CCCR[8] FDOE bit. A value of '0' on the primary configuration port (mcanss_enable_fdoe) will force the MCAN_CCCR[8] FDOE bit during write to the MCAN_CCCR register which will prevent the device from enabling and using the CAN FD mode.

22.1.2.4 Operating Modes

22.1.2.4.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to '1' starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output mcan_tx pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = '1'. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15:0] TOC field is preset to the value configured by the MCAN_TOCC[31:16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = '1'.

The following registers are only writeable while MCAN_CCCR[1] CCE = '0'

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = '1' and MCAN_CCCR[1] CCE = '1'. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = '1' and MCAN_CCCR[1] CCE = '1'.

22.1.2.4.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0 / Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

NOTE: Automated transmission on reception of remote frames is not supported.

22.1.2.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical '1') signifies a CAN FD frame, FDF = dominant (logical '0') signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = '0'), this causes the operation state to change from Receiver (MCAN_PSR[4:3] ACT = '10') to Integrating (MCAN_PSR[4:3] ACT = '00') at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = '1'), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = '1', transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = '0', received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = '0', the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = '1' and MCAN_CCCR[9] BRSE = '0', only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = '1' and MCAN_CCCR[9] BRSE = '1', transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

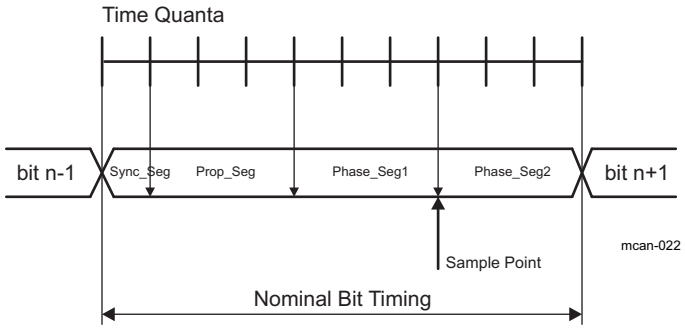
The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to Table 22-1.

Table 22-1. DLC Coding in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

For CAN FD frames with bit rate switchingIn, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 22-2) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

Figure 22-2. CAN Bit Timing



The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

22.1.2.4.4 Transmitter Delay Compensation

22.1.2.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the mcan_tx pin the MCAN module receives the transmitted data from its local CAN transceiver via the mcan_rx pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

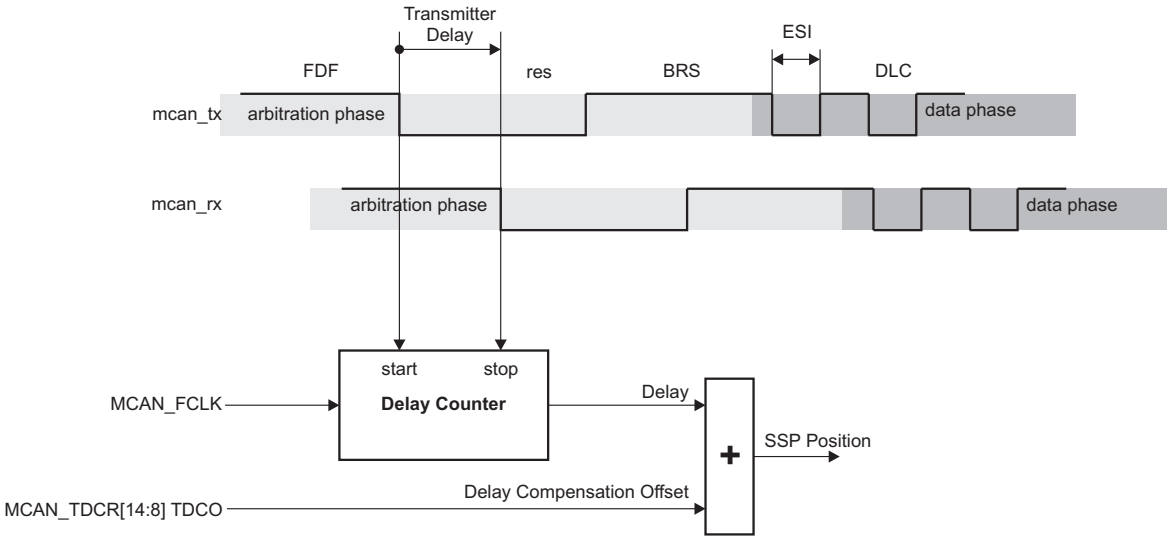
The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in the new ISO11898-1). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to '1'.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output mcan_tx pin through the transceiver to the receive input mcan_rx pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14:8] TDCO field (see Figure 22-3). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22:16] TDCV field. This filed is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

Figure 22-3. Transmitter Delay Measurement



22.1.2.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = '1'), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input mcan_rx pin of the transmitter. The resolution of this measurement is one mtq (see Figure 22-3). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6:0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the mcan_rx pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6:0] TDCF field and the mcan_rx pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the mcan_tx pin to the mcan_rx pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the mcan_tx pin to the mcan_rx pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

22.1.2.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The recieve and transmit error counters (MCAN_ECR[14:8] REC and MCAN_ECR[7:0] TEC) are frozen while CAN error logging (MCAN_ECR[23:16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[1] INIT bits are set to '1'.

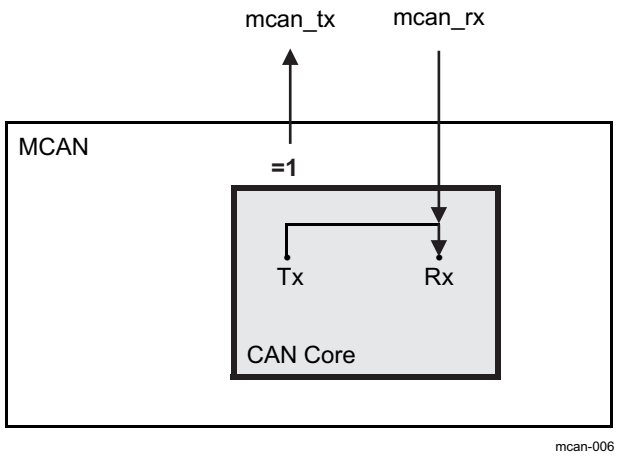
The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

NOTE: The Restricted Operation Mode must not be combined with the Loop Back Mode.

22.1.2.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN_CCCR[5] MON bit to '1'. In this mode (see ISO11898-1, *Bus Monitoring*), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 22-4 shows the connection of the mcan_tx and mcan_rx signals to the MCAN module in Bus Monitoring Mode.

Figure 22-4. Connection of Signals in Bus Monitoring Mode



22.1.2.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1, *Recovery Management*), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR[6] DAR bit).

22.1.2.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = '10' (transmission in spite of cancellation).

22.1.2.4.8 Power Down (Sleep Mode)

Entering Power Down mode is controlled via the input clock stop request signal (mcanss_clkstp_clkstop_req) or MCAN_CCCR[4] CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as '1'. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[1] INIT to '1' to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal (mcanss_clkstop_clkstop_ack) to '1' and the MCAN_CCCR[3] CSA bit to '1'. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR[1] INIT bit will have no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN_CCCR[1] INIT bit.

22.1.2.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to '1' (for more information, see Section 22.1.2.4.8.3, *Wakeup request*). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

22.1.2.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] FREE and MCANSS_CTRL[2] SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to '1' (for more information, see Section 22.1.2.4.8.3, *Wakeup request*). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23:16] CEL
- MCAN_PSR[2:0] LEC
- MCAN_PSR[10:8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

22.1.2.4.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive mcan_rx pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the MCANSS_CTRL[4] WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

22.1.2.4.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to '1'. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit mcan_tx pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6:5] TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

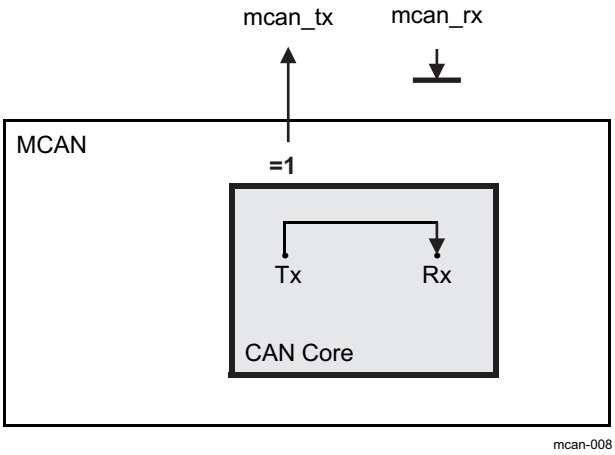
The actual value of the CAN receive mcan_rx pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6:5] TX filed until the new configuration is visible at the output mcan_tx pin. This applies also when reading input mcan_rx pin via the MCAN_TEST[7] RX bit.

NOTE: Test modes should be used for self test only. The software control for mcan_tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

22.1.2.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to '1'. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the mcan_tx and mcan_rx pins. In this mode mcan_rx pin is disconnected from the MCAN module and mcan_tx pin is held recessive. Figure 22-5 shows the connection of the mcan_tx and mcan_rx pins to the MCAN module in case of Internal Loop Back Mode.

Figure 22-5. Internal Loop Back Mode



22.1.2.5 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19:16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15:0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 22.1.2.11, *Message RAM*.

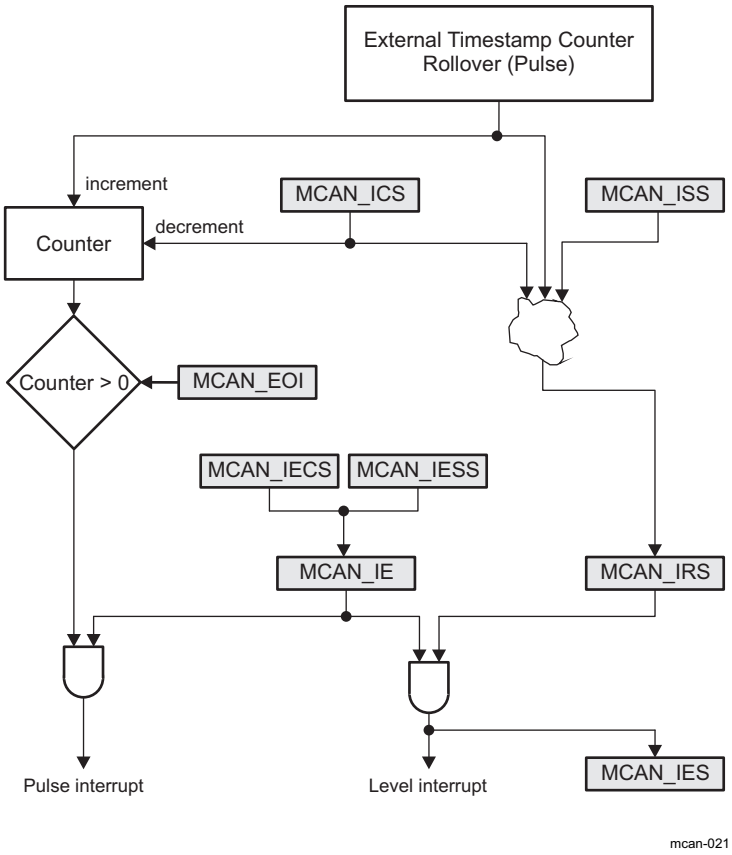
22.1.2.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1:0] TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23:0] PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN_IRQ_TS interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the MCANSS_IRS register is set (see Figure 22-6). The MCANSS_IE register can be affected by writing to the MCAN_IESS register to set or to the MCANSS_IECS register to clear. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

Figure 22-6. External Timestamp Counter Interrupt



22.1.2.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19:16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15:0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[1] INIT = '0' and stopped when MCAN_CCCR[1] INIT = '1' (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2:1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_TOCV[1] INIT = '0', a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31:16] TOP field.

22.1.2.7 Safety

The Message Memory is wrapped in an ECC wrapper provididing SECDED parity functionalilty. The ECC wrapper is controlled by an ECC Aggregator.

22.1.2.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

22.1.2.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

22.1.2.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

22.1.2.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register (MCANSS_ECC_AGGR_REVISION), ECC Vector Register (MCANSS_ECC_VECTOR), Misc Status Register (MCANSS_ECC_MISC_STATUS), ECC Control Register (MCANSS_ECC_CONTROL), and ECC Wrapper Revision Register (MCANSS_ECC_WRAP_REVISION).
- Control and status registers - ECC Error Control Registers (MCANSS_ECC_ERR_CTRL1 and MCANSS_ECC_ERR_CTRL2) and ECC Error Status Registers (MCANSS_ECC_ERR_STAT1 and MCANSS_ECC_ERR_STAT2).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANSS_ECC_SEC_EOI_REG
  - MCANSS_ECC_SEC_STATUS_REG0
  - MCANSS_ECC_SEC_ENABLE_SET_REG0
  - MCANSS_ECC_SEC_ENABLE_CLR_REG0
  - MCANSS_ECC_DED_EOI_REG
  - MCANSS_ECC_DED_STATUS_REG0
  - MCANSS_ECC_DED_ENABLE_SET_REG0
  - MCANSS_ECC_DED_ENABLE_CLR_REG0

22.1.2.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR field to select the ECC RAM for control or status.

- Software writes '1' to the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.
- Software then polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is '1'. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

22.1.2.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the MCANSS_ECC_SEC_ENABLE_SET_REG0 / MCANSS_ECC_DED_ENABLE_SET_REG0 register.
- Software writes the ECC RAM ID in the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR.
- Software writes the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger the read.
- Software writes the MCANSS_ECC_ERR_STAT1 register address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the MCANSS_ECC_VECTOR register again if it needs to read the MCANSS_ECC_ERR_STAT2 register.
- Software polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit. When this bit is set, a read of the MCANSS_ECC_ERR_STAT1 / MCANSS_ECC_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANSS_ECC_ERR_STAT1[8] CLR_ECC_SEC or MCANSS_ECC_ERR_STAT1[9] CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the MCANSS_ECC_ERR_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANSS_ECC_SEC_EOI_REG / MCANSS_ECC_DED_EOI_REG register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write '1' to the MCANSS_ECC_EOI[8] ECC_EOI bit.

22.1.2.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

22.1.2.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled / disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 22.1.2.11, *Message RAM*) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see Section 22.1.2.2.1, *DMA Requests*.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
  New Data flag (MCAN_NDAT1 / MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields).
- Rx FIFO:
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 22.1.2.8.2.2 have to be considered.

22.1.2.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = '00' / Extended Filter Type EFT = '00'). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 22.1.2.11.5, *Standard Message ID Filter Element* and Section 22.1.2.11.6, *Extended Message ID Filter Element*.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = '00': The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = '11': The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

22.1.2.8.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT ='01' / Extended Filter Type EFT ='01'). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see Section 22.1.2.11.5, *Standard Message ID Filter Element* and Section 22.1.2.11.6, *Extended Message ID Filter Element*.

22.1.2.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT ='10' / Extended Filter Type EFT ='10'). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A '0' bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are '1' are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are '1': a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are '0': all Message IDs match.

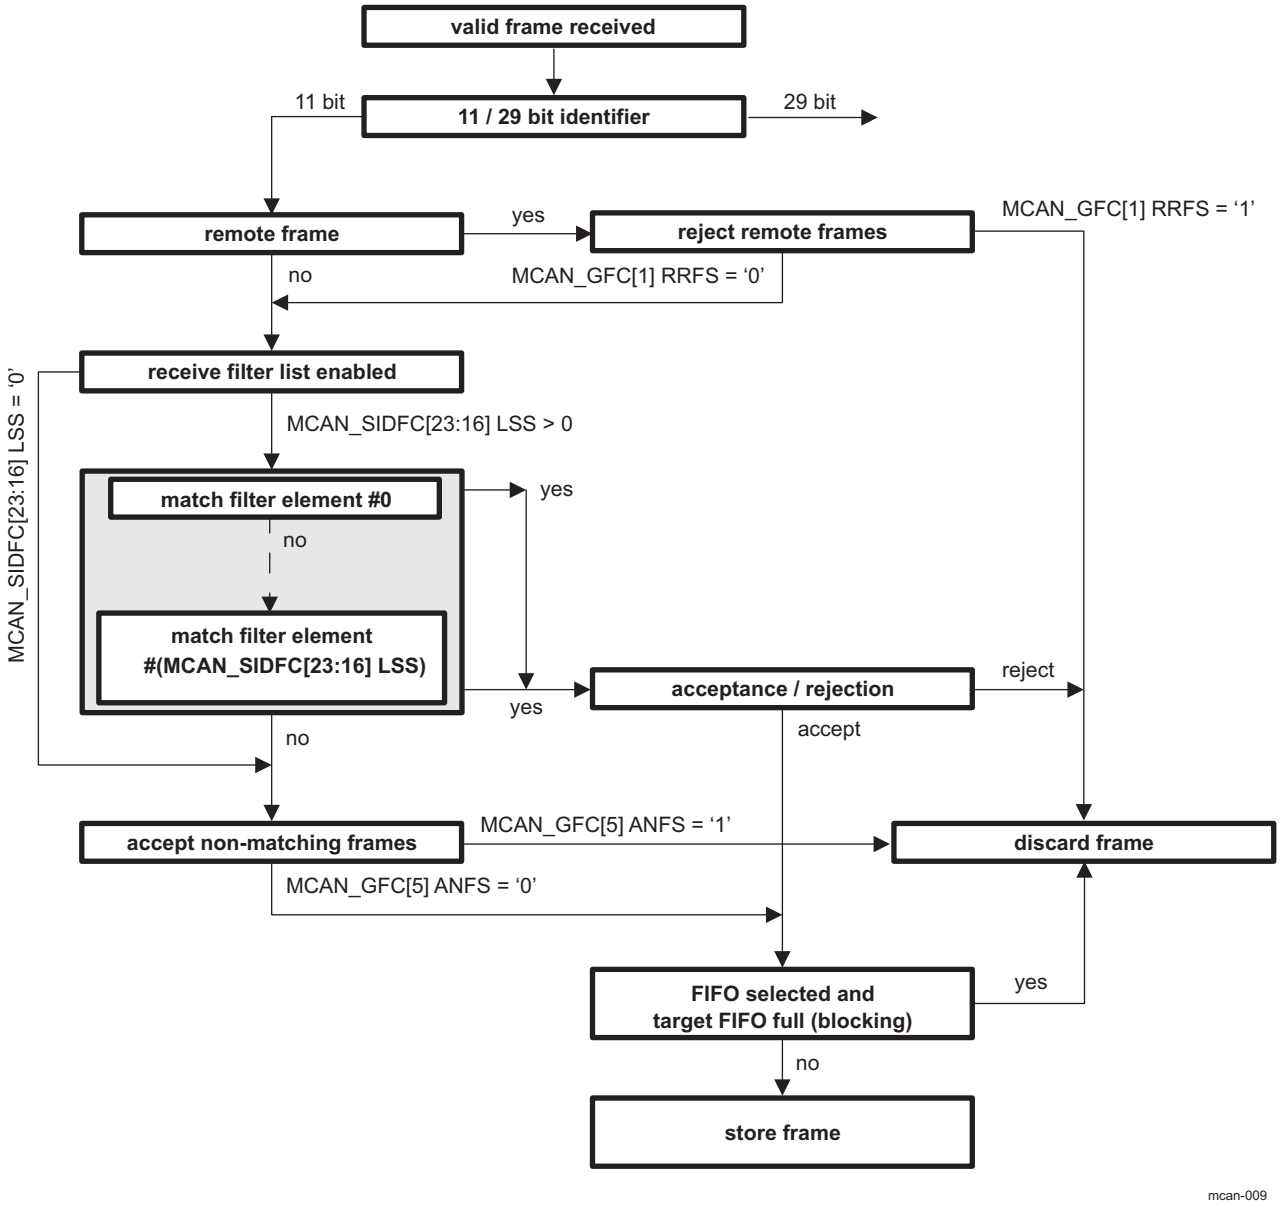
22.1.2.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in Figure 22-7. Section 22.1.2.11.5, *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

Figure 22-7. Standard Message ID Filter Path



22.1.2.8.1.5 Extended Message ID Filtering

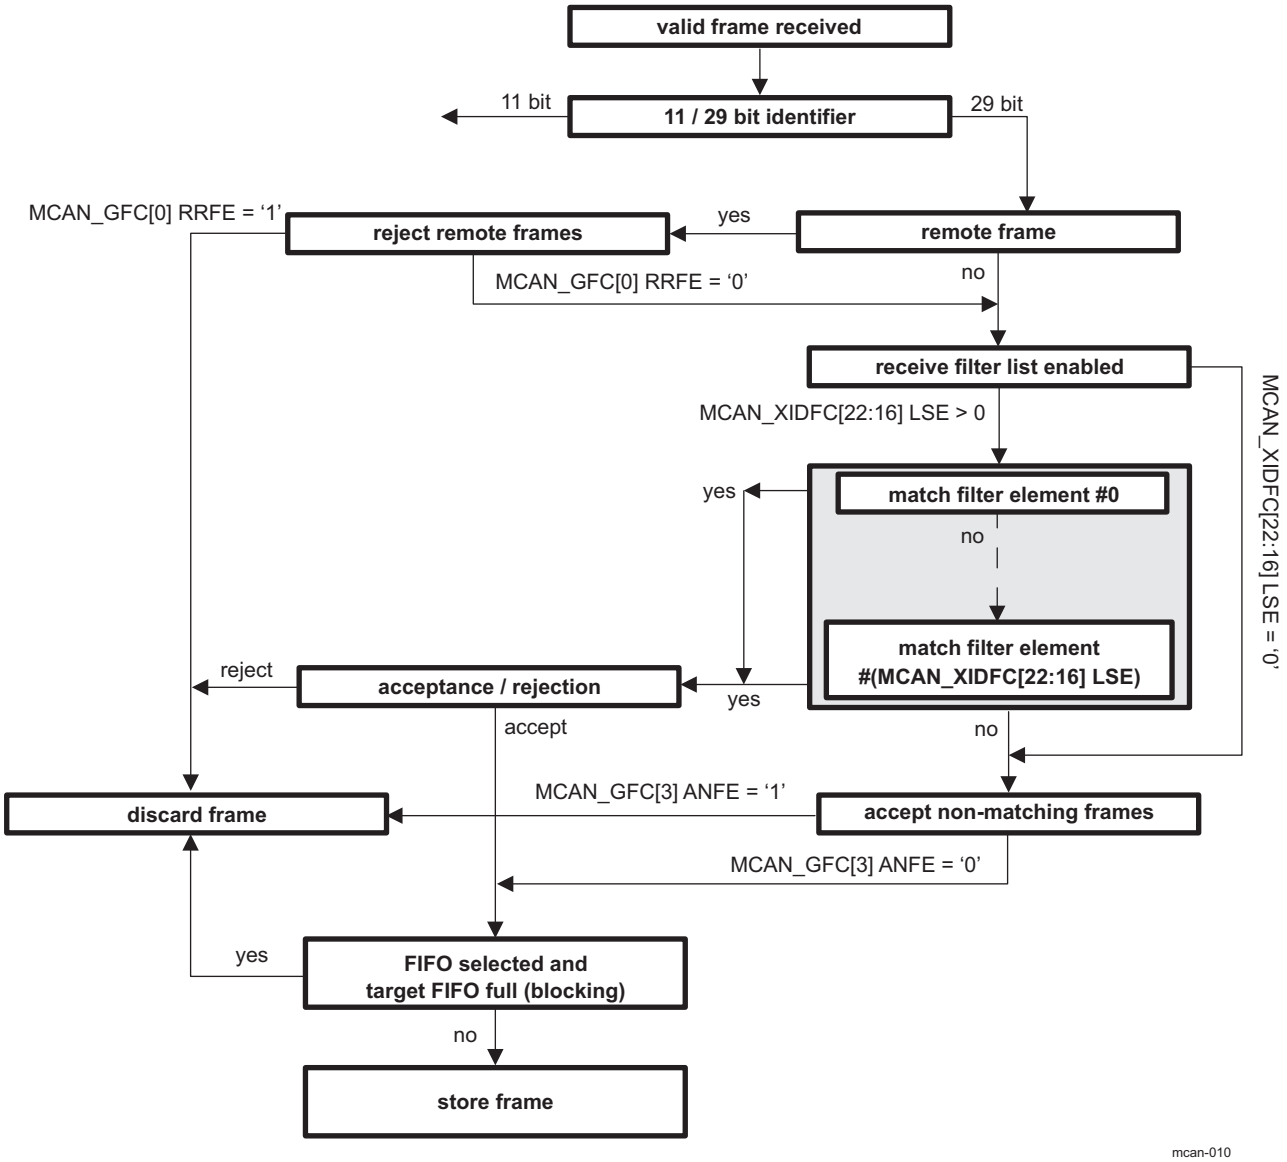
The extended Message ID (29-bit ID) filtering flow is shown in Figure 22-8. Section 22.1.2.11.6, *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

Figure 22-8. Extended Message ID Filter Path



22.1.2.8.2 Rx FIFOs

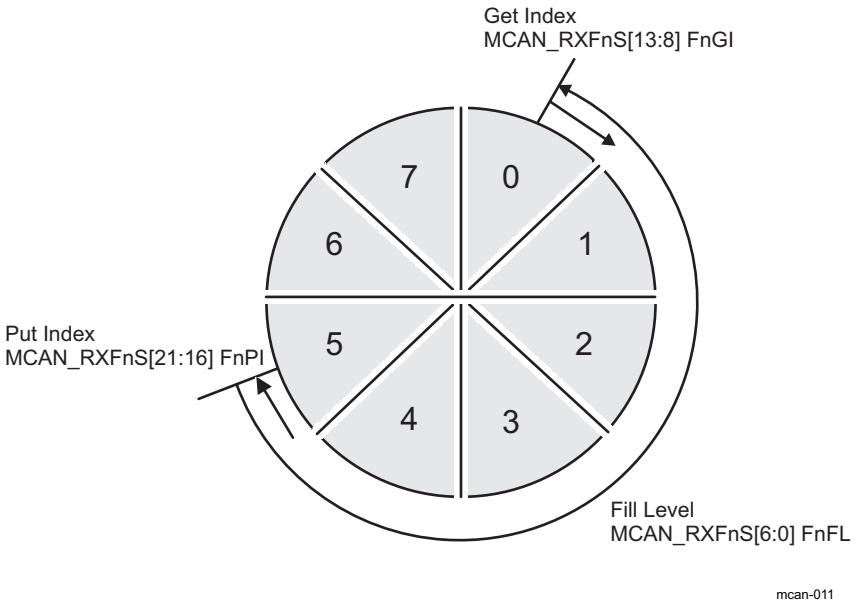
The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in Section 22.1.2.8.1, *Acceptance Filtering*. Section 22.1.2.11.2, *Rx Buffer and FIFO Element* describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W / MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F / MCAN_IR[6] RF1F is set. Figure 22-9 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

Figure 22-9. Rx FIFO Status



Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 22-2 presents Rx Buffer / Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 22-2. Rx Buffer / Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS / MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

22.1.2.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = '0'.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = '1' and interrupt flag MCAN_IR[2] RF0F / MCAN_IR[6] RF1F is set.

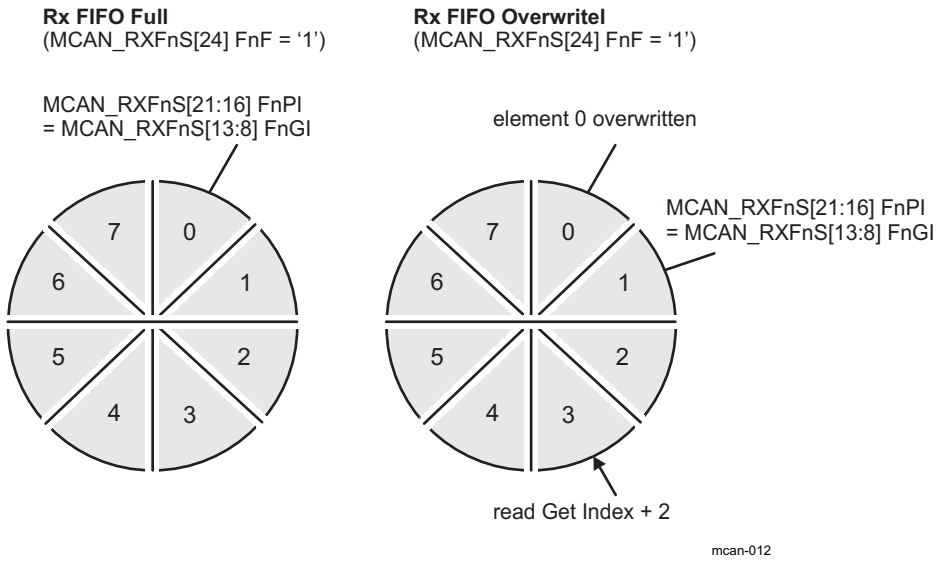
In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = '1' and interrupt flag MCAN_IR[3] RFnL / MCAN_IR[25] RFnL is set.

22.1.2.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = '1'. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = '1', the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index / Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 22-10 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 22-10. Rx FIFO Overflow Handling



After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = '0').

22.1.2.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (see Section 22.1.2.11.5, *Standard Message ID Filter Element* and Section 22.1.2.11.6, *Extended Message ID Filter Element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 22-3 shows Example Filter Configuration for Rx Buffers.

Table 22-3. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1 / MCAN_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

22.1.2.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

22.1.2.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers / Tx FIFO or dedicated Tx Buffers / Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 22.1.2.11.3 describes the Tx Buffer Element. Table 22-4 shows the possible configurations for message transmission.

Table 22-4. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

NOTE: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

22.1.2.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = '0'). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

22.1.2.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 22-5 shows Tx Buffer / Tx FIFO / Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20:16] TFQPI) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

Table 22-5. Tx Buffer / Tx FIFO / Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

22.1.2.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = '0'. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12:8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = '1') the Put Index is incemented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20:16] TFQPI = MCAN_TXFQS[12:8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = '1'. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 22-5). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

22.1.2.9.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = '1'. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 22-5). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

22.1.2.9.5 Mixed Dedicated Tx Buffers / Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29:24] TFQS field

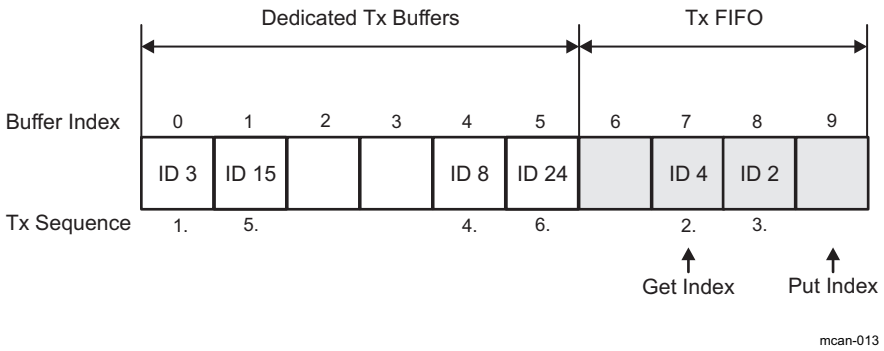
If the MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12:8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 22-11 shows Mixed Dedicated Tx Buffers / Tx FIFO example.

Figure 22-11. Mixed Dedicated Tx Buffers / Tx FIFO (example)



22.1.2.9.6 Mixed Dedicated Tx Buffers / Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29:24] TFQS field

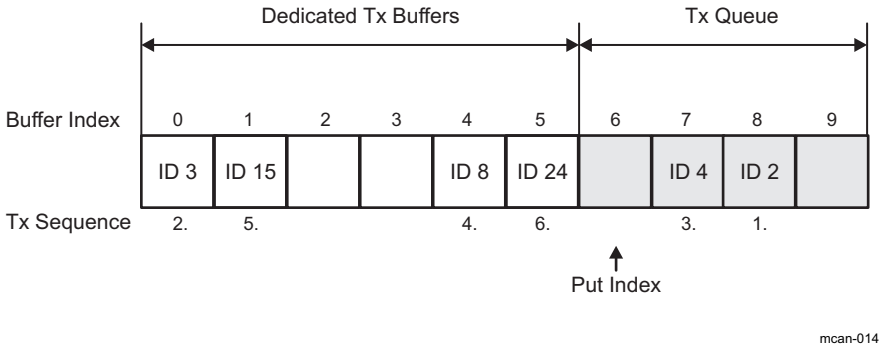
If MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 22-12 shows Mixed Dedicated Tx Buffers / Tx Queue example.

Figure 22-12. Mixed Dedicated Tx Buffers / Tx Queue (example)



22.1.2.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = '1' (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = '1').

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = '1'.

NOTE: If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

22.1.2.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 22.1.2.11.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12:8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29:24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS[12:8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15:2] EFSA field.

22.1.2.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

NOTE: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

22.1.2.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

22.1.2.11.1 Message RAM Configuration

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from 0xFF50 0000 to 0xFF50 43FC.

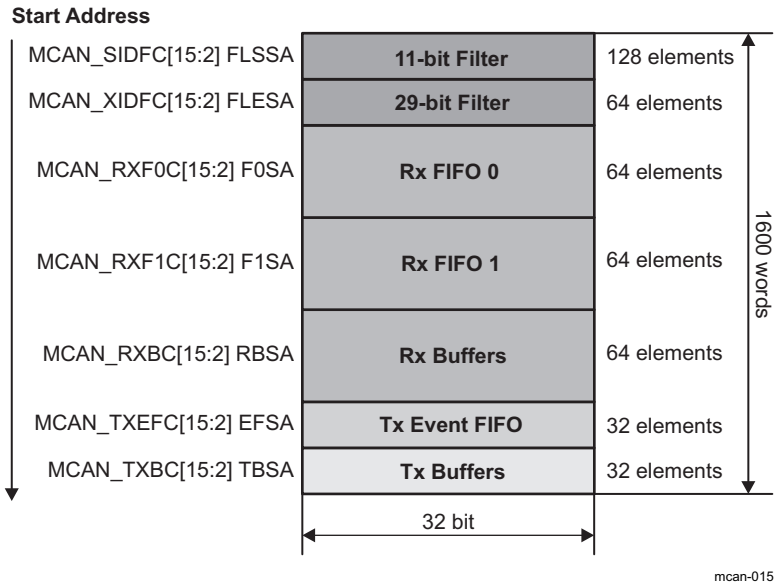
The Message RAM is capable to include each of the sections listed in Figure 22-13. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2:0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6:4] F1DS field
- Rx Buffers via the MCAN_RXESC[10:8] RBDS field
- Tx Buffers via the MCAN_TXESC[2:0] TBDS field

Figure 22-13. Message RAM Configuration



The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

NOTE: The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

22.1.2.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 22-14 shows Rx Buffer / Rx FIFO element structure.

Figure 22-14. Rx Buffer / Rx FIFO Element Structure

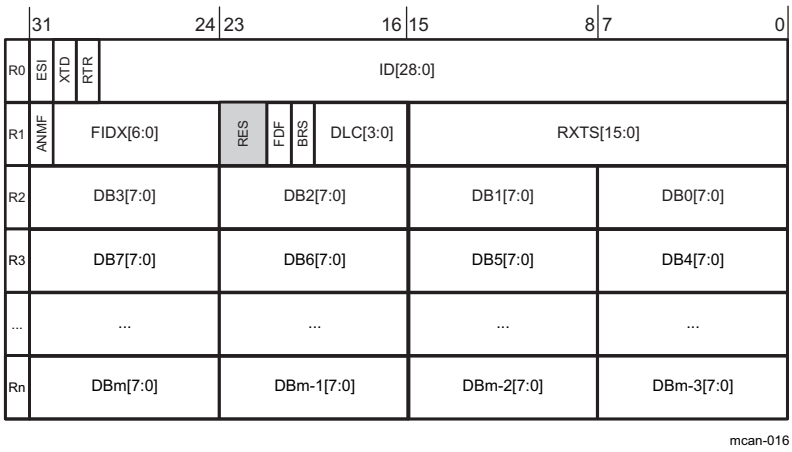


Table 22-6 shows Rx Buffer / Rx FIFO element field descriptions.

Table 22-6. Rx Buffer / Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = '1'), RTR bit reflects the state of the reserved r1 bit (RES[23]).
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5:4] ANFS and MCAN_GFC[3:2] ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to MCAN_SIDFC[23:16] LSS - 1 respectively MCAN_XIDFC[22:16] LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP.
R2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 22-6. Rx Buffer / Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

22.1.2.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO / Tx Queue via the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 22-15 shows Tx Buffer element structure.

Figure 22-15. Tx Buffer Element Structure

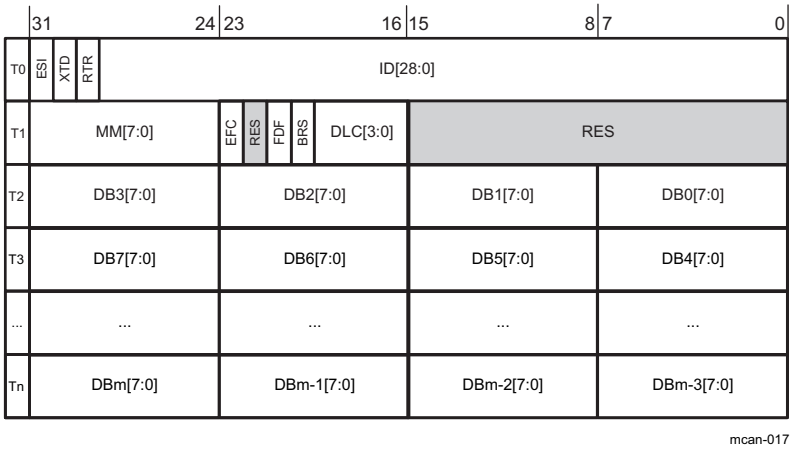

Table 22-7 shows Tx Buffer element field descriptions.

Table 22-7. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1, even if the MCAN_CCCR[8] FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 22-8).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled vie the MCAN_CCCR[8] FDOE bit. BRS bit is only evaluated when in addition the MCAN_CCCR[9] BRSE = '1'.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 22-7. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

22.1.2.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 22-16 shows Tx Event FIFO element structure.

Figure 22-16. Tx Event FIFO Element Structure

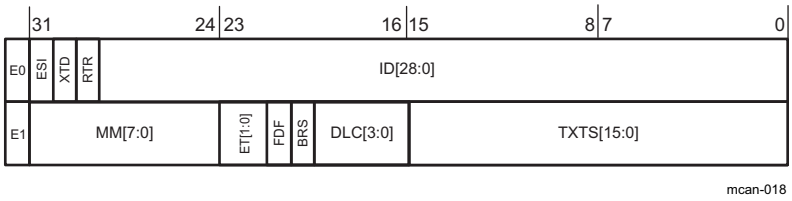

Table 22-8 shows Tx Event FIFO element field descriptions.

Table 22-8. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 22-8. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 22-7).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP filed.

22.1.2.11.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN_SIDFC[15:2] FLSSA field plus the index of the filter element (0-127).

Figure 22-17 shows Standard Message ID Filter element structure.

Figure 22-17. Standard Message ID Filter Element Structure

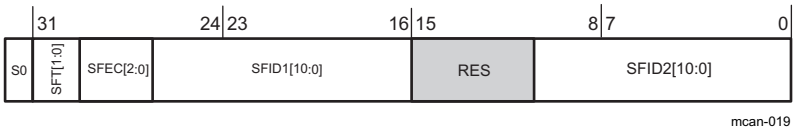

Table 22-9 shows Standard Message ID Filter element field descriptions.

Table 22-9. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = '11' the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = '000')
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = '100', '101', or '110' a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer, configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • 1) SFEC = '001' - '110' Second ID of standard ID filter element • 2) SFEC = '111' Filter for Rx Buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

22.1.2.11.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN_XIDFC[15:2] FLESA field plus two times the index of the filter element (0-63).

Figure 22-18 shows Extended Message ID Filter element structure.

Figure 22-18. Extended Message ID Filter Element Structure

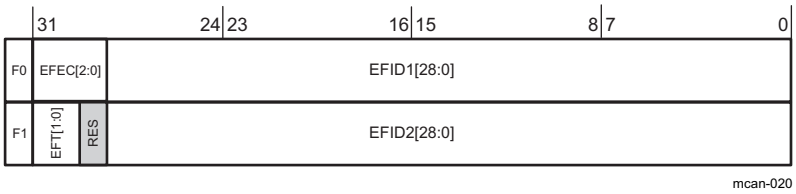

Table 22-10 shows Extended Message ID Filter element field descriptions.

Table 22-10. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 22.1.2.8.1.5, *Extended Message ID Filtering*) is used.

Table 22-10. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • 1) EFEC = '001' - '110' Second ID of extended ID filter element • 2) EFEC = '111' Filter for Rx Buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

22.1.3 MCAN Register Manual

22.1.3.1 MSS_MCAN_CFG Registers

Table 22-11 lists the memory-mapped registers for the MSS_MCAN_CFG. All register offset addresses not listed in Table 22-11 should be considered as reserved locations and the register contents should not be modified.

Table 22-11. MSS_MCAN_CFG Registers

Complex bit access types are encoded to fit into small table cells. Table 22-12 shows the codes that are used for access types in this section.

Table 22-12. MSS_MCAN_CFG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W W	Write Write
W0C	W 0C	Write 0 to clear

22.1.3.1.1 MCANSS_PID Register (Offset = 0h) [reset = 68E02A00h]

MCANSS_PID is shown in Figure 22-19 and described in Table 22-13.

Return to Summary Table.

SS_PID

22.2 Modular Controller Area Network (68xx MCAN)

22.2.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 10 Mbit/s data rate and is compliant to the CAN protocol specification 2.0 part A, B and ISO 11898-1.

22.2.1.1 Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock / Host clock)
- Parity / ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)

- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

22.2.2 MCAN Functional Description

The MCAN module performs CAN protocol communication according to the CAN protocol Specification 2.0 part A, B and ISO 11898-1. The bit rate can be programmed to values up to 10 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

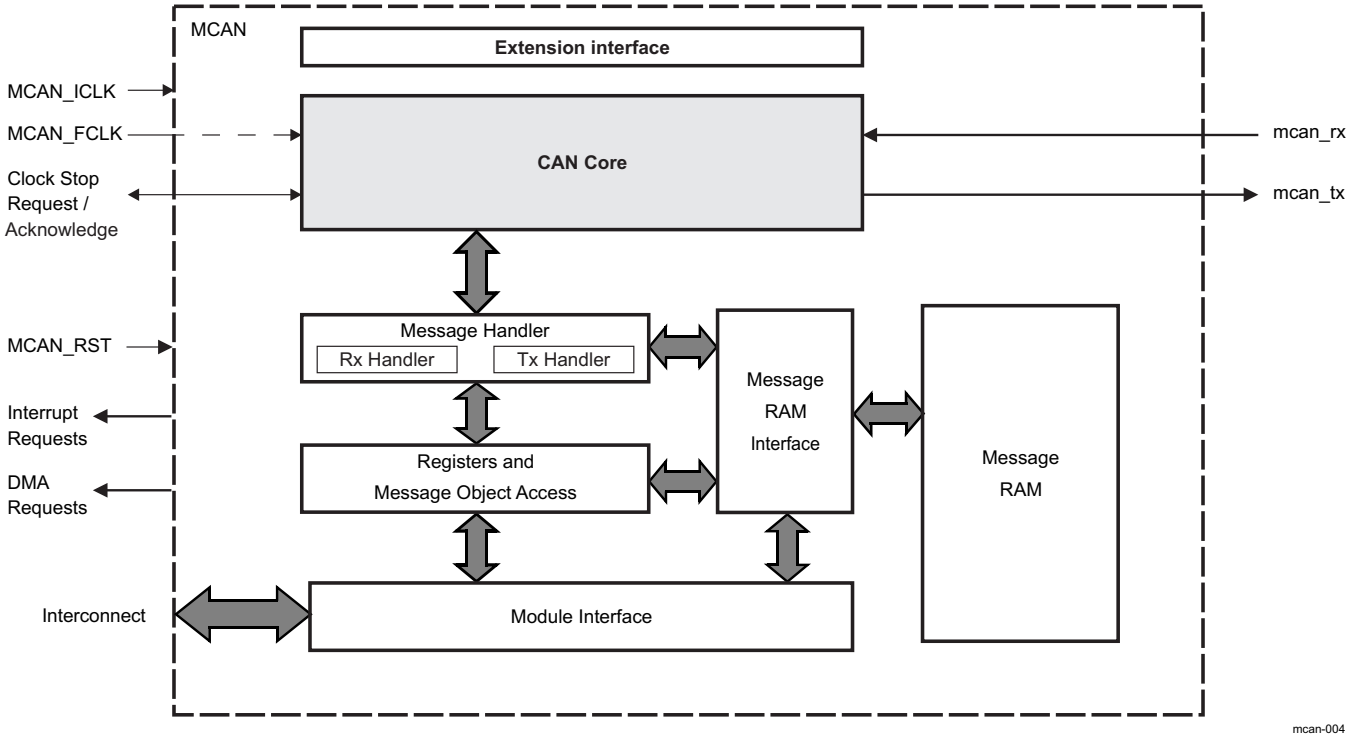
For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 22-112 shows the MCAN module block diagram.

Figure 22-112. MCAN Block Diagram



The MCAN module blocks description:

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler**: the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 22.2.2.11, *Message RAM*).
- **Message RAM Interface**: enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access**: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.

- **Module Interface**: The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.
- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface**: All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

22.2.2.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

NOTE: MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$f_{0,\ ICLK}(OCP) \pm \Delta f_{FM,\ ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see , *PRCM* and the device data manual.

22.2.2.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see Section 22.2.2.4.8.2, *Suspend Mode*).

22.2.2.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write '1' to MCANSS_ECC_EOI[8] ECC_EOI bit (for more information, see Section 22.2.2.7.2, *ECC Aggregator*).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see Section 22.2.2.5.1, *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)

- Interrupt Enable Status (MCANSS_IES)
- End Of Interrupt (MCANSS_EOI)
- External Timestamp Prescaler (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

22.2.2.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extention Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

22.2.2.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing '1' to MCAN_CCCR[8] FDOE bit. A value of '0' on the primary configuration port (mcanss_enable_fdoe) will force the MCAN_CCCR[8] FDOE bit during write to the MCAN_CCCR register which will prevent the device from enabling and using the CAN FD mode.

22.2.2.4 Operating Modes

22.2.2.4.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to '1' starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output mcan_tx pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = '1'. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15:0] TOC field is preset to the value configured by the MCAN_TOCC[31:16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = '1'.

The following registers are only writeable while MCAN_CCCR[1] CCE = '0'

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = '1' and MCAN_CCCR[1] CCE = '1'. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = '1' and MCAN_CCCR[1] CCE = '1'.

22.2.2.4.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0 / Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

NOTE: Automated transmission on reception of remote frames is not supported.

22.2.2.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical '1') signifies a CAN FD frame, FDF = dominant (logical '0') signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = '0'), this causes the operation state to change from Receiver (MCAN_PSR[4:3] ACT = '10') to Integrating (MCAN_PSR[4:3] ACT = '00') at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = '1'), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = '1', transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = '0', received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = '0', the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = '1' and MCAN_CCCR[9] BRSE = '0', only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = '1' and MCAN_CCCR[9] BRSE = '1', transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN

communication.

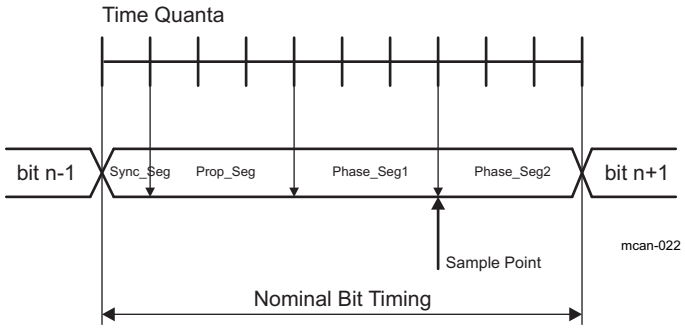
The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to Table 22-108.

Table 22-108. DLC Coding in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

For CAN FD frames with bit rate switchingIn, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 22-113) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

Figure 22-113. CAN Bit Timing



The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

22.2.2.4.4 Transmitter Delay Compensation

22.2.2.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the mcan_tx pin the MCAN module receives the transmitted data from its local CAN transceiver via the mcan_rx pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

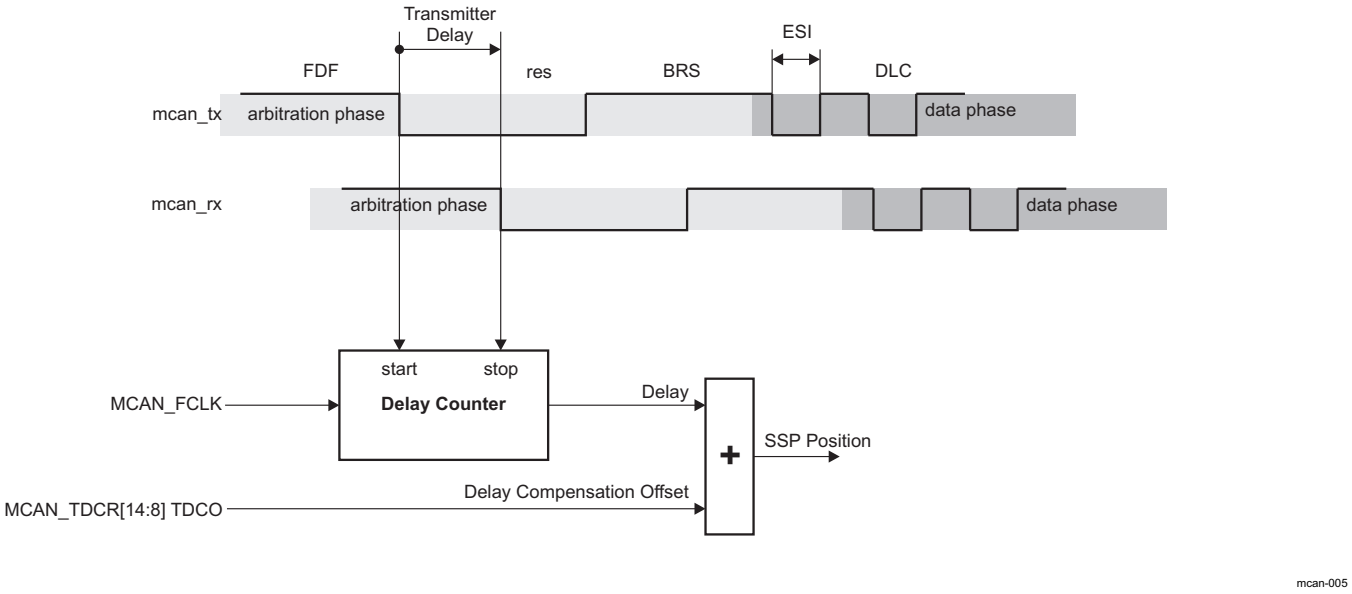
The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in the new ISO11898-1). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to '1'.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output mcan_tx pin through the transceiver to the receive input mcan_rx pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14:8] TDCO field (see Figure 22-114). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22:16] TDCV field. This filed is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

Figure 22-114. Transmitter Delay Measurement



22.2.2.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = '1'), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input mcan_rx pin of the transmitter. The resolution of this measurement is one mtq (see Figure 22-114). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6:0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the mcan_rx pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6:0] TDCF field and the mcan_rx pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the mcan_tx pin to the mcan_rx pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the mcan_tx pin to the mcan_rx pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

22.2.2.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The recieve and transmit error counters (MCAN_ECR[14:8] REC and MCAN_ECR[7:0] TEC) are frozen while CAN error logging (MCAN_ECR[23:16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[1] INIT bits are set to '1'.

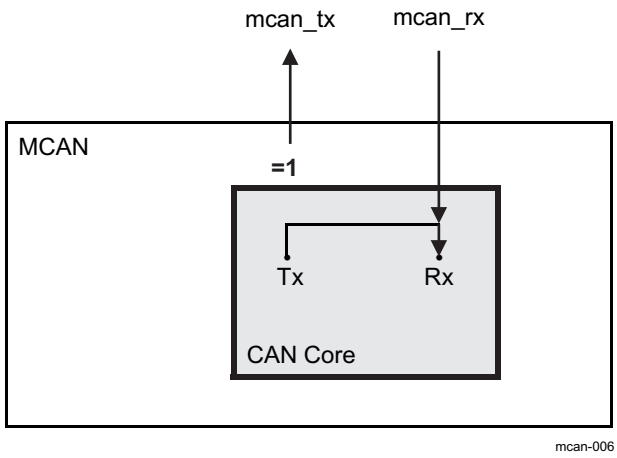
The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

NOTE: The Restricted Operation Mode must not be combined with the Loop Back Mode.

22.2.2.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN_CCCR[5] MON bit to '1'. In this mode (see ISO11898-1, *Bus Monitoring*), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 22-115 shows the connection of the mcan_tx and mcan_rx signals to the MCAN module in Bus Monitoring Mode.

Figure 22-115. Connection of Signals in Bus Monitoring Mode



22.2.2.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1, *Recovery Management*), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR[6] DAR bit).

22.2.2.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = '10' (transmission in spite of cancellation).

22.2.2.4.8 Power Down (Sleep Mode)

Entering Power Down mode is controlled via the input clock stop request signal (mcanss_clkstp_clkstop_req) or MCAN_CCCR[4] CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as '1'. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[1] INIT to '1' to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal (mcanss_clkstop_clkstop_ack) to '1' and the MCAN_CCCR[3] CSA bit to '1'. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR[1] INIT bit will have no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN_CCCR[1] INIT bit.

22.2.2.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to '1' (for more information, see Section 22.2.2.4.8.3, *Wakeup request*). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

22.2.2.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] FREE and MCANSS_CTRL[2] SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to '1' (for more information, see Section 22.2.2.4.8.3, *Wakeup request*). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23:16] CEL
- MCAN_PSR[2:0] LEC
- MCAN_PSR[10:8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

22.2.2.4.8.3 Wakeup Request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive mcan_rx pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the MCANSS_CTRL[4] WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

22.2.2.4.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to '1'. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit mcan_tx pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6:5] TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

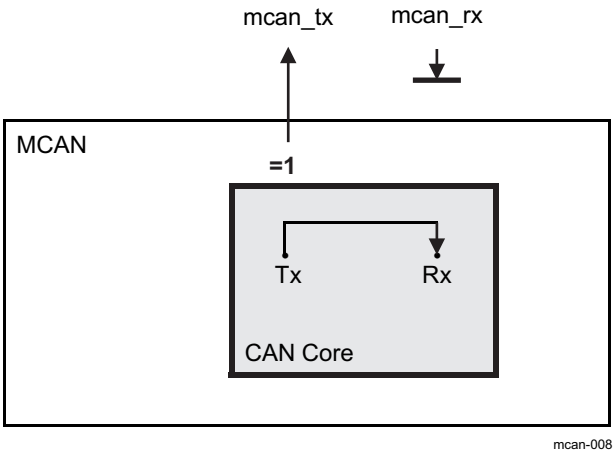
The actual value of the CAN receive mcan_rx pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6:5] TX filed until the new configuration is visible at the output mcan_tx pin. This applies also when reading input mcan_rx pin via the MCAN_TEST[7] RX bit.

NOTE: Test modes should be used for self test only. The software control for mcan_tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

22.2.2.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to '1'. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the mcan_tx and mcan_rx pins. In this mode mcan_rx pin is disconnected from the MCAN module and mcan_tx pin is held recessive. Figure 22-116 shows the connection of the mcan_tx and mcan_rx pins to the MCAN module in case of Internal Loop Back Mode.

Figure 22-116. Internal Loop Back Mode



22.2.2.5 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19:16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15:0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 22.2.2.11, *Message RAM*.

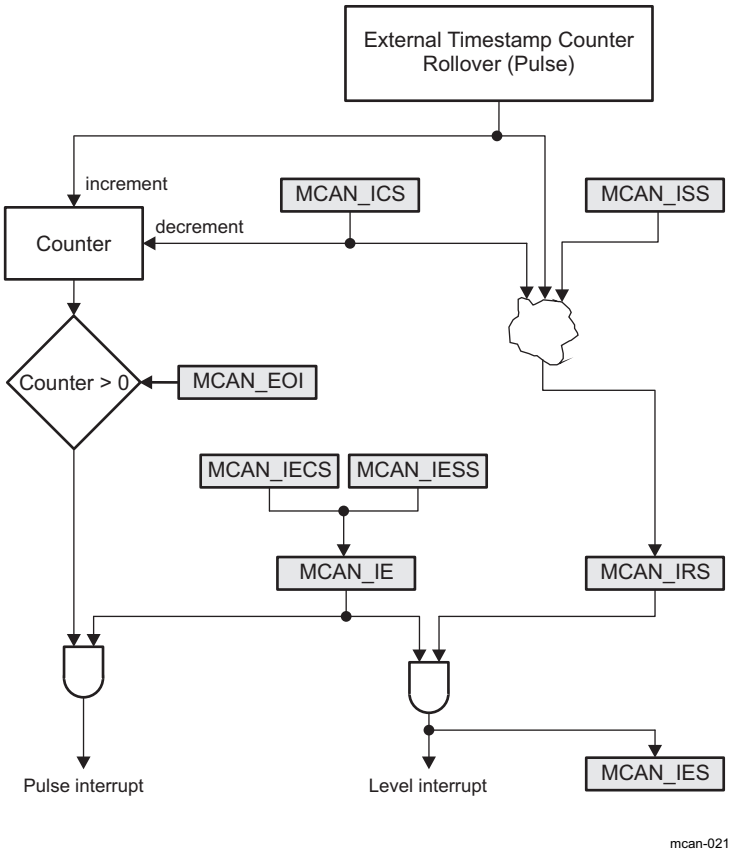
22.2.2.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1:0] TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23:0] PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN_IRQ_TS interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the MCANSS_IRS register is set (see Figure 22-117). The MCANSS_IE register can be affected by writing to the MCAN_IESS register to set or to the MCANSS_IECS register to clear. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

Figure 22-117. External Timestamp Counter Interrupt



22.2.2.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19:16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15:0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[1] INIT = '0' and stopped when MCAN_CCCR[1] INIT = '1' (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2:1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_TOCV[1] INIT = '0', a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31:16] TOP field.

22.2.2.7 Safety

The Message Memory is wrapped in an ECC wrapper provididing SECDED parity functionalilty. The ECC wrapper is controlled by an ECC Aggregator.

22.2.2.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

22.2.2.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

22.2.2.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

22.2.2.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register (MCANSS_ECC_AGGR_REVISION), ECC Vector Register (MCANSS_ECC_VECTOR), Misc Status Register (MCANSS_ECC_MISC_STATUS), ECC Control Register (MCANSS_ECC_CONTROL), and ECC Wrapper Revision Register (MCANSS_ECC_WRAP_REVISION).
- Control and status registers - ECC Error Control Registers (MCANSS_ECC_ERR_CTRL1 and MCANSS_ECC_ERR_CTRL2) and ECC Error Status Registers (MCANSS_ECC_ERR_STAT1 and MCANSS_ECC_ERR_STAT2).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANSS_ECC_SEC_EOI_REG
  - MCANSS_ECC_SEC_STATUS_REG0
  - MCANSS_ECC_SEC_ENABLE_SET_REG0
  - MCANSS_ECC_SEC_ENABLE_CLR_REG0
  - MCANSS_ECC_DED_EOI_REG
  - MCANSS_ECC_DED_STATUS_REG0
  - MCANSS_ECC_DED_ENABLE_SET_REG0
  - MCANSS_ECC_DED_ENABLE_CLR_REG0

22.2.2.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR field to select the ECC RAM for control or status.

- Software writes '1' to the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.
- Software then polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is '1'. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

22.2.2.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the MCANSS_ECC_SEC_ENABLE_SET_REG0 / MCANSS_ECC_DED_ENABLE_SET_REG0 register.
- Software writes the ECC RAM ID in the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR.
- Software writes the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger the read.
- Software writes the MCANSS_ECC_ERR_STAT1 register address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the MCANSS_ECC_VECTOR register again if it needs to read the MCANSS_ECC_ERR_STAT2 register.
- Software polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit. When this bit is set, a read of the MCANSS_ECC_ERR_STAT1 / MCANSS_ECC_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANSS_ECC_ERR_STAT1[8] CLR_ECC_SEC or MCANSS_ECC_ERR_STAT1[9] CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the MCANSS_ECC_ERR_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANSS_ECC_SEC_EOI_REG / MCANSS_ECC_DED_EOI_REG register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write '1' to the MCANSS_ECC_EOI[8] ECC_EOI bit.

22.2.2.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

22.2.2.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled / disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 22.2.2.11, *Message RAM*) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see Section 22.2.2.2.1, *DMA Requests*.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
  New Data flag (MCAN_NDAT1 / MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields).
- Rx FIFO:
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 22.2.2.8.2.2 have to be considered.

22.2.2.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = '00' / Extended Filter Type EFT = '00'). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 22.2.2.11.5, *Standard Message ID Filter Element* and Section 22.2.2.11.6, *Extended Message ID Filter Element*.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = '00': The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = '11': The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

22.2.2.8.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT ='01' / Extended Filter Type EFT ='01'). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see Section 22.2.2.11.5, *Standard Message ID Filter Element* and Section 22.2.2.11.6, *Extended Message ID Filter Element*.

22.2.2.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT ='10' / Extended Filter Type EFT ='10'). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A '0' bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are '1' are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are '1': a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are '0': all Message IDs match.

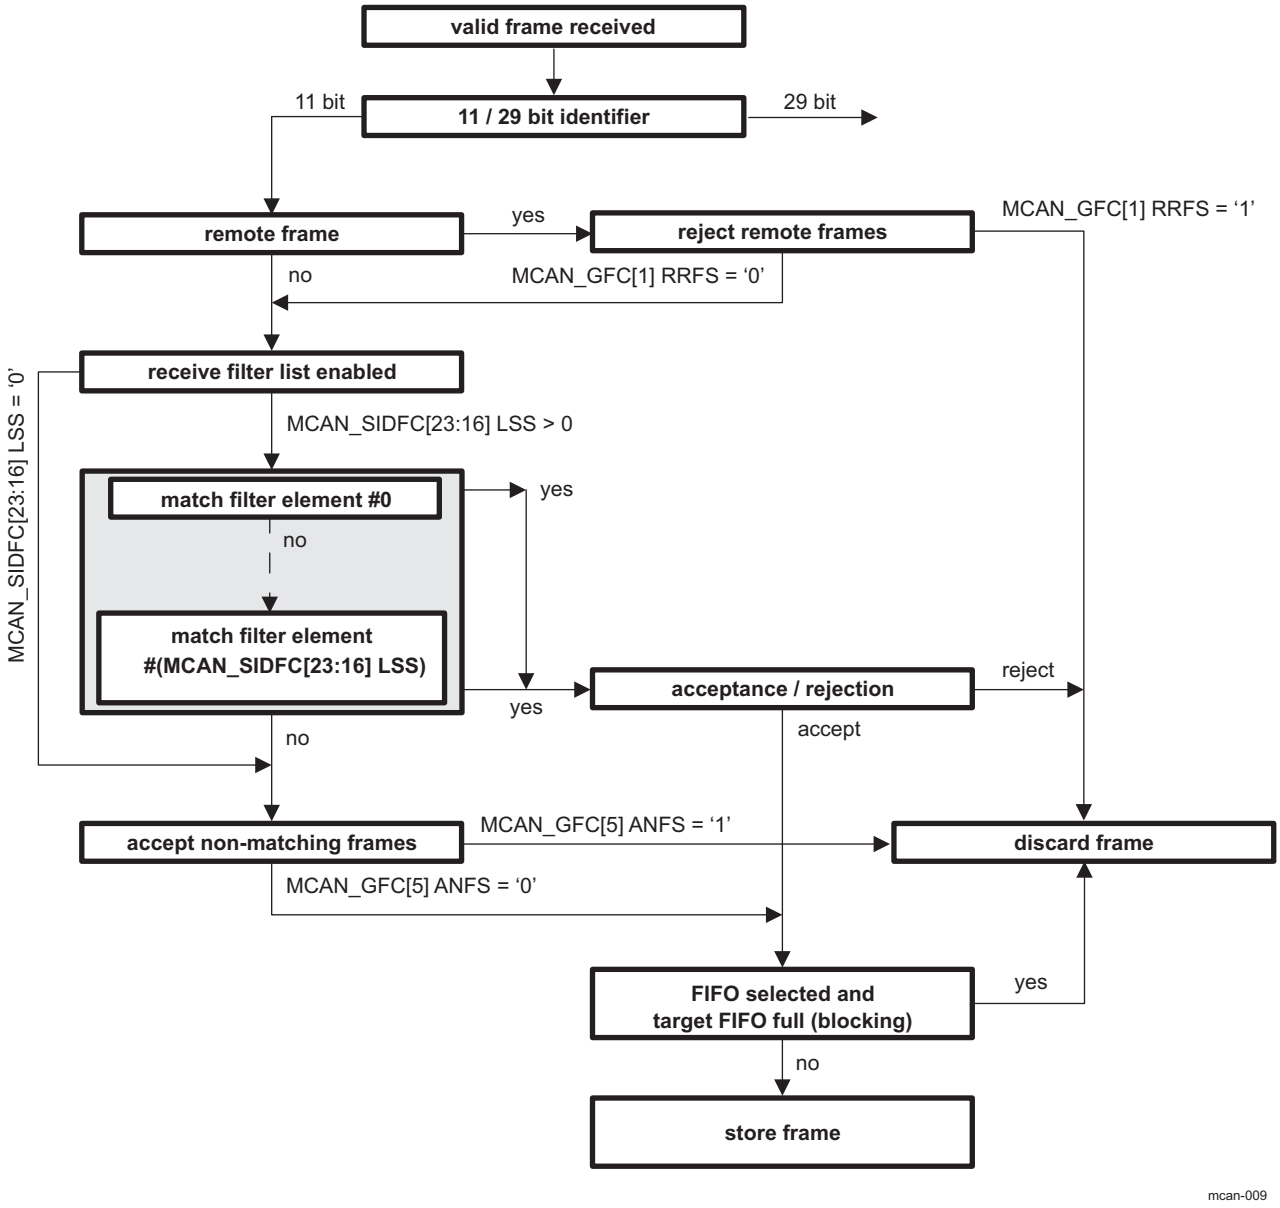
22.2.2.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in Figure 22-118. Section 22.2.2.11.5, *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

Figure 22-118. Standard Message ID Filter Path



22.2.2.8.1.5 Extended Message ID Filtering

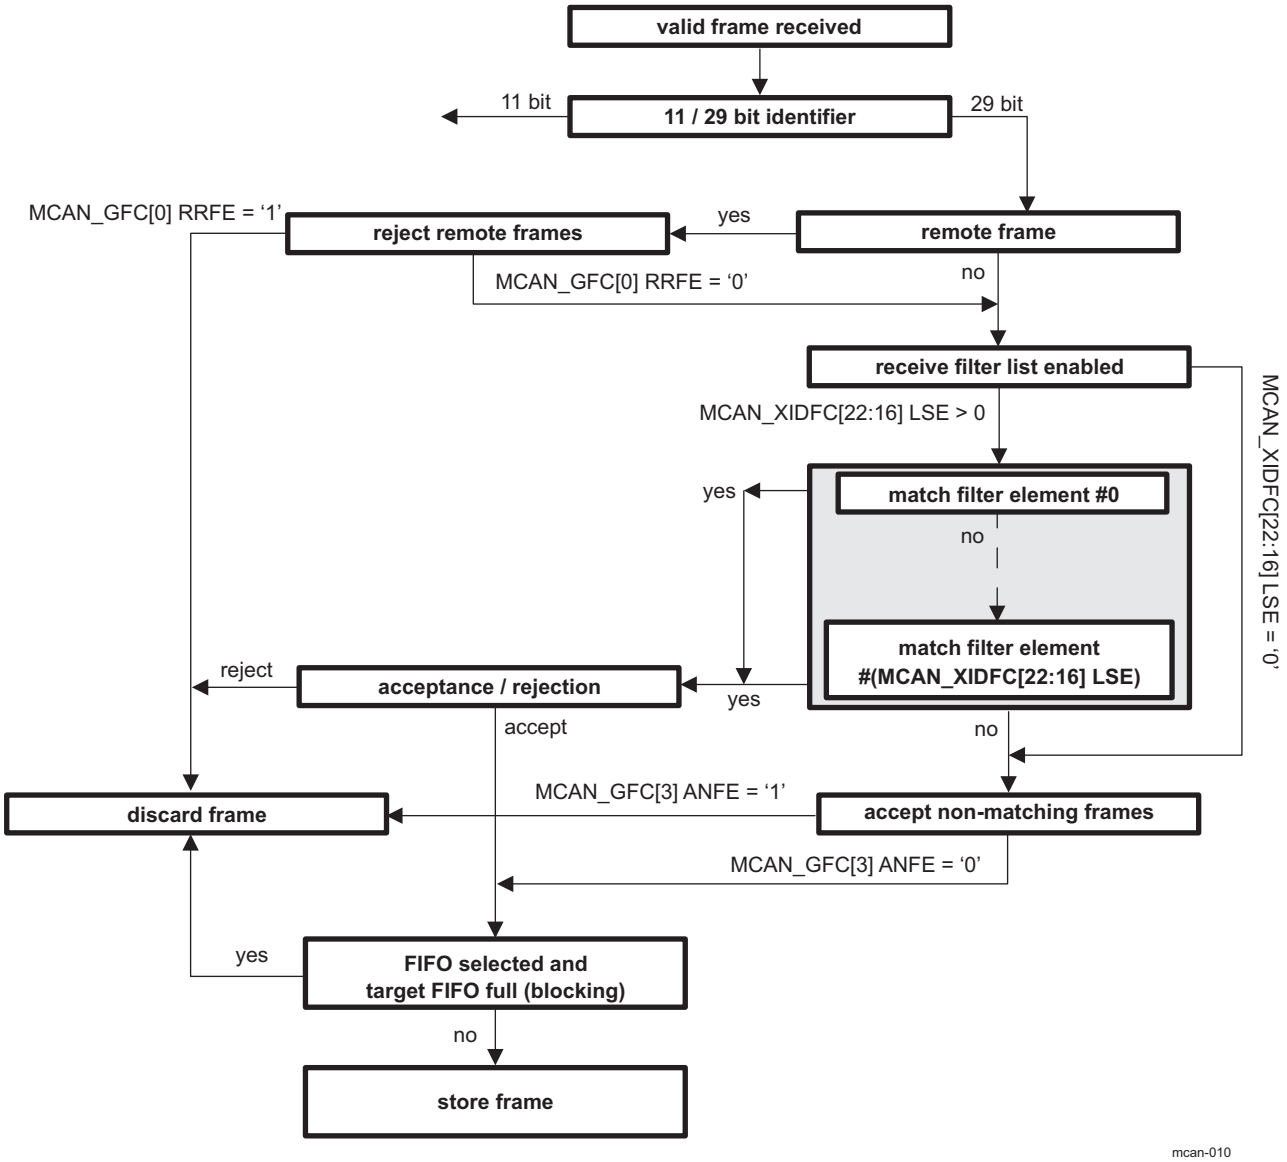
The extended Message ID (29-bit ID) filtering flow is shown in Figure 22-119. Section 22.2.2.11.6, *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

Figure 22-119. Extended Message ID Filter Path



22.2.2.8.2 Rx FIFOs

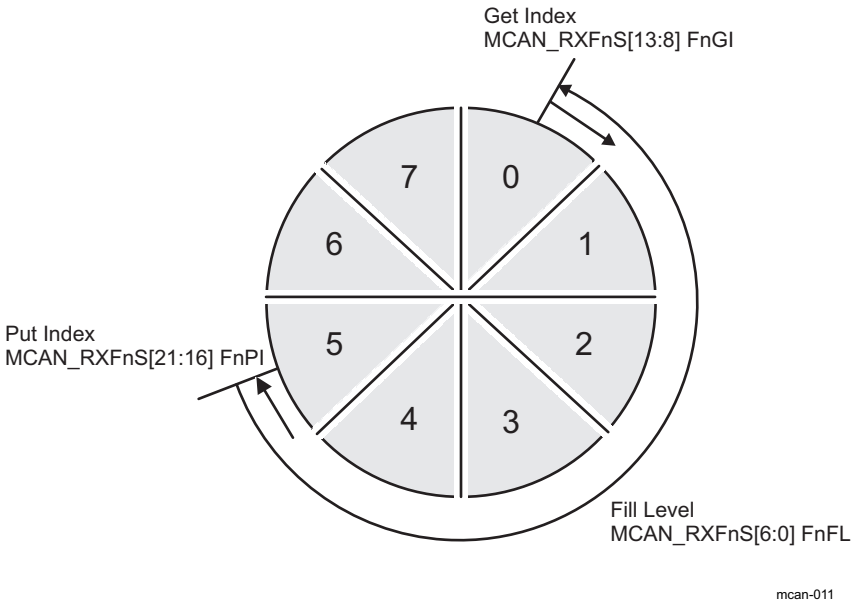
The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in Section 22.2.2.8.1, *Acceptance Filtering*. Section 22.2.2.11.2, *Rx Buffer and FIFO Element* describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W / MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F / MCAN_IR[6] RF1F is set. Figure 22-120 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

Figure 22-120. Rx FIFO Status



Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 22-109 presents Rx Buffer / Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 22-109. Rx Buffer / Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS / MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

22.2.2.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = '0'.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = '1' and interrupt flag MCAN_IR[2] RF0F / MCAN_IR[6] RF1F is set.

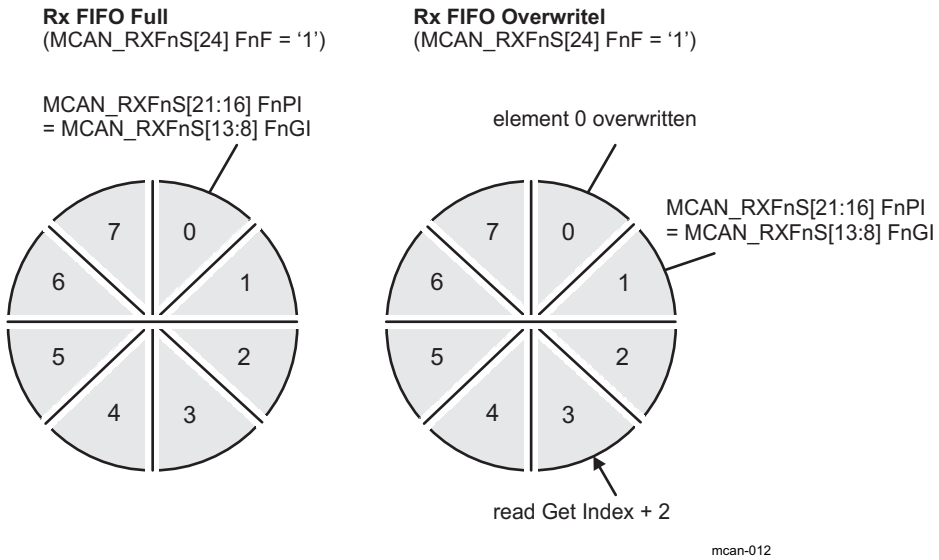
In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = '1' and interrupt flag MCAN_IR[3] RFnL / MCAN_IR[25] RFnL is set.

22.2.2.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = '1'. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = '1', the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index / Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 22-121 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 22-121. Rx FIFO Overflow Handling



After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = '0').

22.2.2.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (see Section 22.2.2.11.5, *Standard Message ID Filter Element* and Section 22.2.2.11.6, *Extended Message ID Filter Element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 22-110 shows Example Filter Configuration for Rx Buffers.

Table 22-110. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1 / MCAN_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

22.2.2.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

22.2.2.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers / Tx FIFO or dedicated Tx Buffers / Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 22.2.2.11.3 describes the Tx Buffer Element. Table 22-111 shows the possible configurations for message transmission.

Table 22-111. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

NOTE: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

22.2.2.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = '0'). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

22.2.2.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 22-112 shows Tx Buffer / Tx FIFO / Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20:16] TFQPI) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

Table 22-112. Tx Buffer / Tx FIFO / Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

22.2.2.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = '0'. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12:8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = '1') the Put Index is incemented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20:16] TFQPI = MCAN_TXFQS[12:8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = '1'. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 22-112). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

22.2.2.9.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = '1'. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 22-112). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) * Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

22.2.2.9.5 Mixed Dedicated Tx Buffers / Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29:24] TFQS field

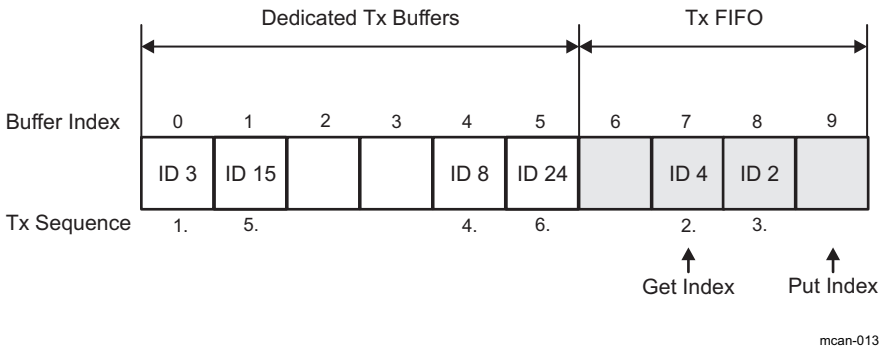
If the MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12:8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 22-122 shows Mixed Dedicated Tx Buffers / Tx FIFO example.

Figure 22-122. Mixed Dedicated Tx Buffers / Tx FIFO (example)



22.2.2.9.6 Mixed Dedicated Tx Buffers / Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29:24] TFQS field

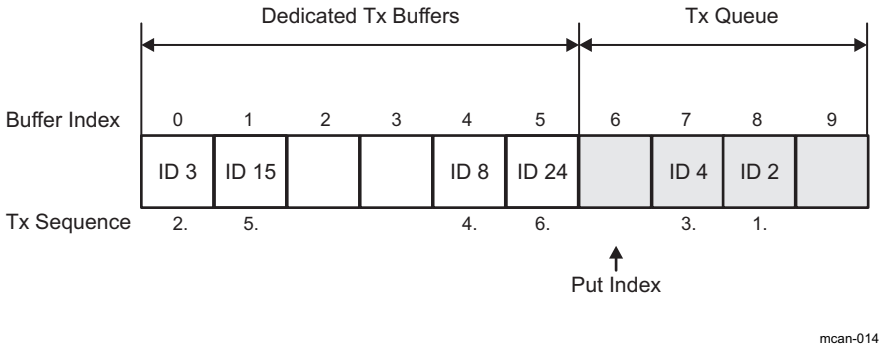
If MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 22-123 shows Mixed Dedicated Tx Buffers / Tx Queue example.

Figure 22-123. Mixed Dedicated Tx Buffers / Tx Queue (example)



22.2.2.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = '1' (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = '1').

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = '1'.

NOTE: If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

22.2.2.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 22.2.2.11.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12:8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29:24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS[12:8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15:2] EFSA field.

22.2.2.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

NOTE: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

22.2.2.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

22.2.2.11.1 Message RAM Configuration

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from 0xFF50 0000 to 0xFF50 43FC.

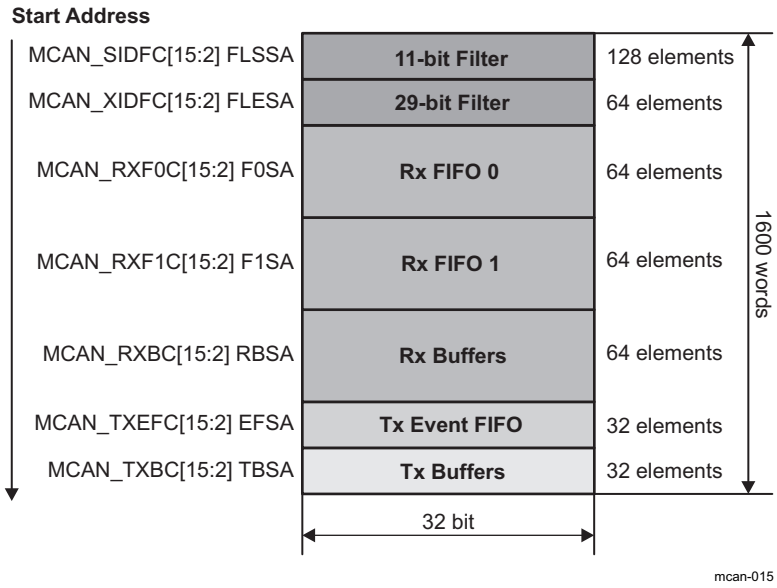
The Message RAM is capable to include each of the sections listed in Figure 22-124. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2:0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6:4] F1DS field
- Rx Buffers via the MCAN_RXESC[10:8] RBDS field
- Tx Buffers via the MCAN_TXESC[2:0] TBDS field

Figure 22-124. Message RAM Configuration



The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

NOTE: The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

22.2.2.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 22-125 shows Rx Buffer / Rx FIFO element structure.

Figure 22-125. Rx Buffer / Rx FIFO Element Structure

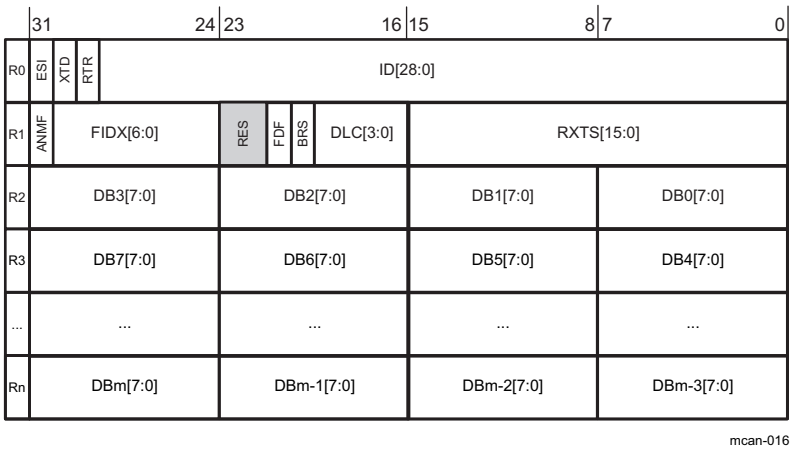


Table 22-113 shows Rx Buffer / Rx FIFO element field descriptions.

Table 22-113. Rx Buffer / Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = '1'), RTR bit reflects the state of the reserved r1 bit (RES[23]).
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5:4] ANFS and MCAN_GFC[3:2] ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to MCAN_SIDFC[23:16] LSS - 1 respectively MCAN_XIDFC[22:16] LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP.
R2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 22-113. Rx Buffer / Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

22.2.2.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO / Tx Queue via the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 22-126 shows Tx Buffer element structure.

Figure 22-126. Tx Buffer Element Structure

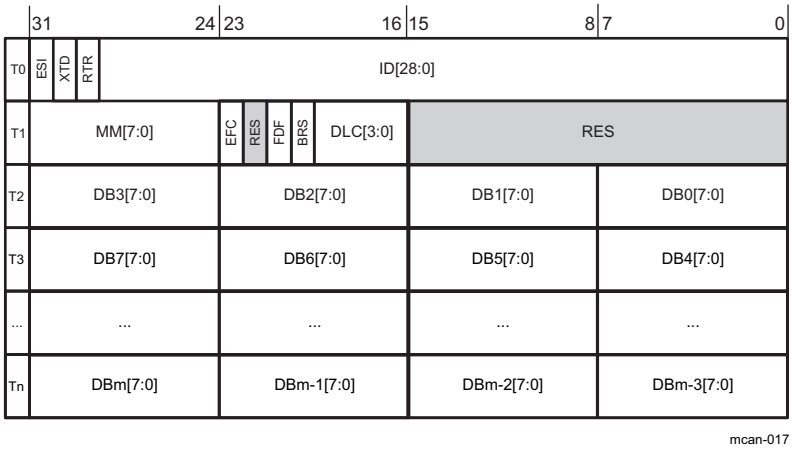

Table 22-114 shows Tx Buffer element field descriptions.

Table 22-114. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1, even if the MCAN_CCCR[8] FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 22-115).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled vie the MCAN_CCCR[8] FDOE bit. BRS bit is only evaluated when in addition the MCAN_CCCR[9] BRSE = '1'.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 22-114. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

22.2.2.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 22-127 shows Tx Event FIFO element structure.

Figure 22-127. Tx Event FIFO Element Structure

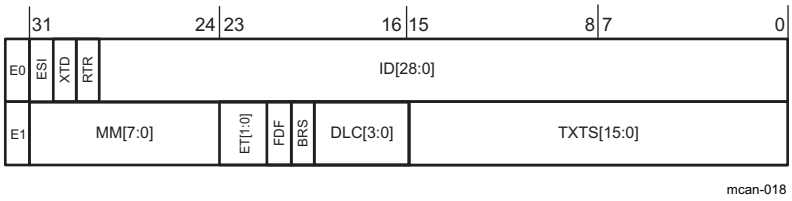

Table 22-115 shows Tx Event FIFO element field descriptions.

Table 22-115. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 22-115. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 22-114).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP filed.

22.2.2.11.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN_SIDFC[15:2] FLSSA field plus the index of the filter element (0-127).

Figure 22-128 shows Standard Message ID Filter element structure.

Figure 22-128. Standard Message ID Filter Element Structure

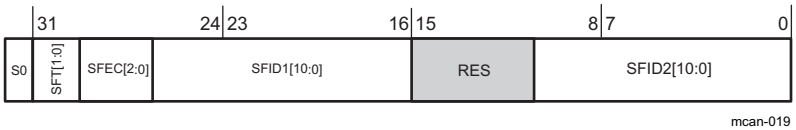

Table 22-116 shows Standard Message ID Filter element field descriptions.

Table 22-116. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = '11' the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = '000')
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = '100', '101', or '110' a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer, configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • 1) SFEC = '001' - '110' Second ID of standard ID filter element • 2) SFEC = '111' Filter for Rx Buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

22.2.2.11.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN_XIDFC[15:2] FLESA field plus two times the index of the filter element (0-63).

Figure 22-129 shows Extended Message ID Filter element structure.

Figure 22-129. Extended Message ID Filter Element Structure

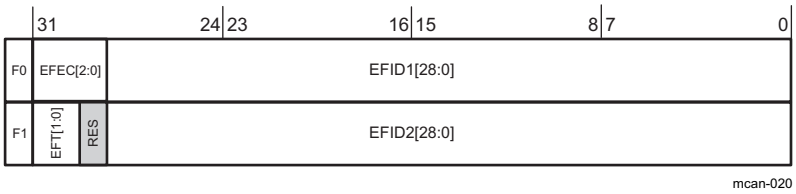

Table 22-117 shows Extended Message ID Filter element field descriptions.

Table 22-117. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 22.2.2.8.1.5, *Extended Message ID Filtering*) is used.

Table 22-117. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • 1) EFEC = '001' - '110' Second ID of extended ID filter element • 2) EFEC = '111' Filter for Rx Buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

22.2.3 MCAN Register Manual

22.2.3.1 MSS_MCAN_CFG Registers

Table 22-194 lists the MSS_MCAN_CFG registers. All register offset addresses not listed in Table 22-194 should be considered as reserved locations and the register contents should not be modified.

Table 22-118. MSS_MCAN_CFG Registers

Multi-Buffered Serial Peripheral Interface Module (MibSPI)

This section provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This section also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this section, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

Table 23-1. Register Control From MSS-RCM Configuration Space

spib_trig_src[5:0]	Driven for configuration register from MSS_RCM	MSS_RCM:SPITRIGSRC: SPIBTRIG[5:0]
spib_mem_init	Driven for configuration register from MSS_RCM	MSS_RCM:MEMINITSTART: SPIBMEM
spib_mem_init_done	Status, which can be read from MSS_RCM Register space	MSS_RCM:MEMINITDONE: SPIBMEM

NOTE: This section describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation (SPInENA).

Topic **Page**

23.1 Overview **2872**
23.2 Basic Operation **2874**
23.3 Control Registers **2909**
23.4 Multi-Buffer RAM **3142**
23.5 Parity\ECC Memory **3148**
23.6 MibSPI Pin Timing Parameters **3153**

23.1 Overview

23.1.1 Features

The MibSPI/SPI is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (two to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The MibSPI/SPI is normally used for communication between the microcontroller and external peripherals or another microcontroller. Typical applications include interface to external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters. MibSPI is an Extension of SPI. MibSPI works in 2 Modes.

- Compatibility Mode
- Multi-buffer Mode

The Compatibility mode of MibSPI makes it behave exactly like that of SPI and ensures full compatibility with the same. Everything described about compatibility mode of MibSPI , in this document, is directly applicable to SPI.

The Multi-buffer mode of operation is specific to MibSPI alone. This feature is not available in SPI.

The MibSPI supports memory fault detection/correction via internal Parity/ECC circuit. MibSPI is configurable to include or not include Memory Parity/ECC logic during circuit synthesis.

The SPI / MibSPI can be configured in three pin, four pin or five pin mode of operation. The SPI / MibSPI allows multiple programmable chip-selects.

The MibSPI has a programmable Multi-buffer array that enables programed transmission to be completed without CPU intervention. The buffers are combined in different transfer groups that could be triggered by external events (Timers, I/O, and so on) or by the internal tick counter. The internal tick counter can support periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different transfer group, allowing the user to move data from/to internal memory to/from external slave with a minimal CPU interaction.

The pins SPICLK, SPISIMO and SPISOMI are used in all MibSPI pin modes. The pins SPIENA and SPISCS[7:0] are optional and may be used if the pin are present on a given device.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 8-bit baud clock generator
- Serial Clock (SPICLK) I/O pin
- SPI enable ($\overline{\text{SPIENA}}$) pin (4 or 5-pin mode only)
- Up to 8 slave chip select (Slave Chip Select $\overline{\text{SPISCS}}$[7:0]) pin (4 or 5-pin mode only)
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

The SPI / MibSPI allows software to program the following options:

- SPISOMI/SPISIMO pin direction configuration
- SPICLK pin source (external/internal)
- MibSPI pins as functional or digital I/O pins. For each Buffer, following features can be selected from 4 different combinations of Formats using the control fields in the buffer.
  - SPICLK frequency
  - Charecter length
  - Phase,Polarity
  - Enable/Disable parity for transmit and receive
  - Enable/Disable timers for ChipSelect Hold and Setup timers
  - Direction of shifting, MSBit first or LSBit first
  - Configurable Parallel modes to use multiple SIMO/SOMI pin
  - Configurable number of ChipSelects

In Multi-buffer Mode, in addition to the above, many other features are configurable

- Number of buffers for each peripheral (or data source/destination, up to 256 buffers supported) or group (up to 8 groupings)
- Number of DMA controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
- Triggers for each groups, trigger types, trigger sources for individual groups(up to 14 external trigger sources and 1 internal trigger source)
- Number of DMA transfers for each buffer (up to 65536 for up to 8 buffers)
- Un-interrupted DMA buffer transfer (NOBREAK buffer)

NOTE: SIMO - Slave In Master Out Pin
SOMI - Slave Out Master In Pin
CS - SPI Chip Select Pin
ENA - SPI Enable Pin.

23.1.2 Pin Configurations

The SPI supports data connections as shown in Table 23-3.

Table 23-3. Pin Configurations

Pin	Master Mode		Slave Mode	
SPICLK	Drives the clock to external devices		Receives the clock from the external master	
SPISOMI	Receives data from the external slave		Sends data to the external master	
SPISIMO	Transmits data to the external slave		Receives data from the external master	
SPIENA	**SPIENA disabled:** GIO	**SPIENA enabled:** Receives ENA signal from the external slave	**SPIENA disabled:** GIO	**SPIENA enabled:** Receives ENA signal from the external master
SPICS[7:0]	**SPICS disabled:** GIO	**SPICS enabled:** Selects one or more slave devices	**SPICS disabled:** GIO	**SPICS enabled:** Receives the CS signal from the external master

NOTE:

1. When the SPICS[3:0] signals are disabled, the chip-select field in the transmit data is not used.
2. When the SPIENA signal is disabled, the $\overline{\text{SPIENA}}$ pin is ignored in master mode, and not driven as part of the SPI transaction in slave mode.

23.1.3 MibSPI /SPI Configurations

Table 23-4. MibSPI/SPI Configurations

MibSPIx/SPIx	I/Os

SPI2 (SPI-B)	SPI2SIMO, ZSPI2SOMI, SPI2CLK, SPI2nCS[1:0], SPI2nENA
SPI3 (SPI-C)	SPI3SIMO, ZSPI3SOMI, SPI3CLK, SPI3nCS[1:0], SPI3nENA

23.2 Basic Operation

This section details the basic operation principle of the SPI mode and the MibSPI mode operation of the device.

23.2.1 SPI Mode

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

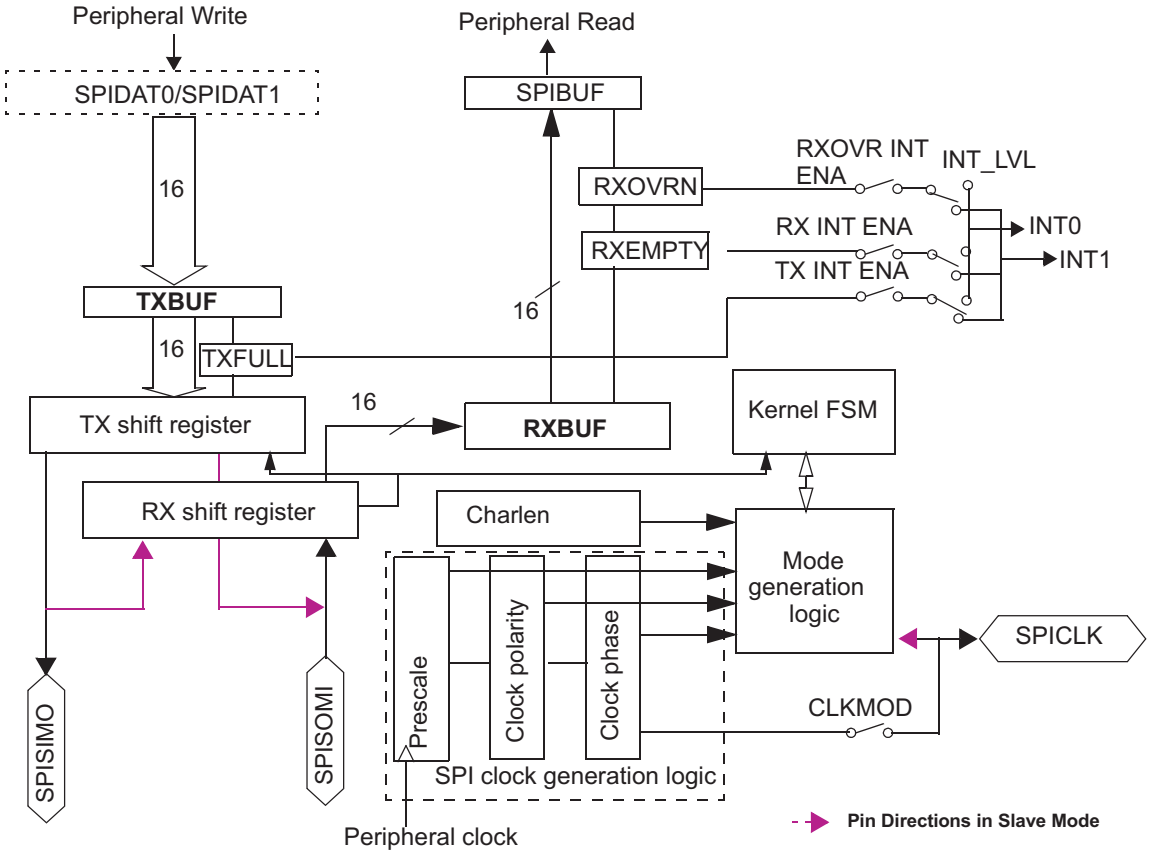
The slave chip select ($\overline{\text{SPISCS}}$[7:0]) pins, are used when communicating with multiple slave devices. When the a write occurs to SPIDAT1 in master mode, the $\overline{\text{SPISCS}}$ pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the $\overline{\text{SPIENA}}$ pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exch ange of data.

23.2.1.1 SPI Mode Operation Block Diagram

Figure 23-1 shows the SPI transaction hardware. TXBUF and RXBUF are internal buffers that are intended to improve the overall throughput of data transfer. TXBUF is a transmit buffer, while RXBUF is a receive buffer.

Figure 23-1. SPI Functional Logic Diagram



1 This is a representative diagram, which shows three-pin mode hardware.
2 TXBUF, RXBUF, and SHIFT_REGISTER are user-invisible registers.
3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

23.2.1.2 Data Flow and Handling for TX and RX

23.2.1.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX_DMA_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is expty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

23.2.1.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register

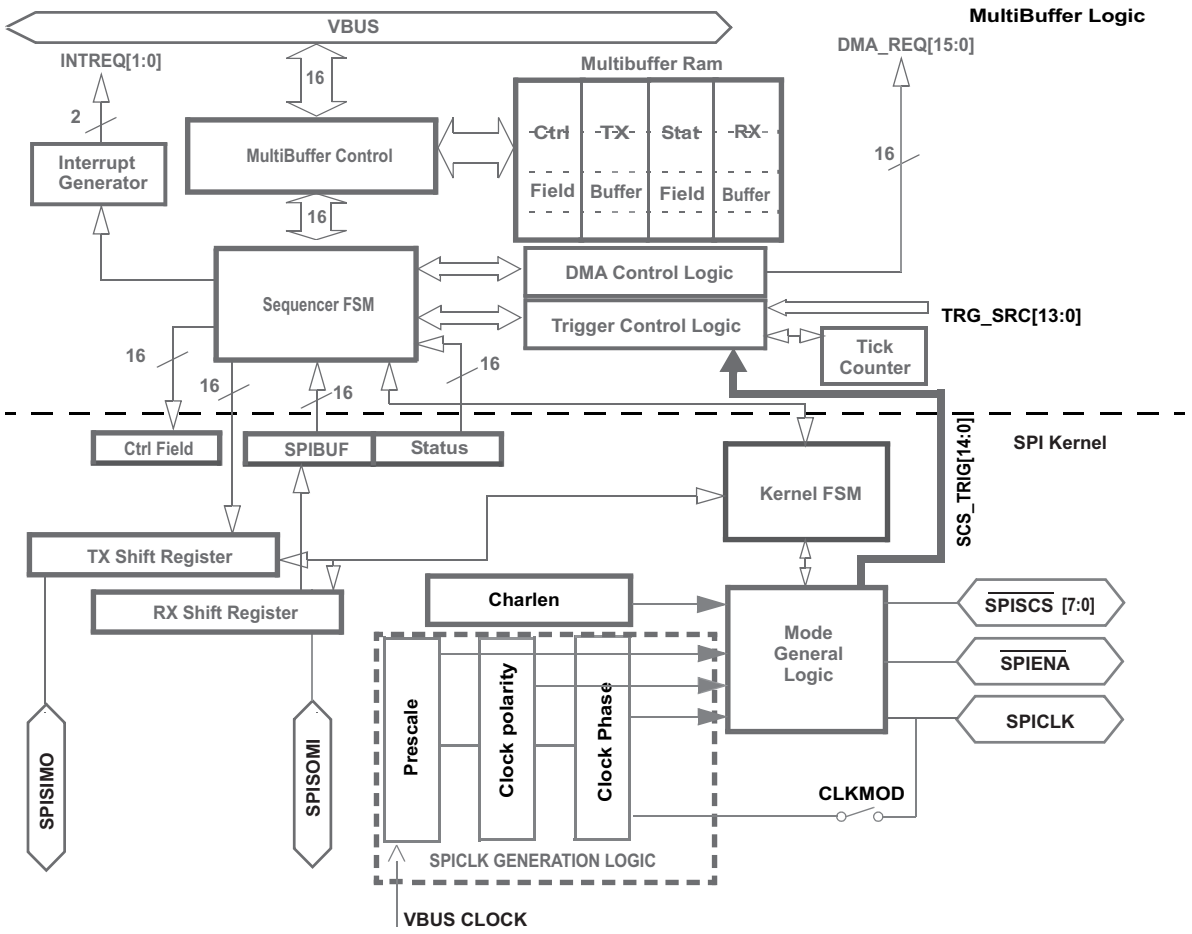
- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.

NOTE: Prefetching is done only in Master mode. In Slave mode, since the TG to be serviced is known only after a valid ChipSelect assertion, no prefetching is done.

23.2.2 MibSPI Mode

Figure 23-2 shows multi-buffered mode operation. In Multi-buffer mode the transmit data has to be written to the TXRAM locations and the receive data has to be read from RXRAM locations of the multi-buffer RAM. A MibSPI supports up to 256 locations each for Transmit and Receive Data.

Figure 23-2. MibSPI Functional Logic Diagram



23.2.2.1 Data Handling for TX and RX Transfer Groups

23.2.2.1.1 Data Sequencing of a Transmit Data

In multi-buffer mode, any buffer that needs to be transmitted over by the SPI, should be associated with a Transfer Group. Each TG (Transfer Group) will have a Trigger Source based on which it'll be triggered. Once a TG is triggered, the buffers belonging to it will be transmitted.

Sequencer (FSM) controls the data flow from the multi-buffer RAM to the Shift Register. The Multi-buffer Control Logic has arbitration logic between VBUS and the Sequencer accessing the multi-buffer RAM. Sequencer picks up a highest priority Transfer Group from among the active TGs to be serviced. For the selected TG the starting buffer to be transferred is obtained from the PSTART of the respective TGxCTRL register.

Sequencer requests for the selected buffer through the Multi-buffer Control Logic, and once it receives the data, it reads the control fields to determine the subsequent action. Once the buffer is determined to be ready for transfer, the data is written to the TX SHIFT REGISTER by the Sequencer. This triggers the Kernel FSM to initiate the SPI transfer.

Once the Sequencer is finished writing to the TX SHIFT REGISTER, it prefetches the next buffer to be transferred from the multi-buffer RAM and stores the Data.

Once the Sequencer is finished writing to the TX SHIFT REGISTER, it prefetches the next buffer to be transferred from the multi-buffer RAM and stores the Data.

Sequencer writes the prefetched Transmit Data to the Shift Register immediately upon request by the Kernel. This way, the throughput of the SPI transfer is increased in Master mode of operation. In case of Slave mode, after the Receive data is copied to the RX RAM, Sequencer waits for the next active Chip Select trigger to fetch the next data.

23.2.2.1.2 Data Sequencing of the Received Data

At the end of a SPI transfer, the received Data is copied to SPIBUF register and then forwarded to the Sequencer. The Sequencer then, requests the Multi-buffer Control Logic to write the received data to the respective RXRAM location. Along with Received Data, the Status fields like Transmission Error Flags and the Last Chip Select Number (LCSNR) are forwarded to be updated in the Status Field of the RXRAM.

Sequencer clears the RXEMPTY bit while writing a new Received Data in the RXRAM. If the RXEMPTY bit is already 0, then the Sequencer sets the RCVR_OVRN bit to 1 to indicate that this particular location has been overwritten in the RXRAM.

23.2.3 DMA Requests

In order to reduce CPU overhead in handling SPI message traffic on a character-by-character basis, SPI can use the DMA controller to transfer the data

23.2.3.1 SPI/MibSPI Compatibility Mode DMA Requests

. The DMA request enable bit (DMA REQ EN) controls the assertion of requests to the DMA controller module. When a character is being transmitted or received, the SPI will signal the DMA via the DMA request signals, TX_DMA_REQ and RX_DMA_REQ. The DMA controller will then perform the required data transfer.

For efficient behavior during DMA operations, the transmitter empty and receive-buffer full interrupts can be disabled. For specific DMA features, see the DMA controller specification.

The SPI generates a request on the TX_DMA_REQ line each time the TX data is copied to the TX shift register either from the TXBUF or from peripheral data bus (when TXBUF is empty).

The first TX_DMA_REQ pulse is generated when either of the following is true:

- DMA REQ EN (SPIINT0[16]) is set to 1 while SPIEN (SPIGCR1[24]) is already 1.
- SPIEN (SPIGCR1[24]) is set to 1 while DMA REQ EN (SPIINT0[16]) is already 1.

The SPI generates a request on the RX_DMA_REQ line each time the received data is copied to the SPIBUF.

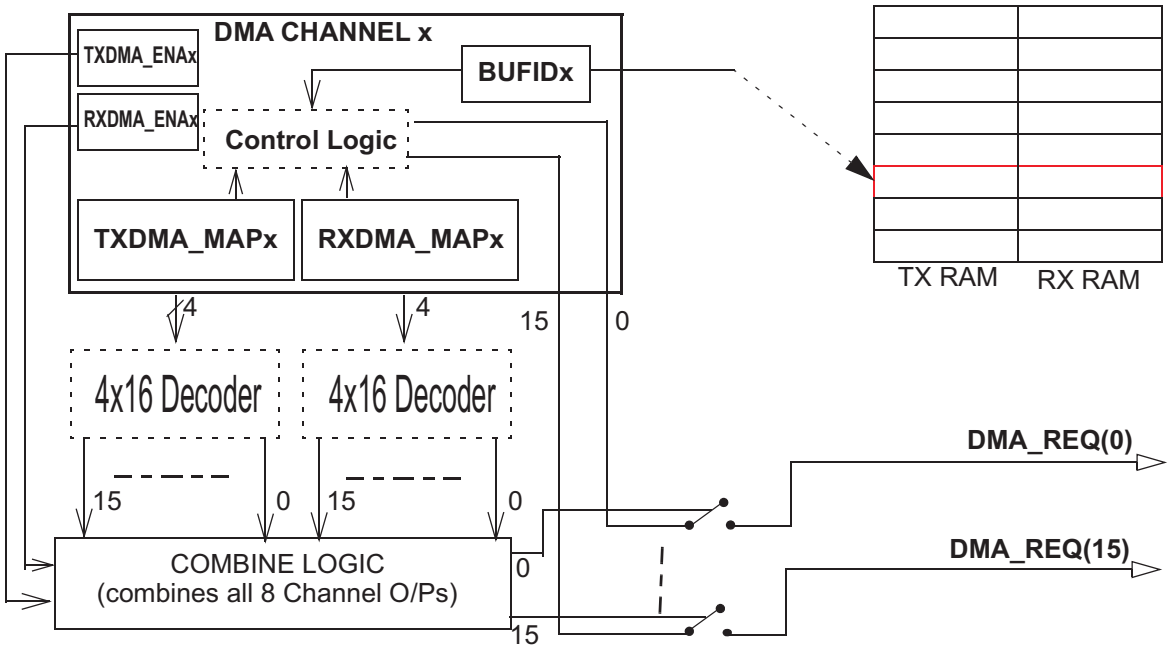
23.2.3.2 DMA in Multi-Buffer Mode

The MibSPI provides sophisticated programmable DMA control logic that completely eliminates the necessity of CPU intervention for data transfers, once programmed. When the multi-buffer mode is used, the DMA enable bit in the SPIINT0 register is ignored. DMA source or destination should be only the multi-buffer RAM and not SPIDAT0 / SPIDAT1 or SPIBUF register as in case of compatibility mode DMA.

The MibSPI offers up to eight DMA channels (for SEND and RECEIVE). All of the DMA channels are programmable individually and can be hooked to any buffer. The MibSPI provides up to 16 DMA request lines, and DMA requests from any channel can be programmed to be routed through any of these 16 lines. A DMA transfer can trigger both transmit and receive.

Each DMA channel has the capability to transfer a block of up to 32 data words without interruption using only one buffer of the array by configuring the DMAxCTRL register. Using the DMAxCOUNT and DMACTNTLEN register, up to 65535 (64K) words of data can be transferred without any interruption using just one buffer of the array. This enables the transfer of memory blocks from or into an external SPI memory.

Figure 23-3. DMA Channel and Request Line (Logical) Structure in Multi-buffer Mode



23.2.4 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

NOTE: Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive.A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

23.2.4.1 Interrupts in Multi-Buffer Mode

In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

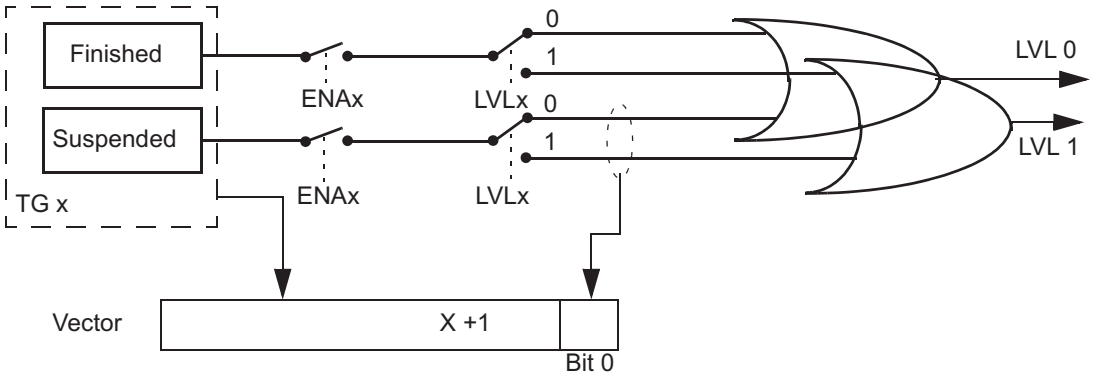
When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

Figure 23-4 illustrates the TG interrupts.

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

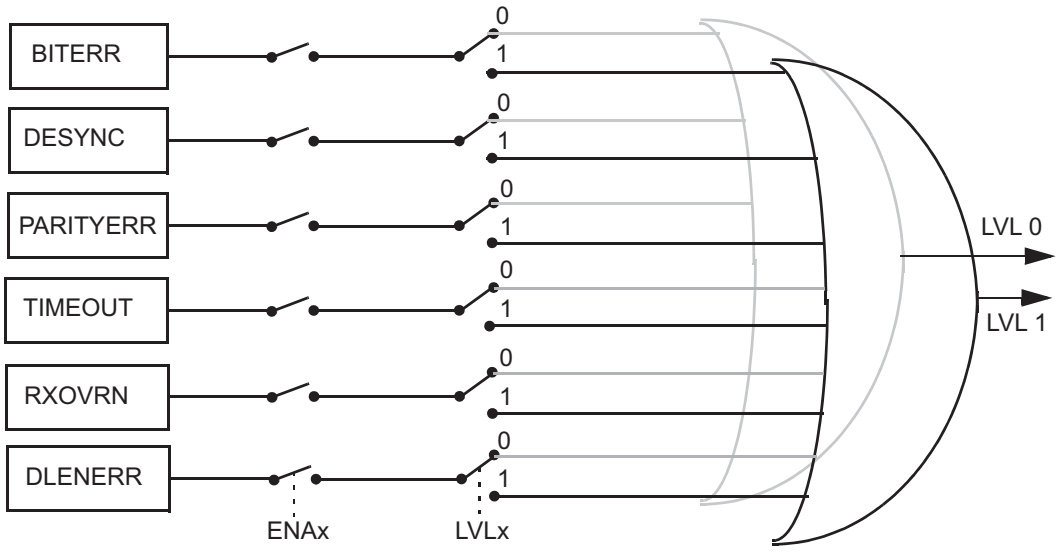
Figure 23-4. TG Interrupt Structure



The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

Figure 23-5. SPIFLG Interrupt Structure



Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

23.2.5 Physical Interface

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The slave chip select ($\overline{\text{SPISCS}}$[7:0]) pins, are used when communicating with multiple slave devices. When the a write occurs to SPIDAT1 in master mode, the $\overline{\text{SPISCS}}$ pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the $\overline{\text{SPIENA}}$ pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exch ange of data.

23.2.5.1 Three-Pin Mode

In master mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see Figure 23-6).

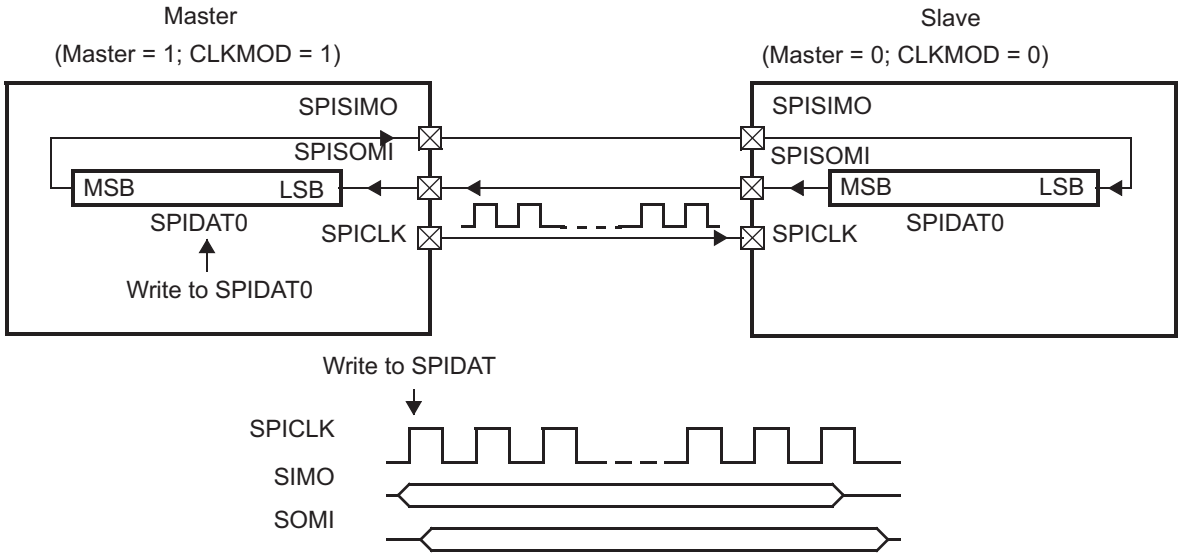
Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See Section 23.2.1.2.2 and Section 23.2.2 for details about the data handling for transmit and receive operations.

In slave mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network master. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the slave simultaneously, it must be written to the SPIDAT0 or SPIDAT1register before the beginning of the SPICLK signal.

Figure 23-6. SPI Three-Pin Operation



23.2.5.2 Four-Pin Mode with Chip Select

The three-pin option and the four-pin options of the SPI / MibSPI are identical in the master mode (CLKMOD = 1), except that the four-pin option uses either $\overline{\text{SPIENA}}$ or $\overline{\text{SPISCS}}$ [7:0] pins. The I/O directions of these pins are determined by the CLKMOD control bit as SPI / MibSPI and not general purpose I/O.

23.2.5.2.1 Four-Pin Option with $\overline{\text{SPISCS}}$

In master mode, each chip select signal is used to select a specific slave. In slave mode, chip select signal is used to enable/disable the transfer. Chip-select functionality is enabled by setting one of the $\overline{\text{SPISCS}}$ [7:0] pins as chip selects. It is disabled by setting all $\overline{\text{SPISCS}}$ [7:0] pins as GIOs in SPIPC0[3:0]

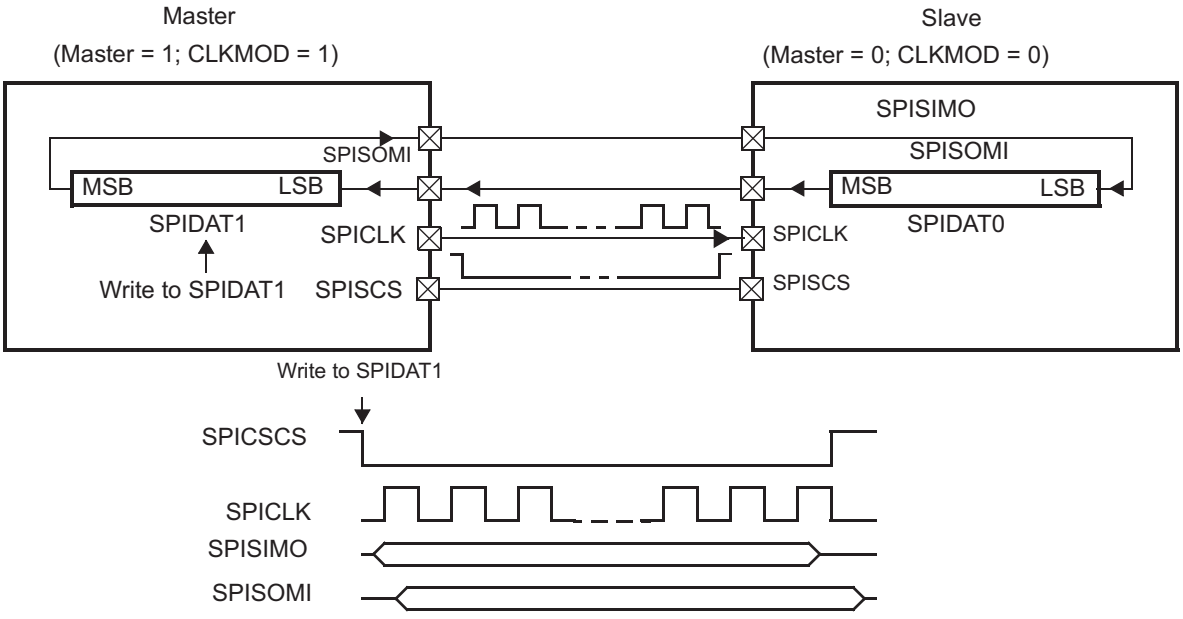
23.2.5.2.1.1 Multiple Chip Selects

The $\overline{\text{SPISCS}}$ [7:0] pins that are used must be configured as functional pins in the SPIPC0[7:0] register. The default pattern to be put on the $\overline{\text{SPISCS}}$ [7:0] when all the slaves are deactivated is set in the SPIDEF register. This pattern allows different slaves with different chip-select polarity to be activated by the SP/MibSPI.

The master-mode SPI is capable of driving either 0 or 1 as the active value for any $\overline{\text{SPISCS}}$[3:0] output pin. The drive state for $\overline{\text{SPISCS}}$[7:0] pins is controlled by the CSNR field of SPIDAT1. The pattern that is driven will select the slave to which the transmission is dedicated.

In slave mode, the SPI can only be selected by an active value of 0 on any of its selected $\overline{\text{SPISCS}}$ input pin.

Figure 23-7. Operation with $\overline{\text{SPISCS}}$



23.2.5.2.2 Four-Pin Option with $\overline{\text{SPIENA}}$

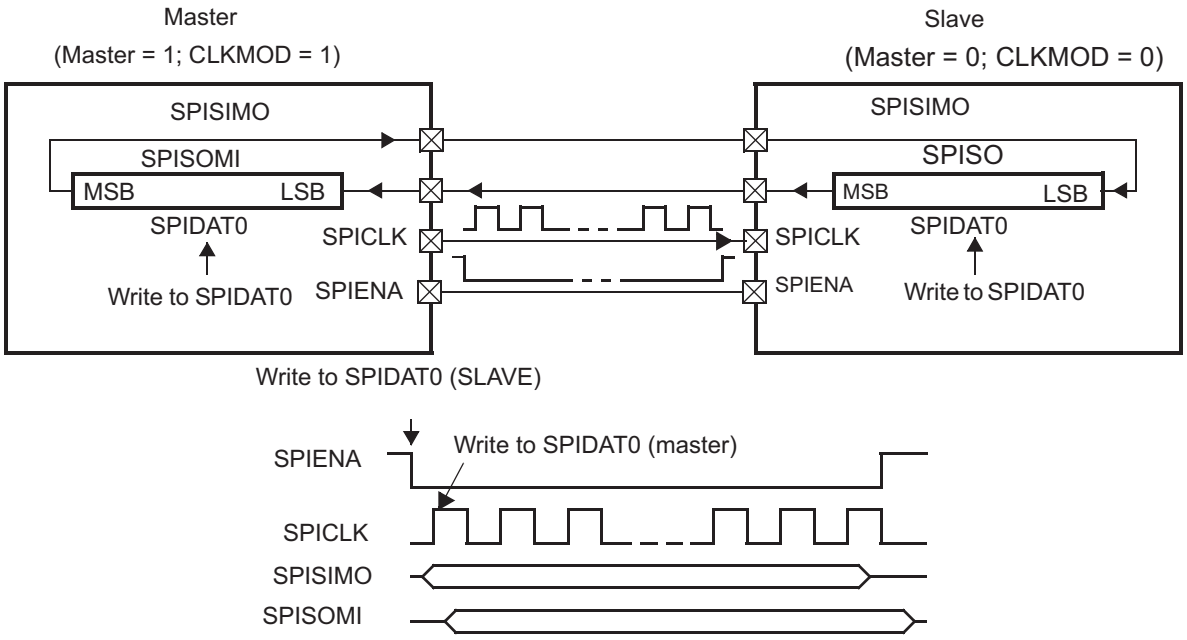
The $\overline{\text{SPIENA}}$ operates as a WAIT signal pin. For both the slave and the master, the $\overline{\text{SPIENA}}$ pin must be configured to be functional (SPIPC0[8] = 1). In this mode, an active low signal from the slave on the $\overline{\text{SPIENA}}$ pin allows the master SPI to drive the clock pulse stream. A high signal tells the master to hold the clock signal (and delay SPI activity).

If the $\overline{\text{SPIENA}}$ pin is in high-z mode (ENABLE_HIGHZ = 1), the slave will put $\overline{\text{SPIENA}}$ into the high-impedance once it completes receiving a new character. If the $\overline{\text{SPIENA}}$ pin is in push-pull mode (ENABLE_HIGHZ = 0), the slave will drive $\overline{\text{SPIENA}}$ to 1 once it completes receiving a new character. The slave will drive $\overline{\text{SPIENA}}$ low again for the next word to transfer, after new data is written to the slave TX shift register.

In master mode (CLKMOD = 1), if the $\overline{\text{SPIENA}}$ pin is configured as functional, then the pin will act as an input pin. If configured as a slave SPI and as functional, the $\overline{\text{SPIENA}}$ pin acts as an output pin.

NOTE: During a transfer, if a slave-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and $\overline{\text{SPIENA}}$ (if ENABLE_HIGHZ bit is set to 1) in high-z mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an DLENERR error flag and generates an interrupt (if enabled).

Figure 23-8. Operation with $\overline{\text{SPIENA}}$



23.2.5.3 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the SPIENA pin and the required number of SPISCS [3:0] pins must be configured as functional pins.

If the SPIENA pin is in high-z mode (ENABLE_HIGHZ = 1), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal SPIENA low when new data is written to the slave shift register and the slave has been selected by the master (SPISCS is low).

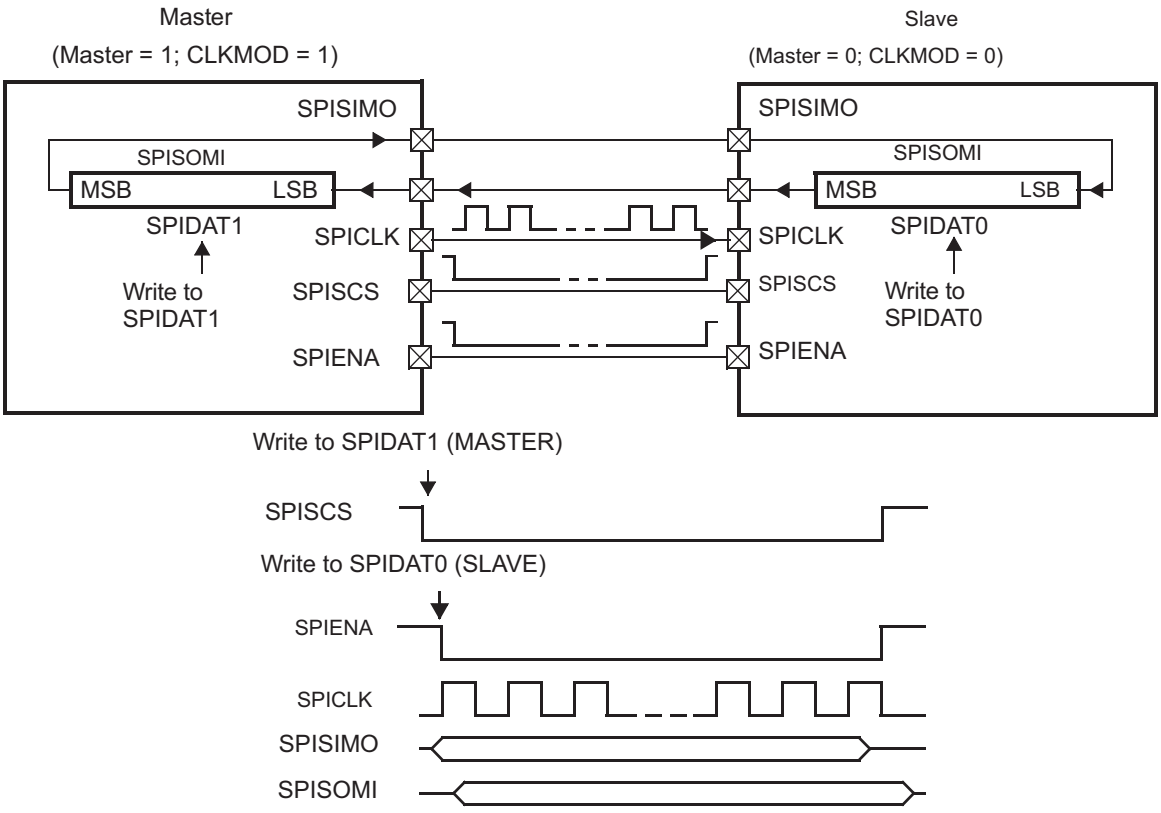
If the SPIENA pin is in push-pull mode (ENABLE_HIGHZ = 0), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the SPIENA signal low when new data is written to the slave shift register (SPIDAT0/SPIDAT1) and the slave is selected by the master (SPISCS is low). If the slave is deselected by the master (SPISCS goes high), the slave SPIENA signal is driven high.

NOTE: Push-pull mode of the SPIENA pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common SPIENA pin, all of the slaves should configure their SPIENA pins in high-Z mode.

In master mode, if the SPISCS pins are configured as functional pins, then the pins will be in output mode. A write to the master's SPIDAT1/SPIDAT0 register will automatically drive the SPISCS signals low. The master will drive the SPISCS signals high again after completing the transfer of the bits of the data.

In slave mode (CLKMOD = 0), the SPISCS pins will act as SPI functional inputs.

Figure 23-9. SPI Five-Pin Option with SPIENA and SPISCS



23.2.6 Advanced Module Configuration Options

23.2.6.1 Data Formats

To support multiple different types of slaves in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the master-mode SPI can drive two consecutive accesses to the same slave, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed slave. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **master** and the **slave**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

NOTE: Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

Figure 23-10 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

Figure 23-10. Format for Transmitting an 12-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
x	x	x	x	1	1	1	0	1	1	0	0	1	0	0	1

NOTE: The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

Figure 23-11 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

Figure 23-11. Format for Receiving an 10-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	0	1	0	1	0	0	0	1	0

23.2.6.2 Clocking Modes

SPICLK may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.

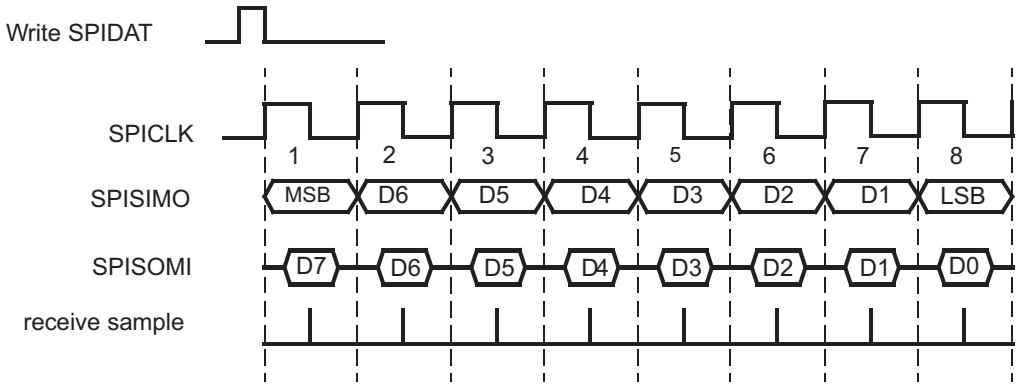
The data input and output edges depend on the values of both POLARITY and PHASE as shown in Table 23-5.

Table 23-5. Clocking Modes

POLARITY	PHASE	Action
0	0	Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.
0	1	Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.
1	0	Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.
1	1	Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.

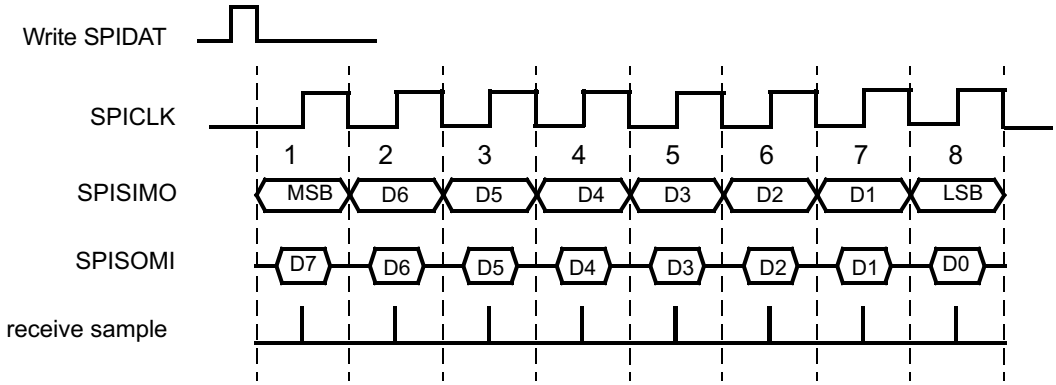
Figure 23-12 to Figure 23-15 illustrate the four possible configurations of **SPICLK** corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.

Figure 23-12. Clock Mode with Polarity = 0 and Phase = 0



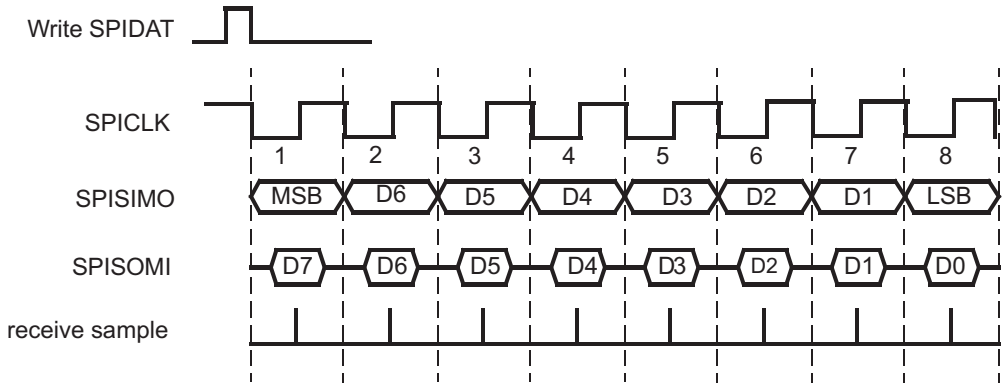
Data is output on the rising edge of SPICLK.
Input data is latched on the falling edge of SPICLK.

Figure 23-13. Clock Mode with Polarity = 0 and Phase = 1



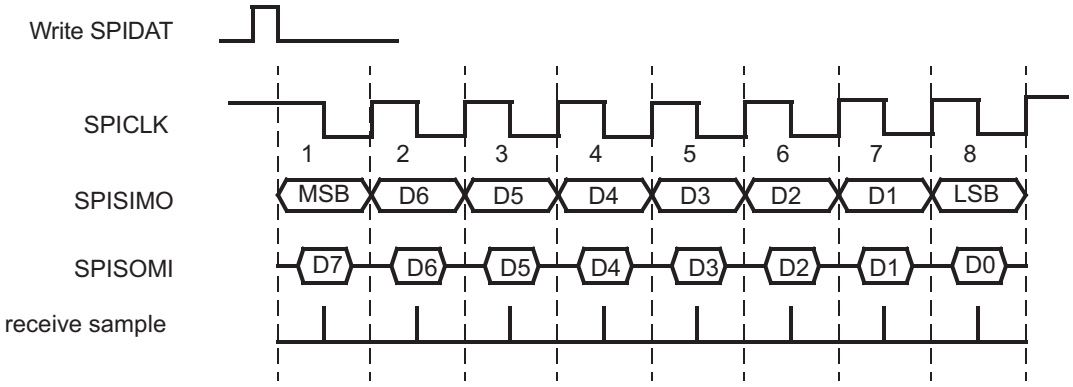
Data is output one-half cycle before the first rising edge of SPICLK and on subsequent falling edges of SPICLK
Input data is latched on the rising edge of SPICLK

Figure 23-14. Clock Mode with Polarity = 1 and Phase = 0



Data is output on the falling edge of SPICLK.
Input data is latched on the rising edge of SPICLK.

Figure 23-15. Clock Mode with Polarity = 1 and Phase = 1

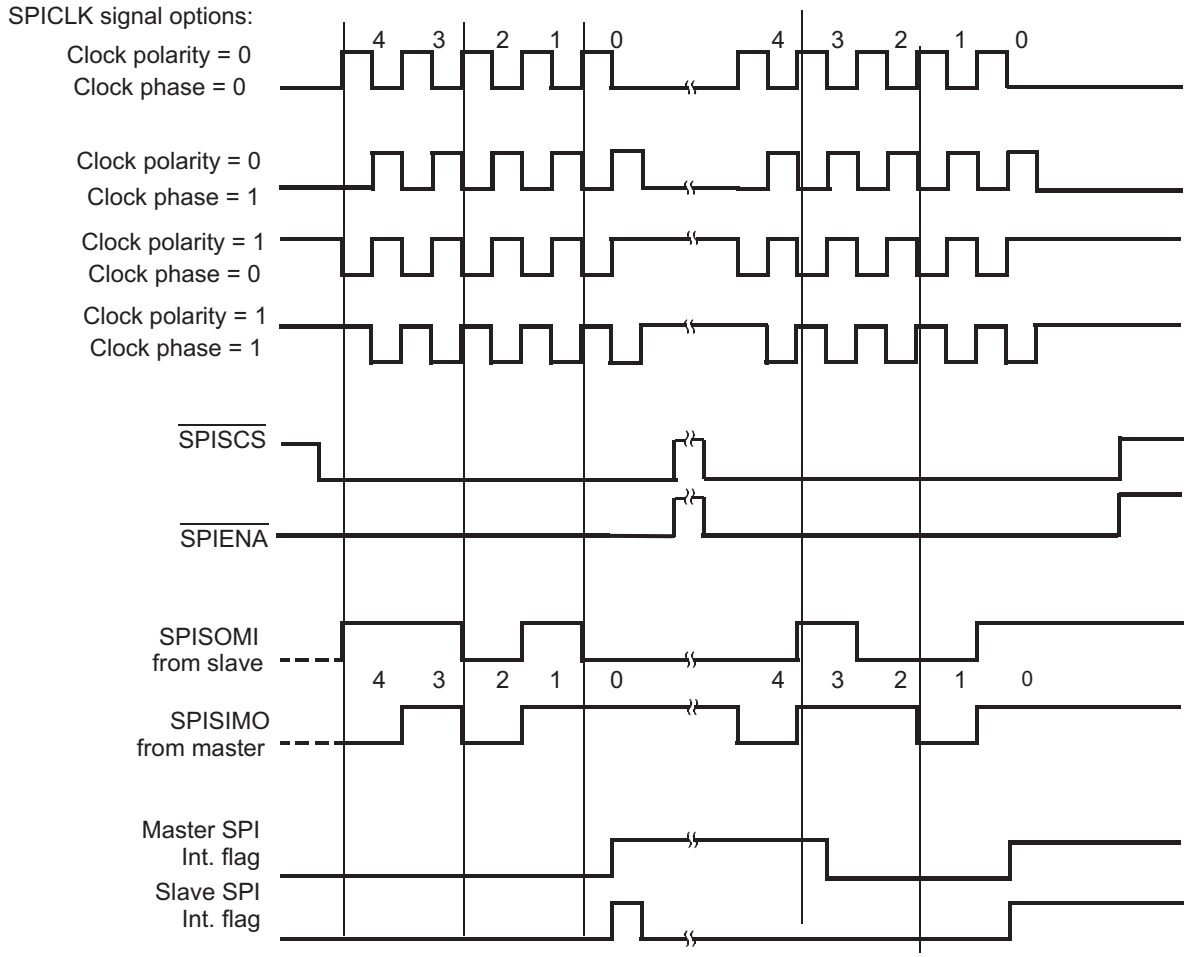


Data is output one-half cycle before the first falling edge of SPICLK and on the subsequent rising edges of SPICLK.
Input data is latched on the falling edge of SPICLK.

23.2.6.2.1 Data Transfer Example

Figure 23-16 illustrates a SPI data transfer between two devices using a character length of five bits.

Figure 23-16. Five Bits per Character (5-Pin Option)



23.2.6.3 Decoded and Encoded Chip Select (Master Only)

In this device the SPI can connect to up to 4 individual slave devices using chip-selects by routing one wire to each slave. The 4 chip selects in the control field are directly connected to the 4 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR[7:0]) of the SPIDAT1 register (SPIDAT1[23:16]) is driven on the $\overline{\text{SPISCS}}$ [4:0] pins. When the transmission finishes the default chip-select value (defined by the CSDEF register) is put on the $\overline{\text{SPISCS}}$ [4:0] pins.

The SPI can support more than 4 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active $\overline{\text{SPISCS}}$ pins at the same time, which enables binary encoded chip selects from 0 to 16. To use encoded chip selects, all four chip select lines have to be connected to each slave device and each slave needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example, *n* $\overline{\text{SPISCS}}$ pins can be used for encoding a *n*-bit address and the remaining pins can be connected to decoded-mode slaves.

23.2.6.4 Chip Select Timing Control

This section describes few fields of the contrlol register SPIDELAY this register decides the chip select and timing control for the device

23.2.6.4.1 Chip-Select-Active-to-Transmit-Start-Delay (C2TDELAY)

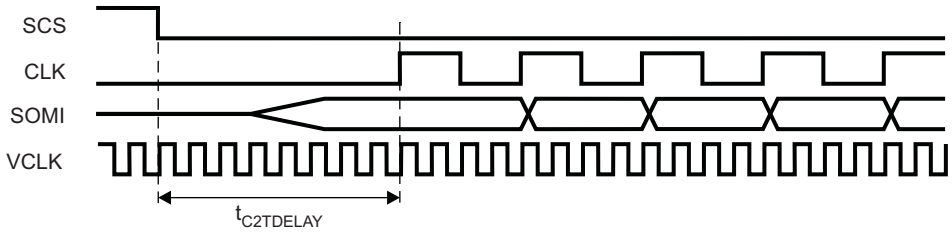
C2TDELAY is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of VBUSPCLK cycles. ChipSelect-active-to-transmission delays between 2 to 257 VBUSPCLK cycles can be achieved.

The setup time value is calculated as:

$t_{C2TDELAY}$= (C2TDELAY + 2) × VCLK Period

Figure 23-17 is the timing diagram when C2TDELAY of 8 VCLK Cycles.

Figure 23-17. Example: $t_{C2TDELAY}$= 8 VCLK Cycles



23.2.6.4.2 Transmit-End-to-Chip-Select-Inactive-Delay (T2CDELAY)

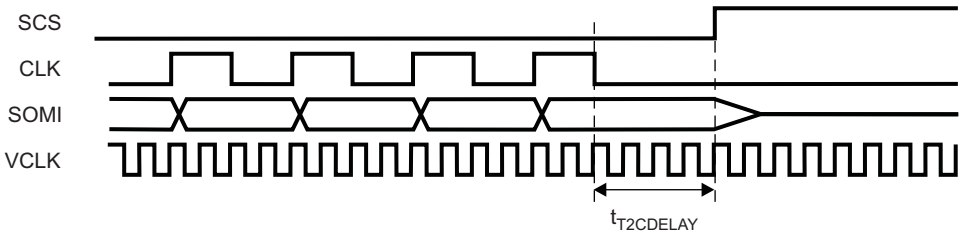
T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VBUSPCLK cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 VBUSPCLK cycles.

The hold time value is calculated as:

$t_{T2CDELAY}$= (T2CDELAY +1) × VCLK Period

Figure 23-18 is the timing diagram when T2CDELAY of 4 VCLK Cycles.

Figure 23-18. Example: $t_{T2CDELAY}$= 4 VCLK Cycles



23.2.6.4.3 Transmit-Data-Finished-to-ENA-Pin-Inactive-Time-Out (T2EDELAY)

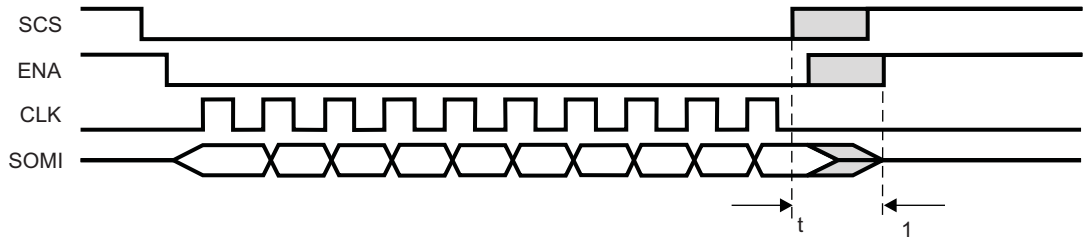
T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before the ENAble signal has to become inactive and after the CS becomes inactive. The SPI clock depends on which data format is selected. If the slave device is missing one or more clock edges, it is becoming de-synchronized. Although the master has finished the data transfer the

The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the ENA signal isn't deactivated in time. DESYNC flag is set to indicate that the Slave device did not deassert its SPIENA pin in time to acknowledge that it has received all the bits of the sent character.

The timeout value is calculated as:

$t_{T2EDELAY}$ = T2EDELAY/SPIclock

Figure 23-19. Transmit-Data-Finished-to-ENA-Inactive-Timeout



NOTE: If T2CDELAY is programmed a non-zero value, then T2EDELAY will start only after the T2CDELAY completes. This should be taken into consideration to determine an optimum value of T2EDELAY.

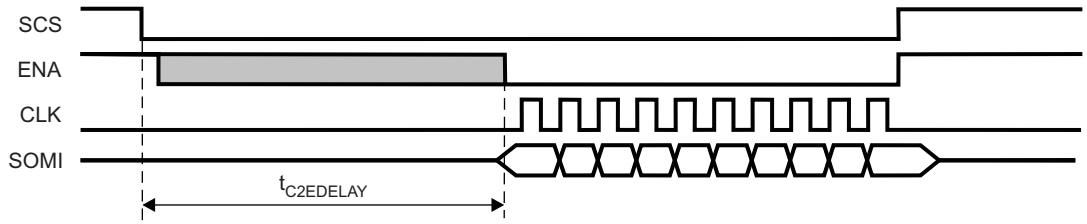
23.2.6.4.4 Chip-Select-Active-to-ENA-Signal-Active-Time-Out (C2EDELAY)

C2EDELAY is utilized only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between the SPI / MibSPI activating the chip select signal and the addressed slave responding by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected.

The timeout value is calculated as:

$t_{C2EDELAY}$ = C2EDELAY/SPIclock

Figure 23-20. Chip-Select-Active-to-ENA-Signal-Active-Timeout



NOTE:

- If the slave device is not responding with the ENA signal before the time-out value is reached, the TIMEOUT flag in SPIFLG register is set and an interrupt is asserted if enabled.
- If a time-out occurs the MibSPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer and continues with the transfer of the next buffer in the sequence that is enabled.
- If C2TDELAY is programmed a non-zero value, then C2EDELAY will start only after the C2TDELAY completes. This should be taken into consideration to determine an optimum value of C2EDELAY.

23.2.6.5 Multiple Transfers to Same Slave and Variable Chip Select Setup and Hold Timing

This section gives information on the Variable chip select setup and it shows how CSHOLD bit is used and how the multiple transfers to same slave is enabled in the devic

23.2.6.5.1 Variable Chip Select Setup and Hold Timing (Master Only)

In order to support slow slave devices a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with peripheral clock(VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pin(s), then they can be disabled in the corresponding SPIFMTx register.

23.2.6.5.2 Hold Chip-Select Active

Some slave devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both master and slave modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in master mode and slave mode are different.

NOTE: If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

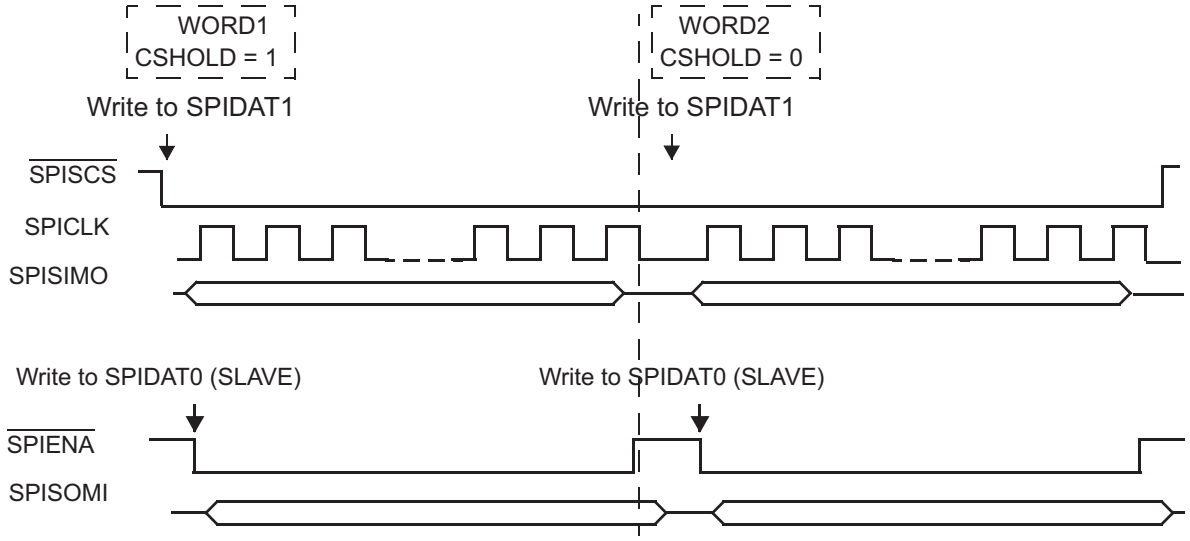
23.2.6.5.2.1 CSHOLD Bit in Master Mode

Each word in a master-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 23-21 shows the SPI pins when a master-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

Figure 23-21. Typical Diagram when a Buffer in Master is in CSHOLD Mode (SPI-SPI)



23.2.6.5.2.2 CSHOLD Bit in Slave Mode (Multi-buffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the $\overline{\text{SPISCS}}$ pins to be de-activated at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a slave in multi-buffer mode to do multiple data transfers without requiring the $\overline{\text{SPISCS}}$ pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a slave MibSPI, even after the shift operation is done, the MibSPI waits until the $\overline{\text{SPISCS}}$ pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the slave in multi-buffer mode requires its $\overline{\text{SPISCS}}$ pins to be deasserted between any two buffer transfers; otherwise, the Slave SPI will be unable to respond to the next data transfer.

NOTE: In compatibility mode, the slave does not require the $\overline{\text{SPISCS}}$ pin to be deasserted between two buffer transfers. The CSHOLD bit of the slave will be ignored in compatibility mode.

23.2.6.6 Parallel Mode (Multiple SIMO/SOMI Support, not available on all devices)

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (Parallel 2, 4 or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (SOMI and SIMO lines)
- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the SIMO/SOMI lines. The receive parity is expected on bit0 of the SOMI/SIMO pins.

Parallel mode can be programmed using the PMODEx[1:0] bits of SPIPMCTRL register. See for details about this register.

After reset the parallel mode selection bits are cleared (single SIMO/SOMI lines).

23.2.6.6.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (master mode) the shift register bits 15 and 7 will be connected to the pins SIMO[1] and SIMO[0], and the shift register bits 8 and 0 will be connected to the pins SOMI[1] and SOMI[0] or vice versa in slave mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on SIMO[1] and SIMO[0] on the rising edge if SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[1] and SOMI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. (SIMO[1] will shift the data out from bit 15 to 8, SIMO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 23-24 shows the clock /data diagram of the 2-data line mode. Figure 23-25 shows the timing of a two-pin parallel transfer.

Figure 23-24. 2-data Line Mode (Phase 0, Polarity 0)

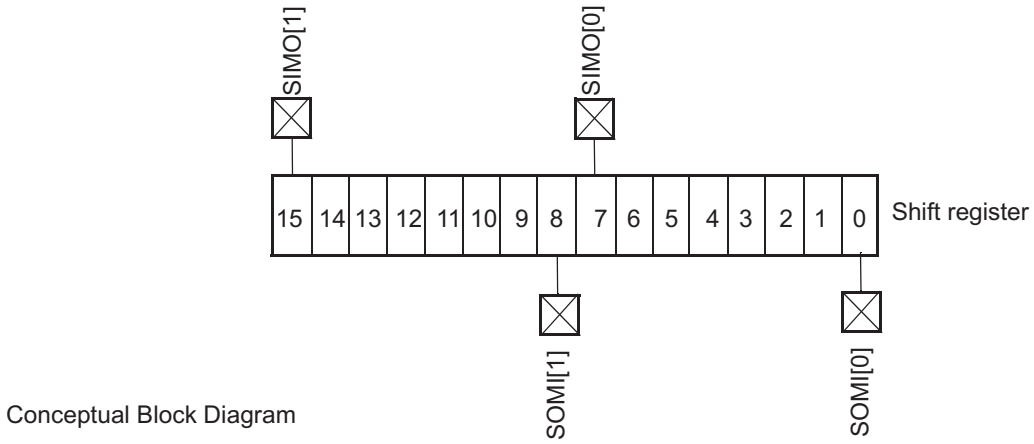

Figure 23-25. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)

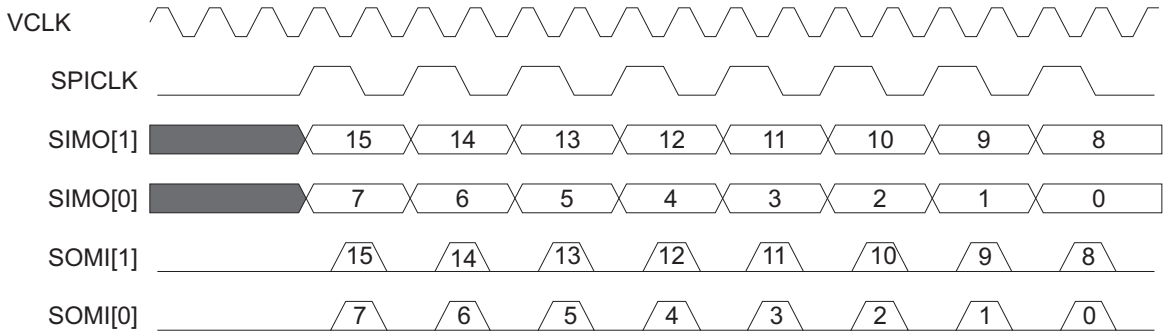

23.2.6.6.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left (SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 23-26 shows the clock/data diagram of the four-data line mode. Figure 23-27, shows the timing diagram for four-data line mode.

Figure 23-26. 4-Data Line Mode (Phase 0, Polarity 0)

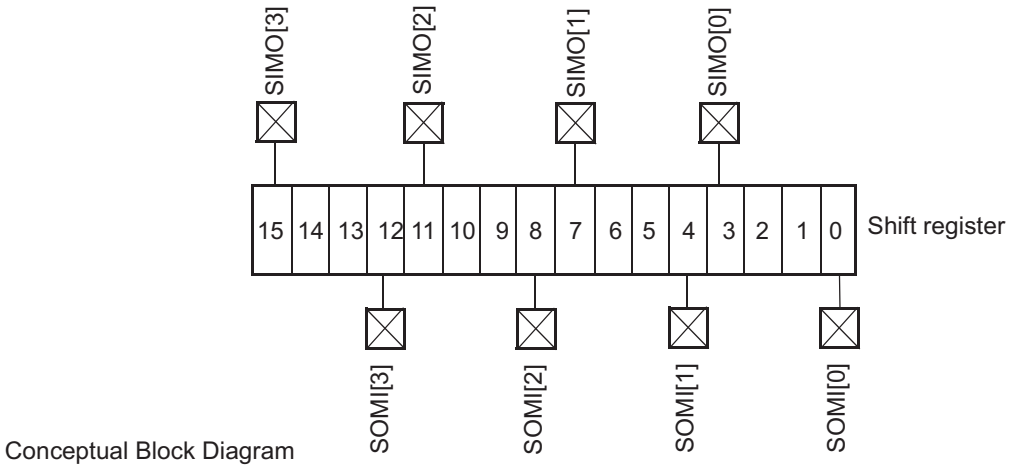

Figure 23-27. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

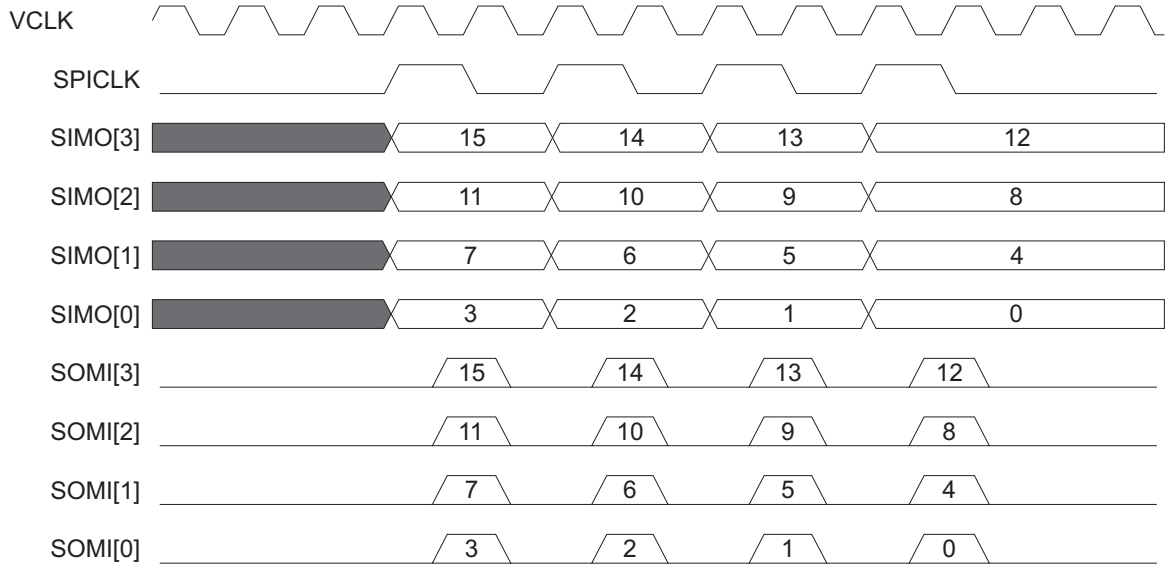


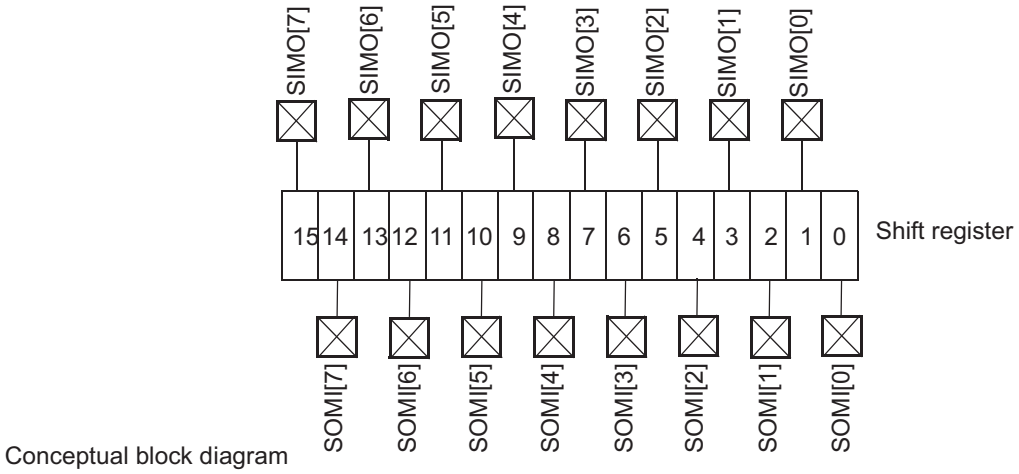
23.2.6.6.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (master mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on SOMI[8], SOMI[7], SOMI[6],SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by one bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. Figure 23-28 shows the clock/data diagram of the 8-data line mode. Figure 23-29 shows the pin timings for 8-data line mode.

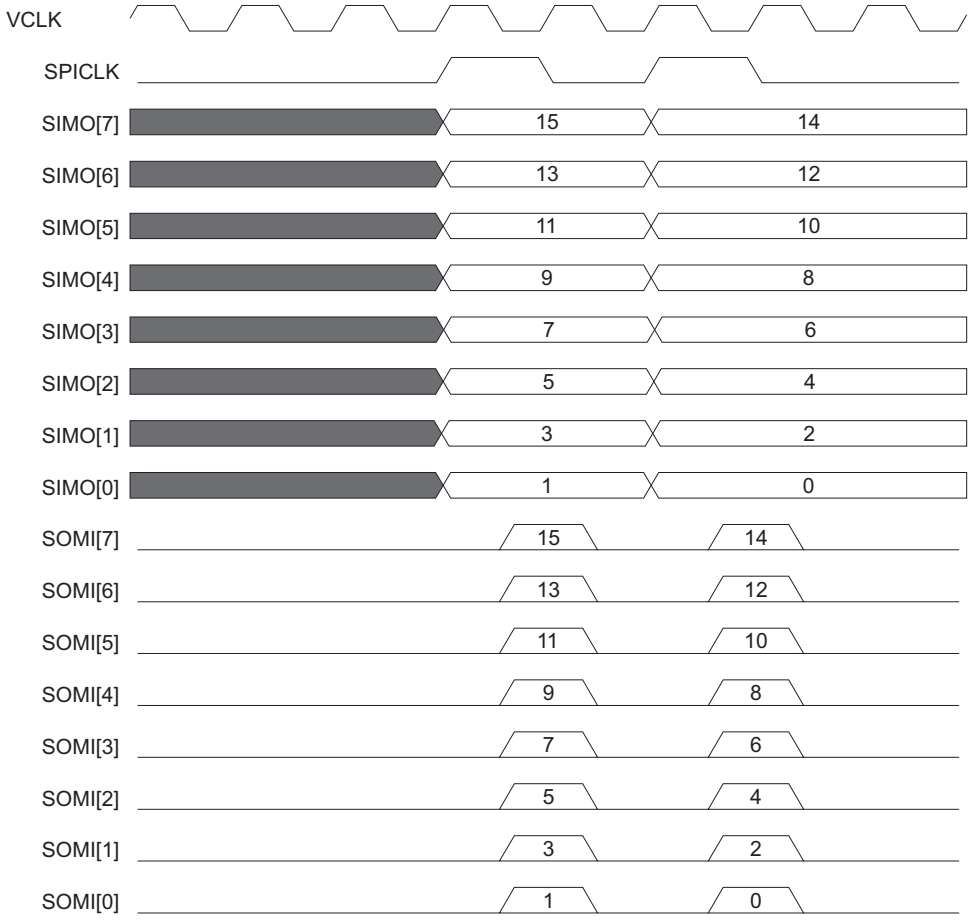
Figure 23-28. Eight-data Line Mode (Phase 0, Polarity 0)



NOTE: Parity Support

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

Figure 23-29. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)



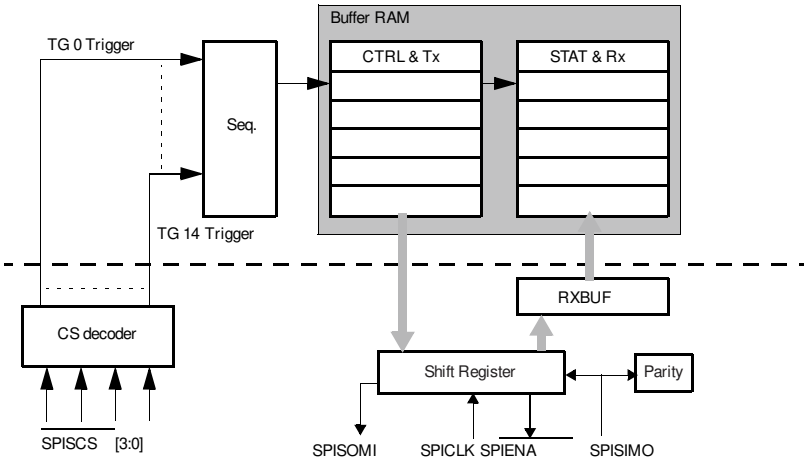
NOTE: Modulo Count Parallel Mode is not supported in this device.

23.2.6.7 MibSPI Slave in Multi-buffer Configuration

When operating in slave mode, the MibSPI uses the chip-select pins 0 to 3 to generate a trigger to the corresponding Transfer Group. For example, putting “0000” on the chip-select pins triggers Transfer Groups 0 and putting “0001” triggers TG 1. When the value “1111” is set to the chip-select, the MibSPI is deselected, that is Transfer Group 15 is not available in slave mode. The chip-select pins 4 to 7 should stay in GPIO mode. In slave mode, the fields like trigger source and trigger event are not taken into account by the sequencer. Only the SPISCS pins can trigger a Transfer Group. The chip-select trigger operates as a level-sensitive trigger. However, when the MibSPI is in 3-pin or 4-pin with SPIENA mode, just one Transfer Group can be triggered and it is restricted to Transfer Group 0 (TG 0). In Slave mode, the PRST field should be cleared to 0. If the corresponding Transfer Group is enabled, the Multi-buffer reads the current buffer of the TG and writes it into SPIDAT1. If Transfer Group is disabled, the Multi-buffer does not update the SPIDAT1 register.

NOTE: If the selected Transfer Group is disabled and no update of the SPIDAT1 register has been done, the data to be transferred is meaningless. Even the received data will not be copied to the multi-buffer RAM. However it will be available on SPIBUF register until it is overwritten by the subsequent receive data.

Figure 23-30. Multi-buffer in Slave Mode



When the SPIDAT1 register is updated, the enable signal is released, and the transaction could begin. If the enable signal is not used, the master should wait for 6 VBUSPCLK cycles before sending the clock to begin the transaction. This time allows the MibSPI to update the SPIDAT1 register.

Once the transaction is finished, the MibSPI writes back the content of the shift-register into the Rx buffer and updates the status field.

NOTE: If all the Transfer Groups are not needed, the number of SPISCS that need to be in functional mode could be reduced to 3, 2 or 1 by using the SPIPC0 register. In these cases, the maximum number of Transfer Group accessible are respectively 7, 3 and 1. The pins that are set in GPIO mode are not decoded.

MibSPI in 3-pin and 4pin (with SPIENA) configuration, supports multi-buffer mode too. However it is restricted to have just one transfer group. Only the transfer group0 (TG0) can be used in this mode. Entire multi-buffer RAM can be configured for TG0 alone. “PSTART” field in TG1CTRL register should be used to configure the size of the multi-buffer (end of the buffers) for TG0.

NOTE: The maximum input frequency on the SPICLK pin when in slave mode is VBUSPCLK frequency /2. If the Slave is configured in either 3-pin or 4-pin (without SPIENA) modes, then, between end of last SPICLK and the start of SPICLK for next buffer, there should be at least 6 VCLK cycles of delay.

23.2.6.8 Transfer Groups

The size of the multi-buffer RAM depends on the implementation. It comprises 0 to 128/256 buffers, whereas 0 buffers considers the special case of no multi-buffer RAM. Each entry in the multi-buffer RAM consists of 4 parts: a 16-bit transmit field, a 16-bit receive field, a 16-bit control field and a 16-bit status field. The multi-buffer RAM can be partitioned into multiple transfer group with variable number of buffers each.

23.2.6.8.1 Configuring Transfer Groups and Trigger Events

Each TG can be configured via one dedicated control register, TGxCTRL. This register even configures the trigger events for the transfer group. The register is described in . The actual number of available control registers varies by device.

23.2.6.8.2 Sequencer-Which Handled the Sequencing of Triggered Transfer Groups

Sequencer(FSM) controls the data flow from the multi-buffer RAM to the Shift Register. The Multi-buffer Control Logic has arbitration logic between VBUS and the Sequencer accessing the multi-buffer RAM. Sequencer picks up a highest priority Transfer Group from among the active TGs to be serviced. For the selected TG the starting buffer to be transferred is obtained from the PSTART of the respective TGxCTRL register.

Sequencer requests for the selected buffer through the Multi-buffer Control Logic, and once it receives the data, it reads the control fields to determine the subsequent action. Once the buffer is determined to be ready for transfer, the data is written to the TX SHIFT REGISTER by the Sequencer. This triggers the Kernel FSM to initiate the SPI transfer.

23.2.6.8.3 Inter-group Prioritization and Arbitration

Transfer Group0 (TG0) has the highest priority and TG15 has the lowest priority among the transfer groups TG0 to TG15.Where as under the following conditions under the following conditions a lower priority Transfer Group cannot be interrupted by a higher priority TG.

- When there's a CSHOLD or LOCK buffer, until the completion of the next buffer transfer which is a non-CSHOLD or non-LOCK buffer, the Transfer Group cannot be interrupted by any higher priority TGs.
- An entire sequence of buffer transfer for NOBRK DMA buffer cannot be interrupted by any higher priority TG.
- Once the last buffer in a Transfer Group is prefetched, a higher priority TG cannot interrupt it until the completion of the Transfer Group.

These prioritizations made among the transfer groups also decide the arbitration logic among the multiple transfer groups which are active

23.2.6.8.4 Transmission Lock Capability

Some slave devices require to have "command" followed by "data". In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows consecutive transfer to happen without being interrupted by another higher priority group transfer.

23.2.7 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPCx control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode
- input-buffer enabling/disabling (controlled by the PULDIS and PSEL bits)

23.2.8 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

NOTE: Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

23.2.9 Safety Features

23.2.9.1 Detection of Slave Desynchronization (Master Only)

When a slave supports generation of an enable signal (ENA), desynchronization can be detected. With the enable signal a slave indicates to the master that it is ready to exchange data. A desynchronization can occur if one or more clock edges are missed by the slave. In this case the slave may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the desynchronized slave and the consecutive data word. A configurable 8-bit time-out counter (T2EDELAY), which is clocked with SPICLK, is implemented to detect this slave malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the slave does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

NOTE: Inconsistency of Desynchronization Flag in Compatibility Mode MibSPI

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desynchronization condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always assured to be for the current buffer.

23.2.9.2 ENA Signal Time-Out (Master Only)

The SPI in master mode waits for the hardware handshake signal (ENA) coming from the addressed slave before performing a data transfer. To avoid stalling the SPI by a non-responsive slave device, a time-out value can be configured using C2EDELAY. If the time-out counter overflows before an active ENA signal is sampled, the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

NOTE: When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

23.2.9.3 Data-Length Error

A SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

Data-Length Error in Master Mode: During a data transfer, if the SPI detects a de-assertion of the $\overline{\text{SPIENA}}$ pin (by the slave) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a slave receiving extra clocks (for example, due to noise on the SPICLK line).

NOTE: In a master mode SPI, the data length error will be generated only if the $\overline{\text{SPIENA}}$ pin is enabled as a functional pin.

Data-Length Error in Slave Mode: During a transfer, if the SPI detects a de-assertion of the $\overline{\text{SPISCS}}$ pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise If the slave SPI misses one or more SPICLK pulses from the master. This error in slave mode implies that both the transmitted and received data were not complete.

NOTE: In a slave-mode SPI, the data-length error flag will be generated only if at least one of the $\overline{\text{SPISCS}}$(x) pins are configured as functional, and are being used for selecting the slave.

23.2.9.4 Continuous Self-Test (Master/Slave)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

NOTE: The compare is made from the output pin using its input buffer.

23.2.10 Test Features

23.2.10.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally fedback to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

NOTE: This mode cannot be changed during transmission.

23.2.10.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 23-31 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See for details of the register field controlling these features.

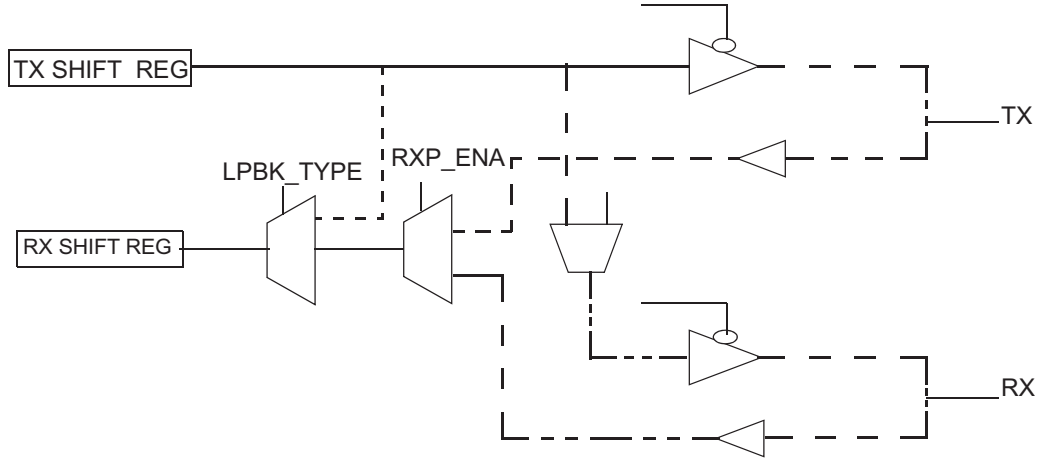
In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.

In Input/Output loopback test modes, if the module is in master mode, the nENA signal is also generated by internal logic so that an external interface is not required.

NOTE: Usage Guideline for Input/Output Loopback

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.

Figure 23-31. I/O Paths During I/O Loopback Modes



1 This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

23.2.10.2.1 IO Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving $\overline{\text{SPISCS}}$[3:0] to 0x0. The actual number of chip selects can be programmed to have any or all of the $\overline{\text{SPISCS}}$ pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR[3:0] field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

23.2.11 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multi-buffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

23.2.11.1 Compatibility (SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as SPIENA is held low the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, CLK and optional CSx, ENA pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the CS to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register (0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIENA to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- User must wait for TXFULL to reset or TXINT before writting next data to SPIDAT1 register.
- User must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

23.2.11.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as SPIENA is held low the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, CLK and optional CSx, ENA pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers × Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIENA to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register 16 Bit Control fields in every TXRAM buffer in the TG has to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the data to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- User can poll Transfer-group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

23.3 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

NOTE: TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

23.3.1 MSS_MIBSPIA Registers

Table 23-10 lists the memory-mapped registers for the MSS_MIBSPIA. All register offset addresses not listed in Table 23-10 should be considered as reserved locations and the register contents should not be modified.

Table 23-10. MSS_MIBSPIA Registers

Offset	Acronym	Register Name	Section
0h	SPIGCR0	SPI / MibSPI Global Control Register 0	Section 23.3.2.1
4h	SPIGCR1	SPI / MibSPI Global control register 1	Section 23.3.2.2
8h	SPIINT0	SPI / MibSPI Interrupt Enable Register	Section 23.3.2.3
Ch	SPILVL	SPI / MibSPI Interrupt Level Register	Section 23.3.2.4
10h	SPIFLG	SPI / MibSPI Flag Register	Section 23.3.2.5
14h	SPIPC0	SPI / MibSPI Pin Control Register 0 (SPIPC0) - SPIFUN Note: Duplicate Control Bits for SIMO0 & SOMI0 Bit 24 is not physically implemented. it is a mirror of Bit11. Any write to Bit 24 will be reflected on Bit11 and when Bit 24 & Bit 11 simultaneously written, the value of Bit11 will control the SOMI pin. Read value of Bit 24 always reflects the Bit 11 value. This is true for the Bit 24 & Bit 11 of all of SPIPC0 to SPIPC9 registers. Same is true for SIMO pin with Bit16 & Bit 10 of SPIPC0 to SPIPC9 registers.	Section 23.3.2.6
18h	SPIPC1	SPI / MibSPI Pin Control Register 1 (SPIPC1) - SPIDIR	Section 23.3.2.7
1Ch	SPIPC2	SPI / MibSPI Pin Control Register 2 (SPIPC2) - SPIDIN	Section 23.3.2.8
20h	SPIPC3	SPI / MibSPI Pin Control Register 3 (SPIPC3) - SPIDOUT	Section 23.3.2.9
24h	SPIPC4	SPI / MibSPI Pin Control Register 4 (SPIPC4) - SPIDSET	Section 23.3.2.10
28h	SPIPC5	SPI / MibSPI Pin Control Register 5 (SPIPC5) - SPIDCLR	Section 23.3.2.11
2Ch	SPIPC6	SPI / MibSPI Pin Control Register 6 (SPIPC6) - SPIPDR	Section 23.3.2.12
38h	SPIDAT0	SPI / MibSPI Transmit Data Register 0 Note: Accessibility of SPIDAT0 The SPIDAT0 register is not accessible in Multibuffer Mode of MibSPI. It is only accessible in compatibility mode.	Section 23.3.2.13
3Ch	SPIDAT1	SPI / MibSPI Transmit Data Register 1 When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned.	Section 23.3.2.14
40h	SPIBUF	SPI / MibSPI Receive Buffer Register	Section 23.3.2.15
44h	SPIEMU	SPI / MibSPI Emulation Register Note: All the fields ot SPIEMU register are Read-Only. Read operation on this register under any mode will not have any impact on the status of this or any other registers.	Section 23.3.2.16
48h	SPIDELAY	SPI / MibSPI Delay Register	Section 23.3.2.17
4Ch	SPIDEF	SPI / MibSPI Default Chip select Register	Section 23.3.2.18
50h	SPIFMT0	SPI / MibSPI Data Format Register 0	Section 23.3.2.19
54h	SPIFMT1	SPI / MibSPI Data Format Register 1	Section 23.3.2.20
58h	SPIFMT2	SPI / MibSPI Data Format Register 2	Section 23.3.2.21
5Ch	SPIFMT3	SPI / MibSPI Data Format Register 3	Section 23.3.2.22
60h	TGINTVECT0	SPI Interrupt Vector Register 0 / MibSPI Transfer Group Interrupt Vector Register 0	Section 23.3.2.23
64h	TGINTVECT1	SPI Interrupt Vector Register 1 / MibSPI Transfer Group Interrupt Vector Register 1	Section 23.3.2.24

Table 23-10. MSS_MIBSPIA Registers (continued)

Offset	Acronym	Register Name	Section
68h	SPIPC9	SPI/MibSPI Pin Control Register 9 (SPIPC9) - SPISRSEL	Section 23.3.2.25
6Ch	SPIPMCTRL	SPI/MibSPI Parallel/Modulo Mode Control Register	Section 23.3.2.26
70h	MIBSPIE	MibSPI Enable Register	Section 23.3.2.27

120h	PAR_ECC_CTRL	Parity/ECC Control Register	Section 23.3.2.54
124h	PAR_ECC_STAT	Parity/ECC Status Register	Section 23.3.2.55
128h	UERRADDR1	Uncorrectable Parity or double bit ECC error Address Register - RXRAM	Section 23.3.2.56
12Ch	UERRADDR0	Uncorrectable Parity or double bit ECC error address register - TXRAM	Section 23.3.2.57
130h	RXOVRN_BUF_ADDR	Receive RAM Overrun Buffer Address Register	Section 23.3.2.58

Table 23-10. MSS_MIBSPIA Registers (continued)

Offset	Acronym	Register Name	Section
134h	IOLPBKTSTCR	SPI/MibSPI IO Loopback Test Control Register This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog ones in this test mode. In addition it contains control bits to induce some of the error condition into the module. These are to be used for test purpose only. All the control/status bits in this register are valid only when IO LPBK TST ENA field is set to “1010”.	Section 23.3.2.59
138h	EXTENDED_PRESCALE1	SPI/MibSPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1(7:0) of EXTENDED_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.	Section 23.3.2.60
13Ch	EXTENDED_PRESCALE2	SPI/MibSPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This register is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT2(7:0) of EXTENDED_PRESCALE2 and PRESCALE2(7:0) of SPIFMT2 register will always reflect the same contents. Similarly EPRESCALE_FMT3(7:0) and PRESCALE3(7:0) of SPIFMT3 reflect the same contents.	Section 23.3.2.61
140h	ECCDIAG_CTRL	ECC Diagnostic Control register	Section 23.3.2.62
144h	ECCDIAG_STAT	ECC Diagnostic Status register	Section 23.3.2.63
148h	SBERRADDR1	Single Bit Error Address Register - RXRAM	Section 23.3.2.64
14Ch	SBERRADDR0	Single Bit ECC Error Address Register - TXRAM	Section 23.3.2.65
1FCh	SPIREV	SPI / MibSPI Revision ID Register	Section 23.3.2.66

Complex bit access types are encoded to fit into small table cells. Table 23-11 shows the codes that are used for access types in this section.

Table 23-11. MSS_MIBSPIA Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	-0 R	Returns 0s Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

23.3.1.1 SPIGCR0 Register (Offset = 0h) [reset = 0h]

SPIGCR0 is shown in Figure 23-98 and described in Table 23-80.

Return to Summary Table.

SPI / MibSPI Global Control Register 0

Table 23-12. SPIGCR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	NU	R	0h	Reserved, Reads return ‘0’ and writes have no effect.
0	nRESET	R/W	0h	This is the local reset control for the module. This bit needs to be set to ‘1’ before any operation on SPI / MibSPI can be done. Only after setting this bit to ‘1’, the Auto Initialization of Multibuffer RAM starts. Clearing this bit to ‘0’ will result in all of the control and status register values to return to their default values. 0 = SPI / MibSPI is in reset state 1 = SPI / MibSPI is out of reset state.

23.3.1.2 SPIGCR1 Register (Offset = 4h) [reset = 0h]

SPIGCR1 is shown in Figure 23-99 and described in Table 23-81.

Return to Summary Table.

SPI / MibSPI Global control register 1

Figure 23-33. SPIGCR1 Register

31	30	29	28	27	26	25	24

7	6	5	4	3	2	1	0
NU1						CLKMOD	MASTER
R-0h						R/W-0h	R/W-0h

Table 23-13. SPIGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	SPIEN	R/W	0h	SPI enable. This bit enables the SPI/MibSPI transfers. This bit must be set to 1 after all other SPI / MibSPI configuration bits have been written. When SPIEN bit is 0 or cleared to 0, the following SPI/MibSPI registers get forced to their default states (to ‘0’s except for RXEMPTY bit in SPIBUF): - Both TX & RX Shift Registers - The TXDATA fields of SPIDAT0 and SPIDAT1 registers - All the fields of SPIFLG register - Contents of SPIBUF & the internal RXBUF registers 0=SPI / MibSPI is not activated for transfers. 1=Activates SPI / MibSPI
23-17	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	LOOPBACK	R/W	0h	LOOP BACK. Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO pin is internally connected to the SPISOMI pin. The transmit data is looped back as receive data and is stored in the receive field of the concerned buffer. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI remains in high-impedance state. The SPI / MibSPI has to be initialized in master mode before the loop-back can be selected. If the SPI / MibSPI is initialized in slave mode or a data transfer is ongoing, errors may result. 1 =Internal loop-back test mode enabled. 0 =Internal loop-back test mode disabled. This loopback mode can be used only in Master mode. This automatically selects digital loopback path. When this Loopback mode is selected, CLKMOD bit should be set to ‘1’, meaning that SPICLK can only be internal.
15-9	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
8	POWERDOWN	R/W	0h	POWERDOWN. When active, the SPI / MibSPI state machines enter a powerdown state. 0=MibSPI in active mode 1=MibSPI in powerdown mode
7-2	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
1	CLKMOD	R/W	0h	CLKMOD. Clock mode Selects either an internal or external clock source. This bit also determines the I/O direction of the SPIENA and SPISCS[7:0] pins in functional mode. 0=Clock is external 1=Clock is internal

Table 23-13. SPIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	MASTER	R/W	0h	MASTER: SPISIMO/SPISOMI pin direction determination. Determines the direction of the SPISIMO and SPISOMI pins. This bit determines whether the SPI/MibSPI is in Master mode or Slave mode. This bit also controls the Master-only features like the C2T/T2C counters, C2E/T2E timers, most of the Error conditions specific to Master mode. 0=SPISIMO pin an input, SPISOMI pin an output 1=SPISOMI pin an input, SPISIMO pin an output Note: Although there are two different bits which control the Master/Slave mode functions, only two of their combinations are valid. For compatibility reasons both the bits are retained. For Master mode of operation: MASTER = '1', CLKMOD = '1' For Slave mode of operation: MASTER = '0', CLKMOD = '0' Any other combinations of these two bits may not yield any desirable operation of the module.

23.3.1.3 SPIINT0 Register (Offset = 8h) [reset = 0h]

SPIINT0 is shown in Figure 23-100 and described in Table 23-82.

Return to Summary Table.

SPI / MibSPI Interrupt Enable Register

R-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 23-14. SPIINT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU5	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	ENABLEHIGHZ	R/W	0h	SPIENA pin high-z enable. When active, the SPIENA pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to place it is output in high-z when not driving a low signal. If inactive, then the pin will output both a high and a low signal. 0=SPIENA pin is pulled high when not active. 1=SPIENA pin remains in high-z when not active.
23-17	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	DMAREQEN	R/W	0h	DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to ‘1’. 0=DMA is not used 1=DMA Requests will be generated. A DMA request will be generated on TX DMA REQ line each time a transmit data is copied to the Shift Register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes. A DMA request will be generated on RX DMA REQ line each time a received data is copied to SPIBUF register either from RXBUF or directly from the Shift Register.
15-10	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
9	TXINTENA	R/W	0h	An interrupt is to be generated everytime data is written to the “Shift Register”, so that a new data can be written to TXBUF. Setting this bit will generate an interrupt if TXINTFLG bit (SPIFLG.9) is set to ‘1’. 0=No interrupt will be generated upon TXINTFLG getting set to ‘1’. 1=Interrupt will be generated upon TXINTFLG getting set to ‘1’. An interrupt request will be generated as soon as this bit is set to ‘1’. By default it will be generated on INT0 line. SPILVL register can be programmed before-hand to change this default.
8	RXINTENA	R/W	0h	An interrupt is to be generated when the RXINTFLAG bit (SPIFLG.8) is set by hardware. Otherwise, no interrupt will be generated. 0=Interrupt will not be generated 1=Interrupt will be generated Both Transmitter Empty & Receiver Full interrupts are valid in SPI or Compatibility mode of MibSPI only. In Multibuffered mode these interrupts will not be generated even if enabled.
7	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-14. SPIINT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	OVRNINTENA	R/W	0h	Overrun interrupt enable. An interrupt is to be generated when the RCVR OVRN flag bit (SPIFLG.6) is set by hardware. Otherwise, no interrupt will be generated. 0=Overrun interrupt will not be generated 1=Overrun interrupt will be generated
5	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
4	BITERRENA	R/W	0h	Enables interrupt on bit error. 1 =Enables an interrupt on a bit error (BITERR = 1). 0 =No interrupt asserted upon bit error.
3	DESYNCENA	R/W	0h	Enables interrupt on de-synchronized slave. DESYNCENA is used in master mode only. 1 =Enables an interrupt on de-synchronization of the slave (DESYNC = 1). 0 =No interrupt asserted upon de-synchronization error.
2	PARERRENA	R/W	0h	Enables interrupt on parity error. 1 =Enables an interrupt on a parity error (PARITYERR = 1). 0 =No interrupt asserted upon parity error.
1	TIMEOUTENA	R/W	0h	Enables interrupt on ENA signal time-out. 1 =Enables an interrupt on a time-out of the ENA signal (TIMEOUT = 1). 0 =No interrupt asserted upon ENA signal time-out.
0	DLENERRENA	R/W	0h	Data Length Error interrupt Enable. 1 = Enables an interrupt when Data Length Error occurs. 0 = No interrupt is generated upon Data Length Error. A Data Length Error occurs under the following conditions. Master: In a 4-pin with SPIENA mode or 5-pin mode, if the SPIENA pin from the slave is deasserted before the Master has completed its transfer, the Data Length Error is set. That is, if the Character Length counter has not completed counting while SPIENA deassertion is detected, then it means that the Slave has neither received full data from the Master nor has it transmitted complete data. Slave: In a 4-pin with ChipSelects mode or 5-pin mode, if the incoming valid SPISCS pin is de-activated before the Character Length counter completes counting, then Data Length Error is set.

23.3.1.4 SPILVL Register (Offset = Ch) [reset = 0h]

SPILVL is shown in Figure 23-101 and described in Table 23-83.

Return to Summary Table.

Table 23-16. SPIFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	BUFINITACTIVE	R	0h	Indicates the status of Multibuffer initialization process. Software should poll this bit to determine if it can proceed with the configuration of Multibuffer mode registers or Multibuffer RAM handling. Refer to Section 3.10.7 for details on Initialization of Multibuffer RAM. 1 = Multibuffer RAM is still being initialized. Do not attempt to write to either Multibuffer RAM or any Multibuffer mode registers. Refer to Section 3.3 for a classification of registers into compatibility mode and Multibuffer mode. 0 = Multibuffer RAM initialization is complete. This bit will show a value of ‘1’ as long as the nRESET bit is ‘0’, but does not really indicate that Buffer initialization is underway. Internal automatic buffer initialization starts only when the nRESET bit is set to ‘1’. For SPI, this bit reads ‘1’ always. For MibSPI, BUF INIT ACTIVE bit will show up as ‘1’ for a maximum of 128/256 (will vary depending upon the actual size of the Multibuffer RAM implemented) VCLK cycles after the nRESET bit in GCR0 is set to ‘1’ and then settle to ‘0’. If Auto Memory Initialization is triggered through System (MEM_AUTO_INIT pulse), then BUF INIT ACTIVE bit will show up as ‘1’ for a maximum of 128/256 (will vary depending upon the actual size of the Multibuffer RAM implemented) VCLK cycles and then settle to ‘0’.
23-10	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
9	TXINTFLG	R	0h	Transmitter Empty Interrupt Flag. Serves as an interrupt flag indicating that Transmit Buffer (TXBUF) is empty and a new data can be written to it. This flag is set when a data is copied to the “Shift Register” either directly or from the TXBUF register. This bit is cleared by one of following ways: Writing a new data to either SPIDAT0 or SPIDAT1 Writing a ‘0’ to SPIEN (SPIGCR1.24) 0= Transmit Buffer is now full. No interrupt pending for Transmitter Empty 1= Transmit Buffer is empty. An interrupt is pending to fill the transmitter.

Table 23-16. SPIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	RXINTFLG		0h	Receiver Full Interrupt Flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit. This bit is cleared under the following ways: Reading the SPIBUF register Reading TGINTVECT0 or TGINTVECT1 register when there is a “Receive Buffer Full” interrupt Writing a ‘1’ to this bit Writing a ‘0’ to SPIEN (SPIGCR1.24) System reset 0= No new received data pending. Receive buffer is Empty. 1= A newly received data is ready to be read. Receive buffer is full. Note: Exception for clearing of RXINT If both SPIBUF and RXBUF (internal buffer) are full, then, reading TGINTVECT0 or TGINTVECT1 register (while it shows 10010) does not clear the RXINTFLG in SPIFLG register. In this case, only way to clear the Interrupt is to read the SPIBUF (twice) and clear all the received data. Note: Side effects of Write Clear to RXINTFLG Clearing RXINTFLG bit by writing a ‘1’ before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. This way, one can ignore a received data. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and RXEMPTY bit will be cleared again. SPIBUF contents should be read first if this situation needs to be avoided.
7	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
6	OVRNINTFLG		0h	Receiver overrun flag. The SPI / MibSPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI / MibSPI will generate an interrupt request if this bit is set and the OVRN INTEN bit (SPIINT0.6) is set high. 0 = Overrun condition did not occur 1 = Overrun condition has occurred In SPI or Compatibility mode of MibSPI, this bit is cleared under the following conditions: Reading TGINTVECT0 or TGINTVECT1 register when there is a “Receive Buffer Overrun” interrupt Writing a ‘1’ to OVRNINTFLG in SPIFLG register itself Reading SPIBUF register does not clear this OVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the Overrun buffer. This is due to the fact that the Overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF. Note: A special condition under which OVRNINTFLG flag gets set. If both SPIBUF & RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR & DLEN_ERR occur, then RXOVR in RXBUF & OVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal Receiver Overrun. In Multibuffer mode of MibSPI, this bit is cleared under the following conditions. Reading the RXOVRN_BUF_ADDR register Writing a ‘1’ to OVRNINTFLG in SPIFLG register itself In Multibuffer mode, if OVRNINTFLG is set, then the address of the buffer which experienced the Overrun is available in RXOVRN_BUF_ADDR.
5	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
4	BITERRFLG		0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the Flag BITERR is set. If BITERRENA is set an interrupt is asserted. A possible reason for a bit error can be a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred. This flag can be cleared by one of the following ways. Write a ‘1’ to this bit. Set SPIEN bit to ‘0’.

Table 23-16. SPIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	DESYNCFLG		0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 = A slave device is de-synchronized. The master monitors the ENAble signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'. Note: Inconsistency of Desync flag in SPI/Compatibility mode MibSPI Due to the nature of this Error, under some circumstances it is possible for Desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that Receive Completion flag/interrupt will be generated when the buffer transfer is completed. But Desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct Desync condition. This inconsistency in Desync flag is valid only in SPI or Compatibility mode of MibSPI. In Multibuffer mode, Desync flag is always guaranteed to be for the current buffer.
2	PARERRFLG		0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. 0 =No parity error detected. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'.
1	TIMEOUTFLG		0h	Time-out due to non-activation of ENA signal. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, i.e. the SPI / MibSPI doesn't re-start a data transfer from this buffer. 0 =No ENA-signal time-out occurred. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'.
0	DLENERRFLG		0h	Data Length Error Flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'. A Data Length Error occurs under the following conditions. Master: In a 4-pin with SPIENA mode or 5-pin mode, if the SPIENA pin from the slave is deasserted before the Master has completed its transfer, the Data Length Error is set. That is, if the Character Length counter has not completed counting while SPIENA pin deassertion is detected, then it means that the Slave has neither received full data from the Master nor has it transmitted complete data. Slave: In a 4-pin with ChipSelects mode or 5-pin mode, if the incoming valid SPISCS pin is de-activated before the Character Length counter completes counting, then Data Length Error is set. Note: Clearing of Transmission Error Flags in SPIBUF during Error conditions Whenever any Transmission Errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected, and the Error Flag are cleared by writing to the Error bit in SPIFLG register, the corresponding Error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all the older status bits in SPIBUF are cleared before starting the next transfer.

23.3.1.6 SPIPC0 Register (Offset = 14h) [reset = 0h]

SPIPC0 is shown in Figure 23-103 and described in Table 23-85.

Return to Summary Table.

SPI / MibSPI Pin Control Register 0 (SPIPC0) - SPIFUN Note: Duplicate Control Bits for SIMO0 & SOMI0 Bit 24 is not physically implemented. it is a mirror of Bit11. Any write to Bit 24 will be reflected on Bit11 and when Bit 24 & Bit 11 simultaneously written, the value of Bit11 will control the SOMI pin. Read value of Bit 24 always reflects the Bit 11 value. This is true for the Bit 24 & Bit 11 of all of SPIPC0 to SPIPC9 registers. Same is true for SIMO pin with Bit16 & Bit 10 of SPIPC0 to SPIPC9 registers.

Table 23-17. SPIPC0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMIFUN	R/W	0h	Slave out, master in function. Determines whether the SPISOMIx pins are to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISOMIx pin is a GPIO 1=SPISOMIx pin is a SPI / MibSPI functional pin
23-16	SIMOFUN	R/W	0h	Slave in, master out function. Determines whether the SPISIMOx pin is to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISIMOx pin is a GPIO 1=SPISIMOx pin is a SPI / MibSPI functional pin Note: Generic based bit implementation Register bits 31 to 24 and 23 to 16 of SPIPC0 to SPIPC9 are implemented depending upon the generic parameter NUM_PARLL_PINS which determines the number of SIMO/SOMI data lines to be supported. Only if 8 dataline support is selected at the time of logic synthesis, bits 31 to 16 are implemented. Un-implemented bits return ‘0’ upon read and are not writable.
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMIFUN0	R/W	0h	Slave out, master in function. Determines whether the SPISOMI0 pin is to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISOMI0 pin is a GPIO 1=SPISOMI0 pin is a SPI / MibSPI functional pin Note: Bit 11 or bit 24 can be used to set the function mode for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOFUN0	R/W	0h	Slave in, master out function. Determines whether the SPISIMO0 pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPISIMO0 pin is a GPIO 1=SPISIMO0 pin is a SPI / MibSPI functional pin Note: Bit 10 or bit 16 can be used to set the function mode for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKFUN	R/W	0h	SPI / MibSPI clock function. Determines whether the SPICLK pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPICLK pin is a GPIO 1=SPICLK pin is a SPI / MibSPI functional pin

Table 23-17. SPIPC0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENAFUN	R/W	0h	SPIENA function. Determines whether the SPIENA pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPIENA pin is a GPIO 1=SPIENA pin is a SPI / MibSPI functional pin
7-0	SCSFUN	R/W	0h	SPISCS[7:0] function. Determines whether the SPISCSx pins are to be used as a general-purpose I/O pins or as SPI functional pins. If the slave SPISCSx pins are in functional mode and receive an inactive high signal, the slave SPI will place it is output in high-z and disable shifting. 0=SPISCSx pin is a GPIO 1=SPISCSx pin is a SPI functional pin Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSFUN[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read ‘0’ always.

23.3.1.7 SPIPC1 Register (Offset = 18h) [reset = 0h]

SPIPC1 is shown in Figure 23-104 and described in Table 23-86.

Return to Summary Table.

Table 23-18. SPIPC1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMIDIR	R/W	0h	SPISOMIx direction. Controls the direction of the SPISOMIx pin when it is used as a general-purpose I/O pin. If the SPISOMIx pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISOMIx pin is an input 1=SPISOMIx pin is an output
23-16	SIMODIR	R/W	0h	SPISIMOx direction. Controls the direction of the SPISIMOx pin when it is used as a general-purpose I/O pin. If the SPISIMOx pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISIMOx pin is an input 1=SPISIMOx pin is an output
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMIDIR0	R/W	0h	SPISOMI0 direction. Controls the direction of the SPISOMI0 pin when it is used as a general-purpose I/O pin. If the SPISOMI0 pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISOMI0 pin is an input 1=SPISOMI0 pin is an output Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMODIR0	R/W	0h	SPISIMO0 direction. Controls the direction of the SPISIMO0 pin when it is used as a general-purpose I/O pin. If the SPISIMO0 pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISIMO0 pin is an input 1=SPISIMO0 pin is an output Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKDIR	R/W	0h	SPICLK direction. Controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit. 0=SPICLK pin is an input 1=SPICLK pin is an output
8	ENADIR	R/W	0h	SPIENA direction. Controls the direction of the SPIENA pin when it is used as a general-purpose I/O. If the SPIENA pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1.1). 0=SPIENA pin is an input 1=SPIENA pin is an output

Table 23-18. SPIPC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	SCSDIR	R/W	0h	SPISCS[7:0] direction. Controls the direction of the SPISCSx pins when they are used as a general-purpose I/O pin. Each pins could be configured independently from the others If the SPISCSx is used as a SPI functional pin, the I/O direction is determined by the CLKMOD bit (SPIGCR1.1). 0=SPISCSx pin is an input 1=SPISCSx pin is an output Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSDIR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always.

23.3.1.8 SPIPC2 Register (Offset = 1Ch) [reset = 0h]

SPIPC2 is shown in Figure 23-105 and described in Table 23-87.

Return to Summary Table.

Table 23-21. SPIPC4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMISET	R/W	0h	SPISOMIx dataout set. Only active when the SPISOMIx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISOMIDOUTx bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISOMIx pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUTx is 0. 1= Current value on SOMIDOUTx is 1.
23-16	SIMOSET	R/W	0h	SPISIMOx dataout set. Only active when the SPISIMOx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISIMODOUTx bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISIMOx pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUTx is 0. 1= Current value on SIMODOUTx is 1
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMISET0	R/W	0h	SPISOMI0 dataout set. Only active when the SPISOMI0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISOMIDOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISOMI0 pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUT0 is 0. 1= Current value on SOMIDOUT0 is 1. Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOSET0	R/W	0h	SPISIMO0 dataout set. Only active when the SPISIMO0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISIMODOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISIMO0 pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUT0 is 0. 1= Current value on SIMODOUT0 is 1. Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKSET	R/W	0h	SPICLK dataout set. Only active when the SPICLK pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding CLKDOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPICLK pin if it is in General Purpose O/P mode Read: 0= Current value on CLKDOUT pin is logic 0. 1= Current value on CLKDOUT pin is logic 1

Table 23-21. SPIPC4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENASET	R/W	0h	SPIENA dataout set. Only active when the SPIENA pin is configured as a general-purpose output pin. A value of '1' written to this bit sets the corresponding ENABLEDOUT bit to '1'. Write: 0= Has no effect 1= Logic 1 placed on SPIENA pin if it is in General Purpose O/P mode Read: 0= Current value on ENADOUT is 0. 1= Current value on ENADOUT is 1
7-0	SCSSET	R/W	0h	SPISCS[7:0] dataout set. Only active when the SPISCSx pins are configured as a general-purpose output pins. A value of '1' written to these bits set the corresponding SCSDOUT bit to '1'. Write: 0= Has no effect 1= Logic 1 placed on SPISCSx pin if it is in General Purpose O/P mode Read: 0= Current value on SCSDOUTx is 0. 1= Current value on SCSDOUTx is 1. Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSSET[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Register Read Read of SPIPC4 register gives out contents of the SPIPC3 register.

23.3.1.11 SPIPC5 Register (Offset = 28h) [reset = 0h]

SPIPC5 is shown in Figure 23-108 and described in Table 23-90.

Return to Summary Table.

Table 23-22. SPIPC5 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMICLR	R/W	0h	SPISOMIx dataout clear. Only active when the SPISOMIx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISOMIDOUTx bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISOMIx pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUTx is 0. 1= Current value on SOMIDOUTx is 1.
23-16	SIMOCLR	R/W	0h	SPISIMOx dataout clear. Only active when the SPISIMOx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISIMODOUTx bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISIMOx pin if it is in General Purpose O/P mode Read: 0=Current value on SIMODOUTx is 0. 1=Current value on SIMODOUTx is 1.
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMICLR0	R/W	0h	SPISOMI0 dataout clear. Only active when the SPISOMI0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISOMIDOUT bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISOMI0 pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUT0 is 0. 1= Current value on SOMIDOUT0 is 1. Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOCLR0	R/W	0h	SPISIMO0 dataout clear. Only active when the SPISIMO0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SIMODOUT0 bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISIMO0 pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUT0 is 0. 1= Current value on SIMODOUT0 is 1. Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKCLR	R/W	0h	SPICLK dataout clear. Only active when the SPICLK pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding CLKDOUT bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPICLK pin if it is in General Purpose O/P mode Read: 0= Current value on CLKDOUT is 0. 1= Current value on CLKDOUT is 1.

Table 23-22. SPIPC5 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENACLR	R/W	0h	SPIENA dataout clear. Only active when the SPIENA pin is configured as a general-purpose output pin. A value of '1' written to this bit clears the corresponding ENABLEDOUT bit to '0'. Write: 0= Has no effect 1= Logic 0 placed on SPIENA pin if it is in General Purpose O/P mode Read: 0= Current value on ENADOUT is 0. 1= Current value on ENADOUT is 1.
7-0	SCSCLR	R/W	0h	SPISCS[7:0] dataout clear. Only active when the SPISCSx pins are configured as a general-purpose output pins. A value of '1' written to this bit clears the corresponding SCSDOUT bit to '0.. Write: 0= Has no effect 1= Logic 0 placed on SPISCSx pin if it is in General Purpose O/P mode Read: 0= Current value on SCSDOUTx is 0. 1= Current value on SCSDOUTx is 1 Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSCLR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Register Read Read of SPIPC5 register gives out contents of the SPIPC3 register.

23.3.1.12 SPIPC6 Register (Offset = 2Ch) [reset = 0h]

SPIPC6 is shown in Figure 23-109 and described in Table 23-91.

Return to Summary Table.

8	ENAPDR	R/W	0h	SPIENA Open drain enable Enables Open drain capability for the pin SPIENA if the following conditions are met. ENABLEDIR = 1 (SPIENA pin configured in GPIO mode as output pin) ENABLEDOUT = 1 0 = Output value on SPIENA pin is logic ‘1’ 1 = Output pin SPIENA is Tri-stated

Table 23-23. SPIPC6 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	SCSPDR	R/W	0h	SPISCSx Open drain enable Enables Open drain capability for the pin SPISCSx if the following conditions are met. SCSDIRx = 1 (SPISCS pin configured in GPIO mode as output pin) SCSDOUTx = 1 0 = Output value on SPISCSx pin is logic '1' 1 = Output pin SPISCSx is Tri-stated Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSPDR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always.

23.3.1.13 SPIDAT0 Register (Offset = 38h) [reset = 0h]

SPIDAT0 is shown in Figure 23-110 and described in Table 23-92.

Return to Summary Table.

SPI / MibSPI Transmit Data Register 0 Note: Accessibility of SPIDAT0 The SPIDAT0 register is not accessible in Multibuffer Mode of MibSPI. It is only accessible in compatibility mode.

Figure 23-44. SPIDAT0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU																TXDATA															
R-0h																R/W-0h															

Table 23-24. SPIDAT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
15-0	TXDATA	R/W	0h	SPI / MibSPI Transmit Data. When written, these bits will be copied to the Shift Register if it is empty. If the Shift Register is not empty, the TXBUF will hold the written values. SPIEN (SPICGR1.24) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 register to 0x00. When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned. As the data is shifted out from either the MSB or the LSB of Transmit Shift Register depending upon SHIFTDIR bit (SPIFMTx.20). Simultaneously, the received bit will be shifted into the Receive Shift Register either through LSB or MSB depending upon SHIFTDIR bit. This allows the concurrent transmission and reception of data. Note: Irrespective of the character length, the Transmit data should be right justified before writing to SPIDAT0 register. The default Data Format Control register for SPIDAT0 is SPIFMT0. However it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 prior to using SPIDAT0, to select a different SPIFMTx register.

23.3.1.14 SPIDAT1 Register (Offset = 3Ch) [reset = 0h]

SPIDAT1 is shown in Figure 23-111 and described in Table 23-93.

Return to Summary Table.

SPI / MibSPI Transmit Data Register 1 When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned.

Figure 23-45. SPIDAT1 Register

Table 23-25. SPIDAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
28	CSHOLD	R/W	0h	Chip select hold mode. In SPI or compatibility mode MibSPI, the CSHOLD bit is supported in master mode only. In slave mode, this bit is ignored. CSHOLD defines the behavior of the chip select line at the end of a data transfer. 1 =The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select information equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared or until the chip select information changes. 0 =The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for atleast 2VCLK cycles before it is activated again.
27	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26	WDEL	R/W	0h	Enable the delay counter at the end of the current transaction. WDELAY bit is supported in Master mode only. In Slave mode, this bit will be ignored. 1 = After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPISCS pins will be de-activated for atleast (WDELAY + 2) * VCLK_Period duration. 0 = No delay will be inserted. However, SPISCS pins will still be de-activated for atleast for 2VCLK cycles if CSHOLD = ‘0’. In SPI or Compatibility mode of MibSPI, the duration for which the SPISCS pin remaining de-activated will also depend upon time taken to supply a new data after completing the shifting operation. If the internal buffer - TXBUF is already full, then the SPISCS will be deasserted for atleast 2 VCLK cycles(if WDEL = ‘0’).
25-24	DFSEL	R/W	0h	DFSEL1 DFSEL0 Description 0 0 Data word format 0 is selected 0 1 Data word format 1 is selected 1 0 Data word format 2 is selected 1 1 Data word format 3 is selected

Table 23-25. SPIDAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-16	CSNR	R/W	0h	Chip select number. CSNR defines the chip select that shall be activated during the data transfer. The value of CSNR[7:0] will be driven on SPISCS[7:0] lines during the transfer. Note: Effect of NUM_CS_PINS generic on CSNR bits. Actual number of bits implemented in CSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Preselecting a Format Register. Writing to just the Control Field (using byte writes) does not initiate any SPI transfer in Master mode. This feature can be used to setup SPICLK Phase or Polarity before actually starting the transfer by just updating the DFSEL fields in the control field to select the required Phase/Polarity combination.
15-0	TXDATA	R/W	0h	SPI / MibSPI Transmit Data. When written, these bits will be copied to the Shift Register if it is empty. If the Shift Register is not empty, the TXBUF will hold the written values. SPIEN must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT1 register to 0x00. Write to this register ONLY when using the automatic Slave Chip Select feature. See section 3, Operation Modes, on page 14. A write to this register will drive the contents of CSNR[7:0] into the respective pins in SPISCS[7:0] if those are configured as functional pins. When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned. Irrespective of the character length, the Transmit data should be right justified before writing to SPIDAT1 register.

23.3.1.15 SPIBUF Register (Offset = 40h) [reset = 80000000h]

SPIBUF is shown in Figure 23-112 and described in Table 23-94.

Return to Summary Table.

SPI / MibSPI Receive Buffer Register

Figure 23-46. SPIBUF Register

31	30	29	28	27	26	25	24
RXEMPTY	RXOVR	TXFULL	BITERR	DESYNC	PARITYERR	TIMEOUT	DLENERR

RXDATA							
R-0h							
7	6	5	4	3	2	1	0
RXDATA							
R-0h							

Table 23-26. SPIBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RXEMPTY		1h	Receive data buffer empty. When host reads the SPIBUF field or the whole SPIBUF register this will automatically set the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, the RXEMPTY flag is cleared. 1 =No data received since last reading of SPIBUF register. 0 =A new Data is received and copied into SPIBUF field. This flag gets set to '1' under following conditions: oReading RXDATA portion of the SPIBUF register. oWriting '1' to clear the RXINTFLG bit in SPIFLG register. Write-Clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA portion of the SPIBUF register. So, reading the full of SPIBUF register itself clears the Receiver Full Interrupt Flag.
30	RXOVR		0h	Receive data buffer overrun. When a data transfer is completed and the received data is copied into the RXBUF while it is already full, RXOVR is set. Refer to Figure 1 for a view of internal logic diagram. An Overrun always occurs to the RXBUF, and SPIBUF contents never get Overwritten until after it is read by the VBUSP Master. If enabled, RXOVRN interrupt gets generated when RXBUF is Overwritten, and reading SPIFLG or SPIVECTx register shows the RXOVRN condition. However, two read operations to the SPIBUF register are required to reach the Overrun buffer. 1 =A receive data overrun condition occurred since last time reading the data field. 0 =No receive data overrun condition occurred since last time reading the data field. This bit is cleared to '0' under the following conditions: o RXDATA portion of the SPIBUF register is read. o OVRNINTFLG bit in SPIFLG register is write-cleared. When an Overrun occurs, the SPIBUF contents will not be overwritten. Only the RXBUF contents are overwritten. When the SPIBUF is read out , the RXBUF contents get copied to the SPIBUF if RXBUF is full. So, the first data read out will be intact when an Overrun occurs. Note: A special condition under which RXOVR flag gets set. If both SPIBUF & RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR & DLEN_ERR occur, then RXOVR in RXBUF & SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal Receiver Overrun.

Table 23-26. SPIBUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	TXFULL	R	0h	Transmit data buffer full. This flag is a read-only flag. Writing into SPIDAT0 or SPIDAT1 field while TX Shift Register is full will automatically set the TXFULL flag. Once the data is copied to the Shift Register the TXFULL flag will be cleared. Writing to SPIDAT0/SPIDAT1 register when both TXBUF & the TX Shift Register are empty does not set the TXFULL flag. 1 =Transmit buffer is full, SPIDAT0/SPIDAT1 is not ready to accept a new data. 0 =Transmit buffer is empty, SPIDAT0/SPIDAT1 is ready to accept a new data.
28	BITERR		0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.
27	DESYNC		0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 =A slave device is de-synchronized. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This bit is valid in Master mode only. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read. Note: Possible inconsistency of Desync flag in SPI/Compatibility mode MibSPI Due to the nature of this Error, under some circumstances it is possible for Desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that Receive Completion flag/interrupt will be generated when the buffer transfer is completed. But Desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct Desync condition. This inconsistency in Desync flag is valid only in SPI or Compatibility mode of MibSPI. In Multibuffer mode, Desync flag is always guaranteed to be for the current buffer.
26	PARITYERR		0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set. 0 =No parity error detected. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.
25	TIMEOUT		0h	Time-out due to non-activation of ENA pin. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn’t responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer and in the SPIFLG register is set. 0 =No ENA-pin time-out occurred. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read. This bit is valid in Master mode only.
24	DLENERR		0h	Data Length Error flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.

Table 23-26. SPIBUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-16	LCSNR	R	0h	Last Chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It defines the chip select that has been activated during the last data transfer from the corresponding buffer. This is the copy of CSNR bits from SPIDAT1 latched at the end of a transfer. Note: Effect of NUM_CS_PINS generic on LCSNR bits. Actual number of bits implemented in LCSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will read '0' always
15-0	RXDATA	R	0h	SPI Receive Data. This is the received data, transferred from the Receive Shift-Register at the end of a transfer completion. Irrespective of the programmed character length & the direction of shifting, the received data is stored right-justified in the register.

23.3.1.16 SPIEMU Register (Offset = 44h) [reset = 80000000h]

SPIEMU is shown in Figure 23-113 and described in Table 23-95.

Return to Summary Table.

SPI / MibSPI Emulation Register Note: All the fields ot SPIEMU register are Read-Only. Read operation on this register under any mode will not have any impact on the status of this or any other registers.

31	RXEMPTY	R	1h	Receive data buffer empty. 1 = No data received since last reading of SPIBUF register. 0 = A new Data is received and copied into SPIBUF field.
30	RXOVR	R	0h	Receive data buffer overrun. 1 =A receive data overrun condition occurred since last time reading the data field. 0 =No receive data overrun condition occurred since last time reading the data field.
29	TXFULL	R	0h	Transmit data buffer full. 1 =Transmit buffer is full, SPIDAT0/SPIDAT1 is not ready to accept a new data. 0 =Transmit buffer is empty, SPIDAT0/SPIDAT1 is ready to accept a new data.
28	BITERR	R	0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred.
27	DESYNC	R	0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 =A slave device is de-synchronized. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This bit is valid in Master mode only.
26	PARITYERR	R	0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set. 0 =No parity error detected.

Table 23-27. SPIEMU Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	TIMEOUT	R	0h	Time-out due to non-activation of ENA pin. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer and in the SPIFLG register is set. 0 =No ENA-pin time-out occurred. This bit is valid in Master mode only.
24	DLENERR	R	0h	Data Length Error flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured.
23-16	LCSNR	R	0h	Last Chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It defines the chip select that has been activated during the last data transfer from the corresponding buffer. This is the copy of CSNR bits from SPIDAT1 latched at the end of a transfer. Note: Effect of NUM_CS_PINS generic on LCSNR bits. Actual number of bits implemented in LCSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will read '0' always.
15-0	RXDATA	R	0h	SPI Receive Data. SPI / MibSPI emulation is a mirror of the SPIBUF register. The only difference between SPIEMU and SPIBUF is that a read from SPIEMU does not clear any of the status flags.

23.3.1.17 SPIDELAY Register (Offset = 48h) [reset = 0h]

SPIDELAY is shown in Figure 23-114 and described in Table 23-96.

Return to Summary Table.

SPI / MibSPI Delay Register

R/W-0h								R/W-0h								R/W-0h								R/W-0h							

Table 23-28. SPIDELAY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	C2TDELAY	R/W	0h	Chip-select-active-to-transmit-start-delay. C2TDELAY is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of VBUSPCLK cycles. ChipSelect-active-to-transmission delays between 2 to 257 VBUSPCLK cycles can be achieved. If Phase = '1', the delay between SCS fall-edge to the first edge of SPICLK will have an additional 0.5 SPICLK Period delay. This delay is as per the SPI protocol.
23-16	T2CDELAY	R/W	0h	Transmit-end-to-chip-select-inactive-delay. T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VBUSPCLK cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 VBUSPCLK cycles. If Phase = '0', then between the last edge of SPICLK and rise-edge of SCS, there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol Both C2TDELAY and T2CDELAY counters do not have any dependancy on SPIENA pin value. Even if the SPIENA pin is asserted by the Slave, Master will continue to delay the start of SPICLK until the C2TDELAY counter overflows. Similarly, even if the SPIENA pin is deasserted by the Slave, Master will continue to hold the SPISCS pins active until the T2CDELAY counter overflows. This way, it is guaranteed that the setup/hold times of the SPISCS pins is determined by the Delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.
15-8	T2EDELAY	R/W	0h	Transmit-data-finished-to-ENA-pin-inactive-time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before the ENAble signal has to become inactive and after the CS becomes inactive. The SPI clock depends on which data format is selected. If the slave device is missing one or more clock edges, it is becoming de-synchronized. Although the master has finished the data transfer the slave is still waiting for the missed clock pulses and the ENA signal isn't disabled. The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the ENA signal isn't deactivated in time. DESYNC flag is set to indicate that the Slave device did not deassert its SPIENA pin in time to acknowledge that it has received all the bits of the sent character. If T2CDELAY is programmed a non-zero value, then T2EDELAY will start only after the T2CDELAY completes. This should be taken into consideration to determine an optimum value of T2EDELAY. Note: Zero T2EDELAY If T2EDELAY is not programmed or programmed to '0', then the Master SPI/MibSPI does not wait for SPIENA pin to be deasserted. It ignores the state of the SPIENA pin after the transmission is completed.

Table 23-28. SPIDELAY Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	C2EDELAY	R/W	0h	Chip-select-active-to-ENA-signal-active-time-out C2EDELAY is utilized only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between the SPI / MibSPI activating the chip select signal and the addressed slave responding by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. If the slave device is not responding with the ENA signal before the time-out value is reached, the TIMEOUT flag in SPIFLG register is set and an interrupt is asserted if enabled. If a time-out occurs the MibSPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer and continues with the transfer of the next buffer in the sequence that is enabled. If C2TDELAY is programmed a non-zero value, then C2EDELAY will start only after the C2TDELAY completes. This should be taken into consideration to determine an optimum value of C2EDELAY. Note: Zero C2EDELAY If C2EDELAY is not programmed or programmed to ‘0’, then the Master SPI/MibSPI waits until the SPIENA pin to asserted before it can start the transfer. If the SPIENA pin is not asserted due to a malfunctioning Slave, the Master will wait forever. This might cause hang-up situation. it is recommended to program to C2EDELAY to a suitable value whenever SPIENA pin is used as functional.

23.3.1.18 SPIDEF Register (Offset = 4Ch) [reset = 1h]

SPIDEF is shown in Figure 23-115 and described in Table 23-97.

Return to Summary Table.

Table 23-30. SPIFMT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-30. SPIFMT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

23.3.1.20 SPIFMT1 Register (Offset = 54h) [reset = 0h]

SPIFMT1 is shown in Figure 23-117 and described in Table 23-99.

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-31. SPIFMT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-32. SPIFMT2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

23.3.1.22 SPIFMT3 Register (Offset = 5Ch) [reset = 0h]

SPIFMT3 is shown in Figure 23-119 and described in Table 23-101.

Return to Summary Table.

R-0h			R/W-0h				

Table 23-33. SPIFMT3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-33. SPIFMT3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

23.3.1.23 TGINTVECT0 Register (Offset = 60h) [reset = 0h]

TGINTVECT0 is shown in Figure 23-120 and described in Table 23-102.

Return to Summary Table.

SPI Interrupt Vector Register 0 / MibSPI Transfer Group Interrupt Vector Register 0

R-0h				R-0h			R-0h

Table 23-34. TGINTVECT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
5-1	INTVECT0	R	0h	Interrupt vector for interrupt line INT0. INTVECT0 returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupts are pending, INTVECT0 always references the highest priority interrupt source first. The vectors generated are different for SPI / Compatibility mode of MibSPI and Multibuffer mode of MibSPI. INTVECT0 field just reflects the status of SPIFLG register in a vectorized format. So, any updates to SPIFLG will automatically reflect in the Vector value in this register. SPI / Compatibility mode - MibSPI The interrupts available for SPI or Compatibility mode - MibSPI, in the descending order of their priorities are as given below. Transmission Error Interrupt Receive Buffer Overrun Interrupt Receive Buffer Full Interrupt Transmit Buffer Empty Interrupt Vectors for each of these interrupts will be reflected on the INTVECT0 bits, when they occur. Reading the vectors for the “Receive Buffer Overrun” & “Receive Buffer Full” interrupts will automatically clear the respective flags in the SPIFLG register. On reading the INTVECT0 bits, the vector of the next highest priority interrupt (if any) will be then reflected on the INTVECT0 bits. If two or more interrupts occur simultaneously, the vector for the higest priority interrupt will be reflected on the INTVECT0 bits. Reading the Vector register when “Transmitter Empty” is indicated does not clear the TXINTFLG in SPIFLG register. Writing a new data to SPIDATx register clears the “Transmitter Empty” interrupt. INTVECT0[4:0] Description 00000b no interrupt pending 10001b Error interrupt pending. Refer to Least Significant (LS) Byte of SPIFLG to determine more details about the type of error. 10011b Pending interrupt is “Receive Buffer Overrun Interrupt” 10010b Pending interrupt is “Receive Buffer Full Interrupt” 10100b Pending interrupt is “Transmit Buffer Empty Interrupt” All other bit combinations Reserved Note: Exception for clearing of RXINT If both SPIBUF and RXBUF (internal buffer) are full, then, reading TGINTVECT0 register (while it shows 10010) does not clear the RXINTFLG in SPIFLG register. In this case, only way to clear the Interrupt is to read the SPIBUF again until there’s no more unread RX data.

Table 23-34. TGINTVECT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SUSPEND0	R	0h	“Transfer suspended” or “transfer finished” interrupt.(MibSPI only) The SUSPEND0 flag is updated depending on the type of interrupt reflected by the VECTOR value field. 1 =The interrupt type is a “transfer suspended” interrupt. I.e. the transfer group referenced by INTVECT0 has asserted an interrupt, because the buffer to be transferred next is in “suspend to wait” mode. 0 =The interrupt type is a “transfer finished” interrupt. I.e. the buffer array referenced by INTVECT0 has asserted an interrupt, because all of the data from the whole transfer group has been transferred. Note: Special case for SUSPEND interrupt When there’s a “transfer suspended” interrupt (SUSPEND0 bit is set to ‘1’), reading the TGINTVECT0 register does not clear the “TG Suspended” interrupt. The SUSPEND condition should be resolved first before the interrupt can be cleared. The SUSPEND condition can be cleared by writing a new data to that TXRAM location and/or reading the data from that RXRAM location depending upon the SUSPEND criteria programmed in the “BUFMODE” field of that TXRAM location. The SUSPEND0 bit always returns value ‘0’ in SPI / Compatibility mode MibSPI. When there is an RXOVRN or any Error interrupt in Multibuffer mode, SUSPEND0 bit stays ‘0’. Refer to Section 6.2 on page 77 & Section 6.3 on page 77 for more details and notes on better handling of interrupts. Note: Reading Error Vector Reading an Error Vector in the TGINTVECT0 register will NOT clear the Error flags in the SPIFLG register. The Error Flags in SPIFLG need to be write-cleared after servicing them suitably. If “TG Completed” interrupt occurs for a TG and after a while “TG Suspended” flag too gets set for the same TG, then the TGINTVECT0 register will show “TG Completed” interrupt giving it higher priority than the “TG Suspended” interrrupt.

23.3.1.24 TGINTVECT1 Register (Offset = 64h) [reset = 0h]

TGINTVECT1 is shown in Figure 23-121 and described in Table 23-103.

Return to Summary Table.

Table 23-37. SPIPMCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
30	HSM_MODE3	R/W	0h	High Speed Modulo Mode control bit for Data Format 3. Controls whether the PMODE3 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE3 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE3 bits are non-zero
29	MODCLKPOL3	R/W	0h	Modulo mode SPICLK Polarity for Data Format 3 Determines the Polarity of the SPICLK in Modulo mode only. If MODULO MODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected
28-26	MMODE3	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 3.000 = Normal single dataline mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
25-24	PMODE3	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 3. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
23	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
22	HSM_MODE2	R/W	0h	High Speed Modulo Mode control bit for Data Format 2. Controls whether the PMODE2 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE2 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE2 bits are non-zero

Table 23-37. SPIPMCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	MODCLKPOL2	R/W	0h	Modulo mode SPICLK Polarity for Data Format 2. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected
20-18	MMODE2	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 2. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
17-16	PMODE2	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 2. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”)10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
15	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
14	HSM_MODE1	R/W	0h	High Speed Modulo Mode control bit for Data Format 1. Controls whether the PMODE1 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE1 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE1 bits are non-zero.
13	MODCLKPOL1	R/W	0h	Modulo mode SPICLK Polarity for Data Format 1. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected.
12-10	MMODE1	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 1. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
9-8	PMODE1	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 1. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
7	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
6	HSM_MODE0	R/W	0h	High Speed Modulo Mode control bit for Data Format 0. Controls whether the PMODE0 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE0 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE0 bits are non-zero.
5	MODCLKPOL0	R/W	0h	Modulo mode SPICLK Polarity for Data Format 0. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected.

Table 23-37. SPIPMCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-2	MMODE0	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 0. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
1-0	PMODE0	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 0. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)

23.3.1.27 MIBSPIE Register (Offset = 70h) [reset = 500h]

MIBSPIE is shown in Figure 23-124 and described in Table 23-106.

Return to Summary Table.

MibSPI Enable Register

Figure 23-58. MIBSPIE Register

31	30	29	28	27	26	25	24
NU3							
R-0h							
23	22	21	20	19	18	17	16
NU3							RXRAMACCESS
R-0h							R/W-0h
15	14	13	12	11	10	9	8
NU2				EXTENDED_BUF_ENA			
R-0h				R/W-5h			
7	6	5	4	3	2	1	0
NU1							MSPIENA
R-0h							R/W-0h

Table 23-38. MIBSPIE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	RXRAMACCESS	R/W	0h	Receive RAM Access control Bit. During normal operating mode of MibSPI, the Receive Data/Status portion of Multibuffer RAM is read-only. To enable testing of Data Integrity checks of Receive RAM, a special read/write access control is provided through this bit. 0 = The RX portion of Multibuffer RAM is not writable by the CPU. That is, portion of Multibuffer RAM, addressed by an offset of 0x200-0x3FF is write protected. 1 = The whole of Multibuffer RAM is fully accessible for read/write by the CPU.
15-12	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect
11-8	EXTENDED_BUF_ENA	R/W	5h	Enables the support for 256 buffers. By default MibSPI supports up to 128 buffers for both TX and RX. It is also possible to extend the support to 256 buffers as a parameterized implementation. This field can be used to enable/disable the support for Extended Buffers. This Enable field is implemented only if “EXTENDED_BUF” parameter is set to ‘1’. If the parameter is set to ‘0’, this field is read-only and reads the disable value. Write (Privilege mode only) 1010 - Enable the Extended Buffer mode - up to 256 buffers can be used 0101 - Disable the Extended Buffer mode - MibSPI supports only 128 buffers All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read (both privilege and user modes) 1010 - Extended Buffer mode is enabled - up to 256 buffers can be used 0101 - Extended Buffer mode is disabled - MibSPI supports only 128 buffers
7-1	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-38. MIBSPIE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	MSPIENA	R/W	0h	Multibuffer mode Enable. After power-up or reset MSPIENA remains cleared, which means that the MibSPI runs in compatibility mode by default. If Multibuffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. Unless MSPIENA is set to '1', the Multibuffer mode registers are not writable. Refer to Section 3.3 for the grouping of registers into Compatibility mode and Multibuffer mode. 1 =The MibSPI is configured to run in MibSPI mode (Multibuffer mode). In this mode the additional features are available. 0 =The MibSPI runs in compatibility mode, i.e. in this mode the MibSPI is fully code compliant to the standard TMS470 Platform SPI. No Multibuffer feature is supported

23.3.1.28 TGITENST Register (Offset = 74h) [reset = 0h]

TGITENST is shown in Figure 23-125 and described in Table 23-107.

Return to Summary Table.

Read: 1 = "The Transfer group x completed " interrupt is set to line INT1 0 = "The Transfer group x completed " interrupt is set to line INT0
15-0	CLRINTLVLSUS	R/W	0h	Transfer group suspended" interrupt Level clear register Write: 1 = Sets the "The Transfer group x suspended " interrupt to line INT0 0 = Has no effect. Read: 1 = "The Transfer group x suspended " interrupt is set to line INT1 0 = "The Transfer group x suspended " interrupt is set to line INT0

23.3.1.32 TGINTFLAG Register (Offset = 84h) [reset = 0h]

TGINTFLAG is shown in Figure 23-129 and described in Table 23-111.

Return to Summary Table.

Transfer Group Interrupt Flag Register

Figure 23-63. TGINTFLAG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTFLGRDY																INTFLGSUS															
R-0h																R-0h															

Table 23-43. TGINTFLAG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	INTFLGRDY	R	0h	Transfer group interrupt flag for “transfer finished” interrupt. Read: 1 =A “transfer finished” interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don’t care) or whether the interrupt is mapped to line INT0 or INT1, INTFLGRDYx is set right after the transfer from transfer group x is finished. 0 =No “transfer finished” interrupt occurred since last clearing of the flag INTFLGRDYx. Write: 1 = Clears the corresponding bit flag. 0 = Has no effect.
15-0	INTFLGSUS	R	0h	Transfer group interrupt flag for “transfer suspend” interrupt. Read: 1 =A “transfer suspended” interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don’t care) or whether the interrupt is mapped to line INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended. 0 =No ”transfer suspended” interrupt occurred since last clearing of the flag INTFLGSUSx. Note: Read Clear Behavior Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if SUSPEND0/SUPEND1 bit in the Vector registers is ‘0’.

23.3.1.33 TICKCNT Register (Offset = 90h) [reset = 0h]

TICKCNT is shown in Figure 23-130 and described in Table 23-112.

Return to Summary Table.

Tick Count Register

Figure 23-64. TICKCNT Register

31	30	29	28	27	26	25	24

TICKVALUE							
R/W-0h							
7	6	5	4	3	2	1	0
TICKVALUE							
R/W-0h							

Table 23-44. TICKCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TICKENA	R/W	0h	Tick counter enable. 1 =The MibSPI internal tick counter is enabled and is clocked by the clock source selected by CLKCTRL[1:0]. When the tick counter is enabled it starts down-counting from its current value. When TICKENA goes from “0” to “1” the tick counter is automatically loaded with the TICKVALUE. 0 =The MibSPI internal tick counter is disabled. The counter value remains unchanged. Note: When the tick counter is disabled the trigger signal is forced low.
30	RELOAD	R-0/W	0h	Re-load tick counter. RELOAD is a set-only bit, i.e. writing a “1” to it automatically reloads the Tick Counter with the value stored in TICKVALUE. Reading RELOAD always returns a “0”. Note: When the tick counter is reloaded by the RELOAD bit, the trigger signal is not toggled.
29-28	CLKCTRL	R/W	0h	Tick counter clock source control. CLKCTRL[1:0] defines the clock source that is used to clock the MibSPI internal tick counter.CLKCTRL[1:0] Description 00b SPICLK of Data word format 0 is selected as clock source of tick counter 01b SPICLK of Data word format 1 is selected as clock source of tick counter 10b SPICLK of Data word format 2 is selected as clock source of tick counter 11b SPICLK of Data word format 3 is selected as clock source of tick counter
27-16	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
15-0	TICKVALUE	R/W	0h	Initial value for tick counter. TICKVALUE stores the initial value for the tick counter. The tick counter is loaded with TICKVALUE every time an under-flow condition occurs and every time the RELOAD flag is set by the host

23.3.1.34 LTGPEND Register (Offset = 94h) [reset = 0h]

LTGPEND is shown in Figure 23-131 and described in Table 23-113.

Return to Summary Table.

Last Transfer Group End Pointer

Figure 23-65. LTGPEND Register

Table 23-45. LTGPEND Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	NU3	R	0h	Reserved.Reads return ‘0’ and writes have no effect
28-24	TGINSERVICE	R	0h	Transfer Group currently being serviced by the Sequencer. Read-Only field indicating the current Transfer Group that is being serviced. This field can generally be used for code debug purpose. Read Value:TG IN SERVICE[4:0] Description 00000b No Transfer Group is being serviced by the Sequencer 00001b Transfer Group0 is being serviced by the Sequencer ... ... 10000b Transfer Group15 is being serviced by the Sequencer 10001b - 11111b Invalid values
23-16	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect
15-8	LPEND	R/W	0h	Last Transfer Group End Pointer Usually the transfer group end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent transfer group (PSTART). The transfer group ends at the buffer one before the next transfer group starts (PEND[x]=PSTART[x+1] - 1). For a full configuration of MibSPI, the 15th transfer group has no subsequent transfer group, i.e. no end address is inherently defined. Therefore LPEND has to be programmed to specify explicitly the end address of the 15th transfer group. Number of Transfer Groups implemented in a MibSPI can vary from one MibSPI to another since it is a generic parameter based implementation. If in a MibSPI, only 4 Transfer Groups are implemented, then the PEND of the 4th TG is defined by LPEND values defined in this LTGPEND register.
7-0	NU1	R	0h	Reserved.Reads return ‘0’ and writes have no effect

23.3.1.35 TG0CTRL Register (Offset = 98h) [reset = 0h]

TG0CTRL is shown in Figure 23-132 and described in Table 23-114.

Return to Summary Table.

MibSPI Transfer Group Control Register The number of transfer groups is scalable by design up to a maximum of 16. Depending on the implementation the number of transfer groups and hence the number of transfer group control register may vary. Each transfer group can be configured via one dedicated control register. The register description below shows one exemplary control register(x) which is identical for all transfer groups. E.g. the control register for transfer group 2 is named “TG2CTRL” and is located at address base0+98h+4*2.

Figure 23-66. TG0CTRL Register

7	6	5	4	3	2	1	0
PCURRENT							
R-0h							

Table 23-46. TG0CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.

Table 23-46. TG0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.
28	TGTD	R	0h	Transfer group triggered. This bit is read-only. 1 =The transfer group has been triggered and is either currently in service or waiting for servicing. 0 =The corresponding transfer group has not been triggered or is no more waiting for service. Use the “TG IN SERVICE” field in LTGPEND register to determine the exact Transfer Group being currently serviced
27-24	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
23-20	TRIGEVT	R/W	0h	Type of trigger event. After reset, the trigger event types of all transfer groups are set to inactive TypesTRIGEVTx[3:0] Type Description 0000b never 0001b rising edge A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0010b falling edge A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0011b both edges Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0100b reserved 0101b high-active Repetitive group transfer while trigger is high: While the selected trigger source (TRIGSRCx) is at a logic high level (1) the group transfer is continued and at the end of one group transfer restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. 0110b low-active Repetitive group transfer while trigger is low: While the selected trigger source (TRIGSRCx) is at a logic low level (0) the group transfer is continued and at the end of one restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. 0111b always A repetitive group transfer will be performed. Setting ONESHOTx allows a software controlled single transfer modea a. By setting the TRIGSRC to 0000b, the TRIGEVT to ALWAYS (0111b) the ONESHOT bit to 1. This allows a software control trigger on this Transfer Group. Then by setting the TGENA bit, the Transfer Group is immediately triggered. . If ONESHOTx is cleared a continuous mode for this Transfer Group is selected.1xxxb reserved

Table 23-46. TG0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-16	TRIGSRC	R/W	0h	Trigger source. After reset the trigger sources of all transfer groups are disabled. Table 22. Trigger SourcesTRIGSRCx[3:0] Type Description 0000b disabled 0001b EXT0 MibSPI external trigger source 0. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0010b EXT1 MibSPI external trigger source 1. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0011b EXT2 MibSPI external trigger source 2. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0100b EXT3 MibSPI external trigger source 3. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). ... ... 1110b EXT13 MibSPI external trigger source 13. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 1111b TICK MibSPI internal periodic event trigger. The tick counter can initiate periodic group transfers.
15-8	PSTART	R/W	0h	transfer group start address. PSTARTx stores the start address of the corresponding transfer group. The corresponding end address is inherently defined by the subsequent transfer groups start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: o the transfer group is enabled o the end of the transfer group is reached during a transfer o a trigger event occurs while PRST is set to 1
7-0	PCURRENT	R	0h	transfer group pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127/255) of the buffer that is currently transferred or that will be transferred after a trigger event occurs (if PRSTx=0) or after the transfer group resumes from suspend to wait mode. If the transfer group switches mode from active transfer mode to “suspend to wait”, PCURRENTx keeps the address of the currently Suspended buffer. After the transfer group resumes from “suspend to wait” mode the next buffer will be transferred. I.e. no buffer data is multiply transferred or not at all transferred due to “suspend to wait” mode.

Table 23-47. TG1CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.

I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.

Table 23-50. TG4CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	TGTD	R	0h	Transfer group triggered. This bit is read-only. 1 =The transfer group has been triggered and is either currently in service or waiting for servicing. 0 =The corresponding transfer group has not been triggered or is no more waiting for service. Use the “TG IN SERVICE” field in LTGPEND register to determine the exact Transfer Group being currently serviced
27-24	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
23-20	TRIGEVT	R/W	0h	Type of trigger event. After reset, the trigger event types of all transfer groups are set to inactive TypesTRIGEVTx[3:0] Type Description 0000b never 0001b rising edge A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0010b falling edge A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0011b both edges Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0100b reserved 0101b high-active Repetitive group transfer while trigger is high: While the selected trigger source (TRIGSRCx) is at a logic high level (1) the group transfer is continued and at the end of one group transfer restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. 0110b low-active Repetitive group transfer while trigger is low: While the selected trigger source (TRIGSRCx) is at a logic low level (0) the group transfer is continued and at the end of one restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. 0111b always A repetitive group transfer will be performed. Setting ONESHOTx allows a software controlled single transfer modea a. By setting the TRIGSRC to 0000b, the TRIGEVT to ALWAYS (0111b) the ONESHOT bit to 1. This allows a software control trigger on this Transfer Group. Then by setting the TGENA bit, the Transfer Group is immediately triggered. . If ONESHOTx is cleared a continuous mode for this Transfer Group is selected.1xxxb reserved
19-16	TRIGSRC	R/W	0h	Trigger source. After reset the trigger sources of all transfer groups are disabled. Table 22. Trigger SourcesTRIGSRCx[3:0] Type Description 0000b disabled 0001b EXT0 MibSPI external trigger source 0. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0010b EXT1 MibSPI external trigger source 1. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0011b EXT2 MibSPI external trigger source 2. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0100b EXT3 MibSPI external trigger source 3. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). ... ... 1110b EXT13 MibSPI external trigger source 13. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 1111b TICK MibSPI internal periodic event trigger. The tick counter can initiate periodic group transfers.
15-8	PSTART	R/W	0h	transfer group start address. PSTARTx stores the start address of the corresponding transfer group. The corresponding end address is inherently defined by the subsequent transfer groups start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: o the transfer group is enabled o the end of the transfer group is reached during a transfer o a trigger event occurs while PRST is set to 1

Table 23-50. TG4CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	PCURRENT	R	0h	transfer group pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127/255) of the buffer that is currently transferred or that will be transferred after a trigger event occurs (if PRSTx=0) or after the transfer group resumes from suspend to wait mode. If the transfer group switches mode from active transfer mode to “suspend to wait”, PCURRENTx keeps the address of the currently Suspended buffer. After the transfer group resumes from “suspend to wait” mode the next buffer will be transferred. I.e. no buffer data is multiply transferred or not at all transferred due to “suspend to wait” mode.

23.3.1.40 TG5CTRL Register (Offset = ACh) [reset = 0h]

TG5CTRL is shown in Figure 23-137 and described in Table 23-119.

Return to Summary Table.

Table 23-51. TG5CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.

Table 23-54. DMA0CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ONESHOT	R/W	0h	Auto-disable of DMA channel after ICOUNT+1 transfers. 1 =ONESHOTx allows a block transfer of defined length (ICOUNTx+1) mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx +1 transfers the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer. 0 =The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.
30-24	BUFID	R/W	0h	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the “suspend to wait until...” modes must be used (for more details refer to Section 8.53.1).
23-20	RXDMA_MAP	R/W	0h	Receive data DMA Request Map Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to ‘1’, then RXDMA_MAPx[3:0] shall differ from TXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.
19-16	TXDMA_MAP	R/W	0h	Transmit data DMA channel Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. ne request line for receive data and the other for request line for transmit data. TXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set then TXDMA_MAPx[3:0] shall differ from RXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.

Table 23-54. DMA0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15	RXDMAENA	R/W	0h	Receive data DMA channel enable. 1 =The physical DMA Request line for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The concerned buffer should be configured in the mode “skip until RXEMPTY is set” or “suspend to wait until RXEMPTY is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new receive data.
14	TXDMAENA	R/W	0h	Transmit data DMA channel enable. 1 =The physical DMA Request line for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The concerned buffer should be configured in the mode “skip until TXFULL is set” or “suspend to wait until TXFULL is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new transmit data
13	NOBRK	R/W	0h	Non-interleaved DMA block transfer(Master mode only). 1 =NOBRKx ensures that ICOUNTx+1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx+1 transfers have been processed. E.g: this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD=1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. Triggering of higher priority transfer groups or enabling of higher priority DMA channels will not interrupt NOBRK block transfer. 0 =The DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or transfer groups. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer
12-8	ICOUNT	R/W	0h	Initial Count of DMA transfers ICOUNTx[4:0] is used to preset the transfer counter COUNTx[4:0]. Every time COUNTx[4:0] hits zero it is reloaded with ICOUNTx[4:0]. The real number of transfer equals ICOUNTx[4:0] plus one. If ONESHOTx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
7	BUFID7	R/W	0h	Extended bit of BUFIDx field when Extended Buffer feature is implemented. This bit represents the 8th bit of BUFID field such that any buffers between 127-255 can be configured as DMA capable buffers
6	COUNTBIT17	R	0h	The 17th bit of COUNT field of DMAxCOUNT register. This bit is useful only when ICOUNTx in DMAxCOUNT register is programmed to be 0xFFFF. During all other values, this bit remains to be ‘0’.
5-0	COUNT	R	0h	Actual number of remaining DMA transfer COUNTx[5:0] is a read-only bit field. It comprises the actual number of DMA transfers that remain, until the DMA channel is disabled if ONESHOTx is set.

23.3.1.44 DMA1CTRL Register (Offset = DCh) [reset = 0h]

DMA1CTRL is shown in Figure 23-141 and described in Table 23-123.

Return to Summary Table.

Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer
12-8	ICOUNT	R/W	0h	Initial Count of DMA transfers ICOUNTx[4:0] is used to preset the transfer counter COUNTx[4:0]. Every time COUNTx[4:0] hits zero it is reloaded with ICOUNTx[4:0]. The real number of transfer equals ICOUNTx[4:0] plus one. If ONESHOTx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
7	BUFID7	R/W	0h	Extended bit of BUFIDx field when Extended Buffer feature is implemented. This bit represents the 8th bit of BUFID field such that any buffers between 127-255 can be configured as DMA capable buffers
6	COUNTBIT17	R	0h	The 17th bit of COUNT field of DMAxCOUNT register. This bit is useful only when ICOUNTx in DMAxCOUNT register is programmed to be 0xFFFF. During all other values, this bit remains to be ‘0’.
5-0	COUNT	R	0h	Actual number of remaining DMA transfer COUNTx[5:0] is a read-only bit field. It comprises the actual number of DMA transfers that remain, until the DMA channel is disabled if ONESHOTx is set.

23.3.1.48 ICOUNT0 Register (Offset = F8h) [reset = 0h]

ICOUNT0 is shown in Figure 23-145 and described in Table 23-127.

Return to Summary Table.

MibSPI DMAxCOUNT

Figure 23-79. ICOUNT0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ICOUNT																COUNT															
R/W-0h																R-0h															

Table 23-59. ICOUNT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ICOUNT	R/W	0h	Initial Number of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits zero it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus one. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
15-0	COUNT	R	0h	Actual number of remaining DMA transfer COUNTx is a read-only bit field. It comprises the actual number of DMA transfers that remain, until the DMA channel is disabled if ONESHOTx is set. Since the real COUNTx is always ICLOUNTx +1, the 17th bit of COUNTx is available on DMAxCTRL(6) bit.

23.3.1.49 ICOUNT1 Register (Offset = FCh) [reset = 0h]

ICOUNT1 is shown in Figure 23-146 and described in Table 23-128.

Return to Summary Table.

MibSPI DMAxCOUNT

Table 23-64. DMACNTLEN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
0	LARGE_COUNT	R/W	0h	0: Writes to the DMAxCTRL register will modify the ICOUNT value. Reading ICOUNT and COUNT can be done from the DMAxCTRL register. The DMAxCOUNT register should not be used since any write to this register will be overwritten by a subsequent write to DMAxCTRL register to set the TXDMAENA or RXDMAENA bits. 1: Writes to the DMAxCTRL register will not modify the ICOUNT value. The ICOUNT value must be written to in the DMAxCOUNT register before the RXDMAENA or TXDMAENA bits are set in the DMAxCTRL register. The DMAxCOUNT register should be used for reading COUNT or ICOUNT.

23.3.1.54 PAR_ECC_CTRL Register (Offset = 120h) [reset = 050A0005h]

PAR_ECC_CTRL is shown in Figure 23-151 and described in Table 23-133.

Return to Summary Table.

Table 23-65. PAR_ECC_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	NU4	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
27-24	SBE_EVT_EN	R/W	5h	Single Bit Error Event Enable This bit controls the generation of Error signaling (on MIBSPI_SBERR port) whenever a Single Bit Errors (SBE) is detected on TXRAM/RXRAM. This signal can be used to generate interrupt if required. Write: 0101 - Disable Error Event indication upon detection of SBE on TXRAM/RXRAM 1010 - Enable Error Event upon detection of SBE on TXRAM/RXRAM All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read: Returns the current value of the field
23-20	NU3	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
19-16	EDAC_MODE	R/W	Ah	Error Detection And Correction Mode These bits determine whether Single Bit Errors (SBE) detected by the SECDED block will be corrected or not. Write: 0101 - Disable correction of SBE detected by the SECDED block 1010 - Enable correction of SBE detected by the SECDED block All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read: Returns the current value of the field
15-9	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
8	PTESTEN	R/W	0h	Parity/ECC memory Test Enable. This bit, maps the parity/ecc bits corresponding to Multibuffer RAM locations into the peripheral RAM frame to make them accessible by the CPU. User and privilege mode (read): 0 = parity/ecc bits are not memory mapped 1 = parity/ecc bits are memory mapped Privilege mode (write): 0 = disable memory mapping of Parity/ECC locations 1 = enable memory mapping of Parity/ECC locations
7-4	NU1	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
3-0	EDEN	R/W	5h	Error Detection Enable These bits enable Parity/ECC Error Detection. Write: 0101: Disables Parity/ECC Error Detection Logic(default) Others : Enables Parity/ECC Error Detection Logic. Read: Returns the current value of this field

23.3.1.55 PAR_ECC_STAT Register (Offset = 124h) [reset = 0h]

PAR_ECC_STAT is shown in Figure 23-152 and described in Table 23-134.

Return to Summary Table.

Table 23-68. UERRADDR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
10-0	UERRADDR0	R	0h	Uncorrectable Parity or double bit ECC error address This register holds the address when a parity error is generated while reading the MibSPI (Transmit) TXRAM. The TXRAM can be read either by CPU or by the MibSPI Sequencer FSM logic for transmission. The address captured is byte alligned. This error address is frozen from being updated until it is read by the VBUSP host. Reading this register clears its contents to the default value of 0x000. Writes to this register are ignored.

23.3.1.58 RXOVRN_BUF_ADDR Register (Offset = 130h) [reset = 200h]

RXOVRN_BUF_ADDR is shown in Figure 23-155 and described in Table 23-137.

Return to Summary Table.

Receive RAM Overrun Buffer Address Register

Figure 23-89. RXOVRN_BUF_ADDR Register

Table 23-69. RXOVRN_BUF_ADDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
10-0	RXOVRN_BUF_ADDR	R	200h	Address of the RAM location of RXRAM for which an Overwrite occured. This address value will show only the offset address of the RAM location in the Multibuffer RAM address space. Refer to the device Spec for the actual absolute address of RXRAM. Content of this register are valid only when any of the TGINTVECT0 or TGINTVECT1 and SPIFLG registers show an RXOVRN error vector while in Multibuffer mode. If there are multiple Overrun errors, then this register holds address of first overrun address until it is read.

23.3.1.59 IOLPBKTSTCR Register (Offset = 134h) [reset = 0h]

IOLPBKTSTCR is shown in Figure 23-156 and described in Table 23-138.

Return to Summary Table.

SPI/MibSPI IO Loopback Test Control Register This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog ones in this test mode. In addition it contains control bits to induce some of the error condition into the module. These are to be used for test purpose only. All the control/status bits in this register are valid only when IO LPBK TST ENA field is set to “1010”.

Figure 23-90. IOLPBKTSTCR Register

NU1			ERRSCSPIN		CTRLSCSPINERR	LPBKTYPE	RXPENA
R-0h			R/W-0h		R/W-0h	R/W-0h	R/W-0h

Table 23-70. IOLPBKTSTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	SCSFAILFLG		0h	Bit indicating a failure on SPISCS pin compare during analog loopback during IO Loopback Test mode. Read 1 = A comparison between the internal CSNR field and the analog looped back value of SPISCS[7:0] pins failed. A stuck-at fault is detected on one of the SPISCS[7:0]. Comparison is done only on the pins which are configured as functional and during transfer operation. 0 = No miscompares on any of the 8 chipselect pin value comparison with the internal Chipselect number CSNR during transfers. Write 1 = Clear this Flag bit. 0 = No effect.
23-21	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
20	CTRLBITERR	R/W	0h	Controls inducing of BITERR during IO Loopback Test mode. 1 = The value of incoming data from the loopback Transmit pin is flipped. 0 = No affect on BIT ERROR.
19	CTRLDESYNC	R/W	0h	Controls inducing of DESYNC Error during IO Loopback Test mode. 1 = Forces the incoming SPIENA pin (if functional) to remain ‘0’ even after the transfer complete. This forcing will be retained until the Kernel reaches IDLE state. 0 = No affect on DESYNC Error.
18	CTRLPARERR	R/W	0h	Controls inducing of Parity Error during IO Loopback Test mode. 1 = Flips the Parity Polarity signal being used for transmit parity generation logic 0 = No affect on Parity Error
17	CTRLTIMEOUT	R/W	0h	Controls inducing of TIMEOUT Error during IO LoopbacK Test mode. 1 = Forces the incoming SPIENA pin (if functional) to remain ‘1’ when transmission is initiated. The forcing will be retained until the Kernel reaches IDLE state. 0 = No affect on TIMEOUT Error.

Table 23-70. IOLPBKTSTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	CTRLDLENERR	R/W	0h	Controls inducing of Data Length Error during IO Loopback Test mode. 1 = When in Master mode, forces the SPIENA pin(if functional) to '1' when the module starts Shifting the data. When in Slave mode, forces the incoming SPISCS pin(if functional) to '1' when the module starts shifting the data.. 0 = No affect on Data Length Error.
15-12	NU2	R	0h	Reserved. Reads return '0' and writes have no effect.
11-8	IOLPBKTSTENA	R/W	0h	Module I/O Loopback Test Enable Key User and Privileged mode reads. Write access only in Privileged mode. Write: 1010 = I/O DFT is enabled All other values = I/O DFT is disabled Read: 1010 = I/O DFT is enabled All other values = I/O DFT is disabled
7-6	NU1	R	0h	Reserved. Reads return '0' and writes have no effect.
5-3	ERRSCSPIN	R/W	0h	Inject Error on ChipSelect Pin. The value in this field is decoded to find out the ChipSelect pin on which to inject an error. During the analog loopback of IO Loopback Test mode if CTRL SCS PIN ERR bit is set to '1', then the chipselect pin selected by this field is forced to the opposite of its original CSNR bit. 000 - Select SPISCS[0] for injecting error 001 - Select SPISCS[1] for injecting error . 111 - Select SPISCS[7] for injecting error
2	CTRLSCSPINERR	R/W	0h	Control bit to enable the injection of an error on SPISCS[7:0] pins. Individual pins of SPISCS[7:0] can be choosen using ERR SCS PIN. 1 = Enable the error inducing logic to the SPISCS pins. 0 = Disable the error inducing logic.
1	LPBKTYPE	R/W	0h	Module IO Loopback Type (Analog/Digital). User and Privileged mode reads. Write access only in Privileged mode. Write/Read : 1 = Analog loopback is enabled in module I/O DFT mode when IOLPBKTSTENA = 1010) 0 = Digital loopback is enabled in module I/O DFT mode when IOLPBKTSTENA = 1010
0	RXPENA	R/W	0h	Module Analog loopback through Receive Pin Enable. User and Privileged mode reads. Write only in privileged mode: Write/Read : 1 = Analog loopback through receive pin 0 = Analog loopback through transmit pin. This bit is valid only when LPBK TYPE = '1' which chooses Analog loopback mode.

23.3.1.60 EXTENDED_PRESCALE1 Register (Offset = 138h) [reset = 0h]

EXTENDED_PRESCALE1 is shown in Figure 23-157 and described in Table 23-139.

Return to Summary Table.

SPI/MibSPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1(7:0) of EXTENDED_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.

Figure 23-91. EXTENDED_PRESCALE1 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NU2					EPRESCLAE_FMT1										
R-0h					R/W-0h										
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU1					EPRESCLAE_FMT0										
R-0h					R/W-0h										

Table 23-71. EXTENDED_PRESCALE1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26-16	EPRESCLAE_FMT1	R/W	0h	Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 can be modified in privilege mode only. EPRESCALE_FMT1 determines the bit transfer rate of Data Format 1 if the SPI/MibSPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT1(7:0) bits and PRESCALE1(7:0) bits of SPIFMT1 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT1(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EXTENDED_PRESCALE1(26:16) or SPIFMT1(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. BRFormatx = VBUSPCLK/(EXTENDEDPRESCALEy+1) When EPRESCALE_FMTy (y=1,2) is set to zero(0), the SPI clock rate defaults to VBUSPCLK/2.
15-11	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-71. EXTENDED_PRESCALE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-0	EPRESCLAE_FMT0	R/W	0h	EPRESCALE_FMT0 can be modified in privilege mode only. EPRESCALE_FMT0 determines the bit transfer rate of Data Format 0 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT0(7:0) bits and PRESCALE0(7:0) bits of SPIFMT0 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT0(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EPRESCALE0(26:16) or SPIFMT0(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK.

23.3.1.61 EXTENDED_PRESCALE2 Register (Offset = 13Ch) [reset = 0h]

EXTENDED_PRESCALE2 is shown in Figure 23-158 and described in Table 23-140.

Return to Summary Table.

SPI/MibSPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This register is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT2(7:0) of EXTENDED_PRESCALE2 and PRESCALE2(7:0) of SPIFMT2 register will always reflect the same contents. Similarly EPRESCALE_FMT3(7:0) and PRESCALE3(7:0) of SPIFMT3 reflect the same contents.

Figure 23-92. EXTENDED_PRESCALE2 Register

R-0h					R/W-0h										

Table 23-72. EXTENDED_PRESCALE2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26-16	EPRESCLAE_FMT3	R/W	0h	EPRESCALE_FMT3 can be modified in privilege mode only. EPRESCALE_FMT3 determines the bit transfer rate of Data Format 3 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT3(7:0) bits and PRESCALE3(7:0) bits of SPIFMT3 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT3(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EPRESCALE3(26:16) or SPIFMT3(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK.
15-11	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
10-0	EPRESCLAE_FMT2	R/W	0h	EPRESCALE_FMT2 can be modified in privilege mode only. EPRESCALE_FMT2 determines the bit transfer rate of Data Format 2 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT2(7:0) bits and PRESCALE2(7:0) bits of SPIFMT2 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT3(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EXTENDED_PRESCALE2(26:16) or SPIFMT2(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK.

23.3.1.62 ECCDIAG_CTRL Register (Offset = 140h) [reset = Ah]

ECCDIAG_CTRL is shown in Figure 23-159 and described in Table 23-141.

Return to Summary Table.

ECC Diagnostic Control register

Figure 23-93. ECCDIAG_CTRL Register

Table 23-75. SBERRADDR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU1	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
10-0	SBERRADDR1	R	0h	Single Bit ECC Error Address This register holds the address of the RAM location when a single bit error is generated by SECDED block while reading the MibSPI (Receive) RXRAM. This error address is frozen from being updated until it is read by the VBUS host. Reading this register clears its contents to the default value The default value is 0x400 if Extended Buffer feature is enabled, else it is 0x200 Writes to this register are ignored.

23.3.1.65 SBERRADDR0 Register (Offset = 14Ch) [reset = 0h]

SBERRADDR0 is shown in Figure 23-162 and described in Table 23-144.

Return to Summary Table.

Single Bit ECC Error Address Register - TXRAM

Figure 23-96. SBERRADDR0 Register

Table 23-77. SPIREV Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	Identification Scheme Used to distinguish different ID schemes. Reads 0x01
29-28	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
27-16	FUNC	R	A05h	Indicates functionally equivalent module family Reads 0xA05
15-11	RTL	R	0h	RTL version number Read value will provide an approximate RTL revision number. The design release version can be obtained from the device specification
10-8	MAJOR	R	3h	Major Revision number Reads 0x3
7-6	CUSTOM	R	0h	Indicates device specific implementation Reads 0x0
5-0	MINOR	R	8h	Minor Revision number Reads 0x8

23.3.2 MSS_MIBSPIB Registers

Table 23-78 lists the memory-mapped registers for the MSS_MIBSPIB. All register offset addresses not listed in Table 23-78 should be considered as reserved locations and the register contents should not be modified.

Table 23-78. MSS_MIBSPIB Registers

Offset	Acronym	Register Name	Section
0h	SPIGCR0	SPI / MibSPI Global Control Register 0	Section 23.3.2.1
4h	SPIGCR1	SPI / MibSPI Global control register 1	Section 23.3.2.2
8h	SPIINT0	SPI / MibSPI Interrupt Enable Register	Section 23.3.2.3
Ch	SPILVL	SPI / MibSPI Interrupt Level Register	Section 23.3.2.4
10h	SPIFLG	SPI / MibSPI Flag Register	Section 23.3.2.5
14h	SPIPC0	SPI / MibSPI Pin Control Register 0 (SPIPC0) - SPIFUN Note: Duplicate Control Bits for SIMO0 & SOMI0 Bit 24 is not physically implemented. it is a mirror of Bit11. Any write to Bit 24 will be reflected on Bit11 and when Bit 24 & Bit 11 simultaneously written, the value of Bit11 will control the SOMI pin. Read value of Bit 24 always reflects the Bit 11 value. This is true for the Bit 24 & Bit 11 of all of SPIPC0 to SPIPC9 registers. Same is true for SIMO pin with Bit16 & Bit 10 of SPIPC0 to SPIPC9 registers.	Section 23.3.2.6
18h	SPIPC1	SPI / MibSPI Pin Control Register 1 (SPIPC1) - SPIDIR	Section 23.3.2.7

120h	PAR_ECC_CTRL	Parity/ECC Control Register	Section 23.3.2.54
124h	PAR_ECC_STAT	Parity/ECC Status Register	Section 23.3.2.55
128h	UERRADDR1	Uncorrectable Parity or double bit ECC error Address Register - RXRAM	Section 23.3.2.56
12Ch	UERRADDR0	Uncorrectable Parity or double bit ECC error address register - TXRAM	Section 23.3.2.57
130h	RXOVRN_BUF_ADDR	Receive RAM Overrun Buffer Address Register	Section 23.3.2.58

Table 23-78. MSS_MIBSPIB Registers (continued)

Offset	Acronym	Register Name	Section
134h	IOLPBKTSTCR	SPI/MibSPI IO Loopback Test Control Register This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog ones in this test mode. In addition it contains control bits to induce some of the error condition into the module. These are to be used for test purpose only. All the control/status bits in this register are valid only when IO LPBK TST ENA field is set to “1010”.	Section 23.3.2.59
138h	EXTENDED_PRESCALE1	SPI/MibSPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1(7:0) of EXTENDED_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.	Section 23.3.2.60
13Ch	EXTENDED_PRESCALE2	SPI/MibSPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This register is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT2(7:0) of EXTENDED_PRESCALE2 and PRESCALE2(7:0) of SPIFMT2 register will always reflect the same contents. Similarly EPRESCALE_FMT3(7:0) and PRESCALE3(7:0) of SPIFMT3 reflect the same contents.	Section 23.3.2.61
140h	ECCDIAG_CTRL	ECC Diagnostic Control register	Section 23.3.2.62
144h	ECCDIAG_STAT	ECC Diagnostic Status register	Section 23.3.2.63
148h	SBERRADDR1	Single Bit Error Address Register - RXRAM	Section 23.3.2.64
14Ch	SBERRADDR0	Single Bit ECC Error Address Register - TXRAM	Section 23.3.2.65
1FCh	SPIREV	SPI / MibSPI Revision ID Register	Section 23.3.2.66

Complex bit access types are encoded to fit into small table cells. Table 23-79 shows the codes that are used for access types in this section.

Table 23-79. MSS_MIBSPIB Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	-0 R	Returns 0s Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

23.3.2.1 SPIGCR0 Register (Offset = 0h) [reset = 0h]

SPIGCR0 is shown in Figure 23-98 and described in Table 23-80.

Return to Summary Table.

SPI / MibSPI Global Control Register 0

7	6	5	4	3	2	1	0
NU							nRESET
R-0h							R/W-0h

Table 23-80. SPIGCR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	NU	R	0h	Reserved, Reads return ‘0’ and writes have no effect.
0	nRESET	R/W	0h	This is the local reset control for the module. This bit needs to be set to ‘1’ before any operation on SPI / MibSPI can be done. Only after setting this bit to ‘1’, the Auto Initialization of Multibuffer RAM starts. Clearing this bit to ‘0’ will result in all of the control and status register values to return to their default values. 0 = SPI / MibSPI is in reset state 1 = SPI / MibSPI is out of reset state.

23.3.2.2 SPIGCR1 Register (Offset = 4h) [reset = 0h]

SPIGCR1 is shown in Figure 23-99 and described in Table 23-81.

Return to Summary Table.

SPI / MibSPI Global control register 1

Figure 23-99. SPIGCR1 Register

31	30	29	28	27	26	25	24
NU4							SPIEN
R-0h							R/W-0h
23	22	21	20	19	18	17	16

R-0h							R/W-0h
7	6	5	4	3	2	1	0
NU1						CLKMOD	MASTER
R-0h						R/W-0h	R/W-0h

Table 23-81. SPIGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	SPIEN	R/W	0h	SPI enable. This bit enables the SPI/MibSPI transfers. This bit must be set to 1 after all other SPI / MibSPI configuration bits have been written. When SPIEN bit is 0 or cleared to 0, the following SPI/MibSPI registers get forced to their default states (to ‘0’s except for RXEMPTY bit in SPIBUF): - Both TX & RX Shift Registers - The TXDATA fields of SPIDAT0 and SPIDAT1 registers - All the fields of SPIFLG register - Contents of SPIBUF & the internal RXBUF registers 0=SPI / MibSPI is not activated for transfers. 1=Activates SPI / MibSPI
23-17	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	LOOPBACK	R/W	0h	LOOP BACK. Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO pin is internally connected to the SPISOMI pin. The transmit data is looped back as receive data and is stored in the receive field of the concerned buffer. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI remains in high-impedance state. The SPI / MibSPI has to be initialized in master mode before the loop-back can be selected. If the SPI / MibSPI is initialized in slave mode or a data transfer is ongoing, errors may result. 1 =Internal loop-back test mode enabled. 0 =Internal loop-back test mode disabled. This loopback mode can be used only in Master mode. This automatically selects digital loopback path. When this Loopback mode is selected, CLKMOD bit should be set to ‘1’, meaning that SPICLK can only be internal.
15-9	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
8	POWERDOWN	R/W	0h	POWERDOWN. When active, the SPI / MibSPI state machines enter a powerdown state. 0=MibSPI in active mode 1=MibSPI in powerdown mode
7-2	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
1	CLKMOD	R/W	0h	CLKMOD. Clock mode Selects either an internal or external clock source. This bit also determines the I/O direction of the SPIENA and SPISCS[7:0] pins in functional mode. 0=Clock is external 1=Clock is internal

Table 23-81. SPIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	MASTER	R/W	0h	MASTER: SPISIMO/SPISOMI pin direction determination. Determines the direction of the SPISIMO and SPISOMI pins. This bit determines whether the SPI/MibSPI is in Master mode or Slave mode. This bit also controls the Master-only features like the C2T/T2C counters, C2E/T2E timers, most of the Error conditions specific to Master mode. 0=SPISIMO pin an input, SPISOMI pin an output 1=SPISOMI pin an input, SPISIMO pin an output Note: Although there are two different bits which control the Master/Slave mode functions, only two of their combinations are valid. For compatibility reasons both the bits are retained. For Master mode of operation: MASTER = '1', CLKMOD = '1' For Slave mode of operation: MASTER = '0', CLKMOD = '0' Any other combinations of these two bits may not yield any desirable operation of the module.

23.3.2.3 SPIINT0 Register (Offset = 8h) [reset = 0h]

SPIINT0 is shown in Figure 23-100 and described in Table 23-82.

Return to Summary Table.

SPI / MibSPI Interrupt Enable Register

R-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 23-82. SPIINT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU5	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	ENABLEHIGHZ	R/W	0h	SPIENA pin high-z enable. When active, the SPIENA pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to place it is output in high-z when not driving a low signal. If inactive, then the pin will output both a high and a low signal. 0=SPIENA pin is pulled high when not active. 1=SPIENA pin remains in high-z when not active.
23-17	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	DMAREQEN	R/W	0h	DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to ‘1’. 0=DMA is not used 1=DMA Requests will be generated. A DMA request will be generated on TX DMA REQ line each time a transmit data is copied to the Shift Register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes. A DMA request will be generated on RX DMA REQ line each time a received data is copied to SPIBUF register either from RXBUF or directly from the Shift Register.
15-10	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
9	TXINTENA	R/W	0h	An interrupt is to be generated everytime data is written to the “Shift Register”, so that a new data can be written to TXBUF. Setting this bit will generate an interrupt if TXINTFLG bit (SPIFLG.9) is set to ‘1’. 0=No interrupt will be generated upon TXINTFLG getting set to ‘1’. 1=Interrupt will be generated upon TXINTFLG getting set to ‘1’. An interrupt request will be generated as soon as this bit is set to ‘1’. By default it will be generated on INT0 line. SPILVL register can be programmed before-hand to change this default.
8	RXINTENA	R/W	0h	An interrupt is to be generated when the RXINTFLAG bit (SPIFLG.8) is set by hardware. Otherwise, no interrupt will be generated. 0=Interrupt will not be generated 1=Interrupt will be generated Both Transmitter Empty & Receiver Full interrupts are valid in SPI or Compatibility mode of MibSPI only. In Multibuffered mode these interrupts will not be generated even if enabled.
7	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-82. SPIINT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	OVRNINTENA	R/W	0h	Overrun interrupt enable. An interrupt is to be generated when the RCVR OVRN flag bit (SPIFLG.6) is set by hardware. Otherwise, no interrupt will be generated. 0=Overrun interrupt will not be generated 1=Overrun interrupt will be generated
5	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
4	BITERRENA	R/W	0h	Enables interrupt on bit error. 1 =Enables an interrupt on a bit error (BITERR = 1). 0 =No interrupt asserted upon bit error.
3	DESYNCENA	R/W	0h	Enables interrupt on de-synchronized slave. DESYNCENA is used in master mode only. 1 =Enables an interrupt on de-synchronization of the slave (DESYNC = 1). 0 =No interrupt asserted upon de-synchronization error.
2	PARERRENA	R/W	0h	Enables interrupt on parity error. 1 =Enables an interrupt on a parity error (PARITYERR = 1). 0 =No interrupt asserted upon parity error.
1	TIMEOUTENA	R/W	0h	Enables interrupt on ENA signal time-out. 1 =Enables an interrupt on a time-out of the ENA signal (TIMEOUT = 1). 0 =No interrupt asserted upon ENA signal time-out.
0	DLENERRENA	R/W	0h	Data Length Error interrupt Enable. 1 = Enables an interrupt when Data Length Error occurs. 0 = No interrupt is generated upon Data Length Error. A Data Length Error occurs under the following conditions. Master: In a 4-pin with SPIENA mode or 5-pin mode, if the SPIENA pin from the slave is deasserted before the Master has completed its transfer, the Data Length Error is set. That is, if the Character Length counter has not completed counting while SPIENA deassertion is detected, then it means that the Slave has neither received full data from the Master nor has it transmitted complete data. Slave: In a 4-pin with ChipSelects mode or 5-pin mode, if the incoming valid SPISCS pin is de-activated before the Character Length counter completes counting, then Data Length Error is set.

23.3.2.4 SPILVL Register (Offset = Ch) [reset = 0h]

SPILVL is shown in Figure 23-101 and described in Table 23-83.

Return to Summary Table.

R-0h	0h	R-0h	0h	0h	0h	0h	0h

Table 23-84. SPIFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	BUFINITACTIVE	R	0h	Indicates the status of Multibuffer initialization process. Software should poll this bit to determine if it can proceed with the configuration of Multibuffer mode registers or Multibuffer RAM handling. Refer to Section 3.10.7 for details on Initialization of Multibuffer RAM. 1 = Multibuffer RAM is still being initialized. Do not attempt to write to either Multibuffer RAM or any Multibuffer mode registers. Refer to Section 3.3 for a classification of registers into compatibility mode and Multibuffer mode. 0 = Multibuffer RAM initialization is complete. This bit will show a value of ‘1’ as long as the nRESET bit is ‘0’, but does not really indicate that Buffer initialization is underway. Internal automatic buffer initialization starts only when the nRESET bit is set to ‘1’. For SPI, this bit reads ‘1’ always. For MibSPI, BUF INIT ACTIVE bit will show up as ‘1’ for a maximum of 128/256 (will vary depending upon the actual size of the Multibuffer RAM implemented) VCLK cycles after the nRESET bit in GCR0 is set to ‘1’ and then settle to ‘0’. If Auto Memory Initialization is triggered through System (MEM_AUTO_INIT pulse), then BUF INIT ACTIVE bit will show up as ‘1’ for a maximum of 128/256 (will vary depending upon the actual size of the Multibuffer RAM implemented) VCLK cycles and then settle to ‘0’.
23-10	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
9	TXINTFLG	R	0h	Transmitter Empty Interrupt Flag. Serves as an interrupt flag indicating that Transmit Buffer (TXBUF) is empty and a new data can be written to it. This flag is set when a data is copied to the “Shift Register” either directly or from the TXBUF register. This bit is cleared by one of following ways: Writing a new data to either SPIDAT0 or SPIDAT1 Writing a ‘0’ to SPIEN (SPIGCR1.24) 0= Transmit Buffer is now full. No interrupt pending for Transmitter Empty 1= Transmit Buffer is empty. An interrupt is pending to fill the transmitter.

Table 23-84. SPIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	RXINTFLG		0h	Receiver Full Interrupt Flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit. This bit is cleared under the following ways: Reading the SPIBUF register Reading TGINTVECT0 or TGINTVECT1 register when there is a “Receive Buffer Full” interrupt Writing a ‘1’ to this bit Writing a ‘0’ to SPIEN (SPIGCR1.24) System reset 0= No new received data pending. Receive buffer is Empty. 1= A newly received data is ready to be read. Receive buffer is full. Note: Exception for clearing of RXINT If both SPIBUF and RXBUF (internal buffer) are full, then, reading TGINTVECT0 or TGINTVECT1 register (while it shows 10010) does not clear the RXINTFLG in SPIFLG register. In this case, only way to clear the Interrupt is to read the SPIBUF (twice) and clear all the received data. Note: Side effects of Write Clear to RXINTFLG Clearing RXINTFLG bit by writing a ‘1’ before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. This way, one can ignore a received data. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and RXEMPTY bit will be cleared again. SPIBUF contents should be read first if this situation needs to be avoided.
7	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
6	OVRNINTFLG		0h	Receiver overrun flag. The SPI / MibSPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI / MibSPI will generate an interrupt request if this bit is set and the OVRN INTEN bit (SPIINT0.6) is set high. 0 = Overrun condition did not occur 1 = Overrun condition has occurred In SPI or Compatibility mode of MibSPI, this bit is cleared under the following conditions: Reading TGINTVECT0 or TGINTVECT1 register when there is a “Receive Buffer Overrun” interrupt Writing a ‘1’ to OVRNINTFLG in SPIFLG register itself Reading SPIBUF register does not clear this OVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the Overrun buffer. This is due to the fact that the Overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF. Note: A special condition under which OVRNINTFLG flag gets set. If both SPIBUF & RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR & DLEN_ERR occur, then RXOVR in RXBUF & OVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal Receiver Overrun. In Multibuffer mode of MibSPI, this bit is cleared under the following conditions. Reading the RXOVRN_BUF_ADDR register Writing a ‘1’ to OVRNINTFLG in SPIFLG register itself In Multibuffer mode, if OVRNINTFLG is set, then the address of the buffer which experienced the Overrun is available in RXOVRN_BUF_ADDR.
5	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
4	BITERRFLG		0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the Flag BITERR is set. If BITERRENA is set an interrupt is asserted. A possible reason for a bit error can be a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred. This flag can be cleared by one of the following ways. Write a ‘1’ to this bit. Set SPIEN bit to ‘0’.

Table 23-84. SPIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	DESYNCFLG		0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 = A slave device is de-synchronized. The master monitors the ENAble signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'. Note: Inconsistency of Desync flag in SPI/Compatibility mode MibSPI Due to the nature of this Error, under some circumstances it is possible for Desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that Receive Completion flag/interrupt will be generated when the buffer transfer is completed. But Desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct Desync condition. This inconsistency in Desync flag is valid only in SPI or Compatibility mode of MibSPI. In Multibuffer mode, Desync flag is always guaranteed to be for the current buffer.
2	PARERRFLG		0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. 0 =No parity error detected. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'.
1	TIMEOUTFLG		0h	Time-out due to non-activation of ENA signal. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, i.e. the SPI / MibSPI doesn't re-start a data transfer from this buffer. 0 =No ENA-signal time-out occurred. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'.
0	DLENERRFLG		0h	Data Length Error Flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured. This flag can be cleared by one of the following ways. Write a '1' to this bit. Set SPIEN bit to '0'. A Data Length Error occurs under the following conditions. Master: In a 4-pin with SPIENA mode or 5-pin mode, if the SPIENA pin from the slave is deasserted before the Master has completed its transfer, the Data Length Error is set. That is, if the Character Length counter has not completed counting while SPIENA pin deassertion is detected, then it means that the Slave has neither received full data from the Master nor has it transmitted complete data. Slave: In a 4-pin with ChipSelects mode or 5-pin mode, if the incoming valid SPISCS pin is de-activated before the Character Length counter completes counting, then Data Length Error is set. Note: Clearing of Transmission Error Flags in SPIBUF during Error conditions Whenever any Transmission Errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected, and the Error Flag are cleared by writing to the Error bit in SPIFLG register, the corresponding Error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all the older status bits in SPIBUF are cleared before starting the next transfer.

23.3.2.6 SPIPC0 Register (Offset = 14h) [reset = 0h]

SPIPC0 is shown in Figure 23-103 and described in Table 23-85.

Return to Summary Table.

SPI / MibSPI Pin Control Register 0 (SPIPC0) - SPIFUN Note: Duplicate Control Bits for SIMO0 & SOMI0 Bit 24 is not physically implemented. it is a mirror of Bit11. Any write to Bit 24 will be reflected on Bit11 and when Bit 24 & Bit 11 simultaneously written, the value of Bit11 will control the SOMI pin. Read value of Bit 24 always reflects the Bit 11 value. This is true for the Bit 24 & Bit 11 of all of SPIPC0 to SPIPC9 registers. Same is true for SIMO pin with Bit16 & Bit 10 of SPIPC0 to SPIPC9 registers.

Table 23-85. SPIPC0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMIFUN	R/W	0h	Slave out, master in function. Determines whether the SPISOMIx pins are to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISOMIx pin is a GPIO 1=SPISOMIx pin is a SPI / MibSPI functional pin
23-16	SIMOFUN	R/W	0h	Slave in, master out function. Determines whether the SPISIMOx pin is to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISIMOx pin is a GPIO 1=SPISIMOx pin is a SPI / MibSPI functional pin Note: Generic based bit implementation Register bits 31 to 24 and 23 to 16 of SPIPC0 to SPIPC9 are implemented depending upon the generic parameter NUM_PARLL_PINS which determines the number of SIMO/SOMI data lines to be supported. Only if 8 dataline support is selected at the time of logic synthesis, bits 31 to 16 are implemented. Un-implemented bits return ‘0’ upon read and are not writable.
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMIFUN0	R/W	0h	Slave out, master in function. Determines whether the SPISOMI0 pin is to be used as a general-purpose I/O pin or as a SPI / MibSPI functional pin. 0=SPISOMI0 pin is a GPIO 1=SPISOMI0 pin is a SPI / MibSPI functional pin Note: Bit 11 or bit 24 can be used to set the function mode for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOFUN0	R/W	0h	Slave in, master out function. Determines whether the SPISIMO0 pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPISIMO0 pin is a GPIO 1=SPISIMO0 pin is a SPI / MibSPI functional pin Note: Bit 10 or bit 16 can be used to set the function mode for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKFUN	R/W	0h	SPI / MibSPI clock function. Determines whether the SPICLK pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPICLK pin is a GPIO 1=SPICLK pin is a SPI / MibSPI functional pin

Table 23-85. SPIPC0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENAFUN	R/W	0h	SPIENA function. Determines whether the SPIENA pin is to be used as a general-purpose I/O pin, or as a SPI / MibSPI functional pin. 0=SPIENA pin is a GPIO 1=SPIENA pin is a SPI / MibSPI functional pin
7-0	SCSFUN	R/W	0h	SPISCS[7:0] function. Determines whether the SPISCSx pins are to be used as a general-purpose I/O pins or as SPI functional pins. If the slave SPISCSx pins are in functional mode and receive an inactive high signal, the slave SPI will place it is output in high-z and disable shifting. 0=SPISCSx pin is a GPIO 1=SPISCSx pin is a SPI functional pin Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSFUN[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read ‘0’ always.

23.3.2.7 SPIPC1 Register (Offset = 18h) [reset = 0h]

SPIPC1 is shown in Figure 23-104 and described in Table 23-86.

Return to Summary Table.

Table 23-86. SPIPC1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMIDIR	R/W	0h	SPISOMIx direction. Controls the direction of the SPISOMIx pin when it is used as a general-purpose I/O pin. If the SPISOMIx pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISOMIx pin is an input 1=SPISOMIx pin is an output
23-16	SIMODIR	R/W	0h	SPISIMOx direction. Controls the direction of the SPISIMOx pin when it is used as a general-purpose I/O pin. If the SPISIMOx pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISIMOx pin is an input 1=SPISIMOx pin is an output
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMIDIR0	R/W	0h	SPISOMI0 direction. Controls the direction of the SPISOMI0 pin when it is used as a general-purpose I/O pin. If the SPISOMI0 pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISOMI0 pin is an input 1=SPISOMI0 pin is an output Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMODIR0	R/W	0h	SPISIMO0 direction. Controls the direction of the SPISIMO0 pin when it is used as a general-purpose I/O pin. If the SPISIMO0 pin is used as a SPI / MibSPI functional pin, the I/O direction is determined by the MASTER bit. 0=SPISIMO0 pin is an input 1=SPISIMO0 pin is an output Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKDIR	R/W	0h	SPICLK direction. Controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit. 0=SPICLK pin is an input 1=SPICLK pin is an output
8	ENADIR	R/W	0h	SPIENA direction. Controls the direction of the SPIENA pin when it is used as a general-purpose I/O. If the SPIENA pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1.1). 0=SPIENA pin is an input 1=SPIENA pin is an output

Table 23-86. SPIPC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	SCSDIR	R/W	0h	SPISCS[7:0] direction. Controls the direction of the SPISCSx pins when they are used as a general-purpose I/O pin. Each pins could be configured independently from the others If the SPISCSx is used as a SPI functional pin, the I/O direction is determined by the CLKMOD bit (SPIGCR1.1). 0=SPISCSx pin is an input 1=SPISCSx pin is an output Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSDIR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read ‘0’ always.

23.3.2.8 SPIPC2 Register (Offset = 1Ch) [reset = 0h]

SPIPC2 is shown in Figure 23-105 and described in Table 23-87.

Return to Summary Table.

SPI / MibSPI Pin Control Register 2 (SPIPC2) - SPIDIN

Bit	Field	Type	Reset	Description
31-24	SOMISET	R/W	0h	SPISOMIx dataout set. Only active when the SPISOMIx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISOMIDOUTx bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISOMIx pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUTx is 0. 1= Current value on SOMIDOUTx is 1.
23-16	SIMOSET	R/W	0h	SPISIMOx dataout set. Only active when the SPISIMOx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISIMODOUTx bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISIMOx pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUTx is 0. 1= Current value on SIMODOUTx is 1
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMISET0	R/W	0h	SPISOMI0 dataout set. Only active when the SPISOMI0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISOMIDOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISOMI0 pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUT0 is 0. 1= Current value on SOMIDOUT0 is 1. Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOSET0	R/W	0h	SPISIMO0 dataout set. Only active when the SPISIMO0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding SPISIMODOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPISIMO0 pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUT0 is 0. 1= Current value on SIMODOUT0 is 1. Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKSET	R/W	0h	SPICLK dataout set. Only active when the SPICLK pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit sets the corresponding CLKDOUT bit to ‘1’. Write: 0= Has no effect 1= Logic 1 placed on SPICLK pin if it is in General Purpose O/P mode Read: 0= Current value on CLKDOUT pin is logic 0. 1= Current value on CLKDOUT pin is logic 1

Table 23-89. SPIPC4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENASET	R/W	0h	SPIENA dataout set. Only active when the SPIENA pin is configured as a general-purpose output pin. A value of '1' written to this bit sets the corresponding ENABLEDOUT bit to '1'. Write: 0= Has no effect 1= Logic 1 placed on SPIENA pin if it is in General Purpose O/P mode Read: 0= Current value on ENADOUT is 0. 1= Current value on ENADOUT is 1
7-0	SCSSET	R/W	0h	SPISCS[7:0] dataout set. Only active when the SPISCSx pins are configured as a general-purpose output pins. A value of '1' written to these bits set the corresponding SCSDOUT bit to '1'. Write: 0= Has no effect 1= Logic 1 placed on SPISCSx pin if it is in General Purpose O/P mode Read: 0= Current value on SCSDOUTx is 0. 1= Current value on SCSDOUTx is 1. Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSSET[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Register Read Read of SPIPC4 register gives out contents of the SPIPC3 register.

23.3.2.11 SPIPC5 Register (Offset = 28h) [reset = 0h]

SPIPC5 is shown in Figure 23-108 and described in Table 23-90.

Return to Summary Table.

Table 23-90. SPIPC5 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	SOMICLR	R/W	0h	SPISOMIx dataout clear. Only active when the SPISOMIx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISOMIDOUTx bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISOMIx pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUTx is 0. 1= Current value on SOMIDOUTx is 1.
23-16	SIMOCLR	R/W	0h	SPISIMOx dataout clear. Only active when the SPISIMOx pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISIMODOUTx bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISIMOx pin if it is in General Purpose O/P mode Read: 0=Current value on SIMODOUTx is 0. 1=Current value on SIMODOUTx is 1.
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMICLR0	R/W	0h	SPISOMI0 dataout clear. Only active when the SPISOMI0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SPISOMIDOUT bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISOMI0 pin if it is in General Purpose O/P mode Read: 0= Current value on SOMIDOUT0 is 0. 1= Current value on SOMIDOUT0 is 1. Note: Bit 11 or bit 24 can be used to set the direction for pin SOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOCLR0	R/W	0h	SPISIMO0 dataout clear. Only active when the SPISIMO0 pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding SIMODOUT0 bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPISIMO0 pin if it is in General Purpose O/P mode Read: 0= Current value on SIMODOUT0 is 0. 1= Current value on SIMODOUT0 is 1. Note: Bit 10 or bit 16 can be used to set the direction for pin SIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKCLR	R/W	0h	SPICLK dataout clear. Only active when the SPICLK pin is configured as a general-purpose output pin. A value of ‘1’ written to this bit clears the corresponding CLKDOUT bit to ‘0’. Write: 0= Has no effect 1= Logic 0 placed on SPICLK pin if it is in General Purpose O/P mode Read: 0= Current value on CLKDOUT is 0. 1= Current value on CLKDOUT is 1.

Table 23-90. SPIPC5 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	ENACLR	R/W	0h	SPIENA dataout clear. Only active when the SPIENA pin is configured as a general-purpose output pin. A value of '1' written to this bit clears the corresponding ENABLEDOUT bit to '0'. Write: 0= Has no effect 1= Logic 0 placed on SPIENA pin if it is in General Purpose O/P mode Read: 0= Current value on ENADOUT is 0. 1= Current value on ENADOUT is 1.
7-0	SCSCLR	R/W	0h	SPISCS[7:0] dataout clear. Only active when the SPISCSx pins are configured as a general-purpose output pins. A value of '1' written to this bit clears the corresponding SCSDOUT bit to '0.. Write: 0= Has no effect 1= Logic 0 placed on SPISCSx pin if it is in General Purpose O/P mode Read: 0= Current value on SCSDOUTx is 0. 1= Current value on SCSDOUTx is 1 Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSCLR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Register Read Read of SPIPC5 register gives out contents of the SPIPC3 register.

23.3.2.12 SPIPC6 Register (Offset = 2Ch) [reset = 0h]

SPIPC6 is shown in Figure 23-109 and described in Table 23-91.

Return to Summary Table.

Bit	Field	Type	Reset	Description
31-24	SOMIPDR	R/W	0h	SPISOMIx Open drain enable Enables Open drain capability for the pin SOMIx if the following conditions are met. SOMIDIRx = 1 (SPISOMI0 pin configured in GPIO mode as output pin) SOMIDOUTx = 1 0 = Output value on SPISOMIx pin is logic ‘1’ 1 = Output pin SPISOMIx is Tri-stated
23-16	SIMOPDR	R/W	0h	SPISIMOx Open drain enable Enables Open drain capability for the pin SPISIMOx if the following conditions are met. SIMODIRx = 1 (SPISIMOx pin configured in GPIO mode as output pin) SIMODOUTx = 1 0 = Output value on SPISIMOx pin is logic ‘1’ 1 = Output pin SPISIMOx is Tri-stated
15-12	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
11	SOMIPDR0	R/W	0h	SPISOMI0 Open drain enable Enables Open drain capability for the pin SPISOMI if the following conditions are met. SOMIDIR0 = 1 (SPISOMI0 pin configured in GPIO mode as output pin) SOMIDOUT0 = 1 0 = Output value on SPISOMI0 pin is logic ‘1’ 1 = Output pin SPISOMI0 is Tri-stated Note: Bit 11 or bit 24 can be used to set the direction for pin SPISOMI0. If a 32 bit write is performed, bit 11 will have priority over bit 24.
10	SIMOPDR0	R/W	0h	SPISIMO0 Open drain enable Enables Open drain capability for the pin SPISIMO0 if the following conditions are met. SIMODIR0 = 1 (SPISIMO pin configured in GPIO mode as output pin) SIMODOUT0 = 1 0 = Output value on SPISIMO0 pin is logic ‘1’ 1 = Output pin SPISIMO0 is Tri-stated Note: Bit 10 or bit 16 can be used to set the direction for pin SPISIMO0. If a 32 bit write is performed, bit 10 will have priority over bit 16.
9	CLKPDR	R/W	0h	SPICLK Open drain enable Enables Open drain capability for the pin CLK if the following conditions are met. CLKDIR = 1 (SPICLK pin configured in GPIO mode as output pin) CLKDOUT = 1 0 = Output value on SPICLK pin is logic ‘1’ 1 = Output pin SPICLK is Tri-stated
8	ENAPDR	R/W	0h	SPIENA Open drain enable Enables Open drain capability for the pin SPIENA if the following conditions are met. ENABLEDIR = 1 (SPIENA pin configured in GPIO mode as output pin) ENABLEDOUT = 1 0 = Output value on SPIENA pin is logic ‘1’ 1 = Output pin SPIENA is Tri-stated

Table 23-91. SPIPC6 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	SCSPDR	R/W	0h	SPISCSx Open drain enable Enables Open drain capability for the pin SPISCSx if the following conditions are met. SCSDIRx = 1 (SPISCS pin configured in GPIO mode as output pin) SCSDOUTx = 1 0 = Output value on SPISCSx pin is logic '1' 1 = Output pin SPISCSx is Tri-stated Note: Effect of NUM_CS_PINS generic on ChipSelect bits. Actual number of bits implemented in SCSPDR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always.

23.3.2.13 SPIDAT0 Register (Offset = 38h) [reset = 0h]

SPIDAT0 is shown in Figure 23-110 and described in Table 23-92.

Return to Summary Table.

SPI / MibSPI Transmit Data Register 0 Note: Accessibility of SPIDAT0 The SPIDAT0 register is not accessible in Multibuffer Mode of MibSPI. It is only accessible in compatibility mode.

Figure 23-110. SPIDAT0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU																TXDATA															
R-0h																R/W-0h															

Table 23-92. SPIDAT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
15-0	TXDATA	R/W	0h	SPI / MibSPI Transmit Data. When written, these bits will be copied to the Shift Register if it is empty. If the Shift Register is not empty, the TXBUF will hold the written values. SPIEN (SPICGR1.24) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 register to 0x00. When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned. As the data is shifted out from either the MSB or the LSB of Transmit Shift Register depending upon SHIFTDIR bit (SPIFMTx.20). Simultaneously, the received bit will be shifted into the Receive Shift Register either through LSB or MSB depending upon SHIFTDIR bit. This allows the concurrent transmission and reception of data. Note: Irrespective of the character length, the Transmit data should be right justified before writing to SPIDAT0 register. The default Data Format Control register for SPIDAT0 is SPIFMT0. However it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 prior to using SPIDAT0, to select a different SPIFMTx register.

23.3.2.14 SPIDAT1 Register (Offset = 3Ch) [reset = 0h]

SPIDAT1 is shown in Figure 23-111 and described in Table 23-93.

Return to Summary Table.

SPI / MibSPI Transmit Data Register 1 When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned.

Figure 23-111. SPIDAT1 Register

Table 23-93. SPIDAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
28	CSHOLD	R/W	0h	Chip select hold mode. In SPI or compatibility mode MibSPI, the CSHOLD bit is supported in master mode only. In slave mode, this bit is ignored. CSHOLD defines the behavior of the chip select line at the end of a data transfer. 1 =The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select information equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared or until the chip select information changes. 0 =The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for atleast 2VCLK cycles before it is activated again.
27	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26	WDEL	R/W	0h	Enable the delay counter at the end of the current transaction. WDELAY bit is supported in Master mode only. In Slave mode, this bit will be ignored. 1 = After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPISCS pins will be de-activated for atleast (WDELAY + 2) * VCLK_Period duration. 0 = No delay will be inserted. However, SPISCS pins will still be de-activated for atleast for 2VCLK cycles if CSHOLD = ‘0’. In SPI or Compatibility mode of MibSPI, the duration for which the SPISCS pin remaining de-activated will also depend upon time taken to supply a new data after completing the shifting operation. If the internal buffer - TXBUF is already full, then the SPISCS will be deasserted for atleast 2 VCLK cycles(if WDEL = ‘0’).
25-24	DFSEL	R/W	0h	DFSEL1 DFSEL0 Description 0 0 Data word format 0 is selected 0 1 Data word format 1 is selected 1 0 Data word format 2 is selected 1 1 Data word format 3 is selected

Table 23-93. SPIDAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-16	CSNR	R/W	0h	Chip select number. CSNR defines the chip select that shall be activated during the data transfer. The value of CSNR[7:0] will be driven on SPISCS[7:0] lines during the transfer. Note: Effect of NUM_CS_PINS generic on CSNR bits. Actual number of bits implemented in CSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be read-only and will read '0' always. Note: Preselecting a Format Register. Writing to just the Control Field (using byte writes) does not initiate any SPI transfer in Master mode. This feature can be used to setup SPICLK Phase or Polarity before actually starting the transfer by just updating the DFSEL fields in the control field to select the required Phase/Polarity combination.
15-0	TXDATA	R/W	0h	SPI / MibSPI Transmit Data. When written, these bits will be copied to the Shift Register if it is empty. If the Shift Register is not empty, the TXBUF will hold the written values. SPIEN must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT1 register to 0x00. Write to this register ONLY when using the automatic Slave Chip Select feature. See section 3, Operation Modes, on page 14. A write to this register will drive the contents of CSNR[7:0] into the respective pins in SPISCS[7:0] if those are configured as functional pins. When this register is read, contents of internal buffer register TXBUF which holds the latest written data will be returned. Irrespective of the character length, the Transmit data should be right justified before writing to SPIDAT1 register.

23.3.2.15 SPIBUF Register (Offset = 40h) [reset = 80000000h]

SPIBUF is shown in Figure 23-112 and described in Table 23-94.

Return to Summary Table.

SPI / MibSPI Receive Buffer Register

Figure 23-112. SPIBUF Register

31	30	29	28	27	26	25	24

RXDATA							
R-0h							

Table 23-94. SPIBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RXEMPTY		1h	Receive data buffer empty. When host reads the SPIBUF field or the whole SPIBUF register this will automatically set the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, the RXEMPTY flag is cleared. 1 =No data received since last reading of SPIBUF register. 0 =A new Data is received and copied into SPIBUF field. This flag gets set to '1' under following conditions: oReading RXDATA portion of the SPIBUF register. oWriting '1' to clear the RXINTFLG bit in SPIFLG register. Write-Clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA portion of the SPIBUF register. So, reading the full of SPIBUF register itself clears the Receiver Full Interrupt Flag.
30	RXOVR		0h	Receive data buffer overrun. When a data transfer is completed and the received data is copied into the RXBUF while it is already full, RXOVR is set. Refer to Figure 1 for a view of internal logic diagram. An Overrun always occurs to the RXBUF, and SPIBUF contents never get Overwritten until after it is read by the VBUSP Master. If enabled, RXOVRN interrupt gets generated when RXBUF is Overwritten, and reading SPIFLG or SPIVECTx register shows the RXOVRN condition. However, two read operations to the SPIBUF register are required to reach the Overrun buffer. 1 =A receive data overrun condition occurred since last time reading the data field. 0 =No receive data overrun condition occurred since last time reading the data field. This bit is cleared to '0' under the following conditions: o RXDATA portion of the SPIBUF register is read. o OVRNINTFLG bit in SPIFLG register is write-cleared. When an Overrun occurs, the SPIBUF contents will not be overwritten. Only the RXBUF contents are overwritten. When the SPIBUF is read out , the RXBUF contents get copied to the SPIBUF if RXBUF is full. So, the first data read out will be intact when an Overrun occurs. Note: A special condition under which RXOVR flag gets set. If both SPIBUF & RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR & DLEN_ERR occur, then RXOVR in RXBUF & SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal Receiver Overrun.

Table 23-94. SPIBUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	TXFULL	R	0h	Transmit data buffer full. This flag is a read-only flag. Writing into SPIDAT0 or SPIDAT1 field while TX Shift Register is full will automatically set the TXFULL flag. Once the data is copied to the Shift Register the TXFULL flag will be cleared. Writing to SPIDAT0/SPIDAT1 register when both TXBUF & the TX Shift Register are empty does not set the TXFULL flag. 1 =Transmit buffer is full, SPIDAT0/SPIDAT1 is not ready to accept a new data. 0 =Transmit buffer is empty, SPIDAT0/SPIDAT1 is ready to accept a new data.
28	BITERR		0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.
27	DESYNC		0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 =A slave device is de-synchronized. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This bit is valid in Master mode only. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read. Note: Possible inconsistency of Desync flag in SPI/Compatibility mode MibSPI Due to the nature of this Error, under some circumstances it is possible for Desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that Receive Completion flag/interrupt will be generated when the buffer transfer is completed. But Desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct Desync condition. This inconsistency in Desync flag is valid only in SPI or Compatibility mode of MibSPI. In Multibuffer mode, Desync flag is always guaranteed to be for the current buffer.
26	PARITYERR		0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set. 0 =No parity error detected. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.
25	TIMEOUT		0h	Time-out due to non-activation of ENA pin. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn’t responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer and in the SPIFLG register is set. 0 =No ENA-pin time-out occurred. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read. This bit is valid in Master mode only.
24	DLENERR		0h	Data Length Error flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured. This flag is cleared to ‘0’ when RXDATA portion of the SPIBUF register is read.

Table 23-94. SPIBUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-16	LCSNR	R	0h	Last Chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It defines the chip select that has been activated during the last data transfer from the corresponding buffer. This is the copy of CSNR bits from SPIDAT1 latched at the end of a transfer. Note: Effect of NUM_CS_PINS generic on LCSNR bits. Actual number of bits implemented in LCSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will read ‘0’ always
15-0	RXDATA	R	0h	SPI Receive Data. This is the received data, transferred from the Receive Shift-Register at the end of a transfer completion. Irrespective of the programmed character length & the direction of shifting, the received data is stored right-justified in the register.

23.3.2.16 SPIEMU Register (Offset = 44h) [reset = 80000000h]

SPIEMU is shown in Figure 23-113 and described in Table 23-95.

Return to Summary Table.

SPI / MibSPI Emulation Register Note: All the fields ot SPIEMU register are Read-Only. Read operation on this register under any mode will not have any impact on the status of this or any other registers.

Table 23-95. SPIEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RXEMPTY	R	1h	Receive data buffer empty. 1 = No data received since last reading of SPIBUF register. 0 = A new Data is received and copied into SPIBUF field.
30	RXOVR	R	0h	Receive data buffer overrun. 1 =A receive data overrun condition occurred since last time reading the data field. 0 =No receive data overrun condition occurred since last time reading the data field.
29	TXFULL	R	0h	Transmit data buffer full. 1 =Transmit buffer is full, SPIDAT0/SPIDAT1 is not ready to accept a new data. 0 =Transmit buffer is empty, SPIDAT0/SPIDAT1 is ready to accept a new data.
28	BITERR	R	0h	Mismatch of internal transmit data and transmitted data. 1 =A bit error occurred. The SPI / MibSPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a to high bit rate / capacitive load or another master/slave trying to transmit at the same time. 0 =No bit error occurred.
27	DESYNC	R	0h	De-synchronization of slave device. De-synchronization monitor is active in master mode only. 1 =A slave device is de-synchronized. The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus tT2EDELAY (see Section 8.21). If DESYNCENA is set an interrupt is asserted. De-synchronization can occur if a slave device misses a clock edge coming from the master. 0 =No slave de-synchronization detected. This bit is valid in Master mode only.
26	PARITYERR	R	0h	Calculated parity differs from received parity bit. 1 =A parity error occurred. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word (see Section 8.23). During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set. 0 =No parity error detected.

Table 23-95. SPIEMU Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	TIMEOUT	R	0h	Time-out due to non-activation of ENA pin. 1 =An ENA signal time-out occurred. The SPI / MibSPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMOUT flag in the status field of the corresponding buffer and in the SPIFLG register is set. 0 =No ENA-pin time-out occurred. This bit is valid in Master mode only.
24	DLENERR	R	0h	Data Length Error flag. 1 = A Data Length Error has occured. 0 = No Data Length Error has occured.
23-16	LCSNR	R	0h	Last Chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It defines the chip select that has been activated during the last data transfer from the corresponding buffer. This is the copy of CSNR bits from SPIDAT1 latched at the end of a transfer. Note: Effect of NUM_CS_PINS generic on LCSNR bits. Actual number of bits implemented in LCSNR[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will read '0' always.
15-0	RXDATA	R	0h	SPI Receive Data. SPI / MibSPI emulation is a mirror of the SPIBUF register. The only difference between SPIEMU and SPIBUF is that a read from SPIEMU does not clear any of the status flags.

23.3.2.17 SPIDELAY Register (Offset = 48h) [reset = 0h]

SPIDELAY is shown in Figure 23-114 and described in Table 23-96.

Return to Summary Table.

SPI / MibSPI Delay Register

Figure 23-114. SPIDELAY Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C2TDELAY								T2CDELAY								T2EDELAY								C2EDELAY							
R/W-0h								R/W-0h								R/W-0h								R/W-0h							

Table 23-96. SPIDELAY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	C2TDELAY	R/W	0h	Chip-select-active-to-transmit-start-delay. C2TDELAY is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of VBUSPCLK cycles. ChipSelect-active-to-transmission delays between 2 to 257 VBUSPCLK cycles can be achieved. If Phase = '1', the delay between SCS fall-edge to the first edge of SPICLK will have an additional 0.5 SPICLK Period delay. This delay is as per the SPI protocol.
23-16	T2CDELAY	R/W	0h	Transmit-end-to-chip-select-inactive-delay. T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VBUSPCLK cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 VBUSPCLK cycles. If Phase = '0', then between the last edge of SPICLK and rise-edge of SCS, there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol Both C2TDELAY and T2CDELAY counters do not have any dependancy on SPIENA pin value. Even if the SPIENA pin is asserted by the Slave, Master will continue to delay the start of SPICLK until the C2TDELAY counter overflows. Similarly, even if the SPIENA pin is deasserted by the Slave, Master will continue to hold the SPISCS pins active until the T2CDELAY counter overflows. This way, it is guaranteed that the setup/hold times of the SPISCS pins is determined by the Delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.
15-8	T2EDELAY	R/W	0h	Transmit-data-finished-to-ENA-pin-inactive-time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before the ENAble signal has to become inactive and after the CS becomes inactive. The SPI clock depends on which data format is selected. If the slave device is missing one or more clock edges, it is becoming de-synchronized. Although the master has finished the data transfer the slave is still waiting for the missed clock pulses and the ENA signal isn't disabled. The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the ENA signal isn't deactivated in time. DESYNC flag is set to indicate that the Slave device did not deassert its SPIENA pin in time to acknowledge that it has received all the bits of the sent character. If T2CDELAY is programmed a non-zero value, then T2EDELAY will start only after the T2CDELAY completes. This should be taken into consideration to determine an optimum value of T2EDELAY. Note: Zero T2EDELAY If T2EDELAY is not programmed or programmed to '0', then the Master SPI/MibSPI does not wait for SPIENA pin to be deasserted. It ignores the state of the SPIENA pin after the transmission is completed.

Table 23-96. SPIDELAY Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	C2EDELAY	R/W	0h	Chip-select-active-to-ENA-signal-active-time-out C2EDELAY is utilized only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between the SPI / MibSPI activating the chip select signal and the addressed slave responding by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. If the slave device is not responding with the ENA signal before the time-out value is reached, the TIMEOUT flag in SPIFLG register is set and an interrupt is asserted if enabled. If a time-out occurs the MibSPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer and continues with the transfer of the next buffer in the sequence that is enabled. If C2TDELAY is programmed a non-zero value, then C2EDELAY will start only after the C2TDELAY completes. This should be taken into consideration to determine an optimum value of C2EDELAY. Note: Zero C2EDELAY If C2EDELAY is not programmed or programmed to ‘0’, then the Master SPI/MibSPI waits until the SPIENA pin to asserted before it can start the transfer. If the SPIENA pin is not asserted due to a malfunctioning Slave, the Master will wait forever. This might cause hang-up situation. it is recommended to program to C2EDELAY to a suitable value whenever SPIENA pin is used as functional.

23.3.2.18 SPIDEF Register (Offset = 4Ch) [reset = 1h]

SPIDEF is shown in Figure 23-115 and described in Table 23-97.

Return to Summary Table.

SPI / MibSPI Default Chip select Register

Figure 23-115. SPIDEF Register

Bit	Field	Type	Reset	Description
31-8	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
7-0	CSDEF0	R/W	1h	Chip select default pattern. Master mode behavior. The CSDEFx bits are output to the chip select pins when no transmission are currently performed. It allows the user to set a chip select pattern which deselects all the SPI slaves. 1 =If CSDEFx is set to “1” the corresponding chip select is set to “1” while SPI/MibSPI is IDLE. 0 =If CSDEFx is set to “0” the corresponding chip select is set to “0” while SPI/MibSPI is IDLE. Note: Effect of NUM_CS_PINS generic on CSDEF bits. Actual number of bits implemented in CSDEF[7:0] will depend upon the NUM_CS_PINS generic set during synthesis. Unimplemented bits will be treated as reserved, read-only and will read ‘0’ always.

23.3.2.19 SPIFMT0 Register (Offset = 50h) [reset = 0h]

SPIFMT0 is shown in Figure 23-116 and described in Table 23-98.

Return to Summary Table.

NU			CHARLEN				
R-0h			R/W-0h				

Table 23-98. SPIFMT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-98. SPIFMT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

23.3.2.20 SPIFMT1 Register (Offset = 54h) [reset = 0h]

SPIFMT1 is shown in Figure 23-117 and described in Table 23-99.

Return to Summary Table.

NU			CHARLEN				
R-0h			R/W-0h				

Table 23-99. SPIFMT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	WDELAY	R/W	0h	Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to: WDELAY * PVBUSPCLK + 2 * PVBUSPCLK. PVBUSPCLK -> Period of VBUSPCLK.
23	PARPOL	R/W	0h	Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3). 1 =An odd parity flag is added at the end of the transmit data stream. 0 =An even parity flag is added at the end of the transmit data stream.
22	PARITYENA	R/W	0h	Parity enable for data format x. 1= A parity is transmitted at the end of each transmit data stream. At the end of a transfer the parity generator compares the received parity bit with the locally calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit. 0= No parity generation/ verification is performed for this data format. If an Uncorrectable Error Flag is set in a Slave mode MibSPI, then wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pin will be forced to transmit all ‘0’s. And parity bit will be transmitted as ‘1’ if even parity is selected and as ‘0’ if odd parity is selected(using the PARPOLx bit of this register). This behavior will be irrespective of an UPE on either TXRAM or RXRAM.
21	WAITENA	R/W	0h	Master waits for ENA signal from slave for data format x. WAITENA is considered in master mode only. In slave mode this bit has no meaning. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines for each buffer whether the addressed slave generates the ENA signal or does not. 1= Before the SPI / MibSPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the Master aborts the transfer and sets the TIMEOUT error flag. 0= The SPI / MibSPI does not wait for the ENA signal from the slaves and directly starts the transfer.

Table 23-99. SPIFMT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SHIFTDIR	R/W	0h	Shift direction for data format x. With bit SHIFTDIRx the shift direction for data format x (x=0,1,2,3) can be selected. 1 =Data format x shift direction: Least significant bit is shifted out first. 0 =Data format x shift direction: Most significant bit is shifted out first.
19	HDUPLEX_ENA	R/W	0h	Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin. 0 = Normal Full Duplex transfer. 1 = If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible). For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX & RX operations at different times.
18	DISCSTIMERS	R/W	0h	Disable Chipselect Timers for this format register. The C2TDELAY & T2CDELAY timers are by default enabled for all the Data Format registers. Using this bit, these timers can be disabled for particular Data Format if not required. When a Master is handling multiple Slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the ChipSelect Delay timers for any Slaves. 0 = Both C2TDELAY & T2CDELAY counts are inserted for the ChipSelects. 1 = No C2TDELAY or T2CDELAY is inserted in the ChipSelect timings.
17	POLARITY	R/W	0h	SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. POLARITYx can be modified in privilege mode only. 1 =If POLARITYx is set to "1" the SPI clock signal is high-inactive, i.e. before and after data transfer the clock signal is high. 0 =If POLARITYx is set to "0" the SPI clock signal is low-inactive, i.e. before and after data transfer the clock signal is low.
16	PHASE	R/W	0h	SPI Data format x clock delay. PHASEx defines the clock delay of data format x. PHASEx can be modified in privilege mode only. 1 =If PHASEx is set to "1" the SPI clock signal is delayed by a half SPI clock cycle versus the transmit / receive data stream. The first transmit bit has to output prior to the first clock edge. Master and slave receive the first bit with the first edge 0 =If PHASEx is set to "0" the SPI clock signal is not delayed versus the transmit / receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge Note: Restriction on SPICLK Phase/Polarity change in Slave Mode In Slave mode if Phase and/or Polarity of SPICLK has to be changed, the following sequence should be used. oClear the GCR1.SPIEN bit to '0'. oSet the required Phase/Polarity values in SPIFMTx registers. oSet the GCR1.SPIEN bit back to '1'. The setting of GCR1.SPIEN bit in Slave SPI/MibSPI to '1' should be done only after the Polarity of the incoming SPICLK signal changes (if POLARITYx bit was changed in the configuration).
15-8	PRESCALE	R/W	0h	SPI data format x prescaler. PRESCALEx can be modified in privilege mode only. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is directly derived from VBUSPCLK. If the SPI / MibSPI is configured as slave, PRESCALEx DOES NOT NEED to be configured. The clock rate for data format x can be calculated as BRFormat = VBUSPCLCK/(PRESCALEx+1) When PRESCALEx is set to zero (0), the SPI clock rate defaults to VBUSPCLK/2. Any write to this field will update EPRESCALE_FMTx field of EPRESCALEy (y=1,2) registers with EPRESCALE_FMTx(11:8) bits rounded off to '000'. Any write to EPRESCALE_FMTx field of the EXTENDED_PRESCALEy (y=1,2) register will cause its lower 8bits to be reflected in this field as well.
7-5	NU	R	0h	Reserved. Reads return '0' and writes have no effect.
4-0	CHARLEN	R/W	0h	SPI data format x data word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 0x10 (data word length = 16). Illegal values, such as 0x00 or 0x1F are not detected and their effect is indeterminate.

23.3.2.21 SPIFMT2 Register (Offset = 58h) [reset = 0h]

SPIFMT2 is shown in Figure 23-118 and described in Table 23-100.

NU				INTVECT0			SUSPEND0
R-0h				R-0h			R-0h

Table 23-102. TGINTVECT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
5-1	INTVECT0	R	0h	Interrupt vector for interrupt line INT0. INTVECT0 returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupts are pending, INTVECT0 always references the highest priority interrupt source first. The vectors generated are different for SPI / Compatibility mode of MibSPI and Multibuffer mode of MibSPI. INTVECT0 field just reflects the status of SPIFLG register in a vectorized format. So, any updates to SPIFLG will automatically reflect in the Vector value in this register. SPI / Compatibility mode - MibSPI The interrupts available for SPI or Compatibility mode - MibSPI, in the descending order of their priorities are as given below. Transmission Error Interrupt Receive Buffer Overrun Interrupt Receive Buffer Full Interrupt Transmit Buffer Empty Interrupt Vectors for each of these interrupts will be reflected on the INTVECT0 bits, when they occur. Reading the vectors for the “Receive Buffer Overrun” & “Receive Buffer Full” interrupts will automatically clear the respective flags in the SPIFLG register. On reading the INTVECT0 bits, the vector of the next highest priority interrupt (if any) will be then reflected on the INTVECT0 bits. If two or more interrupts occur simultaneously, the vector for the higest priority interrupt will be reflected on the INTVECT0 bits. Reading the Vector register when “Transmitter Empty” is indicated does not clear the TXINTFLG in SPIFLG register. Writing a new data to SPIDATx register clears the “Transmitter Empty” interrupt. INTVECT0[4:0] Description 00000b no interrupt pending 10001b Error interrupt pending. Refer to Least Significant (LS) Byte of SPIFLG to determine more details about the type of error. 10011b Pending interrupt is “Receive Buffer Overrun Interrupt” 10010b Pending interrupt is “Receive Buffer Full Interrupt” 10100b Pending interrupt is “Transmit Buffer Empty Interrupt” All other bit combinations Reserved Note: Exception for clearing of RXINT If both SPIBUF and RXBUF (internal buffer) are full, then, reading TGINTVECT0 register (while it shows 10010) does not clear the RXINTFLG in SPIFLG register. In this case, only way to clear the Interrupt is to read the SPIBUF again until there’s no more unread RX data.

Table 23-102. TGINTVECT0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SUSPEND0	R	0h	“Transfer suspended” or “transfer finished” interrupt.(MibSPI only) The SUSPEND0 flag is updated depending on the type of interrupt reflected by the VECTOR value field. 1 =The interrupt type is a “transfer suspended” interrupt. I.e. the transfer group referenced by INTVECT0 has asserted an interrupt, because the buffer to be transferred next is in “suspend to wait” mode. 0 =The interrupt type is a “transfer finished” interrupt. I.e. the buffer array referenced by INTVECT0 has asserted an interrupt, because all of the data from the whole transfer group has been transferred. Note: Special case for SUSPEND interrupt When there’s a “transfer suspended” interrupt (SUSPEND0 bit is set to ‘1’), reading the TGINTVECT0 register does not clear the “TG Suspended” interrupt. The SUSPEND condition should be resolved first before the interrupt can be cleared. The SUSPEND condition can be cleared by writing a new data to that TXRAM location and/or reading the data from that RXRAM location depending upon the SUSPEND criteria programmed in the “BUFMODE” field of that TXRAM location. The SUSPEND0 bit always returns value ‘0’ in SPI / Compatibility mode MibSPI. When there is an RXOVRN or any Error interrupt in Multibuffer mode, SUSPEND0 bit stays ‘0’. Refer to Section 6.2 on page 77 & Section 6.3 on page 77 for more details and notes on better handling of interrupts. Note: Reading Error Vector Reading an Error Vector in the TGINTVECT0 register will NOT clear the Error flags in the SPIFLG register. The Error Flags in SPIFLG need to be write-cleared after servicing them suitably. If “TG Completed” interrupt occurs for a TG and after a while “TG Suspended” flag too gets set for the same TG, then the TGINTVECT0 register will show “TG Completed” interrupt giving it higher priority than the “TG Suspended” interrrupt.

23.3.2.24 TGINTVECT1 Register (Offset = 64h) [reset = 0h]

TGINTVECT1 is shown in Figure 23-121 and described in Table 23-103.

Return to Summary Table.

NU		INTVECT1					SUSPEND1
R-0h		R-0h					R-0h

Table 23-103. TGINTVECT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	NU	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
5-1	INTVECT1	R	0h	Interrupt vector for interrupt line INT1. INTVECT1 returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupt is pending, INTVECT1 always references the highest priority interrupt source first. The vectors generated are different for SPI / Compatibility mode of MibSPI and Multibuffer mode of MibSPI. INTVECT1 field just reflects the status of SPIFLG register in a vectorized format. So, any updates to SPIFLG will automatically reflect in the Vector value in this register. SPI / Compatibility mode - MibSPI The interrupts available for SPI / Compatibility mode - MibSPI, in the descending order of their priorities are as given below. Transmission Error Interrupt Receive Buffer Overrun Interrupt Receive Buffer Full Interrupt Transmit Buffer Empty Interrupt Vectors for each of these interrupts will be reflected on the INTVECT1 bits, when they occur. Reading the vectors for the “Receive Buffer Overrun” & “Receive Buffer Full” interrupts will automatically clear the respective flags in the SPIFLG register. On reading the INTVECT1 bits, the vector of the next highest priority interrupt (if any) will then be reflected on the INTVECT1 bits. If two or more interrupts occur simultaneously, the vector for the higest priority interrupt will be reflected on the INTVECT1 bits. Reading the Vector register when “Transmitter Empty” is indicated does not clear the TXINTFLG in SPIFLG register. Writing a new data to SPIDATx register clears the “Transmitter Empty” interrupt. 00000b no interrupt pending 10001b Error interrupt pending. Refer to LS Byte of SPIFLG to determine more details about the type of error. 10011b Pending interrupt is “Receive Buffer Overrun Interrupt” 10010b Pending interrupt is “Receive Buiffer Full Interrupt” 10100b Pending interrupt is “Transmit Buffer Empty Interrupt” All other bit combinations Reserved Note: Exception for clearing of RXINT If both SPIBUF and RXBUF (internal buffer) are full, then, reading TGINTVECT1 register (while it shows 10010) does not clear the RXINTFLG in SPIFLG register. In this case, only way to clear the Interrupt is to read out the SPIBUF again until there’s no more unread RX data.

Table 23-103. TGINTVECT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SUSPEND1	R	0h	“Transfer suspended” or “transfer finished” interrupt.(MibSPI Only) The SUSPEND1 flag is updated depending on the type of interrupt reflected by the VECTOR value field. 1 =The interrupt type is a “transfer suspended” interrupt. I.e. the transfer group referenced by INTVECT1 has asserted an interrupt, because the buffer to be transferred next is in “suspend to wait” mode. 0 =The interrupt type is a “transfer finished” interrupt. I.e. the buffer array referenced by INTVECT1 has asserted an interrupt, because all data from the whole transfer group has been transferred. Note: Special case for SUSPEND interrupt When there’s a “transfer suspended” interrupt(SUSPEND1 bit is set to ‘1’), reading the TGINTVECT1 register does not clear the “TG Suspended” interrupt. The SUSPEND condition should be resolved first before the interrupt can be cleared. This condition can be cleared by writing a new data to that TXRAM location and/or reading the data from that RXRAM location depending upon the SUSPEND criteria programmed in the “BUFMODE” field of that TXRAM location. The SUSPEND1 bit always returns value ‘0’ in SPI / Compatibility mode MibSPI. Even while there is an RXOVRN or any Error interrupt in Multibuffer mode, SUSPEND1 bit stays ‘0’. Refer to Section 6.2 on page 77 & Section 6.3 on page 77 for more details and notes on better handling of interrupts. Note: Reading Error Vector Reading an Error Vector in the TGINTVECT1 register will NOT clear the Error flags in the SPIFLG register. The Error Flags in SPIFLG need to be write-cleared after servicing them suitably. If “TG Completed” interrupt occurs for a TG and after a while “TG Suspended” flag too gets set for the same TG, then the TGINTVECT1 register will show “TG Completed” interrupt giving it higher priority than the “TG Suspended” interrrupt.

23.3.2.25 SPIPC9 Register (Offset = 68h) [reset = 0h]

SPIPC9 is shown in Figure 23-122 and described in Table 23-104.

Return to Summary Table.

Table 23-105. SPIPMCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
30	HSM_MODE3	R/W	0h	High Speed Modulo Mode control bit for Data Format 3. Controls whether the PMODE3 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE3 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE3 bits are non-zero
29	MODCLKPOL3	R/W	0h	Modulo mode SPICLK Polarity for Data Format 3 Determines the Polarity of the SPICLK in Modulo mode only. If MODULO MODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected
28-26	MMODE3	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 3.000 = Normal single dataline mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
25-24	PMODE3	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 3. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
23	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
22	HSM_MODE2	R/W	0h	High Speed Modulo Mode control bit for Data Format 2. Controls whether the PMODE2 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE2 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE2 bits are non-zero

Table 23-105. SPIPMCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	MODCLKPOL2	R/W	0h	Modulo mode SPICLK Polarity for Data Format 2. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected
20-18	MMODE2	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 2. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
17-16	PMODE2	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 2. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”)10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
15	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
14	HSM_MODE1	R/W	0h	High Speed Modulo Mode control bit for Data Format 1. Controls whether the PMODE1 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE1 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE1 bits are non-zero.
13	MODCLKPOL1	R/W	0h	Modulo mode SPICLK Polarity for Data Format 1. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected.
12-10	MMODE1	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 1. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
9-8	PMODE1	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 1. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)
7	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
6	HSM_MODE0	R/W	0h	High Speed Modulo Mode control bit for Data Format 0. Controls whether the PMODE0 bits will result in Modulo Format data transfer or not. Refer to Section 3.26 for details about the HSM Mode. 0 = Normal mode - Normal Parallel mode if PMODE0 bits are non-zero. 1 = High Speed Modulo Mode. Data transfer will happen in Modulo Format if PMODE0 bits are non-zero.
5	MODCLKPOL0	R/W	0h	Modulo mode SPICLK Polarity for Data Format 0. Determines the Polarity of the SPICLK in Modulo mode only. If MMODE[2:0] bits are “000”, this bit will be ignored. 0 = Normal SPICLK in all the modes. 1 = Polarity of the SPICLK will be inverted if Modulo mode is selected.

Table 23-105. SPIPMCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-2	MMODE0	R/W	0h	These bits determine whether the SPI/MibSPI operates with 1, 2, 4, 5, or 6 data lines (if Modulo Option is supported by the module) for Data Format 0. 000 = 1-data line Mode - Default (PMODE should be set to “00”) 001 = 2-data line Mode (PMODE should be set to “00”) 010 = 3-data line mode (PMODE should be set to “00”) 011 = 4-data line mode (PMODE should be set to “00”) 100 = 5-data line mode (PMODE should be set to “00”) 101 = 6-data line mode (PMODE should be set to “01”) 110 = Reserved 111 = Reserved
1-0	PMODE0	R/W	0h	Parallel mode bits determine whether the SPI/MibSPI operates with 1, 2 ,4 or 8 data lines for Data Format 0. 00 = normal operation / 1-data line (MMODE should be set to “000”) 01 = 2-data line mode (MMODE should be set to “000”) 10 = 4-data line mode (MMODE should be set to “000”) 11 = 8-data line mode (MMODE should be set to “000”)

23.3.2.27 MIBSPIE Register (Offset = 70h) [reset = 500h]

MIBSPIE is shown in Figure 23-124 and described in Table 23-106.

Return to Summary Table.

MibSPI Enable Register

Figure 23-124. MIBSPIE Register

31	30	29	28	27	26	25	24
NU3							
R-0h							
23	22	21	20	19	18	17	16
NU3							RXRAMACCESS
R-0h							R/W-0h
15	14	13	12	11	10	9	8
NU2				EXTENDED_BUF_ENA			
R-0h				R/W-5h			
7	6	5	4	3	2	1	0
NU1							MSPIENA
R-0h							R/W-0h

Table 23-106. MIBSPIE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
16	RXRAMACCESS	R/W	0h	Receive RAM Access control Bit. During normal operating mode of MibSPI, the Receive Data/Status portion of Multibuffer RAM is read-only. To enable testing of Data Integrity checks of Receive RAM, a special read/write access control is provided through this bit. 0 = The RX portion of Multibuffer RAM is not writable by the CPU. That is, portion of Multibuffer RAM, addressed by an offset of 0x200-0x3FF is write protected. 1 = The whole of Multibuffer RAM is fully accessible for read/write by the CPU.
15-12	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect
11-8	EXTENDED_BUF_ENA	R/W	5h	Enables the support for 256 buffers. By default MibSPI supports up to 128 buffers for both TX and RX. It is also possible to extend the support to 256 buffers as a parameterized implementation. This field can be used to enable/disable the support for Extended Buffers. This Enable field is implemented only if “EXTENDED_BUF” parameter is set to ‘1’. If the parameter is set to ‘0’, this field is read-only and reads the disable value. Write (Privilege mode only) 1010 - Enable the Extended Buffer mode - up to 256 buffers can be used 0101 - Disable the Extended Buffer mode - MibSPI supports only 128 buffers All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read (both privilege and user modes) 1010 - Extended Buffer mode is enabled - up to 256 buffers can be used 0101 - Extended Buffer mode is disabled - MibSPI supports only 128 buffers
7-1	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-106. MIBSPIE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	MSPIENA	R/W	0h	Multibuffer mode Enable. After power-up or reset MSPIENA remains cleared, which means that the MibSPI runs in compatibility mode by default. If Multibuffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. Unless MSPIENA is set to '1', the Multibuffer mode registers are not writable. Refer to Section 3.3 for the grouping of registers into Compatibility mode and Multibuffer mode. 1 =The MibSPI is configured to run in MibSPI mode (Multibuffer mode). In this mode the additional features are available. 0 =The MibSPI runs in compatibility mode, i.e. in this mode the MibSPI is fully code compliant to the standard TMS470 Platform SPI. No Multibuffer feature is supported

23.3.2.28 TGITENST Register (Offset = 74h) [reset = 0h]

TGITENST is shown in Figure 23-125 and described in Table 23-107.

Return to Summary Table.

R-0h																R-0h															

Table 23-111. TGINTFLAG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	INTFLGRDY	R	0h	Transfer group interrupt flag for “transfer finished” interrupt. Read: 1 =A “transfer finished” interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don’t care) or whether the interrupt is mapped to line INT0 or INT1, INTFLGRDYx is set right after the transfer from transfer group x is finished. 0 =No “transfer finished” interrupt occurred since last clearing of the flag INTFLGRDYx. Write: 1 = Clears the corresponding bit flag. 0 = Has no effect.
15-0	INTFLGSUS	R	0h	Transfer group interrupt flag for “transfer suspend” interrupt. Read: 1 =A “transfer suspended” interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don’t care) or whether the interrupt is mapped to line INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended. 0 =No ”transfer suspended” interrupt occurred since last clearing of the flag INTFLGSUSx. Note: Read Clear Behavior Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if SUSPEND0/SUPEND1 bit in the Vector registers is ‘0’.

23.3.2.33 TICKCNT Register (Offset = 90h) [reset = 0h]

TICKCNT is shown in Figure 23-130 and described in Table 23-112.

Return to Summary Table.

Tick Count Register

Figure 23-130. TICKCNT Register

TICKVALUE							
R/W-0h							

Table 23-112. TICKCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TICKENA	R/W	0h	Tick counter enable. 1 =The MibSPI internal tick counter is enabled and is clocked by the clock source selected by CLKCTRL[1:0]. When the tick counter is enabled it starts down-counting from its current value. When TICKENA goes from “0” to “1” the tick counter is automatically loaded with the TICKVALUE. 0 =The MibSPI internal tick counter is disabled. The counter value remains unchanged. Note: When the tick counter is disabled the trigger signal is forced low.
30	RELOAD	R-0/W	0h	Re-load tick counter. RELOAD is a set-only bit, i.e. writing a “1” to it automatically reloads the Tick Counter with the value stored in TICKVALUE. Reading RELOAD always returns a “0”. Note: When the tick counter is reloaded by the RELOAD bit, the trigger signal is not toggled.
29-28	CLKCTRL	R/W	0h	Tick counter clock source control. CLKCTRL[1:0] defines the clock source that is used to clock the MibSPI internal tick counter.CLKCTRL[1:0] Description 00b SPICLK of Data word format 0 is selected as clock source of tick counter 01b SPICLK of Data word format 1 is selected as clock source of tick counter 10b SPICLK of Data word format 2 is selected as clock source of tick counter 11b SPICLK of Data word format 3 is selected as clock source of tick counter
27-16	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
15-0	TICKVALUE	R/W	0h	Initial value for tick counter. TICKVALUE stores the initial value for the tick counter. The tick counter is loaded with TICKVALUE every time an under-flow condition occurs and every time the RELOAD flag is set by the host

23.3.2.34 LTGPEND Register (Offset = 94h) [reset = 0h]

LTGPEND is shown in Figure 23-131 and described in Table 23-113.

Return to Summary Table.

Last Transfer Group End Pointer

31-29	NU3	R	0h	Reserved.Reads return ‘0’ and writes have no effect
28-24	TGINSERVICE	R	0h	Transfer Group currently being serviced by the Sequencer. Read-Only field indicating the current Transfer Group that is being serviced. This field can generally be used for code debug purpose. Read Value:TG IN SERVICE[4:0] Description 00000b No Transfer Group is being serviced by the Sequencer 00001b Transfer Group0 is being serviced by the Sequencer ... ... 10000b Transfer Group15 is being serviced by the Sequencer 10001b - 11111b Invalid values
23-16	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect
15-8	LPEND	R/W	0h	Last Transfer Group End Pointer Usually the transfer group end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent transfer group (PSTART). The transfer group ends at the buffer one before the next transfer group starts (PEND[x]=PSTART[x+1] - 1). For a full configuration of MibSPI, the 15th transfer group has no subsequent transfer group, i.e. no end address is inherently defined. Therefore LPEND has to be programmed to specify explicitly the end address of the 15th transfer group. Number of Transfer Groups implemented in a MibSPI can vary from one MibSPI to another since it is a generic parameter based implementation. If in a MibSPI, only 4 Transfer Groups are implemented, then the PEND of the 4th TG is defined by LPEND values defined in this LTGPEND register.
7-0	NU1	R	0h	Reserved.Reads return ‘0’ and writes have no effect

23.3.2.35 TG0CTRL Register (Offset = 98h) [reset = 0h]

TG0CTRL is shown in Figure 23-132 and described in Table 23-114.

Return to Summary Table.

MibSPI Transfer Group Control Register The number of transfer groups is scalable by design up to a maximum of 16. Depending on the implementation the number of transfer groups and hence the number of transfer group control register may vary. Each transfer group can be configured via one dedicated control register. The register description below shows one exemplary control register(x) which is identical for all transfer groups. E.g. the control register for transfer group 2 is named “TG2CTRL” and is located at address base0+98h+4*2.

Table 23-114. TG0CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.

Table 23-114. TG0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.
28	TGTD	R	0h	Transfer group triggered. This bit is read-only. 1 =The transfer group has been triggered and is either currently in service or waiting for servicing. 0 =The corresponding transfer group has not been triggered or is no more waiting for service. Use the “TG IN SERVICE” field in LTGPEND register to determine the exact Transfer Group being currently serviced
27-24	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
23-20	TRIGEVT	R/W	0h	Type of trigger event. After reset, the trigger event types of all transfer groups are set to inactive TypesTRIGEVTx[3:0] Type Description 0000b never 0001b rising edge A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0010b falling edge A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0011b both edges Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0100b reserved 0101b high-active Repetitive group transfer while trigger is high: While the selected trigger source (TRIGSRCx) is at a logic high level (1) the group transfer is continued and at the end of one group transfer restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. 0110b low-active Repetitive group transfer while trigger is low: While the selected trigger source (TRIGSRCx) is at a logic low level (0) the group transfer is continued and at the end of one restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. 0111b always A repetitive group transfer will be performed. Setting ONESHOTx allows a software controlled single transfer modea a. By setting the TRIGSRC to 0000b, the TRIGEVT to ALWAYS (0111b) the ONESHOT bit to 1. This allows a software control trigger on this Transfer Group. Then by setting the TGENA bit, the Transfer Group is immediately triggered. . If ONESHOTx is cleared a continuous mode for this Transfer Group is selected.1xxxb reserved

Table 23-114. TG0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-16	TRIGSRC	R/W	0h	Trigger source. After reset the trigger sources of all transfer groups are disabled. Table 22. Trigger SourcesTRIGSRCx[3:0] Type Description 0000b disabled 0001b EXT0 MibSPI external trigger source 0. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0010b EXT1 MibSPI external trigger source 1. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0011b EXT2 MibSPI external trigger source 2. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0100b EXT3 MibSPI external trigger source 3. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). ... ... 1110b EXT13 MibSPI external trigger source 13. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 1111b TICK MibSPI internal periodic event trigger. The tick counter can initiate periodic group transfers.
15-8	PSTART	R/W	0h	transfer group start address. PSTARTx stores the start address of the corresponding transfer group. The corresponding end address is inherently defined by the subsequent transfer groups start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: o the transfer group is enabled o the end of the transfer group is reached during a transfer o a trigger event occurs while PRST is set to 1
7-0	PCURRENT	R	0h	transfer group pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127/255) of the buffer that is currently transferred or that will be transferred after a trigger event occurs (if PRSTx=0) or after the transfer group resumes from suspend to wait mode. If the transfer group switches mode from active transfer mode to “suspend to wait”, PCURRENTx keeps the address of the currently Suspended buffer. After the transfer group resumes from “suspend to wait” mode the next buffer will be transferred. I.e. no buffer data is multiply transferred or not at all transferred due to “suspend to wait” mode.

23.3.2.36 TG1CTRL Register (Offset = 9Ch) [reset = 0h]

TG1CTRL is shown in Figure 23-133 and described in Table 23-115.

The tick counter can initiate periodic group transfers.
15-8	PSTART	R/W	0h	transfer group start address. PSTARTx stores the start address of the corresponding transfer group. The corresponding end address is inherently defined by the subsequent transfer groups start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: o the transfer group is enabled o the end of the transfer group is reached during a transfer o a trigger event occurs while PRST is set to 1

Table 23-116. TG2CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	PCURRENT	R	0h	transfer group pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127/255) of the buffer that is currently transferred or that will be transferred after a trigger event occurs (if PRSTx=0) or after the transfer group resumes from suspend to wait mode. If the transfer group switches mode from active transfer mode to “suspend to wait”, PCURRENTx keeps the address of the currently Suspended buffer. After the transfer group resumes from “suspend to wait” mode the next buffer will be transferred. I.e. no buffer data is multiply transferred or not at all transferred due to “suspend to wait” mode.

23.3.2.38 TG3CTRL Register (Offset = A4h) [reset = 0h]

TG3CTRL is shown in Figure 23-135 and described in Table 23-117.

Return to Summary Table.

Table 23-117. TG3CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.

Table 23-117. TG3CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	TGTD	R	0h	Transfer group triggered. This bit is read-only. 1 =The transfer group has been triggered and is either currently in service or waiting for servicing. 0 =The corresponding transfer group has not been triggered or is no more waiting for service. Use the “TG IN SERVICE” field in LTGPEND register to determine the exact Transfer Group being currently serviced
27-24	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect

Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0010b EXT1 MibSPI external trigger source 1. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0011b EXT2 MibSPI external trigger source 2. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 0100b EXT3 MibSPI external trigger source 3. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). ... ... 1110b EXT13 MibSPI external trigger source 13. Source has to be defined individually for each Microcontroller derivative (e.g. HET I/O channel, event pin, etc.). 1111b TICK MibSPI internal periodic event trigger. The tick counter can initiate periodic group transfers.
15-8	PSTART	R/W	0h	transfer group start address. PSTARTx stores the start address of the corresponding transfer group. The corresponding end address is inherently defined by the subsequent transfer groups start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: o the transfer group is enabled o the end of the transfer group is reached during a transfer o a trigger event occurs while PRST is set to 1

Table 23-120. TG6CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	PCURRENT	R	0h	transfer group pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127/255) of the buffer that is currently transferred or that will be transferred after a trigger event occurs (if PRSTx=0) or after the transfer group resumes from suspend to wait mode. If the transfer group switches mode from active transfer mode to “suspend to wait”, PCURRENTx keeps the address of the currently Suspended buffer. After the transfer group resumes from “suspend to wait” mode the next buffer will be transferred. I.e. no buffer data is multiply transferred or not at all transferred due to “suspend to wait” mode.

23.3.2.42 TG7CTRL Register (Offset = B4h) [reset = 0h]

TG7CTRL is shown in Figure 23-139 and described in Table 23-121.

Return to Summary Table.

Table 23-121. TG7CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TGENA	R/W	0h	Transfer Group Enable. 1 =The corresponding transfer group is enabled. If the correct event (TRIGEVTx) occurs at the selected source (TRIGSRCx) a group transfer is initiated if no higher priority transfer group is in active transfer mode or if one or more higher priority Transfer Groups are in transfer suspend mode. If higher priority Transfer Groups (TG) are in transfer mode, then the newly enabled TG will wait till all of the higher priority TG transfers are completed. 0 =The corresponding transfer group is disabled. Disabling a transfer group while a transfer is ongoing, will finish the ongoing buffer transfer but not the whole group transfer
30	ONESHOT	R/W	0h	Single transfer for this Transfer Group group. 1 =A transfer from the corresponding transfer group will be performed only once (= one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared by the MibSPI and therefore no additional transfer can be triggered before the host enables the transfer group again. This oneshot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data. 0 =The corresponding transfer group initiates a transfer every time a trigger event occurs and TGENA is set.
29	PRST	R/W	0h	transfer group Pointer Reset mode. With PRST, the way of resolving trigger events during an ongoing transfer from the concerned transfer group can be configured. This bit is meaningful only for Level Triggered Transfer Groups. Edge triggered TGs cannot be re-started before their completion by another edge. PRST bit will have no effect on this behavior. 1 =The corresponding transfer group pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same transfer group is ongoing. I.e. every trigger event resets PCURRENTx no matter whether the concerned transfer group is in transfer mode or not. The trigger events have priority over the ongoing transfer. 0 =If a trigger event occurs during a transfer from the concerned transfer group, the event is ignored and is not stored internally. The transfer group transfer has priority over additional trigger events.

Table 23-121. TG7CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	TGTD	R	0h	Transfer group triggered. This bit is read-only. 1 =The transfer group has been triggered and is either currently in service or waiting for servicing. 0 =The corresponding transfer group has not been triggered or is no more waiting for service. Use the “TG IN SERVICE” field in LTGPEND register to determine the exact Transfer Group being currently serviced
27-24	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect
23-20	TRIGEVT	R/W	0h	Type of trigger event. After reset, the trigger event types of all transfer groups are set to inactive TypesTRIGEVTx[3:0] Type Description 0000b never 0001b rising edge A rising edge (0 to 1) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0010b falling edge A falling edge (1 to 0) at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0011b both edges Rising and falling edges at the selected trigger source (TRIGSRCx) initiates a transfer from the corresponding transfer group 0100b reserved 0101b high-active Repetitive group transfer while trigger is high: While the selected trigger source (TRIGSRCx) is at a logic high level (1) the group transfer is continued and at the end of one group transfer restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to low (0) during an ongoing group transfer, the whole group transfer will be stopped. 0110b low-active Repetitive group transfer while trigger is low: While the selected trigger source (TRIGSRCx) is at a logic low level (0) the group transfer is continued and at the end of one restarted at the beginning. If ONESHOTx is set the transfer is performed only once. If the logic level changes to high (1) during an ongoing group transfer, the whole group transfer will be stopped. 0111b always A repetitive group transfer will be performed. Setting ONESHOTx allows a software controlled single transfer modea a. By setting the TRIGSRC to 0000b, the TRIGEVT to ALWAYS (0111b) the ONESHOT bit to 1. This allows a software control trigger on this Transfer Group. Then by setting the TGENA bit, the Transfer Group is immediately triggered. . If ONESHOTx is cleared a continuous mode for this Transfer Group is selected.1xxxb reserved
19-16	TRIGSRC	R/W	0h	Trigger source. After reset the trigger sources of all transfer groups are disabled. Table 22. Table 23-122. DMA0CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ONESHOT	R/W	0h	Auto-disable of DMA channel after ICOUNT+1 transfers. 1 =ONESHOTx allows a block transfer of defined length (ICOUNTx+1) mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx +1 transfers the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer. 0 =The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.
30-24	BUFID	R/W	0h	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the “suspend to wait until...” modes must be used (for more details refer to Section 8.53.1).
23-20	RXDMA_MAP	R/W	0h	Receive data DMA Request Map Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to ‘1’, then RXDMA_MAPx[3:0] shall differ from TXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.
19-16	TXDMA_MAP	R/W	0h	Transmit data DMA channel Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. ne request line for receive data and the other for request line for transmit data. TXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set then TXDMA_MAPx[3:0] shall differ from RXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.

Table 23-122. DMA0CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15	RXDMAENA	R/W	0h	Receive data DMA channel enable. 1 =The physical DMA Request line for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The concerned buffer should be configured in the mode “skip until RXEMPTY is set” or “suspend to wait until RXEMPTY is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new receive data.
14	TXDMAENA	R/W	0h	Transmit data DMA channel enable. 1 =The physical DMA Request line for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The concerned buffer should be configured in the mode “skip until TXFULL is set” or “suspend to wait until TXFULL is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new transmit data
13	NOBRK	R/W	0h	Non-interleaved DMA block transfer(Master mode only). 1 =NOBRKx ensures that ICOUNTx+1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx+1 transfers have been processed. E.g: this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD=1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. Triggering of higher priority transfer groups or enabling of higher priority DMA channels will not interrupt NOBRK block transfer. 0 =The DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or transfer groups. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer
12-8	ICOUNT	R/W	0h	Initial Count of DMA transfers ICOUNTx[4:0] is used to preset the transfer counter COUNTx[4:0]. Every time COUNTx[4:0] hits zero it is reloaded with ICOUNTx[4:0]. The real number of transfer equals ICOUNTx[4:0] plus one. If ONESHOTx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
7	BUFID7	R/W	0h	Extended bit of BUFIDx field when Extended Buffer feature is implemented. This bit represents the 8th bit of BUFID field such that any buffers between 127-255 can be configured as DMA capable buffers
6	COUNTBIT17	R	0h	The 17th bit of COUNT field of DMAxCOUNT register. This bit is useful only when ICOUNTx in DMAxCOUNT register is programmed to be 0xFFFF. During all other values, this bit remains to be ‘0’.
5-0	COUNT	R	0h	Actual number of remaining DMA transfer COUNTx[5:0] is a read-only bit field. It comprises the actual number of DMA transfers that remain, until the DMA channel is disabled if ONESHOTx is set.

23.3.2.44 DMA1CTRL Register (Offset = DCh) [reset = 0h]

R/W-0h	R/W-0h	R/W-0h	R/W-0h				
7	6	5	4	3	2	1	0
BUFID7	COUNTBIT17	COUNT					
R/W-0h	R-0h	R-0h					

Table 23-125. DMA3CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ONESHOT	R/W	0h	Auto-disable of DMA channel after ICOUNT+1 transfers. 1 =ONESHOTx allows a block transfer of defined length (ICOUNTx+1) mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx +1 transfers the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer. 0 =The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.
30-24	BUFID	R/W	0h	Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the “suspend to wait until...” modes must be used (for more details refer to Section 8.53.1).
23-20	RXDMA_MAP	R/W	0h	Receive data DMA Request Map Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set to ‘1’, then RXDMA_MAPx[3:0] shall differ from TXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.
19-16	TXDMA_MAP	R/W	0h	Transmit data DMA channel Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. ne request line for receive data and the other for request line for transmit data. TXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel. If RXDMAENAx and TXDMAENAx are both set then TXDMA_MAPx[3:0] shall differ from RXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.

Table 23-125. DMA3CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15	RXDMAENA	R/W	0h	Receive data DMA channel enable. 1 =The physical DMA Request line for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The concerned buffer should be configured in the mode “skip until RXEMPTY is set” or “suspend to wait until RXEMPTY is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new receive data.
14	TXDMAENA	R/W	0h	Transmit data DMA channel enable. 1 =The physical DMA Request line for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The concerned buffer should be configured in the mode “skip until TXFULL is set” or “suspend to wait until TXFULL is set” in order to ensure synchronization between DMA controller and MibSPI sequencer. 0 =No DMA request upon new transmit data
13	NOBRK	R/W	0h	Non-interleaved DMA block transfer(Master mode only). 1 =NOBRKx ensures that ICOUNTx+1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx+1 transfers have been processed. E.g: this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD=1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI. Triggering of higher priority transfer groups or enabling of higher priority DMA channels will not interrupt NOBRK block transfer. 0 =The DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or transfer groups. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer
12-8	ICOUNT	R/W	0h	Initial Count of DMA transfers ICOUNTx[4:0] is used to preset the transfer counter COUNTx[4:0]. Every time COUNTx[4:0] hits zero it is reloaded with ICOUNTx[4:0]. The real number of transfer equals ICOUNTx[4:0] plus one. If ONESHOTx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx[4:0] defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer
7	BUFID7	R/W	0h	Extended bit of BUFIDx field when Extended Buffer feature is implemented. This bit represents the 8th bit of BUFID field such that any buffers between 127-255 can be configured as DMA capable buffers
6	COUNTBIT17	R	0h	The 17th bit of COUNT field of DMAxCOUNT register. This bit is useful only when ICOUNTx in DMAxCOUNT register is programmed to be 0xFFFF. During all other values, this bit remains to be ‘0’.
5-0	COUNT	R	0h	Actual number of remaining DMA transfer COUNTx[5:0] is a read-only bit field. It comprises the actual number of DMA transfers that remain, until the DMA channel is disabled if ONESHOTx is set.

23.3.2.47 DMA4CTRL Register (Offset = E8h) [reset = 0h]

DMA4CTRL is shown in Figure 23-144 and described in Table 23-126.

Return to Summary Table.

Table 23-133. PAR_ECC_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	NU4	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
27-24	SBE_EVT_EN	R/W	5h	Single Bit Error Event Enable This bit controls the generation of Error signaling (on MIBSPI_SBERR port) whenever a Single Bit Errors (SBE) is detected on TXRAM/RXRAM. This signal can be used to generate interrupt if required. Write: 0101 - Disable Error Event indication upon detection of SBE on TXRAM/RXRAM 1010 - Enable Error Event upon detection of SBE on TXRAM/RXRAM All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read: Returns the current value of the field
23-20	NU3	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
19-16	EDAC_MODE	R/W	Ah	Error Detection And Correction Mode These bits determine whether Single Bit Errors (SBE) detected by the SECDED block will be corrected or not. Write: 0101 - Disable correction of SBE detected by the SECDED block 1010 - Enable correction of SBE detected by the SECDED block All other values - writes are ignored and the values are not updated into this field. The state of the feature remains unchanged. Read: Returns the current value of the field
15-9	NU2	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
8	PTESTEN	R/W	0h	Parity/ECC memory Test Enable. This bit, maps the parity/ecc bits corresponding to Multibuffer RAM locations into the peripheral RAM frame to make them accessible by the CPU. User and privilege mode (read): 0 = parity/ecc bits are not memory mapped 1 = parity/ecc bits are memory mapped Privilege mode (write): 0 = disable memory mapping of Parity/ECC locations 1 = enable memory mapping of Parity/ECC locations
7-4	NU1	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
3-0	EDEN	R/W	5h	Error Detection Enable These bits enable Parity/ECC Error Detection. Write: 0101: Disables Parity/ECC Error Detection Logic(default) Others : Enables Parity/ECC Error Detection Logic. Read: Returns the current value of this field

23.3.2.55 PAR_ECC_STAT Register (Offset = 124h) [reset = 0h]

PAR_ECC_STAT is shown in Figure 23-152 and described in Table 23-134.

Return to Summary Table.

Table 23-136. UERRADDR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
10-0	UERRADDR0	R	0h	Uncorrectable Parity or double bit ECC error address This register holds the address when a parity error is generated while reading the MibSPI (Transmit) TXRAM. The TXRAM can be read either by CPU or by the MibSPI Sequencer FSM logic for transmission. The address captured is byte alligned. This error address is frozen from being updated until it is read by the VBUSP host. Reading this register clears its contents to the default value of 0x000. Writes to this register are ignored.

23.3.2.58 RXOVRN_BUF_ADDR Register (Offset = 130h) [reset = 200h]

RXOVRN_BUF_ADDR is shown in Figure 23-155 and described in Table 23-137.

Return to Summary Table.

Receive RAM Overrun Buffer Address Register

Figure 23-155. RXOVRN_BUF_ADDR Register

Table 23-137. RXOVRN_BUF_ADDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU	R	0h	Reserved.Reads return ‘0’ and writes have no effect.
10-0	RXOVRN_BUF_ADDR	R	200h	Address of the RAM location of RXRAM for which an Overwrite occured. This address value will show only the offset address of the RAM location in the Multibuffer RAM address space. Refer to the device Spec for the actual absolute address of RXRAM. Content of this register are valid only when any of the TGINTVECT0 or TGINTVECT1 and SPIFLG registers show an RXOVRN error vector while in Multibuffer mode. If there are multiple Overrun errors, then this register holds address of first overrun address until it is read.

23.3.2.59 IOLPBKTSTCR Register (Offset = 134h) [reset = 0h]

IOLPBKTSTCR is shown in Figure 23-156 and described in Table 23-138.

Return to Summary Table.

SPI/MibSPI IO Loopback Test Control Register This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog ones in this test mode. In addition it contains control bits to induce some of the error condition into the module. These are to be used for test purpose only. All the control/status bits in this register are valid only when IO LPBK TST ENA field is set to “1010”.

Table 23-138. IOLPBKTSTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
24	SCSFAILFLG		0h	Bit indicating a failure on SPISCS pin compare during analog loopback during IO Loopback Test mode. Read 1 = A comparison between the internal CSNR field and the analog looped back value of SPISCS[7:0] pins failed. A stuck-at fault is detected on one of the SPISCS[7:0]. Comparison is done only on the pins which are configured as functional and during transfer operation. 0 = No miscompares on any of the 8 chipselect pin value comparison with the internal Chipselect number CSNR during transfers. Write 1 = Clear this Flag bit. 0 = No effect.
23-21	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
20	CTRLBITERR	R/W	0h	Controls inducing of BITERR during IO Loopback Test mode. 1 = The value of incoming data from the loopback Transmit pin is flipped. 0 = No affect on BIT ERROR.
19	CTRLDESYNC	R/W	0h	Controls inducing of DESYNC Error during IO Loopback Test mode. 1 = Forces the incoming SPIENA pin (if functional) to remain ‘0’ even after the transfer complete. This forcing will be retained until the Kernel reaches IDLE state. 0 = No affect on DESYNC Error.
18	CTRLPARERR	R/W	0h	Controls inducing of Parity Error during IO Loopback Test mode. 1 = Flips the Parity Polarity signal being used for transmit parity generation logic 0 = No affect on Parity Error
17	CTRLTIMEOUT	R/W	0h	Controls inducing of TIMEOUT Error during IO LoopbacK Test mode. 1 = Forces the incoming SPIENA pin (if functional) to remain ‘1’ when transmission is initiated. The forcing will be retained until the Kernel reaches IDLE state. 0 = No affect on TIMEOUT Error.

Table 23-138. IOLPBKTSTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	CTRLDLENERR	R/W	0h	Controls inducing of Data Length Error during IO Loopback Test mode. 1 = When in Master mode, forces the SPIENA pin(if functional) to '1' when the module starts Shifting the data. When in Slave mode, forces the incoming SPISCS pin(if functional) to '1' when the module starts shifting the data.. 0 = No affect on Data Length Error.
15-12	NU2	R	0h	Reserved. Reads return '0' and writes have no effect.
11-8	IOLPBKTSTENA	R/W	0h	Module I/O Loopback Test Enable Key User and Privileged mode reads. Write access only in Privileged mode. Write: 1010 = I/O DFT is enabled All other values = I/O DFT is disabled Read: 1010 = I/O DFT is enabled All other values = I/O DFT is disabled
7-6	NU1	R	0h	Reserved. Reads return '0' and writes have no effect.
5-3	ERRSCSPIN	R/W	0h	Inject Error on ChipSelect Pin. The value in this field is decoded to find out the ChipSelect pin on which to inject an error. During the analog loopback of IO Loopback Test mode if CTRL SCS PIN ERR bit is set to '1', then the chipselect pin selected by this field is forced to the opposite of its original CSNR bit. 000 - Select SPISCS[0] for injecting error 001 - Select SPISCS[1] for injecting error . 111 - Select SPISCS[7] for injecting error
2	CTRLSCSPINERR	R/W	0h	Control bit to enable the injection of an error on SPISCS[7:0] pins. Individual pins of SPISCS[7:0] can be choosen using ERR SCS PIN. 1 = Enable the error inducing logic to the SPISCS pins. 0 = Disable the error inducing logic.
1	LPBKTYPE	R/W	0h	Module IO Loopback Type (Analog/Digital). User and Privileged mode reads. Write access only in Privileged mode. Write/Read : 1 = Analog loopback is enabled in module I/O DFT mode when IOLPBKTSTENA = 1010) 0 = Digital loopback is enabled in module I/O DFT mode when IOLPBKTSTENA = 1010
0	RXPENA	R/W	0h	Module Analog loopback through Receive Pin Enable. User and Privileged mode reads. Write only in privileged mode: Write/Read : 1 = Analog loopback through receive pin 0 = Analog loopback through transmit pin. This bit is valid only when LPBK TYPE = '1' which chooses Analog loopback mode.

23.3.2.60 EXTENDED_PRESCALE1 Register (Offset = 138h) [reset = 0h]

EXTENDED_PRESCALE1 is shown in Figure 23-157 and described in Table 23-139.

Return to Summary Table.

SPI/MibSPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE_FMT1(7:0) of EXTENDED_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.

Figure 23-157. EXTENDED_PRESCALE1 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R-0h					R/W-0h										
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU1					EPRESCLAE_FMT0										
R-0h					R/W-0h										

Table 23-139. EXTENDED_PRESCALE1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	NU2	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26-16	EPRESCLAE_FMT1	R/W	0h	Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 can be modified in privilege mode only. EPRESCALE_FMT1 determines the bit transfer rate of Data Format 1 if the SPI/MibSPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT1(7:0) bits and PRESCALE1(7:0) bits of SPIFMT1 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT1(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EXTENDED_PRESCALE1(26:16) or SPIFMT1(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. BRFormatx = VBUSPCLK/(EXTENDEDPRESCALEy+1) When EPRESCALE_FMTy (y=1,2) is set to zero(0), the SPI clock rate defaults to VBUSPCLK/2.
15-11	NU1	R	0h	Reserved. Reads return ‘0’ and writes have no effect.

Table 23-139. EXTENDED_PRESCALE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-0	EPRESCLAE_FMT0	R/W	0h	EPRESCALE_FMT0 can be modified in privilege mode only. EPRESCALE_FMT0 determines the bit transfer rate of Data Format 0 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT0(7:0) bits and PRESCALE0(7:0) bits of SPIFMT0 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT0(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EPRESCALE0(26:16) or SPIFMT0(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK.

23.3.2.61 EXTENDED_PRESCALE2 Register (Offset = 13Ch) [reset = 0h]

EXTENDED_PRESCALE2 is shown in Figure 23-158 and described in Table 23-140.

Return to Summary Table.

SPI/MibSPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This register is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE_FMT2(7:0) of EXTENDED_PRESCALE2 and PRESCALE2(7:0) of SPIFMT2 register will always reflect the same contents. Similarly EPRESCALE_FMT3(7:0) and PRESCALE3(7:0) of SPIFMT3 reflect the same contents.

Figure 23-158. EXTENDED_PRESCALE2 Register

Bit	Field	Type	Reset	Description
31-27	NU4	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
26-16	EPRESCLAE_FMT3	R/W	0h	EPRESCALE_FMT3 can be modified in privilege mode only. EPRESCALE_FMT3 determines the bit transfer rate of Data Format 3 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT3(7:0) bits and PRESCALE3(7:0) bits of SPIFMT3 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT3(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EPRESCALE3(26:16) or SPIFMT3(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK.
15-11	NU3	R	0h	Reserved. Reads return ‘0’ and writes have no effect.
10-0	EPRESCLAE_FMT2	R/W	0h	EPRESCALE_FMT2 can be modified in privilege mode only. EPRESCALE_FMT2 determines the bit transfer rate of Data Format 2 if the SPI is the network master. If the SPI / MibSPI is configured as slave, this field DOES NOT NEED to be configured. These EPRESCALE_FMT2(7:0) bits and PRESCALE2(7:0) bits of SPIFMT2 register will point to the same physically implemented register. Refer to Figure 56 for a graphical representation of the implementation. Write : This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT3(15:8). Read : Reading this field will reflect the PRESCALE value based on the last written register field i.e., EXTENDED_PRESCALE2(26:16) or SPIFMT2(15:8) register. Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK.

23.3.2.62 ECCDIAG_CTRL Register (Offset = 140h) [reset = Ah]

ECCDIAG_CTRL is shown in Figure 23-159 and described in Table 23-141.

Return to Summary Table.

ECC Diagnostic Control register

Figure 23-159. ECCDIAG_CTRL Register

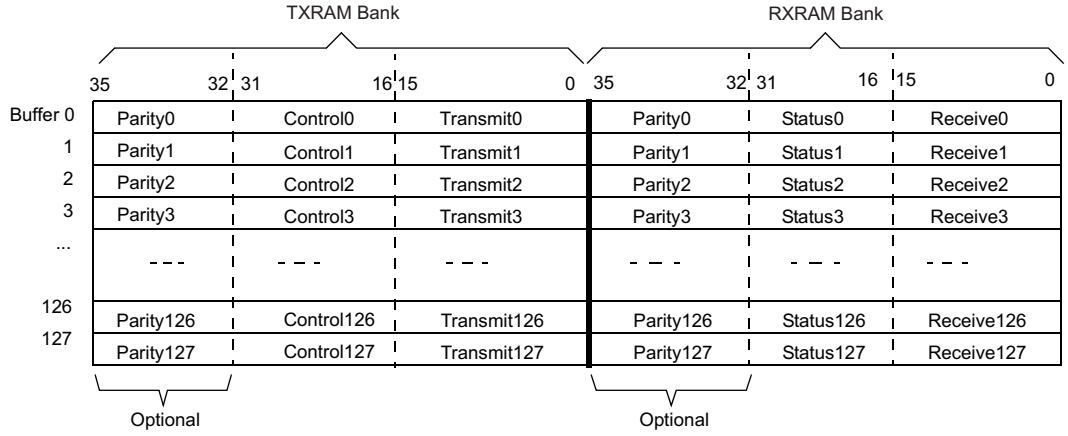
27-16	FUNC	R	A05h	Indicates functionally equivalent module family Reads 0xA05
15-11	RTL	R	0h	RTL version number Read value will provide an approximate RTL revision number. The design release version can be obtained from the device specification
10-8	MAJOR	R	3h	Major Revision number Reads 0x3
7-6	CUSTOM	R	0h	Indicates device specific implementation Reads 0x0
5-0	MINOR	R	8h	Minor Revision number Reads 0x8

23.4 Multi-Buffer RAM

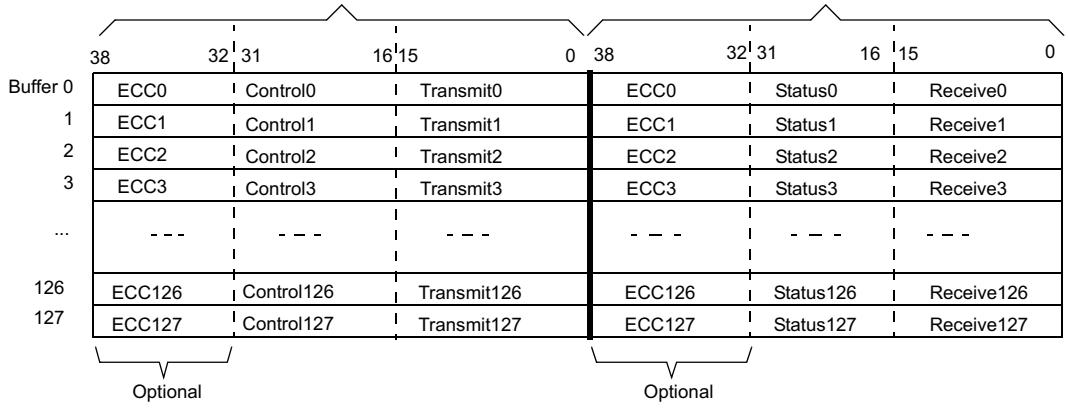
The multi-buffer RAM comprises of all buffers, which can be configured identically. The multi-buffer RAM contains two banks of up to128/256 words of 32 bits for a maximum configuration, one each for TXRAM (replicating the SPIDAT1 register) and RXRAM (replicating the SPIBUF register). The buffers can be partitioned into multiple transfer groups, each containing a variable number of buffers. Each of the buffers can be sub-divided into a 16-bit transmit field, a 16-bit receive field, a 16-bit control field, and a 16-bit status field. A 4-bit parity field per word is also included in each RAM bank, as shown in Figure 23-164. If ECC support is implemented for RAM fault detection, then a 7-bit ECC field per word is also included in each RAM bank, as shown in Figure 23-165.

Figure 23-164. Multi-Buffer RAM Configuration When Parity Check is Supported



Depth will be up to 256 buffers, if EXTENDED_BUF feature is implemented.

Figure 23-165. Multi-Buffer RAM Configuration When ECC Check is Supported



Depth will be up to 256 buffers, if EXTENDED_BUF feature is implemented.

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number bit field CSNR[7:0] of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

NOTE: Refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2nd buffer, and so on.

23.4.1 Multi-Buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be 0 (multi-buffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialization after reset, the auto-initialization sequence can also be done in following ways:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the Architecture User Guide for more details on the memory auto-initialization process.

NOTE: During Auto Initialization process, all the multi-buffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the multi-buffer mode register.

23.4.2 Multi-Buffer RAM Register Summary

This section describes the multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 23-146. Multi-Buffer RAM Register

Offset	Acronym	Register Description	Section
Base + 0h-1FFh	TXRAM	Multi-Buffer RAM Transmit Data Register	Section 23.4.3
Base + 200h-3FFh	RXRAM	Multi-Buffer RAM Receive Buffer Register	Section 23.4.4

23.4.3 Multi-Buffer RAM Transmit Data Register

Each word of TXRAM is a transmit-buffer register.

Figure 23-166. Multi-Buffer RAM Transmit Data Register [offset = Base + 000-1FFh]

Table 23-147. Multi-buffer RAM Transmit Data Register Field Descriptions

Bit	Field	Value	Description
31-29	BUFMODE		Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word. When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer. When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TXFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes.
		0	**disabled.** The buffer is disabled
		1h	**skip single-transfer mode.** Skip this buffer until the corresponding TXFULL flag is set (new transmit data is available).
		2h	**skip overwrite-protect mode.** Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).
		3h	**skip single-transfer overwrite-protect mode**. Skip this buffer until both of the corresponding TXFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).
		4h	**continuous mode.** Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.
		5h	**suspend single-transfer mode.** Suspend-to-wait until the corresponding TXFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).
		6h	**suspend overwrite-protect mode.** Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host.
		7h	**suspend single-transfer overwrite-protect mode.** Suspend-to-wait until the corresponding TXFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).
28	CSHOLD		Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of MibSPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.
		0	The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.
		1	The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.
27	LOCK		Lock two consecutive buffer words. Do not allow interruption by TG's with higher priority.
		0	Any higher-priority TG can begin at the end of the current transaction.
		1	A higher-priority TG cannot occur until after the next unlocked buffer word is transferred.

Table 23-147. Multi-buffer RAM Transmit Data Register Field Descriptions (continued)

Bit	Field	Value	Description
26	WDEL		Enable the delay counter at the end of the current transaction.
			Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.
		0	No delay will be inserted. However, SPISCS pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.
			Note: The duration for which the SPISCS pin remains deactivated also depends upon the time taken to supply a new word after completing the shift operation (in compatibility mode). If TXBUF is already full, then the SPISCS will be deasserted for at least two VCLK cycles (if WDEL = 0).
		1	After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPISCS pins will be de-activated for at least (WDELAY + 2) * VCLK_Period duration.
25-24	DFSEL		Data word format select
		0	Data word format 0 is selected
		1h	Data word format 1 is selected
		2h	Data word format 2 is selected
		3h	Data word format 3 is selected
23-16	CSNR	0-FFh	Chip select number. CSNR defines the chip-select that will be activated during the data transfer.
			Note: Writing to only the control field (using byte writes) does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL fields in the control field to select the required phase/polarity combination.
15-0	TXDATA	0-7FFFh	**Transfer data.**When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.
			SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0.
			Write to this register ONLY when using the automatic slave chip-select feature (see Section 23.2.1.1 for more information). A write to this register will drive the contents of CSNR[7:0] on the SPISCS[3:0] pins, if they are configured as functional pins.
			When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.
			Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.

23.4.4 Multi-buffer RAM Receive Buffer Register

Each word of RXRAM is a receive-buffer register.

Table 23-148. Multi-buffer Receive Buffer Register Field Descriptions

Bit	Field	Value	Description
31	RXEMPTY		**Receive data buffer empty.**When the host reads the SPIBUF field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, and the RXEMPTY flag is cleared.
		0	New data has been received and copied into the SPIBUF field.
		1	No data has been received since the last read of SPIBUF.
			This flag gets set to 1 under the following conditions: • Reading the RXDATA portion of the SPIBUF register. • Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG). Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA portion of SPIBUF (or the entire register).
30	RXOVR		Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor). If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVECTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read). This flag is cleared to 0 when the RXDATA is read. **Note: A special condition under which RXOVR flag gets set.If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.**
		0	No receive data overrun condition occurred since last read of the data field.
		1	A receive data overrun condition occurred since last read of the data field.
29	TXFULL		**Transmit data buffer full.**This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.
		0	The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.
		1	The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.

Table 23-148. Multi-buffer Receive Buffer Register Field Descriptions (continued)

Bit	Field	Value	Description
28	BITERR		**Bit error.**There was a mismatch of internal transmit data and transmitted data.
		0	No bit error occured.
			Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.
		1	A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.
27	DESYNC		**Desynchronization of slave device.**This bit is valid in master mode only.
			The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{T2EDELAY}$. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.
			Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.
		0	No slave desynchronization detected.
			Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.
		1	A slave device is desynchronized.
26	PARITYERR		**Parity error.**The calculated parity differs from the received parity bit.
			If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.
			Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.
		0	No parity error detected.
		1	A parity error occured.
25	TIMEOUT		Time-out because of non-activation of ENA pin.
			The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.
			This bit is valid only in master mode.
			This flag is cleared to 0 when RXDATA portion of the SPIBUF register is read.
		0	No ENA-pin time-out occured.
		1	An ENA signal time-out occured.
24	DLENERR		**Data length error flag.**
			Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.
		0	No data-length error has occurred.
		1	A data length error has occurred.
23-16	LCSNR	0-FFh	**Last chip select number.** LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.
15-0	RXDATA	0-FFFFh	**SPI receive data.** This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

23.5 Parity\ECC Memory

Parity/ECC portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However each read or write operation to the Control/Data/Status portion of the multi-buffer RAM causes reads/writes to the parity/ECC portion as well.

- Each write to the multi-buffer RAM (either from the VBUS interface or by the MibSPI itself) causes a write operation to the Parity/ECC portion of RAM simultaneously to update the equivalent parity/ECC bits.
- Each read operation from the multi-buffer RAM (either from the VBUS interface or by the MibSPI itself) causes a read operation from the Parity/ECC portion of the RAM for parity/ECC comparison purpose.
- Reads/Writes to multi-buffer RAM could either be caused by any CPU/DMA accesses or by the Sequencer logic of MibSPI itself.

For testing the Parity/ECC portion of the multi-buffer RAM which is a 4bit or 7bit field per word address, a separate Parity/ECC Memory Test mode is available. Parity Memory Test Mode can be selecting the PTESTEN bit in PAR_ECC_CTRL register in addition to PAR_ECC_CTRL.PTESTEN bit, ECCDIAG_REG(3:0) should be enabled

During the parity test mode, the parity locations are addressable at the address between RAM_BASE_ADDR + 0x400h and RAM_BASE_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See Figure 23-168 for a diagram of the memory map of parity memory during normal operating mode and during parity test mode while EXTENDED_BUF mode is disabled or the feature is not implemented. See Figure 23-169 for a diagram of the memory map of parity memory during normal operating mode and during parity test mode while EXTENDED_BUF mode is enabled.

During Parity/ECC test mode, after writing the Data/Control portion of the RAM, the Parity/ECC locations can be written with wrong parity/ECC bits to intentionally cause Parity/ECC Errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

NOTE: The RX_RAM_ACCESS bit can also be set to 1 during the Parity/ECC Test mode to be able to write to RXRAM locations for test purpose. Both Parity/ECC bits testing and RXRAM testing can be done together.

There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in Section 23.5.1 for further details.

If ECC is enabled, there are 7 ECC-bits corresponding to each of the 32-bit multi-buffer locations. See the example in Section 23.5.1 for further details.

NOTE: Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

Figure 23-168. Memory-Map for Parity Locations During Normal and Test Mode While EXTENDED_BUF Mode is Disabled or the Feature is Not Implemented

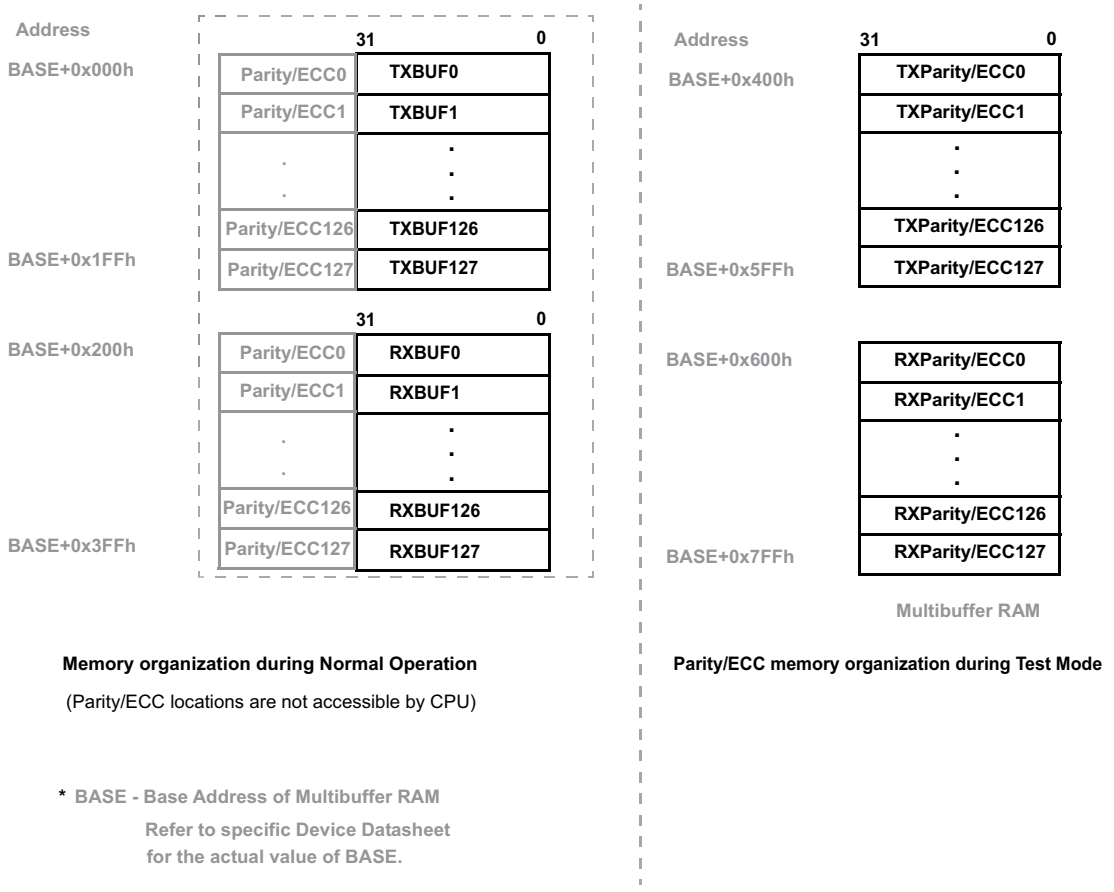

Figure 23-169. Memory-Map for Parity Locations During Normal and Test Mode While EXTENDED_BUF Mode is Enabled

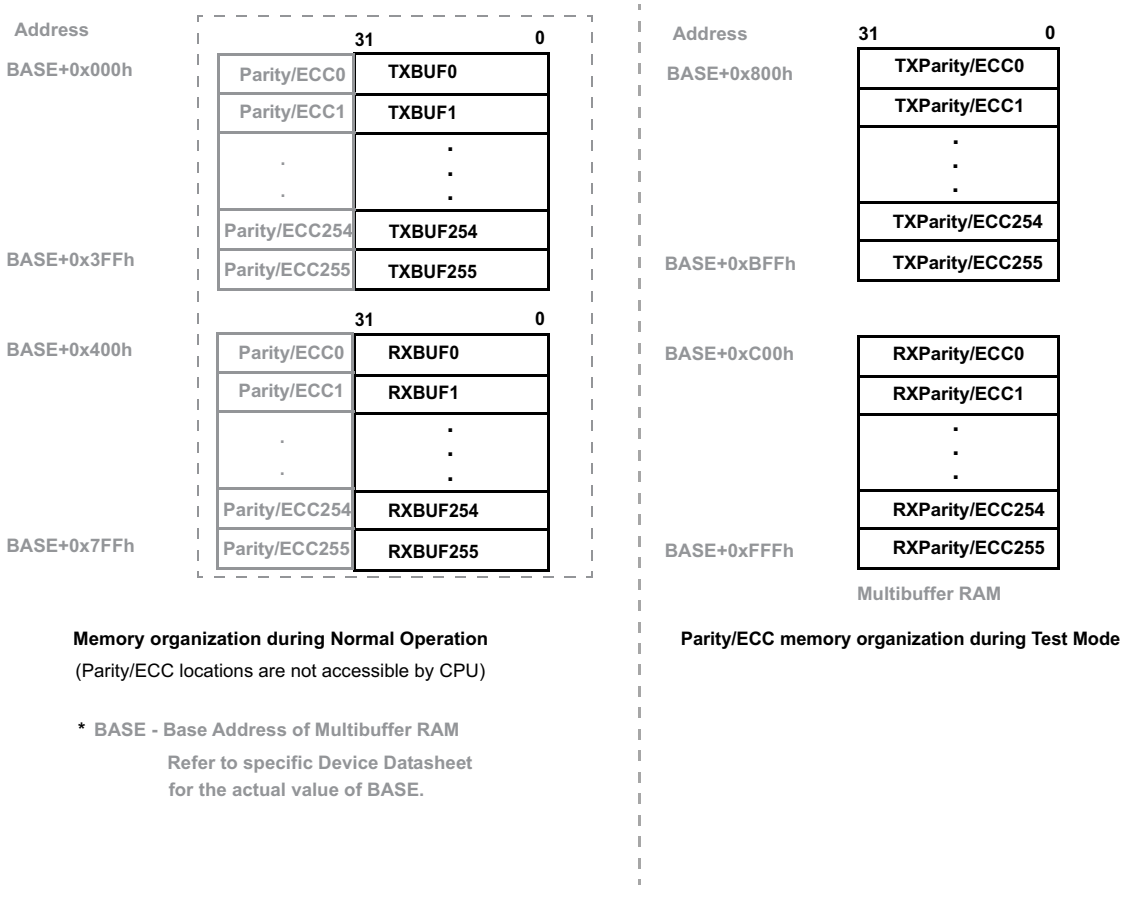
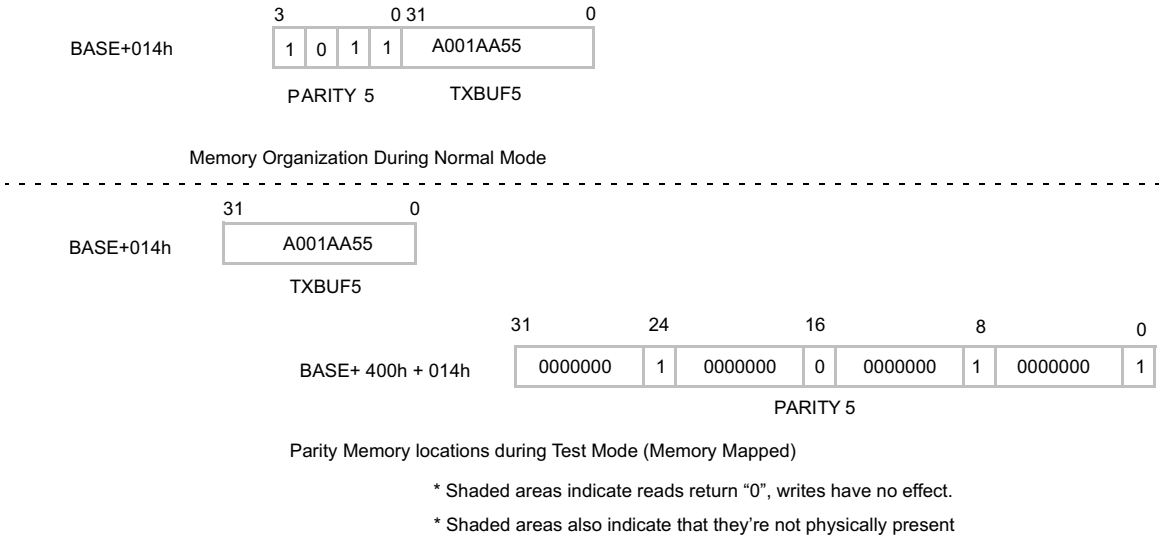


23.5.1 Example of Parity Memory Organization

Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See Figure 23-170 for a diagram.

Figure 23-170. Example of Memory-Mapped Parity Locations During Test Mode



NOTE: Read Access to Parity Memory Locations

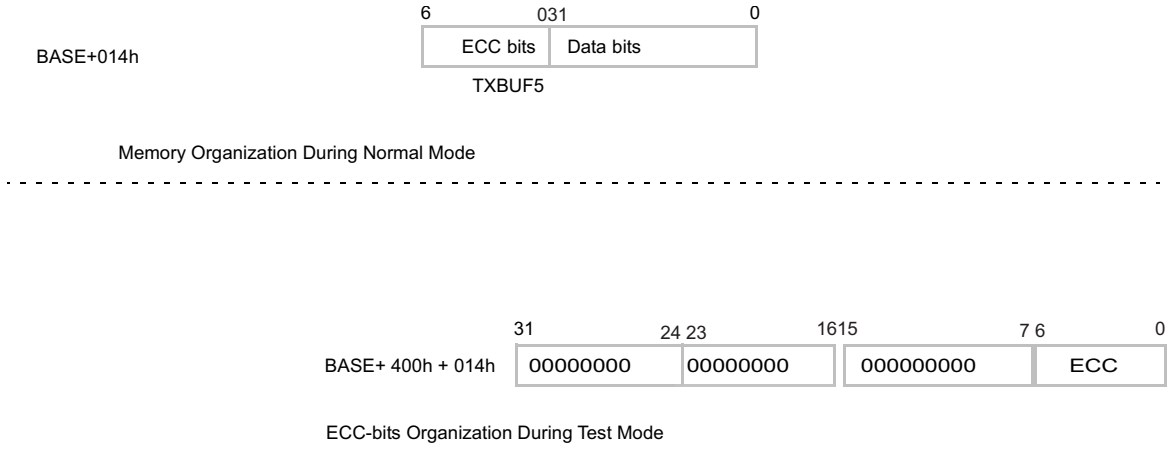
Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.

23.5.2 Example of ECC Memory Organization

Suppose TXBUF5 (6th location in TXRAM portion) in the multi-buffer RAM is written with a value of A001_AA55, then the corresponding ECC-bits will be updated in ECC location.

The ECC bits can be accessed by user, when Memory Test mode is enabled and additionally diagnostic mode is also enabled. The actual ECC bits will be aligned as shown in Figure 23-171.

Figure 23-171. Example of ECC Bit Locations During Test Mode



NOTE: Access to ECC locations

ECC locations can be read/write only when Parity Memory Test mode and diagnostic mode is enabled

23.6 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase & Polarity affect the pin timings.

The pin directions are based on the mode of operation.

Master mode SPI:

- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPISCS}}$[7:0] (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIENA}}$ (SPI slave ready Enable) - Input

Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPISCS}}$ - Input
- SPISOMI - Output
- $\overline{\text{SPIENA}}$ - Output

NOTE: All the following timing diagrams are with Phase = 0 and Polarity = 0, unless explicitly stated otherwise.

23.6.1 Master Mode Timings for SPI/MibSPI

* ENABLE_HIGHZ is set to '0' in Slave SPI

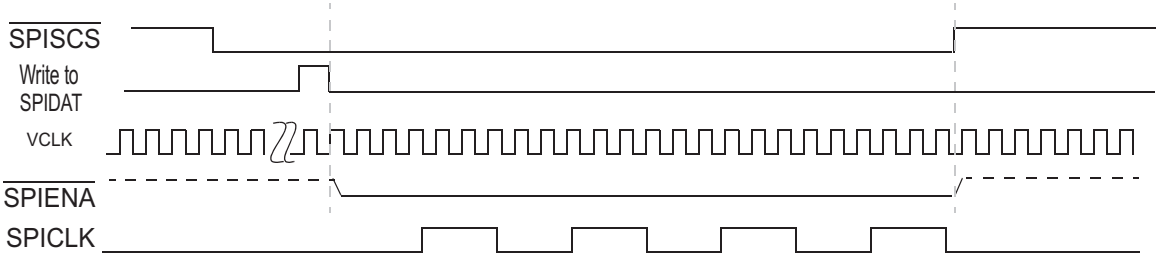
* Diagram shows relationship between the $\overline{\text{SPISCS}}$ from a Master to $\overline{\text{SPIENA}}$ from Slave SPI when $\overline{\text{SPIENA}}$ is configured in Push-Pull mode

Figure 23-179. SPI/MibSPI Pins During Slave Mode in 5-Pin Configuration (Single/Multi-Slave)



* ENABLE_HIGHZ is set to '1' in Slave SPI

* Diagram shows relationship between the $\overline{\text{SPISCS}}$ from a Master to $\overline{\text{SPIENA}}$ from Slave SPI when $\overline{\text{SPIENA}}$ is configured in High-Z mode

23.6.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO with respect to its internal SPICLK. In case of Master mode, the RX data on SPISOMI pin is registered with respect to SPICLK recieved through Input buffer from the I/O pad.

If Chip Select pin is functional, then Master will drive out $\overline{\text{SPISCS}}$ pin(s) before starting the SPICLK. If $\overline{\text{SPIENA}}$ pin is functional, then Master will wait for an active 'low' from Slave on the input pin to start the SPICLK.

23.6.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only SPISOMI and SPIENA pins. All other pins are inputs to it. The RX data on SPISIMO pin will be registered with respect to SPICLK pin. Slave will use $\overline{\text{SPISCS}}$ pin to drive out $\overline{\text{SPIENA}}$ pin if both are functional. If 4pin with $\overline{\text{SPIENA}}$ is configured, then Slave will drive out active low signal on $\overline{\text{SPIENA}}$ pin when a new data is written to the TX Shift Register. Irrespective of 4pin with $\overline{\text{SPIENA}}$ or 5pin configuration, the Slave will deassert the $\overline{\text{SPIENA}}$ pin after the last bit is received. If ENABLE_HIGHZ (SPIINT0.24) bit is 0, the de-asserted value of $\overline{\text{SPIENA}}$ pin will be 1. Otherwise, it will depend upon the internal PullUp or PullDown resistor (if implemented) depending upon the Specification of the Chip.

Quad Serial Peripheral Interface (QSPI)

Topic **Page**

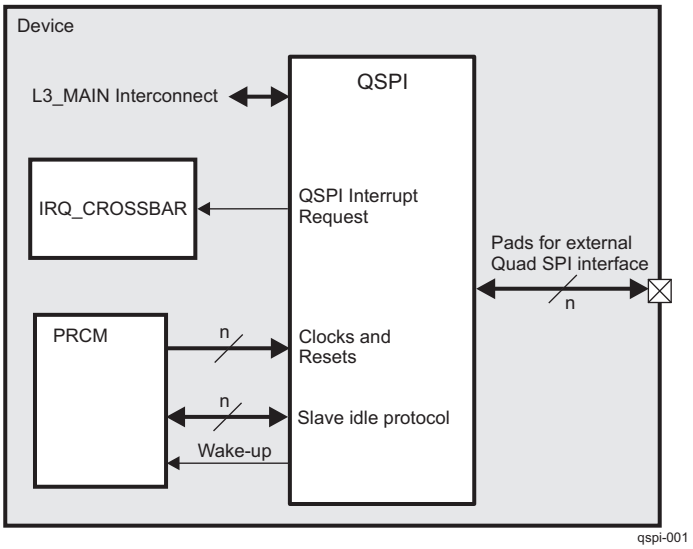
24.1 Quad Serial Peripheral Interface Overview 3158
24.2 QSPI Functional Description 3159
24.3 QSPI Register Manual 3167

24.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI™) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 24-1 shows the QSPI module overview.

Figure 24-1. QSPI Overview



The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 4 external chip-select signals
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support
  - Quad read support
  - Little-endian support only

– Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

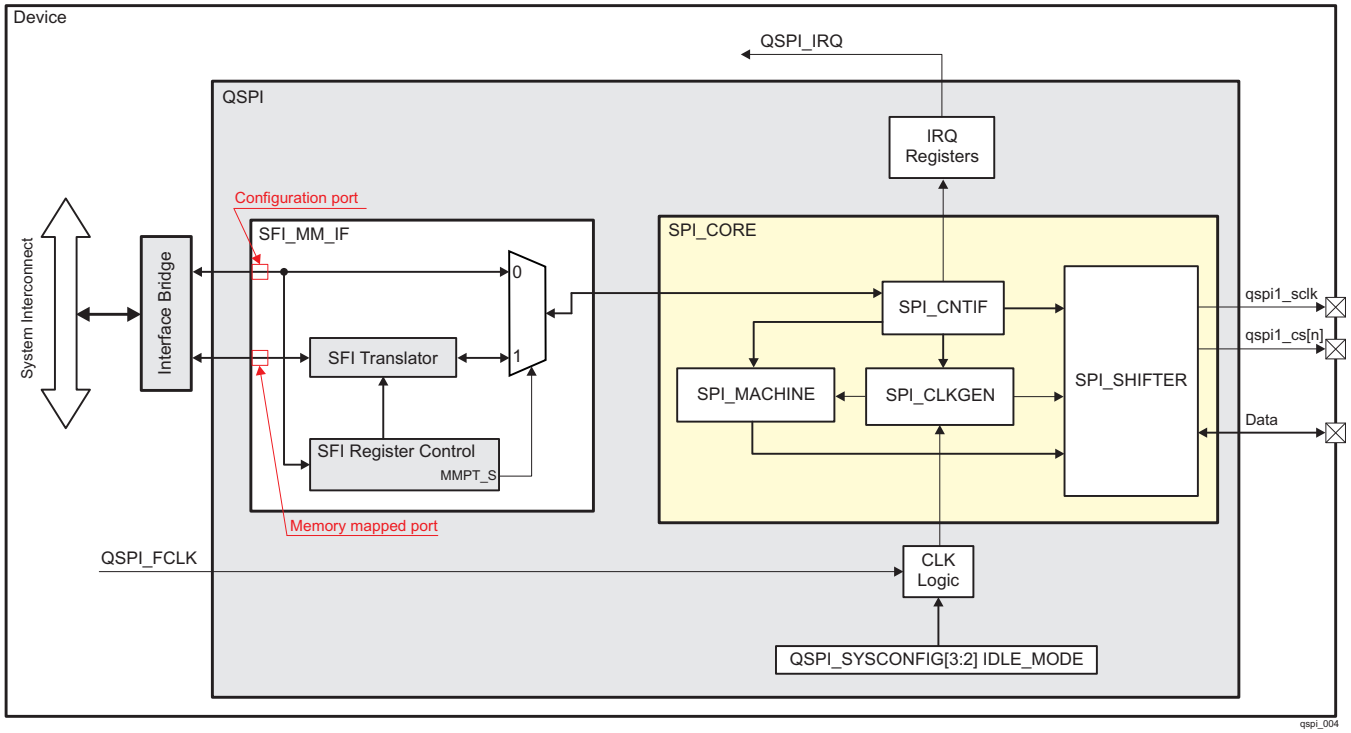
NOTE: The QSPI module does not support cache line wrap mode.

24.2 QSPI Functional Description

24.2.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 24-2 shows the QSPI block diagram.

Figure 24-2. QSPI Block Diagram



The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)

- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

NOTE: The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

24.2.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUPi_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUPi_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SPI_SETUPi_REG[9:8] NUM_A_BYTES bit field
- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUPi_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUPi_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUPi_REG[13:12] READ_TYPE bit field. (i is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUPi_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 24-2) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 24-2) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

24.2.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

24.2.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - QSPI_SPI_DATA_REG
  - QSPI_SPI_DATA_REG_1
  - QSPI_SPI_DATA_REG_2
  - QSPI_SPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG_1 register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previosly described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

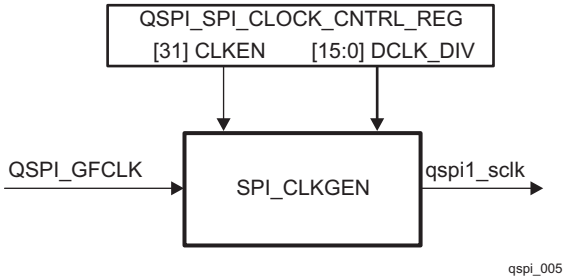
NOTE: The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

24.2.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 24-3 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

Figure 24-3. SPI_CLKGEN Block



24.2.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this decrements the value of the WDCNT bit field and starts shfting data in or out again. This is repeated until the WDCNT bit field reaches 0x0, that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

24.2.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 24-1 lists the four defined clock modes of operation for the QSPI.

Table 24-1. SPI Clock Modes Definition

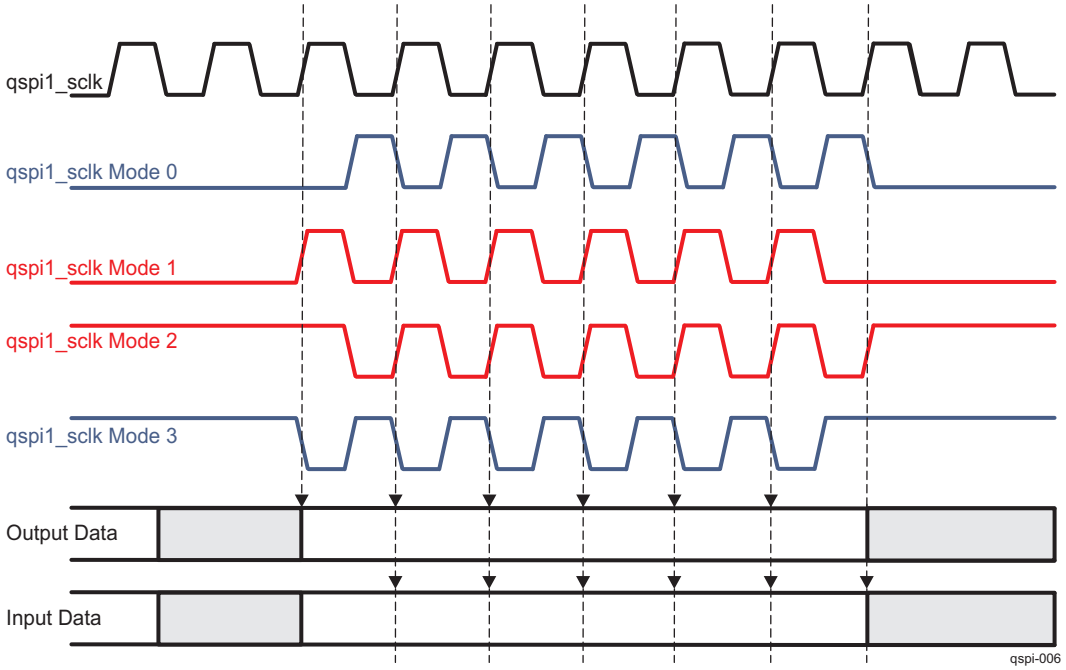
Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

NOTE: Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

Figure 24-4 shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

Figure 24-4. SPI Clock Modes



24.2.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

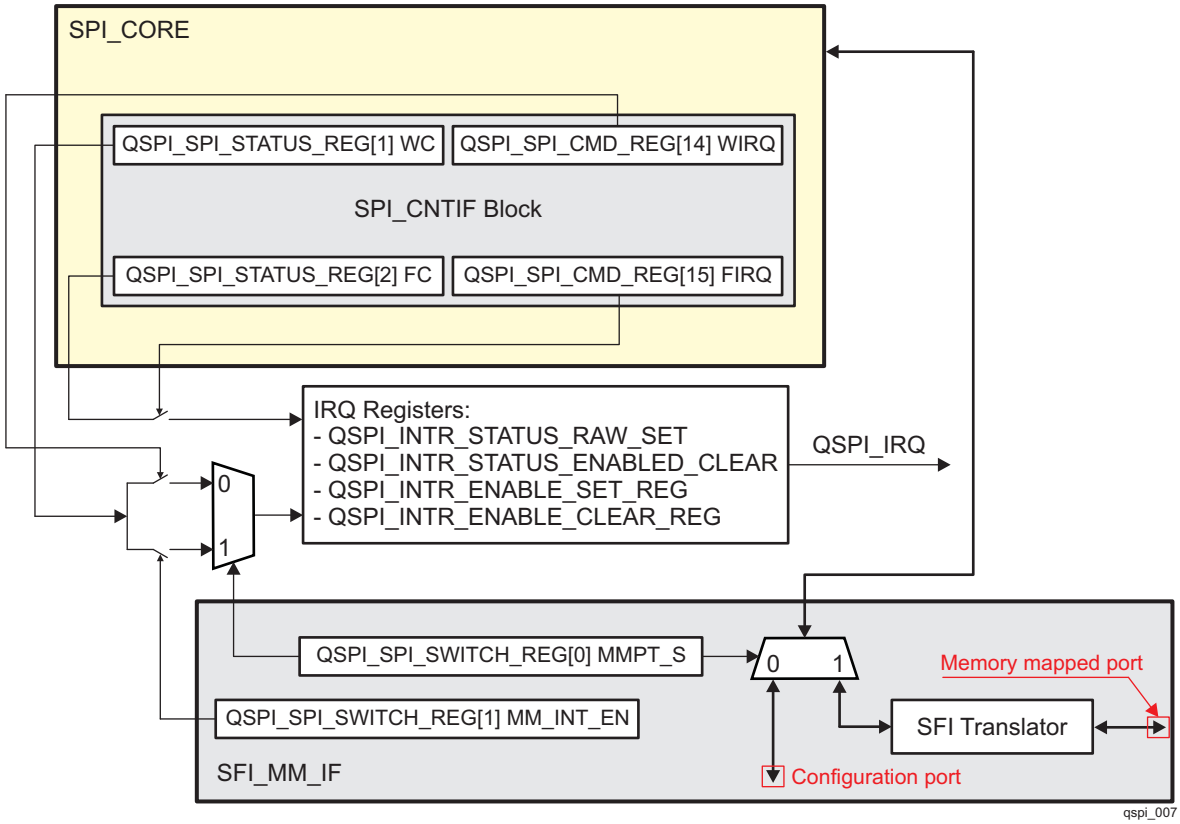
- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

24.2.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in Table 24-2.

Figure 24-5 shows a logical representation of the QSPI interrupt generation scheme.

Figure 24-5. Logical Representation of the QSPI Interrupt Generation Scheme



QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

NOTE: The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 24-2 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 24-2. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[1] WC	QSPI_SPI_CMD_REG[14] WIRQ	
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET	Frame complete interrupt event. Asserted each time after a frame is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[2] FC	QSPI_SPI_CMD_REG[15] FIRQ	

24.2.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the external SPI devices. The start address at which the configuration port is available is 0xC0800000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with external SPI devices. This memory region starts at 0xE0000000 and ends at 0xE0400000.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in . These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available thorough these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

24.3 QSPI Register Manual

24.3.1 MSS_QSPI Registers

Table 24-3 lists the memory-mapped registers for the MSS_QSPI. All register offset addresses not listed in Table 24-3 should be considered as reserved locations and the register contents should not be modified.

Table 24-3. MSS_QSPI Registers

Offset	Acronym	Register Name	Section

Inter-Integrated Circuit (I2C)

This section describes the inter-integrated circuit (I2C or I^2C) module. The I2C is a multi-master communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I^2C-bus specification version 2.1 and connected by an I2C-bus. This module will support any slave or master I2C compatible device.

Topic **Page**

25.1 Overview **3191**
25.2 I2C Module Operation **3195**
25.3 I2C Operation Modes **3199**
25.4 I2C Module Integrity **3201**
25.5 Operational Information **3203**
25.6 MSS_I2C Registers **3206**
25.7 Sample Waveforms **3233**

25.1 Overview

The I2C has the following features:

- Compliance to the Philips I^{2}C bus specification, v2.1 (*The I2C Specification,* Philips document number 9398 393 40011)
  - Bit/Byte format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - START byte
  - Multi-master transmitter/ slave receiver mode
  - Multi-master receiver/ slave transmitter mode
  - Combined master transmit/receive and receive/transmit mode
  - Transfer rates of 10 kbps up to 400 kbps (Phillips fast-mode rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode

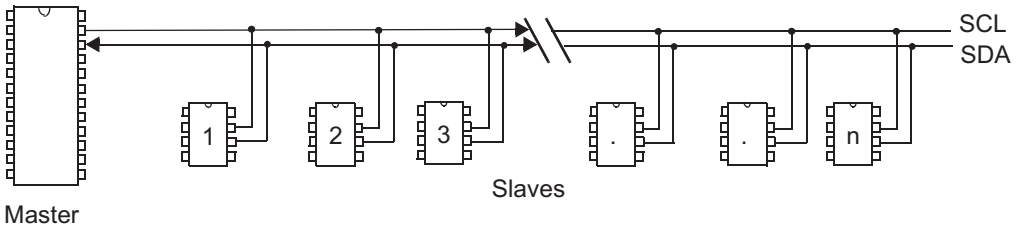
NOTE: This I2C module does **not** support:

- High-speed (HS) mode
- C-bus compatibility mode
- The combined format in 10-bit address mode (the I2C sends the slave address second byte every time it sends the slave address first byte)

25.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. Figure 25-1 shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

Figure 25-1. Multiple I2C Modules Connection Diagram



25.1.2 Functional Overview

The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

NOTE: A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in Figure 25-2. These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

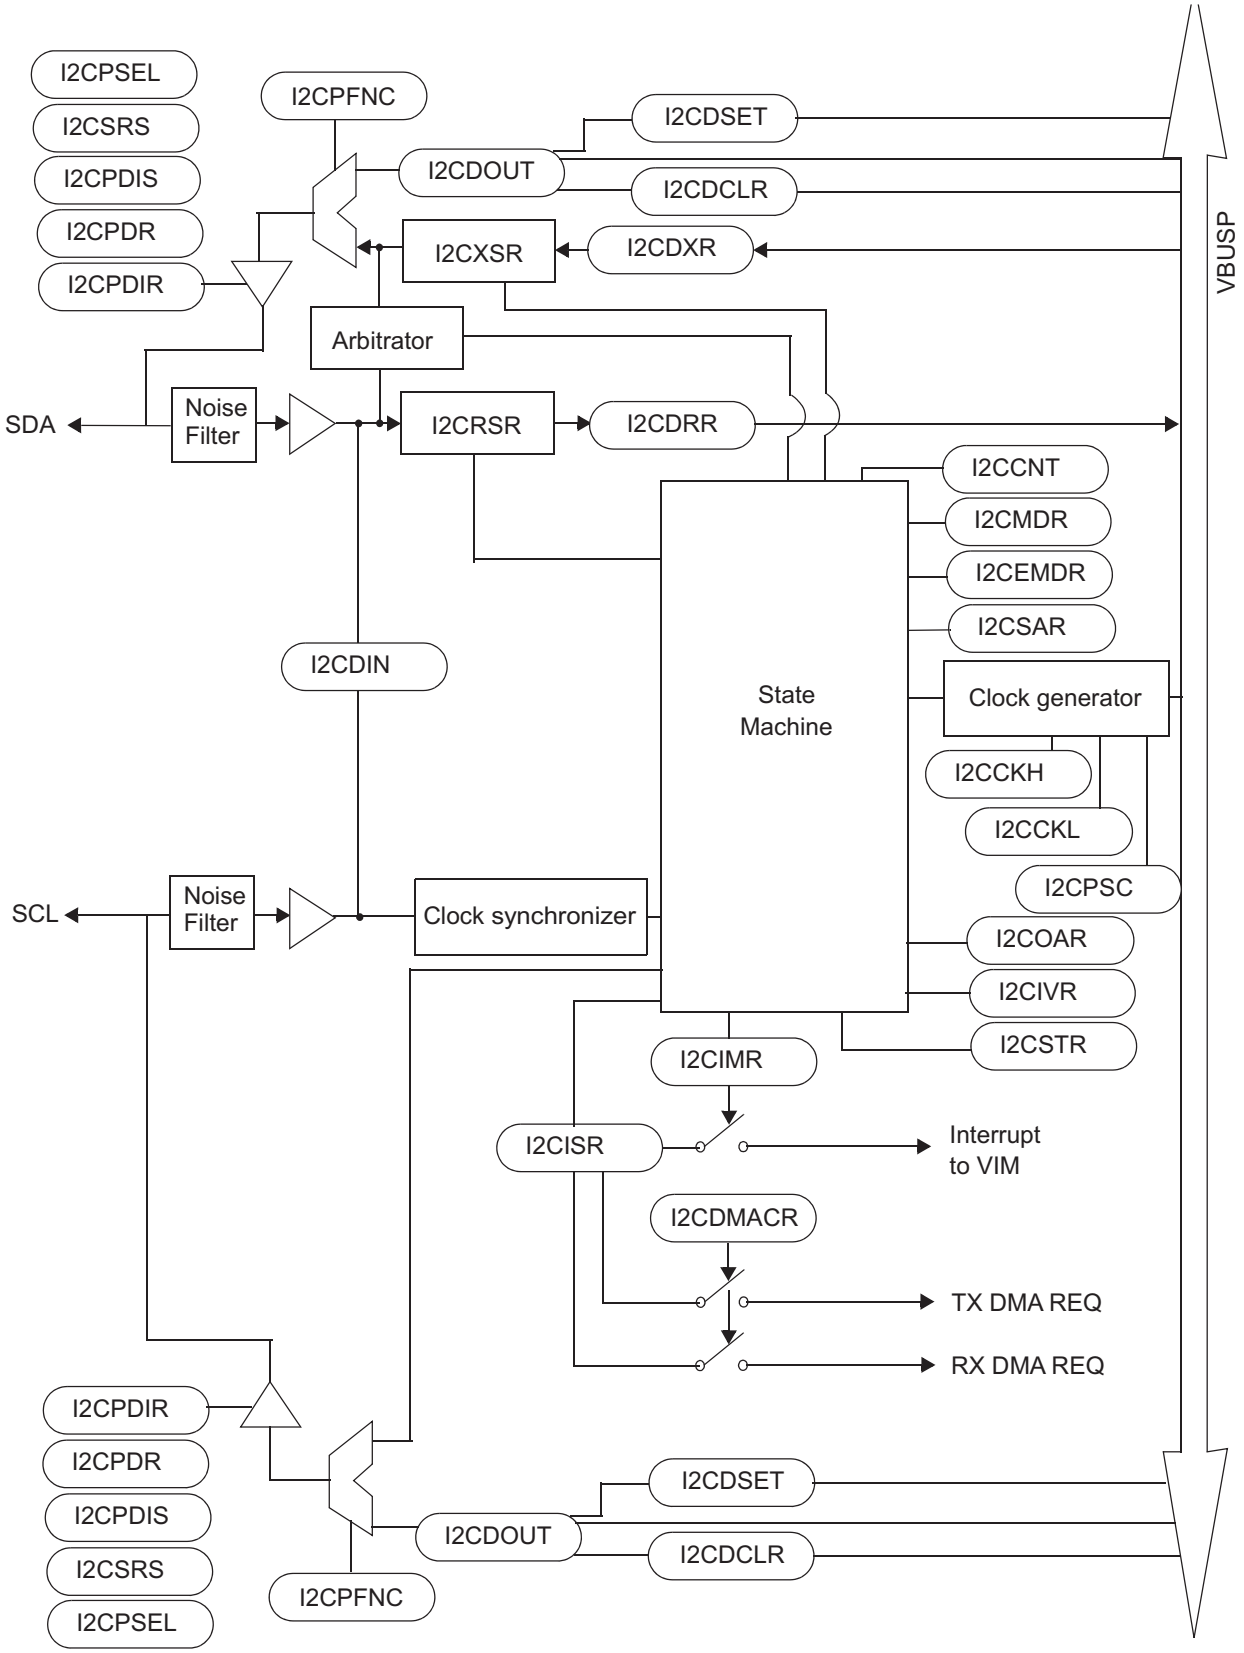
The I2C module consists of the following primary blocks:

- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
  - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
  - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds.
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

  In Figure 25-2, the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

  When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:
- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

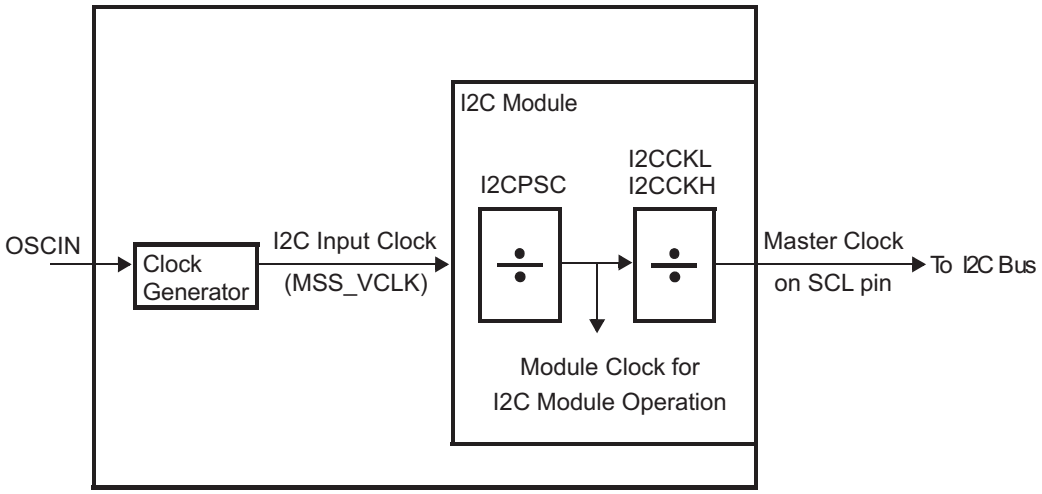
Figure 25-2. Simple I2C Block Diagram



25.1.3 Clock Generation

As shown in Figure 25-3, the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

Figure 25-3. Clocking Diagram for the I2C Module



The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$ModuleClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)} \quad (12)$$

The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in Figure 25-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$MasterClockFrequency = \frac{ModuleClockFrequency}{(I2CCKL + d) + (I2CCKH + d)} \quad (13)$$

$$MasterClockFrequency = \frac{I2CInputClockFrequency}{(I2CPSC + 1)((I2CCKL + d) + (I2CCKH + d))} \quad (14)$$

where *d* depends on the value of I2CPSC:

I2CPSC	d
0	7
1	6
Greater than 1	5

NOTE: The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

25.2 I2C Module Operation

The following section discusses how the I2C module operates.

25.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{CCIO}. For details, see the device specific data sheet.

25.2.2 I2C Module Reset Conditions

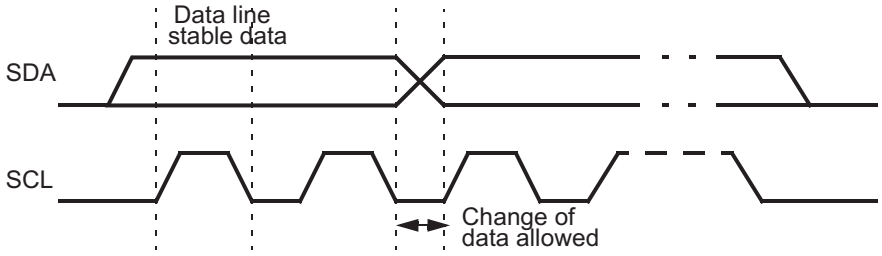
The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the $\overline{\text{IRS}}$ bit in the I2C mode register (I2CMDR). When the global peripheral reset is removed, the $\overline{\text{IRS}}$ bit is cleared to 0, keeping the I2C module in the reset state.

25.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See Figure 25-4. The high and low state of the data line, the SDA, can only change when the clock signal is low.

Figure 25-4. Bit Transfer on the I2C Bus

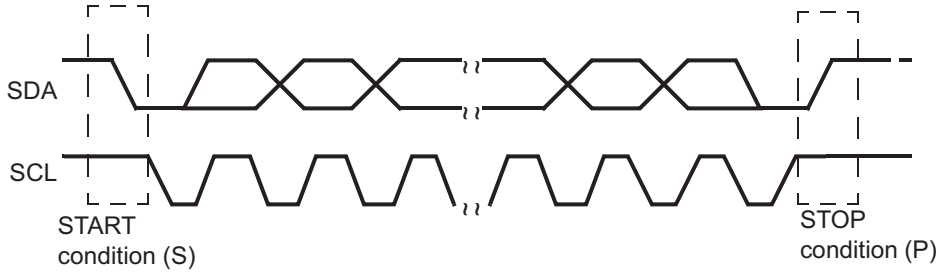


25.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

Figure 25-5. I2C Module START and STOP Conditions

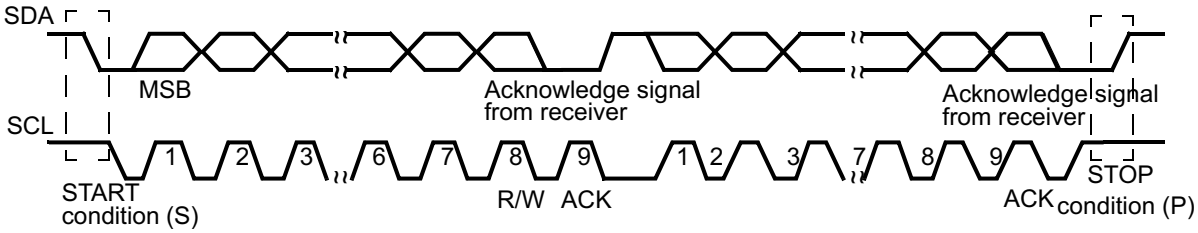


For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

25.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 25-6). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

Figure 25-6. I2C Module Data Transfer



The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/$\overline{W}$ bit, or 8 data bits. The eighth bit, R/W, in the first byte determines the direction of the data. When the R/$\overline{W}$ bit is 0, the master writes (transmits) data to a selected slave device; when the R/$\overline{W}$ bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 25-7)
- 10-bit addressing format (Figure 25-8)
- 7-bit/10-bit addressing format with repeated START condition (Figure 25-9)
- Free-data format (Figure 25-10)

25.2.5.1 7-Bit Addressing Format

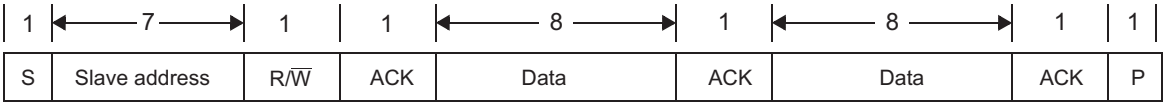
In the 7-bit addressing format (Figure 25-7), the first byte after the START condition consists of a 7-bit slave address followed by the R/$\overline{W}$ bit (in the LSB). The R/$\overline{W}$ bit determines the direction of the data transfer:

- R/$\overline{W}$ = 0: The master writes (transmits) data to the addressed slave.
- R/$\overline{W}$ = 1: The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

Figure 25-7. I2C Module 7-Bit Addressing Format

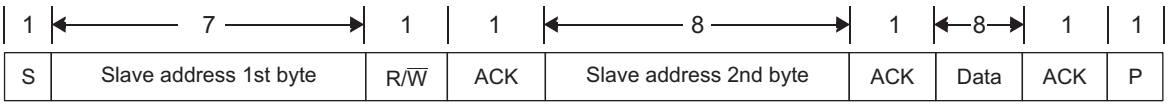


25.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 25-8), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the R/$\overline{W}$ bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

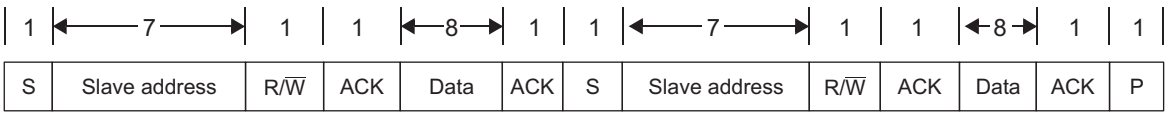
Figure 25-8. I2C Module 10-bit Addressing Format



25.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 25-9). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

Figure 25-9. I2C Module 7-Bit Addressing Format with Repeated START

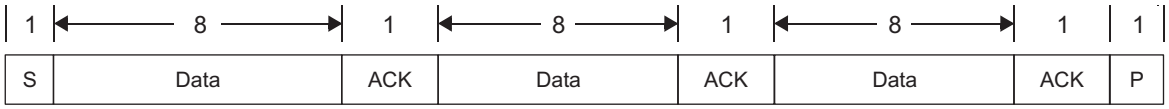


25.2.5.4 Free Data Format

In this format (Figure 25-10), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

Figure 25-10. I2C Module in Free Data Format



25.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 25-1 summarizes the various ways a NACK can be generated.

Table 25-1. Ways to Generate a NACK Bit

I2C Module Condition	Basic NACK Bit Generation Options	Additional Option
Slave receiver mode	Disable data transfers (STT = 0) Allow an overrun condition (RSFULL = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode and repeat mode (RM = 1)	Generate a STOP condition (STP = 1) Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.
Master receiver mode with non-repeat mode (RM = 0)	If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition. If STP = 0, make STP = 1 to generate a STOP condition. Reset the module (IRS = 0)	Set the NACKMOD bit before the rising edge of the last data bit you intend to receive.

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

25.3 I2C Operation Modes

25.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in Figure 25-7, Figure 25-8, or Figure 25-9 is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ($\overline{XSMT}$ = 0) after a byte has been transmitted.

NOTE: If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

25.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in Figure 25-7, Figure 25-8, or Figure 25-9, the master receiver mode is entered after the slave address byte and the R/$\overline{W}$ bit have been transmitted (if the R/$\overline{W}$ bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required (RSFULL = 1) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition (STP =1) after reading the (message size - 1)th data.

25.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in Figure 25-7, Figure 25-8, or Figure 25-9, the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/$\overline{W}$ bit has been transmitted (if the R/$\overline{W}$ bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ($\overline{XSMT}$ = 0) after a byte has been transmitted.

25.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required (RSFULL = 1) after a byte has been received.

25.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module.

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

25.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMDR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

25.3.7 Ignore NACK Mode

The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

25.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

25.4.1 Arbitration

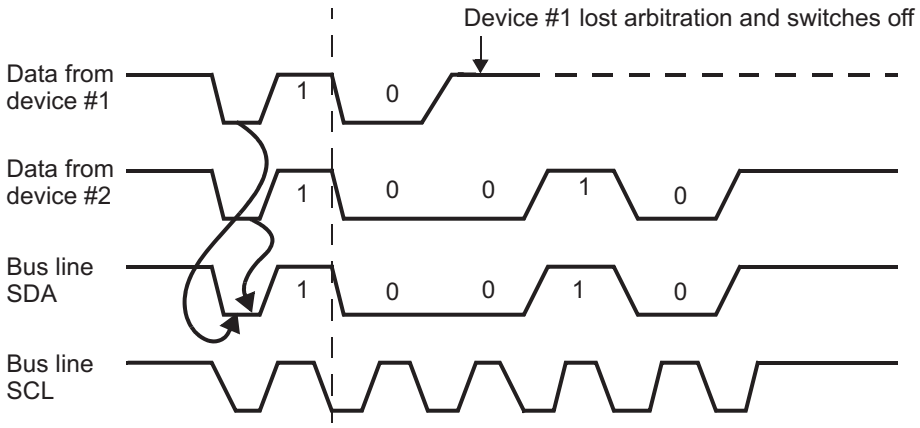
If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. Figure 25-11 illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

Figure 25-11. Arbitration Procedure Between Two Master Transmitters



25.4.2 I2C Clock Generation and Synchronization

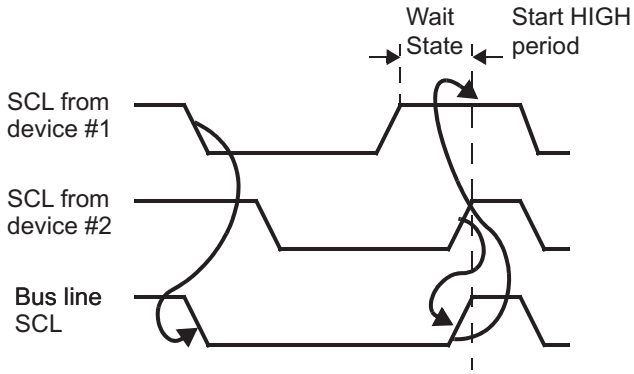
Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 25-12 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

NOTE: I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I²C bus specification, v2.1 (*The I2C Specification,* Philips document number 9398 393 40011), and will result in an I2C protocol fault: I2CCLKH = 2 I2CCLKL = 2I2CPSC = 2. This will cause the SDA data transition to occur while the SCL is high.

Figure 25-12. Synchronization of Two I2C Clock Generators During Arbitration



25.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

25.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

25.5 Operational Information

The following section provides specific information about how the I2C module operates.

25.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

25.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in Table 25-2.

Table 25-2. Interrupt Requests Generated by I2C Module

Flag	Name	Generated
AL	Arbitration-lost interrupt	Generated when the I2C module has lost an arbitration contest with another master-transmitter
NACK	No-acknowledge interrupt	Generated when the master I2C does not receive an acknowledge from the receiver
ARDY	Register-access-ready interrupt	Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.
RXRDY	Receive-data-ready interrupt	Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.
TXRDY	Transmit-data-ready interrupt	Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXSR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR.
SCD	Stop-condition-detect interrupt	Generated when a STOP condition has been detected.
AAS	Address-as-slave interrupt	Generated when the I2C has recognized its own slave address or an address of all zeroes.

The interrupt vector register (I2CIVR) contains the binary-coded-interrupt vector that indicates the highest priority interrupt that is pending and enabled. When I2CIVR is read, the corresponding interrupt flags for AL, NACK and SCD are automatically cleared, if their interrupts are enabled. Reading the I2CIVR will not clear the AAS, ARDY, RXRDY, or TXRDY interrupt pending flags. Please see for the method to clear these four flags.

If more than one interrupt is pending, a new interrupt will be generated for the next highest priority pending interrupt when you re-enable the I2C interrupt.

A transmit interrupt is generated just after the START condition in master transmitter mode. This ensures that the CPU will get an interrupt even if no slave returns an ACK to the slave address following the START condition.

It is important to note that when the I2C is configured to generate interrupts as a slave transmitter and the backward compatibility mode (BCM) bit is set to 1, an extra transmit interrupt occurs. The application should monitor the ACK from the master to determine whether to load another byte into I2CDXR.

25.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXSR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into ICRSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

NOTE: Unexpected DMA transmit and receive event

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

25.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the $\overline{\text{PORRST}}$ pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When $\overline{\text{PORRST}}$ is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

25.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

25.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is disabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

25.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage (V_{OL} or lower), whereas a high value (1) written to the data output register forces the pin to a high-impedance state. The open drain function is disabled when the pin is configured as an input pin.

25.6 MSS_I2C Registers

Table 25-3 lists the memory-mapped I2C registers. All register offset addresses not listed in Table 25-3 should be considered as reserved locations and the register contents should not be modified. The upper word (upper 16 bits) of the registers all read as 0s. Writes have no effect on these bits. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 25-3. MSS_I2C Registers

Offset	Acronym	Register Name	Section
0h	ICOAR	ICOAR	Section 25.6.1

R/W-0h		R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 25-7. ICSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	NU2	R/W	0h	Reserved
14	SDIR	R/W	0h	Slave Direction. This bit is clear to '0' indicating the I2C is a master transmitter/receiver or a slave receiver. This bit is also clear by STOP condition or START condition. It is set to '1' when the I2C slave is a transmitter. In DLB mode (which the configuration should be master-transmitter slave-receiver) this bit is clear to '0'. Writing a"1" to this bit to clear it.
13	NACKSNT	R/W	0h	A No Acknowledge is sent due to NACKMOD is set to a"1". NACKSNT =0: A No Acknowledge is not sent. NACKSNT =1: A No Acknowledge is sent. Writing a"1" to this bit to clear it.
12	BB	R/W	0h	Bus Busy. This bit indicates the state of the serial bus. BB=0: The bus is free. BB=1: The bus is occupied. On reception of a"start" condition the device sets BB to 1. This bit is also set if the I2C detects SCL low state. BB is clear to 0 after reception of a"stop" condition. BB is kept to"0" regardless SCL state when the I2C is in reset (IRS_=0). If the IRS_ is set to"1" during transaction between other I2C devices the BB bit is set at the first falling edge of SCL or START condition. - (RW)
11	RSFULL	R/W	0h	Receive shift full. This bit indicates whether the receiver has experienced overrun. Overrun occurs when the receive shift register (ICRSR) is full and ICDRR has not been read since the ICRSR-to-ICDRR transfer. The FSM is holding for ICDRR read access. RSFULL is clear when reading the ICDRR. RSFULL is set to"1" when the I2C has recognized an overrun. The contents of ICDRR are NOT lost in this case. In repeat mode since double buffer (ICRSR and ICDRR) behaves like a single buffer RSFULL is set to"1" every time the data is received. RSFULL is clear as a result of reading the ICDRR. - (RW)
10	XSMT	R/W	0h	Transmit shift empty not. This bit indicates whether the transmitter has experienced underflow. Underflow occurs when the transmit shift register (ICXSR) is empty and ICDXR has not been loaded. The FSM is holding for ICDXR write access. XSMT_ is cleared when underflow has occurred. XSMT_ is set to"1" as a result of writing to ICDXR. In repeat mode if the I2C in master transmitter mode is holding transfer with XSMT_=0 (i.e. waiting for further action) and the STT or STP bit is set XSMT_ is set to"1" by hardware.

Table 25-7. ICSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	AAS	R/W	0h	Address As Slave. This bit is set to 1 by the device when it has recognized its own slave address or an address of all (8) zeros. The AAS bit is reset by stop condition or detection of any address byte that does not match ICOAR. - (RW)
8	AD0	R/W	0h	Address Zero Status: This bit is set to 1 by device if it detects the address of all (8) zeros (i.e. general call). The AD0 bit is reset to 0 (default value) when a"start" or"stop" condition is detected. - (RW)
7-6	NU1	R/W	0h	Reserved
5	SCD	R/W	0h	Stop Condition Detection bit SCD is set when the I2C sends or receives STOP condition. This bit is cleared by reading ICIVR (as 110) or writing '1' to itself.
4	ICXRDY	R/W	0h	Transmit Data Ready interrupt flag bit. ICXRDY is set to"1" is generated when the transmitted data has been copied from ICDXR to the transmit-shift register (ICXSR). ICRXDY is clear to"0" when the ICDXR is written. This bit can also be polled by the CPU to write a new transmitted data into the ICDXR. Write '1' to this bit will set it and DXR Write will clear it.
3	ICRRDY	R/W	0h	Receive Data Ready interrupt flag bit. ICRRDY is set to"1" when the received data has been copied from ICRSR into the ICDRR. ICRRDY is cleared to"0" when the ICDRR is read. This bit can also be polled by the CPU to read the received data in the ICDRR. Write '1' or DRR Read will clear it.
2	ARDY	R/W	0h	Register-access-ready interrupt flag bit. ARDY is generated by the hardware if the I2C is in the master mode when the previously programmed data and command has been performed and status bit has been updated. This flag is used by the CPU to let it knows that the I2C registers are ready to be accessed again. When RM=0 ARDY is set when the internal data count is passed 0 if STP register bit has not been set. When RM=1 ARDY is set at each byte end. If the I2C is in FDF mode(FDF=1) ARDY is set just after Start condition. This bit is automatically cleared by hardware when writing data to ICDXR in transmit mode reading data from ICDRR in receive mode or setting STT or STP bit. Write '1' will clear it.
1	NACK	R/W	0h	No-Acknowledgement interrupt flag bit. The No Acknowledge flag bit is set when the hardware in "master" mode detects no acknowledge has been received. This bit is NOT set by no-acknowledgement after Start byte Write '1' or Read the ICIVR (as 010) will clear it.
0	AL	R/W	0h	Arbitration-Lost interrupt flag bit. The Arbitration Lost flag bit is set to 1 when the device in the "master" mode senses it has lost an arbitration when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB (bus busy) is 1. When this is set to 1 due to arbitration lost the MST/STT/STP bits are clear the I2C becomes a slave. Write '1' or Read the ICIVR (as 001) will clear it.

25.6.4 ICCLKL Register (Offset = Ch) [reset = 0h]

ICCLKL is shown in Figure 25-16 and described in Table 25-8.

Return to Summary Table.

I2C Clock Divider Low register

Figure 25-16. ICCLKL Register

R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

Table 25-14. ICMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NU2	R/W	0h	Reserved
15	NACKMOD	R/W	0h	No Acknowledge (NACK) mode. This bit is used to send an Acknowledge (ACK) or a No Acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode when the internal data count counter decrements to zero the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is '1'. The NACKMOD bit should be set before the rising edge of the last data bit (bit 8) if a NACK must be sent and this bit is cleared once a NACK has been sent. NACKMOD=0 the I2C sends an ACK to the transmitter during the acknowledge cycle. NACKMOD=1 the I2C sends a NACK to the transmitter during the acknowledge cycle.
14	FREE	R/W	0h	Free Running. This bit is used to determine the state of the I2C when a breakpoint is encountered in the HLL debugger. FREE=0: (default) Stops immediately if SCL is low and keep driving SCL low whether I2C is master transmitter/receiver. If SCL is high I2C waits until SCL becomes low and then stops. If the I2C is a slave it will stop when the transmission/receiving completes. FREE=1: The I2C runs free.
13	STT	R/W	0h	Start Condition (Master only mode). This bit can be set to a"1" by the CPU to generate a Start condition. In master mode when setting Start to"1" generates a Start condition. It is reset to "0" by the hardware after the Start condition has been generated. The Start/Stop bits can be configured to generate different transfer formats. Note that the STT and STP can be used to terminate the repeat mode. STT___STP____Conditions_____Bus Activities _1_____0_____Start_____S-A-D _0_____1_____Stop_____P _1_____1_____Start-Stop (ICCNT= n)_____S-A-D..(n)..D-P _1_____0_____Start (ICCNT= n)_____S-A-D..(n)..D
12	NU1	R/W	0h	Reserved for IDLEEN (IDLE Enable on 5509). - (RW)

Table 25-14. ICMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	Stop Condition (Master mode only). This bit can be set to a"1" by the CPU to generate a Stop condition. It is reset to "0" by the hardware after the Stop condition has been generated. The Stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode(RM=0).
10	MST	R/W	0h	Master. MST=0: The I 2 C peripheral is in the"slave" mode and clock is received from the"master" device. MST=1: The I 2 C peripheral is in the"master" mode and it generates the clock. This bit is clear when the transfer completed.
9	TRX	R/W	0h	Transmitter. TRX=0: The I 2 C is in the"receiver" mode and data on data line SDA is shifted into the data register ICDRR. TRX=1: The I 2 C is in the"transmitter" mode and the data in ICDXR is shifted out on data line SDA. The operating modes (not in FDF mode) are defined as follows. In FDF mode TRX must be configured even if the I2C is in slave mode because there is no address/direction byte in FDF mode. _____ MST___TRX___Operating Modes _0_____x_____"slave receiver" _0_____x_____"slave transmitter" _1_____0_____"master receiver" _1_____1_____"master transmitter" _____
8	XA	R/W	0h	Expanded Address. XA=0: (default) 7-bit address mode (normal address mode). XA=1: 10-bit address mode (expanded address mode) Please note that XA needs to be configured even if the I2C is in slave mode.
7	RM	R/W	0h	Repeat Mode. This bit is set to a"1" by the CPU to put the I2C in the repeat mode. In this mode data is continuously transmitted out of the ICDXR until the STP bit is set to"1" regardless of ICCNT value. This bit is don"t care if the I2C is configured in slave mode. _____ __ RM___STT___STP___Conditions_____Bus Activities_____Mode _0_____0_____0_____Idle_____None_____NA _0_____0_____1_____Stop_____P_____NA _0_____1_____0_____(Re)Start_____S-A-D..(n)..D____Repeat n _0_____1_____1_____(Re)Start-Stop___S-A-D..(n)..D-P__Repeat n _1_____0_____0_____Idle_____none_____NA _1_____0_____1_____Stop_____P _____NA _1_____1_____0_____(Re)Start_____S-A-D-D-D..._____Continuous _1_____1_____1_____Reserved_____None_____NA _____ __
6	DLB	R/W	0h	Digital Loop Back (in master transmit mode only). This bit is set to a"1" by the CPU to put the I2C in the loop back mode. In this mode data transmitted out of the ICDXR will be received in the ICDRR after ((CPU freq/I2C freq)8) CPU cycles via an internal path. The address of the ICOAR is output on SDA.
5	IRS	R/W	0h	I2C Reset Not. This can be set to a"0" by the CPU to put the I2C in reset or to a"1" to take the I2C out of reset. When this bit is reset to 0 all status bits in ICSTR and ICIVR are set to default values. Note that if this bit is reset during a transfer it can cause the I2C bus hang (SDA and SCL are tri-stated).
4	STB	R/W	0h	Start Byte (Master only mode). The Start Byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode the I2C sends "00000001" regardless ICSAR value. Refer to the Philip I2C spec for more details.

Table 25-14. ICMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	FDF	R/W	0h	Free Data Format. This bit can be set to"1" by the CPU to configure the I2C in Free Data Format mode. FDF___MST___TRX_____Operating mode _0_____0_____ x____Slave in non FDF mode _0_____1_____0____Master receive in non FDF mode _0_____1_____1____Master transmit in non FDF mode _1_____0_____0____Slave receiver in FDF mode _1_____0_____1____Slave transmitter in FDF mode _1_____1_____0____Master receiver in FDF mode _1_____1_____1____Master transmitter in FDF mode

26.3 SCI Interrupts **3242**
26.4 SCI DMA Interface **3245**
26.5 SCI Configurations **3246**
26.6 SCI Low Power Mode **3248**
26.7 SCI Control Registers **3250**
26.8 GPIO Functionality **3280**

26.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

26.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

NOTE: SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

26.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

Transmitter (TX) contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VBUSP CLK.

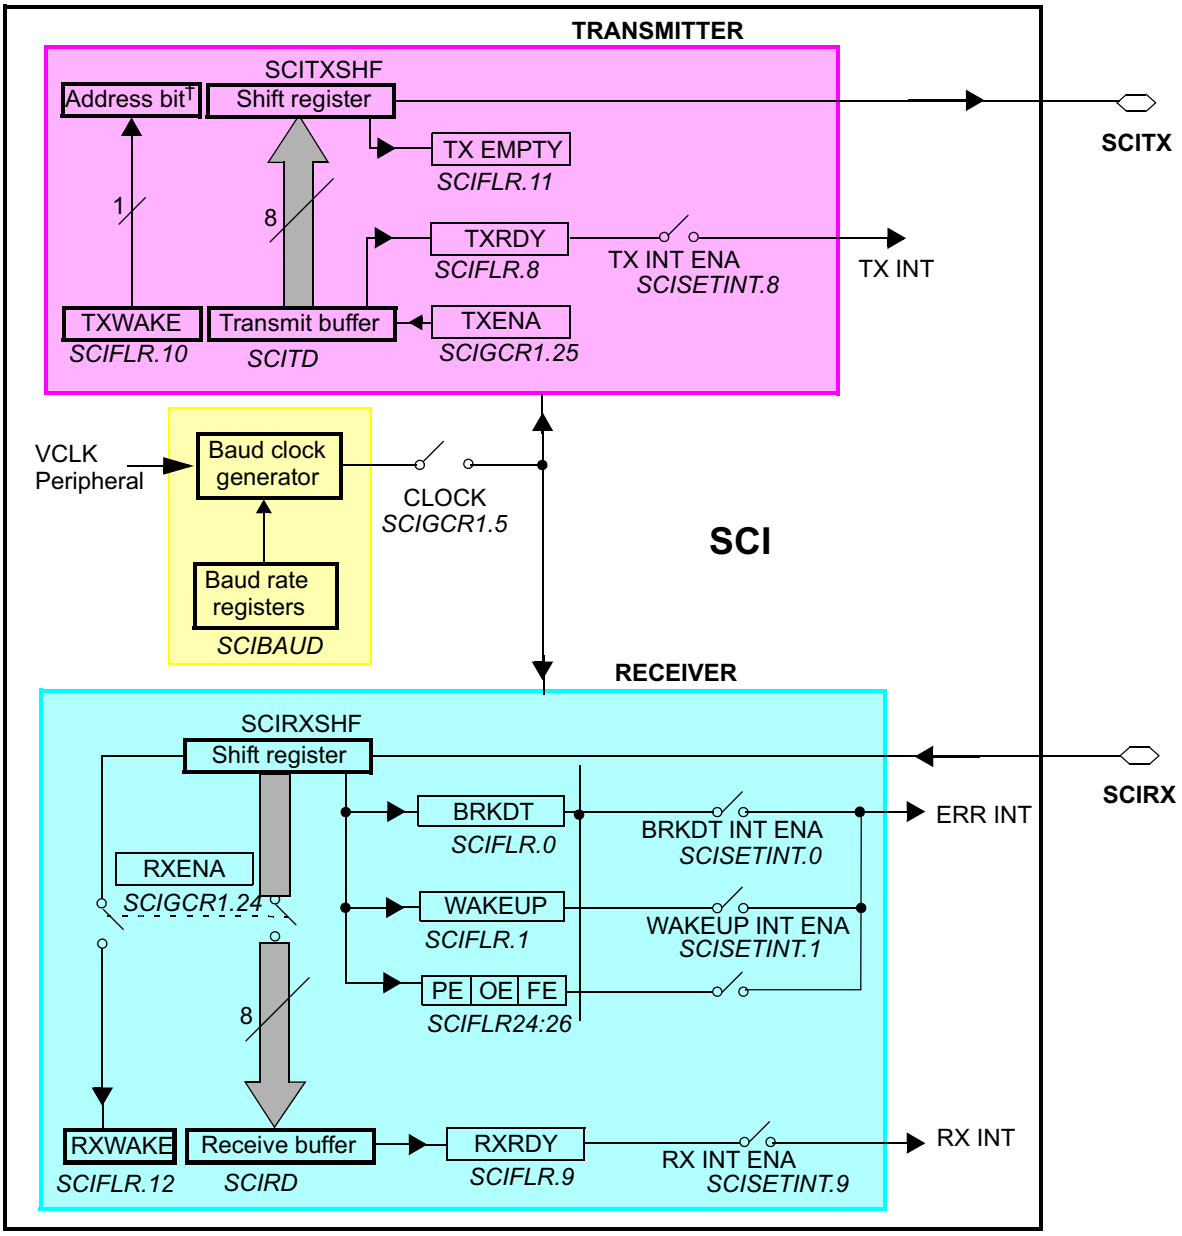
Receiver (RX) contains two major registers to perform double buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 26-1 shows the detailed SCI block diagram.

Figure 26-1. Detailed SCI Block Diagram



26.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

26.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

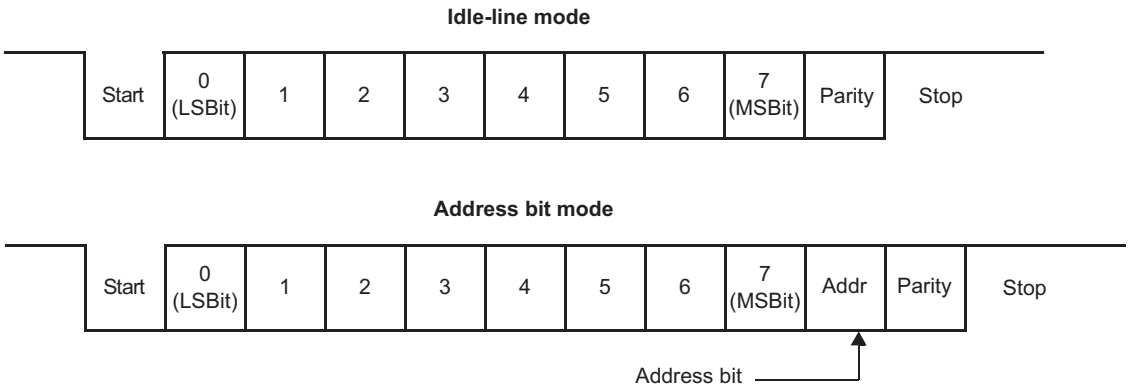
The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 26-2.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in Figure 26-2 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 26-2 use one stop bit per frame.

Figure 26-2. Typical SCI Data Frame Formats



26.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

26.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.

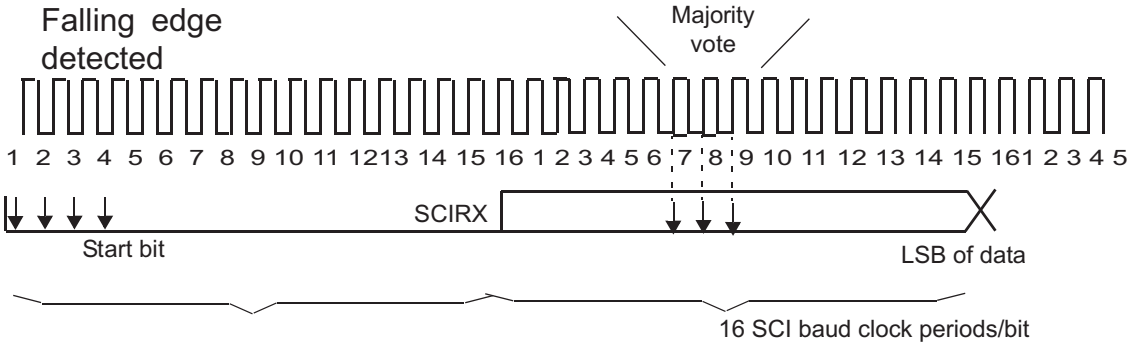
In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 26-3 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

Figure 26-3. Asynchronous Communication Bit Timing



26.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

26.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value in the BRS register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Asynchronous baud value} = \frac{\text{VBUSPCLK Frequency}}{16\ \text{BAUD} + 1}$$

For BAUD = 0,

$$\textit{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (15)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\textit{Isosynchronous baud value} = \frac{\text{VBUSPCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\textit{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (16)$$

26.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

NOTE: Avoid Transmitting Simultaneously on the Same Serial Bus

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

26.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 26-4 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step1 : Write a 1 to the TXWAKE bit.

Step2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

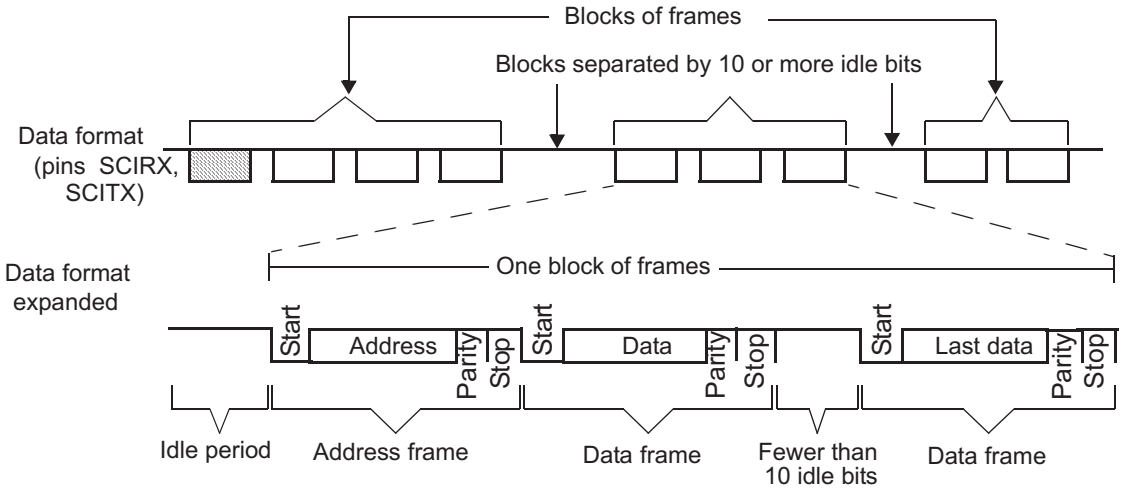
Step3 : Wait for the SCI to clear the TXWAKE flag.

Step4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

Figure 26-4. Idle-Line Multiprocessor Communication Format



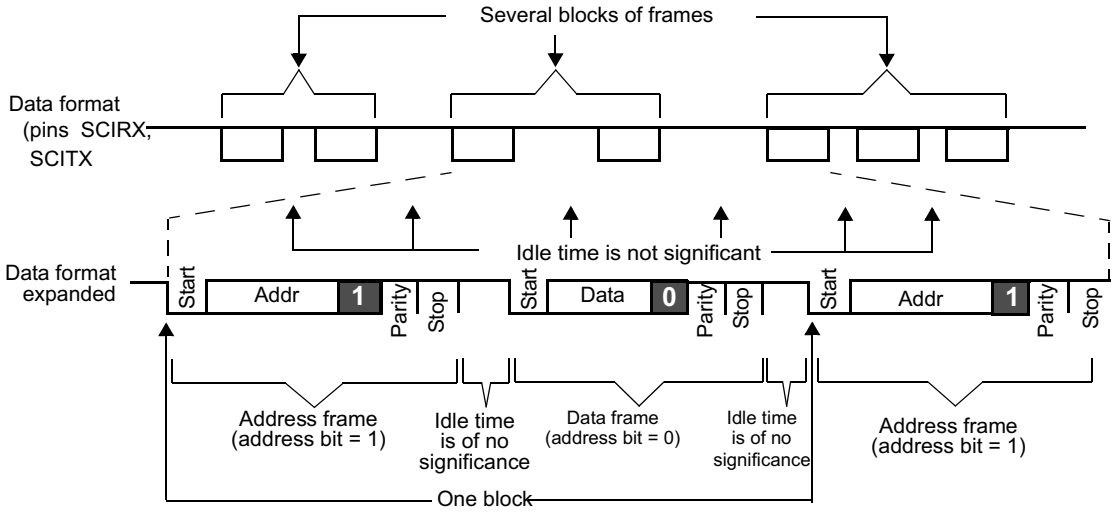
26.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 26-5 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

Figure 26-5. Address-Bit Multiprocessor Communication Format



26.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 26-6). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

Figure 26-6. General Interrupt Scheme

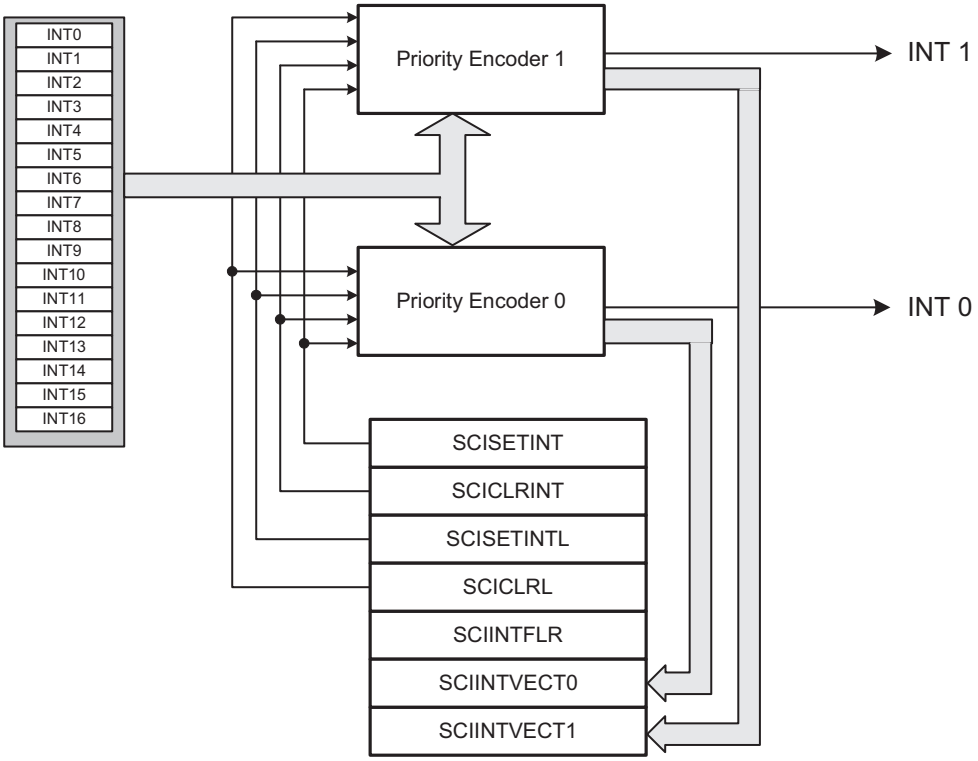


Figure 26-7. Interrupt Generation for Given Flags

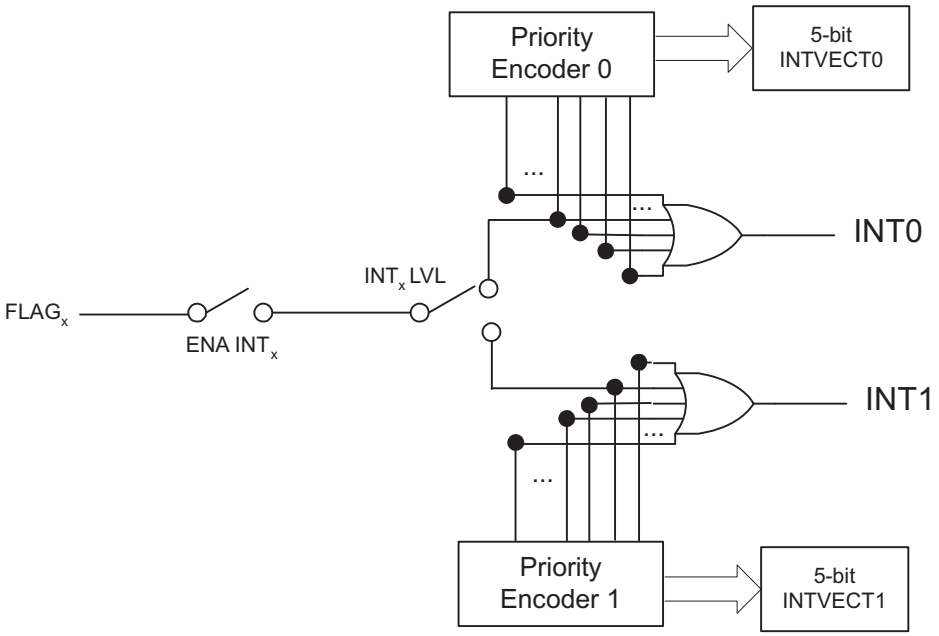

26.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

26.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

26.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interupt is triggered once WAKEUP flag is set.

26.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If any of these errors (PE, FE, BRKDT, OE) is flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports following 7 interrupts as seen in Table 26-1.

Table 26-1. SCI Interrupts

Offset [1]	Interrupt
0	Reserved
1	Wakeup
2	Reserved
3	Parity error
4	Reserved
5	Reserved
6	Frame error
7	Break detect error
8	Reserved
9	Overrun error
10	Reserved
11	Receive
12	Transmit
13 - 15	Reserved

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

26.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

26.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. Table 26-2 specifies the bit values for DMA requests in multiprocessor modes.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

Table 26-2. DMA and Interrupt Requests in Multiprocessor Modes

SET RX INT	SET RX DMA	SET RX DMA ALL	ADDR FRAME INT	ADDR FRAME DMA	DATA FRAME INT	DATA FRAME DMA
0	0	x	N	N	N	N
0	1	0	Y	N	N	Y
0	1	1	N	Y	N	Y
1	0	x	Y	N	Y	N
1	1	0	Y	N	Y	Y
1	1	1	Y	Y	Y	Y

26.4.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits. If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set. In other words, CPU needs to write the first data to start a DMA block transfer. For example, we want to transmit a data buffer of 20 bytes. DMA will be set up to transmit 19 bytes. The first data for DMA to transfer is the second byte in the buffer. CPU will have to write the first byte in the buffer to the SCITD register to start the transfer.

.

26.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit is set to 1. Of particular importance is the SWnRST bit. This active-low bit is initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 (one) is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as SWnRST is held low the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting RESET bit.
- Clear SWnRST to 0 before configuring the SCI.
- Select the desired frame format by programming SCIGCR1.
- Configure the SCIRX and SCITX pins for SCI functionality by setting the RX FUNC and TX FUNC bit.
- Select the baud rate to be used for communication by programming BRS.
- Select internal clock by programming the CLOCK bit.
- Set the CONT bit to make SCI not to halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Set SWnRST to 1 after the SCI is configured.
- Perform Receive or Transmit data (see Section 26.5.1 and Section 26.5.2).

26.5.1 Receiving Data

The SCI receiver is enabled to receive messages if the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets FE, OE, or PE if any of these error conditions were detected in the received data. These error conditions are supported with configurable Interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

User can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for RXRDY bit and read the data from SCIRD register once RXRDY is set high. CPU is unnecessarily overloaded by selecting Polling mode. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET RX INT bit should be set and to use DMA SET RX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment RXRDY is set.

26.5.2 Transmitting Data

The SCI transmitter is enabled if the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits it. The flags TXRDY and TX EMPTY indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

User can transmit data by:

1. Polling Transmit Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for TXRDY bit to go high before writing the data to SCITD register. CPU is unnecessarily overloaded by doing this Polling method. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET TX INT bit should be set and to use DMA SET TX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment TXRDY is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can be done by either disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

NOTE: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

26.6 SCI Low Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

NOTE: Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

26.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 26-11) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

26.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in Table 26-3. Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 26-3. SCI Control Registers Summary

Offset	Acronym	Register Description	Section
00h	SCIGCR0	SCI Global Control Register 0	Section 26.7.1

26.7.1 SCI Global Control Register 0 (SCIGCR0)

The SCIGCR0 register defines the module reset. Figure 26-8 and Table 26-4 illustrate this register.

Figure 26-8. SCI Global Control Register 0 (SCIGCR0) [offset = 00]

Table 26-4. SCI Global Control Register 0 (SCIGCR0) Fied Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Read returns 0. Writes have no effect.
0	RESET		This bit resets the SCI module.
		0	SCI module is in reset.
		1	SCI module is out of reset.
			Note: Read/Write in privileged mode only.

26.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 26-9 and Table 26-5 illustrate this register.

Figure 26-9. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -*n* = value after reset

NOTE: The SCIGCR1 Control Register Bits should not be changed during Frame Transmission or Reception.

Table 26-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Read returns 0. Writes have no effect.
25	TXENA		Transmit enable. Data is transferred from SCITD to the SCITXSHF shift out register only when the TXENA bit is set.
		0	Disable transfers from SCITD to SCITXSHF.
		1	Enable SCI to transfer data from SCITD to SCITXSHF.
			Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent.
24	RXENA		Receive enable. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD.
		0	The receiver will not transfer data from the shift buffer to the receive buffer.
		1	The receiver will transfer data from the shift buffer to the receive buffer.
			Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.
			Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.
			Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not assured to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.
23-18	Reserved	0	Read returns 0. Writes have no effect.
17	CONT		Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI operates when the program is suspended. The
		0	When debug mode is entered, the SCI state machine is frozen. Transmissions are halted and resume when debug mode is exited.
		1	When debug mode is entered, the SCI continues to operate until the current transmit and receive functions are complete.

Table 26-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
16	LOOP BACK		Loopback bit. The self-checking option for the SCI can be selected with this bit. If the SCITX and SCIRX pins are configured with SCI functionality, then the SCITX pin is internally connected to the SCIRX pin. Externally, during loop back operation, the SCITX pin outputs a high value and the SCIRX pin is in a high-impedance state. If this bit value is changed while the SCI is transmitting or receiving data, errors may result.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled.
15-10	Reserved	0	Read returns 0. Writes have no effect.
9	POWERDOWN		Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.
		0	Normal operation.
		1	Low-power mode is enabled.
8	SLEEP		SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.
		0	Sleep mode is disabled.
		1	Sleep mode is enabled.
			Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.
			Note: The SLEEP bit is not automatically cleared when an address byte is detected.
			See Section 26.6.1 for more information on using the SLEEP bit for multiprocessor communication.
7	SWnRST		Software reset (active low).
		0	The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 26-11 and Table 26-12. All affected logic is held in the reset state until a 1 is written to this bit.
		1	The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.
			Note: The SCI should only be configured while SWnRESET = 0.
6	Reserved	0	Read returns 0. Writes have no effect.
5	CLOCK		SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.
		0	The external SCICLK is the clock source.
		1	The internal SCICLK is the clock source.
			Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.
4	STOP		SCI number of stop bits per frame.
		0	One stop bit is used.
		1	Two stop bits are used.
			Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.

Table 26-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)

Bit	Field	Value	Description
3	PARITY		SCI parity odd/even selection. If the PARITY ENA bit is set, PARITY designates odd or even parity.
		0	Odd parity is used.
		1	Even parity is used.
			The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.
			For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.
			For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITY ENA		Parity enable. This bit enables or disables the parity function.
		0	Parity is disabled; no parity bit is generated during transmission or is expected during reception.
		1	Parity is enabled. A parity bit is generated during transmission and is expected during reception.
1	TIMING MODE		SCI timing mode bit.
		0	Synchronous timing is used.
		1	Asynchronous timing is used.
0	COMM MODE		SCI communication mode bit.
		0	Idle-line mode is used.
		1	Address-bit mode is used.

26.7.3 SCI Set Interrupt Register (SCISETINT)

Figure 26-10 and Table 26-6 illustrate this register. SCISETINT register is used to enable the required interrupts supported by the module.

Figure 26-10. SCI Set Interrupt Register (SCISETINT) [offset = 0Ch]

31	27	26	25	24

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Read returns 0. Writes have no effect.
26	SET FE INT		Set framing-error interrupt. Setting this bit enables the SCI module to generate an interrupt when a framing error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
25	SET OE INT		Set overrun-error interrupt. Setting this bit enables the SCI module to generate an interrupt when an overrun error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
24	SET PE INT		Set parity interrupt. Setting this bit enables the SCI module to generate an interrupt when a parity error occurs.
		0	*Read:* The interrupt is disabled. *Write:* No effect.
		1	*Read or write:* The interrupt is enabled.
23-19	Reserved	0	Read returns 0. Writes have no effect.
18	SET RX DMA ALL		Set receive DMA all. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.
		0	*Read:* The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames). *Write:* No effect.
		1	*Read or write:* The DMA request is enabled for address and data frames
17	SET RX DMA		Set receiver DMA. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on bit SCISETINT.
		0	*Read:* The DMA request is disabled. *Write:* No effect.
		1	*Read or write:* The DMA request is enabled for address and data frames

Table 26-6. SCI Set Interrupt Register (SCISETINT) Field Descriptions (continued)

Bit	Field	Value	Description
16	SET TX DMA		Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SET TX INT bit (SCISETINT).
		0	*Read:* Transmit DMA request is disabled.
			Write: No effect.
		1	*Read or write:* Transmit DMA request is enabled.
15-10	Reserved	0	Read returns 0. Writes have no effect.
9	SET RX INT		Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
8	SET TX INT		Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
7-2	Reserved	0	Read returns 0. Writes have no effect.
1	SET WAKEUP INT		Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit lowpower mode. If enabled, the wakeup interrupt is asserted when local lowpower mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during lowpower mode.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.
0	SET BRKDT INT		Set breakdetect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin.
		0	*Read:* The interrupt is disabled.
			Write: No effect.
		1	*Read or write:* The interrupt is enabled.

26.7.4 SCI Clear Interrupt Register (SCICLEARINT)

Figure 26-11 and Table 26-7 illustrate this register. SCICLEARINT register is used to clear the selected enabled interrupts with out accessing SCISETINT register.

Figure 26-11. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved		Read returns 0. Writes have no effect.
26	FE		Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit (SCISETINT[26]). The framing error flag is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 • Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode In multi-buffer mode the frame is defined in the SCIFORMAT register.
		0	*Read:* No framing error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A framing error has been detected since the last clear. *Write:* The bit is cleared to 0.
25	OE		Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit (SCISETINT[25]) is set. The OE flag is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No overrun error has been detected since the last clear. *Write:* No effect.
		1	*Read:* An overrun error has been detected since the last clear. *Write:* The bit is cleared to 0.

Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
24	PE		Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit (SCISETINT[24]) is set. The PE bit is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively. • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No parity error has been detected since the last clear. *Write:* No effect.
		1	*Read:* A parity error has been detected since the last clear. *Write:* The bit is cleared to 0.
23-13	Reserved	0	Read returns 0. Writes have no effect.
12	RXWAKE		Receiver wakeup detect flag. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Upon receipt of a data frame.
		0	The data in SCIRD is not an address.
		1	The data in SCIRD is an address.
11	TX EMPTY		Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. **Note: The RESET bit, an active SW nRESET (SCIGCR1[7]), or a system reset sets this bit. This bit does not cause an interrupt request.**
		0	Transmitter buffer or shift register (or both) are loaded with data.
		1	Transmitter buffer and shift registers are both empty.
10	TXWAKE		Transmitter wakeup method select. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. **Note: TXWAKE is not cleared by the SW nRESET bit.** *Address-bit mode*
		0	Frame to be transmitted will be data (address bit = 0).
		1	Frame to be transmitted will be an address (address bit = 1).
			Idle-line mode
		0	The frame to be transmitted will be data.
		1	The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).

Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
9	RXRDY		Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit (SCISETINT[9]) is set. RXRDY is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the SCIRD register in compatibility mode • Reading the last data byte RDy of the response in LIN mode **Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.**
		0	*Read:* No new data is in SCIRD. *Write:* No effect.
		1	*Read:* New data is ready to be read from SCIRD. *Write:* The bit is cleared to 0.
8	TXRDY		Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write. Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the interrupt enable bit TXINT is set. **Note: 1) TXRDY is also set to 1 by setting of the RESET bit, enabling SW nRST, or by a system reset.** **2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.** **3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1[25]).**
		0	SCITD is full.
		1	SCITD is ready to receive the next character.
7-4	Reserved	0	Read returns 0. Writes have no effect.
3	BUSY		Bus busy flag. TThis bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If SET WAKEUP INT bit (SCISETINT[2]) is set and power down is requested while this bit is set, the SCI automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following: • Setting the SW nRST bit • Setting of the RESET bit • A system reset occurring
		0	The receiver is not currently receiving a frame.
		1	The receiver is currently receiving a frame.
2	IDLE		SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs: • A system reset • An SCI software reset • A power down • The RX pin is configured as a general I/O pin
		0	The idle period has been detected; the SCI is ready to receive.
		1	The idle period has not been detected; the SCI will not receive any data.

Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)

Bit	Field	Value	Description
1	WAKEUP		Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT[2]) is set. It is cleared by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1 For compatibility mode, see the SCI document for more information on low-power mode.
		0	*Read:* The module will not wake up from power-down mode. *Write:* No effect.
		1	*Read:* Wake up from power-down mode. *Write:* The bit is cleared to 0.
0	BRKDT		SCI break-detect flag. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit (SCISETINT[0]) is set. The BRKDT bit is reset by the following: • Setting of the SW nRST bit • Setting of the RESET bit • A system reset • Writing a 1 to this bit • Reading the corresponding interrupt offset in SCIINTVECT0/1
		0	*Read:* No break condition has been detected since the last clear. *Write:* No effect.
		1	*Read:* A break condition has been detected. *Write:* The bit is cleared to 0.

Table 26-11. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After SW nRESET (1)
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with their reset value while SW nRESET = 0.

Table 26-12. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After SW nRESET (1)
TX EMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with their reset value while SW nRESET = 0.

26.7.8 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

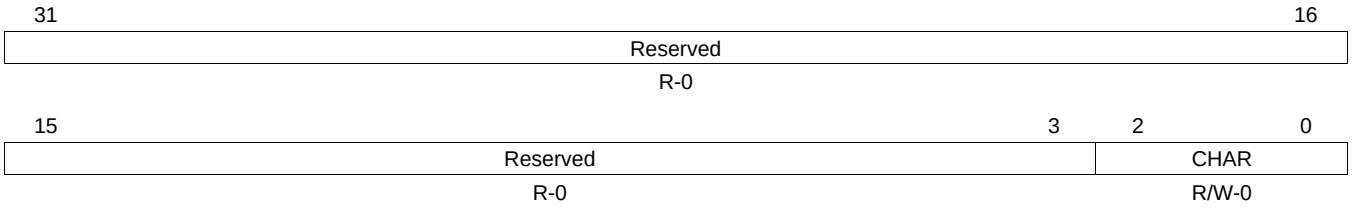
Table 26-14. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Read returns 0. Writes have no effect.
3-0	INVECT1	0-Fh	Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 26-1 for list of interrupts. **Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).**

26.7.10 SCI Format Control Register (SCIFORMAT)

Figure 26-17 and Table 26-15 illustrate this register.

Figure 26-17. SCI Format Control Register (SCIFORMAT) [offset = 28h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-15. SCI Format Control Register (SCIFORMAT) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read returns 0. Writes have no effect.
2-0	CHAR		Character length control bits. These bits set the SCI character length from 1 to 8 bits. **When data of fewer than eight bits in length is received, it is left-justified in SCIRD and padded with trailing zeros.** **Data read from the SCIRD should be shifted by software to make the received data right-justified.** **Data written to the SCITD should be right-justified but does not need to be padded with leading zeros.**
		0	The character is 1 bit long.
		1h	The character is 2 bits long.
		2h	The character is 3 bits long.
		3h	The character is 4 bits long.
		4h	The character is 5 bits long.
		5h	The character is 6 bits long.
		6h	The character is 7 bits long.
		7h	The character is 8 bits long.

26.7.11 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. Figure 26-18 and Table 26-16 illustrate this register.

Figure 26-18. Baud Rate Selection Register (BRS) [offset = 2Ch]

31	24	23	16
Reserved		BAUD	
R-0		R/W-0	

15	0
BAUD	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 26-16. Baud Rate Selection Register (BRS) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Read returns 0. Writes have no effect.
23-0	BAUD	0-FF FFFFh	SCI 24-bit baud selection. The SCI has an internally generated serial clock determined by the VCLK and the prescalers BAUD in this register. The SCI uses the 24-bit integer prescaler BAUD value of this register to select one of over 16,700,000. The baud rate can be calculated using the following formulas: $\text{Asynchronous baud value} = \left(\frac{\text{VBUSPLCK Frequency}}{16(\text{Baud} + 1)}\right)$ (17) $\text{Isosynchronous baud value} = \left(\frac{\text{VBUSPLCK Frequency}}{\text{Baud} + 1}\right)$ (18) For BAUD = 0, $\text{Asynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{32}\right)$ (19) $\text{Isosynchronous baud value} = \left(\frac{\text{VCLK Frequency}}{2}\right)$ (20) Table 26-17 contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode..

Table 26-17. Comparative Baud Values for Different P Values, Asynchronous Mode [(1)(2)]

24-Bit Register Value		Baud Selected		Percent Error
Decimal	Hex	Ideal	Actual	
26	00001A	115200	115740	0.47
53	000035	57600	57870	0.47
80	000050	38400	38580	0.47
162	0000A2	19200	19172	-0.15
299	00012B	10400	10417	0.16
325	000145	9600	9586	-0.15
399	00018F	7812.5	7812.5	0.00
650	00028A	4800	4800	0.00
15624	003BA0	200	200	0.00
624999	098967	5	5	0.00

(1) VCLK = 50 MHz
(2) Values are in decimal except for column 2.

26.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

26.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. Figure 26-19 and Table 26-18 illustrate this register.

Figure 26-19. Receiver Emulation Data Buffer (SCIED) [offset = 30h]

31								16
Reserved								
R-0								
15				8	7			0
Reserved					ED			
R-0					R-0			

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Read returns 0. Writes have no effect.
7-0	ED	0-FFh	Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag (SCIFLR[9]), unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag.

26.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. Figure 26-20 and Table 26-19 illustrate this register.

Figure 26-20. Receiver Data Buffer (SCIRD) [offset = 34h]

31								16
Reserved								
R-0								
15				8	7			0
Reserved					RD			
R-0					R-0			

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-19. Receiver Data Buffer (SCIRD) Field Descriptions

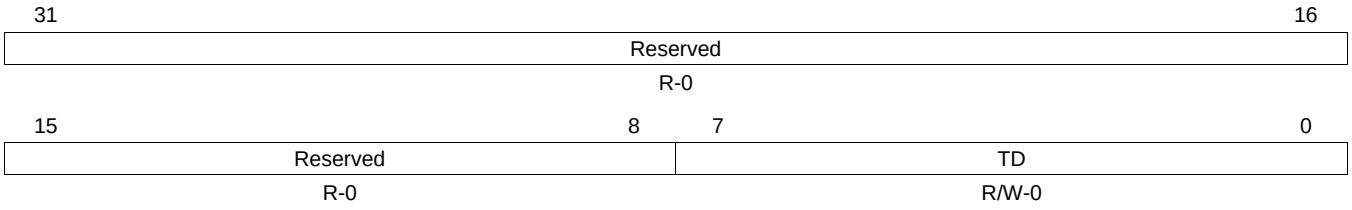
Bit	Field	Value	Description
31-8	Reserved	0	Read returns 0. Writes have no effect.
7-0	RD	0-FFh	Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag (SCIFLR[9]) is set and a receive interrupt is generated if SET RX INT bit (SCISETINT[9]) is set. **Note: When the data is read from SCIRD, the RXRDY flag (SCIFLR[9]) is automatically cleared.**

NOTE: When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

26.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. Figure 26-21 and Table 26-20 illustrate this register.

Figure 26-21. Transmit Data Buffer Register (SCITD) [offset = 38h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-20. Transmit Data Buffer Register (SCITD) Field Descriptions

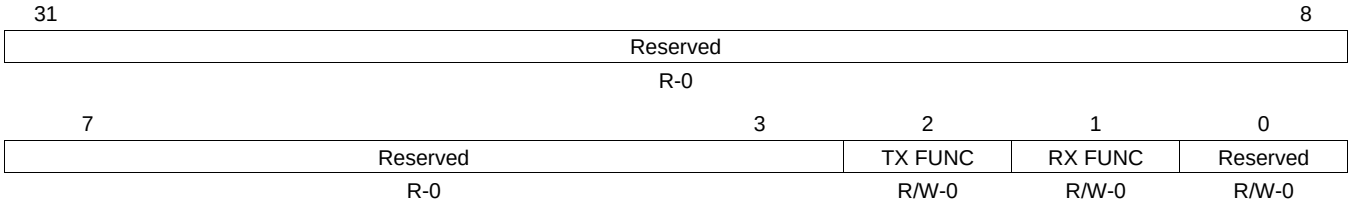
Bit	Field	Value	Description
31-8	Reserved	0	Read returns 0. Writes have no effect.
7-0	TD	0-FFh	Transmit data. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag (SCIFLR[8]), which indicates that SCITD is ready to be loaded with another byte of data. **Note: If SET TX INT bit (SCISETINT[8] is set, this data transfer also causes an interrupt.**

NOTE: Data written to the SCITD register that is fewer than eight bits long must be right-justified, but it does not need to be padded with leading zeros.

26.7.13 SCI Pin I/O Control Register 0 (SCIPIO0)

Figure 26-22 and Table 26-21 illustrate this register.

Figure 26-22. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 26-21. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read returns 0. Writes have no effect.
2	TX FUNC		Transfer function. This bit defines the function of pin SCITX.
		0	SCITX is a general-purpose digital I/O pin.
		1	SCITX is the SCI transmit pin.
1	RX FUNC		Receive function. This bit defines the function of pin SCIRX.
		0	SCIRX is a general-purpose digital I/O pin.
		1	SCIRX is the SCI receive pin.
0	Reserved	0	Writes have no effect.

26.7.14 SCI Pin I/O Control Register 1 (SCIPIO1)

Figure 26-23 and Table 26-22 illustrate this register.

Figure 26-23. SCI Pin I/O Control Register 1 (SCIPIO1) [offset = 40h]

Table 26-22. SCI Pin I/O Control Register 1 (SCIPIO1) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read returns 0. Writes have no effect.
2	TX DIR		Transmit pin direction. This bit determines the data direction on the SCITX pin if it is configured with general-purpose I/O functionality (TX FUNC = 0). See Table 26-23 for the SCITX pin control with this bit and others.
		0	SCITX is a general-purpose input pin.
		1	SCITX is a general-purpose output pin.
1	RX DIR		Receive pin direction. This bit determines the data direction on the SCIRX pin if it is configured with general-purpose I/O functionality (RX FUNC = 0). See Table 26-24 for the SCIRX pin control with this bit and others.
		0	SCIRX is a general-purpose input pin.
		1	SCIRX is a general-purpose output pin.
0	Reserved	0	Writes have no effect.

Table 26-23. SCITX Pin Control

Function	TX IN [1]	TX OUT	TX FUNC	TX DIR
SCITX	X	X	1	X
General-purpose input	X	X	0	0
General-purpose output, high	X	1	0	1
General-purpose output, low	X	0	0	1

(1) TX IN is a read-only bit. Its value always reflects the level of the SCITX pin.

Table 26-24. SCIRX Pin Control

Function	RX IN [1]	RX OUT	RX FUNC	RX DIR
SCIRX	X	X	1	X
General-purpose input	X	X	0	0
General-purpose output, high	X	1	0	1
General-purpose output, low	X	0	0	1

(1) RX IN is a read-only bit. Its value always reflects the level of the SCIRX pin.

26.7.15 SCI Pin I/O Control Register 2 (SCIPIO2)

Table 26-26. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Read returns 0. Writes have no effect.
2	TX OUT		Transmit pin out. This pin specifies the logic to be output on pin SCITX if the following conditions are met: • TX FUNC = 0 (SCITX pin is a general-purpose I/O.) • TX DIR = 1 (SCITX pin is a general-purpose output.) See Table 26-23 for an explanation of this bit's effect in combination with other bits.
		0	The output on the SCITX is at logic low (0).
		1	The output on the SCITX pin is at logic high (1). (Output voltage is V_{OH} or higher if TXPDR = 0 and output is in high impedance state if TXPDR = 1)
1	RX OUT		Receive pin out. This bit specifies the logic to be output on pin SCIRX if the following conditions are met: • RX FUNC = 0 (SCIRX pin is a general-purpose I/O.) • RX DIR = 1 (SCIRX pin is a general-purpose output.) See Table 26-24 for an explanation of this bit's effect in combination with the other bits.
		0	The output on the SCIRX pin is at logic low (0).
		1	The output on the SCIRX pin is at logic high (1). (Output voltage is V_{OH} or higher if RXPDR = 0, and output is in high impedance state if RXPDR = 1)
0	Reserved	0	Writes have no effect.

26.7.17 SCI Pin I/O Control Register 4 (SCIPIO4)

Bit	Field	Value	Description
31-3	Reserved	0	Read returns 0. Writes have no effect.
2	TX PSL		TX pin pull select. This bit selects pull type in the input pin SCITX.
		0	The SCITX pin is a pull down.
		1	The SCITX pin is a pull up.
1	RX PSL		RX pin pull select. This bit selects pull type in the input pin SCIRX.
		0	The SCIRX pin is a pull down.
		1	The SCIRX pin is a pull up.
0	Reserved	0	Writes have no effect.

26.7.22 Input/Output Error Enable (IODFTCTRL) Register

Figure 26-31 and Table 26-32 illustrate this register. After the basic SCI module configuration, enable the required Error mode to be created followed by IODFT Key enable.

NOTE:

1. All the bits are used in IODFT mode only.
2. Each IODFT are expected to be checked individually.

Figure 26-31. Input/Output Error Enable Register (IODFTCTRL) [offset = 90h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 26-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Read returns 0. Writes have no effect.
26	FEN		Frame error enable. This bit is used to create a frame error.
		0	No error is created.
		1	The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.
25	PEN		Parity error enable. This bit is used to create a parity error.
		0	No parity error occurs.
		1	The parity bit received is toggled so that a parity error occurs.
24	BRKD TENA		Break detect error enable. This bit is used to create a BRKDT error.
		0	No error is created.
		1	The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T_{BITS} so that a BRKDT error occurs.
32-21	Reserved	0	Read returns 0. Writes have no effect.
20-19	PIN SAMPLE MASK		Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry.
		0	No mask is used.
		1h	Invert the TX Pin value at 7th SCLK.
		2h	Invert the TX Pin value at 8th SCLK.
		3h	Invert the TX Pin value at 9th SCLK.

Table 26-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
18-16	TX SHIFT		Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.
		0	No delay occurs.
		1h	The value is delayed by 1 SCLK.
		2h	The value is delayed by 2 SCLK.
		3h	The value is delayed by 3 SCLK.
		4h	The value is delayed by 4 SCLK.
		5h	The value is delayed by 5 SCLK.
		6h	The value is delayed by 6 SCLK.
		7h	No delay occurs.
15-12	Reserved	0	Read returns 0. Writes have no effect.
11-8	IODFTENA		IODFT enable key. Write access permitted in Privilege mode only.
		Ah	IODFT is enabled.
		All Others	IODFT is disabled.
7-2	Reserved	0	Read returns 0. Writes have no effect.
1	LPBENA		Module loopback enable. Write access permitted in Privilege mode only.
			Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path.
		0	Digital loopback is enabled.
		1	Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.
0	RXPENA		Module analog loopback through receive pin enable. Write access permitted in Privilege mode only. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode)
		0	Analog loopback through the transmit pin is enabled.
		1	Analog loopback through the receive pin is enabled.

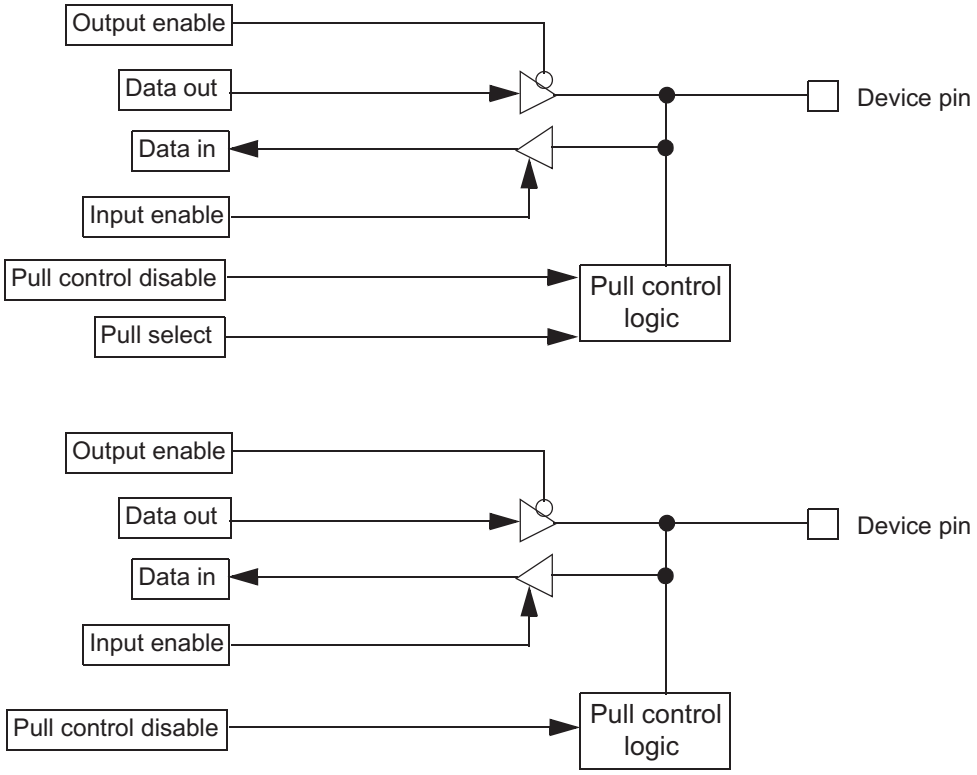
26.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

26.8.1 GPIO Functionality

Figure 26-32 illustrates the GPIO functionality.

Figure 26-32. GPIO Functionality



26.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled or disabled depending on a device-specific option. This feature is configurable for each module separately.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

26.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 26.7.20). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 26.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

NOTE: The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIPIO7 (Section 26.7.20).

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 26.7.14) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 26.7.19).

26.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

NOTE: The open-drain feature is available only in I/O mode (SCIPIO0; Section 26.7.13).

26.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 26-33.

Table 26-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins

Device under Reset?	Pin Direction (DIR) [1][2]	Pull Disable (PULDIS) [1][3]	Pull Select (PULSEL) [1][4]	Pull Control	Output Buffer	Input Buffer
Yes	X	X	X	Device- and module-specific	Disabled	Enabled

(3) PULDIS = 0 for enabling pull control
= 1 for disabling pull control
(4) PULSEL= 0 for pull-down functionality
= 1 for pull-up functionality

Debug Architecture

The debug subsystem contains OneMCUDebugss at its core that allows the JTAG interface access to device components. The debug subsystem is designed to provide the following debug features:

- JTAG debug access to debug resources, mapped through an ARM SWJ-DP and TI ICEPickM scan module
- System memory access without halting the processor
- Trace for C674x DSP
- ETM-based trace for ARM R4F
- Cross trigger to halt and restart MSS and DSP, based on events such as watchdog, timers, DMA, and time-stamp events
- Capability to read the device ID

27.1 Debug Subsystem

Figure 27-1 shows the top-level block diagram of the debug subsystem. Debug acts as master controller to the rest of the debug-enabled subsystems on the device. Trace data is collected from the MSS CR4 and DSP core, and can either be stored in the emulate trace buffer (ETB) or sent over the device trace pins. Cross triggering is established using cross trigger interface (CTI). The debug system CTI interface is connected to the ARM Cortex R4F and DSP core to allow cross triggering of capture based on various events within the device.

Figure 27-1. Block Diagram of the 14xx Debug Subsystem Interconnect

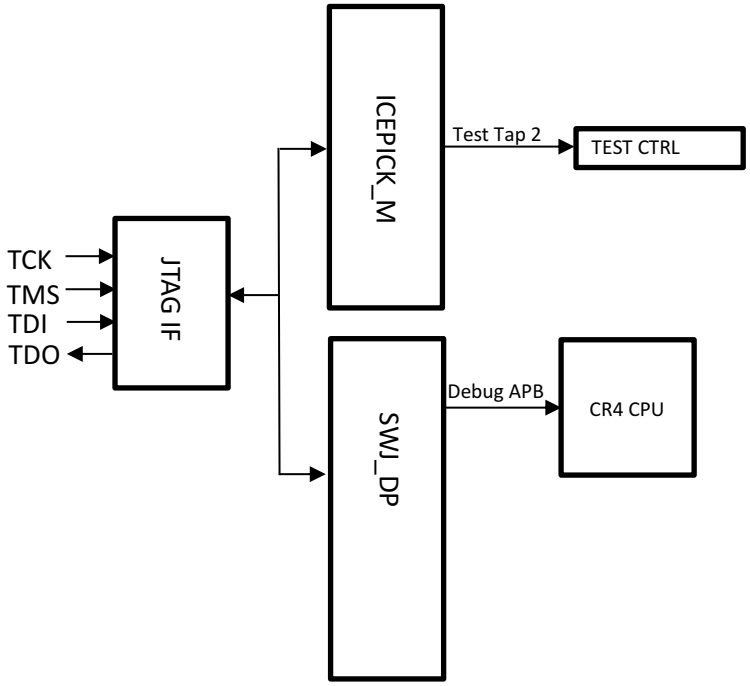

Table 27-1 shows the address map for the debug subsystem.

Table 27-1. 14xx Debug Subsystem Address Map

27.2 Triggering Subsystem

The trigger subsystem consists of CTI modules connected by the CTI channel interface. A trigger connected to any of the CTI can be routed on the trigger of the other CTI. Triggers from MSS CR4 and ETMR4 are connected to MSS CTI. Triggers from MSS CTI are connected to MSS CR4, ETMR4, and CSETB. MSS CTI also received triggers from DMA2, RTI, and Watchdog.

The second CTI module is present inside the debug subsystem. This CTI receives triggers from ADTF, DMA, RTI, and WDT. GEM. The C674x DSP can be halted by any trigger in the subsystem. When GEM trace is enabled, triggers are generated by ADTF by detecting the trigger packets in the trace stream.

28.1 Dual Clock Comparator (DCC)

This section describes the dual-clock comparator (DCC) module.

28.1.1 Introduction

The primary purpose of a DCC module is to measure the frequency of a clock signal using a second known clock signal as a reference. This capability can be used to ensure the correct frequency range for several different device clock sources, thereby enhancing the system safety metrics.

28.1.1.1 Main Features

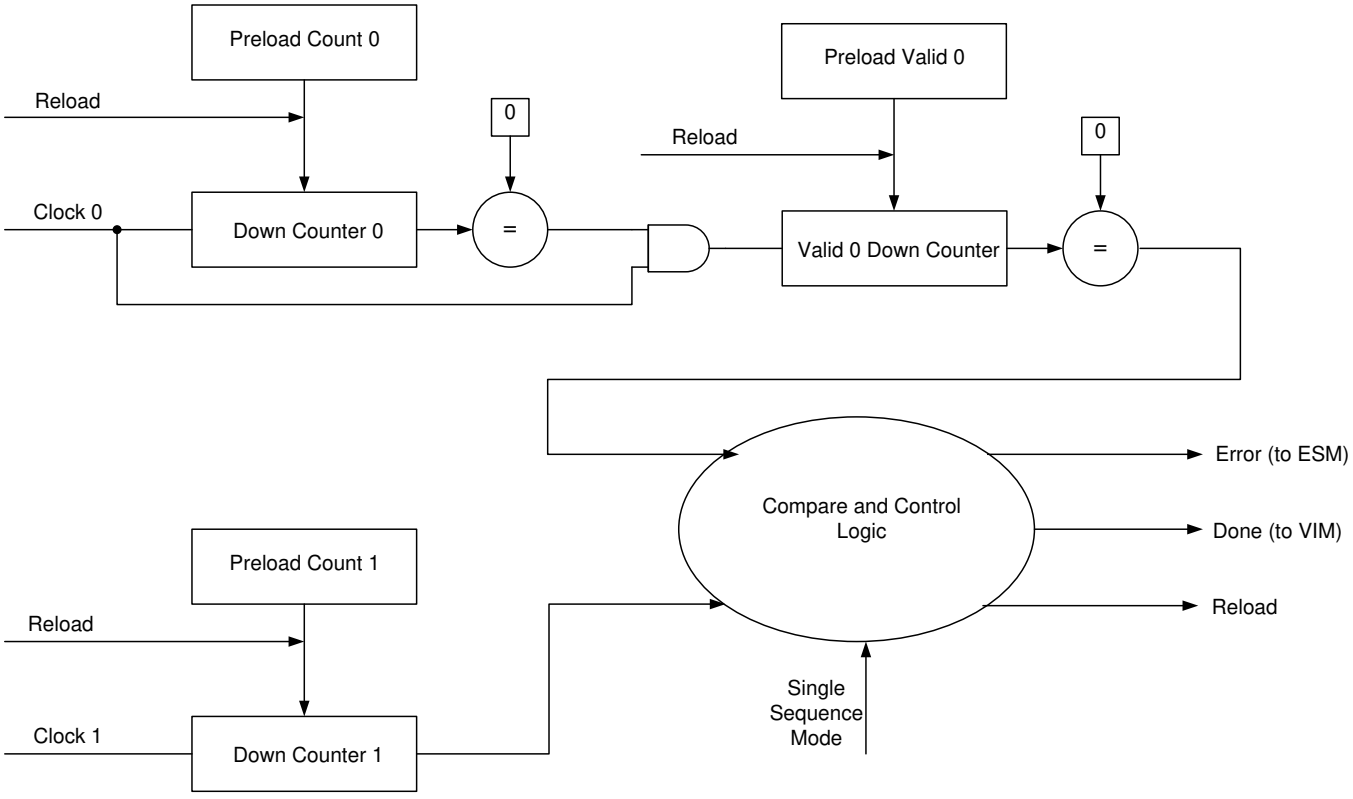
The main features of each of the DCC modules are:

- Allows application to ensure that a fixed ratio is maintained between frequencies of two clock signals
- Supports the definition of a programmable tolerance window in terms of number of reference clock cycles
- Supports continuous monitoring without requiring application intervention
- Also supports a single-sequence mode for spot measurements
- Allows selection of clock source for each of the counters resulting in several specific use cases

28.1.1.2 Block Diagram

Figure 28-1 illustrates the main concept of the DCC module.

Figure 28-1. DCC Operation



28.1.2 Module Operation

As shown in Figure 28-1, the DCC contains two counters – counter0 and counter1, which are driven by two signals – clock0 and clock1. The application programs the seed values for both these counters. The application also configures the tolerance window time by configuring the valid counter for clock0.

Counter0 and counter1 both start counting simultaneously once the DCC is enabled. When counter0 counts down to zero, this automatically triggers the count down of the tolerance window counter (valid0).

The DCC module can be used in two different operating modes:

28.1.2.1 Continuous Monitoring Mode

In this mode, the DCC is used by the application to ensure that two clock signals maintain the correct frequency ratio. Suppose the application wants to ensure that the PLL output signal (clock source # 1) always maintains a fixed frequency relationship with the main oscillator (clock source # 0).

- In this case, the application can use the main oscillator as the clock0 signal (for counter0 and valid0) and the PLL output as the clock1 (for counter1).
- The seed values of counter0, valid0 and counter1 are selected such that if the actual frequencies of clock0 and clock1 are equal to their expected frequencies, then the counter1 will reach zero either at the same time as counter0 or during the count down of the valid0 counter.
- If the counter1 reaches zero during the count down of the valid0 counter, then all the counters (counter0, valid0, counter1) are reloaded with their initial seed values once valid0 has also counted down to zero.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters also all get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

   Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

28.1.2.1.1 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0 and Counter1 all reach 0 without any error

Figure 28-2. Counter Relationship

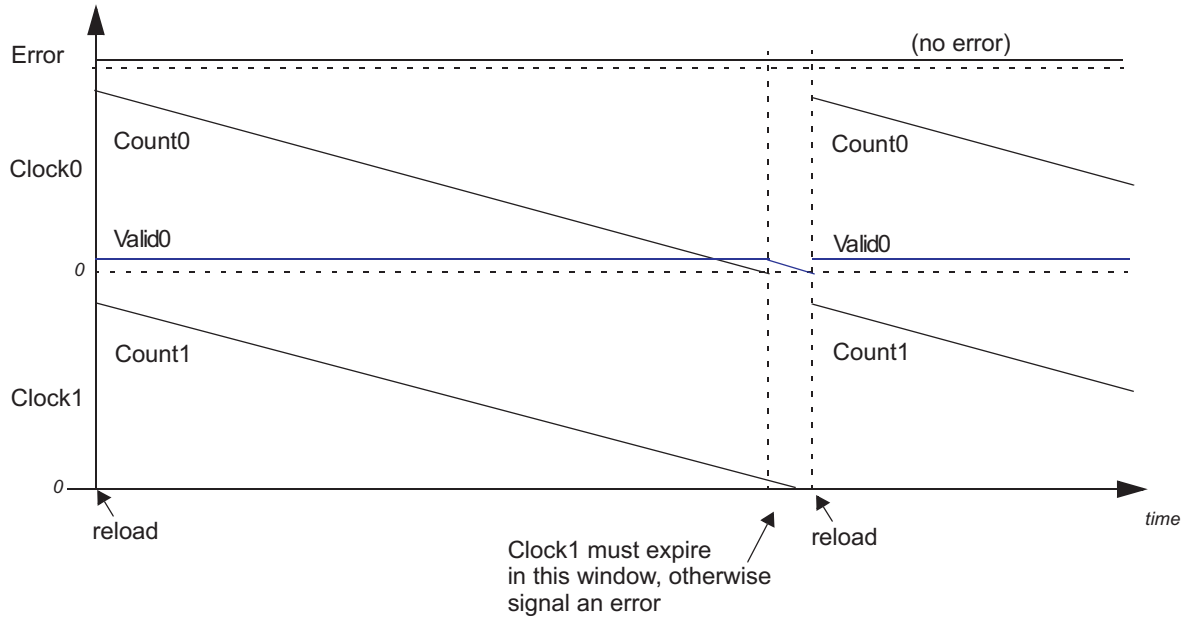


Figure 28-3. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

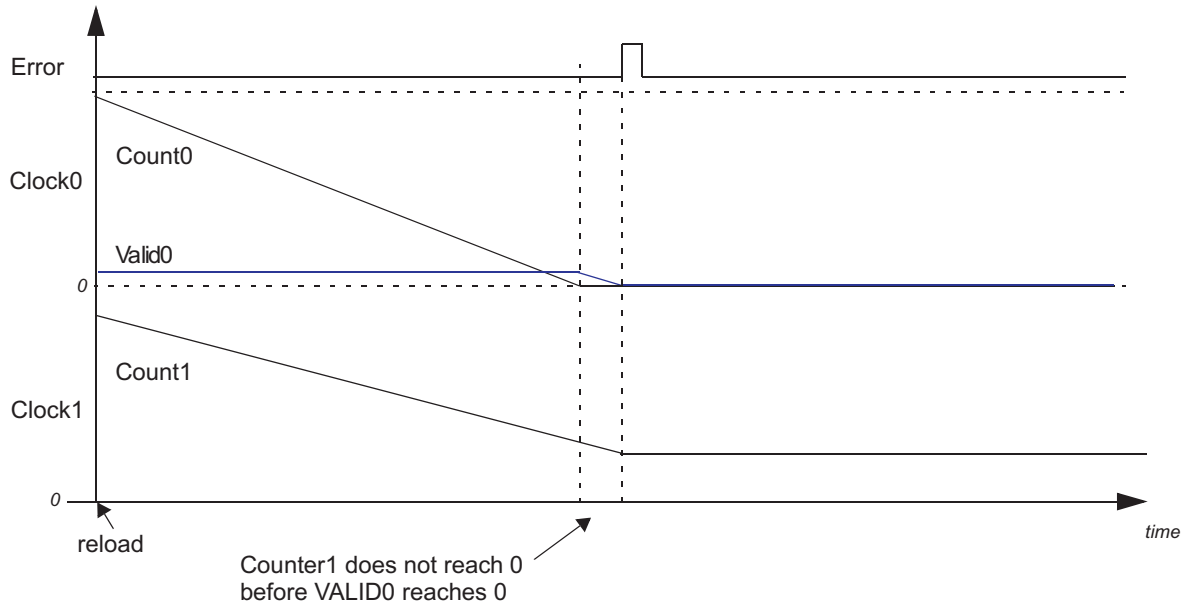

Figure 28-4. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

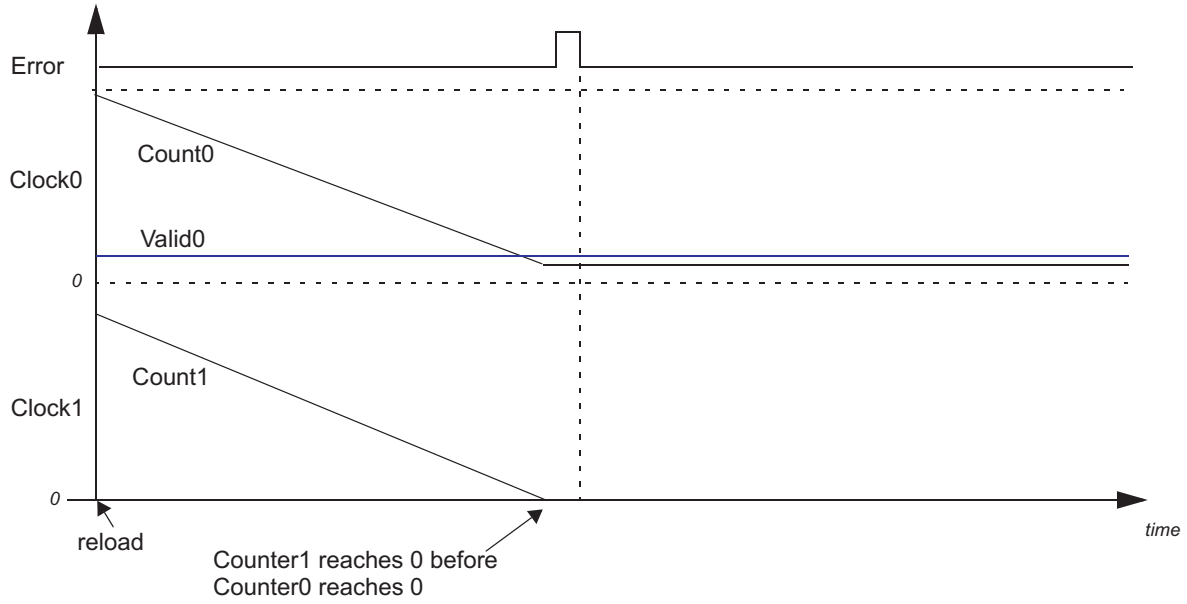

Figure 28-5. Clock1 Not Present - Results in an Error and Stops Counting

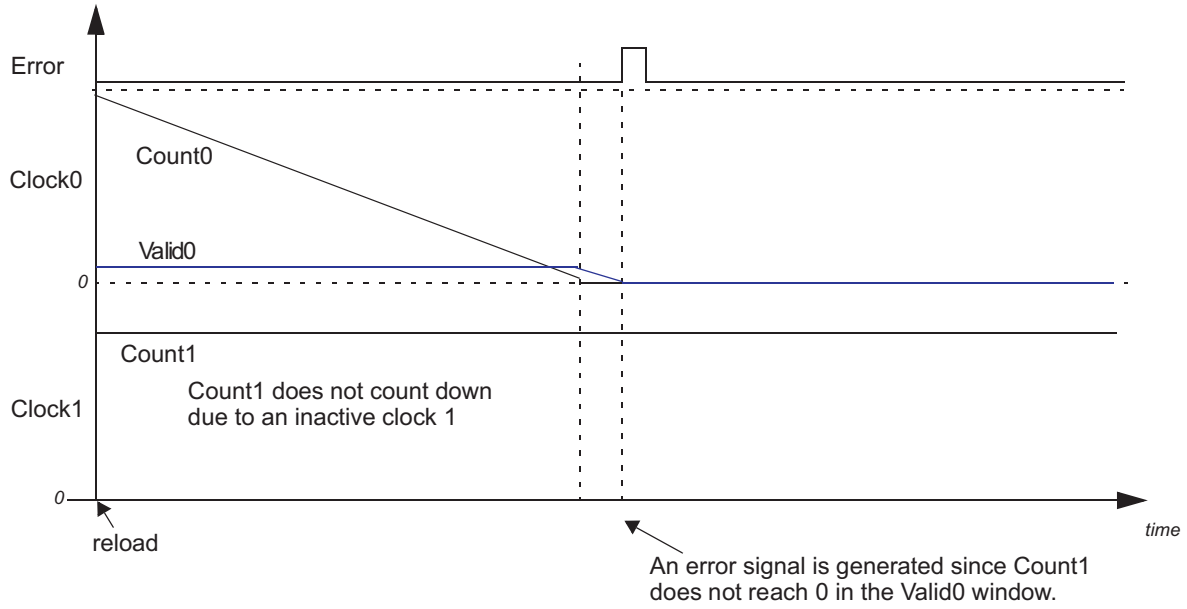

Figure 28-6. Clock0 Not Present - Results in an Error and Stops Counting

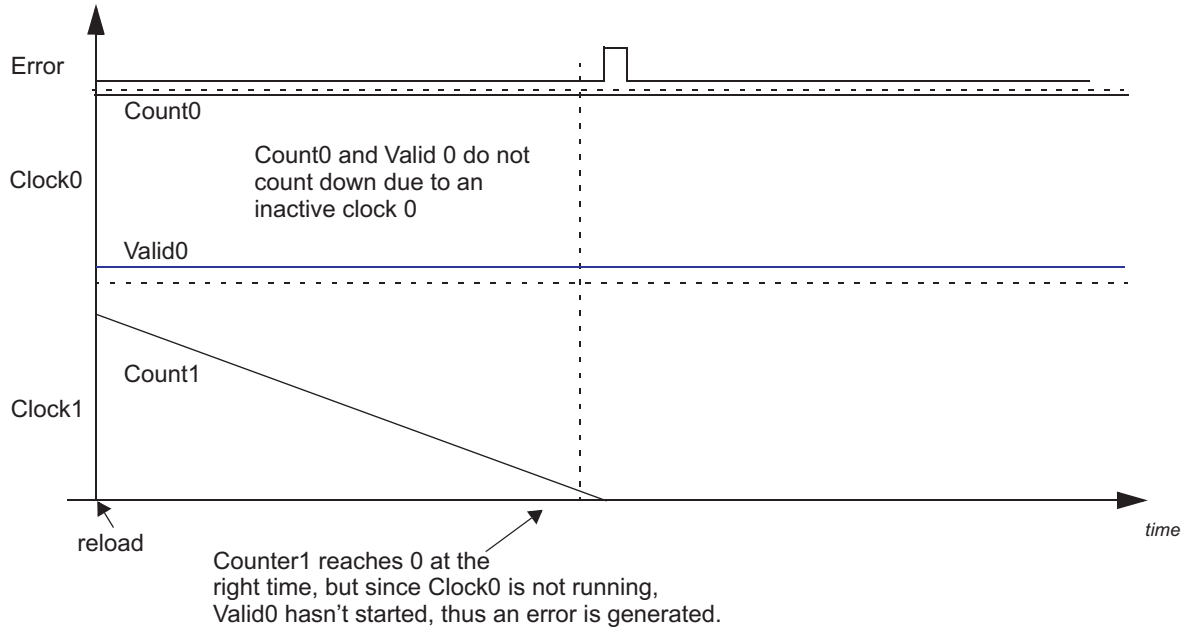

28.1.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0. Alternatively, the DCC can be programmed to stop counting when the down counter1 reaches 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot measurements of the frequency of a signal. This frequency could be an unknown for the application before the measurement.

Example Usage of Single-Shot Measurement Mode: Trimming the High-Frequency Low-Power Oscillator

A practical example of the usage of the spot measurement mode is in trimming the HF LPO (clock source # 5) using the main oscillator as a reference. This measurement sequence would proceed as follows:

- The application sets up the seed values for counter0 and valid0 for the duration of the measurement. Suppose the main oscillator frequency is 10MHz and the intended duration of the measurement is 500µs. The application needs to configure a seed value of 5000.
- These 5000 counts need to be divided between the counter0 and the valid0 counters. The minimum value for the valid0 seed is 4, so the application can configure counter0 seed value as 4996 and the valid0 seed value as 4.
- Suppose the HF LPO frequency is truly unknown. In this case the application can choose the maximum allowed seed value for counter1. This increases the probability of counter0 and valid0 counting down while the counter1 has still not fully counted down to zero. The maximum allowed seed value for counter1 is 1048575.
- Once the DCC is enabled, the counters counter0 and counter1 both start counting down from their seed values.
- When counter0 reaches zero, it automatically triggers the valid0 counter.
- When valid0 reaches zero, if counter1 is not zero as well, an ERROR status flag is set and a "DCC error" is sent to the ESM. Counter1 is also frozen so that it stops counting down any further. The application can enable an interrupt to be generated from the ESM whenever this DCC error is indicated. Refer the device datasheet to identify the ESM group and channel where the DCC error is connected.

- The DCC error interrupt service routine can then check the value of counter1 when the error was generated. Suppose that the counter1 now reads 1044575. This means that counter1 has counted 1048575 - 1044575, or 4000 cycles within the 500µs measurement period. This means that the average frequency of the HF LPO over this 500µs period was 4000 cycles / 500µs, or 8MHz.
- The application then needs to clear the ERROR status flag and restart the DCC module so that it is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

The conditions that cause a DCC error are identical between the continuous monitoring mode and the single-shot measurement mode.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

   Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

Freezing Counters when Counter1 Reaches Zero:

The DCC module also allows the counters to be frozen when the counter1 reaches zero. This allows one of the clock sources for counter1 to be used as a reference for measuring one of the clock sources for counter0. The error conditions are the same as those where (counter0=0 and valid0=0) define the condition when the DCC counters are frozen. That is, an error is indicated if coutner0 and valid0 become zero while counter1 is still non-zero. In this case, however, the application would typically set up the seed values such that the counter1 will become zero before counter0. Essentially the measurement period is defined by the seed value of the counter1. Note that this is also an error condition, and the interrupt service routine can use the measurement period and the actual cycles counted by counter1 to determine the frequency of the clock0 signal.

28.1.3 Clock Source Selection for Counter0 and Counter1

Refer the device datasheet to identify the available options for selecting the clock sources for both counters of the DCC module. Some microcontrollers may include multiple instances of the DCC module. This will also be identified in the device datasheet.

The selection of the clock sources for counter0 and coutner1 is done by a combination of the KEY, CNT0 CLKSRC and CNT1 CLKSRC control fields of the CNT0CLKSRC and CNT1CLKSRC registers.

28.1.4 DCC Registers

Table 28-1 lists the DCC memory-mapped registers. All register offset addresses not listed in Table 28-1 should be considered as reserved locations and the register contents should not be modified.

Table 28-1. DCC Registers

Offset	Acronym	Register Name	Section
0h	DCCGCTRL	DCCGCTRL	Section 28.1.4.1
4h	DCCREV	DCCREV	Section 28.1.4.2

Complex bit access types are encoded to fit into small table cells. Table 28-2 shows the codes that are used for access types in this section.

Table 28-2. DCC Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

28.1.4.1 DCCGCTRL Register (Offset = 0h) [reset = 5555h]

DCCGCTRL is shown in Figure 28-7 and described in Table 28-3.

Return to Summary Table.

28.2 Error Signaling Module (ESM)

This section provides the details of the error signaling module (ESM) that aggregates device errors and provides internal and external error response based on error severity.

28.2.1 Overview

The Error Signaling Module (ESM) collects and reports the various error conditions on the microcontroller. The error condition is categorized based on a severity level. Error response is then generated based on the category of the error. Possible error responses include a low priority interrupt, high priority interrupt, and an external pin action.

28.2.1.1 Feature List

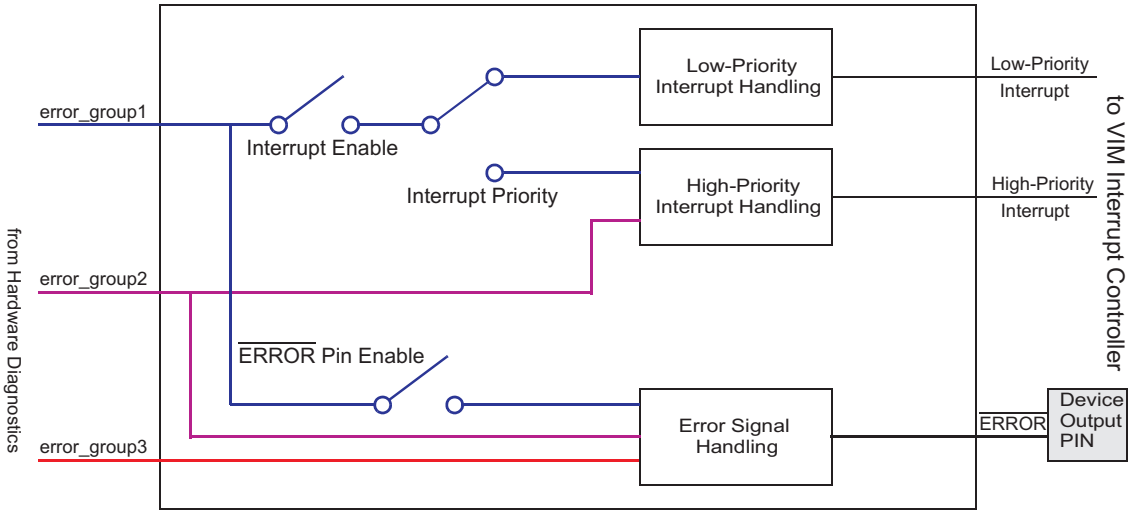
- Up to 128 error channels are supported, divided into 3 different groups:
  - 64 Group1 (low severity) channels with configurable interrupt generation and configurable $\overline{\text{ERROR}}$ pin behavior
  - 32 Group2 (high severity) channels with predefined interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior
  - 32 Group3 (high severity) channels with no interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior. These channels have no interrupt response as they are reserved for CPU based diagnostics that generate aborts directly to the CPU.
- Dedicated device $\overline{\text{ERROR}}$ pin to signal an external observer
- Configurable timebase for $\overline{\text{ERROR}}$ pin output
- Error forcing capability for latent fault testing

28.2.1.2 Block Diagram

As shown in Figure 28-18, the ESM channels are divided into three groups. Group1 channels are considered to be low severity. Group1 errors have a configurable interrupt response and configurable $\overline{\text{ERROR}}$ pin behavior. Note that the ESM Status Register 1 (ESMSR1) for error group 1 gets updated, regardless if the interrupt enable is active or not. Group2 channels are $\overline{\text{ERROR}}$ high severity. Group2 errors always generate a high priority interrupt and an output on the $\overline{\text{ERROR}}$ pin. Group3 errors are reserved for high severity errors generated by diagnostics which have already generated a CPU abort response. Because an abort response is generated, there is no need to generate an interrupt response. Group3 errors always generate an $\overline{\text{ERROR}}$ pin output.

The ESM interrupt and $\overline{\text{ERROR}}$ pin behavior are also summarized in Table 28-14.

Figure 28-18. Block Diagram



Note that the ESM Status Register 1 (ESMSR1) for error_group1 gets updated, regardless if the interrupt enable is active or not.

Table 28-14. ESM Interrupt and $\overline{\text{ERROR}}$ Pin Behavior

Error Group	Interrupt Generated	Interrupt Priority	$\overline{\text{ERROR}}$ Pin Response Generated
1	configurable interrupt	configurable priority	configurable output generation
2	interrupt generated	high priority	output generated
3	no interrupt	NA	output generated

Figure 28-19 and Figure 28-20 show the interrupt response handling and $\overline{\text{ERROR}}$ pin response handling with register configuration. The total active time of the $\overline{\text{ERROR}}$ pin is controlled by the Low-Time Counter Preload register (LTCP) and the key register (ESMEPSR) as shown in Figure 28-20. See Section 28.2.2.2 for details.

Figure 28-19. Interrupt Response Handling

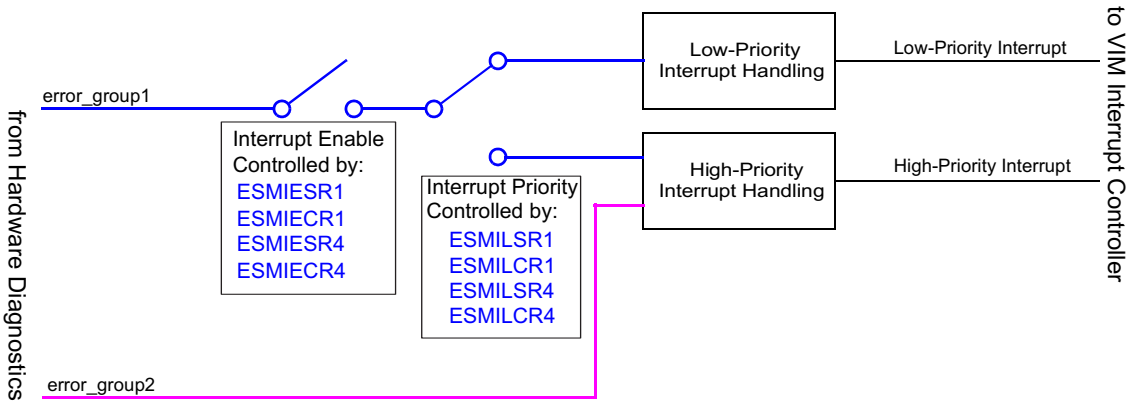


Figure 28-20. $\overline{\text{ERROR}}$ Pin Response Handling

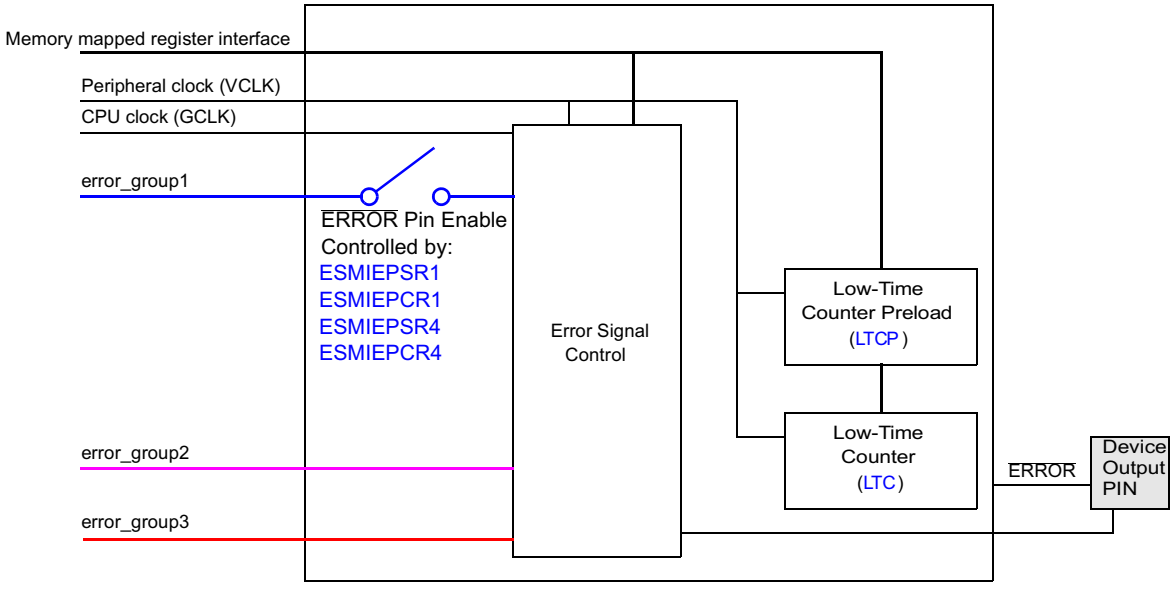


28.2.2 Module Operation

This device has 128 error channels, divided into 3 different error groups. Please refer to the device datasheet for ESM channel assignment details.

The ESM module has error flags for each error channel. The error status registers ESMSR1, ESMSR4, ESMSR2, ESMSR3 provide status information on a pending error of Group1 (Channel 0-31), Group1 (Channel 32-63), Group1 (Channel 64-95), Group2, and Group3, respectively. The ESMEPSR register provides the current $\overline{\text{ERROR}}$ status. The module also provides a status shadow register, ESMSSR2, which maintains the error flags of Group2 until power-on reset ($\overline{\text{PORRST}}$) is asserted. See Section 28.2.2.1 for details of their behavior during power on reset and warm reset.

Once an error occurs, the ESM module will set the corresponding error flags. In addition, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM error pin back to normal state. See Section 28.2.2.2 for details. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR7, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

You can also test the functionality of the $\overline{\text{ERROR}}$ pin by forcing an error. See Section 28.2.2.3 for details.

28.2.2.1 Reset Behavior

Power on reset:

- $\overline{\text{ERROR}}$ pin behavior

  When nPORRST is active, the $\overline{\text{ERROR}}$ pin is in a high impedance state (output drivers disabled).
- Register behavior

  After $\overline{\text{PORRST}}$, all registers in ESM module will be re-initialized to the default value. All the error status registers are cleared to zero.

Warm reset ($\overline{\text{RST}}$):

- $\overline{\text{ERROR}}$ pin behavior

  During $\overline{\text{RST}}$, the $\overline{\text{ERROR}}$ pin is in “output active” state with pull-down disabled. The $\overline{\text{ERROR}}$ pin remains unchanged after $\overline{\text{RST}}$.
- Register behavior

  After $\overline{\text{RST}}$, ESMSR1, ESMSR4, ESMSR7, ESMSSR2, ESMSR3 and ESMEPSR register values remains un-changed. Since $\overline{\text{RST}}$ does not clear the critical failure registers, the user can read those registers to debug the failures after $\overline{\text{RST}}$ pin goes back to high.

  After $\overline{\text{RST}}$, if one of the flags in ESMSR1, ESMSR4 and ESMSR7 is set, the interrupt service routine will be called once the corresponding interrupt is enabled.

NOTE: ESMSR2 is cleared after $\overline{\text{RST}}$. The flag in ESMSR2 gets cleared when reading the appropriate vector in the ESMIOFFHR offset register. Reading ESMIOFFHR will not clear the ESMSR1, ESMSR4, ESMSR7 and the shadow register ESMSSR2. Reading ESMIOFFLR will also not clear the ESMSR1, ESMSR4 and ESMSR7.

28.2.2.2 $\overline{\text{ERROR}}$ Pin Timing

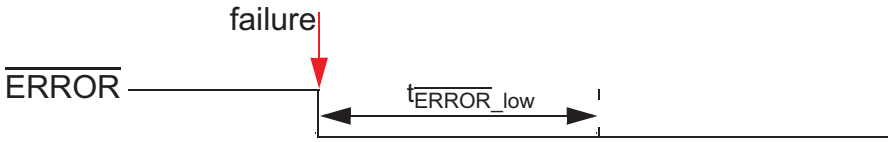
The $\overline{\text{ERROR}}$ pin is an active low function. The state of the pin is also readable from $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). A warm reset ($\overline{\text{RST}}$) does not affect the state of the pin. The pin is in a high-impedance state during power-on reset. Once the ESM module drives the $\overline{\text{ERROR}}$ pin low, it remains in this state for the time specified by the Low-Time Counter Preload register (LTCPR). Based on the time period of the peripheral clock (VCLK), the total active time of the $\overline{\text{ERROR}}$ pin can be calculated as:

$$t_{\overline{ERROR}\_low} = t_{VCLK} \times (LTCP + 1) \quad (21)$$

Once this period expires, the $\overline{\text{ERROR}}$ pin is set to high in case the reset of the $\overline{\text{ERROR}}$ pin was requested. This request is done by writing an appropriate key (0x5) to the key register (ESMEKR) during the $\overline{\text{ERROR}}$ pin low time. Here are a few examples:

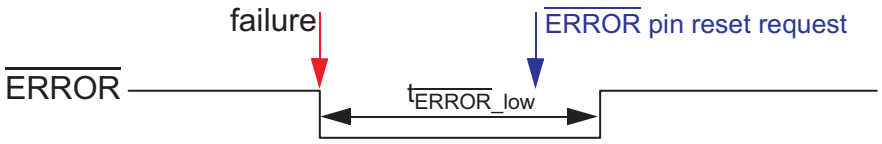
Example 1: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. No $\overline{\text{ERROR}}$ pin reset is requested. The $\overline{\text{ERROR}}$ pin continues outputting low until power on reset occurs.

Figure 28-21. $\overline{\text{ERROR}}$ Pin Timing - Example 1



Example 2: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received before $t_{\overline{ERROR}\_low}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{ERROR}\_low}$ expires.

Figure 28-22. $\overline{\text{ERROR}}$ Pin Timing - Example 2

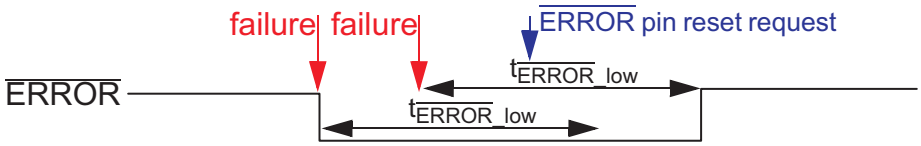


Example 3: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received after $t_{\overline{ERROR}\_low}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $\overline{\text{ERROR}}$ pin reset request is received.

Figure 28-23. $\overline{\text{ERROR}}$ Pin Timing - Example 3

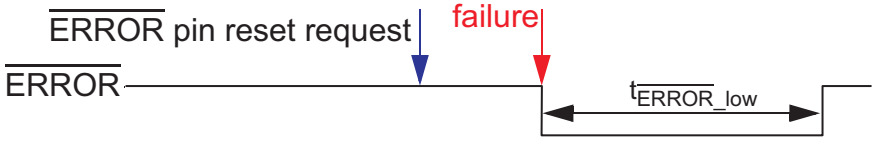
Example 4: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. Another failure occurs within the time the pin stays low. In this case, the low time counter will be reset when the other failure occurs. In other words, $t_{\overline{\text{ERROR}}\_low}$ should be counted from whenever the most recent failure occurs.

Figure 28-24. $\overline{\text{ERROR}}$ Pin Timing - Example 4



Example 5: The reset of the $\overline{\text{ERROR}}$ pin was requested by the software even before the failure occurs. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{\text{ERROR}}\_low}$ expires. This case is not recommended and should be avoided by the application.

Figure 28-25. $\overline{\text{ERROR}}$ Pin Timing - Example 5



28.2.2.3 Forcing an Error Condition

The error response generation mechanism is testable by software by forcing an error condition. This allows testing the $\overline{\text{ERROR}}$ pin functionality. By writing a dedicated key to the error forcing key register (ESMEKR), the $\overline{\text{ERROR}}$ pin is set to low for the specified time. The following steps describe how to force an error condition:

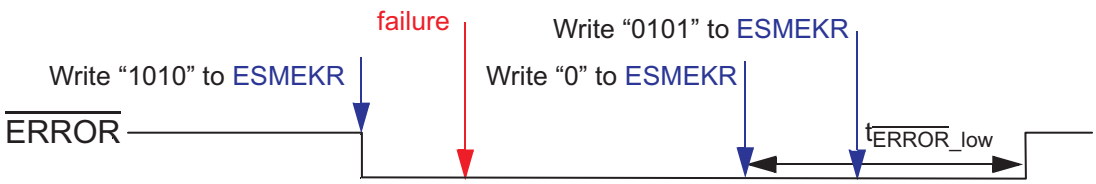
1. Check $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). This register must be 1 to switch into the error forcing mode.

   The ESM module cannot be switched into the error forcing mode if a failure has already been detected in functional mode. The application command to switch to error forcing mode is ignored.
2. Write “1010b” to the error forcing key register (ESMEKR). After that, the $\overline{\text{ERROR}}$ pin should output low (error force mode).

   Once the application puts the ESM module in the error forcing mode, the $\overline{\text{ERROR}}$ pin cannot indicate the normal error functionality. If a failure occurs during this time, it gets still latched and the LTC is reset and stopped. The error output pin is already driven low on account of the error forcing mode. When the ESM is forced back to normal functional mode, the LTC becomes active and forces the $\overline{\text{ERROR}}$ pin low until the expiration of the LTC (see Figure 28-26).
3. Write “0000” to the error forcing key register (ESMEKR) back to the active normal mode.

   If there are no errors detected while the ESM module is in the error forcing mode, the $\overline{\text{ERROR}}$ pin goes high immediately after exiting the error forcing mode.

Figure 28-26. ERROR Pin Timing - Example 6

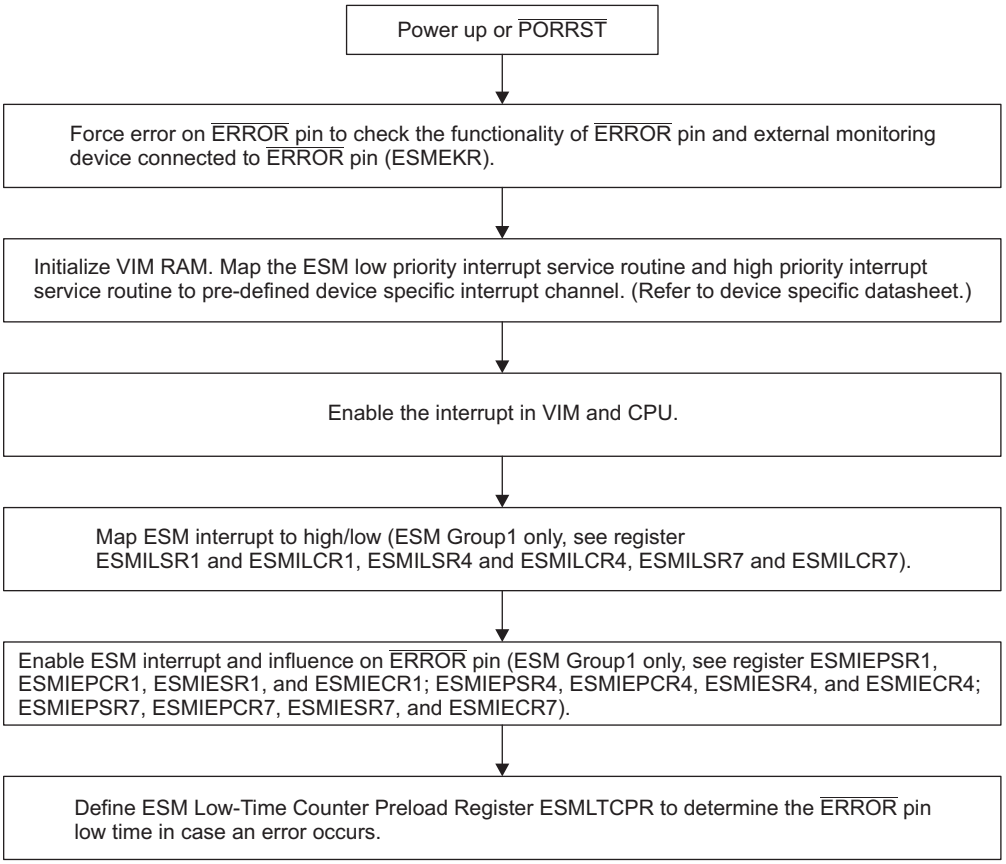


28.2.3 Recommended Programming Procedure

During the initialization stage, the application code should follow the recommendations in Figure 28-27 to initialize the ESM.

Once an error occurs, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM back to normal state. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR7, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

Figure 28-27. ESM Initialization



28.2.4 MSS_ESM Registers

Table 28-15 lists the memory-mapped registers for the MSS_ESM. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Note: After nRST, if one of these flags are set and the corresponding interrupt are enabled, the interrupt service routine will be called.

28.3 Cyclic Redundancy Check (CRC)

This section describes the cyclic redundancy check (CRC) controller module.

NOTE: This section describes a superset implementation of the CRC module that includes features and functionality that require DMA. Because not all devices have DMA capability, consult the device-specific datasheet to determine applicability of these features and functions to the device being used.

28.3.1 Overview

The CRC controller is a module that is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into CRC controller. The responsibility of CRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. CRC controller supports two channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

28.3.1.1 Features

The CRC controller offers:

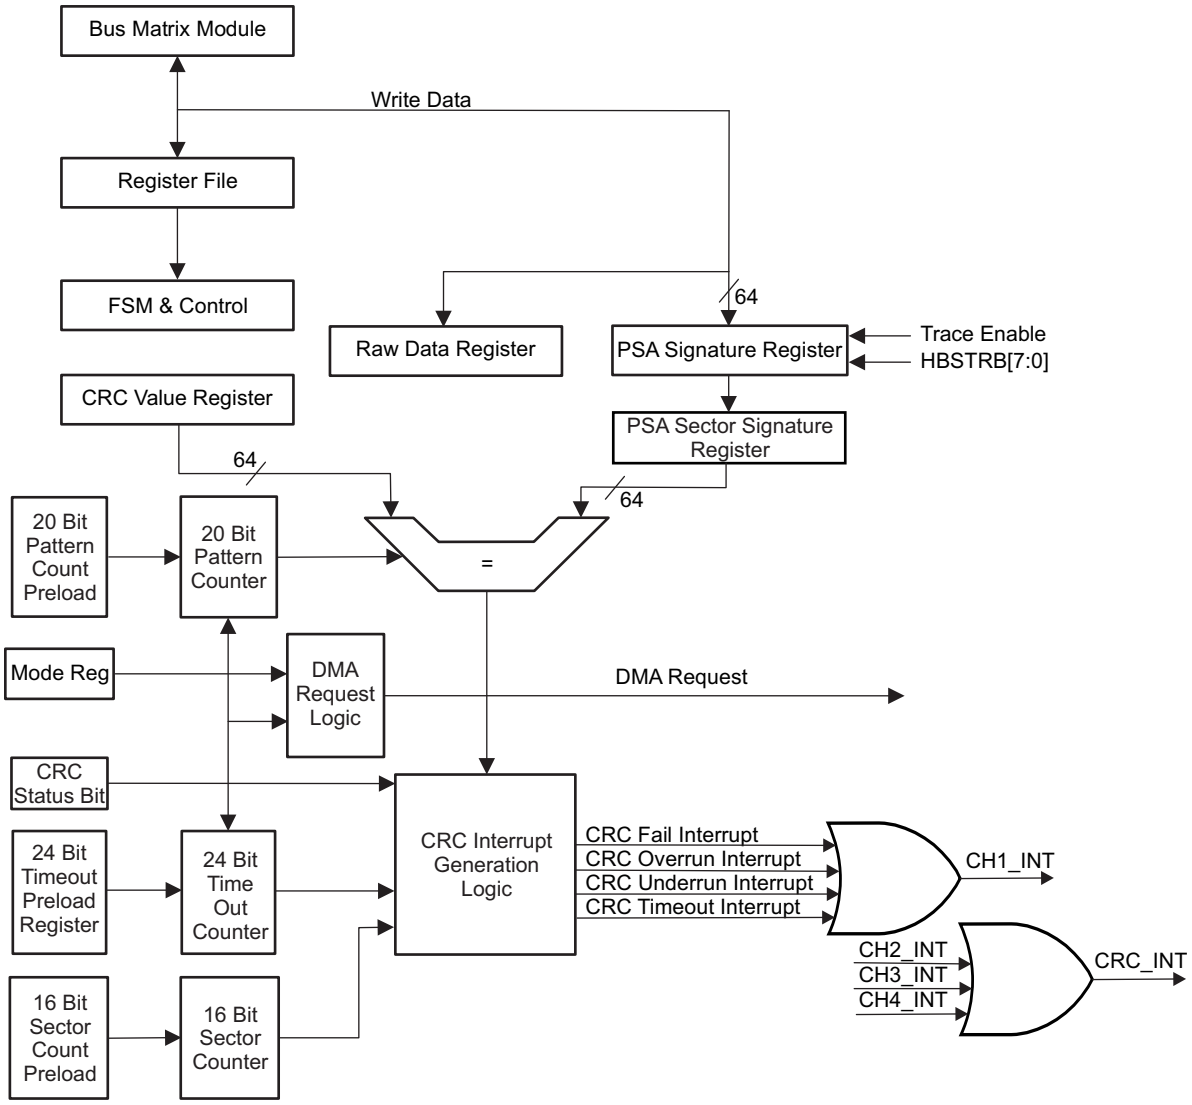
- Two channels to perform background signature verification on any memory sub-system.
- Data compression on 8, 16, 32, and 64 bit data size.
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64 bit primitive polynomial.
- Each channel has a CRC Value Register that contains the pre-determined CRC value.
- Use timed base event trigger from timer to initiate DMA data transfer.
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression.
- Three modes of operation. Auto, Semi-CPU and Full-CPU.
- For each channel, CRC can be performed either by CRC Controller or by CPU.
- Automatically perform signature verification without CPU intervention in AUTO mode.
- Generate interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself.

- Generate CRC fail interrupt in AUTO mode if signature verification fails.
- Generate Timeout interrupt if CRC is not performed within the time limit.
- Generate DMA request per channel to initiate CRC value transfer.

28.3.1.2 Block Diagram

Figure 28-58 shows a block diagram of the CRC controller.

Figure 28-58. CRC Controller Block Diagram For One Channel



28.3.2 Module Operation

28.3.2.1 General Operation

There are two channels in CRC controller and for each channel there is a memory mapped PSA (Parallel Signature Analysis) Signature Register and a memory mapped CRC (Cyclic Redundancy Check) Value register. A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be 8-, 16-, 32-, or 64-bit data. CRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory from which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated. A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by CRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self sustained CRC signature calculation can be achieved without any CPU intervention.

28.3.2.2 CRC Modes of Operation

CRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

28.3.2.2.1 AUTO Mode

In AUTO mode, CRC Controller in conjunction with DMA controller can perform CRC totally without CPU intervention. A sustained transfer of data to both the PSA Signature Register and CRC Value Register are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to CPU. A 16 bit current sector ID register is provided to identify which sector causes a CRC failure.

28.3.2.2.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register. Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register and compare it to a pre-determined CRC value.

28.3.2.2.3 Full CPU Mode

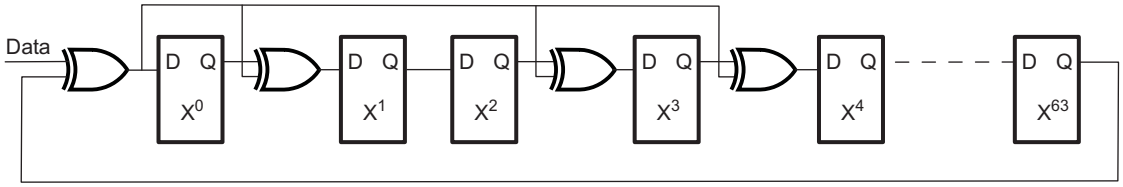
In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register. After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

28.3.2.3 PSA Signature Register

The 64-bit PSA Signature Register is based on the primitive polynomial (as in the following equation) to produce the maximum length LFSR (Linear Feedback Shift Register), as shown in Figure 28-59.

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (22)$$

Figure 28-59. Linear Feedback Shift Register (LFSR)



The serial implementation of LFSF has a limitation that, it requires ‘n’ clock cycles to calculate the CRC values for an ‘n’ bit data stream. The idea is to produce the same CRC value operating on a multi-bit data stream, as would occur if the CRC were computed one bit at a time over the whole data stream. The algorithm involves looping to simulate the shifting, and concatenating strings to build the equations after ‘n’ shift.

The parallel CRC calculation based on the polynomial can be illustrated in the following HDL code:

```
for i in 63 to 0 loop
   NEXT_CRC_VAL(0) := CRC_VAL(63) xor DATA(i);
     for j in 1 to 63 loop
       case j is
          when 1|3|4 =>
               NEXT_CRC_VAL(j) :=
                   CRC_VAL(j - 1) xor CRC_VAL(63) xor DATA(i);
          when others =>
               NEXT_CRC_VAL(j) := CRC_VAL(j - 1);
       end case;
     end loop;
   CRC_VAL := NEXT_CRC_VAL;
end loop;
```

NOTE: 1) The inner loop is to calculate the next value of each shift register bit after one cycle

2) The outer loop is to simulate 64 cycles of shifting. The equation for each shift register bit is thus built before it is compressed into the shift register.

3) MSB of the DATA is shifted in first

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHx_MODE bits. If CHx_MODE=Data Capture, a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

CRC Controller should be used in conjunction with the on chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA master. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After system reset and when AUTO mode is enabled, CRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register. After the comparison the CRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then CRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. The OS can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

CRC Controller supports doubleword, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zero's before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bit because a compressed value is always expressed in 64 bit.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

28.3.2.4 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the PSA Sector Signature Register. PSA Signature Register is a read only register. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will in the ISR read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enable to generate when overrun condition occurs. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

28.3.2.5 CRC Value Register

Associated with each channel there is a CRC Value Register. The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, CRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, CRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU should not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, CRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

CRC Controller supports doubleword, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bit.

28.3.2.6 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the Raw Data Register. This register is read only.

28.3.2.7 Example DMA Controller Setup

DMA controller needs to be setup properly in either either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

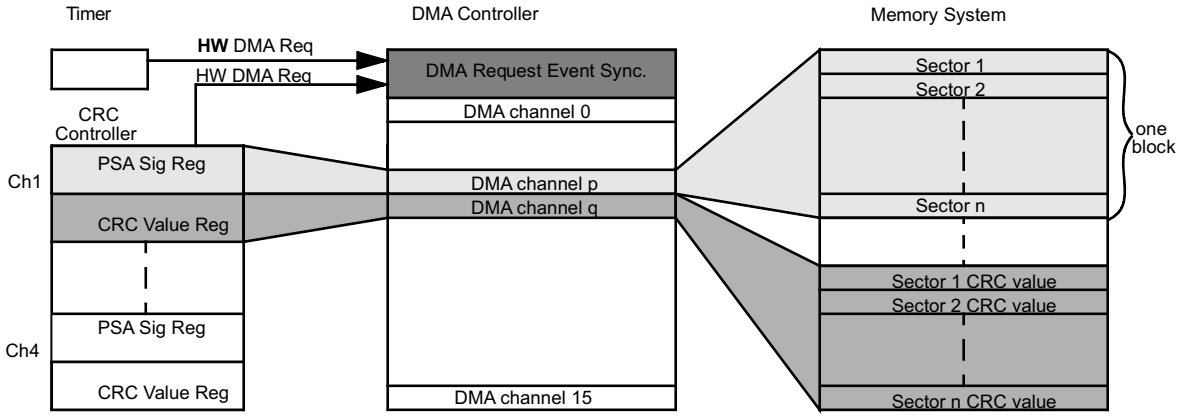
28.3.2.7.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register. The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register. The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in Figure 28-60 a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, CRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the CRC_PCOUNT_REGx and the number of sectors in one block is programmed in the CRC_SCOUNT_REGx of the respective channel. CRC_PCOUNT_REGx multiplies CRC_SCOUNT_REGx and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that an HW DMA request can be programmed to trigger either one frame or one entire block transfer. In Figure 28-60, an HW DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by CRC Controller.

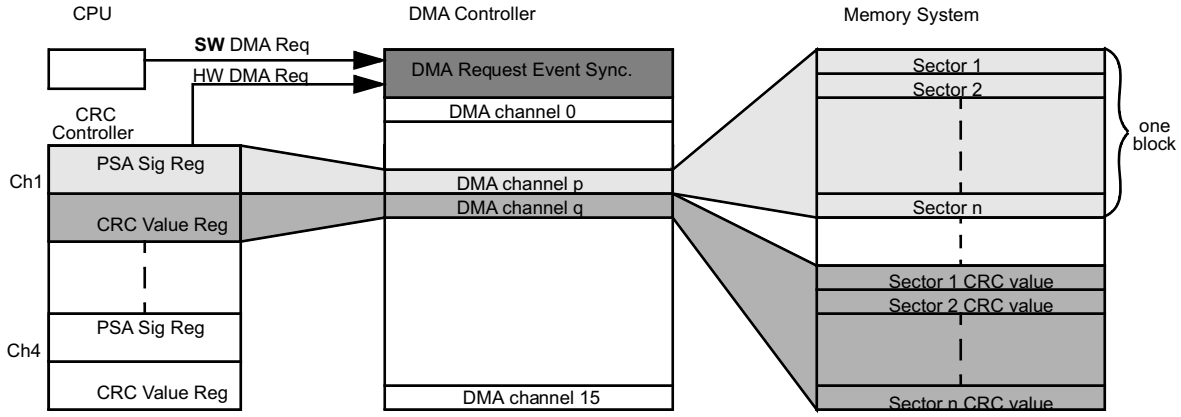
Figure 28-60. AUTO Mode Using Hardware Timer Trigger



28.3.2.7.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. See Figure 28-61 for an illustration.

Figure 28-61. AUTO Mode With Software CPU Trigger



28.3.2.7.3 Semi-CPU Mode Using Hardware Timer Trigger

During semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. Figure 28-62 illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

Figure 28-62. Semi-CPU Mode With Hardware Timer Trigger

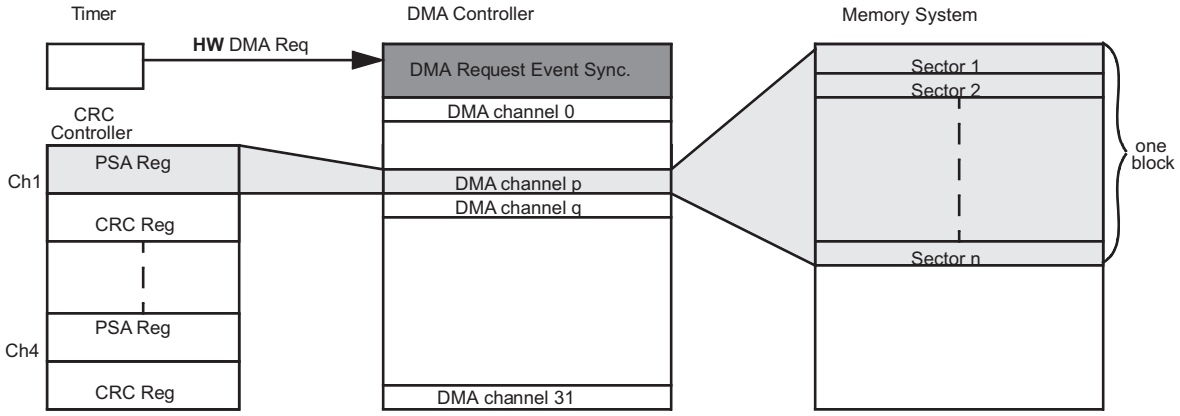


Table 28-47. CRC Modes in Which DMA Request and Counter Logic are Active or Inactive

Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full-CPU	Inactive	Inactive	Inactive	Inactive

28.3.2.8 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register. When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

NOTE: The data pattern count should be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

28.3.2.9 Sector Count Register/Current Sector Register

Each channel contains a 16 bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register. If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure, it is advisable to use the following equation during CRC and DMA setup:

CRC Pattern Count × CRC Sector Count = DMA Element Count × DMA Frame Count

The current sector register is frozen from being updated until both the current sector register is read and CRC fail status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

The current sector register is reset when the PSA software reset is enabled.

NOTE: Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

28.3.2.10 Interrupt

The CRC controller generates several types of interrupts per channel. Associated with each interrupt, there is an interrupt enable bit. No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

Table 28-48. Modes in Which Interrupt Condition Can Occur

	AUTO	Semi-CPU	Full-CPU
Compression Complete	no	yes	no
CRC Fail	yes	no	no
Overrun	yes	yes	no
Underrun	yes	no	no
Timeout	yes	yes	no

28.3.2.10.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated.

28.3.2.10.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set,. CPU should take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

28.3.2.10.3 Overrun Interrupt

Overrun interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register. If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register. If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

28.3.2.10.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, CRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

28.3.2.10.5 Timeout Interrupt

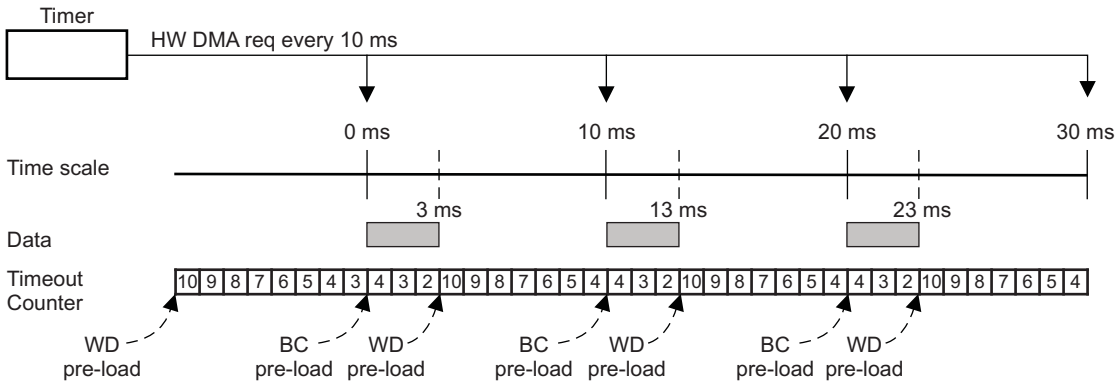
To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24 bit timeout counter per CRC channel. The 24 bit timeout down counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (CRC_WDTOPLDx) and block complete timeout pre-load value (CRC_BCTOPLDx). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of HCLK clock.

First pattern of data must be transferred by the DMA before the timeout counter expires, Watchdog timeout pre-load register (CRC_WDTOPLDx) is used as timeout counter. Block complete timeout pre-load register (CRC_BCTOPLDx) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with CRC_WDTOPLDx after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with CRC_BCTOPLDx the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check it one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with CRC_BCTOPLDx value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count x sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with CRC_WDTOPLDx value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

In Figure 28-63, a timer generates DMA request every 10ms to trigger one block (pattern count x sector count) transfer. Since we want to make sure that DMA does start to transfer a block every 10 ms we would set the first pre-load value to 10ms in CRC_WDTOPLDx. We also want to make sure that one block of data patterns are compressed within 4ms. With such a requirement, we would set the second pre-load value to 4ms in CRC_BCTOPLDx register.

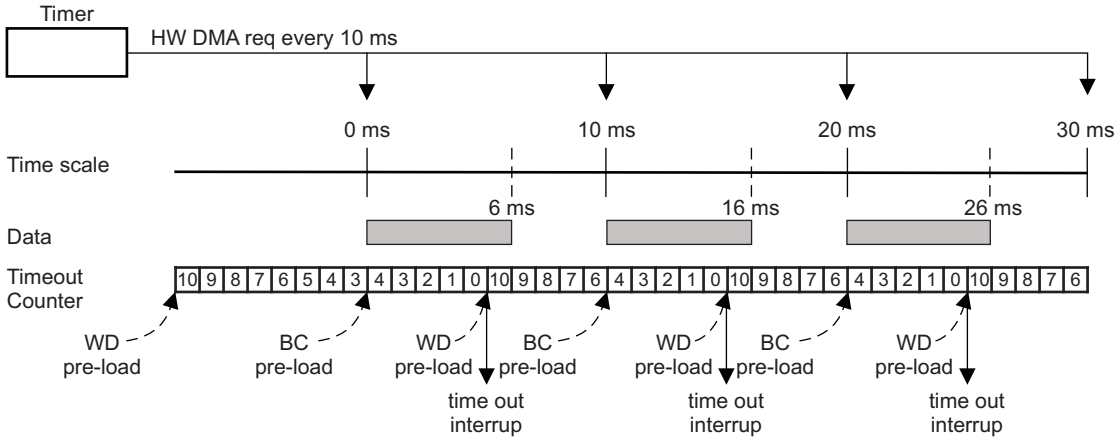
Figure 28-63. Timeout Example 1



WD pre-load = watchdog timeout pre-load (CRC_WDTOPLDx)
BC pre-load = block complete timeout pre-load (CRC_BCTOPLDx)

Note: No timeout interrupt is generated in this example since each block of data patterns are compressed in 3 ms and DMA does initiate a block transfer every 10 ms.

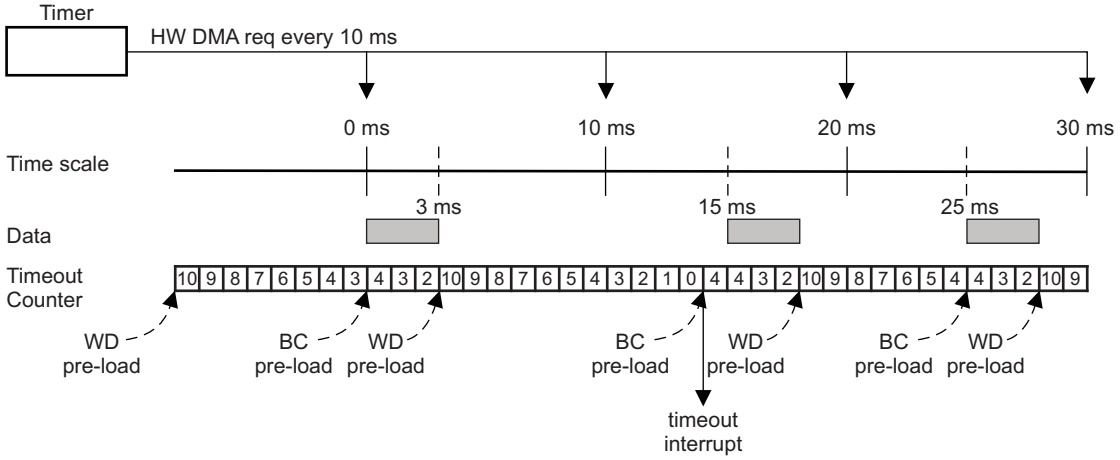
Figure 28-64. Timeout Example 2



WD pre-load = watchdog timeout pre-load (CRC_WDTOPLDx)
BC pre-load = block complete timeout pre-load (CRC_BCTOPLDx)

Note: Timeout interrupt is generated in this example since each block of data patterns are compressed in 6 ms and this is out of the 4ms time frame.

Figure 28-65. Timeout Example 3



WD pre-load = watchdog timeout pre-load (CRC_WDTOPLDx)
BC pre-load = block complete timeout pre-load (CRC_BCTOPLDx)

Note: Timeout interrupt is generated in this example since DMA can not transfer the second block of data within 10ms time limit and the reason may be that DMA is set up in fixed priority scheme and DMA is serving other higher priority channels at the time before it can service the timer request.

28.3.2.10.6 Interrupt Offset Register

CRC Controller only generates one interrupt request to interrupt manager. A interrupt offset register is provided to indicate the source of the pending interrupt with highest priority. Table 28-49 shows the offset interrupt vector address of each interrupt condition in an ascending order of priority.

Table 28-49. Interrupt Offset Mapping

Offset Value	Interrupt Condition
0	Phantom
1h	Ch1 CRC Fail
2h	Ch2 CRC Fail
3h-8h	Reserved
9h	Ch1 Compression Complete
Ah	Ch2 Compression Complete
Bh-10h	Reserved
11h	Ch1 Overrun
12h	Ch2 Overrun
13h-18h	Reserved
19h	Ch1 Underrun
1Ah	Ch2 Underrun
1Bh-20h	Reserved
21h	Ch1 Timeout
22h	Ch2 Timeout
23h-24h	Reserved

28.3.2.10.7 Error Handling

When an interrupt is generated, host CPU should take appropriate actions to identify the source of error and restart the respective channel in DMA and CRC module. To restart a CRC channel, the user should perform the following steps in the ISR:

1. Write to software reset bit in CRC_CTRL register to reset the respective PSA Signature Register.
2. Reset the CHx_MODE bits to 00 in CRC_CTRL register as Data capture mode.
3. Set the CHx_MODE bits in CRC_CTRL register to desired new mode again.
4. Release software reset.

The host CPU should use byte write to restart each individual channel.

28.3.2.11 Power Down Mode

CRC module can be put into power down mode when the power down control bit PWDN is set. The module wakes up when the PWDN bit is cleared.

28.3.2.12 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading an interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No Peripheral Master bus error should be generated if reading from the unimplemented locations.

28.3.2.13 Peripheral Bus Interface

CRC is a Peripheral slave module. The register interface is similar to other peripheral modules. CRC supports following features:

- Different sizes of burst operation.
- Aligned and unaligned accesses.
- Abort is generated for any illegal address accesses.

28.3.3 Example

This section illustrates several of the ways in which the CRC Controller can be utilized to perform CRC.

28.3.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2Mbyte (256k doubleword) is to be checked in the background of CPU. CRC is to be performed every 1K byte (128 doubleword). Therefore there should be 2048 pre-recorded CRC values. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all DMA transfers are carried out in 64-bit transfer size.

28.3.3.1.1 DMA Setup

- Set up DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use ***hardware*** DMA request for channel 1 to trigger a ***frame*** transfer.
- Set up DMA channel 2 with the source address from which the contents of memory to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 2048. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use ***hardware*** DMA request for channel 2 to trigger an entire ***block*** transfer.

28.3.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Set up timer to generate DMA request associated with DMA channel 2. For example, an OS can set up the timer to generate a DMA request every 10ms.

28.3.3.1.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load (CRC_BCTOPLDx) value to 15625 (5 ms / (1 HCLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, CRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generate a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2Mbyte are consumed. If the timeout counter reached zero before the entire 2Mbytes are compressed a timeout interrupt is generated. After 2MBytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and CRC Controller. The CRC is performed totally without any CPU intervention.

28.3.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1kbytes is to be checked in the background of CPU. CRC is to be performed every 1Kbytes. Therefore there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all transfers carried out by DMA are in 64 bit transfer size.

28.3.3.2.1 DMA Setup

- Set up DMA channel 1 with the source address from which the pre-determined CRC value is stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use ***hardware*** DMA request for channel 1.
- Set up DMA channel 2 with the source address from which the memory area to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a ***software*** DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

28.3.3.2.2 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 1.
- Leaving the timeout count register with the reset value of zero means no timeout interrupt is generated.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, the CRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a ***software*** DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generates a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 again after one sector is compressed. After 1kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

28.3.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system, the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2Mbyte is to be verified with the help of the CPU. CRC operation is to be performed every 1K byte. Since there are 2Mbyte (256k doublewords) of memory to be check and we want to perform a CRC every 1Kbyte (128 doublewords) and therefore there should be 2048 pre-recorded CRC values. In Semi-CPU mode, the CRC Value Register is not updated and contains indeterminate data.

28.3.3.3.1 DMA Setup

Set up DMA channel 1 with the source address from which the memory area to be verified are mapped. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

28.3.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

Set up timer to generate DMA request associated with DMA channel 1. For example, an OS can set up the timer to generate a DMA request every 10ms.

28.3.3.3.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load value to 15625 (5 ms / (1 HCLK period × 64)) if CRC is operating at 200 MHz.
- Enable Semi-CPU mode and enable all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the PSA Signature Register, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the PSA Sector Signature Register. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2Mbyte are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from PSA Sector Signature Register before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

28.3.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2Mbyte is to be checked with the help of the CPU. CRC verification is to be performed every 1K byte. In CPU mode, the CRC Value Register is not updated and contains indeterminate data.

28.3.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the PSA Signature Register inside CRC Controller. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After ***2MBytes*** data patterns are compressed, CPU can read from the PSA Signature Register. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

28.3.4 MSS_MCRC Registers

Table 28-50 lists the memory-mapped registers for the MSS_MCRC. All register offset addresses not listed in Table 28-50 should be considered as reserved locations and the register contents should not be modified.

Table 28-50. MSS_MCRC Registers

Offset	Acronym	Register Name	Section
0h	CRC_CTRL0	CRC Global Control Register 0	Section 28.3.4.1
8h	CRC_CTRL1	CRC Global Control Register 1	Section 28.3.4.2
10h	CRC_CTRL2	CRC Global Control Register 2	Section 28.3.4.3
18h	CRC_INTS	CRC Interrupt Enable Set Register	Section 28.3.4.4

RESERVED																CRC_CURSEC1															
R-0h																R/W-0h															

Table 28-62. CRC_CURSEC_REG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	CRC_CURSEC1	R/W	0h	Channel 1 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erro- neous sector number.

28.3.4.12 CRC_WDTOPLD1 Register (Offset = 4Ch) [reset = 0h]

CRC_WDTOPLD1 is shown in Figure 28-77 and described in Table 28-63.

Return to Summary Table.

Channel 1 timeout pre-load value to check if within a given time DMA initiates a block transfer

Table 28-75. CRC_CURSEC_REG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	CRC_CURSEC2	R/W	0h	Channel 2 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erro- neous sector number.

28.3.4.25 CRC_WDTOPLD2 Register (Offset = 8Ch) [reset = 0h]

CRC_WDTOPLD2 is shown in Figure 28-90 and described in Table 28-76.

Return to Summary Table.

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	CRC_CURSEC4	R/W	0h	Channel 4 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erro- neous sector number.

28.4 Programmable Built-In Self-Test (PBIST)

This section describes the programmable built-in self-test (PBIST) controller module used for testing the on-chip memories.

28.4.1 Overview

The PBIST (Programmable Built-In Self-Test) controller architecture provides a run-time-programmable memory BIST engine for varying levels of coverage across many embedded memory instances.

Table 28-113. Register Base Address (16xx/18xx)

Name	Frame Address (Hex) Start	Frame Address (Hex) End	Size	Description
MSS_PBIST	0xFFFF_E400	0xFFFF_E5FF	64B	PBIST module configuration registers. This IP covers memory test for all memories excluding DSP L1P, L1D and associated TAG memories.
DSP_PBIST	0x01BD_0000	0x01BD_FFFF	64B	DSP PBIST module configuration registers. This IP covers memory test for DSP L1P, L1D and associated TAG memories.

NOTE: DSP_PBIST register space is accessible only by the DSP core.

Table 28-114. Register Base Address (14xx)

Name	Frame Address (Hex) Start	Frame Address (Hex) End	Size	Description
MSS_PBIST	0xFFFF_E400	0xFFFF_E5FF	464B	PBIST module configuration registers. This IP covers memory test for all memories excluding DSP L1P, L1D and associated TAG memories.

28.4.1.1 PBIST vs. Application Software-Based Testing

The PBIST architecture consists of a small coprocessor with a dedicated instruction set targeted specifically toward testing memories. This coprocessor executes test routines stored in the PBIST ROM and runs them on multiple on-chip memory instances. The on-chip memory configuration information is also stored in the PBIST ROM.

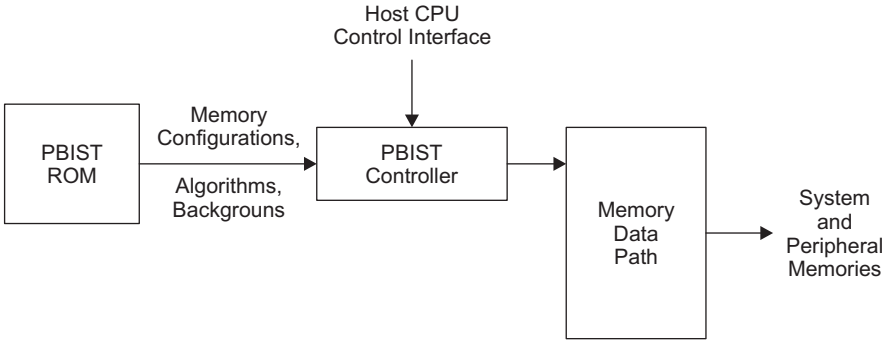
The PBIST Controller architecture offers significant advantages over tests running on the main Cortex-R4F processor (application software-based testing):

- Embedded CPUs have a long access path to memories outside the tightly-couple memory sub-system, while the PBIST controller has a dedicated path to the memories specifically for the self-test
- Embedded CPUs are designed for their targeted use and are often not easily programmed for memory test algorithms.
- The memory test algorithm code on embedded CPUs is typically significantly larger than that needed for PBIST.
- The embedded CPU is significantly larger than the PBIST controller.

28.4.1.2 PBIST Block Diagram

Figure 28-127 illustrates the basic PBIST blocks and its wrapper logic for the device.

Figure 28-127. PBIST Block Diagram



28.4.1.2.1 On-chip ROM

The on-chip ROM contains the information regarding the algorithms and memories to be tested.

28.4.1.2.2 Host Processor Interface to the PBIST Controller Registers

The Cortex-R4F CPU can select the algorithm and RAM groups for the memories' self-test from the on-chip ROM based on the application requirements. Once the self-test has executed, the CPU can query the PBIST controller registers to identify any memories that failed the self-test and to then take appropriate next steps as required by the application's author.

28.4.1.2.3 Memory Data Path

This is the read and write data path logic between different system and peripheral memories tightly coupled to the PBIST memory interface. The PBIST controller executes each selected algorithm on each valid memory group sequentially until all the algorithms are executed.

NOTE: Not all algorithms are designed to run on all RAM groups. If an algorithm is selected to run on an incompatible memory, this will result in a failure. Refer to and for RAM grouping and algorithm information.

28.4.2 RAM/ROM Grouping and Algorithm

28.4.2.1 RAM Algorithm: March13N

This section provides a brief description for some of the test algorithms used for memory self-test.

- **March13N:**
  - March13N is the baseline test algorithm for SRAM testing. It provides the highest overall coverage. The other algorithms provide additional coverage of otherwise missed boundary conditions of the SRAM operation.
  - The concept behind the general march algorithm is to indicate:
    - The bit cell can be written and read as both a 1 and a 0.
    - The bits around the bit cell do not affect the bit cell.
  - The basic operation of the march is to initialize the array to a know pattern, then march a different pattern through the memory.
  - Type of faults detected by this algorithm:
    - Address decoder faults
    - Stuck-At faults
    - Coupled faults
    - State coupling faults
    - Parametric faults
    - Write recovery faults
    - Read/write logic faults

28.4.2.2 ROM Algorithm: Triple Read XOR Read

The triple read reads the array, all the way through, three times while summing the reads to compare the sums for all three read formats. The algorithm checks if there is enough margin in both the erasure and programmation to operate at full speed with the CPU. This can be addressed with the XOR Read (Memory Contents XOR Memory Address). An error in the XOR Read indicates that the interaction between adjacent bit cells, being a different polarity, may be causing speed issues when the CPU exercises worst-case instruction sequencing. Each read can be performed on any memory block, and an associated checksum is calculated to determine PASS or FAIL.

Type of faults detected by this algorithm:

- Address decoder faults
- Stuck-At faults
- Coupled faults
- State coupling faults
- Parametric faults
- Read logic faults

NOTE: March13N is the most recommended algorithm for the memory self-test.

28.4.3 PBIST Registers

Table 28-115 lists the memory-mapped registers for the PBIST. All register offset addresses not listed in Table 28-115 should be considered as reserved locations and the register contents should not be modified.

Table 28-115. PBIST Registers

Offset	Acronym	Register Name	Section
164h	PBIST_DLR	Datalogger 0	Section 28.4.3.1

3-0	PBIST_OVR	R/W	9h	PBIST Overrides. [0] : RINFO Override Bit While doing ROM-based testing, each algorithm downloaded from the ROM has a memory mask associated with it that defines the applicable memory groups the algorithm will be run on. By default, this bit is set to 1, which means the memory mask that is downloaded from the ROM will overwrite the RAM info registers. The override bit can be reset by writing a 0 to it. In this case, the application can select the RAM groups to be tested by configuring the RAM info registers. NOTE: When this override bit = 0, each algorithm selected in ALGO register will run on each RAM selected in RINFOL and RINFOU register. It must be ensured that: a. Only the same type of memories (single port or two port) are selected, and b. Only memories that are valid for all algorithms enabled via the ALGO register are selected. If the above two requirements are not met, the memory self-test will fail. [3:1] : Reserved. This bit must not be changed from its default value of 0.

28.5.2 General Description

The enhanced Self-Test Controller (STC) is used to test logic cores based on the On-Product Multiple Input Signature Register (OPMISR) scan compression architecture.

Software-based self-test programs for the cores are available, but offer less test coverage. Due to the complexity of the soft cores, it is difficult to achieve the required coverage; also, the program size is larger. For these complex cores, on-chip logic BIST support for the self-test is preferred.

The main features of this solution include:

- Implements the OPMISR controller, along with the on-chip self-test controller for the synthesizable module logic, which enables high test coverage.
- Can divide the complete test run into independent test sets (intervals).
- Capable of running the complete test, and running several intervals at a time.
- Can continue from the last executed interval (test set), and restart from the beginning (first interval in the ROM), or start from the first interval of each segment.
- A single self-test controller can support a test of up to 4 logical segments. A segment identifier corresponding to each interval is stored in the self-test ROM.
- The self-test controller facilitates complete isolation of the logical segment under the test from the rest of the system during the self-test run. Configure critical control signals in the master and slave ports of the logical segment under the test to a safe state.
- The self-tested CPU core master bus transaction signals are configured to be in idle mode during the self-test run.
- Can capture the failure interval number.
- Time-out counter for the self-test run as a fail-safe feature.
- Can read the MISR data (shifted from the OPMISR controller) of the last executed interval of the self-

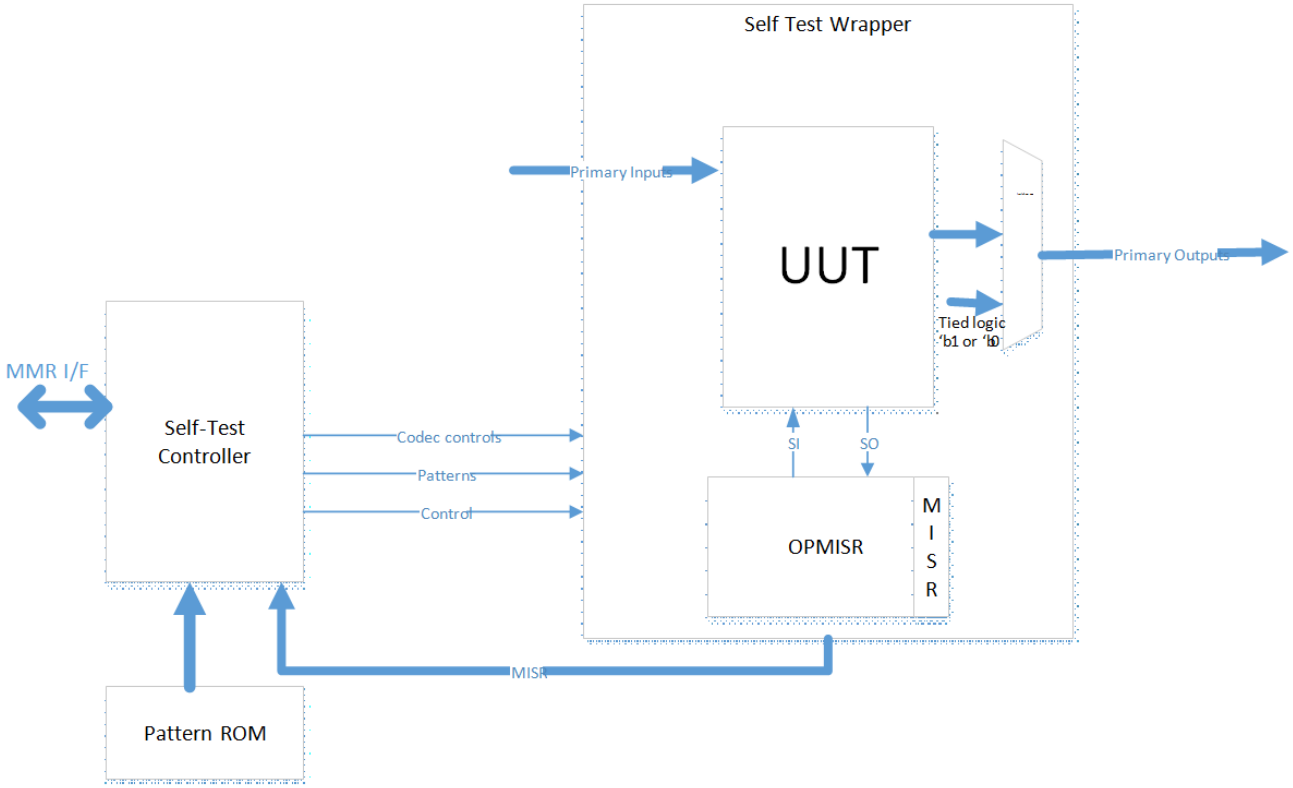
test run, for debugging purposes.

- Can capture power reduction using dead cycles before and after the capture pulse.
- Coverage improvements technique – ROM inverse access mode. In this, the patterns are read in a reverse order from ROM and applied to the UUT. Pattern randomization due to this approach results in coverage improvement, without an increase in the number of patterns. Corresponding INV_MISR is also stored in the ROM.

A self test segment corresponds to a portion of discreet safety-critical logic which can be tested in isolation from the rest of the system by the self test controller and OPMISR logic.

28.5.2.1 OPMISR Concept

Figure 28-140. OPMISR Conceptual Diagram



The On-Product Multiple-Input Signature Register (OPMISR) is a methodology which moves the test pattern generation on-chip. Logic BIST is implemented on functional partitions (BIST'ed COREs) that are speed-critical and have high gate count. A conceptual diagram of OPMISR implementation is shown in Figure 28-140.

The MISR test structure modifies the typical fullscan scan chain such that each scan data input internally drives many chains. These chains feed to the inserted MISR structure. The chain's values are captured into the MISR during shift, generating a resulting signature that can be shifted out.

A given Unit Under Test (UUT) is scan-inserted, and the scan chains are hooked to the OPMISR logic. The self-test wrapper created around the UUT and the OPMISR logic includes the isolation muxes for the output ports of the core, to ensure that the core and UUT are isolated from the rest of the system during the self-test.

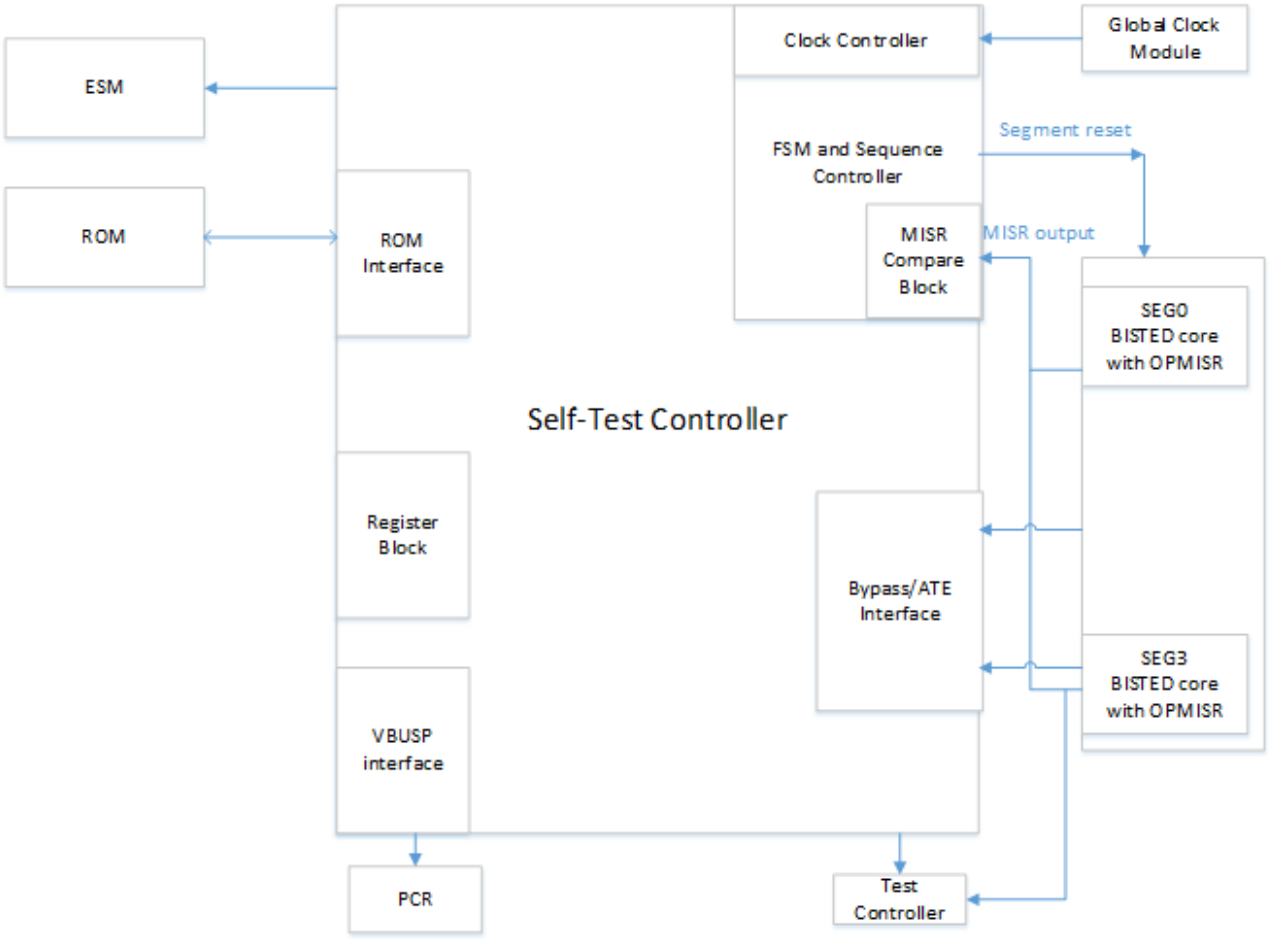
28.5.3 Block Diagram

The STC module is composed of following blocks:

- ROM interface

- FSM and sequence control
- Register file
- STC bypass / ATE interface
- Peripheral bus interface (VBUSP interface)

Figure 28-141. Block Diagram for STC With Multiple Segments



28.5.4 Module Description

28.5.4.1 ROM Interface

This block handles the ROM address and control signal generation to read the self-test microcode from the ROM. The test microcode, patterns, and golden signature value for each interval is stored in ROM. Detailed information of the ROM microcode is available at ROM.

28.5.4.2 FSM and Sequence Control

This block generates the signals and data to OPMISR controller based on the test type and scan chain depth. The sequence of operation per interval is defined in Section 28.5.5.

28.5.4.2.1 Clock Control

The CLOCK CNTRL sub-block handles the clock selection and clock generation for ROM, OPMISR controller, and BIST'ed CORE clocks.

28.5.4.2.2 MISR Compare Block

At the end of the each self-test interval, an 896-bit MISR value from the OPMISR controller is shifted into NSTC. This is compared with the MISR_GOLDEN value, which is copied into a buffered register before the start of the interval. The result is updated into the status registers.

28.5.4.3 Register Block

This block implements the user-programmable control registers that determine when to start a self test, at what clock frequency the scan test should be performed, which segment to be selected for the test, how many pattern intervals to be completed before stopping, and so forth.

The register block also captures various status information of the self test for the user.

28.5.4.4 STC Bypass / ATE Interface

This is a production test interface. This section bypasses the self-test FSM. The OPMISR signal interface is brought out directly to the module ports, and these are accessible to the ATE (tester) at the device level using the test controller module. The intent of the block is to provide capability for fault isolation for parts failing the logic self test run.

This block receives two sets of signals; one from the device test controller, and another similar set from the self-test FSM (test sequencer). The bypass indicator signal is used to select one of the two sets of signals to be routed to the OPMISR controller.

28.5.4.5 VBUSP Interface

The control and the status registers of the STC module can be accessed through the VBUSP interface. During application programming, configuration registers are programmed through the peripheral interface, to enable and run the self-test controller.

CFG for interval 1, when rom_access_inversion =1 (same as when_rom_access_inversion =0)	Reserved	pattern_count[9:0]	Reserved	clk_domain_off[7:0]	Reserved	Seg_ID[1]	Seg_ID[0]	FT	TR_T

The ROM contains the data to be processed by STC for the self-test run. This includes the control fields such as Segment ID, Pattern Count, and Golden MISR value for the STC, and the pattern scan data for the OPMISR controller.

The ROM space is divided into chunks, with each chunk containing the data corresponding to one OPMISR interval. The size required for an interval varies depending on the number patterns packed into the interval and the length of internal scan chains required.

Because each interval requires 64 rows of ROM for storing control and Golden MISR values, minimizing the number of intervals by packing more patterns into each interval provides the best ROM size. This works best if the self-test must be run only as a part of the boot-up sequence. However, if the self-test is performed during application IDLE time, the number of patterns that can be packed into each interval will be dictated by the IDLE time available for the self-test, because an interval is the smallest granularity of a self-test run.

Details of the ROM image micro-code fields are given in the following sections.

28.5.6.1 TR_T: Transition Delay Methodology Type

This specifies the transition delay methodology for the current transition delay interval.

0	Launch-on-System-Clock
1	Launch-on-Last-Shift

28.5.6.2 FT: Fault Model for the BIST Run

This specifies the fault model for the current interval of the test.

0	Stuck-at
1	Transition Delay

28.5.6.3 SEG_ID[1:0]

This indicates which logical segment is selected for the associated interval during the self-test run.

SEG_SEL[1:0]	Segment Under Test
00	Segment 0
01	Segment 1
10	Segment 2
11	Segment 3

28.5.6.4 Pattern Count (patt_count[9:0])

This specifies the number of scan data patterns within a self-test interval. The pattern counts can vary from a minimum of 2 to a maximum of 1024.

patt_count[9:0]	Patterns per Interval
00_0000_0000	Not a valid interval [defaults to 2 patterns per interval]
00_0000_0001	2 patterns per interval
00_0000_0010	3 patterns per interval
...	...
11_1111_1110	1023 patterns per interval
11_1111_1111	1024 patterns per interval

28.5.6.5 CLK_DOMAIN_OFF[7:0] (Not Supported in This Version)

This specifies whether to enable or switch off the particular clock domain or clock groups (consisting of multiple clock domains of the same maximum spec frequency) of the BIST'ed CORE logic during the capture phase of the At-speed OPMISR pattern of the current interval.

Domain	Value	Description
clk_domain_off[0]	0	Clock0 enabled
	1	Clock0 disabled
clk_domain_off[1]	0	Clock1 enabled
	1	Clock1 disabled
clk_domain_off[2]	0	Clock2 enabled
	1	Clock2 disabled

Domain	Value	Description
clk_domain_off[3]	0	Clock3 enabled
	1	Clock3 disabled
clk_domain_off[4]	0	Clock4 enabled
	1	Clock4 disabled
clk_domain_off[5]	0	Clock5 enabled
	1	Clock5 disabled
clk_domain_off[6]	0	Clock6 enabled
	1	Clock6 disabled
clk_domain_off[7]	0	Clock7 enabled
	1	Clock7 disabled

28.5.6.6 MISR_GOLDEN[895:0]: Golden Signature Data Bits

This part of ROM contains the golden signature data of the current interval. This value is used to compare with the actual MISR value, when ST_GCR1.ROM_ACCESS_INV=0 and ST_GCR1.LP_SCAN_MODE=0, to generate the pass/fail information of the interval.

28.5.6.7 LP_MISR_GOLDEN[895:0]: Low Power Mode Golden Signature Data Bits

This part of ROM contains the LP golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=0 and STCGCR1.LP_SCAN_MODE=1, to generate the pass/fail information of the interval.

28.5.6.8 INV_MISR_GOLDEN[895:0]: Inverse Mode Golden Signature Data Bits

This part of ROM contains the inverse mode golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=1 and STCGCR1.LP_SCAN_MODE=0, to generate the pass/fail information of the interval.

28.5.6.9 LP_INV_MISR_GOLDEN[895:0]: Low Power Inverse Mode Golden Signature Data Bits

This part of ROM contains the low-power inverse mode golden signature data of the current interval. This value is used to compare with the actual MISR value, when STCGCR1.ROM_ACCESS_INV=1 and STCGCR1.LP_SCAN_MODE=1, to generate the pass/fail information of the interval.

28.5.6.10 Pn_SDm[7:0] (n - no. of patterns, m - scan chain length): OP-MISR Scan Data

This part of the ROM contains the scan data corresponding to each pattern. Each interval can have n number of scan patterns, as defined in the patt_count field. The number of 7bits of scan data in a pattern is equal to the length of the scan chain formed inside the UUT.

28.5.7 STC Registers

Table 28-132 lists the memory-mapped registers for the STC. All register offset addresses not listed in Table 28-132 should be considered as reserved locations and the register contents should not be modified.

Table 28-134. STCGCR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	INTCOUNT_B16	R/W	1h	Number of intervals of the self test run (RWP - Read, Priviledge Mode Write only) Count of intervals that need to be covered for a specific selftest run. The selftest controller sends out “complete” indication once it runs all of the intervals programmed in this field. INTCOUNT_B16=0 is an invalid configuration for a selftest.
15-11	NU0	R	0h	Reserved bits
10-8	CAP_IDLE_CYCLE	R/W	1h	Idle cycles before and after capture clock (RWP - Read, Priviledge Mode Write only) Idle Cycles before and after capture clock. This value is used to insert that many idle cycles in the Capture phase. Programmable idle cycles allow implementation flexibility on SCAN_EN signal at chip level based on the size of the UUT and timing requirements.
7-5	SCANEN_HIGH_CAP_IDLE_CYCLE	R/W	1h	Idle cycles before and after capture clock (RWP - Read, Priviledge Mode Write only). *NOT BYTE ACCESSIBLE Idle Cycles between scan_en going high to func_clk_en generation and scan_en going high to misr_log_en generation. This value is used to insert that many idle cycles in the shift clock (scan_en going high to func_clk_en generation) and misr_log_clk (scan_en going high to misr_log_en generation) generation. Programmable idle cycles allow implementation flexibility on SCAN_EN signal at chip level based on the size of the UUT and timing requirements.
4-2	NU1	R	0h	Reserved bits
1-0	RS_CNT_B1	R/W	0h	Restart/Continue or preload (RWP - Read, Priviledge Mode Write only) This bit specifies the selftest controller whether to continue the run from next interval onwards, restart from ROM address 0 or preload from a prescribed interval. This bit gets reset after the completion of selftest run. 00 = Continue NSTC run from previous interval 01 = Restart NSTC run from ROM address 0 1X = Start from segment number specified in STC_SEGPLR register

28.5.7.2 STCGCR1 Register (Offset = 4h) [reset = 25h]

STCGCR1 is shown in Figure 28-145 and described in Table 28-135.

Return to Summary Table.

R/W-FFFFFFFFh																															

Table 28-136. STCTPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TO_PRELOAD	R/W	FFFFFFFFh	Self test time out preload (RWP - Read, Priviledge Mode Write only) This register contains the total number of STC clock cycles it will take before a self-test timeout error will be triggered after the initiation of the self-test run. This is a fail safe feature to avoid system hang-up situation on account of any run away self test issues. This register should be loaded with a meaningful count value for this feature to be effective. This register value (preload count value) gets loaded into the self test timeout down counter whenever a self test run is initiated (ST_ENA is enabled). and gets disabled on completion of a self test run.

28.5.7.4 STC_CADDR Register (Offset = Ch) [reset = 0h]

STC_CADDR is shown in Figure 28-147 and described in Table 28-137.

Return to Summary Table.

The MISR values should be read only after the Self Test is completed.

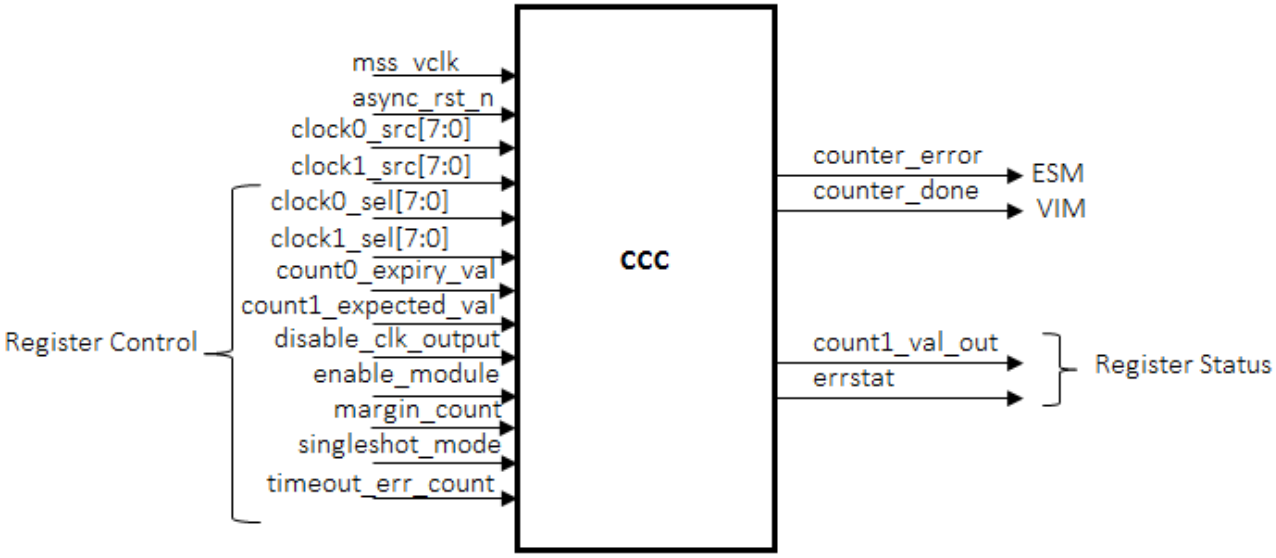
28.6 Core Clock Comparator (CCC) Module

Figure 28-215. Core Clock Comparator Module



28.6.1 Description

CCC supports singleshot and continuous mode of an operation such as DCC. In continuous mode, the programmed values are reloaded after every successful comparison.

Module accepts 7 clock inputs for clock 0 and clock 1. One of these clock inputs is selected to counter 0 and counter 1. Counter 0 is a down counter, and is preloaded with a value before enabling the module. Counter 1 is an up counter which operates on clock 1.

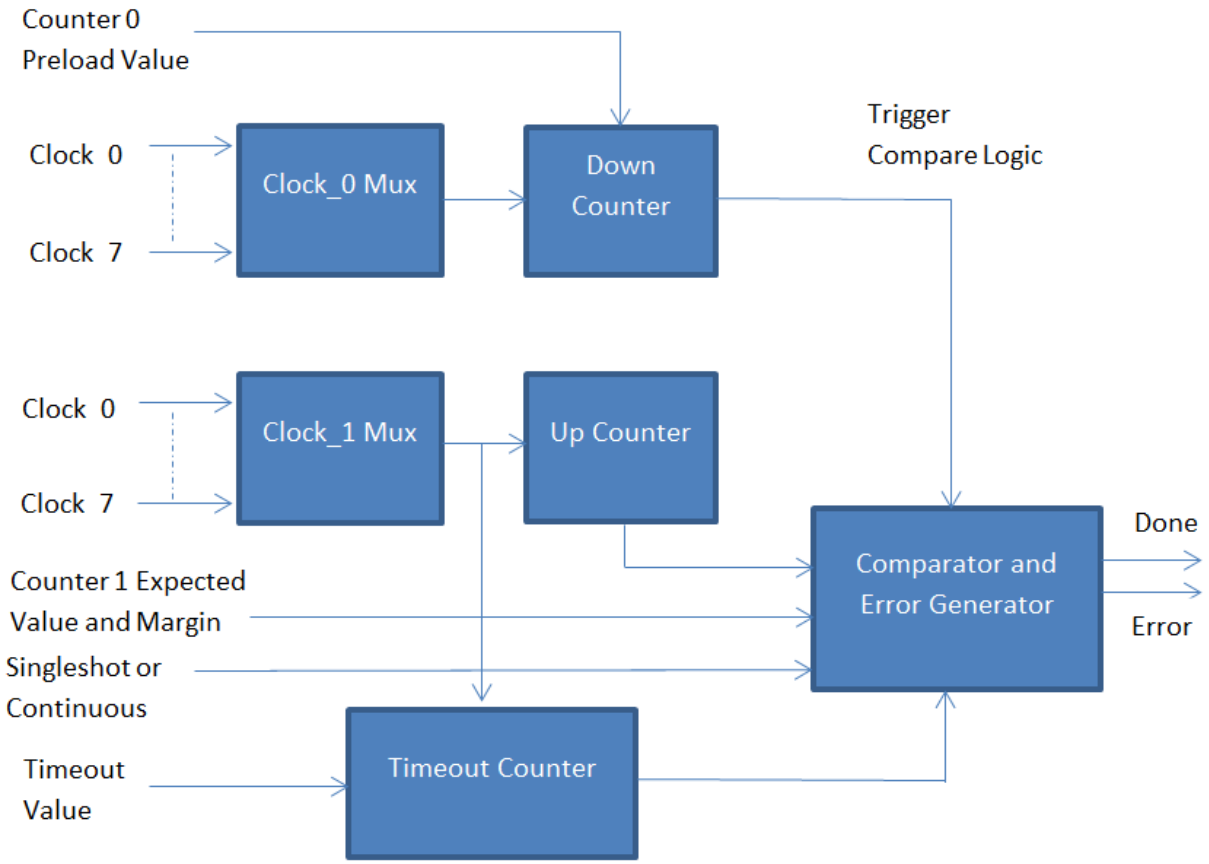
At the expiry of counter 0, value in the counter 1 is compared against the programmed expected value of the counter. After a successful comparison, a done signal is asserted in singleshot mode, whereas in continuous mode, counter 0 is reloaded for the next comparison. Margin value programming provides the tolerance for the comparison. An error signal is asserted when the counter 1 value differs from the expected value beyond the tolerance range.

When an error occurs, the module stops comparison in both singleshot and continuous mode.

There is a time-out counter functioning on clock 1. A time-out value must be loaded into the time-out counter before enabling the module. If the time-out counter expires before the expiry of counter 0, an error condition is indicated. In continuous mode, after the successful comparison, the time-out value is also reloaded along with counter 0.

28.6.2 Block Diagram

Figure 28-216. Block Diagram



28.6.3 Perform Clock Comparison

1. Select clock 0.
2. Select clock 1.
3. Load value for down counting in counter 0.
4. Load expected value of counter 1.
5. Load margin value for tolerance.
6. Set singleshot or continuous mode.
7. Load time-out value.
8. Enable module.

9. Wait for done or error indication.

28.6.4 Recommended Programmation

- Clock source 1 must be faster than clock source 0 for a successful comparison of clocks.
- The time-out value must always be loaded for successful comparison. The time-out value must be greater than the duration of comparison operation.

  - CCCACNTVAL
  - CCCBCNTVAL
  - CCCABERRSTAT
  - CCCBWDEN (applicable for the 16xx/18xx device only)

Glossary

1

1MS— One milisecond

2

2D— Two Dimensional

3

3A— AF + AE + AWB

3D— Three Dimensional

3G— 3rd Generation of mobile communication systems

3GPP— 3rd Generation Partnership Project

8

8B— 8 bits

10

10B/8B— 10 bit to 8 bit conversion (i.e., 8B/10B decoding)

A

A/D— Analog to Digital Converter

ABB— Adaptive Body Bias

ABBLDO— Adaptive Body Bias Low Drop Out

ABS— Absolute Value

ACB— AC–bias frequency

ACBI— AC–bias line transitions per interrupt

ACE— ASIC Compiler Environment.

ACK— Acknowledge

ADC— Analog-to-Digital Converter/Conversion.

ADMA— Advanced DMA

ADPLL— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase–sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

AER— Advanced Error Reporting (PCIe)

AES— Advanced Encryption Standard

AET— Advanced Event Triggering - this capability can be used to debug complex problems as well as understand performance characteristics of user applications

AF— Auto Focus

AFE— Analog Front End

AFSX— Audio transmit frame synchronization

AHB— Advanced High-performance Bus

AHB-AP— Advanced High-performance Bus - Access Port

AIC— Analog Interface Chip.

ALE— Address Latch Enable

AM— Amplitude Modulation

AMBA— Advanced Micro-Controller Bus Architecture

AMMU— Attribute Memory Management Unit

ANSI— American National Standards Institute

AP— Address Protection

APB— Advanced Peripheral Bus

APB-AP— Advanced Peripheral Bus - Access Port

APE— Application Engine

API— Application Programming Interface

APLL— Analog Phase–Locked Loop

APWM— Asymmetrical Pulse Width Modulation (eCAP module related)

AR— Automatic Reload

ARGB— Alpha Red Green Blue

ARI— Alternative Routing-ID Interpretation (PCIe)

ARM— Advanced RISC Machine

ASCII— American Standard Code for Information Interchange

ASIC— Application–Specific Integrated Circuit

ASP— Application-Specific Peripheral

ASPM— Active State Power Management: Automatic PM in PCIe link layer FSM (PCIe)

ATA— Interface standard for the connection of storage devices (Advanced Technology Attachment)

ATAPI— ATA Packet Interface

ATB— AMBA Advanced Trace Bus

ATS— Address Translation Service (PCIe)

AVB— Audio Video Bridging

AVS— Adaptive Voltage Scaling

AWB— Auto White Balance

AWS— Audio Word Select

AXI— Adavced eXtensible Interface

B

B— Byte, 8 bits

BARn— Base Address Register (PCIe)

BB— Bus Busy

BCD— Binary-Coded Decimal.

BCH— Bose-Chaudhuri-Hocquenghem (CRC Code)

BCM— BIST Combiner Module

BDF— Bus / Device/ Function: (PCIe) function identifier

BE— Big Endian.

BFSW— Buffer Switch

BGA— Ball Grid Array

BGAP— Band Gap

BGT— Block Guard Time

BIOS— Basic Input/Output System. First software run after reset. Known also as ROM Code.

BIST— Built-In Self-Test

BIU— Bus Interface Unit

BL— Buffer Logic

BME— Bus Master Enable (PCI CFG bit)

BNC— British Naval Connector, Bayonet Nut Connector, or Bayonet Neill Concelman

BOF— Beginning of Frame

BOL— Beginning of Line

BPP— Bits Per Pixel

BS— Block Synchronization

BSP— Buffered Serial Port.

BTA— Bus Turn Around

BW— Band Width

BWM— Band Width Manager (functional entity in the TMS320C66x DSP CorePac)

BWS— Baseband Word Select

C

CABAC— Context-Adaptive Binary Arithmetic Coding

CAF— Combing Artifacts Calculation

CALC3— Transform and Quantization Calculation Engine

CAN— Controller Area Network

CAS— Column Address Strobe

CAVLC— Context-Adaptive Variable Length Coder

CB— Copy Back

CBC— Cipher Block Chaining

CBP— Coded Block Pattern

CBUF— Circular Buffer (Associated with OCMC)

CC— Channel Controller

CCC— Command Completion Coalescing feature

CDP— Coprocessor Data Operation

CDR— Clock Data Recovery

CE— Chip Enable

CEA-861-D— Video standard. It defines the video timing requirements, discovery structures, and data transfer structure.

CEC— Consumer Electronics Control

CFI— Common Flash Interface device

CH— Configuration Header. To use different settings than ROM Code defaults, i.e. clock frequencies, SDRAM settings, GPMC settings.

CID— Card Identification Number

CIF— Common Intermediate Format.

CIR— Consumer Infra Red

CLB— Command List Base Address

CLE— Command Latch Enable

CLK— Clock

CLO— Command List Override feature

CLUT— Color Look-Up Table

CM— Clock Management

CMOS— Complimentary Metal Oxide Semiconductor

CO— Controlled Oscillator

CODEC— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

COS— Class Of Service

CP15— Arm® Cortex®-A15 system control coprocessor. This coprocessor controls and provides status information for the functions implemented in the main processor

CPFROM— Customer Programable eFuse ROM

CPPI— Communications Port Programming Interface

CPR— Color Phase Rotation

CPS— Cell Search Platform

CPSR— Current Program Status Register

CPU— Central Processing Unit

CRC— Cyclic Redundancy Check

CS— Chip-Select

CSL— Chip Support Library

CSWR— Closed switch retention

CTM— Counter-Timer Module

CTR— Hardware block for CCTrCh processing

CTRL— Control

CTS— Clear to Send

ConnID— Connection Identifier.An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for security and error logging mechanism.

D

D2H— Device to Host transfer of a FIS

DAC— Digital to Analog Converter

DAP— Debug Access Port

DBI— Display Buffer Interface

DC— Direct Current

DCAN— CAN Controller Module

DCC— Duty Cycle Correction Circuit

DCD— Data Carrier Detect

DCO— Digitally Controlled Oscillator

DCT— Discrete Cosine Transform.

DDC— Display Data Channel

DDR— Double Data Rate

DE— Data Enable

DED— Double Error Detection

DEI— Deinterlacer

DES— Data Encryption Standard.

DES3DES— Data Encryption Standard and triple DES

DFF— Data Flip-Flop

DFT— Design For Test

DIN— Data In

DIR— Digital audio Interface Receiver

DISPC— Display Controller

DL— Data Length

DLB— Data Loopback.

DLL— Delay-Locked Loop

DLLP— Data Link Layer Packet: PCIe (compare PLP, TLP)

DMA— Direct Memory Access.

DMC— Digital Motor Control

DMEM— Data Memory

DMM— Dynamic Memory Management

DMT— Display Monitor Timing

DO— Data Out

DPC— Defect Pixel Correction

DPI— Display Parallel Interface

DPLL— Digital Phase-Locked Loop. Digital implementation of PLL.

DPS— Digital Power Switching

DRDY— Data Ready

DRM— Digital Rights Management

DS— Downstream: from the host (or a hub) to a device (or hub).

DSP— Digital Signal Processor.

DSR— Data Set Ready

DSS— Display Sub-System. Also DISS

DTBC— Data Buffer Controller

DTC— Debug and Trace Controller

DTCM— Data Tightly Coupled Memory

DTR— Data Transmit Ready

DVFS— Dynamic Voltage and Frequency Scaling

DVI— Digital Video Interface

DWORD— Double WORD (32-bit sized portion of data)

E

EAV— End of Active Video

ECAM— Enhanced Configuration Access Mechanism (PCIe)

ECC— Error Checking and Correction. Also Error Correction Code.

ECD3— Entropy Coder/Decoder

ECRC— End-to-end Cyclic Redundancy Check (optional, compare LCRC)

ED— Endpoint Descriptor

EDC— Error Detection Code

EDI— Edge Directed Interpolation

EDMA— Enhanced DMA

EDMA_TPCC— Enhanced DMA Third Party Channel Controller

EDMA_TPTC— Enhanced DMA Third Party Transfer Controller

EEE— Energy Efficient Ethernet

EEPROM— Electrically Erasable Programmable Read Only Memory

EFUSE— Electrical Fuse. A one-time programmable memory location usually set at the factory

EMC— External Memory Controller

EMI— Electromagneric interference

EMIF— External Memory Interface

EOB— End of Block

EOF— End of Frame

EOL— End of Line

EOP— End of Packet

EOT— End of Transfer

EP— Entry Point. Also End Point in USB and PCIe controller context.

EPM— Emulation Pin Manager

ES— Erase Status

ESC— Escape

ESR— Event Set Register

ETB— Embdedded Trace Bus

ETM— Embedded Trace Macrocell

EVM— Evaluation Module

F

FB— Received FISes base address

FBB— Forward Body-Bias

FC— Frame Counter

FCLK— Functional Clock

FCS— Frame Check Sequence

FD— Face Detect

FE— Framing Error

FF— Flip-Flop

FIFO— First In First Out

FIQ— Fast Interrupt Request. See ISR.

FIR— Fast Infrared

FLR— Function Level Reset (PCIe)

FM— Frequency Modulation

FMD— Film Mode Detection

FPGA— Field Programmable Gate Array.

FPKA— Fast-Public Key Accelerator

FROM— eFuse ROM

FS— Full-Speed

FSM— Finite State Machine.

FTS— Fast Training Sequence (PCIe)

FW— Firewall

G

GDP— Generic Dot Product

GFX— Graphics

GHB— Global History Buffer

GIC— Secure interrupt controller

GMII— Gigabit Media Independent Interface

GP— General-purpose

GPIO— General Purpose Input/Output

GPMC— General Purpose Memory Controller

GPU— Graphics-processing unit

GT/s— Gigatransfers per second

GZ— Ground Zero

H

H.263— Video Codec Standard

H.264— Video Codec Standard

H/W— Hardware

H2D— Host to Device transfer of a FIS

HAL— Hardware Abstraction Layer

HBA— Host bus adapter

HBP— Horizontal Back Porch

HC— Host Controller

HCI— Host Controller Interface

HD— High Definition

HDCP— High-bandwidth Digital Content Protection

HDD— Hard-disk drive

HDMI— High-Definition Multimedia Interface

HDTV— High-Definition Television

HFP— Horizontal Front Porch

HLOS— High-Level Operating System

HMI— Human Machine Interface

HNP— Host Negotiation Protocol (OTG feature)

HPF— High-Pass Filter

HS— High-Speed

HSDPA— High Speed Downlink Packet Access

HSSCLL— High-Speed Serial Control Channel

HSUPA— High Speed Uplink Packet Access

HSW— Horizontal Synchronization Pulse Width

HSYNC— Horizontal Synchronization.

HW— Hardware

HWA— Hardware Accelerators.

HWOBS— Hardware Observability

I

I/F— Interface

I/O— Input/Output

I2C— Inter-Integrated Circuit

I2S— Inter-IC Sound

IA— Identifier Address

IATU— Internal Address Translation Unit (PCIe controller)

IBR— An ATU Inbound Region (PCIe)

ICE— In-Circuit Emulation

ICEPICK— Generic TAP for emulation control

ICLK— Interface Clock

ICONT— Imaging Controller

ICR— Intersystem Communication Registers

ID— Identification

IDCT— Inverse Discrete Cosine Transform. See DCT.

IDE— Integrated Development Environment. A programming environment integrated into an application.

IDO— ID-based Ordering (PCIe)

IIS— Inter–IC Sound

ILF3— Improved Loop Filter engine

IM— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).

IME3— Improved Motion Estimation engine

INT— Interrupt

INTC— Interrupt Controller

IP— Intellectual Property

IPC— Interprocessor Communication. Also referred to as "mailbox" on occasion

IPE3— Intra Prediction Estimation engine

IPU— Image-processing unit

IQ— Inverse Quantization

IR— Incremental Redundancy Buffer

IRQ— Interrupt Request.

ISA— Instruction Set Architecture

ISE— I/O Space Enable: (PCI CFG bit)

ISO— Isochronous.

ISP— Image Signal Processor

ISR— Interrupt Service Routine.

IST— Interrupt Service Thread.

ITCCHEN— Intermediate transfer completion chaining enable.

ITCINTEN— Intermediate transfer completion interrupt enable.

ITCM— Instruction Tightly Coupled Memory

IVA— Image and Video Accelerator

IVA-HD— High Definition Image and Video Accelerator

IrDA— Infrared Data Association.

J

JEDEC— Joint Electronic Devices Engineering Council

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group.

K

KB— Kilobyte, 1024 Bytes

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect

L4— Second level of interconnect

LA— Logical Address

LAN— Local Area Network

LBA— Logical Block Addressing

LC— Logical Channel

LCD— Liquid Crystal Display.

LCRC— Link Cyclic Redundancy Check (mandatory, compare ECRC)

LCh— Logical DMA Channel. Also LCH

LD— Lens Distortion

LDO— Low Dropout

LE— Little Endian.

LEC— Line End Code

LED— Light Emitting Diode.

LF— Loop Filter

LFPS— Low Frequency Periodic Signaling defined in USB 3.0 SuperSpeed standard

LFSR— Linear-Feedback Shift Register

LH— Local Host

LINK— Link Layer Device

LISA— Local Interconnect and Synchronization Agent

LLC— Link Layer Control

LLP— Low-Level Protocol

LP— Low-Power, operation mode for PHY

LPAE— Large Physical Address Extensions

LPM— Low Power Mode (also known as LPMODE)

LPP— Lines Per Panel

LRU— Least Recently Used

LS— Low-Speed

LSB— Least Significant Bit

LSE— IVA Load and Store Engine

LSM— LISA Section Manager

LSR— Linear Shift Register

LSW— Least Significant Word

LTR— Latency Tolerance Reporting (PCIe)

LTSSM— Link Training and Status State Machine: In PCIe - PM FSM of PCIe physical layer

LUT— Look-up Table

LVCMOS— Low Voltage Complementary Metal Oxide Semiconductor

LVDS— Low-Voltage Differential Signaling

M

M2— Micro Memory

MAC— Message Authentication Code

MAP— Maximum a posteriori algorithm

MB— Megabyte, 1024 KB

MBAFF— MB-Level Adaptive Frame/Field

MBMS— Multimedia Broadcast Multicast Service

MC3— Motion Compensation Engine

McSPI— Multichannel Serial Peripheral Interface

MCU— Microcontroller Unit. Refers to the MPU.

MDIO— Management Data Input/Output

MDMA— Modem DMA. Also Master DMA port of the DSPSS TMS320C66x CorePac.

MDT— Motion Detection

ME— Motion Estimation

MEMIF— Memory Interface

MIF— Memory InterFace

MII— Media Independent Interface

MIPI— Mobile Industry Processor Interface

MIR— Medium Infrared

MJPEG— Motion JPEG

MMR— Memory Mapped Register

MMU— Memory Management Unit.

MP3— MPEG Layer 3.

MPEG— Motion Pictures Expert Group.

MPEG1— The first MPEG compression scheme specification.

MPS— Maximum Packet Size

MPU— Microprocessor Unit.

MRRS— Maximum Read Request Size (PCIe)

MS— Memory Stick

MSB— Most Significant Bit

MSGIF— Message Interface

MSS— Master Subsystem

MUX— Multiplex/Multiplexer

MV— Motion Value

Mb— Megabit

Mbps— Mega bits per second

Modem— Modulator Demodulator

MuxMode— 3 bits field of the PIN/PAD Control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

N

N/A— Not Applicable. Also Not Available.

NAC— Network Access Control

NAND— NAND Flash memory.

NIU— Network Interface Unit

NMI— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.

NOP— No OPeration (DSP/CPU instruction)

NOR— A type of flash memory

NRZ— Non-Return-to-Zero

NTSC— National Television System Committee. Television broadcast system.

NVIC— Nested Vectored Interrupt Controller

O

OCM— On-chip Memory

OCMC— On-chip Memory Controller

OCP— Open-Core Protocol

OE— Output Enable

OOB— Out of Band signaling

OPP— Operating Performance Point

OS— Operating System

P

PA— Program Address

PATA— Parallel-ATA

PBIAS— PMOS Bias transistor to provide the bias voltage to extended drain IOs

PC— Program Counter

PCI— Peripheral Component Interconnect.

PCLK— Pixel Clock

PCM— Pulse Code Modulation.

PCS— Physical Coding Sublayer (component related to PCIePHY)

PD— Program Data

PDA— Personal Digital Assistant

PDC— Power-down Controller

PE— Parity Error

PFPW— Prefetch and Prewrite posting engine

PHY— Physical Layer Device

PI— Pixel Interpolation

PID— Protocol Identifier. The PID register is used in Windows CE mode only.

PIO— A programmed input/output transfer supported by IDE devices

PIPE3— Physical Interface for PCI Express rev.3.0

PLD— Programmable Logic Devices

PLL— Phase–Locked Loop.

PM— Programming Model

PMA— Physical Media Attachment sublayer

PMEM— Program Memory

PMFW— Power Management FrameWork

PMIC— Power management Integrated Circuit

PMP— Power Management Port

PMU— Performance Monitoring Unit

POR— Power–On Reset

PPA— Primary Protected Application.

PPC— Palm–size PC

PPI— Physical Layer Protocol Interface

PPL— Pixels per Line

PPM— Parts per million

PRCM— Power, Reset and Clock Management

PRD— Physical Region Descriptor

PRM— Power and Reset manager

PRT— PRD Table

PS— Packet Start

PSC— Prescaler Counter

PSS— Program Suspend Status

PT— Packet Type

PTI— Parallel Trace Interface

PTV— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.

PWL— Pulse Width Light (modulator). A 4096-bit randomsequence generator that provides control of the LCD backlighting and keypad.

PWM— Pulse Width Modulation

PaRAM— Programmable RAM that stores 32-byte channel transfer definition that EDMA channels, QDMA channels, and linking uses.

Q

QDMA— Quick DMA

QIQ— Quantization and Inverse Quantization

QOS— Quality of Service

QP— Quantization Parameter

QSPI— Quad Serial Peripheral Interface

R

R/W— Read/Write. Also RW.

R5— Release 5 of 3GPP specifications on IMS and HSDPA standards

R6— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards

RAM— Random Access Memory.Fast-access but volatile memory type.

RC— PCIe Root Complex

RDR— Receive Data Register

RE— Read Enable

REQ— Request

RF— Radio Frequency

RFF— Retention Flip-Flop

RFU— Reserved for Future Use

RGB— Red Green Blue

RGBA— Red Green Blue Alpha

RGMII— Reduced Gigabit Media Independent Interface

RI— Ring Indicator

RISC— Reduced Instruction Set Computing. A CPU whose instruction set and related decode mechanism are much simpler than those of microprogrammed complex instruction set computers. The result is a higher instruction throughput and a faster real–time interrupt service response from a smaller, cost-effective chip.

RM— Reed-Muller code

RMII— Reduced Media Independent Interface

RNG— Random Number Generator

RO— Read Only

ROM— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

RSS— Reset System Simulator

RST— Reset

RT— Real–Time

RTA— Retention Till Access

RTL— Register Transfert Level

RTOS— Real–Time Operating System

RTS— Request to Send

RV— RealVideo (codec)

RVLC— Reversible Variable Length Coder

RX— Receive/Receiver

RXD— Receive Data

RXN— PHY differential receiver (de-serializer) negative line

RXP— PHY differential receiver (de-serializer) positive line

S

S/PDIF— Sony/Philips Digital Interface

S/W— Software

SAF— Standby Associated Function

SAM— Signal Amplitude Modulation

SAR— Save and Restore. Hardware context saving for power saving.

SAV— Start of Active Video

SB— Silicon Backplane (Trade Mark)

SBC— Stream Buffer Controller

SBH— Synchronization Box Handler

SCL— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

SCM— System Control Module

SCP— Serial Configuration Port

SCTM— System Counter Timer Module

SCU— Snoop Control Unit

SD— Also Standard Definition (television system).

SDA— Serial Data. Serial data bus in the I2C interface.

SDMA— The Slave DMA port of the DSPSS TMS320C66x CorePac

SDP— Software Development Platform

SDR— Single Data Rate

SDRAM— Synchronous Dynamic Random Access Memory

SDRC— SDRAM Controller.

SDTV— Standard Definition Television

SE— Secure Environment.Execution environment inside a device, which is protected against tampering

SEC— Single Error Correction

SECDED— Single-Error Correction Dual-Error Detection

SFI— Serial Flash Interface

SGX— Accronym for Grafics Accelerator

SIF— Source Input Format

SIMD— Single Instruction-Stream, Multiple Data-Stream

SIR— Slow Infrared

SL2— Shared Level 2 (memory/interface)

SL2IF— Shared L2 Interface

SLC— Single Level Cell devices

SLM— Static Leakage Management

SMC— Secure Monitor Call

SMP— Symmetric Multiprocessor Platform

SMPS— Switch Mode Power Supply

SMSET— Software Message and System Event Trace module

SOC— System-On-a-Chip

SOF— Start Of Frame

SP— Serial Port or Small Page

SPC— Serial Port Control

SPI— Serial Peripheral Interface. A signaling protocol for exchanging serial data.

SR— SmartReflex

SR3-APG— SmartReflex3 Automatic Power Gating

SRAM— Static Random Access Memory

SRC— Sample Rate Conversion

SRMD— Single Request, Multiple Data

SRP— Session Request Protocol (OTG feature)

SS— Subsystem

SSC— Spread Spectrum Clocking

SSD— Solid State Drive

ST— Start Timer

STC— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG2 encoder or decoder system.

STM— Synchronous Transfer Mode or Store Multiple.

STN— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.

SVC— Supervisor Call

SW— Software

SWI— Software Interrupt

SXGA— Super eXtended Graphics Array

SYNCDIM— Transfer synchronization dimension.

SYSCTRL— IVA System Control module

T

TA— Target Agent

TAP— Test Access Port

TC— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP. Also, in PCI Express context this means Traffic Class, mapped to a virtual channel

TCCHEN— Transfer complete chaining enable.

TCINTEN— Transfer complete interrupt enable.

TCK— Test Clock

TCM— Tightly Coupled Memory

TD— Transfer Descriptor, in PCI Express this means TLP Digest (see also ECRC)

TDI— Test Data Input

TDM— Time Division Multiplex/Multiplexing

TDO— Test Data Output

TERC4— TMDS Error Reduction Coding

TFT— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.

TI— Texas Instruments

TILER— Tiling Isometric Lightweight Engine for Rotation

TLB— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.

TLP— Transaction Layer Packet: PCIe (compare PLP, DLLP)

TM— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).

TMDS— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.

TMS— Test Mode Select

TOC— Table of Contents

TP— Tiny Page

TPH— TLP Processing Hints (PCIe)

TPIU— Trace Port Interface Unit

TR— Tranfer Request

TRM— Technical Reference Manual

TRST— Test Reset

TS— Transmission Start

TSHUT— Temperature Shutdown.

TTL— Transistor Transistor Logic

TWL— Table Walking Logic

TX— Transmit//Transmitter

TXD— Transmit Data

TXN— PHY differential transmitter (serializer) negative line

TXP— PHY differential transmitter (serializer) positive line

U

UART— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.

USB— Universal Serial Bus.

USSE— Universal Scalable Shader Engine

V

VA— Virtual Address

VBP— Vertical Back Porch

VBUF— Virtual Frame Buffer

VC— Virtual Channel

VC-1— Video Codec Standard

VCA— Via Channel Array technology

VCO— Voltage Controlled Oscillator

VDMA— Video Direct Memory Access module

VESA— Video Electronics Standards Association

VFP— Vertical Front Porch

VGA— Video Graphics Array. An industry standard for video cards.

VID— VLAN Identifier

VIP— Video Input Port

VLAN— Virtual Local Area Network

VLC— Variable Length Decoder

VLD— Variable Length Coder

VLIW— Very Long Instruction Word

VMODE— Bi-level voltage control interface

VPE— Video Processing Engine

VR— Voice Recognition

VS— Vertical Synchronization

VSW— Vertical Synchronization Pulse Width

VSYNC— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

W

WB— Write Buffer

WC— Word Count

WD— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows and triggers a reset.

WDT— Watchdog Timer. See WD.

WE— Write Enable

WFI— Wait For Interrupt

WIR— Wait In Reset

WNP— Write Non-Posted

WP— Write Protect

WT— Write Through

WTBU— Wireless Terminal Business Unit

Word16— 16 bits word

X

X-LOADER— A user-defined pre-operating system bootstrap code that resides at the beginning of the external flash.

XIP— eXecution In Place

XMC— Extended Memory Controller (a functional entity in the TMS320C66X DSP CorePac)

Y

YUV— Luminance-Bandwidth-Chrominance

e

eCAP— Enhanced Capture Module

x

xHCI— Extensible Host Controller Interface

Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from September 1, 2019 to June 30, 2020 (from D Revision (September 2019) to E Revision)	Page
• Added 64xx information.	247
• Added DSS_HW_ACC_MC_PING to Master Subsystem, Cortex-R4F Memory Map table.	253
• Added DSS_HW_ACC_MC_PONG to Master Subsystem, Cortex-R4F Memory Map table.	253
• Added MSS_RTID to Master Subsystem, Cortex-R4F Memory Map table.	255
• Added MSS_RTIC to Master Subsystem, Cortex-R4F Memory Map table.	255
• Added DSS_HW_ACC_MC_PING to DSP C674x Memory Map table.	258
• Added DSS_HW_ACC_MC_PONG to DSP C674x Memory Map table.	258
• Updated SYSRSTCAUSE Register Field Descriptions.	310
• Updated RSTCAUSE Register Field Descriptions.	369
• Added SPARE0_3 register.	488
• Added SPARE4_9 register.	488
• Updated SYSRSTCAUSE Register Field Descriptions.	497
• Updated CLKSRCSEL0 Register.	539
• Updated CLKGATE Register.	541
• Added RTICURRCLKDIV Register.	544
• Updated RSTCAUSE Register Field Descriptions.	569
• Updated CLKINUSE Register .	572
• Updated ECCCAPTMSSBSS Register Field Description.	574
• Added GPCFG6 Register.	584
• Added SPARE0_3 register.	787
• Added SPARE4_9 register.	787
• Updated SYSRSTCAUSE Register Field Descriptions.	796
• Updated RSTCAUSE Register Field Descriptions.	878
• Added GPCFG6 Register.	895
• Added SPARE0_3 register.	1097
• Added SPARE4_9 register.	1097
• Updated SYSRSTCAUSE Register Field Descriptions.	1106
• Updated CLKSRCSEL0 Register.	1148
• Updated CLKGATE Register.	1150
• Added RTICURRCLKDIV Register.	1153
• Updated RSTCAUSE Register Field Descriptions.	1178
• Updated CLKINUSE Register .	1181
• Updated ECCCAPTMSSBSS Register Field Description.	1183
• Added GPCFG6 Register.	1193
• Updated Transmit Subsystem section.	1398
• Updated Receive Subsystem section.	1399
• Removed EDMA_TPTC Configuration section.	1603
• Updated Reset values and Field Descriptions of EDMA_TPCC_CCCFG Register.	1621
• Updated STAT bit description in EDMA_TPTC_ERRDET Register Field Descriptions table.	1820
• Updated ADC Buffer Single-Chirp and Multi-Chirp Mode Programming Sequence table.	1847
• Updated ADC Buffer Continuous Mode Programming Sequence table.	1848
• Updated MSS_GIO Registers.	2160
• Updated TBCTL_CLKDIV bit description in TBCTL_TBSTS Register Field Descriptions table.	2384
• Updated TBCTL_HSPCLKDIV bit description in TBCTL_TBSTS Register Field Descriptions table.	2384
• Updated MCAN Block Diagram.	2601
• Updated MCAN Functional Description section.	2601
• Updated SPI_DC Register Field Descriptions table.	3177
• Updated SWnRST bit description in the SCI Global Control Register 1 (SCIGCR1).	3253

- Updated CRC Registers. 3355
