IWR14xx/16xx/18xx/68xx/64xx Industrial Radar Family

Technical Reference Manual

Literature Number: SWRU522E
May 2017–Revised June 2020

Contents

Preface **133**

1 14xx **134**

1.1 14xx Introduction 135

1.1.1 14xx Overview 135

1.1.2 14xx Description 135

1.2 14xx Memory Map 138

1.2.1 System Interconnect 138

1.2.2 Master Subsystem Cortex-R4F Memory Map 139

1.2.3 EDMA Memory Map 142

1.3 14xx Integration 143

1.3.1 Cortex-R4F Subsystem 143

1.3.2 Clock Comparator 144

1.3.3 Direct Memory Access Controller (MSS_DMA) 146

1.3.4 Real Time Interrupt (MSS_RTIA) and RTI With Digital Watchdog Timer (MSS_RTIB) 148

1.3.5 General Purpose I/0 (MSS_GIO) 148

1.3.6 Vectored Interrupt Manager (MSS_VIM) 149

1.3.7 Controller Area Network (MSS_DCAN) 152

1.3.8 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPIA) 153

1.3.9 Serial Peripheral Interface (MSS_SPIB) 153

1.3.10 Quad Serial Peripheral Interface (MSS_QSPI) 154

1.3.11 Enhanced Direct Memory Access (EDMA) 154

1.3.12 Error Signaling Module (MSS_ESM) 157

1.3.13 High-Speed Interface (HSI) 160

1.3.14 Handshake RAM (HSRAM) 160

2 16xx/18xx **161**

2.1 16xx Introduction 162

2.1.1 16xx Overview 162

2.1.2 16xx Description 162

2.2 16xx Memory Map 166

2.2.1 System Interconnect 166

2.2.2 Master Subsystem Cortex-R4F Memory Map 167

2.2.3 DSP Subsystem Memory Map 171

2.2.4 EDMA Memory Map 172

2.3 16xx Integration 173

2.3.1 Cortex-R4F Subsystem 173

2.3.2 Clock Comparator 174

2.3.3 C674x DSP Subsystem 176

2.3.4 Direct Memory Access Controller (MSS_DMA) 179

2.3.5 Real Time Interrupt (MSS_RTIA) and RTI With Digital Watchdog Timer (MSS_RTIB) 183

2.3.6 General Purpose I/0 (MSS_GIO) 183

2.3.7 Data Modification Module (MSS_DMM) 185

2.3.8 Enhanced Pulse Width Modulator (MSS_ETPWM) 186

2.3.9 Vectored Interrupt Manager (MSS_VIM) 187

2.3.10 Controller Area Network (MSS_DCAN) 190

2.3.11 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPI) 191

2.3.12 Quad Serial Peripheral Interface (MSS_QSPI) 192
2.3.13 Enhanced Direct Memory Access (EDMA) 192
2.3.14 Error Signaling Module (MSS_ESM/DSS_ESM) 199
2.3.15 High-Speed Interface (HSI) 203
2.3.16 Handshake RAM (DSS_HSRAM1) 203
2.4 18xx Introduction 203
2.4.1 18xx Overview 203
2.4.2 18xx Description 204
2.5 18xx Memory Map 207
2.5.1 System Interconnect 207
2.5.2 Master Subsystem Cortex-R4F Memory Map 208
2.5.3 DSP Subsystem Memory Map 213
2.5.4 EDMA Memory Map 214
2.6 18xx Integration 215
2.6.1 Cortex-R4F Subsystem 215
2.6.2 Clock Comparator 216
2.6.3 C674x DSP Subsystem 218
2.6.4 Direct Memory Access Controller (MSS_DMA) 221
2.6.5 Real Time Interrupt (MSS_RTIA) and RTI With Digital Watchdog Timer (MSS_RTIB) 225
2.6.6 General Purpose I/0 (MSS_GIO) 225
2.6.7 Data Modification Module (MSS_DMM) 227
2.6.8 Enhanced Pulse Width Modulator (MSS_ETPWM) 228
2.6.9 Vectored Interrupt Manager (MSS_VIM) 229
2.6.10 Controller Area Network (MSS_DCAN) 232
2.6.11 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPI) 233
2.6.12 Quad Serial Peripheral Interface (MSS_QSPI) 234
2.6.13 Enhanced Direct Memory Access (EDMA) 234
2.6.14 Error Signaling Module (MSS_ESM/DSS_ESM) 241
2.6.15 High-Speed Interface (HSI) 245
2.6.16 Handshake RAM (DSS_HSRAM1) 245
3 68xx/64xx 246
3.1 68xx/64xx Introduction 247
3.1.1 Overview 247
3.1.2 Description 247
3.2 Memory Map 251
3.2.1 System Interconnect 251
3.2.2 Master Subsystem Cortex-R4F Memory Map 253
3.2.3 DSP Subsystem Memory Map (Applicable Devices Only) 257
3.2.4 EDMA Memory Map 259
3.3 68xx/64xx Integration 260
3.3.1 Cortex-R4F Subsystem 260
3.3.2 Clock Comparator 261
3.3.3 C674x DSP Subsystem (Applicable Devices Only) 263
3.3.4 Direct Memory Access Controller (MSS_DMA) 266
3.3.5 Real Time Interrupt (MSS_RTIA) and RTI With Digital Watchdog Timer (MSS_RTIB) 269
3.3.6 General Purpose I/0 (MSS_GIO) 269
3.3.7 Data Modification Module (MSS_DMM) 271
3.3.8 Enhanced Pulse Width Modulator (MSS_ETPWM) 272
3.3.9 Vectored Interrupt Manager (MSS_VIM) 273
3.3.10 Module Controller Area Network (MSS_MCAN) 276
3.3.11 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPI) 277
3.3.12 Quad Serial Peripheral Interface (MSS_QSPI) 278
3.3.13 Enhanced Direct Memory Access (EDMA) 278

3.3.14 Error Signaling Module (MSS_ESM/DSS_ESM) 285
3.3.15 High-Speed Interface (HSI) 289
3.3.16 Handshake RAM (DSS_HSRAM1) 289
4 Power, Reset, Clock Management and Control Registers (IWR) 290
4.1 PRCM Overview 291
4.2 Digital Clock Domains 291
4.2.1 Clock Overview 291
4.2.2 Device Clock Sources (For Digital Logic) 292
4.2.3 Device Clock Domains 292
4.2.4 Clock Initialization Sequence 293
4.2.5 PMIC Clock 293
4.3 Resets 294
4.3.1 Reset Overview 294
4.3.2 Reset Types and Sources 295
4.3.3 Reset Domains 295
4.3.4 Reset Cause Registers 296
4.3.5 Module Resets 296
4.4 Power Domain 296
4.4.1 Available Device Power Domains 296
4.4.2 Power Domain Control 297
4.5 Boot 300
4.5.1 Bootloader Modes 300
4.5.2 ROM Eclipsing 300
4.6 14xx Control Registers 301
4.6.1 MSS_TOPRCM Registers 302
4.6.2 MSS_RCM Registers 342
4.6.3 MSS_GPCFG_REG Registers 377
4.6.4 DSS_REG Registers 395
4.7 16xx Control Registers 487
4.7.1 MSS_TOPRCM Registers 488
4.7.2 MSS_RCM Registers 534
4.7.3 MSS_GPCFG_REG Registers 577
4.7.4 DSS_REG Registers 613
4.7.5 DSS_REG2 Registers 727
4.8 68xx/64xx Control Registers 786
4.8.1 MSS_TOPRCM Registers 787
4.8.2 MSS_RCM Registers 833
4.8.3 MSS_GPCFG_REG Registers 888
4.8.4 DSS_REG Registers 924
4.8.5 DSS_REG2 Registers 1038
4.9 18xx Control Registers 1096
4.9.1 MSS_TOPRCM Registers 1097
4.9.2 MSS_RCM Registers 1143
4.9.3 MSS_GPCFG_REG Registers 1186
4.9.4 DSS_REG Registers 1222
4.9.5 DSS_REG2 Registers 1336
5 RADAR Subsystem 1395
5.1 Block Diagram 1396
5.1.1 Clock Subsystem 1397
5.1.2 Transmit Subsystem 1398
5.1.3 Receive Subsystem 1399
6 Master Subsystem Cortex-R4F 1400
6.1 Introduction 1401

6.2 Cortex-R4F Subsystem ... 1401
6.2.1 Cortex-R4F Integration ... 1401
6.2.2 Tightly Coupled Memories ... 1401
6.2.3 Memory Module Hardware Initialization ... 1401

7 Direct Memory Access Controller (DMA) ... 1402
7.1 Module Operation ... 1403
7.1.1 Block Diagram ... 1403
7.1.2 Memory Space ... 1403
7.1.3 DMA Data Access ... 1403
7.1.4 Addressing Modes ... 1405
7.1.5 DMA Channel Control Packets ... 1405
7.1.6 Priority Queue ... 1409
7.1.7 Data Packing and Unpacking ... 1411
7.1.8 DMA Request ... 1414
7.1.9 Auto-Initiation ... 1415
7.1.10 Interrupts ... 1415
7.1.11 Debugging ... 1417
7.1.12 Power Management ... 1417
7.1.13 FIFO Buffer ... 1417
7.1.14 Channel Chaining ... 1418
7.1.15 Memory Protection ... 1419
7.1.16 Parity Checking ... 1420
7.1.17 Parity Testing ... 1421
7.1.18 Initializing RAM with Parity ... 1421
7.2 Control Registers and Control Packets ... 1422
7.2.1 DMA Control Registers ... 1423
7.2.2 Channel Configuration ... 1503
7.3 DMA Request Map ... 1508

8 Vectored Interrupt Manager (VIM) ... 1509
8.1 Overview ... 1510
8.2 Device Level Interrupt Management ... 1511
8.2.1 Interrupt Generation at the Peripheral ... 1511
8.2.2 Interrupt Handling at the CPU ... 1512
8.2.3 Software Interrupt Handling Options ... 1513
8.3 Interrupt Handling Inside VIM ... 1514
8.3.1 VIM Interrupt Channel Mapping ... 1515
8.3.2 VIM Input Channel Management ... 1517
8.4 Interrupt Vector Table (VIM RAM) ... 1518
8.4.1 Interrupt Vector Table Operation ... 1518
8.4.2 VIM ECC Syndrome ... 1519
8.4.3 Interrupt Vector Table Initialization ... 1520
8.4.4 Interrupt Vector Table ECC Testing ... 1520
8.5 VIM Wakeup Interrupt ... 1523
8.6 Capture Event Sources ... 1524
8.7 Examples ... 1524
8.7.1 Examples - Configure CPU To Receive Interrupts ... 1524
8.7.2 Examples - Register Vector Interrupt and Index Interrupt Handling ... 1525
8.8 VIM Control Registers ... 1527
8.8.1 Interrupt Vector Table ECC Status Register (ECCSTAT) ... 1528
8.8.2 Interrupt Vector Table ECC Control Register (ECCCTL) ... 1529
8.8.3 Uncorrectable Error Address Register (UERRADDR) ... 1530
8.8.4 Fallback Vector Address Register (FBVECADDR) ... 1530
8.8.5 Single Bit Error Address Register (SBERRADDR) ... 1531

8.8.6 VIM Offset Vector Registers 1531
8.8.7 IRQ Index Offset Vector Register (IRQINDEX) 1532
8.8.8 FIQ Index Offset Vector Registers (FIQINDEX) 1532
8.8.9 FIQ/IRQ Program Control Registers (FIRQPR[0:3]) 1533
8.8.10 Pending Interrupt Read Location Registers (INTREQ[0:3]) 1534
8.8.11 Interrupt Enable Set Registers (REQENASET[0:3]) 1535
8.8.12 Interrupt Enable Clear Registers (REQENACLR[0:3]) 1536
8.8.13 Wake-Up Enable Set Registers (WAKEENASET[0:3]) 1537
8.8.14 Wake-Up Enable Clear Registers (WAKEENACLR[0:3]) 1538
8.8.15 IRQ Interrupt Vector Register (IRQVECREG) 1539
8.8.16 FIQ Interrupt Vector Register (FIQVECREG) 1539
8.8.17 Capture Event Register (CAPEVT) 1540
8.8.18 VIM Interrupt Control Registers (CHANCTRL[0:31]) 1541
8.9 Interrupt Request Assignments 1542
9 DSP Subsystem C674x 1543
9.1 Introduction 1544
9.2 TMS320C674x Megamodule 1545
9.2.1 Internal Memory Controllers 1545
9.2.2 Internal Peripherals 1545
9.3 Memory Map 1546
9.4 Advanced Event Triggering (AET) 1546
9.5 DSP Event Assignment 1547
10 DSS_L3 Memory Organization 1548
10.1 DSS_L3 Memory Organization for 14xx 1549
10.1.1 Functional Description 1549
10.1.2 Memory Auto Initialization 1550
10.1.3 Memory TAB Register 1551
10.2 DSS_L3 Memory Organization for 16xx/18xx 1551
10.2.1 Functional Description 1551
10.2.2 Memory Auto-Initialization 1552
10.2.3 Memory TAB Register 1552
10.3 DSS_L3 Memory Organization for 68xx 1552
10.3.1 Functional Description 1553
10.3.2 Memory Auto-Initialization 1553
10.3.3 Memory TAB Register 1554
11 Handshake RAM (HSRAM) 1555
12 Enhanced Direct Memory Access (EDMA) 1556
12.1 EDMA Module Overview 1557
12.1.1 EDMA Features 1558
12.2 EDMA Controller Functional Description 1559
12.2.1 Block Diagram 1559
12.2.2 Types of EDMA controller Transfers 1562
12.2.3 Parameter RAM (PaRAM) 1564
12.2.4 Initiating a DMA Transfer 1576
12.2.5 Completion of a DMA Transfer 1579
12.2.6 Event, Channel, and PaRAM Mapping 1580
12.2.7 EDMA Channel Controller Regions 1582
12.2.8 Chaining EDMA Channels 1584
12.2.9 EDMA Interrupts 1586
12.2.10 Memory Protection 1594
12.2.11 Event Queue(s) 1599
12.2.12 EDMA Transfer Controller (EDMA_TPTC) 1601

12.2.13 Event Dataflow 1603
12.2.14 EDMA Controller Prioritization 1604
12.2.15 Emulation Considerations 1606
12.3 EDMA Transfer Examples 1607
12.3.1 Block Move Example 1607
12.3.2 Subframe Extraction Example 1609
12.3.3 Data Sorting Example 1610
12.3.4 Setting Up an EDMA Transfer 1612
12.4 EDMA Debug Checklist and Programming Tips 1614
12.4.1 EDMA Debug Checklist 1614
12.4.2 EDMA Programming Tips 1615
12.5 EDMA Request Map 1615
12.6 EDMA Register Manual 1616
12.6.1 EDMA Registers 1616
13 ADC Buffer 1845
13.1 Functional Description 1846
13.1.1 DFE Data Write Operation 1846
13.1.2 Support for Hardware in Loop (HIL) 1848
13.1.3 Test Pattern Generator Support 1849
13.1.4 ADC Buffer Data Formats 1849
14 High-Speed Interface (HSI) 1851
14.1 Overview 1852
14.2 CBUFF 1852
14.2.1 CBUFF Overview 1852
14.2.2 CBUFF Sequencing 1853
14.2.3 Sequence-Related CBUFF Configuration Fields 1855
14.2.4 CBUFF Linklist Concept 1855
14.2.5 CBUFF Interrupts 1858
14.3 LVDS 1859
14.3.1 LVDS Overview 1859
14.3.2 LVDS Programming Sequence 1859
14.3.3 CBUFF and LVDS Registers 1861
14.4 CSI2 1998
14.4.1 CSI2 Overview 1998
14.4.2 CSI2 Protocol Engine and Phy 2009
14.4.3 CSI2 Programming Sequence 2021
14.4.4 CSI2_PROTOCOL_ENGINE Registers 2025
14.4.5 CSI2_PHY Registers 2095
15 Hardware Accelerator 2113
15.1 Introduction 2114
15.2 Register Map 2114
16 Real Time Interrupt (RTI) and RTI With Digital Watchdog Timer (WDT) 2115
16.1 Overview 2116
16.1.1 Features 2116
16.1.2 Industry Standard Compliance Statement 2116
16.2 Module Operation 2117
16.2.1 Counter Operation 2117
16.2.2 Interrupt/DMA Requests 2119
16.2.3 Digital Watchdog (DWD) 2120
16.2.4 Halting Debug Mode Behaviour 2123
16.3 RTI Control Registers 2124
16.3.1 RTI Global Control Register (RTIGCTRL) 2125

16.3.2 RTI Timebase Control Register (RTITBCTRL) 2126
16.3.3 RTI Capture Control Register (RTICAPCTRL) 2127
16.3.4 RTI Compare Control Register (RTICOMPCTRL) 2128
16.3.5 RTI Free Running Counter 0 Register (RTIFRC0) 2129
16.3.6 RTI Up Counter 0 Register (RTIUC0) 2129
16.3.7 RTI Compare Up Counter 0 Register (RTICPUC0) 2130
16.3.8 RTI Capture Free Running Counter 0 Register (RTICAFRC0) 2130
16.3.9 RTI Capture Up Counter 0 Register (RTICAUC0) 2131
16.3.10 RTI Free Running Counter 1 Register (RTIFRC1) 2131
16.3.11 RTI Up Counter 1 Register (RTIUC1) 2132
16.3.12 RTI Compare Up Counter 1 Register (RTICPUC1) 2133
16.3.13 RTI Capture Free Running Counter 1 Register (RTICAFRC1) 2134
16.3.14 RTI Capture Up Counter 1 Register (RTICAUC1) 2134
16.3.15 RTI Compare 0 Register (RTICOMP0) 2135
16.3.16 RTI Update Compare 0 Register (RTIUDCP0) 2135
16.3.17 RTI Compare 1 Register (RTICOMP1) 2136
16.3.18 RTI Update Compare 1 Register (RTIUDCP1) 2136
16.3.19 RTI Compare 2 Register (RTICOMP2) 2137
16.3.20 RTI Update Compare 2 Register (RTIUDCP2) 2137
16.3.21 RTI Compare 3 Register (RTICOMP3) 2138
16.3.22 RTI Update Compare 3 Register (RTIUDCP3) 2138
16.3.23 RTI Timebase Low Compare Register (RTITBLCOMP) 2139
16.3.24 RTI Timebase High Compare Register (RTITBHCOMP) 2139
16.3.25 RTI Set Interrupt Enable Register (RTISETINTENA) 2140
16.3.26 RTI Clear Interrupt Enable Register (RTICLEARINTENA) 2142
16.3.27 RTI Interrupt Flag Register (RTIINTFLAG) 2144
16.3.28 Digital Watchdog Control Register (RTIDWDCTRL) 2145
16.3.29 Digital Watchdog Preload Register (RTIDWDPRLD) 2146
16.3.30 Watchdog Status Register (RTIWDSTATUS) 2147
16.3.31 RTI Watchdog Key Register (RTIWDKEY) 2148
16.3.32 RTI Digital Watchdog Down Counter (RTIDWDCNTR) 2149
16.3.33 Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) 2149
16.3.34 Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL) 2150
16.3.35 RTI Compare Interrupt Clear Enable Register (RTIINTCLRENABLE) 2151
16.3.36 RTI Compare 0 Clear Register (RTICMP0CLR) 2152
16.3.37 RTI Compare 1 Clear Register (RTICMP1CLR) 2152
16.3.38 RTI Compare 2 Clear Register (RTICMP2CLR) 2153
16.3.39 RTI Compare 3 Clear Register (RTICMP3CLR) 2153

17 General Purpose I/0 (GIO) 2154

17.1 Overview 2155
17.2 Quick Start Guide 2155
17.3 Functional Description of GIO Module 2157
17.3.1 I/O Functions 2157
17.3.2 Interrupt Function 2158
17.3.3 GIO Block Diagram 2158
17.4 Device Modes of Operation 2160
17.4.1 Emulation Mode 2160
17.4.2 Power-Down Mode (Low-Power Mode) 2160
17.5 MSS_GIO Registers 2161
17.5.1 GIOGCR Register (Offset = 0h) [reset = 0h] 2163
17.5.2 GIOPWDN Register (Offset = 4h) [reset = 0h] 2164
17.5.3 GIOINTDET Register (Offset = 8h) [reset = 0h] 2165
17.5.4 GIOPOL Register (Offset = Ch) [reset = 0h] 2166

17.5.5 GIOENASET Register (Offset = 10h) [reset = 0h] 2167
17.5.6 GIOENACLR Register (Offset = 14h) [reset = 0h] 2168
17.5.7 GIOLVLSET Register (Offset = 18h) [reset = 0h] 2169
17.5.8 GIOLVLCLR Register (Offset = 1Ch) [reset = 0h] 2170
17.5.9 GIOFLG Register (Offset = 20h) [reset = 0h] 2171
17.5.10 GIOOFFA Register (Offset = 24h) [reset = 0h] 2172
17.5.11 GIOOFFB Register (Offset = 28h) [reset = 0h] 2173
17.5.12 GIOEMUA Register (Offset = 2Ch) [reset = 0h] 2174
17.5.13 GIOEMUB Register (Offset = 30h) [reset = 0h] 2175
17.5.14 GIODIRA Register (Offset = 34h) [reset = 0h] 2176
17.5.15 GIODINA Register (Offset = 38h) [reset = 0h] 2177
17.5.16 GIODOUTA Register (Offset = 3Ch) [reset = 0h] 2178
17.5.17 GIOSETA Register (Offset = 40h) [reset = 0h] 2179
17.5.18 GIOCLRA Register (Offset = 44h) [reset = 0h] 2180
17.5.19 GIOPDRA Register (Offset = 48h) [reset = 0h] 2181
17.5.20 GIOPULDISA Register (Offset = 4Ch) [reset = 0h] 2182
17.5.21 GIOPSLA Register (Offset = 50h) [reset = 0h] 2183
17.5.22 GIODIRB Register (Offset = 54h) [reset = 0h] 2184
17.5.23 GIODINB Register (Offset = 58h) [reset = 0h] 2185
17.5.24 GIODOUTB Register (Offset = 5Ch) [reset = 0h] 2186
17.5.25 GIOSETB Register (Offset = 60h) [reset = 0h] 2187
17.5.26 GIOCLRB Register (Offset = 64h) [reset = 0h] 2188
17.5.27 GIOPDRB Register (Offset = 68h) [reset = 0h] 2189
17.5.28 GIOPULDISB Register (Offset = 6Ch) [reset = 0h] 2190
17.5.29 GIOPSLB Register (Offset = 70h) [reset = 0h] 2191
17.5.30 GIODIRC Register (Offset = 74h) [reset = 0h] 2192
17.5.31 GIODINC Register (Offset = 78h) [reset = 0h] 2193
17.5.32 GIODOUTC Register (Offset = 7Ch) [reset = 0h] 2194
17.5.33 GIOSETC Register (Offset = 80h) [reset = 0h] 2195
17.5.34 GIOCLRC Register (Offset = 84h) [reset = 0h] 2196
17.5.35 GIOPDRC Register (Offset = 88h) [reset = 0h] 2197

19 Data Modification Module (DMM) 2260
19.1 Overview 2261
19.1.1 Features 2261
19.1.2 Block Diagram 2261
19.2 Module Operation 2262
19.2.1 Data Format 2262
19.2.2 Data Port 2264
19.2.3 Error Handling 2265
19.2.4 Interrupts 2266
19.3 Control Registers 2267
19.3.1 DMM Global Control Register (DMMGLBCTRL) 2268
19.3.2 DMM Interrupt Set Register (DMMINTSET) 2270
19.3.3 DMM Interrupt Clear Register (DMMINTCLR) 2274

19.3.4 DMM Interrupt Level Register (DMMINTLVL) 2279
19.3.5 DMM Interrupt Flag Register (DMMINTFLG) 2281
19.3.6 DMM Interrupt Offset 1 Register (DMMOFF1) 2285
19.3.7 DMM Interrupt Offset 2 Register (DMMOFF2) 2286
19.3.8 DMM Direct Data Mode Destination Register (DMMDDMDEST) 2287
19.3.9 DMM Direct Data Mode Blocksize Register (DMMDDMBL) 2287
19.3.10 DMM Direct Data Mode Pointer Register (DMMDDMPT) 2288
19.3.11 DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT) 2288
19.3.12 DMM Destination x Region 1 (DMMDESTxREG1) 2289
19.3.13 DMM Destination x Blocksize 1 (DMMDESTxBL1) 2290
19.3.14 DMM Destination x Region 2 (DMMDESTxREG2) 2291
19.3.15 DMM Destination x Blocksize 2 (DMMDESTxBL2) 2292
19.3.16 DMM Pin Control 0 (DMMPC0) 2293
19.3.17 DMM Pin Control 1 (DMMPC1) 2294
19.3.18 DMM Pin Control 2 (DMMPC2) 2296
19.3.19 DMM Pin Control 3 (DMMPC3) 2297
19.3.20 DMM Pin Control 4 (DMMPC4) 2298
19.3.21 DMM Pin Control 5 (DMMPC5) 2300
19.3.22 DMM Pin Control 6 (DMMPC6) 2301
19.3.23 DMM Pin Control 7 (DMMPC7) 2303
19.3.24 DMM Pin Control 8 (DMMPC8) 2304

20 Enhanced Pulse Width Modulator (ePWM) 2306

20.1 Introduction 2307
20.1.1 Submodule Overview 2307
20.1.2 Register Mapping 2310
20.2 ePWM Submodules 2311
20.2.1 Overview 2311
20.2.2 Time-Base (TB) Submodule 2313
20.2.3 Counter-Compare (CC) Submodule 2321
20.2.4 Action-Qualifier (AQ) Submodule 2326
20.2.5 Dead-Band Generator (DB) Submodule 2339
20.2.6 PWM-Chopper (PC) Submodule 2344
20.2.7 Trip-Zone (TZ) Submodule 2348
20.2.8 Event-Trigger (ET) Submodule 2354
20.2.9 Digital Compare (DC) Submodule 2359
20.2.10 Proper Interrupt Initialization Procedure 2365
20.3 Application Examples 2366
20.3.1 Overview of Multiple Modules 2366
20.3.2 Key Configuration Capabilities 2366
20.3.3 Controlling Multiple Buck Converters With Independent Frequencies 2368
20.3.4 Controlling Multiple Buck Converters With Same Frequencies 2371
20.3.5 Controlling Multiple Half H-Bridge (HHB) Converters 2374
20.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM) 2376
20.3.7 Practical Applications Using Phase Control Between PWM Modules 2379
20.4 MSS_ETPWM1 Registers 2381
20.4.1 TBCTL_TBSTS Register (Offset = 0h) [reset = 0h] 2383
20.4.2 TBPHS Register (Offset = 4h) [reset = 0h] 2385
20.4.3 TBCTR_TBPRD Register (Offset = 8h) [reset = 0h] 2386
20.4.4 CMPCTL Register (Offset = Ch) [reset = 0h] 2387
20.4.5 CMPA Register (Offset = 10h) [reset = 0h] 2389
20.4.6 CMPB_AQCTLA Register (Offset = 14h) [reset = 0h] 2390
20.4.7 AQCTLB_AQSFRC Register (Offset = 18h) [reset = 0h] 2392
20.4.8 AQCSFRC_DBCTL Register (Offset = 1Ch) [reset = 0h] 2394

20.4.9 DBRED_DBFED Register (Offset = 20h) [reset = 0h] 2396
20.4.10 TZSEL_TZDCSEL Register (Offset = 24h) [reset = 0h] 2397
20.4.11 TZCTL_TZEINT Register (Offset = 28h) [reset = 0h] 2399
20.4.12 TZFLG_TZCLR Register (Offset = 2Ch) [reset = 0h] 2401
20.4.13 TZFRC_ETSEL Register (Offset = 30h) [reset = 0h] 2403
20.4.14 ETPS_ETFLG Register (Offset = 34h) [reset = 0h] 2405
20.4.15 ETCLR_ETFRC Register (Offset = 38h) [reset = 0h] 2407
20.4.16 PCCTL Register (Offset = 3Ch) [reset = 0h] 2408
20.4.17 Reserved1 Register (Offset = 40h) [reset = 0h] 2409
20.4.18 Reserved2 Register (Offset = 44h) [reset = 0h] 2410
20.4.19 Reserved3 Register (Offset = 48h) [reset = 0h] 2411
20.4.20 Reserved4 Register (Offset = 4Ch) [reset = 0h] 2412
20.4.21 Reserved5 Register (Offset = 50h) [reset = 0h] 2413
20.4.22 Reserved6 Register (Offset = 54h) [reset = 0h] 2414
20.4.23 Reserved7 Register (Offset = 58h) [reset = 0h] 2415
20.4.24 Reserved8 Register (Offset = 5Ch) [reset = 0h] 2416
20.4.25 DCTRIPSEL_DCACTL Register (Offset = 60h) [reset = 0h] 2417
20.4.26 DCBCTL_DCFCTL Register (Offset = 64h) [reset = 0h] 2419
20.4.27 DCCAPCTL_DCFOFFSET Register (Offset = 68h) [reset = 0h] 2420
20.4.28 DCFOFFSETCNT_DCFWINDOW Register (Offset = 6Ch) [reset = 0h] 2421
20.4.29 DCFWINDOWCNT_DCCAP Register (Offset = 70h) [reset = 0h] 2422

21 Controller Area Network (DCAN) 2423

21.1 Overview 2424
21.1.1 Features 2424
21.1.2 Functional Description 2424
21.2 CAN Blocks 2425
21.2.1 CAN Core 2425
21.2.2 Message RAM 2425
21.2.3 Message Handler 2425
21.2.4 Message RAM Interface 2426
21.2.5 Register and Message Object Access 2426
21.2.6 Dual Clock Source 2426
21.3 CAN Bit Timing 2427
21.3.1 Bit Time and Bit Rate 2427
21.3.2 DCAN Bit Timing Registers 2429
21.4 CAN Module Configuration 2431
21.4.1 DCAN RAM Initialization Through Hardware 2431
21.4.2 CAN Module Initialization 2431
21.5 Message RAM 2434
21.5.1 Structure of Message Objects 2434
21.5.2 Addressing Message Objects in RAM 2436
21.5.3 Message RAM Representation in Debug/Suspend Mode 2437
21.5.4 Message RAM Representation in Direct Access Mode 2437
21.5.5 ECC RAM 2438
21.6 Message Interface Register Sets 2439
21.6.1 Message Interface Register Sets 1 and 2 2439
21.6.2 Using Message Interface Register Sets 1 and 2 2440
21.6.3 Message Interface Register 3 2441
21.7 Message Object Configurations 2442
21.7.1 Configuration of a Transmit Object for Data Frames 2442
21.7.2 Configuration of a Transmit Object for Remote Frames 2442
21.7.3 Configuration of a Single Receive Object for Data Frames 2442
21.7.4 Configuration of a Single Receive Object for Remote Frames 2443

21.7.5 Configuration of a FIFO Buffer 2443
21.7.6 Reconfiguration of Message Objects for the Reception of Frames 2443
21.7.7 Reconfiguration of Message Objects for the Reception of Frames 2443
21.8 Message Handling 2444
21.8.1 Message Handler Overview 2444
21.8.2 Receive/Transmit Priority 2444
21.8.3 Transmission of Messages in Event Driven CAN Communication 2445
21.8.4 Updating a Transmit Object 2445
21.8.5 Changing a Transmit Object 2445
21.8.6 Acceptance Filtering of Received Messages 2446
21.8.7 Reception of Data Frames 2446
21.8.8 Reception of Remote Frames 2446
21.8.9 Reading Received Messages 2446
21.8.10 Requesting New Data for a Receive Object 2447
21.8.11 Storing Received Messages in FIFO Buffers 2447
21.8.12 Reading from a FIFO Buffer 2447
21.9 CAN Message Transfer 2449
21.9.1 Automatic Retransmission 2449
21.9.2 Auto-Bus-On 2450
21.10 Interrupt Functionality 2450
21.10.1 Message Object Interrupts 2450
21.10.2 Status Change Interrupts 2451
21.10.3 Error Interrupts 2451
21.11 Global Power Down Mode 2452
21.11.1 Entering Global Power Down Mode 2452
21.11.2 Wakeup From Global Power Down Mode 2452
21.12 Local Power Down Mode 2453
21.12.1 Entering Local Power Down Mode 2453
21.12.2 Wakeup From Local Power Down 2453
21.13 GIO Support 2453
21.14 Test Modes 2455
21.14.1 Silent Mode 2455
21.14.2 Loop Back Mode 2456
21.14.3 External Loop Back Mode 2457
21.14.4 Loop Back Combined with Silent Mode 2458
21.14.5 Software Control of CAN_TX Pin 2458
21.15 SECDED Mechanism 2459
21.15.1 Behavior on Single Bit Error 2459
21.15.2 Behavior on Double Bit Error 2459
21.15.3 SECDED Testing 2459
21.16 Debug/Suspend Mode 2460
21.17 MSS_DCAN Registers 2461
21.17.1 CTL Register (Offset = 0h) [reset = 1401h] 2464
21.17.2 ES Register (Offset = 4h) [reset = 7h] 2467
21.17.3 ERRC Register (Offset = 8h) [reset = 0h] 2469
21.17.4 BTR Register (Offset = Ch) [reset = 2301h] 2470
21.17.5 INT Register (Offset = 10h) [reset = 0h] 2471
21.17.6 TEST Register (Offset = 14h) [reset = 80h] 2472
21.17.7 Reserved_1 Register (Offset = 18h) [reset = 0h] 2473
21.17.8 PERR Register (Offset = 1Ch) [reset = 0h] 2474
21.17.9 DCAN_REV_ID Register (Offset = 20h) [reset = 0h] 2475
21.17.10 ECCDIAG Register (Offset = 24h) [reset = 0h] 2476
21.17.11 ECCDIAG_STAT Register (Offset = 28h) [reset = 0h] 2477

21.17.12 ECC_CS Register (Offset = 2Ch) [reset = 0h] 2478
21.17.13 ECC_SERR Register (Offset = 30h) [reset = 0h] 2479
21.17.14 TTCAN1 Register (Offset = 34h) [reset = 0h] 2480
21.17.15 TTCAN2 Register (Offset = 38h) [reset = 0h] 2481
21.17.16 TTCAN3 Register (Offset = 3Ch) [reset = 0h] 2482
21.17.17 TTCAN4 Register (Offset = 40h) [reset = 0h] 2483
21.17.18 TTCAN5 Register (Offset = 44h) [reset = 0h] 2484
21.17.19 TTCAN6 Register (Offset = 48h) [reset = 0h] 2485
21.17.20 TTCAN7 Register (Offset = 4Ch) [reset = 0h] 2486
21.17.21 TTCAN8 Register (Offset = 50h) [reset = 0h] 2487
21.17.22 TTCAN9 Register (Offset = 54h) [reset = 0h] 2488
21.17.23 TTCAN10 Register (Offset = 58h) [reset = 0h] 2489
21.17.24 TTCAN11 Register (Offset = 5Ch) [reset = 0h] 2490
21.17.25 TTCAN12 Register (Offset = 60h) [reset = 0h] 2491
21.17.26 TTCAN13 Register (Offset = 64h) [reset = 0h] 2492
21.17.27 TTCAN14 Register (Offset = 68h) [reset = 0h] 2493
21.17.28 TTCAN15 Register (Offset = 6Ch) [reset = 0h] 2494
21.17.29 TTCAN16 Register (Offset = 70h) [reset = 0h] 2495
21.17.30 TTCAN17 Register (Offset = 74h) [reset = 0h] 2496
21.17.31 TTCAN18 Register (Offset = 78h) [reset = 0h] 2497
21.17.32 TTCAN19 Register (Offset = 7Ch) [reset = 0h] 2498
21.17.33 ABOTR Register (Offset = 80h) [reset = 0h] 2499
21.17.34 TXRQ_X Register (Offset = 84h) [reset = 0h] 2500
21.17.35 TXRQ12 Register (Offset = 88h) [reset = 0h] 2501

1.1 14xx Introduction

1.1.1 14xx Overview

The 14xx is highly integrated single-chip RADAR device in TI's 45-nm low-power RFCMOS technology, a FCBGA 0.65-mm pitch automotive-grade package.

1.1.1.1 Features

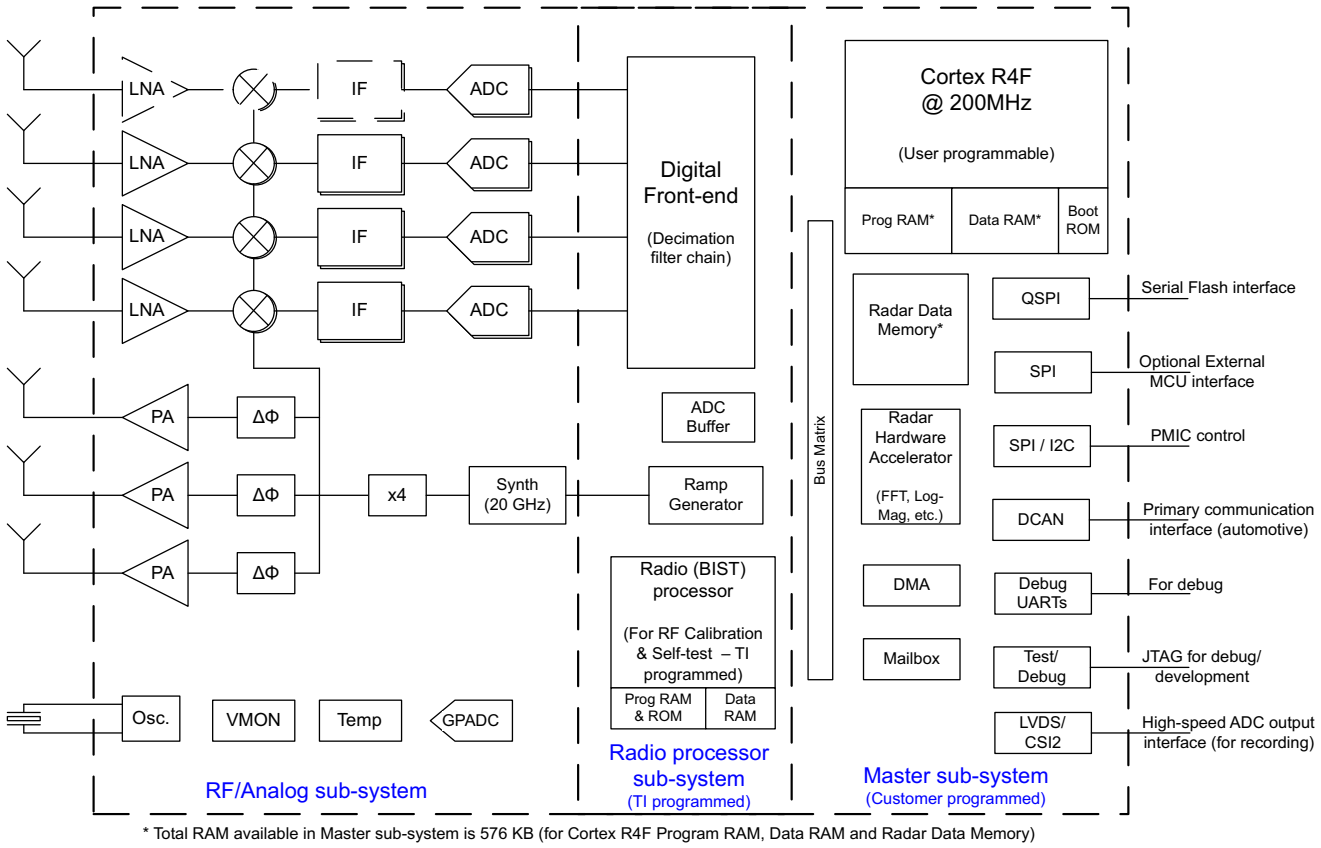
- Frequency-Modulated Continuous Wave Radio Frequency Transceiver With 76-81-GHz Band
- Supports Three Transmitter Chains and Four Receiver Chains
- Chirp Profiles With Programmable Period and Slope
- 40-MHz XTAL/OSC Reference Input Clock
- 12, 14, and 16-bit Real/Complex ADC With Variable Baseband ADC Sampling Rates up to 18.75 MHz at 12-bits Complex
- Cortex R4F at 200-MHz Application Processor for Control Functionality and Safety-Critical Algorithms
- Cortex R4F– Radio Processor at 200 MHz for Continuous Monitoring and Calibration of Analog/RF Functionality
- High-Performance Data Transfer With Multiple DMA and EDMA-TPCC Engines
- CAN Support for ECU Interface
- QSPI Serial Flash Support
- MIBSPI, SPI, I2C, and UART Serial Interfaces Support
- Four Data, One Clock Lane Serial LVDS Interface Support

1.1.2 14xx Description

1.1.2.1 Block Diagram

Figure 1-1 shows the block diagram of the 14xx device.

Figure 1-1. 14xx Block Diagram



* Total RAM available in Master sub-system is 576 KB (for Cortex R4F Program RAM, Data RAM and Radar Data Memory)

Table 1-1. 14xx Acronyms

ADC	Analog-to-Digital Convertor
CSI-2	Camera Serial Interface 2
DCAN	Controller Area Network
DMA	Direct Memory Access
GPADC	General Purpose Analog-to-Digital Convertor
I2C	Inter-Integrated Circuit
IF	Intermediate Frequency
LNA	Low-Noise Amplifier
LVDS	Low Voltage Differential Signaling
Osc	Oscillator
PA	Power Amplifier
QSPI	Quad Serial Peripheral Interface
SPI	Serial Peripheral Interface
UART	Univeral Asynchronous Receiver/Transmitter
VMON	Voltage Monitor
ΔΦ	Phase Modulator

1.1.2.2 Radar Subsystem

The RADAR subsystem is responsible for the RF and analog functionality of the device. The subsystem incorporates a built-in self-test processor for the continuous motoring and calibration of the analog and RF modules. The subsystem consists of:

- FMCW transceiver
  - Integrated PLL, transmitter, receiver, baseband, and A2D
  - 76-81-GHz coverage with 4-GHz available bandwidth
  - Four receive channels
  - Two transmit channels
  - Ultra-accurate chirp engine based on fractional-n PLL
  - 12,14, or 16-bit complex analog to digital converter
- Radio processor for built-in calibration and self-test
  - ARM Cortex R4F-based radio control system
  - Built-in firmware (ROM)
  - Self-calibrating system across frequency and temperature

This subsystem is TI-programmed with an API interface to the on-chip Cortex-R4F application processor.

1.1.2.3 Master Subsystem

The master subsystem consists of the following features:

- Dual Cortex-R4F core ARMv7-R, VFPv3-D16, and ARMv7 debug architecture
- Tightly-coupled memories
  - 96 KB of ROM
  - 128KB of program RAM with ECC
  - 64KB of data RAM with ECC
- Hardware auto-initialization of the memories
- Vectored interrupt manager for prioritizing and controlling the interrupts for different sources

1.1.2.3.1 Serial Interfaces

- One DCAN controller supporting bit rates of up to 1 Mbit/s, and compliant to the controller area network (CAN) 2.0B protocol specification
- One I2C controller module with rates up to 400 kbps
- Two high-speed synchronous serial input/output MIBSPI modules
- Two serial communication interface (SCI) modules implementing standard universal asynchronous receiver-transmitter (UART)
- One quad SPI module support with maximum rate of 40 MHz

1.1.2.3.2 System Peripherals

- Multiple general-purpose input/output (GPIO) modules
- Direct memory access modules for high-performance data transfers
- One watchdog timer and a general purpose timer implemented by the real-time interrupt (RTI) modules
- Mailbox module for interprocessor communication
- System reset and control module, which contains registers for the following functions:
  - Status
  - Efuse logic
  - I/O configuration
  - PAD configuration
  - System boot decoding logic

1.1.2.4 Functional Safety Deliverables

See the Device Safety Manual for supported features.

1.1.2.5 On-Chip Debug Support

The on-chip debug support has the following features:

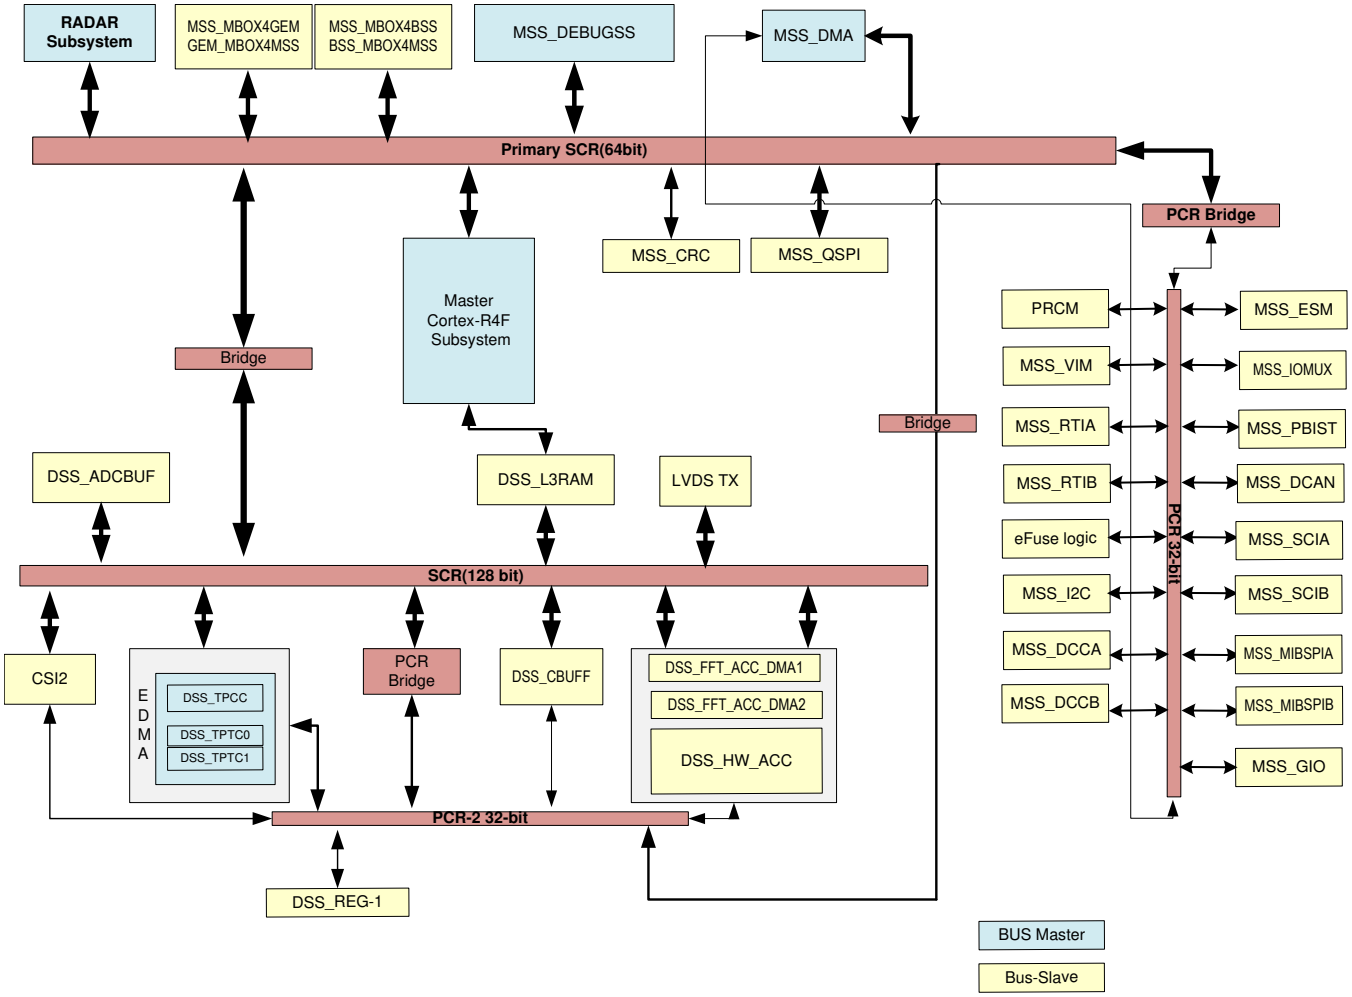
- The following device cores can be debugged through Code Composer Studio (CCS):
  - Cortex-R4F
- Target debugging using IEEE1149.1 (JTAG®) port
- The debug subsystem includes:
  - IEEE1149.7 adapter
  - Generic TAP for emulation and test control (ICEPick-D™)
  - Debug access port (DAP)
  - Embedded trace macro (ETM)
  - Trace port interface Unit (TPIU)
  - Embedded trace buffer (ETB)

1.2 14xx Memory Map

1.2.1 System Interconnect

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols. Figure 1-2 shows the interconnect diagram.

Figure 1-2. System Interconnect



The system interconnect is designed for the high-performance needs of the system. Its divided into interconnect systems local to each subsystem: the RADAR subsystem and master subsystem. The interconnection of all these subsystems is shown in .

In the master subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple masters to each of the slaves. The arbitration priority is always round-robin.

The master subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth. The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

1.2.2 Master Subsystem Cortex-R4F Memory Map

Table 3-2 shows the master subsystem, Cortex-R4F memory map.

Table 1-2. Master Subsystem, Cortex-R4F Memory Map

1.3 14xx Integration

1.3.1 Cortex-R4F Subsystem

1.3.1.1 Tightly Coupled Memories

The total memory (RAM) available in the master subsystem is 576 KB. This is partitioned between the R4F program RAM, R4F data RAM, and radar data memory. The maximum usable size for R4F is 448 KB, and this is partitioned between the R4F's tightly coupled interfaces MSS_TCMA_RAM (320 KB) and MSS_TCMB (128 KB). Although the complete 448 KB is unified memory and can be used for program or data, typical applications use MSS_TCMA_RAM as program and MSS_TCMB as data memory.

The remaining memory, starting at a minimum of 128 KB, is available as radar data memory for storing the 'radar data cube'. The user can increase the radar data memory size in 64 KB increments, at the cost of corresponding reduction in R4F program or data RAM size. The maximum size of radar data memory possible is 384 KB. A few example configurations supported are listed in Table 1-4.

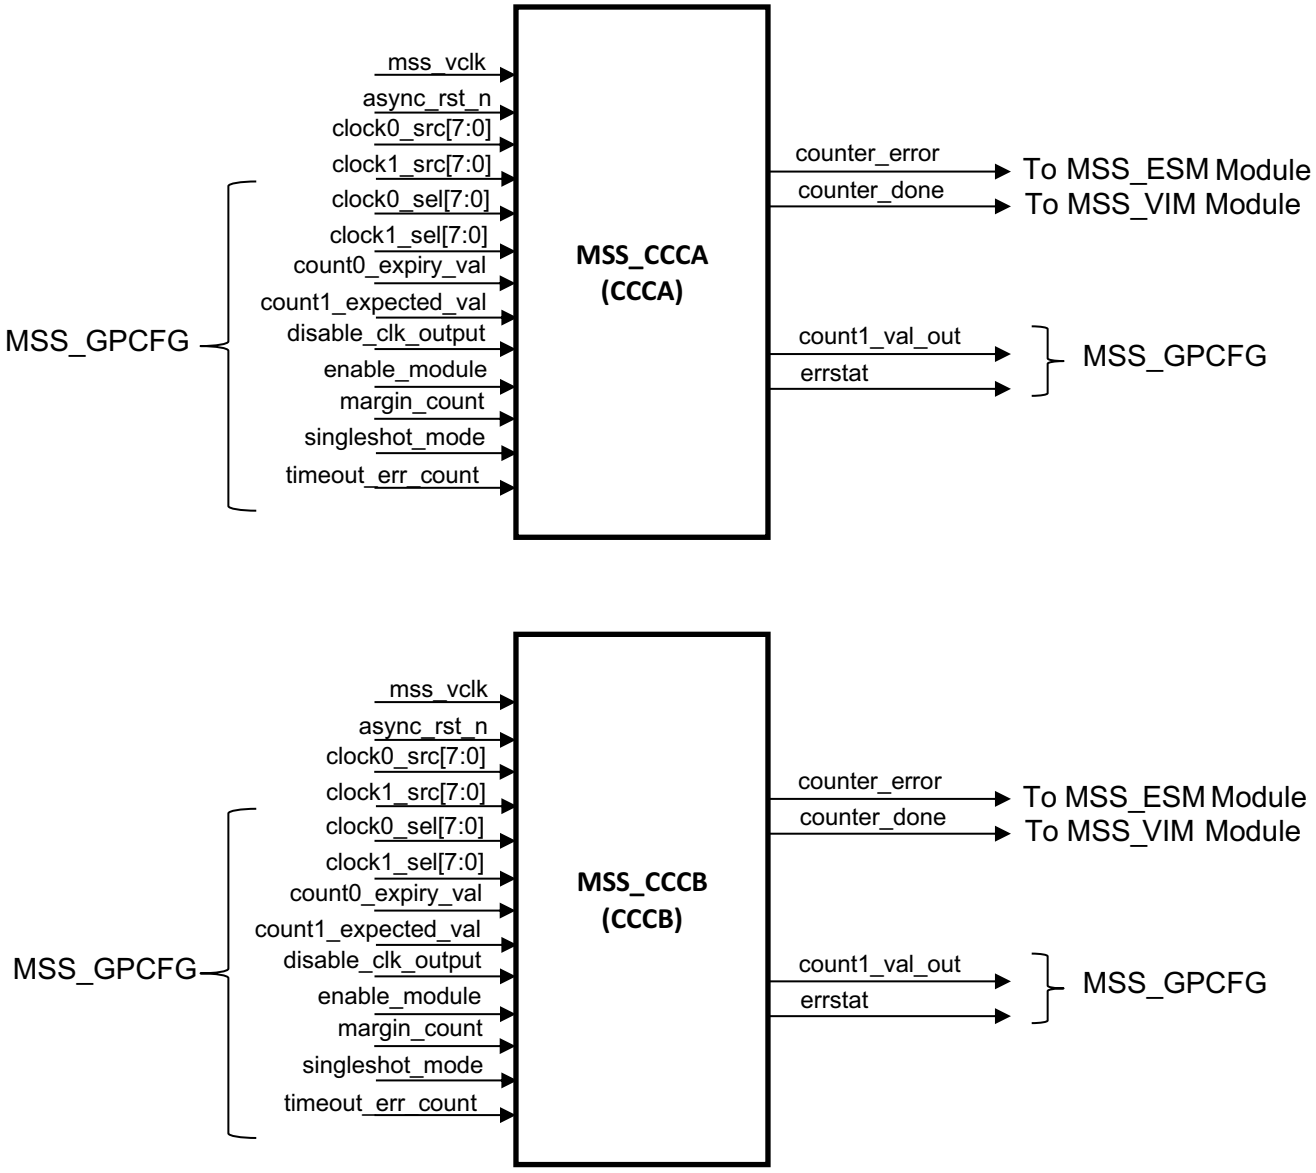
Table 1-4. Example Configurations

Option	R4F Program RAM (KB)	R4F Data RAM (KB)	Radar Data Memory (KB)
1	320	128	128
2	256	128	192
3	256	64	256
4	128	64	384

1.3.2 Clock Comparator

1.3.2.1 Core Clock Comparator (MSS_CCCA/MSS_CCCB)

Figure 1-3. Integration of MSS_CCCA and MSS_CCCB Modules



1.3.2.1.1 MSS_CCCA and MSS_CCCB Integration Connections

This device has two instances of CCC; MSS_CCCA (CCCA) and MSS_CCCB (CCCB). The clock connectivity information for these two instances are provided in Table 1-5. Configuration and status of this module is available through the MSS_GPCFG registers of the device.

Table 1-5. MSS_CCCA and MSS_CCCB Integration Connections

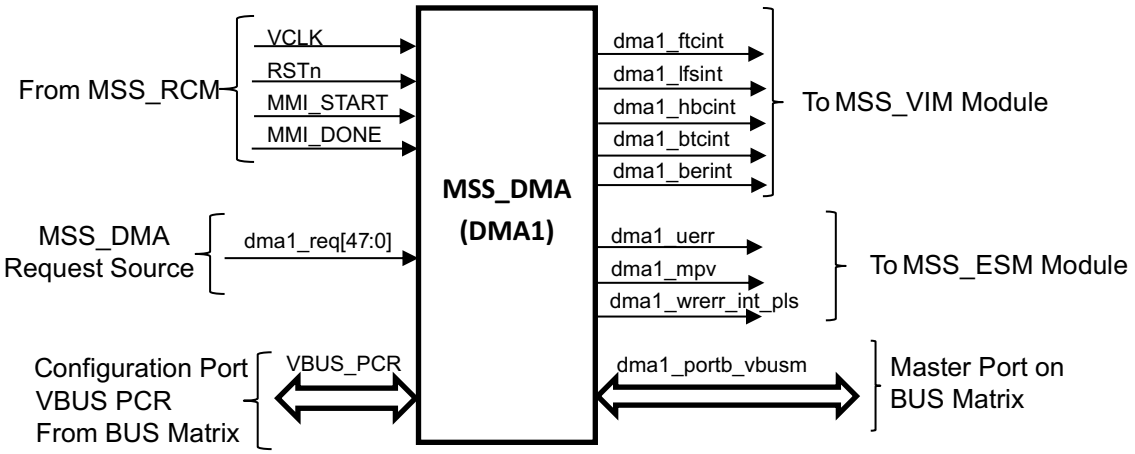
1.3.3 Direct Memory Access Controller (MSS_DMA)

1.3.3.1 MSS_DMA Integration Diagram

The device has one instance of DMA module, MSS_DMA. Integration of the MSS_DMA blocks in the device are shown in Figure 1-5.

Figure 1-5. Integration of MSS_DMA Module



1.3.3.2 MSS_DMA Features

- 64-bit OCP protocol to perform bus master accesses
- INCR-4 64-bit burst accesses
- Multithreading architecture allowing data of two different channel transfers to be interleaved during non-burst accesses
- 2-port configuration for parallel bus master
- Channels can be assigned to either high-priority queue or low-priority queue. Within each queue, fixed or round-robin priorities can be serviced
- Built-in ECC generation and evaluation logic for internal RAM-storing channel transfer information
- Supports multiple interrupt outputs for mapping to multiple interrupt controllers in multicore systems
- 48 requests can be mapped to any 32 channels
- Supports LE endianness
- External ECC Gen/Eval block of MSS_DMA support ECC generation for data transactions, and parity for address, and control signals (following Cortex-R5F standard)
- 8 MPU regions
- Channel-chaining capability
- Hardware and software MSS_DMA requests
- 8-, 16-, 32-, or 64-bit transactions supported
- Multiple addressing modes for source and destination (fixed, increment, offset)
- Auto-initiation

1.3.3.3 MSS_DMA Request Map

The MSS_DMA module has 32 channels and up to 42 hardware MSS_DMA requests. The module contains DREQASIx registers to map the MSS_DMA requests to the MSS_DMA channels. By default, channel 0 is mapped to request 0, channel 1 to request 1, and so forth.

Table 1-8. MSS_DMA Request Map

Module	DMA Request Sources	DMA Request

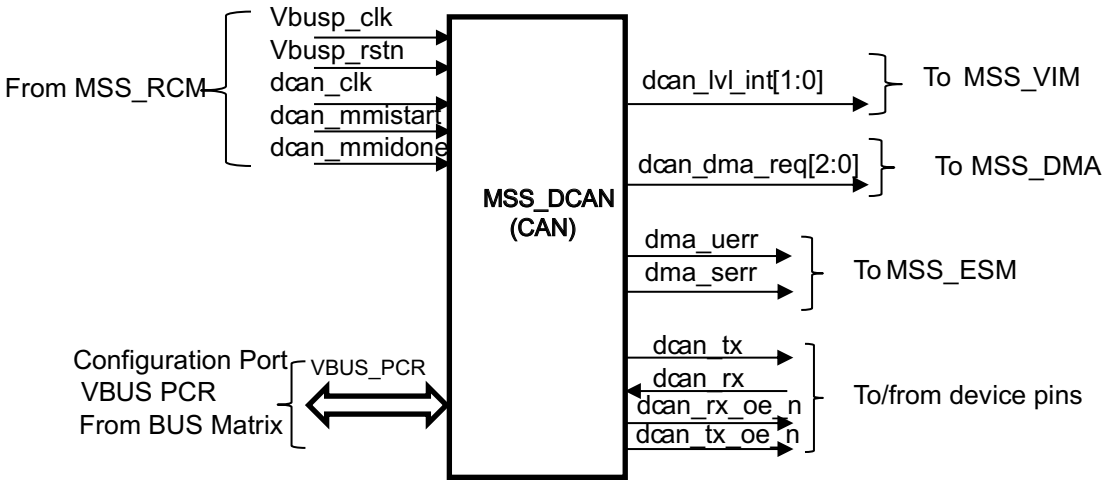
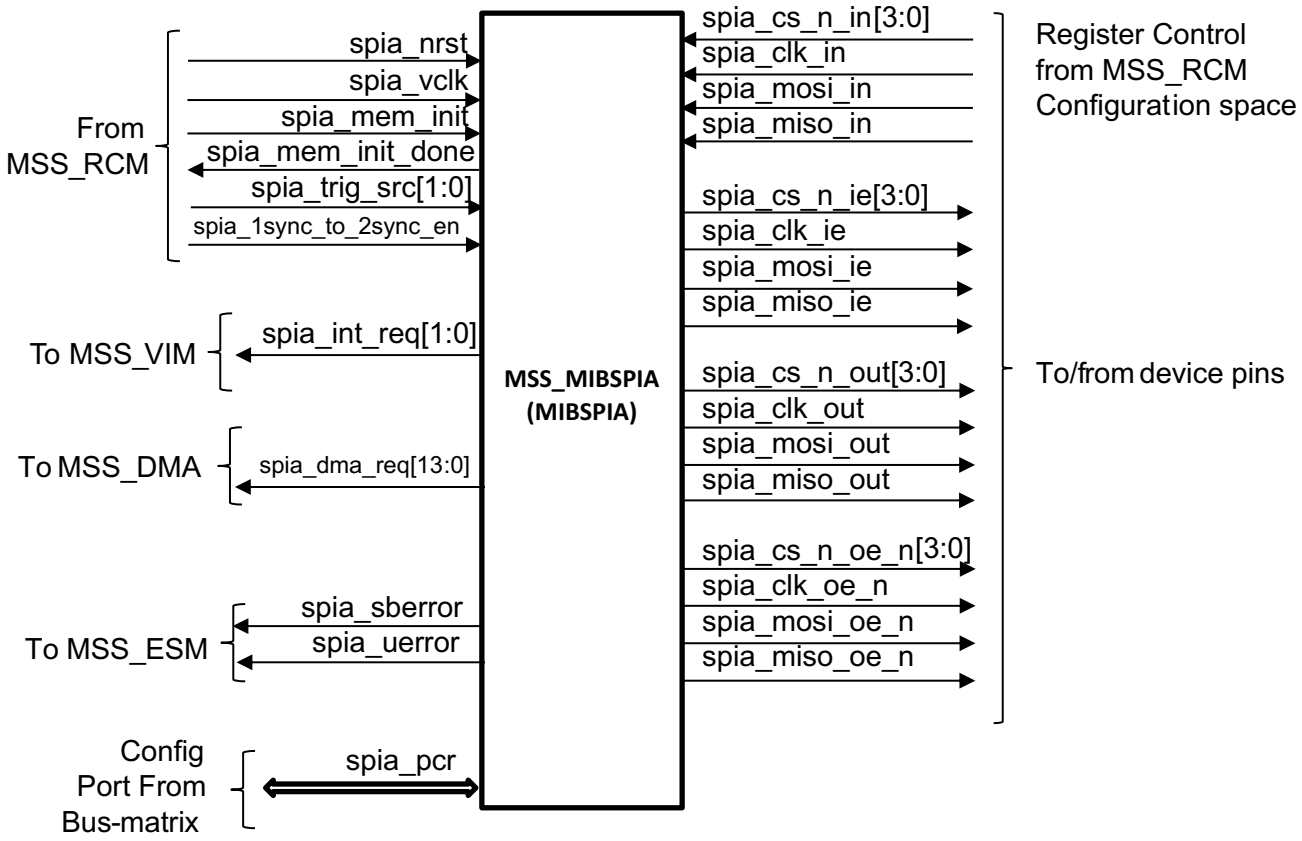
1.3.7 Controller Area Network (MSS_DCAN)

Figure 1-8. Integration Block Diagram for MSS_DCAN Module



1.3.8 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPIA)

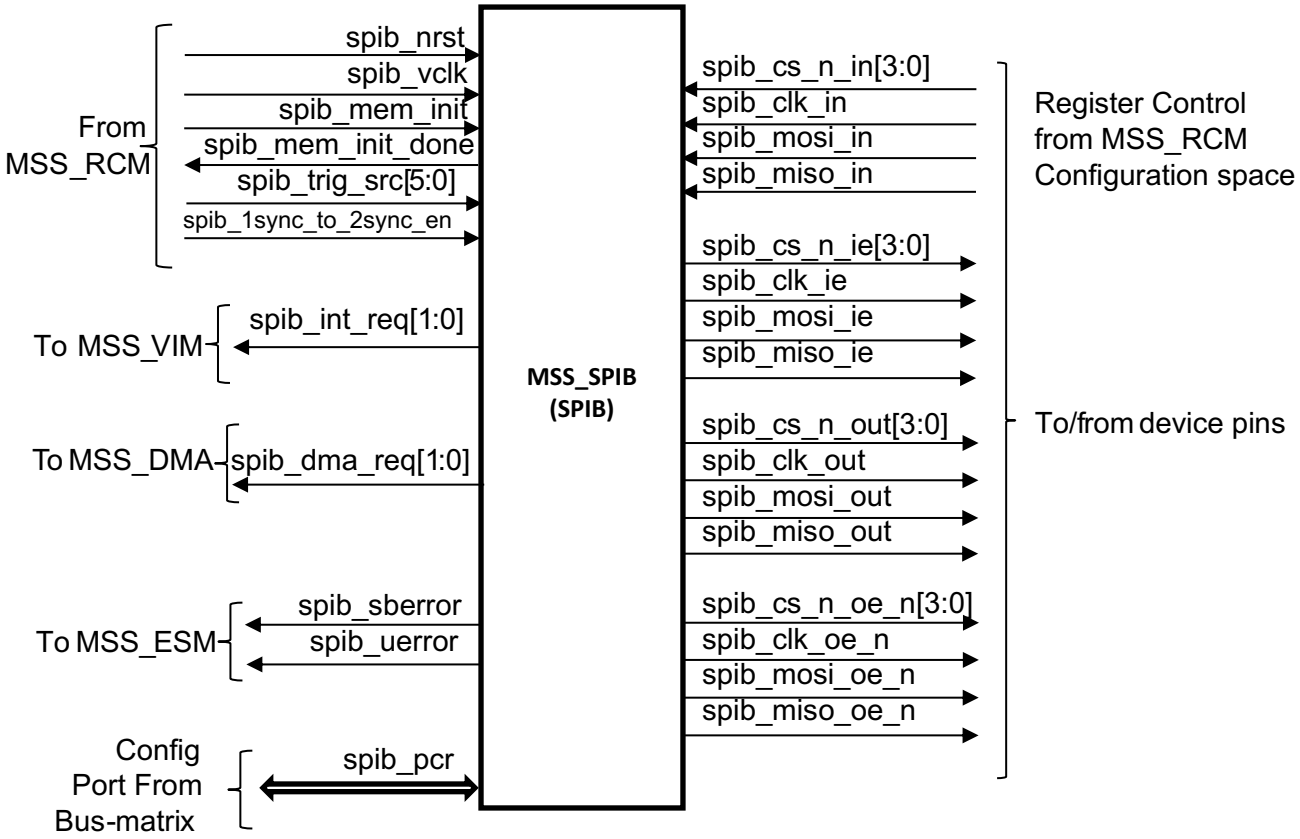
Figure 1-9. MSS_MIBSPIA Integration



1.3.9 Serial Peripheral Interface (MSS_SPIB)

MSS_SPIB module of the 14xx is equivalent in behavior and functionality to MSS_MIBSPIA module configured in compatibility mode for SPI. Users cannot change the compatibility mode configuration of this MSS_SPIB instance.

Figure 1-10. MSS_SPIB Integration Diagram



1.3.10 Quad Serial Peripheral Interface (MSS_QSPI)

The QSPI module of the 14xx only supports one CS pin (qspi1_cs).

1.3.11 Enhanced Direct Memory Access (EDMA)

1.3.11.1 EDMA Controller Integration

The 14xx device has one EDMA channel controller (DSS_TPCC0) on the device:

- DSS_TPCC0 (EDMA TPCC0) has two transfer controllers: DSS_TPTC0 (EDMA TPTC0) and DSS_TPTC1 (EDMA TPTC1)

Table 1-10. DSS_TPCC Configuration

	DSS_TPCC0
Number of DMA channels	64
Number of PaRAM entires	128
Number of QDMA channels	8
Number of event queues	2
Memory protection existence	No
Channel mapping	No
Number of TCs (transfer controllers)	2

Table 1-11. DSS_TPTC Configuration

	DSS_TPTC[0-1]
FIFO size	512 bytes
TR pipe depth	2
Bus width	16 bytes

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 3-13 and Figure 3-14 show the EDMA controller integration.

1.3.12 Error Signaling Module (MSS_ESM)

The 14xx device has one instance of the Error Signaling Module (MSS_ESM), shown in Figure 1-12.

Figure 1-12. 14xx MSS_ESM Integration Diagram

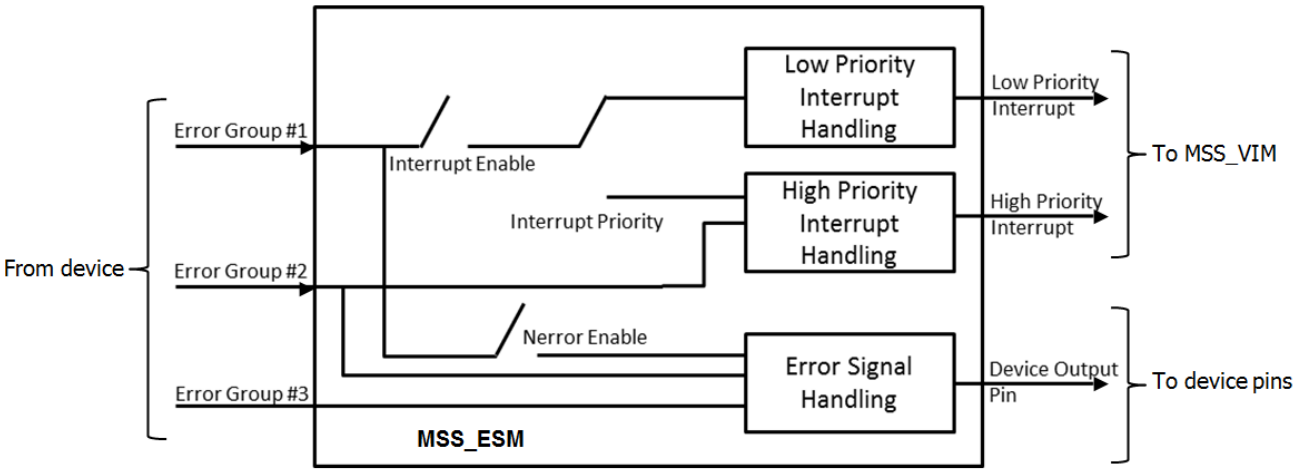

Table 1-13 shows the mapping on the input error inputs to the ESM module from various error sources available for hardware diagnostics within the device.

Table 1-13. MSS_ESM Mapping

ESM Group 1		Channel Type	Description
63	ANA_LIMP_MODE	Error Signal	Error signal at device boot-up, if the CLK monitor finds the REF CLK to be outside the permissible range of frequency
62	MSS_DCCB_ERR	Error Signal	MSS_DCCB frequency comparison error
61	BSS2MSS_MB_FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_BSS2MSS

Table 1-13. MSS_ESM Mapping (continued)

ESM Group 1		Channel Type	Description
60	BSS2MSS_MB_REPAIR_ERR	Alert Signal	Single-bit error/repair indication from MAILBOX_BSS2MSS
59	MSS2BSS_MB_FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_MSS2BSS
58	MSS2BSS_MB_REPAIR_ERR	Alert Signal	Single-bit error/repair indication from MAILBOX_MSS2BSS
57	BSS_CRITICAL_ERR	Error Signal	BSS critical Error Indication. Mask control to be configured in IRQ_CTL for individual error signals.

2.1 16xx Introduction

2.1.1 16xx Overview

The 16xx is highly integrated single-chip RADAR device in TI's 45-nm low-power RFCMOS technology, a FCBGA 0.65-mm pitch automotive-grade package.

2.1.1.1 Features

- Frequency-Modulated Continuous Wave Radio Frequency Transceiver With 76-81-GHz Band
- Supports Two Transmitter Chains and Four Receiver Chains
- Chirp Profiles With Programmable Period and Slope
- 40-MHz, 50-MHz, 80-MHz, and 100-MHz XTAL/OSC Reference Input Clock
- 12, 14, and 16-bit Real/Complex ADC With Variable Baseband ADC Sampling Rates up to 18.75 MHz at 12-bits Complex
- Cortex R4F at 200-MHz Application Processor for Control Functionality and Safety-Critical Algorithms
- C674x DSP at up to 600 MHz for RADAR Data Processing
- Cortex R4F– Radio Processor at 200 MHz for Continuous Monitoring and Calibration of Analog/RF Functionality
- On-Chip Multicore Debug Support
- Customer-Programmable Efuse Support
- Up to 768KB of L3 Shared Memory Support
- High-Performance Data Transfer With Multiple DMA and EDMA-TPCC Engines
- CAN Support for ECU Interface
- QSPI Serial Flash Support
- MIBSPI, SPI, I2C, and UART Serial Interfaces Support
- Hardware in Loop (HIL) Support
- Two-Lane Serial LVDS Interface Support
- AES, SHA, PKA, and TRNG Engines for Security
- I2C Serial Interface Support
- 3 EPWM (Three Enhanced Pulse Width Modulator)

2.1.2 16xx Description

2.1.2.1 Block Diagram

Figure 2-17 shows the block diagram of the 16xx device.

Figure 2-1. 16xx Block Diagram

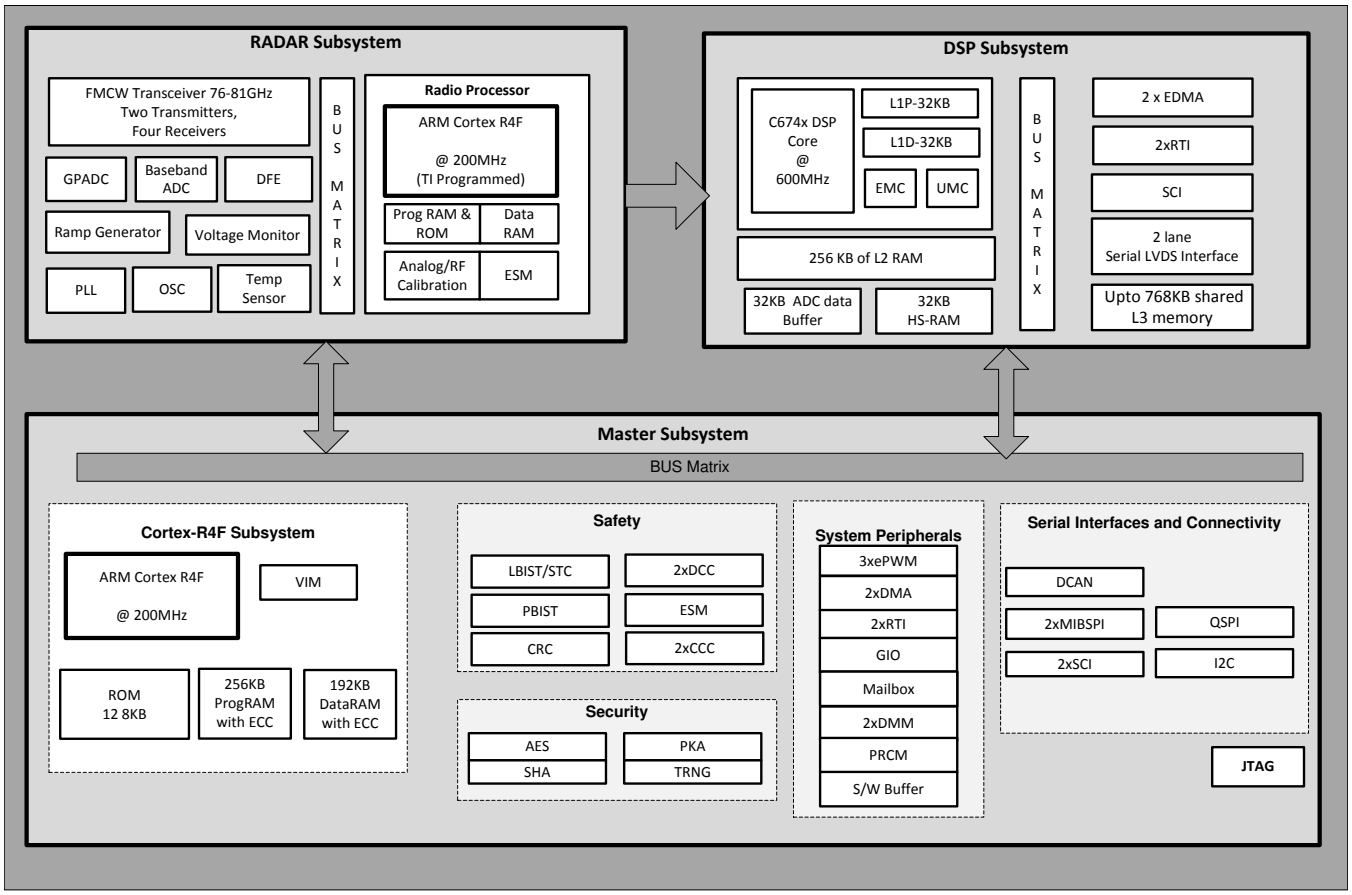

Table 2-1. 16xx Acronyms

ADC	Analog-to-Digital Convertor
AES	Advanced Encryption Standard
CRC	Cyclic Redundancy Check
DCAN	Controller Area Network
DCC	Digital Clock Comparator
DFE	Digital Front End
DMA	Direct Memory Access
DMM	Data Modification Module
ECC	Error Correcting Code
EDMA	Enhanced Direct Memory Access
EMC	Extended Memory Controller
ePWM	Enhanced Pulse Width Modulator
ESM	Error Signaling Module
GIO	General Input/Output
GPADC	General Purpose Analog-to-Digital Convertor
HS-RAM	Handshake RAM
I2C	Inter-Integrated Circuit
JTAG	Joint Test Action Group
L1D	Level 1 Data Memory Controller
L1P	Level 1 Program Memory Controller

Table 2-1. 16xx Acronyms (continued)

L2	Level 2
L3	Level 3
LBIST	Logic Built-In Self-Test
LVDS	Low Voltage Differential Signaling
MIBSPI	Multi-Buffered Serial Peripheral Interface Module
OSC	Oscillator
PBIST	Programmable Built-In Self-Test
PKA	Public Key Algorithm
PLL	Phase Locked Loops
PRCM	Power, Reset, Clock Management
QSPI	Quad Serial Peripheral Interface
RTI	Real Time Interrupt
S/W Buffer	Software Buffer
SCI	Serial Communication Interface
SHA	Secure Hash Algorithm
STC	Self-Test Controller
TRNG	True Random Number Generator
UMC	Unified Memory Controller
VIM	Vectored Interrupt Manager

2.1.2.2 Radar Subsystem

The RADAR subsystem is responsible for the RF and analog functionality of the device. The subsystem incorporates a built-in self-test processor for the continuous motoring and calibration of the analog and RF modules. The subsystem consists of:

- FMCW transceiver
  - Integrated PLL, transmitter, receiver, baseband, and A2D
  - 76-81-GHz coverage with 4-GHz available bandwidth
  - Four receive channels
  - Two transmit channels
  - Ultra-accurate chirp engine based on fractional-n PLL
  - 12,14, or 16-bit complex analog to digital converter
- Radio processor for built-in calibration and self-test
  - ARM Cortex R4F-based radio control system
  - Built-in firmware (ROM)
  - Self-calibrating system across frequency and temperature

This subsystem is TI-programmed with an API interface to the on-chip Cortex-R4F application processor.

2.1.2.3 DSP Subsystem

The DSP subsystem consists of the following:

- The TMS320C674x™ VLIW DSP core from the generation, and the TMS320C64x+™ DSP architecture for RADAR data processing. These are enhancements from TI's C64x+™ DSP architecture, with additional features.
- 32KB L1D and 32KB of L1P cache/RAM
- 256KB of L2 RAM
- On-chip L3 shared memory of 768KB, with 256KB dedicated to DSP and 512 KB of memory shared between the DSP and master subsystems.

- 32KB of memory for storing ADC samples from the RADAR subsystem
- Multiple Enhanced Direct Memory Access (EDMA) engines – TPCCs for high-performance data transfers
- 2-lane LVDS interface with support of up to 900 Mbps per lane for the RADAR raw ADC data transfer
- One watchdog timer and a general purpose timer implemented by the real time interrupt (RTI) modules
- One serial communication Interface (SCI) module implementing standard universal asynchronous receiver-transmitter (UART).
- Emulation capabilities
- Little Endian

2.1.2.4 Master Subsystem

The master subsystem consists of the following features:

- Cortex-R4F core supporting ARMv7-R, VFPv3-D16, and ARMv7 debug architecture
- Tightly-coupled memories
  - 128 KB of ROM
  - 256KB of program RAM with ECC
  - 192KB of data RAM with ECC
- Hardware auto-initialization of the memories
- Vectored interrupt manager for prioritizing and controlling the interrupts for different sources

2.1.2.4.1 Serial Interfaces

- One DCAN controller supporting bit rates of up to 1 Mbit/s, and compliant to the controller area network (CAN) 2.0B protocol specification
- One I2C controller module with rates up to 400 kbps
- Two MIBSPI modules
- Two serial communication interface (SCI) modules implementing standard universal asynchronous receiver-transmitter (UART) with baud rates of up to 3.125 Mbps
- One quad SPI module support with maximum rate of 40 MHz

2.1.2.4.2 System Peripherals

- Multiple general-purpose input/output (GPIO) modules
- Direct memory access modules for high-performance data transfers
- One watchdog timer and a general purpose timer implemented by the real-time interrupt (RTI) modules
- Mailbox module for interprocessor communication
- Two data modification modules (DMM) with up to 65 Mbit/s data rate per pin
- Three enhanced pulse width (ePWM) modulator modules
- System reset and control module, which contains registers for the following functions:
  - Status
  - Efuse logic
  - I/O configuration
  - PAD configuration
  - System boot decoding logic

2.1.2.5 Functional Safety Deliverables

See the Device Safety Manual for supported features.

2.1.2.6 On-Chip Debug Support

The on-chip debug support has the following features:

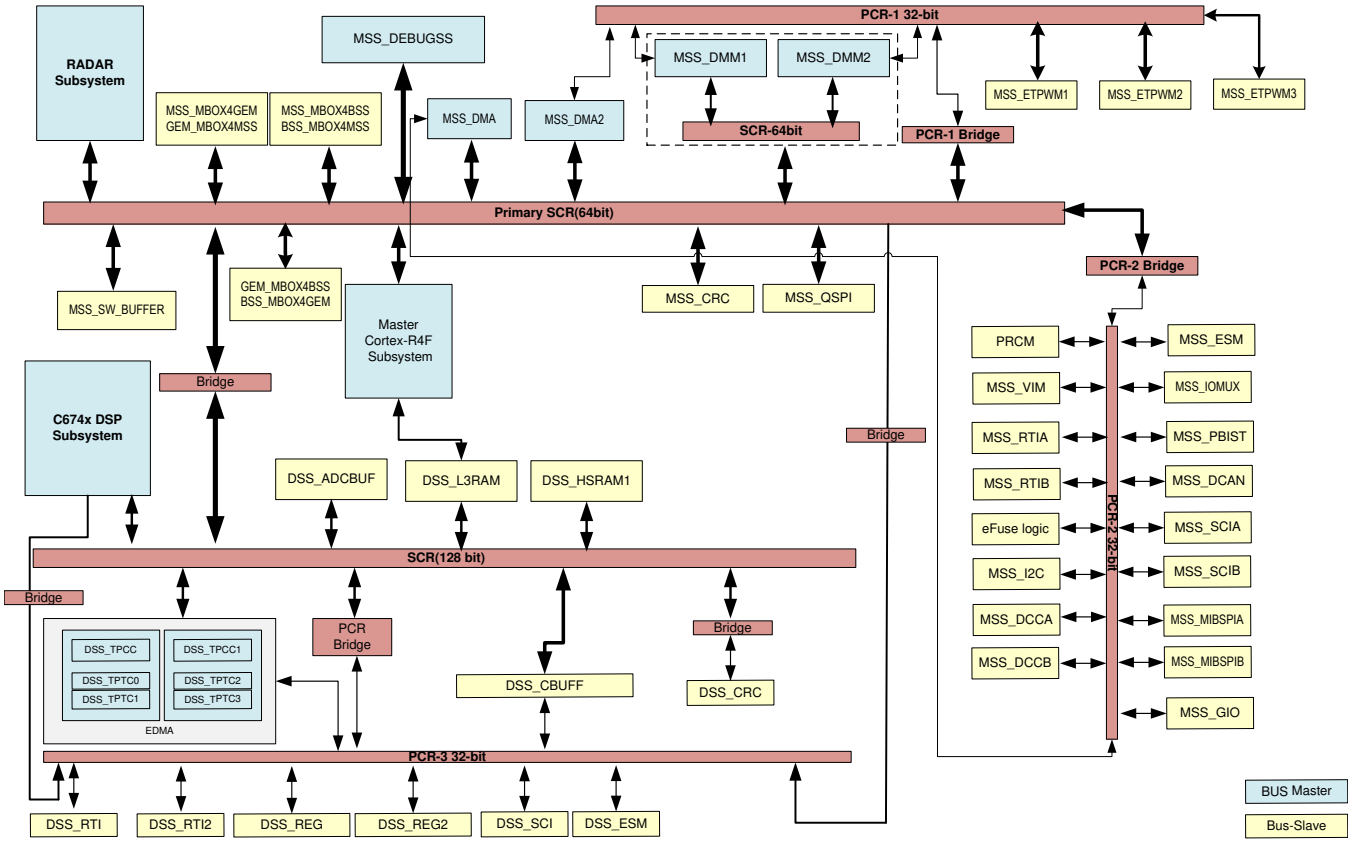
- Multiprocessor debugging to let users control multiple cores embedded in the device, such as:
  - Global starting and stopping of individual or multiple processors
  - Each processor can generate triggers to alter the execution flow of other processors
  - Interconnection of multiple devices
  - Channel triggering
- The following device cores can be debugged through Code Composer Studio (CCS):
  - Cortex-R4F
  - DSP
- Target debugging using IEEE1149.1 (JTAG®) port
- The debug subsystem includes:
  - IEEE1149.7 adapter
  - Generic TAP for emulation and test control (ICEPick-D™)
  - Debug access port (DAP)
  - Embedded trace macro (ETM)
  - Trace port interface Unit (TPIU)
  - Embedded trace buffer (ETB)

2.2 16xx Memory Map

2.2.1 System Interconnect

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols. Figure 2-18 shows the interconnect diagram.

Figure 2-2. System Interconnect



The system interconnect is designed for the high-performance needs of the system. Its divided into three interconnect systems local to each of the three subsystems: the RADAR subsystem, DSP subsystem, and master subsystem. The interconnection of all these subsystems is shown in Figure 3-2.

In the master subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple masters to each of the slaves. The arbitration priority is always round-robin.

The master subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth. The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

Similarly, the 128-bit VBUSM SCR in the DSP subsystem manages the arbitration between accesses from the multiple masters to the slaves. The DSP subsystem has a 32-bit VBUSP PCR for the system and non-system peripherals.

2.2.2 Master Subsystem Cortex-R4F Memory Map

Table 3-2 shows the master subsystem, Cortex-R4F memory map.

Table 2-2. Master Subsystem, Cortex-R4F Memory Map

2.2.2.1 Radar Subsystem Interface

The RADAR subsystem is accessible through a set of TI-implemented high-level API calls by the application running on the master CR4F. For more information on the 16xx RADAR subsystem interface, see the 16xx Interface control document.

2.2.3 DSP Subsystem Memory Map

Table 3-3 shows the DSP C674x memory map.

2.3 16xx Integration

2.3.1 Cortex-R4F Subsystem

2.3.1.1 Tightly Coupled Memories

Table 3-5 lists the dedicated MSS_TCMA_RAM and MSS_TCMB sizes for the Cortex R4F processor in the master subsystem, and also mentions the total available L3 shared RAM in the device. A portion of this L3 shared memory (DSS_L3RAM) can be allotted as TCM, to further increase the MSS_TCMA_RAM and MSS_TCMB available for the Cortex R4F.

Table 2-5. TCM and Shared Memory Available for Cortex R4F in Master Subsystem

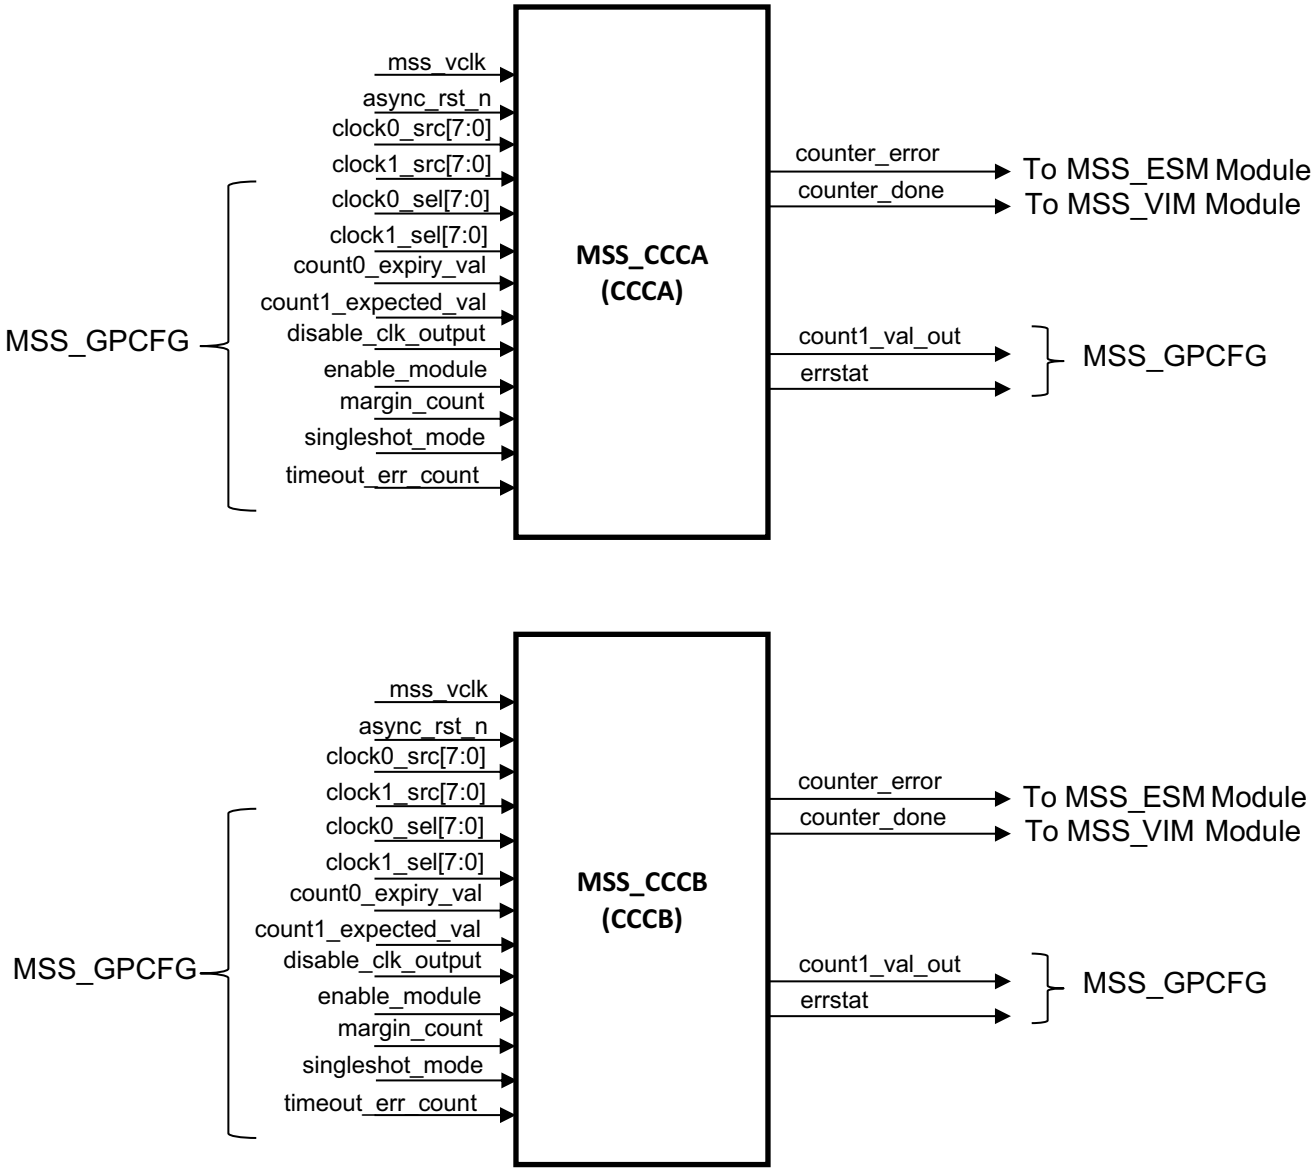
Cortex R4F		Shared
MSS_TCMA_RAM (Program RAM) (KB)	MSS_TCMB (Data RAM) (KB)	L3 Shared (KB)
256	192	768

See on how the L3 shared memory (DSS_L3RAM) can be assigned between the Cortex R4F of the master subsystem and the DSP core.

2.3.2 Clock Comparator

2.3.2.1 Core Clock Comparator (MSS_CCCA/MSS_CCCB)

Figure 2-3. Integration of MSS_CCCA and MSS_CCCB Modules



2.3.2.1.1 MSS_CCCA and MSS_CCCB Integration Connections

This device has two instances of CCC: MSS_CCCA (CCCA) and MSS_CCCB (CCCB). The clock connectivity information for these two instances is provided in Table 3-6. Configuration and status of this module is available through the MSS_GPCFG registers of the device.

Table 2-6. MSS_CCCA and MSS_CCCB Integration Connections

	MSS_CCCA (CCCA)	MSS_CCCB (CCCB)
counter_error	ESM_GRP1[1]	ESM_GRP1[4]
counter_done	IRQ[80]	IRQ[81]

Table 2-6. MSS_CCCA and MSS_CCCB Integration Connections (continued)

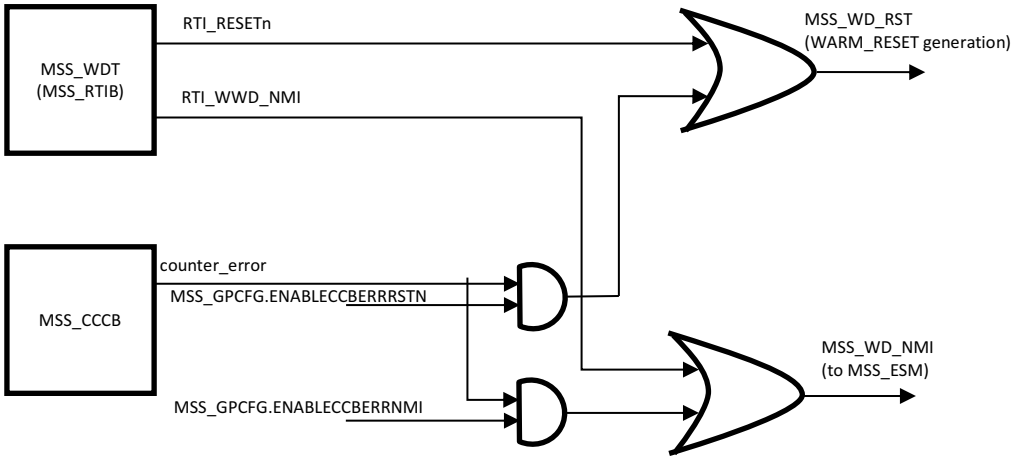
clock1_src[6]	RCCLK	BSSCLK
clock1_src[7]	RCCLK	QSPICLK

2.3.2.1.2 MSS_CCCB Integration to MSS_WD

As a safety requirement, WDT IP should work on an independent clock source instead of the clock used by the MSS CR4. Because the WDT IP does not allow this flexibility, an additional monitoring logic is added in the form of CCM (MSS_CCCB instance), coupled along with the watchdog. MSS_CCCB is used to compare CR4_VCLK to an independent reference clock, such as XTAL. If the CR4 clock indicates a deviation from the expected frequency, a WD reset or a WD NMI can be issued.

Figure 2-4. MSS_CCCB Integration to MSS_WD



2.3.2.2 Dual Clock Comparator (MSS_DCCA/MSS_DCCB)

Figure 2-5. MSS_DCCA/MSS_DCCB Integration Diagram

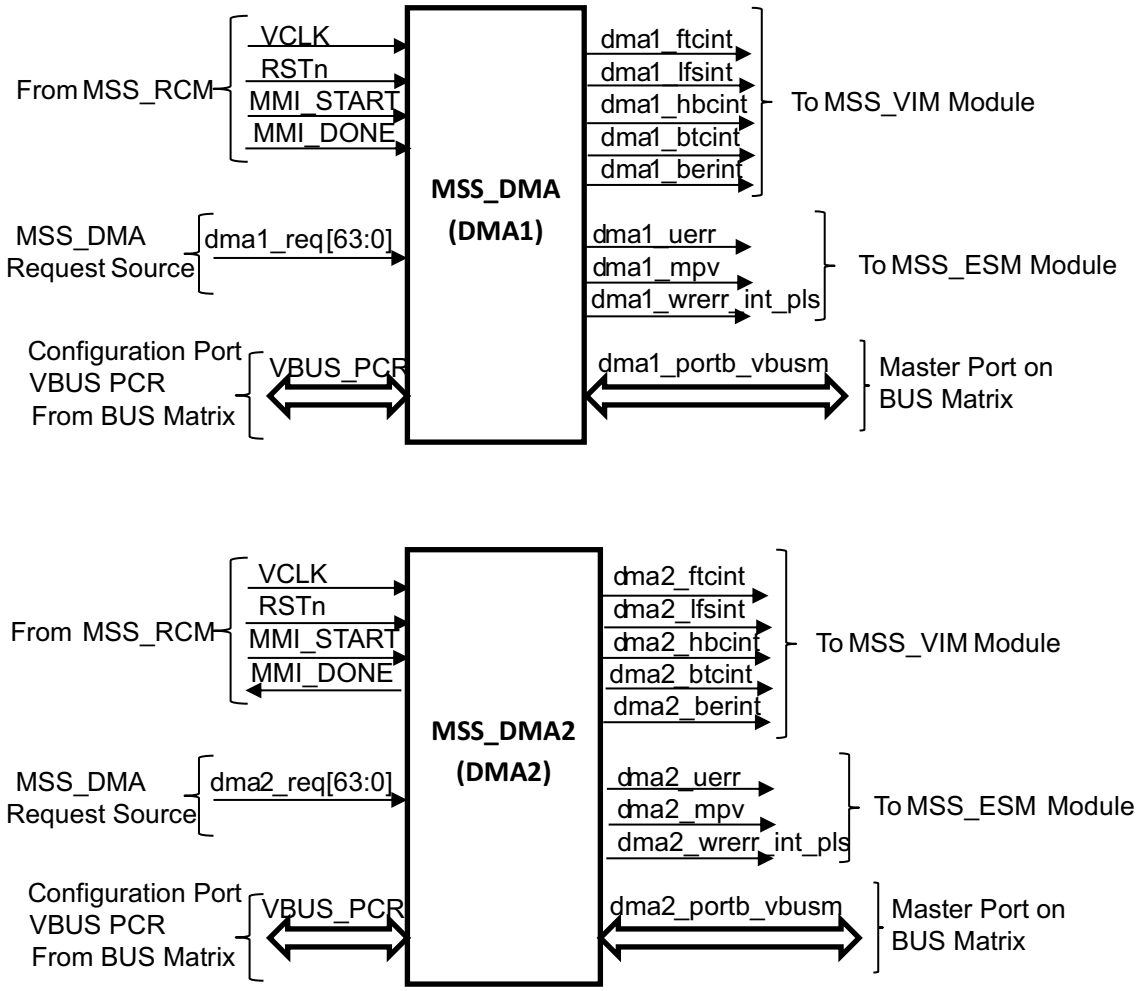
2.3.4 Direct Memory Access Controller (MSS_DMA)

2.3.4.1 MSS_DMA Integration Diagrams

The device has two instances of DMA module, MSS_DMA and MSS_DMA2. Integration of the two DMA blocks in the device are shown in Figure 3-5 and .

Figure 2-6. Integration of MSS_DMA and MSS_DMA2 Module



2.3.4.2 MSS_DMA Features

- 64-bit OCP protocol to perform bus master accesses
- INCR-4 64-bit burst accesses
- Multithreading architecture allowing data of two different channel transfers to be interleaved during non-burst accesses
- 2-port configuration for parallel bus master
- Channels can be assigned to either high-priority queue or low-priority queue. Within each queue, fixed or round-robin priorities can be serviced
- Built-in ECC generation and evaluation logic for internal RAM-storing channel transfer information
- Supports multiple interrupt outputs for mapping to multiple interrupt controllers in multicore systems
- 48 requests can be mapped to any 32 channels
- Supports LE endianness
- External ECC Gen/Eval block of MSS_DMA support ECC generation for data transactions, and parity for address, and control signals (following Cortex-R5F standard)
- 8 MPU regions
- Channel-chaining capability
- Hardware and software MSS_DMA requests

- 8-, 16-, 32-, or 64-bit transactions supported
- Multiple addressing modes for source and destination (fixed, increment, offset)
- Auto-initiation

2.3.4.3 MSS_DMA Request Map

Both instances of MSS_DMA have 64 lines of request and are connected to identical input triggers, as shown in Table 3-10. This allows the two DMAs to trigger different types of transfers for the same request.

Table 2-10. MSS_DMA Request Map

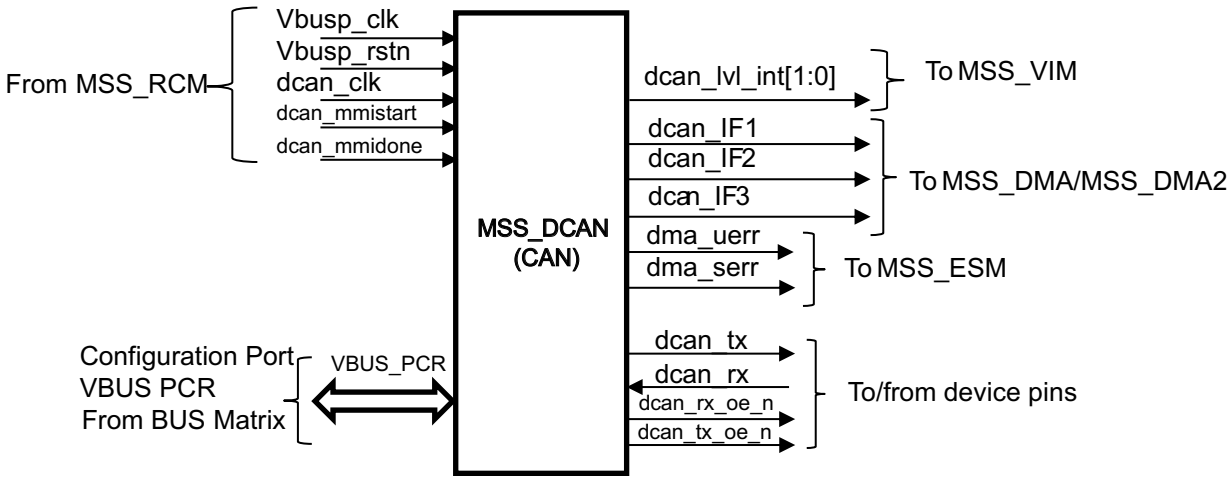
2.3.10 Controller Area Network (MSS_DCAN)

Figure 2-11. Integration Block Diagram for MSS_DCAN Module



2.3.11 Multi-Buffered Serial Peripheral Interface Module (MSS_MIBSPI)

Figure 2-12. MSS_MIBSPIA Integration

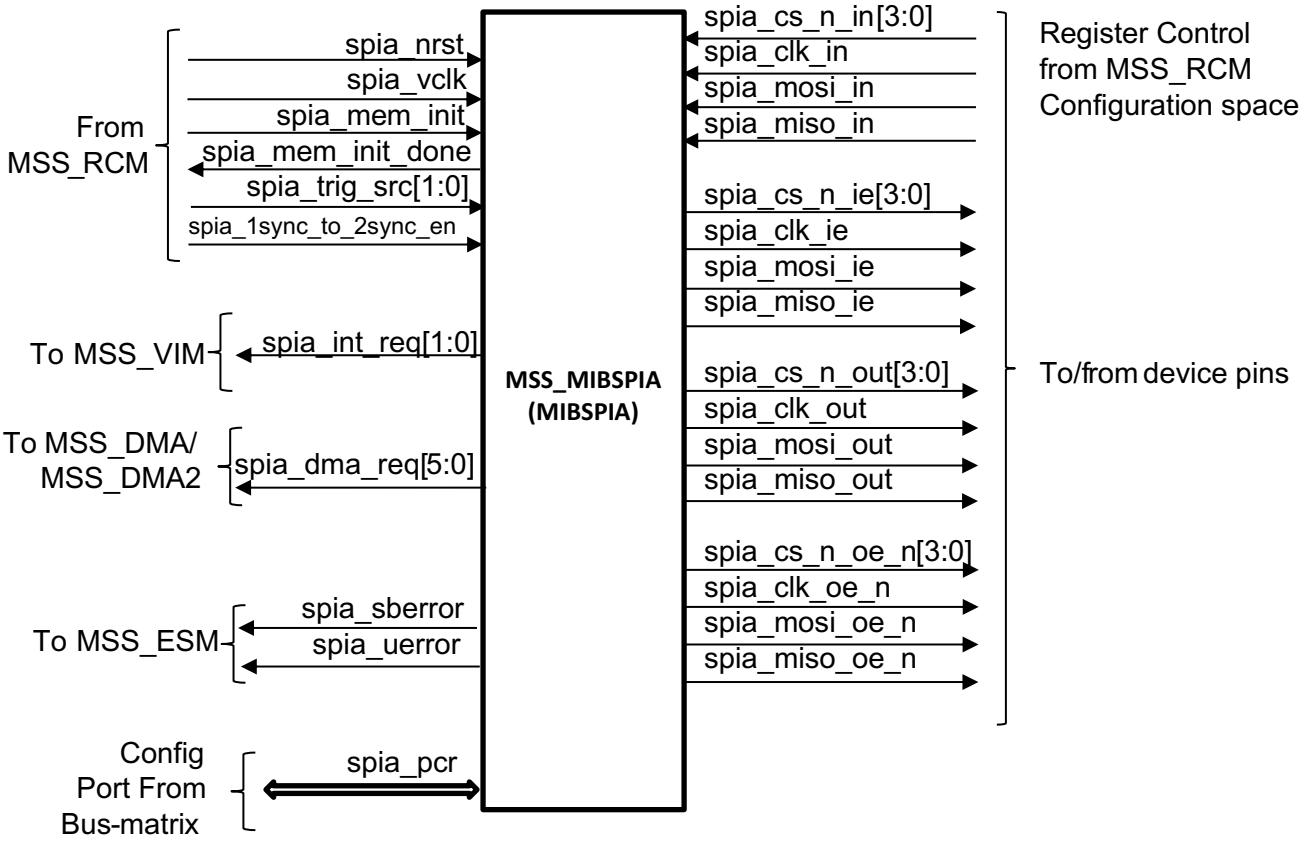


Figure 2-13. MSS_MIBSPIB Integration

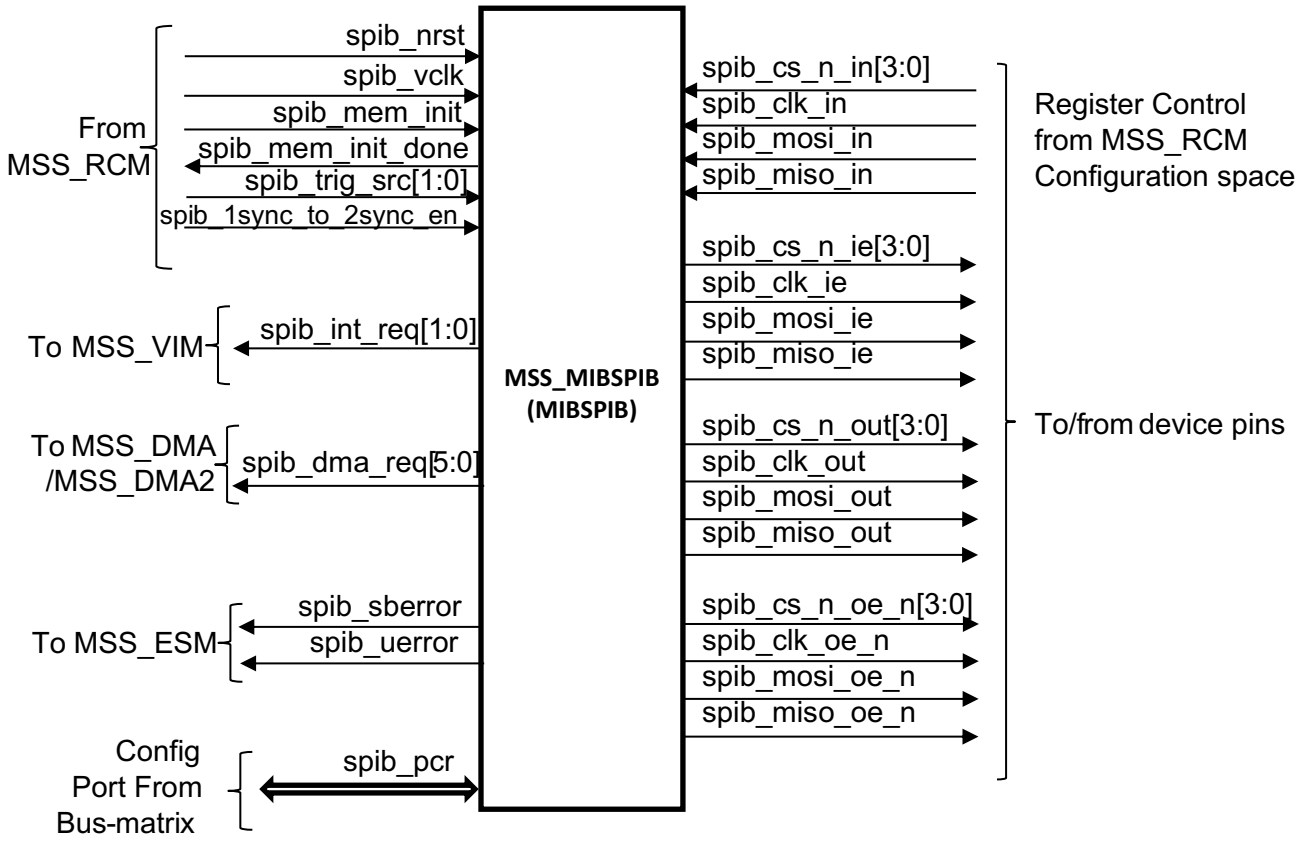

2.3.12 Quad Serial Peripheral Interface (MSS_QSPI)

The MSS_QSPI module of the 16xx only supports one CS pin, (qspi1_cs).

2.3.13 Enhanced Direct Memory Access (EDMA)

2.3.13.1 EDMA Controller Integration

The 16xx device has two EDMA channel controllers (DSS_TPCC0 and DSS_TPCC1) on the device:

- DSS_TPCC0 (EDMA TPCC0) has two transfer controllers: DSS_TPTC0 (EDMA TPTC0) and DSS_TPTC1 (EDMA TPTC1)
- DSS_TPCC1 (EDMA TPCC1) has two transfer controllers: DSS_TPTC2 (EDMA TPTC2) and DSS_TPTC3 (EDMA TPTC3)

NOTE: The 16xx device does not support the region interrupt feature of the EDMA peripheral. Only the global interrupt feature of the EDMA module is supported.

Table 2-12. DSS_TPCC Configuration

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of MSS_DMA channels	64	64
Number of PaRAM entires	128	256
Number of QDMA channels	8	8

Table 2-12. DSS_TPCC Configuration (continued)

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of event queues	2	2
Memory protection existence	No	No
Channel mapping	No	No
Number of TCs (transfer controllers)	2	2

Table 2-13. DSS_TPTC Configuration

	DSS_TPTC[0-1]	DSS_TPTC[2-3]
FIFO size	512 bytes	128 bytes
TR pipe depth	2	2
Bus width	16 bytes	16 bytes

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 3-13 and Figure 3-14 show the EDMA controller integration.

2.3.14 Error Signaling Module (MSS_ESM/DSS_ESM)

The 16xx device has two instances of the Error Signaling Module (MSS_ESM/DSS_ESM), shown in Figure 3-15.

Figure 2-16. 16xx MSS_ESM/DSS_ESM Integration Diagram

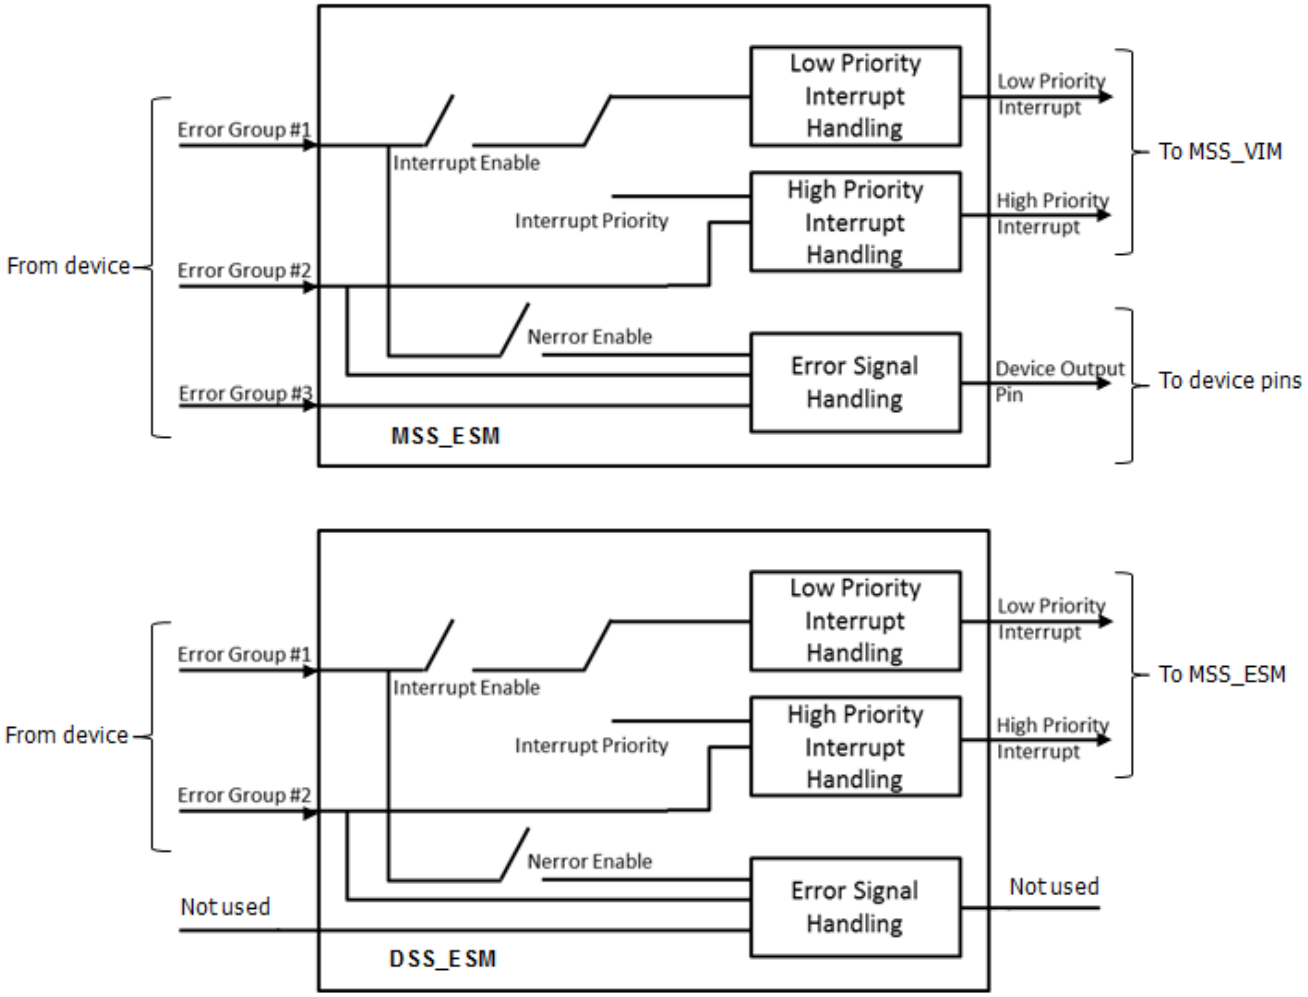

Table 3-15 shows the mapping on the input error inputs to the ESM module from various error sources available for hardware diagnostics within the device.

Table 2-15. MSS_ESM Mapping

MSS_ESM Group 1		Channel Type	Description
63	ANA_LIMP_MODE	Error Signal	Error signal at device boot-up, if the CLK monitor finds the REF CLK to be outside the permissible range of frequency
62	MSS_DCCB_ERR	Error Signal	MSS_DCCB frequency comparison error
61	MAILBOX_BSS2MSS_FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_BSS2MSS
60	MAILBOX_BSS2MSS _REPAIR_ERR	Alert Signal	Single-bit error/repair indication from MAILBOX_BSS2MSS
59	MAILBOX_MSS2BSS _FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_MSS2BSS
58	MAILBOX_MSS2BSS _REPAIR_ERR	Alert Signal	Single-bit error/repair indication from MAILBOX_MSS2BSS
57	BSS_CRITICAL_ERR	Error Signal	BSS critical Error Indication. Mask control to be configured in IRQ_CTL for individual error signals.
56	Reserved	Reserved	Reserved

Table 2-15. MSS_ESM Mapping (continued)

MSS_ESM Group 1		Channel Type	Description

2.3.15 High-Speed Interface (HSI)

Table 3-17 lists the high-speed interfaces available for the 16xx device.

Table 2-17. 16xx High-Speed Interfaces

CSI2	N/A
LVDS	2 lanes

2.3.16 Handshake RAM (DSS_HSRAM1)

The 16xx device has 32KB memory for HSRAM in the DSP subsystem.

2.4 18xx Introduction

2.4.1 18xx Overview

The 18xx is highly integrated single-chip RADAR device in TI's 45-nm low-power RFCMOS technology, a FCBGA 0.65-mm pitch automotive-grade package.

2.4.1.1 Features

- Frequency-Modulated Continuous Wave Radio Frequency Transceiver With 76-81-GHz Band
- Supports Three Transmitter Chains and Four Receiver Chains
- Chirp Profiles With Programmable Period and Slope
- 40-MHz, 50-MHz, 80-MHz, and 100-MHz XTAL/OSC Reference Input Clock
- 12, 14, and 16-bit Real/Complex ADC With Variable Baseband ADC Sampling Rates up to 18.75 MHz at 12-bits Complex
- Cortex R4F at 200-MHz Application Processor for Control Functionality and Safety-Critical Algorithms
- C674x DSP at up to 600 MHz for RADAR Data Processing
- Cortex R4F– Radio Processor at 200 MHz for Continuous Monitoring and Calibration of Analog/RF Functionality
- On-Chip Multicore Debug Support
- Customer-Programmable Efuse Support
- Up to 1024KB of L3 Shared Memory Support
- High-Performance Data Transfer With Multiple DMA and EDMA-TPCC Engines
- CAN Support for ECU Interface
- QSPI Serial Flash Support
- MIBSPI, SPI, I2C, and UART Serial Interfaces Support
- Hardware in Loop (HIL) Support
- Two-Lane Serial LVDS Interface Support
- AES, SHA, PKA, and TRNG Engines for Security

- 3 EPWM (Three Enhanced Pulse Width Modulator)
- Hardware Accelerator for FFT, Filtering, and CFAR Processing

2.4.2 18xx Description

2.4.2.1 Block Diagram

Figure 2-17 shows the block diagram of the 18xx device.

Figure 2-17. 18xx Block Diagram

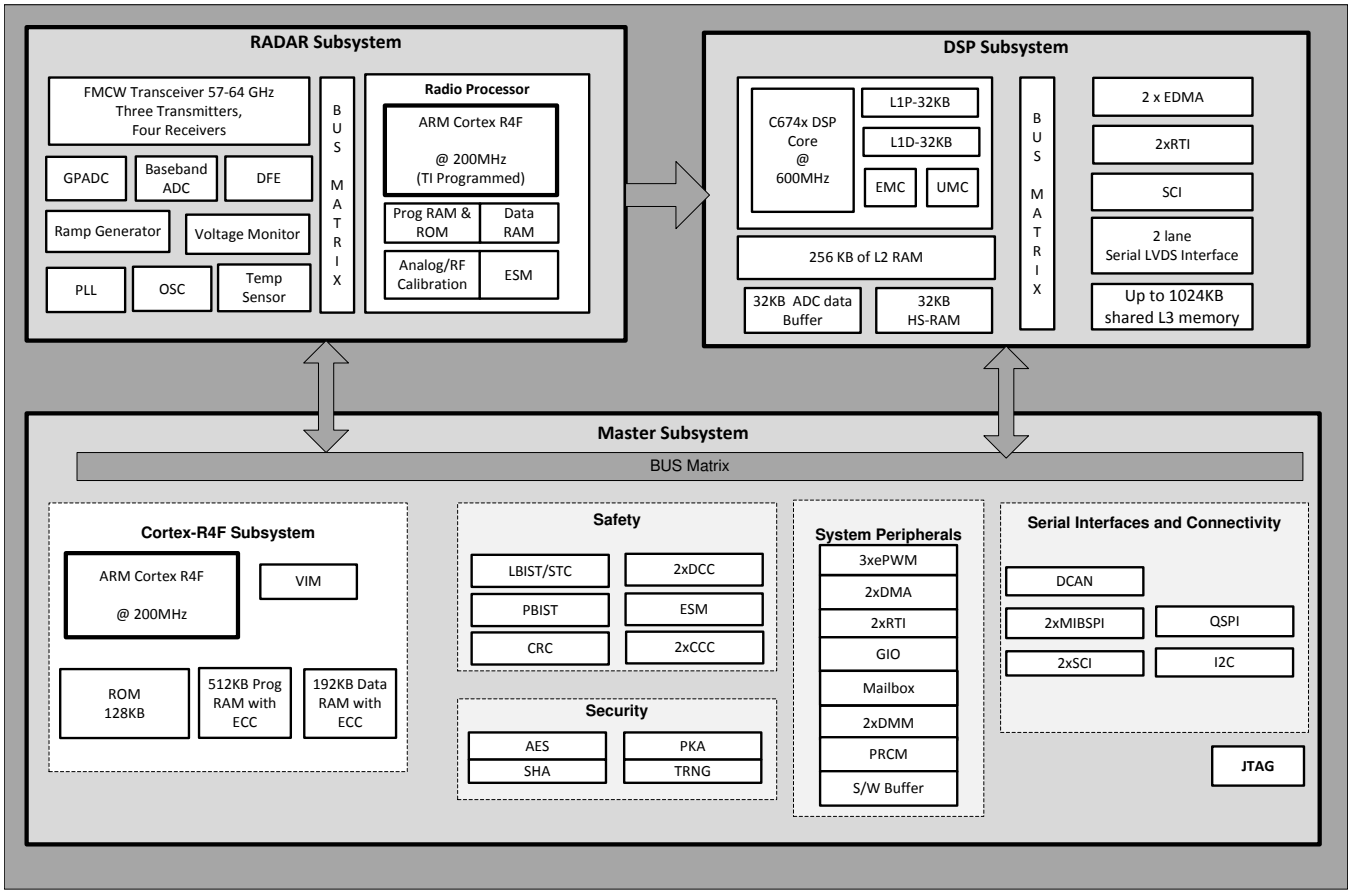

Table 2-18. 18xx Acronyms

ADC	Analog-to-Digital Convertor
AES	Advanced Encryption Standard
CRC	Cyclic Redundancy Check
MCAN	Controller Area Network
DCC	Digital Clock Comparator
DFE	Digital Front End
DMA	Direct Memory Access
DMM	Data Modification Module
ECC	Error Correcting Code
EDMA	Enhanced Direct Memory Access
EMC	Extended Memory Controller
ePWM	Enhanced Pulse Width Modulator
ESM	Error Signaling Module

Table 2-18. 18xx Acronyms (continued)

GIO	General Input/Output
GPADC	General Purpose Analog-to-Digital Convertor
HS-RAM	Handshake RAM
I2C	Inter-Integrated Circuit
JTAG	Joint Test Action Group
L1D	Level 1 Data Memory Controller
L1P	Level 1 Program Memory Controller
L2	Level 2
L3	Level 3
LBIST	Logic Built-In Self-Test
LVDS	Low Voltage Differential Signaling
MIBSPI	Multi-Buffered Serial Peripheral Interface Module
OSC	Oscillator
PBIST	Programmable Built-In Self-Test
PKA	Public Key Algorithm
PLL	Phase Locked Loops
PRCM	Power, Reset, Clock Management
QSPI	Quad Serial Peripheral Interface
RTI	Real Time Interrupt
S/W Buffer	Software Buffer
SCI	Serial Communication Interface
SHA	Secure Hash Algorithm
STC	Self-Test Controller
TRNG	True Random Number Generator
UMC	Unified Memory Controller
VIM	Vectored Interrupt Manager

2.4.2.2 Radar Subsystem

The RADAR subsystem is responsible for the RF and analog functionality of the device. The subsystem incorporates a built-in self-test processor for the continuous motoring and calibration of the analog and RF modules. The subsystem consists of:

- FMCW transceiver
  - Integrated PLL, transmitter, receiver, baseband, and A2D
  - 76-81-GHz coverage with 4-GHz available bandwidth
  - Four receive channels
  - Three transmit channels
  - Ultra-accurate chirp engine based on fractional-n PLL
  - 12,14, or 16-bit complex analog to digital converter
- Radio processor for built-in calibration and self-test
  - ARM Cortex R4F-based radio control system
  - Built-in firmware (ROM)
  - Self-calibrating system across frequency and temperature

This subsystem is TI-programmed with an API interface to the on-chip Cortex-R4F application processor.

2.4.2.3 DSP Subsystem

The DSP subsystem consists of the following:

- The TMS320C674x™ VLIW DSP core from the generation, and the TMS320C64x+™ DSP architecture for RADAR data processing. These are enhancements from TI's C64x+™ DSP architecture, with additional features.
- 32KB L1D and 32KB of L1P cache/RAM
- 256KB of L2 RAM
- On-chip L3 shared memory of 1024KB, with 512KB dedicated to DSP and 512 KB of memory shared between the DSP and master subsystems.
- 32KB of memory for storing ADC samples from the RADAR subsystem
- Multiple Enhanced Direct Memory Access (EDMA) engines – TPCCs for high-performance data transfers
- 2-lane LVDS interface with support of up to 900 Mbps per lane for the RADAR raw ADC data transfer
- One watchdog timer and a general purpose timer implemented by the real time interrupt (RTI) modules
- One serial communication Interface (SCI) module implementing standard universal asynchronous receiver-transmitter (UART).
- Emulation capabilities
- Little Endian

2.4.2.4 Master Subsystem

The master subsystem consists of the following features:

- Cortex-R4F core supporting ARMv7-R, VFPv3-D16, and ARMv7 debug architecture
- Tightly-coupled memories
  - 128 KB of ROM
  - 512KB of program RAM with ECC
  - 192KB of data RAM with ECC
- Hardware auto-initialization of the memories
- Vectored interrupt manager for prioritizing and controlling the interrupts for different sources

2.4.2.4.1 Serial Interfaces

- One MCAN controller supporting bit rates of up to 10 Mbit/s. compliant to the controller area network (CAN) 2.0 part A, B protocol specification and ISO 11898-1, and CAN FD® V1.0 specification with up to 64 data bytes support.
- One I2C controller module with rates up to 400 kbps
- Two MIBSPI modules
- Two serial communication interface (SCI) modules implementing standard universal asynchronous receiver-transmitter (UART) with baud rates of up to 3.125 Mbps
- One quad SPI module support with maximum rate of 40 MHz

2.4.2.4.2 System Peripherals

- Multiple general-purpose input/output (GPIO) modules
- Direct memory access modules for high-performance data transfers
- One watchdog timer and a general purpose timer implemented by the real-time interrupt (RTI) modules
- Mailbox module for interprocessor communication
- Two data modification modules (DMM) with up to 65 Mbit/s data rate per pin
- Three enhanced pulse width (ePWM) modulator modules
- System reset and control module, which contains registers for the following functions:
  - Status
  - Efuse logic
  - I/O configuration

- PAD configuration
- System boot decoding logic

2.4.2.5 Functional Safety Deliverables

See the Device Safety Manual for supported features.

2.4.2.6 On-Chip Debug Support

The on-chip debug support has the following features:

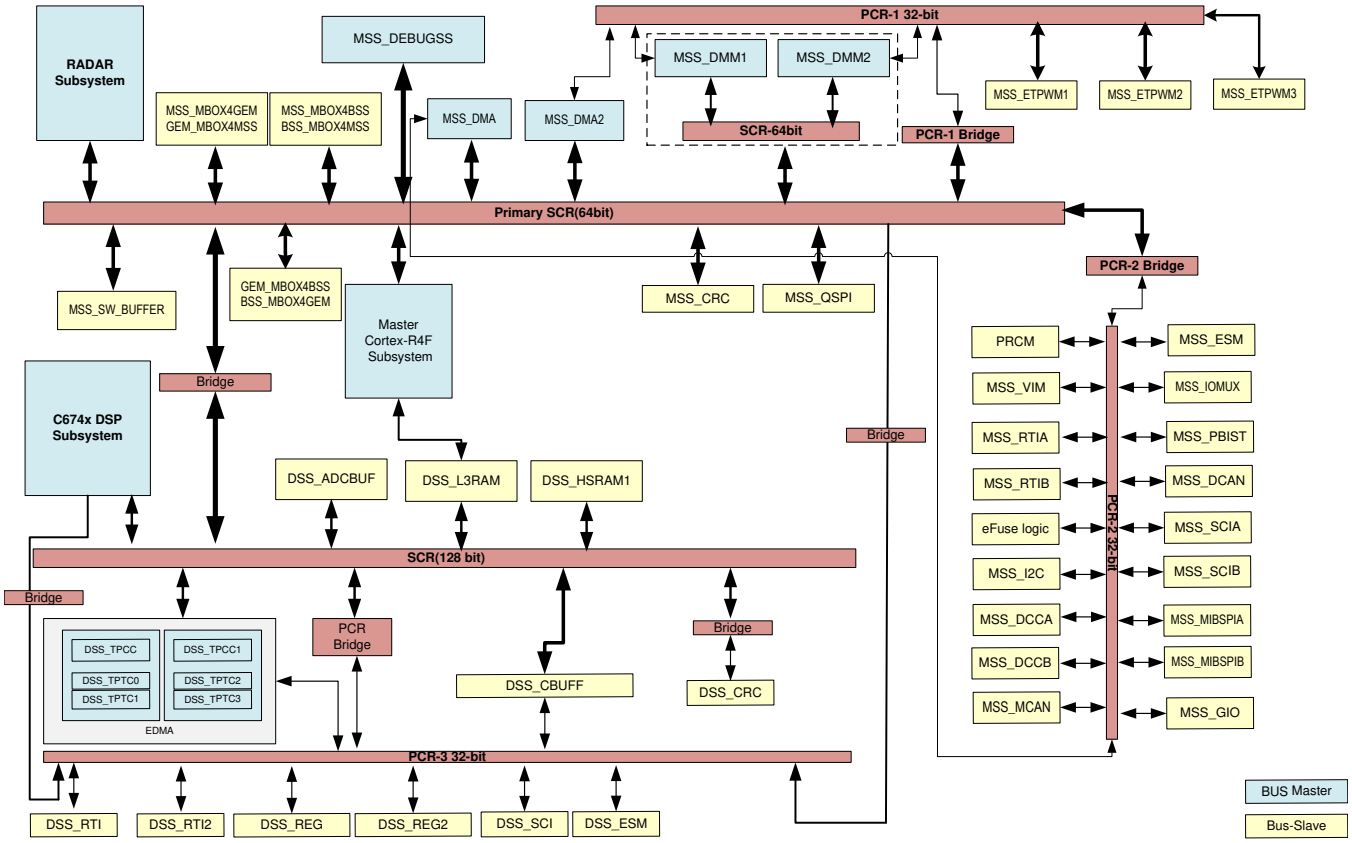
- Multiprocessor debugging to let users control multiple cores embedded in the device, such as:
  - Global starting and stopping of individual or multiple processors
  - Each processor can generate triggers to alter the execution flow of other processors
  - Interconnection of multiple devices
  - Channel triggering
- The following device cores can be debugged through Code Composer Studio (CCS):
  - Cortex-R4F
  - DSP
- Target debugging using IEEE1149.1 (JTAG®) port
- The debug subsystem includes:
  - IEEE1149.7 adapter
  - Generic TAP for emulation and test control (ICEPick-D™)
  - Debug access port (DAP)
  - Embedded trace macro (ETM)
  - Trace port interface Unit (TPIU)
  - Embedded trace buffer (ETB)

2.5 18xx Memory Map

2.5.1 System Interconnect

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols. Figure 2-18 shows the interconnect diagram.

Figure 2-18. System Interconnect



The system interconnect is designed for the high-performance needs of the system. Its divided into three interconnect systems local to each of the three subsystems: the RADAR subsystem, DSP subsystem, and master subsystem. The interconnection of all these subsystems is shown in Figure 3-2.

In the master subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple masters to each of the slaves. The arbitration priority is always round-robin.

The master subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth. The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

Similarly, the 128-bit VBUSM SCR in the DSP subsystem manages the arbitration between accesses from the multiple masters to the slaves. The DSP subsystem has a 32-bit VBUSP PCR for the system and non-system peripherals.

2.5.2 Master Subsystem Cortex-R4F Memory Map

Table 3-2 shows the master subsystem, Cortex-R4F memory map.

Table 2-19. Master Subsystem, Cortex-R4F Memory Map

2.5.2.1 Radar Subsystem Interface

The RADAR subsystem is accessible through a set of TI-implemented high-level API calls by the application running on the master CR4F. For more information on the 18xx RADAR subsystem interface, see the 18xx Interface control document.

2.5.3 DSP Subsystem Memory Map

Table 3-3 shows the DSP C674x memory map.

Table 2-20. DSP C674x Memory Map

2.6 18xx Integration

2.6.1 Cortex-R4F Subsystem

2.6.1.1 Tightly Coupled Memories

Table 3-5 lists the dedicated MSS_TCMA_RAM and MSS_TCMB sizes for the Cortex R4F processor in the master subsystem, and also mentions the total available L3 shared RAM in the device. A portion of this L3 shared memory (DSS_L3RAM) can be allotted as TCM, to further increase the MSS_TCMA_RAM and MSS_TCMB available for the Cortex R4F.

Table 2-22. TCM and Shared Memory Available for Cortex R4F in Master Subsystem

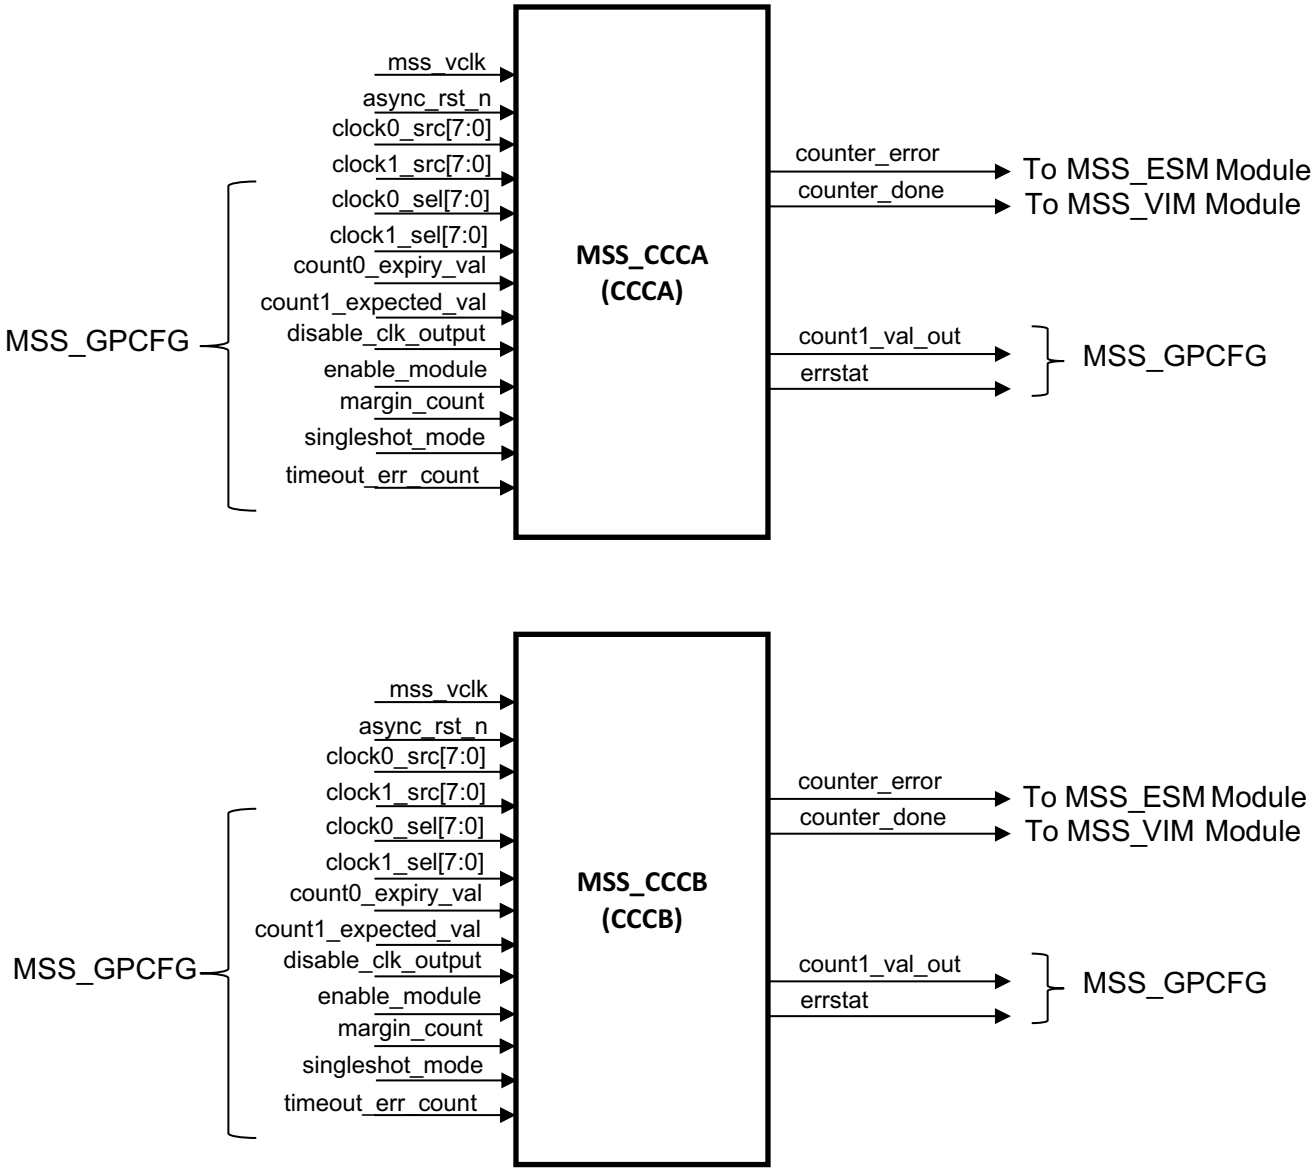
Cortex R4F		Shared
MSS_TCMA_RAM (Program RAM) (KB)	MSS_TCMB (Data RAM) (KB)	L3 Shared (KB)
512	192	1024

See on how the L3 shared memory (DSS_L3RAM) can be assigned between the Cortex R4F of the master subsystem and the DSP core.

2.6.2 Clock Comparator

2.6.2.1 Core Clock Comparator (MSS_CCCA/MSS_CCCB)

Figure 2-19. Integration of MSS_CCCA and MSS_CCCB Modules



2.6.2.1.1 MSS_CCCA and MSS_CCCB Integration Connections

This device has two instances of CCC: MSS_CCCA (CCCA) and MSS_CCCB (CCCB). The clock connectivity information for these two instances is provided in Table 3-6. Configuration and status of this module is available through the MSS_GPCFG registers of the device.

Table 2-23. MSS_CCCA and MSS_CCCB Integration Connections

	MSS_CCCA (CCCA)	MSS_CCCB (CCCB)
counter_error	ESM_GRP1[1]	ESM_GRP1[4]
counter_done	IRQ[80]	IRQ[81]

Table 2-23. MSS_CCCA and MSS_CCCB Integration Connections (continued)

	MSS_CCCA (CCCA)	MSS_CCCB (CCCB)
clock0_src[0]	REFCLK	CR4_VCLK
clock0_src[1]	CPUCLK	DSSCLK

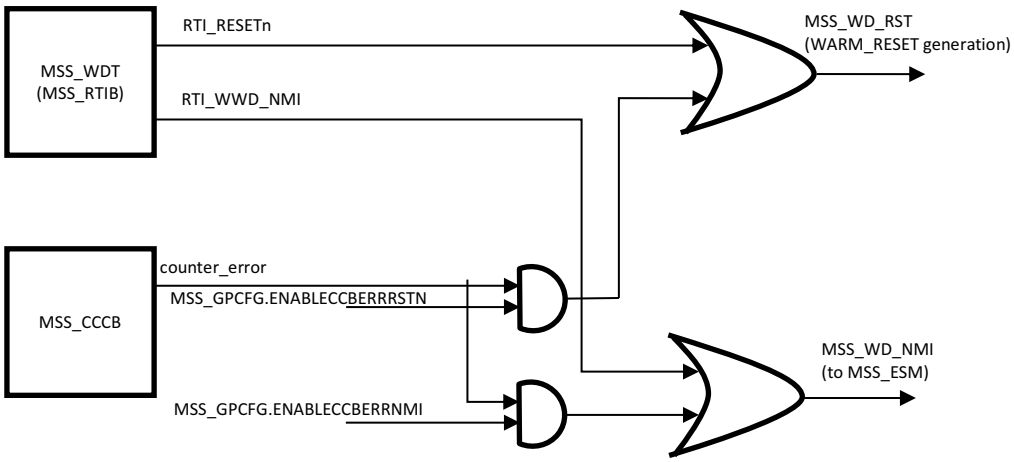
clock1_src[2]	PLL 240Mhz	CPUCLK
clock1_src[3]	RCCLK	CR4_VCLK
clock1_src[4]	RCCLK	MSS_VCLK
clock1_src[5]	RCCLK	DSSCLK
clock1_src[6]	RCCLK	BSSCLK
clock1_src[7]	RCCLK	QSPICLK

2.6.2.1.2 MSS_CCCB Integration to MSS_WD

As a safety requirement, WDT IP should work on an independent clock source instead of the clock used by the MSS CR4. Because the WDT IP does not allow this flexibility, an additional monitoring logic is added in the form of CCM (MSS_CCCB instance), coupled along with the watchdog. MSS_CCCB is used to compare CR4_VCLK to an independent reference clock, such as XTAL. If the CR4 clock indicates a deviation from the expected frequency, a WD reset or a WD NMI can be issued.

Figure 2-20. MSS_CCCB Integration to MSS_WD



2.6.2.2 Dual Clock Comparator (MSS_DCCA/MSS_DCCB)

Figure 2-21. MSS_DCCA/MSS_DCCB Integration Diagram

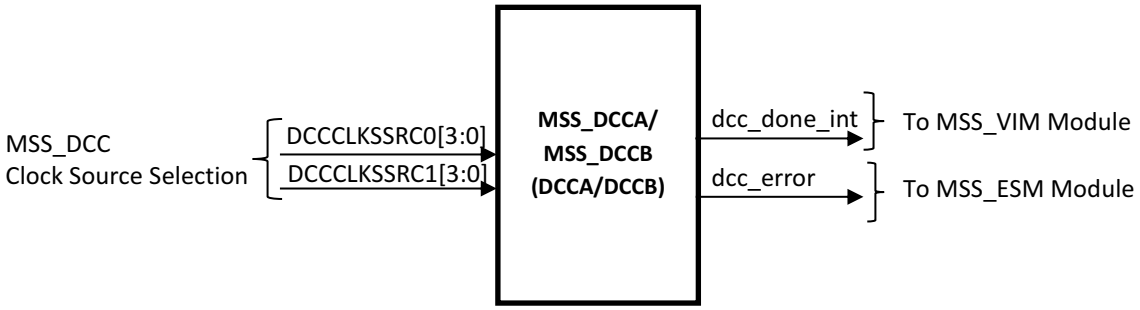


Table 2-24. MSS_DCCA Clock Source Selection Table

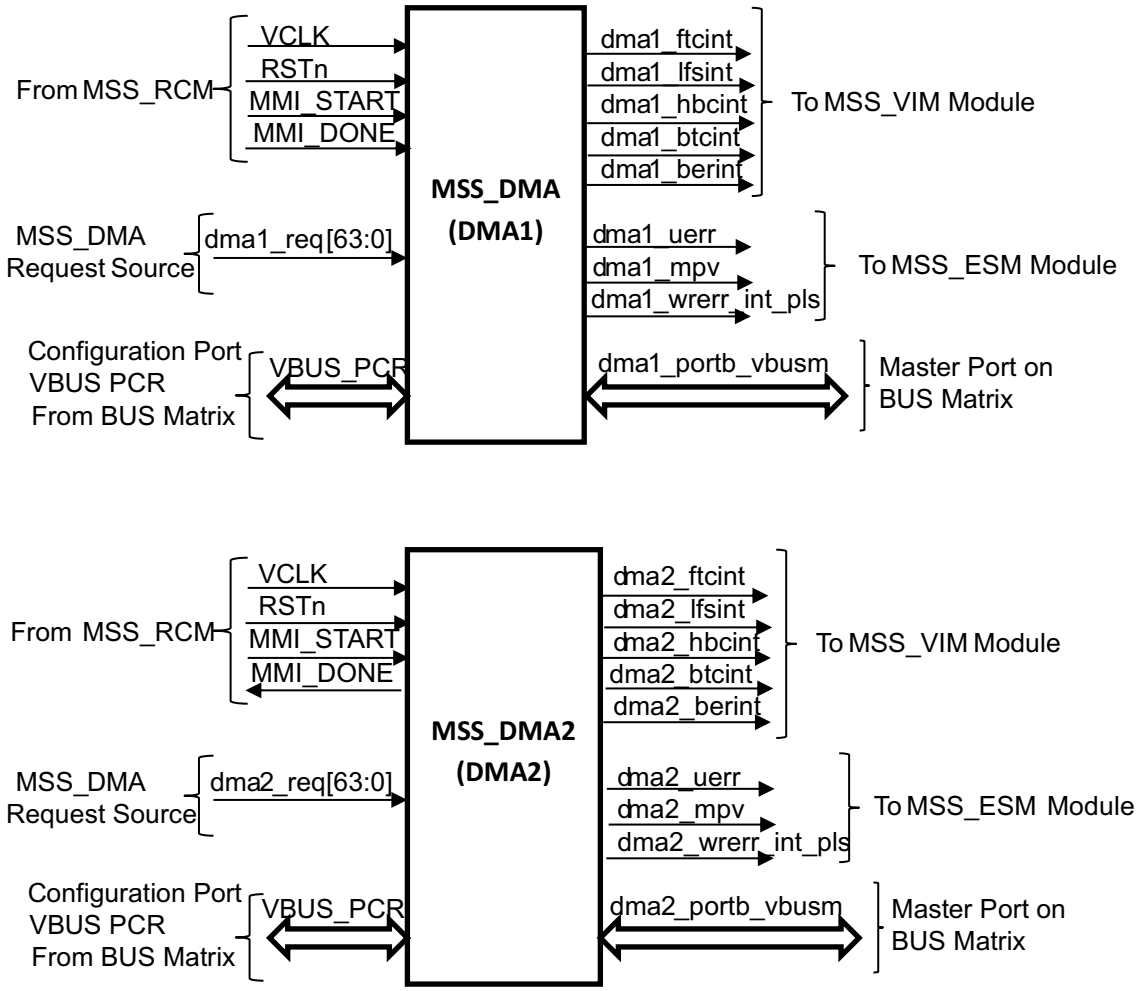
2.6.4 Direct Memory Access Controller (MSS_DMA)

2.6.4.1 MSS_DMA Integration Diagrams

The device has two instances of DMA module, MSS_DMA and MSS_DMA2. Integration of the two DMA blocks in the device are shown in Figure 3-5 and .

Figure 2-22. Integration of MSS_DMA and MSS_DMA2 Module



2.6.4.2 MSS_DMA Features

- 64-bit OCP protocol to perform bus master accesses
- INCR-4 64-bit burst accesses
- Multithreading architecture allowing data of two different channel transfers to be interleaved during non-burst accesses
- 2-port configuration for parallel bus master
- Channels can be assigned to either high-priority queue or low-priority queue. Within each queue, fixed or round-robin priorities can be serviced
- Built-in ECC generation and evaluation logic for internal RAM-storing channel transfer information
- Supports multiple interrupt outputs for mapping to multiple interrupt controllers in multicore systems
- 48 requests can be mapped to any 32 channels
- Supports LE endianness
- External ECC Gen/Eval block of MSS_DMA support ECC generation for data transactions, and parity for address, and control signals (following Cortex-R5F standard)
- 8 MPU regions
- Channel-chaining capability
- Hardware and software MSS_DMA requests

- 8-, 16-, 32-, or 64-bit transactions supported
- Multiple addressing modes for source and destination (fixed, increment, offset)
- Auto-initiation

2.6.4.3 MSS_DMA Request Map

Both instances of MSS_DMA have 64 lines of request and are connected to identical input triggers, as shown in Table 3-10. This allows the two DMAs to trigger different types of transfers for the same request.

Table 2-27. MSS_DMA Request Map

Figure 2-28. MSS_MIBSPIA Integration

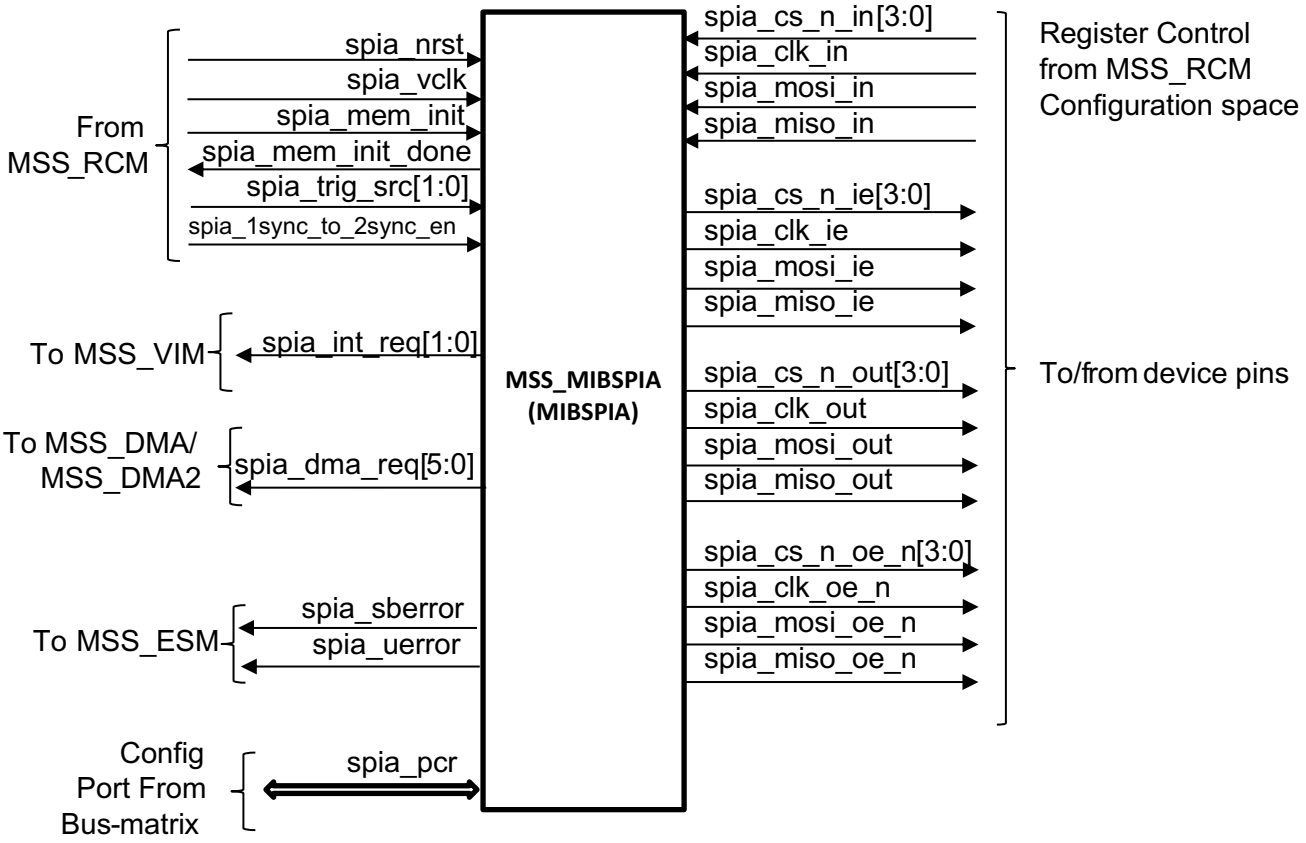

Figure 2-29. MSS_MIBSPIB Integration

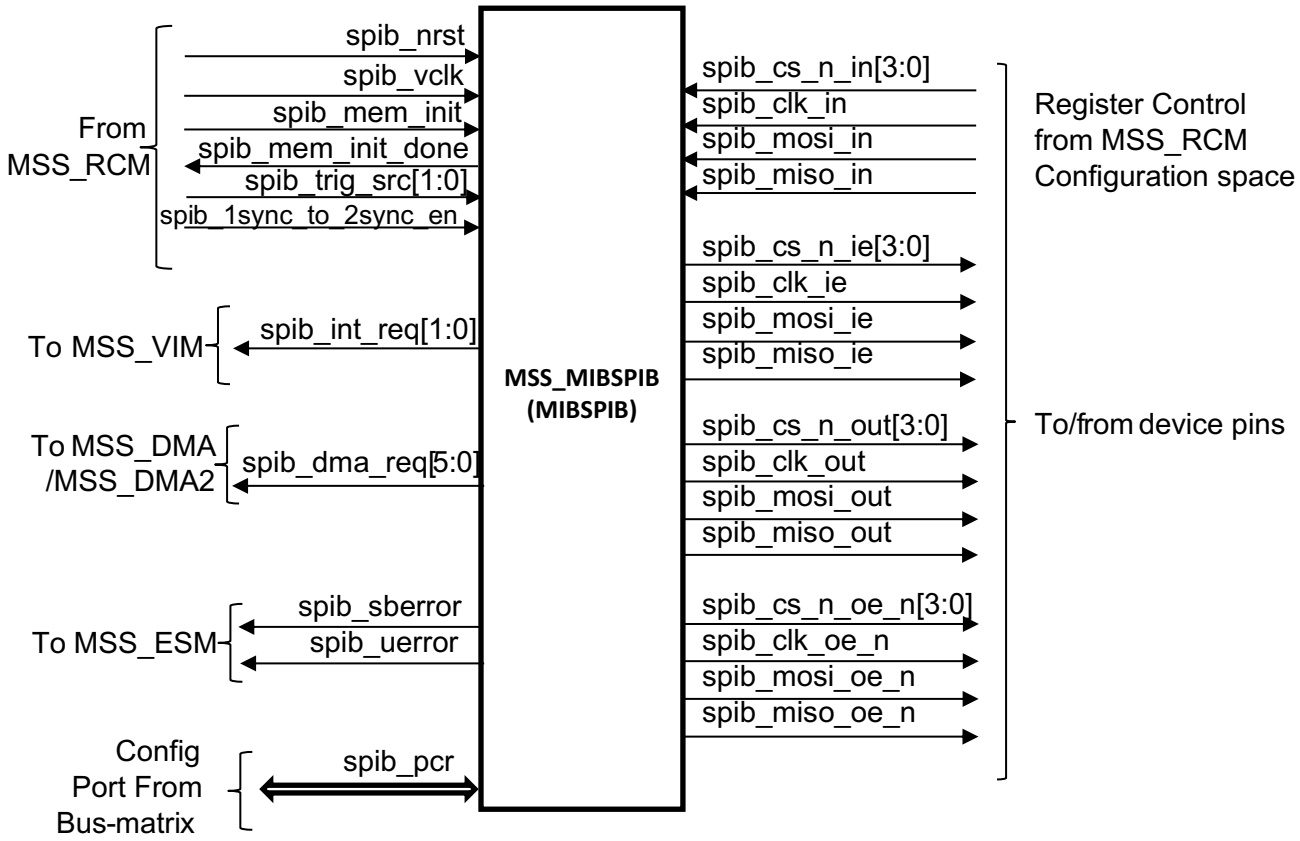

2.6.12 Quad Serial Peripheral Interface (MSS_QSPI)

The MSS_QSPI module of the 18xx only supports one CS pin, (qspi1_cs).

2.6.13 Enhanced Direct Memory Access (EDMA)

2.6.13.1 EDMA Controller Integration

The 18xx device has two EDMA channel controllers (DSS_TPCC0 and DSS_TPCC1) on the device:

- DSS_TPCC0 (EDMA TPCC0) has two transfer controllers: DSS_TPTC0 (EDMA TPTC0) and DSS_TPTC1 (EDMA TPTC1)
- DSS_TPCC1 (EDMA TPCC1) has two transfer controllers: DSS_TPTC2 (EDMA TPTC2) and DSS_TPTC3 (EDMA TPTC3)

NOTE: The 18xx device does not support the region interrupt feature of the EDMA peripheral. Only the global interrupt feature of the EDMA module is supported.

Table 2-29. DSS_TPCC Configuration

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of MSS_DMA channels	64	64
Number of PaRAM entires	128	256
Number of QDMA channels	8	8

Table 2-29. DSS_TPCC Configuration (continued)

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of event queues	2	2
Memory protection existence	No	No
Channel mapping	No	No
Number of TCs (transfer controllers)	2	2

Table 2-30. DSS_TPTC Configuration

	DSS_TPTC[0-1]	DSS_TPTC[2-3]
FIFO size	512 bytes	128 bytes
TR pipe depth	2	2
Bus width	16 bytes	16 bytes

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 3-13 and Figure 3-14 show the EDMA controller integration.

2.6.14 Error Signaling Module (MSS_ESM/DSS_ESM)

The 18xx device has two instances of the Error Signaling Module (MSS_ESM/DSS_ESM), shown in Figure 3-15.

Figure 2-32. 18xx MSS_ESM/DSS_ESM Integration Diagram

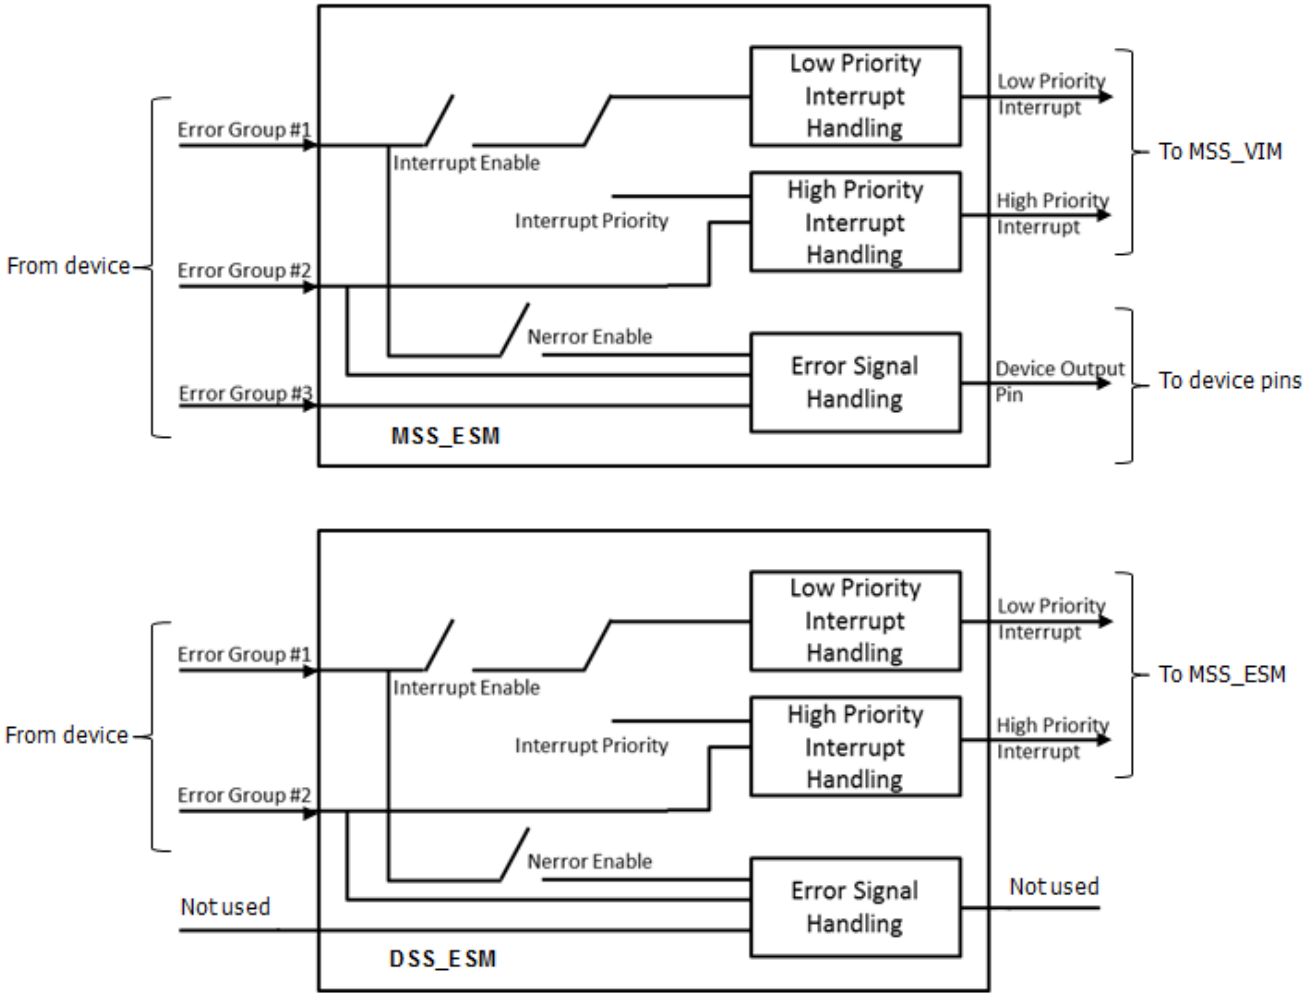

Table 3-15 shows the mapping on the input error inputs to the ESM module from various error sources available for hardware diagnostics within the device.

Table 2-32. MSS_ESM Mapping

MSS_ESM Group 1		Channel Type	Description
63	ANA_LIMP_MODE	Error Signal	Error signal at device boot-up, if the CLK monitor finds the REF CLK to be outside the permissible range of frequency
62	MSS_DCCB_ERR	Error Signal	MSS_DCCB frequency comparison error
61	MAILBOX_BSS2MSS_FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_BSS2MSS

3.1 68xx/64xx Introduction

3.1.1 Overview

This device is highly integrated single-chip RADAR device in TI's 45-nm low-power RFCMOS technology.

3.1.1.1 Features

- Frequency-Modulated Continuous Wave Radio Frequency Transceiver With 60-64-GHz Band
- Supports Three Transmitter Chains and Four Receiver Chains
- Chirp Profiles With Programmable Period and Slope
- 40-MHz, 50-MHz, 80-MHz, and 100-MHz XTAL/OSC Reference Input Clock
- 12, 14, and 16-bit Real/Complex ADC With Variable Baseband ADC Sampling Rates up to 12.5 MHz at 12-bits Complex
- Cortex R4F at 200-MHz Application Processor for Control Functionality and Safety-Critical Algorithms
- 68xx only: C674x DSP at up to 600 MHz for RADAR Data Processing
- Cortex R4F– Radio Processor at 200 MHz for Continuous Monitoring and Calibration of Analog/RF Functionality
- On-Chip Multicore Debug Support
- Customer-Programmable Efuse Support
- Up to 768KB of L3 Shared Memory Support
- High-Performance Data Transfer With Multiple DMA and EDMA-TPCC Engines
- CAN-FD Support
- QSPI Serial Flash Support
- MIBSPI, SPI, I2C, and UART Serial Interfaces Support
- Hardware in Loop (HIL) Support
- Two-Lane Serial LVDS Interface Support
- AES, SHA, PKA, and TRNG Engines for Security
- 3 EPWM (Three Enhanced Pulse Width Modulator)
- Hardware Accelerator for FFT, Filtering, and CFAR Processing

3.1.2 Description

3.1.2.1 Block Diagram

Figure 3-1 shows the block diagram of the device.

Figure 3-1. 68xx Block Diagram

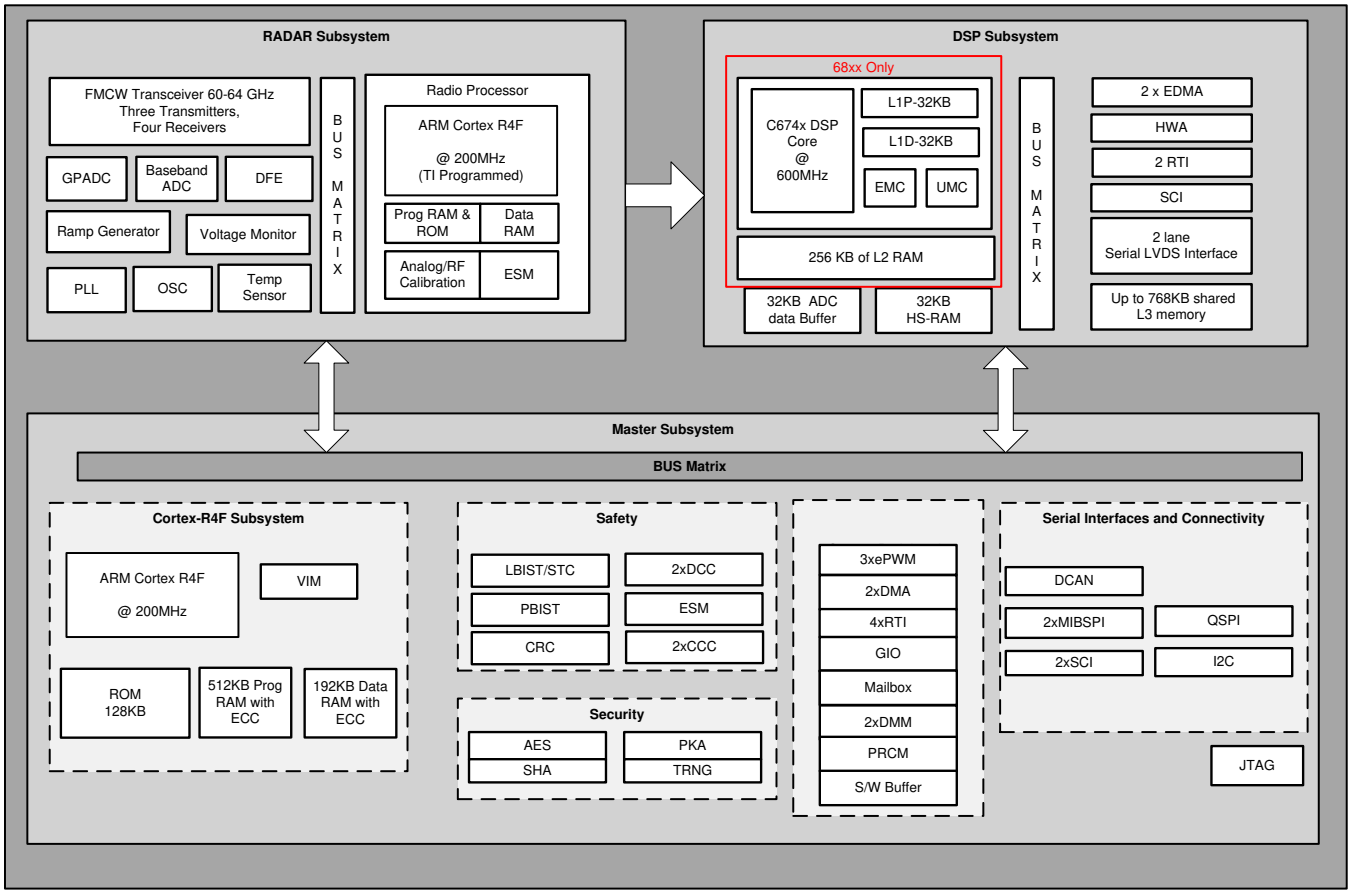

Table 3-1. Acronyms

ADC	Analog-to-Digital Convertor
AES	Advanced Encryption Standard
CRC	Cyclic Redundancy Check
DCAN	Controller Area Network
DCC	Digital Clock Comparator
DFE	Digital Front End
DMA	Direct Memory Access
DMM	Data Modification Module
ECC	Error Correcting Code
EDMA	Enhanced Direct Memory Access
EMC	Extended Memory Controller
ePWM	Enhanced Pulse Width Modulator
ESM	Error Signaling Module
GIO	General Input/Output
GPADC	General Purpose Analog-to-Digital Convertor
HS-RAM	Handshake RAM
HWA	Hardware Accelerator
I2C	Inter-Integrated Circuit
JTAG	Joint Test Action Group
L1D	Level 1 Data Memory Controller

Table 3-1. Acronyms (continued)

L1P	Level 1 Program Memory Controller
L2	Level 2
L3	Level 3
LBIST	Logic Built-In Self-Test
LVDS	Low Voltage Differential Signaling
MIBSPI	Multi-Buffered Serial Peripheral Interface Module
OSC	Oscillator
PBIST	Programmable Built-In Self-Test
PKA	Public Key Algorithm
PLL	Phase Locked Loops
PRCM	Power, Reset, Clock Management
QSPI	Quad Serial Peripheral Interface
RTI	Real Time Interrupt
S/W Buffer	Software Buffer
SCI	Serial Communication Interface
SHA	Secure Hash Algorithm
STC	Self-Test Controller
TRNG	True Random Number Generator
UMC	Unified Memory Controller
VIM	Vectored Interrupt Manager

3.1.2.2 Radar Subsystem

The RADAR subsystem is responsible for the RF and analog functionality of the device. The subsystem incorporates a built-in self-test processor for the continuous motoring and calibration of the analog and RF modules. The subsystem consists of:

- FMCW transceiver
  - Integrated PLL, transmitter, receiver, baseband, and A2D
  - 60-64-GHz coverage with 4-GHz available bandwidth
  - Four receive channels
  - Three transmit channels
  - Ultra-accurate chirp engine based on fractional-n PLL
  - 12,14, or 16-bit complex analog to digital converter
- Radio processor for built-in calibration and self-test
  - ARM Cortex R4F-based radio control system
  - Built-in firmware (ROM)
  - Self-calibrating system across frequency and temperature

This subsystem is TI-programmed with an API interface to the on-chip Cortex-R4F application processor.

3.1.2.3 DSP Subsystem (Applicable Devices Only)

The DSP subsystem consists of the following:

- The TMS320C674x™ VLIW DSP core from the generation, and the TMS320C64x+™ DSP architecture for RADAR data processing. These are enhancements from TI's C64x+™ DSP architecture, with additional features.
- 32KB L1D and 32KB of L1P cache/RAM
- 256KB of L2 RAM
- On-chip L3 shared memory of 768KB, with 256KB dedicated to DSP and 512 KB of memory shared

between the DSP and master subsystems.

- 32KB of memory for storing ADC samples from the RADAR subsystem
- Multiple Enhanced Direct Memory Access (EDMA) engines – TPCCs for high-performance data transfers
- 2-lane LVDS interface with support of up to 900 Mbps per lane for the RADAR raw ADC data transfer
- One watchdog timer and a general purpose timer implemented by the real time interrupt (RTI) modules
- One serial communication Interface (SCI) module implementing standard universal asynchronous receiver-transmitter (UART).
- Emulation capabilities
- Little Endian

3.1.2.4 Master Subsystem

The master subsystem consists of the following features:

- Cortex-R4F core supporting ARMv7-R, VFPv3-D16, and ARMv7 debug architecture
- Tightly-coupled memories
  - 128 KB of ROM
  - 512 KB of program RAM with ECC
  - 192KB of data RAM with ECC
- Hardware auto-initialization of the memories
- Vectored interrupt manager for prioritizing and controlling the interrupts for different sources

3.1.2.4.1 Serial Interfaces

- One MCAN controller supporting bit rates of up to 10 Mbit/s. Compliant to the controller area network (CAN) 2.0 part A, B protocol specification and ISO 11898-1, and CAN FD® V1.0 specification with up to 64 data bytes support.
- One I2C controller module with rates up to 400 kbps
- Two MIBSPI modules
- Two serial communication interface (SCI) modules implementing standard universal asynchronous receiver-transmitter (UART) with baud rates of up to 3.125 Mbps
- One quad SPI module support with maximum rate of 40 MHz

3.1.2.4.2 System Peripherals

- Multiple general-purpose input/output (GPIO) modules
- Direct memory access modules for high-performance data transfers
- One watchdog timer and a general purpose timer implemented by the real-time interrupt (RTI) modules
- Mailbox module for interprocessor communication
- Two data modification modules (DMM) with up to 65 Mbit/s data rate per pin
- Three enhanced pulse width (ePWM) modulator modules
- System reset and control module, which contains registers for the following functions:
  - Status
  - Efuse logic
  - I/O configuration
  - PAD configuration
  - System boot decoding logic

3.1.2.5 Functional Safety Deliverables

See the Device Safety Manual for supported features.

3.1.2.6 On-Chip Debug Support

The on-chip debug support has the following features:

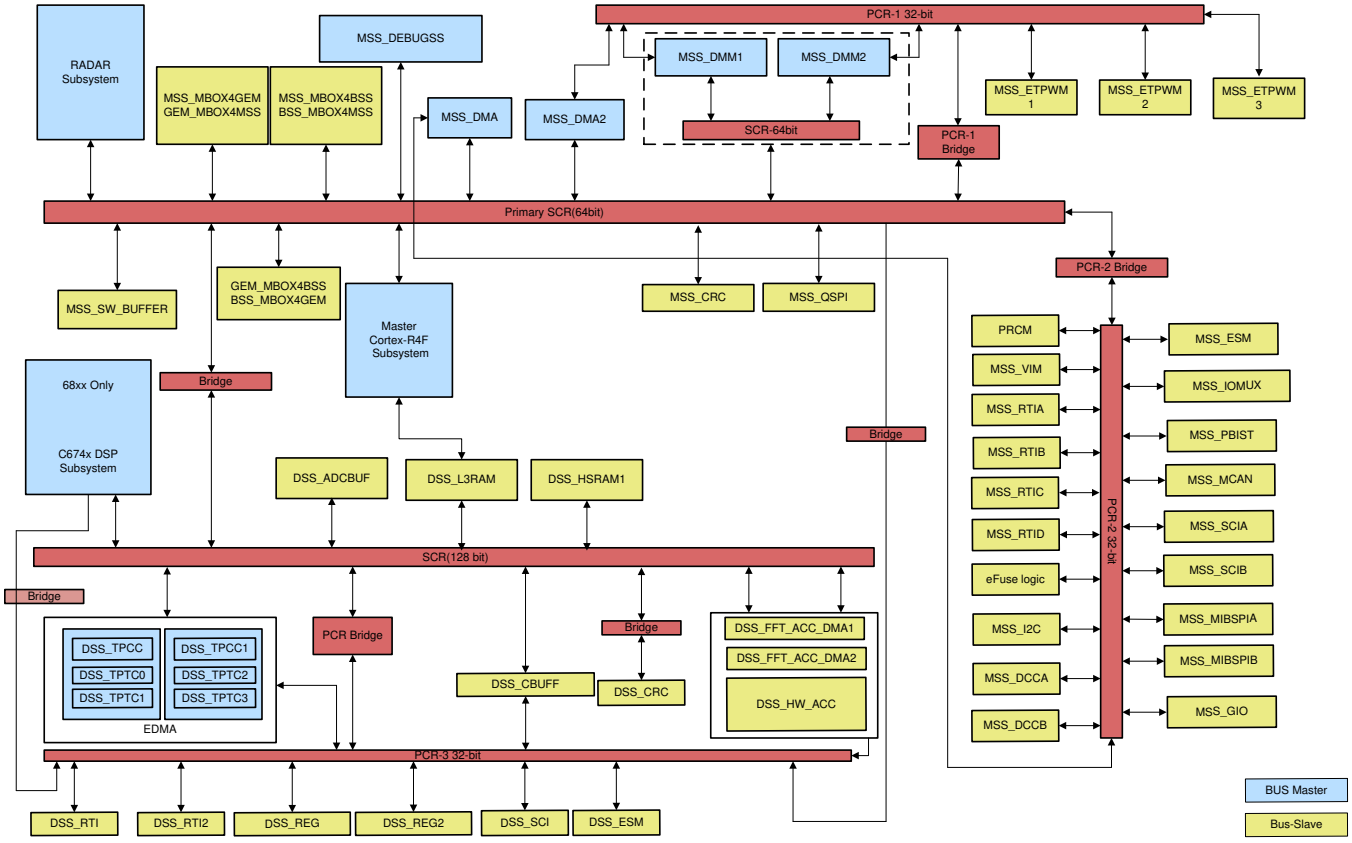
- Multiprocessor debugging to let users control multiple cores embedded in the device, such as:
  - Global starting and stopping of individual or multiple processors
  - Each processor can generate triggers to alter the execution flow of other processors
  - Interconnection of multiple devices
  - Channel triggering
- The following device cores can be debugged through Code Composer Studio (CCS):
  - Cortex-R4F
  - DSP
- Target debugging using IEEE1149.1 (JTAG®) port
- The debug subsystem includes:
  - IEEE1149.7 adapter
  - Generic TAP for emulation and test control (ICEPick-D™)
  - Debug access port (DAP)
  - Embedded trace macro (ETM)
  - Trace port interface Unit (TPIU)
  - Embedded trace buffer (ETB)

3.2 Memory Map

3.2.1 System Interconnect

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols. Figure 3-2 shows the interconnect diagram.

Figure 3-2. System Interconnect



The system interconnect is designed for the high-performance needs of the system. Its divided into three interconnect systems local to each of the three subsystems: the RADAR subsystem, DSP subsystem, and master subsystem. The interconnection of all these subsystems is shown in Figure 3-2.

In the master subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple masters to each of the slaves. The arbitration priority is always round-robin.

The master subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth. The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

Similarly, the 128-bit VBUSM SCR in the DSP subsystem manages the arbitration between accesses from the multiple masters to the slaves. The DSP subsystem has a 32-bit VBUSP PCR for the system and non-system peripherals.

3.2.2 Master Subsystem Cortex-R4F Memory Map

Table 3-2 shows the master subsystem, Cortex-R4F memory map.

3.2.2.1 Radar Subsystem Interface

The RADAR subsystem is accessible through a set of TI-implemented high-level API calls by the application running on the master CR4F. For more information on the 68xx RADAR subsystem interface, see the mmWave SDK user guide.

3.2.3 DSP Subsystem Memory Map (Applicable Devices Only)

Table 3-3 shows the DSP C674x memory map.

Table 3-3. DSP C674x Memory Map

3.3 68xx/64xx Integration

3.3.1 Cortex-R4F Subsystem

3.3.1.1 Tightly Coupled Memories

Table 3-5 lists the dedicated MSS_TCMA_RAM and MSS_TCMB sizes for the Cortex R4F processor in the master subsystem, and also mentions the total available L3 shared RAM in the device. A portion of this L3 shared memory (DSS_L3RAM) can be allotted as TCM, to further increase the MSS_TCMA_RAM and MSS_TCMB available for the Cortex R4F.

Table 3-5. TCM and Shared Memory Available for Cortex R4F in Master Subsystem

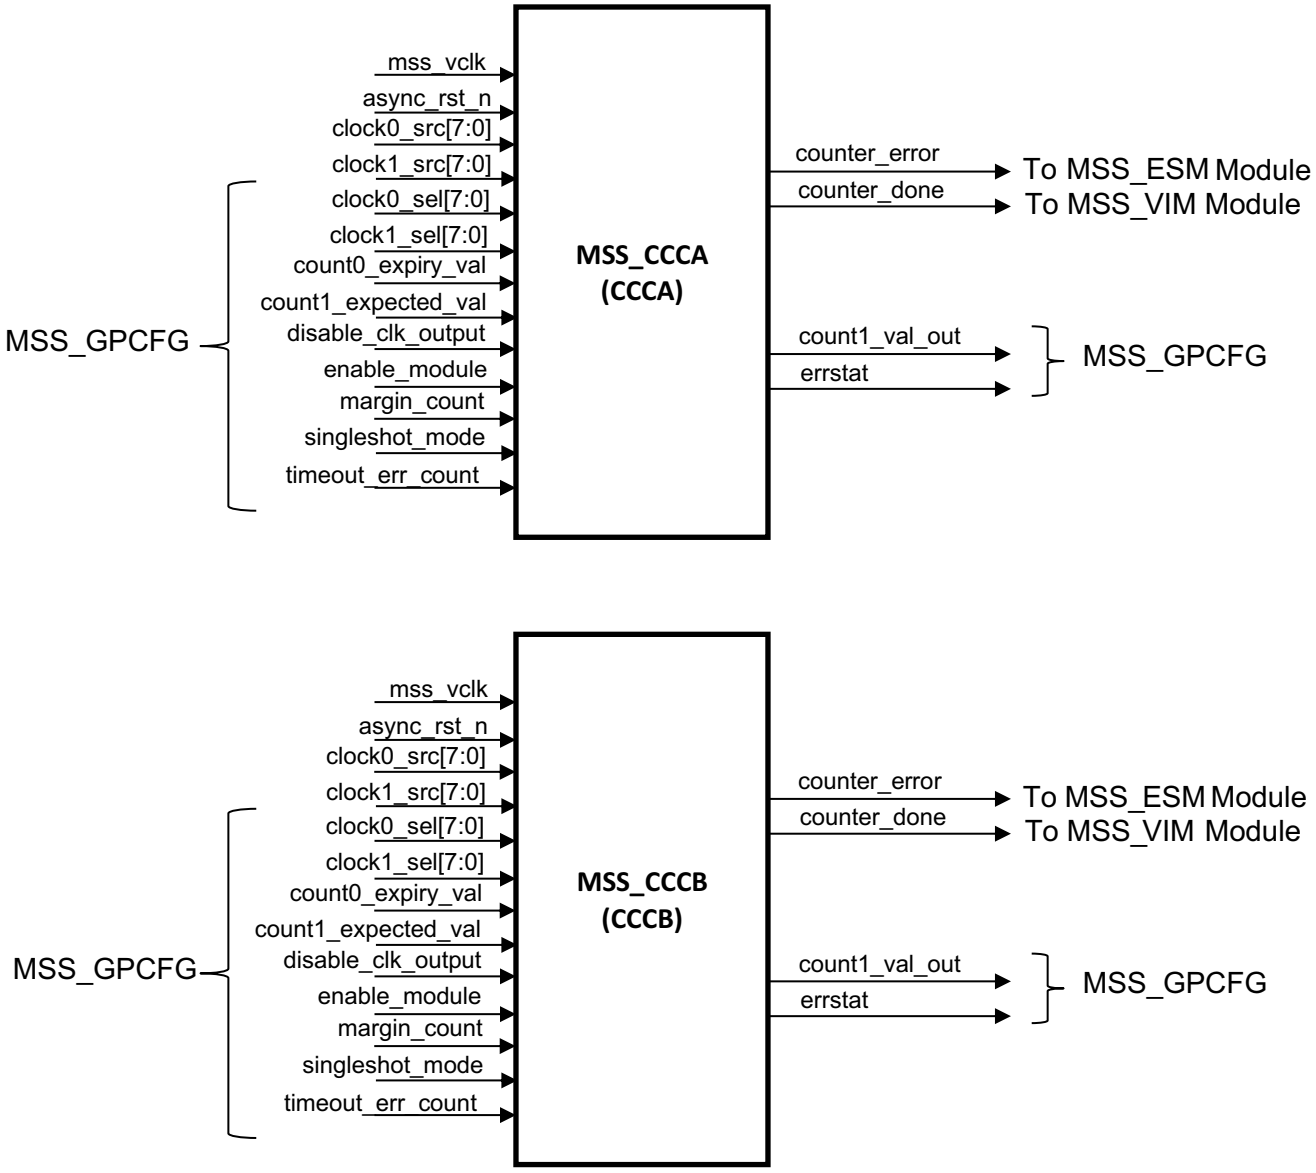
Cortex R4F		Shared
MSS_TCMA_RAM (Program RAM) (KB)	MSS_TCMB (Data RAM) (KB)	L3 Shared (KB)
512	192	768

See on how the L3 shared memory (DSS_L3RAM) can be assigned between the Cortex R4F of the master subsystem and the DSP core.

3.3.2 Clock Comparator

3.3.2.1 Core Clock Comparator (MSS_CCCA/MSS_CCCB)

Figure 3-3. Integration of MSS_CCCA and MSS_CCCB Modules



3.3.2.1.1 MSS_CCCA and MSS_CCCB Integration Connections

This device has two instances of CCC: MSS_CCCA (CCCA) and MSS_CCCB (CCCB). The clock connectivity information for these two instances is provided in Table 3-6. Configuration and status of this module is available through the MSS_GPCFG registers of the device.

Table 3-6. MSS_CCCA and MSS_CCCB Integration Connections

	MSS_CCCA (CCCA)	MSS_CCCB (CCCB)
counter_error	ESM_GRP1[1]	ESM_GRP1[4]
counter_done	IRQ[80]	IRQ[81]

Table 3-6. MSS_CCCA and MSS_CCCB Integration Connections (continued)

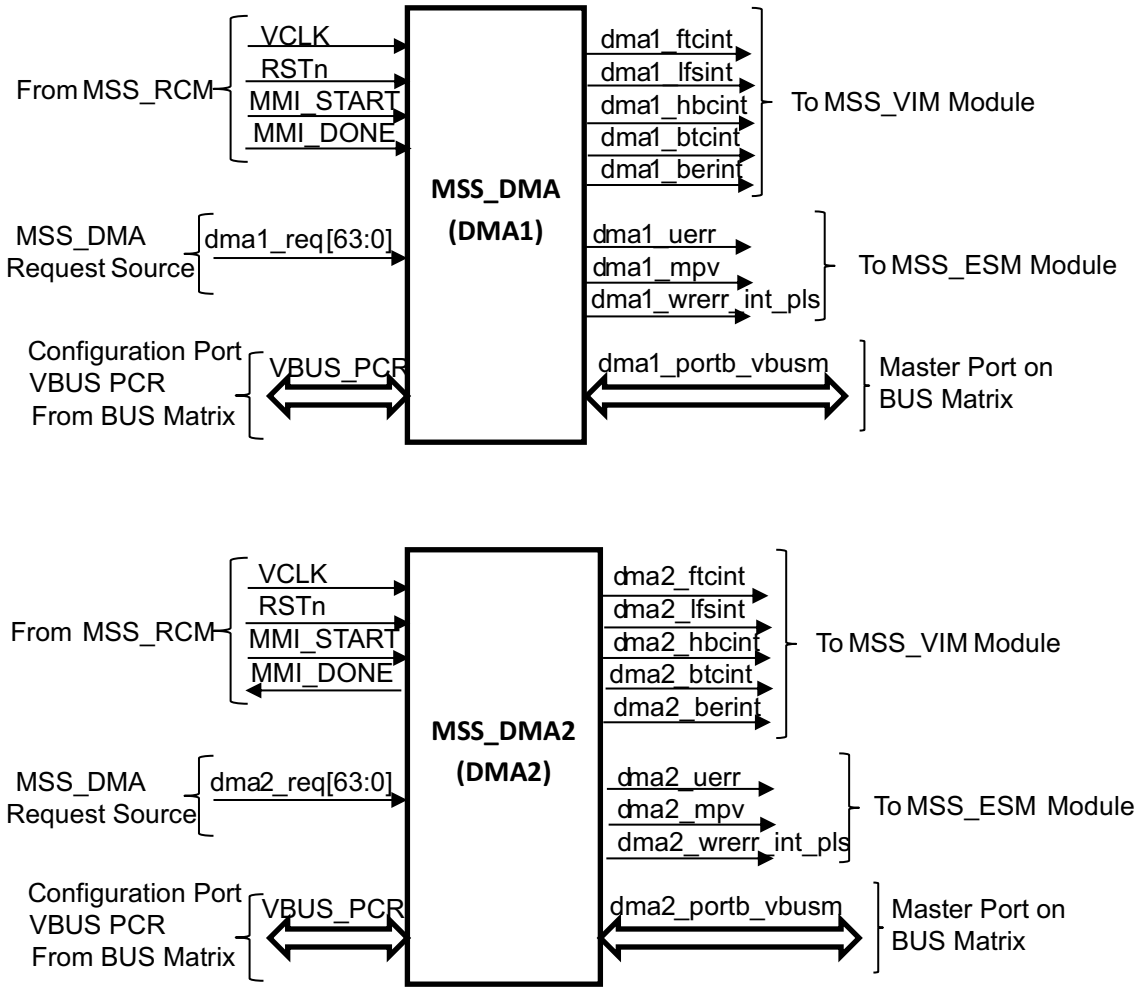
3.3.4 Direct Memory Access Controller (MSS_DMA)

3.3.4.1 MSS_DMA Integration Diagrams

The device has two instances of DMA module, MSS_DMA and MSS_DMA2. Integration of the two DMA blocks in the device are shown in Figure 3-5 and .

Figure 3-5. Integration of MSS_DMA and MSS_DMA2 Module



3.3.4.2 MSS_DMA Features

- 64-bit OCP protocol to perform bus master accesses
- INCR-4 64-bit burst accesses
- Multithreading architecture allowing data of two different channel transfers to be interleaved during non-burst accesses
- 2-port configuration for parallel bus master
- Channels can be assigned to either high-priority queue or low-priority queue. Within each queue, fixed or round-robin priorities can be serviced
- Built-in ECC generation and evaluation logic for internal RAM-storing channel transfer information
- Supports multiple interrupt outputs for mapping to multiple interrupt controllers in multicore systems
- 48 requests can be mapped to any 32 channels
- Supports LE endianness

- External ECC Gen/Eval block of MSS_DMA support ECC generation for data transactions, and parity for address, and control signals (following Cortex-R5F standard)
- 8 MPU regions
- Channel-chaining capability
- Hardware and software MSS_DMA requests
- 8-, 16-, 32-, or 64-bit transactions supported
- Multiple addressing modes for source and destination (fixed, increment, offset)
- Auto-initiation

3.3.4.3 MSS_DMA Request Map

Both instances of MSS_DMA have 64 lines of request and are connected to identical input triggers, as shown in Table 3-10. This allows the two DMAs to trigger different types of transfers for the same request.

Table 3-10. MSS_DMA Request Map

Module	DMA Request Sources	DMA Request	Mux Setting Register

Figure 3-11. MSS_MIBSPIA Integration

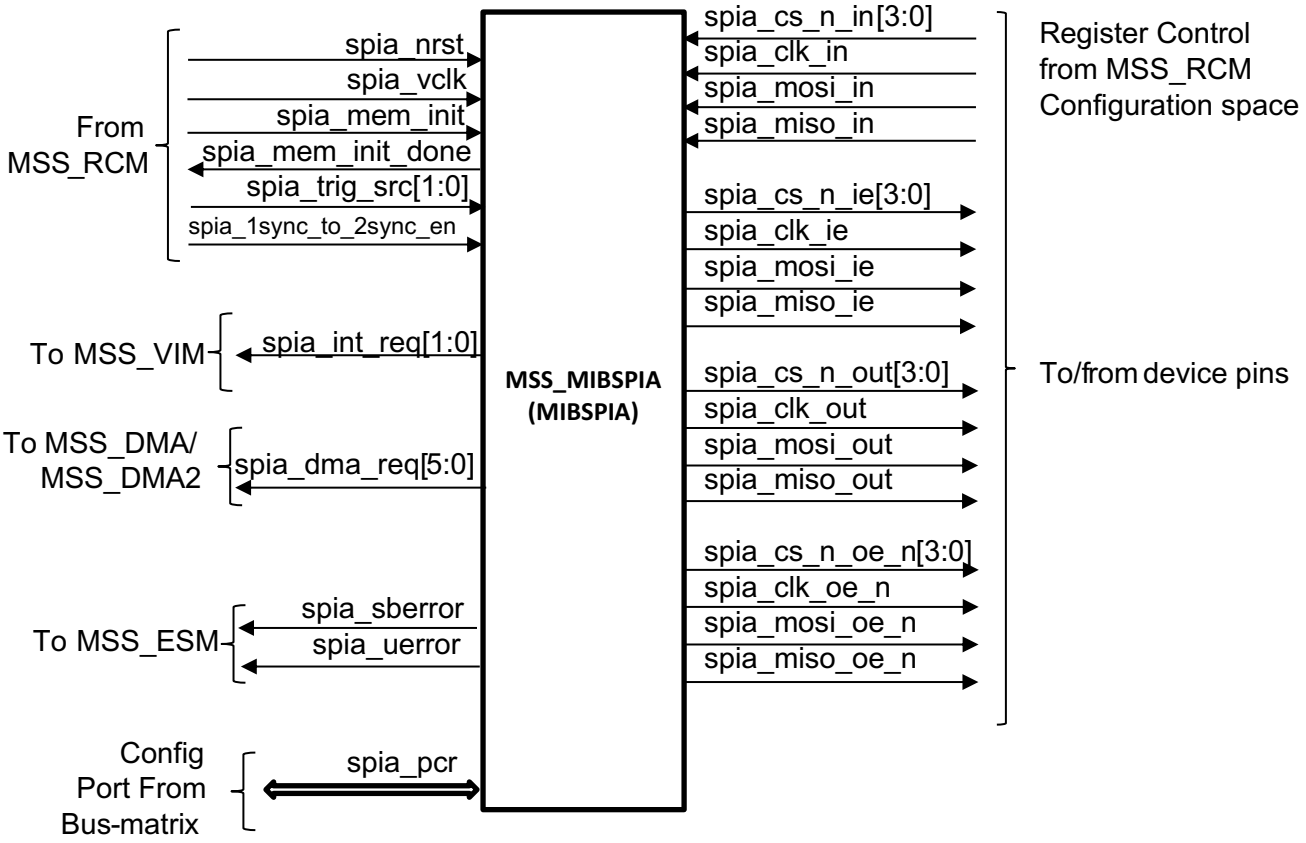

Figure 3-12. MSS_MIBSPIB Integration

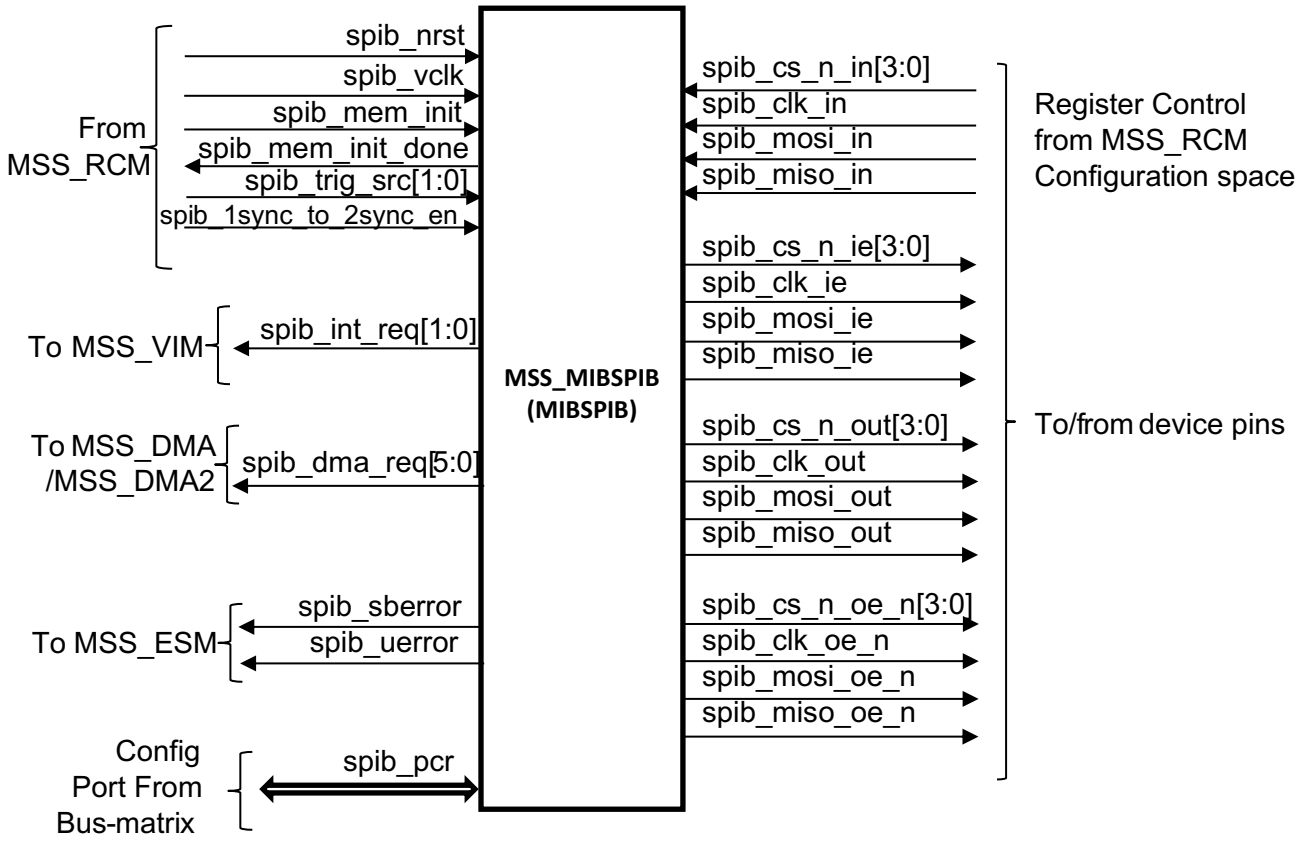

3.3.12 Quad Serial Peripheral Interface (MSS_QSPI)

The MSS_QSPI module of the the device only supports one CS pin, (qspi1_cs).

3.3.13 Enhanced Direct Memory Access (EDMA)

3.3.13.1 EDMA Controller Integration

This device has two EDMA channel controllers (DSS_TPCC0 and DSS_TPCC1) on the device:

- DSS_TPCC0 (EDMA TPCC0) has two transfer controllers: DSS_TPTC0 (EDMA TPTC0) and DSS_TPTC1 (EDMA TPTC1)
- DSS_TPCC1 (EDMA TPCC1) has two transfer controllers: DSS_TPTC2 (EDMA TPTC2) and DSS_TPTC3 (EDMA TPTC3)

NOTE: This device does not support the region interrupt feature of the EDMA peripheral. Only the global interrupt feature of the EDMA module is supported.

Table 3-12. DSS_TPCC Configuration

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of MSS_DMA channels	64	64
Number of PaRAM entires	128	256
Number of QDMA channels	8	8

Table 3-12. DSS_TPCC Configuration (continued)

	DSS_TPCC0 (EDMA TPCC0)	DSS_TPCC1 (EDMA TPCC1)
Number of event queues	2	2
Memory protection existence	No	No
Channel mapping	No	No
Number of TCs (transfer controllers)	2	2

Table 3-13. DSS_TPTC Configuration

	DSS_TPTC[0-1]	DSS_TPTC[2-3]
FIFO size	512 bytes	128 bytes
TR pipe depth	2	2
Bus width	16 bytes	16 bytes

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 3-13 and Figure 3-14 show the EDMA controller integration.

3.3.14 Error Signaling Module (MSS_ESM/DSS_ESM)

The 68xx device has two instances of the Error Signaling Module (MSS_ESM/DSS_ESM), shown in Figure 3-15.

Figure 3-15. 68xx MSS_ESM/DSS_ESM Integration Diagram

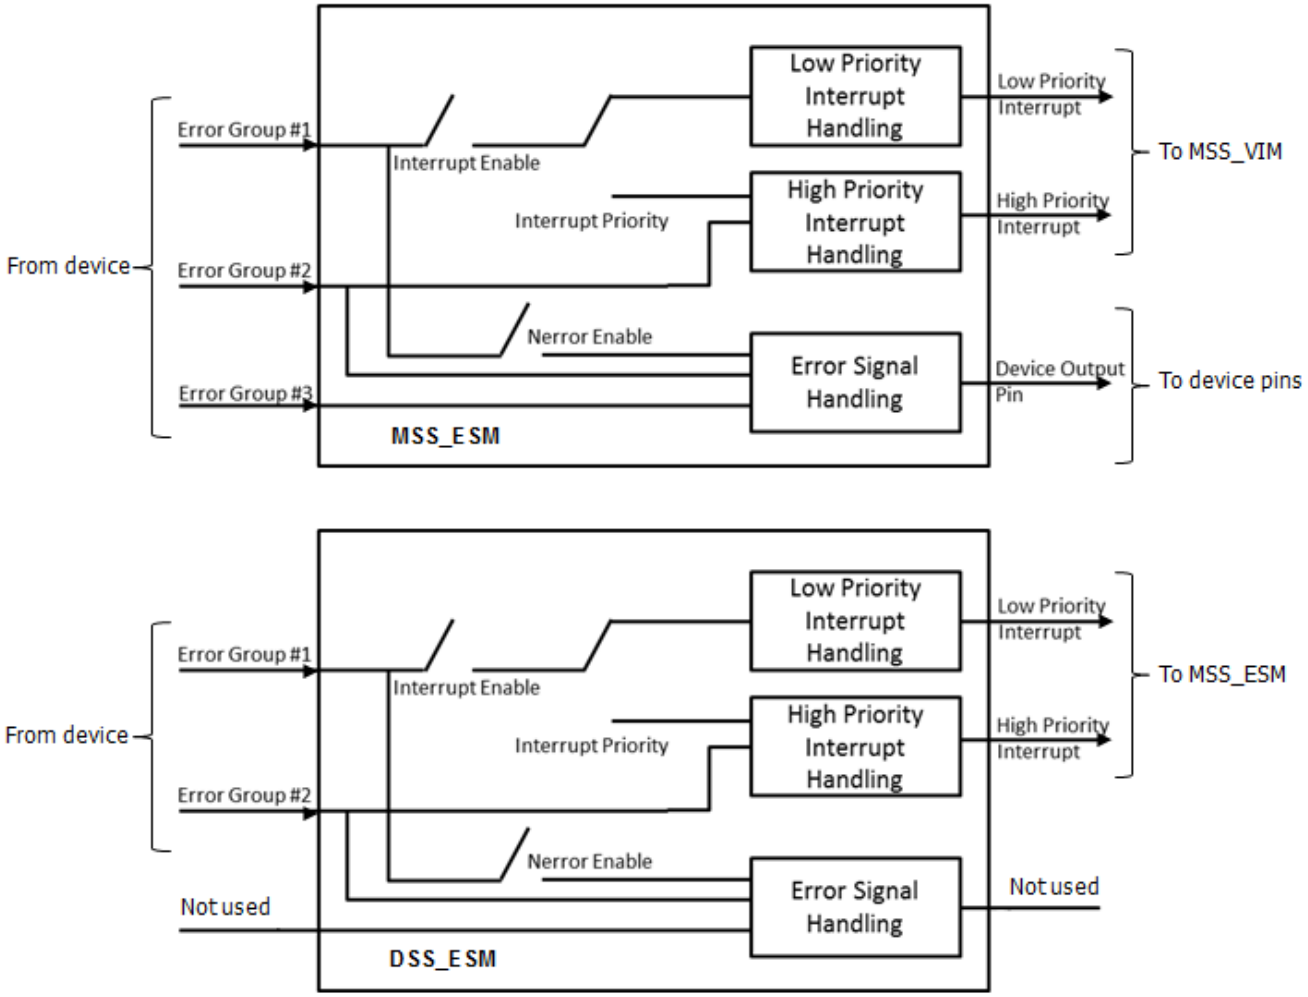

Table 3-15 shows the mapping on the input error inputs to the ESM module from various error sources available for hardware diagnostics within the device.

Table 3-15. MSS_ESM Mapping

MSS_ESM Group 1		Channel Type	Description
63	ANA_LIMP_MODE	Error Signal	Error signal at device boot-up, if the CLK monitor finds the REF CLK to be outside the permissible range of frequency
62	MSS_DCCB_ERR	Error Signal	MSS_DCCB frequency comparison error
61	MAILBOX_BSS2MSS_FATAL_ERR	Error Signal	Multi-bit error indication from MAILBOX_BSS2MSS
60	MAILBOX_BSS2MSS _REPAIR_ERR	Alert Signal	Single-bit error/repair indication from MAILBOX_BSS2MSS

4.8	68xx/64xx Control Registers	786
4.9	18xx Control Registers	1096

4.1 PRCM Overview

PRCM manages clocks, resets, and power domain control of subsystems and modules inside the device. Additionally, configuration of certain device level features is also performed through this module. PRCM has control and status registers to achieve this functionality. The available address space of PRCM is divided as shown in Table 4-1, specific to various subsystems in the device.

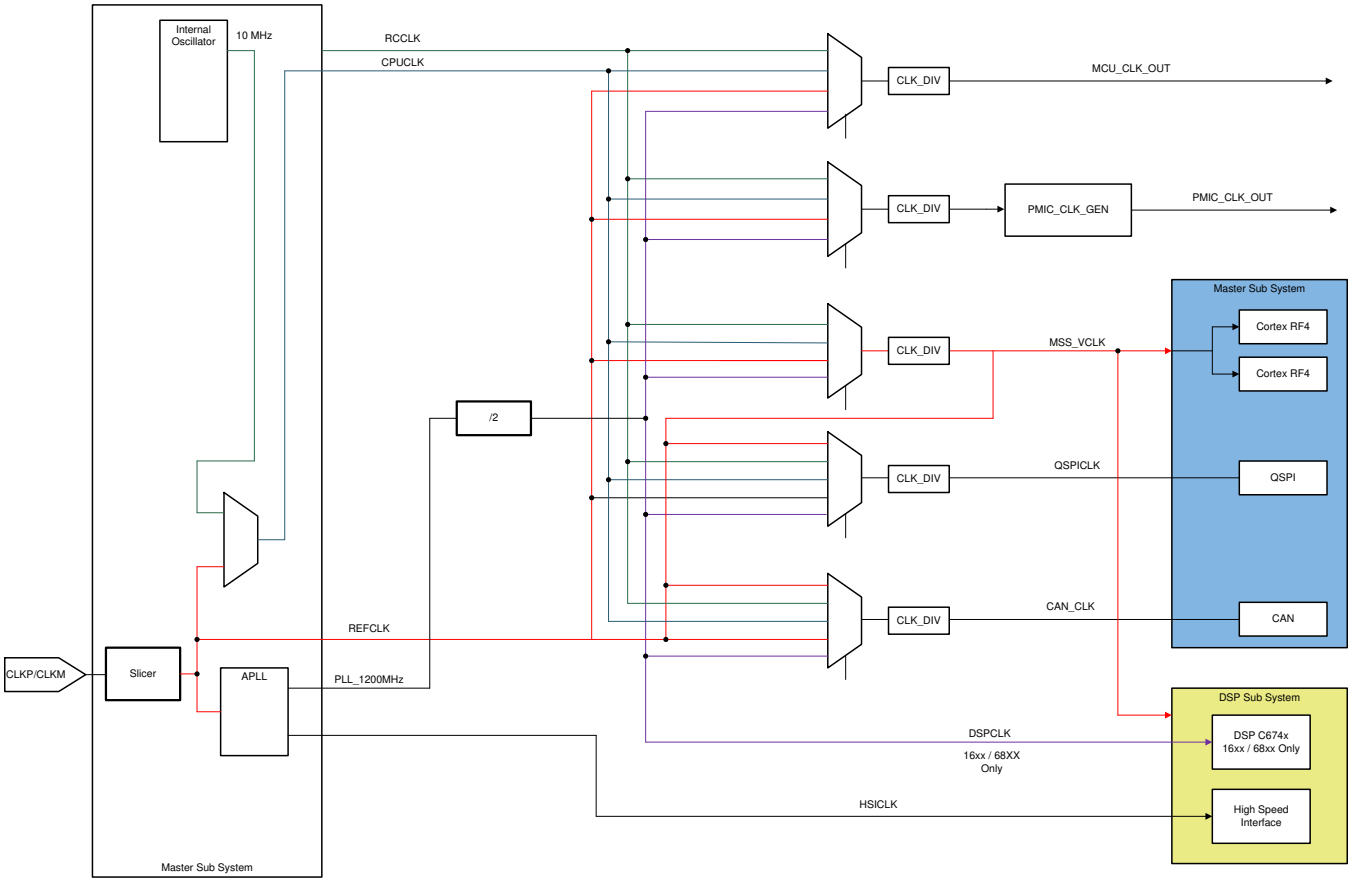
Table 4-1. PRCM Overview

PRCM Space	Description	Devices
MSS_TOPRCM	Top-level reset, clock management registers	16xx/14xx/18xx/68xx
MSS_RCM	MSS reset, clock management registers	16xx/14xx/18xx/68xx
MSS_GPCFG	General purpose control registers	16xx/14xx/18xx/68xx
DSS_REG	DSP subsystem control registers	16xx/14xx/18xx/68xx
DSS_REG2	DSPSS control module registers	16xx/18xx/68xx

4.2 Digital Clock Domains

4.2.1 Clock Overview

Figure 4-1. Clock Overview



The device has one external clock input source on the CLKP/M pins, and one internal reference clock generator. Other device-level clock sources are generated internally from these clocks by the radar subsystem. See Table 4-2 for the clocks available, based on the device.

4.2.1.1 REFCLK

External clock input can be a forced clock, or generated through a crystal between the CLKP/M pins. REFCLK is expected to operate between 40 MHz and 100 MHz. See Table 4-2 for a set of supported frequencies.

4.2.1.2 RCCLK

The RCCLK is generated by internal oscillator and is 10 MHz +/- 10%.

4.2.1.3 CPUCLK

If the REFCLK is within the permissible range of frequency of 40 MHz to 100 MHz, the CPUCLK is fed through a version of REFCLK. If the REFCLK is not within the range, the CPUCLK is switched to RCCLK.

4.2.1.4 PLLCLK

REFCLK is used as reference for PLL in the design to generate 1200-MHz clock, and its divide down versions as listed in Table 4-2.

4.2.1.5 HSICLK

This is a 300-MHZ to 1800-MHz clock generated by PLL for high-speed interfaces, such as LVDS and CSI.

4.2.2 Device Clock Sources (For Digital Logic)

Table 4-2 shows a list of available clock sources in the device and their description. These clocks serve as source clocks for various clock domains in the device. Configuration of these clocks is performed by boot ROM code.

Table 4-2. Clock Sources

Clock Source Name	Frequency	Description	Devices
RCCLK	10 MHz +/- 5%	Output of internal oscillator	16xx/14xx/18xx/68xx
REFCLK	40 MHz, 50 MHz, 80 MHz, 100 MHz	Same as the clock at input pins CLKP/M slicer. This pin can be either driven by an external clock input or connected to a crystal.	16xx/14xx/18xx/68xx
CPUCLK	RCCLK or REFCLK	The CPU CLK is fed through of the REF CLK once the CLK monitor ensures the REF CLK is within the permissible range of frequency (40 to 100 MHz). In the event the REF CLK is not within the range, the CPU CLK is switched to RCCLK during the course of wake-up.	16xx/14xx/18xx/68xx
PLLCLK_1200	1200 MHz	Output of internal PLL. REFCLK serves as the reference input to this PLL.	16xx/14xx/18xx/68xx
PLLCLK_600	600 MHz	Divided version of PLLCLK_1200 clock	16xx/14xx/18xx/68xx
HSICLK	300 to 1800 MHz	High speed clock used by LVDS/CSI interface. Programmed and controlled using the Radar Subsystem API.	16xx/14xx/18xx/68xx

4.2.3 Device Clock Domains

Table 4-3 shows the clock domains available in the device that are generated from available clock sources.

Table 4-3. Clock Domains

Clock Domain	Selectable Clock Sources	Clock Source Select (Module.Register.Field)	Clock Divider (Register.Field)	Clock Gate Register (Register.Field)	Frequency	Description	Devices
MSS_VCLK	CPUCLK RCCLK REFCLK PLLCLK_600	MSS_RCM.CLKSRCSEL1.VCLKCLKSRCSEL	MSS_RCM.CLKDIVCTL0.VCLKCLKDIV	NA	200 MHz maximum	Clock for Cortex CR4F and other modules with following exceptions: DSP Core, QSPI, CAN	16xx/14xx/18xx/68xx
DSPCLK	PLLCLK_600	NA	NA	NA	600 MHz maximum	Clock source for DSP sub system. Fixed value.	16xx/18xx/68xx
QSPICLK	CPUCLK RCCLK REFCLK PLLCLK_600 MSS_VCLK	MSS_RCM.CLKSRCSEL0.QSPICLKSRCSEL	MSS_RCM.CLKDIVCTL2.QSPICLKDIV	MSS_RCM.CLKGATE.QSPICLKGATE	60 MHz maximum	QSPI peripheral clock	16xx/14xx/18xx/68xx
CAN_CLK	CPUCLK RCCLK REFCLK PLLCLK_600 MSS_VCLK	MSS_RCM.CLKSRCSEL0 DCANCLKSRCSEL	MSS_RCM.CLKDIVCTL0 DCANCLKDIV	MSS_RCM.CLKGATE.DCANCLKGATE	10 MHz maximum	CAN peripheral clock	16xx/18xx/68xx
MCU_CLK	CPUCLK RCCLK REFCLK PLLCLK_600	TOP_RCM.EXTCLKSRCSEL.EXTCLK1SRCSEL	TOP_RCM.EXTCLKDIV.EXTCLK1DIV	MSS_TOPRCM.EXTCTL.EXTCLK1GATE	20 to 25 MHz default. 15 - 40 MHz configurable	Clock out from device. Intended for external microcontroller	16xx/14xx/18xx/68xx
PMIC_CLK	CPUCLK RCCLK REFCLK PLLCLK_600	TOP_RCM.EXTCLKSRCSEL.EXTCLK2SRCSEL	TOP_RCM.EXTCLKDIV.EXTCLK2DIV	MSS_TOPRCM.EXTCTL.EXTCLK2GATE	1.7 to 2.2 MHz configurable	Clock out from device. Intended for external PMIC	16xx/14xx/18xx/68xx

Configuration of the clock domains in terms of clock source selection and frequency is controlled through registers mentioned in Table 4-3. Multiple clock sources are available for each of the clock domains; required clock sources can be selected by the clock domains clock source register. Clock domains have programmable divider registers which allow the clock domain to get a divided down clock of the selected source clock.

Boot ROM code performs the default initialization of these registers. MSS_VCLK is setup before other clocks; this is the clock for most of the device components and subsystems except for the peripherals such as those mentioned in Table 4-3, which have their independently selectable clock sources and divider values.

4.2.4 Clock Initialization Sequence

Typically the clock initialization of MSS_VCLK and DSPCLK is managed by boot ROM, and the user is not expected to alter these configurations.

The initialization sequence for QSPICLK, CAN_CLK, MCU_CLK, and PMIC_CLK is listed below. See the applicable register.field for the clock in Table 4-3.

1. Disable the clock by gating off the clock using the Clock Gate register field.
2. Write a divider value based on the desired clock frequency to the clock divider register field.
3. Write the clock source register field with the selection from the available clock sources mentioned in Table 4-2. The corresponding clock source values are mentioned in the register field descriptions.
4. Enable the clock by gating the clock by writing to the Clock Gate register field.

4.2.5 PMIC Clock

The generated PMIC_CLK can be divided down further in the PMIC_CLK_GEN module by configuring the registers shown in Table 4-4. These registers should be programmed before doing the setup of PMIC_CLK registers listed in Table 4-3.

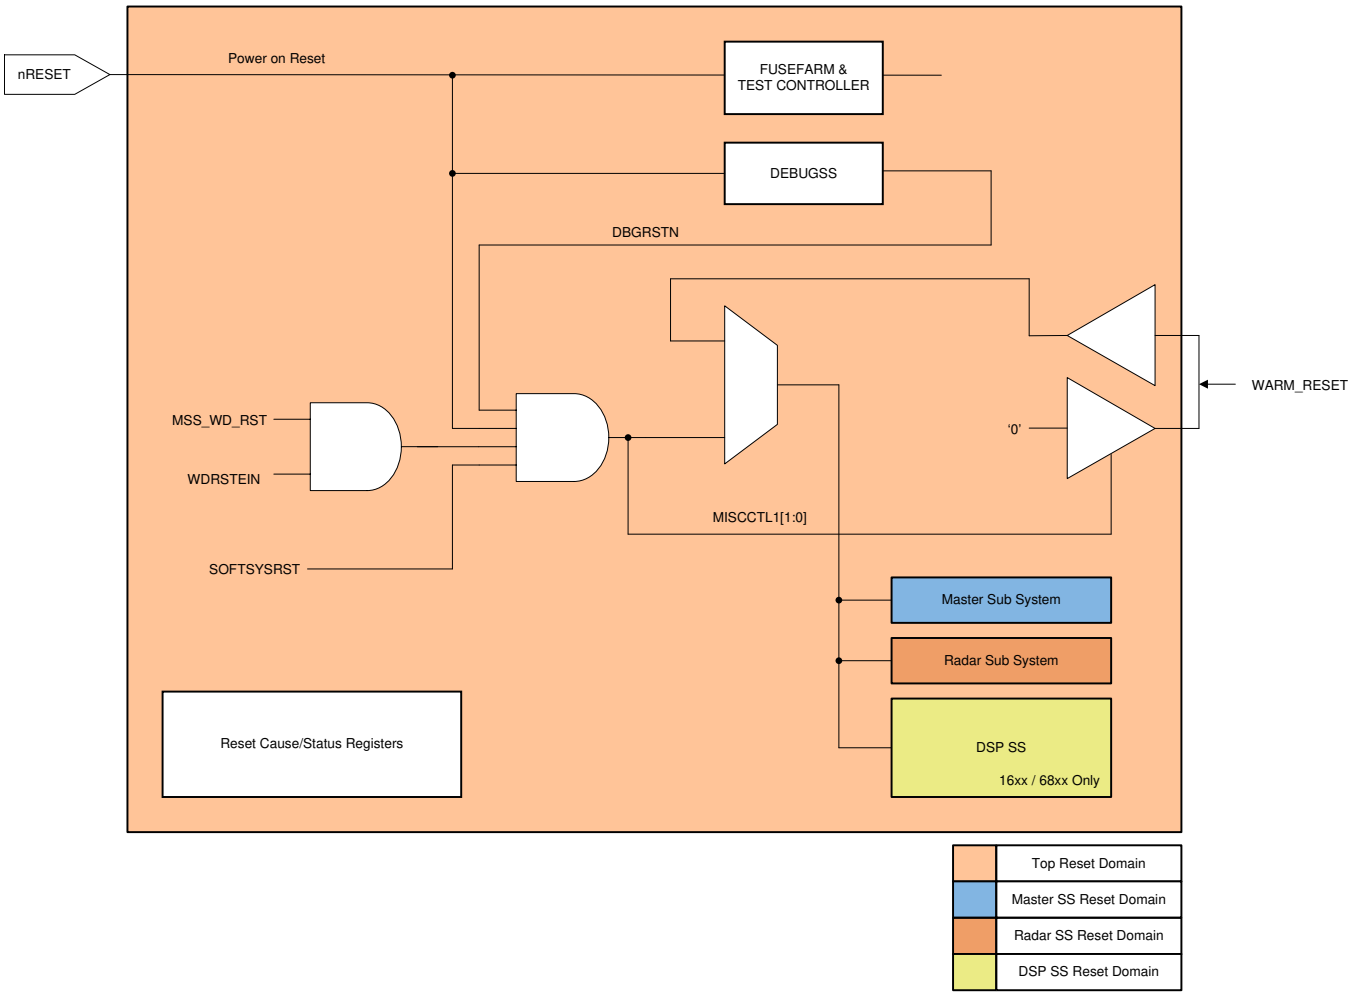
Table 4-4. PMIC Registers

Register	Description
MSS_TOPRCM.DCDCCTL0.DCDCCTL0	Controls the slope of the output PMIC_CLK_OUT. Set to 0.
MSS_TOPRCM.DCDCCTL1.DCDCRST	Dithering control block reset. Set to 0
MSS_TOPRCM.DCDCCTL1.DCDCLKEN	Enable Clk. Set to 1.
MSS_TOPRCM.DCDCCTL1.DCDCCTL1[8]	Set to 0.
MSS_TOPRCM.DCDCCTL1.DCDCCTL1[9]	Set to 0.
MSS_TOPRCM.DCDCCTL1.DCDCCTL1[23:16]	Set to divider value to get appropriate PMIC clk out frequency. Minimum 2.
MSS_TOPRCM.DCDCCTL1.DCDCCTL1[31:24]	Set to divider value to get appropriate PMIC clk out frequency. Minimum 2.

4.3 Resets

4.3.1 Reset Overview

Figure 4-2. Reset Overview



Two device resets are available that can be controlled from the device pins: the power-on reset pin NRESET and the bidirectional WARM_RESET signal. The warm reset signal is implemented as an I/O, so that an external monitor can be utilized to detect changes to the state of the internal warm reset control signal.

Device registers can capture recent reset events, and can be used by software to manage failure recovery. Certain registers in the device are immune to WARM_RESET, and can only be reset by power-on reset.

4.3.2 Reset Types and Sources

Table 4-5. Reset Types and Sources

Reset Type	Reset Source	Description	Devices
Power On Reset	Device Pin NRESET	Reset triggered by the device reset pin NREST. This resets the entire device, including all subsystems and interfaces. This is an active low asynchronous Power ON reset signal, and must be asserted for minimum 500 ns to reset the device.	16xx/14xx/18xx/68xx
Warm Reset	Soft Reset, Watch Dog Reset, Device Pin WARM_RESET pin	This is an active low warm reset internally generated by the device, or triggered by device pin WARM_RESET. A write to the TOP_RCM.SOFTSYSRST register or watch dog module can generate this reset; additionally, the external pin WARM_RESET can also be used to trigger this reset. Selection is controlled through the TOP_RCM.MISCTL1 register. The WARM_RESET pin is an open-drain failsafe IO which can be used to reset the device from the external world or to report the reset to the external world if it is generated by an internal source such as watchdog. A write to the TOP_RCM.SOFTSYSRST, as explained in register description, can create this reset. The watch dog module in the master subsystem can be configured to trigger this reset. Check the watch dog module description for details. This feature is enabled by the TOP_RCM. WDRSTEN register.	16xx/14xx/18xx/68xx

As listed in Table 4-5, various reset sources can generate the different resets used inside the device to reset various components and submodules.

A Warm_rest excludes certain modules and spaces listed in Table 4-5 from reset. These can only be reset by power-on reset.

4.3.3 Reset Domains

The device can be divided into various reset domains, as listed in Table 4-6. The top reset domains cover the entire device and all of the subsystems. Additional subsystem-level reset domains are available, and can be reset independently based on resets mentioned in Table 4-6.

Table 4-6. Reset Domains

Reset Domain	Description	Resets	Devices
Top reset domain	This top device-level reset domain resets entire device and all subsystems. All other reset domains are subdomains of this domain, and resetting this domain issues a reset to these subdomains. Only power-on reset can reset this domain, and it is immune to any other system reset type. Sub reset domain can be independently reset, as mentioned in the respective rows.	Power-on reset	16xx/14xx/18xx/68xx
Master subsystem reset domain	This reset subdomain controls the reset to the master susbsystem and the modules inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset	16xx/14xx/18xx/68xx
Radar subsystem reset domain	This reset subdomain controls the reset to the radar susbsystem and all components inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset	16xx/14xx/18xx/68xx

Table 4-6. Reset Domains (continued)

Reset Domain	Description	Resets	Devices
DSP subsystem reset domain	This reset subdomain controls the reset to the DSP subsystem and all components inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset	16xx/14xx/18xx/68xx

4.3.4 Reset Cause Registers

Various reset cause registers are available that show the last reset issued to the device or subsystem, as shown in Table 4-7.

Table 4-7. Reset Cause Registers

Register	Description
MSS_RCM.RSTCAUSE.RSTCAUSE	Records the cause for the master SS reset domain reset
MSS_TOPRCM.SYSRSTCAUSE.SYSRSTCAUSE	Records the cause for the top reset domain reset
DSS_REG.GEMRSTCAUSE.GEMLRSTCAUSE	Records the cause of the local reset of the DSP reset domain
DSS_REG.GEMRSTCAUSE.GEMGRSTCAUSE	Records the cause of the global reset of the DSP reset domain
DSS_REG.GEMRSTCAUSE.GEMPORCAUSE	Records the cause of the POR reset of the DSP reset domain

4.3.5 Module Resets

4.3.5.1 MSS CR4 Soft Reset Sequence

Use the steps below to soft reset the MSS CR4:

1. Write 0xAD to ALTIUS:MSS_RCM:SOFTCORERST:RST_WFICHECKEN (before asserting the reset to CR4, wait for CR4 to enter WFI).
2. Write 0xAD to ALTIUS:MSS_RCM:SOFTRST1:CR4SYSRST (write 0xAD to assert a MSS CR4-only reset).

This automatically asserts and deasserts the MSS CR4 reset.

4.3.5.2 VIM Reset Consideration

Issue a soft reset to the VIM module using the following steps:

1. Write value 0xAD to register MSS_RCM:SOFTRST2:VIMRST.
2. Release reset for VIM module by writing 0x0 to register MSS_RCM:SOFTRST2:VIMRST. This only resets the VIM module and its state.

NOTE: This does not reset the RAM memory within the VIM module.

4.4 Power Domain

Switchable power domains are only for the 16xx/18xx/68xx device.

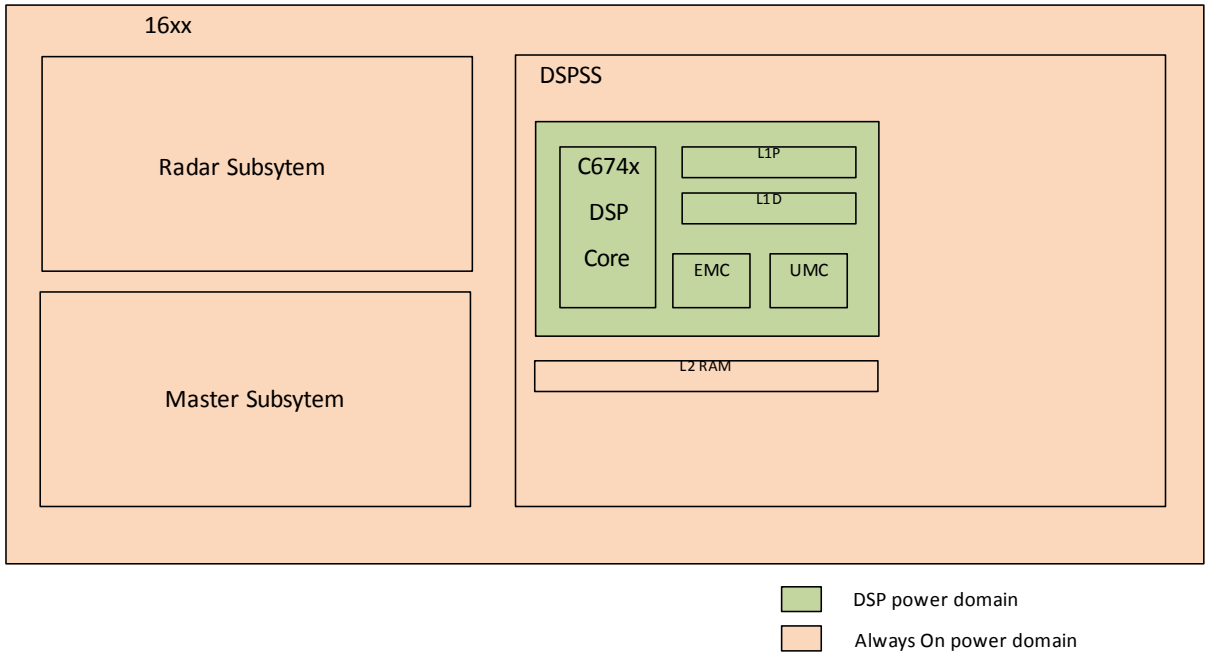
4.4.1 Available Device Power Domains

The device has two power domains:

- Always-on power domain: This power domain supplies power to entire device except for the DSP core. It cannot be switched off dynamically within the device.
- DSP power domain: The DSP C674x core inside the DSP subsystem is placed on switchable power

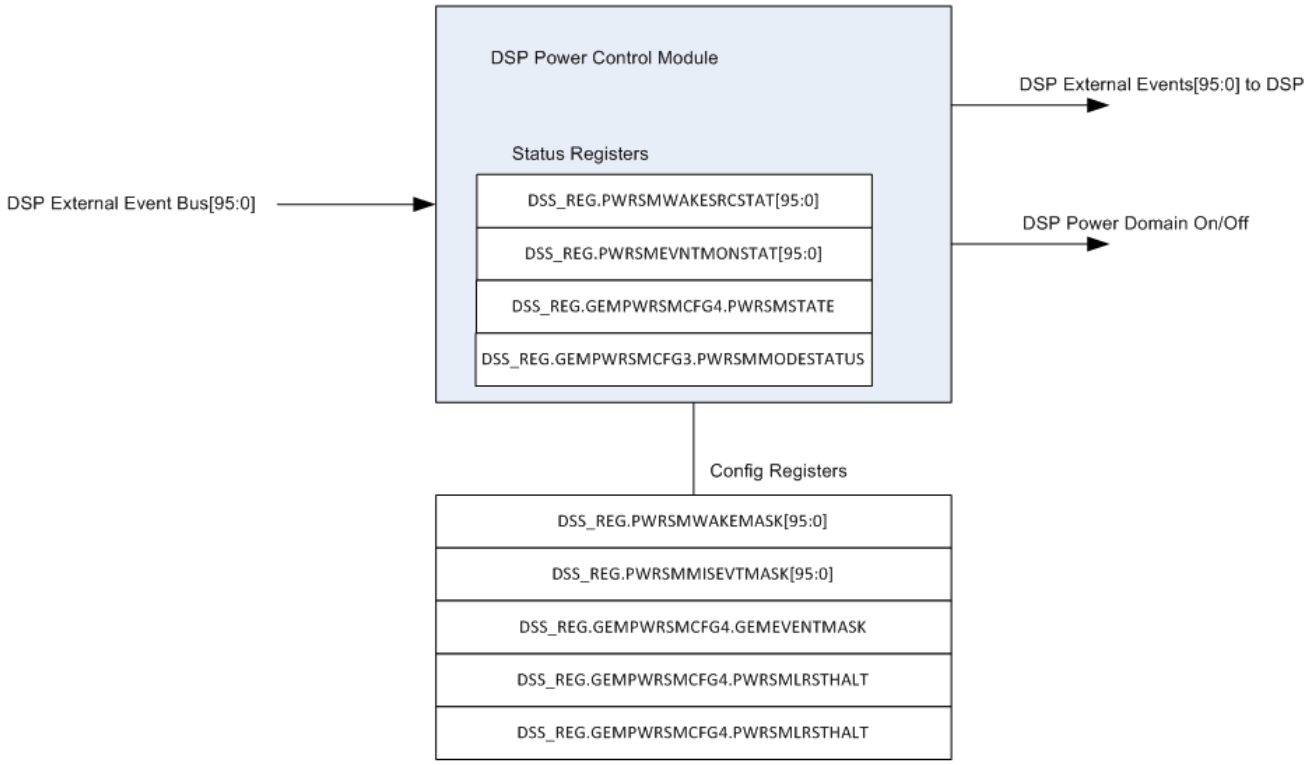
domain, and can be switched on or off as needed. This feature can be used to reduce power consumption of the device when the DSP core is not in use. By default, the state of this power domain is OFF.

Figure 4-3. Power Domains



4.4.2 Power Domain Control

Figure 4-4. Power Domain Controls



The DSP can be power cycled ON and OFF using the DSP power control module to save power when inactive. On POR, the DSP is powered OFF.

Any of the external DSP events can be used as a wakeup event to power on the DSP. The events can be configured as wakeup events by unmasking the event in DSS_REG.PWRSMWAKEMASK. After power up, the events that triggered the wakeup are registered in DSS_REG.PWRSMWAKESRCSTAT.

During power OFF, the control module ensures that none of the external DSP events are sent to the DSP. This is done by setting the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK field before triggering a power down. When this field is set, the events are captured inside the control module, so there is a record of the missed events during power-off. When the DSP is powered back on, the SW clears the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK field so that any new HW events are now routed to the DSP. Any events that occurred during power off are saved in the PWRSMEVNTMONSTAT register. There is an option provided to send any of the missed events directly on the HW lines to the DSP at the time of clearing the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK after power up. To enable this feature, unmask these events in the PWRSMMISEVTMASK registers to enable any missed event to propagate on the HW lines on clearing the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK field. After processing the missed events and wakeup source, the SW must clear all these events by writing to the DSS_REG.PWRSMWAKESRCSTATCLR register.

4.4.2.1 Power Domain Status

The current status of the DSP power domain can be read at DSS_REG.GEMPWRSMCFG3.PWRSMMODESTATUS. Table 4-8 shows the decoding of the value read.

Table 4-8. Power Domain Status

PWRSMMODESTATUS	DSP Power Domain State
0	GEM is OFF
1	GEM transitioning from OFF to ON
2	GEM transitioning from ON to OFF
3	GEM is ON

4.4.2.2 Power ON Control Sequence

Below is the detailed sequence to power on the DSP.

Master subsystem-controlled DSP power ON sequence — This sequence is used to power on the DSP core.

1. Ensure the DSP resets from the TOP RCM are de-asserted. The resets are then fully controlled by the power state machine.
2. Unmask the wakeup event: by default, all DSP interrupts are masked as wakeup events. To unmask a wakeup event, write the corresponding bit in registers DSS_REG.PWRSMWAKEMASK[0-2]. The 96-bit configuration corresponds to the [95:0] interrupt lines to the DSP.
3. If the program code must be downloaded into the DSP L2 memory before starting the DSP execution, then set the DSS_REG.GEMPWRSMCFG4.PWRSMLRSTHALT bit to 0x1.
4. Trigger the wakeup: when an unmasked interrupt is generated to the DSP, a wakeup trigger is generated.
5. Wait for DSP to be powered on by polling the field DSS_REG.GEMPWRSMCFG4.PWRSMSTATE for the value 0xB. SW can now configure and trigger the DMA for the program code download.
6. When the program code is completed, SW can now release the halt by clearing the DSS_REG.GEMPWRSMCFG4.PWRSMLRSTHALT bit; DSP begins execution.
7. Follow the steps in the DSP Execution on Power ON section below.

Autonomous DSP power ON HW event — This sequence is used to power on the DSP after a DSP power off sequence where the event used to wakeup is already unmasked before power down in the DSS_REG.PWRSMWAKEMASK[0-2].

1. The unmasked HW event triggers the DSP wakeup and power on DSP, and DSP begins execution.
2. In the DSP program execution, after booting, unmask all the events to the DSP by clearing the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK field to 0x0.
3. Any events that occurred between the previous GEM_EVENT_MASK set and unmasked in DSS_REG. DSS_REG__PWRSMMISEVTMASK[0-2] appear on the HW interrupt request lines to be serviced.
4. Reading the DSS_REG.PWRSMWAKESRCSTAT[0-2] provides the event that caused the wakeup.
5. Reading the DSS_REG.PWRSMEVNTMONSTAT[0-2] provides the events that occurred between the previous GEM_EVENT_MASK set.
6. Writing 0x1 to the field in the DSS_REG.PWRSMWAKESRCSTATCLR[0-2] clears the corresponding interrupt[95:0] status in the DSS_REG.PWRSMWAKESRCSTAT and DSS_REG.PWRSMEVNTMONSTAT

4.4.2.3 Power OFF Control Sequence

Below is the detailed sequence to power off the DSP.

DSP execution to power OFF the DSP:

1. Ensure that all previous registered events during the previous power down are cleared.
2. Set up the DSP interrupt routine for INTH_INT_ID_DSS_PDC_INT (Gem event number : 118)

a. This interrupt routine executes when the Clock Stop request is sent to the DSP, such that DSP sends back the Clock Stop Ack Set the bit DSP_ICFG.PDCCMD.GEMPD and executes the "idle" instruction.

3. If GEM powers up in autonomous mode without the program download, set the DSS_REG.GEMPWRSMCFG4.PWRSMLRSTHALT bit to 0x0.
4. Unmask the events to use as wakeup events in DSS_REG.PWRSMWAKEMASK[0-2].
5. Unmask the events to receive as HW event pulses after the next power up in DSS_REG. DSS_REG__PWRSMMISEVTMASK[0-2].
6. Mask all interrupts from DSP by setting the DSS_REG.GEMPWRSMCFG4.GEMEVENTMASK field to 0x1.
7. Trigger a power down by setting the DSS_REG.GEMPWRSMCFG4.PWRSMSLEEPTRIG field to 0x1, and wait in a while loop. This triggers the interrupt INTH_INT_ID_DSS_PDC_INT, followed by the power down of the DSP core by the control module.

The state of the DSP power domain can be polled by other master subsystem CR4F cores to ensure the DSP power down.

4.5 Boot

4.5.1 Bootloader Modes

The device supports two boot modes, Functional Mode and Flashing Mode. During boot, the device checks the value on the device pins SOP0, SOP1, and SOP2, to determine the boot mode. After boot, any change in the value does not affect the boot mode of the device. To change the boot mode, the new SOP values must be applied before power-cycling the device. Refer to Table 4-9 for the SOP pin values for each mode.

Table 4-9. SOP Table

SOP2	SOP1	SOP0	Bootloader mode and operation
0	0	1	Functional Mode This mode is used to read the image from the onboard serial flash. The image is loaded into the internal RAM and executes it.
1	0	1	Flashing Mode This mode is used to write the image to the onboard serial flash. The image is accepted over UART, and loads it to the serial flash connected to the QSPI port.

NOTE: These are the only valid SOP combinations supported by the device. Any other values may result in unknown device behavior.

4.5.2 ROM Eclipsing

ROM eclipsing is a feature that is used to change the visibility of MSS_TCMA_ROM in the master subsystem. Typically at address 0x0000_0000, MSS_TCMA_ROM address space begins. However, when ROM eclipsing is enabled, the address 0x0000_0000 gets remapped to the start address MSS_TCMA_RAM. As a result, MSS_TCMA_ROM is effectively eclipsed and not accessible in the address space.

After the device boots, the application view is always the post-eclipse view, as the ROM eclipsing step is performed by the device bootrom code. The pre-eclipse view is provided for completeness purposes. Refer to the device-specific memory map for unlisted modules.

Table 4-10. Pre-Eclipse View of Master Subsystem Cortex-R4F

Module Name	Frame Address (Hex)		Size Used	Description
	Start	End		
MSS_TCMA_ROM	0x0000_0000	0x0001_7FFF	128KiB	MSS_TCMA_ROM (TCMA) Program ROM

Table 4-10. Pre-Eclipse View of Master Subsystem Cortex-R4F (continued)

Module Name	Frame Address (Hex)		Size Used	Description
	Start	End		
Reserved	0x0001_8000	0x001F_FFFF		Reserved
MSS_TCMA_RAM	0x0020_0000	0x07FF_FFFF	128KiB/256KiB/ 512KiB	MSS_TCMA_RAM (TCMA) size varies based on device and DSS_L3 (L3) sharing options configured
MSS_TCMB	0x0800_0000	0x0C1F_FFFF	192KiB	MSS_TCMB (TCMB) Data RAM

Table 4-11. Post-Eclipse View of Master Subsystem Cortex-R4F

Module Name	Frame Address (Hex)		Size Used	Description
	Start	End		
MSS_TCMA_RAM	0x0000_0000	0x07FF_FFFF	128KiB/256KiB/5 12KiB	MSS_TCMA_RAM (TCMA) size varies based on device and DSS_L3 (L3) sharing options configured
MSS_TCMB	0x0800_0000	0x0C1F_FFFF	192KiB	MSS_TCMB (TCMB) Data RAM

Table 4-12 lists the steps to enable the ROM eclipsing feature, as performed by the device bootrom (the application does not need to do this).

Table 4-12. Enable ROM Eclipsing

#	Step	Description
1	Write 0xAD to MSS_RCM.CR4CTL.MEMSWAPWAIT	Post-eclipse address map is effective only after soft reset is issued to Cortex R4F.
2	Write 0xAD to MSS_RCM.CR4CTL.CR4MEMSWAP	Enables the eclipsing feature that allows the address remap. The Cortex R4F does not see the new address space until it goes through a soft reset.
3	Write 0xAD to MSS_RCM.SOFTRST1.CR4SYSRST	Issue soft reset to Cortex R4F. This makes the post-eclipse address space visible.

4.6 14xx Control Registers

Registers from the TOP_RCM, MSS_RCM, MSS_GPCFG, DSS_REG, and DSS_REG2 provide control and status information over various features of the SoC. The following sections provide a description of the registers and fields available under these modules specific to the 14xx and 16xx/18xx/68xx devices.

4.6.1 MSS_TOPRCM Registers

Table 4-802 lists the memory-mapped registers for the MSS_TOPRCM. All register offset addresses not listed in Table 4-802 should be considered as reserved locations and the register contents should not be modified.

Table 4-13. MSS_TOPRCM Registers

Offset	Acronym	Register Name	Section
8h	BSSCTL	Control Signals to BSS	Section 4.6.1.1
10h	EXTCLKDIV	Clock divide value for MCU_CLKOUT and PMIC_CLKOUT	Section 4.6.1.2
14h	EXTCLKSRCSEL	Clock source select value for MCU_CLKOUT and PMIC_CLKOUT	Section 4.6.1.3
18h	EXTCLKCTL	Clock gate control for MCU_CLKOUT and PMIC_CLKOUT	Section 4.6.1.4
1Ch	SOFTSYSRST	Software triggered Warm Reset	Section 4.6.1.5

Bit	Field	Type	Reset	Description
31-22	RESERVED	R/W	0h	Reserved
21-17	ADCBUFNUMCHRP	R/W	0h	Number of chirps to be stored in each Ping and Pong buffer. This register should be programmed with one less than the actual number needed.
16	RESERVED	R	1h	Reserved
15	ADCBUFCONTSTOPPL		0h	Stop Pulse for Continuous mode. The data capture will stop once this register is set.
14	ADCBUFCONTSTRTPL		0h	Start Pulse for Continuous mode. The data capture will start from Address 0 once this register is set. All the other configurations like Enable, Sample Count are expected to be programmed before this pulse.
13	ADCBUFCONTMODEEN	R/W	0h	Continuous mode enable for ADC Buffer. This is set when a fixed number of samples have to be stored in Ping/Pong and not depend on Chirp time-lines (Eg: Analog Lab characterization to stream out continuous data from DFE).
12	ADCBUFWRITEMODE	R/W	0h	0 --> Interleaved, 1 --> Non-interleaved
11-10	RESERVED	R/W	0h	Reserved
9	RX3EN	R/W	0h	Enable for Rx3 write
8	RX2EN	R/W	0h	Enable for Rx2 write
7	RX1EN	R/W	0h	Enable for Rx1 write
6	RX0EN	R/W	0h	Enable for Rx0 write
5	ADCBUFIQSWAP	R/W	0h	0 -->[I is stored in LSB part and Q is stored in MSB part]. 1 --> [Q is stored in LSB and I in MSB]
4-3	RESERVED	R/W	0h	Reserved
2	ADCBUFREALONLYMODE	R/W	0h	0-->Complex Data mode, 1-->Real data mode
1-0	RESERVED	R/W	0h	Reserved

4.6.4.3 ADCBUFCFG2 Register (Offset = 60h) [reset = 01000000h]

ADCBUFCFG2 is shown in Figure 4-989 and described in Table 4-1032.

Return to Summary Table.

Figure 4-95. ADCBUFCFG2 Register

R-																		R/W-400h													

Table 4-113. ADCBUFCFG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	NU	R		
13-0	ADCBUFSAMPCNT	R/W	400h	No of samples to store in each Ping and Pong register in continuous mode of ADC Buffer. In real only mode this refers to the number of real samples and in complex mode, this refers to number of complex samples. This refers to the number of samples per channel. This counter increments once for every new sample from DFE (as long as 1 or more channels are enabled). The max allowed value varies depending on other configurations (No of channels enabled and real/complex data). Ex: It is 8192 for real only mode one channel, and 4096 for complex mode one channel. It is only 2048 for real mode 4 channels and 1024 for complex mode 4 channels.

4.6.4.6 CQCFG1 Register (Offset = 6Ch) [reset = 40200000h]

CQCFG1 is shown in Figure 4-887 and described in Table 4-930.

Return to Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 4-928 shows the codes that are used for access types in this section.

Table 4-325. DSS_REG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

4.7.4.1 RTIEVENTCAPTURESEL Register (Offset = 50h) [reset = 0h]

RTIEVENTCAPTURESEL is shown in Figure 4-886 and described in Table 4-929.

Return to Summary Table.

Figure 4-302. RTIEVENTCAPTURESEL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU2									EVT1							NU1									EVT0							
R-0h									R/W-0h							R-0h									R/W-0h						

Table 4-326. RTIEVENTCAPTURESEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	NU2	R	0h	
22-16	EVT1	R/W	0h	Setting the source of interrupt for Counter value capture for RTI1 Event1
15-7	NU1	R	0h	
6-0	EVT0	R/W	0h	Setting the source of interrupt for Counter value capture for RTI1 Event0.

4.7.4.2 CQCFG1 Register (Offset = 6Ch) [reset = 40100000h]

CQCFG1 is shown in Figure 4-887 and described in Table 4-930.

Return to Summary Table.

Figure 4-303. CQCFG1 Register

31	30	29	28	27	26	25	24
NU3	CQ2BASEADDR

23	22	21	20	19	18	17	16
CQ2BASEADDR			CQ1BASEADDR				
R/W-100h			R/W-80h				
15	14	13	12	11	10	9	8
CQ1BASEADDR			CQ0BASEADDR				
R/W-80h			R/W-0h				
7	6	5	4	3	2	1	0
CQ0BASEADDR				CQ96BITPACKEN	NU	CQDATAWIDTH	
R/W-0h				R/W-0h	R-0h	R/W-0h	

Table 4-327. CQCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NU3	R	0h	
30-22	CQ2BASEADDR	R/W	100h	128-bit Address offset which inidcates the start address for storing CQ0 (ADC/RxIF Saturation Detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
21-13	CQ1BASEADDR	R/W	80h	128-bit Address offset which inidcates the start address for storing CQ0 (Signal Image Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
12-4	CQ0BASEADDR	R/W	0h	128-bit Address offset which inidcates the start address for storing CQ0 (Wide Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
3	CQ96BITPACKEN	R/W	0h	This is used to pack the CQ data into only the LSB 96 bits of each row of the CQ memory. This can be used in 3 channel mode of LVDS where the ADC data and Chirp Params occupy only LSB 96 bits of each memory row.
2	NU	R	0h	
1-0	CQDATAWIDTH	R/W	0h	This is used to appropriately pack the valid CQ data bits in appropriate bits in the CQ memory. 00, 01->Raw 16, 10-->Raw 12, 11-->Raw14

4.7.4.3 TPCCPARSTATCFG Register (Offset = 80h) [reset = 0h]

TPCCPARSTATCFG is shown in Figure 4-888 and described in Table 4-931.

Return to Summary Table.

Figure 4-304. TPCCPARSTATCFG Register

31	30	29	28	27	26	25	24

31-26	RESERVED	R	0h	Reserved
25-21	ADCBUFNUMCHRPPONG	R/W	0h	Number of chirps to be stored in Pong buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Ping
20-16	ADCBUFNUMCHRPPING	R/W	0h	Number of chirps to be stored in Ping buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Pong
15-0	ADCBUFSAMPCNT	R/W	400h	No of samples to store in each Ping and Pong register in continuous mode of ADC Buffer. In real only mode this refers to the number of real samples and in complex mode, this refers to number of complex samples. This refers to the number of samples per channel. This counter increments once for every new sample from DFE (as long as 1 or more channels are enabled). The max allowed value varies depending on other configurations (No of channels enabled and real/complex data). Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode

4.7.4.107 STCPBISTSMCFG1 Register (Offset = 34Ch) [reset = 18h]

STCPBISTSMCFG1 is shown in Figure 4-992 and described in Table 4-1035.

Return to Summary Table.

Table 4-432. STCPBISTSMCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-21	RESERVED	R	0h	Reserved
20	PBISTTESTSTATCLR	W	0h	Clear bit for PBIST Status: this is a wspecial access type - awrite to this field generates a pulse.
19-18	PBISTTESTSTAT	R	0h	PBIST status from GEM. [0] - Fail Indication [1] - Done indication
17-12	STCPBISTSMSTATE	R	0h	Current state of STC PBIST state machine
11-5	RESERVED	R/W	0h	Reserved
4	STCPBISTCKSTPACKMASK	R/W	1h	Mask bit for ignoring the clock stop ack from GEM. This will be used for ignoring clock stop ack during boot-up. 1 --> Ignore clock stop ack from GEM. 0 --> Wait for clock stop ack from GEM after giving clock stop request.
3	STCPBISTLRSTDASRTHALT	R/W	1h	Configuration to halt the state machine before the final de-assertion of LRST to enable program download. 1 --> Halt, 0 --> Proceed.
2	STCPBISTSMTRIG	W	0h	Trigger pulse for the STC PBIST state machine. This is a self-clearing pulse.
1-0	STCPBISTEN	R/W	0h	Enable for PBIST and STC. 00 - Reserved, 01 --> STC only 10 --> PBIST only 11 --> PBIST followed by STC.

4.7.4.108 STCPBISTSMCFG2 Register (Offset = 350h) [reset = 2410h]

STCPBISTSMCFG2 is shown in Figure 4-993 and described in Table 4-1036.

Return to Summary Table.

SYSRST							
0h							

Table 4-542. SOFTRST0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	NU		0h	
24	SYSRSTDBGRSTEN	R/W	0h	This bit is implemented as multibit in HW. 1 : DBG Reset by writing to CR4 debug register will trigger MSS subsystem reset. 0 : Trigger CR4 only reset
23-16	SYSRSTCLKGATEEN	R/W	0h	0xAD : Gate MSS clock before MSS subsystem reset and ungate after reset assertion. 0x0 : Dont gate clock before reset assertion.
15-8	SYSRSTIDLECHKEN	R/W	0h	0xAD : Reset MSS only after cross subsystem buses are in idle state. I.e : No pending transaction. This is applicable for MSS Wdog reset and SW reset using SYSRST 0X0: Dont wait for cross susbsytem to be idle. - This can hang the bus when the reset happens when there is cross susbsystem transaction going on.
7-0	SYSRST		0h	Write 0xAD to assert a MSS subsystem only reset.Self clearing By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.

4.8.2.2 SOFTRST1 Register (Offset = 4h) [reset = 0h]

SOFTRST1 is shown in Figure 4-514 and described in Table 4-543.

Return to the Table 4-541.

Figure 4-514. SOFTRST1 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMARST								DCCBRST

DCCARST								CR4SYSRST							
R/W-0h								0h							

Table 4-543. SOFTRST1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	DMARST	R/W	0h	Write 0xAD to assert a DMA only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
23-16	DCCBRST	R/W	0h	Write 0xAD to assert a DCCB only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
15-8	DCCARST	R/W	0h	Write 0xAD to assert a DCCA only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
7-0	CR4SYSRST		0h	Write 0xAD to assert a MSS CR4 only reset.Self clearing By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.

4.8.2.3 SOFTRST2 Register (Offset = 8h) [reset = 0h]

SOFTRST2 is shown in Figure 4-515 and described in Table 4-544.

Return to the Table 4-541.

Figure 4-515. SOFTRST2 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VIMRST								ESMRST								RTIRST								UARTARST							
R/W-0h								R/W-0h								R/W-0h								R/W-0h							

Table 4-544. SOFTRST2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	VIMRST	R/W	0h	Write 0xAD to assert a VIM only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
23-16	ESMRST	R/W	0h	Write 0xAD to assert a ESM only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
15-8	RTIRST	R/W	0h	Write 0xAD to assert a RTI only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
7-0	UARTARST	R/W	0h	Write 0xAD to assert a UARTA/SCIA only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.

4.8.2.4 SOFTRST3 Register (Offset = Ch) [reset = 0h]

SOFTRST3 is shown in Figure 4-516 and described in Table 4-545.

Return to the Table 4-541.

Figure 4-516. SOFTRST3 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRCRST								SCRRST								CRCRST								WDTRST							
R/W-0h								0h								R/W-0h								R/W-0h							

Table 4-545. SOFTRST3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	FRCRST	R/W	0h	Write 0xAD to assert a FRC only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
23-16	SCRRST		0h	Reserved. Altering the reset value can impact Chip functionality.
15-8	CRCRST	R/W	0h	Write 0xAD to assert a CRC only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.
7-0	WDTRST	R/W	0h	Write 0xAD to assert a WDT (RTI used for watch dog) only reset. By design reset will happen either lower 4 bit is 0XD or Upper four bit is 0xA.

4.8.2.5 MCUIFSOFTRST0 Register (Offset = 10h) [reset = 0h]

MCUIFSOFTRST0 is shown in Figure 4-517 and described in Table 4-546.

Return to the Table 4-541.

Figure 4-517. MCUIFSOFTRST0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Complex bit access types are encoded to fit into small table cells. Table 4-928 shows the codes that are used for access types in this section.

Table 4-632. DSS_REG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

4.8.4.1 RTIEVENTCAPTURESEL Register (Offset = 50h) [reset = 0h]

RTIEVENTCAPTURESEL is shown in Figure 4-886 and described in Table 4-929.

Return to Summary Table.

Figure 4-600. RTIEVENTCAPTURESEL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NU2									EVT1							NU1									EVT0							
R-0h									R/W-0h							R-0h									R/W-0h						

Table 4-633. RTIEVENTCAPTURESEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	NU2	R	0h	
22-16	EVT1	R/W	0h	Setting the source of interrupt for Counter value capture for RTI1 Event1
15-7	NU1	R	0h	
6-0	EVT0	R/W	0h	Setting the source of interrupt for Counter value capture for RTI1 Event0.

4.8.4.2 CQCFG1 Register (Offset = 6Ch) [reset = 40100000h]

CQCFG1 is shown in Figure 4-887 and described in Table 4-930.

Return to Summary Table.

Figure 4-601. CQCFG1 Register

31	30	29	28	27	26	25	24
NU3	CQ2BASEADDR						
R-0h	R/W-100h						
23	22	21	20	19	18	17	16
CQ2BASEADDR			CQ1BASEADDR				
R/W-100h			R/W-80h				
15	14	13	12	11	10	9	8
CQ1BASEADDR			CQ0BASEADDR				
R/W-80h			R/W-0h				
7	6	5	4	3	2	1	0
CQ0BASEADDR				CQ96BITPACKEN	NU	CQDATAWIDTH	
R/W-0h				R/W-0h	R-0h	R/W-0h	

Table 4-634. CQCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NU3	R	0h	
30-22	CQ2BASEADDR	R/W	100h	128-bit Address offset which inidcates the start address for storing CQ0 (ADC/RxIF Saturation Detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
21-13	CQ1BASEADDR	R/W	80h	128-bit Address offset which inidcates the start address for storing CQ0 (Signal Image Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
12-4	CQ0BASEADDR	R/W	0h	128-bit Address offset which inidcates the start address for storing CQ0 (Wide Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
3	CQ96BITPACKEN	R/W	0h	This is used to pack the CQ data into only the LSB 96 bits of each row of the CQ memory. This can be used in 3 channel mode of LVDS where the ADC data and Chirp Params occupy only LSB 96 bits of each memory row.
2	NU	R	0h	
1-0	CQDATAWIDTH	R/W	0h	This is used to appropriately pack the valid CQ data bits in appropriate bits in the CQ memory. 00, 01->Raw 16, 10-->Raw 12, 11-->Raw14

4.8.4.3 TPCCPARSTATCFG Register (Offset = 80h) [reset = 0h]

TPCCPARSTATCFG is shown in Figure 4-888 and described in Table 4-931.

Return to Summary Table.

Figure 4-602. TPCCPARSTATCFG Register

31	30	29	28	27	26	25	24
NU							
R-0h							
23	22	21	20	19	18	17	16

R-0h							
15	14	13	12	11	10	9	8
NU					TPCCPARITYTSTEN	TPCCPARITYEN	TPCCPARITYCLR
R-0h					R/W-0h	R/W-0h	0h
7	6	5	4	3	2	1	0
TPCCPARITYSTAT							
R-0h							

Table 4-635. TPCCPARSTATCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	NU	R	0h	
10	TPCCPARITYTSTEN	R/W	0h	Enable bit for the self test of the Parity logic in TPCC
9	TPCCPARITYEN	R/W	0h	Enable bit for the Parity computation in TPCC
8	TPCCPARITYCLR		0h	Write 0x1 to clear the status. This is a special access type; a write to this field generates a pulse.
7-0	TPCCPARITYSTAT	R	0h	Parity address from TPCC

4.8.4.4 TPTC0WRMPUSTADD0 Register (Offset = 104h) [reset = 0h]

TPTC0WRMPUSTADD0 is shown in Figure 4-889 and described in Table 4-932.

Return to Summary Table.

Figure 4-603. TPTC0WRMPUSTADD0 Register

Table 4-700. DMMSWINT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	NU2	R	0h	Not Used
22	DMMCQWREN	R/W	0h	CQ Write Enable from DMM. 0 --> Write to CQ memory will happen from DFE and Ping-pong select will come from HW FSM (same as ADC Buffer ping-pong select). 1 --> Write to CQ memory will happen from CQ_W slave port in DSS interconnect using DMM as master and Ping-pong select will come from DMMCQPINPONSEL register.
21	DMMCQPINPONSEL	R/W	0h	CQ Ping Pong select for HIL Mode
20	DMMCPBPMMEMSEL	R/W	0h	Select signal for Muxing between HW Registers/Memory for CPBPM data. 0 --> Read access from CPBPM_MEM slave in DSS interconnect will be routed to HW Registers which is populated by DFE/RampGen, 1 --> Read access from CPBPM_MEM slave in DSS interconnect will be routed to appropriate CPBPM memory (Ping/Pong).
19	DMMCPBPMWREN	R/W	0h	CPBPM Write Enable from DMM. 0 --> Ping-pong select will come from HW FSM (same as ADC Buffer ping-pong select). 1 --> Ping-pong select will come from DMMCPBPMPINPONSEL register.
18	DMMCPBPMPINPONSEL	R/W	0h	CP BPM Ping Pong select for HIL Mode
17	DMMADCBUFWREN	R/W	0h	ADC Buffer Write Enable from DMM. 0 --> Write to ADC BUF memory will happen from DFE and Ping-pong select will come from HW FSM (same as ADC Buffer ping-pong select). 1 --> Write to CQ memory will happen from ADCBUF_W slave port in DSS interconnect using DMM as master and Ping-pong select will come from DMMADCBUFPINPONSEL register.
16	DMMADCBUFPINPONSEL	R/W	0h	ADC Buffer Ping Pong select for HIL Mode
15-0	NU1	R	0h	Not Used

4.8.4.69 DSSINTRCFG Register (Offset = 270h) [reset = 0h]

DSSINTRCFG is shown in Figure 4-954 and described in Table 4-997.

Return to Summary Table.

Table 4-719. GEMPWRSMCFG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18	GEMEVENTMASK	R/W	1h	Mask bit for events going to DSP. When this bit is set (during GEM sleep/power down mode), the events are monitored outside and will be available for DSP to read and clear them once GEM wakes-up. The monitored events can be read from PWRSMEVNTMONSTATx registers.
17	PWRSMLRSTHALT	R/W	1h	Signal to halt DSP Power cycle state machine before de-asserting LRST of DSP. This is used during code download for the first time power up.
16	PWRSMSLEEPTRIG		0h	Sleep mode trigger for DSP power down state machine. This is honoured only when DSP is in GEM_ON state: it is a wspecial access type; a write to this field generates a pulse.
15-0	RESERVED	R	0h	Reserved

4.8.4.88 PWRSMWAKEMASK0 Register (Offset = 2D4h) [reset = FFFFFFFFh]

PWRSMWAKEMASK0 is shown in Figure 4-973 and described in Table 4-1016.

Return to Summary Table.

Table 4-735. ADCBUFCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	Reserved
15	ADCBUFCONTSTOPPL	W	0h	Stop Pulse for Continuous mode. The data capture will stop once this register is set. Continuous mode is expected to be only used for CZ and ADC Buffer Testpattern mode
14	ADCBUFCONTSTRTPL	W	0h	Start Pulse for Continuous mode. The data capture will start from Address 0 once this register is set. All the other configurations like Enable, Sample Count are expected to be programmed before this pulse. Continuous mode is expected to be only used for CZ and ADC Buffer Testpattern mode
13	ADCBUFCONTMODEEN	R/W	0h	Continuous mode enable for ADC Buffer. This is set when a fixed number of samples have to be stored in Ping/Pong and not depend on Chirp time-lines (Eg: Analog Lab characterization to stream out continuous data from DFE). Continuous mode is expected to be only used for CZ and ADC Buffer Testpattern mode
12	ADCBUFWRITEMODE	R/W	0h	This needs to be programmed to 0x1 in 16xx 0 --> Interleaved, 1 --> Non-interleaved
11-10	RESERVED	R/W	0h	Reserved
9	RX3EN	R/W	0h	Enable for Rx3 write
8	RX2EN	R/W	0h	Enable for Rx2 write
7	RX1EN	R/W	0h	Enable for Rx1 write
6	RX0EN	R/W	0h	Enable for Rx0 write
5	ADCBUFIQSWAP	R/W	0h	0 --> I is stored in LSB and Q is stored in MSB 1 --> Q is stored in LSB and I is stored in MSB
4-3	RESERVED	R/W	0h	Reserved
2	ADCBUFREALONLYMODE	R/W	0h	0-->Complex Data mode, 1-->Real data mode
1-0	RESERVED	R/W	0h	Reserved

4.8.4.104 ADCBUFCFG2 Register (Offset = 340h) [reset = 02000000h]

ADCBUFCFG2 is shown in Figure 4-989 and described in Table 4-1032.

Return to Summary Table.

Table 4-738. ADCBUFCFG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25-21	ADCBUFNUMCHRPPONG	R/W	0h	Number of chirps to be stored in Pong buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Ping
20-16	ADCBUFNUMCHRPPING	R/W	0h	Number of chirps to be stored in Ping buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Pong
15-0	ADCBUFSAMPCNT	R/W	400h	No of samples to store in each Ping and Pong register in continuous mode of ADC Buffer. In real only mode this refers to the number of real samples and in complex mode, this refers to number of complex samples. This refers to the number of samples per channel. This counter increments once for every new sample from DFE (as long as 1 or more channels are enabled). The max allowed value varies depending on other configurations (No of channels enabled and real/complex data). Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode

4.8.4.107 STCPBISTSMCFG1 Register (Offset = 34Ch) [reset = 18h]

STCPBISTSMCFG1 is shown in Figure 4-992 and described in Table 4-1035.

Return to Summary Table.

CQ0BASEADDR				CQ96BITPACKEN	NU	CQDATAWIDTH	
R/W-0h				R/W-0h	R-0h	R/W-0h	

Table 4-930. CQCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	NU3	R	0h	
30-22	CQ2BASEADDR	R/W	100h	128-bit Address offset which inidcates the start address for storing CQ0 (ADC/RxIF Saturation Detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
21-13	CQ1BASEADDR	R/W	80h	128-bit Address offset which inidcates the start address for storing CQ0 (Signal Image Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
12-4	CQ0BASEADDR	R/W	0h	128-bit Address offset which inidcates the start address for storing CQ0 (Wide Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
3	CQ96BITPACKEN	R/W	0h	This is used to pack the CQ data into only the LSB 96 bits of each row of the CQ memory. This can be used in 3 channel mode of LVDS where the ADC data and Chirp Params occupy only LSB 96 bits of each memory row.
2	NU	R	0h	
1-0	CQDATAWIDTH	R/W	0h	This is used to appropriately pack the valid CQ data bits in appropriate bits in the CQ memory. 00, 01->Raw 16, 10-->Raw 12, 11-->Raw14

4.9.4.3 TPCCPARSTATCFG Register (Offset = 80h) [reset = 0h]

TPCCPARSTATCFG is shown in Figure 4-888 and described in Table 4-931.

Return to Summary Table.

Figure 4-888. TPCCPARSTATCFG Register

31	30	29	28	27	26	25	24

Table 4-1034. ADCBUFCFG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25-21	ADCBUFNUMCHRPPONG	R/W	0h	Number of chirps to be stored in Pong buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Ping
20-16	ADCBUFNUMCHRPPING	R/W	0h	Number of chirps to be stored in Ping buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Pong
15-0	ADCBUFSAMPCNT	R/W	400h	No of samples to store in each Ping and Pong register in continuous mode of ADC Buffer. In real only mode this refers to the number of real samples and in complex mode, this refers to number of complex samples. This refers to the number of samples per channel. This counter increments once for every new sample from DFE (as long as 1 or more channels are enabled). The max allowed value varies depending on other configurations (No of channels enabled and real/complex data). Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode

4.9.4.107 STCPBISTSMCFG1 Register (Offset = 34Ch) [reset = 18h]

STCPBISTSMCFG1 is shown in Figure 4-992 and described in Table 4-1035.

Return to Summary Table.

RADAR Subsystem

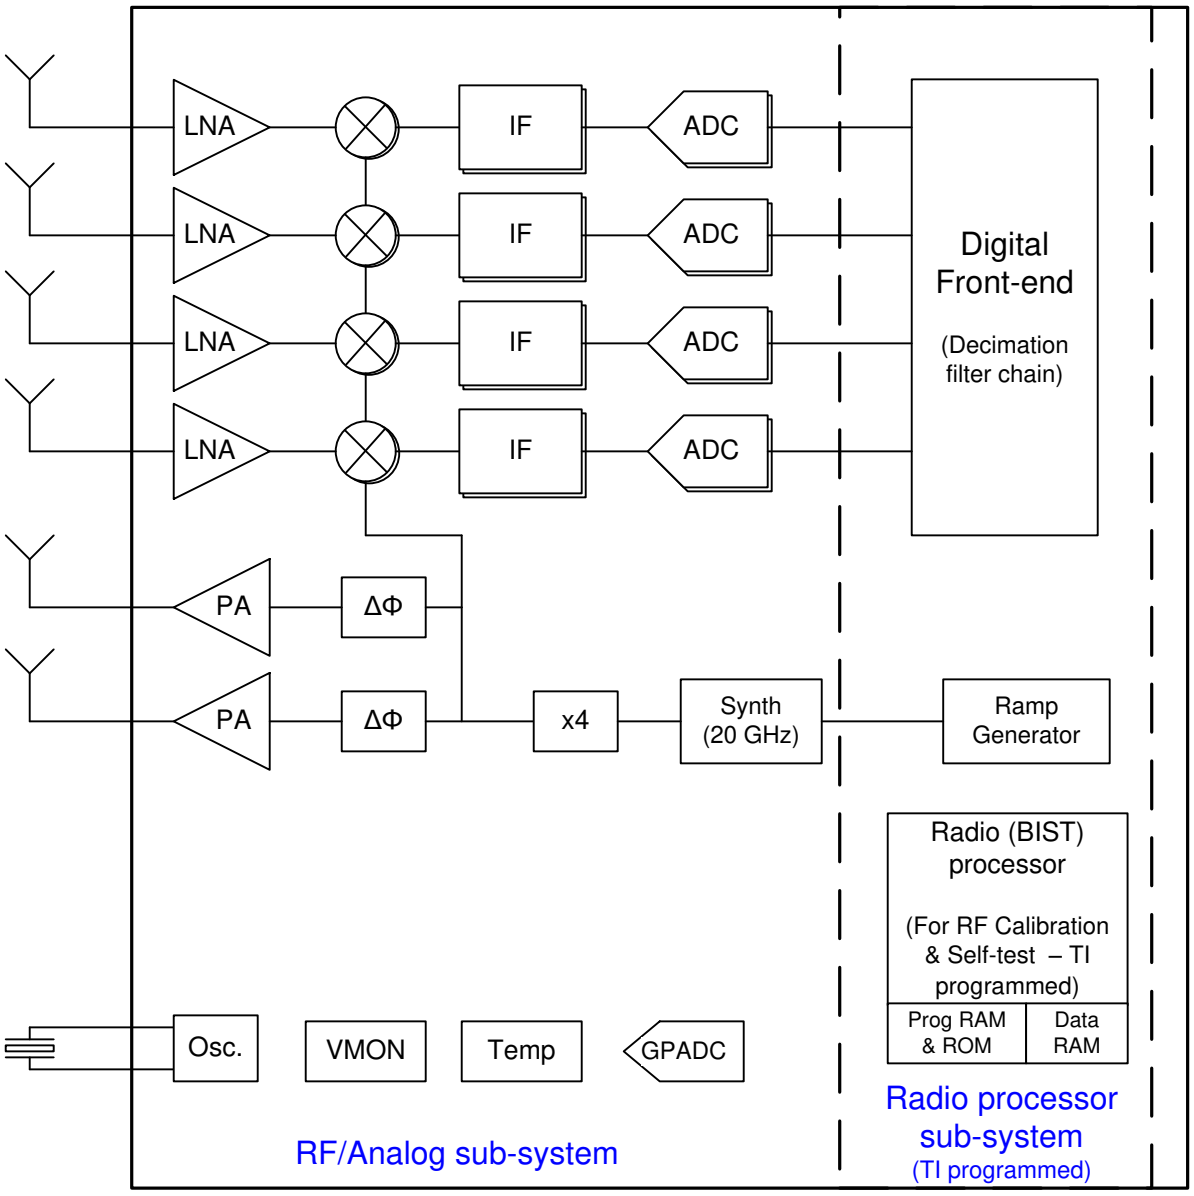
Topic **Page**

5.1 Block Diagram **1396**

5.1 Block Diagram

Figure 5-1 shows the RADAR subsystem block diagram.

Figure 5-1. RADAR Subsystem Block Diagram



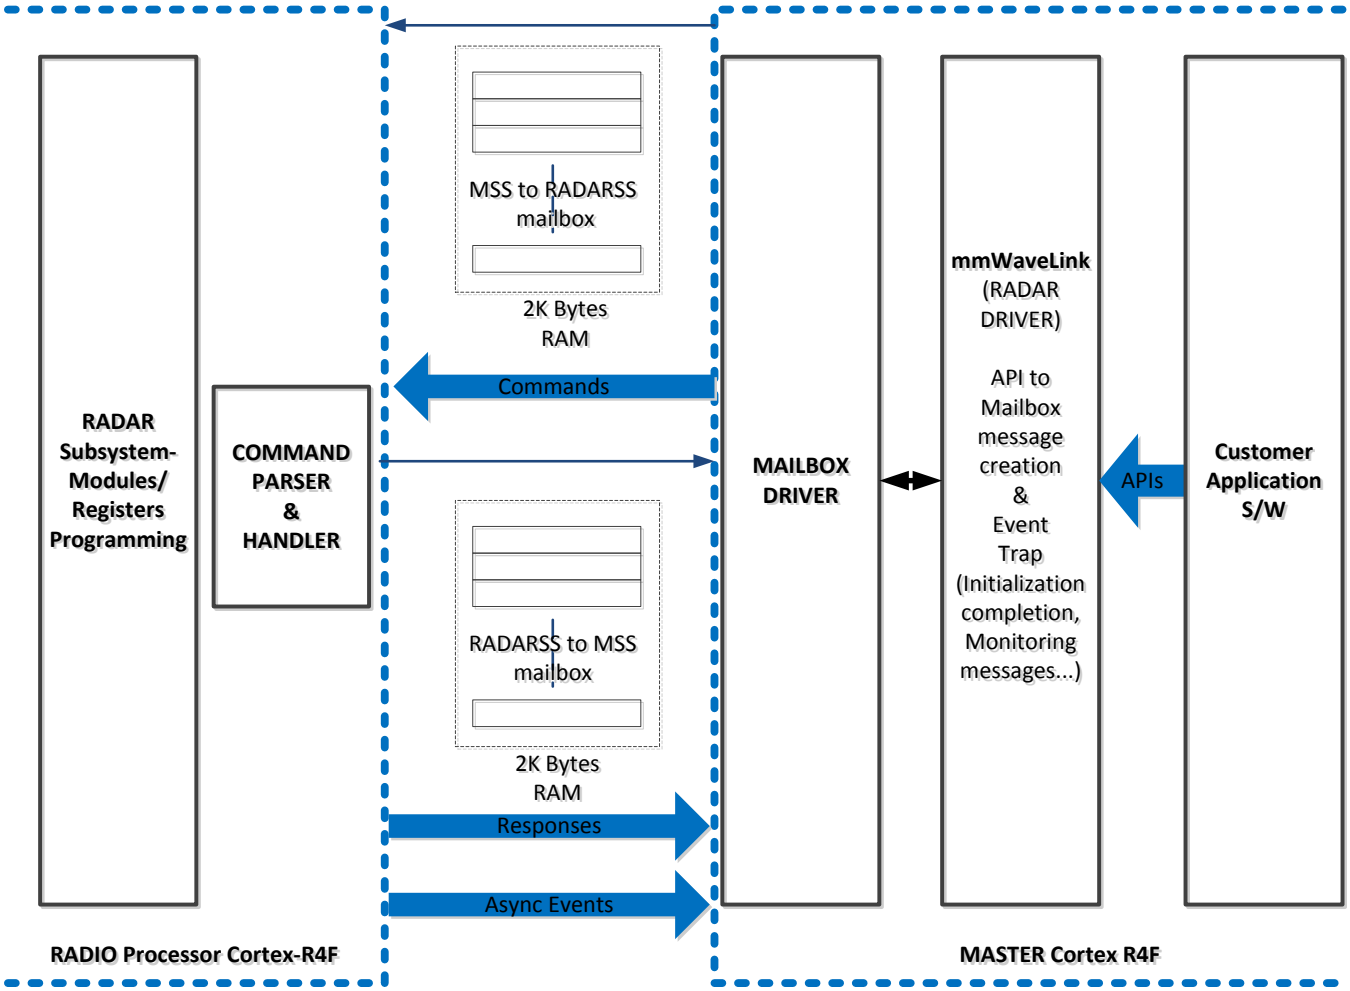
The RADAR subsystem consists of the RF/Analog subsystem and the radio processor subsystem.

The RF/analog subsystem implements the frequency-modulated continuous-wave transceiver system with RF and analog circuitry – namely, the synthesizer, PA, LNA, mixer, IF, and ADC. This subsystem also includes the crystal oscillator and temperature sensors. The two transmit channels can be operated up to a maximum of two at a time simultaneously. The four receive channels can all be operated simultaneously.

The radio processor subsystem includes the digital front-end, the ramp generator, and an internal processor for controlling and configuring the low-level RF/analog and ramp generator registers, based on well-defined API messages from the master subsystem. This radio processor is programmed by TI, and addresses both RF calibration needs and some basic self-test and monitoring functions (BIST); this processor is not available directly for customer use. The digital front-end filters and decimates the raw sigma-delta ADC output, and provides the final ADC data samples at a programmable sampling rate.

The programming of this RADAR subsystem is abstracted at a TI-defined API interface. Figure 5-2 below explains the high-level architecture and programming model.

Figure 5-2. Programming Model



The radar subsystem is accessed through a well-defined set of APIs. The application software running on the master Cortex-R4F processor, through the API call, invokes the mmWaveLink-Radar driver, which then converts these APIs into mailbox-based messages. When a message is written into the mailbox memory, an interrupt is raised to the radio processor, which then passes the message and executes the command conveyed through the mailbox message. A mailbox message read event is raised to the master CR4F to indicate the radio processor has read the message. For more details, refer to the API interface document.

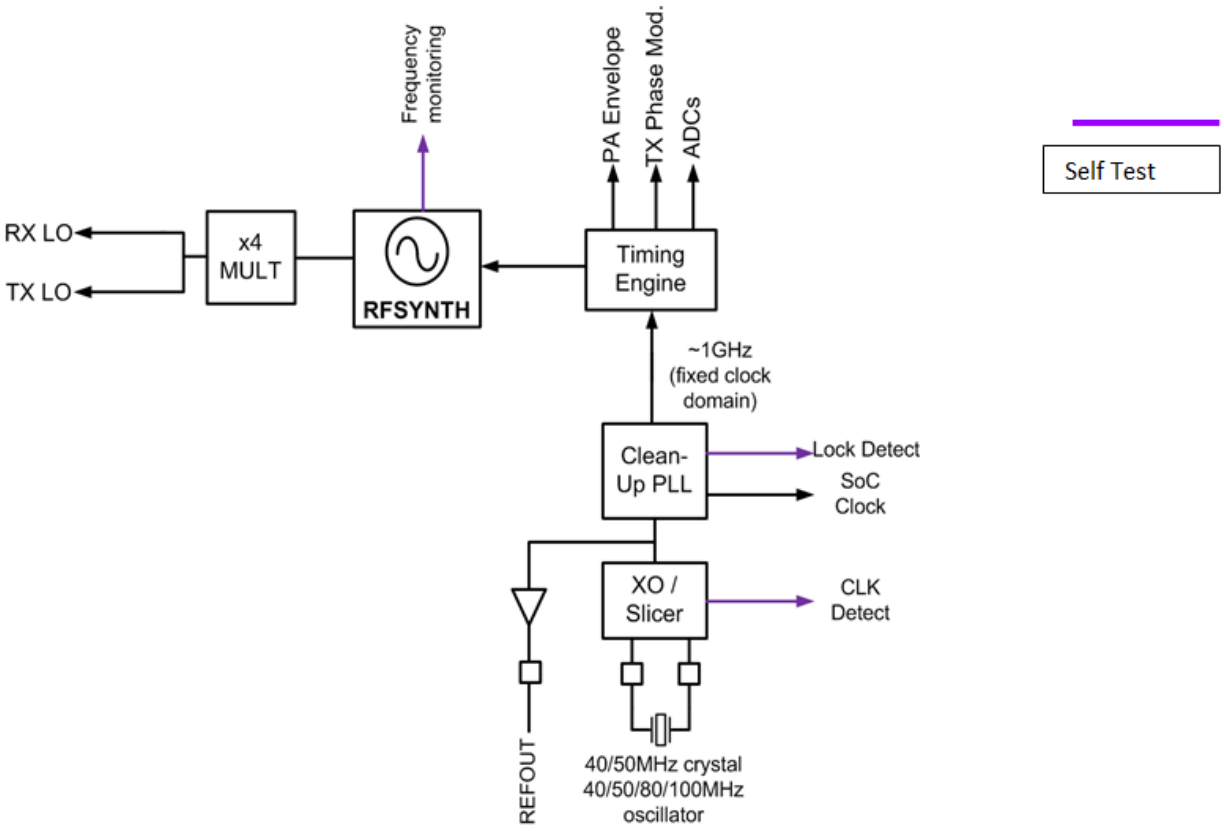
5.1.1 Clock Subsystem

The 16xx/14xx/18xx/68xx clock subsystem generates 76-71 (14xx/16xx/18xx) or 60-64 (68xx) GHz from an input reference of a 40-MHz crystal. The subsystem has a built-in oscillator circuit, followed by a clean-up PLL and an RF synthesizer circuit, as shown in Figure 5-3. The output of the RF synthesizer is then processed by an X4 multiplier to create the required frequency in the 76-71 (14xx/16xx/18xx) or 60-64 (68xx) GHz spectrum. The RF synthesizer output is modulated by the timing engine block to create the required waveforms for effective sensor operation. The timing engine is highly flexible and is programmed through the R4F-based radio controller subsystem. For details on waveforms and programming models, refer to the Radio Control API application note.

The clean-up PLL provides a reference clock for the host processor after system wakeup.

The clock subsystem has built-in mechanisms for detecting the presence of a crystal and monitoring the quality of the generated clock.

Figure 5-3. Clocking Subsystem

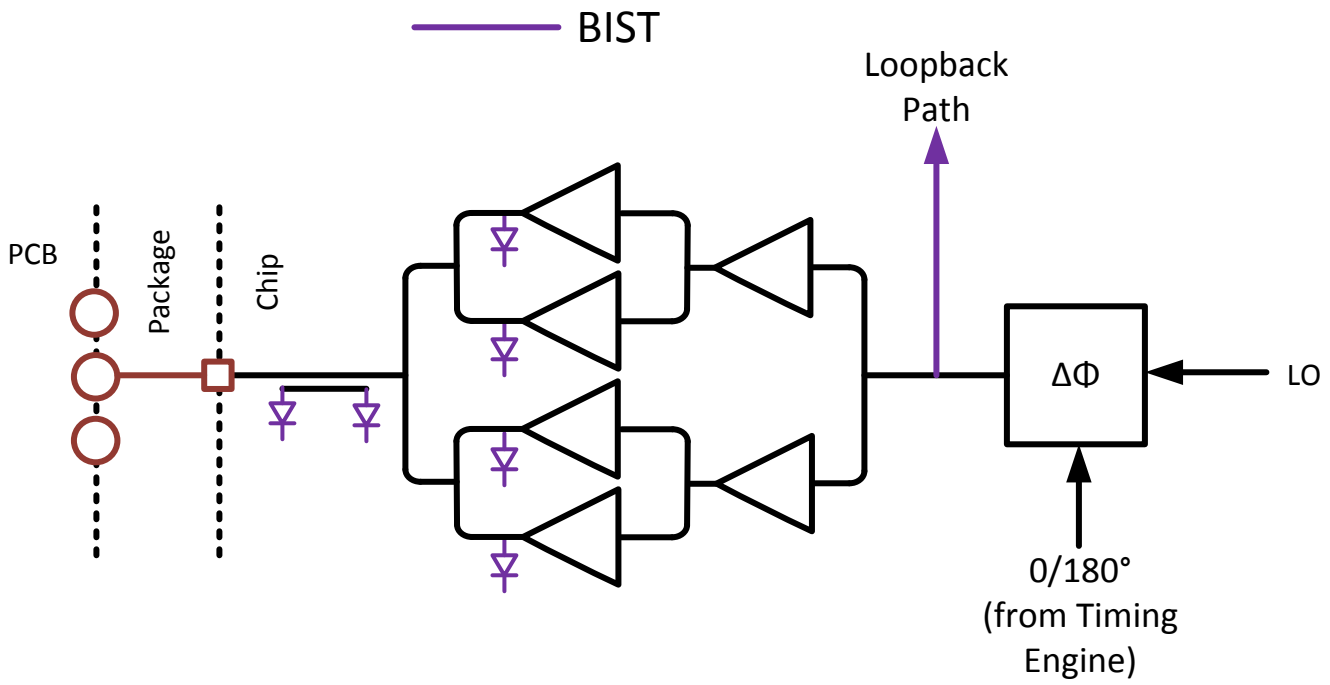


5.1.2 Transmit Subsystem

The transmit subsystem consists of three parallel transmit chains (other than the x16xx which has two), each with independent phase and amplitude control, as shown in Figure 5-4. Both transmit chains can be operational at the same time. The device supports binary phase modulation for MIMO radar and interference mitigation.

Each transmit chain is capable of delivering optimal power at the antenna port on the PCB, and supports programmable back-off for system optimization.

Figure 5-4. Transmit Subsystem



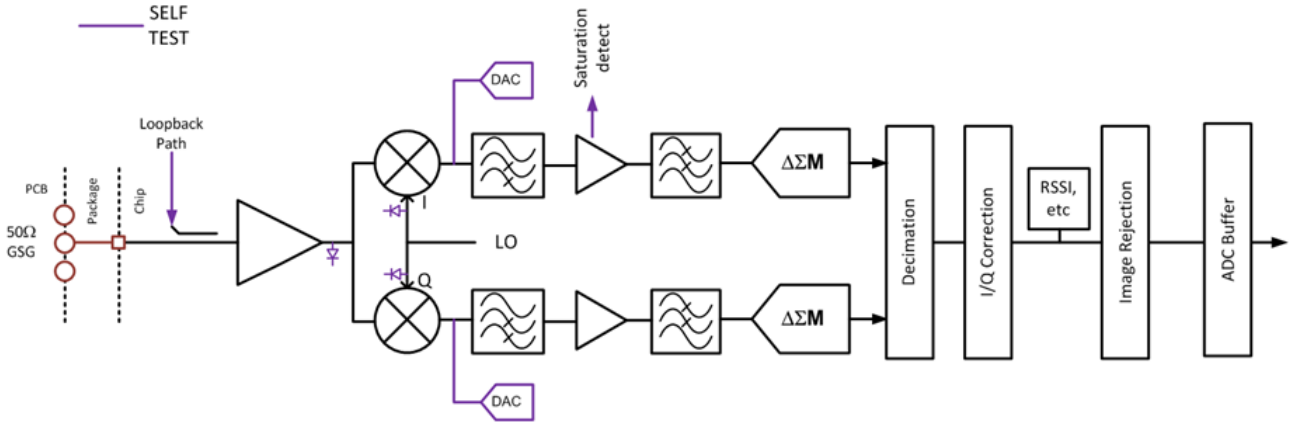
5.1.3 Receive Subsystem

The 16xx/14xx/18xx/68xx receive subsystem consists of four parallel channels, as shown in Figure 5-5. A single receive channel consists of an LNA, mixer, IF filtering, A2D conversion, and decimation. All four receive channels can be operational at the same time. An individual power down option is also available for system optimization.

Unlike conventional read-only receivers, the 16xx/14xx/18xx/68xx device supports a complex baseband architecture which uses quadrature mixer, dual IF, and ADC chains to provide complex I and Q outputs for each receiver channel. Refer to the Complex Receiver Baseband Application Note for further details.

The 16xx/14xx/18xx/68xx is targeted for fast chirp systems. The bandpass IF chain has configurable lower cutoff frequencies above 350 kHz, and can support bandwidths up to 15 MHz.

Figure 5-5. Receive Subsystem (Per Channel)



Master Subsystem Cortex-R4F

Topic **Page**

6.1 Introduction 1401
6.2 Cortex-R4F Subsystem 1401

6.1 Introduction

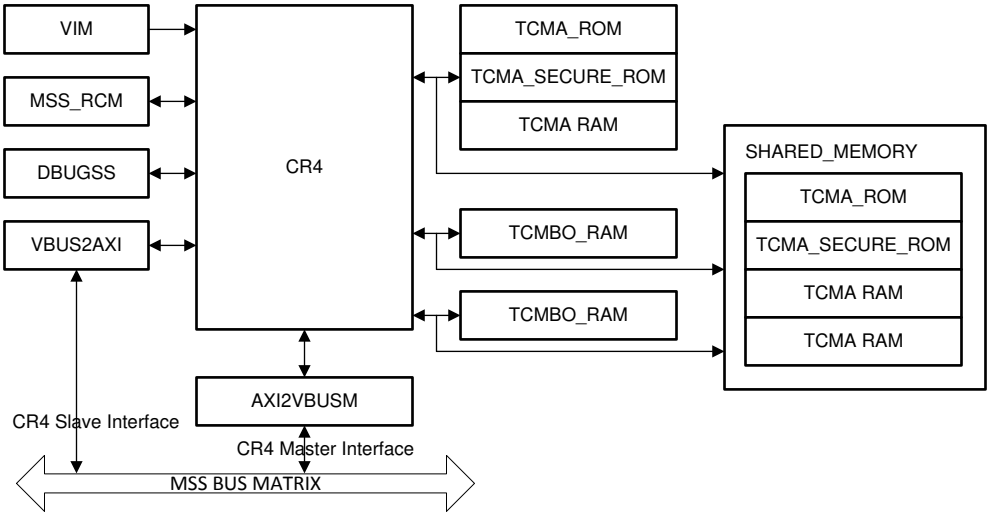
The master system includes an ARM Cortex R4F processor, clocked using a MSS_VCLK clock with a maximum operating frequency of 200 MHz. User applications executing on this processor control the overall operation of the device, including radar control through well-defined API messages, radar signal processing (assisted by the radar hardware accelerator), and peripherals for external interfaces.

Master (control) system enables autonomous operation of the device as a radar-on-a-chip sensor.

6.2 Cortex-R4F Subsystem

6.2.1 Cortex-R4F Integration

Figure 6-1. Cortex-R4F Integration



Features of Cortex R4F supported:

- No Icache/Dcache support
- TCMA, TCMB RAM/ROM supported
- Little Endianess only
- Memory protection supported

6.2.2 Tightly Coupled Memories

See the device-specific Integration chapter for

- Available dedicated TCMA RAM and TCMB RAM sizes for the Cortex-R4F processor in the master subsystem
- Total available L3 RAM in the device

A portion of L3 shared memory can be allotted to the Cortex-R4F as additional TCM, to further increase the TCMA and TCMB RAM. See the device-specific DSS_L3 chapter for details on sharing available L3 memory as MSS Coretex-R4F TCM.

6.2.3 Memory Module Hardware Initialization

The RAM memory can be initialized by using the dedicated auto-initialization hardware. The TCRAM wrapper initializes the entire memory when the auto-init is enabled for the RAM. All RAM data memory is initialized to zeros and the ECC memory is initialized to the correct ECC value for zeros, that is, 0x0C.

Direct Memory Access Controller (DMA)

The DMA controller is used to transfer data between two locations in the memory map in the background of CPU operations. Typically, the DMA is used to:

- Transfer blocks of data between external and internal data memories
- Restructure portions of internal data memory
- Continually service a peripheral

Topic **Page**

7.1 Module Operation **1403**
7.2 Control Registers and Control Packets **1422**
7.3 DMA Request Map **1508**

7.1 Module Operation

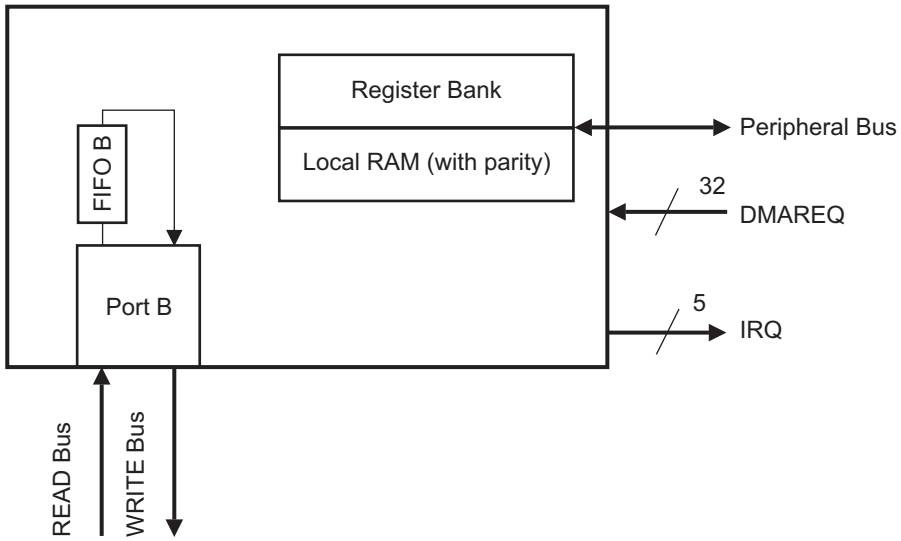
The DMA acts as an independent master in the platform architecture. All DMA memory and register accesses are performed in user mode. If the DMA writes to registers that are only accessible in privileged mode, the write will not be performed.

The DMA registers and its local RAM can only be accessed in privilege mode. Therefore, it is not possible for the DMA to reprogram itself.

7.1.1 Block Diagram

Figure 7-1 gives a detailed view of the DMA internal architecture. DMA data read and write access happens through Port B. FIFO B is 4 levels deep and 64-bits wide. 64 DMA requests go into the DMA that can trigger DMA transfers. Five interrupt request lines go out of the DMA to signal that a certain transfer status is reached. Register banks hold the memory mapped DMA configuration registers. Local RAM consists of DMA control packets and is secured by parity. All the programming and configuration of the DMA controller is done through the peripheral bus.

Figure 7-1. DMA Block Diagram



7.1.2 Memory Space

The DMA controller makes no distinction between program memory and data memory. The DMA controller can transfer to and from any space within the 4 gigabyte physical address map, by programming the absolute address for the source and destination in the control packet. Control packets store the transfer information such as source address, destination address, transfer count and control attributes for each channel.

7.1.3 DMA Data Access

The DMA controller refers to data in three levels of granularity:

- **Element:** Depending on the programmed data type, an 8-bit, 16-bit, 32-bit, or a 64-bit value. The type can be individually selected for the source (read) and destination (write). See Figure 7-2 and Figure 7-3 for an example of the use of elements. An element transfer cannot be interrupted.
- **Frame:** One or more elements to be transferred as a unit. A frame transfer can be interrupted between element transfers. See Figure 7-2 for an example.
- **Block:** One or more frames to be transferred as a unit. Each channel can transfer one block of data (once or multiple times). See Figure 7-3 for an example.

Figure 7-2. Example of a DMA Transfer Using Frame Trigger Source

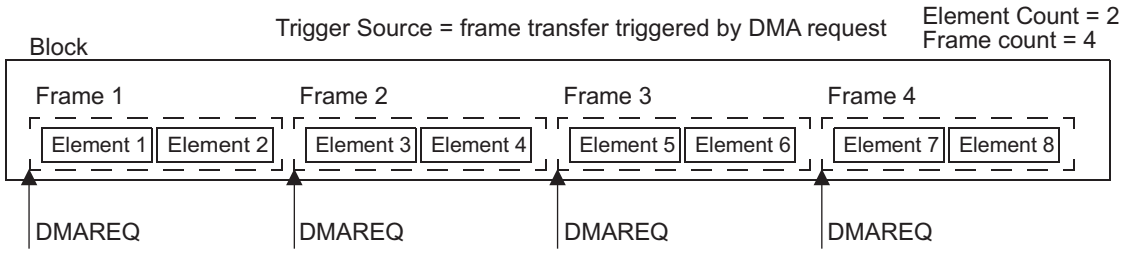


Figure 7-3. Example of a DMA Transfer Using Block Trigger Source

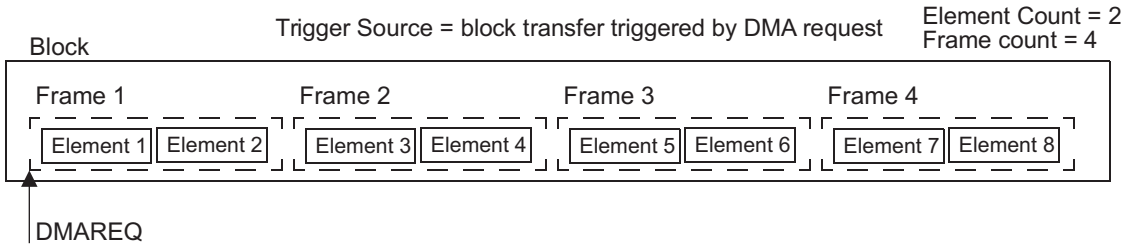

7.1.4 Addressing Modes

There are three addressing modes supported by the DMA controller that can be setup independent for the source and the destination address:

- Constant -- source and/or destination addresses do not change.
- Post incremented -- source and/or destination address are post-incremented by the element size.
- Indexed -- source and/or destination address is post-incremented as defined in the Element Index Offset Register (Section 7.2.2.5) and the Frame Index Offset Register (Section 7.2.2.6).

An unaligned address with respect to the element size is not supported.

7.1.5 DMA Channel Control Packets

There are a total of 16 control packets. Each control packet is associated with a channel in a fixed order. For example, control packet 0 stores channel information for channel 0. The DMA requests can be mapped to the individual channels as described in Section 7.1.8. The mapping scheme between DMA requests and channels is shown in Figure 7-4. Each control packet contains nine fields. The first six fields compose the primary control packet and are programmable during DMA setup. The last three fields compose working control packet and are only readable by the CPU. The working control packets are used to support auto-initiation. The organization of control packets is shown in Figure 7-5.

The primary control packet contains channel information such as source address, destination address, transfer count, element/frame index pointer and channel configuration. Source address, destination address and transfer count also have their respective working images. The three fields of working images compose a working control packet and are not accessible to the CPU in write access.

The first time a DMA channel is selected for a transaction, the following process occurs:

1. The primary control packet is first read by the DMA state machine.
2. Once the channel is arbitrated, the current source address, destination address and transfer count are then copied to their respective working images.
3. When the channel is serviced again by the DMA, the state machine will read both the primary control packet and the working control packet to continue the DMA transaction until the end of an entire block transfer.

When the same channel is requested again, the state machine will start again by reading only the primary control packet and then continue the same process described above. The user software need not set up control packets again because the contents of the primary control packet were never lost. The working images of the control packets are reducing the software overhead and interaction with the DMA module to a minimum.

NOTE: Changing the contents of a channel control packet will clear the corresponding pending bit () if the channel has a pending status. If the control packet of an active channel (as indicated in) is changed, then the channel will stop immediately at an arbitration boundary. When the same channel is triggered again, it will begin with the new control packet information.

7.1.5.1 Initial Source Address

This field stores the absolute 32-bit source address of the DMA transfer.

7.1.5.2 Initial Destination Address

This field stores the absolute 32-bit destination address of the DMA transfer.

Figure 7-4. DMA Request Mapping and Control Packet Organization

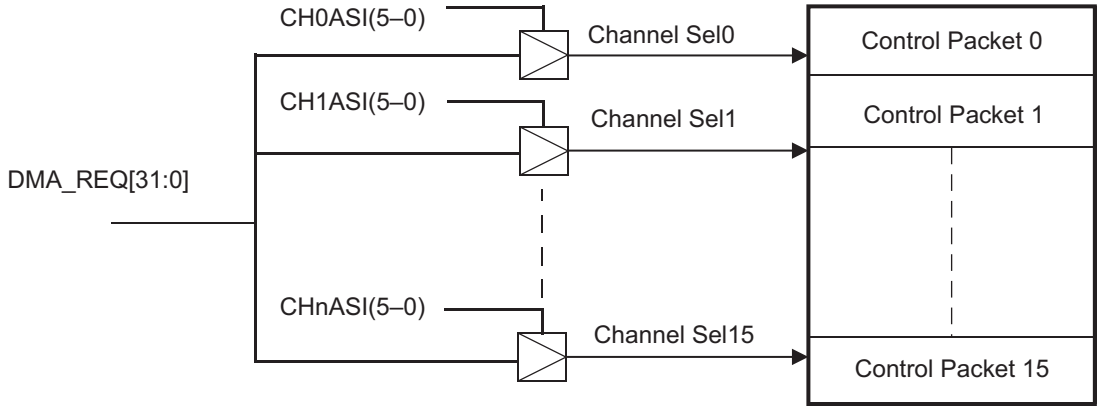

Figure 7-5. Control Packet Organization and Memory Map

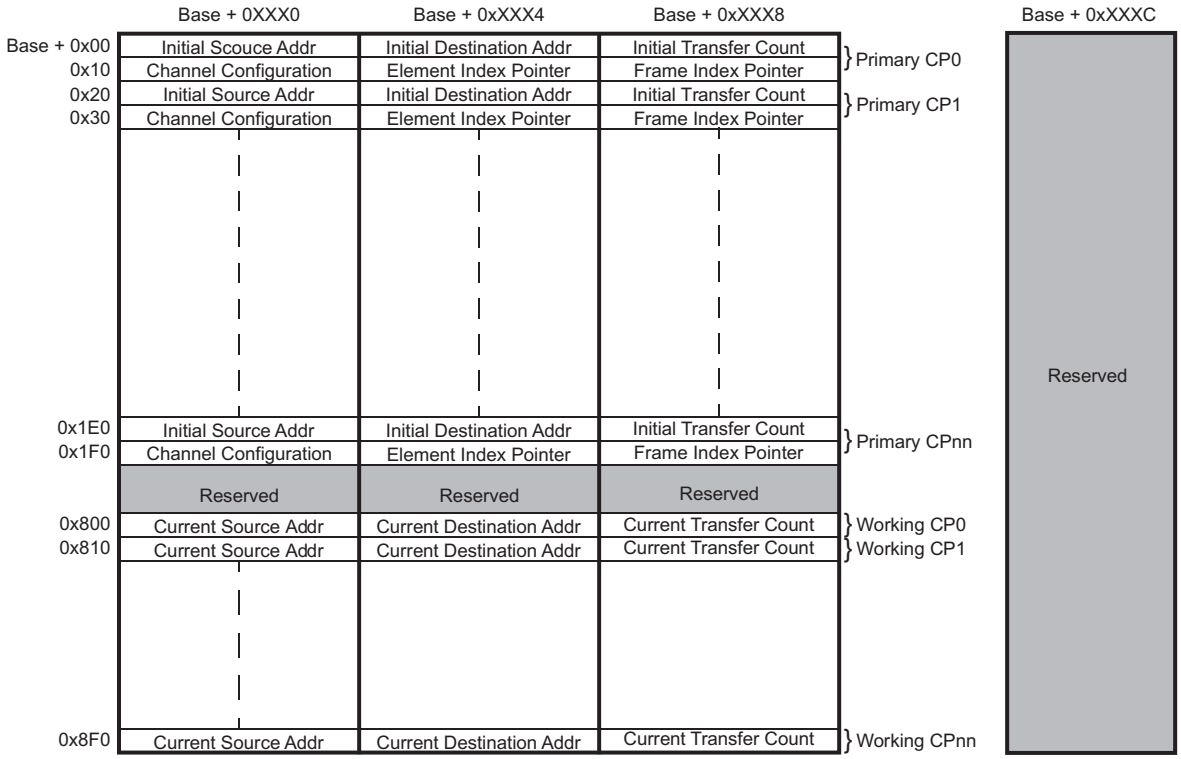


7.1.5.3 Initial Transfer Count

The transfer count field is composed of two parts. The frame transfer count value and the element transfer count value. Each count value is 13 bits wide. As a Single Block transfer maximum of 512 Mbytes of data can be transferred. Element count and frame count are programmed according to the source data structure.

The total transfer size is calculated as:

$$T_{sz} = E_{rsz} \bullet E_{tc} \bullet F_{tc} \quad (1)$$

where

T_{sz} = Total Transfer Size

E_{rsz} = Read Element Size

E_{tc} = Element Transfer Count

F_{tc} = Frame Transfer Count

NOTE: A zero element count with a non-zero frame count or a non-zero element count with a zero frame count are all considered as zero total transfer count. No DMA transaction is initiated with any of the counters set to 0.

7.1.5.4 Channel Configuration Word

The channel configuration defines the following individual parameters

- Read element size
- Write element size
- Trigger type (frame or block)
- Addressing mode for source
- Addressing mode for destination
- Auto-initiation mode
- Next control packet to be triggered at control packet finish (Channel Chaining)

7.1.5.5 Element/Frame Index Pointer

There are 4 index pointers that allow the creation of different types of buffers in RAM and address registers in a structured manner: an element index pointer for source and destination and a frame index pointer for source and destination.

The element index pointer for source and/or destination defines the offset to be added after each element transfer to the source and/or destination address. The frame index pointer for source and/or destination defines the offset to be added to the source and/or destination address after the element count reaches zero. The element and frame index pointers must be defined in terms of the number of bytes of offset. The DMA controller does not adjust the element/frame index number according to the element size. An index of 2 means *increment the address by 2* and not by 16 when the element size is 64 bits.

7.1.5.6 Current Source Address

The current source address field contains the current working source address during a DMA transaction. The current source address is incremented during post increment addressing mode or indexing mode.

7.1.5.7 Current Destination Address

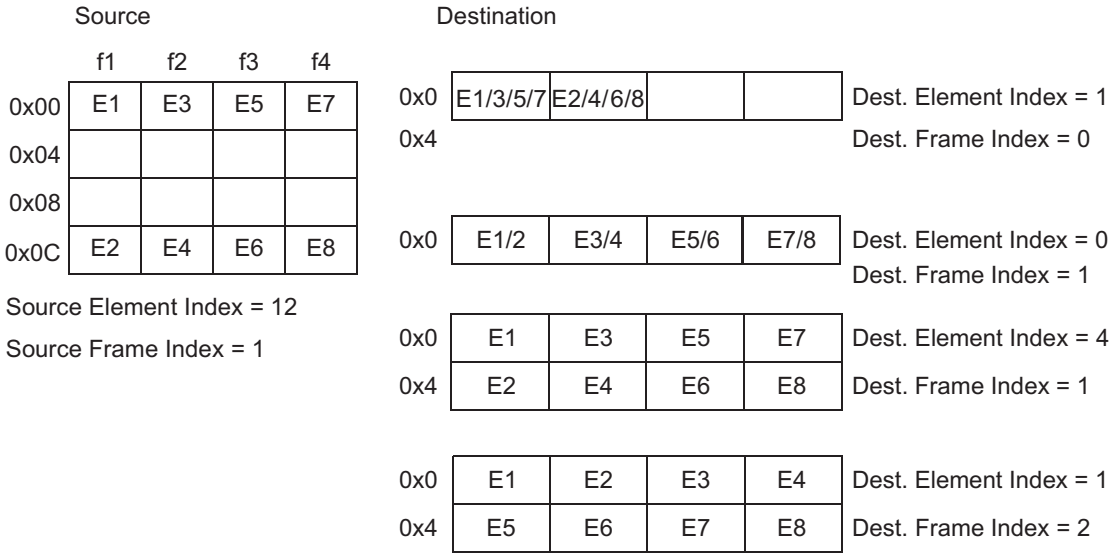
The current destination address field contains the current working destination address during a DMA transaction. The current destination address is incremented during post-increment addressing mode or indexing mode.

7.1.5.8 Current Transfer Count

The current transfer count stores the remaining number of elements to be transferred in a block. It is decremented by one for each element read from the source location.

Figure 7-6, Figure 7-7, and Figure 7-8 show some examples of DMA transfers.

Figure 7-6. DMA Transfer Example 1



The example assumes the following setup.

Read Element Size = 8 bit
Write Element Size = 8 bit
Element Count = 2
Frame Count = 4

Figure 7-7. DMA Indexing Example 1

	f1		f2		f3		f4	
0x0	E1		E5		E9		E13

0x80	E3	E6	E9	E12	E15	E18	E21	E23

Element Index = 64
Frame Index = 4

This example can be applied to either source or destination indexing and assumes the following setup.

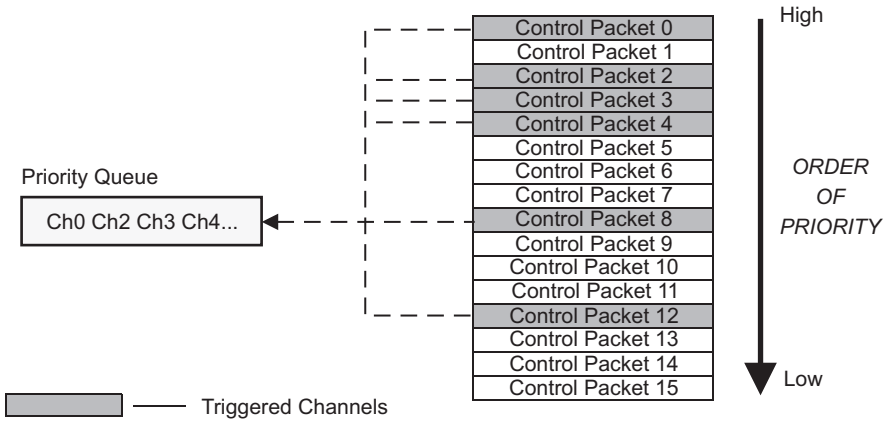
Element Size = 32 bit
Element Count = 3
Frame Count = 8

7.1.6 Priority Queue

User can assign channels in to priority queues to facilitate request handling during arbitration. The port has two priority queues: a high and a low priority queue. The queue can be configured to follow a fixed or rotating priority scheme. Fixed priority is such that the lower the channel number (Figure 7-9), the higher its priority. Rotating priority is based on a round-robin scheme. Initially, the priority list is sorted according to the fixed priority scheme. Channels assigned to the high priority queue are always serviced first according to the selected priority scheme before channels in the low priority queue are serviced. Table 7-1 describes how arbitration is performed according to different priority schemes.

NOTE: Since the DMA controller provides the capability to map any one of the 32 hardware DMA request lines to any channel, the numerical order of the hardware DMA request does not imply any priority. The priority of each hardware DMA request is programmed and determined by software.

Figure 7-9. Fixed Priority Scheme



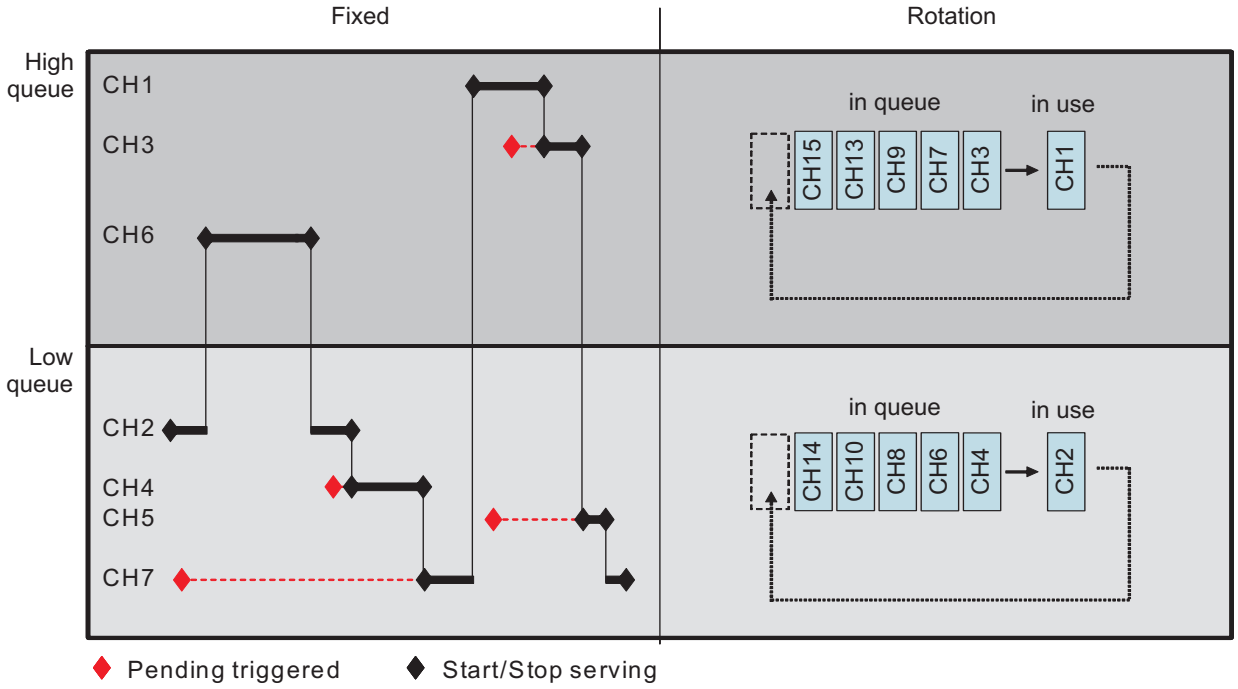
The above figure illustrates that by default Lower the channel number, higher the Priority.

Table 7-1. Arbitration According to Priority Queues and Priority Schemes

Queue	Priority Scheme	Remark
High priority	Fixed	Channels are serviced in an ascending order according to the channel number. The lower the channel number, the higher the priority. A channel will be arbitrated out whenever there is a higher pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero before the next highest pending channel is serviced. When there is no pending channels left in high queue then the DMA switches to service low queue channels.
	Rotating	Channels are arbitrated by using the round-robin scheme. Arbitration is performed when the FIFO is empty. When there are no pending channels left in high queue then the DMA switches to service low queue channels.
Low priority	Fixed	Channels are serviced in an ascending order according to the channel number. The lower the channel number the higher the priority. A channel will be arbitrated out whenever there is a higher-priority pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero, before the next highest pending channel is serviced. If there is a pending channel in the high-priority queue while DMA is servicing a low queue channel then DMA will switch back to service high queue channel after an arbitration boundary.
	Rotating	Channels are arbitrated by using round-robin scheme. Arbitration is performed when the FIFO is empty.

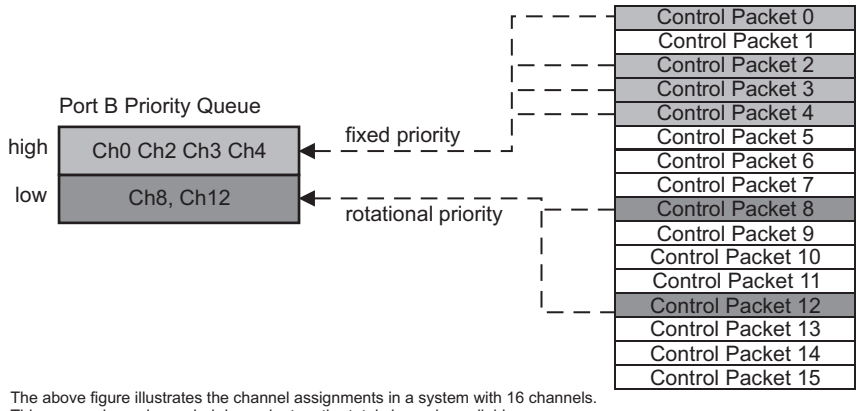
A Simple Priority Queues example in both Fixed and Rotation Scheme is shown in Figure 7-10.

Figure 7-10. Example of Priority Queues



For optimal system performance, the high priority channels should be put in fixed arbitration scheme and low priority channels in the rotating priority scheme as illustrated in Figure 7-11.

Figure 7-11. Example Channel Assignments



1 The above figure illustrates the channel assignments in a system with 16 channels. This approach can be scaled dependent on the total channels available.

7.1.7 Data Packing and Unpacking

The DMA controller automatically performs the necessary data packing and unpacking when the read element size differs from the write element size. Data packing is required when the read element size is smaller than the write element size; data unpacking is required when the read element size is larger than the write element size. When the read element size is equal to the write element size, no packing is performed during read, nor is any unpacking performed during write.

Figure 7-12 shows an example of data unpacking in which the DMA is used to transfer 128 transmit data elements to the MibSPI FIFO buffer. In this example, data unpacking is required because the read element size is 64 while the write element size is 16. The DMA first performs an 64-bit read from the source into its FIFO buffer. After the 64-bit data is read into the DMA FIFO buffer, it must unpack the data into four 16-bit data elements before writing out to the destination. Therefore the DMA would need to perform four 16-bit write operations to the destination.

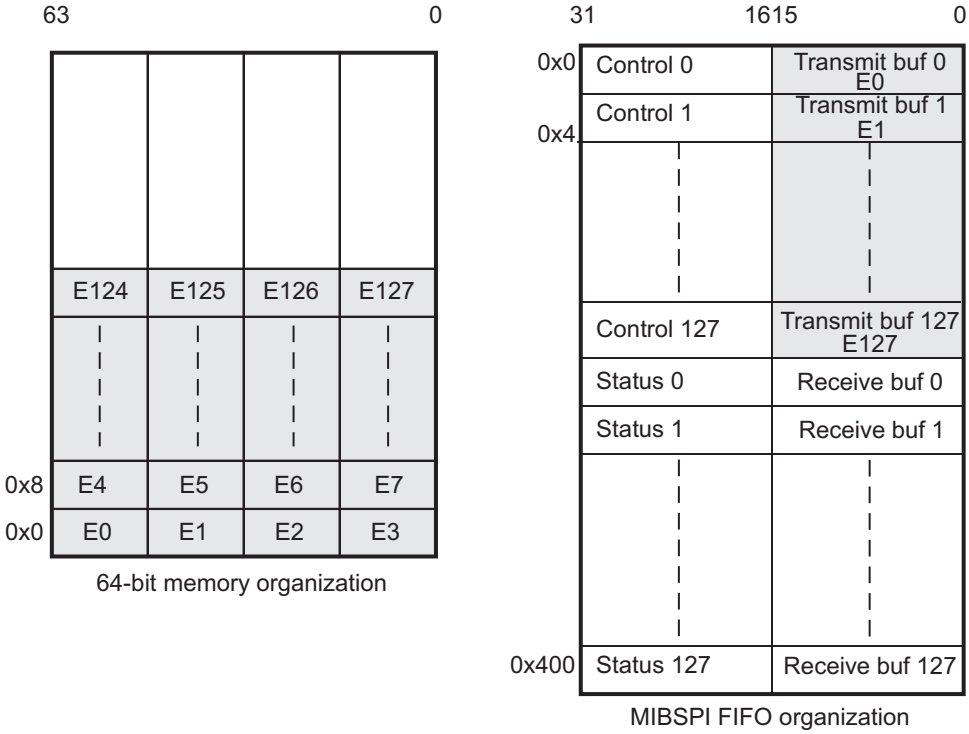
NOTE: In the example in Figure 7-12, to transmit data at the lower bits of the MibSPI, bits 15:0, the destination address should be incremented by a factor of 2.

NOTE: 1) The element Count (Section 7.2.2.3) refers only to the read element.

2) Data unpacking does not require the DMA request. Once the DMA request is received, data from Source is moved in to FIFO and unpacking happens until the FIFO is empty.

3) DMA assumes the destination is always ready and will perform write immediately. In case of data unpacking and Constant Addressing Mode write (Section 7.2.2.4 (1 - 0) = 0) the destination data will be overwritten by next data or next data might be skipped in case the destination has overflow protection (eg., SCITD register). User should configure DMA to avoid data unpacking if the Destination is configured as Constant Addressing Mode write to avoid data loss.

Figure 7-12. Example of DMA Data Unpacking



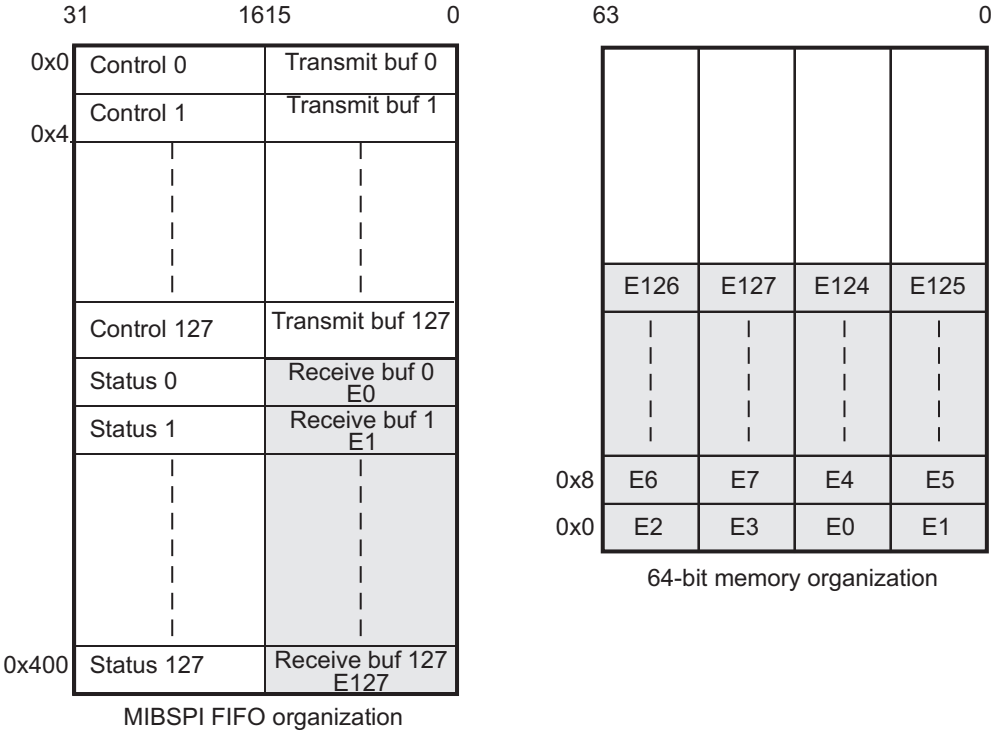
In this example, initialization of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 64 bit
Write Element Size = 16 bit
Element Count = 32
Frame Count = 1
Source Element Index = n/a, use post increment addressing mode
Source Frame Index = n/a, use post increment addressing mode
Destination Element Index = 4
Destination Frame Index = 0

When the read element size is smaller than the write element size, the DMA controller needs to perform data packing. The number of elements to pack is equal to the ratio between the write element size and read element size. In the example in Figure 7-13, the read element size is 16 bits and the write element size is 64 bits. The DMA controller would first pack the first four elements by performing four consecutive 16-bit read accesses of E0, E1, E2, and E3 into the first word of the DMA's internal FIFO. The DMA controller would then perform one single 64-bit write operation to transfer the data to the 64-bit destination memory.

Normally, the DMA controller carries out bus transactions on the bus according to the element size. For example, the DMA controller would perform a 16-bit read transaction if the read element size is programmed as 16 bits, or an 8-bit write transaction if the write element size is programmed as 8 bit. The exception is when the total transfer size is as defined in Equation 1 is not a multiple of the write element size.

Figure 7-13. Example of DMA Data Packing



In this example, a read of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 16 bit
Write Element Size = 64 bit
Element Count = 128
Frame Count = 1
Source Element Index = 4
Source Frame Index = 0
Destination Element Index = n/a, use post increment addressing mode
Destination Frame Index = n/a, use post increment addressing mode

For example, if the read element size is 8 bits, the element transfer count is equal to 9, and the write element size is 64 bit. The DMA controller would first perform eight 8-bit read transactions from the source. It would then perform a 64-bit write to the destination. When the same channel wins arbitration again, the DMA controller would first perform one 8-bit read from the source, followed by one 8-bit write to the destination, even though the write element size is 64 bit.

NOTE: Since peripherals are slower, it is advised to use data packing feature with caution for reading data from peripherals. Improper use might delay servicing other pending DMA channels.

7.1.8 DMA Request

There are three ways to start a DMA transfer:

- **Software request:** The transfer will be triggered by writing to SW Channel Enable Set and Status Register (). The software request can trigger either a block or a frame transfer depending on the setting of the TTYPE bit in the Channel Control Register (Section 7.2.2.4).
- **Hardware request**: The DMA controller can handle up to 32 DMA Request lines. A hardware request can trigger either a frame or a block transfer depending on the setting of the TTYPE bit in the Channel Control Register (Section 7.2.2.4).
- **Triggered by other control packet:** When a control packet finishes the programmed number of transfers it can trigger another channel to initiate its transfers.

Each time a DMA request is made, either one frame transfer or one block transfer can be chosen. An active DMA request signal will trigger a DMA transaction.

The DMA controller has a two-level buffer to capture HW requests per channel. When a HW request is generated and the channel is enabled, the corresponding bit in the DMA Status Register () is set. The pending register acts as a first-level buffer. Typically, a peripheral acting as a source of a transfer would initiate another request after its data registers have been read out by DMA, even though that data has not been completely transferred to the destination. If a second HW request is generated by the peripheral, the DMA controller has an extra request buffer to capture this second request and service it after the first request is complete.

NOTE: The DMA cannot capture more than three requests if its request buffers are already full. If any request occur during this moment DMA will discard it.

The DMA controller also supports a mix of hardware and software requests on the same channel. Note that such interchangeable usage may result into an out of sync for DMA channel and peripheral. The application needs to be careful as the DMA does not have a built-in mechanism to protect against this loss of synchronization.

If a software request is generated, the corresponding bit in the Channel Pending Register () is set accordingly. If the pending request is not completely serviced by the DMA and a hardware request is generated by a peripheral onto the same channel, the DMA will capture and recognize this hardware request into its request buffer.

NOTE: The DMA controller cannot recognize two software requests on the same channel if the first software request is still pending. If such request occur DMA will discard it. Therefore the user software should check the pending register before issuing a new software request.

The DMA module has 16 channels and up to 32 hardware DMA requests. The module contains DREQASIx registers that are used to map the DMA requests to the DMA channels. By default, channel 0 is mapped to request 0, channel 1 to request 1, and so on.

Some DMA requests have multiple sources, as shown in . The application must ensure that only one of these DMA request sources is enabled at any time.

7.1.9 Auto-Initiation

When Auto-initiation Mode (AIM) bit of Channel Control Register (Section 7.2.2.4) is enabled for a channel and the channel is triggered by a software request for a block transfer, the channel will restart again using the same channel information stored at the respective control packet after one block transfer is completed. In the case of Hardware Request, the channel needs to be retriggered each time after a block is complete even if auto-initiation is enabled.

7.1.10 Interrupts

Each channel can be configured to generate interrupts on several transfer conditions:

- Frame transfer complete (FTC) interrupt: an interrupt is issued after the last element of a frame has been transferred.
- Last frame transfer started (LFS) interrupt: an interrupt is issued before the first element of the last frame of a block transfer has started.
- First half of block complete (HBC) interrupt: an interrupt is issued if more than half of the block is transferred.
  - If the number of frames *n* is odd, then the HBC interrupt is generated at the end of the frame when *(n+1) / 2* number of frames are left in the block.
  - If the number of frames *n* is even, then the HBC interrupt is generated at the end of the frame after *n/2* number of frames are left in the block.
- Block transfer complete (BTC) interrupt: an interrupt is issued after the last element of the last frame has been transferred.
- External imprecise error on read: an interrupt can be issued when a bus error (Illegal transaction with ok response) is detected. The imprecise read error is connected to the ESM module.
- External imprecise error on write: an interrupt can be issued when a bus error (Illegal transaction with ok response) is detected. The imprecise write error is connected to the ESM module.
- Memory Protection Unit error (MPU): an interrupt is issued when the DMA detects that the access falls outside of a memory region programmed in the MPU registers of the DMA. The MPU interrupt is connected to the ESM module.
- Parity error (PAR): an interrupt is issued when the DMA detects a parity error when reading one of the control packets. The PAR interrupt is connected to the ESM module.

The DMA outputs 5 interrupt lines for control packet handling, a parity interrupt and a memory protection interrupt (Figure 7-14). Each type of transfer interrupt condition is grouped together. For example, all block-transfer complete interrupts that are routed to a port are combined (ORed). The channel that caused the interrupt is given in the corresponding interrupt channel offset register. Priority between interrupts among the same interrupt type is resolved by a fixed priority scheme. Priority between different interrupt types is resolved in the Vector Interrupt Manager. Figure 7-15 explains the Frame Transfer Complete Interrupt structure in detail.

NOTE: Each Channel Specific interrupts in DMA module are routed towards Group A or B to support two different CPUs individually. For devices with Single CPU or Dual CPU where both CPUs are running same code in delayed lock-step as safety feature:

Group A - Interrupts (FTC, LFS, HBC, and BTC) are routed to the ARM CPU.

Group B - Interrupts (FTC, LFS, HBC, and BTC) are not routed out.

User software should configure only Group A interrupts.

Figure 7-14. DMA Interrupts

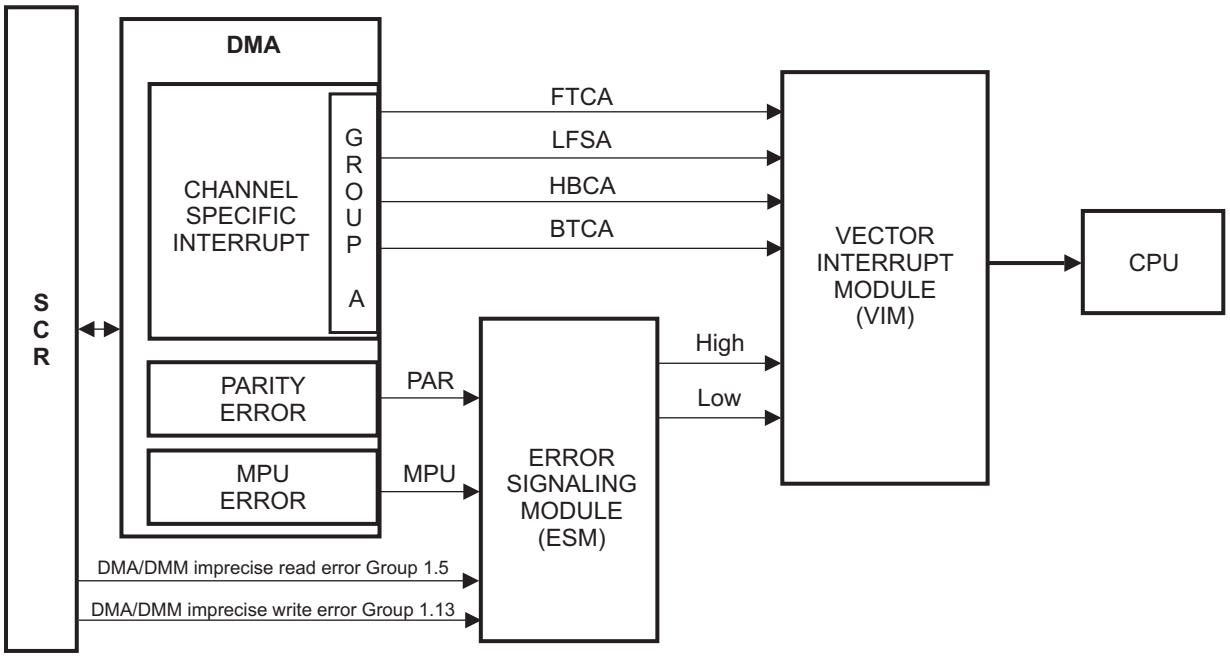


Figure 7-15. Detailed Interrupt Structure (Frame Transfer Complete Path)

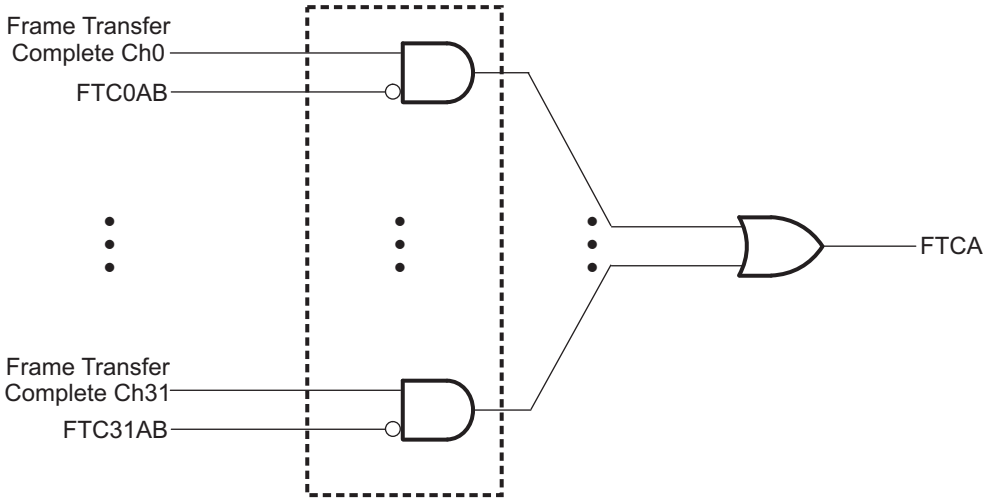


This figure is applicable for the HBC, LFS, and BTC interrupt.

7.1.11 Debugging

The DMA supports four different behaviors in suspend mode. These behaviors can be configured by the user as per the application requirement.

- Immediate stop at a DMA channel arbitration boundary. Please refer to Table 7-2 and Table 7-3 for arbitration boundary definition.
- Finish current frame transfer and continue after suspend ends.
- Finish current block transfer and continue after suspend ends.
- Ignore the suspend. The DMA continues to be operational as in functional mode when debug mode is active.

When the DMA controller enters suspend mode, it continues to sample incoming hardware DMA requests, but the Channel Pending Register () is frozen from being updated. After the suspend ends, all new requests that were received during suspend mode are reflected in the Channel Pending Register ().

Except when the DMA controller is configured to ignore suspend mode, no channel arbitration is performed during suspend mode. The current channel under which suspend mode was entered will finish its entire frame or block-transfer after suspend mode ends, depending how the debug option was chosen.

To facilitate debugging, a Watch Point Register () and a Watch Mask Register () are used. The watch point register together with the watch mask register can be configured to watch for a unique address or a range of addresses. When the condition to watch is true, the DMA freezes its state and generates a debug request signal to the host CPU so the state of the DMA can be examined.

7.1.12 Power Management

The DMA offers two power-management modes: run and sleep. In run mode, the DMA is fully operational.

The sleep mode shuts down the DMA if no pending channels are waiting to be serviced. If a DMA request is received or a software request is generated by the user software, then the DMA wakes up immediately.

The sleep mode may be used to optimize the DMA module power consumption.

When the system module issues a global low power mode request, the DMA will respond to the system module with an acknowledge if no DMA requests are pending.

NOTE: When the DMA is in global low power mode, the clock is stopped and therefore it cannot detect any DMA request. The device must be woken up before a peripheral can generate a DMA request.

7.1.13 FIFO Buffer

DMA FIFO is 4 levels deep and 64-bit wide (can hold up to 4 x 64-bits of data). They are used for Data packing and unpacking.

The DMA FIFO has two states:

- EMPTY : The FIFO contains no data.
- FULL : The FIFO is filled or the element count has reached zero; the read operation has to be stopped.

DMA channels can only be switched when the FIFO is empty. This also implies that arbitration between channels is done when the FIFO is empty.

The FIFO buffer may be bypassed through the use of the bypass feature in the port control register; see Port Control Register () for register details. Writing 1 to this bit limits the FIFO depth to the size of one element. That means after one element is read the write out to the destination will start. This feature is particularly useful to minimize switching latency in-between channels. When bypass mode is enabled, the DMA will perform minimal bus cycles on AHB bus. In addition, the bypass feature allows arbitration between channels that can be carried out at a source element granularity.

However, it has to be considered that while in bypass mode, the DMA controller does not make optimal use of the bus bandwidth. Since the read and write element sizes can be different, then the number of read and write transactions will be different. Table 7-2 and Table 7-3 show a comparison between the number of read and write transactions performed by the DMA controller from one channel to another before arbitration in non-bypass and bypass mode.

Table 7-2. Maximum Number of DMA Transactions per Channel in Non-Bypass Mode

	Write Element Size	8 bit		16 bit		32 bit		64 bit	
Read Element Size	8 bit	4 read	4 write	4 read	2 write	4 read	1 write	8 read	1 write
	16 bit	2 read	4 write	4 read	4 write	4 read	2 write	4 read	1 write
	32 bit	1 read	4 write	2 read	4 write	4 read	4 write	4 read	2 write
	64 bit	1 read	8 write	1 read	4 write	2 read	4 write	4 read	4 write

Table 7-3. Maximum Number of DMA Transactions per Channel in Bypass Mode

	Write Element Size	8 bit		16 bit		32 bit		64 bit	
Read Element Size	8 bit	1 read	1 write	2 read	1 write	4 read	1 write	8 read	1 write
	16 bit	1 read	2 write	1 read	1 write	2 read	1 write	4 read	1 write
	32 bit	1 read	4 write	1 read	2 write	1 read	1 write	2 read	1 write
	64 bit	1 read	8 write	1 read	4 write	1 read	2 write	1 read	1 write

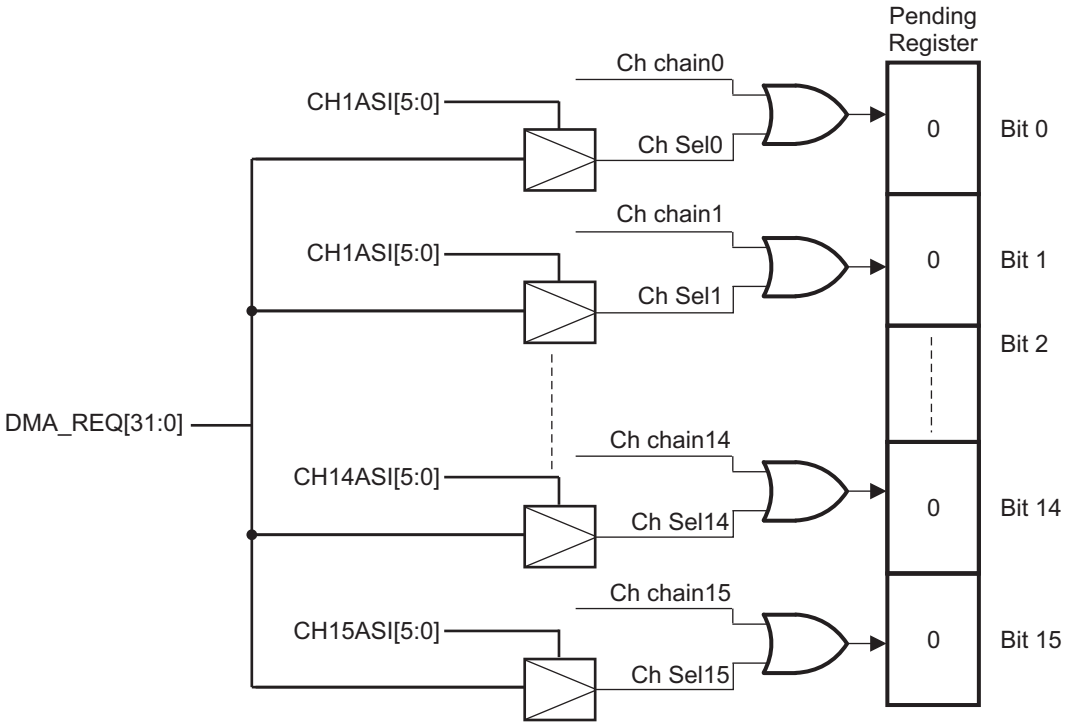
7.1.14 Channel Chaining

Channel chaining is used to trigger a single or multiple channels with out an external DMA request. This is possible by chaining one control packet to other. Chain[5:0] field of the Channel Control Register (Section 7.2.2.4) is used to program the chaining control packet. Chained control packets follow arbitration rules within the pending register. For example if CH1, CH2, CH4, CH5 are triggered together and CH3 is chained with CH1. The order of channels serviced in spite of chaining will be CH1 -> CH2 -> CH3 -> CH4 -> CH5.

In order to setup up channel chain feature, the Channel Control Register (Section 7.2.2.4) needs to be enabled for all chained channels before triggering first DMA request.

Figure 7-16 illustrates how internally chained request is generated after completing the required transfers and stored in pending register. In this example CH1 is Chained to CH0. When CH0 is triggered CH1 is captured as pending in the Channel Pending Register () even when it is not triggered.

Figure 7-16. Example of Channel Chaining



7.1.15 Memory Protection

The DMA controller is capable of access to the full address range of the device. The protection mechanism allows the protection of up to four memory regions to restrict accesses to those address ranges. This will allow the application to protect critical application data from unintentionally being accessed by the DMA controller.

7.1.15.1 Protection Mechanism

The memory protection mechanism consists of the access privilege for a given memory region, the start and end address for the region, and notification of an access violation for the protected region.

Each region to be protected is configured by software by writing the start address and end address for each region into the DMA Memory Protection Registers, DMAMPRxS and DMAMPRxE. The definition of these registers can be found starting at . Any region in the valid address space can be protected from inappropriate accesses.

The access privileges can be set to one of four permission settings as shown below:

- Full access
- Read only access
- Write only access
- No access

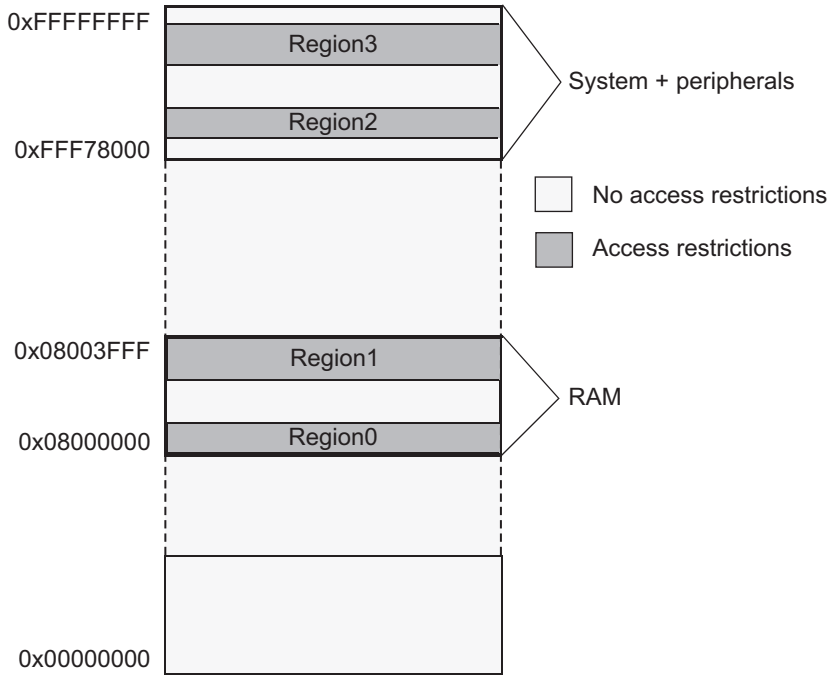
The permissions for a given region are selected by writing the appropriate values in the DMA Memory Protection Control Register ().

NOTE: If the regions defined by the start and end addresses overlap, the region defined first in the register space determines the access privilege. For example, if region 0 and region 1 overlap, the access permissions defined for region 0 will take precedence since region 0 registers are before region 1.

In a case where a memory protection violation occurs, a flag will be set and an interrupt will be generated, if interrupts are enabled. The DMA Memory Protection Status Register () contains the status flags for the memory protection mechanism, and the DMA Memory Protection Control Register () contains the interrupt enable bits. Upon detection of the memory protection violation, the DMA Channel that caused the violation will be stopped and the next available DMA channel will be serviced.

Figure 7-17 Illustrates a protection mechanism.

Figure 7-17. Example of Protection Mechanism



7.1.16 Parity Checking

Parity checking is implemented using parity on a per-byte basis for DMA Control Packets in the RAM. Checking for even or odd parity can be programmed by a 4-bit key located in the system module that controls the parity configuration on a global basis. This ensures that all modules using parity are acting in the same manner. The default setup after reset is odd parity.

In addition, parity checking can be enabled and disabled within the module by a 4-bit key. The key is located in the Parity Control Register ().

During a read access, regardless if it was read by the DMA state machine or another master (CPU), the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. If any word fails the parity check, then a parity error interrupt is generated. The address that generated the error is detected and is captured for host system debugging in the DMA Parity Error Address Register (). The address is frozen from being updated until it is read by the bus master.

Additional error handling is dependent on the requestor.

- DMA reading from a control packet RAM: The transmission requested by DMA request will not take place.
- CPU reading from the control packet RAM: The data will be retrieved by the CPU and a parity error interrupt will be generated.

In both cases, the control packet will be left active or the DMA will be switched off dependent on the ERRA bit in the Parity Control Register ().

7.1.17 Parity Testing

The parity RAM is accessible to allow manually inserting faults so that the parity checking feature can be tested. Test mode is entered by asserting the TEST bit in the Parity Control Register (). Once the bit is set, the parity bits are mapped to the control packet RAM starting address A00h.

NOTE: When in test mode, no parity checking will be done when reading from parity memory, but parity checking will be performed on the normal memory.

Each byte in Control Packet RAM has its own parity bit in the Control Packet Parity RAM as shown in Table 7-4, Table 7-5, and Table 7-6. P0 is the parity bit for byte 0, P1 is the parity bit for byte 1 and so on.

Each byte in the control packet RAM has its own parity bit in the control packet parity RAM as shown in Table 7-4 and Table 7-5.

Table 7-4. Control Packet RAM

Bit	31 24	23 16	15 8	7 0
Word0	Byte 0	Byte 1	Byte 2	Byte 3

	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

7.1.18 Initializing RAM with Parity

After power up, the RAM content including the parity bit cannot be guaranteed. To avoid parity failures when reading RAM, the RAM has to be initialized. The RAM can be initialized by writing known values into it. When the known value is written, the corresponding parity bit will be automatically calculated and updated.

Another possibility to initialize the memory is to follow the Auto-Initialization of On-Chip SRAM Modules subsection in the *Architecture* chapter. The RAM will be initialized to 0. Depending on the even/odd parity selection, the parity bit will be calculated accordingly.

To allow for parity calculation during initialization, the parity functionality has to be enabled as discussed in Section 7.1.16.

7.2 Control Registers and Control Packets

The master subsystem has two DMA modules, DMA1 and DMA2. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved. The DMA control registers are summarized in Table 7-7. The control packets are summarized in Table 7-8. All registers and control packets are accessible in 8,16, and 32 bit.

NOTE: The register definitions are given for a full DMA module configuration (32 channels, 64 requests, 2 Ports, Dual CPU support). Writes and Reads of bits pertaining to features not included in the DMA implementation as defined in the device-specific data manual are possible without error; however, they will have no affect on device operation.

7.2.1 DMA Control Registers

Table 7-7 lists the memory-mapped DMA registers. All register offset addresses not listed in Table 7-7 should be considered as reserved locations and the register contents should not be modified.

Table 7-7. DMA Control Registers

31-0	PEND	R/W	0h	Channel Pending Register Writing has no effect. Reading from PEND gives the channel pending information no matter if the channel was initiated by SW or HW. Once set, it remains set even if the corresponding channel is disabled via HWCHENA or SWCHENA. The pending bit is automatically cleared for the following conditions: 1)At the end of a frame or a block transfer depending on how the channel is triggered as programmed in the TTYPE bit field of Section 1.6.3.4, "CHANNEL CONTROL Register (CHCTRL)" . 2)The control packet is modified after the pending bit is set. 3)An AHB bus error occurs. 1 the associated channel is pending and is waiting for service. 0 the associated channel is inactive.

7.2.1.3 FBREG Register (Offset = 8h) [reset = 505h]

FBREG is shown in Figure 7-20 and described in Table 7-11.

Return to Summary Table.

Fall back register for EMC

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved
11-8	FSM FB	R/W	5h	FSM FB: FSM Fallback feature Used to switch off RTL clock gating for all FSM logics used for saving power. “1010” = Disable RTL clock gating in RTL. “0101” = Enable RTL clock gating in RTL. others = no effect will be in same state as before
7-4	RESERVED	R	0h	Reserved
3-0	VBUSP FB	R/W	5h	VBUSP FB: VBUSP Fallback feature Used to switch off RTL clock gating for all VBUSP logics used for saving power. “1010” = Disable RTL clock gating in RTL. “0101” = Enable RTL clock gating in RTL. others = no effect will be in same state as before

7.2.1.4 DMASTAT Register (Offset = Ch) [reset = 0h]

DMASTAT is shown in Figure 7-21 and described in Table 7-12.

Return to Summary Table.

Channel active information

Figure 7-21. DMASTAT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STCH																															
R/W-0h																															

Table 7-12. DMASTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	STCH	R/W	0h	0STCH: Status of DMA channels 1 channel active (means channel is currently in DMA's execution queue). 0 channel inactive. Since the DMA has two Ports only two channels can be active at a time. Writing has no effect. Note: The status of a channel currently in DMA's execution queue remains active even if emulation mode is entered or DMA is disabled via DMA_EN bit

7.2.1.5 HWCHENAS Register (Offset = 14h) [reset = 0h]

HWCHENAS is shown in Figure 7-22 and described in Table 7-13.

Return to Summary Table.

Enables a channel for HW trigger

Figure 7-22. HWCHENAS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HWCHENA																															
R/W-0h																															

Table 7-13. HWCHENAS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	HWCHENA	R/W	0h	HWCHENA: HW Channel Enable Bit Writing a one to a bit enables the according channel for HW triggering. Writing a zero has no effect. An active HW DMA request can not initiate DMA transfer unless the associated HW enable bit is set. The associated HW enable bit is cleared automatically for the following conditions: 1)At the end of a block transfer if autoinitiation bit AIM in Section 1.6.3.4, "CHANNEL CONTROL Register (CHCTRL)" is not active. 2)If an AHB bus error is detected for an active channel as indicated by HRESP signal. Reading from HWCHENAS gives the status (enabled/disabled) of channels 0 through 31. 1 the associated channel is enabled for HW triggering. 0 the associated channel is disabled for HW triggering.

7.2.1.6 HWCHENAR Register (Offset = 1Ch) [reset = 0h]

HWCHENAR is shown in Figure 7-23 and described in Table 7-14.

Return to Summary Table.

Disables a channel for HW trigger

Figure 7-23. HWCHENAR Register

R/W-0h																															

Table 7-14. HWCHENAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	HWCHDIS	R/W	0h	HW Channel Disable Bit. Writing a one to a bit disables the according channel for HW triggering. Writing a zero has no effect. Reading from CHENAR gives the status (enabled/disabled) of channels 0 through 31. 1 the associated channel is enabled for HW triggering. 0 the associated channel is disabled for HW triggering. Note: All Set and Reset registers throughout DMA controller such as HWCHENAS and HWCHENAR are two logical locations mapped to one physical register.

7.2.1.7 SWCHENAS Register (Offset = 24h) [reset = 0h]

SWCHENAS is shown in Figure 7-24 and described in Table 7-15.

Return to Summary Table.

Activate a SW request

Figure 7-24. SWCHENAS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWCHENA																															
R/W-0h																															

Table 7-15. SWCHENAS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SWCHENA	R/W	0h	SWCHENA: SW Channel Enable Bit. Writing a one to a bit trigger a SW request on the associated channel to start DMA transaction. The associated bit is automatically cleared by the following conditions. 1)The associated bit is cleared after one frame transfer if the TTYPE bit in Section 1.6.3.4, "CHANNEL CONTROL Register (CHCTRL)" is programmed for frame transfer. 2)The associated bit is cleared after one block transfer if the corresponding TTYPE bit is programmed for block transfer and the autoinitiation bit is not enabled. 3)The control packet is modified after the pending bit is set. 4)The associated bit is cleared after one block transfer when TTYPE bit is programmed for blocks transfer and if the corresponding bit in HW Channel Enable Register (HWCHENAS) is enabled. When a channel is enabled for both HW and SW, the state machine will initiate transfers based on the SW first. After one block transfer is complete, the associated bit in the SWCHENA register is then cleared. The same channel is serviced again by a HW DMA request. 5)The associated bit is cleared if an AHB bus error is detected for an active channel as indicated by HRESP signal. Reading from SWCHENAS gives the status (enabled/disabled) of channels 0 through 31 1 the associated channel was triggered by SW request. 0 the associated channel was not triggered by SW request

7.2.1.8 SWCHENAR Register (Offset = 2Ch) [reset = 0h]

SWCHENAR is shown in Figure 7-25 and described in Table 7-16.

Return to Summary Table.

Disables a SW request

Figure 7-25. SWCHENAR Register

7	6	5	4	3	2	1	0
RESERVED				PARITY_ENA			
R-0h				R/W-5h			

Table 7-73. DMAPCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	Reserved
16	ERRA	R/W	0h	ERRA: Error Action 0 = If a parity error is detected on Control Packet x (x = 0, 1, ...or 31), then the enable/disable state of Control Packet x remains unchanged. 1 = If a parity error is detected on Control Packet x (x = 0, 1, ...or 31), then DMA is disabled immediately. If a frame on Control Packet x is processed at the time the parity error is detected, then remaining elements of this frame will no more be transferred. Disabling of the DMA will be done, regardless of whether the error was detected during a read to the Control Packet RAM performed by the DMA state machine or by a different master.
15-9	RESERVED	R	0h	Reserved
8	TEST	R/W	0h	TEST. When this bit is set, the parity bits are memory mapped to make them accessible by the CPU. 0 = parity bits are not memory mapped 1 = parity bits are memory mapped
7-4	RESERVED	R	0h	Reserved
3-0	PARITY_ENA	R/W	5h	PARITY_ENA: Parity Error Detection Enable. This bit field enables or disables the parity check on read operations and the parity calculation on write operations. If parity checking is enabled and a parity error is detected the DMA_UERR signal is activated. During memory initiallization this bit field needs to be enable inorder to generate parity bits inside memory. 0101 = disable all other = enable NOTE: It is recommended to write a ‘1010’ to enable error detection, to guard against soft error from flipping PARITY_ENA to a disable state

7.2.1.66 DMAPAR Register (Offset = 1ACh) [reset = 0h]

DMAPAR is shown in Figure 7-83 and described in Table 7-74.

Return to Summary Table.

The address of the control packet memory, where the uncorrectable error occured

7.2.2 Channel Configuration

The channel configuration is defined by the channel control packet: channel control, transfer count, index pointers, source/destination address.

- It is stored in local RAM, which is protected by parity.
- Each control packet contains a total of nine fields.
- The first six fields are programmable, while the last three fields are read only.
- The RAM is accessible by queue A and queue B state machines as well as CPU.
- When there are simultaneous accesses, the priority is resolved in a fixed priority scheme with the CPU having the highest priority.

All the control packets look the same. Following, there is the detailed layout of these registers shown for control packet 0.

8.9 Interrupt Request Assignments 1542

8.1 Overview

The vectored interrupt manager (VIM) provides hardware assistance for prioritizing and controlling the many interrupt sources present on a device. Interrupts are caused by events outside of the normal flow of program execution. Normally, these events require a timely response from the central processing unit (CPU); therefore, when an interrupt occurs, the CPU switches execution from the normal program flow to an interrupt service routine (ISR).

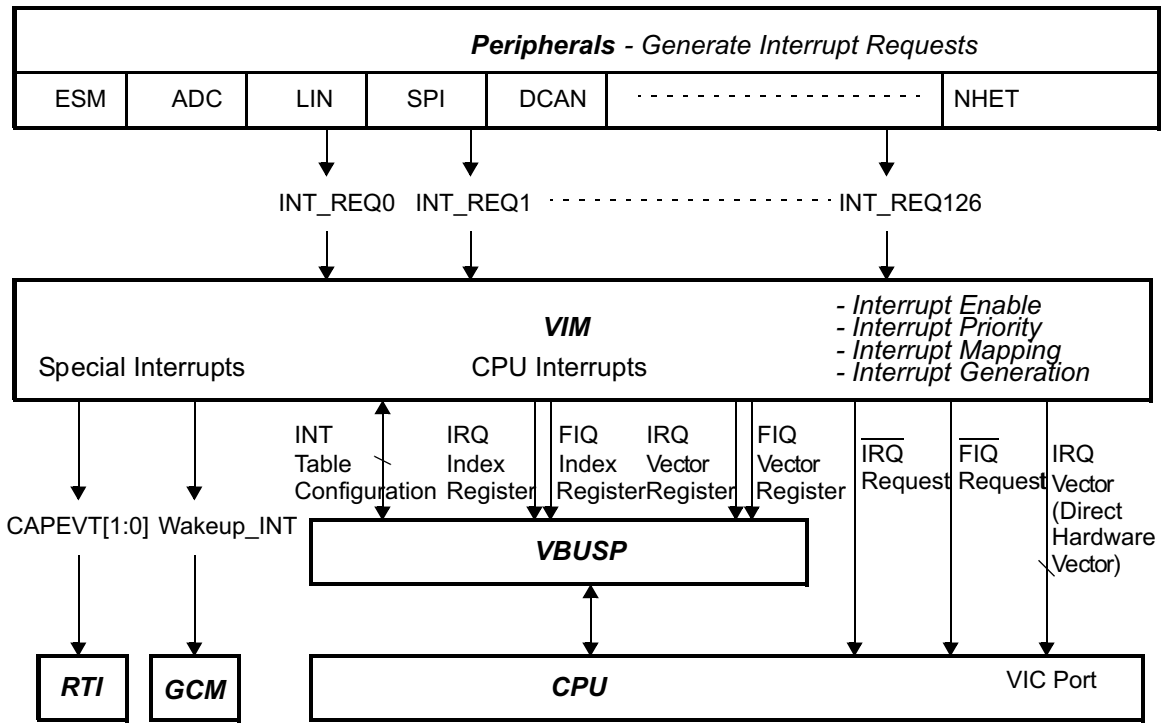
The VIM module has the following features:

- Supports 127 interrupt channels, in both register vectored interrupt and hardware vectored interrupt mode.
  - Provides IRQ vector directly to the CPU VIC port
  - Provides FIQ/IRQ vector through registers
  - Provides programmable priority and enable for interrupt request lines
- Provides a direct hardware dispatch mechanism for fastest IRQ dispatch.
- Provides two software dispatch mechanisms for backward compatibility with earlier generation of TI processors.
  - Index interrupt
  - Register vectored interrupt
- ECC (Error Code Correction) protected vector interrupt table against soft errors.

8.2 Device Level Interrupt Management

A block diagram of device level interrupt handling is shown in Figure 8-1. When an event occurs within a peripheral, the peripheral makes an interrupt request to the VIM. Then, VIM prioritizes the requests from peripherals and provides the address of the highest interrupt service routine (ISR) to the CPU. Finally, CPU starts executing the ISR instructions from that address in the ISR. Section 8.2.1 through Section 8.2.3 provide additional details about these three steps.

Figure 8-1. Device Level Interrupt Block Diagram



8.2.1 Interrupt Generation at the Peripheral

Interrupt generation begins when an event occurs within a peripheral module. Some examples of interrupt-capable events are expiration of a counter within a timer module, receipt of a character in a communications module, and completion of a conversion in an analog-to-digital converter (ADC) module. Some device peripherals are capable of requesting interrupts on more than one interrupt request line.

Interrupts are not always generated when an event occurs; the peripheral must make an interrupt request to the VIM based on the event occurrence. Typically, the peripheral contains:

- An interrupt flag bit for each event to signify the event occurrence.
- An interrupt enable bit to control whether the event occurrence causes an interrupt request to the VIM.

8.2.2 Interrupt Handling at the CPU

The ARM CPU provides two vectors for interrupt requests—fast interrupt requests (FIQs) and normal interrupt requests (IRQs). FIQs are higher priority than IRQs, and FIQ interrupts may interrupt IRQ interrupts.

NOTE: The FIQ implemented in Cortex-R4F/R5F is Non-Maskable Fast Interrupts (NMFI). Once FIQ is enabled (by clearing F bit in CPSR), it can NOT be disabled by setting F bit in CPSR. Only a reset or an FIQ will be able to set the F bit in CPSR. By hardware, Non Maskable FIQ are not reentrant.

After reset (power reset or warm reset), both FIQ and IRQ are disabled. The CPU may enable these interrupt request channels individually within the CPSR (Current Program Status Register); CPSR bits 6 and 7 must be cleared to enable the FIQ (bit 6) and IRQ (bit 7) interrupt requests at the CPU. CPSR is writable in privilege mode only. Example 8-2 shows how to enable the IRQ and FIQ through CPSR.

When the CPU receives an interrupt request, the CPSR mode field changes to either FIQ or IRQ mode. When an IRQ interrupt is received, the CPU disables other IRQ interrupts by setting CPSR bit 7. When an FIQ interrupt is received, the CPU disables both IRQ and FIQ interrupts by setting CPSR bits 6 and 7.

A write of 1 to CPSR bit 7 disables the IRQ from CPU. However, a write of 1 to CPSR bit 6 leaves it unchanged. Example 8-2 also shows how to disable the IRQ through CPSR.

8.2.3 Software Interrupt Handling Options

The device supports three different possibilities for software to handle interrupts

1. Index interrupts mode

   After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ) to execute the main ISR. The main ISR routine reads the offset register (IRQINDEX, FIQINDEX) to determine the source of the interrupt.

2. Register vectored interrupts (automatically provide vector address to application)

   Before enabling interrupts, the application software also has to initiate the interrupt vector table (VIM RAM).

   Once the VIM receives an interrupt, it loads the address of ISR from interrupt vector table, and store it into the interrupt vector register (IRQVECREG for IRQ interrupt, FIQVECREG for FIQ interrupt).

   After the interrupt is received by the CPU, the CPU executes the instruction placed at 0x18 or 0x1C (IRQ or FIQ vector) to load the address of ISR (interrupt vector) from the interrupt vector register. Example 8-3 illustrates the configuration for the exception vectors using this mode.

3. Hardware vectored interrupts (automatically dispatch to ISR, IRQ only)

   Before enabling interrupts, the application software must initiate the interrupt vector table (VIM RAM) pointing to the ISR for each interrupt channel.

   After the interrupt (IRQ) is received by the CPU, CPU reads the address of ISR directly from the interface with VIM (VIC port) instead of branching to 0x18. The CPU will branch directly to the ISR.

   The hardware vectored interrupt behavior must be explicitly enabled by setting the vector enable (VE) bit in the CP15 R1 register. This bit resets to 0, so that the default state after reset is backward compatible to earlier ARM CPU. Example 8-1 shows how to enable the hardware vectored interrupt.

   NOTE: This mode is NOT available for FIQ.

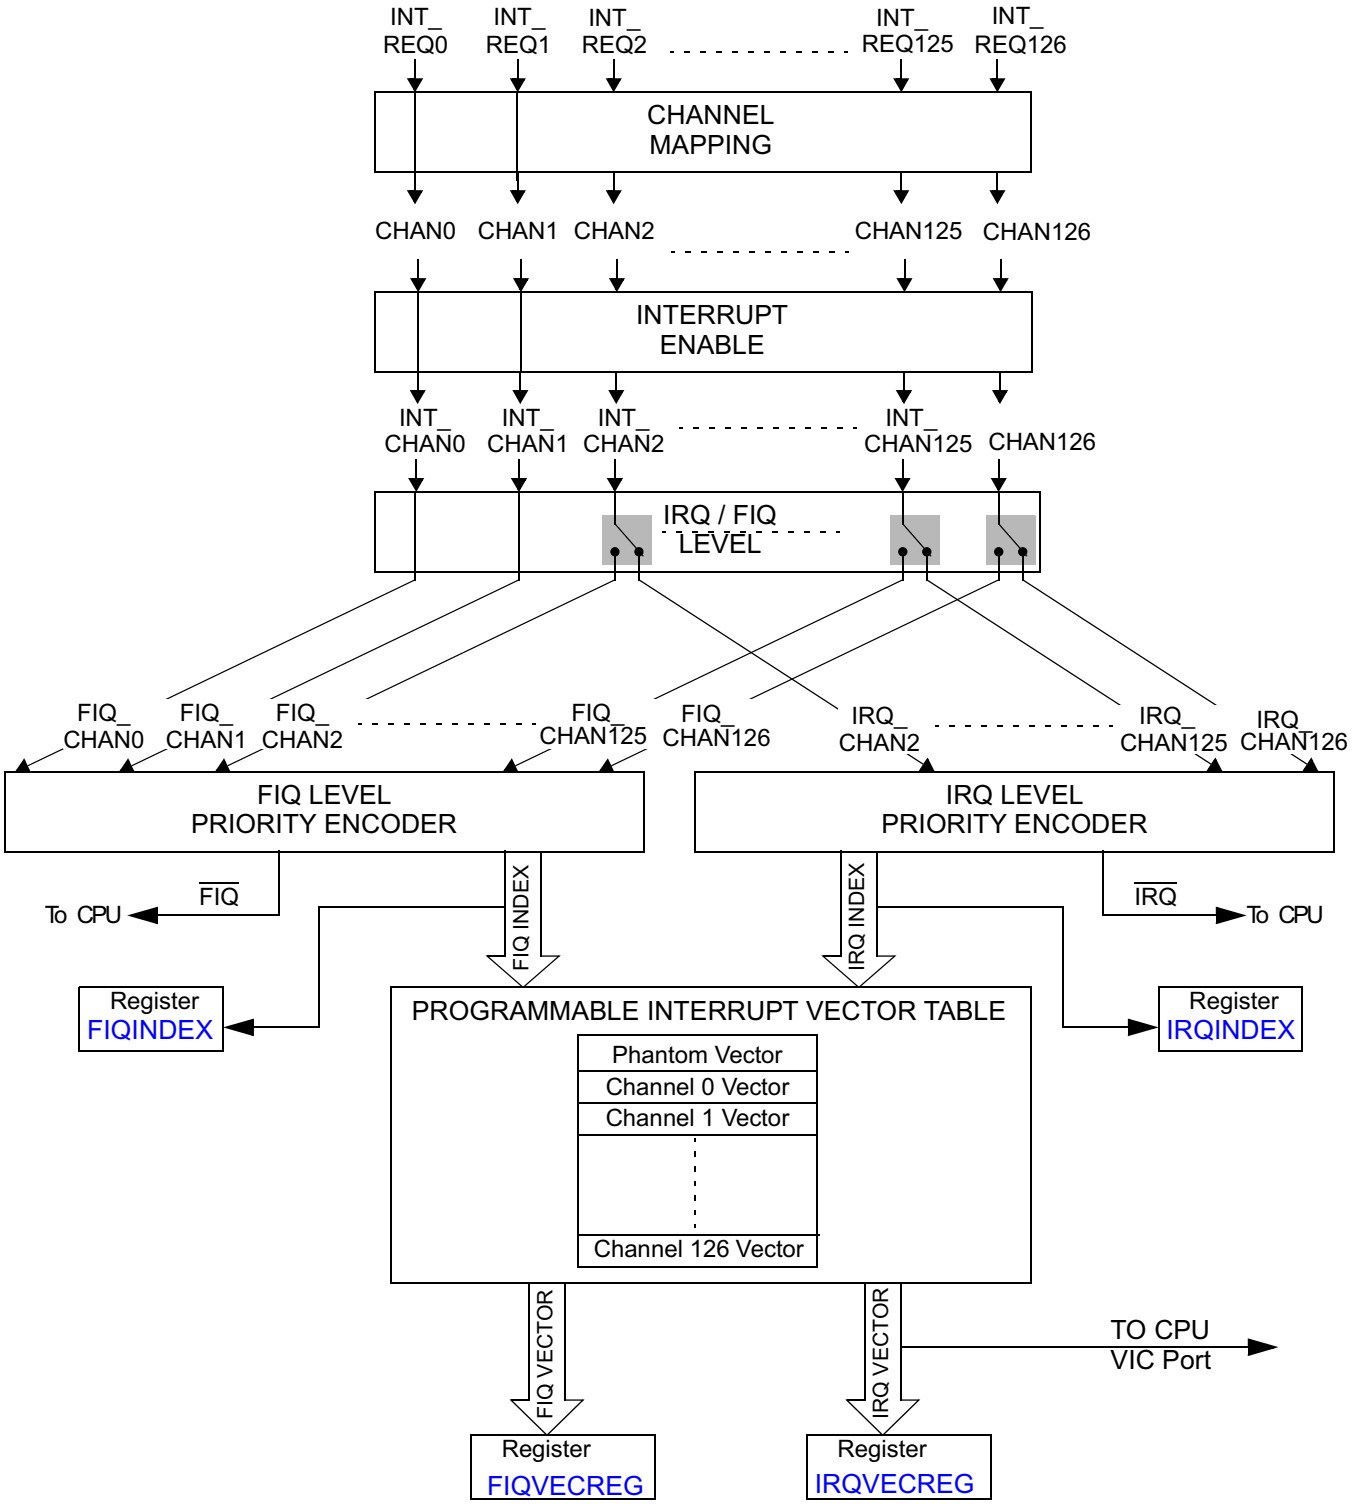
4. Software-Based Priority Decoding Scheme

   If the application uses a software-based interrupt priority decoding scheme instead of the hardware vector capabilities, then there is an additional step which was not required on earlier devices. This version of the VIM will hold an interrupt request generated by a peripheral. When the software clears the interrupt condition in the source module (for example, RTI, GIO, and so on), then it must also perform an additional clear of the interrupt request in the VIM. This can be done by reading the IRQVECREG register (Section 8.8.15) or FIQVECREG register (Section 8.8.16), or by writing a 1 to the INTREQ(i) bit (Section 8.8.10) in the VIM. This is not necessary if any of the three previous methods are used as the interrupt request bit in the VIM will be automatically cleared when the vector is read.

8.3 Interrupt Handling Inside VIM

A block diagram of the interrupt handling inside VIM is shown in Figure 8-2

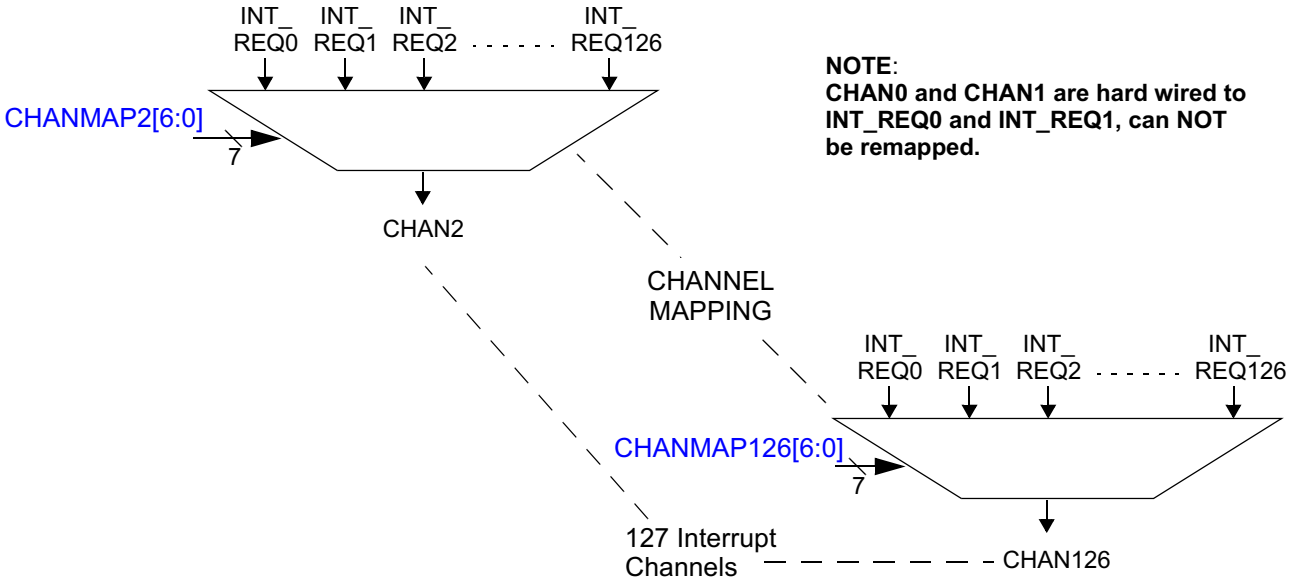
Figure 8-2. VIM Interrupt Handling Block Diagram



8.3.1 VIM Interrupt Channel Mapping

The VIM support 128 interrupt channels (including phantom interrupt). A block diagram of the VIM interrupt requests arrangement from peripheral modules to the interrupt channels is provided in Figure 8-3. Each interrupt channel (CHANx) has a corresponding mapping register bit field (CHANMAPx[6:0]). This mapping register determines which interrupt channel it maps each VIM interrupt request. With this scheme, the same request can be mapped to multiple channels. A lower numbered channel in each FIQ and IRQ has higher priority. The programmability of the VIM allows software to control the interrupt priority.

Figure 8-3. VIM Channel Mapping



NOTE: CHAN127

CHAN127 has no dedicated interrupt vector table entry. Therefore, CHAN127 shall NOT be remapped to other INT_REQ (INT_REQ127 is reserved at device level).

In the reset state, the VIM maps all of the interrupt requests in the system to their respective interrupt channels. Figure 8-4 shows the default state following the reset.

Figure 8-5 shows the VIM INT2 is remapped to both Channel 2 and 4, and INT3 is mapped to channel 3.

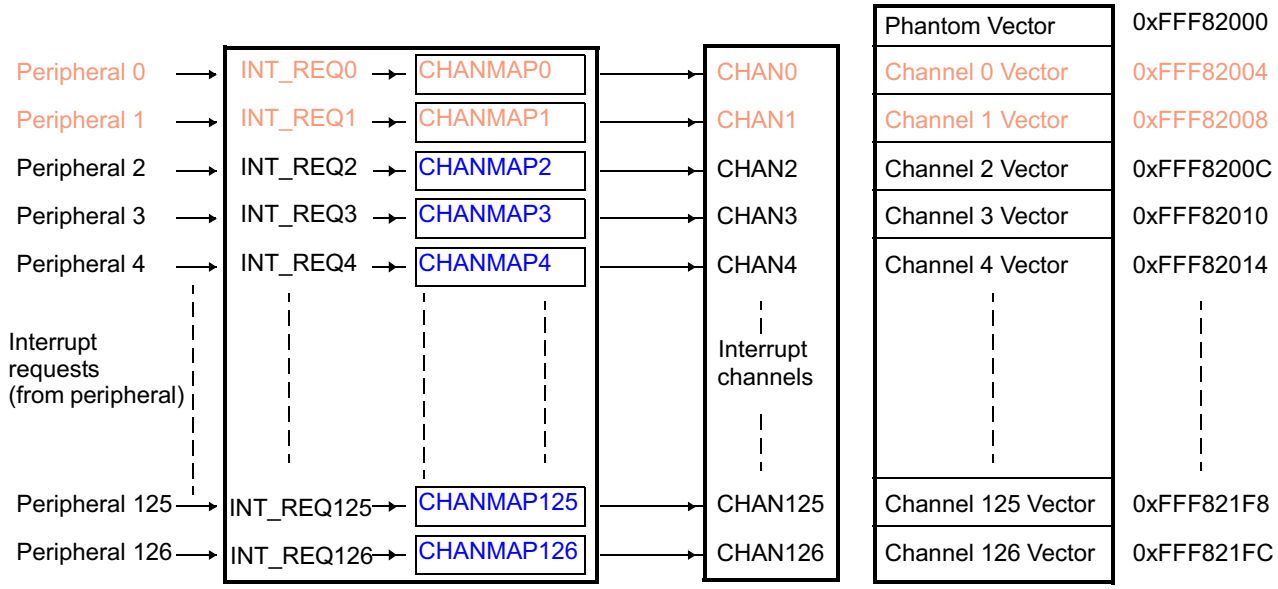
NOTE: By mapping INT2 to channel 2 and channel 4, and mapping INT3 to channel 3, it is possible for the software to change the priority dynamically by changing the ENABLE register (REQENASET and REQENACLR). When channel 2 is enabled, the priority is:

1. INT0
2. INT1
3. INT2
4. INT3

Disabling channel 2, the priority becomes:

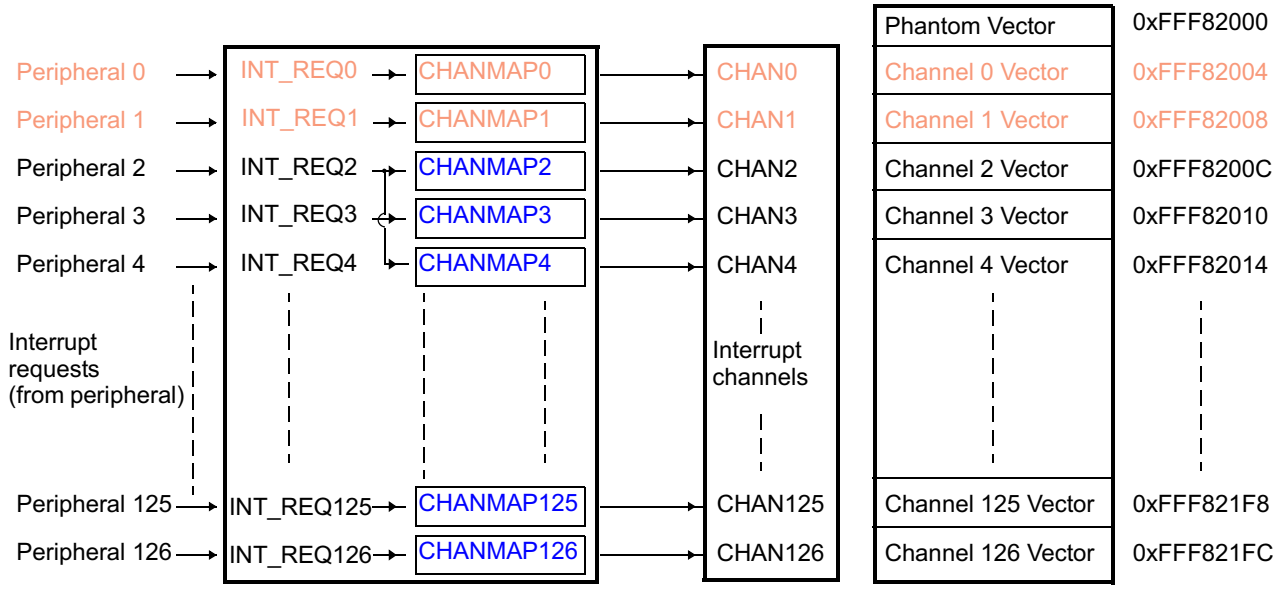
1. INT0
2. INT1
3. INT3
4. INT2

Figure 8-4. VIM in Default State



NOTE: CHAN0 and CHAN1 are hardwired to INT_REQ0 and INT_REQ1, so they cannot be remapped.

Figure 8-5. VIM in a Programmed State



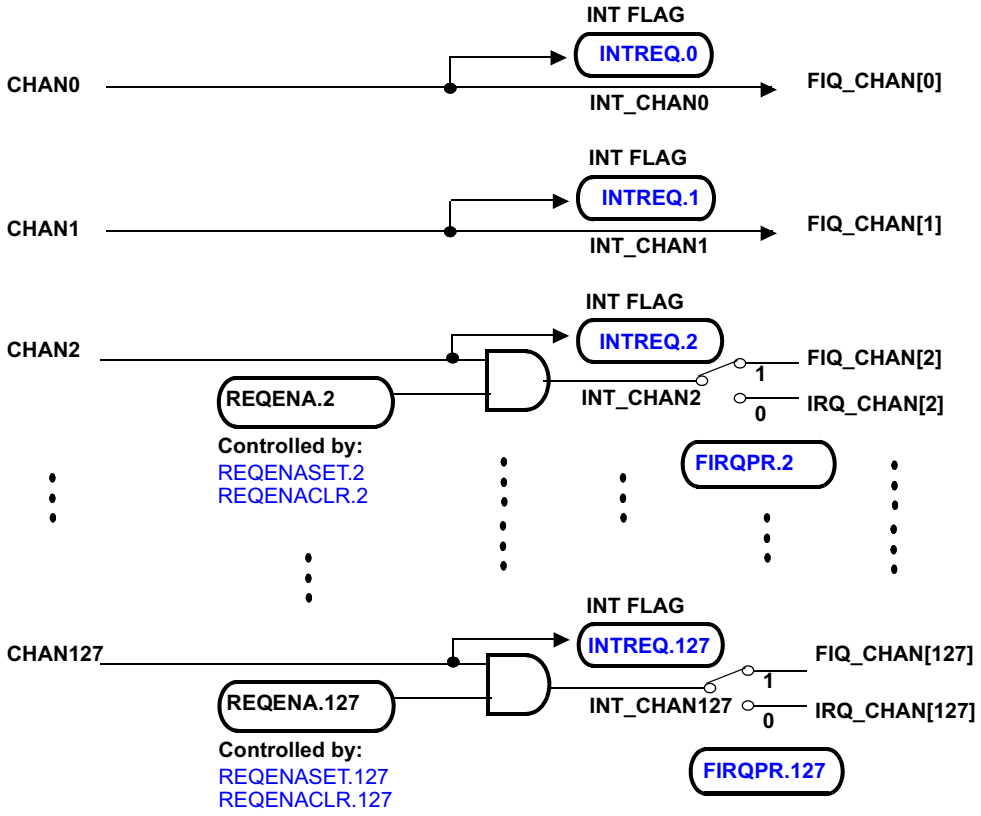
NOTE: CHAN0 and CHAN1 are hard wired to INT_REQ0 and INT_REQ1, so they cannot be remapped.

8.3.2 VIM Input Channel Management

As shown in Figure 8-6, the VIM enables channels on a channel-by-channel basis (in the REQENASET and REQENACLR registers); unused channels may be masked to prevent spurious interrupts.

NOTE: The interrupt ENABLE register does not affect the value of INTREQ.

Figure 8-6. Interrupt Channel Management



By default, interrupt CHAN0 is mapped to ESM (Error Signal Module) high level interrupt and CHAN1 is reserved for other NMI. For safety reasons, these two channels are mapped to FIQ only and can **NOT** be disabled through ENABLE registers.

NOTE: NMI Channel

Channel 0 and channel 1 are not maskable by the REQENASET / REQENACLR bit and both channel are routed exclusively to FIQ/NMI request line (FIRQPR0 and FIRQPR1 have no effect).

The VIM prioritizes the received interrupts based upon a programmed prioritization scheme. The VIM can send two interrupt requests to the CPU simultaneously—one IRQ and one FIQ. If both interrupt types are enabled at the CPU level, then the FIQ has greater priority and is handled first. Each interrupt channel, except channel 0 and 1, can be assigned to send either an FIQ or IRQ request to the CPU (in the FIRQPR register).

The VIM provides a default prioritization scheme, which sends the lowest numbered active channel (in each FIQ and IRQ classes) to the CPU. Within the FIQ and IRQ classes of interrupts, the lowest channel has the highest priority interrupt. The channel number is programmable through register CHANMAPx.

After the VIM has generated the vector corresponding to the highest active IRQ, it updates the FIQINDEX or the IRQINDEX register, depending on the class of interrupt. Then, it accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. If the request is an FIQ class interrupt, the address read from the interrupt vector table, is written to the FIQVECREG register. If the request is an IRQ class interrupt, the address is written to the IRQVECREG register and put on the VIC port of the CPU (in case of hardware vectored interrupt is enabled).

All of the interrupt registers are updated when a new high priority interrupt line becomes active.

8.4 Interrupt Vector Table (VIM RAM)

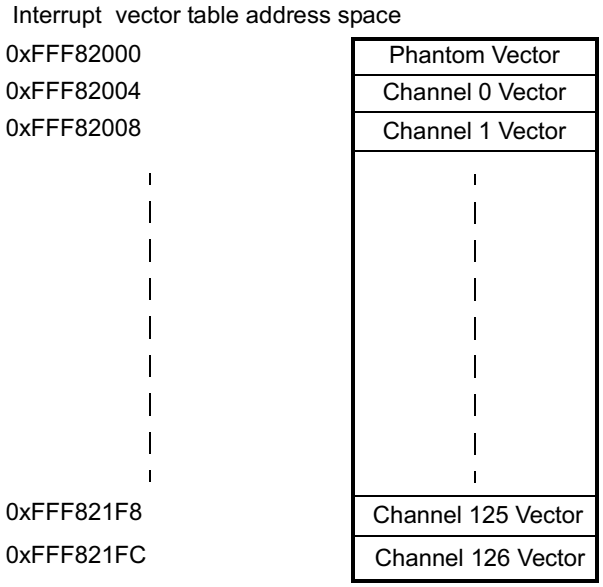
Interrupt vector table stores the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR.

For safety reasons, the interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC scheme is implemented as a continuous background check based on memory access. The ECC logic inside VIM supports Single bit Error Correction and Double bit Error Detection (SECDED). Section 8.4.1 through Section 8.4.4 describe how ECC works in the interrupt vector table.

8.4.1 Interrupt Vector Table Operation

The interrupt vector table is organized in 128 words of 32 bits. Figure 8-7 shows the interrupt memory mapping. The table base address is 0xFFF82000.

Figure 8-7. VIM Interrupt Address Memory Map



NOTE: The interrupt vector table only has 128 entries, one phantom vector and 127 interrupt channels. Channel 127 does not have a dedicated vector and shall not be used.

There are seven bits of ECC per 32-bit ISR address. When a write is performed into the interrupt vector table, the ECC bits are calculated for the 32-bit word and written into the corresponding ECC region of interrupt vector table if ECC is enabled in VIM.

NOTE: Only 32-bit write/read access are allowed on interrupt vector table if ECC is required. Non 32-bit access might result in ECC errors.

When a read occurs from the CPU or VIM, the VIM calculates the ECC bits from the data coming from the interrupt vector table and compares it to the known good ECC value stored in the table. If a single bit error is detected in the data, the SECDED block will automatically correct it. The read data will be a corrected one in this case. If double bit errors are detected, the read data will be the uncorrected one. The access of the data and the ECC bits are performed in the same clock cycle.

The Double Bit Error (DBE) and Single Bit Error (SBE) events will be generated only if the ECC feature is enabled by ECCENA field. Correction of the data upon a SBE event will be done only if enabled EDAC_MODE field. Any double bit error will be flagged out to ESM module and as UERR flag in ECCSTAT register. The address of the data for which UERR is detected will also be stored as UERRADDR register.

Any single bit error will be registered into SBERR flag in ECCSTAT register and the corresponding address will be captured as SBERRADDR register. If SBE_INT_EN field on ECCCTL register is set to enable value, then it will be flagged out to ESM module.

Since the interrupt vector table may have an uncorrectable error (e.g. DBE), the FBVECADDR register will provide to the VIC port, IRQVECREG and FIQVECREG, a fall-back address to an ISR that can restore the interrupt vector table content. The FB_VECADDR register should be set before intializing the interrupt in the interrupt vector table, to avoid branching to an unpredictable location.

The normal operation is restored when the ECCSTAT is cleared by the CPU. It is recommended to restore the content of the VIM before clearing the ECCSTAT.

8.4.2 VIM ECC Syndrome

The VIM ECC is controlled by the ECCENA bits of ECCCTL register. After reset, the SECDED feature is disabled. The SECDED feature can be enabled by writing 0xA (1010b) in the ECCENA[3:0] bit field of the ECCCTL register.

The ECC generation is done according to the ECC syndrome table as shown in Table 8-1 and Table 8-2. Each ECC bit is build by generating the parity of the 'XOR'ed bits of the data word, whereas ECC bit 2 and 3 are even parity and the other bits odd parity

Table 8-1. ECC Syndrome Table

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	ECC

	x						5
		x					4
			x				3
				x			2
					x		1
						x	0

8.4.3 Interrupt Vector Table Initialization

After reset, the interrupt vector table content, including the ECC bits is not initialized. Therefore, the interrupt vector table has to be initialized first before enabling the corresponding interrupt channel. This can be done either using the hardware initialization mechanism (in Chapter Architecture Overview) or it can be done by writing known values into the interrupt vector table by software. If ECC is required, this initialization should be done after the ECC functionality is enabled. In this way, the corresponding ECC bits will be automatically updated. This initialization is only required when vectored interrupts are used, index interrupt management does not need the table to be initialized.

1. Disable FIQ and IRQ for Cortex by writing to the CPSR register.
2. Initialize VIMRAM. See the VIMRAM initialization sequence.
3. Soft Reset VIM module(MSS_RCM:SOFTRST2:VIMRST = 0xAD) (this only resets the VIM state machine and not the VIMRAM).
4. Release reset for VIM module (MSS_RCM:SOFTRST2:VIMRST = 0x0)
5. Enable FIQ and IRQ for Cortex by writing to the CPSR register.

8.4.4 Interrupt Vector Table ECC Testing

To test the ECC checking mechanism, the ECC bits allows manual insertion of faults. This option is implemented using the TEST_DIAG_EN bit in the ECCCTL register control bit. Once TEST_DIAG_EN is enabled, the ECC bits are mapped to 0xFFF82400. In this mode, the user can modify the ECC bits without changing the data bits. If ECCENA is disabled, writing to data bits does not automatically update ECC bits. The CPU reads and writes under different conditions are summarized in Table 8-3 and Table 8-4. After that, user can force faults into either the data or the ECC bits. Finally, the ECC error can be triggered by reading interrupt vector table (not ECC bits) from VIM or CPU. Please note that no ECC checking will be done for reads of ECC bits in test mode.

Table 8-3. CPU Reads - Address Bit 10 Selects Between Normal Data and ECC Bits

VBUSP_ ADDR(10)	TEST_DIAG_ EN	ECCENA	Action
0	x(don't care)	x(don't care)	Normal RAM location read
1	x	x	ECC bits read

Table 8-4. CPU Writes - Address Bit 10 Selects Between Normal Data and ECC Bits

VBUSP_ ADDR(10)	TEST_DIAG_ EN	ECCENA	Action
0	x	1	Normal RAM locations write with ECC bits
1	0	1	This write will be blocked
1	1	1	ECC bits write
0	x	0	Normal RAM locations write without ECC bits
1	0	0	This write will be blocked
1	1	0	This write is not allowed

Following sequence should be used for injecting faults to ECC bits and testing the ECC check feature.

1. Write the data locations of VIM RAM with the required patterns while keeping ECCENA active. The ECC bits will be automatically initialized along with data bits.
2. Enable ECC test mode using TEST_DIAG_EN field of ECCCTRL register.
3. In this mode, it is possible to corrupt ECC bits using any of the following methods.
   - Read the ECC bits, flip one bit and write back
   - Read the ECC bits, flip 2 bits and write back
4. Depending on the kind corruption created, read back the data bits and check for the correction error (single bit error or double bit error or no error).

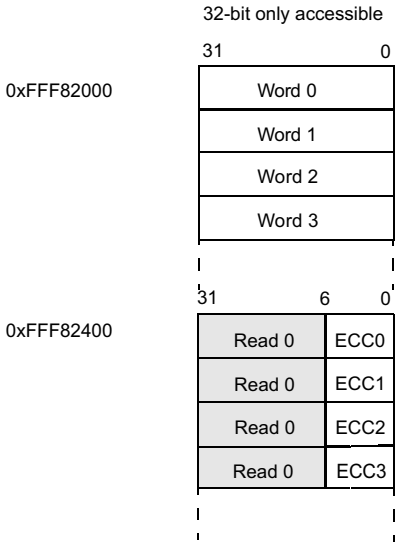
5. Read the UERRADDR and SBERRADDR registers and check for the correct address capture as well.

Following sequence should be used for injecting faults to data bits and testing the ECC check feature.

1. Write the data locations of VIM RAM with the required patterns while keeping ECCENA active. The ECC bits will be automatically initialized along with data bits.
2. Disable ECC by setting ECCENA=0 in ECCCTRL register. In this mode, writing to data bits does not automatically update ECC bits.
3. In this mode, it is possible to corrupt data bits using any of the following methods.
   - Read the data bits, flip one bit and write back
   - Read the data bits, flip 2 bits and write back
4. Depending on the kind corruption created, read back the data bits and check for the correction error (single bit error or double bit error or no error).
5. Read the UERRADDR and SBERRADDR registers and check for the correct address capture as well.

NOTE: After completing the tests for ECC check features, it should be ensured that VIM Interrupt Vector Table is initialized with valid data and corresponding check bits. Care should also be taken to clear the UERR and SBERR flag registers and the error address registers.

Figure 8-8. ECC Bits Mapping

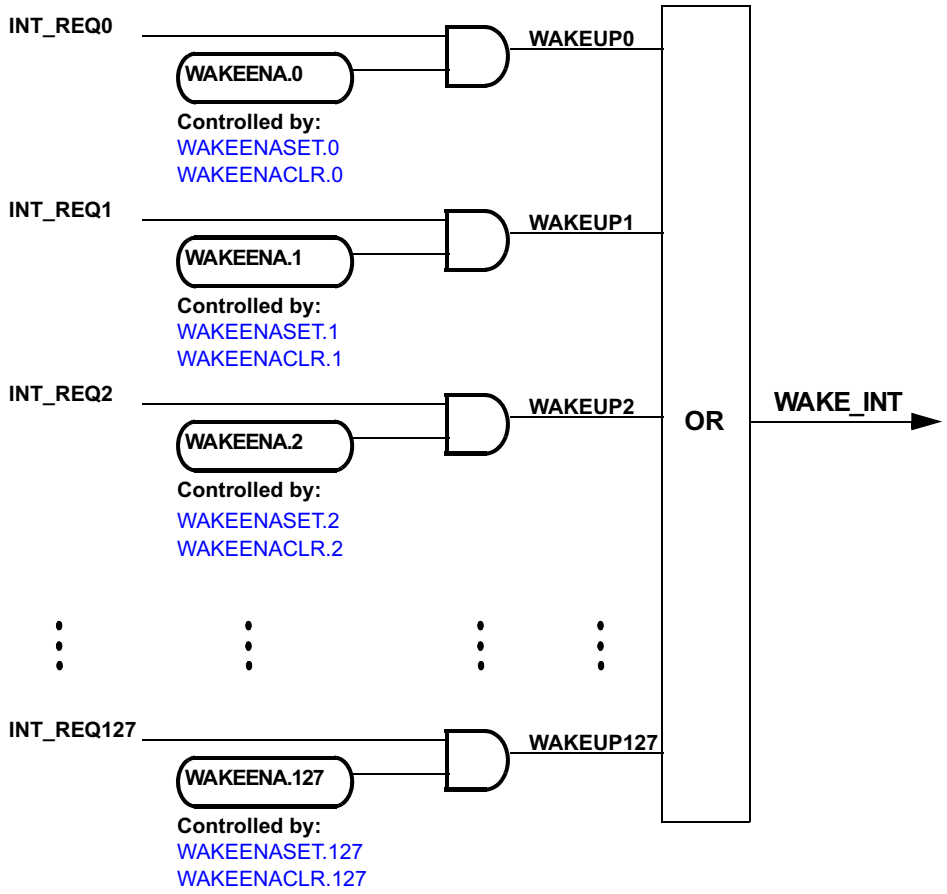


8.5 VIM Wakeup Interrupt

The wakeup interrupts are used to come out of low power mode (LPM). Any interrupt requests can be used to wake up the device. After reset, all interrupt requests are set to wake up from LPM. However, the VIM can mask unwanted interrupt lines for wake-up by using the WAKEENASET and WAKEENACLR register. The value in REQENASET / REQENACLR does NOT impact the wakeup interrupt.

As shown in Figure 8-9, the WAKEENASET and WAKEENACLR registers will enable/disable an interrupt for wake-up from low-power mode. All wake-up interrupts are “ORed” into a single signal WAKE_INT connected to the Global Clock Module.

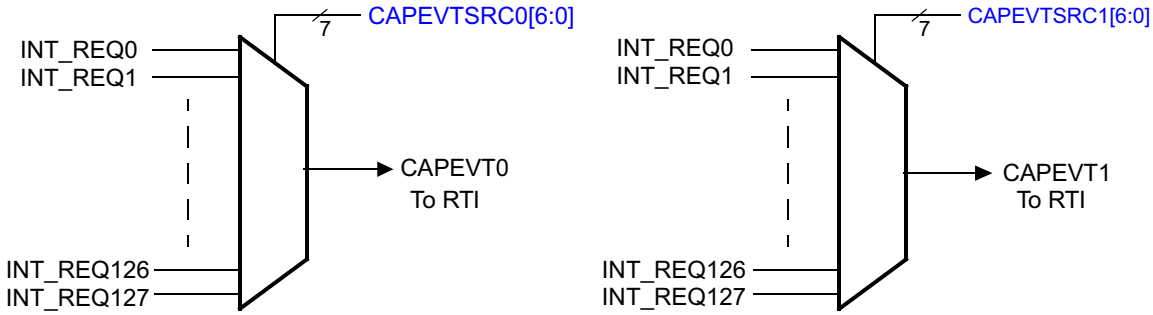
Figure 8-9. Detail of the IRQ Input



8.6 Capture Event Sources

The VIM can select any of the 128 interrupt request to generate up to two capture events for the real-time interrupt (RTI) module (see Figure 8-10). The value in REQENASET / REQENACLR does NOT impact the capture event. Two registers (Section 8.8.17) are available, one for each capture event source.

Figure 8-10. Capture Event Sources



8.7 Examples

The following sections provide examples about the operation of the VIM.

8.7.1 Examples - Configure CPU To Receive Interrupts

Example 8-1 shows how to set the vector enable (VE) bit in the CP15 R1 register to enable the hardware vector interrupt. Example 8-2 shows how to enable/disable the IRQ and FIQ through CPSR. As a convention, the program who calls these subroutines shall preserve register R1 if needed. Example 8-2 can ONLY run in privileged mode. However, in USER mode, the application software can force the program into software interrupt by instruction 'SWI'. Then, in the software interrupt service routine, user can write register SPSR, which is the copy of CPSR in this exception mode.

Example 8-1. Enable Hardware Vector Interrupt (IRQ Only)

```
_HW_Vec_Init

8.7.2 Examples - Register Vector Interrupt and Index Interrupt Handling

Example 8-3 illustrates the configuration for the exception vectors in Register Vector Interrupt handling. After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ). The instruction placed here should be *LDR PC, [PC,#-0x1B0]*. The pending ISR address is written into the corresponding vector register (IRQVECREG for IRQ, FIQVECREG for FIQ). The CPU reads the content of the register and branches to the ISR.

Example 8-3. Exception Vector Configuration for VIM Vector

```
          .sect ".intvecs"
00000000h b _RESET             ; RESET interrupt
00000004h b _UNDEF_INST_INT    ; UNDEFINED INSTRUCTION interrupt
00000008h b _SW_INT            ; SOFTWARE interrupt
0000000Ch b _ABORT_PREF_INT    ; ABORT (PREFETCH) interrupt
00000010h b _ABORT_DATA_INT    ; ABORT (DATA) interrupt
00000014h b #-8                ; Reserved
00000018h ldr pc,[pc,#-0x1B0]  ; IRQ interrupt
0000001Ch ldr pc,[pc,#-0x1B0]  ; FIQ interrupt
```

NOTE: Program Counter (PC) always pointers two instructions beyond the current executed instruction. In this case, PC equals to '*0x18 or 0x1C + 0x08*'. The *LDR* instruction load the memory at '*PC - 0x1B0*', which is '*0x18 or 0x1C + 0x08 - 0x1B0* = 0xFFFFFE70 or 0xFFFFFE74'. These are the address of IRQVECREG and FIQVECREG, which store the pending ISR address.

Example 8-4 shows a fast response to the FIQ interrupt in Index Interrupt and can be applied to a system that has more than one channel assigned as a FIQ. It is built in Index Interrupt compatible with TMS470R1x legacy code.

Example 8-4. How to Respond to FIQ With Short Latency

```
          .sect ".intvecs"          ; Interrupt and exception vector sector
00000000h b _RESET                  ; RESET interrupt
00000004h b _UNDEF_INST_INT         ; UNDEFINED INSTRUCTION interrupt
00000008h b _SW_INT                 ; SOFTWARE interrupt
0000000Ch b _ABORT_PREF_INT         ; ABORT (PREFETCH) interrupt
00000010h b _ABORT_DATA_INT         ; ABORT (DATA) interrupt
00000014h b #-8                     ; Reserved
00000018h b _IRQ_ENTRY_0            ; IRQ interrupt
                                    ;*********************************

                                    ;*********************************
0000001Ch ldrb R8, [PC,#-0x21d]     ; FIQ INTERRUPT ENTRY
                                    ; R8 used to get the FIQ index
                                    ; with address pointer to the
                                    ; first FIQ banked register
00000020h ldr PC, [PC, R8, LSL#2]   ; Branch to the indexed interrupt
                                    ; routine. The prefetch
                                    ; operation causes the PC to be 2
                                    ; words (8 bytes) ahead of the
                                    ; current instruction, so
                                    ; pointing to _INT_TABLE.
00000024h nop                       ; Required due to pipeline.
                                    ;=================================
00000028h _INT_TABLE                ; FIQ INTERRUPT DISPATCH
                                    ;=================================
0000002Ch .word _FIQ_TABLE          ; beginning of FIQ Dispatch
00000030h .word _ISR1               ; dispatch to interrupt routine 1
00000034h .word _ISR2               ; dispatch to interrupt routine 2
          .
          .
```

Another way to improve the FIQ latency is to assign only one channel to the FIQ interrupt and to map the ISR code corresponding to this channel directly starting at 0x1C.

NOTE: When the CPU is in vector-enabled mode, Example 8-3 and Example 8-4 are still valid. The difference is that the CPU will not read from the 0x18 location during IRQ interrupt, but will jump directly to the corresponding ISR routine.

8.8 VIM Control Registers

Table 8-5 lists the VIM module registers. Each register begins on a word boundary. All registers are 32-bit, 16-bit, and 8-bit accessible for read and write. Write is only possible in privilege mode. To determine the base address, refer to the device-specific memory map. The address locations not listed are reserved.

Table 8-5. VIM Control Registers

8.8.1 Interrupt Vector Table ECC Status Register (ECCSTAT)

Figure 8-11 and Table 8-6 describe this register.

Figure 8-11. Interrupt Vector Table ECC Status Register (ECCSTAT) [offset = ECh]

31	16
Reserved	
R-0	

15	9	8	7	1	0
Reserved		SBERR	Reserved		UERR
R-0		R/W1CP-0	R-0		R/W1CP-0

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -*n* = value after reset

Table 8-6. Interrupt Vector Table ECC Status Register (ECCSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Read returns 0. Writes have no effect.
8	SBERR		The SBERR flag indicates that a single bit error has been detected and has been corrected by the SECDED logic and the Interrupt Vector Table is being used for normal operation (not bypassed).
		0	*Read:* No ECC error has occurred. *Write:* No effect.
		1	*Read:* A single bit error has occurred and was corrected by the SECDED logic *Write:* The SBERR is cleared.
7-1	Reserved	0	Read returns 0. Writes have no effect.
0	UERR		The UERR indicates that a double bit error has been found and that the Interrupt Vector Table is bypassed. The resulting vector of any IRQ/FRQ interrupt is then the value contained in the FBVECADDR register until this bit has been cleared.
		0	*Read:* No double bit error has occurred. *Write:* No effect.
		1	*Read:* A double bit error has occurred and the Interrupt Vector Table is bypassed. *Write:* The UERR is cleared and the interrupt vector can be read from the Interrupt Vector Table.

8.8.2 Interrupt Vector Table ECC Control Register (ECCCTL)

Figure 8-12. Interrupt Vector Table ECC Control Register (ECCCTL) [offset = F0h]

31 28	27 24	23 20	19 16
Reserved	SBE_EVT_EN	Reserved	EDAC_MODE
R-0	R/WP-5h	R-0	R/WP-Ah
15 12	**11 8**	**7 4**	**3 0**
Reserved	TEST_DIAG_EN	Reserved	ECCENA
R-0	R/WP-Ah	R-0	R/WP-5h

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -*n* = value after reset

Table 8-7. Interrupt Vector Table ECC Control Register (ECCCTL) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Read returns 0. Writes have no effect.
27-24	SBE_EVT_EN		These bits control the generation of Error signal out based on Single Bit Error (SBE) indications from SECDED logic for the Interrupt Vector Table.
		5h	Disable Error Event indication upon detection of SBE on the Interrupt Vector Table.
		Ah	Enable Error Event upon detection of SBE the Interrupt Vector Table.
		All other values	Writes are ignored and the values are not updated into this field. The state of the feature remains unchanged.
23-20	Reserved	0	Read returns 0. Writes have no effect.
19-16	EDAC_MODE		These bits determine whether Single Bit Errors (SBE) detected by the SECDED block will be corrected or not.
		5h	Disable correction of SBE detected by the SECDED block
		Ah	Enable correction of SBE detected by the SECDED block
		All other values	Writes are ignored and the values are not updated into this field. The state of the feature remains unchanged.
			Note: If an SBE is selected to be not corrected (using EDAC_MODE), then an SBE event will also cause VIM RAM to be bypassed just like UERR and the module to use the FBVECADDR register as the vector address.
15-12	Reserved	0	Read returns 0. Writes have no effect.
11-8	TEST_DIAG_EN		This bit maps the ECC bits into the Interrupt Vector Table frame to make them accessible by the CPU. When enabled, the ECC bits are writable as well as readable independent of data bits.
		5h	Enable memory mapping of ECC bits for read/write operation
		All other values	Disable memory mapping of ECC bits for read/write operation
			Note: To avoid soft error to disable VIM ECC mapping, it is recommended to write Ah to disable ECC bits mapping.
7-4	Reserved	0	Read returns 0. Writes have no effect.
3-0	ECCENA		VIM ECC enable.
		5h	VIM ECC is disabled.
		All other values	VIM ECC is enabled.
			Note: To avoid soft error to disable VIM ECC checking, it is recommended to write Ah to enable ECC checking.

8.8.3 Uncorrectable Error Address Register (UERRADDR)

The uncorrectable error address register gives the address of the first uncorrectable error location.

NOTE: No computation is needed when reading the complete register to retrieve the address in the Interrupt Vector Table.

This register will never be reset by a power-on reset nor any other reset source.

Figure 8-13. Uncorrectable Error Address Register (UERRADDR) [offset = F4h]

31	16
Interrupt Vector Table offset	
R-FFF8h	

15	10	9	2	1	0

R-x		R-x		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 8-8. Uncorrectable Error Address Register (UERRADDR) Field Descriptions

Bit	Field	Description
31-10	Interrupt Vector Table offset	Interrupt Vector Table offset. Reads are always FFF8 2xxxh; writes have no effect
9-2	ADDERR	Uncorrectable error address register. This register gives the address of the first encountered double bit error since the flag has been clear. Subsequent ECC errors will not update this register until the UERR flag has been cleared. **Note: This register is valid only when PARFLG is set (see Section 8.8.1).**
1-0	Word offset	Word offset. Reads are always 0; writes have no effect.

8.8.4 Fallback Vector Address Register (FBVECADDR)

This register provides a fall-back address to the VIM if a uncorrectable error has occurred in the Interrupt Vector Table. Figure 8-14 and Table 8-9 describe this register.

NOTE: This register will never be reset by a power-on reset nor any other reset source.

Figure 8-14. Fallback Vector Address Register (FBVECADDR) [offset = F8h]

31	0
FBVECADDR	
R/WP-x	

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -*n* = value after reset; x = Indeterminate

Table 8-9. Fallback Vector Address Register (FBVECADDR) Field Descriptions

Bit	Field	Description
31-0	FBVECADDR	Fallback Vector Address Register. This register is used by the VIM if the Interrupt Vector Table has been corrupted. The contents of the IRQVECREG and FIQVECREG registers will reflect the value programmed in FBVECADDR. The value provided to the VIC port will also reflect FBVECADDR until the UERR register has been cleared. This register provides the address of the ISR that will restore the integrity of the Interrupt Vector Table.

8.8.5 Single Bit Error Address Register (SBERRADDR)

This register gives the address of the first single bit ECC error detected by the ECC logic.Figure 8-15 and Table 8-10 describe this register.

NOTE: This register will never be reset by a power-on reset nor any other reset source.

Figure 8-15. Single Bit Error Address Register (SBERRADDR) [offset = FCh]

31	0
SBERRADDR	
R/WP-x	

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -*n* = value after reset; x = Indeterminate

Table 8-10. Single Bit Error Address Register (SBERRADDR) Field Descriptions

Bit	Field	Description
31-0	SBERRADDR	Single Bit Error Address Register. This register gives the address of the first single bit error detected by the SECDED logic since the SBERR flag has been clear. Subsequent single bit ECC errors will not update this register until the SBERR flag has been cleared. This register provides the Interrupt Vector Table address (offset from base address word aligned) of the ECC error location. This register is valid only when the SBERR flag is set.

8.8.6 VIM Offset Vector Registers

The VIM offset register provides the user with the numerical index value that represents the pending interrupt with the highest precedence. The register IRQINDEX holds the index to the highest priority IRQ interrupt; the register FIQINDEX holds the index to the highest priority FIQ interrupt. The index can be used to locate the interrupt routine in a dispatch table, as shown in Table 8-11.

Table 8-11. Interrupt Dispatch

IRQINDEX / FIQINDEX Register Bit Field	Highest Priority Pending Interrupt Enabled
0x00	No interrupt
0x01	Channel 0
:	:
0x7F	Channel 126
0x80	Channel 127

NOTE: Channel 127 has no dedicated interrupt vector table entry. Therefore, Channel 127 shall NOT be used in application.

The VIM offset registers are read only. They are updated continuously by the VIM. When an interrupt is serviced, the offset vectors show the index for the next highest pending interrupt or 0x0 if no interrupt is pending.

8.8.7 IRQ Index Offset Vector Register (IRQINDEX)

The IRQ offset register provides the user with the numerical index value that represents the pending IRQ interrupt with the highest priority. Figure 8-16 and Table 8-12 describe this register.

Figure 8-16. IRQ Index Offset Vector Register (IRQINDEX) [offset = 00h]

31	16
Reserved	
R-0	

15	8	7	0
Reserved		IRQINDEX	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 8-12. IRQ Index Offset Vector Register (IRQINDEX) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Read returns 0. Writes have no effect.
7-0	IRQINDEX	0-FFh	**IRQ index vector.** The least-significant bits represent the index of the IRQ pending interrupt with the highest precedence, as shown in Table 8-11. When no interrupts are pending, the least significant byte of IRQINDEX is 0.

8.8.8 FIQ Index Offset Vector Registers (FIQINDEX)

The FIQINDEX register provides the user with a numerical index value that represents the pending FIQ interrupt with the highest priority. Figure 8-17 and Table 8-13 describe this register.

Figure 8-17. FIQ Index Offset Vector Register (FIQINDEX) [offset = F04h]

Table 8-13. FIQ Index Offset Vector Register (FIQINDEX) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Read returns 0. Writes have no effect.
7-0	FIQINDEX	0-FFh	**FIQ index offset vector.** The least-significant bits represent the index of the FIQ pending interrupt with the highest precedence, as shown in Table 8-11. When no interrupts are pending, the least significant byte of FIQINDEX is 0x00.

8.8.9 FIQ/IRQ Program Control Registers (FIRQPR[0:3])

The FIQ/IRQ program control registers determine whether a given interrupt request will be either FIQ or IRQ. Figure 8-18, Figure 8-19, Figure 8-20, Figure 8-21 and Table 8-14 describe these registers.

NOTE: Channel 0 and 1 are FIQ only, not impacted by this register.

Figure 8-18. FIQ/IRQ Program Control Register 0 (FIRQPR0) [offset = 10h]

Table 8-14. FIQ/IRQ Program Control Registers (FIRQPR) Field Descriptions

Bit	Field	Value	Description
127-2	FIRQPRx[*n*]		**FIQ/IRQ program control bits.** These bits determine whether an interrupt request from a peripheral is of type FIQ or IRQ. Bit FIRQPRx[127:2] corresponds to request channel[127:2].
		0	Interrupt request is of IRQ type.
		1	Interrupt request is of FIQ type.
1-0	Reserved	3h	Read only. Writes have no effect.

8.8.10 Pending Interrupt Read Location Registers (INTREQ[0:3])

The pending interrupt register gives the pending interrupt requests. The register is updated every vbus clock cycle. Figure 8-22, Figure 8-23, Figure 8-24, Figure 8-25 and Table 8-15 describe this register.

Figure 8-22. Pending Interrupt Read Location Register 0 (INTREQ0) [offset = 20h]

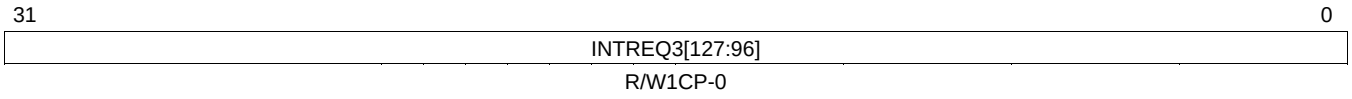
Figure 8-25. Pending Interrupt Read Location Register 3 (INTREQ3) [offset = 2Ch]



LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -*n* = value after reset

Table 8-15. Pending Interrupt Read Location Registers (INTREQ) Field Descriptions

Bit	Field	Value	Description
127-0	INTREQx[*n*]		**Pending interrupt bits.** These bits determine whether an interrupt request is pending for the request channel between 0 and 127. The interrupt ENABLE register does not affect the value of the interrupt pending bit. Bit INTREQx[127:0] corresponds to request channel[127:0].
			User and Privilege Mode read:
		0	No interrupt event has occurred.
		1	An interrupt is pending.
			Privilege Mode write only:
		0	Writing 0 has no effect.
		1	Clears the "interrupt pending" status flag. This write-clear functionality is intended to allow clearing those interrupts which have been signaled to VIM before enabling the interrupt channel, if they are undesired.

8.8.11 Interrupt Enable Set Registers (REQENASET[0:3])

The interrupt register enable selectively enables individual request channels. Figure 8-26, Figure 8-27, Figure 8-28, Figure 8-29 and Table 8-16 describe these registers.

NOTE: Channel 0 and 1 are always enabled, not impacted by this register.

Table 8-16. Interrupt Enable Set Registers (REQENASET) Field Descriptions

Bit	Field	Value	Description
127-2	REQENASETx[*n*]		**Request enable set bits.** This vector determines whether the interrupt request channel is enabled. Bit REQENASETx[127:2] corresponds to request channel[127:2].
		0	*Read:* Interrupt request channel is disabled. *Write:* No effect.
		1	*Read or Write:* The interrupt request channel is enabled.
1-0	Reserved	3h	Read only. Writes have no effect.

8.8.12 Interrupt Enable Clear Registers (REQENACLR[0:3])

The interrupt register enable selectively disables individual request channels. Figure 8-30, Figure 8-31, Figure 8-32, Figure 8-33 and Table 8-17 describe these registers.

NOTE: Channel 0 and 1 are always enabled, not impacted by this register.

1-0	Reserved	3h	Read only. Writes have no effect.

8.8.13 Wake-Up Enable Set Registers (WAKEENASET[0:3])

The wake-up enable registers selectively enables individual wake-up interrupt request lines. Figure 8-34, Figure 8-35, Figure 8-36, Figure 8-37 and Table 8-18 describe these registers.

8.8.15 IRQ Interrupt Vector Register (IRQVECREG)

The interrupt vector register gives the address of the enabled and active IRQ interrupt. Figure 8-42 and Table 8-20 describe these registers.

Figure 8-42. IRQ Interrupt Vector Register (IRQVECREG) [offset = 70h]

Bit	Field	Value	Description
31-23	Reserved	0	Reads are indeterminate and writes have no effect.
22-16	CAPEVTSRC1		Capture event source 1 mapping control. These bits determine which interrupt request maps to the capture event source 1 of the RTI:
		0	Interrupt request 0.
		1h	Interrupt request 1.
		:	:
		7Fh	Interrupt request 127.
15-7	Reserved	0	Reads are indeterminate and writes have no effect.
6-0	CAPEVTSRC0		Capture event source 0 mapping control. These bits determine which interrupt request maps to the capture event source 0 of the RTI:
		0	Interrupt request 0.
		1h	Interrupt request 1.
		:	:
		7Fh	Interrupt request 127.

8.8.18 VIM Interrupt Control Registers (CHANCTRL[0:31])

Thirty-two interrupt control registers control the 128 interrupt channels of the VIM. Each register controls four interrupt channels: each of them is indexed from 0 to 127. Table 8-23 shows the organization of all the registers and the reset value of each. Each four fields of the register has been named with a generic index that refers to the detailed register organization. Figure 8-45 and Table 8-24 describe these registers.

Table 8-23. Interrupt Control Registers Organization

Address	Register Acronym	Register Field 31:24 CHANMAPx$_0$	Register Field 23:16 CHANMAPx$_1$	Register Field 15:8 CHANMAPx$_2$	Register Field 7:0 CHANMAPx$_3$	Reset Value
FFFF FE80h	CHANCTRL0	CHANMAP0	CHANMAP1	CHANMAP2	CHANMAP3	0001 0203h
FFFF FE84h	CHANCTRL1	CHANMAP4	CHANMAP5	CHANMAP6	CHANMAP7	0405 0607h
:	:	:	:	:	:	:

15	Reserved	0	Reads are indeterminate and writes have no effect.
14-8	$CHANMAPx_2$		$CHANMAPx_2$(6-0). Interrupt $CHANx_2$ mapping control. These bits determine which interrupt request the priority channel $CHANx_2$ maps to:
		0	*Read:* Interrupt request 0 maps to channel priority $CHANx_2$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_2$ is set with the interrupt request.
		1h	*Read:* Interrupt request 1 maps to channel priority $CHANx_2$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_2$ is set with the interrupt request.
		:	:
		7Fh	*Read:* Interrupt request 127 maps to channel priority $CHANx_2$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_2$ is set with the interrupt request.
7	Reserved	0	Reads are indeterminate and writes have no effect.
6-0	$CHANMAPx_3$		$CHANMAPx_3$(6-0). Interrupt $CHANx_3$ mapping control. These bits determine which interrupt request the priority channel $CHANx_3$ maps to:
		0	*Read:* Interrupt request 0 maps to channel priority $CHANx_3$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_3$ is set with the interrupt request.
		1h	*Read:* Interrupt request 1 maps to channel priority $CHANx_3$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_3$ is set with the interrupt request.
		:	:
		7Fh	*Read:* Interrupt request 127 maps to channel priority $CHANx_3$. *Write:* The default value of this bit after reset is given in Table 8-23. The channel priority $CHANx_3$ is set with the interrupt request.

8.9 Interrupt Request Assignments

For a complete list of interrupt request assignments, refer to Section 1.3.6 for the 14xx, Section 2.3.9 for the 16xx/18xx, and Section 3.3.9.1 for the 68xx devices.

DSP Subsystem C674x

See the device-specific Integration section to check the availability and configuration of this module.

Topic **Page**

9.1	Introduction	1544
9.2	TMS320C674x Megamodule	1545
9.3	Memory Map	1546
9.4	Advanced Event Triggering (AET)	1546
9.5	DSP Event Assignment	1547

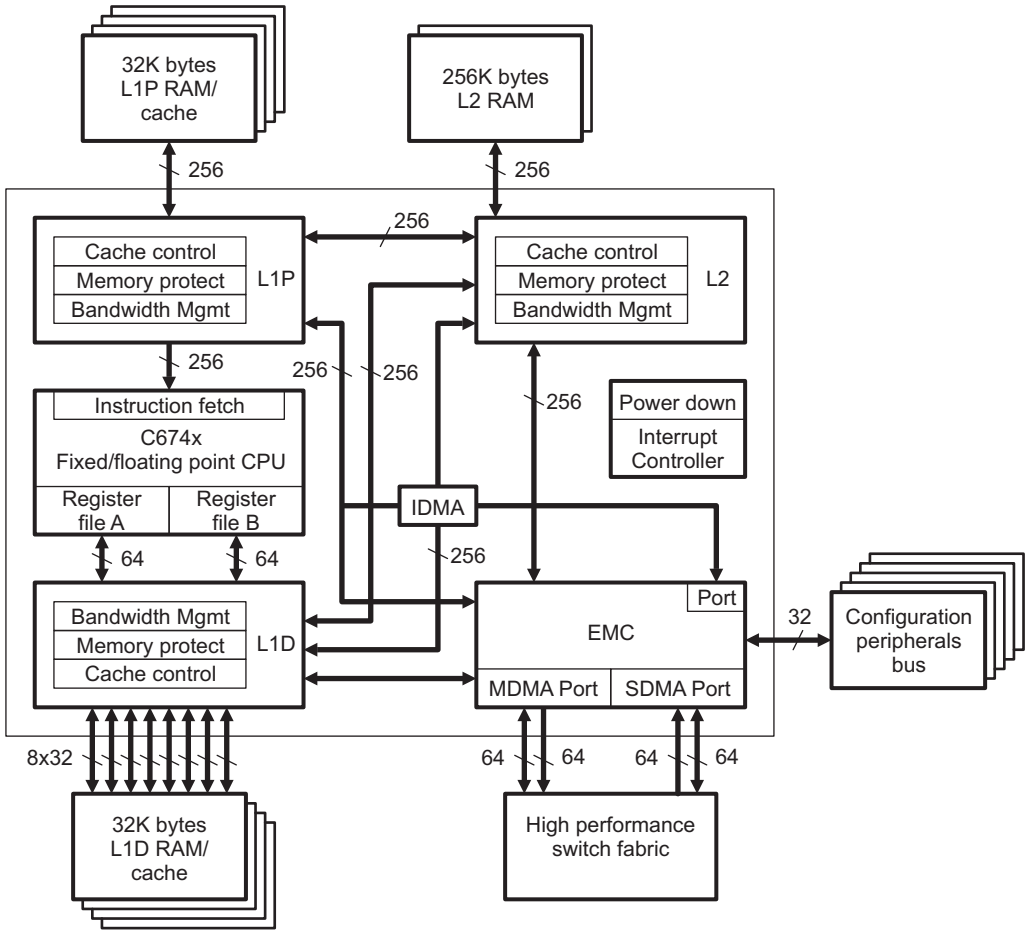
9.1 Introduction

The DSP subsystem (Figure 9-1) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). This section provides an overview of the DSP subsystem and the following considerations associated with it:

- Memory mapping
- Interrupts
- Power management

For more information on the TMS320C674x megamodule, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5), the *TMS320C674x DSP CPU and Instruction Set Reference Guide* (SPRUFE8), and the *TMS320C674x DSP Cache User's Guide* (SPRUG82).

Figure 9-1. TMS320C674x Megamodule Block Diagram



9.2 TMS320C674x Megamodule

The C674x megamodule (Figure 9-1) consists of the following components:

- TMS320C674x CPU
- Internal memory controllers:
  - Level 1 program memory controller (PMC)
  - Level 1 data memory controller (DMC)
  - Level 2 unified memory controller (UMC)
  - Extended memory controller (EMC)
  - Internal direct memory access (IDMA) controller
- Internal peripherals:
  - Interrupt controller (INTC)
  - Power-down controller (PDC)
  - Bandwidth manager (BWM)
- Advanced event triggering (AET)

For more information about each of these controllers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

9.2.1 Internal Memory Controllers

The C674x megamodule implements a two-level internal cache-based memory architecture with external memory support. Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). L1 memory is accessible to the CPU without stalls. Level 2 memory (L2) can also be split into L2 RAM (normal addressable on-chip memory) and L2 cache for caching external memory locations. The internal direct memory access controller (IDMA) manages DMA among the L1P, L1D, and L2 memories.

9.2.2 Internal Peripherals

The C674x megamodule includes the following internal peripherals:

- DSP interrupt controller (INTC)
- DSP power-down controller (PDC)
- Bandwidth manager (BWM)
- Internal DMA (IDMA) controller

This section briefly describes the INTC, PDC, BWM, and IDMA controller. For more information on these internal peripherals, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

9.2.2.1 Interrupt Controller (INTC)

The C674x megamodule includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps DSP device events to 12 CPU interrupts. All DSP device events are listed in . The INTC is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

9.2.2.1.1 Interrupt Controller Registers

For more information on the DSP interrupt controller (INTC) registers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

9.2.2.2 Power-Down Controller (PDC)

DSP core supports power-down feature. For details on how to power up/down the DSP core, see Section 4.4

9.2.2.3 Bandwidth Manager (BWM)

The bandwidth manager (BWM) provides a programmable interface for optimizing bandwidth among the requesters for resources, which include the following:

- EDMA3-initiated DMA transfers (and resulting coherency operations)
- DSP subsystem IDMA-initiated transfers (and resulting coherency operations)
- Programmable cache coherency operations
  - Block based coherency operations
  - Global coherency operations
- CPU direct-initiated transfers
  - Data access (load/store)
  - Program access

The resources include the following:

- L1P memory
- L1D memory
- L2 memory
- Resources outside of the C674x megamodule: external memory, on-chip peripherals, registers

Because any given requestor could potentially block a resource for extended periods of time, the bandwidth manager is implemented to assure fairness for all requesters.

The bandwidth manager implements a weighted-priority-driven bandwidth allocation. Each requestor (EDMA3, DSP subsystem IDMA, CPU, and so forth) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system. There are a total of nine priority levels, where priority zero is the highest priority and priority eight is the lowest priority. When requests for a single resource contend, access is granted to the highest-priority requestor. When the contention occurs for multiple successive cycles, a contention counter assures that the lower-priority requestor gets access to the resource every 1 out of *n* arbitration cycles, where *n* is programmable. A priority level of -1 represents a transfer whose priority has been increased due to expiration of the contention counter or a transfer that is fixed as the highest-priority transfer to a given resource.

9.2.2.4 Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the C674x megamodule. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port. The IDMA cannot transfer data to or from the internal DSP memory-mapped register space. The IDMA is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

9.3 Memory Map

Refer to the device-specific memory map section for the addresses of the memory-map registers.

9.4 Advanced Event Triggering (AET)

The C674x megamodule supports advanced event triggering (AET). This capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware program breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

9.5 DSP Event Assignment

For DSP event assignments, refer to Table 3-9.

DSS_L3 Memory Organization

Topic **Page**

10.1 DSS_L3 Memory Organization for 14xx 1549
10.2 DSS_L3 Memory Organization for 16xx/18xx 1551
10.3 DSS_L3 Memory Organization for 68xx 1552

10.1 DSS_L3 Memory Organization for 14xx

On-chip shared memory of the 14xx device serves two main purposes:

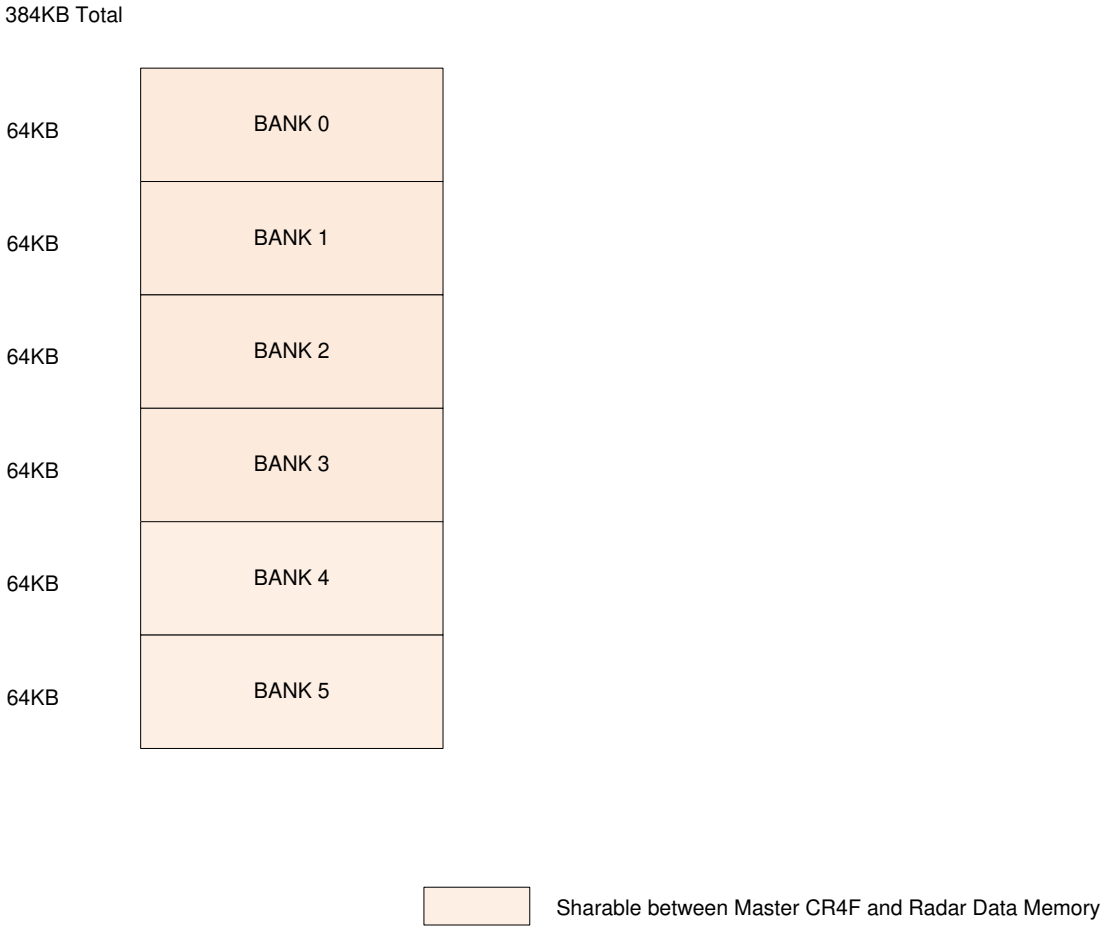
1. Radar data memory
2. A way to extend the tightly coupled memories of the Master Cortex-R4

All registers mentioned in this chapter reside in the MSS_TOPRCM module, in the device-specific control registers.

10.1.1 Functional Description

A max of 384KB of memory is available as shared memory. This memory is structured into sections of 64KB banks, as shown in Figure 10-1.

Figure 10-1. DSS_L3 Memory Organization



NOTE: Bank 0, Bank 1, Bank 2 - MSS_TCMA,DSS

Bank 3-MSS_TCMB,DSS

Bank 4, 5-DSS

Only Banks 0,1,2 has ECC

Each bank can be allotted either to MSS CR4F TCMA, MSS CR4F TCMB, or radar data memory by using register configurations to MSS_TOPRCM registers as shown in Table 10-1. Memory banks assigned to the radar data cube are accessible as DSS_L3 shared memory.

Set the appropriate bit in range bit[5:0] in the following register to assign the available bank to the desired master.

Table 10-1. MSS_TOPRCM Registers

MSS_TOPRCM Register	Description	Applicable devices
DSSMEMBANKEN	Setting bit N=1 in this register will allow shared memory's Nth bank to be accessed as Radar Data Memory. (L3 shared memory). Note: Only bits [5:0] are valid for 14xx	14xx
TCMAMEMBANK_EN	Setting bit N=1 in this register will allow shared memory's Nth bank to be accessed as TCMA ram by Master Subsystem Cortex R4F Note: Only bits [5:0] are valid for 14xx	14xx
TCMBMEMBANKEN	Setting bit N=1 in this register will allow shared memory's Nth bank to be accessed as TCMB ram by Master Subsystem Cortex R4F Note: Only bits [5:0] are valid for 14xx	14xx

NOTE: The user must ensure that each bank is assigned to only one master while writing to the above registers.

Based on the number of bits set as 1 in the xMEMBANKEN registers, that many multiples of 64KB memory spaces are allotted to the desired master. Each of these masters has a xMEMTAB register that decides which 64Kb address range is routed to which available shared memory bank. This can be set through the following MSS_TOPRCM registers, as shown in Table 10-2.

Table 10-2. MSS_TOPRCM Registers

MSS_TOPRCM Register	Description	Applicable devices
DSSMEMTAB0	Each consecutive 4 bits represent the shared memory number to which Nth 64KB address from Radar Data memory (L3 shared memory) get routed to. Bits [3:0] represent the first 64Kb address range in L3 shared memory.	14xx
TCMAMEMTAB0	Each consecutive 4 bits represent the shared memory number to which Nth 64KB address in TCMA range get routed to. Bits [3:0] represent the first 64Kb address range in L3 shared memory.	14xx
TCMBMEMTAB0	Each consecutive 4 bits represent the shared memory number to which Nth 64KB address TCMB range get routed to. Bits [3:0] represent the first 64Kb address range in L3 shared memory.	14xx

NOTE: For the 14xx, the value of each 4-bit field should be between 0 to 5.

NOTE: Shared memory bank numbers written to this field should be assigned to the master in the xMEMBANKEN register.

See Section 10.1.3 for more on memory tab initialization.

10.1.2 Memory Auto Initialization

Hardware auto initialization of the L3 memory banks is supported at reset, so that false ECC failures are not reported by writing to the MEMINITSTART register. Memory initialization is provided for each bank of 64KB. The memory is initialized to all zero values, and for every 32-bit word calculated, ECC is 0x0C. Memory initialization status is available in the MEMINITDONE register. The user must program the memory address range to be initialized by programming the SHMEMINITADDR and the ECC value in the SHMEMINITECC register.

10.1.3 Memory TAB Register

The set of memory banks allocated to the either of the masters can be ordered as per the needs of the application software. The DSSMEMTAB0, TCMAMEMTAB, and TCMBMEMTAB registers are programmed accordingly to achieve the memory bank ordering.

For example, if Banks 2,3, and 4 are enabled and allocated radar data memory (L3 shared) by writing the following set of registers:

DSSMEMBANKEN = 0x0000001C

the DSS mem tab for these banks are set to 2,3, and 4, respectively, as follows:

DSSMEMTAB0 = 0x000432XX

The rest of the banks are disabled. The first 64KB accesses to the shared memory space result in access to BANK2; 128KB accesses on bank-3, and so forth.

If the DSSMEMTAB0 is programmed to a value of 0x000234XX, then the first 128KB accesses to the shared memory space result in access to bank-4, 128KB accesses on bank-3, and so forth.

10.2 DSS_L3 Memory Organization for 16xx/18xx

The on-chip shared memory of the 16xx/18xx device serves two main purposes:

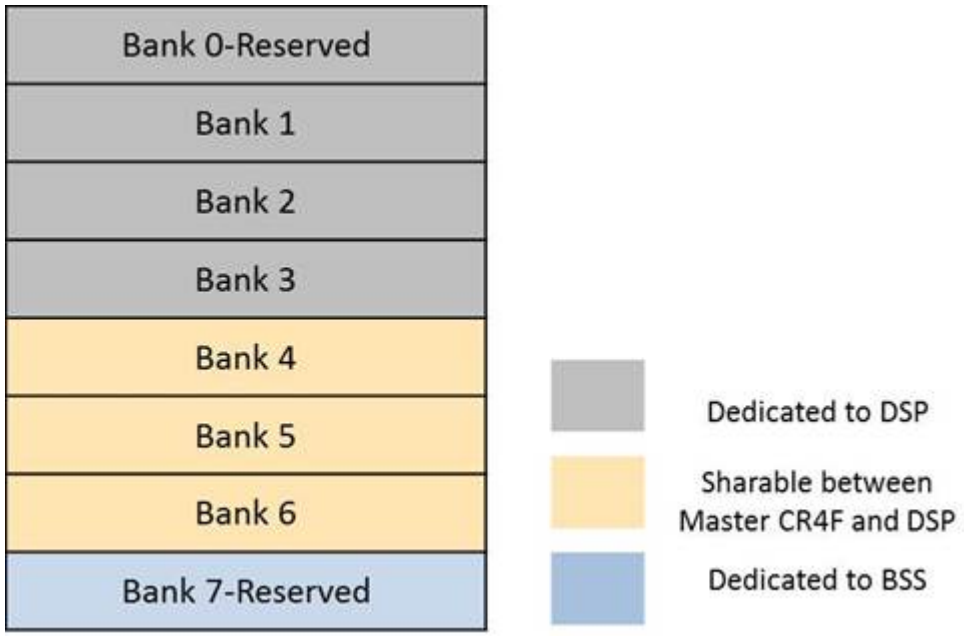
- Radar data memory
- A way to extend the tightly coupled memories of the Master Cortex-R4

All registers mentioned in this chapter reside in the MSS_TOPRCM module, in the device-specific control registers.

10.2.1 Functional Description

A maximum of 768KB of ECC-enabled memory is available as shared DSS_L3 memory in the DSP subsystem. The memory is structured into sections of 128KB, out of which can be allocated to the DSP or master Cortex-R4F, as shown in Figure 10-2.

Figure 10-2. DSS_L3 Memory Organization



As shown in Figure 10-2, the available DSS_L3 memory is 768K bytes. Some banks in the L3 shared memory are reserved (not available) or dedicated to the DSP, and the remaining memory can be shared between DSP and the Master Cortex-R4F at 128Kbyte granularity. For the Cortex-R4F, the shared memory can be an extension to the tightly coupled memories TCMA and TCMB, with the same access latencies as the TCMA and TCMB.

Any access to the DSP-dedicated space by the Master CR4F results in an ABORT. The user may decide to share the remaining memory by configuring the registers SHMEMBANKSEL. Information about how this sharing should be done is either provided by the header on the QSPI flash or over the SPI interface, before downloading the application image. ECC with the SECDED feature is supported on the DSS_L3 memory. An example of register programming for various configurations of memory allocations is shown in Table 10-3.

Table 10-3. Register Programming

DSP	CR4-TCMA	CR4-TCMB	Register Programming
768KB	256KB	192KB	SHMEMBANKSEL7TO4=0x10010101
512KB	384KB	320KB	SHMEMBANKSEL7TO4=0x10040201
512KB	512KB	192KB	SHMEMBANKSEL7TO4=0x10020201

10.2.2 Memory Auto-Initialization

Hardware auto-initialization of the DSS_L3 memory banks is supported at reset, so that false ECC failures are not reported by writing to the MSS_TOPRCM.MEMINITSTARTSHMEM register. Memory initialization is provided for each bank of 128KB. The memory is initialized to all zero values, and for every 32-bit word calculated, ECC is 0x0C. Memory initialization status is available in the MSS_TOPRCM.MEMINITDONESHMEM register.

10.2.3 Memory TAB Register

The set of memory banks allocated to the either of the master can be ordered as per the needs of application software. The DSSMEMTAB0, TCMAMEMTAB, and TCMBMEMTAB registers in MSS_TOPRCM are programmed to achieve the memory bank ordering.

For example, if banks 2, 3, and 4 are enabled or allocated for DSP by writing the following set of registers:

SHAREDBANKSEL3TO0 = 0x0101XXXX

SHAREDBANKSEL7TO4 = 0x00000001

and the DSS memory tab for these banks are set to 2, 3, and 4, respectively, as follows:

DSSMEMTAB0 = 0x000432XX

The rest of the banks are disabled by setting 0x0. Any access beyond the enabled banks wraps back to bank 2. According to this programming, the first 128KB accesses to the shared memory space result in access to BANK2, then 128KB accesses on bank-3, and so forth.

If the DSSMEMTAB0 is programmed to the value 0x000234XX, then the first 128KB accesses to the shared memory space result in access to bank-4, then 128KB accesses on bank-3, and so forth.

10.3 DSS_L3 Memory Organization for 68xx

The on-chip shared memory of the 68xx device serves two main purposes:

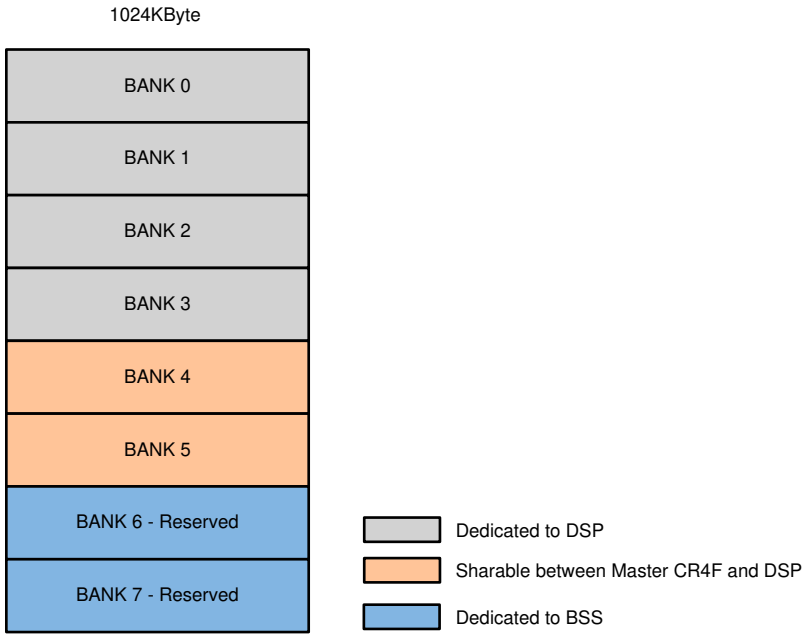
- Radar data memory
- A way to extend the tightly coupled memories of the Master Cortex-R4

All registers mentioned in this chapter reside in the MSS_TOPRCM module, in the device-specific control registers.

10.3.1 Functional Description

A maximum of 768KB of ECC-enabled memory is available as shared DSS_L3 memory in the DSP subsystem. The memory is structured into sections of 128KB, out of which can be allocated to the DSP or master Cortex-R4F, as shown in Figure 10-3.

Figure 10-3. DSS_L3 Memory Organization



As shown in Figure 10-3, the available DSS_L3 memory is 768K bytes. Some banks in the DSS_L3 memory are reserved (not available) or dedicated to the DSP, and the remaining memory can be shared between DSP and the Master Cortex-R4F at 128Kbyte granularity. For the Cortex-R4F, the shared memory can be an extension to the tightly coupled memories TCMA and TCMB, with the same access latencies as the TCMA and TCMB.

Any access to the DSP-dedicated space by the Master CR4F results in an ABORT. The user may decide to share the remaining memory by configuring the registers SHMEMBANKSEL. Information about how this sharing should be done is either provided by the header on the QSPI flash or over the SPI interface, before downloading the application image. ECC with the SECDED feature is supported on the DSS_L3 memory. An example of register programming for various configurations of memory allocations is shown in Table 10-4.

Table 10-4. Register Programming

DSP	CR4-TCMA	CR4-TCMB	Register Programming
768KB	512KB	192KB	SHMEMBANKSEL7TO4=0x10100101
512KB	640KB	320KB	SHMEMBANKSEL7TO4=0x10100402
512KB	768KB	192KB	SHMEMBANKSEL7TO4=0x10100202

10.3.2 Memory Auto-Initialization

Hardware auto-initialization of the DSS_L3 memory banks is supported at reset, so that false ECC failures are not reported by writing to the MSS_TOPRCM.MEMINITSTARTSHMEM register. Memory initialization is provided for each bank of 128KB. The memory is initialized to all zero values, and for every 32-bit word calculated, ECC is 0x0C. Memory initialization status is available in the MSS_TOPRCM.MEMINITDONESHMEM register.

10.3.3 Memory TAB Register

The set of memory banks allocated to the either of the master can be ordered as per the needs of application software. The DSSMEMTAB0, TCMAMEMTAB, and TCMBMEMTAB registers in MSS_TOPRCM are programmed to achieve the memory bank ordering.

For example, if banks 2, 3, and 4 are enabled or allocated for DSP by writing the following set of registers:

SHAREDBANKSEL3TO0 = 0x0101XXXX

SHAREDBANKSEL7TO4 = 0x00000001

and the DSS memory tab for these banks are set to 2, 3, and 4, respectively, as follows:

DSSMEMTAB0 = 0x000432XX

The rest of the banks are disabled by setting 0x0. Any access beyond the enabled banks wraps back to bank 2. According to this programming, the first 128KB accesses to the shared memory space result in access to BANK2, then 128KB accesses on bank-3, and so forth.

If the DSSMEMTAB0 is programmed to the value 0x000234XX, then the first 128KB accesses to the shared memory space result in access to bank-4, then 128KB accesses on bank-3, and so forth.

Handshake RAM (HSRAM)

The main use of these memories is to transfer the detected object list to the Master R4F from DSP. L3 shared memory can also be used for the same purpose, but considering the arbitration losses on L3, an additional memory of various size is kept for the asynchronous access by Cortex R4F without impacting the throughput, due to any kind of arbitration in the system.

Enhanced Direct Memory Access (EDMA)

This section describes the Enhanced Direct Memory Access (EDMA) controller. This chapter covers features of EDMA module. For features applicable to the EDMA instances in the device, see the device-specific Integration section. The primary purpose of the EDMA controller is to service data transfers programmed between two memory-mapped slave endpoints on the device. The EDMA controller consists of two principle blocks:

- EDMA channel controllers: EDMA_TPCC
- EDMA transfer controllers: EDMA_TPTC

Devices can have multiple instances of EDMA channel controllers, each associated with multiple EDMA transfer controllers.

The EDMA channel controller serves as the user interface for the EDMA controller. The EDMA_TPCC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TR) to the EDMA3 transfer controller.

The EDMA transfer controllers are responsible for data movement. The transfer request packets (TRP) submitted by the EDMA_TPCC contain the transfer context, based on which the transfer controller issues read/write commands to the source and destination addresses programmed for a given transfer.

12.2 EDMA Controller Functional Description **1559**
12.3 EDMA Transfer Examples **1607**
12.4 EDMA Debug Checklist and Programming Tips **1614**
12.5 EDMA Request Map **1615**
12.6 EDMA Register Manual **1616**

12.1 EDMA Module Overview

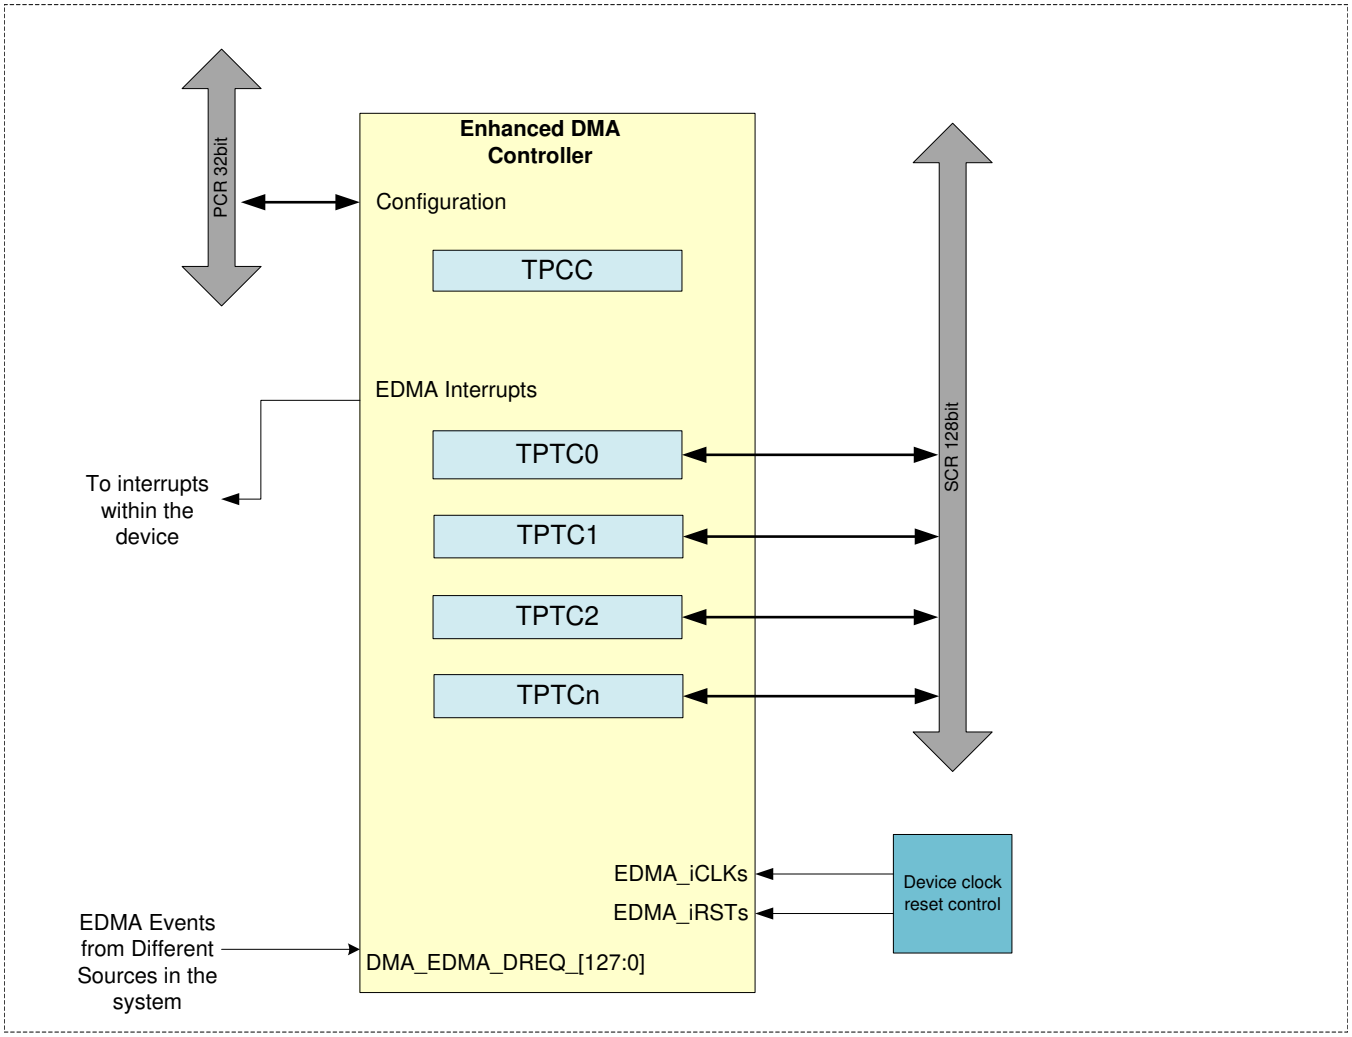
The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

Figure 12-1 shows an overview of the EDMA module.

Figure 12-1. EDMA Module Overview



For EDMA instances available on the device, see the device-specific integration section.

The **TPCC** is a high flexible channel controller that serves as both a user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals, and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals, as programmed in the Active and Pending set of the registers. The transfer controllers are responsible for data movement, and issue read/write commands to the source and destination addresses programmed for a given transfer in the EDMA_TPCC.

12.1.1 EDMA Features

This section shows generic EDMA features. For features applicable to the EDMA instances in the devicem, see the device-specific Integration section.

The EDMA_TPCC channel controller has the following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions
  - A-synchronized transfers: one dimension serviced per event
  - AB-synchronized transfers: two dimensions serviced per event
  - Independent indexes on source and destination
  - Chaining feature allowing a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes
  - Linking mechanism allows automatic PaRAM set update
  - Chaining allows multiple transfers to execute with one event
- Interrupt generation for the following:
  - Transfer completion
  - Error conditions
- Debug visibility:
  - Queue water marking/threshold
  - Error and status recording to facilitate debug
- 64 DMA request channels:
  - Event synchronization
  - Manual synchronization (CPUs write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 384 PaRAM sets, EDMA_TPCC0:128, EDMA_TPCC1:256:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Multiple transfer controllers/event queues.
- 16 event entries per event queue.

The **EDMA_TPTC** transfer controller has the following features:

- 128-bit wide read and write ports per TC
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the third dimension)
- Support for increment or constant addressing mode transfers
- Interrupt and error support
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness

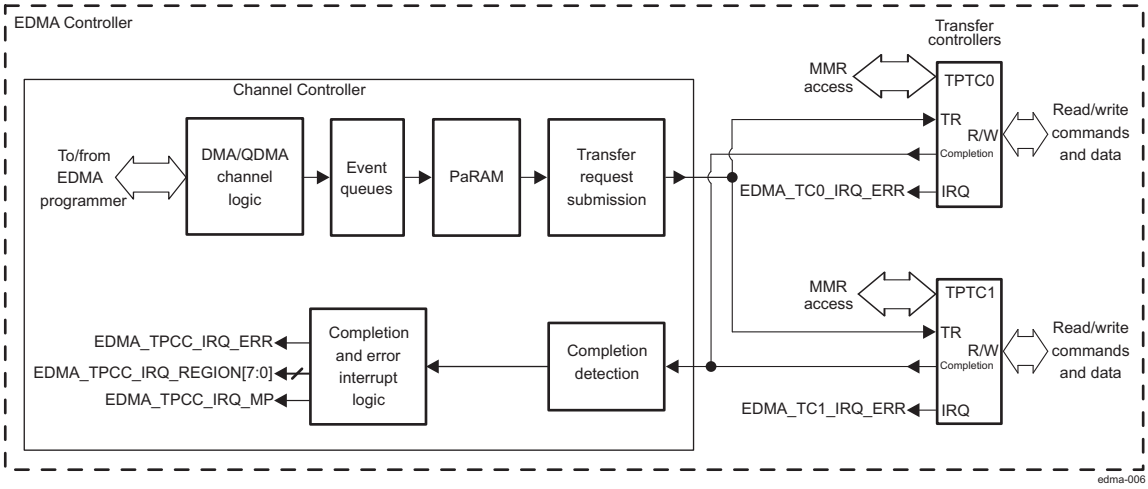
12.2 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller. The description contained in this section is generic to the EDMA module, and not all features mentioned here are supported by the device. See the EDMA configuration section of the device to determine the applicability of these features.

12.2.1 Block Diagram

Figure 12-2 shows the functional block diagram of the EDMA controller.

Figure 12-2. EDMA Controller Block Diagram



12.2.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 12-3 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- EDMA event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

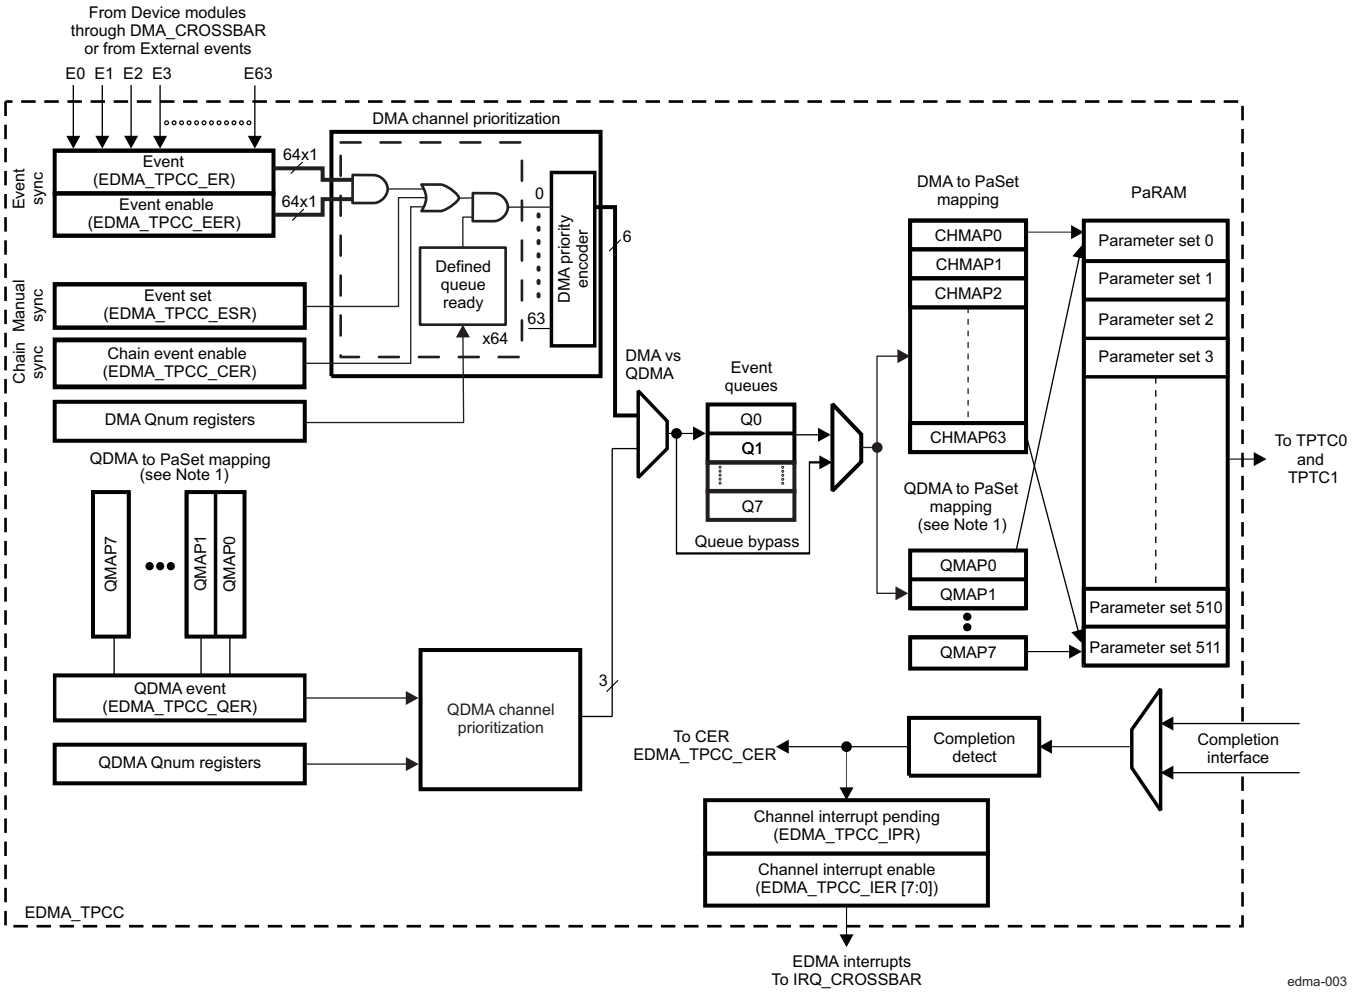
- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 12-3 is a block diagram of the EDMA_TPCC.

Figure 12-3. EDMA Channel Controller Block Diagram



(1) Although it is depicted twice in Figure 12-3, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry.

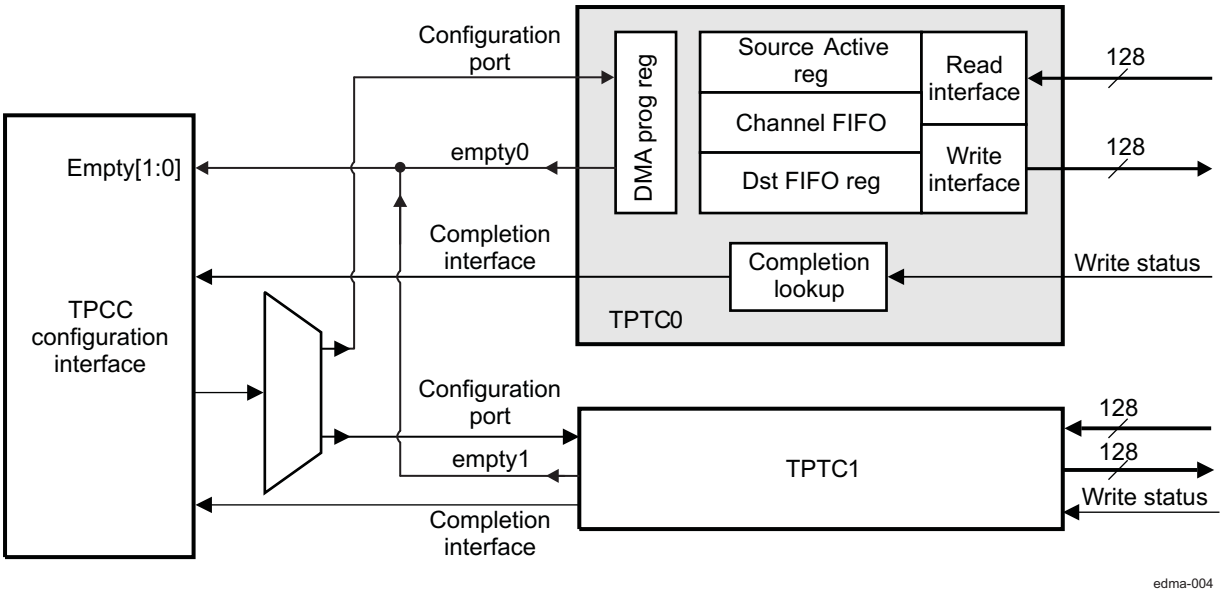
The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

12.2.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 12-4 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

Figure 12-4. TPTC Block Diagram



NOTE: The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- DMA Program Register Set: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- Source Active Register Set : Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in

progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

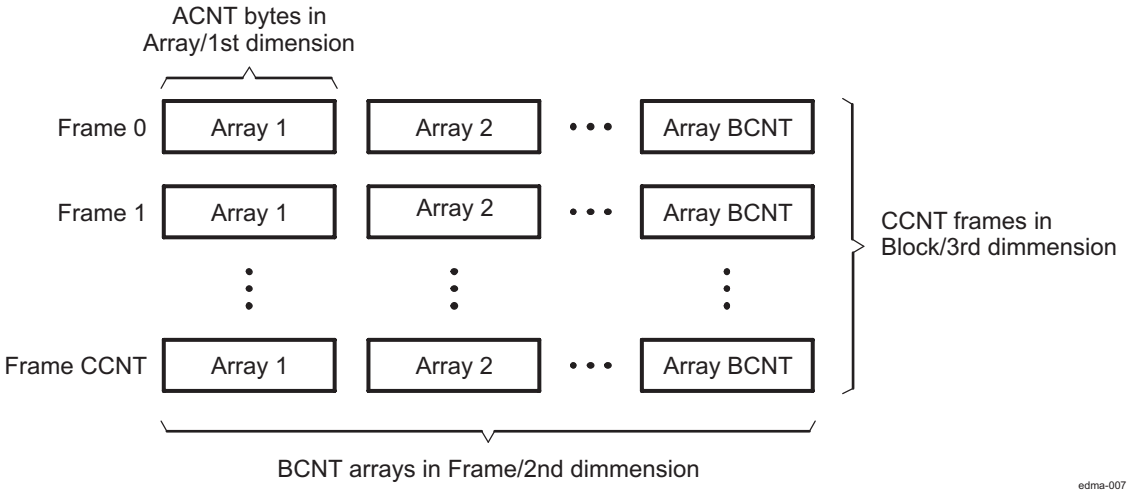
12.2.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 12-5 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

NOTE: The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 12-5. Definition of ACNT, BCNT, and CCNT



12.2.2.1 A-Synchronized Transfers

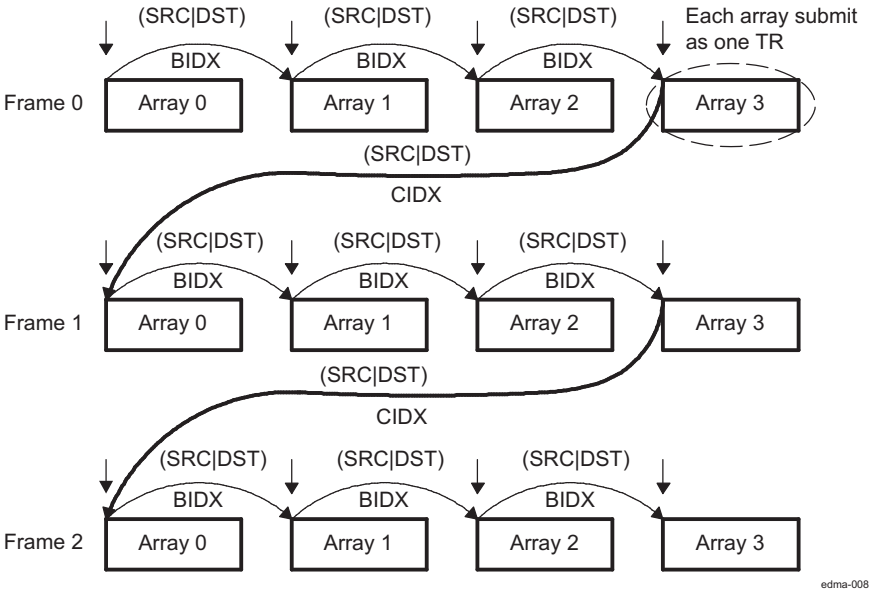
In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0]SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 12-6, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 12-6, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 12-6 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 12-6 for details on parameter set updates.

Figure 12-6. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



12.2.2.2 AB-Synchronized Transfers

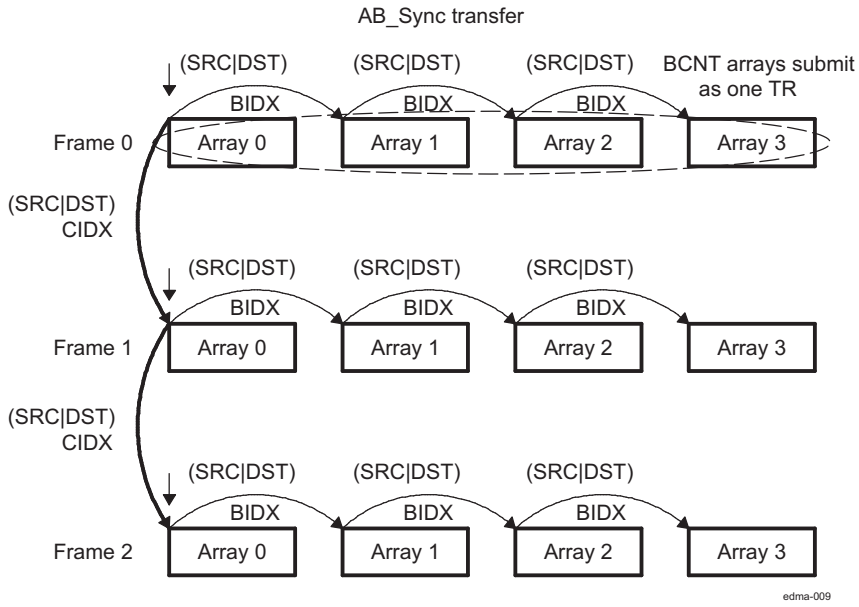
In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 12-7. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 12.2.3.6 *Parameter Set Updates* for details on parameter set updates.

Figure 12-7 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 12-7. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



NOTE: ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

12.2.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels

- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 12-1. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters[1]
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

(1) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

12.2.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 12-8 and described in Table 12-2. Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 12-8. PaRAM Set

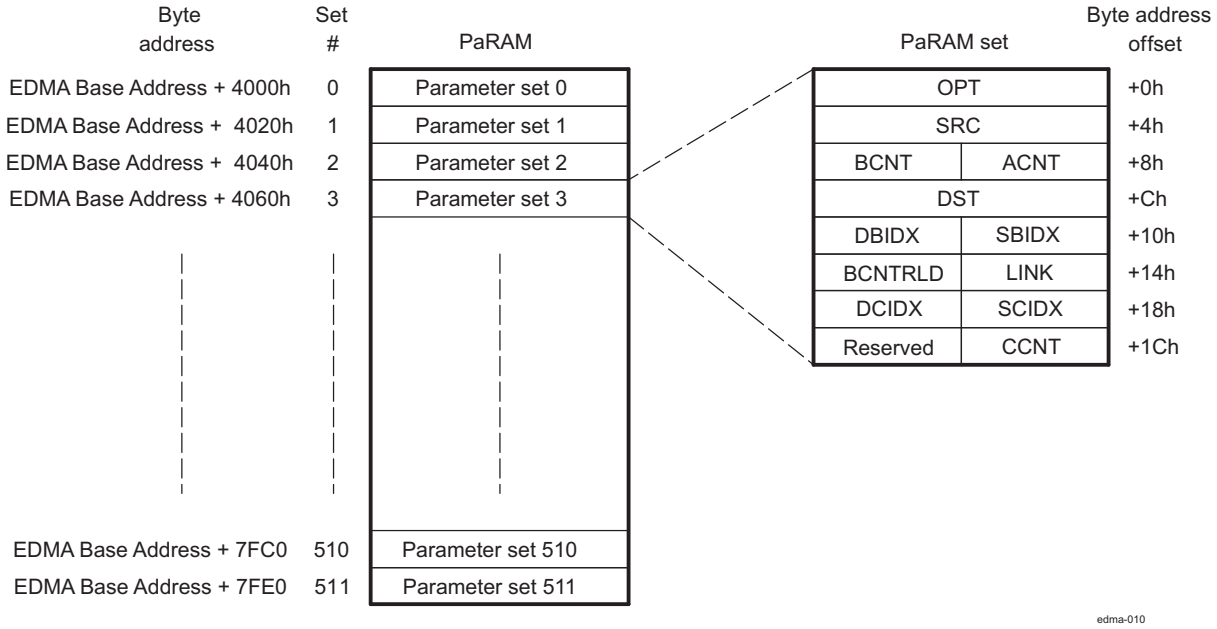


Table 12-2. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h[1]	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h[1]	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h[1]	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h[1]	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

12.2.3.2 EDMA Channel PaRAM Set Entry Fields

12.2.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in , *EDMA_TPCC Register Description*.

12.2.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 12.2.12.3 *Error Generation* for additional details.

12.2.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 12.2.12.3 *Error Generation* for additional details.

12.2.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 12.2.3.5 *Dummy Versus Null Transfer Comparison* and Section 12.2.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

12.2.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 12.2.3.5 *Dummy Versus Null Transfer Comparison* and Section 12.2.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

12.2.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to Section 12.2.3.5 *Dummy Versus Null Transfer Comparison* and Section 12.2.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

12.2.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

12.2.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

12.2.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to Section 12.2.3.2.8 *Source B Index (SBIDX)* for examples.

12.2.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 12-6), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 12-7).

12.2.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 12-6), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 12-7).

12.2.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see Section 12.2.5 *Completion of a DMA Transfer* for details on terminating a transfer.

12.2.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).
This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

12.2.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

12.2.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EDMA_TPCC_EMR to get set and the E*n* bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 12-3 summarizes the conditions and effects of null and dummy transfer requests.

Table 12-3. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

12.2.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to Table 12-4 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 12.2.3.7 *Linking Transfers*.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.

NOTE: PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 12.2.12 *EDMA Transfer Controller (EDMA_TPTC)*. For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

Table 12-4 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 12-4. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_CCNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TPTC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TPTC	+= DCIDX	= Link.EDMA_TPCC_DST_n
ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT
BCNT	–= 1	= BCNTRLD	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT	in EDMA_TPTC	N/A	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT
CCNT	None	–= 1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT	in EDMA_TPTC	-=1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT
SBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TPTC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
SCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TPTC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT[1]	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

NOTE: The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

12.2.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

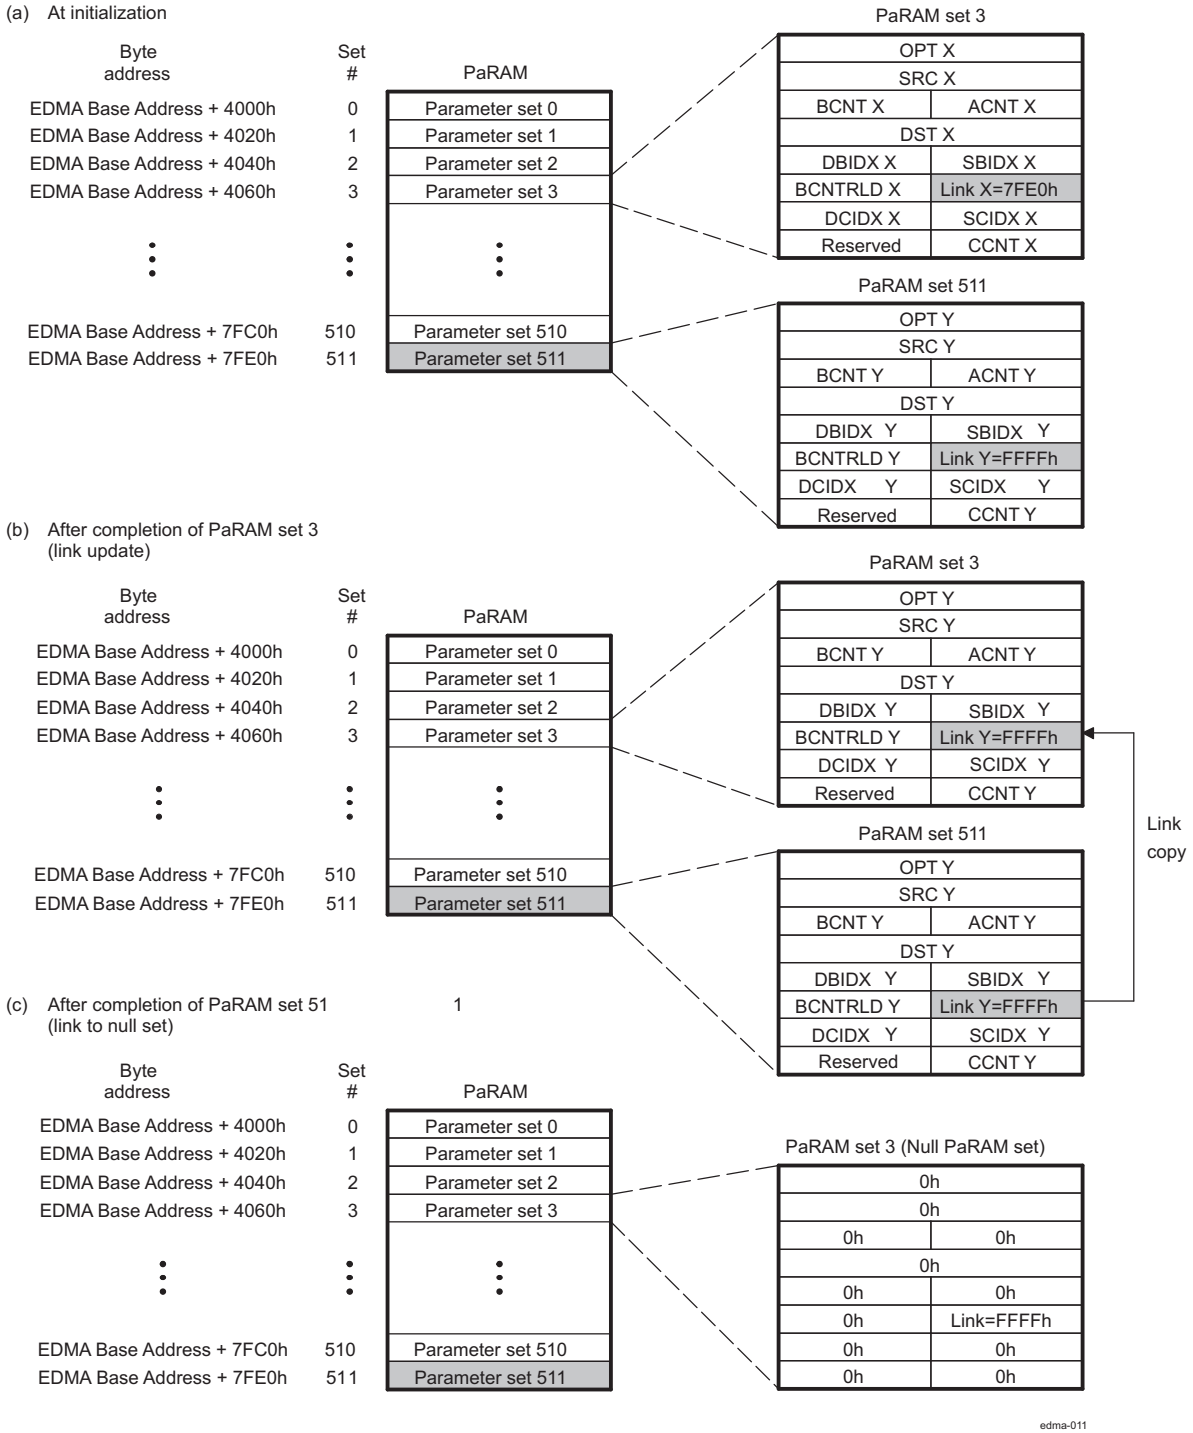
NOTE: It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to Section 12.2.3.3 *Null PaRAM Set*.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set. Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 12-9 shows an example of a linked transfer.

Figure 12-9. Linked Transfer

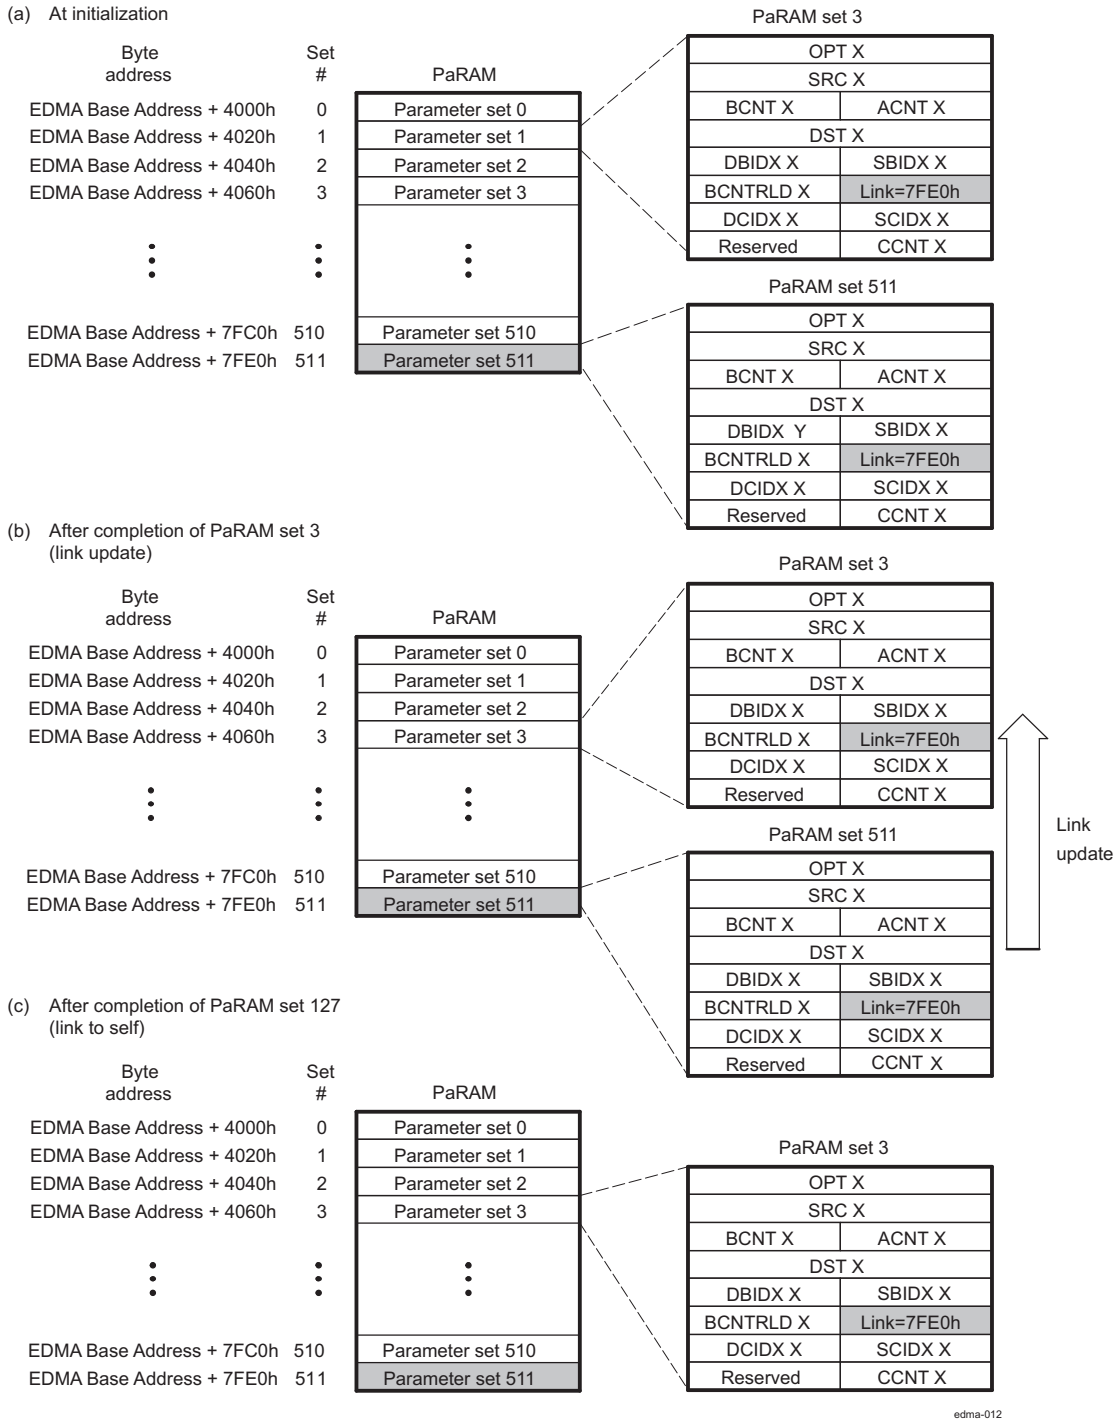


Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 12.2.6 *Event, Channel, and PaRAM Mapping*) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to Section 12.2.4.2 *QDMA Channels*.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 12-10 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

Figure 12-10. Link-to-Self Transfer



NOTE: If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

12.2.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to Section 12.2.12.3 *Error Generation*.

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM =0) by appropriately programming the count and indices values.

12.2.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

12.2.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

12.2.4.1 DMA Channels

12.2.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] E*n* = 1). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.
If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] E*n* bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see Section 12.2.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] E*n* = 1), regardless of the state of EDMA_TPCC_EER[31:0] E*n*. If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] E*n* = 1 and EDMA_TPCC_EER[31:0] E*n* = 0), the EDMA_TPCC_ER[31:0] E*n* bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] E*n* = 1).

12.2.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 12.2.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] E*n* = 1 prior to the original being cleared EDMA_TPCC_ESR[31:0] E*n* = 0, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

12.2.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] E[TCC] = 1).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 12.2.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

NOTE: Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E*n* can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

12.2.4.2 QDMA Channels

12.2.4.2.1 Auto-Triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] E*n* = 1. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] E*n* = 1 and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] E*n* = 1.

12.2.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

NOTE: The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT =1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

12.2.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 12-5 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 12-5. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to Section 12.2.8 *Chaining EDMA Channels* for details on chaining (intermediate/final chaining) and Section 12.2.9 *EDMA Interrupts* for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to Section 12.2.3.7 *Linking Transfers* for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to Section 12.2.3.5 *Dummy Versus Null Transfer Comparison*.

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

12.2.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

12.2.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

12.2.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set Section 12.2.3.4 or null set Section 12.2.3.3. In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

12.2.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[3:0] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

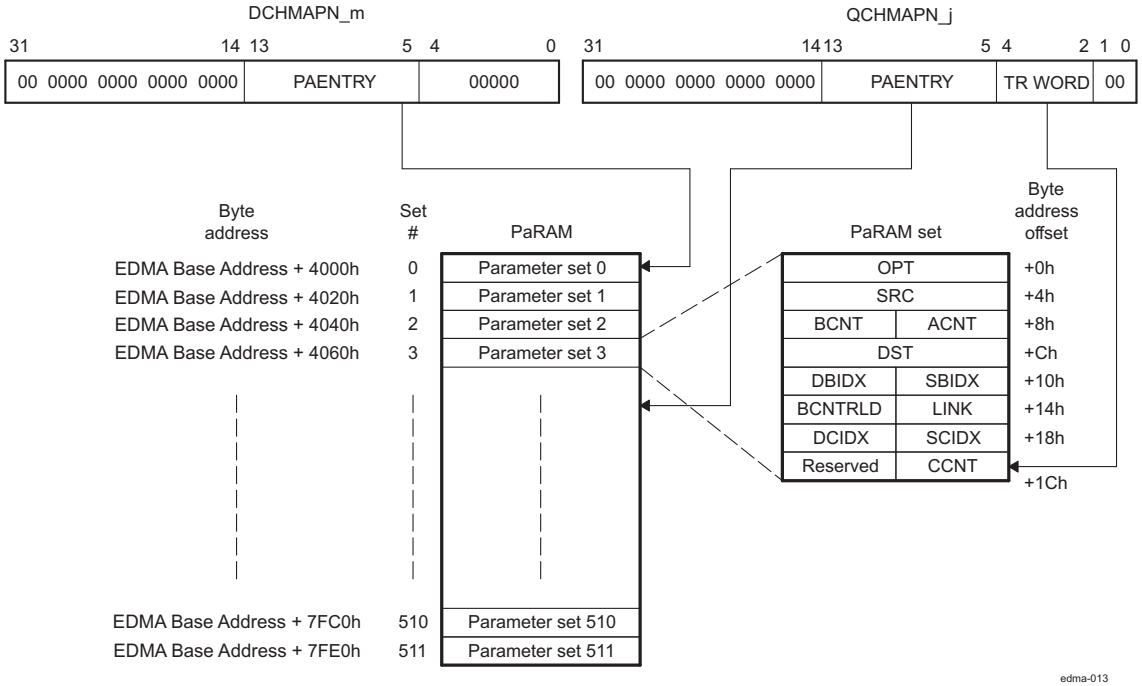
The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

12.2.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 12-1). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 12-11 illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

Figure 12-11. DMA Channel and QDMA Channel to PaRAM Mapping



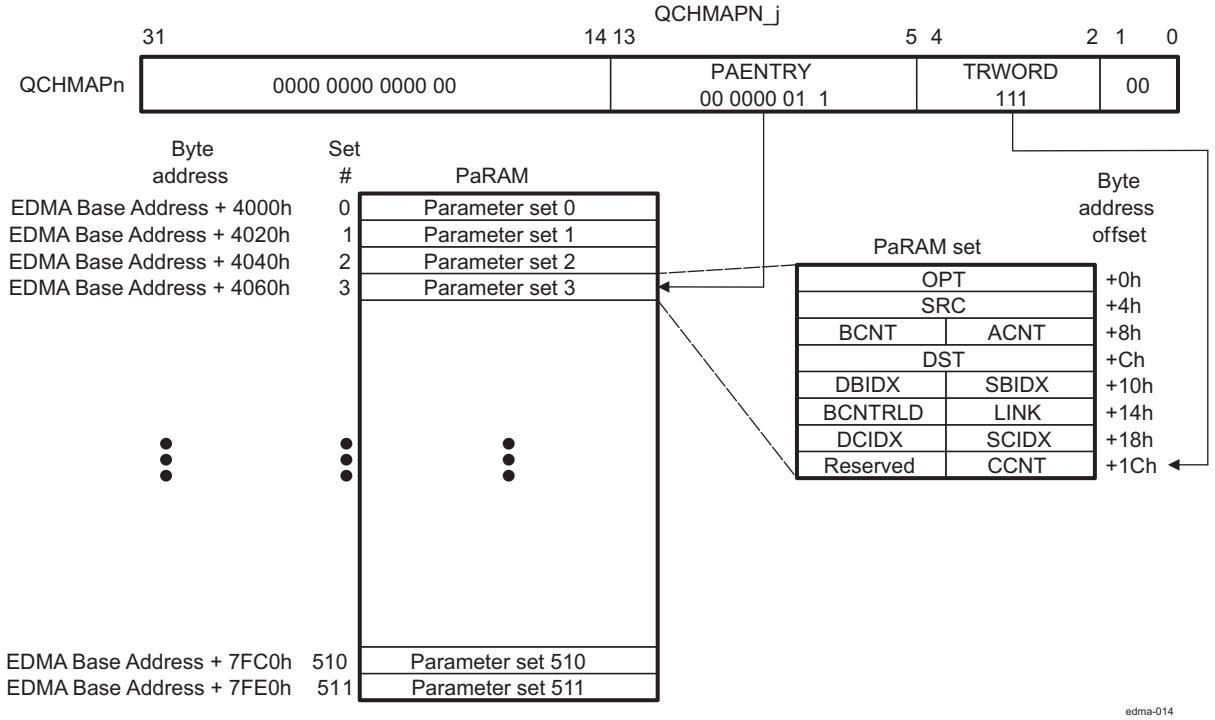
12.2.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register EDMA_TPCC_QCHMAPN_j in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 12-12 illustrates the use of EDMA_TPCC_QCHMAPN_j.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by EDMA_TPCC_QCHMAPN_j for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

Figure 12-12. QDMA Channel to PaRAM Mapping



12.2.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in Section 12.2.10 *Memory Protection*.

12.2.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). Table 12-6 lists the registers in the shadow region memory map. Refer to *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Table 12-6. Shadow Region Registers

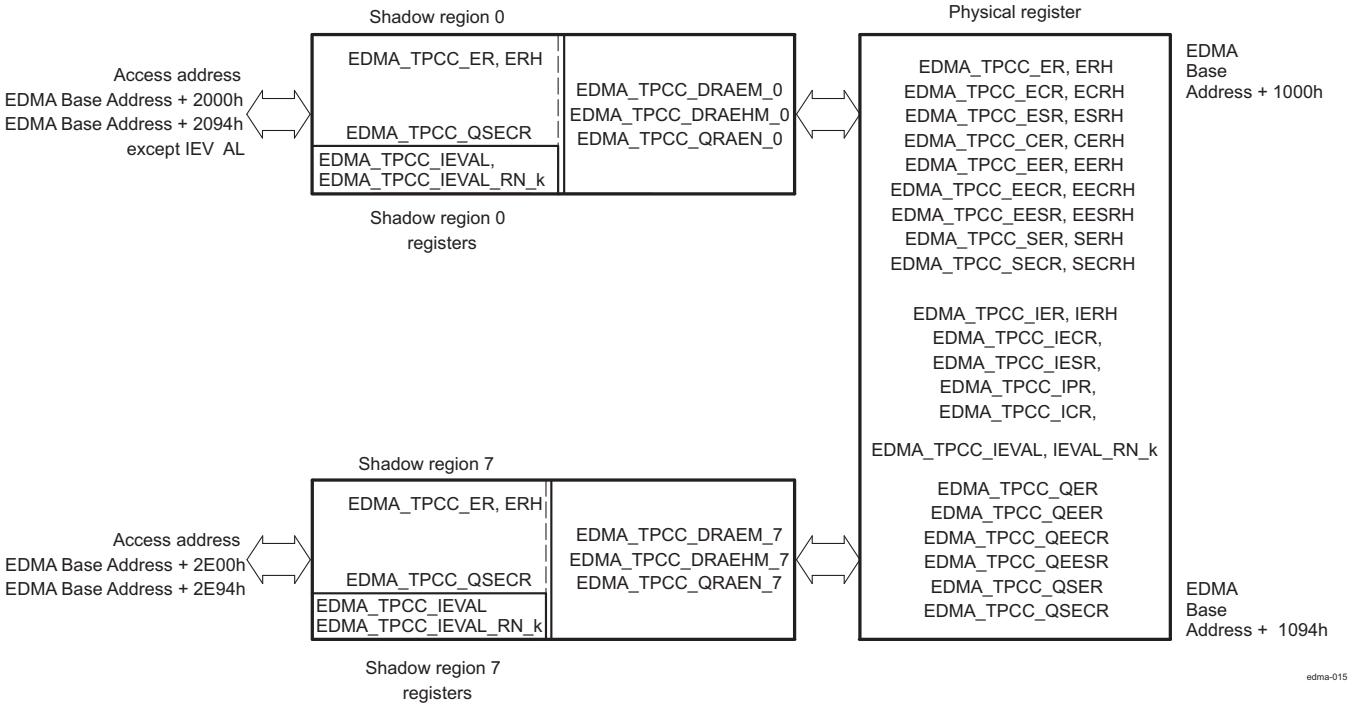
Figure 12-13 illustrates the conceptual view of the regions.

Figure 12-13. Shadow Region Registers



12.2.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMA_TPCC_DRAEM_k and EDMA_TPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMA_TPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMA_TPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMA_TPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMA_TPCC_QEESR there will be no the desired effect.
- EDMA_TPCC_MPPAN_k and EDMA_TPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k have the associated bit set.

Example 12-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

12.2.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to *Hardware Request* for more information about EDMA Interrupts.

12.2.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 12.2.3.7 *Linking Transfers*). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see Section 12.2.4.1.3 *Chain-Triggered Transfer Request*).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 12-7 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 12-7. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

12.2.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 12-8. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 12-8. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
EDMA_TPCC_INT3	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 12-9. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

12.2.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 12.2.9.1.1 *Enabling Transfer Completion Interrupts* for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 12-10. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set[1]
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	...	...	...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 12-11 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 12-11. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

12.2.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

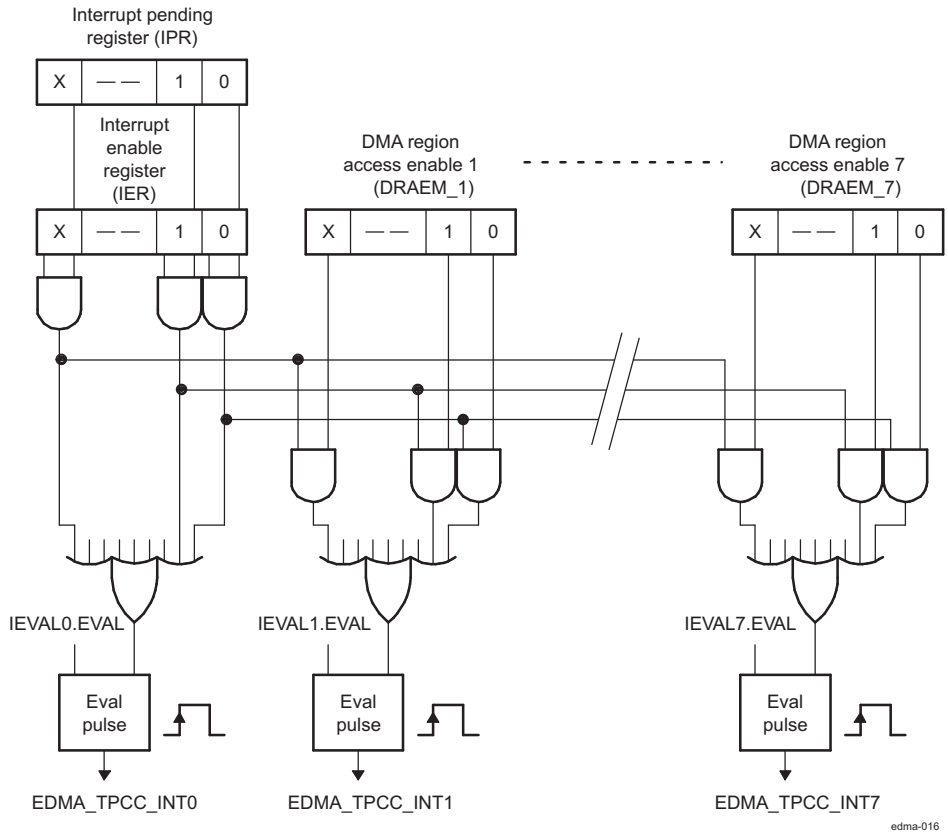
All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see Figure 12-14

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

Figure 12-14 shows the Interrupt diagram of the EDMA controller.

Figure 12-14. Interrupt Diagram



The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | …| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

NOTE: The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

12.2.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

12.2.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in Example 12-2 and Example 12-3.

The ISR routine in Example 12-2 is more exhaustive and incurs a higher latency.

Example 12-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

Example 12-2. Interrupt Servicing (continued)

b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, assure that all of the enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

Example 12-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 12-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the EDMA_TPCC_IEVAL[0] EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
3. For the condition that is set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA_TPCC after step 2).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH prior to exiting the ISR:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, then exit the ISR.
   b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, then set EDMA_TPCC_IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

12.2.9.3 Interrupt Evaluation Operations

The EDMA_TPCC has interrupt evaluate registers EDMA_TPCC_IEVAL that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k. Writing a 1 to the EDMA_TPCC_IEVAL[0] EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMA_TPCC_IER / EDMA_TPCC_IERH) is still pending EDMA_TPCC_IPR / EDMA_TPCC_IPRH. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to Example 12-3 about the use of EDMA_TPCC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register EDMA_TPCC_EEVAL exists in the global region. Writing a 1 to the EDMA_TPCC_EEVAL[0] EVAL bit causes the pulsing of the error interrupt if any pending errors are in EDMA_TPCC_EMR / EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR. See Section 12.2.9.4 *Error Interrupts* for additional information regarding error interrupts.

NOTE: While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

12.2.9.4 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

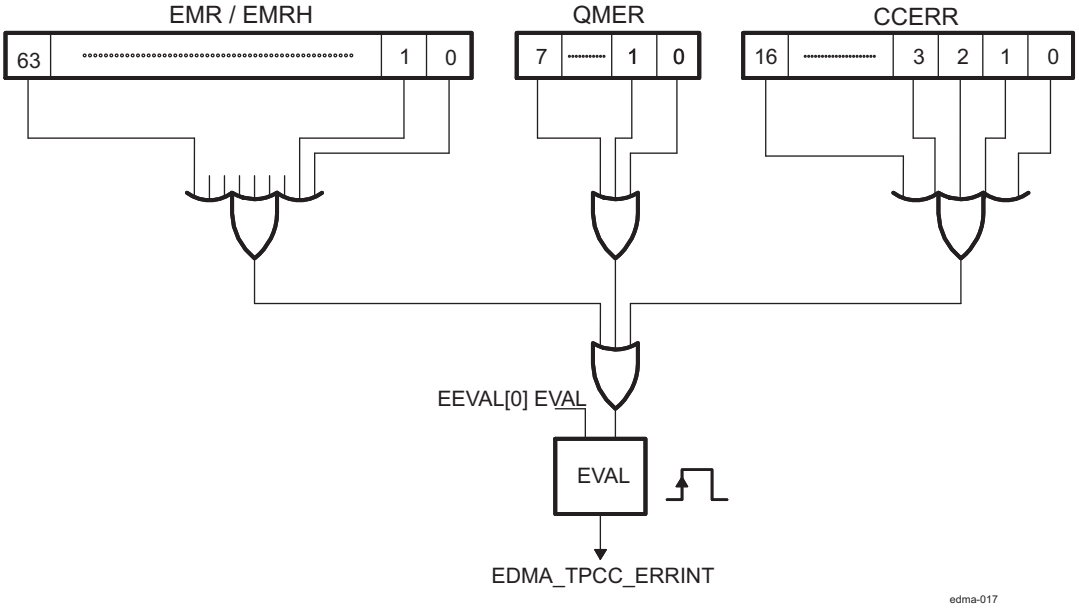
Figure 12-15 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with ‘1’ after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

Figure 12-15. Error Interrupt Operation



12.2.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

12.2.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to *EDMA_TPCC Registers Mapping Summary*.

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

Table 12-12 shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. TheEDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 12-12. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 12-13 describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 12-13. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect[1]	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k. MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example *Access denied.*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

NOTE: The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 12-14. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1.
	X	Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example *Access Allowed*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

NOTE: The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k

register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.

6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 12-15. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

12.2.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in Figure 12-16.

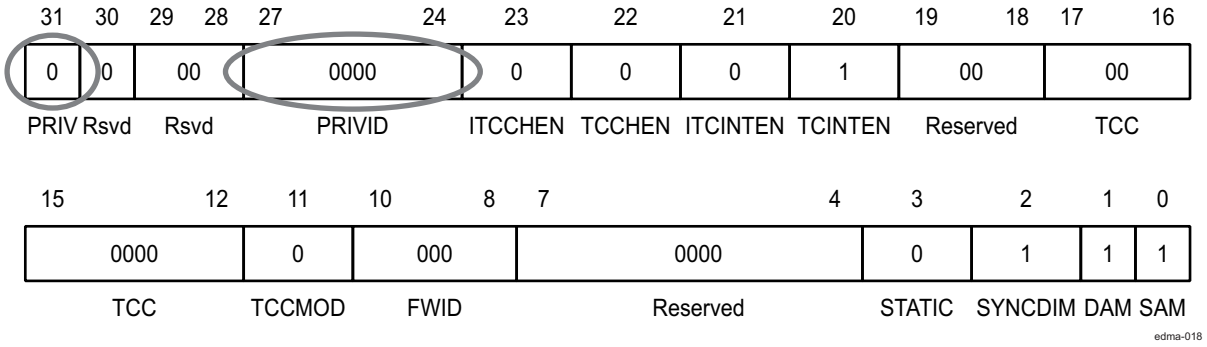
Figure 12-16. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 12-17. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT_n) Content



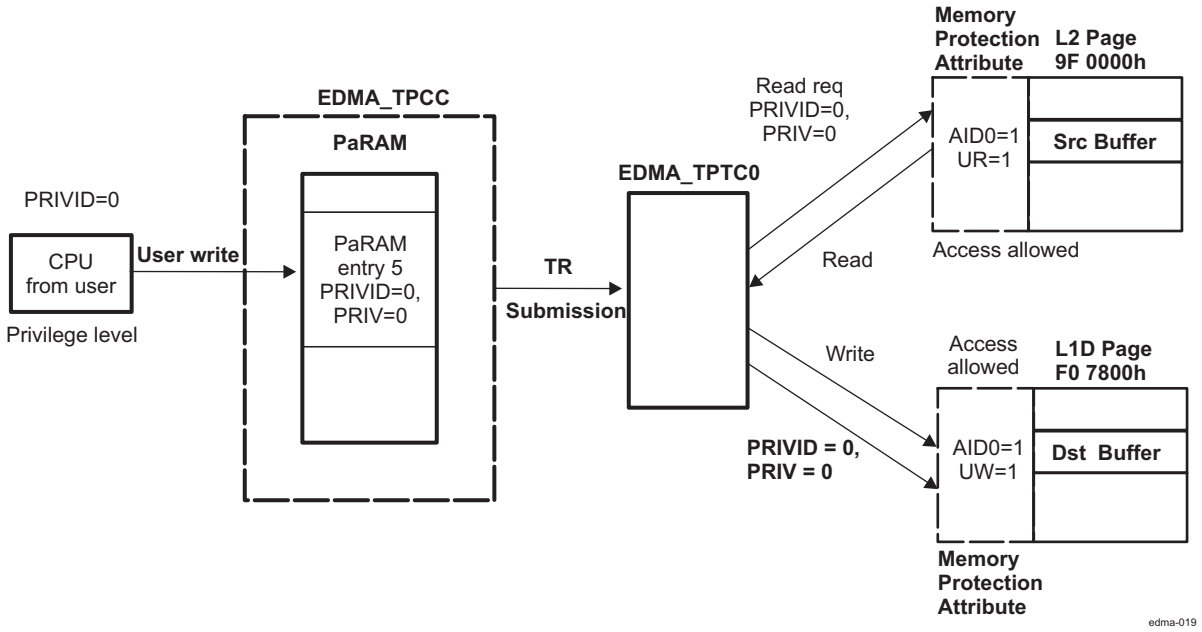
The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 12-18 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

Figure 12-18. Proxy Memory Protection Example



12.2.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to Section 12.2.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to *EDMA_TPCC Register Description* for EDMA_TPCC_Q0E_p / EDMA_TPCC_Q1E_p descriptions of the bit fields.

12.2.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to Section 12.2.11.4 *System-level Performance Considerations*.

NOTE: If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

12.2.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (Q*x*E*y* Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n* EDMA_TPCC_QSTATN_i) includes fields for the start pointer EDMA_TPCC_QSTATN_i[3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN_i[12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN_i[3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN_i[12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

12.2.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN_i[20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN_i[12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRXCD*n* bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN_i[24] THRXCD bit, where *n* stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

12.2.11.4 Performance Considerations

The device system bus infrastructure arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to *Control Module Register Manual* in *Control Module* chapter).

12.2.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

12.2.12.1 Architecture Details

12.2.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in *EDMA_TPTC Configuration*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_ABCNT_n[31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 12-16 lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

Table 12-16 lists conditions in which the optimizations are performed.

Table 12-16. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

12.2.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 12-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8, EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10, EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.
2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1, EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

12.2.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

12.2.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

12.2.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.

- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

12.2.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

NOTE: If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

12.2.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

12.2.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]E*n* / EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0] E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[7:0] E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] E*n* \ EDMA_TPCC_SERH[31:0] E*n* (or EDMA_TPCC_QSER[7:0] E*n*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the

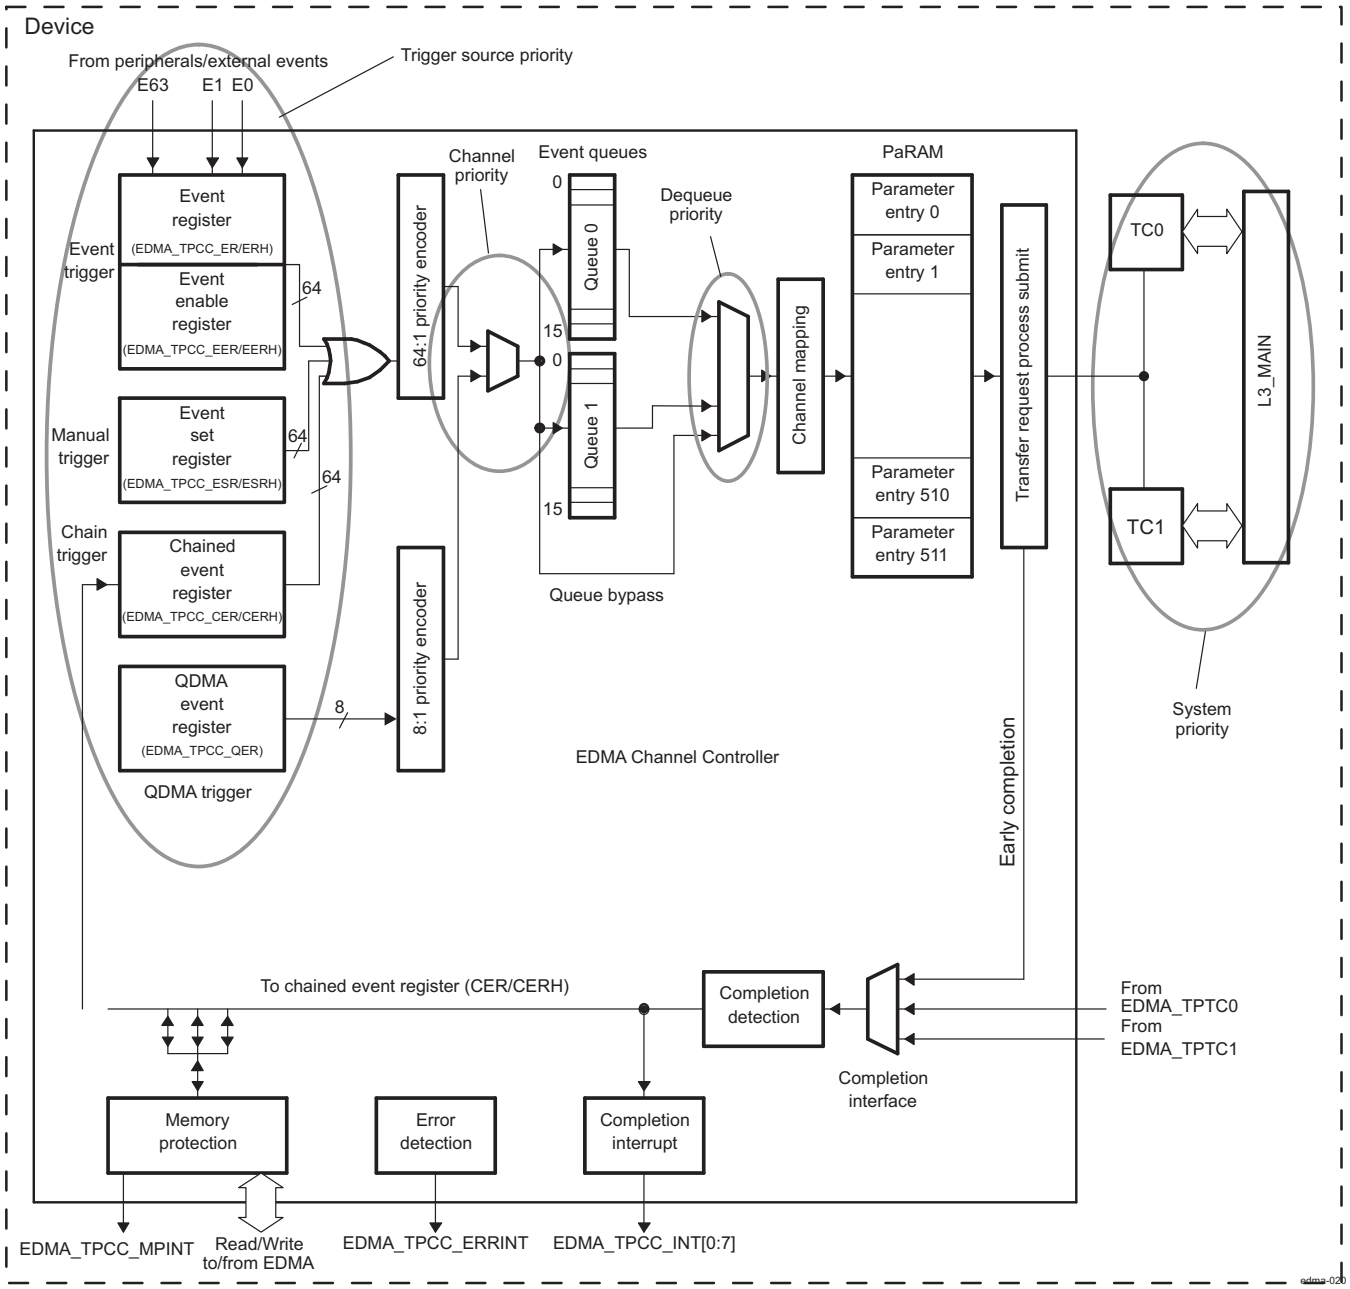
queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.

3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] E*n*/ EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0]E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[31:0] E*n*) bit and the EDMA_TPCC_SER[31:0] E*n*/EDMA_TPCC_SERH[31:0] E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] E*n*/ EDMA_TPCC_SERH[31:0] E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC*n* then signals completion status to the EDMA_TPCC.

12.2.14 EDMA Controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 12-19 shows the different places EDMA priorities come into play.

Figure 12-19. EDMA Prioritization



12.2.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

12.2.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] E*n* = 1, EDMA_TPCC_ESR[31:0] E*n* = 1 , EDMA_TPCC_CER[31:0] E*n* = 1) , then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] E0 = 1 and EDMA_TPCC_CER[0] E0 = 1 at the same time, then the EDMA_TPCC_ER[0] E0 event is always queued before the EDMA_TPCC_CER[0] E0 event.

12.2.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

12.2.15 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

12.3 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

12.3.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 12-20.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 12-21 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 12-21 shows the parameters Block Move transfer.

(a) EDMA Parameters

Parameter Contents	
0010 0008h	
Channel Source Address (SRC)	
0001h	0100h
Channel Destination Address (DST)	
0000h	0000h
0000h	FFFFh
0000h	0000h
0000h	0001h

Parameter	
Channel Options Parameter (OPT)	
Channel Source Address (SRC)	
Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)	
Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
BCNT Reload (BCNTRLD)	Link Address (LINK)
Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

12.3.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 12-22 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 12-23 shows the parameters for Subframe Extraction transfer.

Figure 12-22. Subframe Extraction Transfer

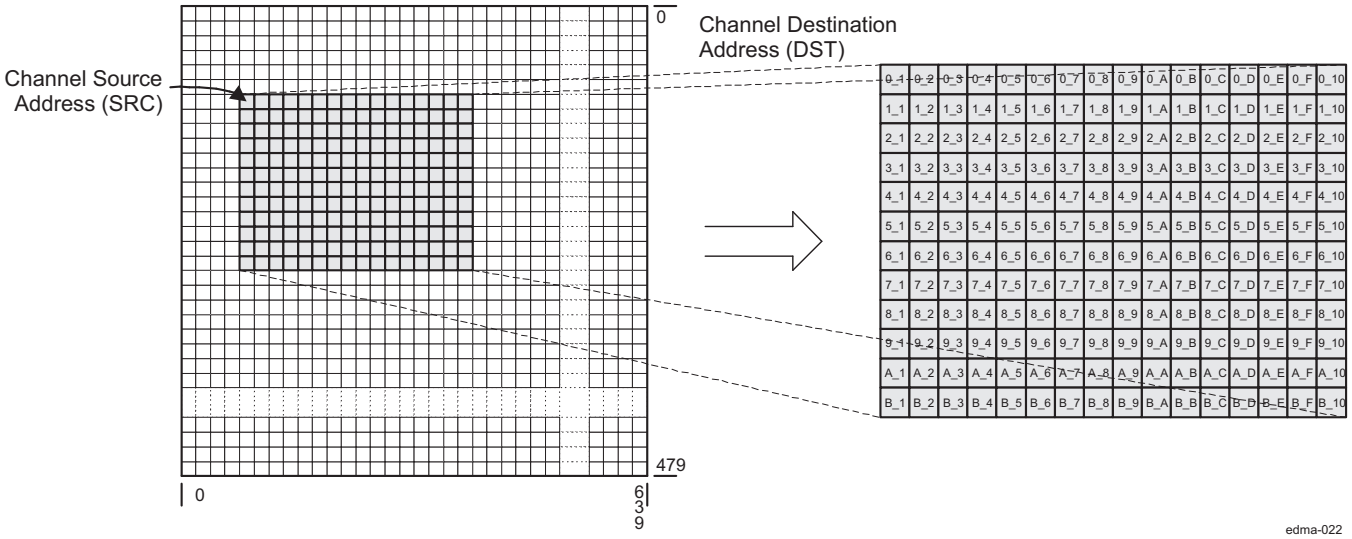

Figure 12-23. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents	
0010 000Ch	
Channel Source Address (SRC)	
000Ch	0020h
Channel Destination Address (DST)	
0020h	0500h
0000h	FFFFh

BCNT Reload (BCNTRLD)	Link Address (LINK)
Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

12.3.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 12-25 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 12-24 shows the Data Sorting transfer

- EDMA_TPCC_OPT_n[23] ITCCHEN = 0x1

12.3.4 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
   i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
   ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 12.2.7.1.)
4. Determine the type of triggering used.
   i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
   ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
5. Queue setup
   i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
   ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.

Step 2. Parameter set setup

1. Program the PaRAM set number associated with the channel. Note that

NOTE: If it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

Step 3. Interrupt setup

1. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
2. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA interrupt.

Step 4. Initiate transfer

1. This step is highly dependent on the event trigger source:
   i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
   ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
   iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
   iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

12.4 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

12.4.1 EDMA Debug Checklist

Table 12-17 provides some common issues and their probable causes and resolutions.

Table 12-17. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] E*n* and EDMA_TPCC_EMR[31:0] E*n* set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 12.2.9.1.2 *Clearing Transfer Complerion Interrupts* for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

12.4.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers.

   For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAE / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.

   For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.

   However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

12.5 EDMA Request Map

For the EDMA request map, refer to Table 2-14 for the 16xx/18xx, Table 3-14 for the 68xx, and Table 1-12 for the 14xx.

12.6 EDMA Register Manual

12.6.1 EDMA Registers

12.6.1.1 EDMA_TPCC Registers

Table 12-18 lists the memory-mapped registers for the EDMA_TPCC. All register offset addresses not listed in Table 12-18 should be considered as reserved locations and the register contents should not be modified.

Bit	Field	Type	Reset	Description
31-7	RES29	R	0h	RESERVE FIELD
6-4	PRIQ1	R/W	0h	Priority Level for Queue 1 Dictates the priority level used for the OPTIONS field programmation for Qn TRs. Sets the priority used for TC read and write commands.
3	RES30	R	0h	RESERVE FIELD
2-0	PRIQ0	R/W	0h	Priority Level for Queue 0 Dictates the priority level used for the OPTIONS field programmation for Qn TRs. Sets the priority used for TC read and write commands.

12.6.1.1.8 EDMA_TPCC_EMR Register (Offset = 300h) [reset = 0h]

EDMA_TPCC_EMR is shown in Figure 12-33 and described in Table 12-26.

Return to Summary Table.

Event Missed Register: The Event Missed register is set if 2 events are received without the first event being cleared or if a Null TR is serviced. Chained events (CER) Set Events (ESR) and normal events (ER) are treated individually. If any bit in the EMR register is set (and all errors (including QEMR/CCERR) were previously clear) then an error will be signaled with TPCC error interrupt.

12.6.1.1.11 EDMA_TPCC_EMCRH Register (Offset = 30Ch) [reset = 0h]

EDMA_TPCC_EMCRH is shown in Figure 12-36 and described in Table 12-29.

Return to Summary Table.

Event Missed Clear Register (High Part): CPU write of '1' to the EMCR.En bit causes the EMR.En bit to be cleared. CPU write of '0' has no effect.. All error bits must be cleared before additional error interrupts will be asserted by CC.

12.6.1.1.12 EDMA_TPCC_QEMR Register (Offset = 310h) [reset = 0h]

EDMA_TPCC_QEMR is shown in Figure 12-37 and described in Table 12-30.

Return to Summary Table.

QDMA Event Missed Register: The QDMA Event Missed register is set if 2 QDMA events are detected without the first event being cleared or if a Null TR is serviced.. If any bit in the QEMR register is set (and all errors (including EMR/CCERR) were previously clear) then an error will be signaled with TPCC error interrupt.

Bit	Field	Type	Reset	Description
31-17	RES33	R	0h	RESERVE FIELD
16	TCERR	R	0h	Transfer Completion Code Error: TCCERR = 0 : Total number of allowed TCCs outstanding has not been reached. TCCERR = 1 : Total number of allowed TCCs has been reached. TCCERR can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors were previously clear) then an error will be signaled with TPCC error interrupt.
15-8	RES34	R	0h	RESERVE FIELD
7	QTHRXCD7	R	0h	Queue Threshold Error for Q7: QTHRXCD7 = 0 : Watermark/threshold has not been exceeded. QTHRXCD7 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD7 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
6	QTHRXCD6	R	0h	Queue Threshold Error for Q6: QTHRXCD6 = 0 : Watermark/threshold has not been exceeded. QTHRXCD6 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD6 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
5	QTHRXCD5	R	0h	Queue Threshold Error for Q5: QTHRXCD5 = 0 : Watermark/threshold has not been exceeded. QTHRXCD5 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD5 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

Table 12-32. EDMA_TPCC_CCERR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	QTHRXCD4	R	0h	Queue Threshold Error for Q4: QTHRXCD4 = 0 : Watermark/threshold has not been exceeded. QTHRXCD4 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD4 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
3	QTHRXCD3	R	0h	Queue Threshold Error for Q3: QTHRXCD3 = 0 : Watermark/threshold has not been exceeded. QTHRXCD3 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD3 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
2	QTHRXCD2	R	0h	Queue Threshold Error for Q2: QTHRXCD2 = 0 : Watermark/threshold has not been exceeded. QTHRXCD2 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD2 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
1	QTHRXCD1	R	0h	Queue Threshold Error for Q1: QTHRXCD1 = 0 : Watermark/threshold has not been exceeded. QTHRXCD1 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD1 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.
0	QTHRXCD0	R	0h	Queue Threshold Error for Q0: QTHRXCD0 = 0 : Watermark/threshold has not been exceeded. QTHRXCD0 = 1 : Watermark/threshold has been exceeded. CCERR.QTHRXCD0 can be cleared by writing a '1' to corresponding bit in CCERRCLR register. If any bit in the CCERR register is set (and all errors (including EMR/QEMR) were previously clear) then an error will be signaled with the TPCC error interrupt.

12.6.1.1.15 EDMA_TPCC_CCERRCLR Register (Offset = 31Ch) [reset = 0h]

EDMA_TPCC_CCERRCLR is shown in Figure 12-40 and described in Table 12-33.

Return to Summary Table.

12.6.1.1.18 EDMA_TPCC_DRAEM Register (Offset = 340h) [reset = 0h]

EDMA_TPCC_DRAEM is shown in Figure 12-43 and described in Table 12-36.

Return to Summary Table.

DMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt.

12.6.1.1.19 EDMA_TPCC_DRAEHM Register (Offset = 344h) [reset = 0h]

EDMA_TPCC_DRAEHM is shown in Figure 12-44 and described in Table 12-37.

Return to Summary Table.

DMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt. En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt.

12.6.1.1.20 EDMA_TPCC_QRAEN Register (Offset = 380h) [reset = 0h]

EDMA_TPCC_QRAEN is shown in Figure 12-45 and described in Table 12-38.

Return to Summary Table.

QDMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any QDMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any QDMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region n interrupt.

Table 12-56. EDMA_TPCC_QSTATN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RES55	R	0h	RESERVE FIELD
24	THRXCD	R	0h	Threshold Exceeded: THRXCD = 0 : Threshold specified by QWMTHR(A B).Qn has not been exceeded. THRXCD = 1 : Threshold specified by QWMTHR(A B).Qn has been exceeded. QSTATn.THRXCD is cleared via CCERR.WMCLRn bit.
23-21	RES56	R	0h	RESERVE FIELD
20-16	WM	R	0h	Watermark for Maximum Queue Usage: Watermark tracks the most entries that have been in QueueN since reset or since the last time that the watermark (WM) was cleared. QSTATn.WM is cleared via CCERR.WMCLRn bit. Legal values = 0x0 (empty) to 0x10 (full)
15-13	RES57	R	0h	RESERVE FIELD
12-8	NUMVAL	R	0h	Number of Valid Entries in QueueN: Represents the total number of entries residing in the Queue Manager FIFO at a given instant. Always enabled. Legal values = 0x0 (empty) to 0x10 (full)
7-4	RES58	R	0h	RESERVE FIELD
3-0	STRTPTR	R	0h	Start Pointer: Represents the offset to the head entry of QueueN in units of entries. Always enabled. Legal values = 0x0 (0th entry) to 0xF (15th entry)

12.6.1.1.39 EDMA_TPCC_QWMTHRA Register (Offset = 620h) [reset = 1010h]

EDMA_TPCC_QWMTHRA is shown in Figure 12-64 and described in Table 12-57.

Return to Summary Table.

Queue Threshold A for Q[3:0]: CCERR.QTHRXCDn and QSTATn.THRXCD error bit is set when the number of Events in QueueN at an instant in time (visible via QSTATn.NUMVAL) equals or exceeds the value specified by QWMTHRA.Qn. Legal values = 0x0 (ever used?) to 0x10 (ever full?) A value of 0x11 disables threshold errors.

0	CLR	W	0h	AET Clear command: CPU write of '1' to the CLR bit causes the tpcc_aet output signal and AETSTAT.STAT register to be cleared. CPU write of '0' has no effect..

12.6.1.1.44 EDMA_TPCC_ER Register (Offset = 1000h) [reset = 0h]

EDMA_TPCC_ER is shown in Figure 12-69 and described in Table 12-62.

Return to Summary Table.

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

12.6.1.1.50 EDMA_TPCC_CER Register (Offset = 1018h) [reset = 0h]

EDMA_TPCC_CER is shown in Figure 12-75 and described in Table 12-68.

Return to Summary Table.

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

12.6.1.1.52 EDMA_TPCC_EER Register (Offset = 1020h) [reset = 0h]

EDMA_TPCC_EER is shown in Figure 12-77 and described in Table 12-70.

Return to Summary Table.

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

12.6.1.1.53 EDMA_TPCC_EERH Register (Offset = 1024h) [reset = 0h]

EDMA_TPCC_EERH is shown in Figure 12-78 and described in Table 12-71.

Return to Summary Table.

Event Enable Register (High Part): Enables DMA transfers for ERH.En pending events. ERH.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CERH) or Event Set Register (ESRH). Note that if a bit is set in ERH.En while EERH.En is disabled no action is taken. If EERH.En is enabled at a later point (and ERH.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EERH.En is not directly writeable. Events can be enabled via writes to EESRH and can be disabled via writes to EECRH register. EERH.En = 0: ER.En is not enabled to trigger DMA transfers. EERH.En = 1: ER.En is enabled to trigger DMA transfers.

12.6.1.1.59 EDMA_TPCC_SERH Register (Offset = 103Ch) [reset = 0h]

EDMA_TPCC_SERH is shown in Figure 12-84 and described in Table 12-77.

Return to Summary Table.

Secondary Event Register (High Part): The secondary event register is used along with the Event Register (ERH) to provide information on the state of an Event. En = 0 : Event is not currently in the Event Queue. En = 1 : Event is currently stored in Event Queue. Event arbiter will not prioritize additional events.

Table 12-90. EDMA_TPCC_IEVAL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RES69	R	0h	RESERVE FIELD
1	SET	W	0h	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (IPRn). CPU write of '0' has no effect.
0	EVAL	W	0h	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (IPRn). CPU write of '0' has no effect..

12.6.1.1.73 EDMA_TPCC_QER Register (Offset = 1080h) [reset = 0h]

EDMA_TPCC_QER is shown in Figure 12-98 and described in Table 12-91.

Return to Summary Table.

QDMA Event Register: If QER.En bit is set then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a '1' to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set then the corresponding bit in the QDMA Event Missed Register is set.

Figure 12-98. EDMA_TPCC_QER Register

12.6.1.1.74 EDMA_TPCC_QEER Register (Offset = 1084h) [reset = 0h]

EDMA_TPCC_QEER is shown in Figure 12-99 and described in Table 12-92.

Return to Summary Table.

QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. QEER.En is not directly writeable. QDMA channels can be enabled via writes to QEESR and can be disabled via writes to QEECR register. QEER.En = 1 The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in QER.En. QEER.En = 0 The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in QER.En.

12.6.1.1.80 EDMA_TPCC_ER_RN Register (Offset = 2000h) [reset = 0h]

EDMA_TPCC_ER_RN is shown in Figure 12-105 and described in Table 12-98.

Return to Summary Table.

Event Register: If ER.En bit is set and the EER.En bit is also set then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high) regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the ECR pseudo-register.

12.6.1.1.86 EDMA_TPCC_CER_RN Register (Offset = 2018h) [reset = 0h]

EDMA_TPCC_CER_RN is shown in Figure 12-111 and described in Table 12-104.

Return to Summary Table.

Chained Event Register: If CER.En bit is set (regardless of state of EER.En) then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface or is generated internally via Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared via software.

12.6.1.1.88 EDMA_TPCC_EER_RN Register (Offset = 2020h) [reset = 0h]

EDMA_TPCC_EER_RN is shown in Figure 12-113 and described in Table 12-106.

Return to Summary Table.

Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EER.En is not directly writeable. Events can be enabled via writes to EESR and can be disabled via writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

12.6.1.1.89 EDMA_TPCC_EERH_RN Register (Offset = 2024h) [reset = 0h]

EDMA_TPCC_EERH_RN is shown in Figure 12-114 and described in Table 12-107.

Return to Summary Table.

Event Enable Register (High Part): Enables DMA transfers for ERH.En pending events. ERH.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (CERH) or Event Set Register (ESRH). Note that if a bit is set in ERH.En while EERH.En is disabled no action is taken. If EERH.En is enabled at a later point (and ERH.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EERH.En is not directly writeable. Events can be enabled via writes to EESRH and can be disabled via writes to EECRH register. EERH.En = 0: ER.En is not enabled to trigger DMA transfers. EERH.En = 1: ER.En is enabled to trigger DMA transfers.

12.6.1.1.95 EDMA_TPCC_SERH_RN Register (Offset = 203Ch) [reset = 0h]

EDMA_TPCC_SERH_RN is shown in Figure 12-120 and described in Table 12-113.

Return to Summary Table.

Secondary Event Register (High Part): The secondary event register is used along with the Event Register (ERH) to provide information on the state of an Event. En = 0 : Event is not currently in the Event Queue. En = 1 : Event is currently stored in Event Queue. Event arbiter will not prioritize additional events.
