

AMC23C11 Fast Response, Reinforced Isolated Comparator With Adjustable Threshold and Latch Function

1 Features

- Wide high-side supply range: 3V to 27V
- Low-side supply range: 2.7V to 5.5V
- Adjustable threshold: 20mV to 2.7V
- Reference current for threshold adjustment:
 - 100µA, ±1%
- Trip threshold error: ±1% (max) at 250mV
- Open-drain output with optional latch mode
- Propagation delay: 240ns (typ)
- High CMTI: 75V/ns (min)
- Safety-related certifications:
 - 7000V_{PK} reinforced isolation per DIN EN IEC 60747-17 (VDE 0884-17)
 - 5000V_{RMS} isolation for 1 minute per UL1577
- Fully specified over the extended industrial temperature range: –40°C to +125°C

2 Applications

- Overcurrent or overvoltage detection in:
 - Motor drives
 - Frequency inverters
 - Solar inverters
 - DC/DC converters

3 Description

The AMC23C11 is an isolated comparator with a short response time. The open-drain output is separated from the input circuitry by an isolation barrier that is highly resistant to magnetic interference. This barrier is certified to provide reinforced galvanic isolation of up to 5kV_{RMS} according to VDE 0884-17 and UL1577, and supports a working voltage of up to 1kV_{RMS}.

The trip threshold is adjustable from 20mV to 450mV in low-hysteresis mode and from 600mV to 2.7V in high-hysteresis mode through a single external resistor.

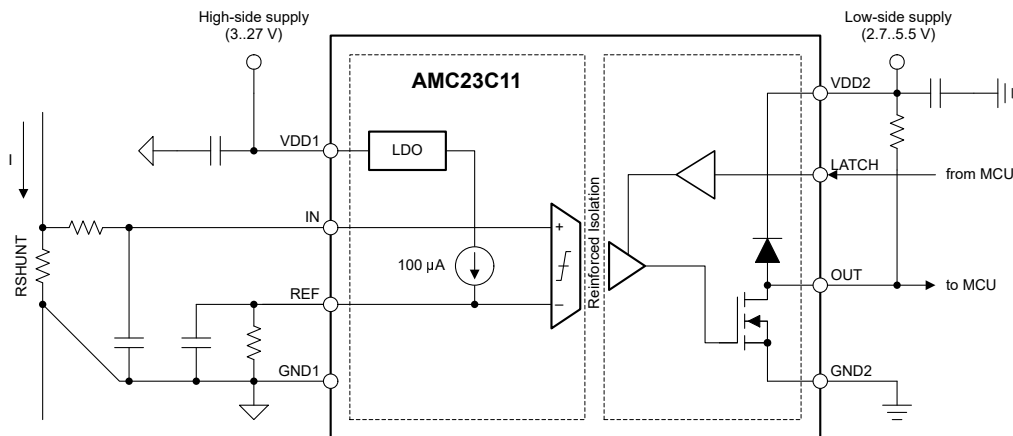

The open-drain output on the device supports transparent mode (LATCH input tied to GND2) where the output follows the input state, or latch mode, where the output is cleared on the falling edge of the latch input signal.

The AMC23C11 is available in an 8-pin, wide-body SOIC package and is specified over the extended industrial temperature range of –40°C to +125°C.

Package Information

PART NUMBER	PACKAGE ⁽¹⁾	PACKAGE SIZE ⁽²⁾
AMC23C11	DWV (SOIC, 8)	5.85mm × 11.5mm

- (1) For all available packages, see the orderable addendum at the end of the data sheet.
- (2) The package size (length × width) is a nominal value and includes pins, where applicable.

4 Pin Configuration and Functions

Figure 4-1. DWV Package, 8-Pin SOIC (Top View)

Table 4-1. Pin Functions

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	VDD1	High-side power	High-side power supply ⁽¹⁾
2	IN	Analog input	Analog input pin to the comparator
3	REF	Analog input	Reference pin that defines the trip threshold. The voltage on this pin also affects the hysteresis of the comparator, as explained in the Reference Input section. This pin is internally connected to a 100µA current source. Connect a resistor from REF to GND1 to define the trip threshold, and a capacitor from REF to GND1 to filter the reference voltage. For best transient noise immunity, place the capacitor as closely to the pin as possible. This pin can also be driven by an external voltage source.
4	GND1	High-side ground	High-side ground
5	GND2	Low-side ground	Low-side ground
6	OUT	Digital output	Open-drain output of the comparator. Connect to an external pullup resistor.
7	LATCH	Digital input	Digital input to select latch mode (high) or transparent mode (low) of the open-drain output. Do not leave the input pin unconnected (floating). Connect to GND2 when not used.
8	VDD2	Low-side power	Low-side power supply ⁽¹⁾

(1) See the [Power Supply Recommendations](#) section for power-supply decoupling recommendations.

5 Specifications

5.1 Absolute Maximum Ratings

see⁽¹⁾

		MIN	MAX	UNIT
Power-supply voltage	VDD1 to GND1	-0.3	30	V
	VDD2 to GND2	-0.3	6.5	
Analog input voltage	REF to GND1	-0.5	6.5	V
	IN to GND1	-6	5.5	
Digital input voltage	LATCH to GND2	-0.5	VDD2 + 0.5	V
Digital output voltage	OUT to GND2	-0.5	VDD2 + 0.5	V
Input current	Continuous, any pin except power-supply pins	-10	10	mA
Temperature	Junction, T _J		150	°C
	Storage, T _{stg}	-65	150	

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

5.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per ANSI/ESDA/JEDEC JS-002 ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating ambient temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
POWER SUPPLY						
V _{VDD1}	High-side power-supply voltage	VDD1 to GND1	3.0	5	27	V
V _{VDD2}	Low-side power supply voltage	VDD2 to GND2	2.7	3.3	5.5	V
ANALOG INPUT						
V _{IN}	Input voltage	IN to GND1, VDD1 ≤ 4.3 V	−0.4	VDD1 − 0.3		V
		IN to GND1, VDD1 > 4.3 V	−0.4	4		
V _{REF}	Reference voltage	Low hysteresis mode	20 ⁽²⁾	450		mV
		High hysteresis mode	600	2700 ⁽¹⁾		
	Reference voltage headroom	VDD1 − V _{REF}	1.4			V
	Filter capacitance on REF pin		20	100		nF
DIGITAL I/O						
	Digital input voltage	LATCH pin	GND2	VDD2		V
	Digital output voltage	OUT to GND2	GND2	VDD2		V
	Sink current	OUT	0	4		mA
TEMPERATURE RANGE						
T _A	Specified ambient temperature		−40	25	125	°C

- (1) Reference voltages (V_{REF}) > 1.6V require V_{VDD1} > V_{VDD1,MIN} to maintain minimum headroom (V_{VDD1} − V_{REF}) of 1.4V.
(2) The device has been tested with V_{REF} as low as 5mV. The device remains functional but relative switching threshold accuracy can decrease because of offset errors.

5.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DWV (SOIC)	UNIT
		8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	102.8	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	45.1	°C/W
R _{θJB}	Junction-to-board thermal resistance	63.0	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	14.3	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	61.1	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	n/a	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application note.

5.5 Power Ratings

PARAMETER	TEST CONDITIONS	VALUE	UNIT
P _D	VDD1 = 25 V, VDD2 = 5.5 V	95	mW
	VDD1 = VDD2 = 5.5 V	30	
	VDD1 = VDD2 = 3.6 V	20	
P _{D1}	VDD1 = 25 V	83	mW
	VDD1 = 5.5 V	18	
	VDD1 = 3.6 V	12	
P _{D2}	VDD2 = 5.5 V	12	mW
	VDD2 = 3.6 V	8	

5.6 Insulation Specifications (Reinforced Isolation)

over operating ambient temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	VALUE	UNIT
GENERAL				
CLR	External clearance ⁽¹⁾	Shortest pin-to-pin distance through air	≥ 8.5	mm
CPG	External creepage ⁽¹⁾	Shortest pin-to-pin distance across the package surface	≥ 8.5	mm
DTI	Distance through insulation	Minimum internal gap (internal clearance) of the double insulation	≥ 15.4	μm
CTI	Comparative tracking index	DIN EN 60112 (VDE 0303-11); IEC 60112	≥ 600	V
	Material group	According to IEC 60664-1	I	
	Overvoltage category per IEC 60664-1	Rated mains voltage ≤ 600V _{RMS}	I-III	
		Rated mains voltage ≤ 1000V _{RMS}	I-II	
DIN EN IEC 60747-17 (VDE 0884-17)⁽²⁾				
V _{IORM}	Maximum repetitive peak isolation voltage	At AC voltage	1410	V _{PK}
V _{IOWM}	Maximum-rated isolation working voltage	At AC voltage (sine wave)	1000	V _{RMS}
		At DC voltage	1410	V _{DC}
V _{IOTM}	Maximum transient isolation voltage	V _{TEST} = V _{IOTM} , t = 60s (qualification test), V _{TEST} = 1.2 × V _{IOTM} , t = 1s (100% production test)	7070	V _{PK}
V _{IMP}	Maximum impulse voltage ⁽³⁾	Tested in air, 1.2/50μs waveform per IEC 62368-1	7700	V _{PK}
V _{IOSM}	Maximum surge isolation voltage ⁽⁴⁾	Tested in oil (qualification test), 1.2/50μs waveform per IEC 62368-1	10000	V _{PK}
q _{pd}	Apparent charge ⁽⁵⁾	Method a, after input/output safety test subgroups 2 and 3, V _{pd(ini)} = V _{IOTM} , t _{ini} = 60s, V _{pd(m)} = 1.2 × V _{IORM} , t _m = 10s	≤ 5	pC
		Method a, after environmental tests subgroup 1, V _{pd(ini)} = V _{IOTM} , t _{ini} = 60s, V _{pd(m)} = 1.6 × V _{IORM} , t _m = 10s	≤ 5	
		Method b1, at preconditioning (type test) and routine test, V _{pd(ini)} = 1.2 × V _{IOTM} , t _{ini} = 1s, V _{pd(m)} = 1.875 × V _{IORM} , t _m = 1s	≤ 5	
		Method b2, at routine test (100% production) ⁽⁷⁾ V _{pd(ini)} = V _{pd(m)} = 1.2 × V _{IOTM} , t _{ini} = t _m = 1s	≤ 5	
C _{IO}	Barrier capacitance, input to output ⁽⁶⁾	V _{IO} = 0.5 V _{PP} at 1MHz	≅ 1.5	pF
R _{IO}	Insulation resistance, input to output ⁽⁶⁾	V _{IO} = 500V at T _A = 25°C	> 10 ¹²	Ω
		V _{IO} = 500V at 100°C ≤ T _A ≤ 125°C	> 10 ¹¹	
		V _{IO} = 500V at T _S = 150°C	> 10 ⁹	
	Pollution degree		2	
	Climatic category		55/125/21	
UL1577				
V _{ISO}	Withstand isolation voltage	V _{TEST} = V _{ISO} , t = 60s (qualification test), V _{TEST} = 1.2 × V _{ISO} , t = 1s (100% production test)	5000	V _{RMS}

- (1) Apply creepage and clearance requirements according to the specific equipment isolation standards of an application. Care must be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed circuit board (PCB) do not reduce this distance. Creepage and clearance on a PCB become equal in certain cases. Techniques such as inserting grooves, ribs, or both on a PCB are used to help increase these specifications.
- (2) This coupler is suitable for *safe electrical insulation* only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- (3) Testing is carried out in air to determine the surge immunity of the package.
- (4) Testing is carried in oil to determine the intrinsic surge immunity of the isolation barrier.
- (5) Apparent charge is electrical discharge caused by a partial discharge (pd).
- (6) All pins on each side of the barrier are tied together, creating a two-pin device.
- (7) Either method b1 or b2 is used in production.

5.7 Safety-Related Certifications

Certificate number: 40040142	File number: E181974

5.8 Safety Limiting Values

Safety limiting⁽¹⁾ intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry. A failure of the I/O can allow low resistance to ground or the supply and, without current limiting, dissipate sufficient power to overheat the die and damage the isolation barrier potentially leading to secondary system failures.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I _S	Safety input, output, or supply current	R _{θJA} = 102.8°C/W, VDD1 = VDD2 = 5.5 V, T _J = 150°C, T _A = 25°C			220	mA
		R _{θJA} = 102.8°C/W, VDD1 = VDD2 = 3.6 V, T _J = 150°C, T _A = 25°C			340	
P _S	Safety input, output, or total power	R _{θJA} = 102.8°C/W, T _J = 150°C, T _A = 25°C			1220	mW
T _S	Maximum safety temperature				150	°C

- (1) The maximum safety temperature, T_S, has the same value as the maximum junction temperature, T_J, specified for the device. The I_S and P_S parameters represent the safety current and safety power, respectively. Do not exceed the maximum limits of I_S and P_S. These limits vary with the ambient temperature, T_A.

The junction-to-air thermal resistance, R_{θJA}, in the *Thermal Information* table is that of a device installed on a high-K test board for leaded surface-mount packages. Use these equations to calculate the value for each parameter:

$T_J = T_A + R_{\theta JA} \times P$, where P is the power dissipated in the device.

$T_{J(max)} = T_S = T_A + R_{\theta JA} \times P_S$, where T_{J(max)} is the maximum junction temperature.

$P_S = I_S \times AVDD_{max} + I_S \times DVDD_{max}$, where AVDD_{max} is the maximum high-side voltage and DVDD_{max} is the maximum controller-side supply voltage.

5.9 Electrical Characteristics

minimum and maximum specifications apply from $T_A = -40^\circ\text{C}$ to 125°C , $V_{DD1} = 3.0\text{ V}$ to 27 V , $V_{DD2} = 2.7\text{ V}$ to 5.5 V , $V_{REF} = 20\text{ mV}$ to 2.7 V ⁽¹⁾, and $V_{IN} = -400\text{ mV}$ to 4 V ⁽³⁾; typical specifications are at $T_A = 25^\circ\text{C}$, $V_{DD1} = 5\text{ V}$, $V_{DD2} = 3.3\text{ V}$, and $V_{REF} = 250\text{ mV}$ (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
ANALOG INPUT						
R_{IN}	Input resistance	IN pin, $0 \leq V_{IN} \leq 4\text{ V}$		1		$\text{G}\Omega$

6 Detailed Description

6.1 Overview

The AMC23C11 is an isolated comparator with an open-drain output and optional latch function. The comparator compares the input voltage (V_{IN}) against the V_{IT+} threshold that is adjustable from 20mV to 2.7V through an internally generated 100 μ A reference current and a single external resistor. The open-drain output is actively pulled low when the input voltage (V_{IN}) is higher than the reference value V_{REF} . The behavior when V_{IN} drops below the trip threshold is determined by the LATCH pin, as described in the [Open-Drain Digital Output](#) section.

Galvanic isolation between the high- and low-voltage side of the device is achieved by transmitting the comparator states across a SiO₂-based, reinforced capacitive isolation barrier. This isolation barrier supports a high level of magnetic field immunity, as described in the [ISO72x Digital Isolator Magnetic-Field Immunity application note](#). The digital modulation scheme used in the AMC23C11 to transmit data across the isolation barrier, and the isolation barrier characteristics, result in high reliability and common-mode transient immunity.

6.2 Functional Block Diagram

6.3 Feature Description

6.3.1 Analog Input

The comparator trips when the input voltage (V_{IN}) rises above the V_{IT+} threshold that is defined as the reference value plus the internal hysteresis voltage. The comparator releases when V_{IN} drops below the V_{IT-} threshold that equals the reference value.

The difference between V_{IT+} and V_{IT-} is referred to as the *comparator hysteresis* and is 4mV for reference voltages below 450mV. The integrated hysteresis makes the AMC23C11 less sensitive to input noise and provides stable operation in noisy environments without having to add external positive feedback to create hysteresis. The hysteresis increases to 25mV for reference values (V_{REF}) greater than 600mV. See the [Reference Input](#) description for more details.

Figure 6-1 shows a timing diagram of the relationship between hysteresis and switching thresholds.

Figure 6-1. Switching Thresholds and Hysteresis

6.3.2 Reference Input

The voltage on the REF pin determines the trip threshold of the comparator. The internal precision current source forces a 100µA current through an external resistor connected from the REF pin to GND1. The resulting voltage across the resistor (V_{REF}) equals the trip threshold, see Figure 6-1. Place a 100nF capacitor parallel to the resistor to filter the reference voltage. This capacitor must be charged by the 100µA current source during power-up and the charging time can exceed the high-side blanking time ($t_{HS,BLK}$). In this case, as shown in Figure 6-2, the comparator can output an incorrect state after the high-side blanking time has expired until V_{REF} reaches the final value. See the *Power-Up and Power-Down Behavior* section for more details on power-up behavior.

Figure 6-2. Output Behavior for Long Settling Times of the Reference Voltage

The reference pin can be driven by an external voltage source to change the comparator threshold during operation. However, do not drive V_{REF} dynamically across the V_{MSEL} threshold during normal operation because doing so changes the hysteresis of the comparator and can lead to unintentional switching of the output.

Figure 6-3 shows a mode selection timing diagram.

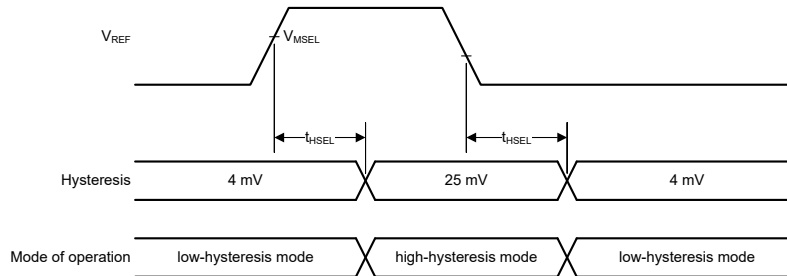

Figure 6-3. Mode Selection

6.3.3 Isolation Channel Signal Transmission

The AMC23C11 uses an on-off keying (OOK) modulation scheme, as shown in [Figure 6-4](#), to transmit the comparator output states across the SiO₂-based isolation barrier. The transmit driver (TX) shown in the [Functional Block Diagram](#) transmits an internally-generated, high-frequency carrier across the isolation barrier to represent a digital *one* and does not send a signal to represent a digital *zero*.

The receiver (RX) on the other side of the isolation barrier recovers and demodulates the signal and provides the data for the logic that drives the open-drain output buffer. The AMC23C11 transmission channel is optimized to achieve the highest level of common-mode transient immunity (CMTI) and the lowest level of radiated emissions caused by the high-frequency carrier and RX/TX buffer switching.

Figure 6-4. OOK-Based Modulation Scheme

6.3.4 Open-Drain Digital Output

The AMC23C11 provides an open-drain output with an optional latching function. The output is actively pulled low when V_{IN} exceeds the threshold value defined by the voltage on the REF pin, see [Figure 6-1](#).

The open-drain output is diode-connected to the VDD2 supply (see the [Functional Block Diagram](#)), meaning that the output cannot be pulled more than 500mV above the VDD2 supply before significant current begins to flow into the OUT pin. In particular, the open-drain output is clamped to one diode voltage above ground if VDD2 is at the GND2 level. This behavior is indicated by the gray shadings in [Figure 6-5](#) through [Figure 6-10](#).

On a system level, the CMTI performance of an open-drain signal line depends on the value of the pullup resistor. During a common-mode transient event with a high slew rate (high dV/dt), the open-drain signal line can be pulled low because of parasitic capacitive coupling between the high side and the low side of the printed circuit board (PCB). The effect of the parasitic coupling on the signal level is a function of the pullup strength and a lower value pullup resistor results in better CMTI performance. The AMC23C11 is characterized by a relatively weak pullup resistor value of 10k Ω to make sure that the specified CMTI performance is met in a typical application with a 4.7k Ω or lower pullup resistor.

6.3.4.1 Transparent Output Mode

The device is set to transparent mode when the LATCH pin is pulled low, thus allowing the output state to change and follow the input signal with respect to the programmed trip threshold. For example, when the input signal rises above the trip threshold, the OUT pin is pulled low. When the input signal drops below the trip threshold, the output returns to the default high output state. A common implementation using the device in transparent mode is to connect the OUT pin to a hardware interrupt input on a controller. As soon as an out-of-range condition is detected by the device and the OUT pin is pulled low, the controller interrupt terminal detects the output state change and can begin making changes to the system operation needed to address the out-of-range condition.

6.3.4.2 Latch Output Mode

Some applications do not have the functionality available to continuously monitor the state of the OUT pin to detect an overcurrent condition. A typical example of this application is a system that is only able to poll the OUT terminal state periodically to determine if the system is functioning correctly. If the device is set to transparent mode in this type of application, a change in the state of the OUT pin can be missed if the out-of-range condition does not appear during one of these periodic polling events.

Latch mode is specifically intended to accommodate these applications. The device is placed in latch mode by setting the voltage on the LATCH terminal to a logic high level. The difference between latch mode and transparent mode is how the output responds when an out-of-range event ends. In transparent mode, when the input signal drops below the trip threshold, the output state returns to the default high setting to indicate that the out-of-range event has ended.

In latch mode, when an out-of-range condition is detected and the OUT pin is pulled low, the OUT pin does not return to the default high level when the input signal drops below the trip threshold level. To clear the event, the LATCH terminal must be pulled low for at least 4 μ s. Pulling the LATCH pin low allows the OUT pin to return to the default high level, provided that the input signal has dropped below the trip threshold. If the input signal is still above the threshold when the LATCH pin is pulled low, the OUT terminal remains low. When the out-of-range event is detected by the system controller, the LATCH pin can be set back to high to place the device back into latch mode.

6.3.5 Power-Up and Power-Down Behavior

The open-drain output powers up in a high-impedance (Hi-Z) state when the low-side supply (VDD2) turns on. After power-up, if the high-side is not functional yet, the output is actively pulled low. As shown in Figure 6-5, this condition happens after the low-side start-up time plus the high-side fault detection delay time ($t_{LS,STA} + t_{HS,FLT}$). Similarly, if the high-side supply drops below the undervoltage threshold ($VDD1_{UV}$), as described in Figure 6-8, for more than the high-side fault detection delay time during normal operation, the open-drain output is pulled low. This delay allows the system to shut down reliably when the high-side supply is missing.

Communication start between the high-side and low-side of the comparator is delayed by the high-side blanking time ($t_{HS,BLK}$, a time constant implemented on the high-voltage side) to allow the voltage on the REF pin to settle, and to avoid unintentional switching of the comparator output during power-up.

Figure 6-5 through Figure 6-10 depict typical power-up and power-down scenarios.

In Figure 6-5, the low-side supply (VDD2) turns on but the high-side supply (VDD1) remains off. The output powers up in a Hi-Z state. After $t_{HS,FLT}$, OUT is pulled low indicating a no-power fault on the high side.

In Figure 6-6, the high-side supply (VDD1) turns on long after the low-side supply (VDD2) turns on. The output is initially in an active-low state, see Figure 6-5. After the high-side supply is enabled, there is a duration of $t_{HS,STA} + t_{HS,BLK}$ before the device assumes normal operation and the output reflects the current state of the comparator.

Figure 6-5. VDD2 Turns On, VDD1 Stays Off

Figure 6-6. VDD2 is On; VDD1 Turns On (Long Delay)

In Figure 6-7, the low-side supply (VDD2) turns on, followed by the high-side supply (VDD1) with only a short delay. The output is initially in a Hi-Z state. The high-side fault detection delay ($t_{HS,FLT}$) is shorter than the high-side blanking time ($t_{HS,BLK}$), and therefore the output is pulled low after $t_{HS,FLT}$, indicating that the high-side is not operational yet. After the high-side blanking time ($t_{HS,BLK}$) elapses, the device assumes normal operation and the output reflects the current state of the comparator.

In Figure 6-8, the high-side supply (VDD1) turns off, followed by the low-side supply (VDD2). After the high-side fault detection delay time ($t_{HS,FLT}$), the output is actively pulled low. As soon as VDD2 drops below the $VDD2_{UV}$ threshold, the output enters a Hi-Z state.

Figure 6-7. VDD2 Turns On, Followed by VDD1 (Short Delay)

Figure 6-8. VDD1 Turns Off, Followed by VDD2

In [Figure 6-9](#), the low-side supply (VDD2) turns on after the high-side is fully powered up (the delay between VDD1 and VDD2 is greater than $(t_{HS,STA} + t_{HS,BLK})$). After the low-side start-up time ($t_{LS,STA}$), the device enters normal operation.

In [Figure 6-10](#), the low-side supply (VDD2) turns off, followed by the high-side supply (VDD1). As soon as VDD2 drops below the VDD2_{UV} threshold, the output enters a Hi-Z state.

Figure 6-9. VDD1 Turns On, Followed by VDD2 (Long Delay)

Figure 6-10. VDD2 Turns Off, Followed by VDD1

6.3.6 VDD1 Brownout and Power-Loss Behavior

Brownout is a condition where the VDD1 supply drops below the specified operating voltage range but the device remains functional. Power loss is a condition where the VDD1 supply drops below a level where the device stops being functional. Depending on the duration and the voltage level, a brownout condition can or can not be noticeable at the output of the device. A power-loss condition is always signaled on the output of the isolated comparator.

Figure 6-11 through Figure 6-13 show typical brownout and power-loss scenarios.

In Figure 6-11, VDD1 droops below the undervoltage detection threshold ($VDD1_{UV}$) but recovers before the high-side-fault detection delay time ($t_{HS,FLT}$) expires. The brownout event has no effect on the comparator output.

In Figure 6-12, VDD1 droops below the undervoltage detection threshold ($VDD1_{UV}$) for more than the high-side-fault detection delay time ($t_{HS,FLT}$). The brownout condition is detected as a fault and the output is pulled low after a delay equal to $t_{HS,FLT}$. The device resumes normal operation as soon as VDD1 recovers above the $VDD1_{UV}$ threshold.

Figure 6-11. Output Response to a Short Brownout Event on VDD1

Figure 6-12. Output Response to a Long Brownout Event on VDD1

In Figure 6-13, VDD1 droops below the power-on-reset (POR) threshold ($VDD1_{POR}$). The power-loss condition is detected as a fault and the output is pulled low after a delay equal to $t_{HS,FLT}$. The device resumes normal operation after a delay equal to $t_{HS,STA} + t_{HS,BLK}$ after VDD1 recovers above the $VDD1_{UV}$ threshold.

Figure 6-13. Output Response to a Power-Loss Event on VDD1

6.4 Device Functional Modes

The AMC23C11 is operational when the power supplies VDD1 and VDD2 are applied, as specified in the [Recommended Operating Conditions](#) table.

The voltage on the REF pin affects the threshold of the comparator. For reference voltages below the V_{MSEL} threshold, the comparator operates in low-hysteresis mode. For reference voltages above the V_{MSEL} threshold, the comparator operates in high-hysteresis mode as described in the [Reference Input](#) section.

The device has two output operating modes that are selected based on the LATCH input pin setting: transparent mode and latch mode. These modes affect how the OUT pin responds to the changing input signal conditions. See the [Open-Drain Digital Output](#) section for details.

7 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

7.1 Application Information

With low response time, high common-mode transient immunity (CMTI), and a reinforced isolation barrier, the AMC23C11 is designed to provide fast and reliable overcurrent and overvoltage detection for high-voltage applications in harsh and noisy environments.

7.2 Typical Application

7.2.1 DC Link Overcurrent Detection

DC link overcurrent detection is a common requirement in DC/DC converter and motor-drive designs. Although the inductor current of a DC/DC converter or the phase currents of a motor drive are typically sensed for control purposes, phase current monitoring alone is not sufficient to detect all possible overcurrent conditions (such as shoot-through in the power stage, or DC+ and DC– shorts to ground). The most comprehensive way of implementing DC link overcurrent detection is to monitor the current in the DC+ and DC– lines. This detection, as illustrated in [Figure 7-1](#), can be achieved by monitoring the voltage drop across two shunt resistors.

The DC+ load current flowing through the shunt resistor R10 produces a positive voltage with respect to GND1 that is monitored by the AMC23C11. When the voltage drop across R10 exceeds the reference value set by the external resistor R11, the comparator trips and signals the overcurrent event on the open-drain output OUT.

The DC– load current flowing through the shunt resistor R20 produces a negative voltage in respect to GND1 that is monitored by a [AMC23C12](#). When the voltage drop across R20 exceeds the reference value set by the external resistor R21, the comparator trips and signals the overcurrent event on the open-drain output OUT.

The open-drain outputs from both isolated comparators are shorted together to form a single alert signal to the microcontroller unit (MCU). Similarly, both LATCH signals are tied together and can be controlled by a single GPIO pin from the MCU.

The isolated comparator on the DC+ side requires a high-side power supply that is referenced to the DC+ potential. A low-cost solution is based on the push-pull driver [SN6501](#) and a transformer that supports the desired isolation voltage ratings. The integrated low-dropout (LDO) regulator on the high-side of the AMC23C11 allows direct connection of the VDD1 pin to the transformer output and no further preregulation of the transformer output voltage is required.

The isolated comparator on the DC– side requires a high-side power supply that is referenced to the DC– potential. A common solution is to power the isolated comparator from the low-side gate driver supply, as illustrated in [Figure 7-1](#), or any other voltage supply referenced to DC–. The integrated low-dropout (LDO)

regulator on the high side of the AMC23C12 supports a wide range of input voltages and greatly simplifies the power-supply design.

The fast response time and high common-mode transient immunity (CMTI) of the AMC23C11 provide reliable and accurate operation even in high-noise environments.

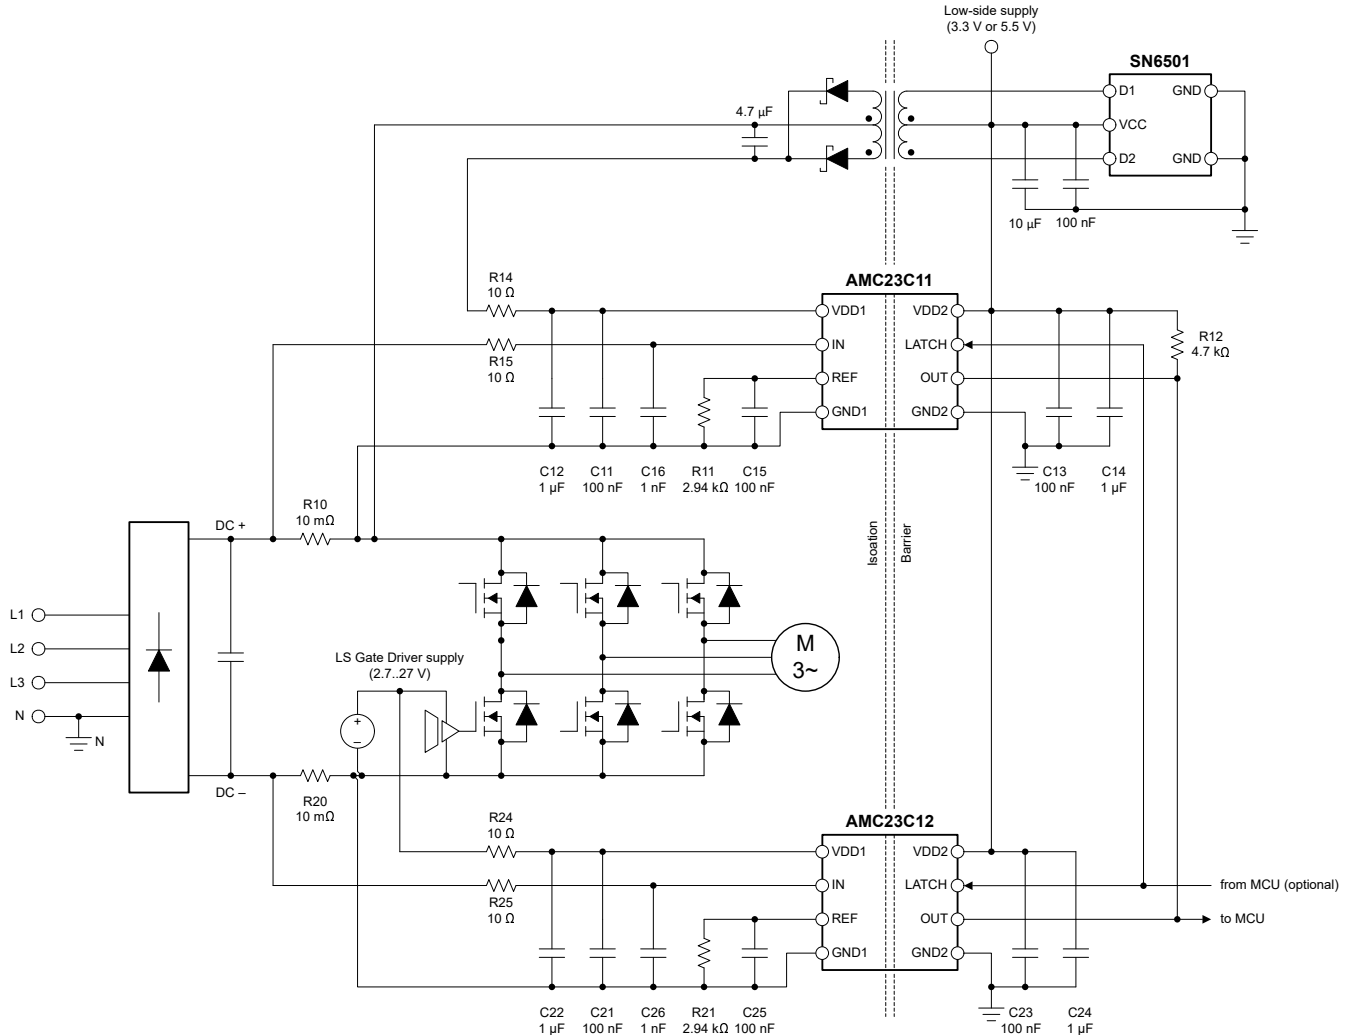

Figure 7-1. Using the AMC23C11 for DC+ Overcurrent Detection

7.2.1.1 Design Requirements

Table 7-1 lists the parameters for the application example in Figure 7-1.

Table 7-1. Design Requirements

PARAMETER	VALUE
High-side supply voltage	3V to 27V
Low-side supply voltage	2.7V to 5.5V
Shunt-resistor value	10mΩ
Overcurrent detection threshold	30A

7.2.1.2 Detailed Design Procedure

The value of the shunt resistors (R10 and R20) in this example is 10mΩ. At the desired 30A overcurrent detection level, the voltage drop across the shunt resistor is $10\text{m}\Omega \times 30\text{A} = 300\text{mV}$. The positive-going trip threshold of the comparator is $V_{\text{REF}} + V_{\text{HYS}}$, where V_{HYS} is 4mV (as specified in the [Electrical Characteristics](#) table) and V_{REF} is the voltage across R11 (R12, respectively) that is connected between the REF and GND1 pins. R11 and R12 are calculated as $(V_{\text{TRIP}} - V_{\text{HYS}}) / I_{\text{REF}} = (300\text{mV} - 4\text{mV}) / 100\mu\text{A} = 2.96\text{k}\Omega$. The next lower value from the E96 series (1% accuracy) is 2.94kΩ, resulting in an overcurrent trip threshold (rising) of 29.8A.

A 10Ω, 1nF RC filter (R15, C16 and R25, C26, respectively) is placed at the input of the comparator to filter the input signal and reduce noise sensitivity. This filter adds $10\Omega \times 1\text{nF} = 10\text{ns}$ of propagation delay that must be considered when calculating the overall response time of the protection circuit. Larger filter constants are preferable to increase noise immunity if the system can tolerate the additional delay.

Table 7-2 summarizes the key parameters of the design.

Table 7-2. Overcurrent Detection Design Example

PARAMETER	VALUE
Reference resistor value (R11, R21)	2.94kΩ
Reference capacitor value (C15, C25)	100nF
Reference voltage	296mV
Reference voltage settling time (to 90% of final value)	690μs
Overcurrent trip threshold (rising)	298mV / 29.8A
Overcurrent trip threshold (falling)	294mV / 29.4A

7.3 Application Curves

Figure 7-2 shows the typical response of the AMC23C11 to a triangular input waveform with an amplitude of 310mV_{PP}. The output (OUT) switches when VIN crosses the 250mV level determined by the REF pin voltage that is biased to 250mV in this example.

Figure 7-2. Output Response of the AMC23C11 to a Triangular Input Waveform

The integrated LDO of the AMC23C11 greatly relaxes the power-supply requirements on the high-voltage side and allows powering the device from non-regulated transformer, charge pump, and bootstrap supplies. As given by the following image, the internal LDO provides a stable operating voltage to the internal circuitry, allowing the trip thresholds to remain mostly undisturbed even at ripple voltages of 2V_{PP} and higher.

Figure 7-3. Trip Threshold Sensitivity to VDD1 Ripple Voltage (f_{RIPLLE} = 10kHz)

7.4 Best Design Practices

Keep the connection between the low-side of the sense resistor and the GND1 pin of the AMC23C11 short and low impedance. Any voltage drop in the ground line adds error to the voltage sensed at the input of the comparator and leads to inaccuracies in the trip thresholds.

For best common-mode transient immunity, place the filter capacitor C5 as closely to the REF pin as possible as illustrated in [Figure 7-5](#). Use a low-value pullup resistor (<10k Ω) on the open-drain output, as explained in the [Open-Drain Digital Output](#) section, to minimize the effect of capacitive coupling on the open-drain signal line during a common-mode transient event.

Do not operate the device with the REF pin biased close to the V_{MSEL} threshold (450mV to 600mV range) to avoid dynamic switching of the comparator hysteresis as explained in the [Reference Input](#) section.

The AMC23C11 provides a limited 200 μ s blanking time ($t_{HS,BLK}$) to allow the reference voltage (V_{REF}) to settle during start-up. For many applications, the reference voltage takes longer to settle than the 200 μ s blanking time and the output of the comparator can possibly glitch during system start-up as described in [Figure 6-2](#). Consider the reference voltage settling time in the overall system start-up design.

7.5 Power Supply Recommendations

The AMC23C11 does not require any specific power-up sequencing. The high-side power supply (VDD1) is decoupled with a low-ESR, 100nF capacitor (C1) parallel to a low-ESR, 1μF capacitor (C2). The low-side power supply (VDD2) is equally decoupled with a low-ESR, 100nF capacitor (C3) parallel to a low-ESR, 1μF capacitor (C4). Place all four capacitors (C1, C2, C3, and C4) as close to the device as possible. Figure 7-4 shows a decoupling schematic for the AMC23C11.

For high VDD1 supply voltages (>5.5V) place a 10Ω resistor (R4) in series with the VDD1 power supply for additional filtering.

Figure 7-4. Decoupling of the AMC23C11

Capacitors must provide adequate effective capacitance under the applicable DC bias conditions experienced in the application. Multilayer ceramic capacitors (MLCCs) typically exhibit only a fraction of the nominal capacitance under real-world conditions and this factor must be taken into consideration when selecting these capacitors. This problem is especially acute in low-profile capacitors, in which the dielectric field strength is higher than in taller components. Reputable capacitor manufacturers provide capacitance versus DC bias curves that greatly simplify component selection.

7.6 Layout

7.6.1 Layout Guidelines

Figure 7-5 shows a layout recommendation with the critical placement of the decoupling capacitors (as close as possible to the AMC23C11 supply pins) and placement of the other components required by the device.

7.6.2 Layout Example

10 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
AMC23C11DWV	ACTIVE	SOIC	DWV	8	64	RoHS & Green	NIPDAU	Level-3-260C-168 HR	-40 to 125	MC23C11	Samples
AMC23C11DWVR	ACTIVE	SOIC	DWV	8	1000	RoHS & Green	NIPDAU	Level-3-260C-168 HR	-40 to 125	MC23C11	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#) or other applicable terms available either on [ti.com](https://www.ti.com) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
