QPOSINIT																															
R/W-0h																															

Table 21-9. QPOSINIT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	QPOSINIT	R/W	0h	Position Counter Init This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

21.12.2.3 QPOSMAX Register (Offset = 4h) [Reset = 00000000h]

QPOSMAX is shown in Figure 21-28 and described in Table 21-10.

Return to the Summary Table.

Maximum Position Count

Figure 21-28. QPOSMAX Register

Chapter 22

Serial Peripheral Interface (SPI)

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion using devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the controller or peripheral operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

22.1 Introduction

22.1.1 Features

The SPI module features include:

- SPIPOCI: SPI peripheral-output/controller-input pin
- SPIPICO: SPI peripheral-input/controller-output pin
- $\overline{\text{SPIPTE}}$: SPI peripheral transmit-enable pin
- SPICLK: SPI serial-clock pin

Note

All four pins can be used as GPIO if the SPI module is not used.

- Two operational modes: Controller and Peripheral
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device data sheet for more details.
- Data word length: 1 to 16 data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPIPTE}}$ inversion for digital audio interface receive mode on devices with two SPI modules

22.1.3 Block Diagram

Figure 22-1 shows the SPI CPU interfaces.

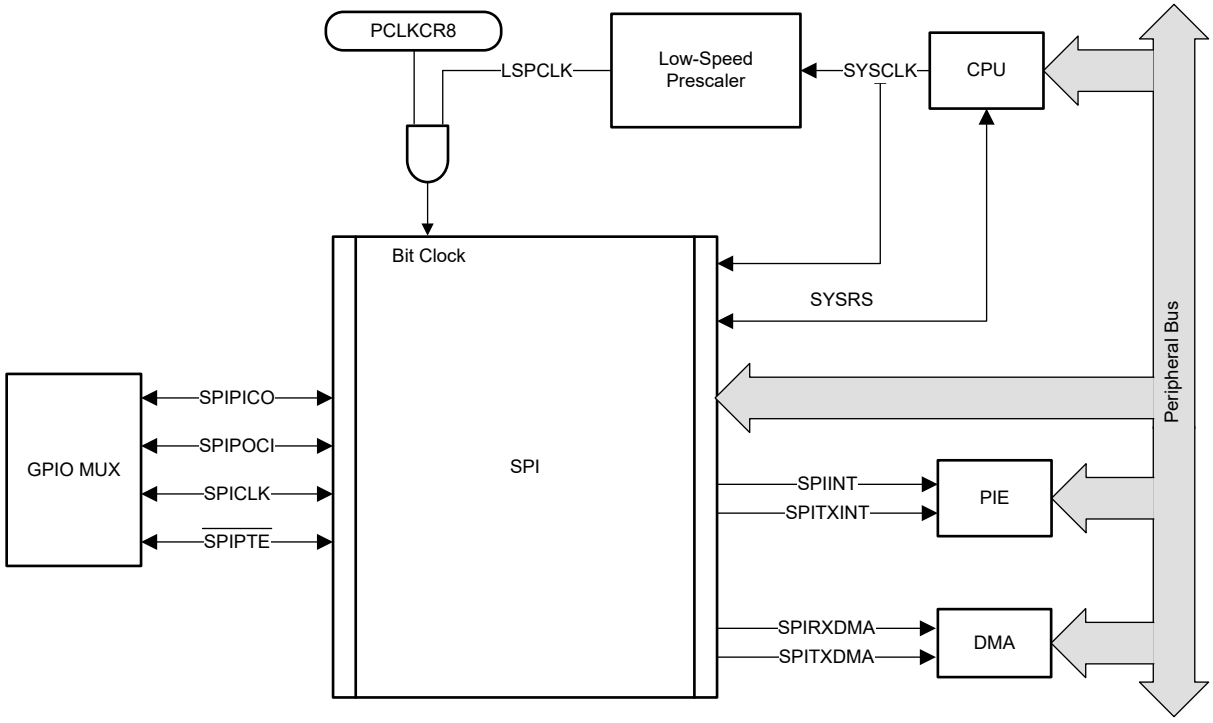

Figure 22-1. SPI CPU Interface

22.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

22.2.1 SPI Module Signals

Table 22-1 classifies and provides a summary of the SPI module signals.

Table 22-1. SPI Module Signal Summary

Signal Name	Description
External Signals	
SPICLK	SPI clock
SPIPICO	SPI peripheral in, controller out
SPIPOCI	SPI peripheral out, controller in
$\overline{\text{SPIPTE}}$	SPI peripheral transmit enable
Control	
SPI Clock Rate	LSPCLK
Interrupt Signals	
SPIINT/SPIRXINT	Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT)
	Receive interrupt in FIFO mode
SPITXINT	Transmit interrupt in FIFO mode
DMA Triggers	
SPITXDMA	Transmit request to DMA
SPIRXDMA	Receive request to DMA

Special Considerations

The $\overline{\text{SPIPTE}}$ signal provides the ability to gate any spurious clock and data pulses when the SPI is in peripheral mode. A HIGH logic signal on $\overline{\text{SPIPTE}}$ does not allow the peripheral to receive data. This prevents the SPI peripheral from losing synchronization with the controller. TI does not recommend that the $\overline{\text{SPIPTE}}$ always be tied to the active state.

If the SPI peripheral does ever lose synchronization with the controller, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in Section 22.6.

Configuring a GPIO to Emulate $\overline{\text{SPIPTE}}$

In many systems, a SPI controller can be connected to multiple SPI peripherals using multiple instances of $\overline{\text{SPIPTE}}$. Though this SPI module does not natively support multiple $\overline{\text{SPIPTE}}$ signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the controller. Rather than using the GPIO Mux to select $\overline{\text{SPIPTE}}$, the application can configure pins to be GPIO outputs, one GPIO per SPI peripheral. Before transmitting any data, the application can drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select can be driven to the inactive state. This process can be repeated for many peripherals that share the SPICLK, SPIPICO, and SPIPOCI lines.

22.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

22.2.2.1 GPIOs Required for High-Speed Mode

To enable the high-speed enhancements, set SPICCR.HS_MODE to 1. Make sure that the capacitive loading on the pin does not exceed the value stated in the device data sheet.

When not operating in high-speed mode or if the capacitive loading on the pins exceed the value stated in the device data sheet, SPICCR.HS_MODE can be set to 0.

22.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module. The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT_FLAG), or there is overrun in the receiver (OVERRUN_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT_FLAG generates an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN_FLAG generates an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) is set. SPIRXINT is triggered in the PIE block, if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) is set. SPITXINT is triggered in the PIE block, if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 22-2 and Table 22-2 show how these control bits influence the SPI interrupt generation.

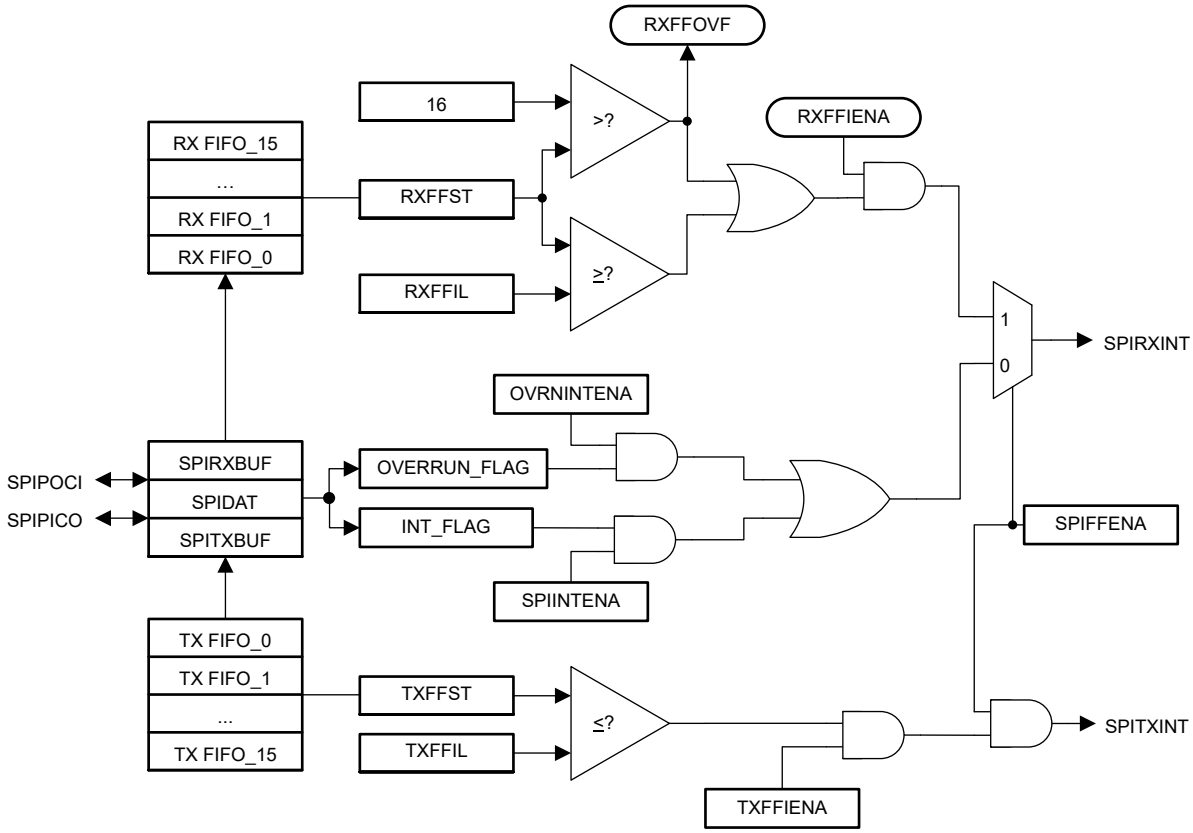

Figure 22-2. SPI Interrupt Flags and Enable Logic Generation

Table 22-2. SPI Interrupt Flag Modes

FIFO Options	SPI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable (SPIFFENA)	Interrupt Line (1)
SPI without FIFO	Receive overrun	RXOVRN	OVRNINTENA	0	SPIRXINT
	Data receive	SPIINT	SPIINTENA	0	SPIRXINT
	Transmit empty	SPIINT	SPIINTENA	0	SPIRXINT
SPI FIFO mode	FIFO receive	RXFFIL	RXFFIENA	1	SPIRXINT
	Transmit empty	TXFFIL	TXFFIENA	1	SPITXINT

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C28x devices.

22.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers using the internal peripheral bus. This access is limited to 16-bit register reads and writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers, refer to Section 22.3.8.

Figure 22-3 is a block diagram showing the DMA trigger generation from the SPI module.

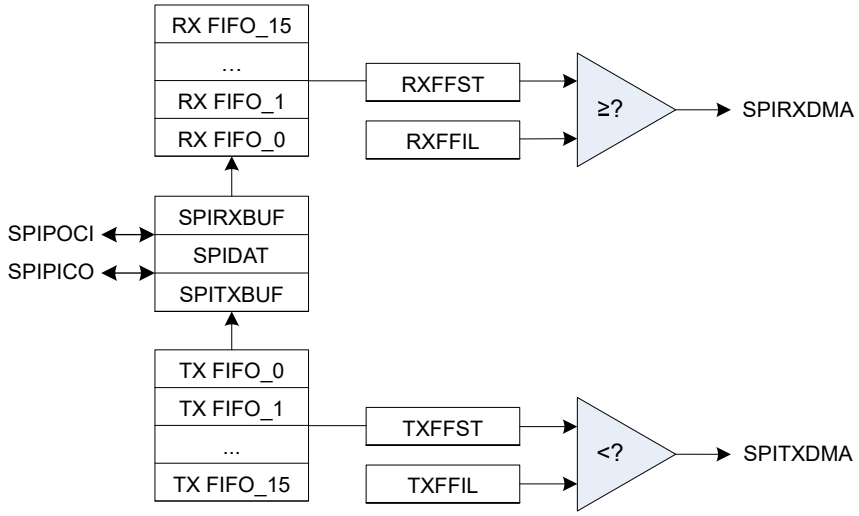

Figure 22-3. SPI DMA Trigger Diagram

22.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

22.3.1 Introduction to Operation

Figure 22-4 shows typical connections of the SPI for communications between two controllers: a controller and a peripheral.

The controller transfers data by sending the SPICLK signal. For both the peripheral and the controller, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Controller sends data; peripheral sends dummy data.
- Controller sends data; peripheral sends data.
- Controller sends dummy data; peripheral sends data.

The controller can initiate data transfer at any time because the controller controls the SPICLK signal. The software, however, determines how the controller detects when the peripheral is ready to broadcast data.

The SPI operates in controller or peripheral mode. The CONTROLLER_PERIPHERAL bit selects the operating mode and the source of the SPICLK signal.

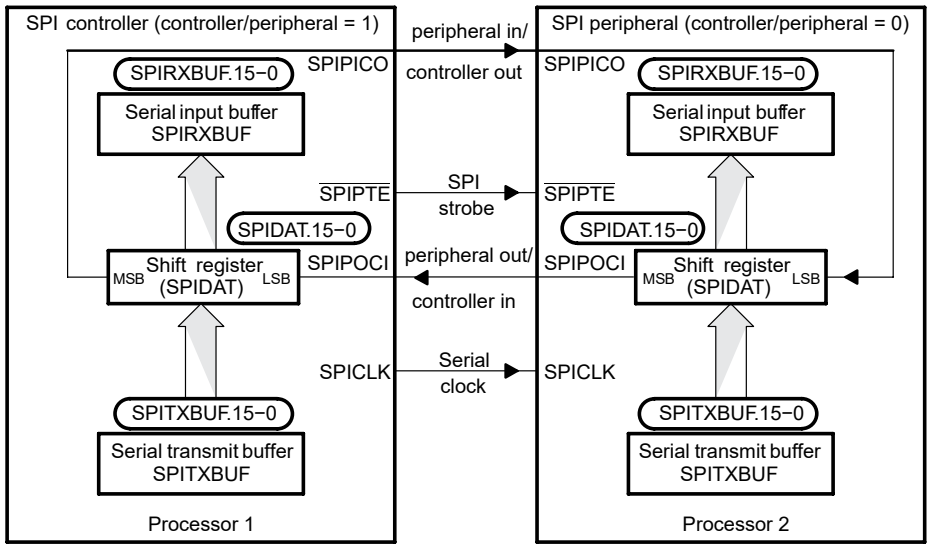

Figure 22-4. SPI Controller/Peripheral Connection

22.3.2 Controller Mode

In controller mode (CONTROLLER_PERIPHERAL = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPIPICO pin and latched from the SPIPOCI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPIPICO pin, MSB (most-significant bit) first. Simultaneously, received data is shifted through the SPIPOCI pin into the LSB (least- significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the transmit buffer full flag (BUFFULL_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the $\overline{\text{SPIPTE}}$ pin serves as a chip-enable pin for a SPI peripheral device. This pin is driven low by the controller before transmitting data to the peripheral and is taken high after the transmission is complete.

Figure 22-5 is a block diagram of the SPI in controller mode. The block diagram shows the basic control blocks available in SPI controller mode.

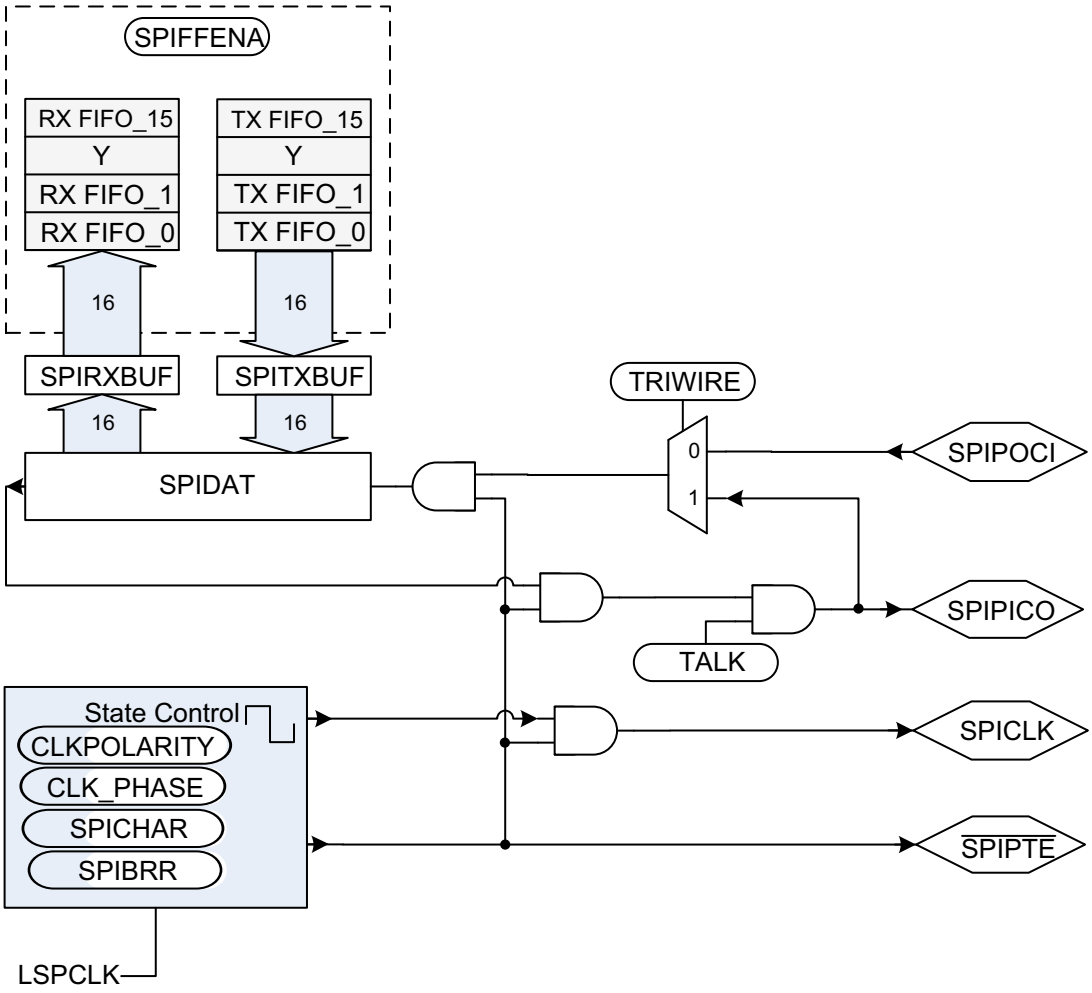

Figure 22-5. SPI Module Controller Configuration

22.3.3 Peripheral Mode

In peripheral mode (CONTROLLER_PERIPHERAL = 0), data shifts out on the SPIPOCI pin and in on the SPIPICO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network controller. The transfer rate is defined by this clock. The SPICLK input frequency can be no greater than the LSPCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network controller. A character written to the SPITXBUF register is copied to the SPIDAT register when all bits of the current character in SPIDAT have been shifted out. If no character was previously copied to SPIDAT, then any character written to SPITXBUF is immediately copied to SPIDAT. If a character was previously copied to SPIDAT, any data written to SPITXBUF is not copied to SPIDAT until the current character in SPIDAT has been shifted out. To receive data, the SPI waits for the network controller to send the SPICLK signal and then shifts the data on the SPIPICO pin into SPIDAT. If data is to be transmitted by the peripheral simultaneously, and SPIDAT has not been previously loaded, the character must be written to SPITXBUF before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPIPOCI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPIPOCI is forced into the high-impedance state. This makes sure that the SPI is still able to

receive incoming data correctly. This TALK bit allows many peripheral devices to be tied together on the network, but only one peripheral at a time is allowed to drive the SPIPOCI line.

The $\overline{\text{SPIPTE}}$ pin operates as the peripheral-select pin. An active-low signal on the $\overline{\text{SPIPTE}}$ pin allows the peripheral SPI to transfer data to the serial data line; an inactive-high signal causes the peripheral SPI serial shift register to stop and the serial output pin to be put into the high-impedance state. This allows many peripheral devices to be tied together on the network, although only one peripheral device is selected at a time.

Figure 22-6 is a block diagram of the SPI in peripheral mode. The block diagram shows the basic control blocks available in SPI peripheral mode.

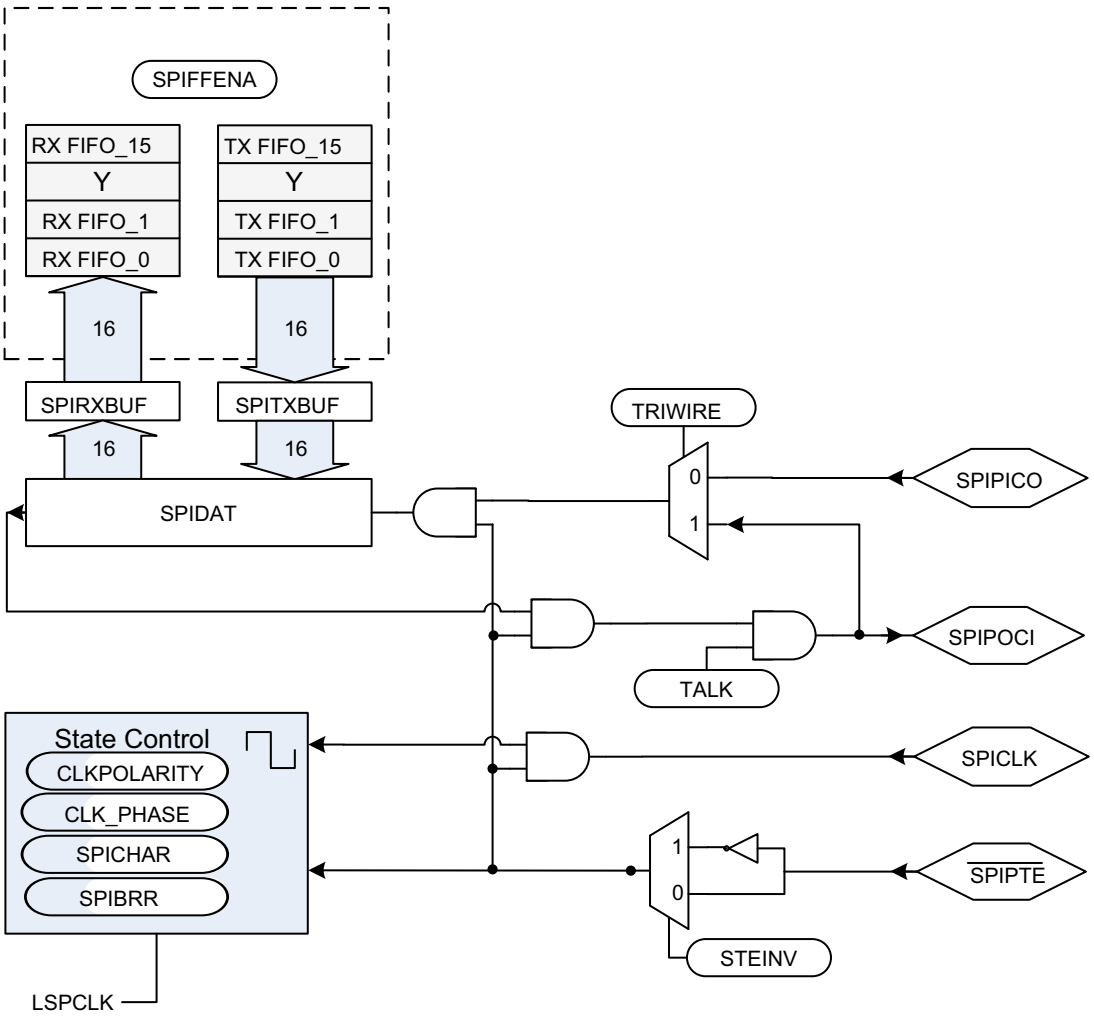

Figure 22-6. SPI Module Peripheral Configuration

22.3.4 Data Format

The four-bit SPICHAR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in Example 22-1).

Example 22-1. Transmission of Bit from SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in SPICHAR bits)
2. The current value of SPIDAT = 737Bh

SPIDAT (before transmission)																
	0	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1
SPIDAT (after transmission)																
(TXed) 0 ←	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1) ← (RXed)
SPIRXBUF (after transmission)																
	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1)

(1) x = 1, if SPIPOCI data is high; x = 0, if SPIPOCI data is low; controller mode is assumed.

22.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in peripheral or controller mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the peripheral mode, the SPI clock is received on the SPICLK pin from the external source and can be no greater than the LSPCLK frequency divided by 4.
- In the controller mode, the SPI clock is generated by the SPI and is output on the SPICLK pin and can be no greater than the LSPCLK frequency divided by 4.

Note

The baud rate must be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device data sheet for the maximum GPIO toggle frequency.

Example 22-2 shows how to determine the SPI baud rates.

Example 22-3 shows how to calculate the baud rate of the SPI module in standard SPI mode (HS_MODE = 0).

Example 22-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)}$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4}$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the controller SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (that is device-specific) and the baud rate at which you are operating.

Example 22-3. Baud Rate Calculation in Non-High Speed Mode (HS_MODE = 0)

$$SPI\ Baud\ Rate = \frac{LSPCLK}{SPIBRR + 1'} \quad LSPCLK = 50\ MHz$$

$$= \frac{50 \times 10^6}{3 + 1}$$

$$= 12.5\ Mbps$$

22.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are:

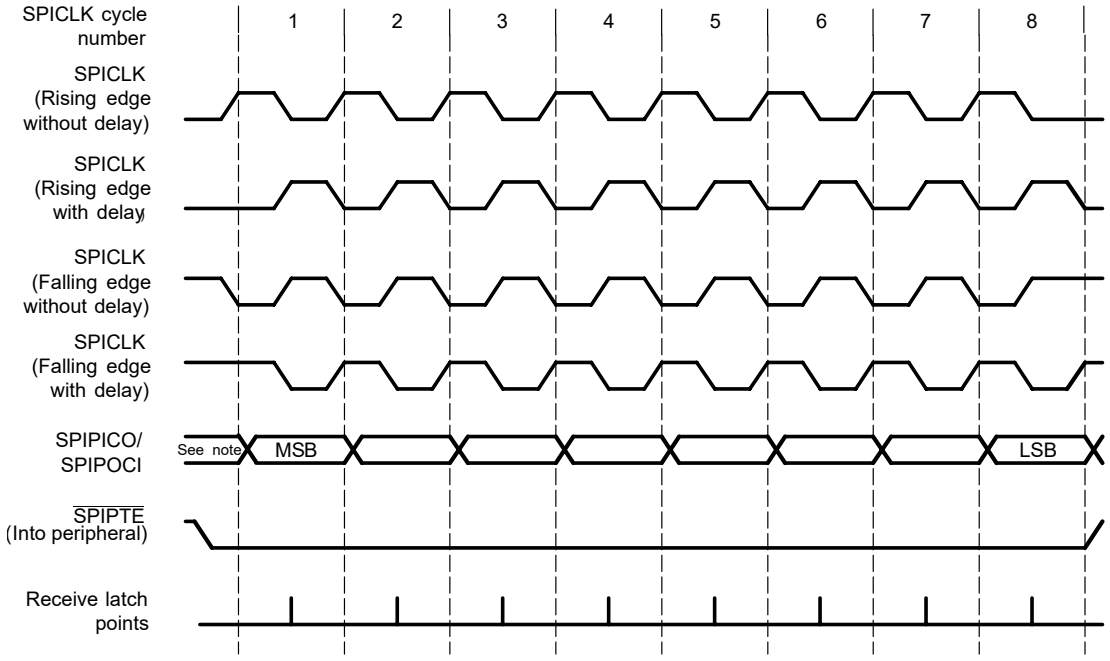
- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in Table 22-3. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 22-7.

Table 22-3. SPI Clocking Scheme Selection Guide

SPICLK Scheme	CLKPOLARITY(1)	CLK_PHASE(1)
Rising edge without delay	0	0
Rising edge with delay	0	1
Falling edge without delay	1	0
Falling edge with delay	1	1

(1) The description of CLK_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.



Note: Previous data bit

Figure 22-7. SPICLK Signal Options

SPICLK symmetry is retained only when the result of (SPIBRR + 1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in Figure 22-8.

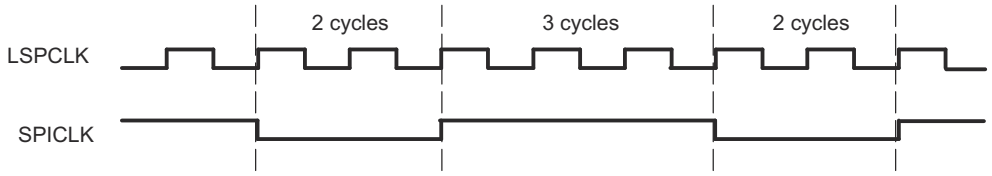


Figure 22-8. SPI: SPICLK-LSPCLK Characteristic when (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1

22.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode works with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT are active.
5. **Interrupts.** FIFO mode has two interrupts: one for the transmit FIFO, SPITXINT; one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI are disabled and this interrupt is serviced as SPI receive FIFO interrupt. For more information, refer to Section 22.2.3.
6. **Buffers.** Transmit and receive buffers are each supplemented with a 16-word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register can define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) reset the FIFO pointers to zero when these bits are set to 1. The FIFOs resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

22.3.8 SPI DMA Transfers

22.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA_BURST_SIZE) must be no greater than 16 - TXFFIL, to prevent the DMA from writing to an already full FIFO. This leads to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of words to be transmitted. [NUM_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM_WORDS: 128

TXFFIL: 8

DMA_TRANSFER_SIZE: (NUM_WORDS /(16 - TXFFIL)) - 1 = (128/8) - 1 = 15 (16 transfers)

DMA_BURST_SIZE: (16 - TXFFIL) - 1 = (16 - 8) - 1 = 7 (8 words per burst)

Note

Avoid setting TXFFIL to 0h or 10h to make sure of proper DMA configuration.

22.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST_SIZE) must be no greater than RXFFIL to prevent the DMA from reading from an empty FIFO. To make sure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size can equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the total number of words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM_WORDS = 200

RXFFIL: 4

DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) - 1 = (200/4) - 1 = 49 (50 transfers)

DMA_BURST_SIZE = RXFFIL - 1 = 3 (4 words per burst)

Note

Avoid setting RXFFIL to 0h to make sure proper DMA configuration.

22.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer to the device data sheet.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single controller to single peripheral configuration is supported.
- Loading on the pins must not exceed the value stated in the device data sheet.

When configuring the GPIOs to support high-speed mode, refer to Section 22.2.2.1 for more information.

22.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In controller mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPIPICOx becomes the bi-directional SPICOCIx (SPI controller out, controller in) pin, and SPIPOCIx is no longer used by the SPI. In peripheral mode, if the TRIWIRE bit is set, SPIPOCIx becomes the bi-directional SPIPIPOx (SPI peripheral in, peripheral out) pin, and SPIPICOx is no longer used by the SPI.

Table 22-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a controller and peripheral SPI.

Table 22-4. 4-wire versus 3-wire SPI Pin Functions

4-wire SPI	3-wire SPI (Controller)	3-wire SPI (Peripheral)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPIPICOx	SPICOCIx	Free
SPIPOCIx	Free	SPIPIPOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In controller mode, to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPICOCI pin) before reading from the data register.

Figure 22-9 and Figure 22-10 illustrate 3-wire controller and peripheral mode.

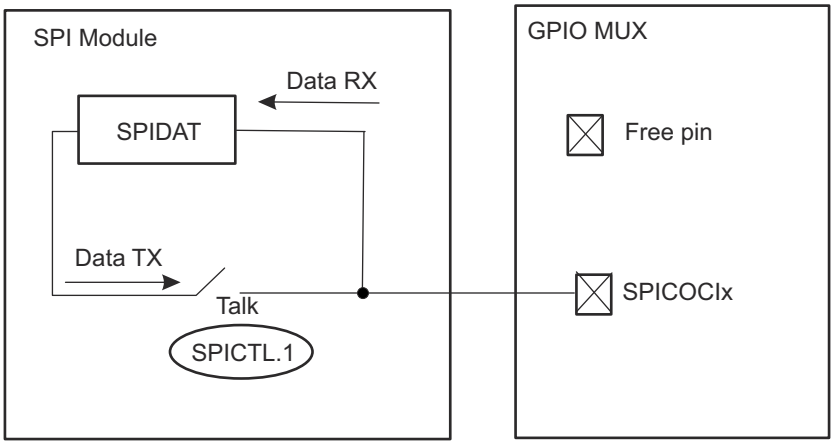

Figure 22-9. SPI 3-wire Controller Mode

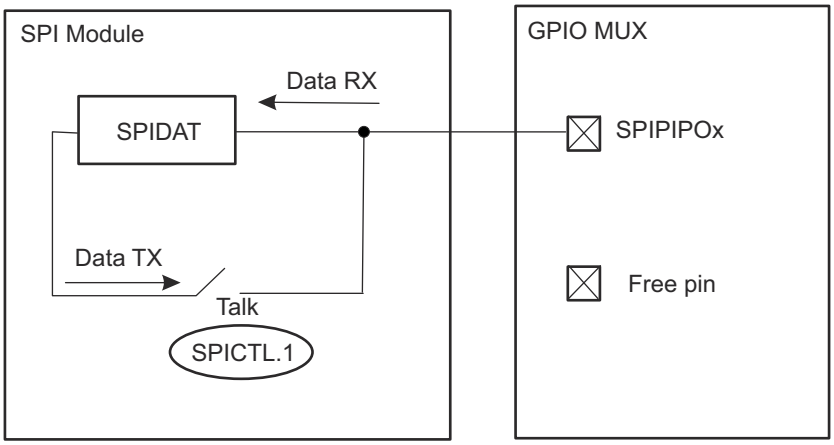

Figure 22-10. SPI 3-wire Peripheral Mode

Table 22-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

Table 22-5. 3-Wire SPI Pin Configuration

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPIPICO	SPIPOCI
		Controller Mode		
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
		Peripheral Mode		
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

22.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

22.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a peripheral module (CONTROLLER_PERIPHERAL = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

22.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

Note

Do not change the SPI configuration when communication is in progress.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
   - Select either controller or peripheral mode (CONTROLLER_PERIPHERAL).
   - Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
   - Set the desired baud rate (SPIBRR).
   - Set the SPI character length (SPICHAR).
   - Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
   - Enable $\overline{\text{SPIPTE}}$ inversion (STEINV), if needed.
   - Enable 3-wire mode (TRIWIRE), if needed.
   - If using FIFO enhancements:
     - Enable the FIFO enhancements (SPIFFENA).
     - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
     - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
     - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
   - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
   - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

22.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = LSPCLK/(SPIBRR+1) = 25MHz

```
SpiaRegs.SPIBRR = 0x3;
```

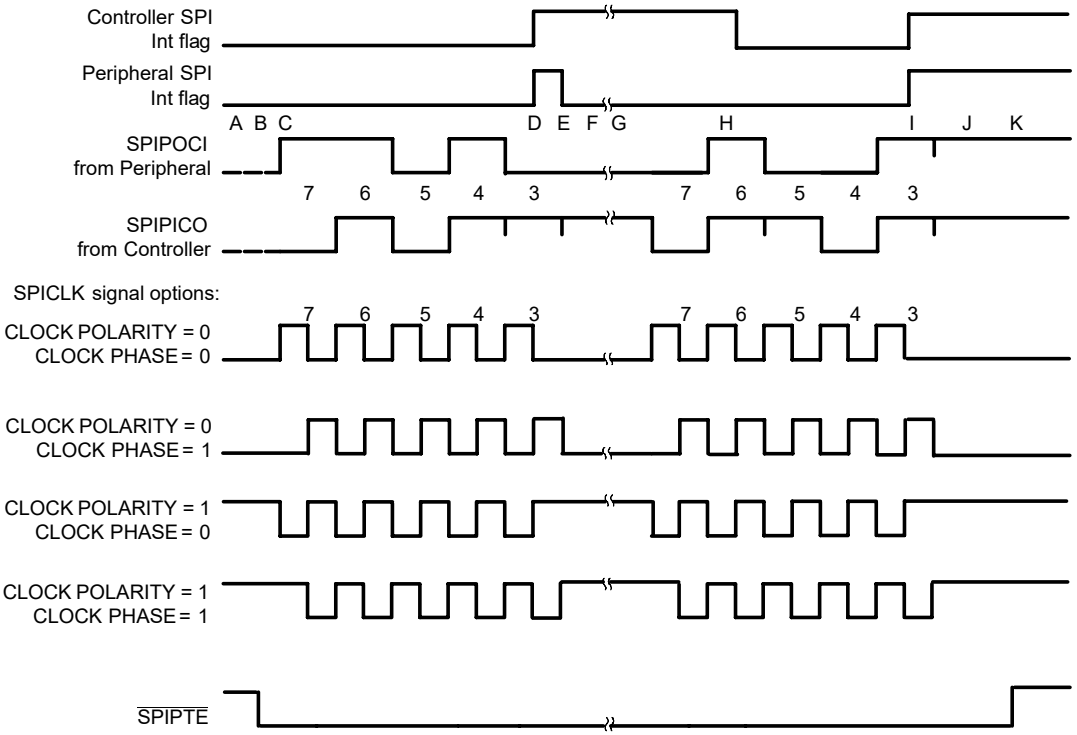
There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts operates without change.

22.4.4 Data Transfer Example

The timing diagram shown in Figure 22-11 shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 22-8) shares similar characterizations with Figure 22-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 22-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.



A. Peripheral writes 0D0h to SPIDAT and waits for the controller to shift out the data.
B. Controller sets the peripheral $\overline{\text{SPIPTE}}$ signal low (active).
C. Controller writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Peripheral reads 0Bh from the SPIRXBUF (right-justified).
F. Peripheral writes 04Ch to SPIDAT and waits for the controller to shift out the data.
G. Controller writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Controller reads 01Ah from the SPIRXBUF (right-justified).
I. Second byte is finished and sets the interrupt flags.
J. Controller reads 89h and the peripheral reads 8Dh from the respective SPIRXBUF. After the user software masks off the unused bits, the controller receives 09h and the peripheral receives 0Dh.
K. Controller clears the peripheral $\overline{\text{SPIPTE}}$ signal high (inactive).

Figure 22-11. Five Bits per Character

22.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire controller and peripheral mode. The following examples demonstrate these considerations.

In 3-wire controller mode, SPICLKx, $\overline{\text{SPIPTE}}$x, and SPIPICOx pins must be configured as SPI pins (SPIPOCIx pin can be configured as non-SPI pin). When the controller transmits, the controller receives the data the controller transmits (because SPIPICOx and SPIPOCIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

Example 22-4. 3-Wire Controller Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Controller transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data because
                                                // rx'd same data as tx'd
```

To receive data in 3-wire controller mode, the controller must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data to initiate the transfer from the peripheral. Because the TALK bit is 0, unlike in transmit mode, the controller dummy data does not appear on the SPIPICOx pin, and the controller does not receive the dummy data. Instead, the data from the peripheral is received by the controller.

Example 22-5. 3-Wire Controller Mode Receive

```
Uint16 rdata;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPIPICOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Controller reads data
```

In 3-wire peripheral mode, SPICLKx, SPISTEx, and SPIPOCIx pins must be configured as SPI pins (SPIPICOx pin can be configured as non-SPI pin). Like in controller mode, when transmitting, the peripheral receives the data transmitted and must clear this junk data from the receive buffer.

Example 22-6. 3-Wire Peripheral Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Peripheral transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data
```

As in 3-wire controller mode, the TALK bit must be cleared to 0. Otherwise, the peripheral receives data normally.

Example 22-7. 3-Wire Peripheral Mode Receive

```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Peripheral reads data
```

22.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in peripheral mode. The SPI module that receives a normal active-low $\overline{\text{SPIPTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPIPTE}}$ signal stores left-channel data from the controller. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 22-12.

Note

This configuration is only applicable to peripheral mode (CONTROLLER_PERIPHERAL = 0). When the SPI is configured as controller (CONTROLLER_PERIPHERAL = 1), the STEINV bit has no effect on the $\overline{\text{SPIPTE}}$ pin.

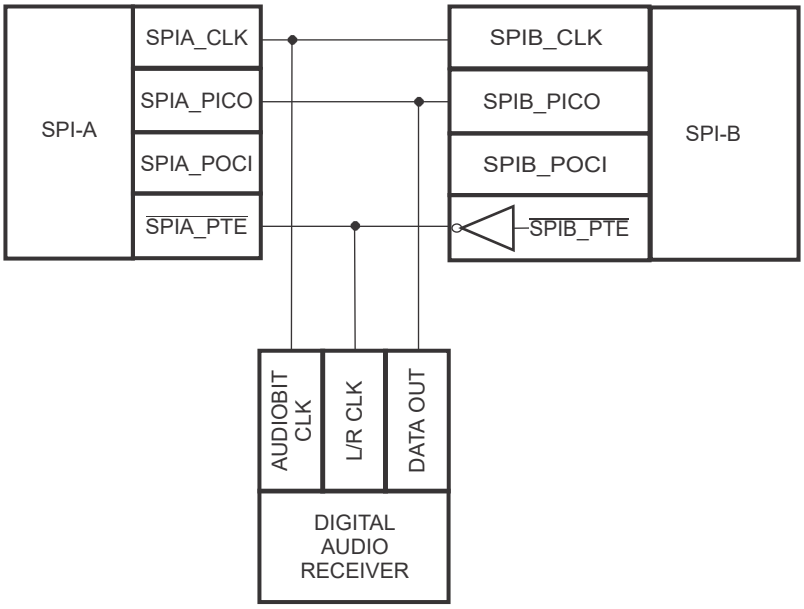


Figure 22-12. SPI Digital Audio Receiver Configuration Using Two SPIs

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 22-13.

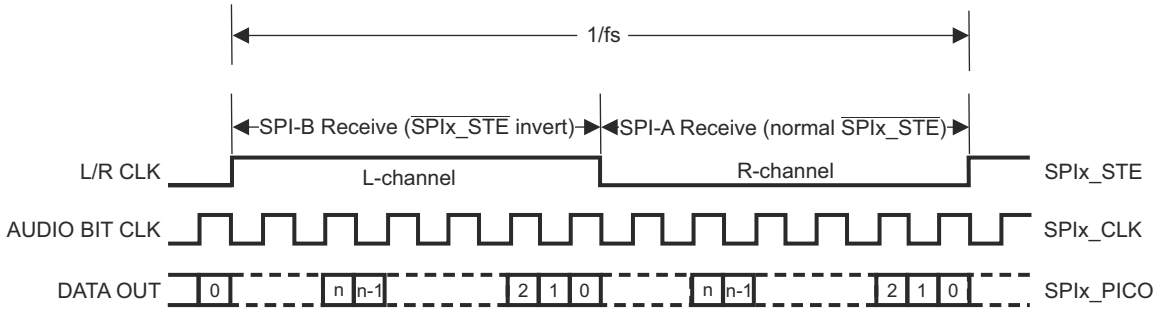

Figure 22-13. Standard Right-Justified Digital Audio Data Format

22.5.2 SPI Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/spi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

22.5.2.1 SPI Digital Loopback

FILE: spi_ex1_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configure through the sysconfig file.

The sent data looks like this:
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000

This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

22.5.2.2 SPI Digital Loopback with FIFO Interrupts

FILE: spi_ex2_loopback_fifo_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

22.5.2.3 SPI Digital External Loopback without FIFO Interrupts

FILE: spi_ex3_external_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

Watch Variables
- *TxData_SPIA* - Data send from SPIA (peripheral)
- *TxData_SPIB* - Data send from SPIB (controller)
- *RxData_SPIA* - Data received by SPIA (peripheral)
- *RxData_SPIB* - Data received by SPIB (controller)

22.5.2.4 SPI Digital External Loopback with FIFO Interrupts

FILE: spi_ex4_external_loopback_fifo_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and their interrupts are used. SPIA is configured as a peripheral and receives data from SPI B which is configured as a controller.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

22.5.2.5 SPI Digital Loopback with DMA

FILE: spi_ex5_loopback_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

22.5.2.6 SPI EEPROM

FILE: spi_ex6_eeprom.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: SPI character length is configured to 8 bits in SysConfig, and not changed throughout the execution of the program. Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

External Connections
- Connect external SPI EEPROM
- Connect GPIO08 (PICO) to external EEPROM SI pin
- Connect GPIO10 (POCI) to external EEPROM SO pin
- Connect GPIO09 (CLK) to external EEPROM SCK pin
- Connect GPIO15 (CS) to external EEPROM CS pin

- Connect the external EEPROM VCC and GND pins

Watch Variables

- writeBuffer - Data that is written to external EEPROM
- readBuffer - Data that is read back from EEPROM
- error - Error count

22.5.2.7 SPI DMA EEPROM

FILE: spi_ex7_eeprom_dma.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI using DMA and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: SPI character length is configured to 8 bits in SysConfig, and not changed throughout the execution of the program. Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

External Connections

- Connect external SPI EEPROM
- Connect GPIO08 (PICO) to external EEPROM SI pin
- Connect GPIO10 (POCI) to external EEPROM SO pin
- Connect GPIO09 (CLK) to external EEPROM SCK pin
- Connect GPIO15 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

Watch Variables

- writeBuffer - Data that is written to external EEPROM
- SPI_DMA_Handle.RXdata - Data that is read back from EEPROM when number of received bytes is less than 4
- SPI_DMA_Handle.pSPIRXDMA->pbuffer - Start address of received data from EEPROM
- error - Error count

22.6 SPI Registers

This Section describes the SPI Registers.

22.6.1 SPI Base Address Table

Table 22-7. SPI Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
SpiaRegs	SPI_REGS	SPIA_BASE	0x0000_6100	YES	YES	YES	YES
SpibRegs	SPI_REGS	SPIB_BASE	0x0000_6110	YES	YES	YES	YES

22.6.2 SPI_REGS Registers

Table 22-8 lists the memory-mapped registers for the SPI_REGS registers. All register offset addresses not listed in Table 22-8 should be considered as reserved locations and the register contents should not be modified.

Table 22-8. SPI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SPICCR	SPI Configuration Control Register		Go
1h	SPICTL	SPI Operation Control Register		Go
2h	SPISTS	SPI Status Register		Go
4h	SPIBRR	SPI Baud Rate Register		Go
6h	SPIRXEMU	SPI Emulation Buffer Register		Go
7h	SPIRXBUF	SPI Serial Input Buffer Register		Go
8h	SPITXBUF	SPI Serial Output Buffer Register		Go
9h	SPIDAT	SPI Serial Data Register		Go
Ah	SPIFFTX	SPI FIFO Transmit Register		Go
Bh	SPIFFRX	SPI FIFO Receive Register		Go
Ch	SPIFFCT	SPI FIFO Control Register		Go
Fh	SPIPRI	SPI Priority Control Register		Go

Complex bit access types are encoded to fit into small table cells. Table 22-9 shows the codes that are used for access types in this section.

Table 22-9. SPI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

22.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0000h]

SPICCR is shown in Figure 22-14 and described in Table 22-10.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

Figure 22-14. SPICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0

R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

Table 22-10. SPICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	SPI Software Reset When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. Reset type: SYSRSn 0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPIPTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged. 1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.
6	CLKPOLARITY	R/W	0h	Shift Clock Polarity This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. Reset type: SYSRSn 0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. 1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.

Table 22-10. SPICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	High Speed Mode Enable Bits This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers. Reset type: SYSRSn 0h (R/W) = SPI High Speed mode disabled. This is the default value after reset. 1h (R/W) = SPI High Speed mode enabled,
4	SPILBK	R/W	0h	SPI Loopback Mode Select Loopback mode allows module validation during device testing. This mode is valid only in CONTROLLER mode of the SPI. Reset type: SYSRSn 0h (R/W) = SPI loopback mode disabled. This is the default value after reset. 1h (R/W) = SPI loopback mode enabled, PICO/POCI lines are connected internally. Used for module self-tests.
3-0	SPICHAR	R/W	0h	Character Length Control Bits These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence. SPICHAR = Word length - 1 Reset type: SYSRSn 0h (R/W) = 1-bit word 1h (R/W) = 2-bit word 7h (R/W) = 8-bit word Fh (R/W) = 16-bit word

22.6.2.2 SPICTL Register (Offset = 1h) [Reset = 0000h]

SPICTL is shown in Figure 22-15 and described in Table 22-11.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (PERIPHERAL or CONTROLLER).

Figure 22-15. SPICTL Register

15	14	13	12	11	10	9	8
RESERVED

R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 22-11. SPICTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	Overrun Interrupt Enable Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. Reset type: SYSRSn 0h (R/W) = Disable RECEIVER OVERRUN interrupts. 1h (R/W) = Enable RECEIVER_OVERRUN interrupts.
3	CLK_PHASE	R/W	0h	SPI Clock Phase Select This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (CONTROLLER or PERIPHERAL) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used. Reset type: SYSRSn 0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6). 1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.
2	CONTROLLER_PERIPHERAL	R/W	0h	SPI Network Mode Control This bit determines whether the SPI is a network CONTROLLER or PERIPHERAL. After SPI reset, SPI is automatically configured as a PERIPHERAL Reset type: SYSRSn 0h (R/W) = SPI is configured as a PERIPHERAL. 1h (R/W) = SPI is configured as a CONTROLLER.

Table 22-11. SPICTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	Transmit Enable The TALK bit can disable data transmission (CONTROLLER or PERIPHERAL) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset. Reset type: SYSRSn 0h (R/W) = Disables transmission: - PERIPHERAL mode operation: If not previously configured as a general-purpose I/O pin, the SPIPOCI pin will be put in the high-impedance state. - CONTROLLER mode operation: If not previously configured as a general-purpose I/O pin, the SPIPICO pin will be put in the high-impedance state. 1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPIPTEn input pin.
0	SPIINTENA	R/W	0h	SPI Interrupt Enable This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit. Reset type: SYSRSn 0h (R/W) = Disables the interrupt. 1h (R/W) = Enables the interrupt.

22.6.2.3 SPISTS Register (Offset = 2h) [Reset = 0000h]

SPISTS is shown in Figure 22-16 and described in Table 22-12.

Return to the Summary Table.

SPISTS contrains interrupt and status bits.

Figure 22-16. SPISTS Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
OVERRUN_FLAG	INT_FLAG	BUFFULL_FLAG	RESERVED				
W1C-0h	RC-0h	R-0h	R-0h				

Table 22-12. SPISTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	SPI Receiver Overrun Flag This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways: - Writing a 1 to this bit - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited. Reset type: SYSRSn 0h (R/W) = A receive overrun condition has not occurred. 1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Table 22-12. SPISTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	SPI Interrupt Flag SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways: - Reading SPIRXBUF - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality. Reset type: SYSRSn 0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.
5	BUFFULL_FLAG	R	0h	SPI Transmit Buffer Full Flag This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. Reset type: SYSRSn 0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.
4-0	RESERVED	R	0h	Reserved

22.6.2.4 SPIBRR Register (Offset = 4h) [Reset = 0000h]

SPIBRR is shown in Figure 22-17 and described in Table 22-13.

Return to the Summary Table.

SPIBRR contains the bits used for baud-rate selection.

Figure 22-17. SPIBRR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED	SPI_BIT_RATE						
R-0h	R/W-0h						

Table 22-13. SPIBRR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	SPI Baud Rate Control These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 CONTROLLER. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.) If the SPI is a network PERIPHERAL, the module receives a clock on the SPICLK pin from the network CONTROLLER. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the CONTROLLER should not exceed the PERIPHERAL SPI's LSPCLK signal divided by 4. In CONTROLLER mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula: For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1) For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4 Reset type: SYSRSn 3h (R/W) = SPI Baud Rate = LSPCLK/4 4h (R/W) = SPI Baud Rate = LSPCLK/5 7Eh (R/W) = SPI Baud Rate = LSPCLK/127 7Fh (R/W) = SPI Baud Rate = LSPCLK/128

22.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0000h]

SPIRXEMU is shown in Figure 22-18 and described in Table 22-14.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Figure 22-18. SPIRXEMU Register

Table 22-14. SPIRXEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

22.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0000h]

SPIRXBUF is shown in Figure 22-19 and described in Table 22-15.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

Table 22-15. SPIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

22.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0000h]

SPITXBUF is shown in Figure 22-20 and described in Table 22-16.

Return to the Summary Table.

SPITXBUF stores the next character to be tranmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no tranmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.
In CONTROLLER mode, if no tranmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

22.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0000h]

SPIDAT is shown in Figure 22-21 and described in Table 22-17.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

Bit	Field	Type	Reset	Description
15-0	SDATn	R/W	0h	Serial Data Shift Register - It provides data to be output on the serial output pin if the TALK bit (SPICTL.1) is set. - When the SPI is operating as a CONTROLLER, a data transfer is initiated. When initiating a transfer, check the CLOCK POLARITY bit (SPICCR.6) described in Section 10.2.1.1 and the CLOCK PHASE bit (SPICTL.3) described in Section 10.2.1.2, for the requirements. In CONTROLLER mode, writing dummy data to SPIDAT initiates a receiver sequence. Since the data is not hardware-justified for characters shorter than sixteen bits, transmit data must be written in left-justified form, and received data read in right-justified form. Reset type: SYSRSn

22.6.2.9 SPIFFTX Register (Offset = Ah) [Reset = A000h]

SPIFFTX is shown in Figure 22-22 and described in Table 22-18.

Return to the Summary Table.

SPIFFTX contains both control and status bits related to the output FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

Table 22-20. SPIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	TXDLY	R/W	0h	FIFO Transmit Delay Bits These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer. Reset type: SYSRSn 0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word. 1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word. 2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word. FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.

22.6.2.12 SPIPRI Register (Offset = Fh) [Reset = 0000h]

SPIPRI is shown in Figure 22-25 and described in Table 22-21.

Return to the Summary Table.

SPIPRI controls auxillary functions for the SPI including emulation control, SPIPTE inversion, and 3-wire control.

Figure 22-25. SPIPRI Register

15	14	13	12	11	10	9	8

Table 22-21. SPIPRI Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved

Table 22-21. SPIPRI Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	PTEINV	R/W	0h	SPIPTEn Inversion Bit On devices with 2 or more SPI modules, inverting the SPIPTE signal on one of the modules allows the device to receive left and right-channel digital audio data. This bit is only applicable to PERIPHERAL mode. Writing to this bit while configured as CONTROLLER (CONTROLLER_PERIPHERAL = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPIPTEn is active low (normal) 1h (R/W) = SPIPTE is active high (inverted)
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In CONTROLLER mode, the SPIPICO pin becomes the SPICOCI (CONTROLLER receive and transmit) pin and SPIPOCI is free for non-SPI use. In PERIPHERAL mode, the SPIPOCI pin becomes the SPIPIPO (PERIPHERAL receive and transmit) pin and SPIPICO is free for non-SPI use.

Chapter 23

Serial Communications Interface (SCI)

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has a separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

23.1 Introduction

The SCI interfaces are shown in Figure 23-1.

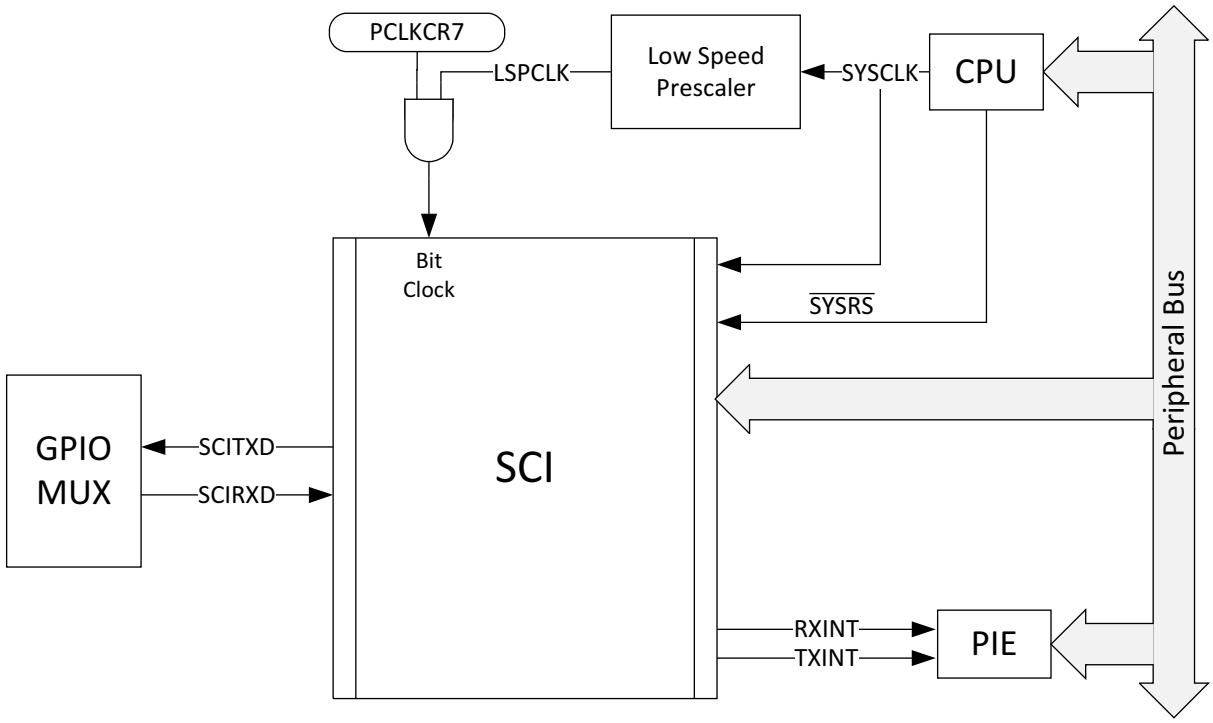

Figure 23-1. SCI CPU Interface

23.1.1 Features

Features of the SCI module include:

- Two external pins (both pins can be used as GPIO, if not used for SCI):
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

23.1.2 SCI Related Collateral

Foundational Materials

- C2000 Academy - SCI
- One Minute RS-485 Introduction (Video)
- RS-232, RS-422, RS-485: What Are the Differences? (Video)

23.1.3 Block Diagram

Figure 23-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 23.15.

23.2 Architecture

The major elements used in full-duplex operation are shown in Figure 23-2 and include:

- A transmitter (TX) and the major registers (upper half of Figure 23-2):
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and the major registers (lower half of Figure 23-2):
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

23.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in Table 23-1.

Table 23-1. SCI Module Signal Summary

Signal Name	Description
External signals	
SCIRXD	SCI Asynchronous Serial Port receive data
SCITXD	SCI Asynchronous Serial Port transmit data
Control	
Baud clock	LSPCLK Prescaled clock
Interrupt signals	
TXINT	Transmit interrupt
RXINT	Receive interrupt

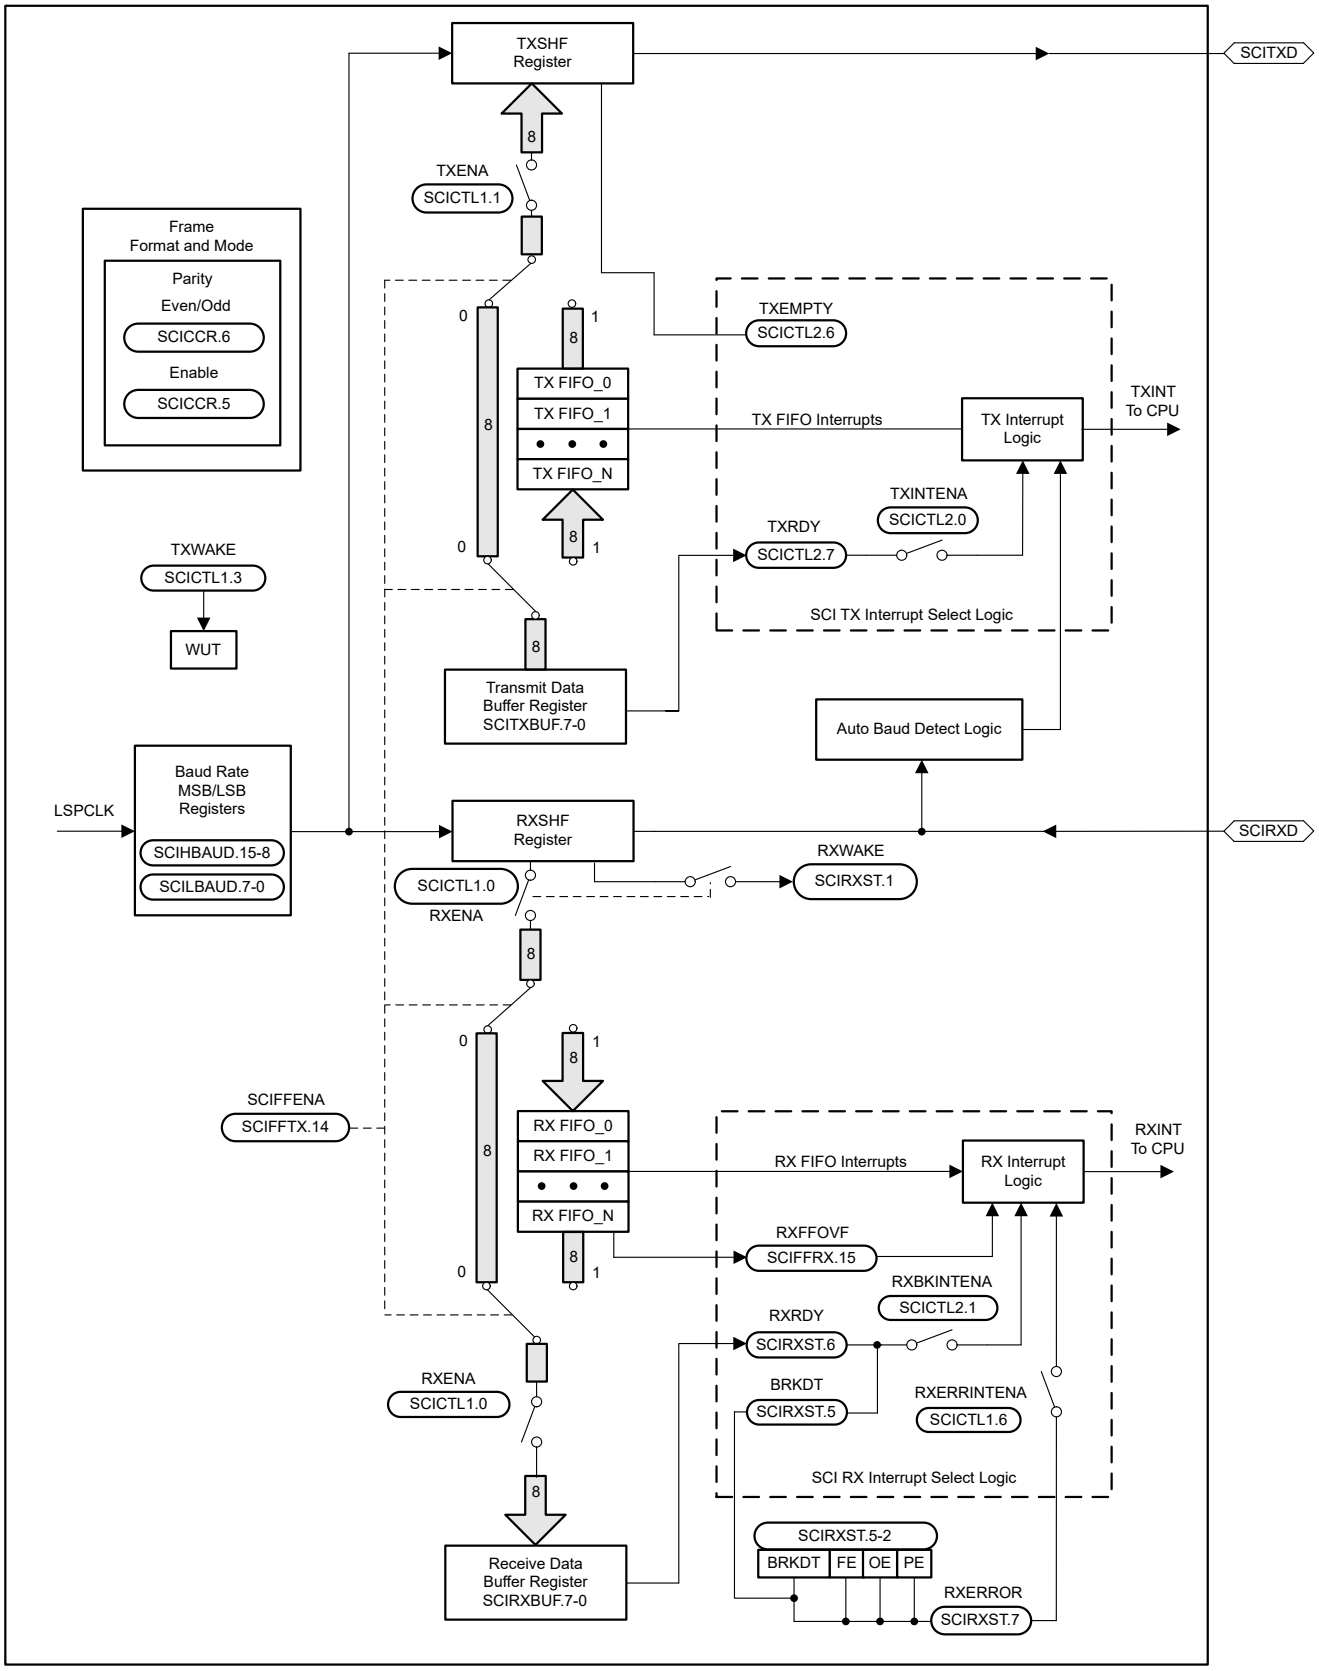

Figure 23-2. Serial Communications Interface (SCI) Module Block Diagram

23.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

23.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see Section 23.8) and the address-bit multiprocessor mode (see Section 23.9). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see Section 23.10) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits

23.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 23-3, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with formatting information is called a frame and is shown in Figure 23-3.

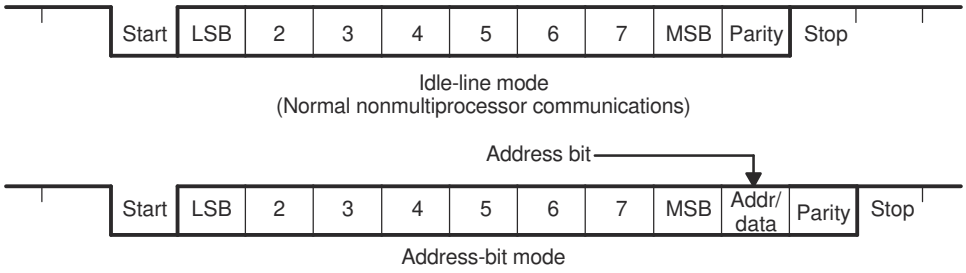

Figure 23-3. Typical SCI Data Frame Formats

To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 23-2.

Table 23-2. Programming the Data Format Using SCICCR

Bits	Bit Name	Designation	Functions
2-0	SCICHAR	SCICCR.2:0	Select the character (data) length (one to eight bits).
5	PARITYENA (ENABLE)	SCICCR.5	Enables the parity function if set to 1, or disables the parity function if cleared to 0.
6	PARITY (EVEN/ODD)	SCICCR.6	If parity is enabled, selects odd parity if cleared to 0; even parity if set to 1.
7	STOPBITS	SCICCR.7	Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1.

23.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there can be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that the processor is interrupted only when the address byte is detected. When the processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, the receiver does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

23.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode (Section 23.8) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than 10 bytes of data. The idle-line mode must be used for typical non-multiprocessor SCI communication.
- The address-bit mode (Section 23.9) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, this mode does not wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

23.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable using the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

23.7.3 Receipt Sequence

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt in non-FIFO mode of operation. In FIFO mode, RXFFINT serves this purpose and to enable this, RXFFINTEN in SCIFFRX register must be enabled with RXFFIL in the same register set to 1). The SCI reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against the device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

23.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit = 0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 23-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

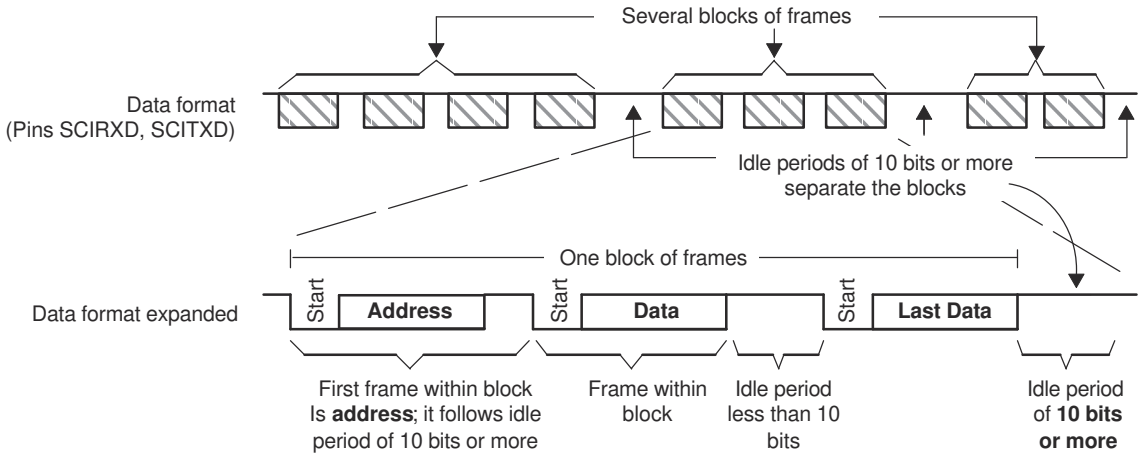

Figure 23-4. Idle-Line Multiprocessor Communication Format

23.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

1. SCI wakes up after receipt of the block-start signal.
2. The processor recognizes the next SCI interrupt.
3. The interrupt service routine compares the received address (sent by a remote transmitter) to the ISR address.
4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute the main program without being interrupted by the SCI port until the next detection of a block start.

Note

In IDLE mode, if the SCI is taking greater than 10 bit periods to read all the RXDATA from the FIFO, the SCI can miss the immediate block start to be detected.

The RXWAKE logic asserts only one time when the SCI identifies 10 bit periods of IDLE. The SCI does not assert again if RXBUF is read (which clears the WAKE condition) even if the line continues to be idle after RXBUF read.

So, if the ISR is taking more than 10 bit periods of time to read all the RXDATA from the FIFO using RXBUF, the SCI can miss to detect the next block start. This is applicable for both FIFO and Non-FIFO mode when the CPU takes greater than 10 bit clocks of SCI to read the data from RXBUF/ FIFO.

To avoid this, either of the following is recommended:

- Set SCICTL1.SWRESET after reading all RX data at the end of the ISR.
- Read and check the RXWAKE status bit before reading the RXBUF register. If RXWAKE is set, do not set the SLEEP bit for RX at the end of the ISR.

23.8.2 Block Start Signal

There are two ways to send a block-start signal:

- **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
- **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

23.8.3 Wake-Up Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in Figure 23-5.

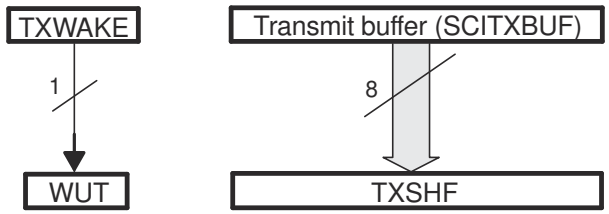

Figure 23-5. Double-Buffered WUT and TXSHF

23.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don’t care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

   Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.
3. Write a new address value to SCITXBUF.

   A don’t-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don’t-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE, if necessary) can be written to again because TXSHF and WUT are both double-buffered.

23.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does the receiver request a receive interrupt until an address frame is detected.

23.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit = 1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 23-6).

23.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

   When this address value is transferred to the TXSHF register and shifted out, the address bit is sent as a 1. This flags the other processors on the serial link to read the address.
2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

Note

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

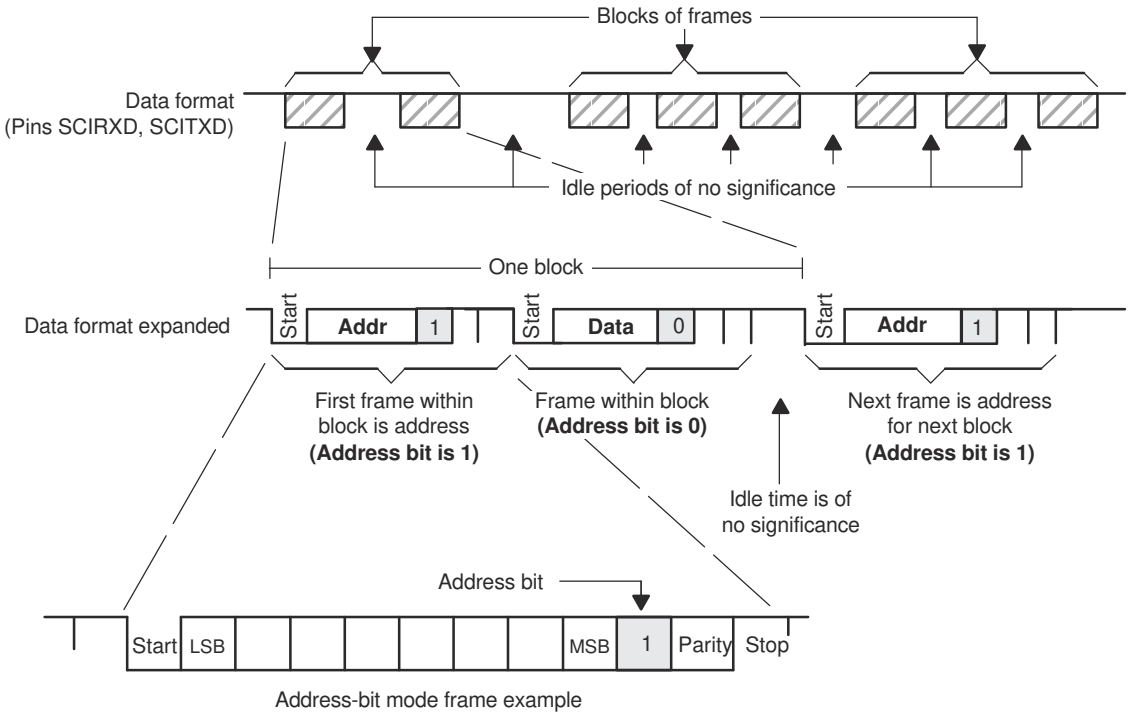

Figure 23-6. Address-Bit Multiprocessor Communication Format

23.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 23-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 23-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 23-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes to frames, the external transmitting and receiving devices do not use a synchronized serial clock. The clock can be generated locally.

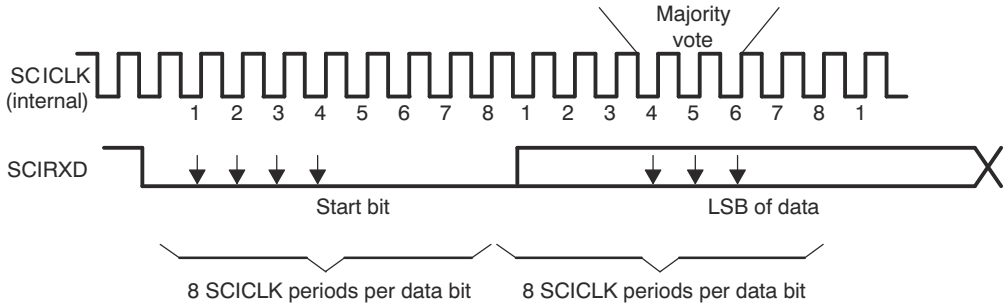

Figure 23-7. SCI Asynchronous Communications Format

23.10.1 Receiver Signals in Communication Modes

Figure 23-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

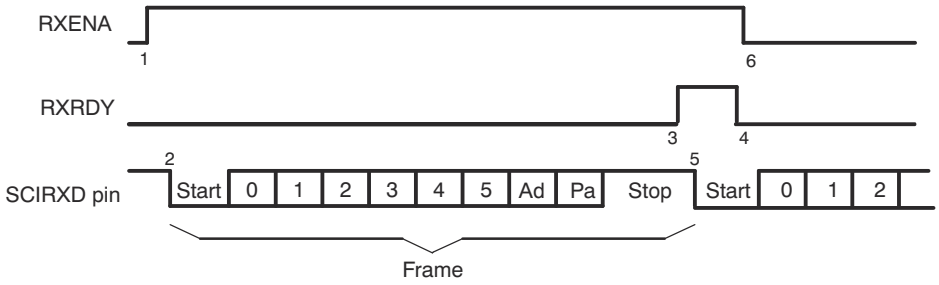

Figure 23-8. SCI RX Signals in Communication Modes

Notes:

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

23.10.2 Transmitter Signals in Communication Modes

Figure 23-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

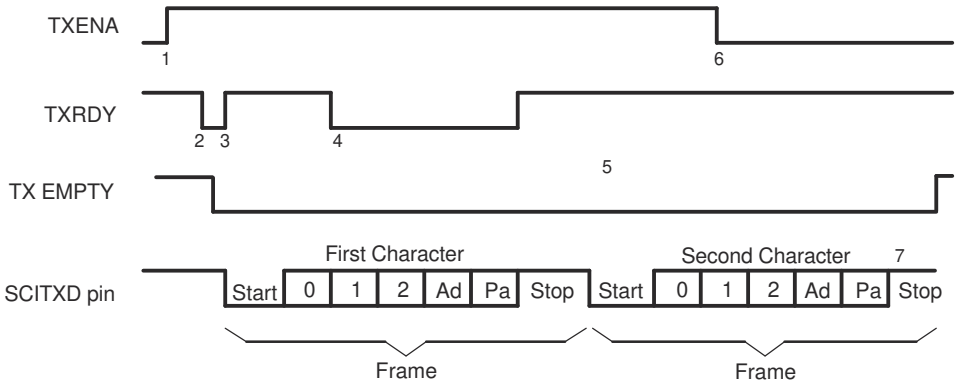

Figure 23-9. SCI TX Signals in Communications Mode

Notes:

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and the transmitter requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

23.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag that is a logical-OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits that are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupts section of the *System Control and Interrupts* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for 9.625 bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

Note

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

23.11.1 Break Detect

A "break" signal (also called a "break detect" or "break sequence") can be sent to the module to signal to the bus a specific condition. This break signal is defined as a low pulse of a certain amount of time, typically at least 1 packet wide (including a missed stop bit). The SCI has two main methods for detecting a "break" signal sent on the line, with certain limitations for each.

The first for break detect method involves reading the SCIRXST.BRKDT bit. A break condition that triggers the BRKDT bit occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI does not flag a break detect. To trigger the first stop bit missed, the typical method is to hold the RX line low for:

- 1 start bit
- 8 data bits
- (optional) 1 address bit
- (optional) 1 parity bit
- 1 stop bit
- 9.625 bits of additional time held low

This is a total of 19.625 (systems using no parity or address bit), 20.625 (systems using either parity or address bit but not both), or 21.625 (systems using both parity and address bit) bit times held low.

The second method for break detect is to instead use the SCIRXST.FE, SCIRXST.PE and SCIRXBUF.SAR bits to detect a break signal of 10 or 11 bits of low. ISR code can use the following combination of flags and received data to determine if a break detect occurred:

- Break signal = 11 bits low (requires parity enabled)
  - FE == 1
  - PE == 1 for odd parity, PE == 0 for even parity
  - SCIRXBUF.SAR (received character) == 0x00
- Break signal = 10 bits low (requires parity disabled)
  - FE == 1
  - SCIRXBUF.SAR (received character) == 0x00

23.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. Table 23-3 shows the baud-select values for common SCI bit rates. LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

Table 23-3. Asynchronous Baud Register Values for Common SCI Bit Rates

	LSPCLK Clock Frequency, 100MHz		
Baud Rate	BRR	Actual Baud Rate	% Error
2400	5207 (1457h)	2400	0
4800	2603 (A2Bh)	4800	0
9600	1301 (515h)	9601	0.01
19200	650 (28Ah)	19201	0.01
38400	324 (144h)	38462	0.16

23.13 SCI Enhanced Features

The C28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

23.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. **Reset.** At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. **Standard SCI.** The standard SCI modes work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. **FIFO enable.** FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. **Interrupts.** FIFO mode has two interrupts; transmit FIFO (TXINT) and receive FIFO (RXINT). The RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI is disabled and this interrupt serves as SCI transmit FIFO interrupt.
6. **Buffers.** Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8-bits wide and receive FIFO registers are 10-bits wide. The one-word transmit buffer (SCITXBUF) of the standard SCI functions as a transition buffer before the transmit FIFO and shift register. SCITXBUF is loaded into either the FIFO (when FIFO is enabled) or the TXSHF (when FIFO is disabled). When FIFO is enabled, SCITXBUF loads into the FIFO only after the last bit of the shift register is shifted out, so SCITXBUF cannot be treated as an additional level of buffer. With the FIFO enabled, TXSHF is directly loaded from the FIFO (not TXBUF) after an optional delay value (SCIFFCT). When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. **Delayed transfer.** The rate that words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.
8. **FIFO status bits.** Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12−8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to 1.
9. **Programmable interrupt levels.** Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12−8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4−0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 23-10 and Table 23-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

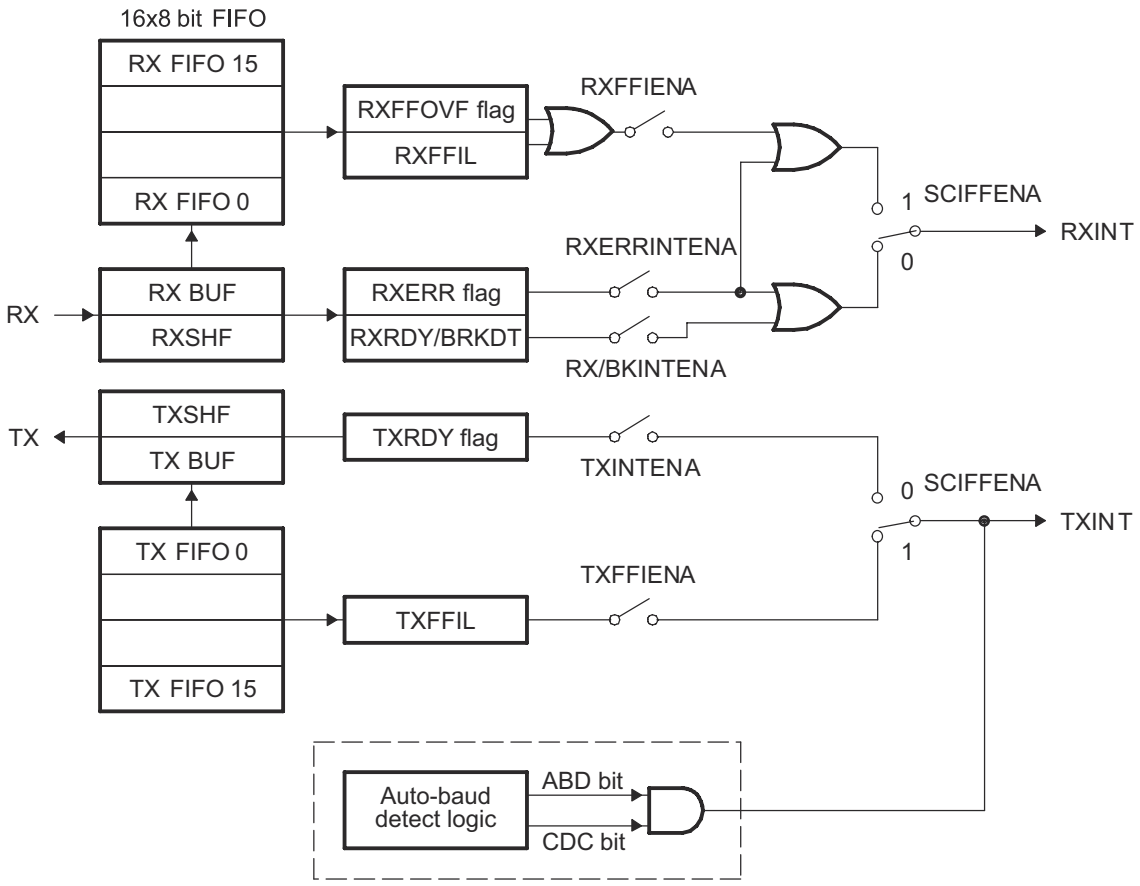

Figure 23-10. SCI FIFO Interrupt Flags and Enable Logic

Table 23-4. SCI Interrupt Flags

FIFO Options[1]	SCI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable SCIFFENA	Interrupt Line
SCI without FIFO	Receive error	RXERR[2]	RXERRINTENA	0	RXINT
	Receive break	BRKDT	RX/BKINTENA	0	RXINT
	Data receive	RXRDY	RX/BKINTENA	0	RXINT
	Transmit empty	TXRDY	TXINTENA	0	TXINT
SCI with FIFO	Receive error and receive break	RXERR	RXERRINTENA	1	RXINT
	FIFO receive	RXFFIL	RXFFIENA	1	RXINT
	Transmit empty	TXFFIL	TXFFIENA	1	TXINT
Auto-baud	Auto-baud detected	ABD	Don't care	x	TXINT

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.
(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag.

23.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

23.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit can be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software. If CDC remains set even after interrupt service, there can be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud-detect hardware detects the incoming baud rate and sets the ABD bit.
4. The auto-detect hardware updates the baud rate register with the equivalent baud value hex. The logic also generates an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software.

Note

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and C28x SCI boot loader using a lower baud rate.
- The host can then handshake with the loaded C28x application to set the SCI baud rate register to the desired higher baud rate.

23.14.2 SCI Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sci

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

23.14.2.1 Tune Baud Rate via UART Example

FILE: baud_tune_via_uart.c

This example demonstrates the process of tuning the UART/SCI baud rate of a C2000 device based on the UART input from another device. As UART does not have a clock signal, reliable communication requires baud rates to be reasonably matched. This example addresses cases where a clock mismatch between devices is greater than is acceptable for communications, requiring baud compensation between boards. As reliable communication only requires matching the EFFECTIVE baud rate, it does not matter which of the two boards executes the tuning (the board with the less-accurate clock source does not need to be the one to tune; as long as one of the two devices tunes to the other, then proper communication can be established).

To tune the baud rate of this device, SCI data (of the desired baud rate) must be sent to this device.
The input SCI baud rate must be within the +/- MARGINPERCENT of the TARGETBAUD chosen below.
These two variables are defined below, and should be chosen based on the application requirements. Higher MARGINPERCENT will allow more data to be considered "correct" in noisy conditions, and may decrease accuracy. The TARGETBAUD is what was expected to be the baud rate, but due to clock differences, needs to be tuned for better communication robustness with the other device.

NOTE: Lower baud rates have more granularity in register options, and therefore tuning is more affective at these speeds.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections* for Control Card

- SCIA_RX/eCAP1 is on GPIO9, connect to incoming SCI communications
- SCIA_TX is on GPIO8, for observation externally

Watch Variables

- *avgBaud* - Baud rate that was detected and set after tuning

23.14.2.2 SCI FIFO Digital Loop Back

FILE: sci_ex1_loopback.c

This program uses the internal loop back test mode of the peripheral. Other then boot mode pin configuration, no other hardware configuration is required. The pinmux and SCI modules are configured through the sysconfig file.

This test uses the loopback test mode of the SCI module to send characters starting with 0x00 through 0xFF. The test will send a character and then check the receive buffer for a correct match.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *Watch Variables*

- *loopCount* - Number of characters sent
- *errorCount* - Number of errors detected
- *sendChar* - Character sent
- *receivedChar* - Character received

23.14.2.3 SCI Digital Loop Back with Interrupts

FILE: sci_ex2_loopback_interrupts.c

This test uses the internal loop back test mode of the peripheral. Other then boot mode pin configuration, no other hardware configuration is required. Both interrupts and the SCI FIFOs are used.

A stream of data is sent and then compared to the received stream. The SCI-A sent data looks like this:
00 01
01 02
02 03
....
FE FF
FF 00
etc..
The pattern is repeated forever.

Watch Variables
- *sDataA* - Data being sent
- *rDataA* - Data received
- *rDataPointA* - Keep track of where we are in the data stream. This is used to check the incoming data

23.14.2.4 SCI Echoback

FILE: sci_ex3_echoback.c

This test receives and echo-backs data through the SCI-A port.

A terminal such as 'putty' can be used to view the data from the SCI and to send information to the SCI. Characters received by the SCI port are sent back to the host.

Running the Application Open a COM port with the following settings using a terminal:
- Find correct COM port
- Bits per second = 9600
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out a greeting and then ask you to enter a character which it will echo back to the terminal.

Watch Variables
- loopCounter - the number of characters sent

External Connections
Connect the USB cable from Control card J1:A to PC

23.14.2.5 stdout redirect example

FILE: sci_ex4_stdout_redirect.c This test transmits data through the SCI-A port to a terminal

A terminal such as 'putty' can be used to view the data from the SCI. Characters received by the SCI port are sent back to the host.

Running the Application Open a COM port with the following settings using a terminal:
- Find correct COM port
- Bits per second = 9600
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out three sentences: one to the SCIA, one to CCS, and a final one to SCIA.

External Connections
Connect the SCI-A port to a PC via a transceiver and cable.
- DEVICE_GPIO_PIN_SCIRXDA is SCI_A-RXD (Connect to Pin3, PC-TX, of serial DB9 cable)

- DEVICE_GPIO_PIN_SCITXDA is SCI_A-TXD (Connect to Pin2, PC-RX, of serial DB9 cable)

23.15 SCI Registers

This Section describes the SCI Registers.

23.15.1 SCI Base Address Table

Table 23-6. SCI Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
SciaRegs	SCI_REGS	SCIA_BASE	0x0000_7200	YES	-	-	YES
ScibRegs	SCI_REGS	SCIB_BASE	0x0000_7210	YES	-	-	YES
ScicRegs	SCI_REGS	SCIC_BASE	0x0000_7220	YES	-	-	YES

23.15.2 SCI_REGS Registers

Table 23-7 lists the memory-mapped registers for the SCI_REGS registers. All register offset addresses not listed in Table 23-7 should be considered as reserved locations and the register contents should not be modified.

Table 23-7. SCI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SCICCR	Communications control register		Go
1h	SCICTL1	Control register 1		Go
2h	SCIHBAUD	Baud rate (high) register		Go
3h	SCILBAUD	Baud rate (low) register		Go

Complex bit access types are encoded to fit into small table cells. Table 23-8 shows the codes that are used for access types in this section.

Table 23-8. SCI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

23.15.2.1 SCICCR Register (Offset = 0h) [Reset = 0000h]

SCICCR is shown in Figure 23-11 and described in Table 23-9.

Return to the Summary Table.

SCICCR defines the character format, protocol, and communications mode used by the SCI.

Figure 23-11. SCICCR Register

15	14	13	12	11	10	9	8

STOPBITS	PARITY	PARITYENA	LOOPBKENA	ADDRIDLE_MODE	SCICHAR		
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

Table 23-9. SCICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	STOPBITS	R/W	0h	SCI number of stop bits. This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit. Reset type: SYSRSn 0h (R/W) = One stop bit 1h (R/W) = Two stop bits
6	PARITY	R/W	0h	SCI parity odd/even selection. If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters). Reset type: SYSRSn 0h (R/W) = Odd parity 1h (R/W) = Even parity
5	PARITYENA	R/W	0h	SCI parity enable. This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation. Reset type: SYSRSn 0h (R/W) = Parity disabled no parity bit is generated during transmission or is expected during reception 1h (R/W) = Parity is enabled
4	LOOPBKENA	R/W	0h	Loop Back test mode enable. This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin. Reset type: SYSRSn 0h (R/W) = Loop Back test mode disabled 1h (R/W) = Loop Back test mode enabled

Table 23-9. SCICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	ADDRIDLE_MODE	R/W	0h	SCI multiprocessor mode control bit. This bit selects one of the multiprocessor protocols.Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications. Reset type: SYSRSn 0h (R/W) = Idle-line mode protocol selected 1h (R/W) = Address-bit mode protocol selected
2-0	SCICHAR	R/W	0h	Character-length control bits 2-0. These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn't need to be padded with leading zeros. Reset type: SYSRSn 0h (R/W) = SCICHAR_LENGTH_1 1h (R/W) = SCICHAR_LENGTH_2 2h (R/W) = SCICHAR_LENGTH_3 3h (R/W) = SCICHAR_LENGTH_4 4h (R/W) = SCICHAR_LENGTH_5 5h (R/W) = SCICHAR_LENGTH_6 6h (R/W) = SCICHAR_LENGTH_7 7h (R/W) = SCICHAR_LENGTH_8

23.15.2.2 SCICTL1 Register (Offset = 1h) [Reset = 0000h]

SCICTL1 is shown in Figure 23-12 and described in Table 23-10.

Return to the Summary Table.

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

Figure 23-12. SCICTL1 Register

Table 23-10. SCICTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RXERRINTENA	R/W	0h	SCI receive error interrupt enable. Setting this bit enables an interrupt if the RX ERROR bit (SCIRXST, bit 7) becomes set because of errors occurring. Reset type: SYSRSn 0h (R/W) = Receive error interrupt disabled 1h (R/W) = Receive error interrupt enabled
5	SWRESET	R/W	0h	SCI software reset (active low). Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. This reset will not reset the FIFO pointers or flush out the data in TX/RX FIFO. If you need to clear the FIFO then perform SWRESET + TXFFINT + RXFFINT or refer to a channel reset SCIFFTX[SCIRST]. The SW RESET bit does not affect any of the configuration bits. All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit. Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST, bit 5). SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values. Once SW RESET is asserted, the flags are frozen until the bit is deasserted. The affected flags are as follows: Value After SW SCI Flag Register Bit RESET 1 TXRDY SCICTL2, bit 7 1 TX EMPTY SCICTL2, bit 6 0 RXWAKE SCIRXST, bit 1 0 PE SCIRXST, bit 2 0 OE SCIRXST, bit 3 0 FE SCIRXST, bit 4 0 BRKDT SCIRXST, bit 5 0 RXRDY SCIRXST, bit 6 0 RX ERROR SCIRXST, bit 7 Reset type: SYSRSn 0h (R/W) = Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. 1h (R/W) = After a system reset, re-enable the SCI by writing a 1 to this bit. There is no time requirement to meet before writing a one to this bit after writing a zero.
4	RESERVED	R	0h	Reserved

Table 23-10. SCICTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	TXWAKE	R/W	0h	SCI transmitter wake-up method select. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3) Reset type: SYSRSn 0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1 1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5) it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.
2	SLEEP	R/W	0h	SCI sleep. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode. The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected. Reset type: SYSRSn 0h (R/W) = Sleep mode disabled 1h (R/W) = Sleep mode enabled
1	TXENA	R/W	0h	SCI transmitter enable. Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later. Reset type: SYSRSn 0h (R/W) = Transmitter disabled 1h (R/W) = Transmitter enabled
0	RXENA	R/W	0h	SCI receiver enable. Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers). Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, this will not stop RX errors from triggering interrupts. To disable interrupts from RX errors use the RXERRINTENA bit. To stop propagation of the BRKDT interrupt use the RXBKINTENA bit. The receiver shift register can continue to assemble characters even while RXENA is cleared. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF. Reset type: SYSRSn 0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers 1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF

23.15.2.3 SCIHBAUD Register (Offset = 2h) [Reset = 0000h]

SCIHBAUD is shown in Figure 23-13 and described in Table 23-11.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	BAUD	R/W	0h	SCI 16-bit baud selection Registers SCIHBAUD (MSbyte). The internally-generated serial clock is determined by the low speed peripheral clock (LSPCLK) signal and the two baud-select registers. The SCI uses the 16-bit value of these registers to select one of 64K serial clock rates for the communication modes. BRR = (SCIHBAUD << 8) + (SCILBAUD) The SCI baud rate is calculated using the following equation: SCI Asynchronous Baud = LSPCLK / ((BRR + 1) *8) Alternatively, BRR = LSPCLK / (SCI Asynchronous Baud * 8) - 1 Note that the above formulas are applicable only when 0 < BRR < 65536. If BRR = 0, then SCI Asynchronous Baud = LSPCLK / 16 Where: BRR = the 16-bit value (in decimal) in the baud-select registers Reset type: SYSRSn

23.15.2.4 SCILBAUD Register (Offset = 3h) [Reset = 0000h]

SCILBAUD is shown in Figure 23-14 and described in Table 23-12.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Table 23-13. SCICTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit data buffer register, SCITXBUF, is ready to receive another character. Writing data to the SCITXBUF automatically clears this bit. When set, this flag asserts a transmitter interrupt request if the interrupt-enable bit, TX INT ENA (SCICTL2.0), is also set. TXRDY is set to 1 by enabling the SW RESET bit (SCICTL1.5) or by a system reset. Reset type: SYSRSn 0h (R/W) = SCITXBUF is full 1h (R/W) = SCITXBUF is ready to receive the next character
6	TXEMPTY	R	1h	Transmitter empty flag. This flag's value indicates the contents of the transmitter's buffer register (SCITXBUF) and shift register (TXSHF). An active SW RESET (SCICTL1.5), or a system reset, sets this bit. This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Transmitter buffer or shift register or both are loaded with data 1h (R/W) = Transmitter buffer and shift registers are both empty
5-2	RESERVED	R	0h	Reserved
1	RXBKINTENA	R/W	0h	Receiver-buffer/break interrupt enable. This bit controls the interrupt request caused by either the RXRDY flag or the BRKDT flag (bits SCIRXST.6 and .5) being set. However, RX/BK INT ENA does not prevent the setting of these flags. Reset type: SYSRSn 0h (R/W) = Disable RXRDY/BRKDT interrupt 1h (R/W) = Enable RXRDY/BRKDT interrupt

Table 23-13. SCICTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TXINTENA	R/W	0h	SCITXBUF-register interrupt enable. This bit controls the interrupt request caused by the setting of TXRDY flag bit (SCICTL2.7). However, it does not prevent the TXRDY flag from being set (which indicates SCITXBUF is ready to receive another character). 0 Disable TXRDY interrupt 1 Enable TXRDY interrupt. In non-FIFO mode, a dummy (or a valid) data has to be written to SCITXBUF for the first transmit interrupt to occur. This is the case when you enable the transmit interrupt for the first time and also when you re-enable (disable and then enable) the transmit interrupt. If TXINTENA is enabled after writing the data to SCITXBUF, it will not generate an interrupt. Reset type: SYSRSn 0h (R/W) = Disable TXRDY interrupt 1h (R/W) = Enable TXRDY interrupt

23.15.2.6 SCIRXST Register (Offset = 5h) [Reset = 0000h]

SCIRXST is shown in Figure 23-16 and described in Table 23-14.

Return to the Summary Table.

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated.

Figure 23-16. SCIRXST Register

Table 23-14. SCIRXST Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	RXERROR	R	0h	SCI receiver error flag. The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE). A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly it is cleared by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No error flags set 1h (R/W) = Error flag(s) set
6	RXRDY	R	0h	SCI receiver-ready flag. When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No new character in SCIRXBUF 1h (R/W) = Character ready to be read from SCIRXBUF

Table 23-14. SCIRXST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	BRKDT	R	0h	SCI break-detect flag. The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI will not flag a break detect. In order to trigger the first stop bit missed, the typical method is to hold the RX line low for 1 start bit, 8 data bits, 1 optional address bit, 1 optional parity bit, 1 stop bit, and 9.625 bits of additional time held low. This is a total of 19.625 (no parity/address bit), 20.625 (either parity or address bit), or 21.625 (both parity and address bit) bit times. To instead detect a 'break seq' or 'break sequence' of 11 bits of low voltage level (0), ISR code can use the following combination of flags and received data: FE==1 && PE==1 && SCIRXBUF.SAR (received character)==0x00. This assumes parity enabled and odd parity set. With even parity, PE==0 instead. The detection of 11 bits of low/0 can be reduced to 10 bits of low if no parity bit is used (then PE flag does not matter to detect the sequence). The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET, SCIRST bit, or by a system reset. It is not cleared by receipt of a character after the break is detected. If Break Detect (BRKDT) is set, then RXRDY won't be set and there will be no further interrupts after the first interrupt where there is an error detected if a SW reset, channel reset, or system reset is not performed. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: If your system is susceptible to break detects, ensure that you have a pull-up resistor on the SCI-RX pin to provide proper return-to-high signal behavior and noise immunity. NOTE: To monitor a break detect, place an oscilloscope on the C2000 SCI-RX line and monitor for a low-signal greater than 9.625 bits wide. If this is found and a break is not expected, please correct the software in the other device that is transmitting to this C2000 device. There should never be a low-signal greater than 9.625 bits wide on the SCI-RX line of the C2000 device unless a break detect is being transmitted purposely. Reset type: SYSRSn 0h (R/W) = No break condition 1h (R/W) = Break condition occurred
4	FE	R	0h	SCI framing-error flag. The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: FE will be flagged prior to BRKDT, except when RX is in sleep mode. In sleep mode, when there is no RX WAKEUP and RXD line is low for greater than 10 bits, BRKDT will be flagged while FE will not be flagged. Reset type: SYSRSn 0h (R/W) = No framing error detected 1h (R/W) = Framing error detected

Table 23-14. SCIRXST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	OE	R	0h	SCI overrun-error flag. The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No overrun error detected 1h (R/W) = Overrun error detected
2	PE	R	0h	SCI parity-error flag. This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No parity error or parity is disabled 1h (R/W) = Parity error is detected
1	RXWAKE	R	0h	Receiver wake-up-detect flag Reset type: SYSRSn 0h (R/W) = No detection of a receiver wake-up condition 1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following: - The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode) - The reading of SCIRXBUF - An active SW RESET - Channel reset (SCIRST) - A system reset
0	RESERVED	R	0h	Reserved

23.15.2.7 SCIRXEMU Register (Offset = 6h) [Reset = 0000h]

SCIRXEMU is shown in Figure 23-17 and described in Table 23-15.

Return to the Summary Table.

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented
it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

23.15.2.8 SCIRXBUF Register (Offset = 7h) [Reset = 0000h]

SCIRXBUF is shown in Figure 23-18 and described in Table 23-16.

Return to the Summary Table.

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

Figure 23-18. SCIRXBUF Register

Table 23-16. SCIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SCIFFFE	R	0h	SCIFFFE. SCI FIFO Framing error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFFE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'FE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a framing error. Reset type: SYSRSn 0h (R/W) = No frame error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A frame error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.
14	SCIFFPE	R	0h	SCIFFPE. SCI FIFO parity error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFPE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'PE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a parity error. Note: If the parity is changed in the middle of data reception, the SCI module will not reinterpret the data with the new parity or other settings that may have changed. Therefore, changing the parameter, the FIFO should be cleared or the user should acknowledge that there will most likely be errors in the data caused by the change. Note: If RX parity errors are occurring intermittently this could be due to the length of the SCI ISR. To help prevent this, ensure that interrupt nesting is limited, increase the SCI interrupt priority, and move as much of the processing as possible out of the ISR (to reduce ISR time to the absolute minimum). Reset type: SYSRSn 0h (R/W) = No parity error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A parity error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.

7-0	SAR	R	0h	Receive Character bits Reset type: SYSRSn

23.15.2.9 SCITXBUF Register (Offset = 9h) [Reset = 0000h]

SCITXBUF is shown in Figure 23-19 and described in Table 23-17.

Return to the Summary Table.

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

Bit	Field	Type	Reset	Description
15	ABD	R	0h	Auto-baud detect (ABD) bit Reset type: SYSRSn 0h (R/W) = Auto-baud detection is not complete. 'A','a' character has not been received successfully. 1h (R/W) = Auto-baud hardware has detected 'A' or 'a' character on the SCI receive register. Auto-detect is complete.
14	ABDCLR	W	0h	ABD-clear bit Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on ABD flag bit. Bit reads back a zero. 1h (R/W) = Write 1 to clear ABD flag in bit 15.
13	CDC	R/W	0h	CDC calibrate A-detect bit Reset type: SYSRSn 0h (R/W) = Disables auto-baud alignment 1h (R/W) = Enables auto-baud alignment
12-8	RESERVED	R	0h	Reserved
7-0	FFTXDLY	R/W	0h	FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit bufferto transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS. When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to. When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1. Reset type: SYSRSn

23.15.2.13 SCIPRI Register (Offset = Fh) [Reset = 0000h]

SCIPRI is shown in Figure 23-23 and described in Table 23-21.

Return to the Summary Table.

SCIPRI determines what happens when an emulation suspend event occurs.

The peripheral can continue whatever it is doing (free-run mode), or if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Immediate stop on suspend 1h (R/W) = Complete current receive/transmit sequence before stopping 2h (R/W) = Free run 3h (R/W) = Free run
2-0	RESERVED	R	0h	Reserved

Chapter 24

Universal Serial Bus (USB) Controller

This chapter discusses the features and functions of the universal serial bus (USB) controller.

24.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has thirty-two endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

24.1.1 Features

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12Mbps) operation in host and device modes as well as low-speed (1.5Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- 32 endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- 4KB dedicated endpoint memory

24.1.3 Block Diagram

The USB block diagram is shown in Figure 24-1.

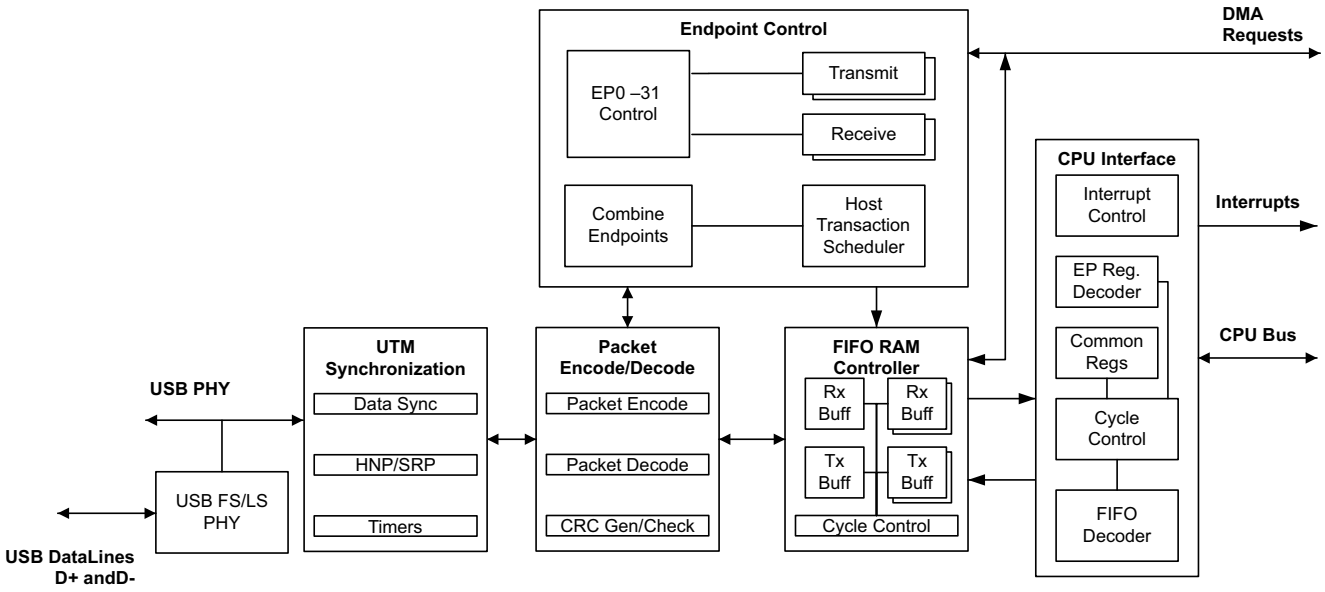

Figure 24-1. USB Block Diagram

24.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and V_{Bus}) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the D+ and D- pins have special buffers to support USB. As such, the position on the chip is not user-selectable. The D+ and D- pins at reset are, by default, GPIOs and must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. Bit 23 in the GPIO A Analog Mode Select Register (GPAAMSEL) and bit 9 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. The signals USB bus voltage (V_{BUS}), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications require these signals be implemented in software using a GPIO. Software that implements these signals is available in the USB software library.

24.1.3.2 VBus Recommendations

Most applications do not need to monitor V_{Bus}. Because of this, a dedicated V_{Bus} monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor V_{Bus}. If you are designing a self-powered device, you need to actively monitor the state of the V_{Bus} pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When V_{BUS} is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0, it is also stated that the D+/D- pull-up resistor must be applied within 100 ms of V_{Bus} reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the V_{Bus} monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide.

The pins of this microcontroller are not 5V tolerant, and because of this, the V_{Bus} signal cannot be directly connected to a GPIO pin. Directly connecting 5V to a pin of the microcontroller destroys the I/O buffer of the pin and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. Also, use a 100kohm series resistor between the V_{Bus} signal and the pin chosen to monitor the pin. A diagram of this setup is shown in Figure 24-2.

In Figure 24-2, if V_{Bus} is above 3.3V or below 0V, one of the ESD clamp diodes is forward-biased, allowing current to flow through the 100kohm resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short over voltage spikes of a high magnitude. The diode clamps do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing the clamps were designed to do, but instead of a short high magnitude pulse, we are giving the clamps a long low magnitude static value using the 100kohm resistor.

Any pin that has digital input and output functionality can potentially be used to monitor V_{Bus}, but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability can also be used, but the input state of the pin must be polled periodically by the application software to make sure appropriate action is taken whenever V_{Bus} is applied or removed. If an interrupt-capable GPIO is chosen, the GPIO can be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements V_{Bus} monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

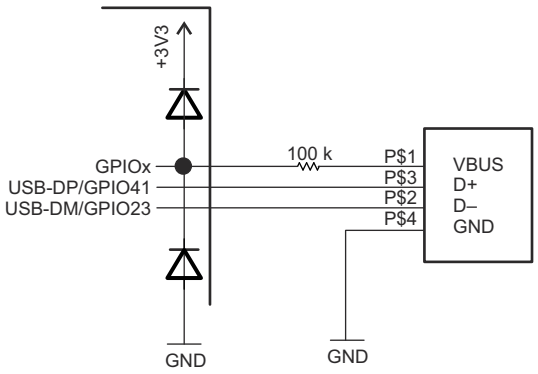

Figure 24-2. USB Scheme

24.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to V_{BUS} and configured to generate an interrupt when the V_{BUS} level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

Note

When a USB is used in the system, the minimum system frequency is 30MHz.

24.2.1 Operation as a Device

This section describes how the USB controller performs when the USB controller is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device must use the dedicated control endpoint on the USB controller’s endpoint 0.

24.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to the register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.
The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. The six endpoints can be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for the IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair can be a bulk endpoint, while the IN portion of that endpoint pair can be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

24.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that can be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

Note

The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register cannot be written to while data is in the FIFO as unexpected results can occur.

Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets can be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

24.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

Note

In all cases, the maximum packet size must not exceed the FIFO size.

Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[*n*]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[*n*]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[*n*] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

Note

The FULL bit in USBRXCSRL[*n*] is not set when the first packet is received. The FULL bit is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[*n*] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

24.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if the transaction was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until the USB controller is ready.

24.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what must have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, the Host is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

Setting the Device Address

When a Host is attempting to enumerate the USB device, the Host requests that the device change the address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care must be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register must only be set after the SET_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register must be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

Note

If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

24.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10ms (a maximum of 15ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode that keeps the controller in a static state.

24.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, the USB receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, the USB expects one every millisecond. If no SOF packet is received after 1.00358ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

24.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

24.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in the normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state that does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if the USB controller has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into the normal mode. Systems with a lengthy initialization procedure can use this to make sure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

Note

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

24.2.2 Operation as a Host

When the USB controller is operating in Host mode, the USB controller can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when the USB controller is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints must take into account the maximum packet size for an endpoint.

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller must use the dedicated control endpoint to communicate with a device's endpoint 0.

24.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See Section 24.1.1 for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as 15 independent OUT and 15 independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications using a hub, the relevant USB Receive Functional Address Endpoint n (USBRXFUNCADDRn) or USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

24.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint must be configured to the number of packets to be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn must be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as can occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

24.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

24.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every n frames, where n is the interval set using the USB Host Transmit Interval Endpoint n (USBTXINTERVAL[*n*]) or USB Host Receive Interval Endpoint n (USBRXINTERVAL[*n*]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process makes sure that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

24.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller using a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint n (USBRXHUBADDRn) and USB Receive Hub Port Endpoint n (USBRXHUBPORTn) or the USB Transmit Hub Address Endpoint n (USBTXHUBADDRn) and USB Transmit Hub Port Endpoint n (USBTXHUBPORTn) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint n (USBTXTYPEn), or USB Host Configure Receive Type Endpoint n (USBRXTYPEn) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

24.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

24.2.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

24.2.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20ms to make sure of correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts the frame counter and transaction scheduler.

24.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

24.2.3 DMA Operation

The USB module DMA trigger signals are not supported on this device. The DMA controller can be used to read and write the USB FIFOs using software triggering. See the *Direct Memory Access (DMA)* chapter for more details about programming the DMA controller. See the *USB DMA Event Trigger* advisory in the device errata for more information.

24.2.4 Address/Data Bus Bridge

This USB controller was originally designed to connect to an ARM AHB bus, but has been modified to function with the C28x device bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32- and 16-bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - int &__byte(int *array, unsigned int byte_index);
  - *array = ptr to address to access, byte_index = always 0 (for USB)
    See Table 24-1 for example.
  - See the *TMS320C28x Optimizing C/C++ Compiler User's Guide* and the *TMS320C28x Assembly Language Tools User's Guide*
- Because of the bridge, the memory view of the USB controller memory space in CCS is not a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, even addresses from within the controller are duplicated into odd address in the view window; old addresses from within the controller are not displayed.
      See Table 24-2 for example.

Table 24-1. USB Memory Access from Software

24.3 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled using the System Control module PCLKCR11 register. In addition, the USB PHY signals must be connected to the respective pins using the GPIO module GPAAMSEL and GPBAMSEL registers. Set bit 23 in GPAAMSEL for USB0DM (GPIO23) and bit 9 in GPBAMSEL for USB0DP (GPIO41).

Set up the USBCLKDIV so a 60MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control and Interrupts* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, must be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

24.3.1 Pin Configuration

To give more flexibility, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware and the user must implement these signals in software. Examples of how to implement these signals in software can be found in the USB Software Guide located in C2000Ware in the \libraries\communications\usb\ directory.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to V_{BUS} must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and must be negated to avoid having two devices driving the V_{BUS} power pin on the USB connector.

When the USB controller is acting as a host, the USB controller is in control of two signals that are attached to an external voltage supply that provides power to V_{BUS}. The Host controller uses the EPEN signal to enable or disable power to the V_{BUS} pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on V_{BUS}. The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, or the PFLT signal can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable

in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

24.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because the endpoint is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint’s FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint’s FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to V_{BUS} using the USB0EPEN signal.

24.4 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to make sure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occurred or not. Finally, the INTFLGCLR bit clears the INTFLG when a value of 1 is written to the field.

24.5.2 USB Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/usb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

24.5.2.1 USB CDC serial example

FILE: usb_ex1_dev_serial.c

This example application turns the evaluation kit into a virtual serial port when connected to the USB host system. The application supports the USB Communication Device Class, Abstract Control Model to redirect SCIA traffic to and from the USB host system.

Connect USB cables from your PC to both the mini and microUSB connectors on the controlCARD.Figure out what COM ports your controlCARD is enumerating (typically done using Device Manager in Windows) and open a serial terminal to each of with the settings 115200 Baud 8-N-1. Characters typed in one terminal should be echoed in the other and vice versa.

A driver information (INF) file for use with Windows XP, Windows 7 and Windows 10 can be found in the windows_drivers directory.

24.5.2.2 USB HID Mouse Device

FILE: usb_ex2_dev_mouse.c

This example application turns the evaluation board into a USB mouse supporting the Human Interface Device class. After loading and running the example simply connect the PC to the controlCARDs microUSB port using a USB cable, and the mouse pointer will move in a square pattern for the duration of the time it is plugged in.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

24.5.2.3 USB Device Keyboard

FILE: usb_ex3_dev_keyboard.c

This example application turns the evaluation board into a USB keyboard supporting the Human Interface Device class. The global variable ui32Button should be modified to wake up the USB. Care should be taken to ensure that the active window can safely receive the text; enter is not pressed at any point so no actions are attempted by the host if a terminal window is used.

The device implemented by this application also supports USB remote wake up allowing it to request the host to reactivate a suspended bus. If the bus is suspended (as indicated on the application display), updating ui32Button will request a remote wakeup assuming the host has not specifically disabled such requests.

To run the example compile the project, load to the target, and run the example. After the example is running, connect a USB cable from the PC to the microUSB port on the controlCARD.Modify ui32Button value in the expressions window and then focus should be on the window so that we can receive keyboard input (i.e. NotePad).

24.5.2.4 USB Generic Bulk Device

FILE: usb_ex4_dev_bulk.c

This example provides a generic USB device offering simple bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN endpoint and a single bulk OUT endpoint. Data received from the host is assumed to be ASCII text and it is echoed back with the case of all alphabetic characters swapped.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. WinUSB is a Windows subsystem allowing user mode applications to access the USB device without the need for a vendor-specific kernel mode driver.

A sample Windows command-line application, usb_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory ~/C2000Ware/utilities/tools/{Device}/usb_bulk_example/Release

24.5.2.5 USB HID Mouse Host

FILE: usb_ex5_host_mouse.c

This application demonstrates the handling of a USB mouse attached to the evaluation kit. Once attached, the position of the mouse pointer and the state of the mouse buttons are output to the display.

SCIA, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When a HID compliant mouse is connected to the microUSB port on the top of the controlCARD, position and button information will be displayed to the console.

24.5.2.6 USB HID Keyboard Host

FILE: usb_ex6_host_keyboard.c

This example application demonstrates how to support a USB keyboard attached to the evaluation kit board. The display will show if a keyboard is currently connected and the current state of the Caps Lock key on the keyboard that is connected on the bottom status area of the screen. Pressing any keys on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit. Any keyboard that supports the USB HID BIOS protocol should work with this demo application.

To run the example you should connect a HID compliant keyboard to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard.

24.5.2.7 USB Mass Storage Class Host

FILE: usb_ex7_host_msc.c

This example application demonstrates reading a file system from a USB mass storage class device. It makes use of FatFs, a FAT file system driver. It provides a simple command console via the SCI for issuing commands to view and navigate the file system on the mass storage device.

The first SCI, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When the program is started a message will be printed to the terminal. Type `help' for command help.

After loading and running the example, open a serial terminal with the above settings to open the command prompt. Then connect a USB MSC device to the microUSB port on the top of the controlCARD.

For additional details about FatFs, see the following site: *FatFs - Generic FAT Filesystem Module*

24.5.2.8 USB Dual Detect

FILE: usb_ex8_dual_detect.c

This program uses a GPIO to do ID detection. If a host is connected to the device's USB port, the stack will switch to device mode and enumerate as mouse. If a mouse device is connected to the device's USB port, the stack will switch to host mode and display the mouses movement and button press information in a serial terminal.

24.5.2.9 USB Throughput Bulk Device Example (usb_ex9_throughput_dev_bulk)

FILE: usb_ex9_dev_bulk_throughput.c

This example provides a throughput numbers of bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN Endpoint and a single bulk OUT Endpoint.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. This is present in utilities/windows_drivers.

A sample Windows command-line application, usb_throughput_bulk_example, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory ~/utilities/tools/usb_throughput_bulk_example/Release.

After running the example in CCS Connect the USB Micro to the PC. Then the example will wait to receive data from the application. Run the usb_throughput_bulk example, the throughput and Data Packets Transferred.

24.5.2.10 USB HUB Host example

FILE: usb_ex10_host_hub.c

This example application demonstrates how to support a USB keyboard and USB Mouse with a USB Hub. The display will show the connected devices on the USB hub.

To run the example you should connect a USB Hub to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard. Allow the example to run with the hub connected and then connect the USB Host Mouse or Keyboard.

When a USB Mouse is connected on the Hub the position of the mouse pointer and the state of the mouse buttons are output to the display. Similarly when a USB Keyboard is connected, any key press on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit.

This example is for depicting the usage of Hub.

There are some limitations in this example :

1. The Example fails to recognize the USB Hub and the device if the Mouse/Keyboard is already connected to the USB Hub and the Hub is connected to the Micro USB of the Control Card.
2. The same port should not be used to connect a Keyboard and mouse.

24.6 USB Registers

This Section describes the USB Registers.

24.6.1 USB Base Address Table

Table 24-4. USB Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
UsbRegs	USB_REGS	USBA_BASE	0x0004_0000	YES	YES	-	YES

24.6.2 USB_REGS Registers

Table 24-5 lists the memory-mapped registers for the USB_REGS registers. All register offset addresses not listed in Table 24-5 should be considered as reserved locations and the register contents should not be modified.

Table 24-5. USB_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	USBFADDR	USB Device Functional Address		Go

Complex bit access types are encoded to fit into small table cells. Table 24-6 shows the codes that are used for access types in this section.

Table 24-6. USB_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 24-6. USB_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

24.6.2.1 USBFADDR Register (Offset = 0h) [Reset = 00h]

USBFADDR is shown in Figure 24-3 and described in Table 24-7.

Return to the Summary Table.

USB Device Functional Address

Figure 24-3. USBFADDR Register

24.6.2.2 USBPOWER Register (Offset = 1h) [Reset = 00h]

USBPOWER is shown in Figure 24-4 and described in Table 24-8.

Return to the Summary Table.

USB Power

Figure 24-4. USBPOWER Register

7	6	5	4	3	2	1	0
ISOUP	SOFT_CONN	RESERVED		RESET	RESUME	SUSPEND	PWRDNPHY
R/W-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-8. USBPOWER Register Field Descriptions

Bit	Field	Type	Reset	Description
7	ISOUP	R/W	0h	Isochronous Update Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - No effect 1h (R/W) = Host Mode - Reserved Device Mode - The USB controller waits for an SOF token from the time the TXRDY bit is set in the USBTXCSRLn register before sending the packet. If an IN token is received before an SOF token, then a zerolength data packet is sent.
6	SOFT_CONN	R/W	0h	Soft Connect/Disconnect Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are tri-stated. 1h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are enabled.
5-4	RESERVED	R	0h	Reserved
3	RESET	R/W	0h	Enable Reset Signaling Reset type: SYSRSn 0h (R/W) = Ends RESET signaling on the bus. 1h (R/W) = Enables RESET signaling on the bus.
2	RESUME	R/W	0h	Enable Resume Signaling. The bit should be cleared by software 20 ms after being set. Reset type: SYSRSn 0h (R/W) = Ends RESUME signaling on the bus. 1h (R/W) = Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND	R/W	0h	Enable Suspend Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables SUSPEND mode.
0	PWRDNPHY	R/W	0h	Power Down PHY Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Powers down the internal USB PHY.

24.6.2.3 USBTXIS Register (Offset = 2h) [Reset = 0000h]

USBTXIS is shown in Figure 24-5 and described in Table 24-9.

Return to the Summary Table.

6	FSDEV	R/W	1h	Full Speed Device Detected Reset type: SYSRSn 0h (R/W) = A full-speed Device has not been detected on the port. 1h (R/W) = A full-speed Device has been detected on the port.
5	LSDEV	R	0h	Low Speed Device Detected Reset type: SYSRSn 0h (R/W) = A low-speed Device has not been detected on the port. 1h (R/W) = A low-speed Device has been detected on the port.
4-3	VBUS	R/W	1h	Vbus Level Reset type: SYSRSn 0h (R/W) = Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V. 1h (R/W) = Above VBusValid. VBUS is detected as above 4.75 V.
2	HOST	R/W	1h	Host Mode Reset type: SYSRSn 0h (R/W) = The USB controller is acting as a Device. 1h (R/W) = The USB controller is acting as a Host. Only valid while a session is in progress.
1	HOSTREQ	R/W	1h	When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Initiates the Host Negotiation when SUSPENDmode is entered.

Table 24-22. USBDEVCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SESSION	R	0h	Session Start/End Reset type: SYSRSn 0h (R/W) = When operating as a Host: When cleared by software, this bit ends a session. When operating as a Device: The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect. 1h (R/W) = When operating as a Host: When set by software, this bit starts a session. When operating as a Device: The USB controller has started a session. When set by software, the Session Request Protocol is initiated. Clearing this bit when the USB controller is not suspended results in undefined behavior.

24.6.2.17 USBTXFIFOSZ Register (Offset = 62h) [Reset = 00h]

USBTXFIFOSZ is shown in Figure 24-19 and described in Table 24-23.

Return to the Summary Table.

24.6.2.21 USBCONTIM Register (Offset = 7Ah) [Reset = 11h]

USBCONTIM is shown in Figure 24-23 and described in Table 24-27.

Return to the Summary Table.

USB Connect Timing

Figure 24-23. USBCONTIM Register

7	6	5	4	3	2	1	0
WTCON				WTID			
R/W-1h				R/W-1h			

Table 24-27. USBCONTIM Register Field Descriptions

Bit	Field	Type	Reset	Description
7-4	WTCON	R/W	1h	The wait ID field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms. Reset type: SYSRSn
3-0	WTID	R/W	1h	The connect wait field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 us. Reset type: SYSRSn

24.6.2.22 USBFSEOF Register (Offset = 7Dh) [Reset = 77h]

USBFSEOF is shown in Figure 24-24 and described in Table 24-28.

Return to the Summary Table.

USB Full-Speed Last Transaction to End of Frame Timing

Figure 24-24. USBFSEOF Register

7	6	5	4	3	2	1	0
FSEOFG							
R/W-77h							

Table 24-28. USBFSEOF Register Field Descriptions

Bit	Field	Type	Reset	Description
7-0	FSEOFG	R/W	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 us. Reset type: SYSRSn

24.6.2.23 USBLSEOF Register (Offset = 7Eh) [Reset = 72h]

USBLSEOF is shown in Figure 24-25 and described in Table 24-29.

Return to the Summary Table.

USB Low-Speed Last Transaction to End of Frame Timing

Figure 24-25. USBLSEOF Register

7	6	5	4	3	2	1	0
LSEOFG							
R/W-72h							

Table 24-29. USBLSEOF Register Field Descriptions

Bit	Field	Type	Reset	Description
7-0	LSEOFG	R/W	72h	The low-speed end-of-frame gap field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 us. The default corresponds to 121.6 us. Reset type: SYSRSn

24.6.2.24 USBTXFUNCADDR0 Register (Offset = 80h) [Reset = 00h]

USBTXFUNCADDR0 is shown in Figure 24-26 and described in Table 24-30.

Return to the Summary Table.

USB Transmit Functional Address Endpoint 0

Figure 24-26. USBTXFUNCADDR0 Register

24.6.2.45 USBCSRL0 Register (Offset = 102h) [Reset = 00h]

USBCSRL0 is shown in Figure 24-47 and described in Table 24-51.

Return to the Summary Table.

USB Control and Status Endpoint 0 Low

Figure 24-47. USBCSRL0 Register

7	6	5	4	3	2	1	0
SETENDC_NAKTO	RXRDYC_STATUS	STALL_RQPKT	SETEND_ERROR	DATAEND_SETUP	STALLED	TXRDY	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-51. USBCSRL0 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	SETENDC_NAKTO	W1C	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register
6	RXRDYC_STATUS	R/W	0h	Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction. Reset type: SYSRSn 0h (R/W) = No transaction 1h (R/W) = The Endpoint 1 transmit interrupt is asserted.
5	STALL_RQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set. This bit is automatically cleared when the STATUS stage is over.
4	SETEND_ERROR	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation.
3	DATAEND_SETUP	R/W	0h	Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet. Reset type: SYSRSn 0h (R/W) = Sends an OUT token. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
2	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received

Table 24-51. USBCSRL0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TXRDY	R/W	0h	Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.
0	RXRDY	R/W	0h	Receive Packet Ready. Software must clear this bit after he packet has been read from the FIFO to acknowledge that the data has been read from the FIFO. Reset type: SYSRSn 0h (R/W) = No receive packet has been received. 1h (R/W) = Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

24.6.2.46 USBCSRH0 Register (Offset = 103h) [Reset = 00h]

USBCSRH0 is shown in Figure 24-48 and described in Table 24-52.

Return to the Summary Table.

USB Control and Status Endpoint 0 High

24.6.2.51 USBTXCSRL1 Register (Offset = 112h) [Reset = 00h]

USBTXCSRL1 is shown in Figure 24-53 and described in Table 24-57.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 1 Low

Figure 24-53. USBTXCSRL1 Register

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRN_ERRO R1	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-57. USBTXCSRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

Table 24-57. USBTXCSRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	UNDRN_ERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

24.6.2.52 USBTXCSRH1 Register (Offset = 113h) [Reset = 00h]

USBTXCSRH1 is shown in Figure 24-54 and described in Table 24-58.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 1 High

Figure 24-54. USBTXCSRH1 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-58. USBTXCSRH1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 24-58. USBTXCSRH1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

24.6.2.53 USBRXMAXP1 Register (Offset = 114h) [Reset = 0000h]

USBRXMAXP1 is shown in Figure 24-55 and described in Table 24-59.

Return to the Summary Table.

Table 24-60. USBRXCSRL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 24-60. USBRXCSRL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

24.6.2.55 USBRXCSRH1 Register (Offset = 117h) [Reset = 00h]

USBRXCSRH1 is shown in Figure 24-57 and described in Table 24-61.

Return to the Summary Table.

Table 24-61. USBRXCSRH1 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

Table 24-61. USBRXCSRH1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

24.6.2.62 USBTXCSRL2 Register (Offset = 122h) [Reset = 00h]

USBTXCSRL2 is shown in Figure 24-64 and described in Table 24-68.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 2 Low

Figure 24-64. USBTXCSRL2 Register

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRNERROR 2	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-68. USBTXCSRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

Table 24-68. USBTXCSRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	UNDRNERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

24.6.2.63 USBTXCSRH2 Register (Offset = 123h) [Reset = 00h]

USBTXCSRH2 is shown in Figure 24-65 and described in Table 24-69.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 2 High

Figure 24-65. USBTXCSRH2 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-69. USBTXCSRH2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 24-69. USBTXCSRH2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

24.6.2.64 USBRXMAXP2 Register (Offset = 124h) [Reset = 0000h]

USBRXMAXP2 is shown in Figure 24-66 and described in Table 24-70.

Return to the Summary Table.

Table 24-71. USBRXCSRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 24-71. USBRXCSRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

24.6.2.66 USBRXCSRH2 Register (Offset = 127h) [Reset = 00h]

USBRXCSRH2 is shown in Figure 24-68 and described in Table 24-72.

Return to the Summary Table.

USB Receive Control and Status Endpoint 2 High

Figure 24-68. USBRXCSRH2 Register

W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-72. USBRXCSRH2 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

Table 24-72. USBRXCSRH2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

24.6.2.67 USBRXCOUNT2 Register (Offset = 128h) [Reset = 0000h]

3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

Table 24-79. USBTXCSRL3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	UNDRNERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed inthis situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

24.6.2.74 USBTXCSRH3 Register (Offset = 133h) [Reset = 00h]

USBTXCSRH3 is shown in Figure 24-76 and described in Table 24-80.

Return to the Summary Table.

USB Transmit Control and Status Endpoint 3 High

Figure 24-76. USBTXCSRH3 Register

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-80. USBTXCSRH3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

Table 24-80. USBTXCSRH3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

24.6.2.75 USBRXMAXP3 Register (Offset = 134h) [Reset = 0000h]

USBRXMAXP3 is shown in Figure 24-77 and described in Table 24-81.

Return to the Summary Table.

USB Maximum Receive Data Endpoint 3

10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

24.6.2.76 USBRXCSRL3 Register (Offset = 136h) [Reset = 00h]

USBRXCSRL3 is shown in Figure 24-78 and described in Table 24-82.

Return to the Summary Table.

USB Receive Control and Status Endpoint 3 Low

Figure 24-78. USBRXCSRL3 Register

7	6	5	4	3	2	1	0
CLRDT	STALLED	STALLREQPKT	FLUSH	DATAERRNAKTO	OVERERROR3	FULL	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 24-82. USBRXCSRL3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note:This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: I ndicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

Table 24-82. USBRXCSRL3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

24.6.2.77 USBRXCSRH3 Register (Offset = 137h) [Reset = 00h]

USBRXCSRH3 is shown in Figure 24-79 and described in Table 24-83.

Return to the Summary Table.

USB Receive Control and Status Endpoint 3 High

Table 24-83. USBRXCSRH3 Register Field Descriptions

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

Table 24-83. USBRXCSRH3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	

Table 24-94. USBEPC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-10	RESERVED	R	0h	Reserved
9-8	PFLTACT	R/W	0h	Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault Reset type: SYSRSn 0h (R/W) = Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Tristate. USB0EPEN is undriven (tristate). 2h (R/W) = Low. USB0EPEN is driven Low. 3h (R/W) = High. USB0EPEN is driven High.
7	RESERVED	R	0h	Reserved
6	PFLTAEN	R/W	0h	Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field.
5	PFLTSEN	R/W	0h	Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition. The complementary state is the inactive state. Reset type: SYSRSn 0h (R/W) = Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit). 1h (R/W) = High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit).

Table 24-94. USBEPC Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	PFLTEN	R/W	0h	Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic. Reset type: SYSRSn 0h (R/W) = Not Used. The USB0PFLT signal is ignored. 1h (R/W) = Used. The USB0PFLT signal is used internally
3	RESERVED	R	0h	Reserved
2	EPENDE	R/W	0h	EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state. The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kOhm) and later configure and drive the output signal to enable the power supply. Reset type: SYSRSn 0h (R/W) = Not Driven. The USB0EPEN signal is high impedance. 1h (R/W) = Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field.
1-0	EPEN	R/W	0h	External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set. 1h (R/W) = Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set. 2h (R/W) = Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized. 3h (R/W) = Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized.

24.6.2.89 USBEPCRIS Register (Offset = 404h) [Reset = 00000000h]

USBEPCRIS is shown in Figure 24-91 and described in Table 24-95.

Return to the Summary Table.

Chapter 25

Fast Serial Interface (FSI)

This chapter contains a general description of the Fast Serial Interface (FSI) module. The FSI is a serial peripheral capable of reliable high-speed communication across isolation barriers.

25.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, isolation devices can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to make sure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, refer to *Fast Serial Interface (FSI) Skew Compensation*.

25.1.2 FSI Features

The FSI module includes the following features:

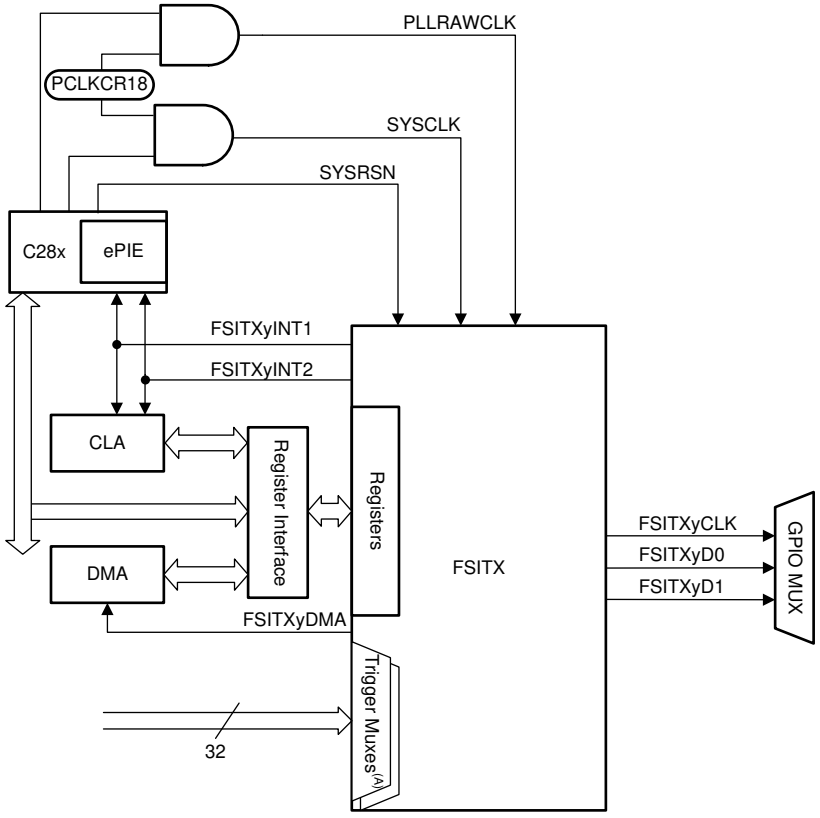
- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally-triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- FSI-SPI compatibility mode (limited features available)
- Tag match notifications

25.2 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features can require additional configuration of modules that are not within the scope of this chapter, the details can be found elsewhere in this TRM.

25.2.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.



A. The signals connected to the trigger muxes are described in Section 25.2.6.

Figure 25-1. FSI Transmitter (FSITX) CPU Interface

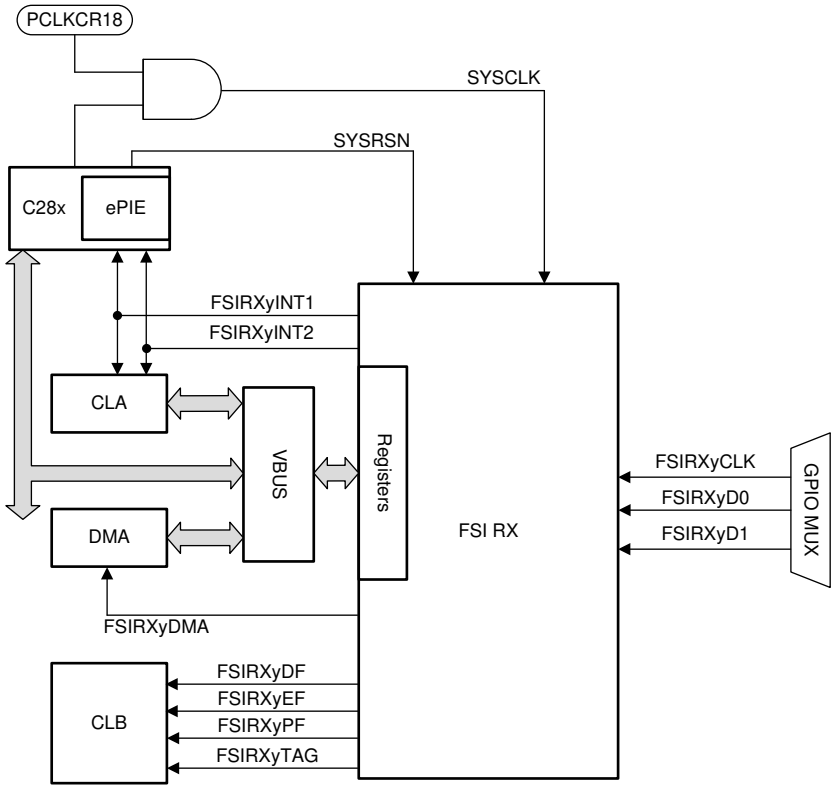


Figure 25-2. FSI Receiver (FSIRX) CPU Interface with CLB

25.2.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core communicates directly to a single FSI receiver core. Similarly, an FSI receiver core receives data from a single FSI transmitter core.

Each FSI core has three signals: one clock and two data signals. Data is always transmitted or received with the most-significant bit of each frame field being first. If multilane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and the GPIOs repurposed for other application needs. Table 25-1 and Table 25-2 describe the various signals that can be selected by the PADCONFIG register to be brought out to device pins.

CAUTION
The maximum RXCLK rate is SYSCLK/2 and must not exceed this limit.

Table 25-1. FSI Receiver Core Signals

Signal Name	Direction	Description	Inactive Level(1)
RXCLK	Input	This is the receive clock input signal for the FSI receive module. This must be connected to TXCLK of the transmitting FSI module.	Logic High
RXD0	Input	This is the primary data input line for reception. This must be connected to the TXD0 of the transmitting FSI module.	Logic High
RXD1	Input	This is an additional data input line for reception. This signal must be connected to the TXD1 of the transmitting FSI module to use multilane transmission.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

Table 25-2. FSI Transmitter Core Signals

Signal Name	Direction	Description	Inactive Level(1)
TXCLK	Output	This is the transmit clock and is driven by the FSI transmit module. During a transmission, four clock edges are transmitted before the start of frame phase (preamble) and four clock edges follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock. In FSI-SPI compatibility mode, the preamble and the post frame clock edges are not transmitted. Data is transmitted only on one edge of the clock. Data transmits on rising edge and received on falling edge of the clock.	Logic High
TXD0	Output	This is the primary data output line for transmission and is driven by the FSI transmit module. When the FSI is configured for multilane transmission, TXD0 contains all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame are transmitted in full.	Logic High
TXD1	Output	This is an additional data output line for transmission, if the FSI is configured for multilane transmission. This signal is driven by the FSI transmit module. During transmission, the data bits are split between TXD0 and TXD1. TXD1 contains all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line are identical to TXD0.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

25.2.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See the *General Purpose Input-Output (GPIO)* chapter for more details on the GPIO mux and settings.

25.2.3 FSI Interrupts

Each FSI module contains multiple interrupt sources that can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT_STS, EVT_FRC, and the EVT_CLR registers, respectively.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX_INT_CTRL register. The receiver events are assigned an interrupt vector using RX_INT1_CTRL and RX_INT2_CTRL registers. If an interrupt is not required, make sure the bit is not set in the respective INT_CTRL register.

25.2.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME_DONE):** This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF_UNDERRUN):** This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CLA, CPU, or DMA.
- **Buffer Overrun (BUF_OVERRUN):** The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun can occur if a piece of data is overwritten before the data has been transmitted.
- **Ping Frame Triggered (PING_TRIGGERED):** The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit is set when the ping counter has timed out or an external ping trigger event has occurred.

25.2.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events:

- **Ping Watchdog Timeout (PING_WD_TO):** This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX_PING_WD_REF register.
- **Frame Watchdog Timeout (FRAME_WD_TO):** This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX_FRAME_WD_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter starts counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog times out and this event is generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **CRC Error (CRC_ERR):** This error indicates that a CRC error has occurred. A CRC error is generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE_ERR):** This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **End-of-Frame Error (EOF_ERR):** This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **Receive Buffer Overrun (BUF_OVERRUN):** This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF_UNDERRUN):** This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads an empty buffer.
- **Frame Done (FRAME_DONE):** This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR_FRAME):** This event indicates that an error frame has been received.
- **Ping Frame Received (PING_FRAME):** This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME_OVERRUN):** This event indicates that a new frame has been received while the FRAME_DONE flag was still set.
- **Data Frame Received (DATA_FRAME):** This event indicates that a data frame has been received.

25.2.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application must select the interrupt vector for each desired event using the TX_INT_CTRL register for the transmitter, and RX_INT1_CTRL and RX_INT2_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

Note

If an event is registered for both interrupt vectors, both interrupts fire. There are no hardware checks for overlapping interrupt vector assignments.

25.2.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user must clear the event flag using the EVT_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt is generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This can cause the application to miss events that can be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine is similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX_EVT_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events that require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX_EVT_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag can still be set at the end of the ISR. As soon as the ISR completes, a new interrupt is generated and this flag is still set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR can cause race conditions that cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both events are handled within the same interrupt line, the software can only respond to one of the events if both events occur close in time.

25.2.4 CLA Task Triggering

In addition to generating interrupt vectors to the PIE, both interrupts lines for each module TX_INT1, TX_INT2, RX_INT1, and RX_INT2 can be assigned to trigger CLA tasks. Refer to the Configuration options table for the list of all sources capable of CLA task triggering. The configuration and use of CLA tasks are described in the CLA Tasks and Interrupt Vectors section in the *Control Law Accelerator (CLA)* chapter. The CLA has access to the entire FSI register map. This allows the CLA to manage the FSI independently from the CPU, freeing it up for other tasks.

25.2.5 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX_DMA_CTRL.DMA_EVT_EN to 1. The transmitter must also set TX_OPER_CTRL_LO.START_MODE to 0x2 to allow either a write to the TX_FRAME_CTRL.START bit or to the TX_FRAME_TAG_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX_DMA_CTRL.DMA_EVT_EN to 1.

Refer to Section 25.3.2 and Section 25.3.3 for more DMA information specific to each FSI Module.

25.2.6 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and generic frames. These muxes are independently configured for each type of frame. The application can select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX_PING_CTRL.EXT_TRIG_SEL to the index of the desired trigger. TX_PING_CTRL.EXT_TRIG_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX_OPER_CTRL_HI.EXT_TRIG_SEL to the index of the desired trigger. TX_OPER_CTRL_LO.START_MODE must be set to 0x1 for a frame to be transmitted by an external trigger.

Note

Triggers generated by the CLB and EPWM XBAR are asynchronous and must be at least 3 SYSCLKs wide.

25.3 FSI Functional Description

25.3.1 Introduction to Operation

The Fast Serial Interface Transmitter and Receiver modules (FSI_TX/FSI_RX) are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

25.3.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU, CLA, and the DMA.

The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- DMA support
- CLA task triggering

Figure 25-3 shows the high-level block diagram of the FSI transmitter. Figure 25-4 shows the block diagram of the transmitter core submodule.

The following sections describe the various aspects of the FSI transmitter in detail.

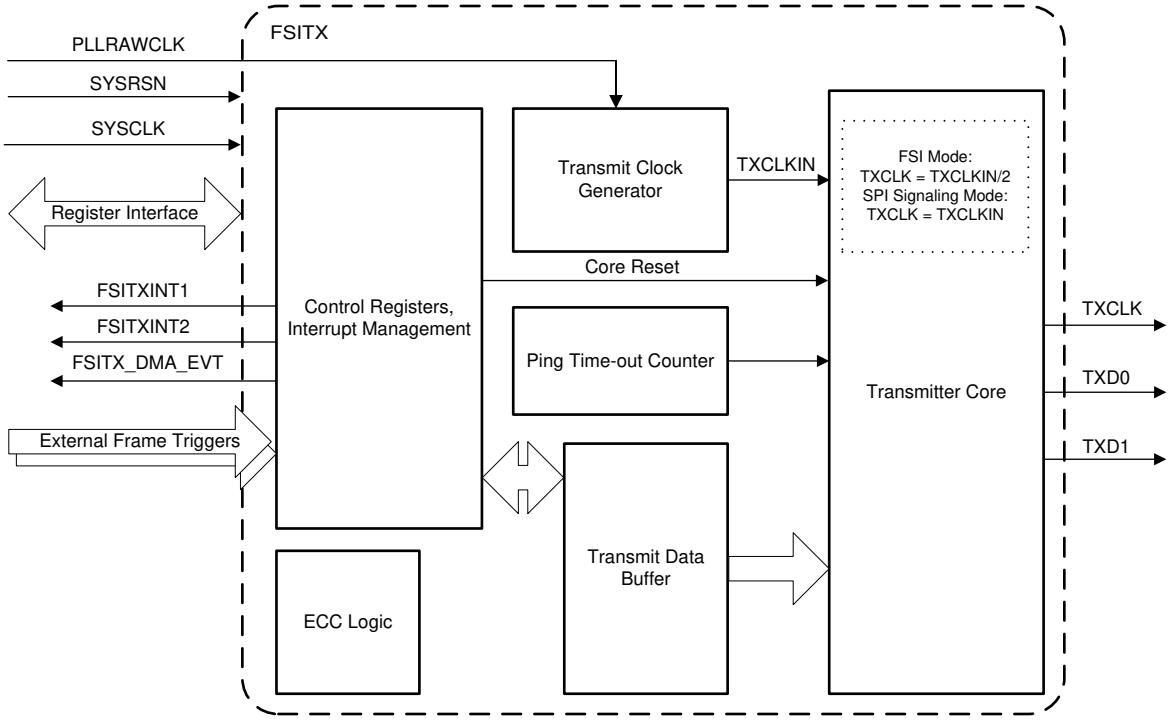

Figure 25-3. FSI Transmitter Block Diagram

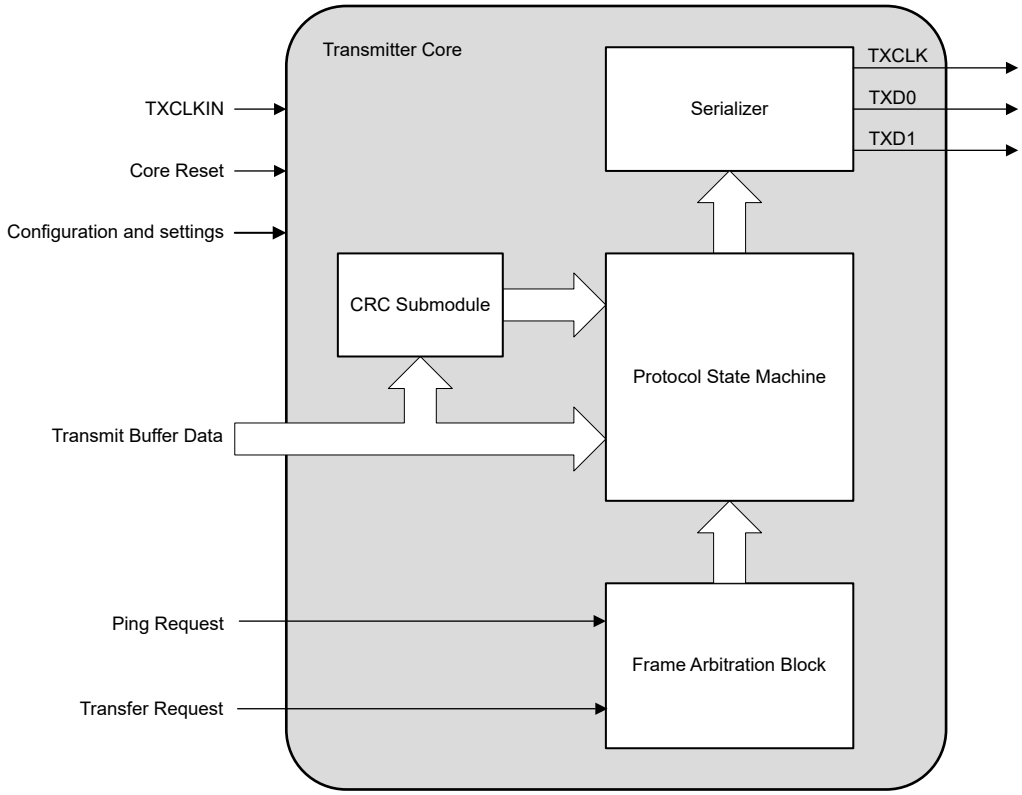

Figure 25-4. FSI Transmitter Core Block Diagram

25.3.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module executes the following initialization sequence to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX_CLK_CTRL.CLK_RST to 1 and subsequently clearing the bit.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX_OPER_CTRL_LO.SEL_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX_CLK_CTRL.PRESCALE_VAL.
4. Enable the transmitter clock divider by setting TX_CLK_CTRL.CLK_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX_MAIN_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX_MAIN_CTRL.

After initialization and configuration, the transmitter module synchronizes with the receiver module before transmitting. The synchronization sequence is described in Section 25.4.1.

CAUTION

Do not change TX_CLK_CTRL.PRESCALE_VAL while the clock is enabled (TX_CLK_CTRL.CLK_EN = 1). Doing so can cause undefined behavior.

25.3.2.2 FSI_TX Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX_CLK_CTRL.PRESCALE_VAL) then setting the clock divider enable bit (TX_CLK_CTRL.CLK_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX_CLK_CTRL.PRESCALE_VAL = 0x0 or 0x1) through 255(TX_CLK_CTRL.PRESCAL_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

CAUTION

TXCLK must never be configured to be faster than SYSCLK/2.

25.3.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps can be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
   - Set the user data
   - Write to the data buffer
   - Set the word length if the frame is a software defined frame length
4. Set the start condition

Note

Transmit Frame Start Restriction:

A new frame transmission can be initiated by one of the methods selected in the TX_OPER_CTRL_LO.START_MODE bits. If there is already a PING frame transmission taking place, due to a hardware initiated PING timer, the new frame transmission begins as soon as the on-going PING transmission is completed.

Once a START of frame has been initiated, the next START of frame is recognized when the first frame has started transmitting the End-of-Frame (EOF) field. If a new START trigger arrives before the current transmission has reached the EOF field, the trigger is lost without a notification.

Note

There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior is:

- The transmitted frame structure is exactly like an NWORD data frame. The size of the data frame is determined by the value in the TX_FRAME_CTRL.N_WORDS register.
- The frame type field of the transmitted data frame is transmitted as programmed. If this is received by an FSI receiver, a Type error is generated.

This mechanism can be used for force a Type error in a received frame for testing purposes.

The following sections describe the specific configuration for each frame type and start condition.

25.3.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps must be executed. Steps 1-6 can be executed in any order before setting TX_FRAME_CTRL.START. Some fields do not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and are retransmitted in the subsequent frame unless modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX_FRAME_CTRL.FRAME_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX_FRAME_CTRL.N_WORDS to 1 less than the number of words to be transmitted if TX_FRAME_CTRL.FRAME_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words are transmitted, N = 16, set TX_FRAME_CTRL.N_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware calculates the CRC to be transmitted. If TX_OPER_CTRL_LO.SW_CRC is 1, the application can calculate a custom CRC value and then set TX_USER_CRC to the result.
5. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired tag.
6. Set TX_FRAME_TAG_UDATA.USER_DATA to the desired user data.
7. Set TX_FRAME_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX_FRAME_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

25.3.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See Section 25.2.6 for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in Section 25.3.2.3.1. The only difference is that in Step 7, the start condition is automatically set when the external trigger condition is met rather than by software.

Note that by externally triggering frames, the frame information to be sent is pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX takes the data as is, and the application software makes sure that this data has been updated as necessary.

Using TX_EVT_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

25.3.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

25.3.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX_PING_CTRL.CNT_RST.
2. Set the desired ping tag to TX_PING_TAG.TAG.
3. Set the ping timer reference value to TX_PING_TO_REF.TO_REF.
4. Enable the ping timer by writing 1 to TX_PING_CTRL.TIMER_EN.

The ping timer is a free-running counter that counts up from 0. The current value of the ping timer counter is found in TX_PING_TO_CNT. When the current value of TX_PING_TO_CNT matches the reference value TX_PING_TO_REF.TO_REF, the TX_EVT_STS.PING_TRIGGERED is set. TX_PING_TO_CNT resets to 0 and resumes counting until the next match has occurred or the ping timer is halted by software (TX_PING_CTRL.TIMER_EN is set to 0).

25.3.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX_FRAME_CTRL.FRAME_TYPE to 0000’b to denote that the frame being sent is a Ping Frame.
2. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired value.
3. Write 1 to TX_FRAME_CTRL.START. This starts the transmission.

Once the frame transmission has started, the TX_FRAME_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

25.3.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers can be selected. See Section 25.2.6 for the list of input sources.

CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX_PING_CTRL.EXT_TRIG_EN is set to 1, the external trigger source takes precedence and the ping timer is ignored.

25.3.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data that is continuously applied with the DMA. A DMA trigger is generated every time a data frame transmission is completed. This is concurrent with the FRAME_DONE signal that sets the TX_EVT_STS.FRAME_DONE flag.

To transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX_DMA_CTRL.DMA_EVT_EN to 1. This allows the DMA trigger to propagate to the DMA module. Next, TX_OPER_CTRL_LO.START_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX_FRAME_CTRL.START or TX_FRAME_TAG_UDATA..

The DMA must also be configured properly for the FSI to send the data. One way of using the DMA to continuously feed the transmit buffer is:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, make sure the DMA channel servicing the data buffer wraps the after 16 words are copied.

Note

Because the frame tag and user data must be written in to initiate the transmission of the frame, use two consecutive DMA channels. This makes sure that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer must be the lower numbered channel and the tag/user data channel must be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

25.3.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer that the FSI transmitter pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way that the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, a buffer went out of sync. This not only affects the current transfer, but can also affect all future transfers due to the ring buffer. Under such conditions, the underrun needs a soft reset to cleanly recover. Alternately, the software can manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and makes sure of a full reset of the control registers.

Due to the flexibility of the transmit buffer, software can implement a simple ping-pong buffer or randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields can be ignored without adversely affecting the transmitter capability. Additionally, the CURR_WORD_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX_BUF_PTR_LOAD. This forces the transmitter to start picking the data from the indicated location in the buffer.

25.3.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX_OPER_CTRL_LO.SW_CRC appropriately.

If hardware CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial 0x7 ($x^8 + x^2 + x + 1$). The transmitter module automatically computes the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC submodule, refer to Section 25.3.7.

If software CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 1), the CRC must be computed by software and placed in the TX_USER_CRC register. The next frame to be transmitted uses the value placed in the TX_USER_CRC register in place of the CRC value generated by the hardware.

As the TX_USER_CRC register is software-programmable, the application can use this field as an extra data field for application-specific purposes. If TX_USER_CRC is used in this manner, the CRC detection on the receiver is not valid and must be ignored.

25.3.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt can or cannot require a soft reset to resume proper operation. This determination is up to the application software. Refer to Section 25.3.2.4 for more information on the transmit buffer.

25.3.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX_MAIN_CTRL.CORE_RST.

A module reset causes the registers to be reset to the default state.

25.3.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after the data lines pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU, CLA, and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- CLA task triggering
- FSI-SPI compatibility mode

Figure 25-5 provides a high-level overview of the internal modules present in the FSI receiver. Figure 25-6 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

The following sections describe the various aspects of the FSI receiver module.

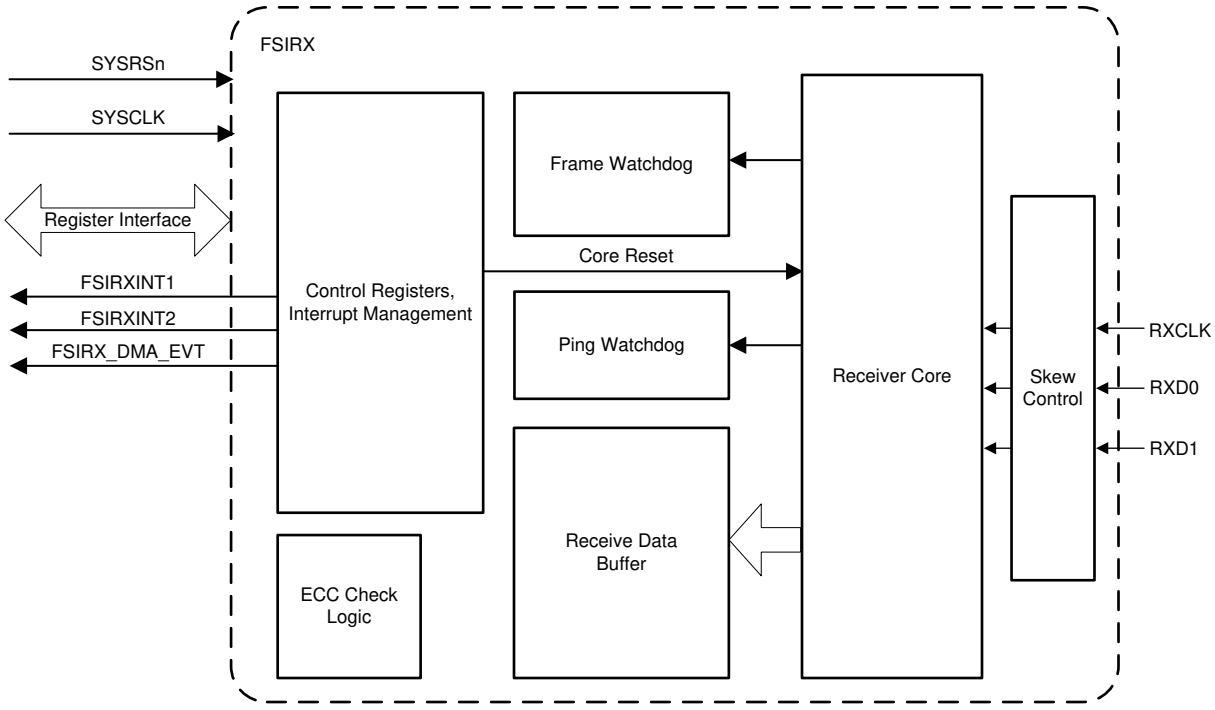

Figure 25-5. FSI Receiver Block Diagram

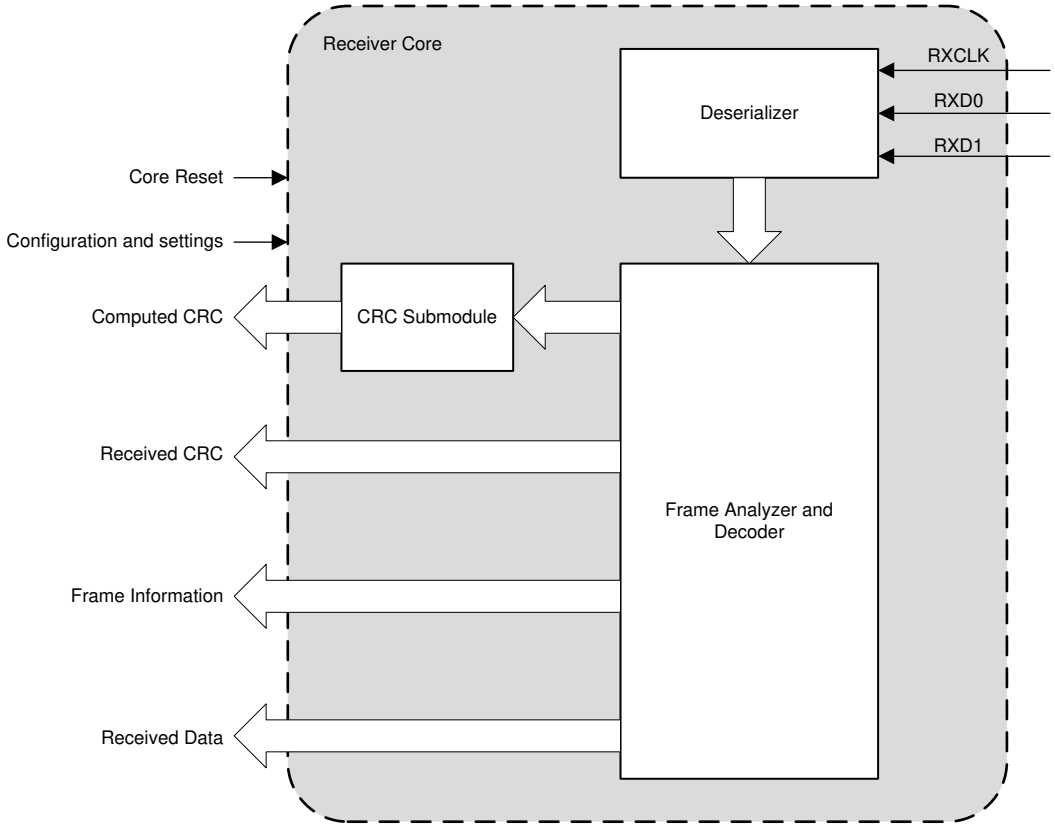

Figure 25-6. FSI Receiver Core Block Diagram

25.3.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module asserts and releases the receiver core reset bit (RX_MAIN_CTRL.CORE_RST) prior to any other initialization. Once the receiver module is initialized, the following steps are executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See Section 25.3.3.4 for configuration details.
3. If required, configure the frame watchdog to make sure that each frame is received within a predetermined window. See Section 25.3.3.5 for configuration details.
4. Initialize the receive buffer pointer by writing to the RX_BUF_PTR_LOAD register. Received data is placed into the buffer starting with the address loaded in this register.
5. Make sure all errors and flags have been cleared from the RX_EVT_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX_EVT_STS register for various conditions. For example, when the RX_EVT_STS.FRAME_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application configures the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in Section 25.4.1.

25.3.3.2 FSI_RX Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

CAUTION

RXCLK must never be faster than SYSCLK.

25.3.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. Note that there is no equivalent to a chip-select signal to gate incoming data. Every valid clock edge latches data into the receiver.

The header information of the received frame is placed in the respective register fields.

- RX_FRAME_INFO.FRAME_TYPE contains the received frame type.
- RX_FRAME_TAG_UDATA.FRAME_TAG contains the received frame tag.
- RX_FRAME_TAG_UDATA.USER_DATA contains the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag is set in the RX_EVT_STS register.

Note

If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The follow errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

25.3.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move the data from the receiver buffer with the DMA. A DMA trigger is generated every time a data frame has been received. This is concurrent with the FRAME_DONE signal that sets the RX_EVT_STS.FRAME_DONE flag. To receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set RX_DMA_CTRL.DMA_EVT_EN to 1. This allows the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One way for using the receiver to continuously feed the DMA is:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, make sure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel that is handling the data buffer execute before the DMA channel handling the received tag and user data.

25.3.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to

periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event is triggered that can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter that is reset and restarted upon the successful reception of a ping frame. The watchdog counter is incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting RX_PING_WD_CTRL.PING_WD_RST to 1 and then subsequently clearing the bit to 0.
2. Set RX_OPER_CTRL.PING_WD_RST_MODE to the desired watchdog reset event, set to 0 for ping frames only or set to 1 for any frame.
3. Set RX_PING_WD_REF to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting RX_PING_WD_CTRL.PING_EN to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the RX_PING_WD_CNT value reaches the value programmed in RX_PING_WD_REF, the RX_EVT_STS.PING_WD_TO flag is set. If configured, an interrupt can be generated on this event.

25.3.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog is triggered that can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions, respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting RX_FRAME_WD_CTRL. FRAME_WD_CNT_RST to 1 and then subsequently clearing the bit to 0.
2. Set RX_FRAME_WD_REF.FRAME_WD_REF to the maximum number of SYSCLK cycles expected to be in the longest frame that can be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the RX_FRAME_WD_CNT reaches the value programmed in RX_FRAME_WD_REF, the RX_EVT_STS.FRAME_WD_TO flag is set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

25.3.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX_DLY_LINE_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values must only be adjusted while the FSIRX is held in soft reset, making sure that there are no active transmissions during this process. Figure 25-7 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits behave similarly.

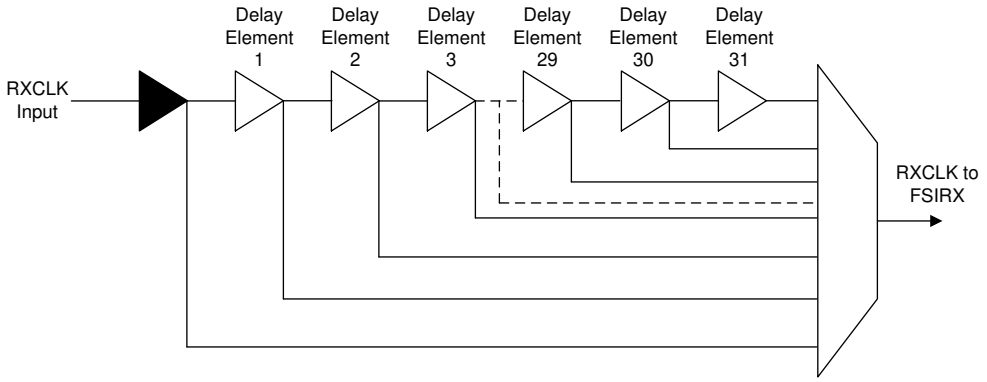

Figure 25-7. Delay Line Control Circuit

For more information on skew compensation, refer to *Fast Serial Interface (FSI) Skew Compensation*.

The FSITX module also has a delay line control circuitry that is placed before the FSITX signals (TXCLK, TXD0, and TXD1) are sent to the TDM signal selection mux (controlled by the SEL_TDM_PATH signal). The TX_DLY_LINE_CTRL register determines the length of the delay for each output line.

25.3.3.7 Buffer Management

The FSI receiver has a 16-word buffer that the data is copied to when the data has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no specified receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer verify that values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields can be ignored without adversely affecting the receiver capability. Additionally, the CURR_WORD_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX_BUF_PTR_LOAD. This forces the receiver to start storing the received data starting at the indicated location in the buffer.

25.3.3.8 CRC Submodule

The receive module automatically calculates the CRC on the incoming data. The received CRC value is placed into RX_CRC_INFO.RX_CRC. The CRC value calculated by hardware on the received data is placed into RX_CRC_INFO.CALC_CRC. These values are compared by hardware and RX_EVT_STS.CRC_ERROR is set if there is a mismatch. The receiver can generate an interrupt based on RX_EVT_STS.CRC_ERROR if enabled.

Since the CRC is only used in data frames, the values found in RX_CRC_INFO.RX_CRC and RX_CRC_INFO.CALC_CRC are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to Section 25.3.7.

If the transmitting module is sending a software-defined CRC value (FSITX.TX_OPER_CTRL_LO.SW_CRC = 1), the receiver module triggers a CRC error event if the received value does not match the hardware-calculated value. As this is an application-level decision, the FSIRX can safely disregard the CRC error event. Application software needs to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field can also be used as an application-specific value, not a CRC. The application can use the RX_CRC_INFO.RX_CRC as required. All CRC errors and flags can be ignored in this situation.

25.3.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (RX_FRAME_TAG_UDATA) register and receiver ping tag (RX_PING_TAG) register)) have the least-significant bit set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions that can be called depending on the tag value. A function pointer needs a 32-bit storage space and, hence, each successive pointer is offset by 2. If the first pointer is at address x, then the second pointer is at address x + 2, the third at address x + 4, and so on. By keeping the LSB to 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

25.3.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver receives data on every clock edge. While there are specific patterns that determine the a start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset to make sure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver can be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (RX_VIS_1.RX_CORE_STS) can be monitored to determine if the receiver core has entered into an error state requiring a soft reset to resume communication. Incorrect frame type and end of frame errors always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout always requires a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. RX_CORE_STS can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also does not cause RX_CORE_STS to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter could have gone offline and never sent a ping frame. Alternately, during idle time, a noise event could have occurred, thereby putting the receiver into a corrupt state. As the receiver is able to detect this during the ping frame watchdog timeout interrupt handler, this type of event is not lost and the application can act appropriately.

As the receiver is clocked by RXCLK, not SYSCLK, a noisy clock or data line can cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Make sure that the clock and data lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the device data sheet. Failure to do so can cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application must check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun can warrant a soft reset to resynchronize with the local application software. Refer to Section 25.3.3.8 for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device must stop transmitting and begin a new synchronization phase.

25.3.3.11 FSI_RX Reset

The receiver module and the registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX_MAIN_CTRL.CORE_RST.

A module reset causes the registers to be reset to the default state. After a module reset, the receiver module must be re-initialized and the data link re-established.

25.3.4 Frame Format

The FSI module transmits and receives information in frames. Each frame contains multiple phases where different information can be found. The number of phases as well as the total length of the frame varies depending on the frame type being transmitted. Frames can be as short as 16-bits long for a ping or error frame or 288-bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown in Table 25-4. Each phase of the frame (such as start-of-frame, frame type, and so on) is transmitted with the most-significant bit first. Table 25-4 describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

Table 25-4. Basic Frame Structure

Idle State	Preamble	Start of Frame	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	End of Frame	Postamble	Idle State
	1111	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	1111	

The FSI also supports a FSI-SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to Section 25.3.13 for more information on how to configure and use the FSI-SPI compatibility mode.

Note

One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI.

25.3.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail.

- **Idle State:** During the idle state, the clock and data lines are driven high, the inactive state.
- **Preamble:** The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare the receiver logic for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame:** The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type:** The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in Section 25.3.4.2. The transmitter must set the TX_FRAME_CTRL.FRAME_TYPE field before transmitting a frame. The received frame type is stored in the RX_FRAME_INFO.FRAME_TYPE.
- **User Data:** The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX_FRAME_TAG_UDATA.USER_DATA. The received user data is stored in RX_FRAME_TAG_UDATA.USER_DATA.
- **Data:** The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and is placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames is found in Section 25.3.4.2.3.
- **CRC Byte:** The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX_OPER_CTRL_LO.SW_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag:** The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX_FRAME_TAG_UDATA.FRAME_TAG bits for data frames. Ping frames use the tag defined in TX_PING_TAG.TAG. The receiver can access the received frame tag in RX_FRAME_TAG_UDATA.FRAME_TAG.
- **End of Frame:** The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble:** The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines are driven high (inactive state). This phase is not present in FSI-SPI compatibility mode.

25.3.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

Table 25-5 provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

Table 25-5. Frame Types and the 4-bit Codes

Frame Type	4-bit Frame Code	Description
PING	0000	Used typically for checking line integrity. A ping frame can be sent either by software or automatically by hardware.
ERROR	1111	Used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software can use an error frame for any purpose.
DATA_1_WORD	0100	1 word data packet (16 bits of data)
DATA_2_WORD	0101	2 word data packet (32 bits of data)
DATA_4_WORD	0110	4 word data packet (64 bits of data)
DATA_6_WORD	0111	6 word data packet (96 bits of data)
DATA_N_WORD	0011	N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules must have the same value programmed.
Reserved	0001, 0010, and 1000-1110	Reserved

25.3.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. Table 25-6 shows the structure of the ping frames.

Table 25-6. Ping Frame

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0000	xxxx	0110	1111	

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to make sure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See Section 25.3.2.3.3 for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between the receiver and the transmitter has been broken. See Section 25.3.3.4 for information on how the receiver handles ping frames.

25.3.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. Table 25-7 shows the structure of an error frame.

Table 25-7. Error Frame

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	1111	xxxx	0110	1111	

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX_FRAME_TAG_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX_FRAME_TAG_UDATA register and act on up to 16 different conditions.

25.3.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. Table 25-8 shows the general structure of data frames.

Table 25-8. Data Frame

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0xxx	xxxx xxxx	1-16 words	xxxx xxxx	xxxx	0110	1111	

The frame type field reflects the 4-bit code of the frame type. A list of frame types can be seen in Table 25-5. The number of the data words transmitted is determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N_WORDS field of the transmitter’s TX_FRAME_CTRL register and receiver’s RX_OPER_CTRL register.

25.3.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits are split between the data lines while the start of frame, frame type, frame tag, and end of frame fields are identical and complete on each line. The user data, data, and CRC fields are split between the data lines. Starting with the most-significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the following example, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12…d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

Table 25-9. Multi-Lane Frame Format

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
TXD0	1111	1001	0011	$u^7u^5u^3u^1$	$d^{15}d^{13}…d^1$	$c^7c^5c^3c^1$	xxxx	0110	1111	
TXD1	1111	1001	0011	$u^6u^4u^2u^0$	$d^{14}d^{12}…d^0$	$c^6c^4c^2c^0$	xxxx	0110	1111	

25.3.5 Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before the receiver can receive and decode frames. The receiver core has an asynchronous reset mechanism that allows the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset is released synchronous to the receive clock (RXCLK). Thus, the receiver requires five full clock pulses to be able to come out of reset. Sending the flush pattern makes sure that these clock edges are received and any subsequent frames sent to the receiver are correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI has the same effect as a flush sequence.

Figure 25-8 shows a sample plot of the flush sequence.

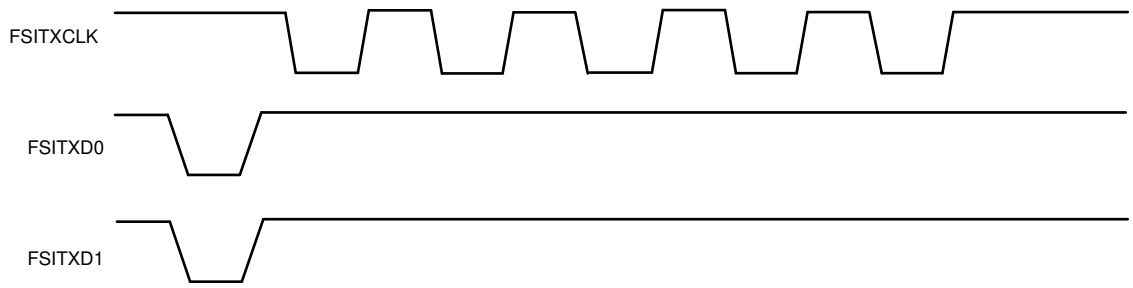

Figure 25-8. Flush Sequence Signals

25.3.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting RX_MAIN_CTRL.INT_LOOPBACK to 1. Internal loopback routes the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter. Figure 25-9 shows the signal connections with internal loopback.

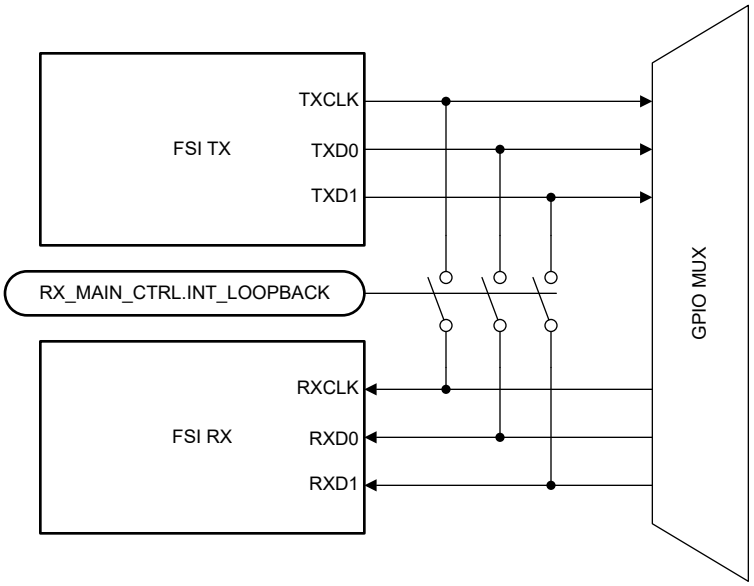

Figure 25-9. FSI with Internal Loopback

Table 25-10. Loopback Connections

TX Module	RX Module
FSIA TX	FSIA RX

25.3.7 CRC Generation

The FSI uses CRC-8 with the polynomial 0x07 for the internal hardware CRC generation. This polynomial is also represented as x^8+x^2+x+1.

For example, for a 2-word data packet the following calculation occurs:

Data-1 = 0x4433

Data-0 = 0x2211

User Data = 0xAA

The CRC is computed with the bytes being taken in the following order (first to last):

0xAA – Byte 0, User Data

0x11 – Byte 1, Data-0, Least-significant byte

0x22 – Byte 2, Data-0, Most-significant byte

0x33 – Byte 3, Data-1, Least-significant byte

0x44 – Byte 4, Data-1, Most-significant byte

25.3.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX_OPER_CTRL_HI.ECC_SEL to 1.
2. Write the data to the TX_ECC_DATA register as well as the transmit buffer.
3. Read TX_ECC_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX_ECC_VAL to TX_FRAME_TAG_UDATA.USER_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX_ECC_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX_FRAME_TAG_UDATA.USER_DATA to the RX_ECC_VAL register.
3. Read the RX_ECC_LOG register. This contains the result of the ECC computation using the RX_ECC_DATA and RX_ECC_VAL registers.
   a. If no ECC errors were detected, RX_ECC_LOG is 0. The correct data is available in RX_ECC_SEC_DATA.
   b. If a single bit error was detected, RX_ECC_LOG.SBE is 1. The autocorrected data is available in RX_ECC_SEC_DATA.
   c. If multiple bit errors occurred, RX_ECC_LOG.MBE is 1. The data in RX_ECC_SEC_DATA is invalid and must not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame a allocate one of the data words to be the ECC value.

25.3.9 Tag Matching

The FSI receiver core has the capability of generating an interrupt when the received data or ping frame's tag matches the reference tag in RX_FRAME_TAG_CMP or RX_PING_TAG_CMP, respectively.

Each tag compare register allows the user to not only select a reference tag (TAG_REF) but also set up a mask (TAG_MASK) to ignore specified bits in the reference tag. For tag matching to be enabled, the CMP_EN bit must be set. When the tag compare is enabled and a successful match occurs, the PING_TAG_MATCH, the DATA_TAG_MATCH or the ERROR_TAG_MATCH in RX_EVT_ERR_STATUS is set. The corresponding match register status can be cleared by writing to RX_EVT_ERR_CLEAR. Also, if required to set the match register status in software, the user must do so by writing to the RX_EVT_ERR_SET register.

The tag matching scheme is not a filtering scheme. Tag matching is only a notification scheme to alert the user when a specific tag is detected in a data or ping frame. Both RX_INTR_EVT_CTRL_1 and RX_INTR_EVT_CTRL_2 interrupts can be set up to generate an interrupt when a tag match event occurs.

Another feature used when tag matching is enabled is the broadcast feature. The broadcast feature can be enabled by setting the BRDCST_EN in RX_FRAME_TAG_CMP or RX_PING_TAG_CMP. When broadcast mode is enabled, the third bit of the tag is treated as a broadcast bit. If the received tag has a third bit set, then the tag is treated as a match regardless of the other tag bit comparisons. Note that a match caused by TAG_REF and TAG_MASK is also considered a match.

Note that the tag matching scheme is not a filtering scheme. For example, if tag matching is enabled and a frame is received with a non-matching tag, the frame is still saved in the buffer and the corresponding event status bits (FRAME_DONE, DATA_FRAME_RCVD) is set.

Tag matching is required in multi-peripheral TDM configurations as described in Section 25.3.11; however, tag matching can also be used in single-peripheral configurations as needed.

25.3.10 User Data Filtering (UDATA Matching)

The FSI receiver core has the capability of filtering data frames and only receive packets when received data UDATA (user data) matches the reference UDATA in RX_UDATA_FILTER.

The UDATA filter compare register allows you to not only select a reference UDATA (UDATA_REF) but also set up a mask (UDATA_MASK) to ignore specified bits in the reference user data. For user data filtering to be enabled, the RX_MAIN_CTRL.DATA_FILTER_EN bit must be set. When the user data filtering is enabled, only a successful match allows the packet to be received in the FSIRX circular buffer and all non-matching packets are ignored.

The user data matching scheme is a filtering scheme.

User data filtering is used in multi-peripheral configurations as described in Section 25.3.11; however, user data filtering can be used in single-peripheral configurations as needed.

25.3.11 TDM Configurations

The FSI module in this device supports multi-node TDM configurations, whereas a single main device can control multiple remote node devices. To use the FSI module in the multi-node TDM configuration described, the remote node device must utilize tag matching and user data filtering.

This multi-node TDM configuration is supported in the FSI module through time-division multiplexing. When TDM is enabled, each remote node device must also have tag matching enabled. Figure 25-10 shows a scheme where a single main device is communicating with multiple remote node devices. All FSI receive modules in the remote node devices are directly connected to the main device transmit module. The transmit modules of the remote node devices are chained serially such that each transmit module is connected to the next remote node device and the last remote node device output connects to the main device receive module. Each remote node device decides, based on the received frame's tag, whether to transmit the data or to enter bypass mode where the previous remote node device transmit module directly connects to the next remote node device. This is done by using the FSI transmit module TDM_IN.

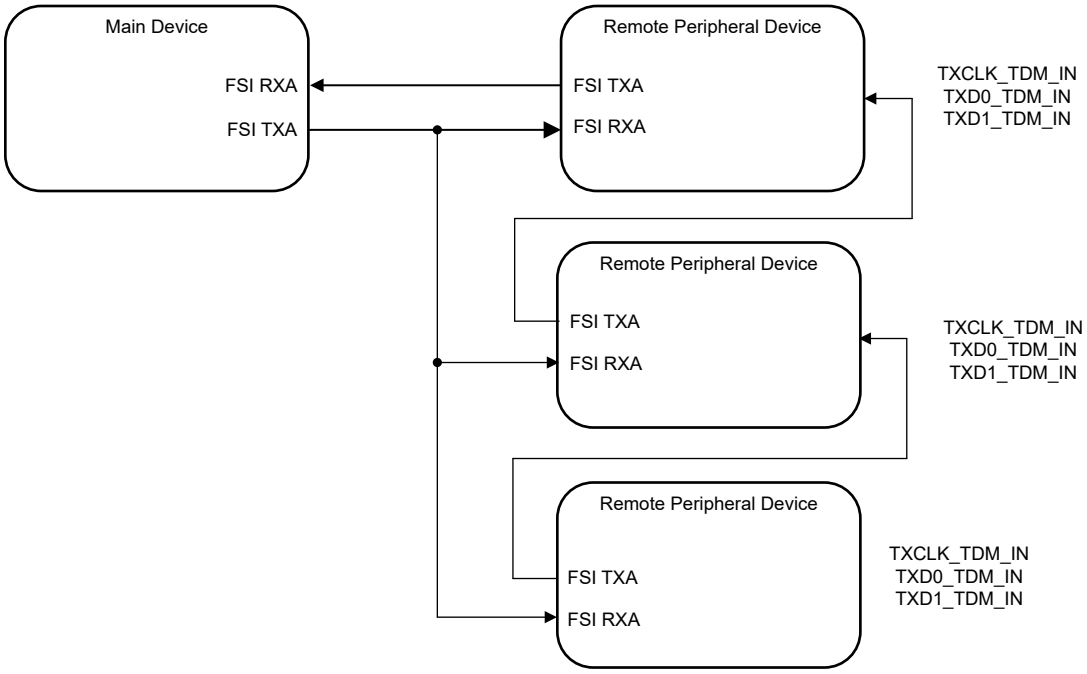

Figure 25-10. FSI Multi-Node TDM Configuration

When an FSI transmitter module is used in TDM mode, TXCLK_TDM_IN, TXD0_TDM_IN and TXD1_TDM_IN pins are used if the transmitter is required to enter bypass mode. Figure 25-11 shows how the FSI module operates when in multi-node TDM mode.

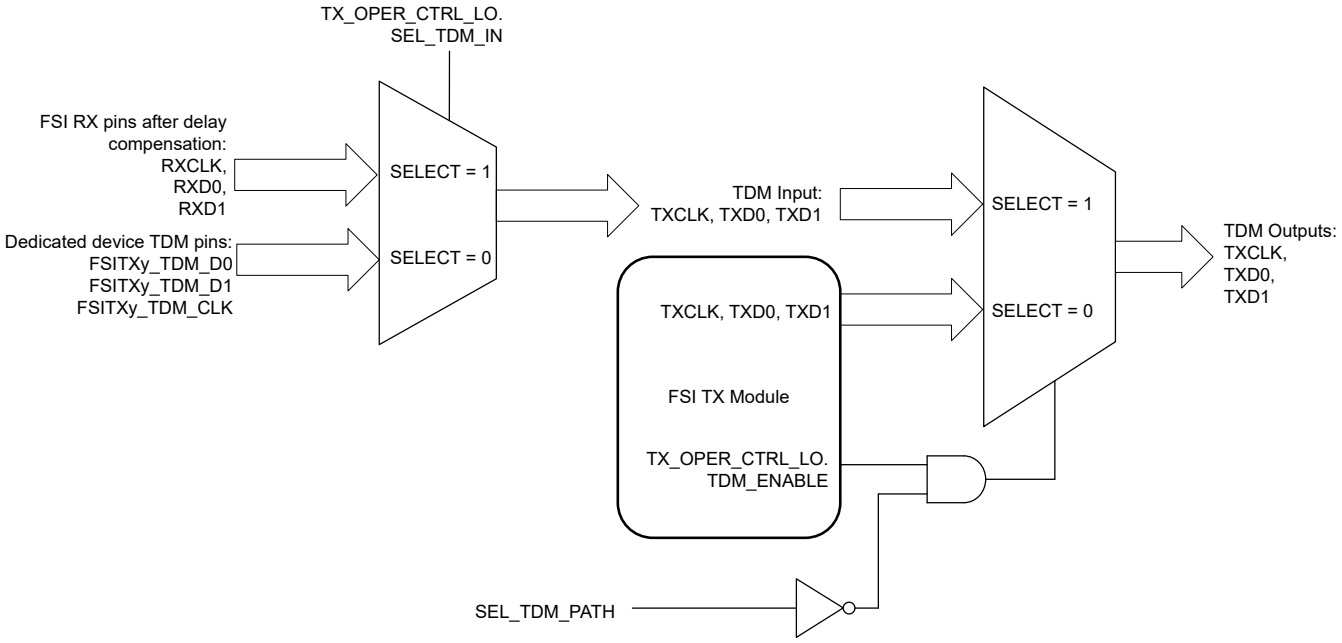

Figure 25-11. FSI Transmitter Multi-Node TDM Multiplexing

The SEL_TDM_PATH signal is sourced from the CLB module. The CLB module also generates the transmit trigger for the FSI transmitter. The CLB module must be configured to decide when to generate the FSI transmit trigger based on the status of the data, ping, and frame tag match generated by the FSI receiver module. The FSITX module must be configured to transmit on an external trigger and the corresponding CLB trigger input must be selected. In a broadcast scenario (FSI tag match notifies all remote node devices that a match has occurred), the CLB module inside each remote node device generates a trigger and SEL_TDM_PATH signal. The main key here is that the trigger and the SEL_TDM_PATH signal must be generated at a different time interval in a non-overlapping manner. Figure 25-12 shows an example of FSI transmit triggers and the multi-node TDM SEL_TDM_PATH signals generated by the RX_TRIGx signal or the CLB module of the remote node devices in a broadcast scenario.

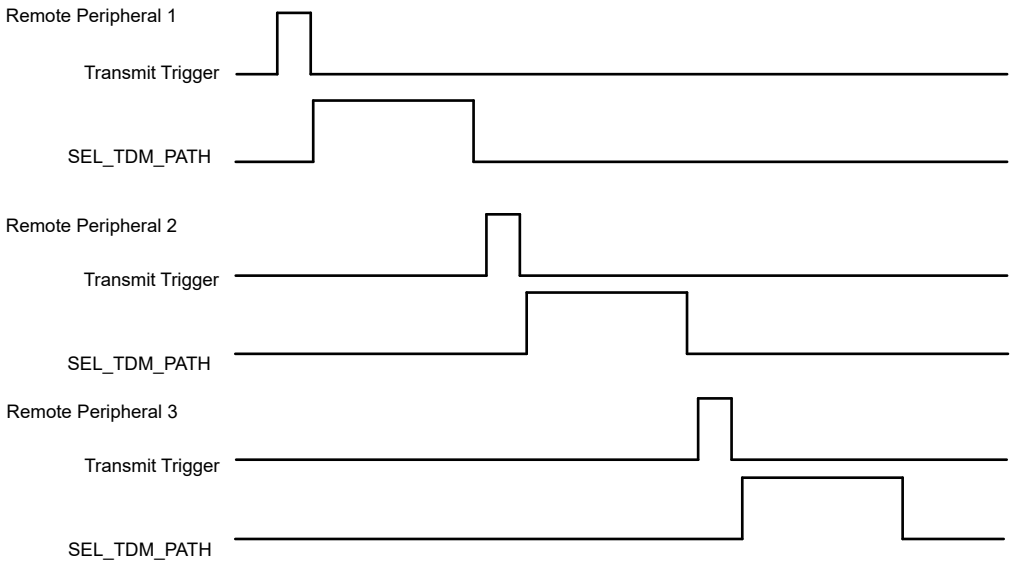

Figure 25-12. Generated Signals for FSI Multi-Node TDM Configuration

25.3.12 FSI Trigger Generation

The RX_TRIGx external trigger can be used to initiate FSITX transmission. RX_TRIG0 must be used if TDM mode (multi-node configuration) is required. RX_TRIG0 must be used as the trigger source for start of transmission while the programmable stretch width RX_TRIG0 signal is used as the SEL_TDM_PATH signal (which decides whether the local FSITX is active or put in bypass mode).

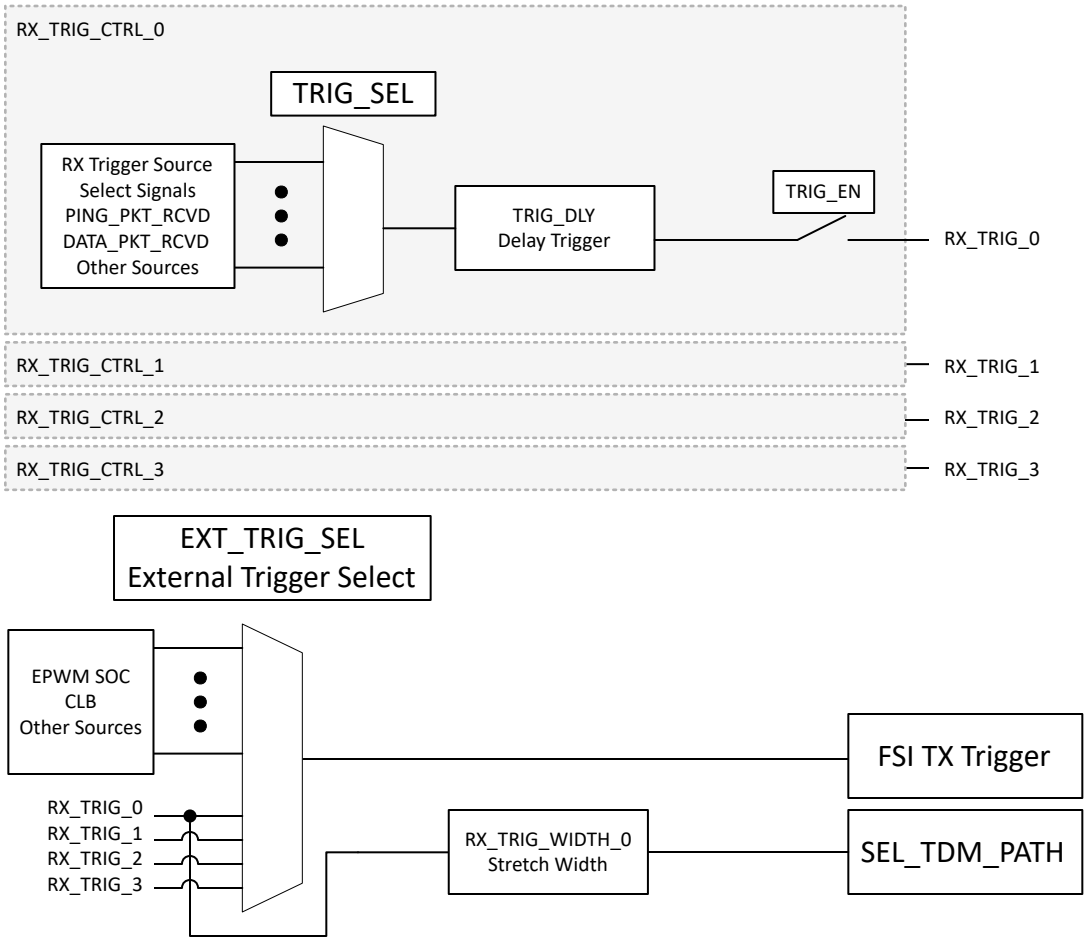

Figure 25-13. RX_TRIGx FSI Trigger

The signal source for the RX_TRIGx signal is selected through the RX_TRIG_CTRL_x.TRIG_SEL bits, as listed in Table 25-11.

Table 25-11. RX_TRIGx Trigger Select Signals

RX_TRIG_CTRLx.TRIG_SEL	Selected Signal
0	Ping Packet Received
1	Data Packet Received
2	Error Packet Received
3	Ping Frame Tag Match Occurred
4	Data Frame Tag Match Occurred
5	Error Frame Tag Match Occurred
6	Frame Done
7	Reserved
8 to 15	Reserved

The RX_TRIGx signals can optionally be delayed (this can be used in TDM scenarios) through the RX_TRIG_CTRL_x.TRIG_DLY.

25.3.13 FSI-SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode are:

- Data transmits on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 is driven like an active-low, chip-select signal. The signal is low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks are transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI peripheral configuration because the FSI TXCLK cannot take an external clock source.

Table 25-12 lists the frame structure of the FSI-SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI peripheral, the standard SPI must encode the transmission to be sent.

Table 25-12. FSI-SPI Compatibility Frame Structure

Idle State	Start of Frame	Frame Type	User Data	Data Words	CRC byte(1)	Frame Tag	End of Frame	Idle State
	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data is arranged in the following manner. The example provided in Table 25-13 assumes a DATA_2_WORD frame has been sent.

Table 25-13. Contents of Data Received by a Standard SPI

SPI Data	Data Contents
SPI word 0	1001, 0100, 8-bit User Data
SPI word 1	Data word 1
SPI word 2	Data word 2
SPI word 3	8-bit CRC, 4-bit Frame Tag, 0110

25.3.13.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with an SPI module.

25.3.13.1.1 FSITX as SPI Controller, Transmit Only

The FSITX can operate as an independent SPI controller module. In this condition, TXCLK is connected to SPICLK, TXD0 is connected to SPIPICO, and TXD1 is connected to $\overline{\text{SPIPTE}}$, the chip select.

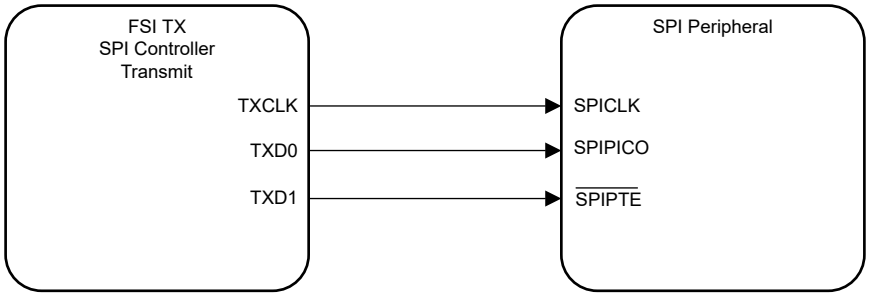

Figure 25-14. FSITX as SPI Controller, Transmit Only

When the FSI is an SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver requires some software to act upon this information.

Table 25-14. FSI as Controller Transmitter, SPI as Peripheral Receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Can be implemented in software on the SPI receiver.
Ability to detect line breaks	Yes	Can be implemented in software on the SPI receiver but requires additional software overhead such as a timer or watchdog.
CRC check	Yes	Can be implemented in software on the SPI receiver. For devices that have VCRC , this is more efficient.
ECC on data	Yes	Can be implemented in software on the SPI receiver
Detection of abruptly terminated frames	No	
Double edge data rate	No	
Recovery from glitches on signal lines between frames	No	
Skew adjustment on signal lines	No	

25.3.13.1.1.1 Initialization

To configure the FSITX module to be an SPI controller for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX_OPER_CTRL_LO.SPI_MODE to 1. This enables the SPI clocking scheme and signaling structure.

25.3.13.1.1.2 Operation

The operation of the FSITX module in FSI-SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to Section 25.3.2 for more information on each of these features.

25.3.13.1.2 FSIRX as SPI Peripheral, Receive Only

The FSIRX can operate as an independent SPI peripheral module. In this usage, RXCLK is connected to SPICLK and RXD0 is connected to SPIPICO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX responds to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence is required to resynchronize the FSIRX module with the controller.

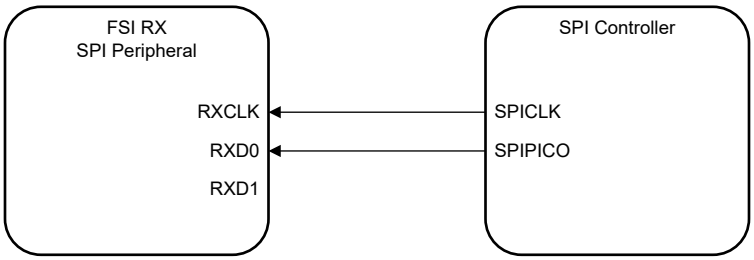

Figure 25-15. FSIRX as SPI Peripheral, Receive Only

When the FSI is an SPI receiver communicating with an SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

Table 25-15. SPI as Controller Transmitter, FSI as Peripheral Receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Standard on FSI
Ability to detect line breaks	Yes	Can be implemented in software on the SPI transmitter but requires the use of a timer or watchdog in the transmitting SPI device.
CRC check	Yes	Can be implemented in software on the SPI transmitter.
ECC on data	Yes	Can be implemented in software on the SPI transmitter.
Detection of abruptly terminated frames	Yes	This is accomplished with the FSI setting up the frame watchdog counter.
Double edge data rate	No	
Recovery from glitches on signal lines between frames	Yes	Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame discards the effects of these glitches and causes the receiver to resynchronize when the real “start-of-frame” pattern is seen. So, the ability to reject glitches in between frames is very high.
Skew adjustment on signal lines	Yes	The FSI receiver has the ability to add delays to the incoming signal lines.

25.3.13.1.2.1 Initialization

To configure the FSIRX module to be an SPI peripheral for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set RX_OPER_CTRL.SPI_MODE to 1. This enables the SPI clocking scheme and signaling structure.

25.3.13.1.2.2 Operation

The operation of the FSIRX module in FSI-SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to Section 25.3.3 for more information on each of these features.

25.3.13.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Controller

In this configuration, the FSITX is the controller clock. The FSITX module drives TXCLK (SPICLK), TXD0 (SPIPICO), and TXD1 (SPISTE/chip select) to the SPI peripheral. The SPIPOCI signal is connected back to the RXD0 signal. RXCLK can be applied either using the internal SPI pairing feature or externally wired, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX can also be thought of as an additional SPI peripheral. Some software logic is required for the FSI to emulate an SPI controller fully.

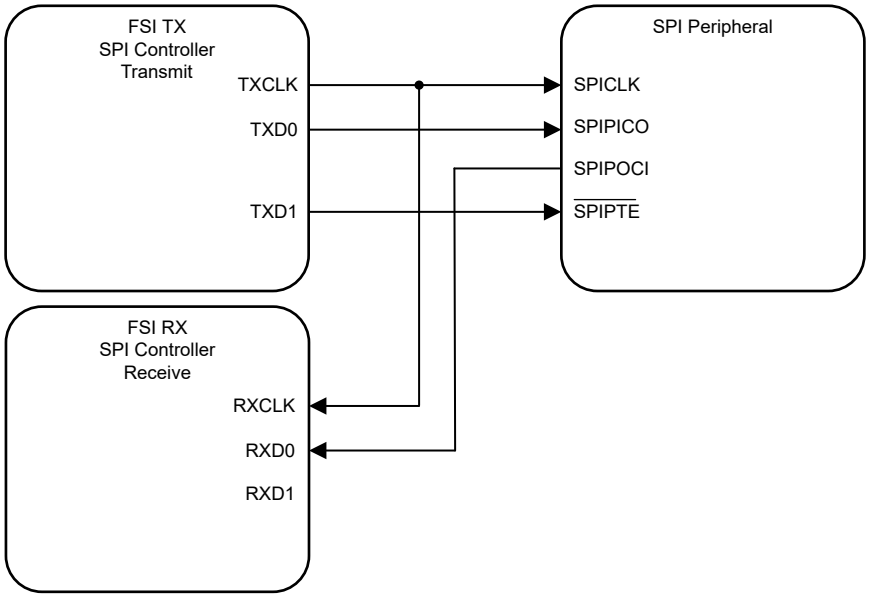

Figure 25-16. FSITX and FSIRX as SPI Controller, Full Duplex

25.3.13.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI controller operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set the respective SPI_MODE bits. This enables the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX_MAIN_CTRL.SPI_PAIRING to 1. This internally connects TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK can be reallocated to other application requirements.

If the application requires an external clock loopback, make sure that TXCLK is connected to RXCLK. This is required if the SPI peripheral is across an isolation barrier and there is latency between TXCLK being launched and SPIPOCI data being received on RXD0.

25.3.13.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI controller module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available, such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

25.4 FSI Programing Guide

This section describes various operational sequences and features for the FSI.

25.4.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules exchange data. Since the receiver accepts data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example provides a suggested approach for establishing a clean communication link on two separate devices that power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to make sure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 25-17 shows the connection of the devices in this example. While there is no true concept of a main device or a remote device node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

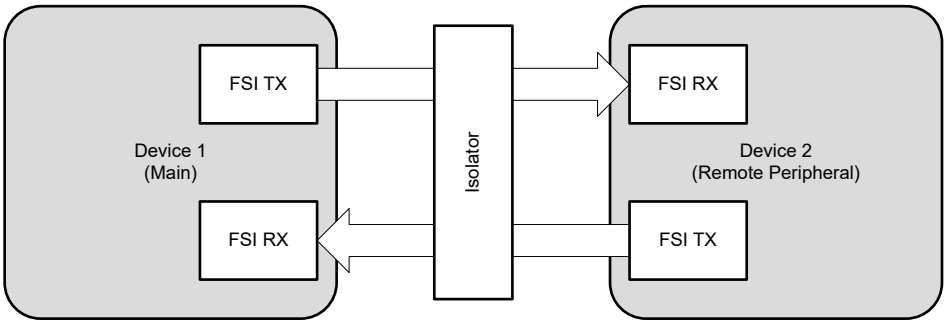

Figure 25-17. Point to Point Connection

Device 1 is the main node; it is the driver of the initialization sequence. Device 2 is the remote node; it responds to the main device commands. In this example, as well as in a real world use-case, neither the main device nor the remote device knows precisely when the other is ready to receive communication.

Sample sequences for both the main device and remote device are provided in the following subsections.

25.4.1.1 Establishing the Communication Link from the Main Device

The following sequence is an example of how the main device node establishes the communication link with the remote device without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
   - Send the flush sequence.
   - Send a ping frame with the frame tag 0000.
   - Wait for some time. (determined by application)
   - If the FSIRX has received a valid ping frame, continue; else, iterate the loop again.
   - If the received ping frame tag was 0001, continue; else, iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point, both the main transmit and receive channels have successfully received a frame from the remote counterparts. The link has been established and standard application communication can begin.

25.4.1.2 Establishing the Communication Link from the Remote Device

The following sequence is an example of how the remote device node establishes the communication link with the main device without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
6. If the received frame tag was 0000, continue; else, discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
11. If the received ping frame tag was 0001, continue; else, if the received frame tag was 0000, return to step 9. This can happen if a second ping frame was already in transit before receiving the remote device response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from the main counterparts. The link has been established and regular communication can now proceed. The application can configure periodic ping frames from the transmitter, initialize the receiver ping and frame watchdogs, and begin the communication required by the application.

25.4.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a main register lock. These protections make sure that no spurious writes or unintentional modifications to these registers are accepted. For the list of registers with write protections available and the register and bit descriptions, refer to the *FSI Registers* section..

EALLOW Protection

EALLOW is a device-level register protection, refer to the *EALLOW Protection* section of the *System Control and Interrupts* chapter for more information on EALLOW. For those registers with EALLOW protection, the EALLOW bit is set before modifying the register. The application then clears the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. To write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX_MAIN_CTRL.CORE_RST must be set. To do this, write 0xA501 to TX_MAIN_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE_RST value. Refer to the *Registers* section for more information on which registers have write keys added.

Control Register Lock Protection

There also exists a main lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the *Registers* section. The control register lock prevents any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX_LOCK_CTRL and TX_LOCK_CTRL for the receiver and transmitter, respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV_CFG_REGS.SOFTPRESx) for the FSI module. Refer to Section 25.3.2.7 for more information on SYSRSn.

25.4.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores are always in free running mode. CPU halts do not have any effect on the operation of the FSI. Reads of registers and data buffers by the debugger do not affect any flags or status of the data buffers.

If you want to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

25.5.2 FSI Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/fsi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

25.5.2.1 FSI Loopback:CPU Control

FILE: fsi_ex1_loopback_cpucontrol.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

User can edit some of configuration parameters as per usecase. These are as below. Default values can be referred in code where these globals are defined

- *nWords* - Number of words per transfer may be from 1 -16
- *nLanes* - Choice to select single or double lane for frame transfers
- *fsiClock* - FSI Clock used for transfers
- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers
- *txPingTimeRefCntr* - Tx Ping timer reference counter
- *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

For any errors during transfers i.e. *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

External Connections

For FSI internal loopback (EXTERNAL_FSI_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL_FSI_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:
- FSIRX_CLK to FSITX_CLK
- FSIRX_RX0 to FSITX_TX0
- FSIRX_RX1 to FSITX_TX1

ControlCard FSI Header GPIOs:
- GPIO_27 -> FSITX_CLK
- GPIO_26 -> FSITX_TX0
- GPIO_25 -> FSITX_TX1
- GPIO_13 -> FSIRX_CLK
- GPIO_12 -> FSIRX_RX0
- GPIO_11 -> FSIRX_RX1

Watch Variables
- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.2 FSI DMA frame transfers:DMA Control

FILE: fsi_ex3_loopback_dmacontrol.c

Example sets up infinite data frame transfers where DMA trigger happens once through CPU and then DMA takes control to transfer data iteratively. This example demonstrates the FSI feature about triggering DMA events which in turn can copy data and trigger next transfer.

Two DMA channels are setup for FSI Tx operation and two for Rx. Four areas in GSx memories are also setup as source and sink for data and tag values of frame under transmission.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any error event occurs, execution will stop.

User Configurations: If "Software Frame Size" is modified in FSI TX or FSI RX Sysconfig, change: DMA CH0 "Destination Wrap Size" DMA CH0 "Burst Size" DMA CH2 "Source Wrap Size" DMA CH2 "Burst Size" FSI TX/RX "Software Frame Size"

: This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
For FSI internal loopback (default setting), no external connections needed

For FSI external loopback (disable "Loopback Mode" in FSI RX Sysconfig), external connections are required. Refer to SysConfig for external connections (GPIO pin numbers) specific to each device.

Watch Variables
- *countDMAtransfers* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.3 FSI data transfer by external trigger

FILE: fsi_ex4_loopback_epwmtrigger.c

FSI frame transfer can be triggered by external sources. It can connect up to 32 trigger sources but as of now, only 16 ePWMx-SOCy(x-1:8, y-A:B) are supported. FSI supports external trigger for both PING and DATA frame

transfers and in this example we demonstrate how to setup infinite DATA transfers using selectable ePWM-SOC as a trigger source. The TB counter for ePWM operation is in up/down count mode for this example.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

External Connections
For FSI internal loopback (EXTERNAL_FSI_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL_FSI_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:
- FSIRX_CLK to FSITX_CLK
- FSIRX_RX0 to FSITX_TX0
- FSIRX_RX1 to FSITX_TX1

ControlCard FSI Header GPIOs:
- GPIO_27 -> FSITX_CLK
- GPIO_26 -> FSITX_TX0
- GPIO_25 -> FSITX_TX1
- GPIO_13 -> FSIRX_CLK
- GPIO_12 -> FSIRX_RX0
- GPIO_11 -> FSIRX_RX1

Watch Variables
- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.4 FSI data transfers upon CPU Timer event

FILE: fsi_ex5_periodic_frame.c

Example sets up infinite data frame transfers where trigger comes from ISR handling the periodic CPU Timer event. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

CPU Timer0 is chosen for setting up periodic timer events. User can choose any other Timer-1/Timer-2 as well.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

External Connections
For FSI internal loopback (EXTERNAL_FSI_ENABLE == 0), no external connections needed

For FSI external loopback (EXTERNAL_FSI_ENABLE == 1), external connections are required. The FSI TX pins should be connected to the respective FSI RX pins of the same device. See below for external connections to include and GPIOs used:

External Connections Required between FSI TX and RX of the same device:
- FSIRX_CLK to FSITX_CLK
- FSIRX_RX0 to FSITX_TX0
- FSIRX_RX1 to FSITX_TX1

ControlCard FSI Header GPIOs:
- GPIO_27 -> FSITX_CLK
- GPIO_26 -> FSITX_TX0
- GPIO_25 -> FSITX_TX1
- GPIO_13 -> FSIRX_CLK

- GPIO_12 -> FSIRX_RX0
- GPIO_11 -> FSIRX_RX1

Watch Variables
- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.5 FSI and SPI communication(fsi_ex6_spi_main_tx)

FILE: fsi_ex6_spi_main_tx.c

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like main Tx and SPI as remote Rx. API to decode FSI frame received at SPI end is implemented and checks are made to ensure received details(frame tag/type, userdata, data) match with transfered frame.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

External Connections
For FSI <-> SPI communication, make below connections in GPIO settings

- GPIO_7 -> GPIO_18 :: To connect FSITXA_CLK with SPICLKA
- GPIO_6 -> GPIO_16 :: To connect FSITXA_D0 with SPIPICOA
- GPIO_5 -> GPIO_19 :: To connect FSITXA_D1 with SPIPTEA

Watch Variables
- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.6 FSI and SPI communication(fsi_ex7_spi_remote_rx)

FILE: fsi_ex7_spi_remote_rx.c

FSI supports SPI compatibility mode to talk to the devices not having FSI but SPI module. Example sets up infinite data frame transfers where FSI acts like remote Rx and SPI as main Rx. API to build the FSI frame at SPI end before transfer is implemented in SW and checks are made to ensure received details(frame tag/type, userdata, data) on FSI Rx match with transferred data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

External Connections
For FSI(Rx) <-> SPI(Tx) communication, make connections in GPIO settings

There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge.

- GPIO_13 -> GPIO_18 :: To connect FSIRXCLKA with SPICLKA
- GPIO_12 -> GPIO_16 :: To connect FSIRXD0A with SPIPICOA

Watch Variables
- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

25.5.2.7 FSI P2Point Connection:Rx Side

FILE: fsi_ex8_ext_p2pconnection_rx.c

Example sets up FSI receiving device in a point to point connection to the FSI transmitting device. Example code to set up FSI transmit device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a main or a remote node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as main and receiving side as remote. Transmitting side will be driver of initialization sequence.

Handshake mechanism which must take place before actual data transmission can be usecase specific; points described below can be taken as an example on how to implement the handshake from receiving side -

- Setup the receiver interrupts to detect PING type frame reception
- Begin the first PING loop
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI_FRAME_TAG0*, come out of loop. Otherwise iterate the loop again.
- Begin the second PING loop
  - Send the Flush sequence
  - Send the PING frame with tag \bFSI_FRAME_TAG1
  - Wait for receiver interrupt
  - If the FSI Rx has received a PING frame with *FSI_FRAME_TAG1*, come out of loop. Otherwise iterate the loop again.

Now, the receiver side has received the acknowledged PING frame(tag1), so it is ready for normal operation further.

After above synchronization steps, FSI Rx can be configured as per usecase i.e. nWords, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per usecase, similar to other examples.

nWords - Number of words per transfer may be from 1 -16 *nLanes* - Choice to select single or double lane for frame transfers *fsiClock* - FSI Clock used for transfers *txUserData* - User data to be sent with Data frame *txDataFrameTag* - Frame tag used for Data transfers *txPingFrameTag* - Frame tag used for Ping transfers *txPingTimeRefCntr* - Tx Ping timer reference counter *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

External Connections
For FSI external P2P connection, external connections are required to be made between two devices. Device 1's FSI TX and RX pins need to be connected to device 2's FSI RX and TX pins respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:
- FSIRX_CLK to FSITX_CLK
- FSIRX_RX0 to FSITX_TX0
- FSIRX_RX1 to FSITX_TX1

ControlCard FSI Header GPIOs:
- GPIO_27 -> FSITX_CLK
- GPIO_26 -> FSITX_TX0
- GPIO_25 -> FSITX_TX1
- GPIO_13 -> FSIRX_CLK
- GPIO_12 -> FSIRX_RX0
- GPIO_11 -> FSIRX_RX1

Watch Variables
- *dataFrameCntr* Number of Data frame received
- *error* Non zero for transmit/receive data mismatch

25.5.2.8 FSI P2Point Connection:Tx Side

FILE: fsi_ex8_ext_p2pconnection_tx.c

Example sets up FSI transmitting device in a point to point connection to the FSI receiving device. Example code to set up FSI receiving device is implemented in a separate file.

In a real scenario two separate devices may power up in arbitrary order and there is a need to establish a clean communication link which ensures that receiver side is flushed to properly interpret the start of a new valid frame.

There is no true concept of a main or a remote node in the FSI protocol, but to simplify the data flow and connection we can consider transmitting device as main and receiving side as remote. Transmitting side will be driver of initialization sequence.

Handshake mechanism which must take place before actual data transmission can be usecase specific; points described below can be taken as an example on how to implement the handshake from transmitting side -

- Setup the receiver interrupts to detect PING type frame reception
- Begin the PING loop
  - Send the Flush sequence
  - Send a PING frame with the frame tag *FSI_FRAME_TAG0*
  - Wait for some time(determined by application)
  - If the FSI Rx has received a PING frame with *FSI_FRAME_TAG1*, come out of loop. Otherwise iterate the loop again

Send a PING frame with the frame tag FSI_FRAME_TAG1

After above synchronization steps, FSI Tx can be configured as per usecase i.e. nWords, lane width, enabling events etc and start the infinite transfers. More details on establishing the communication link can be found in device TRM.

User can edit some of configuration parameters as per usecase, similar to other examples.

nWords - Number of words per transfer may be from 1 -16 *nLanes* - Choice to select single or double lane for frame transfers *fsiClock* - FSI Clock used for transfers *txUserData* - User data to be sent with Data frame *txDataFrameTag* - Frame tag used for Data transfers *txPingFrameTag* - Frame tag used for Ping transfers *txPingTimeRefCntr* - Tx Ping timer reference counter *rxWdTimeoutRefCntr* - Rx Watchdog timeout reference counter

External Connections
For FSI external P2P connection, external connections are required to be made between two devices. Device 1's FSI TX and RX pins need to be connected to device 2's FSI RX and TX pins respectively. See below for external connections to make and GPIOs used:

External connections required between independent RX and TX devices:
- FSIRX_CLK to FSITX_CLK
- FSIRX_RX0 to FSITX_TX0
- FSIRX_RX1 to FSITX_TX1

ControlCard FSI Header GPIOs:
- GPIO_27 -> FSITX_CLK
- GPIO_26 -> FSITX_TX0
- GPIO_25 -> FSITX_TX1
- GPIO_13 -> FSIRX_CLK
- GPIO_12 -> FSIRX_RX0
- GPIO_11 -> FSIRX_RX1

Watch Variables
- *dataFrameCntr* Number of Data frame transmitted
- *error* Non zero for transmit/receive data mismatch

25.6 FSI Registers

This section describes the FSI Registers.

25.6.1 FSI Base Address Table

Table 25-17. FSI Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
FsiTxaRegs	FSI_TX_REGS	FSITXA_BASE	0x0000_6600	YES	YES	YES	YES
FsiRxaRegs	FSI_RX_REGS	FSIRXA_BASE	0x0000_6680	YES	YES	YES	YES

25.6.2 FSI_TX_REGS Registers

Table 25-18 lists the memory-mapped registers for the FSI_TX_REGS registers. All register offset addresses not listed in Table 25-18 should be considered as reserved locations and the register contents should not be modified.

Table 25-18. FSI_TX_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TX_MAIN_CTRL	Transmit main control register	EALLOW	Go
2h	TX_CLK_CTRL	Transmit clock control register	EALLOW and LOCK	Go
4h	TX_OPER_CTRL_LO	Transmit operation control register low	EALLOW and LOCK	Go
5h	TX_OPER_CTRL_HI	Transmit operation control register high	EALLOW and LOCK	Go
6h	TX_FRAME_CTRL	Transmit frame control register		Go
7h	TX_FRAME_TAG_UDATA	Transmit frame tag and user data register		Go
8h	TX_BUF_PTR_LOAD	Transmit buffer pointer control load register	EALLOW	Go
9h	TX_BUF_PTR_STS	Transmit buffer pointer control status register		Go
Ah	TX_PING_CTRL	Transmit ping control register	EALLOW and LOCK	Go
Bh	TX_PING_TAG	Transmit ping tag register		Go
Ch	TX_PING_TO_REF	Transmit ping timeout counter reference	EALLOW and LOCK	Go
Eh	TX_PING_TO_CNT	Transmit ping timeout current count		Go
10h	TX_INT_CTRL	Transmit interrupt event control register	EALLOW and LOCK	Go
11h	TX_DMA_CTRL	Transmit DMA event control register	EALLOW and LOCK	Go
12h	TX_LOCK_CTRL	Transmit lock control register	EALLOW and LOCK	Go
14h	TX_EVT_STS	Transmit event and error status flag register		Go
16h	TX_EVT_CLR	Transmit event and error clear register	EALLOW	Go
17h	TX_EVT_FRC	Transmit event and error flag force register	EALLOW	Go
18h	TX_USER_CRC	Transmit user-defined CRC register		Go
20h	TX_ECC_DATA	Transmit ECC data register		Go
22h	TX_ECC_VAL	Transmit ECC value register		Go
24h	TX_DLYLINE_CTRL	Transmit delay Line control register	EALLOW and LOCK	Go
40h + formula	TX_BUF_BASE_y	Base address for transmit buffer		Go

Complex bit access types are encoded to fit into small table cells. Table 25-19 shows the codes that are used for access types in this section.

Table 25-19. FSI_TX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		

Table 25-19. FSI_TX_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

25.6.2.1 TX_MAIN_CTRL Register (Offset = 0h) [Reset = 0000h]

TX_MAIN_CTRL is shown in Figure 25-18 and described in Table 25-20.

Return to the Summary Table.

Transmit main control register

Figure 25-18. TX_MAIN_CTRL Register

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED						FLUSH	CORE_RST
R-0h						R/W-0h	R/W-0h

Table 25-20. TX_MAIN_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-2	RESERVED	R	0h	Reserved
1	FLUSH	R/W	0h	Flush Operation Start bit This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on. 0h (R/W) = Clear this bit. 1h (R/W) = Setting this bit will Initiate flush sequence. To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Transmitter Main Core Reset bit This bit controls the transmitter main core reset. In order to send any frame, this bit must be cleared. 0h (R/W) = Transmitter core is not in reset and can transmit frames. 1h (R/W) = Transmitter core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

25.6.2.2 TX_CLK_CTRL Register (Offset = 2h) [Reset = 0000h]

TX_CLK_CTRL is shown in Figure 25-19 and described in Table 25-21.

Return to the Summary Table.

Transmit clock control register

Figure 25-19. TX_CLK_CTRL Register

15	14	13	12	11	10	9	8
RESERVED						PRESCALE_VAL	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0
PRESCALE_VAL						CLK_EN	CLK_RST
R/W-0h						R/W-0h	R/W-0h

Table 25-21. TX_CLK_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-2	PRESCALE_VAL	R/W	0h	Clock Divider Prescale Value The input clock is divided by this 8-bit value and fed into the transmitter core. This divided clock is the rate at which TXCLK will operate. 0h (R/W) = Reserved 1h (R/W) = Input clock /1 2h (R/W) = Input clock /2 3h (R/W) = Input clock /3 4h (R/W) = Input clock /4 ... FFh (R/W) = Input clock /255 TXCLKIN = Input clock / PRESCALE_VAL In FSI mode: TXCLK = TXCLKIN / 2 In SPI mode: TXCLK = TXCLKIN Reset type: SYSRSn
1	CLK_EN	R/W	0h	Clock Divider Enable bit This bit will enable and disable the input clock divider and start the clock to the transmitter core. 0h (R/W) = The input clock divider is not enabled and the clock is not connected to the transmitter core. 1h (R/W) = The input clock to the transmitter core is being divided by the PRESCALE_VAL and enabled. Reset type: SYSRSn
0	CLK_RST	R/W	0h	Clock Divider Reset bit This bit will reset the clock counter in the clock divider. 0h (R/W) = The clock divider is set based on the value in PRESCALE_VAL. The input clock will be divided by PRESCALE_VAL if CLK_EN is set. 1h (R/W) = The clock divider will be reset to 0 and will stay reset until software writes a 0 to this bit. Reset type: SYSRSn

25.6.2.3 TX_OPER_CTRL_LO Register (Offset = 4h) [Reset = 0000h]

TX_OPER_CTRL_LO is shown in Figure 25-20 and described in Table 25-22.

Return to the Summary Table.

Transmit operation control register low

Table 25-22. TX_OPER_CTRL_LO Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	SEL_TDM_IN	R/W	0h	Input TDM port Select bit This bit selects the input port for the transmitter core between the TDM input pins or the RX module. When this bit is '0', the inputs selected for TDM are from the TDM input pins. When this bit is '1', then inputs selected for TDM are from the RX module. Reset type: SYSRSn
9	TDM_ENABLE	R/W	0h	Transmit TDM Mode Enable bit. This bit enables the TDM Mode for multi-remote TDM operation. 0h (R/W) Transmit TDM Mode is not enabled. 1h (R/W) Transmit TDM Mode is enabled. Reset type: SYSRSn
8	SEL_PLLCLK	R/W	0h	Input Clock Select bit This bit selects the input clock source for the transmitter core. 0h (R/W) = SYSCLK is the source of the transmitter clock into the clock prescaler. 1h (R/W) = PLLRAWCLK is the source of the transmitter core clock into the clock prescaler. Reset type: SYSRSn
7	PING_TO_MODE	R/W	0h	Ping Counter Reset Mode Select bit This bit selects when the ping counter will reset. 0h (R/W) = The ping counter will reset and restart only on hardware initiated ping frames, when ping counter has timed out. 1h (R/W) = The ping counter will reset and restart on any software initiated frame as well as a ping counter timeout Reset type: SYSRSn
6	SW_CRC	R/W	0h	CRC Source Select bit This bit selects the source of the CRC value that is transmitted. 0h (R/W) = The transmitted CRC value is computed by hardware. 1h (R/W) = The transmitted CRC value is sourced from the value programmed in the TX_USER_CRC register. Reset type: SYSRSn

Table 25-22. TX_OPER_CTRL_LO Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-3	START_MODE	R/W	0h	Transmission Start Mode Select bit These bits select the method by which a new frame transmission is started. 0h (R/W) = Only a software write to TX_FRAME_CTRL.START initiate a new transmission. 1h (R/W) = The configured external trigger will initiate a new transmission. 2h (R/W) = Either writing to TX_FRAME_CTRL.START or the TX_FRAME_TAG_UDATA register will initiate a new transmission. All other combinations of bits are illegal and reserved for future use. Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Select bit This bit enables and disables SPI compatibility mode. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn
1-0	DATA_WIDTH	R/W	0h	Transmit Data Width Select bits These bits define the number of data lines used by the transmitter. 0h (R/W) = Data will be transmitted on one data line (TXD0) 1h (R/W) = Data will be transmitted on two data lines (TXD0 and TXD1). The format of the data is described in the preceeding chapter. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

25.6.2.4 TX_OPER_CTRL_HI Register (Offset = 5h) [Reset = 0000h]

TX_OPER_CTRL_HI is shown in Figure 25-21 and described in Table 25-23.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13-7	EXT_TRIG_SEL	R/W	0h	External Trigger Select bit These bits define which of the 128 external inputs will be used as the source for the external input trigger. 00h (R/W) = Trigger 1 is the source. 01h (R/W) = Trigger 2 is the source. 02h (R/W) = Trigger 3 is the source. ... 7Fh (R/W) = Trigger 128 is the source. Reset type: SYSRSn
6	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between 16-bit and 32-bit ECC computation. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
5	FORCE_ERR	R/W	0h	Error Frame Force bit This bit will force the the CRC value of the transmitted data frame to 0 whenever there is a buffer overrun or underrun condition. This can be used to force a corrupted CRC as the data is not guaranteed to be reliable. The receiver will treat the data as invalid and can handle this as needed. Note: DO NOT use FORCE_ERR if using the SW CRC mode (FSI Transmit). 0h (R/W) = The CRC will not be forced to 0. 1h (R/W) = The CRC will be forced to 0 in a buffer overrun or underrun condition. Reset type: SYSRSn
4-0	RESERVED	R	0h	Reserved

25.6.2.5 TX_FRAME_CTRL Register (Offset = 6h) [Reset = 0000h]

TX_FRAME_CTRL is shown in Figure 25-22 and described in Table 25-24.

Return to the Summary Table.

Transmit frame control register

Figure 25-22. TX_FRAME_CTRL Register

Table 25-24. TX_FRAME_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	START	R/W	0h	Start Transmission bit This bit will cause the FSI to start transmitting the next frame. 0h (R/W) = Writing a 0 to this bit will have no effect. 1h (R/W) = Start the next transmission. This bit will be cleared by hardware. Reset type: SYSRSn
14-8	RESERVED	R	0h	Reserved
7-4	N_WORDS	R/W	0h	Number of Words to be Transmitted This field defines the number of words which will be transmitted in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the receiver. Set this bitfield to be one less than the number of words to be transmitted. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
3-0	FRAME_TYPE	R/W	0h	Transmit Frame Type This field determines the type of frame that will be transmitted next. 0000b (R/W) = Ping Frame. This frame can be sent either by software or automatically by hardware. 0100b (R/W) = DATA_1_WORD Frame. One word data frame (16-bit data). 0101b (R/W) = DATA_2_WORD Frame. Two word data frame (32-bit data). 0110b (R/W) = DATA_4_WORD Frame. Four word data frame (64-bit data). 0111b (R/W) = DATA_6_WORD Frame. Six word data frame (96-bit data). 0011b (R/W) = DATA_N_WORD Frame. The N_WORDS field will determine the number of words (1 to 16) to be sent. Both the transmitter and receiver must have the same value programmed. 1111b (R/W) = Error Frame. This frame can be used during error conditions or any condition where the transmitter wants to notify the receiver of a high priorty status. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

25.6.2.6 TX_FRAME_TAG_UDATA Register (Offset = 7h) [Reset = 0000h]

TX_FRAME_TAG_UDATA is shown in Figure 25-23 and described in Table 25-25.

Return to the Summary Table.

Table 25-36. TX_EVT_CLR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3	PING_TRIGGERED	W	0h	Ping Frame Triggered Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Note: This bit may not always be cleared when writing to the corresponding TX_EVT_CLR bit. If PING_TIMEOUT MODE is configured to be 0, a hardware ping timeout may occur when another frame is actively being transmitted. In this case, if this bit still shows as 1 after the clear bit is written then the ping frame has been triggered but not serviced. This bit does not indicate that the ping frame has been completely sent, only that it has been triggered by the timeout event. Reset type: SYSRSn
2	BUF_OVERRUN	W	0h	Buffer Overrun Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn
1	BUF_UNDERRUN	W	0h	Buffer Underrun Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn
0	FRAME_DONE	W	0h	Frame Done Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn

25.6.2.18 TX_EVT_FRC Register (Offset = 17h) [Reset = 0000h]

TX_EVT_FRC is shown in Figure 25-35 and described in Table 25-37.

Return to the Summary Table.

3Ah	RX_UDATA_FILTER	Receive User Data Filter Control register	EALLOW and LOCK	Go
40h + formula	RX_BUF_BASE_y	Base address for receive data buffer		Go

Complex bit access types are encoded to fit into small table cells. Table 25-44 shows the codes that are used for access types in this section.

Table 25-44. FSI_RX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

25.6.3.1 RX_MAIN_CTRL Register (Offset = 0h) [Reset = 0000h]

RX_MAIN_CTRL is shown in Figure 25-41 and described in Table 25-45.

Return to the Summary Table.

Receive main control register

Figure 25-41. RX_MAIN_CTRL Register

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED			DATA_FILTER_EN	INPUT_ISOLATE	SPI_PAIRING	INT_LOOPBACK	CORE_RST
R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 25-45. RX_MAIN_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-5	RESERVED	R	0h	Reserved
4	DATA_FILTER_EN	R/W	0h	Data Filter Enable Bit. 0h (R/W) = Data filtering is disabled. 1h (R/W) = Data filtering is enabled. Reset type: SYSRSn
3	INPUT_ISOLATE	R/W	0h	When set to 1, the FSI RX inputs (RXCLK, RXD0 and RXD1) will be isolated from what is driven from the device pins and will be held at inactive level of '1'.This isolation facilitates the user to switch the RX inputs to a different set of device pins and hence any potential glitch that could occur during the process of switching will not affect the RX module itself. Reset type: SYSRSn
2	SPI_PAIRING	R/W	0h	Clock Pairing for SPI-like Behavior Enable bit This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI controller, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1) 0h (R/W) = SPI clock pairing is not enabled. 1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

Table 25-45. RX_MAIN_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	INT_LOOPBACK	R/W	0h	Internal Loopback Enable bit This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins. 0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins. 1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Receiver Main Core Reset bit This bit controls the receiver main core reset. In order to receive any frame, this bit must be cleared. Note: For reset to take affect, the FSI RX module must be held in reset for at least 4 SYSCLK cycles. 0h (R/W) = Receiver core is not in reset and can receive frames. 1h (R/W) = Receiver core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

25.6.3.2 RX_OPER_CTRL Register (Offset = 4h) [Reset = 0000h]

RX_OPER_CTRL is shown in Figure 25-42 and described in Table 25-46.

Return to the Summary Table.

Receive operation control register

Figure 25-42. RX_OPER_CTRL Register

15	14	13	12	11	10	9	8

R/W-0h	R/W-0h				R/W-0h	R/W-0h	

Table 25-46. RX_OPER_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	PING_WD_RST_MODE	R/W	0h	Ping Watchdog Timeout Mode Select bit This bit selects the mode by which the ping watchdog counter is reset. The watchdog counter can be reset and restarted only by ping frames or by any received frame. 0h (R/W) = The ping watchdog counter will reset and restart only by ping frames. 1h (R/W) = The ping watchdog counter will reset and restart by any received frame. Reset type: SYSRSn
7	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between whether the ECC computation is done on 16-bit or 32-bit words. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
6-3	N_WORDS	R/W	0h	Number of Words to Receive This field defines the number of words which will be received in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the transmitter. Set this bitfield to be one less than the number of words to be received. This value is only applicable when the frame type received is DATA_N_WORD. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Enable bit This bit enables and disables the SPI compatibility mode of the FSI RX. The received data must be formatted as an FSI frame in order for the data to properly be received. SPI compatibility mode will allow FSI RX to receive data that is sent using SPI signal format. Refer to the applicable section in the FSI TRM chapter for more information. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn

Table 25-46. RX_OPER_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	DATA_WIDTH	R/W	0h	Receive Data Width Select bit These bits decide the number of data lines used for receiving data. 0h (R/W) = Data will be received on one data line, RXD0. 1h (R/W) = Data will be received on two data lines, RXD0 and RXD1. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

25.6.3.3 RX_FRAME_INFO Register (Offset = 6h) [Reset = 0000h]

RX_FRAME_INFO is shown in Figure 25-43 and described in Table 25-47.

Return to the Summary Table.

Table 25-50. RX_EVT_STS Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	ERROR_TAG_MATCH	R	0h	Error Tag Match Flag This bit indicates that an error frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched error frame received. 1h (R) = A tag-matched error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
13	DATA_TAG_MATCH	R	0h	Data Tag Match Flag This bit indicates that a dataframe was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched data frame received. 1h (R) = A tag-matched data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
12	PING_TAG_MATCH	R	0h	Ping Tag Match Flag This bit indicates that a ping frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched ping frame received. 1h (R) = A tag-matched ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
11	DATA_FRAME	R	0h	Data Frame Received Flag This bit indicates that an data frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No data frame has been received. 1h (R) = A data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 25-50. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	FRAME_OVERRUN	R	0h	Frame Overrun Flag This bit indicates that a frame overrun condition has occured. This bit gets set to 1 when a new DATA/ERROR frame is received and the corresponding DATA_FRAME_RCVD/ERROR_FRAME_RCVD flag is still set to 1. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame overrun has not ocurred. 1h (R) = Frame overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
9	PING_FRAME	R	0h	Ping Frame Received Flag This bit indicates that an ping frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No ping frame has been received. 1h (R) = A ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
8	ERR_FRAME	R	0h	Error Frame Received Flag This bit indicates that an error frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No error frame has been received. 1h (R) = An error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
7	BUF_UNDERRUN	R	0h	Receive Buffer Underrun Flag This bit indicates that a buffer underrun condition has occured in the receive buffer. This will happen when software reads the buffer which is empty and has no valid data. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive Buffer Underrun has not ocurred. 1h (R) = Receive Buffer Underrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
6	FRAME_DONE	R	0h	Frame Done Flag This bit indicates that a frame has been successfully received without error. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No frame has been successfully received. 1h (R) = A frame has been successfully received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
5	BUF_OVERRUN	R	0h	Receive Buffer Overrun Flag This bit indicates that a buffer overrun condition has occured in the receive buffer. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive buffer overrun has not ocurred. 1h (R) = Receive buffer overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 25-50. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	EOF_ERR	R	0h	End-of-Frame Error Flag This bit indicates that an invalid end-of-frame bit pattern has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid end-of-frame has not been received. 1h (R) = Invalid end-of-frame has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
3	TYPE_ERR	R	0h	Frame Type Error Flag This bit inditcates that an invalid frame type has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid frame type has not been received. 1h (R) = Invalid frame type has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
2	CRC_ERR	R	0h	CRC Error Flag This bit indicates that a CRC error has occured. A CRC error will be generated on a data frame where the received CRC and the computed CRC do not match. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = CRC error has not occured. 1h (R) = CRC error has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
1	FRAME_WD_TO	R	0h	Frame Watchdog Timeout Flag This bit indicates that the frame watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame watchdog timeout has not occured. 1h (R) = Frame watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
0	PING_WD_TO	R	0h	Ping Watchdog Timeout Flag This bit indicates that the ping watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Ping watchdog timeout has not occured. 1h (R) = Ping watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

25.6.3.7 RX_CRC_INFO Register (Offset = Bh) [Reset = 0000h]

RX_CRC_INFO is shown in Figure 25-47 and described in Table 25-51.

Return to the Summary Table.

7	6	5	4	3	2	1	0
RESERVED						PING_WD_EN	PING_WD_RST
R-0h						R/W-0h	R/W-0h

Table 25-59. RX_PING_WD_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	PING_WD_EN	R/W	0h	Ping Watchdog Counter Enable bit This bit will enable or disable the ping watchdog counter. The counter (RX_PING_WD_CNT) will begin counting from 0 when it is enabled. When the reference value (RX_PING_WD_REF) is reached, it will generate a ping watchdog timeout event (RX_EVT_STS.PING_WD_TO) and the counter value will reset to 0, and resume counting 0h (R/W) = The ping watchdog counter is disabled and not running. 1h (R/W) = The ping watchdog counter logic is enabled and running. Reset type: SYSRSn
0	PING_WD_RST	R/W	0h	Ping Watchdog Counter Reset bit This bit will reset the ping watchdog counter to 0. Writing a 1 to this bit will reset the ping watchdog counter to 0. The counter will stay in reset as long as this bit is set to 1. This bit needs to be cleared to 0 to use the counter 0h (R/W) = Clear the PING_WD_RST. 1h (W) = The ping watchdog counter will be reset to 0. Reset type: SYSRSn

25.6.3.16 RX_PING_TAG Register (Offset = 17h) [Reset = 0000h]

RX_PING_TAG is shown in Figure 25-56 and described in Table 25-60.

Return to the Summary Table.

Receive ping tag register

Chapter 26

Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this chapter. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

26.1 Introduction

The I2C module supports any target or controller I2C-compatible device. Figure 26-1 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

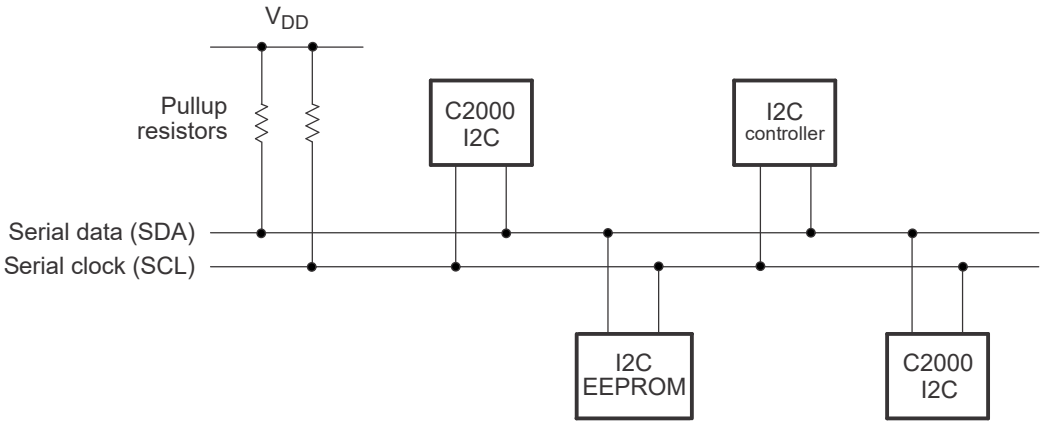

Figure 26-1. Multiple I2C Modules Connected

26.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple controller-transmitters and target-receivers
  - Support for multiple target-transmitters and controller-receivers
  - Combined controller transmit/receive and receive/transmit mode
  - Data transfer rate from 10kbps up to 400kbps (Fast-mode)
- Extended Automatic Clock Stretching and Manual Clock Stretching modes
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as target
  - I2Cx_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

26.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

26.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the controller or the target when performing data transfers. A controller device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this controller is considered a target. The I2C module supports the multi-controller mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in Figure 26-2. These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins are both bidirectional and each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See the I2CCNT register in the *I2C Registers* section for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in the *I2C Registers* section for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with controllers of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when the I2C module is a controller) and another controller
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

Figure 26-2 shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

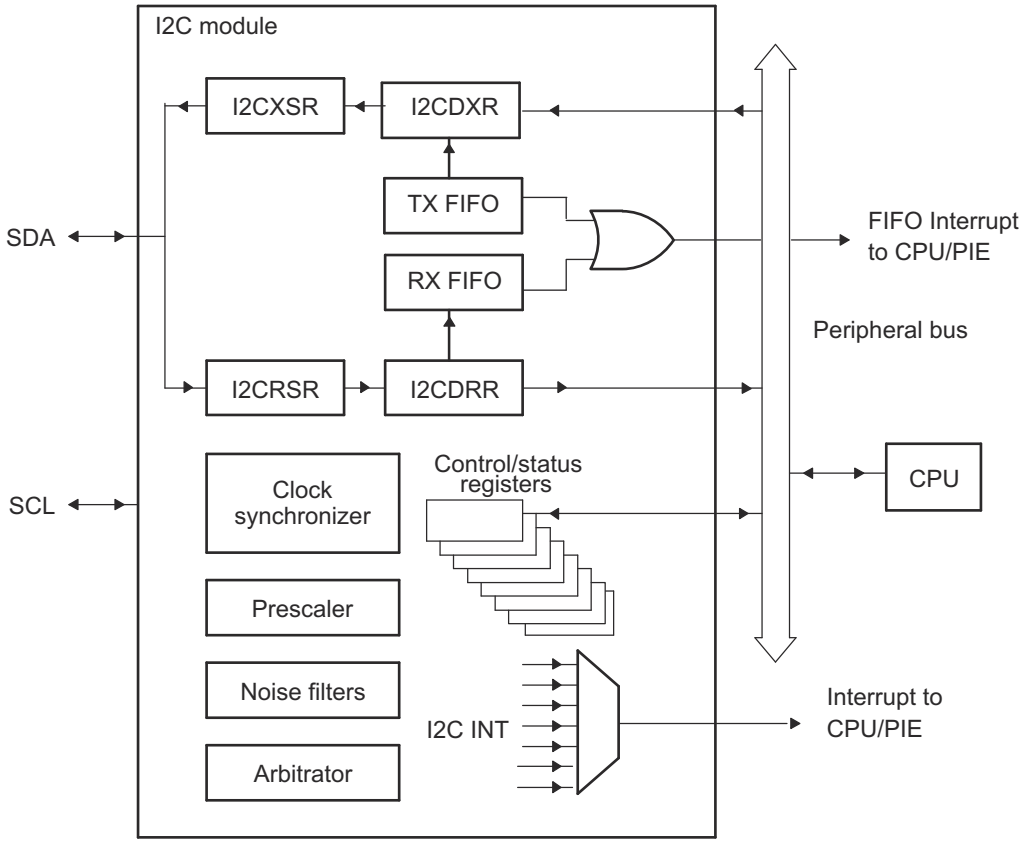

Figure 26-2. I2C Module Conceptual Block Diagram

26.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C controller clock on the SCL pin. Figure 26-3 shows the clock generation diagram for I2C module.

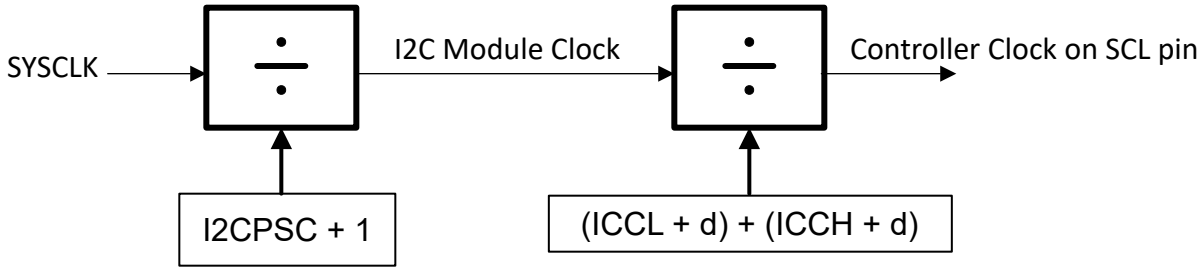

Figure 26-3. Clocking Diagram for the I2C Module

Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 to 12MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (29)$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The controller clock appears on the SCL pin when the I2C module is configured to be a controller on the I2C bus. This clock controls the timing of communication between the I2C module and a target. As shown in Figure 26-3, a second clock divider in the I2C module divides down the module clock to produce the controller clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 26.1.6 for the controller clock frequency equation.

26.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 26.1.5, when the I2C module is a controller, the I2C module clock is divided down further to use as the controller clock on the SCL pin. As shown in Figure 26-4, the shape of the controller clock depends on two divide-down values:

- ICCL in I2CCLKL. For each controller clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCKLH. For each controller clock cycle, ICCH determines the amount of time the signal is high.

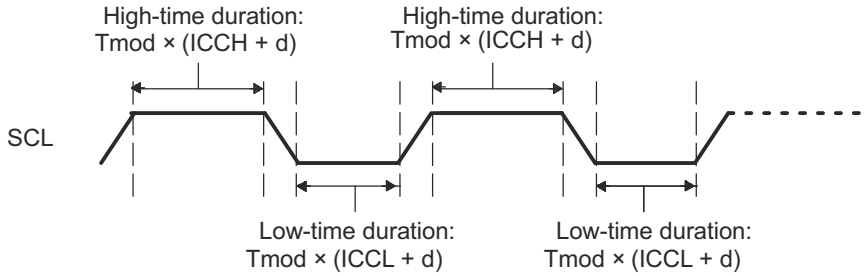

Figure 26-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)

26.1.6.1 Formula for the Controller Clock Period

The controller clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Controller Clock period (Tmst)} = \frac{[\,(\text{ICCH} + d) + (\text{ICCL} + d)\,]}{\text{I2C Module Clock (Fmod)}} \quad (30)$$

where d depends on the divide-down value IPSC, as shown in Table 26-1. IPSC is described in the I2CPSC register.

Table 26-1. Dependency of Delay d on the Divide-Down Value IPSC

IPSC	d
0	7
1	6
Greater than 1	5

26.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Note

To support a wider range of I2C IO levels, certain GPIOs have configurable fail-safe systems, V_{IH} minimum thresholds, and configurable sinking capabilities.

26.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

26.3.1 Input and Output Voltage Levels

One clock pulse is generated by the controller device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{DD}. For details, see the device data sheet.

26.3.2 Selecting Pullup Resistors

The chosen pullup resistor must meet the I2C standard timings. In most circumstances, 2.2kΩ of total bus resistance to VDDIO is sufficient. The value of the pullup resistance used on both the SCL and SDA pins be matched is also recommended. For evaluating pullup resistor values for a particular design, see the *I2C Bus Pullup Resistor Calculation Application Report*.

26.3.3 Data Validity

The data on SDA must be stable during the high period of the clock (see Figure 26-5). The high or low state of the data line, SDA, must change only when the clock signal on SCL is low.

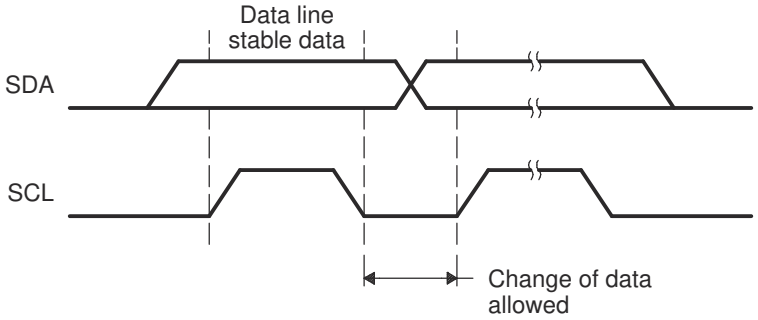

Figure 26-5. Bit Transfer on the I2C bus

26.3.4 Operating Modes

The I2C module has four basic operating modes to support data transfers as a controller and as a target. See Table 26-2 for the names and descriptions of the modes.

If the I2C module is a controller, the I2C module begins as a controller-transmitter and typically transmits an address for a particular target. When giving data to the target, the I2C module must remain a controller-transmitter. To receive data from a target, the I2C module must be changed to the controller-receiver mode.

If the I2C module is a target, the I2C module begins as a target-receiver and typically sends acknowledgment when the I2C module recognizes the target address from a controller. If the controller is sending data to the I2C module, the module must remain a target-receiver. If the controller has requested data from the I2C module, the module must be changed to the target-transmitter mode.

Table 26-2. Operating Modes of the I2C Module

Operating Mode	Description
Target-receiver mode	The I2C module is a target and receives data from a controller. All targets begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the controller. As a target, the I2C module does not generate the clock signal, but can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See Section 26.3.8 for more details.
Target-transmitter mode	The I2C module is a target and transmits data to a controller. This mode can be entered only from the target-receiver mode; the I2C module must first receive a command from the controller. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the target-transmitter mode if the target address byte is the same as the address (in I2COAR) and the controller has transmitted R/ $\overline{W}$ = 1. As a target-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the controller. While a target, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See Section 26.3.8 for more details.
Controller-receiver mode	The I2C module is a controller and receives data from a target. This mode can be entered only from the controller-transmitter mode; the I2C module must first transmit a command to the target. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the controller-receiver mode after transmitting the target address byte and R/ $\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.
Controller-transmitter mode	The I2C module is a controller and transmits control information and data to a target. All controllers begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.

To summarize, SCL is held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Target-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Target-transmitter mode.

I2C target nodes accept and provide data when the I2C controller node requests data.

- To release SCL in target-receiver mode, read data from I2CDRR.
- To release SCL in target-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

Table 26-3. Controller-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR

RM	STT	STP	Bus Activity(1)	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, target address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, target address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, target address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

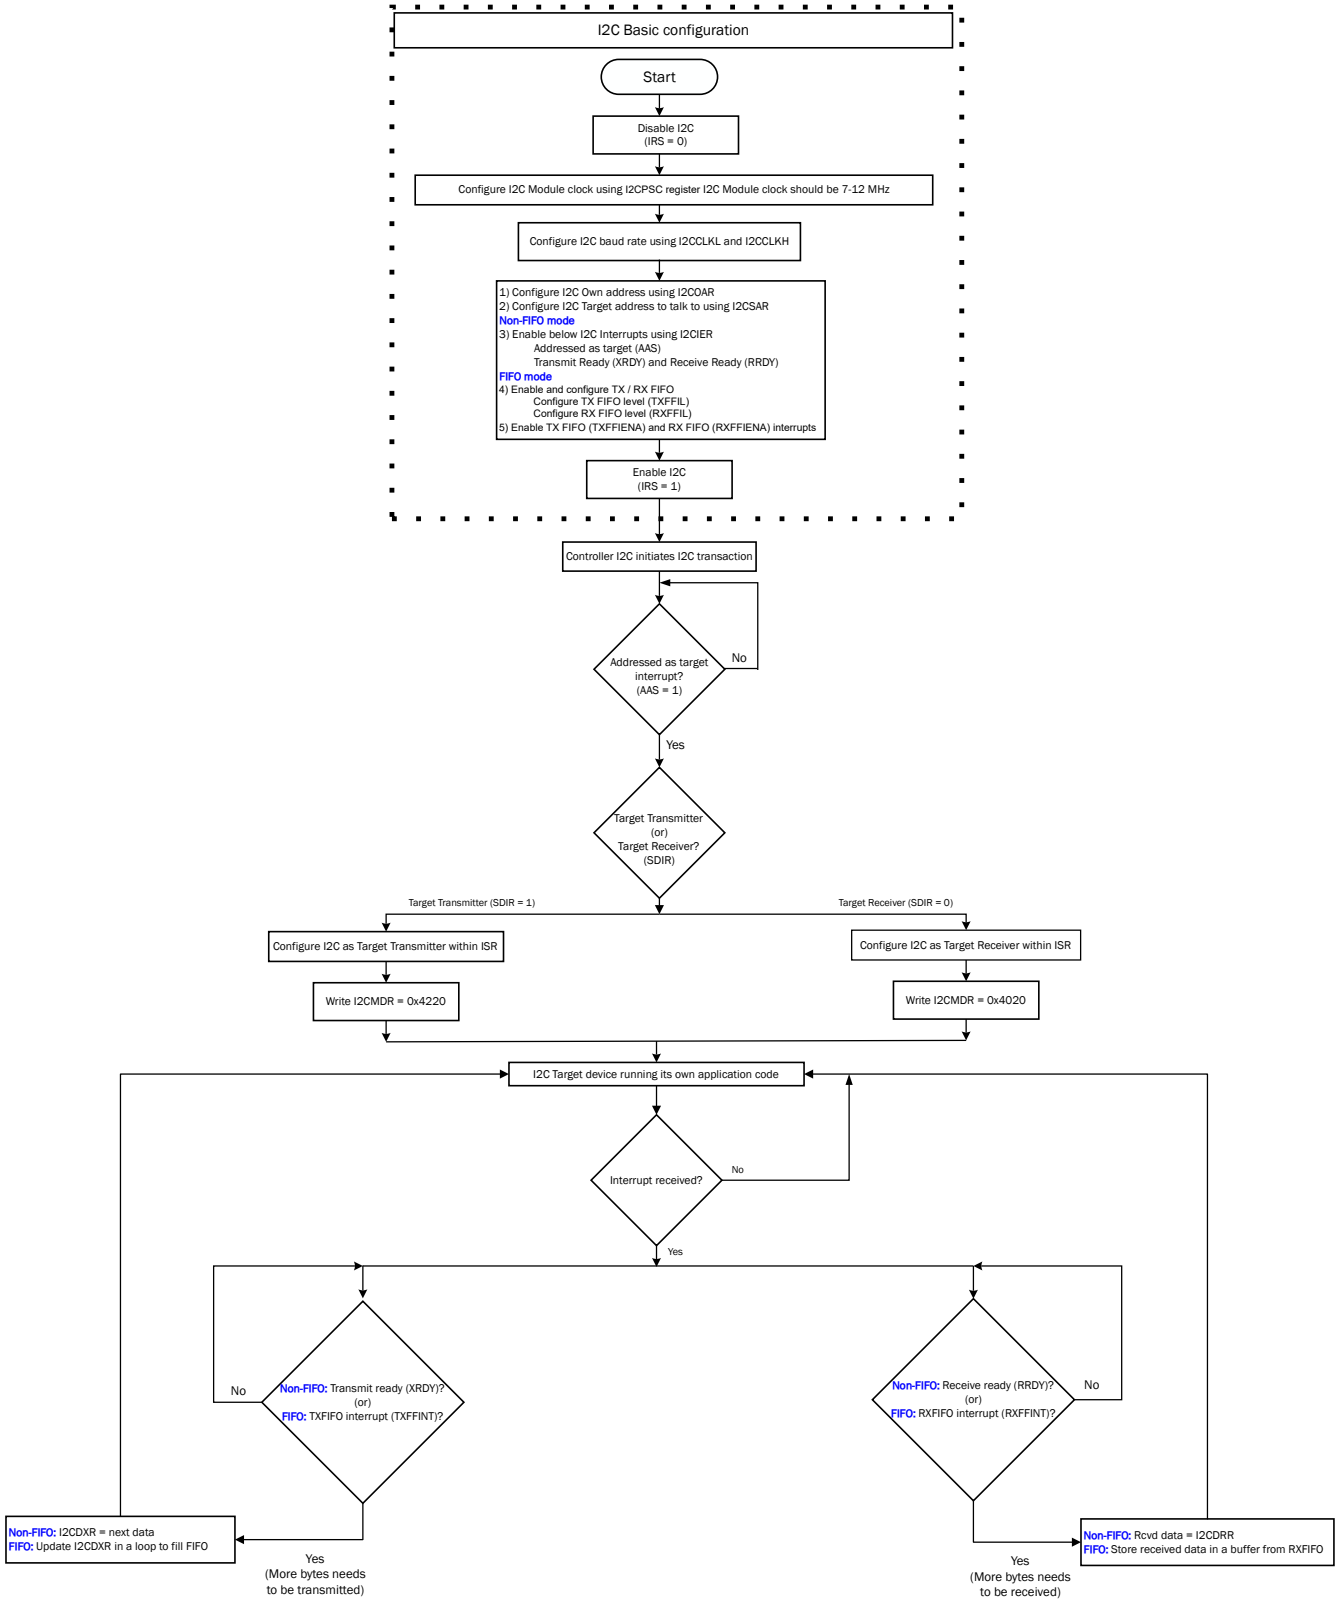

Figure 26-6. I2C Target TX / RX Flowchart

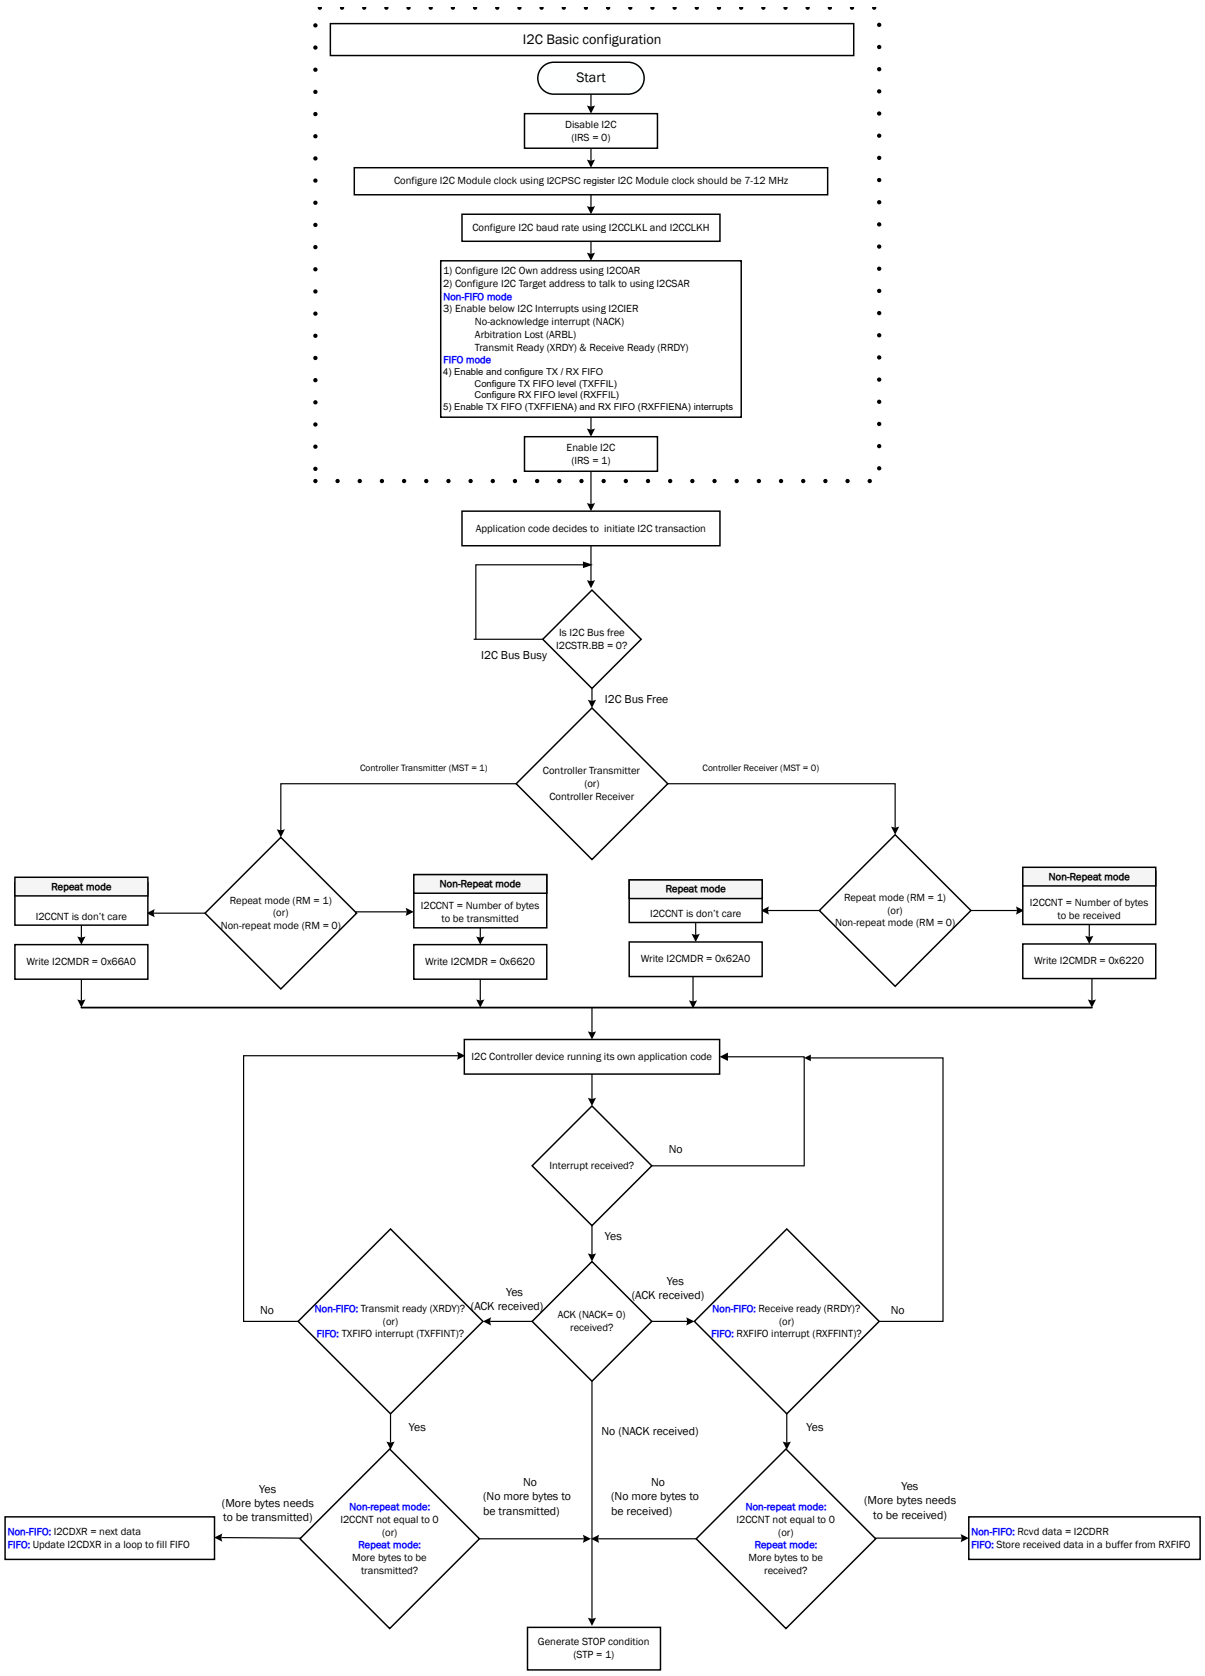

Figure 26-7. I2C Controller TX / RX Flowchart

26.3.5 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a controller on the I2C bus. As shown in Figure 26-8:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A controller drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A controller drives this condition to indicate the end of a data transfer.

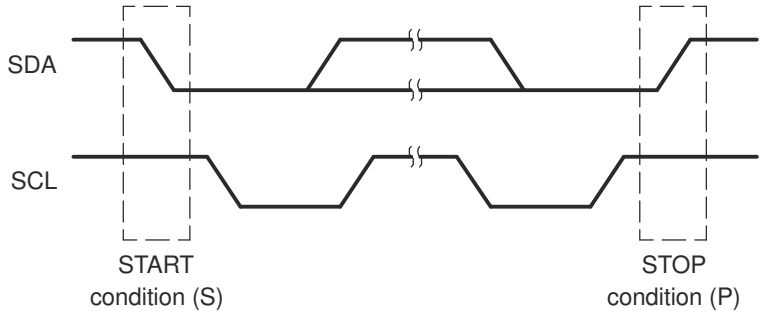

Figure 26-8. I2C Module START and STOP Conditions

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the controller mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and the bits (including MST, STT, and STP), see Section 26.7.

The I2C peripheral cannot detect a START or STOP condition while in reset (IRS = 0). The BB bit remains in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1), the BB bit does not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, make sure that at least one START or STOP condition has occurred on the I2C bus and has been captured by the BB bit. After this period, the BB bit correctly reflects the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers makes sure that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

26.3.6 Non-repeat Mode versus Repeat Mode

Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted or received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit does not get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit or receive 65536 bytes and not 0 bytes.

Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents do not determine the number of bytes to be transmitted or received.
- Number of bytes to be transmitted or received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

Note

Once you start I2C transaction in non-repeat mode or repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

26.3.7 Serial Data Formats

Figure 26-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 26-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 26-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 26-10 through Figure 26-12 and described in the paragraphs that follow the figures.

Note

In Figure 26-9 through Figure 26-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

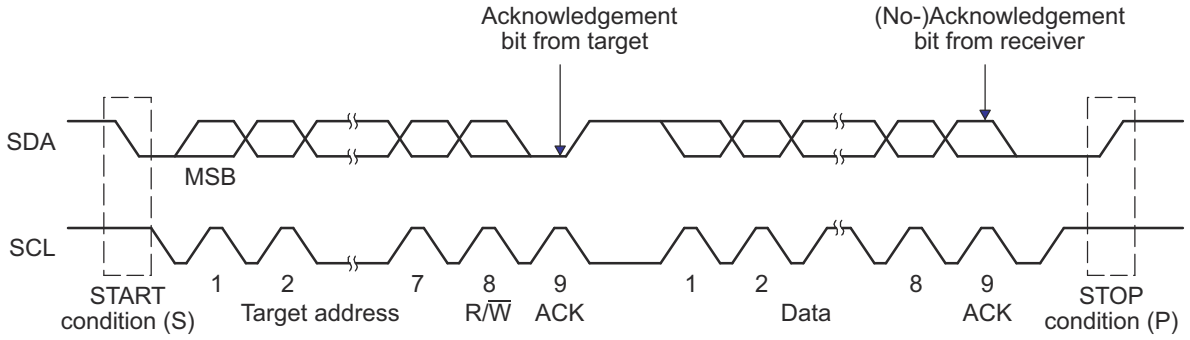

Figure 26-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)

26.3.7.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 26-10), the first byte after a START condition (S) consists of a 7-bit target address followed by a R/$\overline{W}$ bit. R/$\overline{W}$ determines the direction of the data:

- R/$\overline{W}$ = 0: The I2C controller writes (transmits) data to the addressed target. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/$\overline{W}$ = 1: The I2C controller reads (receives) data from the target. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the target after the first byte from the controller, it is followed by n bits of data from the transmitter (controller or target, depending on the R/$\overline{W}$ bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

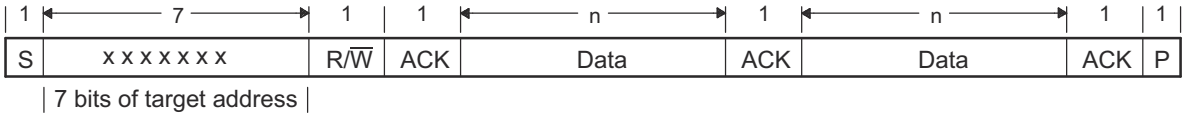

Figure 26-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)

26.3.7.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 26-11) is similar to the 7-bit addressing format, but the controller sends the target address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit target address, and R/$\overline{W}$. The second byte is the remaining 8 bits of the 10-bit target address. The target must send acknowledgment after each of the two byte transfers. Once the controller has written the second byte to the target, the controller can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

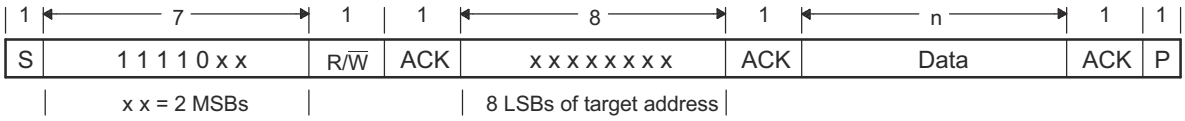

Figure 26-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)

26.3.7.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see Figure 26-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

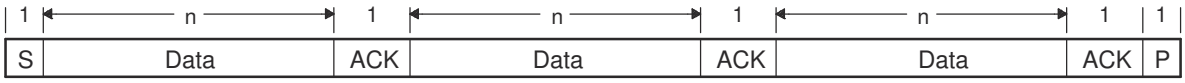

Figure 26-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)

Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

Table 26-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR

MST	FDF	I2C Module State	Function of TRX
0	0	In target mode but not free data format mode	TRX is a don't care. Depending on the command from the controller, the I2C module responds as a receiver or a transmitter.
0	1	In target mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module: TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In controller mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In controller mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

26.3.7.4 Using a Repeated START Condition

I2C controller can communicate with multiple target addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing and 10-bit addressing. Figure 26-13 shows a repeated START condition in the 7-bit addressing format.

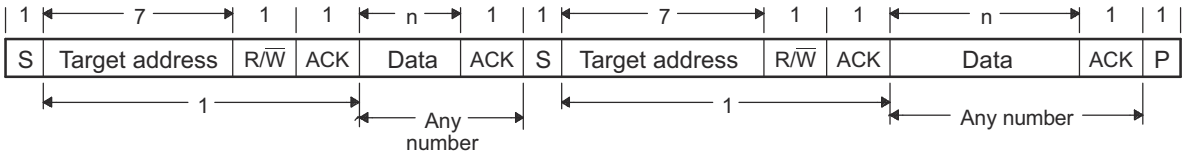

Figure 26-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)

Note

In Figure 26-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

26.3.8 Clock Synchronization

Under normal conditions, only one controller device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more controllers and the clock must be synchronized so that the data output can be compared. Figure 26-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start a low period. The SCL is held low by the device with the longest low period. The other devices that finish the low periods must wait for SCL to be released, before starting the high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a target slows down a fast controller and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

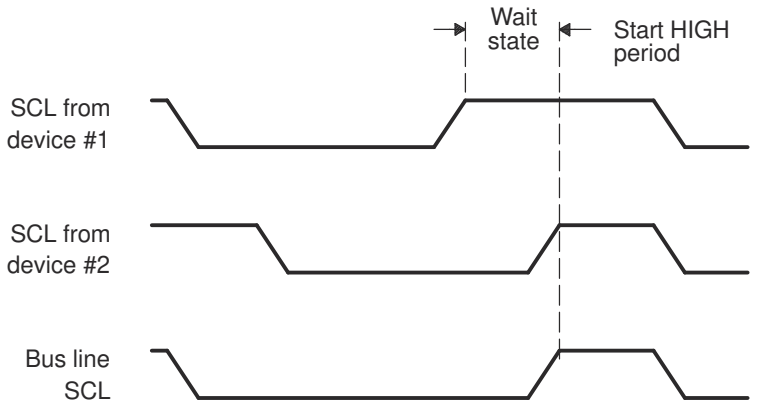

Figure 26-14. Synchronization of Two I2C Clock Generators During Arbitration

26.3.9 Clock Stretching

An I2C target device pulls the SCL line low to push the I2C controller device into the wait state preventing the I2C controller from transmitting data. This concept is called Clock Stretching.

The I2C supports three different types of clock stretching:

- **Automatic Clock Stretching:** Figure 26-15 shows the timing diagram for automatic clock stretching.
  - Target Receiver mode:
    - Non-FIFO mode: I2C clock stretches after receiving 2 bytes from the controller.
    - FIFO mode: I2C clock stretches after receiving 17 bytes from the controller.
  - Target Transmitter mode: I2C clock stretches, if I2C transmit buffer is empty

Note

Automatic Clock Stretching is enabled by default and cannot be disabled.

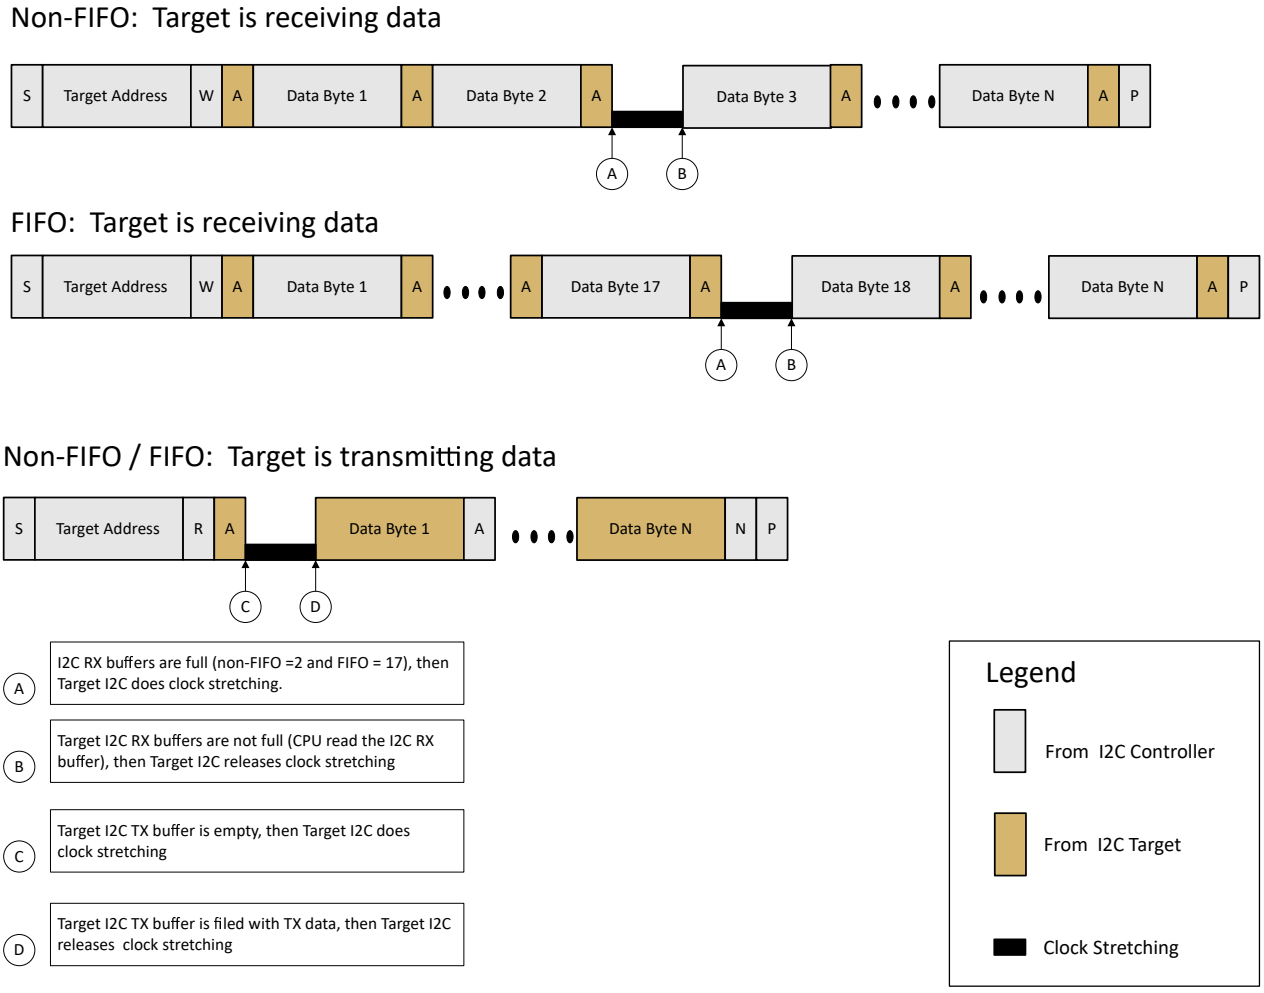

Figure 26-15. Automatic Clock Stretching

- **Extended Automatic Clock Stretching:** Figure 26-16 shows the timing diagram for extended automatic clock stretching.

  Extended Automatic Clock Stretching can be enabled by setting I2CEMDR. ECS = 1. Once this feature is enabled, I2C hardware automatically does clock stretching by pulling the SCL line low after every ACK/NACK cycle and generates an I2C interrupt. Inside the I2C ISR, I2CSTR.SCL_ECS is set to 1 to release the I2C from clock stretching.

Note

Extended Automatic Clock Stretching is disabled by default and can be enabled by setting I2CEMDR.ECS = 1.

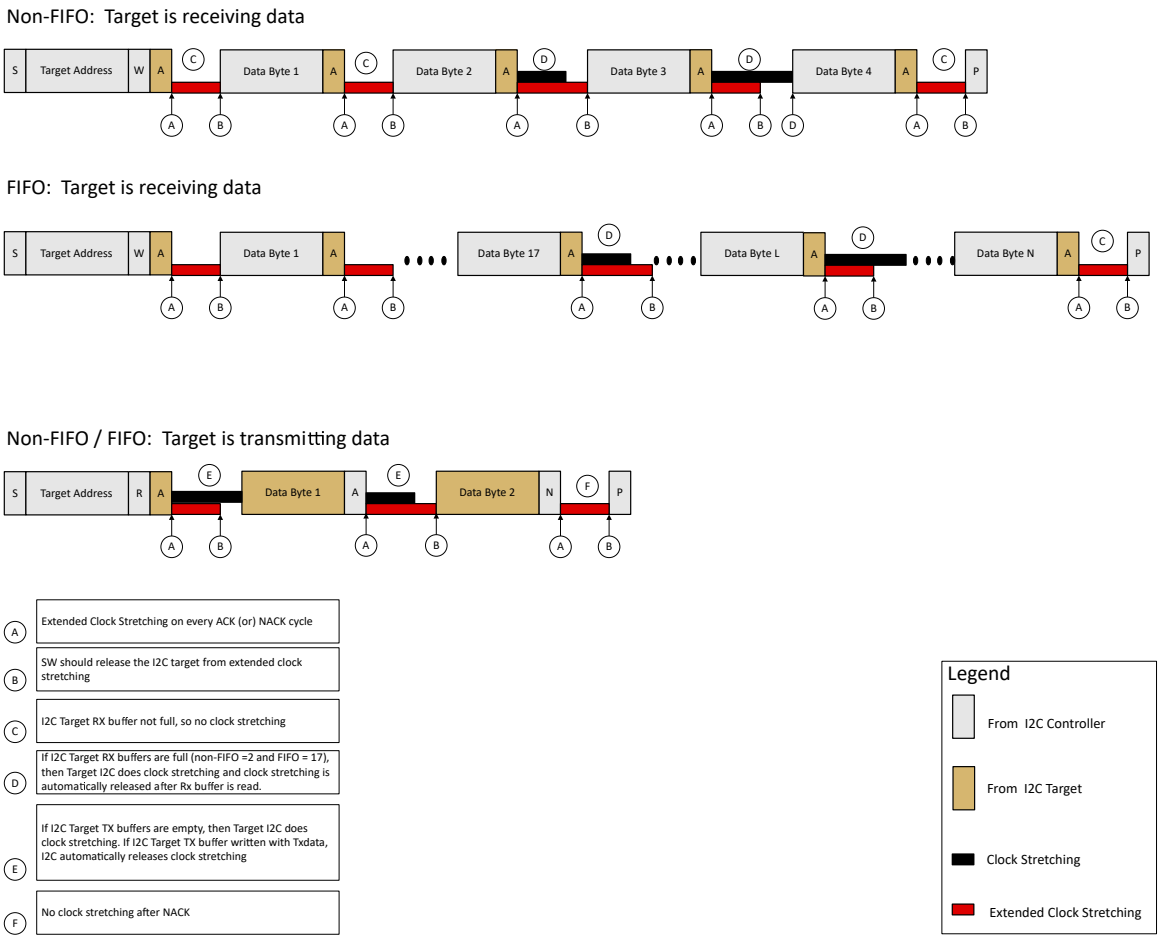

Figure 26-16. Extended Automatic Clock Stretching

- **Manual Clock Stretching:** Manual Clock Stretching can be enabled by setting I2CEMDR.MCS = 1 within an ISR routine. Once this feature is enabled, I2C hardware can be configured to manually do clock stretching by pulling the SCL line low after specific ACK/NACK cycles. I2C module then performs housekeeping and executes normal ISR sequence steps before disabling MCS by setting I2CEMDR.MCS = 0.

Note

Manual Clock Stretching is disabled by default and can be enabled by setting I2CEMDR.MCS = 1. Timing requirements for this type of clock stretching are not provided due to dependency on user configuration and application.

26.3.10 Arbitration

If two or more controller-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 26-17 illustrates the arbitration procedure between two devices. The first controller-transmitter that releases the SDA line high is overruled by another controller-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing controller, the I2c module switches to the target-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the controller-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

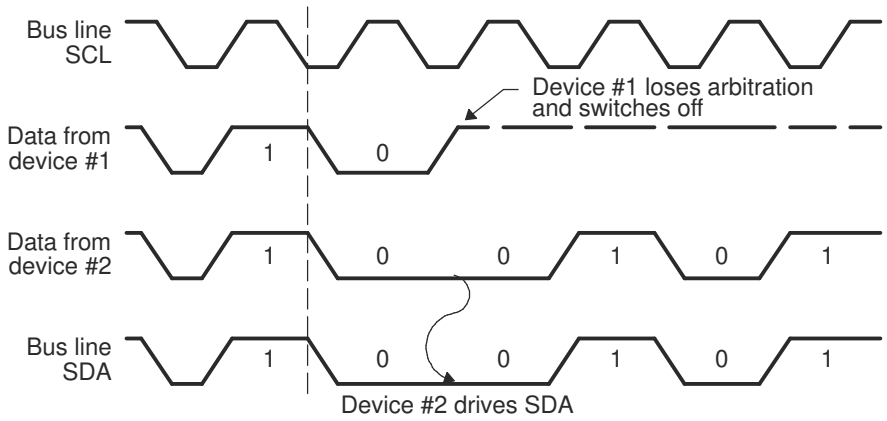

Figure 26-17. Arbitration Procedure Between Two Controller-Transmitters

26.3.11 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

n = 8 * (SYSCLK) / (I2C module clock (Fmod))

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 26-18 shows the signal routing in digital loopback mode.

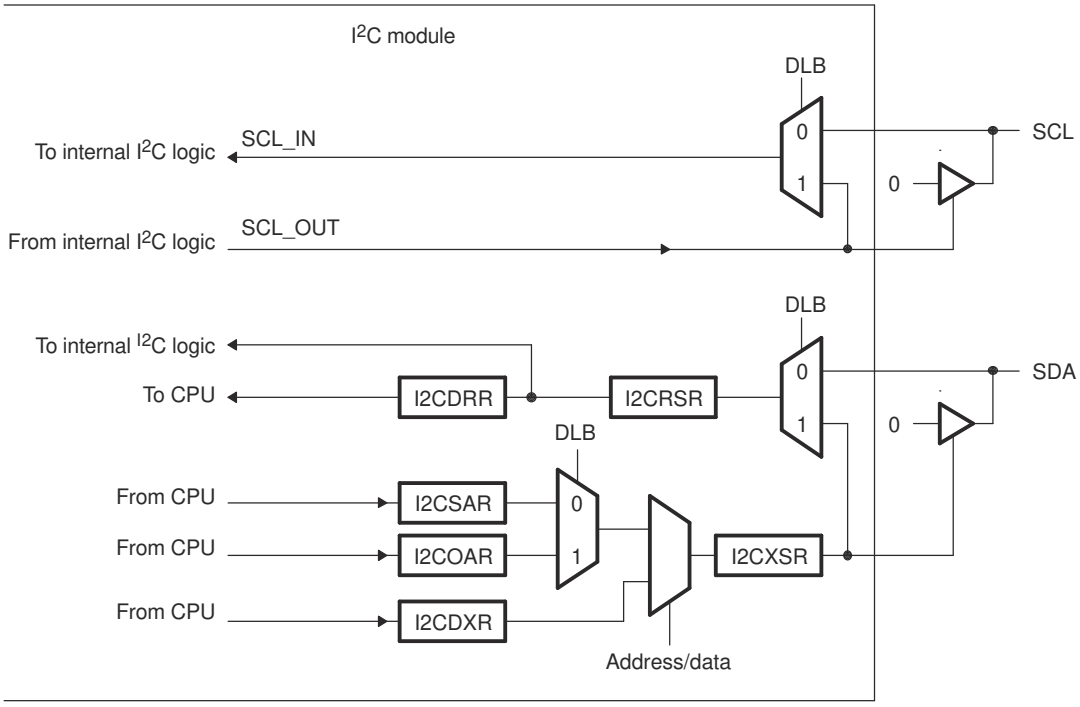

Figure 26-18. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit

Note

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

26.3.12 NACK Bit Generation

When the I2C module is a receiver (controller or target), the I2C module can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 26-5 summarizes the various ways you can allow the I2C module to send a NACK bit.

Note

When a NACK is sent, the following occurs:

1. The STP in I2CMDR is cleared
2. SCL is held low
3. The NACK in I2CSTR is set

Table 26-5. Ways to Generate a NACK Bit

I2C Module Condition	NACK Bit Generation Options
Target-receiver modes	Allow an overrun condition (RSFULL = 1 in I2CSTR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Repeat mode (RM = 1 in I2CMDR)	Generate a STOP condition (STP = 1 in I2CMDR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR)	If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition If STP = 0, make STP = 1 to generate a STOP condition Reset the module (IRS = 0 in I2CMDR) Set STP = 1 to generate a STOP condition Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive

26.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in Section 26.4.1.
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in Section 26.4.2

26.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in Table 26-6. As shown in Figure 26-19, all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if the request is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A_ISR). The I2CINT1A_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to the bit.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

Table 26-6. Descriptions of the Basic I2C Interrupt Requests

I2C Interrupt Request	Interrupt Source
XRDYINT	Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
RRDYINT	Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
ARDYINT	Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR. As an alternative to using ARDYINT, the CPU can poll the ARDY bit.
NACKINT	No-acknowledgment condition: The I2C module is configured as a controller-transmitter and did not received acknowledgment from the target-receiver. As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.
ARBLINT	Arbitration-lost condition: The I2C module has lost an arbitration contest with another controller-transmitter. As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.
SCDINT	Stop condition detected: A STOP condition was detected on the I2C bus. As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.
AASINT	Addressed as target condition: The I2C has been addressed as a target device by another controller on the I2C bus. As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.
SCLECSINT	SCL Extended Automatic Clock Stretching: SCL line is pulled low in extended automatic clock stretching mode. As an alternative to using SCLECSINT, the CPU can poll the SCL_ECS bit of the status register, I2CSTR.

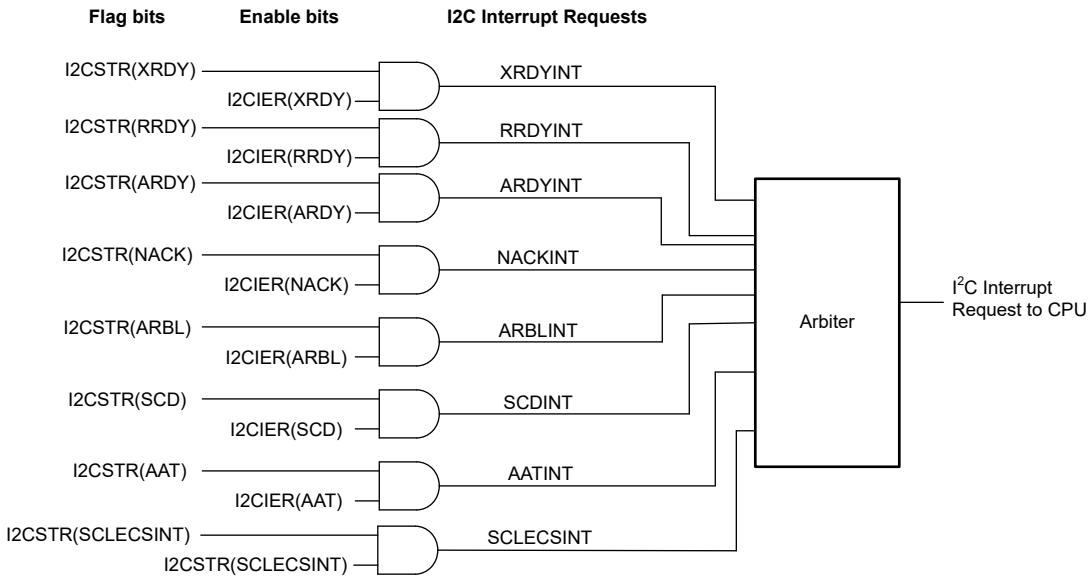

Figure 26-19. Enable Paths of the I2C Interrupt Requests

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AATINT
8. SCLECSINT

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a target-transmitter.

26.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 26-20 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

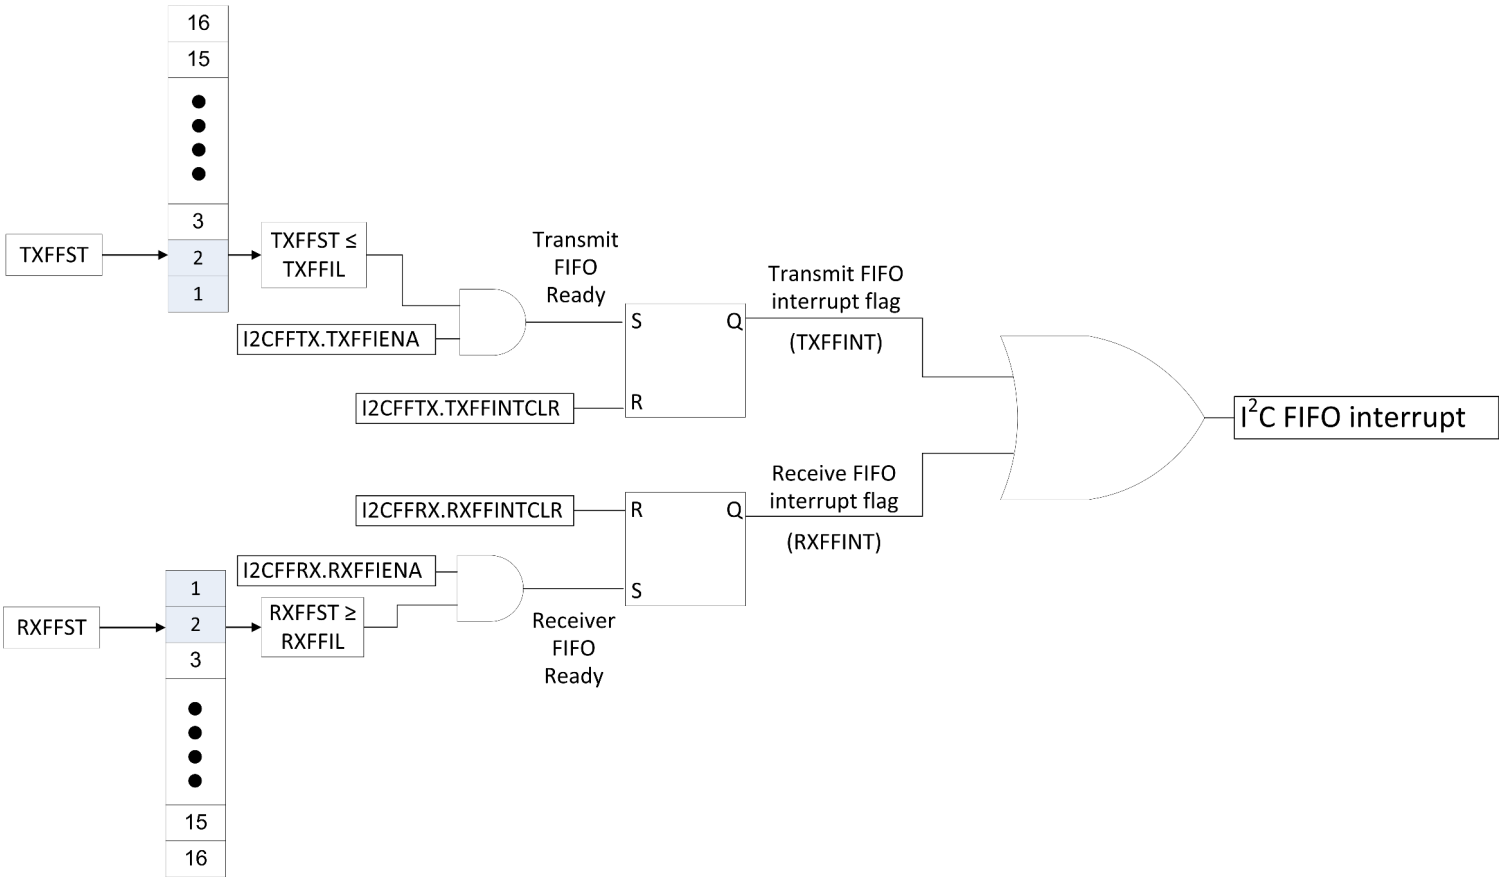

Figure 26-20. I2C FIFO Interrupt

26.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to the default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the $\overline{\text{XRS}}$ pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the $\overline{\text{XRS}}$ pin is released, all I2C module registers are reset to the default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

26.6.2 I2C Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/i2c

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

26.6.2.1 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_interrupt.c

26.6.2.2 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_target_interrupt.c

26.6.2.3 C28x-I2C Library source file for FIFO using polling

FILE: i2cLib_FIFO_polling.c

26.6.2.4 I2C Digital Loopback with FIFO Interrupts

FILE: i2c_ex1_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

26.6.2.5 I2C EEPROM

FILE: i2c_ex2_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, i2cMsgOut. The data read back will be contained in the message structure i2cMsgIn.

External Connections

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE_GPIO_PIN_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE_GPIO_PIN_SCLA on to external EEPROM SCL (serial clock) pin

Watch Variables

- *i2cMsgOut* - Message containing data to write to EEPROM
- *i2cMsgIn* - Message containing data read from EEPROM

26.6.2.6 I2C Digital External Loopback with FIFO Interrupts

FILE: i2c_ex3_external_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

External Connections

- Connect SCLA(DEVICE_GPIO_PIN_SCLA) to SCLB (DEVICE_GPIO_PIN_SCLB)
- and SDAA(DEVICE_GPIO_PIN_SDAA) to SDAB (DEVICE_GPIO_PIN_SDAB)
- Connect DEVICE_GPIO_PIN_LED1 to an LED used to depict data transfers.

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

26.6.2.7 I2C EEPROM

FILE: i2c_ex4_eeprom_polling.c

This program will shows how to perform different EEPROM write and read commands using I2C polling method EEPROM used for this example is AT24C256

External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

26.6.2.8 I2C controller target communication using FIFO interrupts

FILE: i2c_ex5_controller_target_interrupt.c

This program shows how to use I2CA and I2CB modules in both controller and target configuration This example uses I2C FIFO interrupts and doesn't using polling

Example1: I2CA as controller Transmitter and I2CB working target Receiver Example2: I2CA as controller Receiver and I2CB working target Transmitter Example3: I2CB as controller Transmitter and I2CA working target Receiver Example4: I2CB as controller Receiver and I2CA working target Transmitter

External Connections on launchpad should be made as shown below Signal | I2CA | I2CB

SCL | DEVICE_GPIO_PIN_SCLA | DEVICE_GPIO_PIN_SCLB

SDA | DEVICE_GPIO_PIN_SDAA | DEVICE_GPIO_PIN_SDAB

Watch Variables in memory window

- *I2CA_TXdata*
- *I2CA_RXdata*
- *I2CB_TXdata*
- *I2CB_RXdata* stream for error checking

26.6.2.9 I2C EEPROM

FILE: i2c_ex6_eeprom_interrupt.c

This program will shows how to perform different EEPROM write and read commands using I2C interrupts EEPROM used for this example is AT24C256

External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

//Example 1: EEPROM Byte Write //Example 2: EEPROM Byte Read //Example 3: EEPROM word (16-bit) write //Example 4: EEPROM word (16-bit) read //Example 5: EEPROM Page write //Example 6: EEPROM word Paged read

Watch Variables

- *TX_MsgBuffer* - Message buffer which stores the data to be transmitted
- *RX_MsgBuffer* - Message buffer which stores the data to be received

26.6.2.10 I2C Extended Clock Stretching Controller TX

FILE: i2c_ex7_clock_stretching_controller_tx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

26.6.2.11 I2C Extended Clock Stretching Target RX

FILE: i2c_ex7_clock_stretching_target_rx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

26.7 I2C Registers

This Section describes the I2C Registers.

26.7.1 I2C Base Address Table

Table 26-8. I2C Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
I2caRegs	I2C_REGS	I2CA_BASE	0x0000_7300	YES	-	-	YES
I2cbRegs	I2C_REGS	I2CB_BASE	0x0000_7340	YES	-	-	YES

26.7.2 I2C_REGS Registers

Table 26-9 lists the memory-mapped registers for the I2C_REGS registers. All register offset addresses not listed in Table 26-9 should be considered as reserved locations and the register contents should not be modified.

Table 26-9. I2C_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	I2COAR	I2C Own address		Go
1h	I2CIER	I2C Interrupt Enable		Go
2h	I2CSTR	I2C Status		Go
3h	I2CCLKL	I2C Clock low-time divider		Go
4h	I2CCLKH	I2C Clock high-time divider		Go
5h	I2CCNT	I2C Data count		Go
6h	I2CDRR	I2C Data receive		Go
7h	I2CTAR	I2C TARGET address		Go
8h	I2CDXR	I2C Data Transmit		Go
9h	I2CMDR	I2C Mode		Go
Ah	I2CISRC	I2C Interrupt Source		Go
Bh	I2CEMDR	I2C Extended Mode		Go
Ch	I2CPSC	I2C Prescaler		Go
20h	I2CFFTX	I2C FIFO Transmit		Go
21h	I2CFFRX	I2C FIFO Receive		Go

Complex bit access types are encoded to fit into small table cells. Table 26-10 shows the codes that are used for access types in this section.

Table 26-10. I2C_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

26.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0000h]

I2COAR is shown in Figure 26-21 and described in Table 26-11.

Return to the Summary Table.

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own TARGET address, which distinguishes it from other TARGETs connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used
write 0s to bits 9-7.

Figure 26-21. I2COAR Register

15	14	13	12	11	10	9	8
RESERVED						OAR	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0
OAR							
R/W-0h							

Table 26-11. I2COAR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	OAR	R/W	0h	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit TARGET address of the I2C module. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address of the I2C module. Reset type: SYSRSn

26.7.2.2 I2CIER Register (Offset = 1h) [Reset = 0000h]

I2CIER is shown in Figure 26-22 and described in Table 26-12.

Return to the Summary Table.

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

Figure 26-22. I2CIER Register

15	14	13	12	11	10	9	8
SCL_ECS	RESERVED						
R/W-0h	R-0h						
7	6	5	4	3	2	1	0

Table 26-12. I2CIER Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SCL_ECS	R/W	0h	SCL Extended Automatic Clock Stretch interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
14-7	RESERVED	R	0h	Reserved
6	AAT	R/W	0h	Addressed as TARGET interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
5	SCD	R/W	0h	Stop condition detected interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
4	XRDY	R/W	0h	Transmit-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
3	RRDY	R/W	0h	Receive-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
2	ARDY	R/W	0h	Register-access-ready interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
1	NACK	R/W	0h	No-acknowledgment interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
0	ARBL	R/W	0h	Arbitration-lost interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled

26.7.2.3 I2CSTR Register (Offset = 2h) [Reset = 0410h]

I2CSTR is shown in Figure 26-23 and described in Table 26-13.

Return to the Summary Table.

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

Figure 26-23. I2CSTR Register

15	14	13	12	11	10	9	8
SCL_ECS	TDIR	NACKSNT	BB	RSFULL	XSMT	AAT	AD0
R/W1C-0h	R/W1C-0h	R/W1C-0h	R-0h	R-0h	R-1h	R-0h	R-0h

RESERVED	BYTESENT	SCD	XRDY	RRDY	ARDY	NACK	ARBL
R-0h	R/W1C-0h	R/W1C-0h	R-1h	R/W1C-0h	R/W1C-0h	R/W1C-0h	R/W1C-0h

Table 26-13. I2CSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SCL_ECS	R/W1C	0h	SCL Status bit in extended automatic clock stretching mode 0: SCL line is pulled high. 1: SCL line is pulled low after ACK (or) NACK phase. Writing '1' to this bit releases SCL. SCL line is pulled high. Note: This bit is applicable only for extended clock stretching mode Reset type: SYSRSn 0h (R/W) = SCL line is not pulled low in extended automatic clock stretching mode. SCL_ECS bit is cleared by one o fthe following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = SCL line is pulled low in extended automatic clock stretching mode.
14	TDIR	R/W1C	0h	TARGET direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a TARGET transmitter. TDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a TARGET transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.

Table 26-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.
11	RSFULL	R	0h	Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read. Reset type: SYSRSn 0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - The I2C module is reset. 1h (R/W) = Overrun detected
10	XSMT	R	1h	Transmit shift register empty bit. XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin. Reset type: SYSRSn 0h (R/W) = Underflow detected (empty) 1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events: - Data is written to I2CDXR. - The I2C module is reset
9	AAT	R	0h	Addressed-as-TARGET bit Reset type: SYSRSn 0h (R/W) = In the 7-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or by a TARGET address different from the I2C peripheral's own TARGET address. 1h (R/W) = The I2C module has recognized its own TARGET address or an address of all zeros (general call).
8	AD0	R	0h	Address 0 bits Reset type: SYSRSn 0h (R/W) = AD0 has been cleared by a START or STOP condition. 1h (R/W) = An address of all zeros (general call) is detected.
7	RESERVED	R	0h	Reserved

Table 26-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	BYTESENT	R/W1C	0h	Byte Transmit over indication. BYTESENT is set when the CONTROLLER/TARGET has successfully sent the byte on SCL/SDA lines. This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions. Reset type: SYSRSn 0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The I2C module has completed the transmission of a byte.
5	SCD	R/W1C	0h	Stop condition detected bit. SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set. Reset type: SYSRSn 0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events: - I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit. - SCD is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = A STOP condition has been detected on the I2C bus.
4	XRDY	R	1h	Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data. FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead. FCM=1: XRDY is asserted only when next data is required it gets deasserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode. Reset type: SYSRSn 0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR. 1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR. XRDY is also forced to 1 when the I2C module is reset.
3	RRDY	R/W1C	0h	Receive-data-ready interrupt flag bit. When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead. Reset type: SYSRSn 0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - RRDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.

Table 26-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	ARDY	R/W1C	0h	Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the CONTROLLER mode). ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request Reset type: SYSRSn 0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events: - The I2C module starts using the current register contents. - ARDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The registers are ready to be accessed. In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0). In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.
1	NACK	R/W1C	0h	No-acknowledgment interrupt flag bit. NACK applies when the I2C module is a CONTROLLER transmitter (or) TARGET transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK). The CPU can poll NACK or use the NACK interrupt request. Reset type: SYSRSn 0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events: - An acknowledge bit (ACK) has been sent by the TARGET receiver. - NACK is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received. Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more TARGETs send acknowledgment.
0	ARBL	R/W1C	0h	Arbitration-lost interrupt flag bit (only applicable when the I2C module is a CONTROLLER-transmitter). ARBL primarily indicates when the I2C module has lost an arbitration contest with another CONTROLLERtransmitter. The CPU can poll ARBL or use the ARBL interrupt request. Reset type: SYSRSn 0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events: - AL is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an AL interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = Arbitration lost. AL is set by any one of the following events: - The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously. - The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1. When AL becomes 1, the CNT and STP bits of I2CMDR are cleared, and the I2C module becomes a TARGET-receiver.

26.7.2.4 I2CCLKL Register (Offset = 3h) [Reset = 0000h]

I2CCLKL is shown in Figure 26-24 and described in Table 26-14.

Return to the Summary Table.

15-0	I2CCLKH	R/W	0h	Clock high-time divide-down value. To produce the high time duration of the CONTROLLER clock, the period of the module clock is multiplied by (ICCL + d). d is an adjustment factor based on the prescaler. See the Clock Divider Registers section of the Introduction for details. Note: These bits must be set to a non-zero value for proper I2C clock generation. Reset type: SYSRSn

26.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0000h]

I2CCNT is shown in Figure 26-26 and described in Table 26-16.

Return to the Summary Table.

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a CONTROLLER receiver. In the repeat mode (RM = 1), I2CCNT is not used.
The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the CONTROLLER mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

Table 26-16. I2CCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	I2CCNT	R/W	0h	Data count value. I2CCNT indicates the number of data bytes to transfer or receive. If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition. The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1. Reset type: SYSRSn 0h (R/W) = data count value is 65536 1h (R/W) = data count value is 1 2h (R/W) = data count value is 2 FFFFh (R/W) = data count value is 65535

26.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0000h]

I2CDRR is shown in Figure 26-27 and described in Table 26-17.

Return to the Summary Table.

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.
If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.
When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

26.7.2.8 I2CTAR Register (Offset = 7h) [Reset = 03FFh]

I2CTAR is shown in Figure 26-28 and described in Table 26-18.

Return to the Summary Table.

The I2C TARGET address register (I2CSAR) is a 16-bit register for storing the next TARGET address that will be transmitted by the I2C module when it is a CONTROLLER. The SAR field of I2CSAR contains a 7-bit or 10-bit TARGET address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a TARGET, or TARGETs. When the address is nonzero, the address is for a particular TARGET. When the address is 0, the address is a general call to all TARGETs. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used
write 0s to bits 9-7.

9-0	TAR	R/W	3FFh	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit TARGET address that the I2C module transmits when it is in the CONTROLLER-transmitter mode. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address that the I2C module transmits when it is in the CONTROLLER transmitter mode. Reset type: SYSRSn

26.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0000h]

I2CDXR is shown in Figure 26-29 and described in Table 26-19.

Return to the Summary Table.

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.
When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

Table 26-20. I2CMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	NACKMOD	R/W	0h	NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver. Reset type: SYSRSn 0h (R/W) = In the TARGET-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit. In the CONTROLLER-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit 1h (R/W) = In either TARGET-receiver or CONTROLLER-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared. Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.
14	FREE	R/W	0h	This bit controls the action taken by the I2C module when a debugger breakpoint is encountered. Reset type: SYSRSn 0h (R/W) = When I2C module is CONTROLLER: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops. When I2C module is TARGET: A breakpoint forces the I2C module to stop when the current transmission/reception is complete. 1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.
13	STT	R/W	0h	START condition bit (only applicable when the I2C module is a CONTROLLER). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0. Reset type: SYSRSn 0h (R/W) = In the CONTROLLER mode, STT is automatically cleared after the START condition has been generated. 1h (R/W) = In the CONTROLLER mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus
12	RESERVED	R	0h	Reserved

Table 26-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	STOP condition bit (only applicable when the I2C module is a CONTROLLER). In the CONTROLLER mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions. Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message. Reset type: SYSRSn 0h (R/W) = STP is automatically cleared after the STOP condition has been generated 1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.
10	CNT	R/W	0h	CONTROLLER mode bit. CNT determines whether the I2C module is in the TARGET mode or the CONTROLLER mode. CNT is automatically changed from 1 to 0 when the I2C CONTROLLER generates a STOP condition Reset type: SYSRSn 0h (R/W) = TARGET mode. The I2C module is a TARGET and receives the serial clock from the CONTROLLER. 1h (R/W) = CONTROLLER mode. The I2C module is a CONTROLLER and generates the serial clock on the SCL pin.
9	TRX	R/W	0h	Transmitter mode bit. When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode. Reset type: SYSRSn 0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin. 1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.
8	XA	R/W	0h	Expanded address enable bit. Reset type: SYSRSn 0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit TARGET addresses (from bits 6-0 of I2CTAR), and its own TARGET address has 7 bits (bits 6-0 of I2COAR). 1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit TARGET addresses (from bits 9-0 of I2CTAR), and its own TARGET address has 10 bits (bits 9-0 of I2COAR).
7	RM	R/W	0h	Repeat mode bit (only applicable when the I2C module is a CONTROLLER-transmitter or CONTROLLER-receiver). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions Reset type: SYSRSn 0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module. 1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.

Table 26-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the CNT bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: n = ((I2C input clock frequency/module clock frequency) x 8) The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a CONTROLLER. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a TARGET that needs extra time to detect a START condition. When the I2C module is a TARGET, it ignores a START byte from a CONTROLLER, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: 1. A START condition 2. A START byte (0000 0001b) 3. A dummy acknowledge clock pulse 4. A repeated START condition Then, as normal, the I2C module sends the TARGET address that is in I2CTAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).

Table 26-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits. Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified Reset type: SYSRSn 0h (R/W) = 8 bits per data byte 1h (R/W) = 1 bit per data byte 2h (R/W) = 2 bits per data byte 3h (R/W) = 3 bits per data byte 4h (R/W) = 4 bits per data byte 5h (R/W) = 5 bits per data byte 6h (R/W) = 6 bits per data byte 7h (R/W) = 7 bits per data byte

26.7.2.11 I2CISRC Register (Offset = Ah) [Reset = 0000h]

I2CISRC is shown in Figure 26-31 and described in Table 26-21.

Return to the Summary Table.

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

Figure 26-31. I2CISRC Register

15	14	13	12	11	10	9	8

26.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0000h]

I2CPSC is shown in Figure 26-33 and described in Table 26-23.

Return to the Summary Table.

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.
IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

Figure 26-33. I2CPSC Register

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 26-24. I2CFFTX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

Table 26-24. I2CFFTX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO interrupt level. These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

26.7.2.15 I2CFFRX Register (Offset = 21h) [Reset = 0000h]

I2CFFRX is shown in Figure 26-35 and described in Table 26-25.

Return to the Summary Table.

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

Figure 26-35. I2CFFRX Register

15	14	13	12	11	10	9	8
RESERVED		RXFFRST	RXFFST				
R-0h		R/W-0h	R-0h				
7	6	5	4	3	2	1	0
RXFFINT	RXFFINTCLR	RXFFIENA	RXFFIL				
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 26-25. I2CFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

Chapter 27

Power Management Bus Module (PMBus)

This chapter describes the features and operation of the Power Management Bus (PMBus) module.

27.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. The PMBus is based on SMBus, which uses a similar physical layer to the I2C. This chapter assumes you are familiar with the PMBus, SMBus, and I2C bus specifications.

27.1.2 Features

The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for controller and target modes
- Ability to support Zero Hold Time (mentioned in SMBus3.0 specs)
- 5V Fail safe IO and 20mA sink current support. Refer to the device data sheet for more details
- Ability to support VIH = 1.35V. Refer to the device data sheet for more details
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100kHz
  - Fast Mode: Up to 400kHz
  - Fast Mode Plus: Up to 1MHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Target address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

27.1.3 Block Diagram

Figure 27-1 shows the block diagram for PMBus. The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, the PMBus module also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals:

- **SCL** is the bus clock. SCL is normally controlled by the controller, but can be held low by a target to delay a transaction and allow more time for processing.
- **SDA** is the bidirectional data line.
- **CONTROL** is a target input that can trigger an interrupt. CONTROL can be used to shut down a target device.
- **ALERT** is a target output/controller input that allows a target to request attention from the controller.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set by way of the PMBTIMCLK register to provide a bit clock with respect to the module's configured speed.

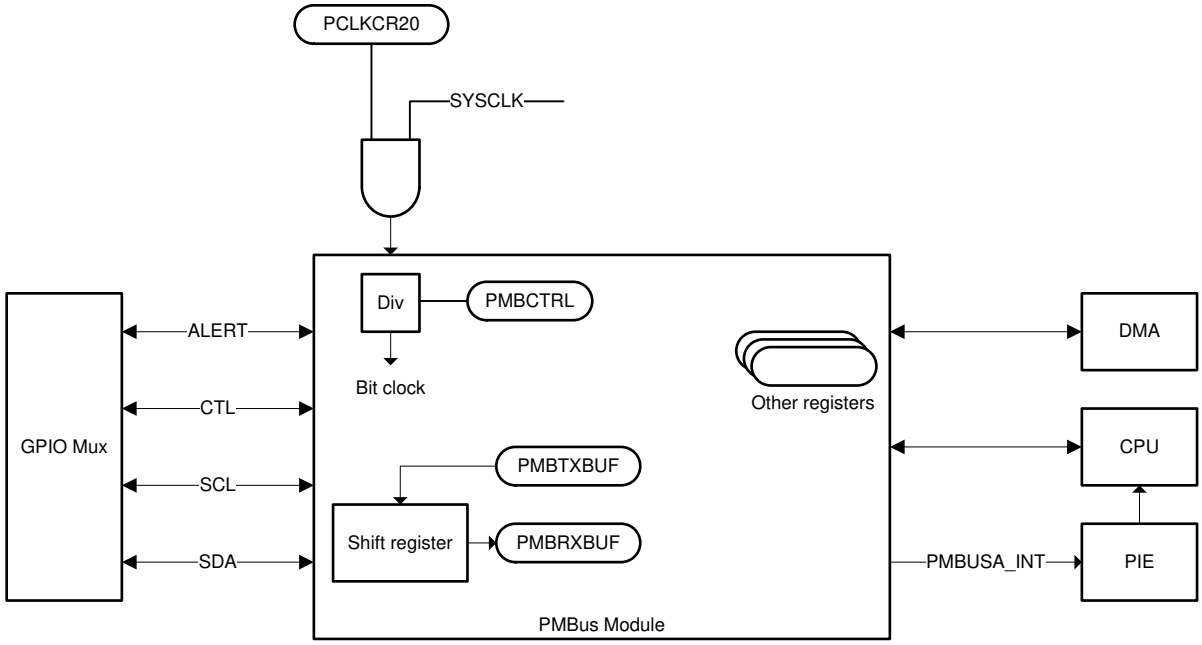

Figure 27-1. PMBus Module Block Diagram

27.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

Note

The GPIO configuration register GPyODR must be set to normal mode when the PMBus is used. The open-drain operation for PMBus is managed by the PMBus module

To support a wider range of PMBus IO levels, certain GPIOs have configurable fail-safe systems, V_{IH} minimum thresholds, and configurable sinking capabilities. ***Specifically, the configurable sink current support is mandated for fast plus mode.***

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

27.3 Target Mode Operation

This section describes the configuration and operation of the PMBus module in target mode.

27.3.1 Configuration

To configure the module, write a clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency with respect to the module's configured speed. To activate target mode, set the TARGET_EN bit in the PMBCTRL register. Next, set up the PMBTCR register. The following options are configurable:

- Target address and mask (TARGET_ADDR and TARGET_MASK): Sets the target address and mask for message acceptance.
- Manual target address acknowledgment (MAN_TARGET_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the target address and mask.
- PEC enable (PEC_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgment (MAN_CMD): Similar to manual target acknowledgment, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX_BYTE_ACK_CNT): This is normally set to the maximum value, which allows the entire receive buffer to be used. However, smaller values can be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgment is done by writing a one to the PMBACK register. Even with automatic acknowledgment, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes much be acknowledged. The PMBus module stretches the clock (hold the clock low) until an ACK is issued. The module then pulls the data line low and releases the clock, providing the ACK signal to the controller.

If the complete message or the last part of the message is less than 4 bytes (or the RX_BYTE_ACK_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit sends a NACK. This can only be done when the module is waiting for an acknowledgment. If a zero is written at any other time, the NACK is issued during the next message.

27.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in target mode. This section is oriented toward the most efficient mode of operation – with automatic address and command acknowledgment and is also oriented toward having Packet Error Checking (PEC) enabled.

If automatic address acknowledgment is disabled, all messages start by setting the TARGET_ADDR_READY bit high. Read commands have two instructions one for the read and one for the write. If automatic command acknowledgment is enabled, the DATA READY bit is set high, as well. If the message has no PEC, the number of bytes available is n-1. For example with PEC, a QUICK COMMAND has one byte. With no PEC, a QUICK COMMAND has zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

27.3.2.1 Quick Command

Quick Commands (Figure 27-2) received by the PMBus module in target mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMBHTA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

Figure 27-2. Quick Command Message

27.3.2.2 Send Byte

A Send Byte message (Figure 27-3) consists of the device address, a single data byte, and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBTCR register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module.

The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte is stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register indicates one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register indicates two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD_BYTE_COUNT) register contains a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

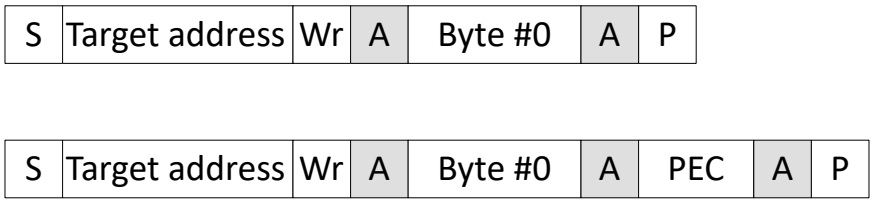

Figure 27-3. Send Byte Message With and Without PEC

27.3.2.3 Receive Byte

A Receive Byte message (Figure 27-4) consists of the device address, a single data byte, and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the target address. The data byte to be sent to the controller is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBTCR register are set to a value of 1. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBTCR register is set to 1, along with the Enable PEC bit (bit 15). The module automatically appends the calculated PEC byte at the completion of the message.

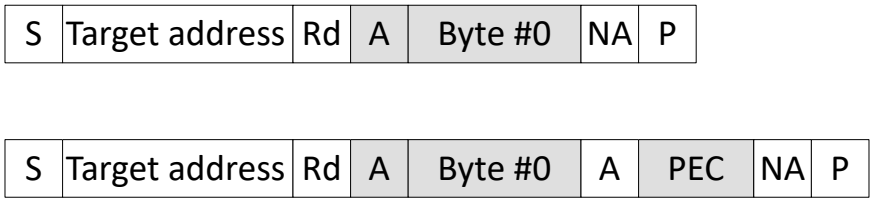

Figure 27-4. Receive Byte Message With and Without PEC

27.3.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 27-5) consist of a target address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBTCR register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the controller. The PMBus module holds SCL low until the firmware responds to the received data.

In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgment back to the controller.

The Write Byte message looks exactly the same as the Send Byte, except the RD_BYTE_COUNT register contains a 3. The Write Word message has a RD_BYTE_COUNT of 4.

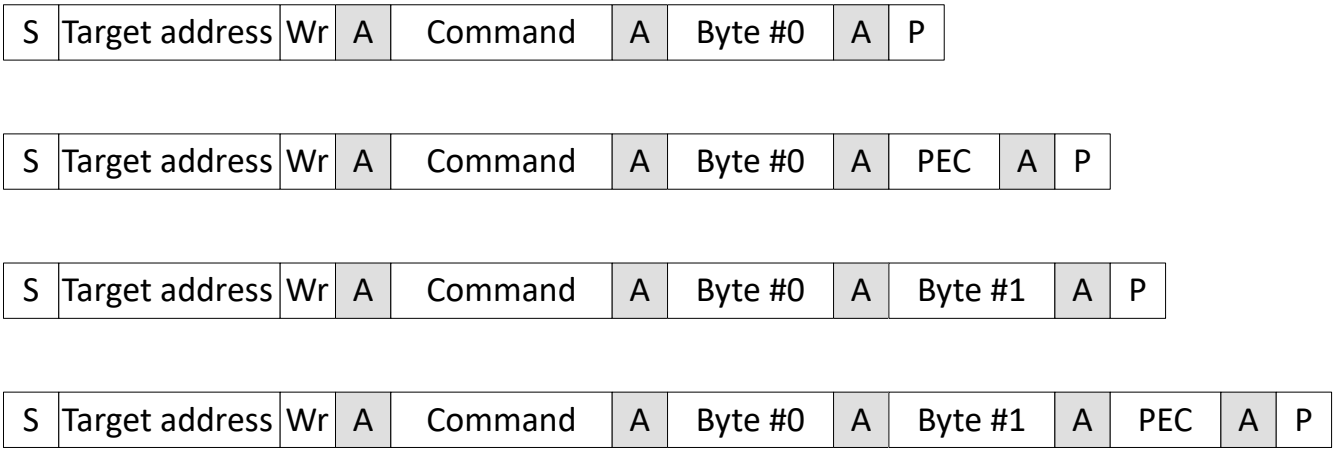

Figure 27-5. Write Byte and Write Word Messages With and Without PEC

27.3.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 27-6) consist of a target address, a command word, received data bytes from a target, and an optional PEC byte. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and target address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBTCR register. If PEC processing is enabled, the Transmit PEC bit must also be asserted. An EOM interrupt indicates completion of the message to the Controller.

When the repeated start (Sr) signal is received, the Data Ready bit is asserted with a RD_BYTE_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit is asserted. If data has already been written to the PMTXBUF register before the Device Address is received, the Data Request bit is not asserted. So if group commands are also expected, read the Data Ready with a RD_BYTE_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If the event is an EOM, the command must be processed as a group send byte. If the event is a Data Request, the command must be processed as a read. Depending on the command, the event can be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits can possibly be set between polling intervals. This must be considered in the design of the firmware.

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. Make sure that the values in the PMBTCR register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes must be written to PMBTXBUF at the same time. After the controller receives the message, the controller NACKs the last byte to indicate that the correct number of bytes have been received. This causes the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

Figure 27-6. Read Byte and Read Word Messages With and Without PEC

27.3.2.6 Process Call

The Process Call (Figure 27-7) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, following receipt of the repeated start and target address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the controller can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the controller. If PEC processing is enabled, the Transmit PEC bit within the PMBTCR register is asserted. The EOM interrupt indicates the read word portion of the Process Call message has been completed by the module.

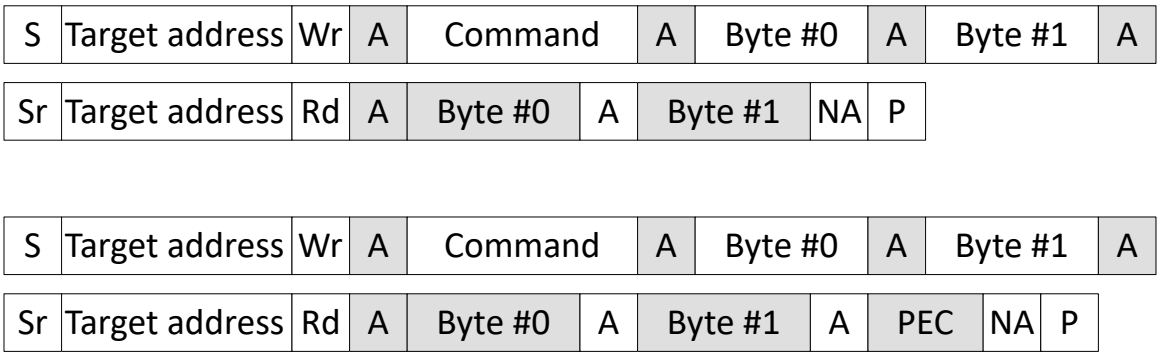

Figure 27-7. Process Call Message With and Without PEC

27.3.2.7 Block Write

The Block Write (Figure 27-8) protocol is similar to Write Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module drives the clock line low, stalling the bus. The data ready interrupts continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

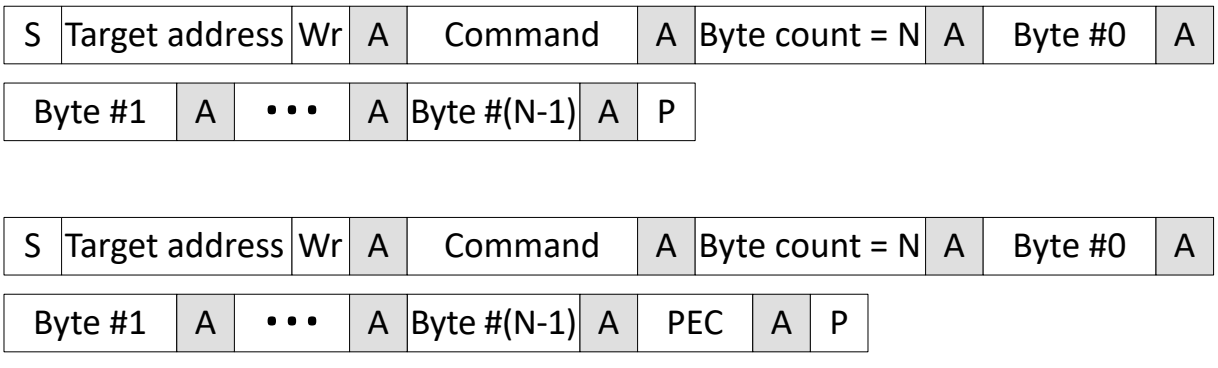

Figure 27-8. Block Write Message With and Without PEC

27.3.2.8 Block Read

The Block Read (Figure 27-9) protocol is similar to a Read Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated target address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the controller can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module issues a data request interrupt and holds SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

Block read starts the same as Read Word or Read Byte, but TX_COUNT is loaded with a 4 the first time, and TX_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the controller is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX_COUNT and then writes the 4 bytes to PMBTXBUF. TX_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX_PEC bit, and writes the data to PMBTXBUF. The PMBus module writes out the data, followed by the PEC, and then the EOM bit is set when the controller NACKs the PEC.

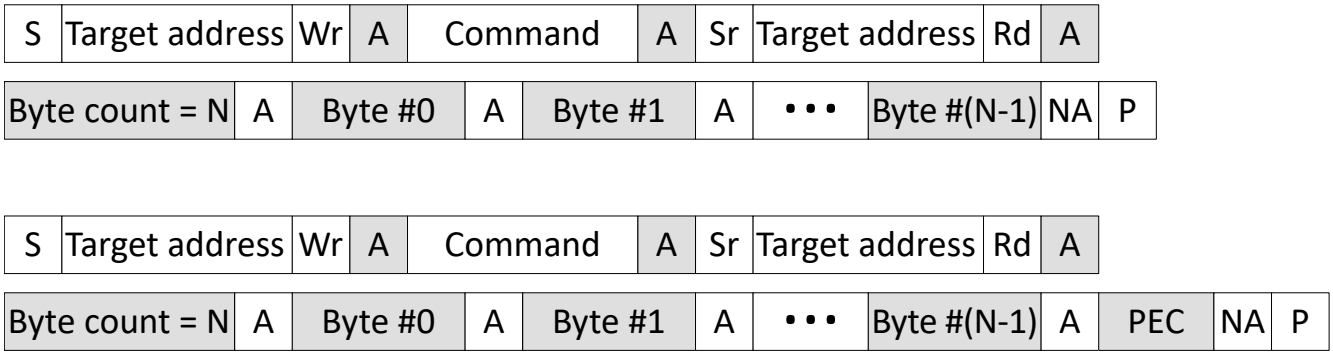

Figure 27-9. Block Read Message With and Without PEC

27.3.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 27-10) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgment of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware is required to load transmit data to send to the controller. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the controller.

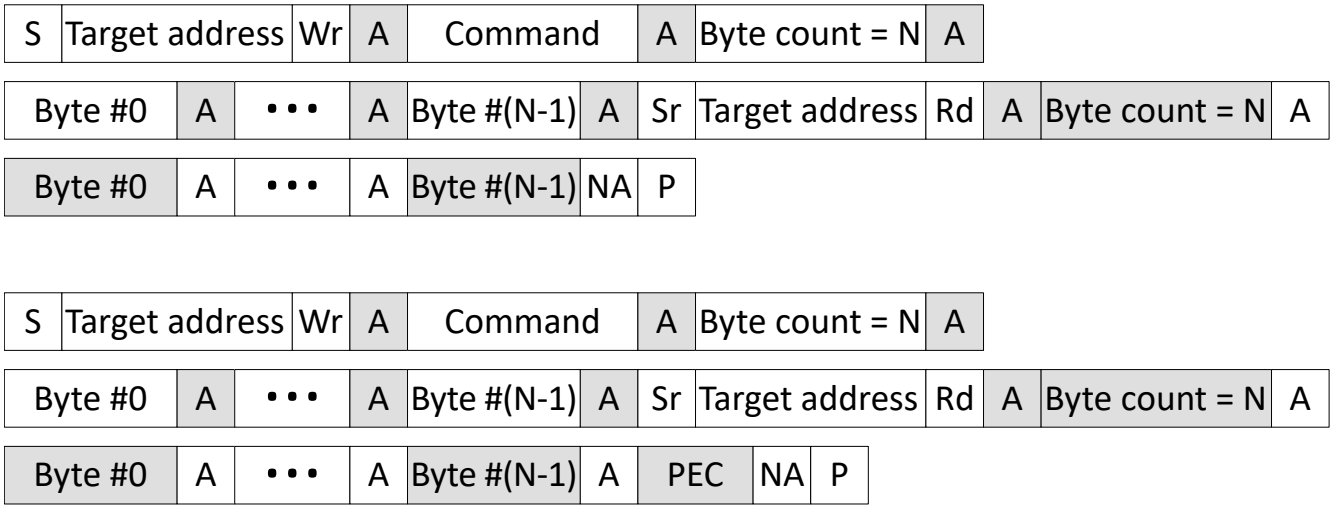

Figure 27-10. Block Write-Block Read Process Call Message With and Without PEC

27.3.2.10 Alert Response

The Alert Response Message (Figure 27-11) is utilized when the controller detects an alert condition from a target on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgment to the controller and sends the programmed target address within the PMBTCR register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module clears the alert condition and the enable bit within the PMBCTRL register.

In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired target address back to the controller. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the controller.

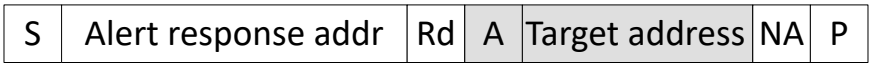

Figure 27-11. Alert Response Message

27.3.2.11 Extended Command

The PMBus module provides support for extended commands that allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte and Write Word messages (Figure 27-12), the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte must hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

For the Extended Command Read Byte and Read Word messages (Figure 27-13), the module generates a data ready and data request interrupt following reception of the repeated device address. The two command bytes are found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware is required to load transmit data to complete the message back to the controller.

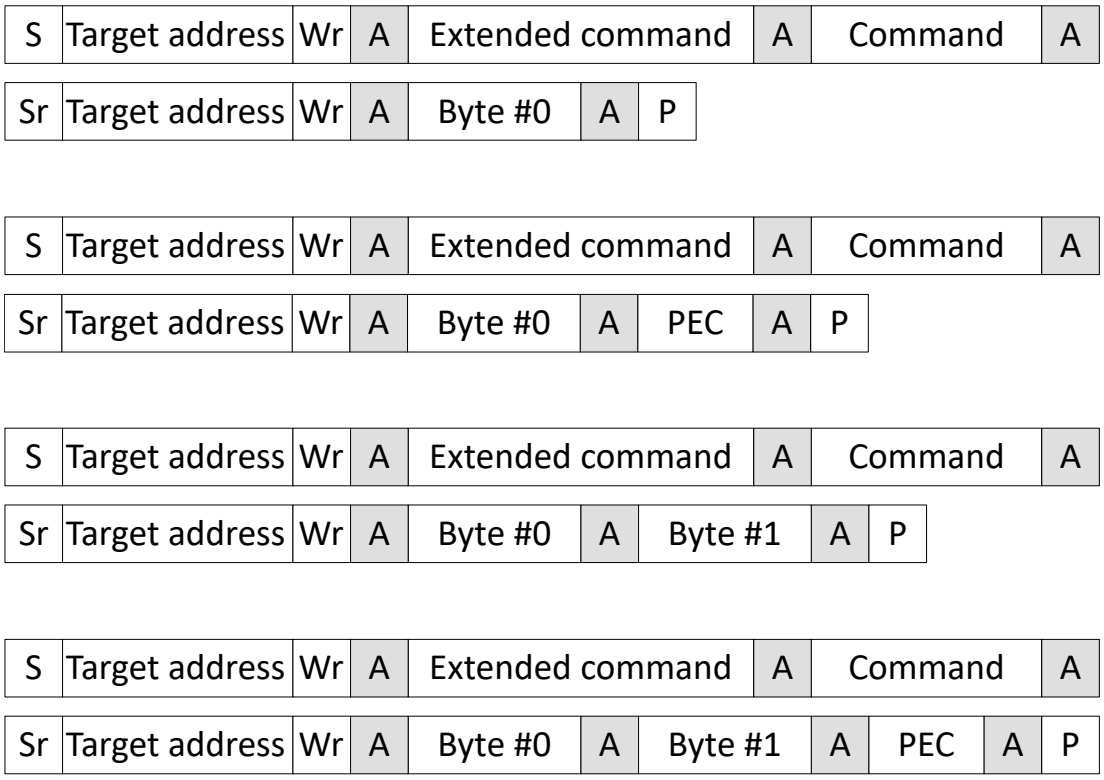

Figure 27-12. Extended Command Write Byte and Write Word Messages With and Without PEC

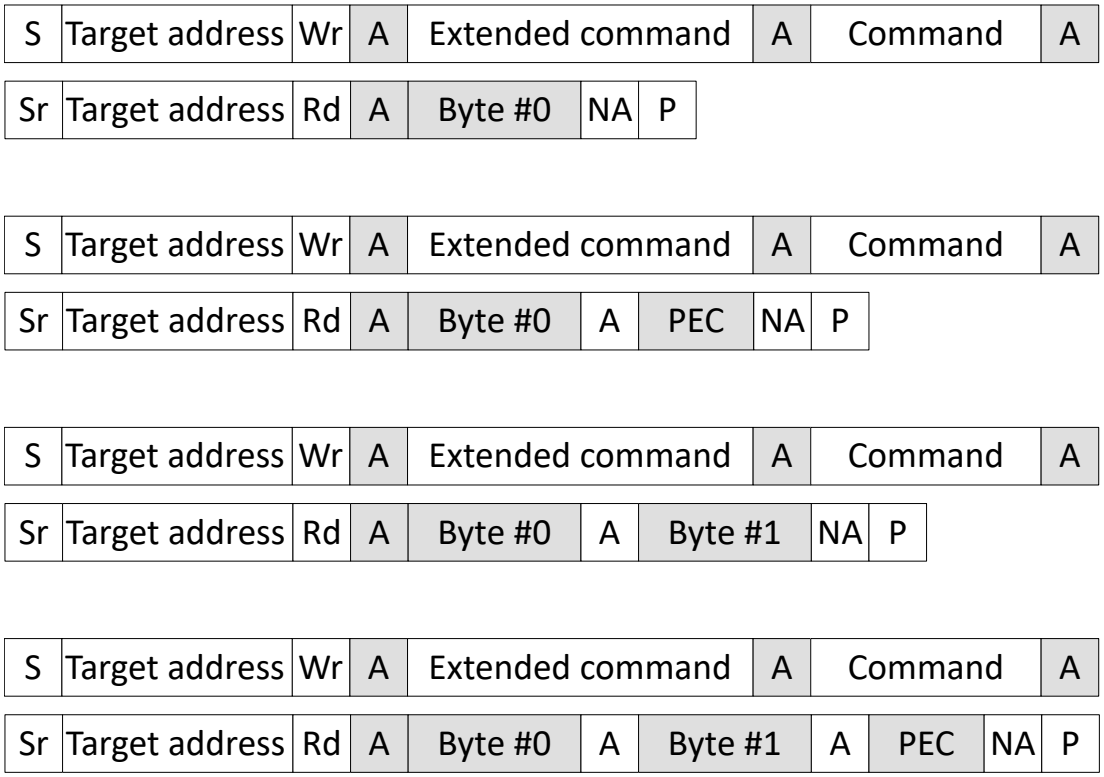

Figure 27-13. Extended Command Read Byte and Read Word Messages With and Without PEC

27.3.2.12 Group Command

The PMBus module supports the Group Command protocol. The Group Command (Figure 27-14) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware must wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

For Group Commands, the data ready bit is set as soon as the repeated start is received. The data can then be read into memory. But the data must not be acted upon until the EOM bit is set, which occurs when all of the messages have been received. Other than this delayed EOM, there is no difference for the target firmware in receiving a Group Command than any other write message.

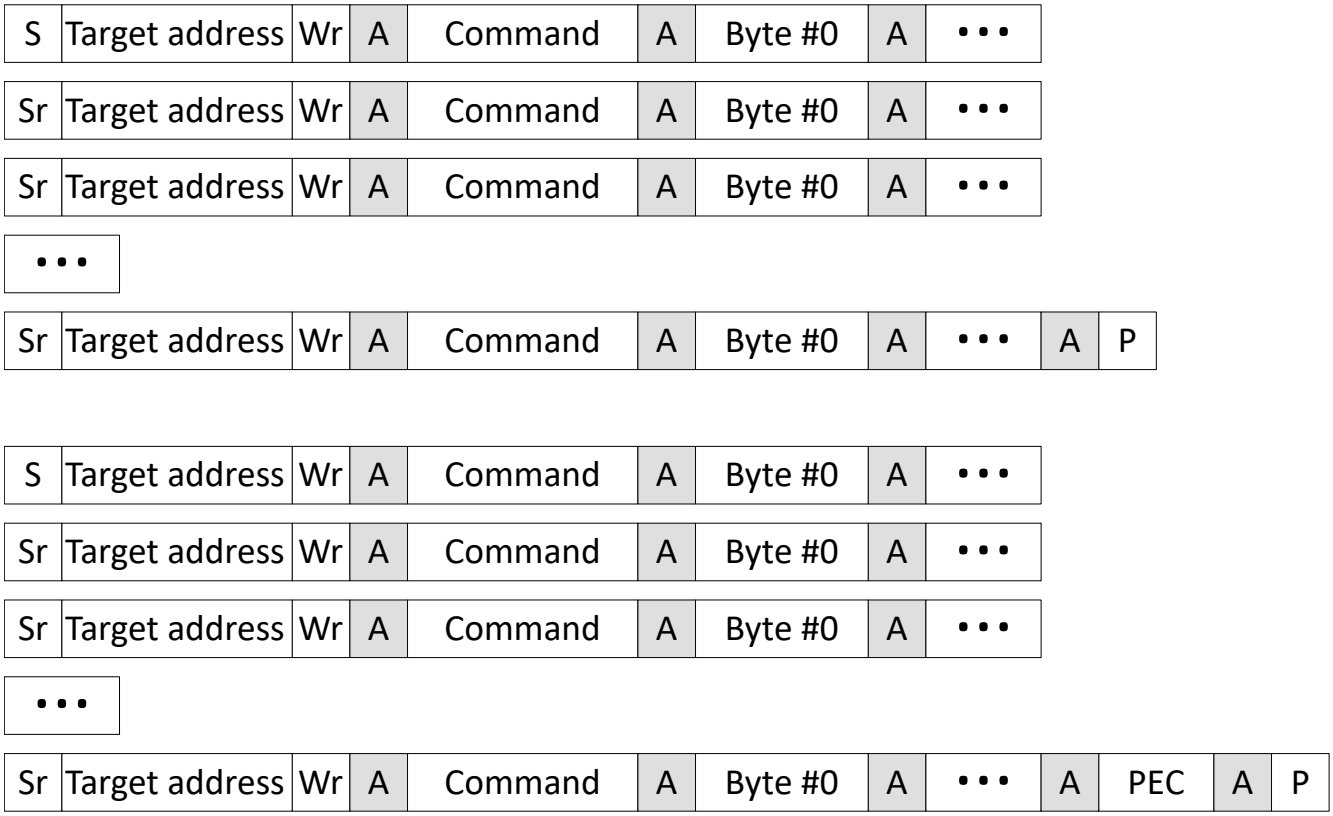

Figure 27-14. Group Command Message With and Without PEC

27.4 Controller Mode Operation

This section describes the configuration and operation of the PMBus module in controller mode.

27.4.1 Configuration

First, write a clock divider to the PMBCTRL register CLKDIV field to produce a bit clock frequency with respect to the module's configured speed. To activate controller mode, set the CONTROLLER_EN bit and clear the TARGET_EN bit in the PMBCTRL register. For each transaction, set up the PMBCCR register. The following options are configurable:

- Target address (TARGET_ADDR): Sets the target address for the next transaction.
- PEC enable (PEC_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT_CMD): When set, uses two bytes for commands.
- Command code enable (CMD_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP_CMD and PRC_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBCCR register starts a transfer.

Manual acknowledgment of received data is not needed.

27.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

27.4.2.1 Quick Command

Quick commands (Figure 27-15) are initiated in controller mode by simply programming the desired target device address into the PMBCCR. The byte count within the PMBCCR register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module monitors the target acknowledgment of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

Figure 27-15. Quick Command Message

27.4.2.2 Send Byte

A Send Byte message (Figure 27-16) consists of the device address, a single data byte, and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the target is loaded into bits 7-0 of the PMBTXBUF register. The PMBCCR register is configured with the device address. To transmit a PEC byte with the message, the PEC_EN bit within the PMBCCR register is asserted high when the address is programmed.

After programming the PMBCCR register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the target properly acknowledged the transmitted data.

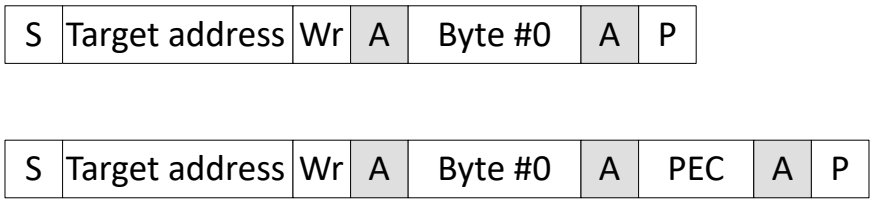

Figure 27-16. Send Byte Message With and Without PEC

27.4.2.3 Receive Byte

A Receive Byte message (Figure 27-17) consists of the device address, a single data byte, and an optional PEC byte. Data is being read from the target in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC_EN into the PMBCCR register. The R/W bit is enabled high to indicate a read message type (data transmitted from target to controller).

After programming the PMBCCR register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper target acknowledgment of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC_EN was asserted in the PMBCCR register, the PEC_VALID bit in the PMBSTS register is also checked to make sure a proper PEC byte was received from the target with the received data.

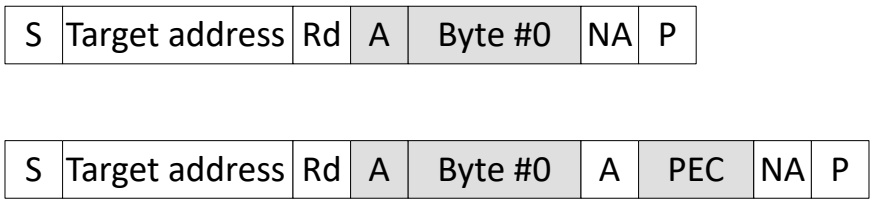

Figure 27-17. Receive Byte Message With and Without PEC

27.4.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 27-18) consist of a device address, a command byte, transmitted data bytes, and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding target module. Similar to the Send Byte protocol, the PMBCCR register is configured to send 1 or 2 bytes, the CMD_EN bit is set to enable command byte transmission and the optional PEC_EN bit is set.

With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the target. The data bytes are programmed into bits 15-8 and bits 23-16.

After programming the PMBCCR register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the target acknowledged the message properly.

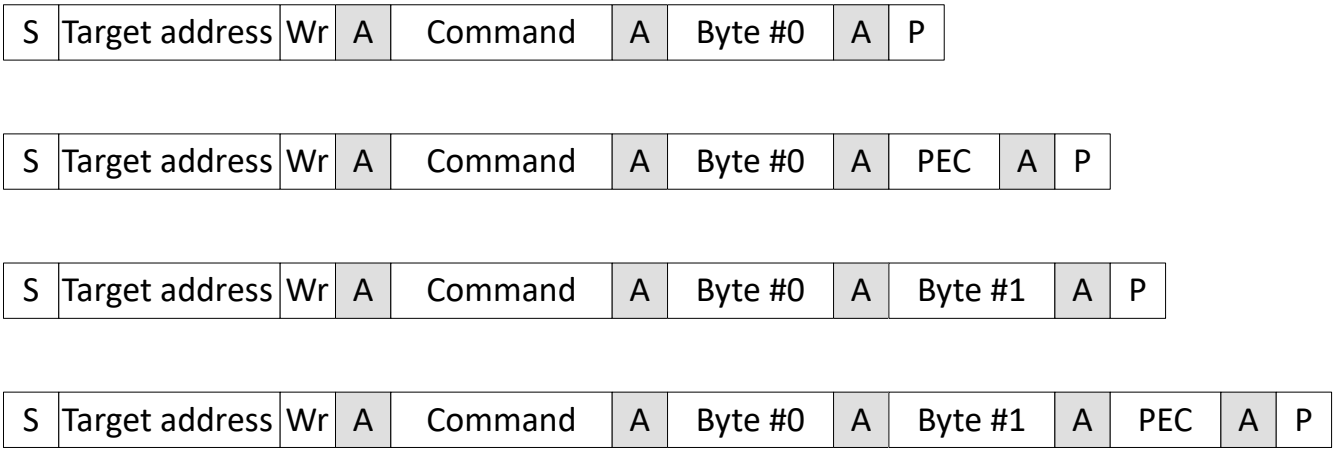

Figure 27-18. Write Byte and Write Word Messages With and Without PEC

27.4.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 27-19) consist of a device address, a command byte, received data bytes from a target, and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the target. Similar to the Receive Byte Protocol, the PMBCCR register is configured to receive 1 or 2 bytes, the CMD_EN bit is set and the PEC_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module automatically terminates the message after the expected number of bytes is received from the target or if the target does not properly acknowledge any portion of the message.

In addition to programming the PMBCCR register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the target is found in the PMBRXBUF register.

Figure 27-19. Read Byte and Read Word Messages With and Without PEC

27.4.2.6 Process Call

The Process Call (Figure 27-20) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the target as an option to the message protocol. The PMBCCR register includes a PRC_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module automatically generates a repeated start condition and initiates the Read Word portion of the message when the process call bit is enabled.

To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBCCR register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register can indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the target acknowledgment of the transmit data. If PEC processing is enabled, the PEC_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the target during the Read Word part of the message.

The PRC_CALL bit within the PMBCCR register must be disabled for the next non-Process Call message. Note that any write to the PMBCCR register initiates a message, so reconfiguration of the controller is not recommended until the firmware requires a new message to be transmitted.

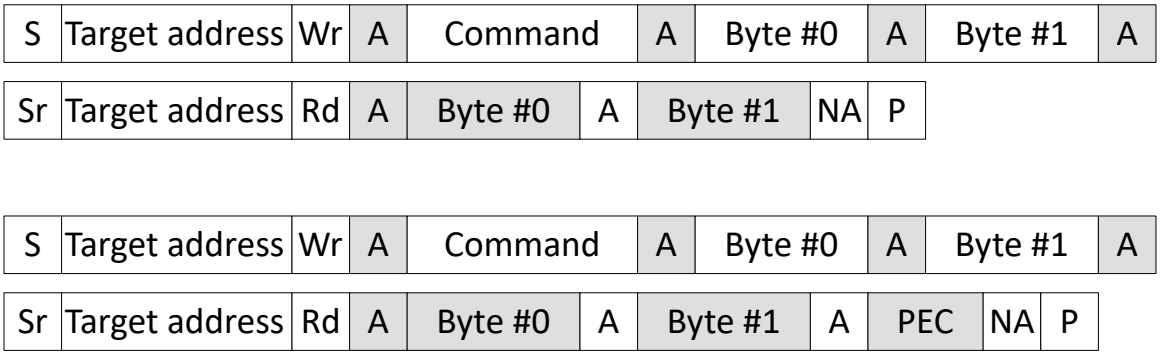

Figure 27-20. Process Call Message With and Without PEC

27.4.2.7 Block Write

The Block Write (Figure 27-21) protocol is similar to a Write Word in structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the target.

To initiate a Block Write message on the bus, the PMBCCR register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module automatically inserts the block length into the message, if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first 3 data bytes following the block length.

Following programming of the PMBCCR register, the Block Write message is transmitted. If the block length exceeds 3 bytes, the PMBus module provides a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware utilizes all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the target accepted the block of write data.

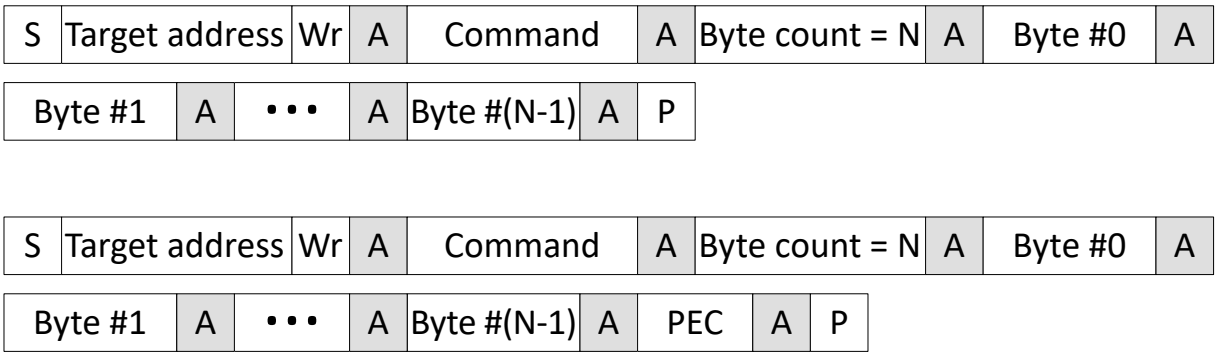

Figure 27-21. Block Write Message With and Without PEC

27.4.2.8 Block Read

The Block Read (Figure 27-22) protocol is similar to a Read Word in structure, with the exception that there are more than 2 data bytes received from the target. The first data byte transmitted by the target represents the block length of the data being written by the target. If PEC processing is enabled, the target appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBCCR register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any target address and the block length bytes in the message. The command byte to be transmitted to the target is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBCCR register.

After configuring the PMBCCR register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the target. If the block length is 3, the EOM interrupt is received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware can verify the received PEC upon detection of the End of Message interrupt.

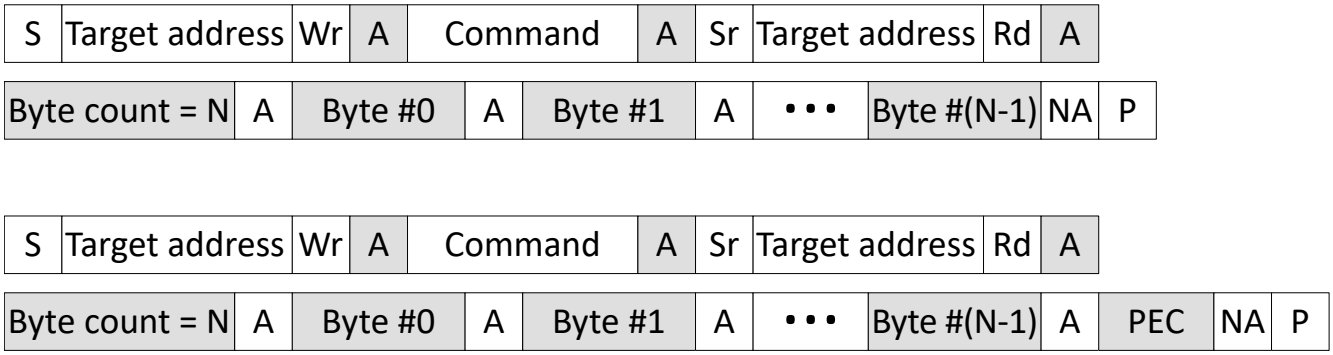

Figure 27-22. Block Read Message With and Without PEC

27.4.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 27-23) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the controller is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBCCR register provides the length of the Block Write portion of the message. In addition, the PRC_CALL bit within the PMBCCR register must be enabled. Upon completion of the Block Write part of the message, the PMBus module automatically issues a Repeated Start condition on the PMBus and starts transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as a simple Block Read Message.

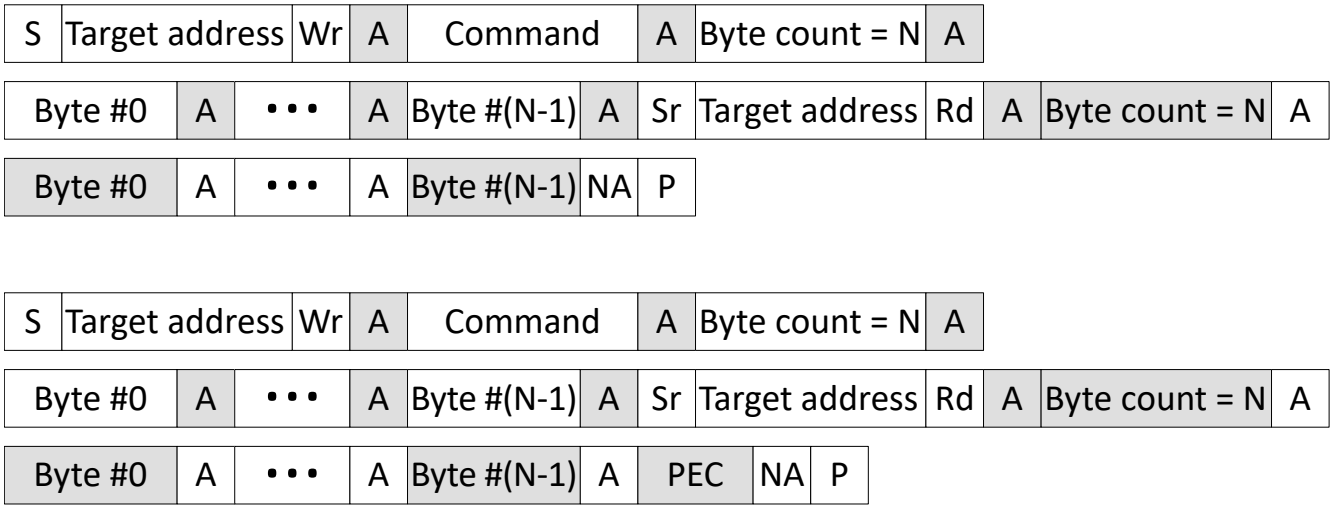

Figure 27-23. Block Write-Block Read Process Call Message With and Without PEC

27.4.2.10 Alert Response

The Alert Response Message (Figure 27-24) is utilized when the controller detects an alert condition from a target. In controller mode, the Alert Response Message is simply a Receive Byte message with PEC disabled and the target address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (target desires to communicate with the controller). Programming the PMBCCR register with the Alert Response address initiates the Alert Response message and provides the device address of the target requesting service. The device address is found in the PMBRXBUF register following receipt of the EOM interrupt.

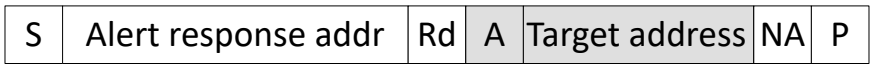

Figure 27-24. Alert Response Message

27.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT_CMD bit within the PMBCCR register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Write Byte and Write Word (Figure 27-25) and the Read Byte and Read Word (Figure 27-26) protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and target address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module interprets the EXT_CMD bit and makes the appropriate format changes.

S	Target address	Wr	A	Extended command	A	Command	A
Sr	Target address	Wr	A	Byte #0	A	P	

S	Target address	Wr	A	Extended command	A	Command	A
Sr	Target address	Wr	A	Byte #0	A	PEC	A	P

S	Target address	Wr	A	Extended command	A	Command	A
Sr	Target address	Wr	A	Byte #0	A	Byte #1	A	P

Sr	Target address	Wr	A	Byte #0	A	Byte #1	A	PEC	A	P

Figure 27-25. Extended Command Write Byte and Write Word Messages With and Without PEC

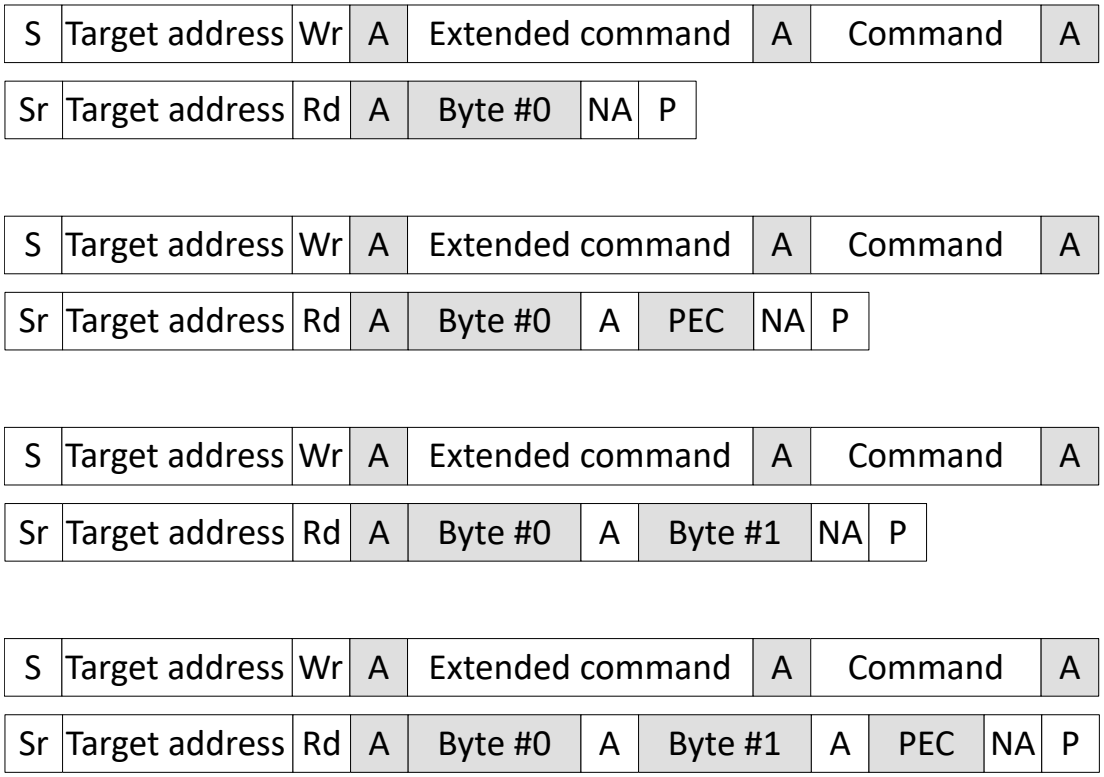

Figure 27-26. Extended Command Read Byte and Read Word Messages With and Without PEC

27.4.2.12 Group Command

The Group Command (Figure 27-27) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP_CMD bit within the PMBCCR register must be set when programming the target address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBCCR register. The PMBus module sends a repeated start on the bus and begins the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP_CMD bit when programming the PMBCCR register.

27.6 PMBUS Registers

This Section describes the PMBUS Registers.

27.6.1 PMBUS Base Address Table

Table 27-2. PMBUS Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
PmbusaRegs	PMBUS_REGS	PMBUSA_BASE	0x0000_6400	YES	YES	YES	YES

27.6.2 PMBUS_REGS Registers

Table 27-3 lists the memory-mapped registers for the PMBUS_REGS registers. All register offset addresses not listed in Table 27-3 should be considered as reserved locations and the register contents should not be modified.

Table 27-3. PMBUS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	PMBCCR	PMBUS CONTROLLER Mode Control Register	EALLOW	Go
2h	PMBTXBUF	PMBUS Transmit Buffer		Go
4h	PMBRXBUF	PMBUS Receive buffer		Go
6h	PMBACK	PMBUS Acknowledge Register		Go
8h	PMBSTS	PMBUS Status Register		Go
Ah	PMBINTM	PMBUS Interrupt Mask Register	EALLOW	Go
Ch	PMBTCR	PMBUS TARGET Mode Configuration Register	EALLOW	Go
Eh	PMBHTA	PMBUS Hold TARGET Address Register		Go
10h	PMBCTRL	PMBUS Control Register	EALLOW	Go
12h	PMBTIMCTL	PMBUS Timing Control Register	EALLOW	Go
14h	PMBTIMCLK	PMBUS Clock Timing Register	EALLOW	Go

1Ch	PMBTIMHIGHTIMOUT	PMBUS Clock High Timeout Value Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 27-4 shows the codes that are used for access types in this section.

Table 27-4. PMBUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

27.6.2.1 PMBCCR Register (Offset = 0h) [Reset = 00000000h]

PMBCCR is shown in Figure 27-28 and described in Table 27-5.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
31-21	RESERVED	R	0h	Reserved
20	PRC_CALL	R/W	0h	0 = Default state for all messages besides Process Call message 1 = Enables transmission of Process Call message Reset type: SYSRSn
19	GRP_CMD	R/W	0h	0 = Default state for all messages besides Group Command message 1 = Enables transmission of Group Command message Reset type: SYSRSn
18	PEC_ENA	R/W	0h	0 = Disables PEC processing 1 = Enables PEC byte transmission/reception Reset type: SYSRSn
17	EXT_CMD	R/W	0h	0 = Use 1 byte for Command Code 1 = Use 2 bytes for Command Code Reset type: SYSRSn
16	CMD_ENA	R/W	0h	0 = Disables use of command code on CONTROLLER initiated messages 1 = Enables use of command code on CONTROLLER initiated messages Reset type: SYSRSn
15-8	BYTE_COUNT	R/W	0h	Indicates number of data bytes transmitted in current message. Byte count does not include any device addresses, command words or block lengths in block messages. In block messages, the PMBus Interface automatically inserts the block length into the message based on the byte count setting. The firmware only needs to load the address, command words and data to be transmitted. PMBus Interface supports byte writes up to 255 bytes. Reset type: SYSRSn

Table 27-5. PMBCCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-1	TARGET_ADDR	R/W	0h	Specifies the address of the TARGET to which the current message is directed towards. Reset type: SYSRSn

Table 27-11. PMBTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-21	RX_BYTE_ACK_CNT	R/W	3h	Configures number of data bytes to automatically acknowledge when receiving data in TARGET mode. 00 = 1 byte received by TARGET. Firmware is required to manually acknowledge every received byte. 01 = 2 bytes received by TARGET. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte. 10 = 3 bytes received by TARGET. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte. 11 = 4 bytes received by TARGET. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte Reset type: SYSRSn
20	MAN_CMD	R/W	0h	0 = TARGET automatically acknowledges received command code 1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message Reset type: SYSRSn
19	TX_PEC	R/W	0h	Asserted when the TARGET needs to send a PEC byte at end of message. PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 18:16). Reset type: SYSRSn

Table 27-11. PMBTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18-16	TX_COUNT	R/W	0h	0 = No bytes valid 1 = One byte valid, Byte #0 (Bits 7:0 of Transmit Data Register) 2 = Two bytes valid, Bytes #0 and #1 (Bits 15:0 of Transmit Data Register) 3 = Three bytes valid, Bytes #0-2 (Bits 23:0 of Transmit Data Register) 4 = Four bytes valid, Bytes #0-3 (Bits 31:0 of Transmit Data Register) Reset type: SYSRSn
15	PEC_ENA	R/W	0h	0 = PEC processing disabled 1 = PEC processing enabled Reset type: SYSRSn
14-8	TARGET_MASK	R/W	7Fh	Used in address detection, the TARGET mask enables acknowledgement of multiple device addresses by the TARGET. Writing a '0' to a bit within the TARGET mask enables the corresponding bit in the TARGET address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the TARGET mask defaults to 7Fh, indicating the TARGET will only acknowledge the address programmed into the TARGET Address (Bits 6-0). Reset type: SYSRSn
7	MAN_TARGET_ACK	R/W	0h	0 = TARGET automatically acknowledges device address specified in TARGET_ADDR, Bits 6:0 1 = Enables the Manual TARGET Address Acknowledgement Mode. Firmware is required to read received address and acknowledge on every message Note: When bit 31 (I2C_mode) of PMBCTRL register is set it is recommended to use manual acknowledging of TARGET address only (MAN_TARGET_ACK =1). Reset type: SYSRSn
6-0	TARGET_ADDR	R/W	7Ch	Configures the current device address of the TARGET. Used in automatic TARGET address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the TARGET Address bits and the mask configured in the TARGET Mask bits. If matching, the TARGET will acknowledge the device address. Reset type: SYSRSn

27.6.2.8 PMBHTA Register (Offset = Eh) [Reset = 00000000h]

PMBHTA is shown in Figure 27-35 and described in Table 27-12.

Return to the Summary Table.

Chapter 28

Modular Controller Area Network (MCAN)

This chapter describes the Modular Controller Area Network (MCAN). MCAN supports both classic CAN and CAN FD protocols.

28.1 MCAN Introduction

The Controller Area Network (CAN) is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. CAN has high immunity to electrical interference and the ability to detect various type of errors. In CAN, many short messages are broadcast to the entire network, which provides data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with flexible data-rate) protocols. The CAN FD feature allows higher throughput and increased payload per data frame. Classic CAN and CAN FD devices can coexist on the same network without any conflict provided that partial network transceivers, which can detect and ignore CAN FD without generating bus errors, are used by the classic CAN devices. The MCAN module is compliant to ISO 11898-1:2015.

Note

The availability of the CAN FD feature is dependent on the device's part number. Refer to the device data sheet for more information.

Figure 28-1 shows an overview of the MCAN module.

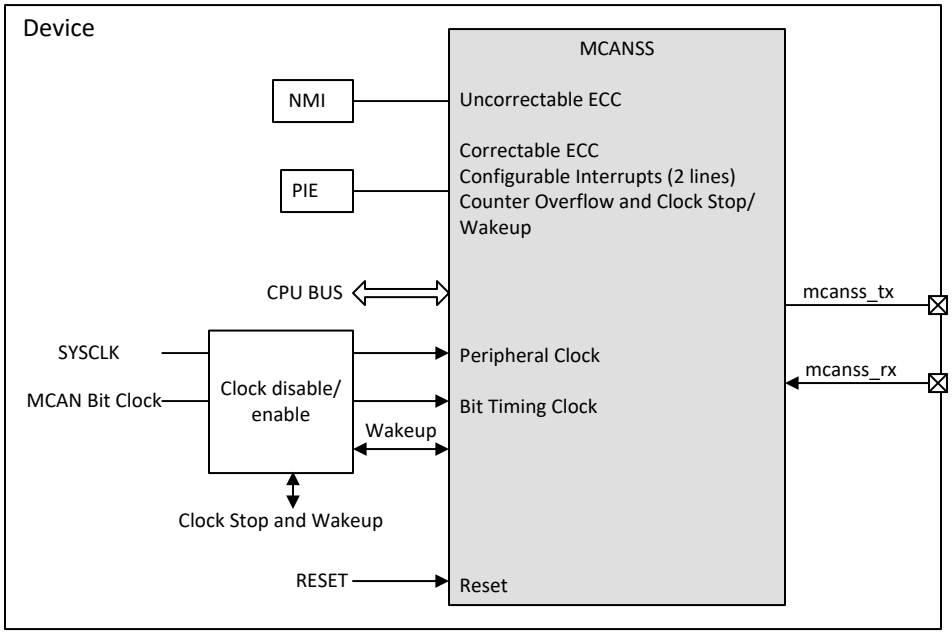

Figure 28-1. MCAN Module Overview

28.1.1 MCAN Related Collateral

Foundational Materials

- C2000 Academy - MCAN
- CAN and CAN FD Overview (Video)
- CAN and CAN FD Protocol (Video)

Getting Started Materials

- *Getting Started with the MCAN (CAN FD) Module Application Report*

28.1.2 MCAN Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit Event FIFO, up to 32 elements
- Up to 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Loop-back mode for self-test
- Maskable interrupt (two configurable interrupt lines, correctable ECC, counter overflow, and clock stop or wakeup)
- Non-maskable interrupt (uncorrectable ECC)
- Two clock domains (CAN clock and host clock)
- ECC check for Message RAM
- Clock stop and wakeup support
- Timestamp counter
- 1-Mbps nominal bit rate, 5-Mbps data bit rate

Non-supported features:

- Host bus firewall
- Clock calibration
- Debug over CAN

28.2 MCAN Environment

The CAN network physical layer consists of a two-wire differential bus, usually twisted pair, and provides a high level of interference immunity. An external CAN transceiver IC is needed to access the bus.

Figure 28-2 shows typical MCAN wiring. Table 28-1 describes the external signals of the MCAN module.

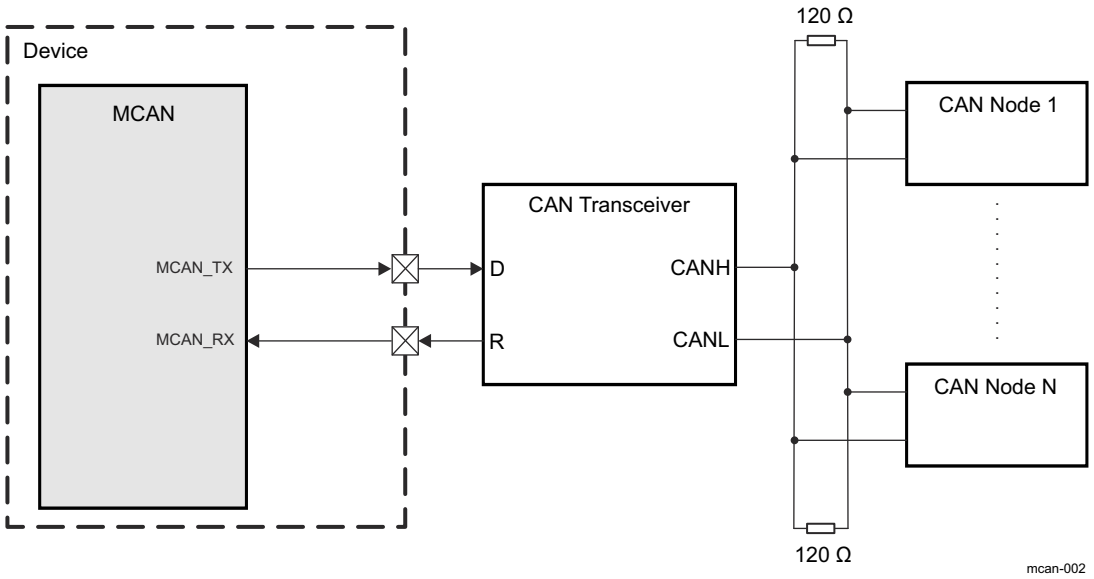

Figure 28-2. MCAN Typical Bus Wiring

Table 28-1. MCAN I/O Description

Module Signal	I/O	Description	Value at Reset
MCAN_RX	Input	Serial data input from external CAN transceiver.	HiZ
MCAN_TX	Output	Serial data output to external CAN transceiver.	HiZ

Note

See the *Terminal Configurations and Functions* section in the device data sheet and the *General-Purpose Input/Output (GPIO)* chapter to configure this peripheral to be connected to the device pins.

28.3 CAN Network Basics

The network basics are:

- The CAN bus is a 2-wire differential bus using non-return-to-zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- When the bus is idle, any node can initiate a transmission to any other node (or nodes). When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique makes sure messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier-based, not address-based.
- The content of the message is labeled by the identifier that is unique throughout the network (for example: RPM, temperature, position, pressure, and so forth).
- All nodes on the network receive the message and each performs an acceptance test on the identifier. If the message is relevant, the message is processed; otherwise, the message is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

28.4 MCAN Integration

Figure 28-3 shows the integration of the MCAN module in the device.

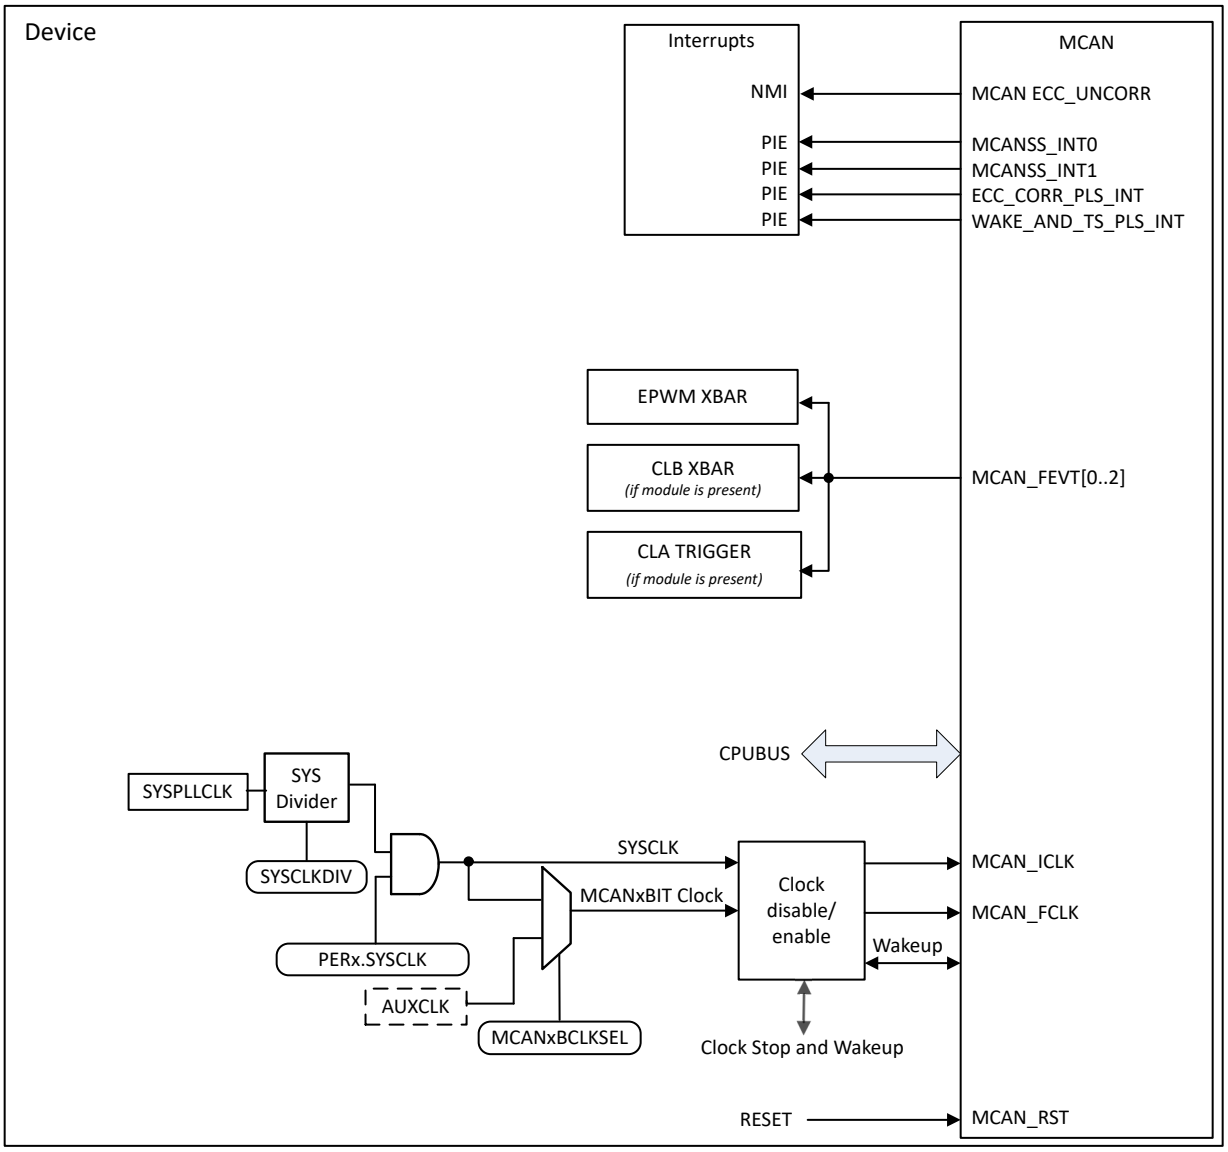

Figure 28-3. MCAN Integration

Table 28-2 and Table 28-3 summarize the integration of the MCAN module in the device.

Table 28-2. MCAN Clocks and Resets

Destination Signal Name	Source Signal Name	Description
Clocks		
MCAN_ICLK	SYSCLK	Interface clock for the MCAN module
MCAN_FCLK	MCANxBIT Clock	Bit timing clock for MCAN
Resets		
MCAN_RST	RESET	Asynchronous reset signal to the MCAN module

Table 28-3. MCAN Hardware Requests

Interrupt Requests(1)	
Source Signal Name	**Description**

(1) See the PIE Channel Mapping section in the *System Control and Interrupts* chapter for interrupt assignments.
(2) See the ePWM XBAR Mux Configuration table in the *Crossbar (X-BAR)* chapter for the trigger position.
(3) See the CLB X-BAR Mux Configuration table in the *Crossbar (X-BAR)* chapter for the trigger position.
(4) See the Configuration Options table in the *Control Law Accelerator (CLA)* chapter for the trigger value.

Note

For more information about the CLA_triggers, see the *Control Law Accelerator (CLA)* chapter.

For more information about the CLB XBAR, see the *Configurable Logic Block (CLB)* chapter.

For more information about the ePWM XBAR module, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

28.5 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The data bit rate can be programmed to values up to 5Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly using the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 28-4 shows the MCAN module block diagram, followed by the description of the MCAN module blocks.

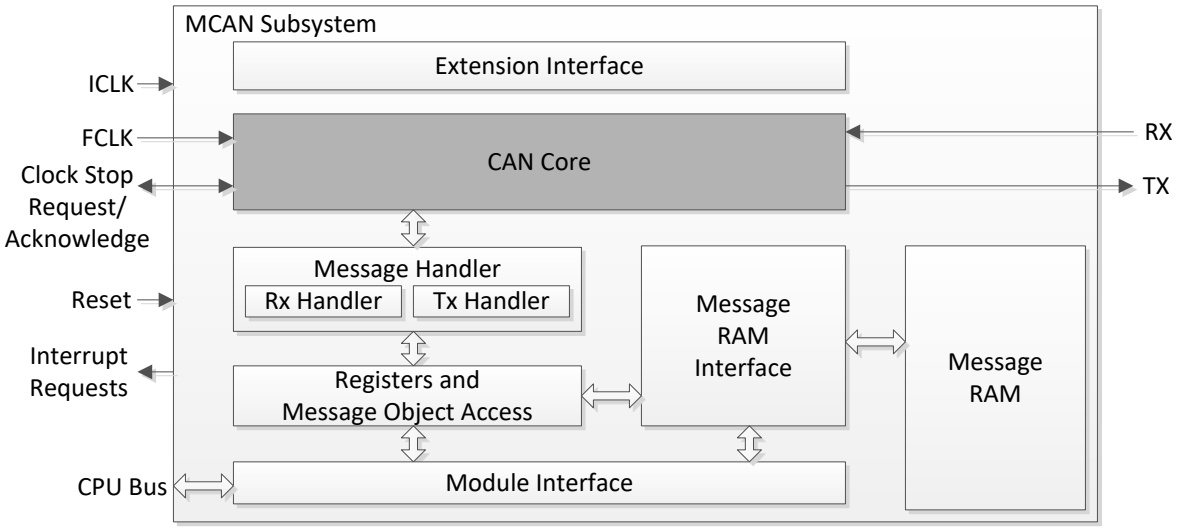

Figure 28-4. MCAN Block Diagram

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. The CAN handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler**: the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. The Message Handler also handles the acceptance filtering and Interrupt generation as programmed in the control registers.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 28.5.16).
- **Message RAM Interface**: enables a connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access**: Data consistency is provided by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface**: The MCAN module registers are accessed by the user's software through a 32-bit peripheral bus interface.
- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface**: All selected internal status and control signals are routed to this interface (except for the indication signals of configuration change enable bit (MCAN_CCCR.CCE) and Interrupt Register bits (MCAN_IR).

28.5.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- Host Clock : peripheral synchronous clock (MCAN_ICLK) as the general module clock source, and
- CAN Clock: peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module, there is a synchronization mechanism implemented to make sure there is safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and conversely, and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

Note

MCAN_ICLK must always be higher or equal to MCAN_FCLK, to achieve a stable functionality of the MCAN module: $f_{ICLK} \geq f_{FCLK}$

The CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than the classic CAN. For performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK for the system. Lower N-divider values increase the loop bandwidth of the PLL, which in turn improves timing margins for CAN-FD.

28.5.2 Interrupt Requests

The MCAN module generates interrupt requests and is configured using the Host CPU. The Suspend mode prevents the interrupt requests from propagating to the Host CPU. The MCAN core has two interrupt lines and 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are level high interrupts. The MCAN core provides two interrupt requests (MCANSS_INT0 and MCANSS_INT1).

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module supports External Timestamp Counter. The External Timestamp Counter produces an interrupt when the count rolls over (see Section 28.5.10.1).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status Register (MCANSS_IES)
- End Of Interrupt Register (MCANSS_EOI)
- External Timestamp Prescaler Register (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter Register (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

To clear IRQ_INT0, IRQ_INT1, and TS_WAKE interrupts, write to the EOI bit field for the corresponding interrupt number that is described in the MCANSS_EOI register. When the MCAN is used by the CPU, in addition to clearing the interrupt sources, clear the interrupt by writing 1 to PIEACK register in the bit position for group 9 (refer to the *PIE Channel Mapping* section of the *System Control and Interrupts* chapter) for successive MCAN interrupts to be recognized.

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write a 1 to the EOI registers (MCANERR_SEC_EOI.EOI_WR/ MCANERR_DED_EOI.EOI_WR). For more information, see Section 28.5.12.2.

28.5.3 Operating Modes

The operating modes are discussed in the following sections.

28.5.3.1 Software Initialization

A software initialization begins when the MCAN_CCCR.INIT bit is set to 1. This is done either by software or by a hardware reset, when an uncorrected bit error is detected in the Message RAM, or by going to a Bus_Off state. While the MCAN_CCCR.INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR.INIT bit does not change any configuration register. Resetting the MCAN_CCCR.INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR.INIT and MCAN_CCCR.CCE bits are set (write protection).

The MCAN_CCCR.CCE bit can only be set/reset while the MCAN_CCCR.INIT = 1. The MCAN_CCCR.CCE bit is automatically reset when the MCAN_CCCR.INIT bit is reset.

The following registers are reset when the MCAN_CCCR.CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RFX1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV.TOC field is preset to the value configured by the MCAN_TOCC.TOP field when the MCAN_CCCR.CCE bit is set.

In addition, the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR.CCE = 1.

The following registers are only writable while MCAN_CCCR.CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR.TEST and MCAN_CCCR.MON bits can only be set by the Host CPU while MCAN_CCCR.INIT = 1 and MCAN_CCCR.CCE = 1. Both bits are reset at any time. The MCAN_CCCR.DAR bit can only be set/reset while MCAN_CCCR.INIT = 1 and MCAN_CCCR.CCE = 1.

Table 28-4 shows the steps to configure the MCAN module.

Table 28-4. Steps to Configure MCAN Module

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR.INIT bit and check that the bit has been set	INIT = 1; If INIT ≠ 1, wait until set
2	Unlock protected registers	Set MCAN_CCCR.CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR.FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for Classic CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR.BRSE bit	BRSE = 1 for bit rate switching BRSE = 0 for no bit rate switching
5	Set nominal bit timing(1)	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR.CCE bit	CCE = 0;

Table 28-4. Steps to Configure MCAN Module (continued)

Step	Operation	Description	Pseudo Code
7	Return MCAN module to normal operation	Clear MCAN_CCCR.INIT bit and check that the bit has been cleared	INIT = 0; If INIT ≠ 0, wait until cleared

(1) See the MCAN_NBTP register on how to program CAN bit timing in the *MCAN_REGS Registers* section.

28.5.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR.INIT bit is reset to zero, the MCAN module synchronizes to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted, dedicated Tx buffers, and a Tx FIFO or a Tx queue can be initialized or updated.

Note

The automated transmission upon reception of remote frames is not supported.

28.5.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 5Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 28-5 and described in Table 28-5, sets a data length of up to 8 or 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate compared to the arbitration phase) are enabled.

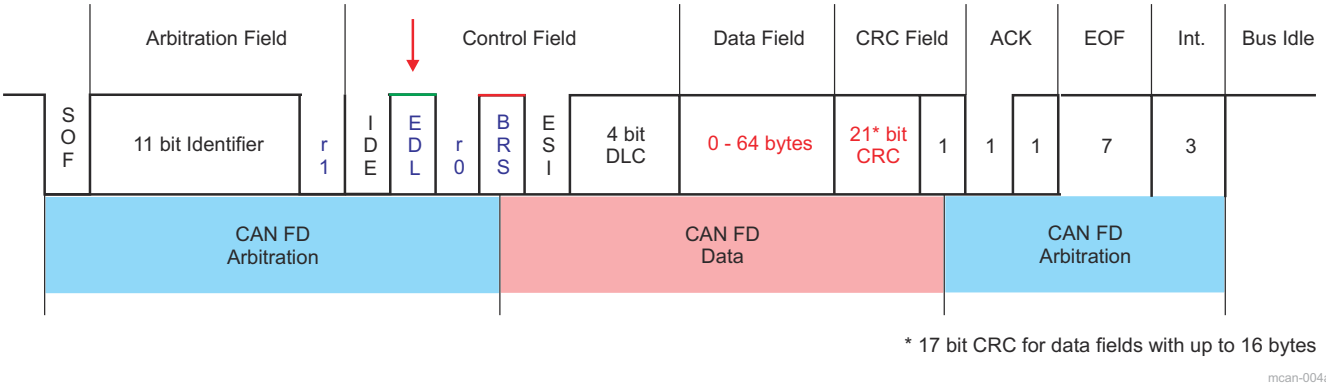

Figure 28-5. CAN FD Frame

Table 28-5. CAN FD Frame Description

Bit	Description
SOF	Start of Frame
IDE	Identifier extension (for 29 bit extended ID)
FDF	Flexible Data Format
BRS	Bit Rate Switching
ESI	Error Status Indicator
DLC	Data Length Code
CRC	Cyclic Redundancy check

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are now decoded as the FDF bit. In the CAN frames, FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. If the MCAN module receives a frame with FDF = recessive and res = recessive, the MCAN signals a Protocol Exception Event by setting the MCAN_PSR.PXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR.PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR.ACT = 10) to Integrating (MCAN_PSR.ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR.PXHD = 1), the MCAN treats a recessive bit as an error and responds with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR.FDOE bit. If MCAN_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured using the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR.FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR.FDOE and MCAN_CCCR.BRSE bits can only be changed while the MCAN_CCCR.INIT and MCAN_CCCR.CCE bits are both set. With MCAN_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR.FDOE = 1 and MCAN_CCCR.BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR.FDOE = 1 and MCAN_CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes are transmitting Classic CAN messages until verified that the nodes are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking must be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to Table 28-6.

Table 28-6. DLC Coding in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

For CAN FD frames, the bit timing is switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 28-6) is used as configured by the Nominal Bit Timing and Prescaler Register (MCAN_NBTP). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register

(MCAN_DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

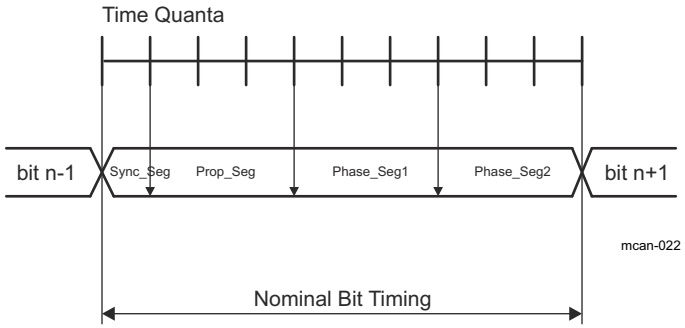

Figure 28-6. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the Error Status Indicator (ESI) bit depends on the transmitter error state (see MCAN_PSR.RESI bit) monitored at the start of the transmission. If the transmitter has an error passive flag, the ESI bit is transmitted recessive; else, the ESI bit is transmitted dominant.

28.5.4 Transmitter Delay Compensation

28.5.4.1 Description

When only one CAN FD node is transmitting and all other nodes are receivers, the length of the bus line has no impact. When transmitting using the TX pin, the MCAN module receives the transmitted data from the CAN transceiver using the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate for the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP.TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase, the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR.TDCO field (see Figure 28-7). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR.TDCV field. This field is cleared when the MCAN_CCCR_INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP.TDC bit is set.

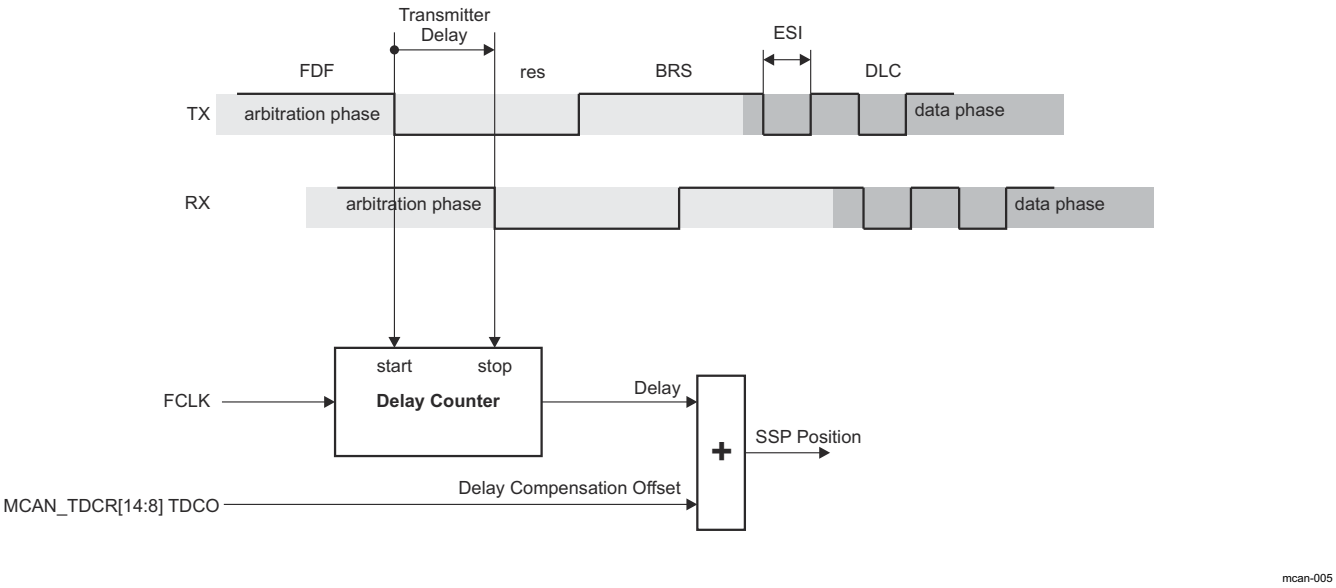

Figure 28-7. Transmitter Delay Measurement

28.5.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP.TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit r0. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 28-7). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming the MCAN_TDCR.TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin that result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR.TDCF field and the RX pin is low.

The following boundary conditions must be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR.TDCO field) is less than 6 bit-times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR.TDCO) field is less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

28.5.5 Restricted Operation Mode

In restricted operation mode, the CAN node is able to receive data and remote frames and to give acknowledgment to valid frames, but the node does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, the node does not send dominant bits; instead the node waits for the occurrence of bus idle condition to resynchronize to the CAN communication. The receive and transmit error counters (MCAN_ECR.REC and MCAN_ECR.TEC) are frozen while CAN error logging (MCAN_ECR.CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting the MCAN_CCCR.ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR.CCE and MCAN_CCCR.INIT bits are set to 1.

The restricted operation mode is automatically entered when the Tx Handler is not able to read data from the Message RAM in time. To leave restricted operation mode, the Host CPU has to reset the MCAN_CCCR.ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after the node has received a valid frame.

Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

28.5.6 Bus Monitoring Mode

Entering bus monitoring mode is done by setting the MCAN_CCCR.MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus can remain in recessive state. In bus monitoring mode, the MCAN_TXBRP register is held in reset state. The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting the bus by the transmission of dominant bits. Figure 28-8 shows the connection of the TX and RX signals to the MCAN module in bus monitoring mode.

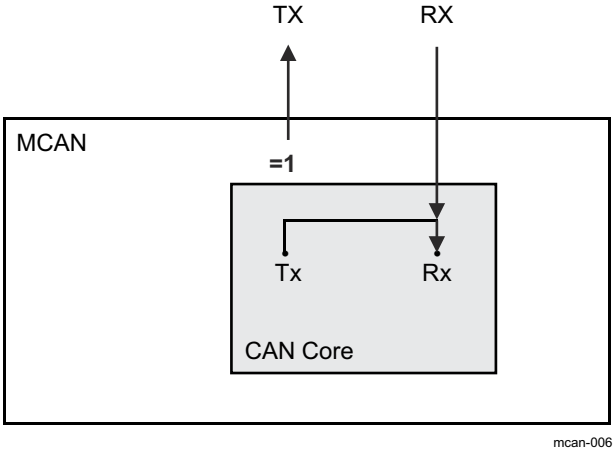

Figure 28-8. Connection of Signals in Bus Monitoring Mode

28.5.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR.DAR bit).

28.5.7.1 Frame Transmission in DAR Mode

In DAR mode, the automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission is disabled. A Tx buffer's Tx Request Pending (MCAN_TXBRP[xx]) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred (MCAN_TXBTO[xx]) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished (MCAN_TXBCF[xx]) CFx bit is set

In the case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

28.5.8 Clock Stop Mode

Entering clock stop mode is controlled by the input clock stop request signal or MCAN_CCCR.CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR.CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR.INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that the module is ready for power down by setting the output clock stop acknowledge signal to 1 and the MCAN_CCCR.CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR.INIT bit has no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK can be switched off.

To leave power-down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR.CSR flag bit. The MCAN acknowledges this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR.CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN_CCCR.INIT bit.

Restoring the clocks from clock stop mode needs to be done according to how the clock stop was initiated.

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode when the clock stop request is asserted, the MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR.INIT bit is set, the MCAN core goes and stays Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits to 1 (for more information, see Section 28.5.8.2). When an external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR.INIT bit is performed to clear the bit.

28.5.8.1 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL.DBGSUSP_FREE bit) when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point, the MCAN_CCCR.INIT bit is set and the MCAN core stays Idle. The suspend state can be verified by reading the MCAN_CCCR.INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits to 1 (for more information, see Section 28.5.8.2). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR.INIT bit is performed to clear the bit.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR.CEL
- MCAN_PSR.LEC
- MCAN_PSR.DLEC
- MCAN_PSR.RESI
- MCAN_PSR.RBRS
- MCAN_PSR.RFDF
- MCAN_PSR.PXE

28.5.8.2 Wakeup Request

Issuing a clock stop request puts the MCAN module into power-down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL.AUTOWAKEUP and MCANSS_CTRL.WAKEUPREQEN bits are enabled, after the MCAN Core responds to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write is issued to clear the MCAN_CCCR.INIT bit and the MCAN core resumes operation.

If the MCANSS_CTRL.WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is deasserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is deasserted
- A reset is applied to the MCAN module

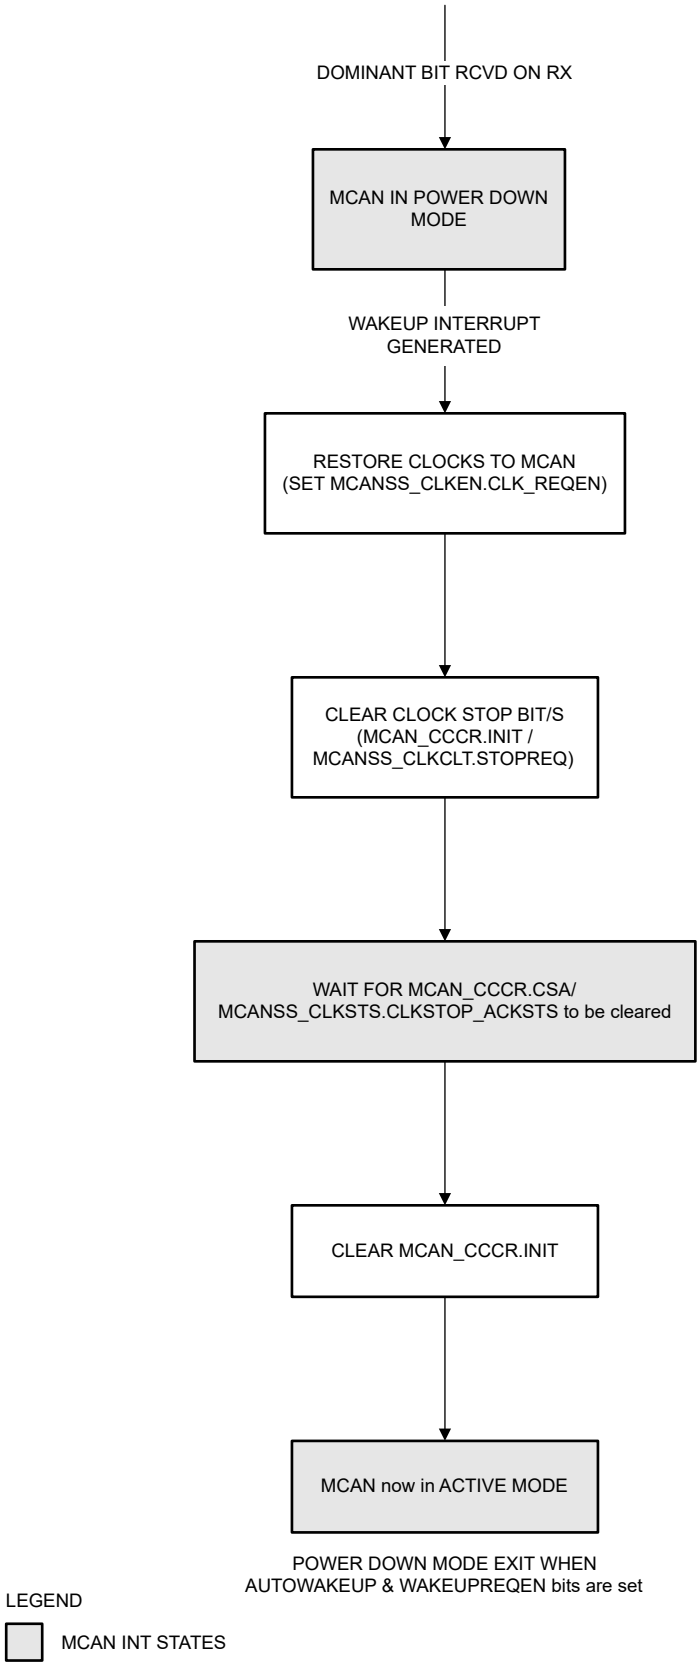

Figure 28-9. Auto Wakeup Enabled Exit from Power Down

28.5.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR.TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The transmit (TX) pin has four different output functions which can be selected by programming the MCAN_TEST.TX field. The default function is the serial data output. The pin can also be driven with a constant dominant or recessive value. It is also possible to drive the sample-point signal to monitor the bit-timing.

The actual value of the receive (RX) pin can be monitored from MCAN_TEST.RX bit. Both functions can be used to check the physical layer. Due to the synchronization mechanism between the CAN clock (MCANx_FCLK) and Host clock (MCANx_ICLK) domain, there can be a delay of several Host clock periods between writing to the MCAN_TEST.TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin by way of the MCAN_TEST.RX bit.

Note

Test modes can be used for self-test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for an application.

28.5.9.1 External Loop Back Mode

The MCAN module can be set into external loop back mode by programming MCAN_TEST.LBCK to 1. In loop back mode, the MCAN treats the transmitted messages as received messages and stores the messages (if the messages pass acceptance filtering) into an Rx Buffer or an Rx FIFO. Figure 28-10 shows the connection of the TX and RX pins to the MCAN module in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the MCAN module ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode, the MCAN module performs an internal feedback from the Tx output to the Rx input. The actual value of the RX input pin is disregarded by the MCAN module. The transmitted messages are monitored at the TX pin.

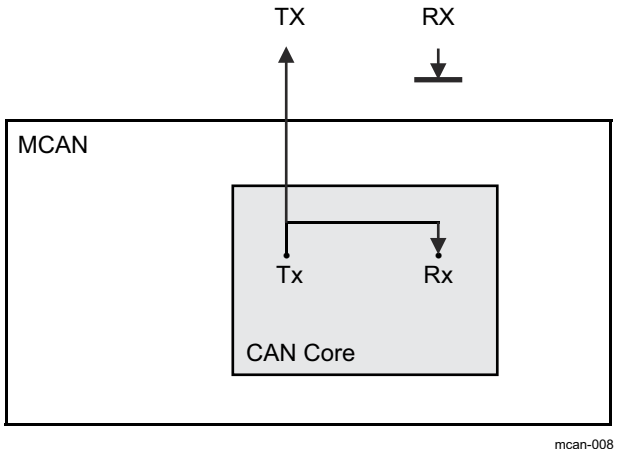

Figure 28-10. External Loop Back Mode

28.5.9.2 Internal Loop Back Mode

The MCAN module can be set into internal loop back mode by programming MCAN_TEST.LBCK and MCAN_CCCR.MON bits to 1. The internal loop back mode is used for a Hot Self-test. The Hot Self-test allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode, the RX pin is disconnected from the MCAN module and the TX pin is held recessive. Figure 28-11 shows the connection of the TX and RX pins to the MCAN module in internal loop back mode.

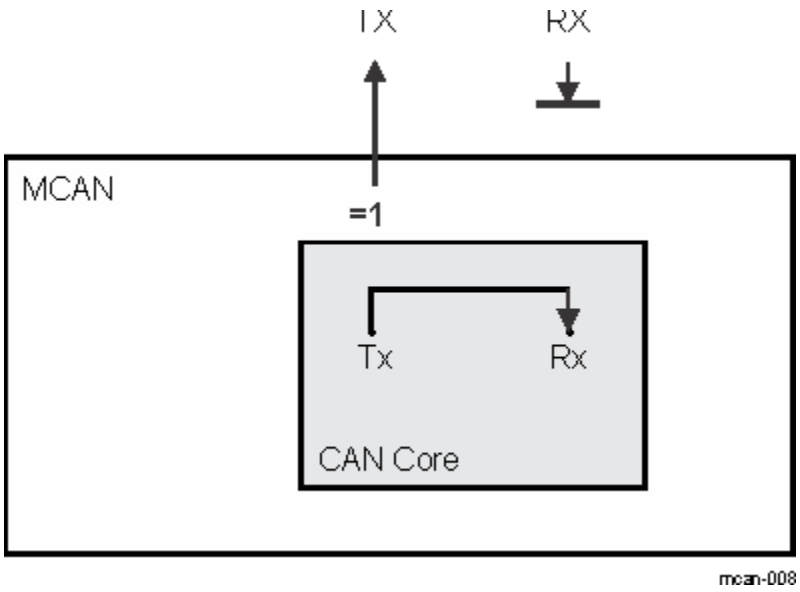

Figure 28-11. Internal Loop Back Mode

28.5.10 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC.TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable by way of the MCAN_TSCV.TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR.TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 28.5.16.

28.5.10.1 External Timestamp Counter

For CAN FD operation mode, the MCAN core requires an external timestamp counter (see Figure 28-12). An externally generated 16-bit vector can substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC.TSS field.

The external timestamp counter uses the interface clock (MCANx_ICLK) as a reference clock. The MCAN core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER.PRESCALER bit field). The external timestamp counter can be enabled or disabled through the MCANSS_CTRL.EXT_TS_CNTR_EN bit. When disabled, the counter is reset back to zero. While enabled, the counter keeps incrementing. When the timestamp rolls over, the MCAN_IRQ_TS interrupt is generated.

When the timestamp rolls over, the MCANSS_IRS register is set. The MCANSS_IE register can be affected by writing to the MCANSS_IESS register to set or to the MCANSS_IECS register to clear. The MCANSS_IESS register is a shadow register mapped to the same address as the MCANSS_IE register. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When a rollover event occurs, the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register also decrements the interrupt counter. Writing to the MCANSS_EOI register issues another pulse, if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS_ISS). The MCANSS_ISS register is a shadow register mapped to the same address as the MCANSS_IRS register.

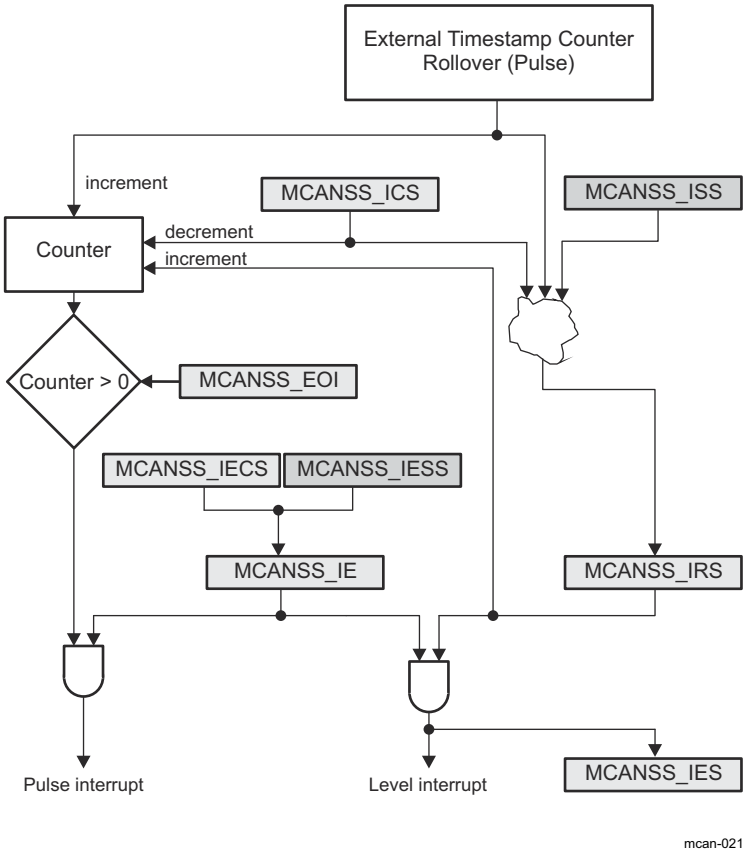

Figure 28-12. External Timestamp Counter Interrupt

28.5.11 Timeout Counter

The MCAN module has an integrated 16-bit timeout counter. The timeout counter is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The timeout counter is configured using the MCAN_TOCC register and is enabled using the MCAN_TOCC.ETOC bit. The timeout counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC.TCP field as the timestamp counter. The actual counter value can be monitored from the MCAN_TOCV.TOC field. The timeout counter can be started only when MCAN_CCCR.INIT = 0 and stopped when MCAN_CCCR.INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC.TOS field. When continuous mode is selected, the counter starts when MCAN_CCCR.INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC.TOP field and continues down-counting.

In case the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC.TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR.TOO flag is set.

In continuous mode, the counter is immediately restarted at the value configured by the MCAN_TOCC.TOP field.

Note

The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore, the point in time where the timeout counter is decremented can vary due to the synchronization/re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

28.5.12 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC aggregator.

28.5.12.1 ECC Wrapper

The ECC wrapper provides single error correction (SEC) and double error detection (DED) parity to the message memory content. The ECC wrapper has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, the error is noted in a FIFO queue that waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

28.5.12.2 ECC Aggregator

This section describes the functional details of the ECC aggregator module.

28.5.12.2.1 ECC Aggregator Overview

The ECC aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bits that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

28.5.12.2.2 ECC Aggregator Registers

There are three groups of registers in the ECC aggregator module:

- **Global registers:** Aggregator Revision Register (MCANERR_REV), ECC Vector Register (MCANERR_VECTOR), Misc Status Register (MCANERR_STAT), ECC Control Register (MCANERR_CTRL), and ECC Wrapper Revision Register (MCANERR_WRAP_REV).
- **Control and status registers:** ECC Error Control Registers (MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2) and ECC Error Status Registers (MCANERR_ERR_STAT1, MCANERR_ERR_STAT2, and MCANERR_ERR_STAT3).
- **Interrupt registers:** interrupt status, interrupt enable set, interrupt enable clear, and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANERR_SEC_EOI
  - MCANERR_SEC_STATUS
  - MCANERR_SEC_ENABLE_SET
  - MCANERR_SEC_ENABLE_CLR
  - MCANERR_DED_EOI
  - MCANERR_DED_STATUS
  - MCANERR_DED_ENABLE_SET
  - MCANERR_DED_ENABLE_CLR

28.5.12.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as:

- Software writes value (the ECC RAM ID) to the MCANERR_VECTOR.ECC_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANERR_VECTOR.RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANERR_VECTOR.RD_SVBUS_ADDRESS field.
- Software then polls the MCANERR_VECTOR.RD_SVBUS_DONE bit to check if the bit is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

28.5.12.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described:

- Software enables the interrupts for the ECC RAM by writing to the MCANERR_SEC_ENABLE_SET/ MCANERR_DED_ENABLE_SET register.
- Software writes the ECC RAM ID in the MCANERR_VECTOR.ECC_VECTOR.
- Software writes the MCANERR_VECTOR.RD_SVBUS bit to trigger the read.
- Software writes the MCANERR_ERR_STAT1 register address to the MCANERR_VECTOR.RD_SVBUS_ADDRESS field. Software needs to load the 'read message' in the rMCANERR_VECTOR register again, if the software needs to read the MCANERR_ERR_STAT2 register.
- Software polls the MCANERR_VECTOR.RD_SVBUS_DONE bit. When this bit is set, a read of the MCANERR_ERR_STAT1/MCANERR_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software clears the interrupt status by writing to the MCANERR_ERR_STAT1.CLR_ECC_SEC or MCANERR_ERR_STAT1.CLR_ECC_DED bit depending on the type of the ECC error.
- Software polls the MCANERR_ERR_STAT1 register to verify that the status bit has been cleared.
- Software writes to the MCANERR_SEC_EOI/MCANERR_DED_EOI register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANERR_SEC_EOI.EOI_WR /MCANERR_DED_EOI.EOI_WR bits.

28.5.13 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

28.5.13.1 Acceptance Filtering

The MCAN module employs two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic bit mask filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 28.5.16) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR.HPM
- Set High Priority Message interrupt flag MCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer: New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type, see MCAN_PSR.LEC and MCAN_PSR.DLEC fields,respectively).
- Rx FIFO: Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type, see MCAN_PSR.LEC and MCAN_PSR.DLEC fields, respectively). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 28.5.13.2.2 must be considered.

Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filters used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

28.5.13.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 28.5.16.5 and Section 28.5.16.6.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

28.5.13.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT =01/ Extended Filter Type EFT =01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information, see Section 28.5.16.5 and Section 28.5.16.6.

28.5.13.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while the SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) masks out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

28.5.13.1.4 Standard Message ID Filtering

Figure 28-13 shows the standard Message ID (11-bit ID) filtering flow. Section 28.5.16.5 describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

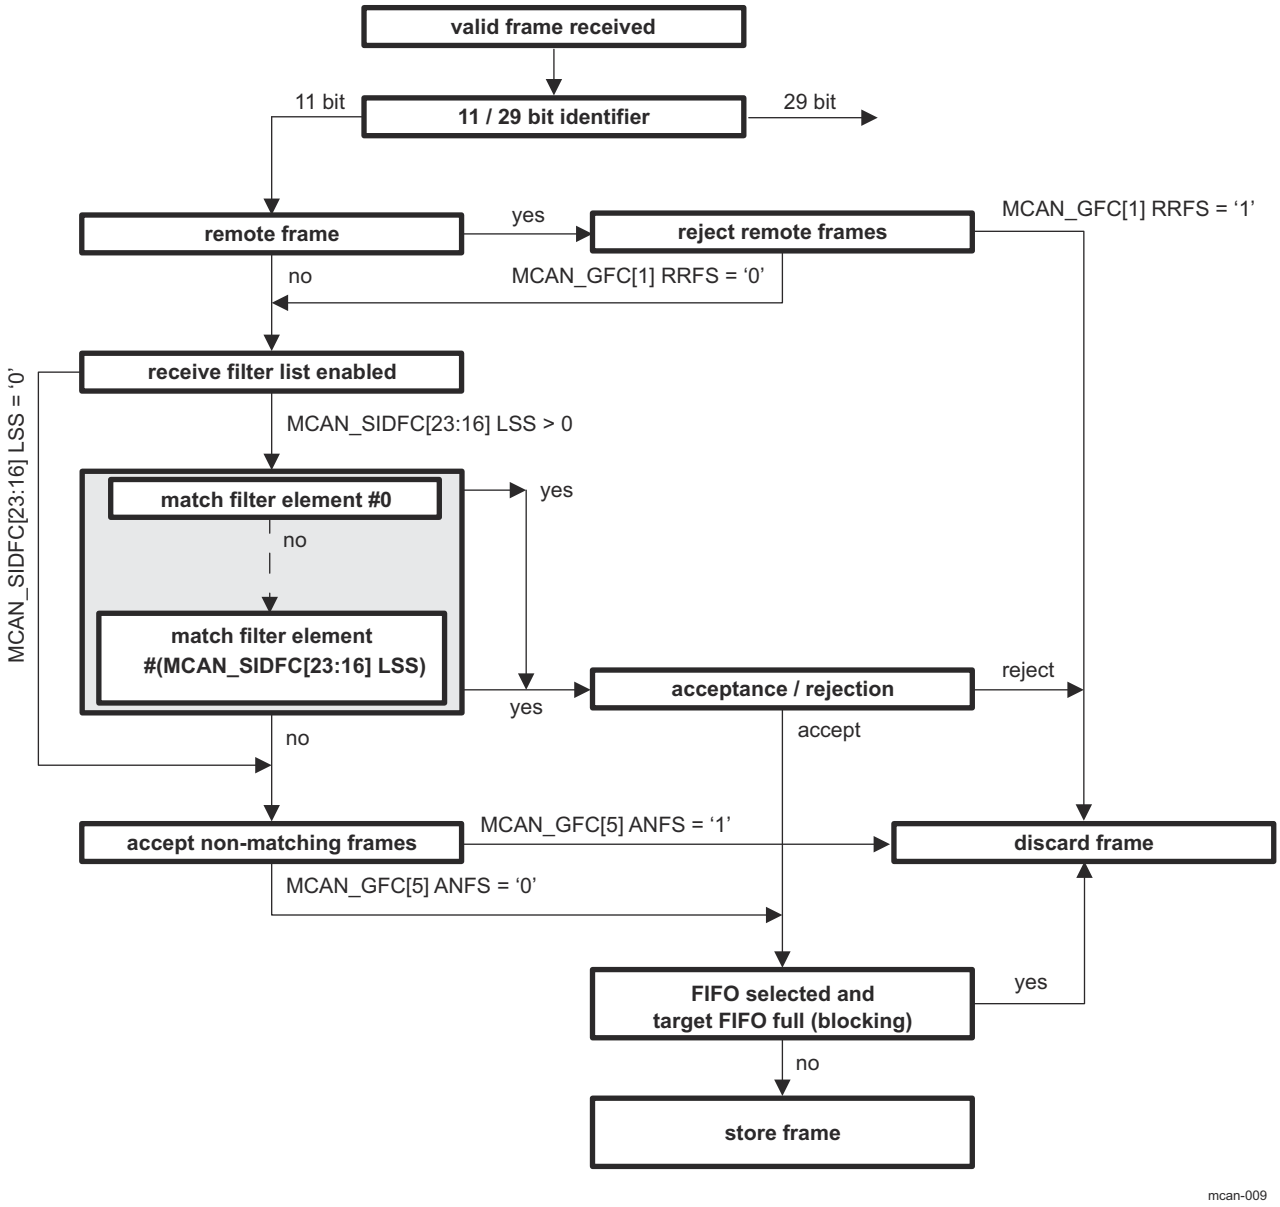

Figure 28-13. Standard Message ID Filter Path

28.5.13.1.5 Extended Message ID Filtering

Figure 28-14 shows the extended Message ID (29-bit ID) filtering flow. Section 28.5.16.6 describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed, the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

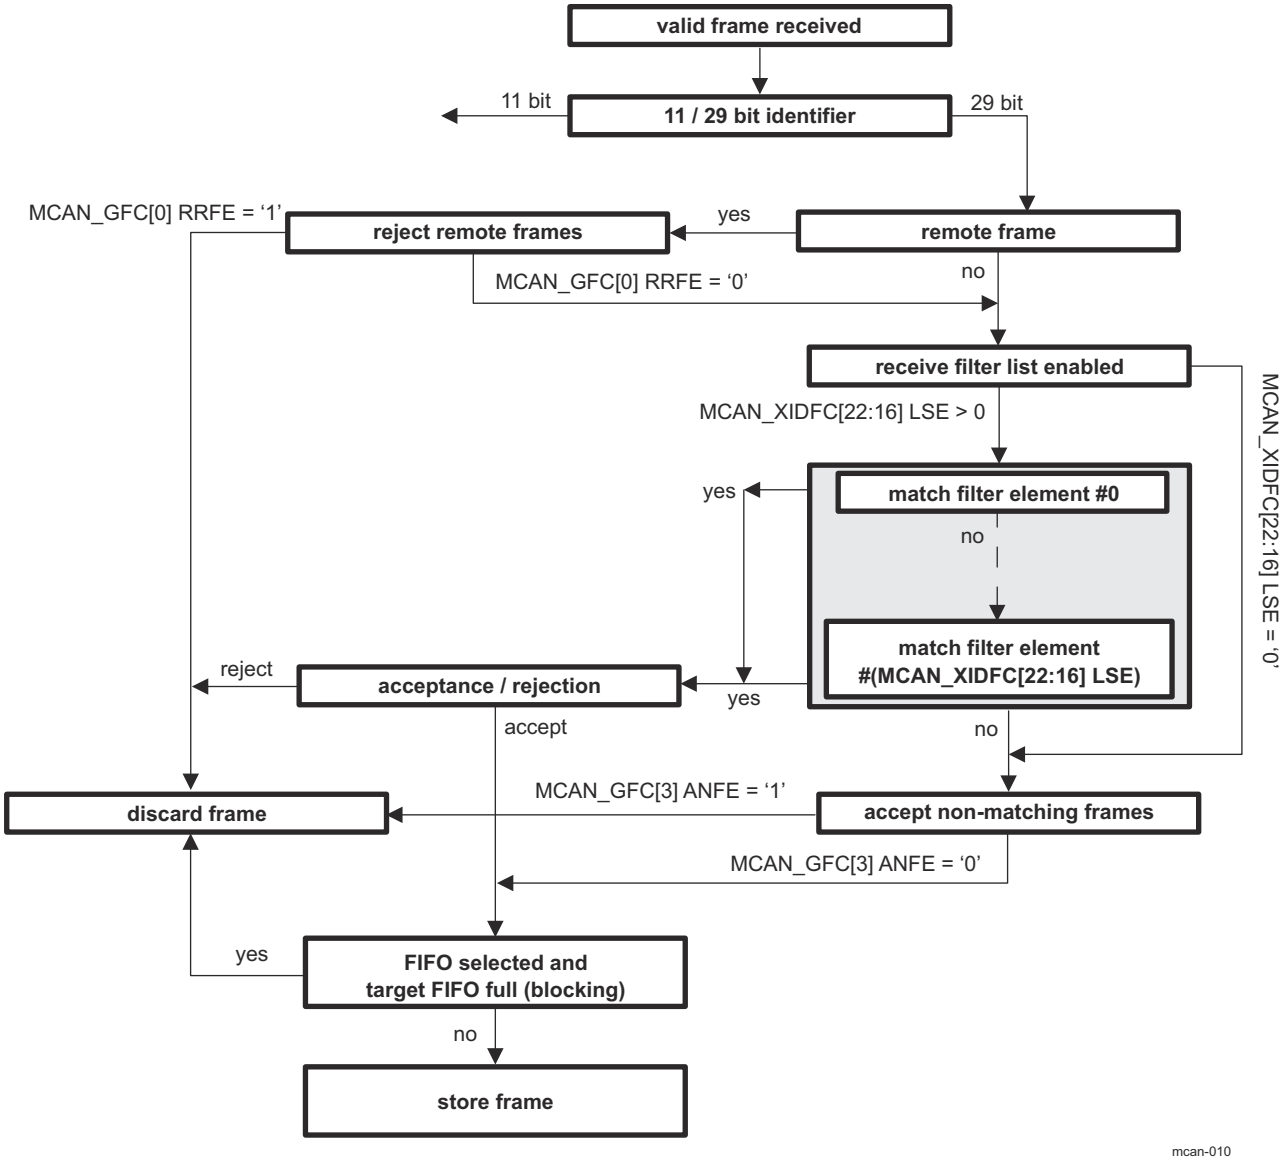

Figure 28-14. Extended Message ID Filter Path

28.5.13.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done by way of the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 are described in Section 28.5.13.1. The Rx FIFO element is described in Section 28.5.16.2.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24].FnWM bit (where: n = 0 or 1), an interrupt flag MCAN_IR.RF0W/MCAN_IR.RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16].FnPI = MCAN_RXFnS[13:8].FnGI), an Rx FIFO Full condition is signaled by the MCAN_RXFnS[24].FnF status bit and interrupt flag MCAN_IR.RF0F/MCAN_IR.RF1F is set. Figure 28-15 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0].FnFL field (the number of elements stored in Rx FIFO).

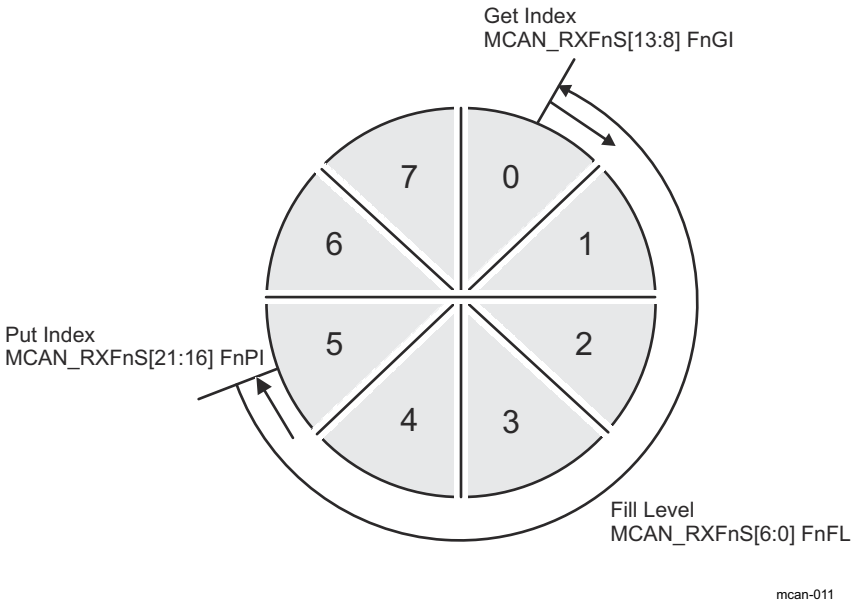

Figure 28-15. Rx FIFO Status

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2].FnSA field) has to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8].FnGI). Table 28-7 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured by way of the MCAN_RXESC register.

Table 28-7. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC Register RBDS/F0DS/F1DS Bits	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

28.5.13.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs and is configured by MCAN_RXFnC[31].FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16].FnPI = MCAN_RXFnS[13:8].FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by the MCAN_RXFnS[24].FnF = 1 and interrupt flag MCAN_IR.RF0F/MCAN_IR.RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signaled by MCAN_RXFnS[25].RFnL = 1 and interrupt flag MCAN_IR.RF0L/ MCAN_IR.RF1L is set.

28.5.13.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by MCAN_RXFnC[31].FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16].FnPI = MCAN_RXFnS[13:8].FnGI) signaled by MCAN_RXFnS[24].FnF = 1, the next accepted message for the FIFO overwrites the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signaled, reading of the Rx FIFO elements starts at least at get index + 1. The reason for this is a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case, inconsistent data can be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 28-16 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case, the two messages stored in element 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0].FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24].FnF = 0).

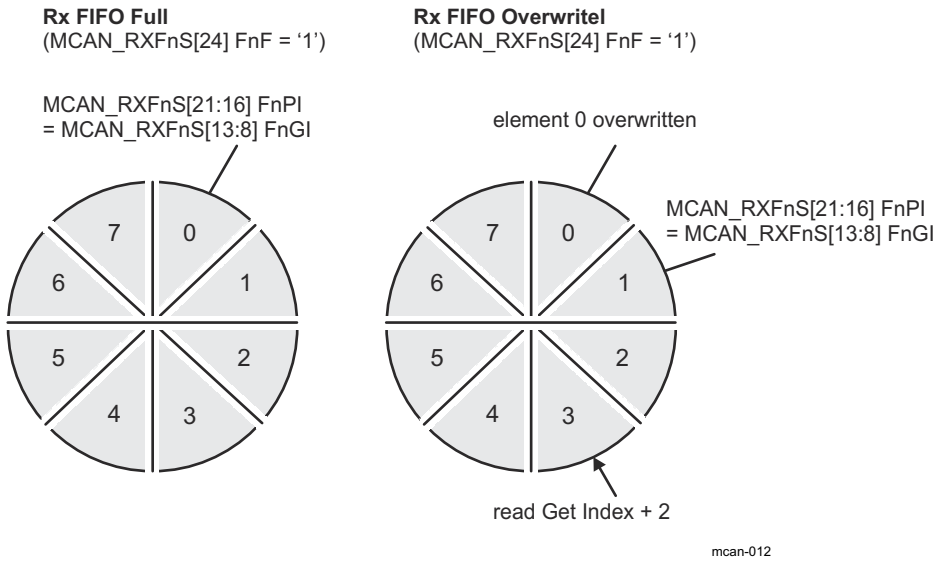

Figure 28-16. Rx FIFO Overflow Handling

28.5.13.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx buffers. The start address of the Rx buffers section in the Message RAM is configured by way of the MCAN_RXBC.RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 28.5.16.5 and Section 28.5.16.6).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition, the flag MCAN_IR.DRX (message stored in Dedicated Rx Buffer) is set.

Table 28-8 shows an example filter configuration for Rx buffers.

Table 28-8. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT1 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags must be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx buffer New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer does not match, causing the acceptance filtering to continue. Following Message ID Filter Elements can cause the received message to be stored into another Rx Buffer, into an Rx FIFO, or the message can be rejected, depending on filter configuration.

28.5.13.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

28.5.14 Tx Handling

The Tx handler is used to handle the Tx requests. The Tx handler controls the transfer of transmit messages from the dedicated Tx buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx buffers. These Tx buffers can be configured as dedicated Tx buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx buffers/Tx FIFO or dedicated Tx buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 28.5.16.3 describes the Tx Buffer Element. Table 28-9 shows the possible configurations for message transmission.

Table 28-9. Possible Configurations for Message Transmission

MCAN_CCCR Register		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending (MCAN_TXBRP) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with the lowest Message ID has highest priority.

Note

AUTOSAR requires at least three Tx Queue buffers and support of transmit cancellation.

28.5.14.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs can have a higher priority than other defined Message IDs, while in a specific application the relative priority can be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR.TXP bit. By default this bit is disabled (MCAN_CCCR.TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if the Message IDs have lower priority.

28.5.14.2 Dedicated Tx Buffers

Dedicated Tx buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done using the MCAN_TXBAR[x]ARn bit (where x = 0 to 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to the Message ID.

Table 28-10 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates element size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS.TFQP) × Element size to the Tx Buffer start address MCAN_TXBC.TBSA field.

Table 28-10. Tx Buffer, Tx FIFO, Tx Queue Element Size

MCAN_TXESC.TBDS	Data Field (bytes)	Element Size (RAM Words)
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

28.5.14.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC.TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS.TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS.TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO.

New transmit messages must be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS.TFQP field. After each Add Request (MCAN_TXBAR[x] ARn = 1), the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS.TFQP = MCAN_TXFQS.TFGI), Tx FIFO Full condition is signaled by bit MCAN_TXFQS.TFQF = 1. In this case, no further messages must be written to the Tx FIFO until the next message is transmitted and the Get Index is incremented.

The number of requested Tx buffers must not exceed the number of free Tx buffers, as indicated by the Tx FIFO Free Level MCAN_TXFQS.TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS.TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates element size 32-bit words in the Message RAM (see Table 28-10). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC.TBSA field.

28.5.14.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC.TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages must be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS.TFQP field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS.TFQF = 1), the Put Index is not valid and no further message must be written to the Tx Queue until at least one of the requested messages is sent out or a pending transmission request is canceled.

The application can use the MCAN_TXBRP register instead of the Put Index and can place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates element size 32-bit words in the Message RAM (see Table 28-10). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC.TBSA field.

28.5.14.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN_TXBC.NDTB field
- Tx FIFO: the number of Tx buffers assigned to the Tx FIFO is configured by the MCAN_TXBC.TFQS field

If the MCAN_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan Dedicated Tx buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS.TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 28-17 shows Mixed Dedicated Tx buffers/Tx FIFO example.

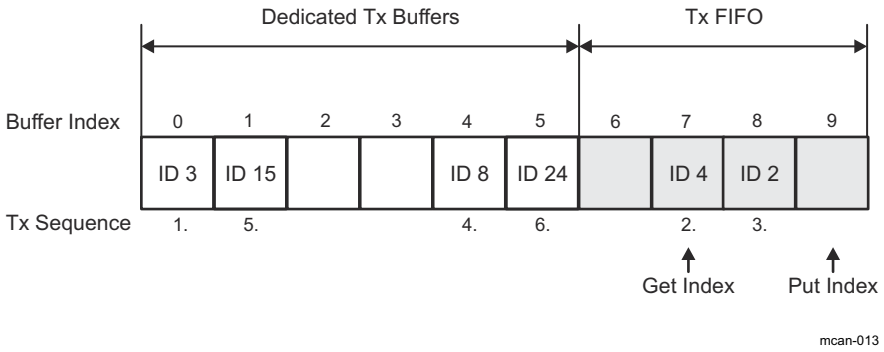

Figure 28-17. Mixed Dedicated Tx Buffers /Tx FIFO (example)

28.5.14.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN_TXBC.NDTB field
- Tx Queue: the number of Tx buffers assigned to the Tx Queue is configured by the MCAN_TXBC.TFQS field

If MCAN_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan all Tx buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 28-18 shows Mixed Dedicated Tx buffers/Tx Queue example.

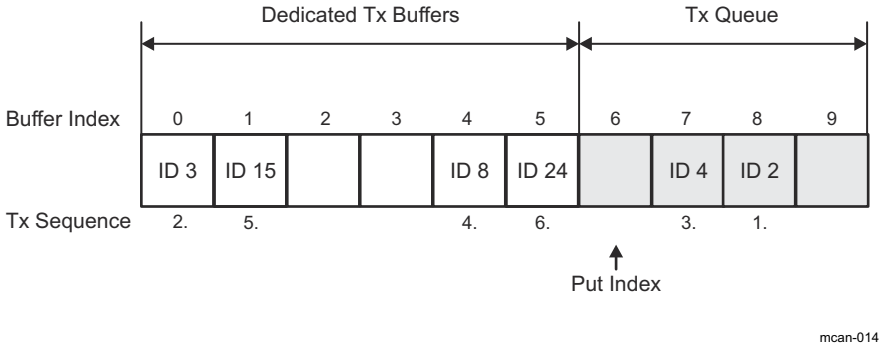

Figure 28-18. Mixed Dedicated Tx Buffers /Tx Queue (example)

28.5.14.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n].CRn = 1 (where n = 0 to 31). The corresponding bit position n is equivalent to the number of the Tx buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n].CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n].TRPn bit remains set as long as the transmission is in progress. If the transmission was

successful, the corresponding MCAN_TXBTO[n].TOn and MCAN_TXBCF[n].CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n].CFn = 1.

Note

If a pending transmission is canceled immediately before this transmission has started, a short time window occurs where no transmission is started even if another message is also pending in this node. This can enable another node to transmit a message that can have a lower priority than the second message in this node.

28.5.14.8 Tx Event Handling

To support Tx Event Handling, the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 28.5.16.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signaled by the MCAN_IR.TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS.EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR.TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC.EFWM field, interrupt flag MCAN_IR.TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS.EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC.EFSA field.

28.5.15 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index sets the FIFO Get Index to the FIFO Acknowledge Index plus one and, thereby, updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. Special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case, the FIFO Acknowledge Index must not be written because this sets the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case, some of the older FIFO elements can be lost.

Note

The application has to make sure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

28.5.16 Message RAM

The MCAN module has a Message RAM. The main purpose of the Message RAM is to store:

- Received Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

28.5.16.1 Message RAM Configuration

The MCAN module is configured to allocate up to words in the Message RAM. The Message RAM has a width of 32 bits.

The address ranges of the Message RAMs is from 0x0005 8000 to 0x0005 8FFF and from 0x0005 A000 to 0x0005 AFFF.

The Message RAM is capable to include each of the sections listed in Figure 28-19. It is not necessary to configure each of the sections (a section in the Message RAM can be 0) and there is no restriction with respect to the sequence of the sections. For parity checking or ECC, a respective number of bits has to be added to each word. When the MCAN module addresses the Message RAM, the MCAN addresses 32-bit words. The start addresses are configurable and are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0, by way of the MCAN_RXESC.F0DS field
- Rx FIFO, 1 by way of the MCAN_RXESC.F1DS field
- Rx buffers, by way of the MCAN_RXESC.RBDS field
- Tx buffers, by way of the MCAN_TXESC.TBDS field

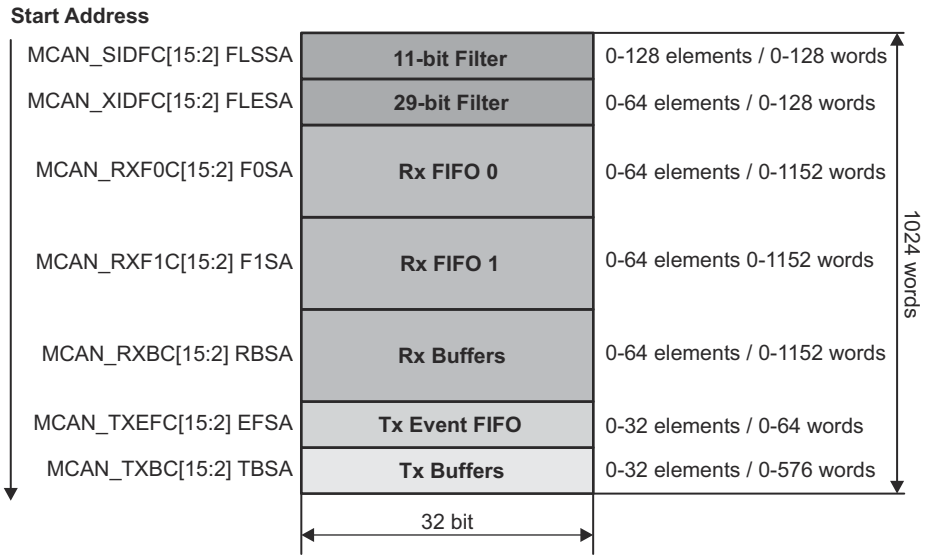

Figure 28-19. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This prevents falsification or loss of data.

28.5.16.2 Rx Buffer and FIFO Element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN_RXESC register.

Figure 28-20 shows the Rx Buffer/Rx FIFO element structure. Table 28-11 shows the Rx Buffer/Rx FIFO element field descriptions.

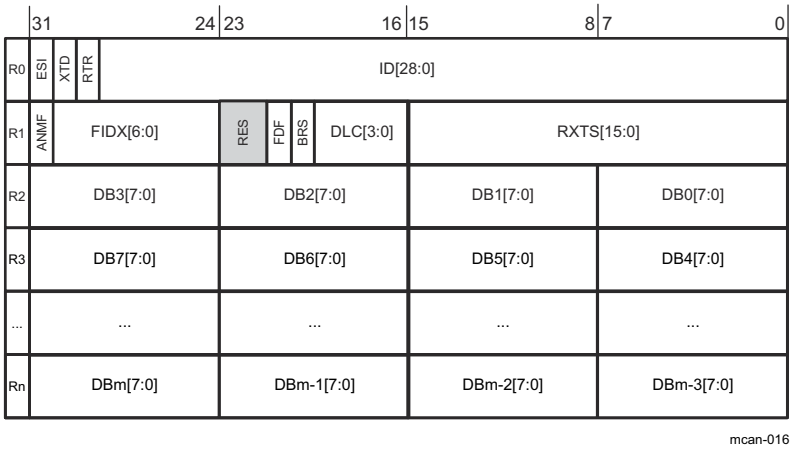

Figure 28-20. Rx Buffer/Rx FIFO Element Structure

Table 28-11. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]). In CAN FD frames (FDF = 1), the dominant RRS (Remote Request Substitution) bit replaces the RTR (Remote Transmission Request) bit.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].

Table 28-11. Rx Buffer/Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames can be enabled using the MCAN_GFC.ANFS and MCAN_GFC.ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC.LSS - 1 respectively MCAN_XIDFC.LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP.
R2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note

Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

28.5.16.3 Tx Buffer Element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx buffers and Tx FIFO/Tx Queue by way of the MCAN_TXBC.TFQS and MCAN_TXBC.NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN_TXESC register.

Figure 28-21 shows the Tx Buffer element structure. Table 28-12 shows the Tx Buffer element field descriptions.

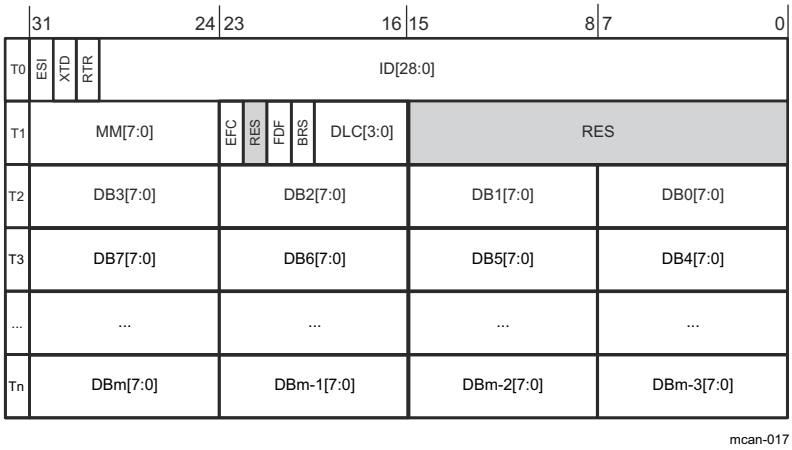

Figure 28-21. Tx Buffer Element Structure

Table 28-12. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is ORed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node can optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR.FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 28-12. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 28-13).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled using the MCAN_CCCR.FDOE bit. BRS bit is only evaluated when MCAN_CCCR.BRSE = 1.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note

Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

28.5.16.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 28-22 shows the Tx Event FIFO element structure. Table 28-13 shows the Tx Event FIFO element field descriptions.

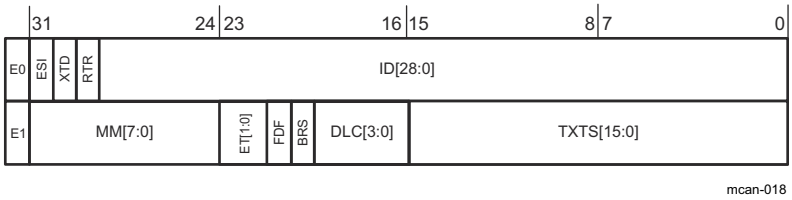

Figure 28-22. Tx Event FIFO Element Structure

Table 28-13. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 28-13. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 28-12).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP filed.

28.5.16.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, the element address is the Filter List Standard Start Address MCAN_SIDFC.FLSSA field plus the index of the filter element (0-127).

Figure 28-23 shows the Standard Message ID Filter element structure. Table 28-14 shows the Standard Message ID Filter element field descriptions.

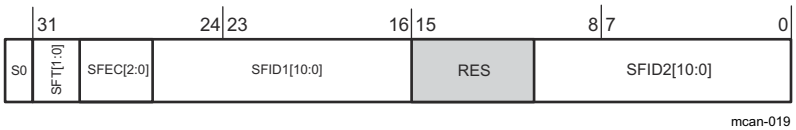

Figure 28-23. Standard Message ID Filter Element Structure

Table 28-14. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000)
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer , configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • SFEC = 001-110: Second ID of standard ID filter element • SFEC = 111: Filter for Rx buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

28.5.16.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, the element address is the Filter List Extended Start Address MCAN_XIDFC.FLESA field plus two times the index of the filter element (0-63).

Figure 28-24 shows the Extended Message ID Filter element structure. Table 28-15 shows the Extended Message ID Filter element field descriptions.

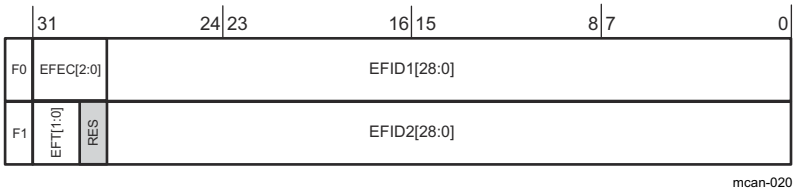

Figure 28-24. Extended Message ID Filter Element Structure

Table 28-15. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 28.5.13.1.5) is used.

Table 28-15. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • EFEC = 001 - 110: Second ID of extended ID filter element • EFEC = 111: Filter for Rx buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

28.6.2 MCAN Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/mcan

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

28.6.2.1 MCAN Internal Loopback with Interrupt

FILE: mcan_ex1_loopback.c

This example shows the MCAN Loopback functionality. The internal loopback mode is entered. The sent message should be received by the node. Use the last address of memory for Rx buffer.

External Connections

- None.

Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

28.6.2.2 MCAN Loopback with Interrupts Example Using SYSCONFIG Tool

FILE: mcan_ex3_loopback_syscfg.c

This example illustrates the MCAN Loopback functionality. The internal loopback mode is entered. The message transmitted would be received by the node. The last address of memory is used for the Rx buffer. Peripheral configuration is done through SYSCONFIG

External Connections

- None.

Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

28.6.2.3 MCAN receive using Rx Buffer

FILE: mcan_ex4_receive.c

This example demonstrates the MCAN receive function. Communication is done between two CAN nodes. The transmitting node could be another MCU or a CAN bus analysis tool capable of transmitting CAN FD frames. The transmit and receive pins of the MCAN module should be connected to a CAN transceiver. Nominal Bit Rate of 500 kbps & Data bit rate of 1 Mbps is used

Only Standard frame with message ID 0x4 is received.

If another C2000 MCU is used as the transmitter, mcan_ex3_transmit.c can be run on it for the transmit function.

Hardware Required

- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- rxMsg

28.6.2.4 MCAN External Reception (with mask filter) into RX-FIFO1

FILE: mcan_ex5_mask_filter_receive.c

This example demonstrates Receiving, with mask filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Bits 0, 1 & 3 of the identifier are masked. So these bits can have any value. This is achieved by using stdFiltelem.sfid1 = 00000001111 and stdFiltelem.sfid2 (mask 0 for X) = 11111110100, which means any message with an ID of 0b0000000X1XX are received and stored into the FIFO. i.e. Following STD IDs are received: 0x004, 0x005, 0x006, 0x007, 0x00C, 0x00D, 0x00E, 0x00F. All other IDs are not received. Classic bit-mask filter is used. This example may be used in conjunction with mcan_ex3_transmit.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

Hardware Required

- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- rxMsg

28.6.2.5 MCAN Classic frames transmission using Tx Buffer

FILE: mcan_ex7_classic_transmit.c

This simple example shows external communication between the MCAN module and another CAN node. It shows how to transmit classic CAN frames. The GPIOs of MCAN should be connected to a CAN Transceiver. Bit Rate is 500 kbps. Extended Identifier 0x15A5A5A5 is transmitted with 8 data bytes.

Hardware Required
- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- txMsg

28.6.2.6 MCAN External Reception (with RANGE filter) into RX-FIFO1

FILE: mcan_ex8_range_filter_receive.c

This example demonstrates Receiving, with RANGE filter configuration. The transmitting node could be a CAN FD capable controller or a CAN bus analysis tool capable of transmitting CAN FD frames. Only Extended IDs from 0x1FFFFF23 to 0x1FFFFF46 are received. Other IDs are not received. RXFIFO1 starts at an offset of 748 (2EC). MCAN Message RAM starts at 0x58000, so received messages will be copied starting at address 0x582EC. Note that as long as the ID matches, "classic" CAN frames will also be received.

The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used.

Hardware Required
- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- rxMsg

28.6.2.7 MCAN External Transmit using Tx Buffer

FILE: mcan_ex9_transmit.c

This example demonstrates the MCAN External Transmit function. External communication is done between two CAN nodes. The receiving node could be another MCU or a CAN bus analysis tool capable of Receiving/ ACKnowledging transmitted frames. The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used. Standard Identifier (STD ID) 0x4 is transmitted with 64 data bytes. #defines that are not required for this test case have been commented out. However, they have been left in the code should the scope of this code be expanded to include Receive and FIFO functions.

If another C2000 MCU is used as the receiver, mcan_ex4_receive.c can be run on it for the receive function.

Hardware Required
- A C2000 board with CAN transceiver

External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- txMsg

28.6.2.8 MCAN receive using Rx Buffer

FILE: mcan_ex10_receive_multiple_buffers.c

This example demonstrates how to receive MCAN messages in multiple buffers, including the configuration and handling of the messages. Communication is done between atleast two CAN nodes. The transmitting node could be another MCU or a CAN bus analysis tool capable of transmitting CAN FD frames. The transmit and receive pins of the MCAN module should be connected to a CAN transceiver. Nominal Bit Rate of 500 kbps & Data bit rate of 1 Mbps is used

Standard frames with message IDs 0x123, 0x124, 0x125, 0x126 are received. (For Extended frames, same procedure to be followed for configuration by adding Extended Message ID Filter Element(s))

Hardware Required

- A C2000 board with CAN transceiver

External Connections

Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables

- rxMsg

28.6.2.9 MCAN Internal Loopback with Interrupt

FILE: mcan_ex12_receive_priority.c

This example shows the MCAN Loopback functionality. The internal loopback mode is entered. The sent message should be received by the node. Use the last address of memory for Rx buffer. This example demonstrates the MCAN receive function for High Priority Messages. Messages with Message IDs from the range 0x1 to 0xB are received in Rx FIFO 1, while messages with Message IDs 0x3 and 0x9 are marked as High Priority by the receiving CAN node (frames in itself conform to CAN Protocol, Priority is only marked from the perspective of the receiving CAN Node), following which a separate interrupt is generated and the messages can be read.

28.6.2.10 MCAN External Transmit using Tx Buffer

FILE: mcan_ex13_transmit_TxEventFIFO.c

This example demonstrates the usage of Tx Event FIFO. External communication is done between two CAN nodes. The receiving node could be another MCU or a CAN bus analysis tool capable of Receiving/ ACKnowledging transmitted frames. The transmit and receive pins of the MCAN module should be connected to a CAN Transceiver. Nominal Bit Rate of 500 kbps and Data bit rate of 1 Mbps is used. Standard Identifier (STD ID) 0x4 is transmitted with 64 data bytes. Tx Event FIFOs store transmit status information from the Tx Buffer allowing the Tx Buffer to be overwritten based on the needs of the application Message Marker Bits are used to link Tx Event FIFO elements to the Tx Messages, while the Tx Timestamp denotes the counter value for when the message was transmitted.

If another C2000 MCU is used as the receiver, mcan_ex4_receive.c can be run on it for the receive function.

Hardware Required

- A C2000 board with CAN transceiver

External Connections
Both nodes should communicate through CAN FD capable transceivers.

- MCAN is on DEVICE_GPIO_PIN_CANRXA (MCANRXA)
- and DEVICE_GPIO_PIN_CANTXA (MCANTXA)

Watch Variables
- txMsg

28.6.2.11 MCAN Internal Loopback with Interrupt

FILE: mcan_ex15_timestamp.c

This example demonstrates the MCAN Timestamping functionality. When the TRANSMIT define is selected, the CAN Controller acts as a Transmitter and sends data to the second CAN Controller connected externally. If TRANMSIT is not defined the CAN Controller acts as a Receiver and waits for message to be transmitted by the External CAN Controller.

External Connections
- None.

Watch Variables
- a_txts - Array that stores Tx Timestamp values read from the Tx Event FIFO
- a_rxts - Array that stores Rx Timestamp values read from Rx FIFO 1

28.7 MCAN Registers

This Section describes the MCAN Registers.

28.7.1 MCAN Base Address Table

Table 28-17. MCAN Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
McanaSsRegs	MCANSS_REGS	MCANASS_BASE	0x0005_9400	YES	-	-	YES
McanaRegs	MCAN_REGS	MCANA_BASE	0x0005_9600	YES	-	-	YES
McanaErrorRegs	MCAN_ERROR_REGS	MCANA_ERROR_BASE	0x0005_9800	YES	-	-	YES

14h	Ah	MCANSS_IECS	MCAN Subsystem Interrupt Enable Clear Shadow Register		Go
18h	Ch	MCANSS_IE	MCAN Subsystem Interrupt Enable Register		Go
1Ch	Eh	MCANSS_IES	MCAN Subsystem Interrupt Enable Status		Go
20h	10h	MCANSS_EOI	MCAN Subsystem End of Interrupt		Go
24h	12h	MCANSS_EXT_TS_PRESCALER	MCAN Subsystem External Timestamp Prescaler 0		Go
28h	14h	MCANSS_EXT_TS_UNSERVICED_INTR_CNTR	MCAN Subsystem External Timestamp Unserviced Interrupts Counter		Go

Complex bit access types are encoded to fit into small table cells. Table 28-19 shows the codes that are used for access types in this section.

Table 28-19. MCANSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

28.7.2.1 MCANSS_PID Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 68E05101h]

MCANSS_PID is shown in Figure 28-25 and described in Table 28-20.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 28-32 shows the codes that are used for access types in this section.

Table 28-32. MCAN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
RS	R S	Read to Set
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1SQ	W 1S Q	Write 1 to set Qualified. A condition must be met for this operation to occur.
WQ	W Q	Write Qualified. A condition must be met for this operation to occur.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

28.7.3.1 MCAN_CREL Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 32380608h]

MCAN_CREL is shown in Figure 28-36 and described in Table 28-33.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
31-0	ETV	R	87654321h	Endianess Test Value. Reading the constant value maintained in this register allows software to determine the endianess of the host CPU. Reset type: SYSRSn

28.7.3.3 MCAN_DBTP Register (Offset (x8) = Ch, Offset (x16) = 6h) [Reset = 00000A33h]

MCAN_DBTP is shown in Figure 28-38 and described in Table 28-35.

Return to the Summary Table.

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 m_can_cclk periods. tq = (DBRP + 1) mtq.
DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.
Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.
The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Bit	Field	Type	Reset	Description
7-4	DTSEG2	R/WQ	3h	Data Time Segment After Sample Point. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
3-0	DSJW	R/WQ	3h	Data Resynchronization Jump Width. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

28.7.3.4 MCAN_TEST Register (Offset (x8) = 10h, Offset (x16) = 8h) [Reset = 000000X0h]

MCAN_TEST is shown in Figure 28-39 and described in Table 28-36.

Return to the Summary Table.

Write access to the Test Register has to be enabled by setting bit CCCR.TEST to '1'. All Test Register functions are set to their reset values when bit CCCR.TEST is reset.
Loop Back Mode and software control of the internal CAN TX pin are hardware test modes. Programming of TX != '00' may disturb the message transfer on the CAN bus.

3	CSA	R	0h	Clock Stop Acknowledge 0 No clock stop acknowledged 1 MCAN may be set in power down by stopping the Host and CAN clocks Reset type: SYSRSn
2	ASM	R/W1SQ	0h	Restricted Operation Mode. Bit ASM can only be set by SW when both CCE and INIT are set to '1'. The bit can be reset by SW at any time. 0 Normal CAN operation 1 Restricted Operation Mode active Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

Table 28-38. MCAN_CCCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CCE	R/WQ	0h	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1') Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
0	INIT	R/W	1h	Initialization 0 Normal Operation 1 Initialization is started Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value. Reset type: SYSRSn

28.7.3.7 MCAN_NBTP Register (Offset (x8) = 1Ch, Offset (x16) = Eh) [Reset = 06000A03h]

MCAN_NBTP is shown in Figure 28-42 and described in Table 28-39.

Return to the Summary Table.

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 m_can_cclk periods. tq = (NBRP + 1) mtq.
NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.
Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.
The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.
Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the MCAN for a bit rate of 500 kBit/s.

Bit	Field	Type	Reset	Description
2-0	LEC	RS	7h	Last Error Code. The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0 No Error: No error occurred since LEC has been reset by successful reception or transmission. 1 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 2 Form Error: A fixed format part of a received frame has the wrong format. 3 AckError: The message transmitted by the MCAN was not acknowledged by another node. 4 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 7 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register. Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error. Note: The Bus_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences. Reset type: SYSRSn

28.7.3.14 MCAN_TDCR Register (Offset (x8) = 48h, Offset (x16) = 24h) [Reset = 00000000h]

MCAN_TDCR is shown in Figure 28-49 and described in Table 28-46.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved
14-8	TDCO	R/WQ	0h	Transmitter Delay Compensation Offset. Offset value defining the distance between the measured delay from the internal CAN TX signal to the internal CAN RX signal and the secondary sample point. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
7	RESERVED	R	0h	Reserved
6-0	TDCF	R/WQ	0h	Transmitter Delay Compensation Filter Window Length. Defines the minimum value for the SSP position, dominant edges on the internal CAN RX signal that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

28.7.3.15 MCAN_IR Register (Offset (x8) = 50h, Offset (x16) = 28h) [Reset = 80000000h]

MCAN_IR is shown in Figure 28-50 and described in Table 28-47.

Return to the Summary Table.

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. Aflag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. Ahard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

28.7.3.17 MCAN_ILS Register (Offset (x8) = 58h, Offset (x16) = 2Ch) [Reset = 00000000h]

MCAN_ILS is shown in Figure 28-52 and described in Table 28-49.

Return to the Summary Table.

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE.EINT0 and ILE.EINT1.

Table 28-69. MCAN_TXBRP Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TRP0	R	0h	Transmission Request Pending 0. Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signalled via TXBCF - after successful transmission together with the corresponding TXBTO bit - when the transmission has not yet been started at the point of cancellation - when the transmission has been aborted due to lost arbitration - when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset. Reset type: SYSRSn

28.7.3.38 MCAN_TXBAR Register (Offset (x8) = D0h, Offset (x16) = 68h) [Reset = 00000000h]

MCAN_TXBAR is shown in Figure 28-73 and described in Table 28-70.

Bit	Field	Type	Reset	Description
31	AR31	R/WQ	0h	Add Request 31. See description for bit 0. Reset type: SYSRSn
30	AR30	R/WQ	0h	Add Request 30. See description for bit 0. Reset type: SYSRSn
29	AR29	R/WQ	0h	Add Request 29. See description for bit 0. Reset type: SYSRSn
28	AR28	R/WQ	0h	Add Request 28. See description for bit 0. Reset type: SYSRSn
27	AR27	R/WQ	0h	Add Request 27. See description for bit 0. Reset type: SYSRSn
26	AR26	R/WQ	0h	Add Request 26. See description for bit 0. Reset type: SYSRSn
25	AR25	R/WQ	0h	Add Request 25. See description for bit 0. Reset type: SYSRSn
24	AR24	R/WQ	0h	Add Request 24. See description for bit 0. Reset type: SYSRSn
23	AR23	R/WQ	0h	Add Request 23. See description for bit 0. Reset type: SYSRSn
22	AR22	R/WQ	0h	Add Request 22. See description for bit 0. Reset type: SYSRSn
21	AR21	R/WQ	0h	Add Request 21. See description for bit 0. Reset type: SYSRSn
20	AR20	R/WQ	0h	Add Request 20. See description for bit 0. Reset type: SYSRSn
19	AR19	R/WQ	0h	Add Request 19. See description for bit 0. Reset type: SYSRSn

Table 28-70. MCAN_TXBAR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	AR18	R/WQ	0h	Add Request 18. See description for bit 0. Reset type: SYSRSn
17	AR17	R/WQ	0h	Add Request 17. See description for bit 0. Reset type: SYSRSn
16	AR16	R/WQ	0h	Add Request 16. See description for bit 0. Reset type: SYSRSn
15	AR15	R/WQ	0h	Add Request 15. See description for bit 0. Reset type: SYSRSn
14	AR14	R/WQ	0h	Add Request 14. See description for bit 0. Reset type: SYSRSn
13	AR13	R/WQ	0h	Add Request 13. See description for bit 0. Reset type: SYSRSn
12	AR12	R/WQ	0h	Add Request 12. See description for bit 0. Reset type: SYSRSn
11	AR11	R/WQ	0h	Add Request 11. See description for bit 0. Reset type: SYSRSn
10	AR10	R/WQ	0h	Add Request 10. See description for bit 0. Reset type: SYSRSn
9	AR9	R/WQ	0h	Add Request 9. See description for bit 0. Reset type: SYSRSn
8	AR8	R/WQ	0h	Add Request 8. See description for bit 0. Reset type: SYSRSn
7	AR7	R/WQ	0h	Add Request 7. See description for bit 0. Reset type: SYSRSn
6	AR6	R/WQ	0h	Add Request 6. See description for bit 0. Reset type: SYSRSn
5	AR5	R/WQ	0h	Add Request 5. See description for bit 0. Reset type: SYSRSn
4	AR4	R/WQ	0h	Add Request 4. See description for bit 0. Reset type: SYSRSn
3	AR3	R/WQ	0h	Add Request 3. See description for bit 0. Reset type: SYSRSn
2	AR2	R/WQ	0h	Add Request 2. See description for bit 0. Reset type: SYSRSn
1	AR1	R/WQ	0h	Add Request 1. See description for bit 0. Reset type: SYSRSn
0	AR0	R/WQ	0h	Add Request 0. Each Tx Buffer has its own Add Request bit. Writing a '1' will set the corresponding Add Request bit writing a '0' has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to TXBAR. TXBAR bits are set only for those Tx Buffers configured via TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed. 0 No transmission request added 1 Transmission requested added Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored. Qualified Write is possible only with CCCR.CCE='0' Reset type: SYSRSn

28.7.3.39 MCAN_TXBCR Register (Offset (x8) = D4h, Offset (x16) = 6Ah) [Reset = 00000000h]

MCAN_TXBCR is shown in Figure 28-74 and described in Table 28-71.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 28-80 shows the codes that are used for access types in this section.

Table 28-80. MCAN_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 28-80. MCAN_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WD	W D	Write Decrement. Decrements the specified bit field by the amount written.
WI	W I	Write Increment. Increments the specified bit field by the amount written.
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

28.7.4.1 MCANERR_REV Register (Offset (x8) = 0h, Offset (x16) = 0h) [Reset = 66A0EA00h]

MCANERR_REV is shown in Figure 28-82 and described in Table 28-81.

Return to the Summary Table.

28.7.4.2 MCANERR_VECTOR Register (Offset (x8) = 8h, Offset (x16) = 4h) [Reset = 00000000h]

MCANERR_VECTOR is shown in Figure 28-83 and described in Table 28-82.

Return to the Summary Table.

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC_VECTOR field, together with the RD_SVBUS trigger and RD_SVBUS_ADDRESS bit field. This initiates the serial read which consummates by setting the RD_SVBUS_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

28.7.4.5 MCANERR_CTRL Register (Offset (x8) = 14h, Offset (x16) = Ah) [Reset = 00000187h]

MCANERR_CTRL is shown in Figure 28-86 and described in Table 28-85.

Return to the Summary Table.

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

Table 28-85. MCANERR_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8	CHECK_SVBUS_TIMEOUT	R/W	1h	Enables Serial VBUS timeout mechanism Reset type: SYSRSn
7	RESERVED	R/W	1h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error. Reset type: SYSRSn
5	FORCE_N_ROW	R/W	0h	Enable single/double-bit error on the next RAM read, regardless of the MCANERR_ERR_CTRL1.ECC_ROW setting. For write through mode, this applies to writes as well as reads. Reset type: SYSRSn
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn

Table 28-88. MCANERR_ERR_STAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	ECC Error Bit Position. Indicates the bit position in the RAM data that is in error on an SEC error. Only valid on an SEC error. 0 Bit 0 is in error 1 Bit 1 is in error 2 Bit 2 is in error 3 Bit 3 is in error ... 31 Bit 31 is in error >32 Invalid Reset type: SYSRSn
15	CLR_CTRL_REG_ERROR	R/W1S	0h	Writing a '1' clears the CTRL_REG_ERROR bit Reset type: SYSRSn
14-13	RESERVED	R/WD	0h	Reserved
12	CLR_ECC_OTHER	R/W1C	0h	Writing a '1' clears the ECC_OTHER bit. Reset type: SYSRSn
11-10	CLR_ECC_DED	R/WD	0h	Clear ECC_DED. A write of a non-zero value to this bit field decrements the ECC_DED bit field by the value provided. Reset type: SYSRSn
9-8	CLR_ECC_SEC	R/WD	0h	Clear ECC_SEC. A write of a non-zero value to this bit field decrements the ECC_SEC bit field by the value provided. Reset type: SYSRSn
7	CTRL_REG_ERROR	R/W1S	0h	Control Register Error. A bit field in the control register is in an ambiguous state. This means that the redundancy registers have detected a state where not all values are the same and has defaulted to the reset state. S/W needs to re-write these registers to a known state. A write of 1 will set this interrupt flag. Reset type: SYSRSn
6-5	RESERVED	R/WI	0h	Reserved

Table 28-88. MCANERR_ERR_STAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	ECC_OTHER	R/W1S	0h	SEC While Writeback Error Status 0 No SEC error while writeback pending 1 Indicates that successive single-bit errors have occurred while a writeback is still pending Reset type: SYSRSn
3-2	ECC_DED	R/WI	0h	Double Bit Error Detected Status. A 2-bit saturating counter of the number of DED errors that have occurred since last cleared. 0 No double-bit error detected 1 One double-bit error was detected 2 Two double-bit errors were detected 3 Three double-bit errors were detected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn
1-0	ECC_SEC	R/WI	0h	Single Bit Error Corrected Status. A 2-bit saturating counter of the number of SEC errors that have occurred since last cleared. 0 No single-bit error detected 1 One single-bit error was detected and corrected 2 Two single-bit errors were detected and corrected 3 Three single-bit errors were detected and corrected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn

28.7.4.9 MCANERR_ERR_STAT2 Register (Offset (x8) = 24h, Offset (x16) = 12h) [Reset = 00000000h]

MCANERR_ERR_STAT2 is shown in Figure 28-90 and described in Table 28-89.

Return to the Summary Table.

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

Chapter 29

Local Interconnect Network (LIN)

This chapter describes the local interconnect network (LIN) module. Since this module can also operate like a conventional serial communications interface (SCI) port, this module is referred to as the SCI/LIN module in this document. In SCI compatibility mode, this module is functionally compatible to the standalone SCI module. However, since the SCI/LIN module uses a different register/bit structure, code written for this module cannot be directly ported to the standalone SCI module and conversely.

This module can be configured to operate in either SCI (UART) or LIN mode.

29.1 LIN Overview

The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*.The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The SCI hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter (UART) that implements the standard non-return to zero format.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-commander/multiple-responder with a message identification for multicast transmission between any network nodes.

Throughout the chapter, compatibility mode refers to SCI mode functionality of the SCI/LIN module. Section 29.2 explains about the SCI functionality and Section 29.3 explains about the LIN functionality. Though the registers are common for LIN and SCI, the register descriptions has notes to identify the register and bit usage in different modes.

29.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard non-return to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports 2^{24} different baud rates provide high accuracy baud rate selection
- At 100MHz peripheral clock, 3.125Mbps is the maximum baud rate achievable
- Capability to use direct memory access (DMA) for transmit and receive data
- Five error flags and seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multibuffered receive and transmit units

Note

The SCI/LIN module is functionally compatible with the C2000™ SCI modules, but not directly software compatible due to different register control structures.

The SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general-purpose I/O pin.

The SCI/LIN module does not support isosynchronous mode as there is no SCICLK pin.

29.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3 , 2.0, and 2.1 protocols
- Configurable baud rate up to 20 kbps
- Two external pins: LINRX and LINTX.
- Multibuffered receive and transmit units
- Identification masks for message filtering
- Automatic commander header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Responder Automatic Synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- 2^{31} programmable transmission rates with 7 fractional bits
- Wakeup on LINRX dominant level from transceiver
- Automatic wakeup support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

29.1.4 Block Diagram

The SCI/LIN module contains the core SCI block with added sub-blocks to support LIN protocol.

The three major components of the SCI Module are:

- **Transmitter** (TX) contains two major registers to perform the double-buffering:
  - The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
  - The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.
- **Baud Clock Generator**
  - A programmable baud generator produces a baud clock scaled from the input clock VCLK
  - LIN VCLK is based on the SYSCLK frequency. VCLK input from SYSCLK and can be divided by 1, 2, or 4 using the CLK_CFG_REGS PERCLKDIVSEL.LINxCLKDIV field for each LIN module individually. By default, VCLK input is SYSCLK divided by 2
- **Receiver** (RX) contains two major registers to perform the double-buffering:
  - The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
  - The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has a separate enable and interrupt bits. The receiver and transmitter can each be operated independently or simultaneously in full duplex mode.

To maintain data integrity, the SCI checks the data the SCI receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 29-1 shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multibuffered receiver and transmitter. The SCI interface, the DMA control sub-blocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. Figure 29-2 shows the SCI/LIN block diagram.

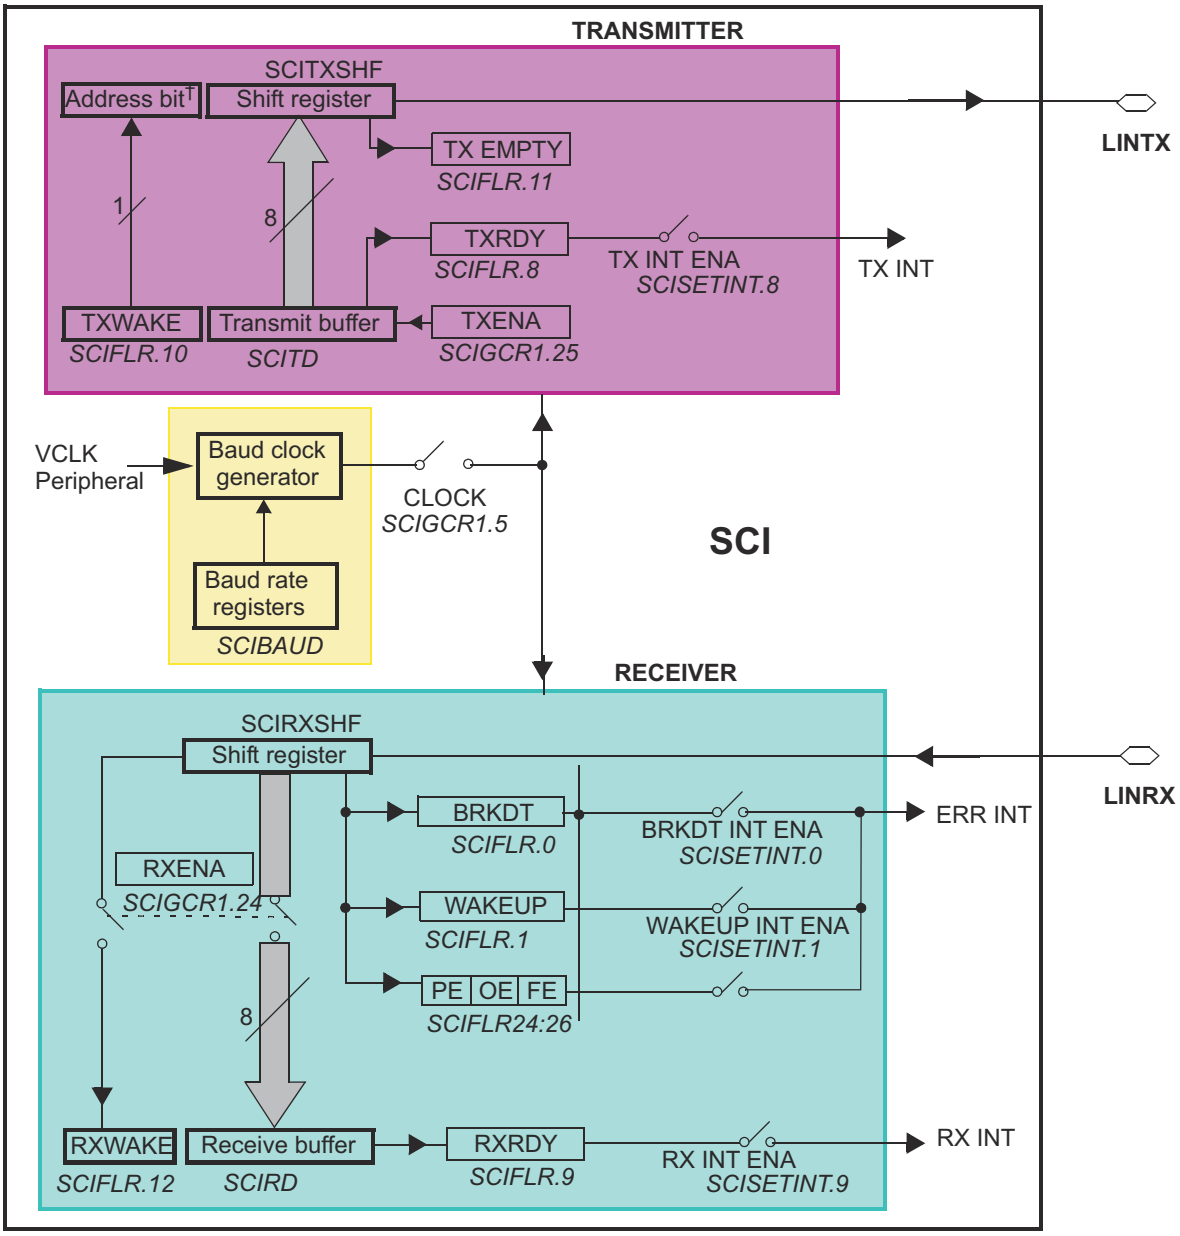

Figure 29-1. SCI Block Diagram

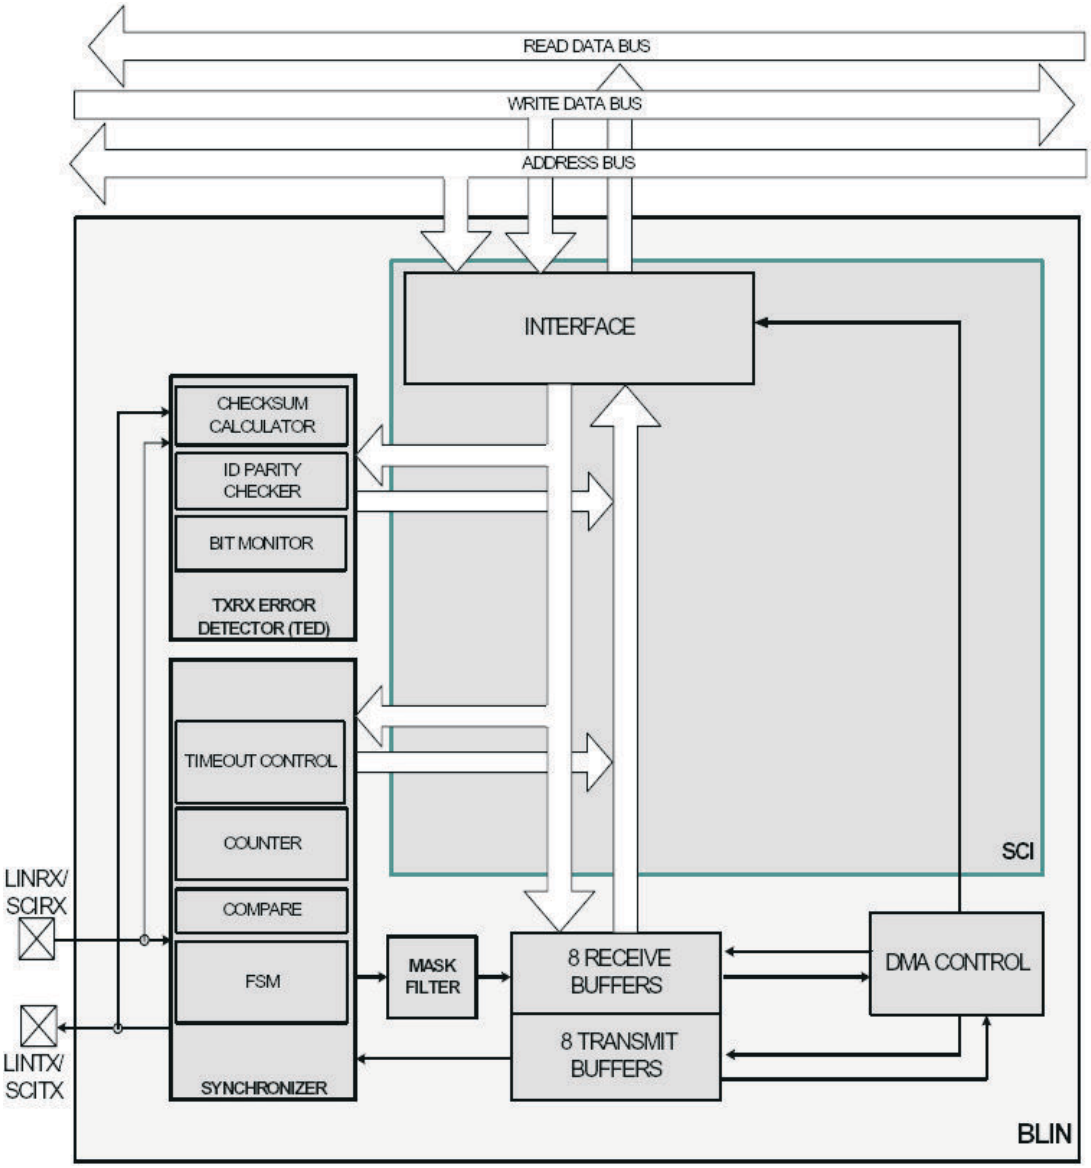

Figure 29-2. SCI/LIN Block Diagram

29.2 Serial Communications Interface Module

29.2.1 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The configuration options are:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

29.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 29-3.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected using the PARITY ENA bit. Both examples in Figure 29-3 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to make sure synchronization between communicating devices. Two stop bits are transmitted, if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 29-3 use one stop bit per frame.

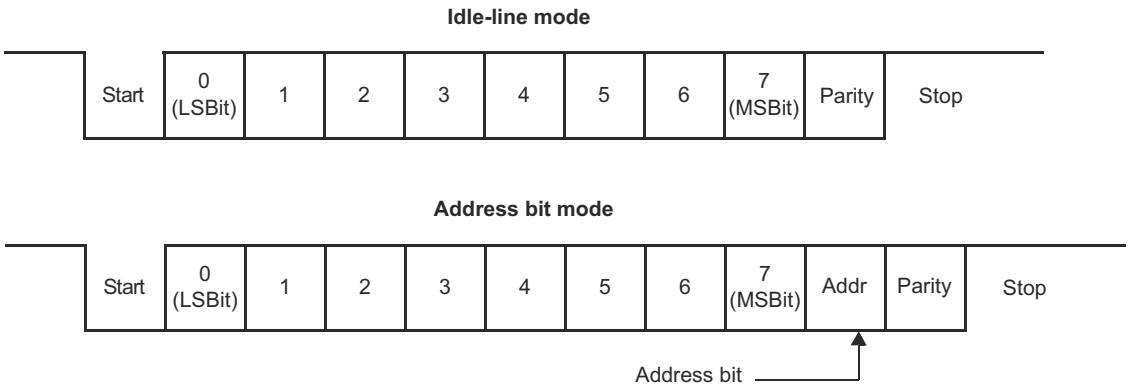

Figure 29-3. Typical SCI Data Frame Formats

29.2.1.2 SCI Asynchronous Timing Mode

The SCI can be configured to use the asynchronous timing mode using TIMING MODE bit in SCIGCR1 register.

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 29-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

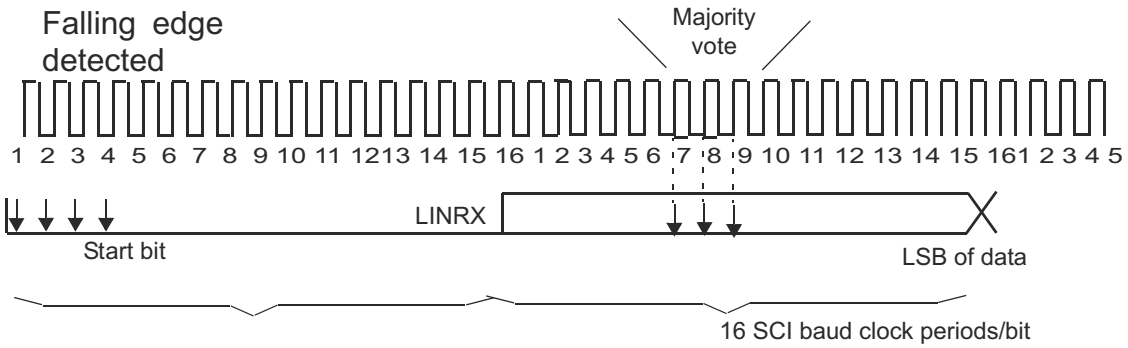

Figure 29-4. Asynchronous Communication Bit Timing

29.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK\ Frequency = \frac{VCLK\ Frequency}{P + 1 + \frac{M}{16}}$$

$$Asynchronous\ baud\ value = \frac{SCICLK\ Frequency}{16}$$

For P = 0,

$$Asynchronous\ baud\ value = \frac{VCLK\ Frequency}{32}$$

29.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see Table 29-2). The bits with a 1 in the table have an additional VCLK period added to the T_{bit}. If the character length is more than 10, then the modulation table is a rolled-over version of the original table (Table 29-1), as shown in Table 29-2.

The baud rate varies over a data field to average according to the BRS[30:28] value by a "**d**" fraction of the peripheral internal clock: **0<d<1.** See Figure 29-5 for a simple Average "d' calculation based on "U" value (BRS[30:28]).

The instantaneous bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0<d<1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

29.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI can be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data can be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when the devices are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received using the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

29.2.1.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 29-6 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software can wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time the SCI sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear the bit.

When idle-line multiprocessor communications are used, software must make sure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also make sure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions results in data interpretation errors by other devices receiving the transmission.

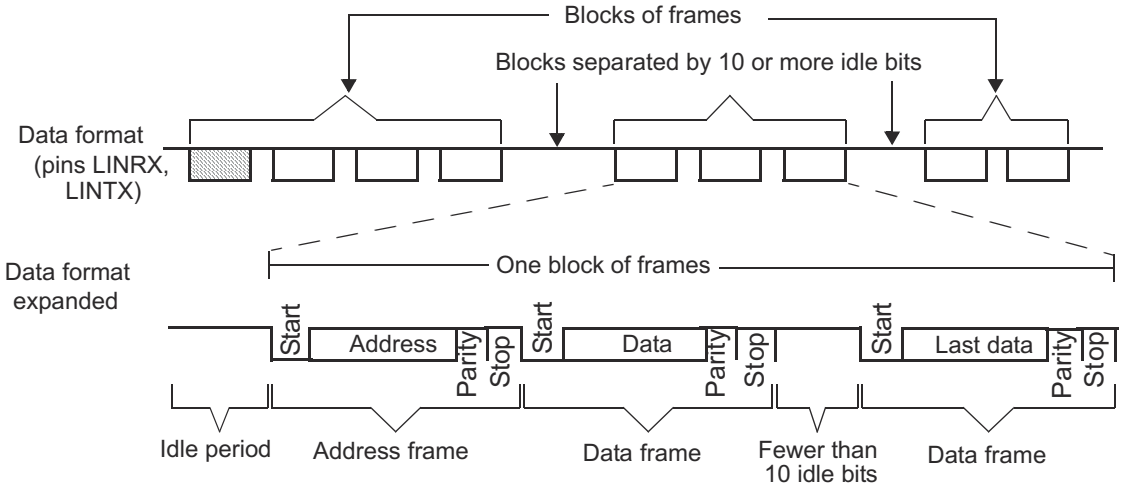

Figure 29-6. Idle-Line Multiprocessor Communication Format

29.2.1.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 29-7 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

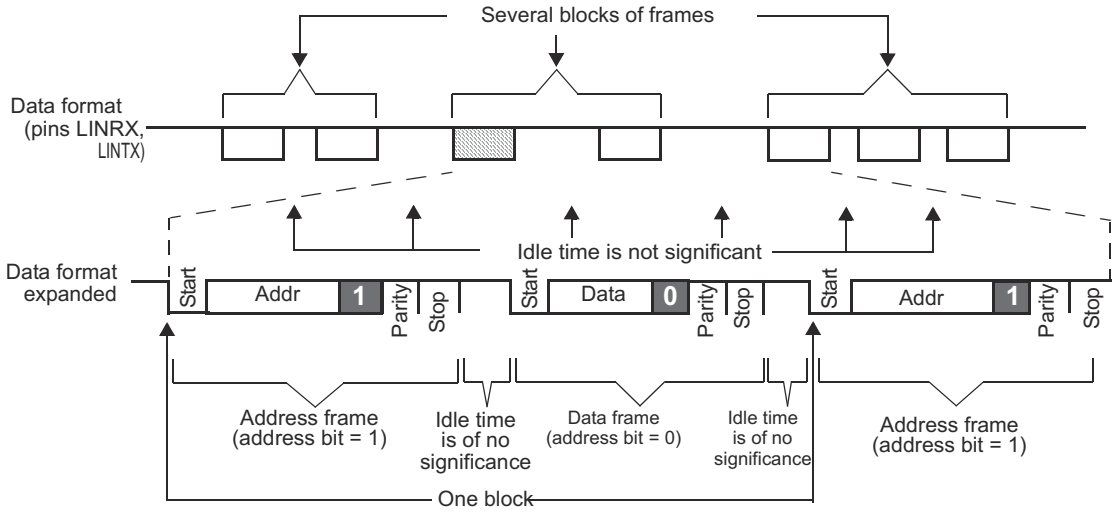

Figure 29-7. Address-Bit Multiprocessor Communication Format

29.2.1.5 SCI Multibuffered Mode

To reduce CPU load when receiving or transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate receive and transmit buffers. Multibuffered mode is enabled by setting the MBUF MODE bit.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) can occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) can occur after transmitting a response.

Figure 29-8 and Figure 29-9 show the receive and transmit multibuffer functional block diagram, respectively.

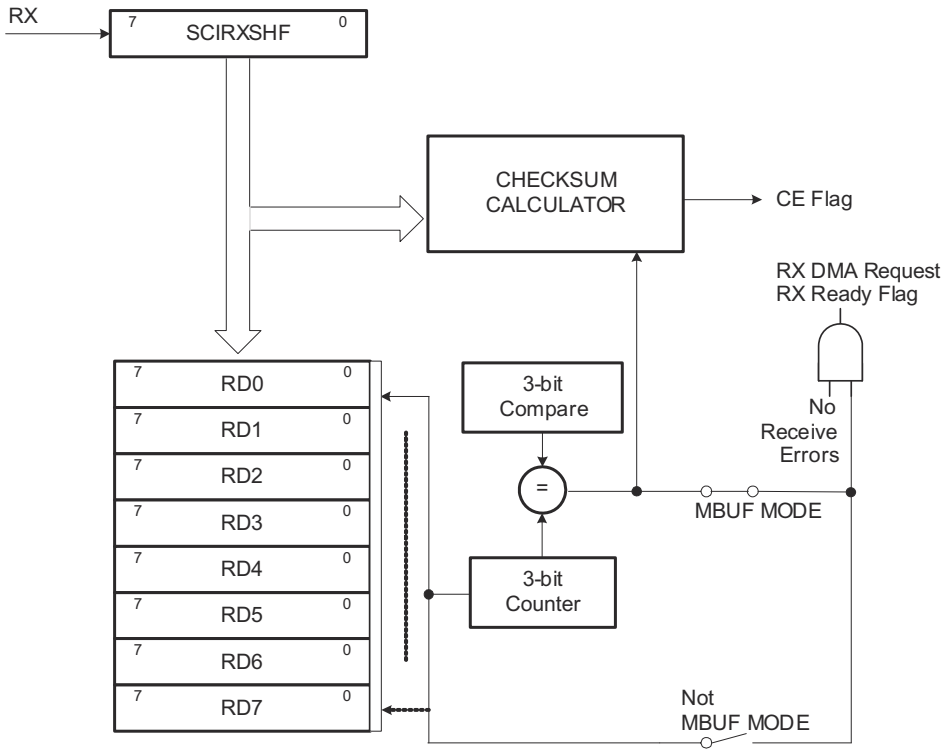

Figure 29-8. Receive Buffers

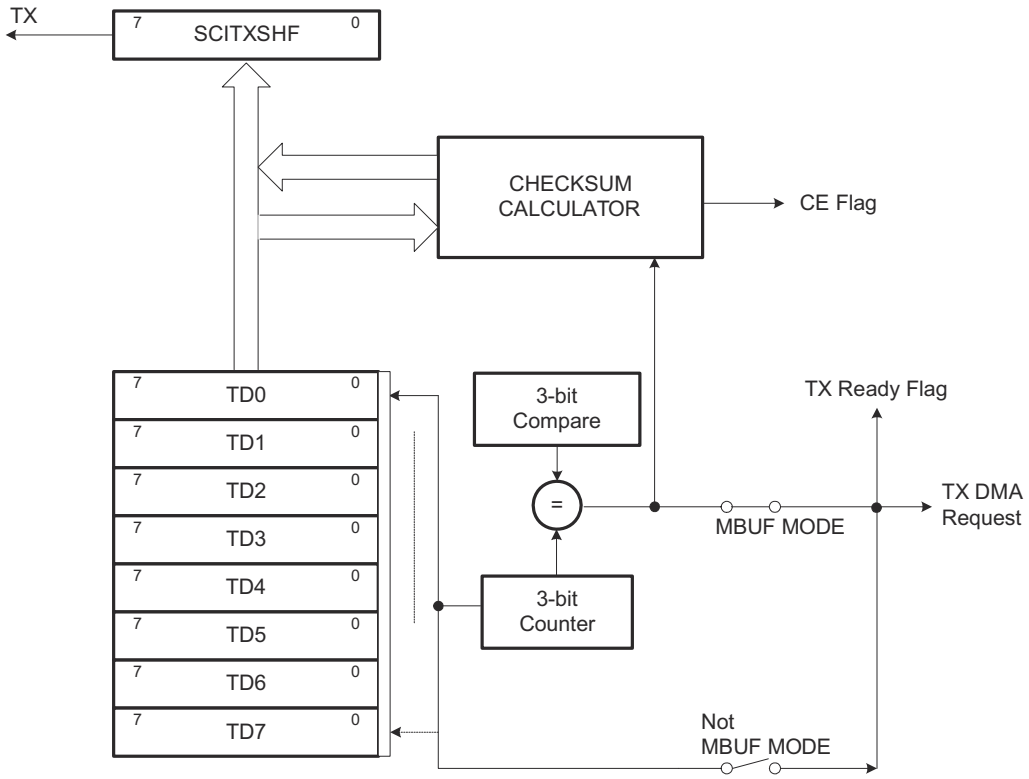

Figure 29-9. Transmit Buffers

29.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 29-10). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0(INT0) or as interrupt level 1(INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

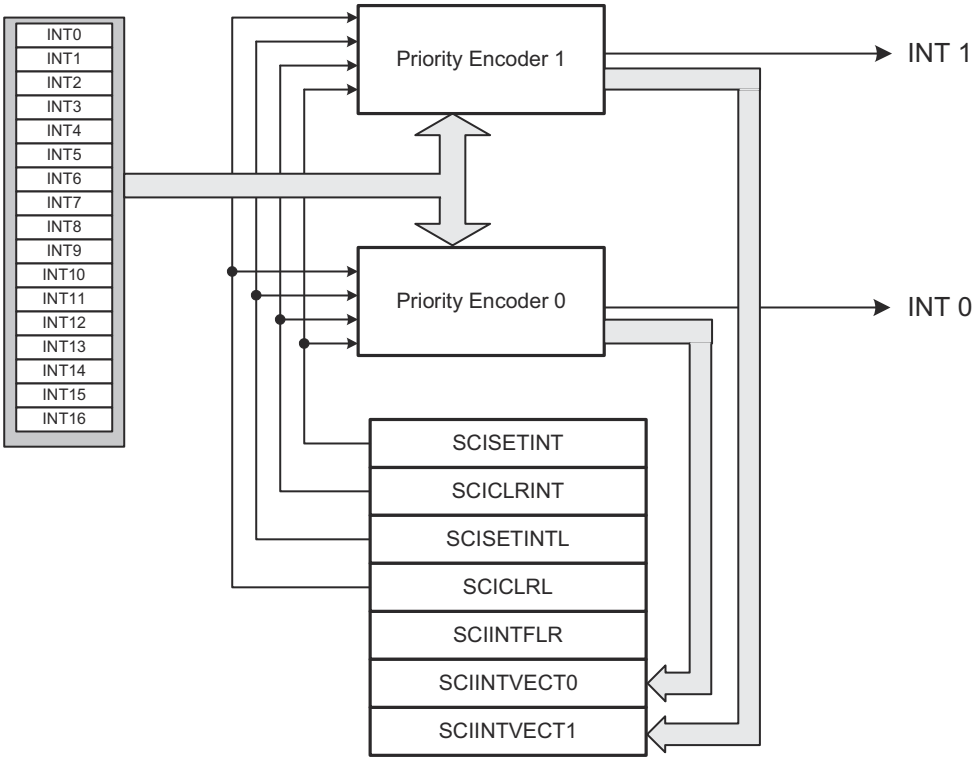

Figure 29-10. General Interrupt Scheme

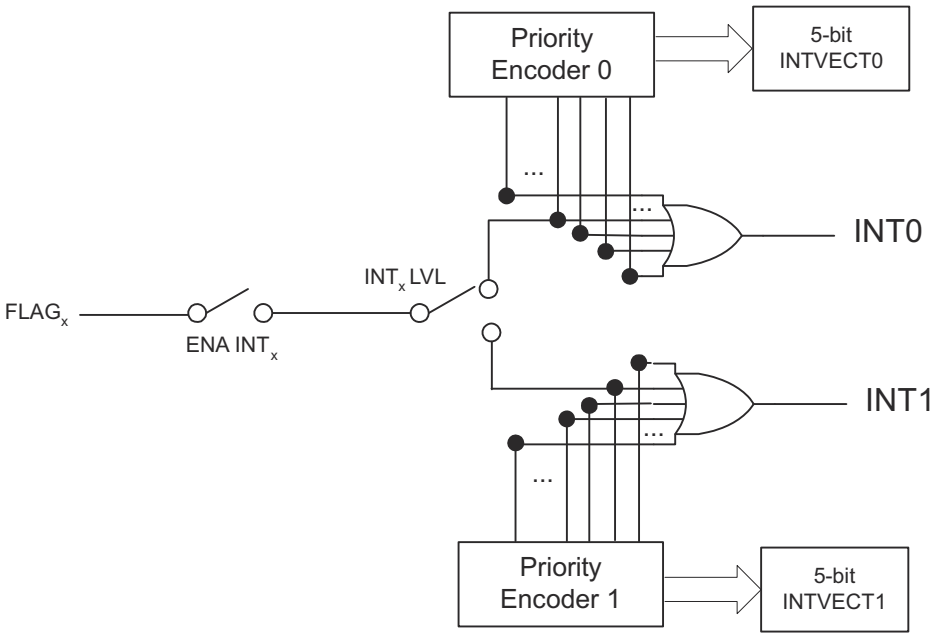

Figure 29-11. Interrupt Generation for Given Flags

29.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SETTXINT bit must be enabled and SET_TX_DMA bit must be cleared in the SCISETINT register. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD/TDy to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD/TDy is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD/TDy and SCITXSHF registers are empty. If the SETTXINT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. The transmit interrupt is not generated immediately after setting the SETTXINT bit unlike the transmit DMA request. The transmit interrupt is generated only after the first transfer from SCITD/TDy to SCITXSHF, that is first data has to be written to SCITD/TDy before any interrupt gets generated. To transmit further data, data can be written to SCITD/TDy in the transmit interrupt service routine.

Writing data to the SCITD/TDy register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLRTXINT bit in the SCICLEARINT register; however, when the SETTXINT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD/TDy, by disabling the transmitter using the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

29.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD/RDy. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SETRXINT bit in the SCISETINT register. If the SETRXINT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with a DMA controller, the SET_RX_DMA bit in the SCISETINT register must be cleared to select interrupt functionality.

29.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SCISETINT.SETWAKEUPINT is set), the wakeup interrupt is triggered once the WAKEUP flag in the SCIFLR register is set.

29.2.2.4 Error Interrupts

The following error detections are supported with an interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

There are 16 interrupt sources in the SCI/LIN module. In SCI mode, 8 interrupts are supported, as listed in Table 29-4.

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver, if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register (Table 29-5 and Table 29-6).

Table 29-4. SCI/LIN Interrupts

Offset(1)	Interrupt	Applicable to SCI	Applicable to LIN
0	No interrupt	-	-
1	Wakeup	Yes	Yes
2	Inconsistent-sync-field error (ISFE)	No	Yes
3	Parity error (PE)	Yes	Yes
4	ID	No	Yes
5	Physical bus error (PBE)	No	Yes
6	Frame error (FE)	Yes	Yes
7	Break detect (BRKDT)	Yes	No
8	Checksum error (CE)	No	Yes
9	Overrun error (OE)	Yes	Yes
10	Bit error (BE)	Yes	Yes
11	Receive	Yes	Yes
12	Transmit	Yes	Yes
13	No-response error (NRE)	No	Yes
14	Timeout after wakeup signal (150ms)	No	Yes
15	Timeout after three wakeup signals (1.5s)	No	Yes
16	Timeout (Bus Idle, 4s)	No	Yes

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

Table 29-5. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After Reset(1)
CE	SCIFLR	29	0
ISFE	SCIFLR	28	0
NRE	SCIFLR	27	0
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BUSY	SCIFLR	3	0
IDLE	SCIFLR	2	1
WAKEUP	SCIFLR	1	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with the reset value while SWnRST = 0.

Table 29-6. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After Reset(1)
BE	SCIFLR	31	0
PBE	SCIFLR	30	0
TXWAKE	SCIFLR	10	0
TXEMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with the reset value while SWnRST = 0.

29.2.3 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA must be configured to transfer to/from the SCITD/SCIRD register if multibuffer mode is disabled (MBUFMODE in the SCIGCR1 register is cleared), and to/from the TDy/RDy registers if multibuffer mode is enabled (MBUFMODE in the SCIGCR1 register is set.)

29.2.3.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SETRXDMA/CLRRXDMA bits, respectively.

In multibuffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RXDMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET_RX_DMA_ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA request is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

29.2.3.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET_TX_DMA/CLR_TX_DMA bits, respectively.

In multibuffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a DMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis.

29.2.4 SCI Configurations

Before the SCI sends or receives data, the SCI registers can be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until the bit is programmed to 1. Therefore, all SCI configuration can be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software can perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until the current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see Section 29.2.4.1 or Section 29.2.4.2).

29.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages, if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffer Mode

After a valid idle period is detected, data is automatically received as the data arrives on the LINRX pin.

29.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY bit is cleared after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the FE, OE, or PE flags are set if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wakeup and break-detect status bits are also set if one of these errors occurs, but the bits do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling the Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, set the SETRXINT bit. To use the DMA method, set the SET_RX_DMA bit. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

29.2.4.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, use the polling, DMA, or interrupt method to read the data. The RXRDY bit is automatically cleared after the new data in SCIRD has been read.

29.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD/TDy before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

The SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffered or Buffered SCI Mode

29.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, the SCI waits for data to be written to SCITD, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling the Transmit Ready Flag
2. Transmit Interrupt
3. DMA

With the polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETTXINT bit is set. To use the DMA method, the SET_TX_DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request must be halted. This can either be done by disabling the transmit interrupt (CLRTXINT) / DMA request (CLRTXDMA bit), or by disabling the transmitter (clear TXENA bit).

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

29.2.4.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. The SCI waits for data to be written to the SCITD register and then transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

29.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wakeup interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wakeup interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wakeup interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wakeup interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

29.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if SETRXINT is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior can be enhanced to provide selective indication of new data. When the SCI receives an address frame that does not match the address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI loads SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI can check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. The bit is set to 1, if the current value in SCIRD is an address; the bit is set to 0, if SCIRD contains data. If the RXWAKE bit is set, then software can check the address in SCIRD against the address. If SCIRD is still being addressed, then sleep mode can remain disabled; otherwise, the SLEEP bit can be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. Otherwise, these interrupts require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 29-5) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software can not change the value of the SLEEP bit and can continue to poll RXRDY.

29.3 Local Interconnect Network Module

29.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls, and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling the LINMODE bit in SCIGCR1 register.

Note

The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10. For the START bit, the first three samples are used.

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see Section 29.7.

29.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

1. Support for LIN 2.0 checksum
2. Enhanced synchronizer FSM support for frame processing
3. Enhanced handling of extended frames
4. Enhanced baud rate generator
5. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware. The Commander Mode of LIN module is compatible with LIN 2.1 standard.

29.3.1.2 Message Frame

The LIN protocol defines a message frame format, shown in Figure 29-12. Each frame includes one commander header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces can be 0.

There is no arbitration in the definition of the LIN protocol; therefore, multiple responder nodes responding to a header can be detected as an error.

The LIN bus is a single-channel wired-AND bus. The bus has a binary level: either dominant for a value of 0 or recessive for a value of 1.

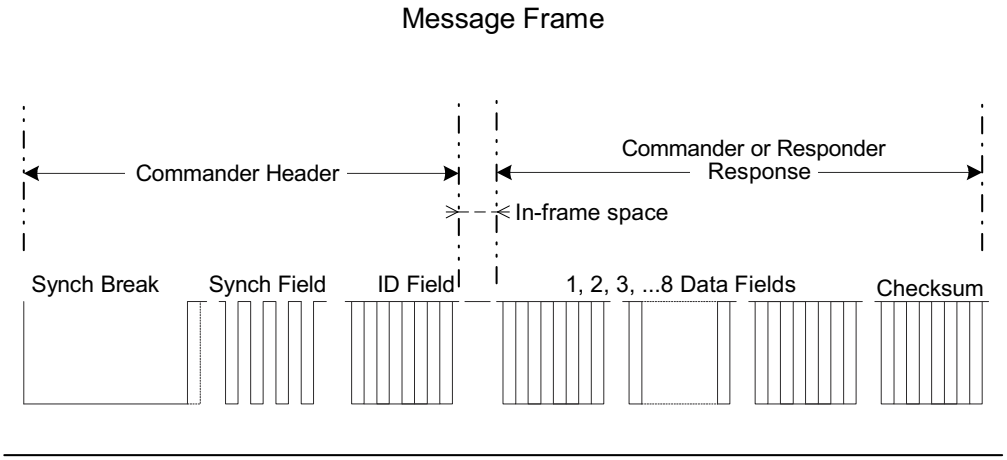

Figure 29-12. LIN Protocol Message Frame Format: Commander Header and Responder Peripheral Response

29.3.1.2.1 Message Header

The header of a message is initiated by a commander (see Figure 29-13) and consists of a three field-sequence:

- The synchronization break field signaling the beginning of a message
- The synchronization field conveying bit rate information of the LIN bus
- The identification field denoting the content of a message

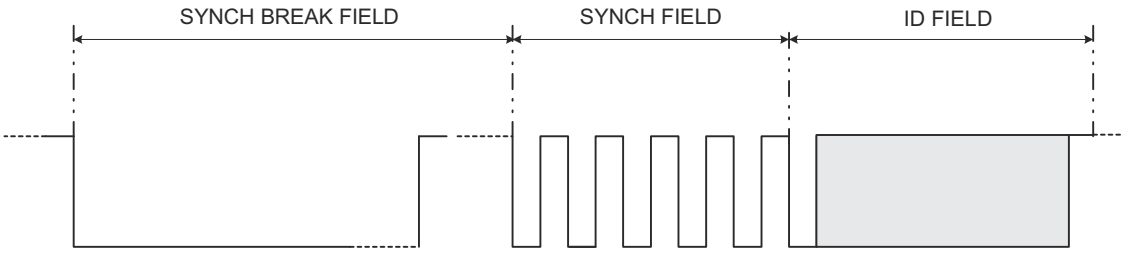

Figure 29-13. Header 3 Fields: Synch Break, Synch, and ID

29.3.1.2.2 Response

The format of the response is as illustrated in Figure 29-14. There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

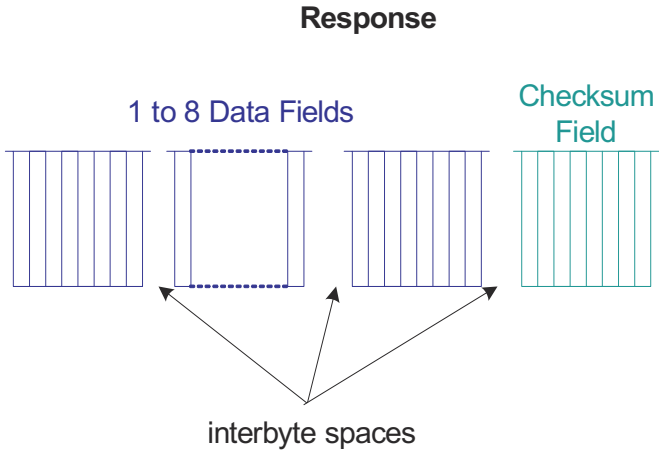

Figure 29-14. Response Format of LIN Message Frame

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames (Section 29.3.1.6). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see Table 29-7, or by LENGTH value in SCIFORMAT[18:16] register; see Table 29-8. The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

Table 29-7. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than v1.3

ID5	ID4	Number of Data Bytes
0	0	2
0	1	2
1	0	4
1	1	8

Table 29-8. Response Length with SCIFORMAT[18:16] Programming

SCIFORMAT[18:16]	Number of Bytes
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

29.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between commander and responder nodes. The synchronizer generates the commander header data stream, the synchronizer synchronizes to the LIN bus for responding, and the synchronizer locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN_speed value in the LIN description file.

The LIN synchronizer performs the following functions: commander header signal generation, responder detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

29.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time T_{bit}. The bit time is derived from the fields P and M in the baud rate selection register (BRSR). There is an additional 3-bit fractional divider value, field U in the BRSR register, which further fine-tunes the data-field baud rate.

The ranges for the prescaler values in the BRSR register are:

P = 0, 1, 2, 3, . . . , 2^{24} - 1

M = 0, 1, 2, . . . , 15

U = 0, 1, 2, 3, 4, 5, 6, 7

The P, M, and U values in the BRSR register are user programmable. The P and M dividers can be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that "**a T $_{VCLK}$** " (with **a** = 0, 1) is added to each T_{bit} as explained in Section 29.3.1.4.2. If the ADAPT bit is set and the LIN peripheral is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as:

$1kHz \le F_{LINCLK} \le 20kHz$

All transmitted bits are shifted in and out at T_{bit} periods.

29.3.1.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time, T_{bit} is expressed in terms of the VCLK period T_{VCLK} as follows:

For all P other than 0, and all M,

$$T_{bit} = 16\left(P + 1 + \frac{M}{16}\right)T_{VCLK}$$

For P = 0 : $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P+1+\frac{M}{16})} \quad \text{For all P other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For P = 0}$$

29.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN commander mode (sync field + identifier field + response field + checksum field)
- LIN responder mode (response field + checksum field)

29.3.1.4.2.1 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in Table 29-9. The sync field (0x55), the identifier field, and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table have an additional VCLK period added to the T_{bit}. In LIN commander mode, bit modulation applies to sync field + identifier field + response field. In LIN responder mode, bit modulation applies to identifier field + response field.

Table 29-9. Superfractional Bit Modulation for LIN Commander Mode and Responder Mode

BRSR[30:28]	Start Bit	D[0]	D[1]	D[2]	D[3]	D[4]	D[5]	D[6]	D[7]	Stop Bit
0h	0	0	0	0	0	0	0	0	0	0
1h	1	0	0	0	0	0	0	0	1	0
2h	1	0	0	0	1	0	0	0	1	0
3h	1	0	1	0	1	0	0	0	1	0
4h	1	0	1	0	1	0	1	0	1	0
5h	1	1	1	0	1	0	1	0	1	1
6h	1	1	1	0	1	1	1	0	1	1
7h	1	1	1	1	1	1	1	0	1	1

The baud rate varies over a LIN data field to average according to the BRSR[30:28] value by a *d* fraction of the peripheral internal clock: 0<d<1.

The instantaneous bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P+1+\frac{M}{16}\right)+d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 < d <1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

29.3.1.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA triggers the LIN state machine to generate a message header. A commander node initiates header generation on the CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the commander to initiate a LIN communication and consists of three fields: synchronization break field, synchronization field, and identification field, as seen in Figure 29-15.

Note

The LIN protocol uses the parity bits in the identifier. The control length bits are optional to the LIN protocol.

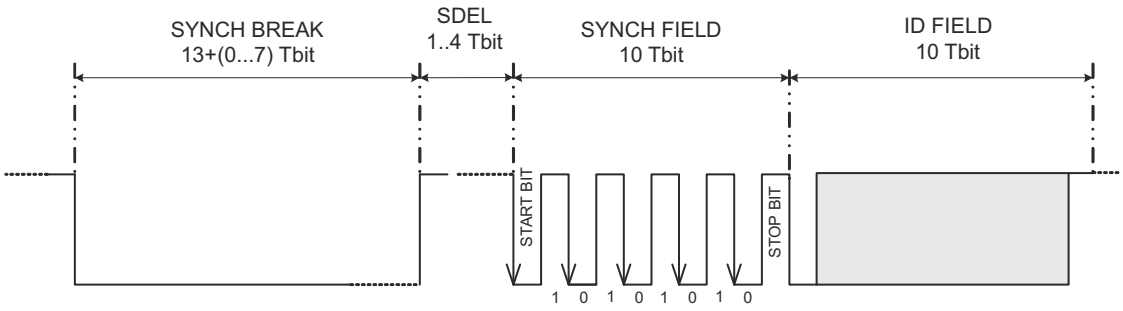

Figure 29-15. Message Header in Terms of T_{bit}

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The sync break length can be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The sync break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. SYNCH FIELD is used to convey T_{bit} information and resynchronize LIN bus nodes.
- The identifier field ID byte can use 6 bits as an identifier, with optional length control and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITYENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 29-16 for an illustration of the ID field.

Note

Optional Control Length Bits

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

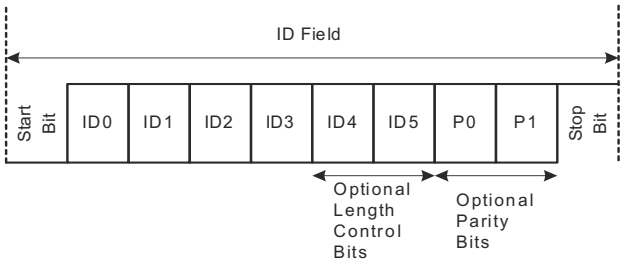

Figure 29-16. ID Field

Note

If the LIN module, configured as a responder in multibuffer mode, is in the process of transmitting data while a new header comes in, the module can end up responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario, the following procedure can be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise, TD0/TD1 can be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data is transmitted by the node.

29.3.1.5.1 Event Triggered Frame Handling

The LIN 2.0 protocol uses event-triggered frames that can occasionally cause collisions. Event-triggered frames are handled in software.

If no responder answers to an event triggered frame header, the commander node sets the NRE flag, and a NRE interrupt occurs if enabled. If a collision occurs, a frame error and checksum error can arise before the NRE error. Those errors are flagged and the appropriate interrupts occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding responders. If the responders are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The BUS BUSY flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision, the flag is cleared in the same cycle as the NRE flag is set.

Software can implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the BUS BUSY flag to get set or the NRE flag to get set.
- If the BUS BUSY flag is not set before the NRE flag, then a true no response is the case (no data has been transmitted onto the bus).
- If the BUS BUSY flag gets set, then wait for the NRE flag to get set or for successful reception. If the NRE flag is set, then a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

29.3.1.5.2 Header Reception and Adaptive Baud Rate

A responder node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a responder measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the responder node programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The responder node adjusts to any measured baud rate that is within ±10% of the programmed baud rate. For example, if the expected baud rate is programmed at 20kbps, the responder node detects any baud rate between 18kbps and 22kbps and adjusts accordingly. The MBRSR register prescaler is determined by the following formula:

$$\text{MBR} = \frac{\text{F}_{\text{VCLK}}}{1.1 \times \text{F}_{\text{LINCLK}}}$$

The LIN synchronizer determines two measurements: BRK_count and BAUD_count (Figure 29-17). These values are always calculated during the Header reception for synch field validation (Figure 29-18).

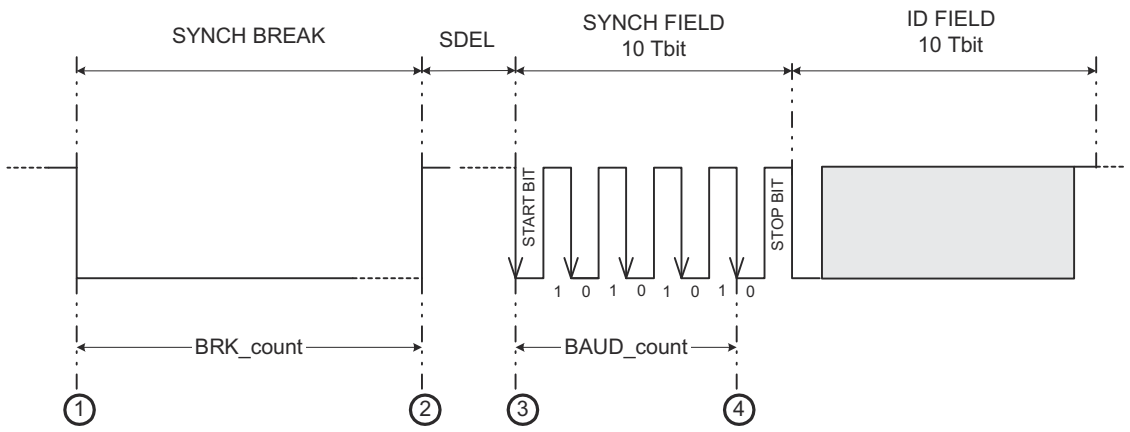

Figure 29-17. Measurements for Synchronization

By measuring the values BRK_count and BAUD_count, a valid sync break sequence can be detected as described in Figure 29-18. The four numbered events in Figure 29-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the sync break relative to the detecting node T_{bit}. For a responder node receiving the sync break, a threshold of 11 T_{bit} is used as required by the LIN protocol. For detection of the dominant data stream of the sync break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the sync break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A responder node can calculate a single T_{bit} time by division of BAUD_count by 8. In addition, for consistency between the detected edges the following is evaluated:

BAUD_count + BAUD_count » 2 + BAUD_count » 3 ≤ BRK_count

The BAUD_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a T_{bit} unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 29-18, if the measured BRK_count value is less than 11 T_{bit}, the sync break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK_count and BAUD_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

Note

In adaptive mode, the MBRS divider can be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte can mistakenly be detected as a sync break.

The break-threshold relative to the responder node is 11 T_{bit}. The break is 13 T_{bit} as specified in LIN v1.3.

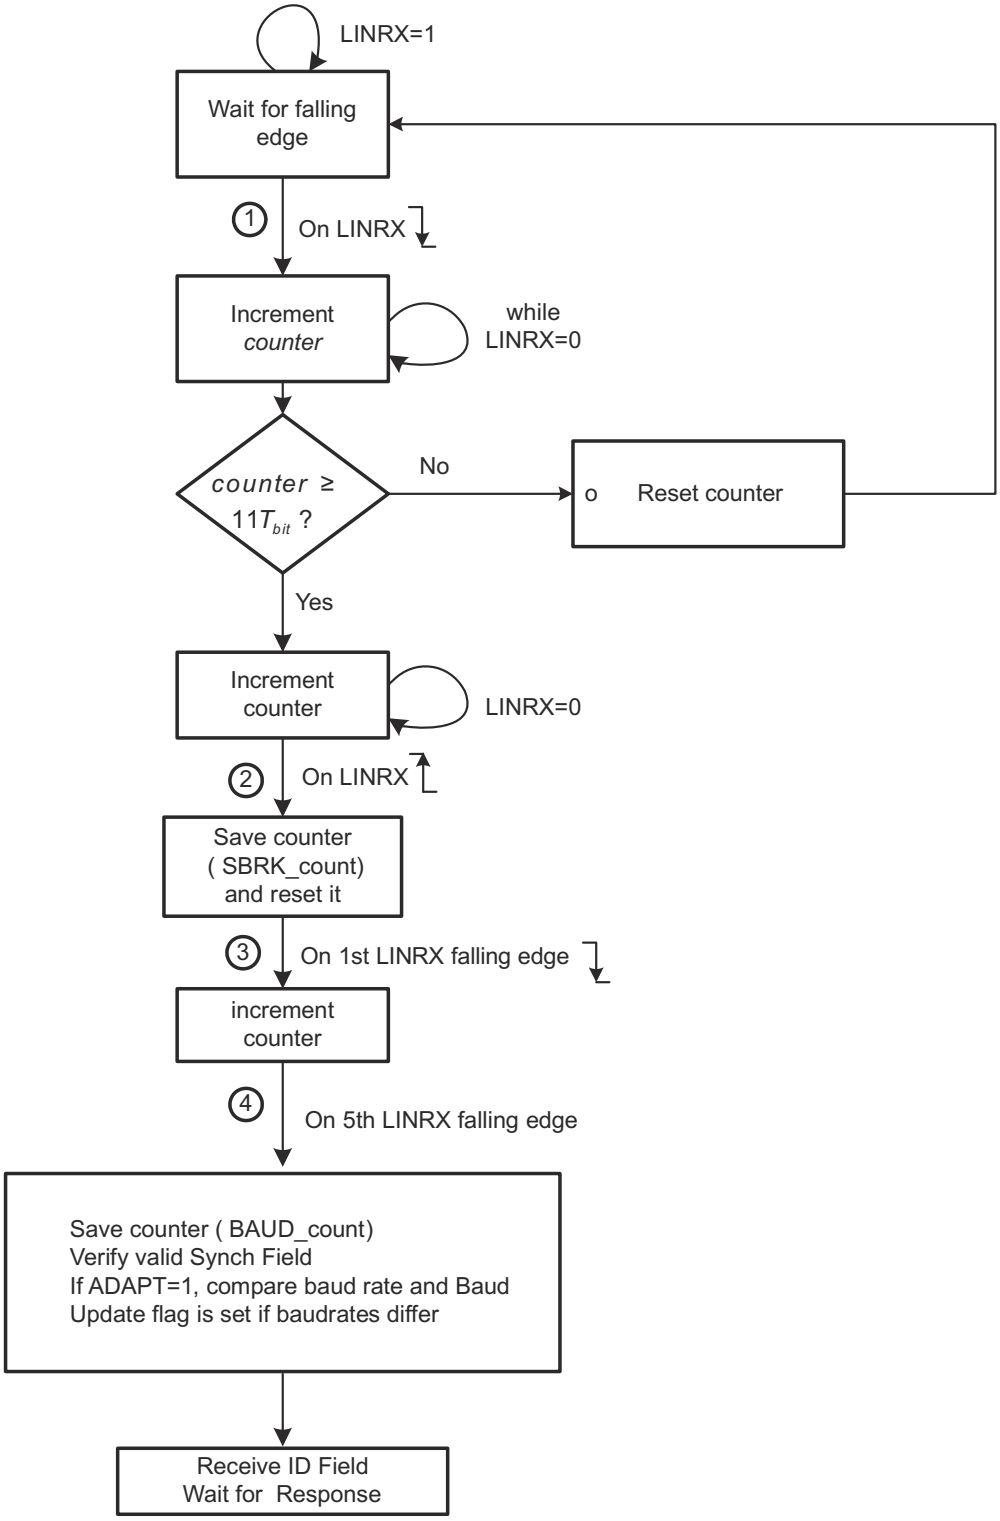

Figure 29-18. Synchronization Validation Process and Baud Rate Adjustment

If the synch field is not detected within the given tolerances, the inconsistent-sync-field-error (ISFE) flag is set. An ISFE interrupt is generated, if enabled by the respective bit in the SCISETINT register. The ID byte can be received after the synch field validation was successful. Any time a valid break (larger than 11 T_{bit}) is detected, the receiver state machine can reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

Note

When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to the normal states.

29.3.1.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier is set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see Figure 29-19. Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

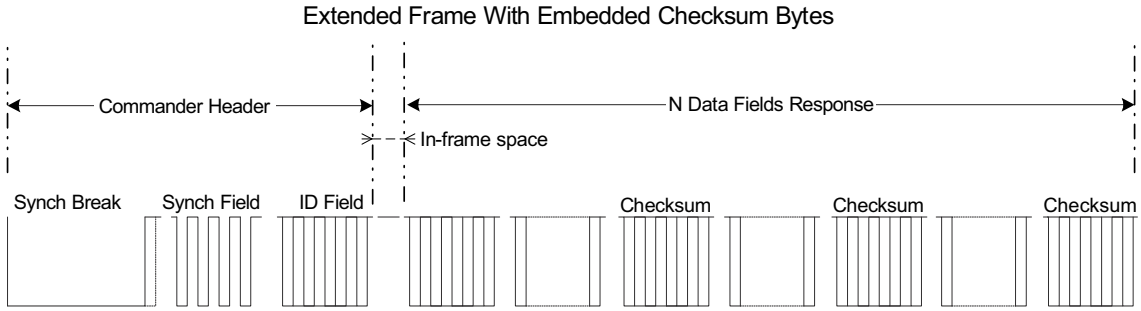

Figure 29-19. Optional Embedded Checksum in Response for Extended Frames

An ID interrupt is generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC initiates an automatic send of the checksum byte. The last data field can always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see Figure 29-20.

Note

The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

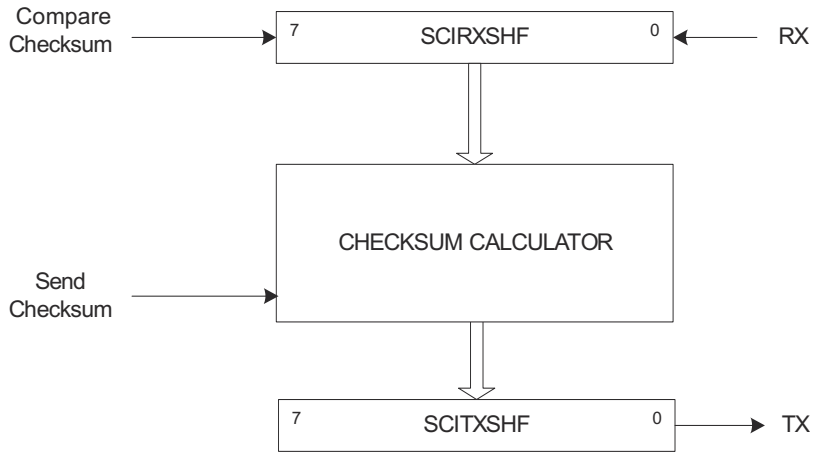

Figure 29-20. Checksum Compare and Send for Extended Frames

29.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a commander node can flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

29.3.1.7.1 No-Response Error (NRE)

The no-response error occurs when any node expecting a response waits for T_{FRAME_MAX} time and the message frame is not fully completed within the maximum length allowed, T_{FRAME_MAX}. After this time, a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered, if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{FRAME\_MIN} = T_{HEADER\_MIN} + T_{DATA\_FIELD} + T_{CHECKSUM\_FIELD} = 44 + 10N$$

where N = number of data fields.

And the maximum time frame is given by:

$$T_{FRAME\_MAX} = T_{FRAME\_MIN} * 1.4 = (44 + 10N) * 1.4$$

The timeout value T_{FRAME_MAX} is derived from the *N* number of data fields value, see Table 29-10. The *N* value is either embedded in the header ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register indicates the value for *N*.

Note

The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE is not handled by the LIN hardware.

Table 29-10. Timeout Values in T_{bit} Units

N	T_{DATA_FIELD}	T_{FRAME_MIN}	T_{FRAME_MAX}
1	10	54	76
2	20	64	90
3	30	74	104
4	40	84	118
5	50	94	132
6	60	104	146
7	70	114	160
8	80	124	174

29.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 seconds (this is 80,000 F_{LINCLK} cycles with the fastest bus rate of 20kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, assume that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

Note

After the timeout was flagged, a SWnRESET must be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame is on the bus before the idle period.

29.3.1.7.3 Timeout After Wakeup Signal and Timeout After Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup must expect a header from the commander within a defined amount of time: timeout after wakeup signal. See Section 29.4.3 for more details.

29.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

29.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor makes sure that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 29-21.

Note

If a bit occurs due to receiving a header during a responder response, NRE/TIMEOUT flag is not set for the new frame.

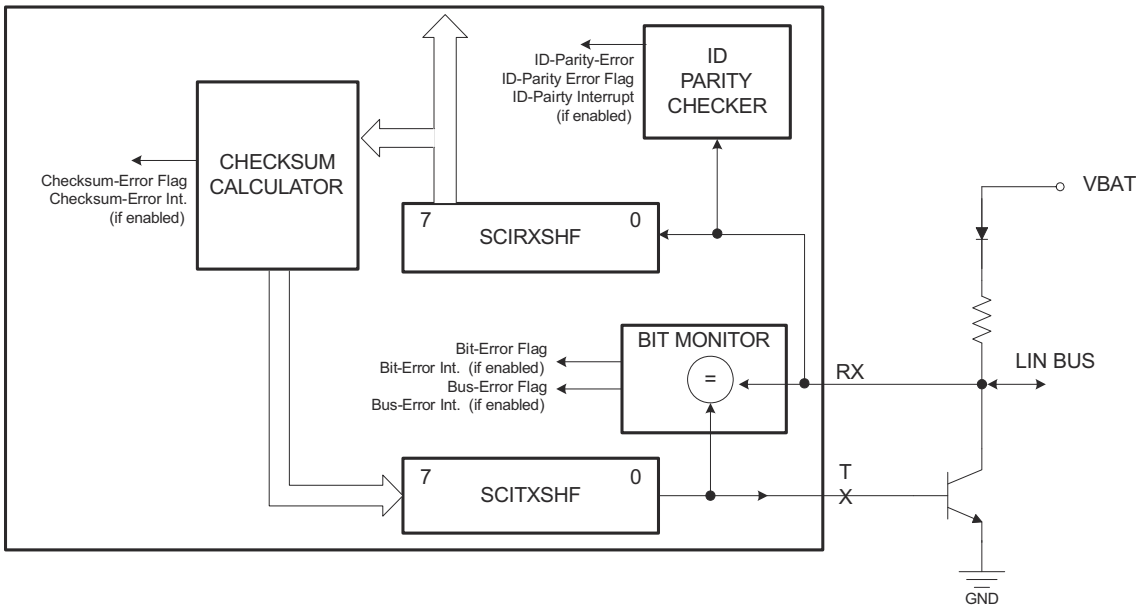

Figure 29-21. TXRX Error Detector

29.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a commander, if no valid message can be generated on the bus (bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break delimiter can be generated (for example, because of a bus shortage to GND). Once the Sync Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

29.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm:

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \ (even\ Parity)$$
$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \ (odd\ Parity)$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 29.3.1.9 for details.

29.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end, if the calculated modulo-256 sum over all received data bytes (including the ID byte if the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of the resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 29-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 29-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation can always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit is overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

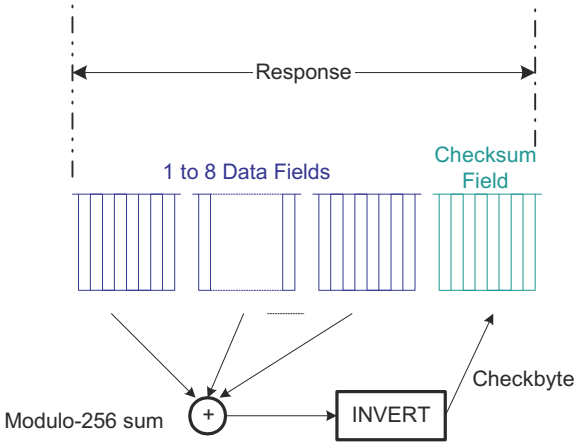

Figure 29-22. Classic Checksum Generation at Transmitting Node

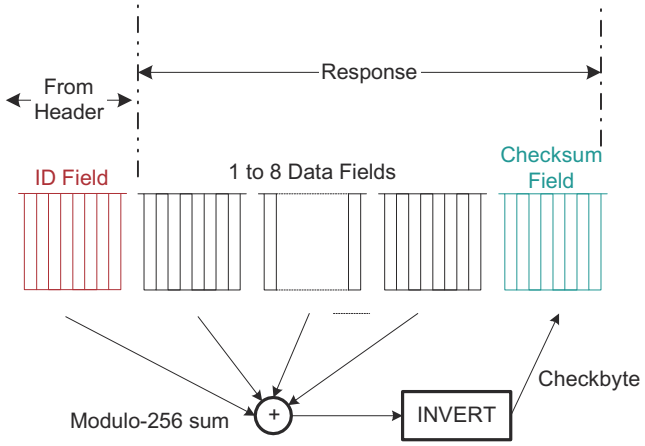

Figure 29-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node

29.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in Figure 29-24. During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in Figure 29-16) to determine whether the nodes transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See Figure 29-24. All nodes compare the received ID to the identifier stored in the ID-Responder Task BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there is an ID TX flag and an interrupt is triggered if enabled in the SCISETINT register.

The masked bits become "don't cares" for the comparison. To build a mask for a set of identifiers, an XOR function can be used.

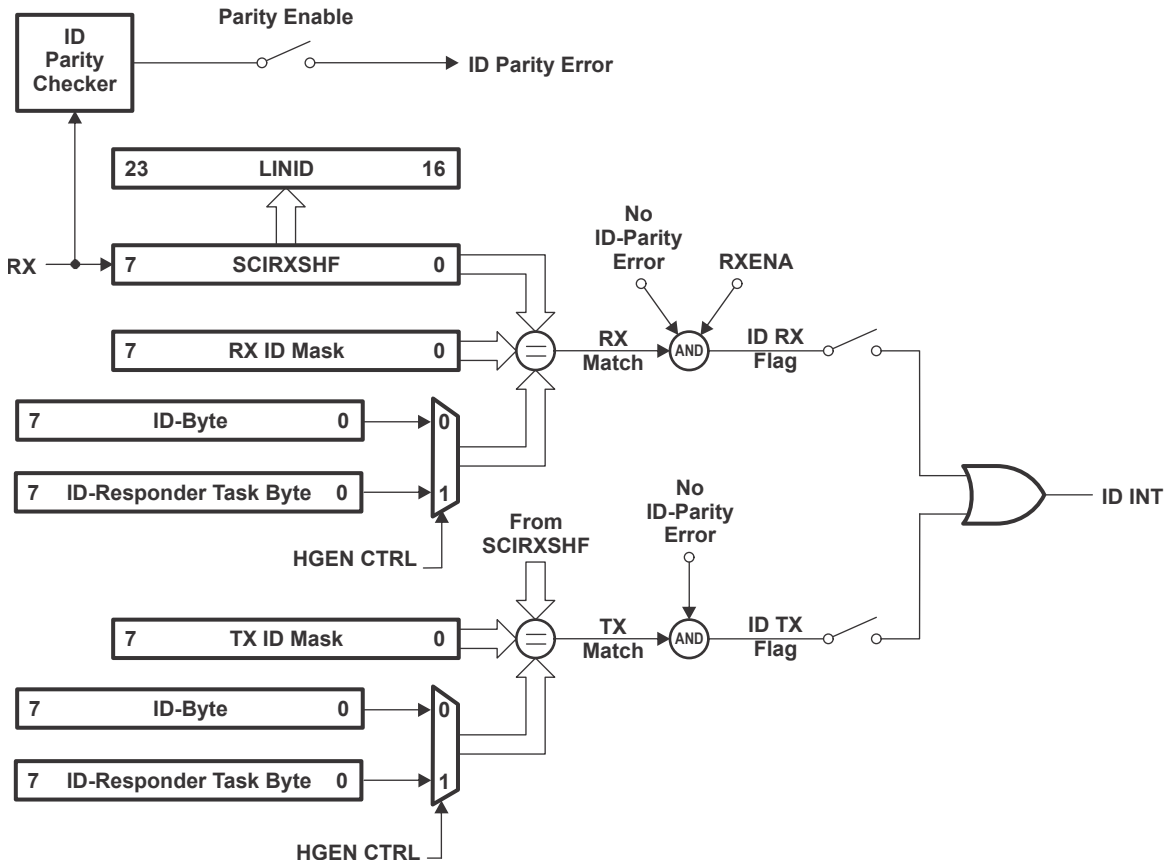

Figure 29-24. ID Reception, Filtering, and Validation

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most-significant bits (MSBs) and filter 3 least-significant bits (LSBs), the acceptance mask can be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07$$

A mask of all zeros compares all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF always causes a match. A mask of all 1s filters all bits of the received identifier, and thus there is an ID match regardless of the content of the ID-Responder Task BYTE field in the LINID register.

Note

When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. A mask of all 0s compares all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s filters all bits of the received identifier and there is no match.

If HGEN CTLR = 1:

- Received ID is compared with the ID-Responder Task byte, using the RXID mask and the TXID mask.
- A mask of all 1s always result in a match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

If HGEN CTRL = 0:

- Received ID is compared with the ID byte, using the RXID mask and the TXID mask.
- A mask of all 1s results in no match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU can read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

Note

When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

In multibuffer mode, the TXRDY flag is set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multibuffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multibuffer mode, the TXEMPTY flag is set when both the transmit buffers TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In non-multibuffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all responder receiving nodes validate the identifier using all eight bits of the received ID byte. The SCI/LIN flags a corrupted identifier if an ID-parity error is detected.

29.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. Figure 29-8 illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt is generated if enabled in the SCISETINT register.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multibuffer mode is enabled, or to RD0 if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the IDBYTE field does not convey message length (see *Note: Optional Control Length Bits* in Section 29.3.1.5), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A receive interrupt, and a receive ready RXRDY flag , and a DMA request (RXDMA) can occur after receiving a response, if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte is compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multibuffer mode is enabled or not (MBUFMODE bit).

Note

In multibuffer mode following are the scenarios associated with clearing the RXRDY flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
2. For LENGTH less than or equal to 4, Read to RD0 register clears the RXRDY flag.
3. For LENGTH greater than 4, Read to RD1 register clears the RXRDY flag.

29.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has 8 transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TDy transmit buffers. Optionally, a DMA transfer can be done on a byte-per-byte basis when multibuffer mode is not enabled (MBUFMODE bit). Figure 29-9 illustrates the transmit buffers.

The multibuffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multibuffer mode is enabled, or from TD0 to SCITXSHF if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in Section 29.3.1.5), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A transmit interrupt (TX interrupt) and a transmit ready flag (TXRDY flag), as well as a DMA request (TXDMA) can occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multibuffer mode is enabled or not (MBUFMODE bit).

The checksum byte is automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multibuffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

Note

The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt using the SCICLRINT register or by disabling the transmitter using the TXENA bit.

29.3.2 LIN Interrupts

LIN and SCI modes have a common interrupt block, as explained in Section 29.2.2. There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in Table 29-4.

A LIN message frame indicating the timing and sequence of the LIN interrupts that can occur is shown in Figure 29-25.

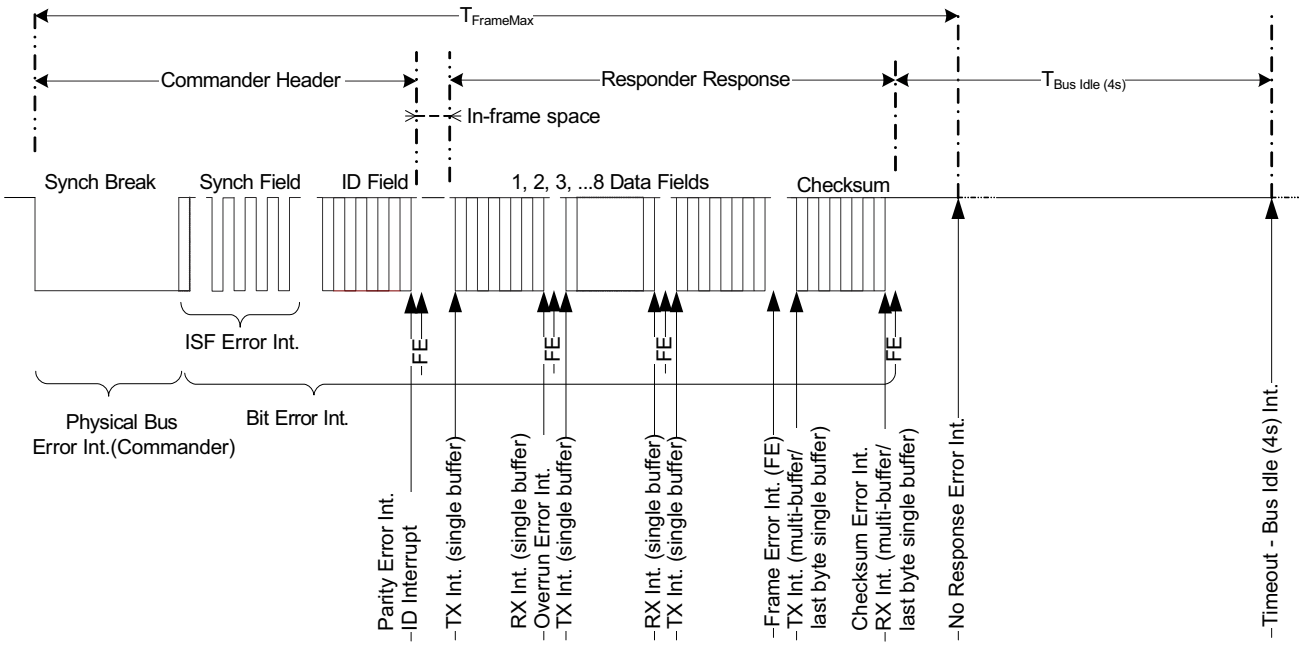

Figure 29-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence

29.3.3 Servicing LIN Interrupts

When servicing an interrupt, clear the corresponding flag in the flag register (SCIFLR) before clearing the global interrupt (LIN_GLB_INT_CLR). The ISR can follow the guidelines below. This prevents any spurious or duplicate interrupt from occurring.

- Clear the LIN interrupt flag in the SCIFLR register.
- Read the LIN interrupt status register to make sure the flag is cleared.
- Clear the global interrupt flag bit in LIN_GLB_INT_CLR.

Note

The transmit interrupt is generated before the LIN transmitter is ready to accept new data. Inside of the LIN transmit ISR, the software can wait until the buffer is completely empty before loading the next data. This can be done by polling for the Bus Busy Flag (SCIFLR.BUSY) to be 0.

29.3.4 LIN DMA Interface

The LIN DMA interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multibuffer mode is enabled or not using the multibuffer enable control bit (MBUFMODE).

Note

Do not use the DMA to transmit data to multiple peripheral IDs. Writing to the LINID register initiates a new transmission. The DMA writes to the LINID register before the LIN state machine is ready to accept the new ID. Doing so causes the LIN to miss this transmission.

29.3.4.1 LIN Receive DMA Requests

In LIN mode, when the multibuffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled and disabled using the SET_RX_DMA and CLRRXDMA bits, respectively.

29.3.4.2 LIN Transmit DMA Requests

In LIN mode with the multibuffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a DMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled and disabled using the SET_TX_DMA and CLRTXDMA bits, respectively.

29.3.5 LIN Configurations

The following list details the configuration steps that software can perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit (SCIGCR0.0).
- Clear SWnRST to 0 before configuring the LIN (SCIGCR1.7).
- Enable the LINRX and LINTX pins by setting the RXFUNC and TXFUNC bits.
- Select LIN mode by programming the LINMODE bit (SCIGCR1.6).
- Select commander or responder mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multibuffer mode by programming MBUFMODE bit (SCIGCR1.10).
- Select the baud rate to be used for communication by programming BRSR.
- Set the maximum baud rate to be used for communication by programming MBRSR.
- Set the CONT bit to make LIN not halt for an emulation breakpoint until the LIN current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOPBACK bit (SCIGCR1.16) to connect the transmitter to the receiver internally if needed (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit (SCIGCR1.24), if data is to be received.
- Select the transmit enable TXENA bit (SCIGCR1.25), if data is to be transmitted.
- Select the RXIDMASK and the TXIDMASK fields in the LINMASK register.
- Set SWnRST (SCIGCR1.7) to 1 after the LIN is configured.
- Receive or Transmit data (see Section 29.3.1.9, Section 29.3.5.1, and Section 29.3.5.2).

Note

If TXENA is set and the SWnRST is released, the LIN immediately generates a new DMA request but not a new transmit interrupt request. If using interrupts, the first transmission must be started with software by writing data to the transmit buffer, followed by writing the chosen ID to the LINID register to initiate the transmission.

29.3.5.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RXFUNC bit and the RXENA bit are set to 1. If the RXFUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The IDRXFLAG in the SCIFLR register is set after a valid LINID is received with an RX Match. An ID interrupt is then generated, if enabled.

29.3.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when the LIN transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETRXINT bit is set. To use the DMA method, the SET_RX_DMA bit must be set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum is compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit is cleared once the checksum is received. A CE is immediately flagged, if there is a checksum error.

29.3.5.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, you can use the polling, DMA, or interrupt method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit is cleared once the checksum is received and compared.

29.3.5.2 Transmitting Data

The LIN transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The IDTXFLAG bit in the SCIFLR register is set after a valid LIN ID is received with a TX Match. An ID interrupt is then generated, if enabled.

29.3.5.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETXINT bit is set. To use the DMA method, the SET_TX_DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request can be halted. This can either be done by disabling the transmit interrupt (CLRTXINT) / DMA request (CLRTXDMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte is sent after the current byte transmission. The SC bit is cleared after the checksum byte has been transmitted.

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

29.3.5.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum is sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit is cleared after the checksum byte has been transmitted.

29.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The LIN module can enter low-power mode either when there was no activity on the LINRX pin for more than 4 seconds (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal terminates the sleep mode of the LIN bus.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wakeup interrupt to clear the power-down bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

29.4.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic commander request frame with identifier 0x3C (60), with the first data field as 0x00. There must be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

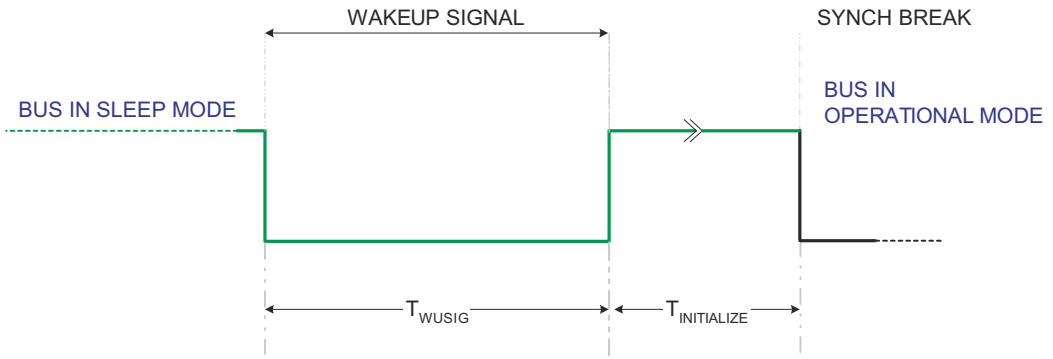
29.4.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit a low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

Note

If the wakeup interrupt is disabled, then the SCI/LIN enters low-power mode whenever the SCI/LIN is requested to do so, but a low level on the receive RX pin does not cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal, see Figure 29-26. A responder node that detects the bus in sleep mode, and with a wakeup request pending, sends a wakeup signal. The wakeup signal is a dominant value on the LIN bus for T_{WUSIG}; this is at least 5 T_{bits} for the LIN bus baud rates. The wakeup signal is generated by sending a 0xF0 byte containing 5 dominant T_{bits} and 5 recessive T_{bits}.



0.25ms ≤ T_{WUSIG} ≤ 5ms

Figure 29-26. Wakeup Signal Generation

Assuming a bus with no noise or loading effects, a write of 0xF0 to TD0 loads the transmitter to meet the wakeup signal timing requirement for T_{WUSIG}. Then, setting the GENWU bit transmits the preloaded value in TD0 for a wakeup signal transmission.

Note

The GENWU bit can be set/reset only when SWnRST is set to 1 and the node is in power-down mode. The bit is cleared on a valid synch break detection. A commander sending a wakeup request, exits power-down mode upon reception of the wakeup pulse. The bit is cleared on a SWnRST. This can be used to stop a commander from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, translates it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, the LIN module generates a wakeup interrupt if enabled in the SCISETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150ms detects it as a wakeup request. The LIN responder is ready to listen to the bus in less than 100ms ($T_{INITIALIZE}$<100ms) after a dominant-to-recessive edge (end-of-wakeup signal).

29.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the commander to send a header. If no synch field is detected before 150ms (3,000 cycles at 20kHz) after a wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5s (30,000 cycles at 20kHz) period after three breaks.

Note

To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to make sure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup can set the MBRS register accordingly to meet the targeted time as 128 Tbits × programmed prescaler.

The LIN handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

29.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. when set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register do not have any effect on the flags in the SCIFLR register.

Note

When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

29.6.2 LIN Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/lin

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

29.6.2.1 LIN Internal Loopback with Interrupts

FILE: lin_ex1_loopback_interrupts.c

This example configures the LIN module in commander mode for internal loopback with interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Upon reception of an ID header, an interrupt is triggered on line 0 and an interrupt service routine (ISR) is called. The received data is then checked for accuracy.

The example can be adjusted to use interrupt line 1 instead of line 0 by un-commenting "LIN_setInterruptLevel1()" *External Connections*

- None.

Watch Variables

- txData - An array with the data being sent

- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)
- level0Count - The number of line 0 interrupts
- level1Count - The number of line 1 interrupts

29.6.2.2 LIN SCI Mode Internal Loopback with Interrupts

FILE: lin_ex2_sci_loopback.c

This example configures the LIN module in SCI mode for internal loopback with interrupts. The LIN module performs as a SCI with a set character and frame length in a non-multi-buffer mode. The module is setup to continuously transmit a character, wait to receive that character, and repeat.

External Connections
- None.

Watch Variables
- rxCount - The number of RX interrupts
- transmitChar - The character being transmitted
- receivedChar - The character received

29.6.2.3 LIN SCI MODE Internal Loopback with DMA

FILE: lin_ex3_sci_dma.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in multi-buffer mode. When the transmit buffers in the LINTD0 and LINTD1 registers have enough space, the DMA will transfer data from global variable sData into those transmit registers. Once the received buffers in the LINRD0 and LINRD1 registers contain data,the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

29.6.2.4 LIN Internal Loopback without interrupts(polled mode)

FILE: lin_ex4_loopback_polling.c

This example configures the LIN module in commander mode for internal loopback without interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Waits for reception of an ID header. The received data is then checked for accuracy.

External Connections
- None.

Watch Variables
- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

29.6.2.5 LIN SCI MODE (Single Buffer) Internal Loopback with DMA

FILE: lin_ex7_sci_dma_single_buffer.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in single-buffer compatibility mode. When the

transmit buffer i.e. the SCITD register is free, the DMA will transfer data from global variable sData into this register. Once the received buffer, i.e. the SCIRD register contains data, the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

29.7 LIN Registers

This section describes the LIN Registers.

29.7.1 LIN Base Address Table

Table 29-12. LIN Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
LinaRegs	LIN_REGS	LINA_BASE	0x0000_6800	YES	YES	YES	YES

29.7.2 LIN_REGS Registers

Table 29-13 lists the memory-mapped registers for the LIN_REGS registers. All register offset addresses not listed in Table 29-13 should be considered as reserved locations and the register contents should not be modified.

Table 29-13. LIN_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SCIGCR0	Global Control Register 0		Go
4h	SCIGCR1	Global Control Register 1		Go

Complex bit access types are encoded to fit into small table cells. Table 29-14 shows the codes that are used for access types in this section.

Table 29-14. LIN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear

Table 29-14. LIN_REGS Access Type Codes (continued)

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

29.7.2.1 SCIGCR0 Register (Offset = 0h) [Reset = 00000000h]

SCIGCR0 is shown in Figure 29-27 and described in Table 29-15.

Return to the Summary Table.

The SCIGCR0 register defines the module reset.

Figure 29-27. SCIGCR0 Register

0	RESET	R/W	0h	This bit resets the SCI/LIN module. This bit is effective in LIN or SCI-compatible mode.. This bit affects the reset state of the SCI/LIN module. Reset type: SYSRSn 0h (R/W) = SCI/LIN module is in held in reset. 1h (R/W) = SCI/LIN module is out of reset.

29.7.2.2 SCIGCR1 Register (Offset = 4h) [Reset = 00000000h]

SCIGCR1 is shown in Figure 29-28 and described in Table 29-16.

Return to the Summary Table.

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

Figure 29-28. SCIGCR1 Register

Table 29-16. SCIGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	TXENA	R/W	0h	Transmit enable. This bit is effective in LIN and SCI modes. Data is transferred from SCITD or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set. Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode). Reset type: SYSRSn 0h (R/W) = Disable transfers from SCITD or TDy to SCITXSHF 1h (R/W) = Enable transfers of data from SCITD or TDy to SCITXSHF

Table 29-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	RXENA	R/W	0h	Receive enable. This bit is effective in LIN or SCI-compatible mode. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers. Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 7) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA. Note: If RXENA is cleared before the time the reception of a frame is complete, the data from the frame is not transferred into the receive buffer. Note: If RXENA is set before the time the reception of a frame is complete, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame Reset type: SYSRSn 0h (R/W) = Prevents the receiver from transferring data from the shift buffer to the receive buffer or multi-buffers 1h (R/W) = Allows the receiver to transfer data from the shift buffer to the receive buffer or multi-buffers
23-18	RESERVED	R	0h	Reserved
17	CONT	R/W	0h	Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. This bit affects the LIN counters. When this bit is set, the counters are not stopped during debug. When this bit is cleared, the counters are stopped during debug. Reset type: SYSRSn 0h (R/W) = When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited. 1h (R/W) = When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.
16	LOOPBACK	R/W	0h	Loopback bit. This bit is effective in LIN or SCI-compatible mode. The self-checking option for the SCI/LIN can be selected with this bit. If the LINTX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result. Reset type: SYSRSn 0h (R/W) = Loopback mode is disabled. 1h (R/W) = Loopback mode is enabled.
15-14	RESERVED	R	0h	Reserved
13	STOPEXTFRAME	R/W	0h	Stop extended frame communication. This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Extended frame communication will be stopped, once current frame transmission/reception is completed.

Table 29-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	HGENCTRL	R/W	0h	HGEN control bit. This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison. Reset type: SYSRSn 0h (R/W) = ID filtering using ID-Byte. RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match. 1h (R/W) = ID filtering using ID-RESPONDERTask byte (Recommended). RECEIVEDID and IDRESPONDERTASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match
11	CTYPE	R/W	0h	Checksum type. This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced. Reset type: SYSRSn 0h (R/W) = Classic checksum is used. This checksum is compatible with LIN 1.3 Responder nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must allways use the classic checksum. 1h (R/W) = Enhanced checksum is used. The enhanced checksum is compatible with LIN 2.0 and newer Responder nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.
10	MBUFMODE	R/W	0h	Multibuffer mode. This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used. Reset type: SYSRSn 0h (R/W) = The multi-buffer mode is disabled. 1h (R/W) = The multi-buffer mode is enabled.
9	ADAPT	R/W	0h	Adapt mode enable. This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN Responder node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Automatic baudrate adjustment is disabled. 1h (R/W) = Automatic baudrate adjustment is enabled.

Table 29-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SLEEP	R/W	0h	SCI sleep. SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode. The receiver still operates when the SLEEP bit is set however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Sleep mode is disabled. 1h (R/W) = Sleep mode is enabled.
7	SWnRST	R/W	0h	Software reset (active low). This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0. Only the following configuration bits can be changed in runtime (i.e., while SWnRESET = 1): - STOP EXT Frame (SCIGCR1[13]) - CC bit (SCIGCR2[17]) - SC bit (SCIGCR2[16]) Reset type: SYSRSn 0h (R/W) = The SCI/LIN is in its reset state no data will be transmitted or received. Writing a 0 to this bit intializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit. 1h (R/W) = The SCI/LIN is in its ready state transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.
6	LINMODE	R/W	0h	LIN mode This bit controls the mode of operation of the module. Reset type: SYSRSn 0h (R/W) = LIN mode is disabled SCI compatibility mode is enabled. 1h (R/W) = LIN mode is enabled SCI compatibility mode is disabled.
5	CLK_COMMANDER	R/W	0h	SCI internal clock enable or LIN Commander/Responder configuration. In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a Responder or Commander. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Reserved. LIN mode: The module is in Responder mode. 1h (R/W) = SCI-compatible mode: Enable clock to the SCI module. LIN mode: The node is in Commander mode.
4	STOP	R/W	0h	SCI number of stop bits. This bit is effective in SCI-compatible mode only. Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = One stop bit is used. 1h (R/W) = Two stop bits are used.

Table 29-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	PARITY	R/W	0h	SCI parity odd/even selection. This bit is effective in SCI-compatible mode only. If the PARITY ENA bit (SCIGCR1.2) is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1. 1h (R/W) = Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITYENA	R/W	0h	Parity enable. Enables or disables the parity function. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Parity disabled no parity bit is generated during transmission or is expected during reception. LIN mode: ID-parity verification is disabled. 1h (R/W) = SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception. LIN mode: ID-parity verification is enabled.
1	TIMINGMODE	R/W	0h	SCI timing mode bit. This bit is effective in SCI-compatible mode only. It must be set to 1 when the SCI mode is used. This bit configures the SCI for asynchronous operation. Reset type: SYSRSn 0h (R/W) = Reserved. 1h (R/W) = Must be set to 1 when module is configured for SCI operation
0	COMMMODE	R/W	0h	SCI/LIN communication mode bit. In compatibility mode, it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Idle-line mode is used. LIN mode: ID4 and ID5 are not used for length control. 1h (R/W) = SCI-compatible mode: Address-bit mode is used. LIN mode: ID4 and ID5 are used for length control.

29.7.2.3 SCIGCR2 Register (Offset = 8h) [Reset = 00000000h]

SCIGCR2 is shown in Figure 29-29 and described in Table 29-17.

Return to the Summary Table.

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

Figure 29-29. SCIGCR2 Register

Table 29-17. SCIGCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17	CC	R/W	0h	Compare Checksum. This mode is effective in LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit. In non multibuffer mode, once the CC bit is set, the checksum will be compared on the byte that is currently being received, expected to be the checkbyte. During Multi-buffer mode, following are the scenarios associated with the CC bit : - If CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed no. of data bytes indicated by SCIFORMAT[18:16], is treated as a checksum byte. - If CC bit is set during the IDLE period (i.e. during inter-frame space), then the next immediate byte will be treated as a checksum byte. A CE will immediatly be flagged if there is a checksum error. This bit is automatically cleared once the checksum is successfully compared. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Compare checksum on expected checkbyte

Table 29-17. SCIGCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	SC	R/W	0h	Send Checksum This mode is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checkbyte. In non multibuffer mode the checkbyte will be sent after the current byte transmission. In multibuffer mode the checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No checkbyte will be sent. 1h (R/W) = A checkbyte will be sent. This bit will automatically get cleared after the checkbyte is transmitted. The checksum will not be sent if this bit is set before transmitting the very first byte, that is, during interframe space.
15-9	RESERVED	R	0h	Reserved
8	GENWU	R/W	0h	Generate wakeup signal. This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. This bit is cleared on reception of a valid sync break. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Transmit TDO for wakeup. This bit will be cleared on a SWnRST (SCIGCR1.7)
7-1	RESERVED	R	0h	Reserved
0	POWERDOWN	R/W	0h	Power down. This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection (more than 4 seconds, i.e. 80,000 cycles at 20kHz) Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Request local low-power mode

29.7.2.4 SCISETINT Register (Offset = Ch) [Reset = 00000000h]

SCISETINT is shown in Figure 29-30 and described in Table 29-18.

Return to the Summary Table.

The SCISETINT register is used to enable the various interrupts available in the LIN module.

Table 29-18. SCISETINT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SETBEINT	R/W1S	0h	Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
30	SETPBEINT	R/W1S	0h	Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
29	SETCEINT	R/W1S	0h	Set checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
28	SETISFEINT	R/W1S	0h	Set inconsistent-sync-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent sync field error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

Table 29-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	SETNREINT	R/W1S	0h	Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
26	SETFEINT	R/W1S	0h	Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
25	SETOEINT	R/W1S	0h	Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
24	SETPEINT	R/W1S	0h	Set parity interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a parity error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
23-19	RESERVED	R	0h	Reserved
18	SET_RX_DMA_ALL	R/W1S	0h	Set receiver DMA for Address & Data frames. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable RX DMA request for address and data frames this bit must be set. If it is cleared, RX interrupt request is generated for address frames and DMA requests are generated for data frames. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled for address frames (RX interrupt request is enabled for address frames). Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled for address and data frames
17	SET_RX_DMA	R/W1S	0h	Set receiver DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the receiver this bit must be set. If it is cleared, interrupt requests are generated depending on SETRXINT. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled.
16	SET_TX_DMA	R/W1S	0h	Set transmit DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SETTXINT. Reset type: SYSRSn 0h (R/W) = Transmit DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Transmit DMA request is enabled

Table 29-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	SETIDINT	R/W1S	0h	Set Identification interrupt. This bit is effective in LIN mode only. This bit is set to enable interrupt once a valid matching identifier is received. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
12-10	RESERVED	R	0h	Reserved
9	SETRXINT	R/W1S	0h	Set Receiver interrupt. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
8	SETTXINT	R/W1S	0h	Set Transmitter interrupt. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
7	SETTOA3WUSINT	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after 3 wakeup signals have been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
6	SETTOAWUSINT	R/W1S	0h	Set Timeout After Wakeup Signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after one wakeup signal has been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINT	R/W1S	0h	Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when no LIN bus activity (bus idle) occurs for at least 4 seconds. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
3-2	RESERVED	R	0h	Reserved

Table 29-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SETWAKEUPINT	R/W1S	0h	Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wake-up interrupt and thereby exit low-power mode. The wake-up interrupt is asserted on falling edge of the wake-up pulse. If enabled, the wake-up interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode. Wake-up interrupt is not asserted upon a wakeup pulse if the module is not in power down mode. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
0	SETBRKDTINT	R/W1S	0h	Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an interrupt if a break condition is detected on the LINRX pin. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

29.7.2.5 SCICLEARINT Register (Offset = 10h) [Reset = 00000000h]

SCICLEARINT is shown in Figure 29-31 and described in Table 29-19.

Return to the Summary Table.

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISETINT register.

Table 29-19. SCICLEARINT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CLRBEINT	R/W1C	0h	Clear Bit Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the bit error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
30	CLRPBEINT	R/W1C	0h	Clear Physical Bus Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the physical-bus error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
29	CLRCEINT	R/W1C	0h	Clear checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the checksum-error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
28	CLRISFEINT	R/W1C	0h	Clear Inconsistent-Sync-Field-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the ISFE interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

Table 29-19. SCICLEARINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	CLRNREINT	R/W1C	0h	Clear No-Reponse-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the no-response error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
26	CLRFEINT	R/W1C	0h	Clear Framing-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables framing-error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
25	CLROEINT	R/W1C	0h	Clear Overrun-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the overrun interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
24	CLRPEINT	R/W1C	0h	Clear Parity Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the parity error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17	CLRRXDMA	R/W1C	0h	Clear receiver DMA. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the receive DMA request. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled. Writing a 1 to this bit will disable the DMA request and clear this bit.
16	CLRTXDMA	R/W1C	0h	Clear transmit DMA. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the transmit DMA request. Reset type: SYSRSn 0h (R/W) = Transmit DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Transmit DMA request is enabled. Writing a 1 to this bit will disable the DMA request and clear this bit.
15-14	RESERVED	R	0h	Reserved
13	CLRIDINT	R/W1C	0h	Clear Identifier interrupt. This bit is effective in LIN mode only. Setting this bit disables the ID interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
12-10	RESERVED	R	0h	Reserved

Table 29-19. SCICLEARINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CLRRXINT	R/W1C	0h	Clear Receiver interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the receiver interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
8	CLRTXINT	R/W1C	0h	Clear Transmitter interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the transmitter interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
7	CLRTOA3WUSINT	R/W1C	0h	Clear Timeout After 3 Wakeup Signals interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout after 3 wakeup signals interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
6	CLRTOAWUSINT	R/W1C	0h	Clear Timeout After Wakeup Signal interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout after one wakeup signal interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
5	RESERVED	R	0h	Reserved
4	CLRTIMEOUTINT	R/W1C	0h	Clear Timeout interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout (LIN bus idle) interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
3-2	RESERVED	R	0h	Reserved
1	CLRWAKEUPINT	R/W1C	0h	Clear Wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the wake-up interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
0	CLRBRKDTINT	R/W1C	0h	Clear Break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit disables the Break-detect interrupt. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

29.7.2.6 SCISETINTLVL Register (Offset = 14h) [Reset = 00000000h]

SCISETINTLVL is shown in Figure 29-32 and described in Table 29-20.

Return to the Summary Table.

The SCISETINTLVL register is used to map individual interrupt sources to the INT1 interrupt line.

Table 29-20. SCISETINTLVL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SETBEINTLVL	R/W1S	0h	Set Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
30	SETPBEINTLVL	R/W1S	0h	Set Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
29	SETCEINTLVL	R/W1S	0h	Set Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
28	SETISFEINTLVL	R/W1S	0h	Set Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

Table 29-20. SCISETINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	SETNREINTLVL	R/W1S	0h	Set No-Reponse-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
26	SETFEINTLVL	R/W1S	0h	Set Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
25	SETOEINTLVL	R/W1S	0h	Set Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
24	SETPEINTLVL	R/W1S	0h	Set Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17-16	RESERVED	R	0h	Reserved
15-14	RESERVED	R	0h	Reserved
13	SETIDINTLVL	R/W1S	0h	Set ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
12-10	RESERVED	R	0h	Reserved
9	SETRXINTOVO	R/W1S	0h	Set Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
8	SETTXINTLVL	R/W1S	0h	Set Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
7	SETTOA3WUSINTLVL	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

Table 29-20. SCISETINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	SETTOAWUSINTLVL	R/W1S	0h	Set Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINTLVL	R/W1S	0h	Set Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
3-2	RESERVED	R	0h	Reserved
1	SETWAKEUPINTLVL	R/W1S	0h	Set Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
0	SETBRKDTINTLVL	R/W1S	0h	Set Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INT1 line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

29.7.2.7 SCICLEARINTLVL Register (Offset = 18h) [Reset = 00000000h]

SCICLEARINTLVL is shown in Figure 29-33 and described in Table 29-21.

Return to the Summary Table.

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

Table 29-21. SCICLEARINTLVL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CLRBEINTLVL	R/W1C	0h	Clear Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
30	CLRPBEINTLVL	R/W1C	0h	Clear Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
29	CLRCEINTLVL	R/W1C	0h	Clear Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
28	CLRISFEINTLVL	R/W1C	0h	Clear Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

Table 29-21. SCICLEARINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	CLRNREINTLVL	R/W1C	0h	Clear No-Reponse-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
26	CLRFEINTLVL	R/W1C	0h	Clear Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
25	CLROEINTLVL	R/W1C	0h	Clear Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
24	CLRPEINTLVL	R/W1C	0h	Clear Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17-16	RESERVED	R	0h	Reserved
15-14	RESERVED	R	0h	Reserved
13	CLRIDINTLVL	R/W1C	0h	Clear ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
12-10	RESERVED	R	0h	Reserved
9	CLRRXINTLVL	R/W1C	0h	Clear Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
8	CLRTXINTLVL	R/W1C	0h	Clear Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

Table 29-21. SCICLEARINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	CLRTOA3WUSINTLVL	R/W1C	0h	Clear Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
6	CLRTOAWUSINTLVL	R/W1C	0h	Clear Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
5	RESERVED	R	0h	Reserved
4	CLRTIMEOUTINTLVL	R/W1C	0h	Clear Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
3-2	RESERVED	R	0h	Reserved
1	CLRWAKEUPINTLVL	R/W1C	0h	Clear Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
0	CLRBRKDTINTLVL	R/W1C	0h	Clear Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INT0 line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

29.7.2.8 SCIFLR Register (Offset = 1Ch) [Reset = 00000904h]

SCIFLR is shown in Figure 29-34 and described in Table 29-22.

Return to the Summary Table.

The SCIFLR register indicates the current status of the various interrupt sources of the LIN module.

Table 29-22. SCIFLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BE	R/W1C	0h	Bit Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a bit error. This is detected by the bit monitor in the internal bit monitor. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No bit error detected. 1h (R/W) = Bit error detected.
30	PBE	R/W1C	0h	Physical Bus Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a physical bus error. This is detected by the bit monitor in TED. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break Note: thie PBE will ony be flagged if no sync break can be generated. (because of a bus shortage to VBAT) or if no sync break delimeter can be generated (because of a bus shortage to GND). This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No physiscal bus error detected. 1h (R/W) = Physical bus error detected.

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	CE	R/W1C	0h	Checksum Error Flag. This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No Checksum error detected. 1h (R/W) = Checksum error detected.
28	ISFE	R/W1C	0h	Inconsistent Sync Field Error Flag. This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the 'Header Reception and Adaptive Baudrate' section for more information. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No Inconsistent Sync Field error detected. 1h (R/W) = Inconsistent Sync Field error detected.
27	NRE	R/W1C	0h	No-Response Error Flag. This bit is effective in LIN mode only. This bit is set when there is no response to a Commander's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length (identifiers 0 to 61). This error is detected by the synchronizer of the module. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No No-Response error detected. 1h (R/W) = No-Response error detected.

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	FE	R/W1C	0h	Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new character (SCI-compatible mode), or frame (LIN mode) In multibuffer mode the frame is defined in the SCIFORMAT register. Reset type: SYSRSn 0h (R/W) = No framing error detected. 1h (R/W) = Framing error detected.
25	OE	R/W1C	0h	Overrun error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit Reset type: SYSRSn 0h (R/W) = No overrun error detected. 1h (R/W) = Overrun error detected.
24	PE	R/W1C	0h	Parity error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the 'SCI Global Control Register (SCIGCR1)' description. If the parity function is disabled (that is, SCIGCR1.2 = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Reception of a new charcter (SCI-compatible mode) or frame (LIN mode) - Writing a 1 to this bit Reset type: SYSRSn 0h (R/W) = No parity error or parity disabled. 1h (R/W) = Parity error detected.
23-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IDRXFLAG	R/W1C	0h	Identifier On Receive Flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with an RX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on an RX match. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Reading the LINID register - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No valid ID received. 1h (R/W) = Valid ID RX received in LINID[23:16] on RX match.
13	IDTXFLAG	R/W1C	0h	Identifier On Transmit Flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with a TX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on a TX match. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - RESET bit (SCIGCR0.0) - Setting SWnRESET - System reset - Reading the LINID register - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No valid ID received. 1h (R/W) = Valid ID received in LINID[23:16] on TX match.
12	RXWAKE	R	0h	Receiver wakeup detect flag. This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. This bit is cleared by: - RESET bit - Setting the SWnRESET bit (SCIGCR1.7) - System reset - Receipt of a data frame This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = The data in SCIRD is not an address. 1h (R/W) = The data in SCIRD is an address. See [1] Section 3.4.4, Sleep Mode for Multiprocessor Communication, on page 16 for more information on using the RXWAKE bit with sleep mode.

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	TXEMPTY	R	1h	Transmitter Empty flag. The value of this flag indicates the contents of the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF). In multibuffer mode, this flag indicates the value of the TDx registers and shift register (SCITXSHF). In non multibuffer mode, this flag indicates the value of LINTD0 (byte) and shift register (SCITXSHF). This bit is set by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET bit (SCIGCR1.7) - System reset. Note: This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer or shift register (or both) are loaded with data. In LIN mode using multibuffer mode: Multibuffer or shift register (or all) are loaded with data. 1h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer and shift registers are both empty. In LIN mode using multibuffer mode: Multibuffer and shift registers are all empty.
10	TXWAKE	R/W	0h	SCI transmitter wakeup method select. This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit (SCIGCR1.7). Reset type: SYSRSn 0h (R/W) = Address-bit mode: Frame to be transmitted will be data (address bit = 0). Idle-line mode: Frame to be transmitted will be data. 1h (R/W) = Address-bit mode: Frame to be transmitted will be an address (address bit=1). Idle-line mode: Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).
9	RXRDY	R/W1C	0h	Receiver ready flag. In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISETINT.9). RXRDY is cleared by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET - System reset - Writing a 1 to this bit - Reading SCIRD in while in SCI compatibility mode - Reading last data byte RDy of the response in LIN mode Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register. Reset type: SYSRSn 0h (R/W) = No new data in SCIRD/RDy. 1h (R/W) = New data ready to be read from SCIRD.

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer(s) register (SCITD in compatibility mode and LINTD0, LINTD1 in MBUF mode) is/are ready to get another character from a CPU write. In SCI compatibility mode, writing data to SCITD automatically clears this bit. In LIN mode, this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer are shifted into the SCITXSHF register. For devices with a DMA module, this event can trigger a transmit DMA event if the DMA enable bit is set. This bit is set to 1 by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET (SCIGCR1.7) - System reset Note: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register. Note: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1.25=0). Reset type: SYSRSn 0h (R/W) = Compatible mode: SCITD is full. LIN mode: The multibuffers are full. 1h (R/W) = Compatible mode: SCITD is ready to receive the next character. LIN mode: The multibuffers are ready to receive the next character(s).
7	TOA3WUS	R/W1C	0h	Timeout After 3 Wakeup Signals flag. This bit is effective in LIN mode only. This flag is set if there is no Sync Break received after 3 wakeup signals and a period of 1.5 seconds have passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No timeout after 3 wakeup signals. 1h (R/W) = Timeout after 3 wakeup signals and 1.5s time.
6	TOAWUS	R/W1C	0h	Timeout After Wakeup Signal flag. This bit is effective in LIN mode only. This bit is set if there is no Sync Break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No timeout after one wakeup signal (150 ms). 1h (R/W) = Timeout after one wakeup signal.
5	RESERVED	R	0h	Reserved

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TIMEOUT	R/W1C	0h	LIN Bus IDLE timeout flag. This bit is effective in LIN mode only. This bit is set if there is no LIN bus activity for at least 4 seconds. LIN bus activity being a transition from recessive to dominant. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No bus idle detected. 1h (R/W) = LIN bus idle detected.
3	BUSY	R	0h	Bus BUSY flag. This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the BUSY bit is cleared. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver but can be cleared by: - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset. Reset type: SYSRSn 0h (R/W) = Receiver is not currently receiving a frame. 1h (R/W) = Receiver is currently receiving a frame.
2	IDLE	R	1h	SCI receiver in idle state. This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state: - After a system reset - Setting the SWnRESET bit (SCIGCR1.7) - After coming out of power down This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Idle period detected, the SCI is ready to receive. 1h (R/W) = Idle period not detected, the SCI will not receive any data.
1	WAKEUP	R/W1C	0h	Wake-up flag. This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT.1) is set. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register. - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Do not wake up from power-down mode. 1h (R/W) = Wake up from power-down mode.

Table 29-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	BRKDT	R/W1C	0h	SCI break-detect flag. This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register. - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - By writing a 1 to this bit. This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = No break condition detected. 1h (R/W) = Break condition detected.

29.7.2.9 SCIINTVECT0 Register (Offset = 20h) [Reset = 00000000h]

SCIINTVECT0 is shown in Figure 29-35 and described in Table 29-23.

Return to the Summary Table.

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

Figure 29-35. SCIINTVECT0 Register

Table 29-25. SCIFORMAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18-16	LENGTH	R/W	0h	Frame length control bits. In LIN mode, these bits indicate the number of bytes in the response field from 1 to 8 bytes. In buffered SCI mode, these bits indicate the number of characters. When these bits are used to indicate LIN response length (SCIGCR1[0] = 1), then when there is an ID RX match, this value should be updated with the expected length of the response. In buffered SCI mode, these bits indicate the number of characters with SCIFORMAT[2:0] bits per character. i.e. these bits indicate the transmitter/receiver format for the number of characters: 1 to 8. There can be up to eight characters with eight bits each. Reset type: SYSRSn 0h (R/W) = The response field has 1 bytes/characters. 1h (R/W) = The response field has 2 bytes/characters. 2h (R/W) = The response field has 3 bytes/characters. 3h (R/W) = The response field has 4 bytes/characters. 4h (R/W) = The response field has 5 bytes/characters. 5h (R/W) = The response field has 6 bytes/characters. 6h (R/W) = The response field has 7 bytes/characters. 7h (R/W) = The response field has 8 bytes/characters.
15-3	RESERVED	R	0h	Reserved
2-0	CHAR	R/W	0h	Character length control bits. These bits are effective in SCI compatible mode only. These bits set the SCI character length from 1 to 8 bits. Note: In compatibility mode or buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified. Note: Data written to the SCITD should be right justified but does not need to be padded with leading zeros. These bits are witable in SCI mode only. Reset type: SYSRSn 0h (R/W) = The character is 1 bits long. 1h (R/W) = The character is 2 bits long. 2h (R/W) = The character is 3 bits long. 3h (R/W) = The character is 4 bits long. 4h (R/W) = The character is 5 bits long. 5h (R/W) = The character is 6 bits long. 6h (R/W) = The character is 7 bits long. 7h (R/W) = The character is 8 bits long.

29.7.2.12 BRSR Register (Offset = 2Ch) [Reset = 00000000h]

BRSR is shown in Figure 29-38 and described in Table 29-26.

Return to the Summary Table.

The BRSR register is used to configure the baud rate of the LIN module.

30-28	U	R/W	0h	Superfractional Divider Selection. (U) These bits are an additional fractional part for the baudrate specification. These bits allow a super fine tuning of the fractional baudrate with 7 more intermediate values for each of the M fractional divider values. See the Superfractional Divider section for more details. Reset type: SYSRSn
27-24	M	R/W	0h	SCI/LIN 4-bit Fractional Divider Selection. (M) These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. Reset type: SYSRSn
23-16	SCI_LIN_PSH	R/W	0h	PRESCALER P (High Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudate selection. Reset type: SYSRSn

Table 29-26. BRSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-0	SCI_LIN_PSL	R/W	0h	PRESCALER P (Low Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudate selection. Reset type: SYSRSn

29.7.2.13 SCIED Register (Offset = 30h) [Reset = 00000000h]

SCIED is shown in Figure 29-39 and described in Table 29-27.

Return to the Summary Table.

The SCIED register is a duplicate copy of SCIRD register that has no affect on the RXRDY flag for use with an emulator.

Figure 29-39. SCIED Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ED

Table 29-28. SCIRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	RD	R	0h	Received Data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA (SCISETINT0.9) is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared. When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified. Reset type: SYSRSn

29.7.2.15 SCITD Register (Offset = 38h) [Reset = 00000000h]

SCITD is shown in Figure 29-41 and described in Table 29-29.

Return to the Summary Table.

The SCITD register is where data to be transmitted is written to by application software.

Figure 29-41. SCITD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-24	RD0	R	0h	8-bit Receive Buffer 0 Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. A read of this byte clears the RXDY byte. Note: RD<x-1> is equivalent to Data byte <x> of the LIN frame. Reset type: SYSRSn
23-16	RD1	R	0h	8-bit Receive Buffer 1. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn
15-8	RD2	R	0h	8-bit Receive Buffer 2. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn
7-0	RD3	R	0h	8-bit Receive Buffer 3. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn

29.7.2.20 LINRD1 Register (Offset = 68h) [Reset = 00000000h]

LINRD1 is shown in Figure 29-46 and described in Table 29-34.

Return to the Summary Table.

The LINRD1 regsiter contains the upper 4 bytes of the received LIN frame data.

Figure 29-46. LINRD1 Register

23-16	RD5	R	0h	8-bit Receive Buffer 5. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn
15-8	RD6	R	0h	8-bit Receive Buffer 6. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn
7-0	RD7	R	0h	8-bit Receive Buffer 7. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn

29.7.2.21 LINMASK Register (Offset = 6Ch) [Reset = 00000000h]

LINMASK is shown in Figure 29-47 and described in Table 29-35.

Return to the Summary Table.

The LINMASK register is used to configure the masks used for filtering incoming ID messages for receive and transmit frames.

Figure 29-47. LINMASK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RXIDMASK								RESERVED								TXIDMASK

Table 29-35. LINMASK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RXIDMASK	R/W	0h	Receive ID mask. This field is effective in LIN mode only.This 8-bit mask is used for filtering an incoming ID message and compare it to the ID-byte. A compare match of the received ID with the RX ID mask will set the ID RX flag and trigger and ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that that bit is filtered and therefore not used in the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn
15-8	RESERVED	R	0h	Reserved
7-0	TXIDMASK	R/W	0h	Transmit ID mask. This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID Mask will set the ID TX flag and trigger an ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore not used for the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn

29.7.2.22 LINID Register (Offset = 70h) [Reset = 00000000h]

LINID is shown in Figure 29-48 and described in Table 29-36.

Return to the Summary Table.

The LINID register contains the identification fields for LIN communication.
NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

Figure 29-48. LINID Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IDRESPONDERTASKBYTE								IDBYTE							
R/W-0h								R/W-0h							

Table 29-36. LINID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RECEIVEDID	R	0h	Received ID. This bit is effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match. Note: If a framing error (FE) is detected during ID reception, the received ID will also not be copied to the LINID register. Reset type: SYSRSn
15-8	IDRESPONDERTASKBYTE	R/W	0h	ID Responder Task byte. This field is effective in LIN mode only. This byte contains the identifier to which the received ID of an incoming header will be compared in order to decide whether a RX response, a TX response, or no action needs to be done by the LIN node. These bits are writable in LIN mode only. Reset type: SYSRSn
7-0	IDBYTE	R/W	0h	ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a Commander node, a write to this register by the CPU initiates a header transmission. For a Responder task, this byte is used for message filtering when HGENCTRL (SCIGCR1.12) is '0'. These bits are writable in LIN mode only. Reset type: SYSRSn

29.7.2.23 LINTD0 Register (Offset = 74h) [Reset = 00000000h]

LINTD0 is shown in Figure 29-49 and described in Table 29-37.

Return to the Summary Table.

The LINTD0 register contains the lower 4 bytes of the data to be transmitted.
NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

Figure 29-49. LINTD0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7-0	TD7	R/W	0h	8-bit Transmit Buffer 7. Byte 7 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn

29.7.2.25 MBRSR Register (Offset = 7Ch) [Reset = 00000DACh]

MBRSR is shown in Figure 29-51 and described in Table 29-39.

Return to the Summary Table.

The MBRSR register is used to configure the expected maximum baud rate of the LIN network.

Figure 29-51. MBRSR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																			MBR												
R-0h																			R/W-DACh											

Table 29-39. MBRSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12-0	MBR	R/W	DACh	Maximum Baud Rate Prescaler. This field is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see the 'Header Reception and Adaptive Baudrate' section) of a responder module if the ADAPT bit is set. In this way, a SCI/LIN responder using automatic or select bit rate modes detects any LIN bus legal rate automatically if the measured baud rate is within ±10% of the programmed baud rate. The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a s 0x00 data byte could mistakenly be detected as sync break. The default value is for a 70MHz VCLK and ~18kbps expected baud rate. (0xDAC). This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20kHz rate. MBR = VCLK Frequency / (1.1*Expected Baud Rate Frequency) Note: The MBR field must be written with a 13-bit value. If the calculated MBR exceeds 2^{13} = 8192, either the baud rate or the VCLK frequency must be adjusted for valid operation. Reset type: SYSRSn

29.7.2.26 IODFTCTRL Register (Offset = 90h) [Reset = 00000500h]

IODFTCTRL is shown in Figure 29-52 and described in Table 29-40.

Return to the Summary Table.

The IODFTCTRL register is used to emulate various error and test conditions.

Figure 29-52. IODFTCTRL Register

Chapter 30

Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

30.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

30.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. Figure 30-1 shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. Figure 30-2 shows the connections between the tile, the CPU interface, and the device.

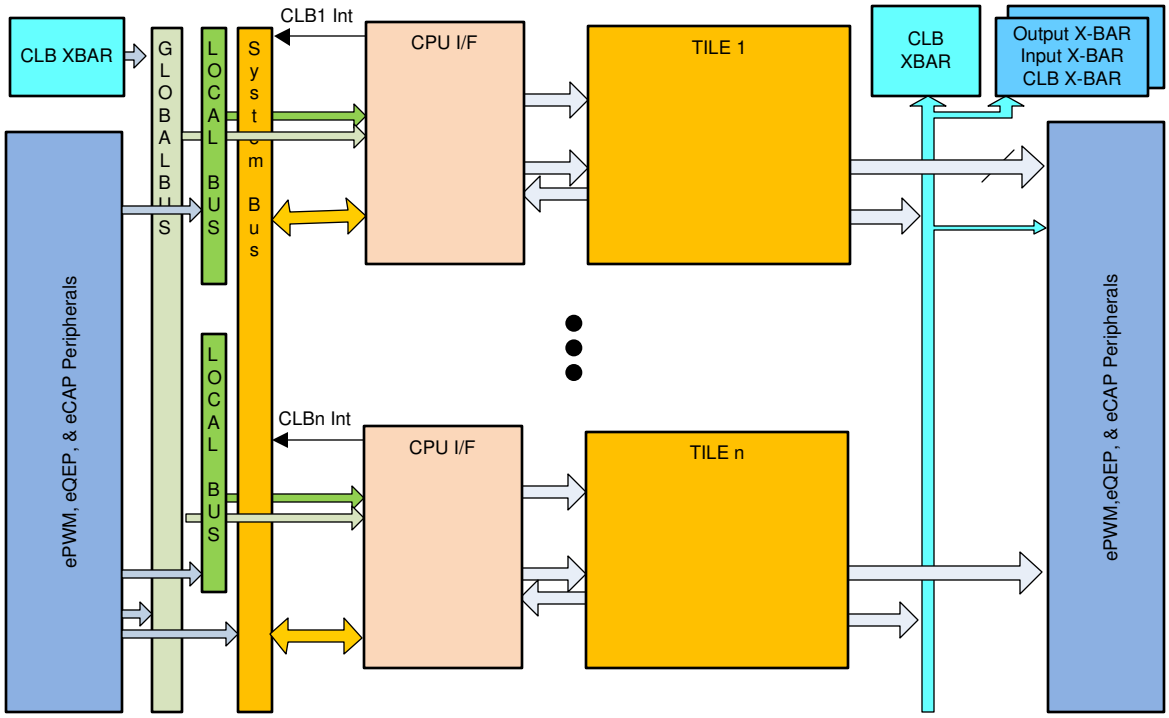

Figure 30-1. Block Diagram of the CLB Subsystem in the Device

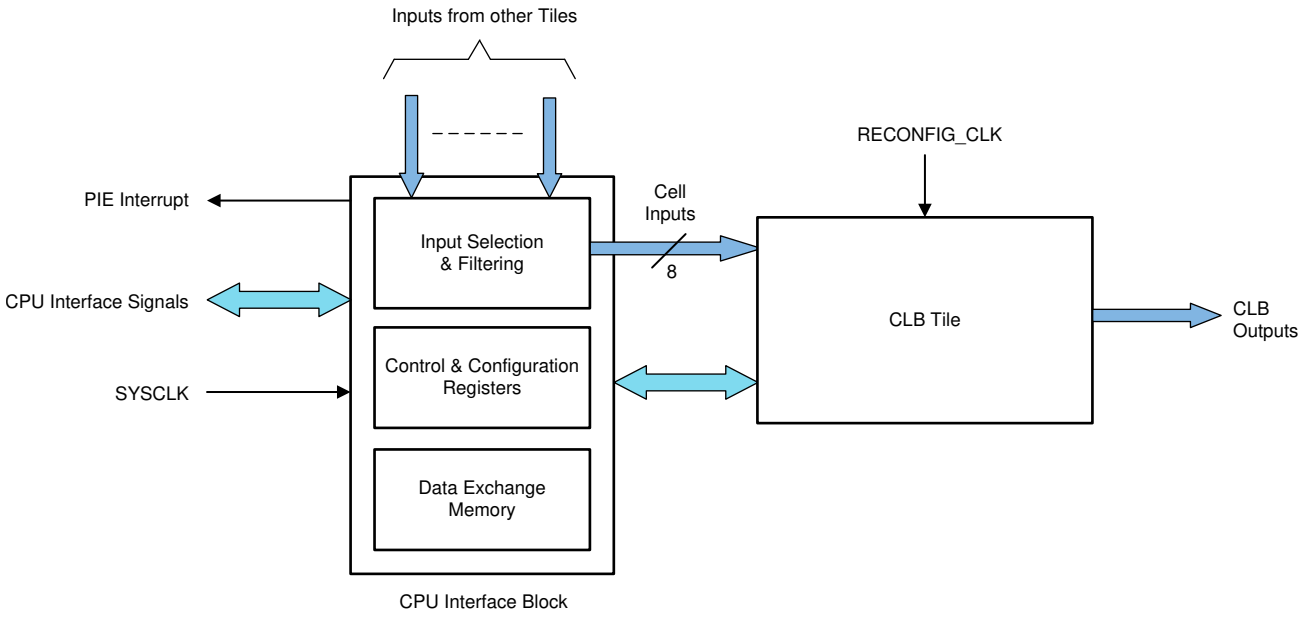

Figure 30-2. Block Diagram of a CLB Tile and CPU Interface

30.2.1 CLB Clock

In this device, the CLB clock is called CLBx clock that can be enabled or disabled by SYSCTL_PERIPH_CLK_CLBx through the SysCtl_enablePeripheral function. The maximum frequency is 150MHz and the clock can be enabled and configured by modifying the CLBx clock.

Note

When in SYNC mode at clock frequencies above 100MHz, PIPELINE mode must be enabled. When in ASYNC mode at clock frequencies above 120MHz, PIPELINE mode must be enabled.

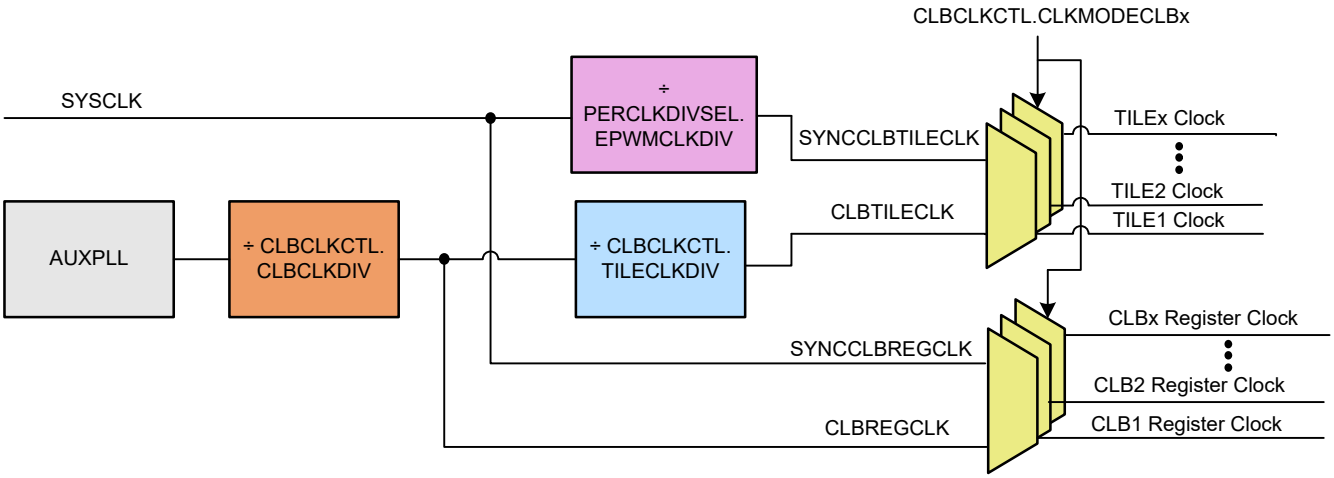

Figure 30-3. CLB Clocking

The CLB TILE clock and CLB register clock can be in ASYNC/SYNC mode with the SYSCLK. An example CLB clock configuration is shown in Table 30-1. Check the device data sheet for details on clocking specifications.

Table 30-1. Example CLB Clocking Configuration

Clock	SYNC Mode (CLKMODECLBx = 0)	ASYNC Mode (CLKMODECLBx = 1)	
		TILECLKDIV = 1	TILECLKDIV = 0
CLB Register Clock	SYSCLK	SYSCLK	SYSCLK
CLB TILE Clock	SYSCLK	SYSCLK / 2	SYSCLK

Starting with CLB Type 2, a clock prescalar module is available. The prescalar module can generate a prescaled version of the CLB clock signal that can be used as an input to the CLB TILE's counter.

Note

The prescalar logic does not change the actual clocking speed of the CLB. The prescalar generates a strobe (that can toggle at the defined prescaled rate) that is made available as another input signal to the CLB logic and the strobe is only used when required.

The prescalar module is shown in Figure 30-4.

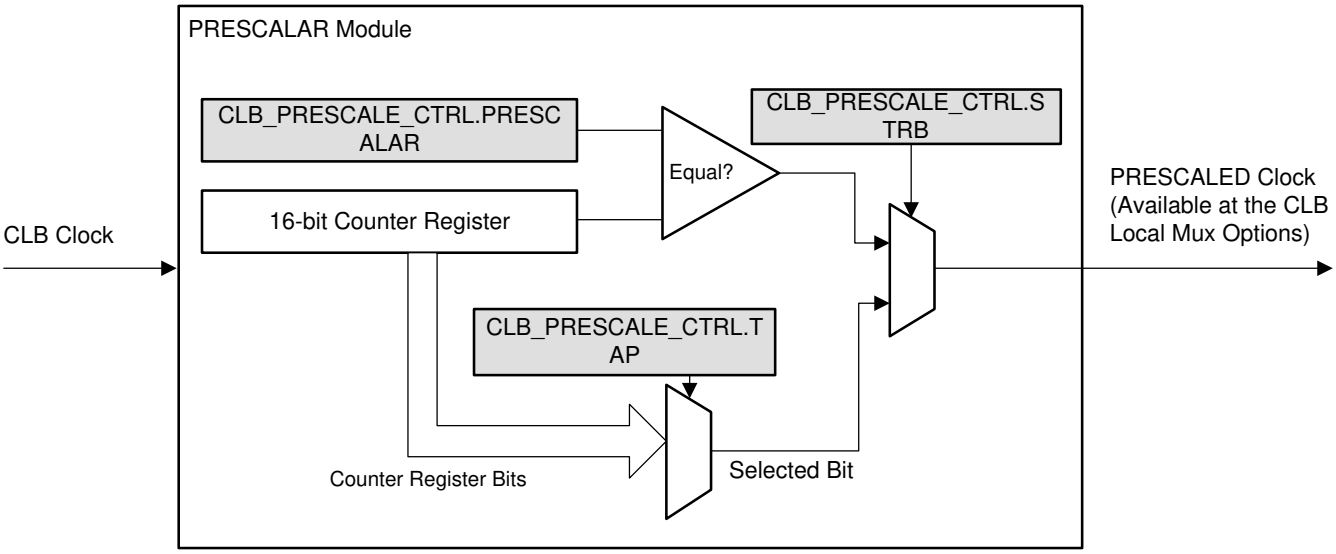

Figure 30-4. CLB Clock Prescalar

30.3 CLB Input/Output Connection

30.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

30.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

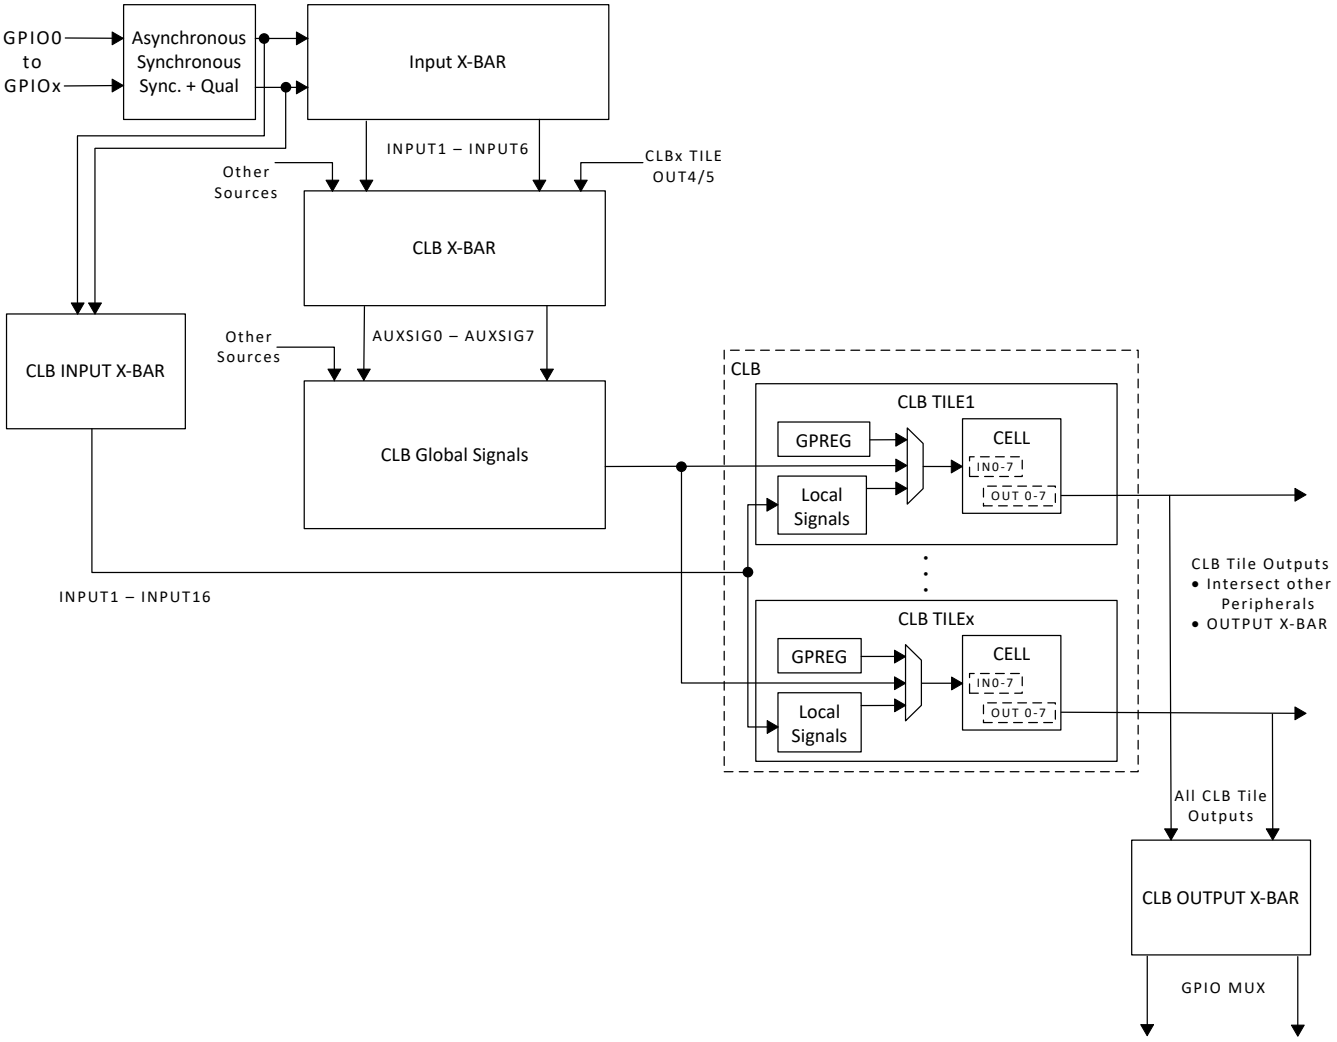

Figure 30-5. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 30-6. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 30-6.

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 30-2. The local input mux settings are shown in Table 30-3.

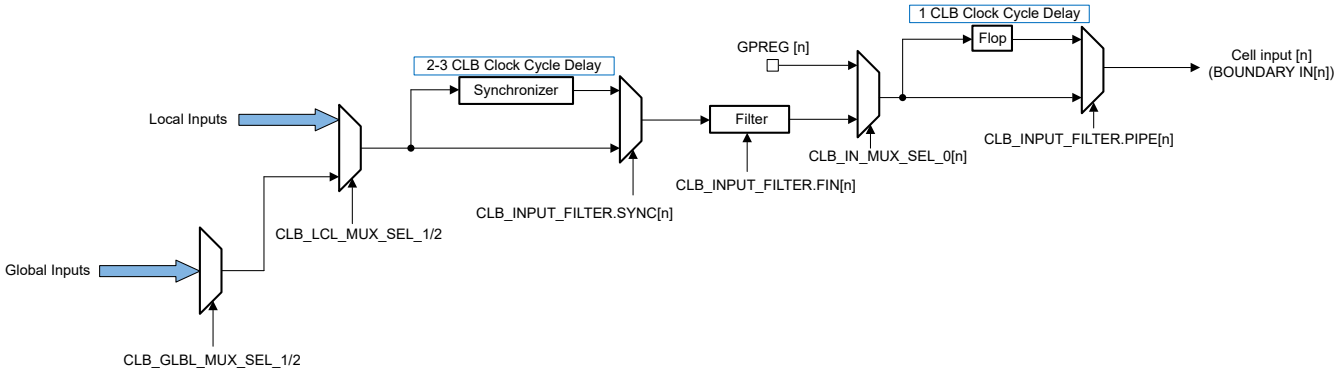

Figure 30-6. CLB Input Mux and Filter

Figure 30-7 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal. Figure 30-8 shows an instance of using input pipelining for a synchronous signal, which here is the ePWM TBCLK signal. Note that these two input configurations are not used simultaneously, and each have a cycle delay that adds to the input path.

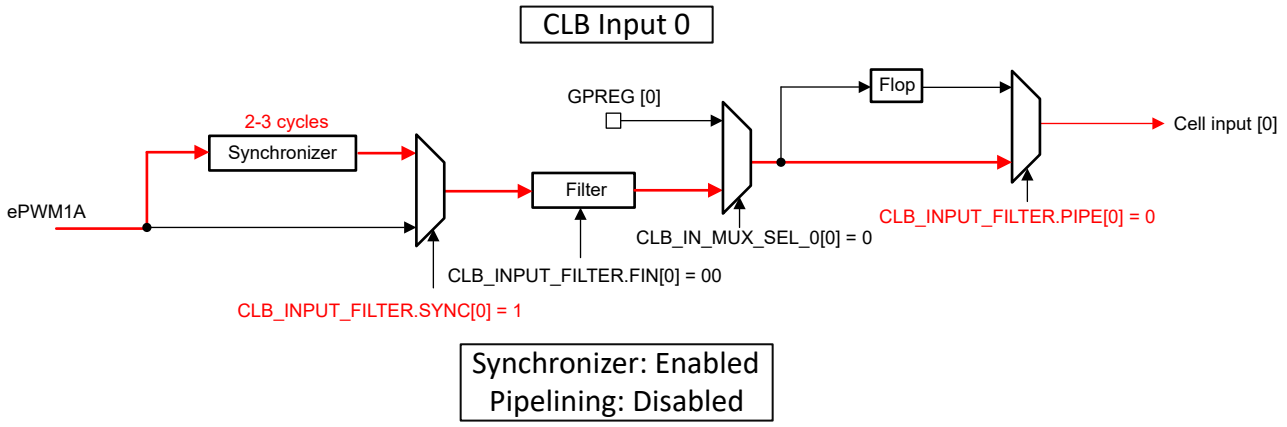

Figure 30-7. CLB Input Synchronization Example

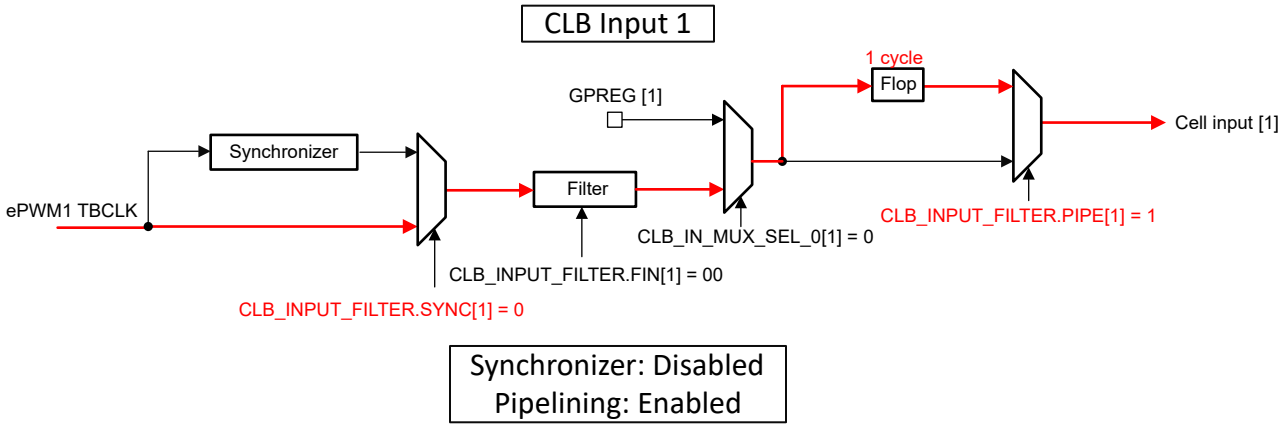

Figure 30-8. CLB Input Pipelining Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

Note

EPWMxA_OE and EPWMxB_OE refer to trip outputs from the respective EPWM module.

EPWMxA_AQ and EPWMxB_AQ refer to the output of the AQ submodule in the respective EPWM module.

EPWMxA_DB and EPWMBx_DB refer to the output of the DB submodule in the respective EPWM module.

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. Figure 30-5 shows how GPIOs can be used as inputs to the CLB tiles.

30.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 32 output signals. Each of these 32 outputs has a separate enable bit defined in the CLB output enable register, CLB_OUT_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 30-9 shows the CLB outputs.

The user has the capability to disable updated to the CLB_OUT_EN register by blocking access to the register through setting the CLB_MISC_ACCESS_CTRL.BLKEN bit. The eight outputs are replicated to generate a total of 32 outputs (shown in Figure 30-9). Some of these new outputs can be used for TILE to TILE connection through the CLB Global Mux inputs.

Note

The output from OUTLUT0 is connected to OUT0, OUT8, OUT16, and OUT24. While the signal is the same, each OUTy has access to a different peripheral as shown in Section 30.3.4. Likewise, OUTLUT1 is connected to OUT1, OUT9, OUT17, and OUT25, and are the same signal.

CLBx_OUT12 through CLBx_OUT15 are unregistered and asynchronous to the CLB clock.

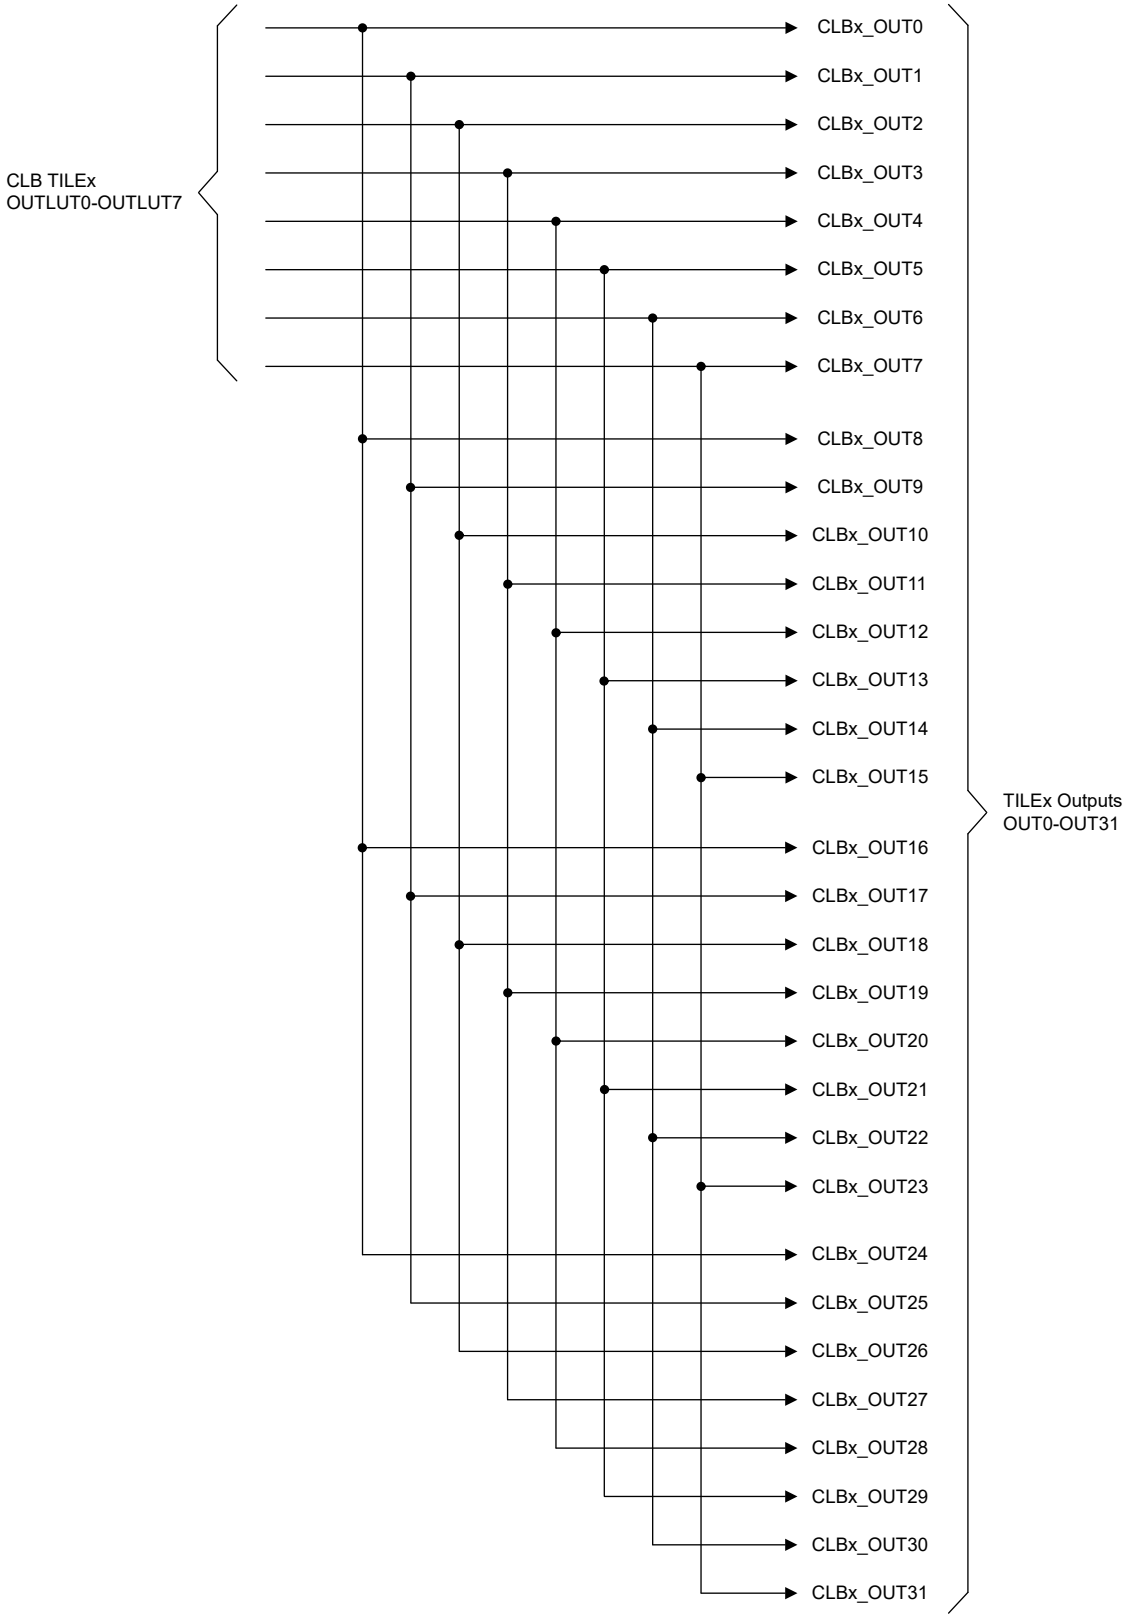

Figure 30-9. CLB Outputs

30.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see Figure 30-10. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB_OUT_EN.

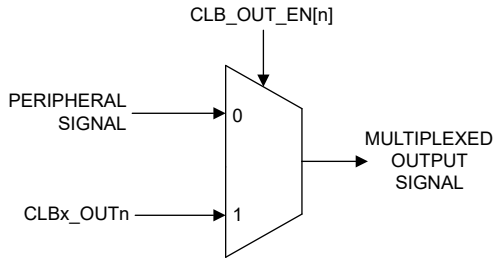

Figure 30-10. CLB Output Signal Multiplexer

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPTUT ENABLE bit for OUT0 must be set to 1.

Table 30-4 shows the allocation of peripheral signals and the CLB outputs.

Note

When not explicitly specified in the table above, refer to corresponding IP chapters for exact CLB Output destinations (that is, FSI, ECAP, XBAR connections).

30.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. Starting with CLB Type 2, the counter module can also operate as a serializer or linear feedback shift register. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **Asynchronous Output Conditioning Block:** The primary purpose of the Asynchronous Output Conditioning (AOC) block is to provide asynchronous conditioning capabilities on the TILE outputs or directly on the inputs of the TILE.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 30-11.

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

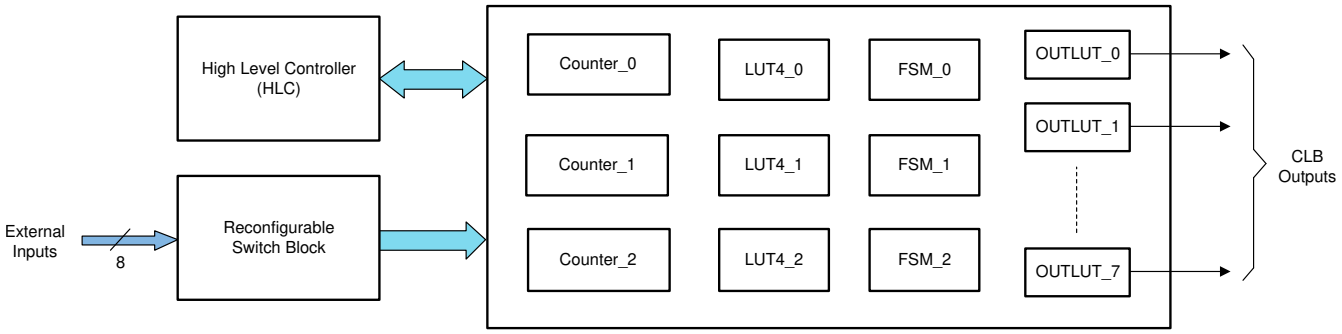

Figure 30-11. CLB Tile Submodules

30.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

Table 30-5. Output Table

Bit Position	Signal Connection	Comment
0	Always 0	This select value is used to tie an input to 0.
1	COUNTER_0 MATCH2	
2	COUNTER_0 ZERO	
3	COUNTER_0 MATCH1	
4	FSM_0 STATE_BIT_0	
5	FSM_0 STATE_BIT_1	
6	FSM_0 LUT output	
7	LUT4_0 output	
8	Always 1	This select value is used to tie an input to 1.
9	COUNTER_1 MATCH2	
10	COUNTER_1 ZERO	
11	COUNTER_1 MATCH1	
12	FSM_1 STATE_BIT_0	
13	FSM_1 STATE_BIT_1	
14	FSM_1 LUT output	
15	LUT4_1 output	
16	Always ‘0’	
17	COUNTER_2 MATCH2	
18	COUNTER_2 ZERO	
19	COUNTER_2 MATCH1	
20	FSM_2 STATE_BIT_0	
21	FSM_2 STATE_BIT_1	
22	FSM_2 LUT output	
23	LUT4_2 output	
24	External Input 0	
25	External Input 1	
26	External Input 2	
27	External Input 3	
28	External Input 4	
29	External Input 5	
30	External Input 6	
31	External Input 7	

Table 30-6. Input Table

Module Name	Port Name	Description
Counter Block	RESET	Acts as an active high reset when used as a counter
	MODE_0	Acts as an enable when used as a counter. The counter counts only when this input is 1.
	MODE_1	Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down.
LUT	IN0	Input 0 of the 4-input LUT.
	IN1	Input 1 of the 4-input LUT.
	IN2	Input 2 of the 4-input LUT.
	IN3	Input 3 of the 4-input LUT.
FSM	EXT_IN0	Input 0 of the FSM block.
	EXT_IN1	Input 1 of the FSM block.
	EXTRA_EXT_IN0	Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode.
	EXTRA_EXT_IN1	Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode.

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in Table 30-5. It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in Table 30-7.

Table 30-7. Ports Tied Off to Prevent Combinatorial Loops

Module Name	Ports of Input MUX Tied Off to 0 to Prevent Combinational Loops
LUT_0	LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
FSM_0	LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
LUT_1	LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.
FSM_1	LUT_2 output, FSM_1 and FSM_2 output.
LUT_2	LUT_2 output, FSM_2 output.
FSM_2	FSM_2 output.

30.4.2 Counter Block

30.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 30-12.

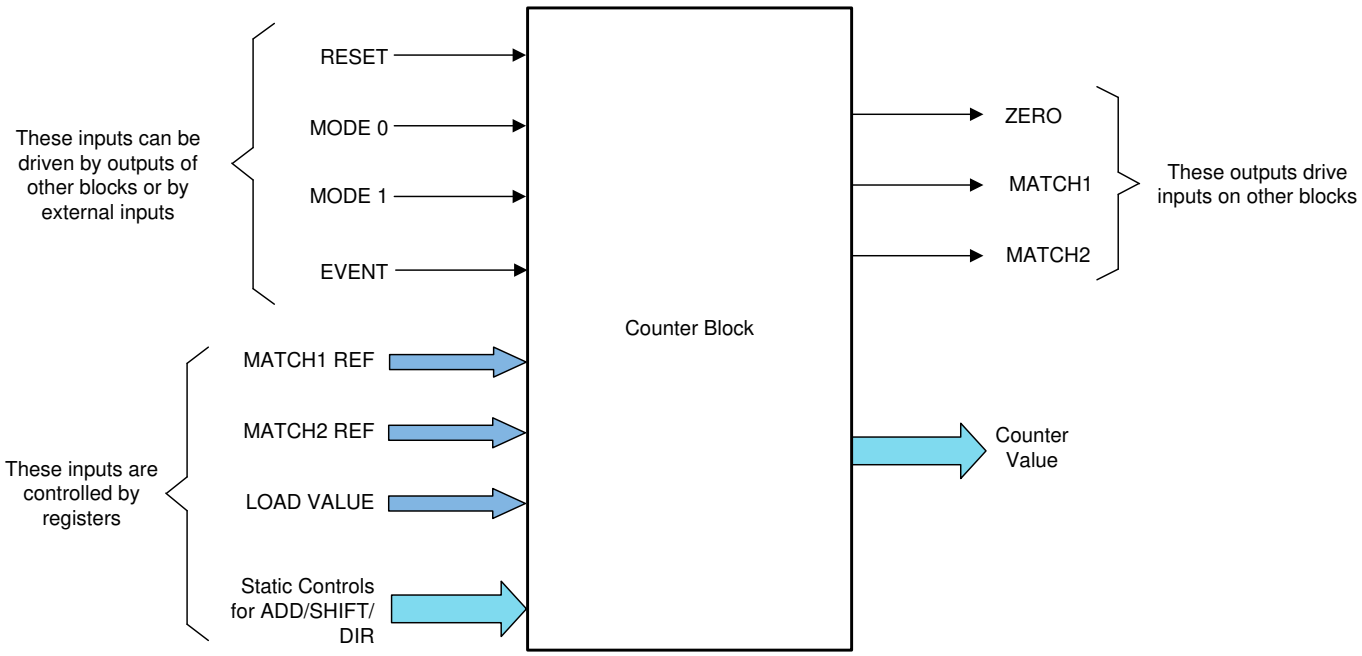

Figure 30-12. Counter Block

30.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE_0 is high. The counter wraps around to 0x0000 0000 after 0xFFFF FFFF when counting up. The counter wraps around to 0xFFFF FFFF after 0x0000 0000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

  Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE_0, MODE_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see Section 30.5.2.

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG_MISC_CTRL register. The following three bits of this register are relevant for each counter. The "x" below refers to the counter instance; 0, 1, or 2. For more information, see the CLB_MISC_CONTROL register description located in Section 30.9.

- COUNT_EVENT_CTRL_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT_ADD_SHIFT_x. 1 means add, 0 means shift.
- COUNT_DIR_x. 1 means left shift or add. 0 means right shift or subtract.

Table 30-8 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load: CNTVAL = EVENT_LOAD_VAL

Shift right: CNTVAL = CNTVAL >> EVENT_LOAD_VAL

Shift left: CNTVAL = CNTVAL << EVENT_LOAD_VAL

Subtract: CNTVAL = CNTVAL - EVENT_LOAD_VAL

Add: CNTVAL = CNTVAL + EVENT_LOAD_VAL

Table 30-8. Counter Block Operating Modes

EVENT	MODE_0	MODE_1	COUNT_EVENT_CTRL_x	COUNT_ADD_SHIFT_x	COUNT_DIR_x	Action on CNTVAL
0	0	0	X	X	X	None
0	0	1	X	X	X	None
0	1	0	X	X	X	Count down
0	1	1	X	X	X	Count up
1	X	X	0	X	X	Load
1	X	X	1	0	0	Shift right
1	X	X	1	0	1	Shift left
1	X	X	1	1	0	Subtract
1	X	X	1	1	1	Add

30.4.2.3 Serializer Mode

Starting with CLB Type 2, the Counter module can operate as a serializer. In this mode of operation, this module acts as a shift register (also referred to as a serializer). In serializer mode of operation, the EVENT input is used to shift one bit of data into the serializer. Either of MATCH1 and MATCH2 can be configured to send out the shift register data.Using the MATCH1/2_TAP_SEL bit of CLB_COUNT_MATCH_TAP_SEL, any bit position of the counter can be brought out on the MATCH1/MATCH2 outputs. The shifting and direction of the counter in this mode is controlled by MODE_0 (enable) and MODE_1 (direction).

To enable the Serializer mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set.

30.4.2.4 Linear Feedback Shift Register (LFSR) Mode

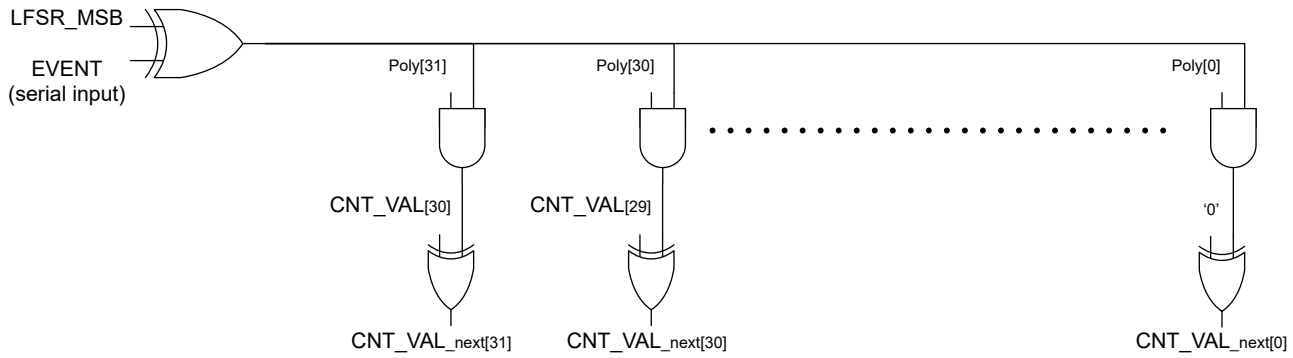
Starting with CLB Type 2, the Counter module operates as a linear feedback shift register. By configuring the characteristics of the LFSR, the counter module is used to compute the CRC on a serial bit stream. The polynomial for LFSR is in the MATCH2 reference register. The feedback bit position is in the MATCH1 reference register.

To enable the LFSR mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set along with COUNT0_LFSR_EN.

There are two types of LSFR that can be selected by changing the MODE1 value (0 or 1), as shown in Figure 30-13.

Structure for LFSR Type 1 (MODE_1 = 0)

CNT_VAL is the 32-bit counter's active register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial



Structure for LFSR Type 2 (MODE_1 = 1)

CNT_VAL is the 32-bit counter register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial

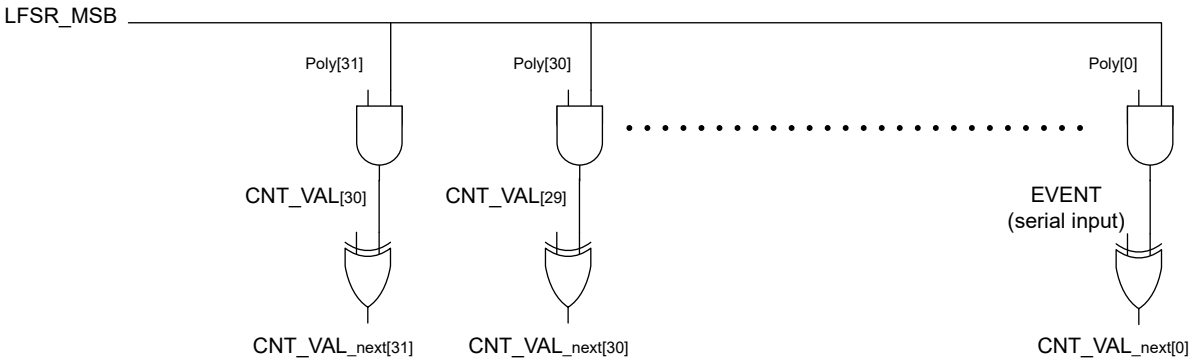


Figure 30-13. LFSR Modes

30.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA_EXT_IN0 and EXTRA_EXT_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 30-14.

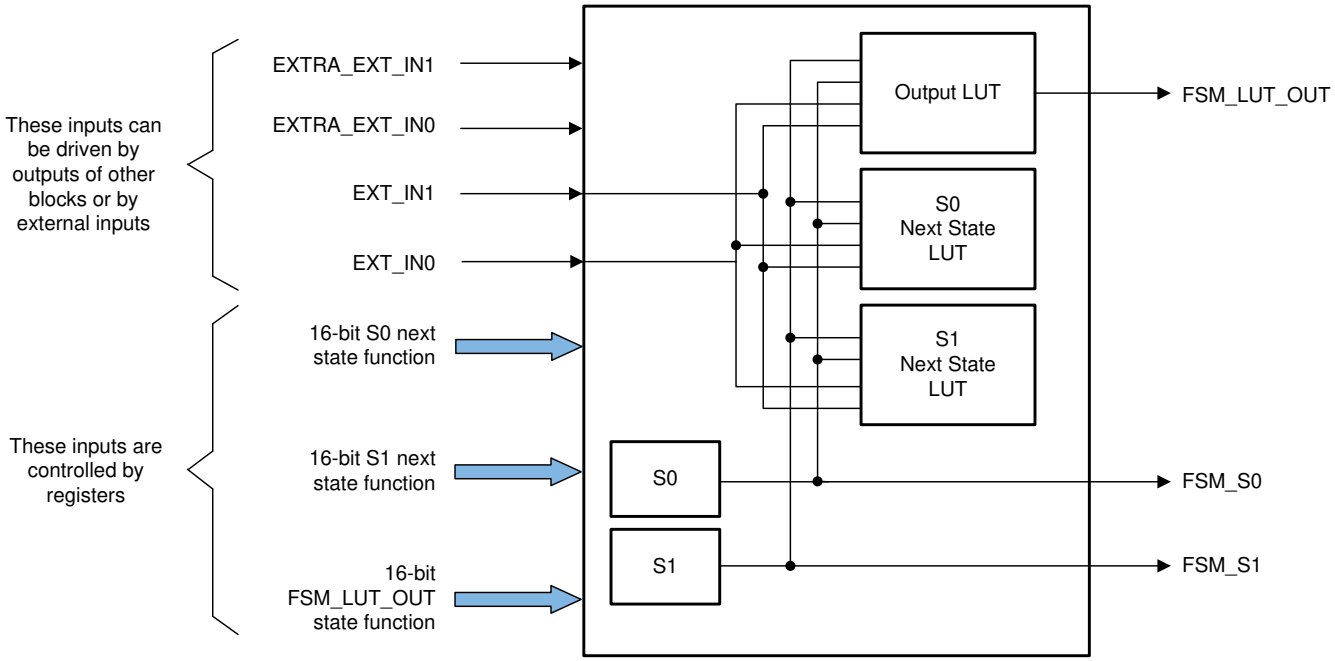

Figure 30-14. FSM Block

The signals and functionality of the FSM block are:

- **EXT_IN0 and EXT_IN1:** These are the two external inputs that can be used to control the output FSM_LUT_OUT or either of the states S0 and S1.
- **S0** and **S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM_LUT_OUT. An additional level of configurability is provided such that FSM_LUT_OUT can use extra inputs in case the states S0 and S1 are unused.

  One extra bit is used to select EXTRA_EXT_IN0 instead of S0. One extra bit is used to select EXTRA_EXT_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM_LUT_OUT by giving up one or two state bits, respectively.

The CFG_MISC_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM_EXTRA_EXT_INx. A 0 means use the state bit, and a 1 means use the FSM_EXTRA_EXT_IN0 / FSM_EXTRA_EXT_IN1 signal.

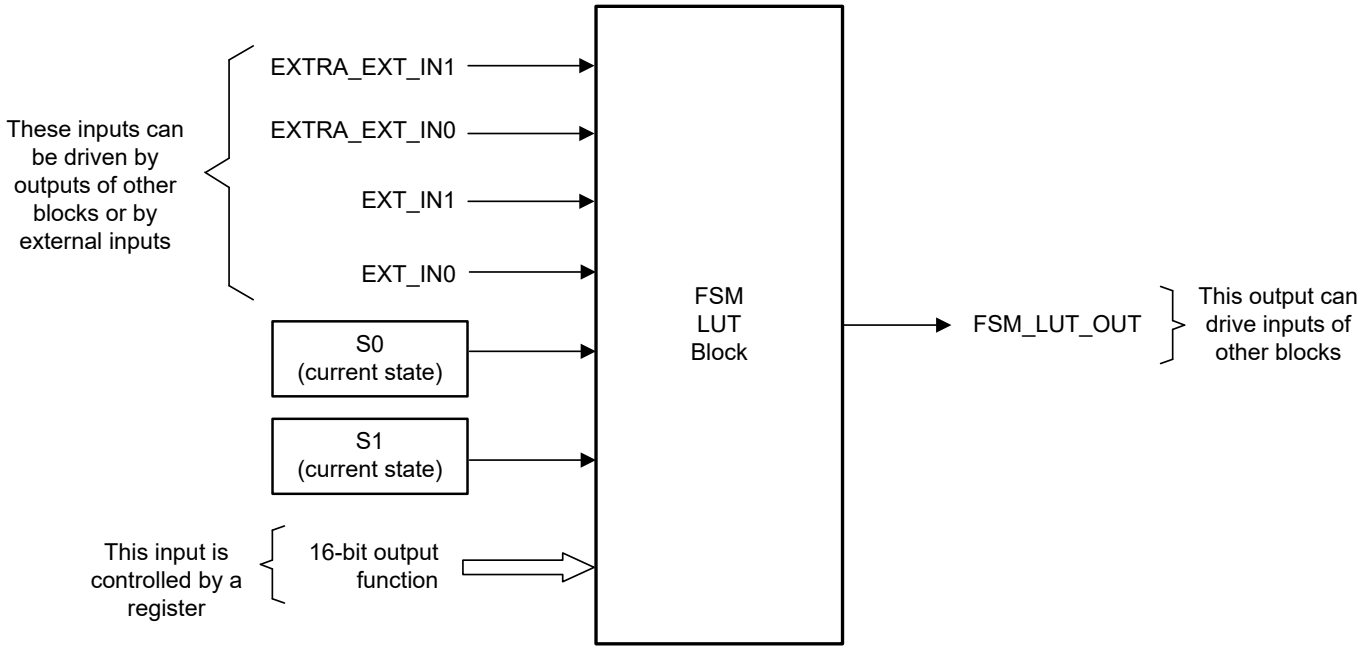

Figure 30-15. FSM LUT Block

30.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see Figure 30-16). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in Section 30.9.

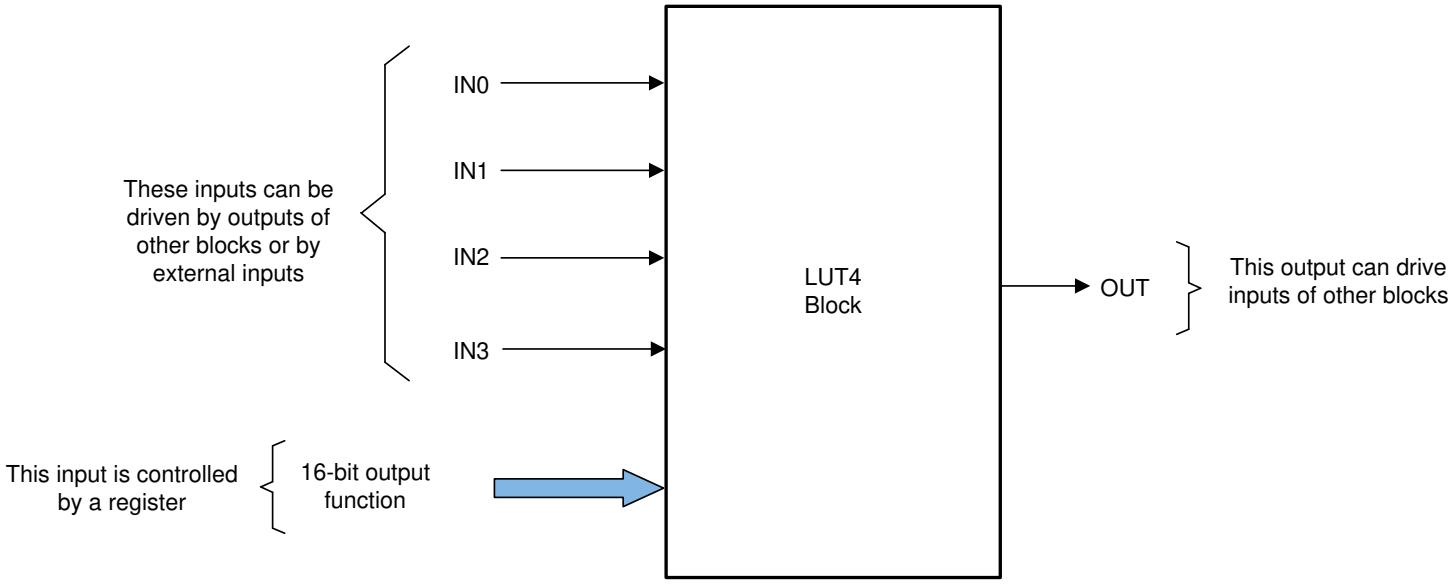

Figure 30-16. LUT4 Block

30.4.5 Output LUT Block

The output LUT block (Figure 30-17) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 30.9.

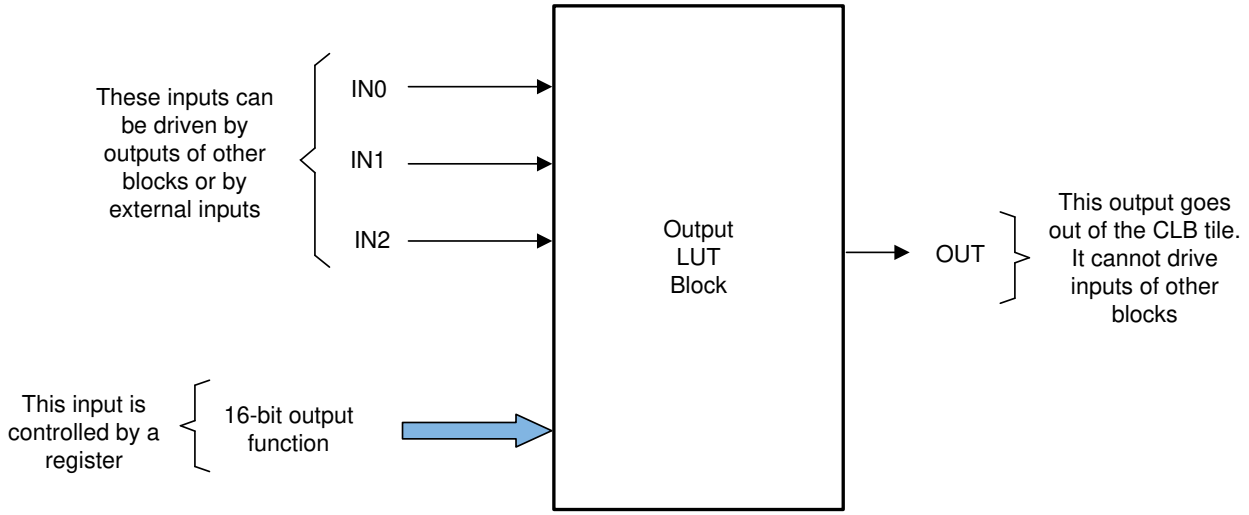

Figure 30-17. Output LUT Block

30.4.6 Asynchronous Output Conditioning (AOC) Block

The logic in the AOC block is organized into three stages with the inputs passing through different types of logic modification at each stage before proceeding to the next level. This is shown in Figure 30-18.

There are 8 inputs to this block. Each of these 8 inputs can pick the corresponding BOUNDARY input to the CLB or the CLB TILE output (for example, the INPUT 0 of the AOC block can choose between CLB BOUNDARY INPUT0 and CLB TILE OUTPUT 0). If the CLB TILE OUTPUT 0 is selected, the CLB TILE OUTPUT 0 is always registered before being sent to the subsequent asynchronous signal conditioning stages. In each of the three stages, there is always an option to do nothing and just send the signal as is to the next stage (bypass).

Stage 1: The input signal can be inverted before sending the signal to the next stage.

Stage 2: The signal coming from Stage 1 can be GATED with a gating control signal. The gating control signal can either be from a software register or can be any of the CLB TILE outputs. The GATING function can be a logical AND, OR, or XOR.

Stage 3: The input signal can be used to either set or clear the output on the rising edge of the signal. This is a purely asynchronous set/clear that occurs without needing any clocks. The release control signal, when high, restores the output to the default state (HIGH if asynchronous clear is selected and LOW if asynchronous set is selected). The release control signal can be either from a software register or can be any of the CLB TILE outputs. Optionally, instead of any of the asynchronous set and clear operations, the input signal can just be delayed by a clock cycle.

The interaction of the CLB TILE and the AOC block is shown in Figure 30-19.

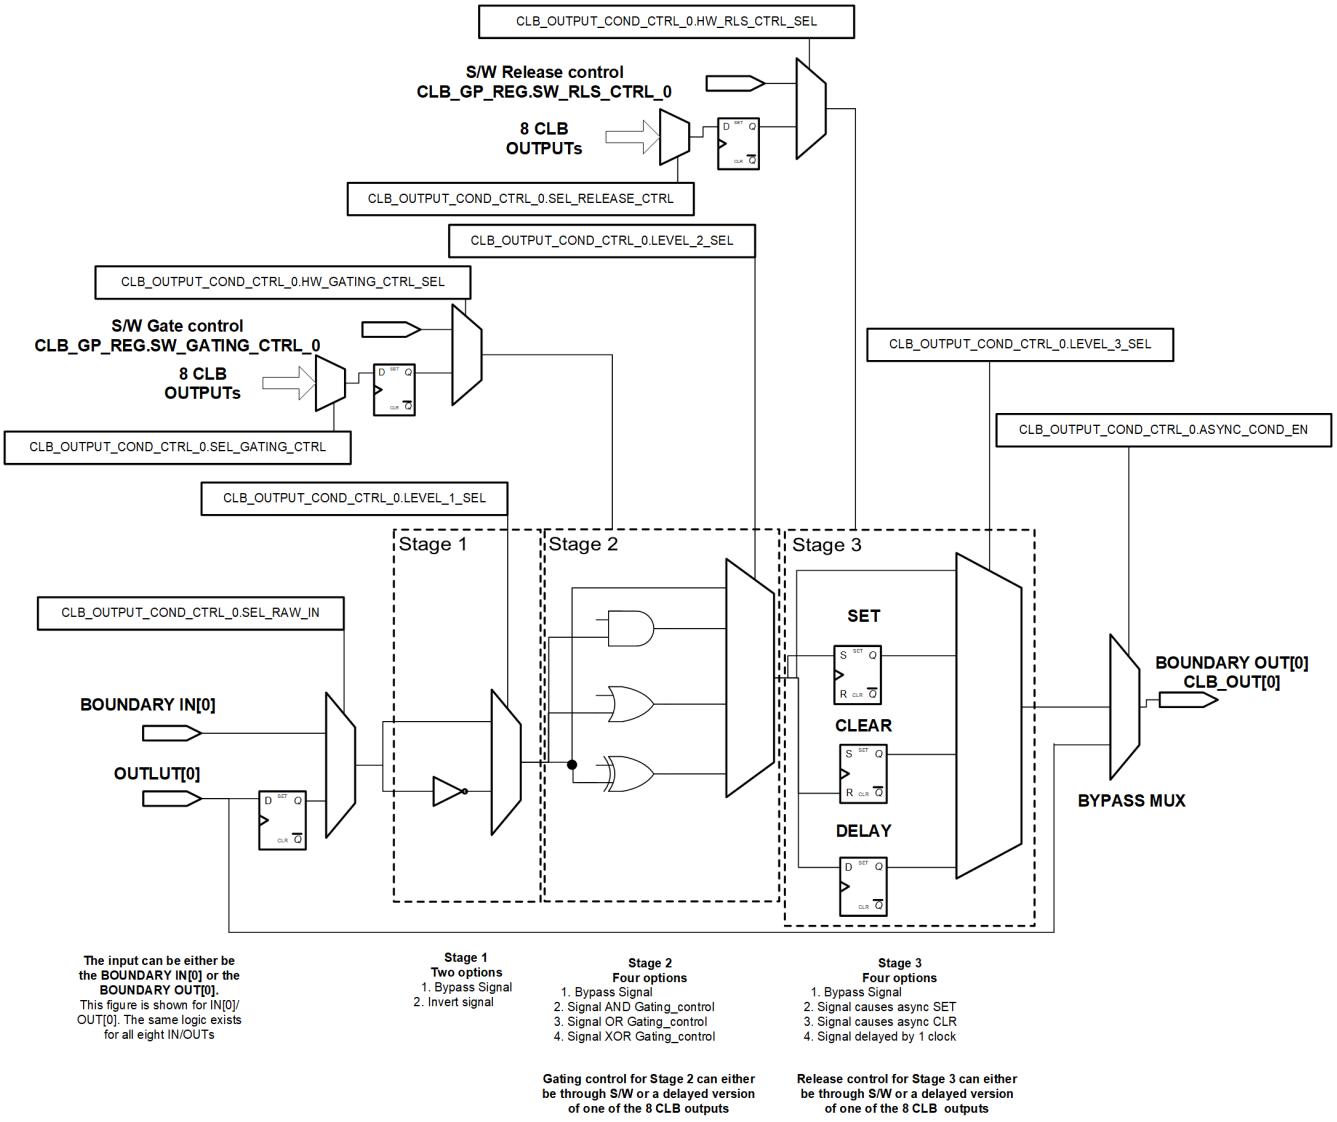

Figure 30-18. AOC Block

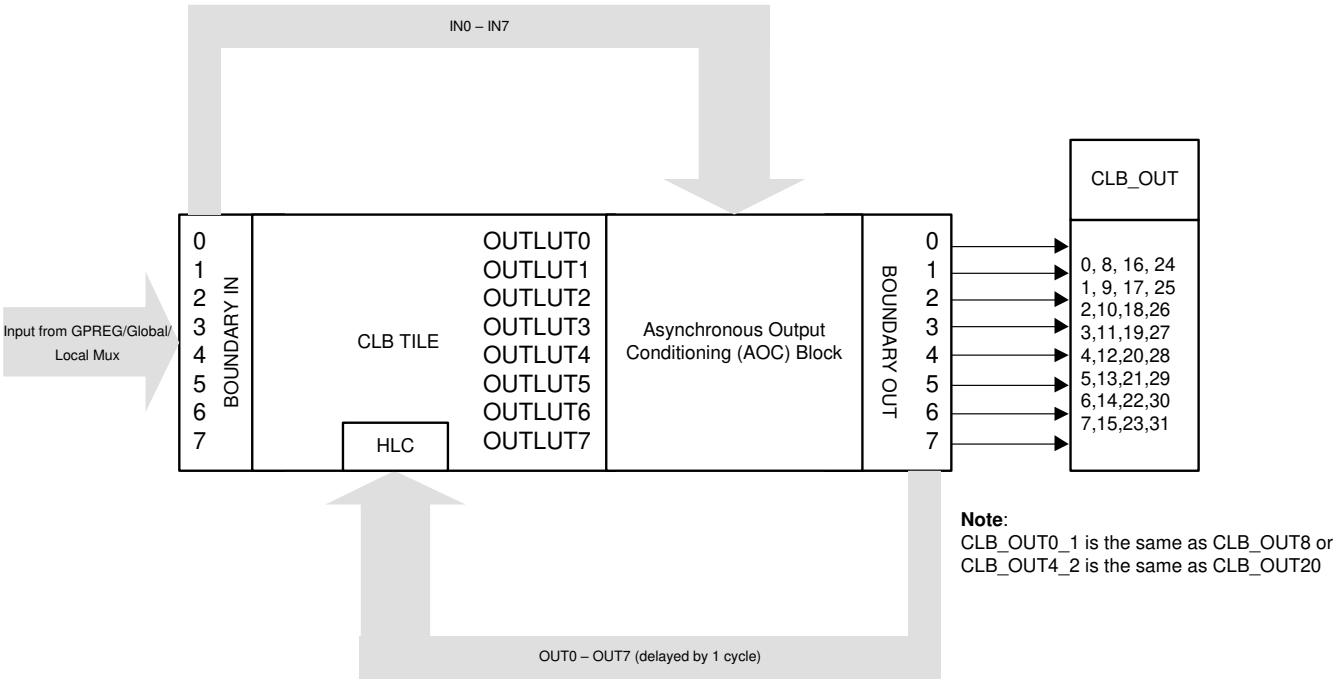

Figure 30-19. AOC Block and The CLB TILE

Note

Only CLB_OUT12 to CLB_OUT15 can be used as ASYNC outputs. This is the same as CLB_OUT4_1 to CLB_OUT7_1. GPIO Output XBAR can be used to route the OUT4_1 and OUT5_1 ASYNC outputs to GPIOs.

30.4.7 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to Section 30.4.7.4 for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 30-20. The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

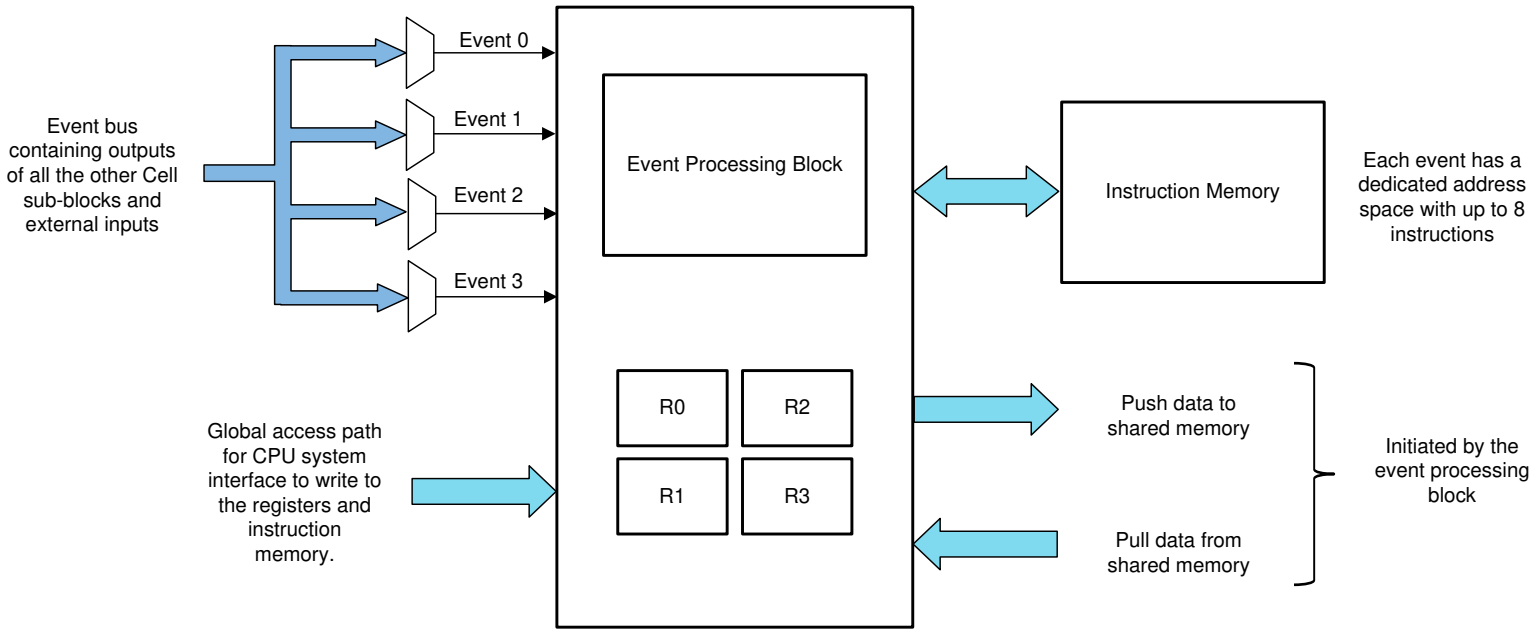

Figure 30-20. High Level Controller Block

30.4.7.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in Table 30-9. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

Table 30-9. HLC Event List

Index	HLC Event Mux
0	Always 0
1	COUNTER_0 MATCH2
2	COUNTER_0 ZERO
3	COUNTER_0 MATCH1
4	FSM_0 STATE_BIT_0
5	FSM_0 STATE_BIT_1
6	FSM_0 LUT output

30.4.7.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event. Starting with CLB Type 2, the option to trigger the execution of instructions using both falling edge and rising edge is available.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in Table 30-11. An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

Table 30-11. HLC Instruction Address Ranges

Address	Instructions for
00000 to 00111	Event 0
01000 to 01111	Event 1
10000 to 10111	Event 2
11000 to 11111	Event 3

The HLC instruction format is shown in Table 30-12.

Table 30-12. HLC Instruction Format

Last Instruction Bit	5-Bit Opcode	3-Bit Source	3-Bit Destination
This bit when set to 1 stops execution after the current instruction.	MOV 00000 MOV_T1 00001 MOV_T2 00010 PUSH 00011 PULL 00100 ADD 00101 SUB 00110 INTR 00111	Source can be R0, R1, R2, R3, C0, C1, C2.	Destination can be R0, R1, R2, R3, C0, C1, C2. Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination.

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. Table 30-13 describes the HLC instructions.

Table 30-13. HLC Instruction Description

Instruction	Description
ADD <Src>, <Dest>	This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.
INTR <6-bit constant>	This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect. **Note** Starting with CLB Type 2, NMI can be generated by the CLB. This feature is DISABLED by default and must be enabled (**CLB_LOAD_EN.NMI_EN**).
MOV <Src>, <Dest>	This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect.

Table 30-13. HLC Instruction Description (continued)

Instruction	Description
MOV_T1 <Src>, <Dest>	This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are: • This instruction moves the count value in C1 into register R0: MOV_T1 C1 R0 • This instruction moves the value in R2 into the Match1 register of counter C0: MOV_T1 R2 C0
MOV_T2 <Src>, <Dest>	This instruction is similar to MOV_T1. The instruction moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.
PULL <Dest>	This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.
PUSH <Src>	This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.
SUB <Src>, <Dest>	This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.

MOV, MOV_T1, MOV_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

30.4.7.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in Table 30-14.

Table 30-14. HLC Register Encoding

Bits	Register
000	R0
001	R1
010	R2
011	R3
100	C0
101	C1
110	C2

30.4.7.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb_ex13_push_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine the value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

30.5 CPU Interface

30.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000–0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100–0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200–0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

Note

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see Section 30.9.

30.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB_LOAD_DATA and CLB_LOAD_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to Section 30.4.7.4.

Load the data to be written into the CLB_LOAD_DATA register, then load the appropriate address into CLB_LOAD_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB_LOAD_EN register then causes an internal write operation to be triggered. The address allocation for the CLB_LOAD_ADDR register is shown in Table 30-15.

Note

The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

Table 30-15. Non-Memory Mapped Register Addresses

Address (Binary)	Resource
000000 to 000010	Counter 0 to 2 Load value
000100 to 000110	Counter 0 to 2 Match1 value
001000 to 001010	Counter 0 to 2 Match2 value
001100 to 001111	R0 to R3 of High Level Controller
100000 to 100111	Instructions for Event 0
101000 to 101111	Instructions for Event 1
110000 to 110111	Instructions for Event 2
111000 to 111111	Instructions for Event 3

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB_LOAD_DATA.
2. Write 0xc to CLB_LOAD_ADDR.
3. Write 0x1 to CLB_LOAD_EN.

Note

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

30.6 DMA Access

The DMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to Section 30.9.

30.7 CLB Data Export Through SPI RX Buffer

For a continuous export of data from the CLB peripherals, SPI RX buffers can be used. CLB data can be exported through the SPI RX buffers without CPU/CLA interventions.

For the F28P55x devices, CLB1 and CLB2 have access to SPIA and SPIB, respectively, as shown in Table 30-16.

Table 30-16. CLB to SPI RX Access

SPI Instance	CLB Instance
SPIA	CLB1
SPIB	CLB2

When the CLB to SPI data exporting is enabled, 16-bit data can be exported from CLB to SPI RX buffers. The 32-bit HLC R0 register is the data that is exported to the SPI RX buffers. The user can select which 16-bit range of the HLC R0 is exported by configuring the CLB_SPI_DATA_CTRL_HI.SHIFT. The CLB also controls when HLC R0 data must be transferred to the SPI RX buffer through CLB_SPI_DATA_CTRL_HI.STRB that selects one of the HLC event signals from the static switch block.

When CLB to SPI data exporting is required, note:

- The selected SPI transmit functionality is not affected.
- Even though the data is being pushed into the SPI RX buffers by the CLB, the SPI RX interrupt and the DMA trigger for SPI RX in the respective peripherals must be configured.
- The SPI can resume normal operation when the CLB to SPI data exporting is disabled.

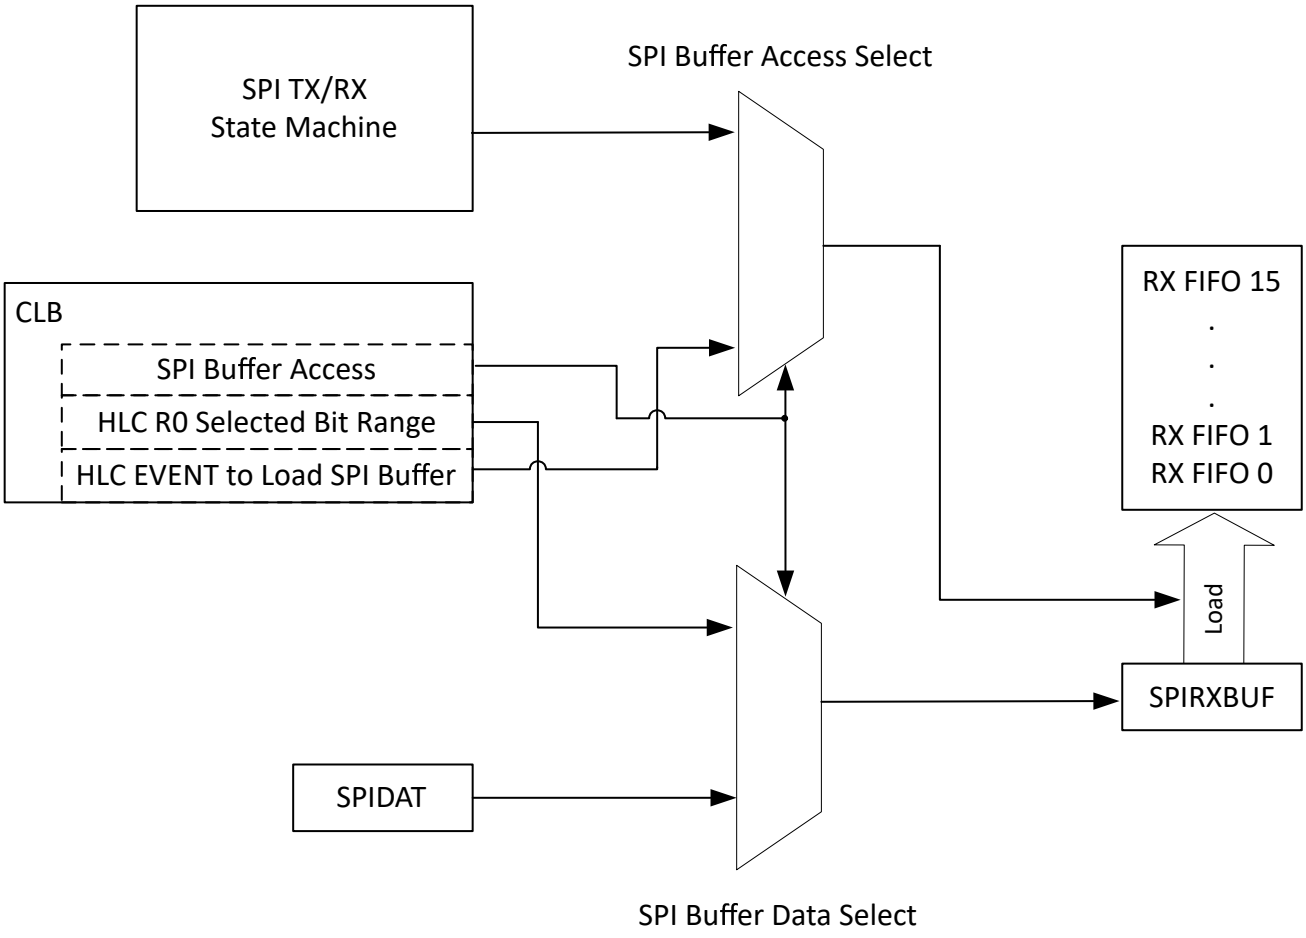

Figure 30-21. CLB Control of SPI RX Buffer

30.8.2 CLB Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/clb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

30.8.2.1 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

30.8.2.2 CLB Combinational Logic

FILE: clb_ex1_combinatorial_logic.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

The objective of this example is to prevent simultaneous high or low outputs on a PWM pair. PWM modules 1 and 2 are configured to generate identical waveforms based on a fixed frequency up-count mode.

30.8.2.3 CLB GPIO Input Filter

FILE: clb_ex2_gpio_input_filter.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example demonstrates use of finite state machines (FSMs) and counters to implement a simple â€˜glitchâ€™ filter which might, for example, be applied to an incoming GPIO signal to remove unwanted short duration pulses.

30.8.2.4 CLB Auxilary PWM

FILE: clb_ex3_auxiliary_pwm.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example configures a CLB tile as an auxiliary PWM generator. The example uses combinatorial logic (LUTs), state machines (FSMs), counters, and the high level controller (HLC) to demonstrate the PWM output generation capabilities using CLB.

30.8.2.5 CLB PWM Protection

FILE: clb_ex4_pwm_protection.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example extends the features of example 1 to ensure an active high complementary pair PWM configuration always operates with a minimum value of dead-band irrespective of how the generating PWM module is configured. The example illustrates the configuration of four separate PWM tiles to implement PWM protection on four PWM modules. The outputs of PWM modules 1 to 4 are operated on by CLB tiles 1 to 4, respectively.

30.8.2.6 CLB Event Window

FILE: clb_ex5_event_window.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses the counter, FSM, and HLC sub-modules of the CLB to implement an event timing feature which detects whether an interrupt service routine takes too long to respond to an interrupt. The example configures four PWM modules to operate in up-count mode and generate a low-to-high edge on a timer zero match event. The zero match event also triggers a PWM ISR which, for the purposes of this example, contains a dummy payload of variable length. At the end of the ISR, a write operation takes place to a CLB GP register to indicate the ISR has ended.

30.8.2.7 CLB Signal Generator

FILE: clb_ex6_siggen.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses CLB1 to generate a rectangular wave and CLB2 to check the rectangular wave generated by CLB1 doesnâ€™t exceed the defined duty cycle and period limits.

30.8.2.8 CLB State Machine

FILE: clb_ex7_state_machine.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\Designing With the C2000 CLB.pdf This application report describes the process of creating this CLB example and can be used as guidance on desiging custom logic with the CLB. This example uses all submodules inside a CLB TILE in order to implement a complete system.

30.8.2.9 CLB External Signal AND Gate

FILE: clb_ex8_external_signal_AND_gate.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, two external signals from two GPIOs are passed through the Input X-BAR and the CLB X-BAR to the CLB TILE. Inside the CLB module these two signals are ANDED. The output of the AND gate is then exported to a GPIO, using Output X-BAR.

30.8.2.10 CLB Timer

FILE: clb_ex9_timer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a COUNTER module is used to create timed events. The use of the GP Register is shown. Through setting/clearing the bits in the GP register, the timer is started, stopped or changes direction. The output of the timer event (1-clock cycle) is exported to a GPIO. Interrupts are generated from the timer event using the HLC module. A GPIO is also toggled inside the CLB ISR. The indirect CLB register access is used to update the timerâ€™s event match value and the active counter register to modify the frequency of the timer.

30.8.2.11 CLB Timer Two States

FILE: clb_ex10_timer_two_states.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the timer is setup the same as the previous example. The difference is the use of the FSM submodule to toggle the output of the CLB which is then exported to a GPIO. The FSM module acts as a single bit memory block. Interrupts are setup in the same format as the previous example. The interrupt delay of the CLB can be seen by comparing the output of the CLB and the GPIO toggled in the ISR.

30.8.2.12 CLB Interrupt Tag

FILE: clb_ex11_interrupt_tag.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a timer is setup with two different match values. These two events are used by the HLC submodule to generate interrupts. The interrupt TAG is used to differentiate between the interrupt generated due to the match1 event of the CLB counter and the match2 event of the CLB counter.

30.8.2.13 CLB Output Intersect

FILE: clb_ex12_output_intersect.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is set up the same as the external_AND_gate example. However, instead of the output being exported to the GPIO using Output X-BAR, the output is exported to the GPIO by replacing the output of ePWM1. This is done by configuring the GPIO for EPWM1A output, followed by enabling output intersection.

30.8.2.14 CLB PUSH PULL

FILE: clb_ex13_push_pull.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the use of the PUSH-PULL interface is shown. Multiple COUNTER submodules, HLC submodule, FSM submodules, and OUTLUT submodules are used. The PUSH-PULL interface is used alongside the GP register to update the COUNTER submodulesâ€™ event frequencies.

30.8.2.15 CLB Multi Tile

FILE: clb_ex14_multi_tile.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a CLB TILE is passed to the input of another CLB TILE. The output of the second CLB TILE is then exported to a GPIO, showcasing how two CLB TILEs can be used in series.

30.8.2.16 CLB Tile to Tile Delay

FILE: clb_ex15_tile_to_tile_delay.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a GPIO is taken into the CLB TILE through INPUT XBAR and the CLB XBAR. The signal is forwarded by the TILE to the next TILE. This time the signal only goes through the CLB XBAR and NOT the Input XBAR. This is done to show that delays are added when the signals are passed from TILE to TILE and the delay is NOT characterized. The user should always avoid passing signals with timing requirements between tiles. The COUNTER modules inside the CLBs will count the amount of delay in cycles.

30.8.2.17 CLB Glue Logic

FILE: clb_ex16_glue_logic.c

For the detailed description of this example, please refer to :
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the user is walked through how to migrate custom logic from an FPGA/CPLD to C2000â„¢ microcontrollers.

30.8.2.18 CLB based One-shot PWM

FILE: clb_ex17_one_shot_pwm.c

For the detailed description of this example, please refer to :
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

30.8.2.19 CLB AOC Control

FILE: clb_ex18_aoc.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously AND gate the input signals to the CLB. This module is only available for CLB types 2 and up.

30.8.2.20 CLB AOC Release Control

FILE: clb_ex19_aoc_release_control.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously set/release the input signals to the CLB. This module is only available for CLB types 2 and up.

30.8.2.21 CLB XBARs

FILE: clb_ex20_clbxbars.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB INPUTXBAR and CLB OUTPUTXBAR are used to take input signals from GPIOs into the CLB TILEs and take output signal from the TILE to GPIOs. The availability of these XBARs are device dependent.

30.8.2.22 CLB AOC Control

FILE: clb_ex21_clockprescalar_nmi.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the clock prescalar of the CLB module is used to divide down the CLB clock and use it as an input to the TILE logic. Also the HLC module is used to generate NMI interrupts. This module is only available for CLB types 2 and up.

30.8.2.23 CLB Serializer

FILE: clb_ex22_serializer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER is used in serializer mode to act as a shift register. This module is only available for CLB types 2 and up.

30.8.2.24 CLB LFSR

FILE: clb_ex23_lfsr.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER module is used in Linear Feedback Shift Register (LFSR) mode. This module is only available for CLB types 2 and up.

30.8.2.25 CLB Lock Output Mask

FILE: clb_ex24_lock_output_mask.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the lock outpt mask feature of the CLB is used to lock the selected output signal override settings. This module is only available for CLB types 3 and up.

30.8.2.26 CLB INPUT Pipeline Mode

FILE: clb_ex25_input_pipeline.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB Input Pipeline mode is enable to delay the input signal by a clock cycle. This module is only available for CLB types 3 and up.

30.8.2.27 CLB Clocking and PIPELINE Mode

FILE: clb_ex26_clocking_pipeline.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB pipeline mode is enable and affects the behavior of the CLB COUNTERs and HLC. This module is only available for CLB types 3 and up.

30.8.2.28 CLB SPI Data Export

FILE: clb_ex27_spi_data_export.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. This module is only available for CLB types 3 and up.

30.8.2.29 CLB SPI Data Export DMA

FILE: clb_ex28_spi_data_export_dma.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. The data received in the SPI RX buffer is transferred to memory using DMA. This module is only available for CLB types 3 and up.

30.8.2.30 CLB Trip Zone Timestamp

FILE: clb_ex29_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:

- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.
- BOUNDARY.boundaryInput0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUDNARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.boundaryInput7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped. tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

30.8.2.31 CLB CRC

FILE: clb_ex30_cyclic_redundancy_check.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is used to perform the cyclic redundancy check (C.R.C.) with twelve messages in bits checked with ten different CRC polynomials.

First element passed in is message length, second is the message stored in input_data

This example is only available for CLB types 2 and up.

The known values in the output_data are compared with expected values from the CLB-based CRC calculation. A total of 120 messages are verified, and the number of matching messages are displayed in passCount

Variables to add to Watch Expressions in debug view: passCount - number of messages that match between generated and known CRC values failCount - number of messages that fail the CRC value verification

30.8.2.32 CLB TDM Serial Port

FILE: clb_ex31_tdm_serial_port.c

For the detailed description of this example, please refer to: How to Implement Custom Serial Interfaces Using the Configurable Logic Block (CLB) Application Note (SPRAD62).

In this example a single CLB tile is used to input a TDM stream and generate a TDM output stream. The CLB generates a CPU interrupt when four 32-bit words are received. The CPU can load four 32-bit values to the CLB FIFO for transmission. The CLB and CPU are configured to run at their maximum speed.

This example is only available on C2000 MCU devices with CLB types 2 and up.

External Connections
TDM Input Signal GPIO pin FSYNC_IN GPIO00 BCLK_IN GPIO01 DATA1_IN GPIO02

TDM Output Signal GPIO pin FSYNC_OUT GPIO04 BCLK_OUT GPIO05 DATA1_OUT GPIO06

30.8.2.33 CLB LED Driver

FILE: clb_ex32_led_driver.c

For the detailed description of this example, please refer to: How to Implement Custom Serial Interfaces Using the Configurable Logic Block (CLB) Application Note (SPRAD62).

In this example two CLB tiles are used to communicate with an LP5891-Q1 LED driver. One CCSI bus is used to transmit data using the CCSI bus protocol, while a second tile is used to receive data from the CCSI bus. The C28x CPU communicates with the CLB logic through a hardware-abstraction layer (HAL). This example also utilizes a PWM to generate the required CCSI clocks, and a timer to generate periodic sync events to the LED driver.

This example is only available on C2000 MCU devices with CLB types 2 and up.

30.9 CLB Registers

This section describes the CLB Registers.

30.9.1 CLB Base Address Table

Table 30-18. CLB Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
Clb1LogicCfgRegs	CLB_LOGIC_CONFIG_REGS	CLB1_LOGICCFG_BASE	0x0000_3000	YES	-	YES	YES
Clb1LogicCtrlRegs	CLB_LOGIC_CONTROL_REGS	CLB1_LOGICCTRL_BASE	0x0000_3100	YES	-	YES	YES
Clb1DataExchRegs	CLB_DATA_EXCHANGE_REGS	CLB1_DATAEXCH_BASE	0x0000_3180	YES	-	YES	YES
Clb2LogicCfgRegs	CLB_LOGIC_CONFIG_REGS	CLB2_LOGICCFG_BASE	0x0000_3400	YES	-	YES	YES
Clb2LogicCtrlRegs	CLB_LOGIC_CONTROL_REGS	CLB2_LOGICCTRL_BASE	0x0000_3500	YES	-	YES	YES
Clb2DataExchRegs	CLB_DATA_EXCHANGE_REGS	CLB2_DATAEXCH_BASE	0x0000_3580	YES	-	YES	YES

30.9.2 CLB_LOGIC_CONFIG_REGS Registers

Table 30-19 lists the memory-mapped registers for the CLB_LOGIC_CONFIG_REGS registers. All register offset addresses not listed in Table 30-19 should be considered as reserved locations and the register contents should not be modified.

Table 30-19. CLB_LOGIC_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
2h	CLB_COUNT_RESET	Counter Block RESET	EALLOW, LOCK	Go
4h	CLB_COUNT_MODE_1	Counter Block MODE_1	EALLOW, LOCK	Go
6h	CLB_COUNT_MODE_0	Counter Block MODE_0	EALLOW, LOCK	Go
8h	CLB_COUNT_EVENT	Counter Block EVENT	EALLOW, LOCK	Go
Ah	CLB_FSM_EXTRA_IN0	FSM Extra EXT_IN0	EALLOW, LOCK	Go
Ch	CLB_FSM_EXTERNAL_IN0	FSM EXT_IN0	EALLOW, LOCK	Go
Eh	CLB_FSM_EXTERNAL_IN1	FSM_EXT_IN1	EALLOW, LOCK	Go
10h	CLB_FSM_EXTRA_IN1	FSM Extra_EXT_IN1	EALLOW, LOCK	Go
12h	CLB_LUT4_IN0	LUT4_0/1/2 IN0 input source	EALLOW, LOCK	Go
14h	CLB_LUT4_IN1	LUT4_0/1/2 IN1 input source	EALLOW, LOCK	Go
16h	CLB_LUT4_IN2	LUT4_0/1/2 IN2 input source	EALLOW, LOCK	Go
18h	CLB_LUT4_IN3	LUT4_0/1/2 IN3 input source	EALLOW, LOCK	Go
1Ch	CLB_FSM_LUT_FN1_0	LUT function for FSM Unit 1 and Unit 0	EALLOW, LOCK	Go
1Eh	CLB_FSM_LUT_FN2	LUT function for FSM Unit 2	EALLOW, LOCK	Go
20h	CLB_LUT4_FN1_0	LUT function for LUT4 block of Unit 1 and 0	EALLOW, LOCK	Go
22h	CLB_LUT4_FN2	LUT function for LUT4 block of Unit 2	EALLOW, LOCK	Go
24h	CLB_FSM_NEXT_STATE_0	FSM Next state equations for Unit 0	EALLOW, LOCK	Go
26h	CLB_FSM_NEXT_STATE_1	FSM Next state equations for Unit 1	EALLOW, LOCK	Go
28h	CLB_FSM_NEXT_STATE_2	FSM Next state equations for Unit 2	EALLOW, LOCK	Go
2Ah	CLB_MISC_CONTROL	Static controls for Ctr,FSM	EALLOW, LOCK	Go
2Ch	CLB_OUTPUT_LUT_0	Inp Sel, LUT fns for Out0	EALLOW, LOCK	Go
2Eh	CLB_OUTPUT_LUT_1	Inp Sel, LUT fns for Out1	EALLOW, LOCK	Go
30h	CLB_OUTPUT_LUT_2	Inp Sel, LUT fns for Out2	EALLOW, LOCK	Go
32h	CLB_OUTPUT_LUT_3	Inp Sel, LUT fns for Out3	EALLOW, LOCK	Go
34h	CLB_OUTPUT_LUT_4	Inp Sel, LUT fns for Out4	EALLOW, LOCK	Go
36h	CLB_OUTPUT_LUT_5	Inp Sel, LUT fns for Out5	EALLOW, LOCK	Go
38h	CLB_OUTPUT_LUT_6	Inp Sel, LUT fns for Out6	EALLOW, LOCK	Go
3Ah	CLB_OUTPUT_LUT_7	Inp Sel, LUT fns for Out7	EALLOW, LOCK	Go
3Ch	CLB_HLC_EVENT_SEL	Event Selector register for the High Level controller	EALLOW, LOCK	Go
3Eh	CLB_COUNT_MATCH_TAP_SEL	Counter tap values for match1 and match2 outputs	EALLOW, LOCK	Go
40h	CLB_OUTPUT_COND_CTRL_0	Output conditioning control for output 0	EALLOW, LOCK	Go
42h	CLB_OUTPUT_COND_CTRL_1	Output conditioning control for output 1	EALLOW, LOCK	Go
44h	CLB_OUTPUT_COND_CTRL_2	Output conditioning control for output 2	EALLOW, LOCK	Go
46h	CLB_OUTPUT_COND_CTRL_3	Output conditioning control for output 3	EALLOW, LOCK	Go
48h	CLB_OUTPUT_COND_CTRL_4	Output conditioning control for output 4	EALLOW, LOCK	Go
4Ah	CLB_OUTPUT_COND_CTRL_5	Output conditioning control for output 5	EALLOW, LOCK	Go
4Ch	CLB_OUTPUT_COND_CTRL_6	Output conditioning control for output 6	EALLOW, LOCK	Go
4Eh	CLB_OUTPUT_COND_CTRL_7	Output conditioning control for output 7	EALLOW, LOCK	Go
50h	CLB_MISC_ACCESS_CTRL	Miscellaneous Access and enable control	EALLOW, LOCK	Go

Table 30-19. CLB_LOGIC_CONFIG_REGS Registers (continued)

Offset	Acronym	Register Name	Write Protection	Section
51h	CLB_SPI_DATA_CTRL_HI	CLB to SPI buffer control High	EALLOW, LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 30-20 shows the codes that are used for access types in this section.

Table 30-20. CLB_LOGIC_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

30.9.2.1 CLB_COUNT_RESET Register (Offset = 2h) [Reset = 00000000h]

CLB_COUNT_RESET is shown in Figure 30-22 and described in Table 30-21.

Return to the Summary Table.

Counter Block RESET

Figure 30-22. CLB_COUNT_RESET Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3Ch	CLB_DBG_C2	Count of Unit 2		Go
3Eh	CLB_DBG_OUT	Outputs of various units in the Cell		Go

Complex bit access types are encoded to fit into small table cells. Table 30-62 shows the codes that are used for access types in this section.

Table 30-62. CLB_LOGIC_CONTROL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		

Table 30-62. CLB_LOGIC_CONTROL_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

30.9.3.1 CLB_LOAD_EN Register (Offset = 0h) [Reset = 0000h]

CLB_LOAD_EN is shown in Figure 30-62 and described in Table 30-63.

Return to the Summary Table.

Global enable & indirect load enable control, only Global Enable Bit is LOCK protected

RESERVED			PIPELINE_EN	NMI_EN	STOP	GLOBAL_EN	LOAD_EN
R-0-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 30-63. CLB_LOAD_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R-0	0h	Reserved
4	PIPELINE_EN	R/W	0h	This bit controls pipelining of all the CLB operations in HLC and Counter blocks. Pipelined operation is enabled when this bit is set to 1. Reset type: SYSRSn
3	NMI_EN	R/W	0h	This bit controls the generation of NMI along with the interrupt whenever a INTR operation is executed by the HLC. NMI generation is disabled by default. It will be enabled when this bit is set to 1. Reset type: SYSRSn
2	STOP	R/W	0h	This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored. Reset type: SYSRSn
1	GLOBAL_EN	R/W	0h	This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected. Reset type: SYSRSn
0	LOAD_EN	R/W	0h	A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL. Reset type: SYSRSn

30.9.3.2 CLB_LOAD_ADDR Register (Offset = 2h) [Reset = 00000000h]

CLB_LOAD_ADDR is shown in Figure 30-63 and described in Table 30-64.

Return to the Summary Table.

R-0-0h		R/W-0h				R/W-0h	R/W-0h

Table 30-75. CLB_PRESCALE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PRESCALE	R/W	0h	16-bit Value of prescaler to be used for the counter as reference to reset when reaching this value. The counter is a simple incrementing counter which will count up to the reference value and reset to 0 and this cycle will continue as long as the counter is enabled. This 16-bit register value is used as a reference for the 16-bit counter to reset to zero whenever count reaches this value. Reset type: SYSRSn
15-6	RESERVED	R-0	0h	Reserved
5-2	TAP	R/W	0h	TAP Select value. These 4 bits will be used as a select to tap one of the 16 register bit position of the counter as the output. 0000 selects Counter Bit position 0 0001 selects Counter Bit position 1 .... 1111 selects Counter Bit position 15 Reset type: SYSRSn
1	STRB	R/W	0h	When set to 0, a strobe output will be sent out whenever the counter value matches the PRESCALE_VALUE. When set to 1, the output of the counter register bit position as selected by TAP_SELECT_VALUE will be sent out. Reset type: SYSRSn
0	CLKEN	R/W	0h	Enable the prescale clock/strobe generator. A 16-bit counter is used to either generate a strobe or send out a selected counter bit position to the CLB CELL. This is meant to be a general purpose strobe/prescaled clock which can be used by the CELL logic if needed. This will be sent to the CELL through one of the LCL_IN MUX ports. Reset type: SYSRSn

30.9.3.14 CLB_INTR_TAG_REG Register (Offset = 20h) [Reset = 0000h]

CLB_INTR_TAG_REG is shown in Figure 30-75 and described in Table 30-76.

Chapter 31

Advanced Encryption Standard (AES) Accelerator

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

31.1 Introduction

This section introduces the Advanced Encryption Standard (AES), and describes the AES main functions and connections in the device.

The AES module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-, 192-, or 256-bit key in hardware for encryption and decryption. The AES module is based on a symmetric algorithm, which means that the encryption and decryption keys are identical. To encrypt data means to convert the data from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data to the original plain text form. The main features of the AES accelerator are:

AES encrypt and decrypt operations are supported by:

- Galois/Counter mode (GCM), with basic GHASH operation
- Counter mode with CBC-MAC (CCM)
- XTS mode

The following feedback operating modes are available:

- Electronic code book mode (ECB)
- Cipher block chaining mode (CBC)
- Counter mode (CTR)
- Cipher feedback mode (CFB), 128-bit
- F8 mode
- Key sizes: 128, 192, and 256 bits
- Support for CBC_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for µDMA transfers
- Fully synchronous design

31.1.1 AES Block Diagram

Figure 31-1 shows the AES block diagram. A single-core or dual-interface architecture is used.

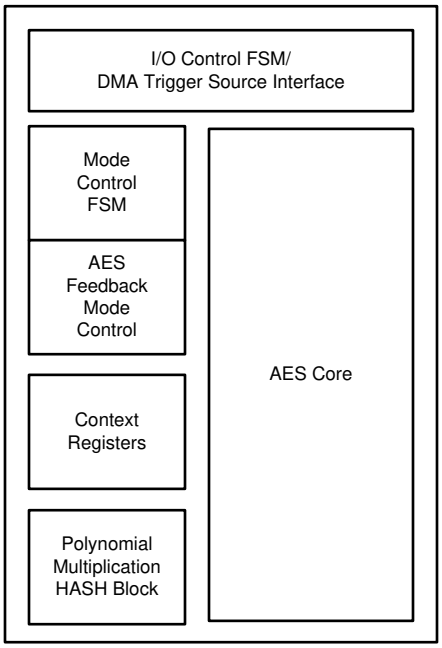

Figure 31-1. AES Block Diagram

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, according to the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: {0 120}||10000111. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers, so that the AES engine can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O control FSM/µDMA request interface.

AES comprises the following major functional blocks:

- Global control FSM and µDMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption or decryption operation
- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2^8) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32-, 38-, and 44-clock cycles, respectively, because {number of clock cycles} = 2 + 3 × {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds, and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one ECB core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128, 192, or 256 bits), this core requires 32-, 38-, or 44-clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, when the pipeline is full, sequential data blocks can be passed every 32-, 38-, or 44-clock cycles.

31.1.1.1 Interfaces

The interface signals to the AES module can be grouped into the following categories:

- Clock enable
- DMA and interrupt interface, used to request new context and packet data or to indicate available result data (encrypted or decrypted data, or authentication result)
- Functional register interface

31.1.1.2 AES Subsystem

The AES subsystem interfaces with the DMA module as shown in Table 31-1. Input/output context and data ports from the AES directly feed to the DMA trigger source. Two interrupt registers are included, AES_GLB_INT_FLG and AES_GLB_INT_CLR. AES_GLB_INT_FLG, that provide the status of the secure interrupt generated by the AES while AES_GLB_INT_CLR clears the flag. AES only allows word access. Non-word access (not 32-bit access) generates an interrupt and is aggregated in SYS_ERR.

Table 31-1. AES Subsystem DMA Interface

Request	DMA Trigger Source
Context Output	AES_ContextIn
Context Input	AES_ContextOut
Data Output	AES_DataOut
Data Input	AES_DataIn

31.1.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core follows:

AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated arbitrarily and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so the AES can generate the subkeys in reverse order.

AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the NIST-SP800-38A specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with *m* set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly j, but α^j, where $\alpha = x^2$ in the GF(2^{128}) domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve designed performance.

31.1.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES keys can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits. The block length is represented by Nb = 4, which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by Nk = 4, 6, or 8, which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm depends on the key size. The number of rounds is represented by Nr, where Nr = 10 when Nk = 4 (128-bit key); Nr = 12 when Nk = 6 (192-bit key); and Nr = 14 when Nk = 8 (256-bit key).

Table 31-2 lists the combinations of keys, blocks, and rounds.

Table 31-2. Key-Block-Round Combinations

Key	Key Length (Nk)	Block Size (Nb)	Number of Rounds (Nr)
128 bits	4	4	10
192 bits	6	4	12
256 bits	8	4	14

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box): This transformation is a nonlinear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of [4 × Nk] bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets: In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ® = 0) is not shifted.
- Mixing the data within each column of the state array: This transformation operates on the state column-by-column, treating each column as a 4-term polynomial. The columns are considered polynomials over GF(2^8) and multiplied modulo $x^4 + 1$ with a fixed polynomial a(x).
- Adding a round key to the state: In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of Nb words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of Nb × (Nr + 1) words: The algorithm requires an initial set of Nb words, and each Nr round requires Nb words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted [w_I], with I in the range $0 \le I \le Nb \times (Nr + 1)$.

31.2 AES Operating Modes

31.2.1 GCM Operation

Figure 31-2 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see Section 31.3.1.

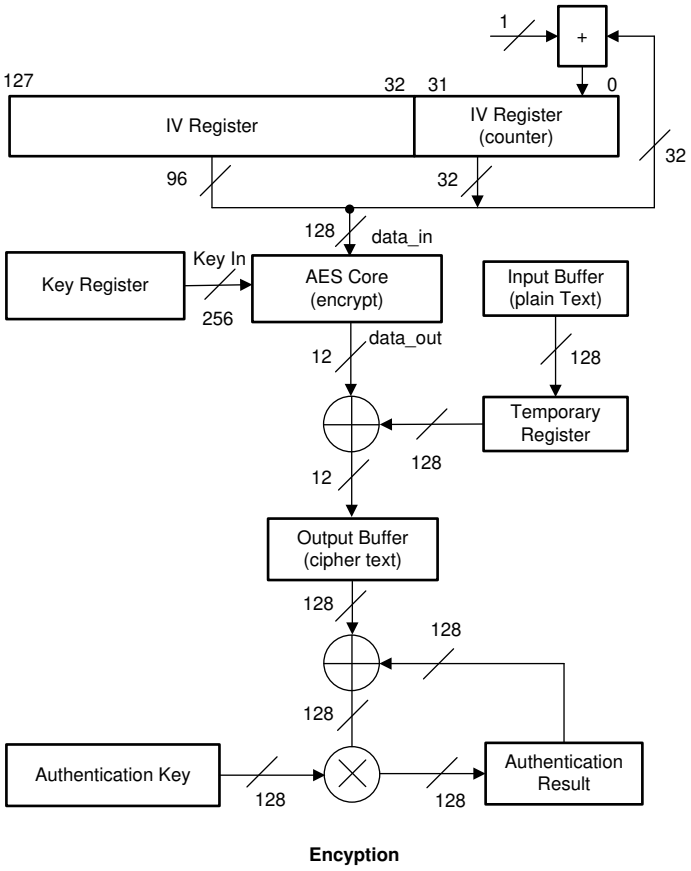

Figure 31-2. AES - GCM Operation

31.2.2 CCM Operation

Figure 31-3 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

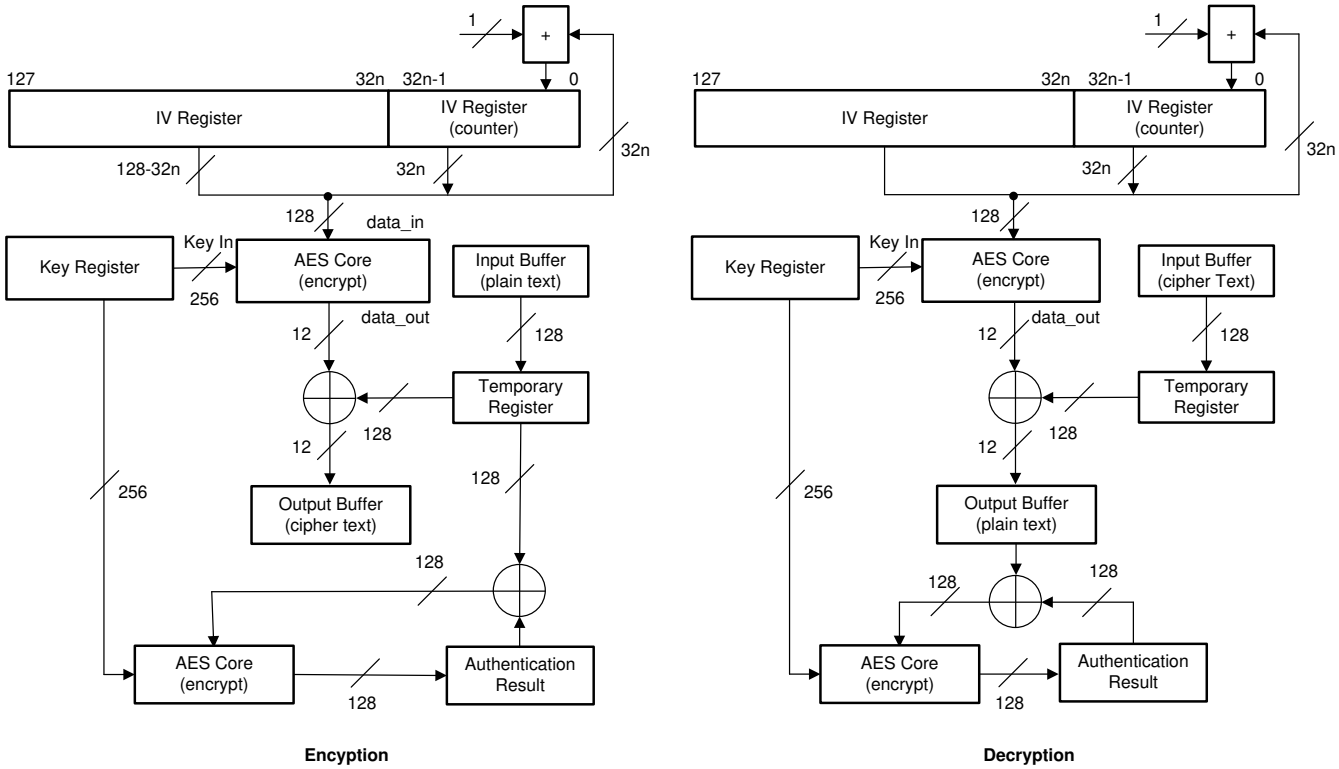

Figure 31-3. AES - CCM Operation

31.2.3 XTS Operation

Figure 31-4 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

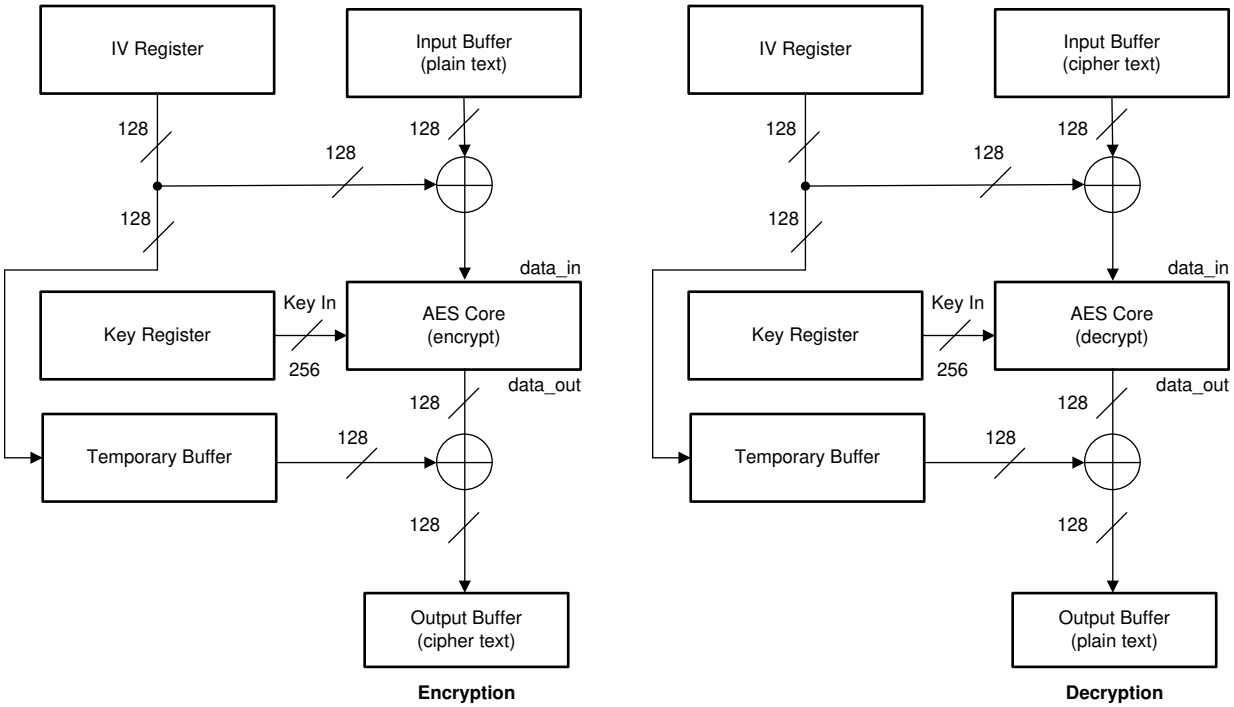

Figure 31-4. AES - XTS Operation

Note

The IV is created with an initial encryption, followed by an LFSR operation for each new block.

31.2.4 ECB Feedback Mode

Figure 31-5 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer. For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

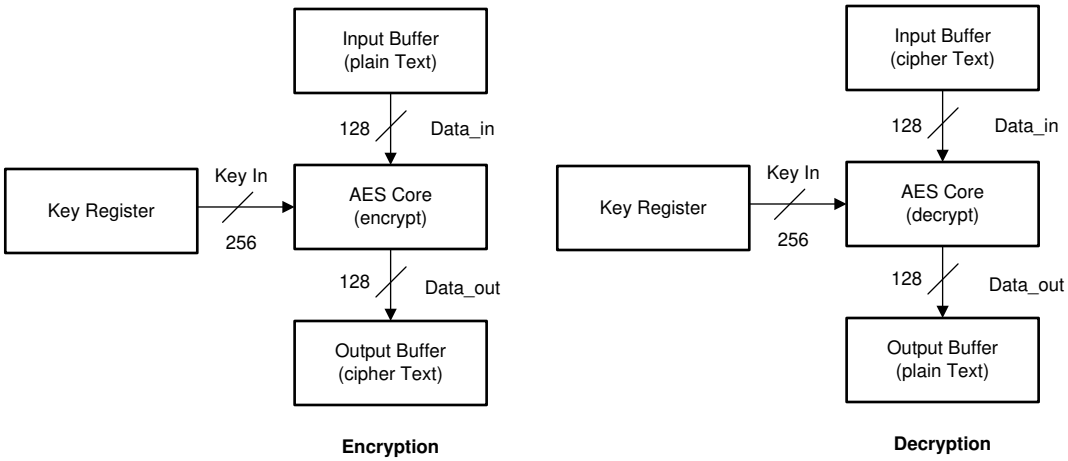

Figure 31-5. AES - ECB Feedback Mode

31.2.5 CBC Feedback Mode

Figure 31-6 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

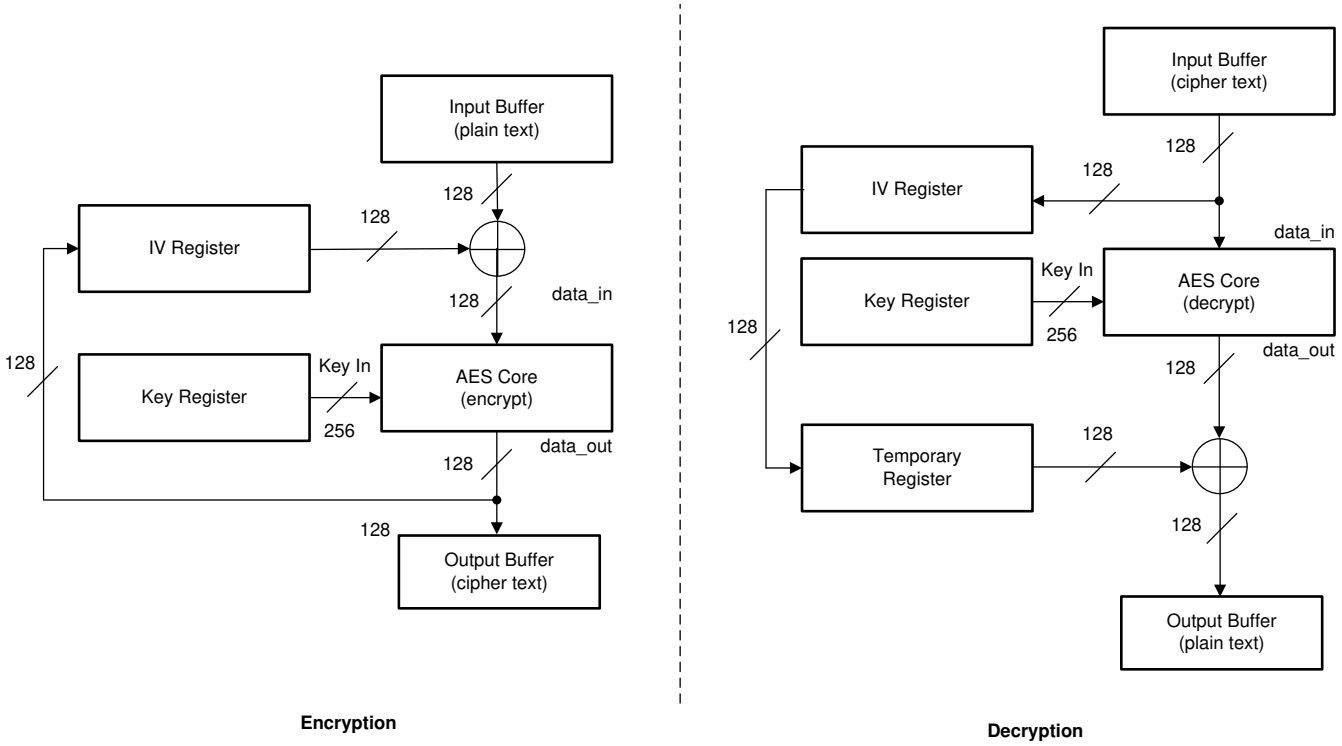

Figure 31-6. AES - CBC Feedback Mode

31.2.6 CTR and ICM Feedback Modes

Figure 31-7 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

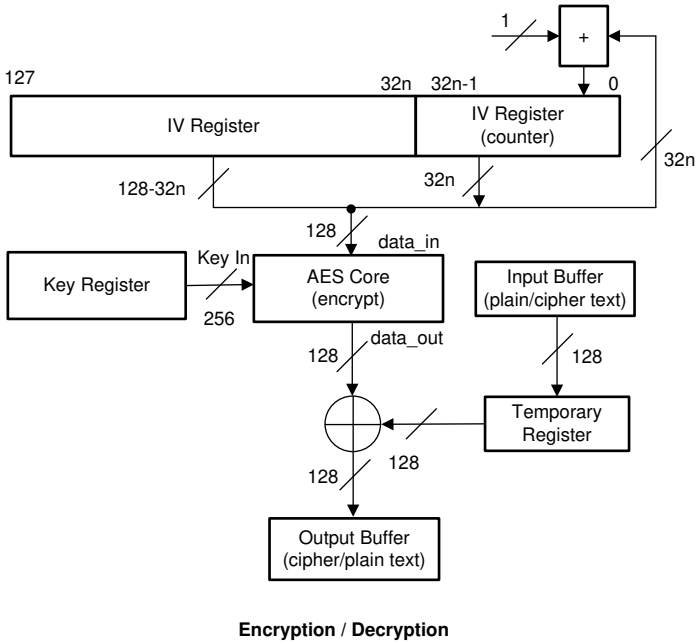

Figure 31-7. AES Encryption With CTR/ICM Mode

Note

The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

31.2.7 CFB Mode

Figure 31-8 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

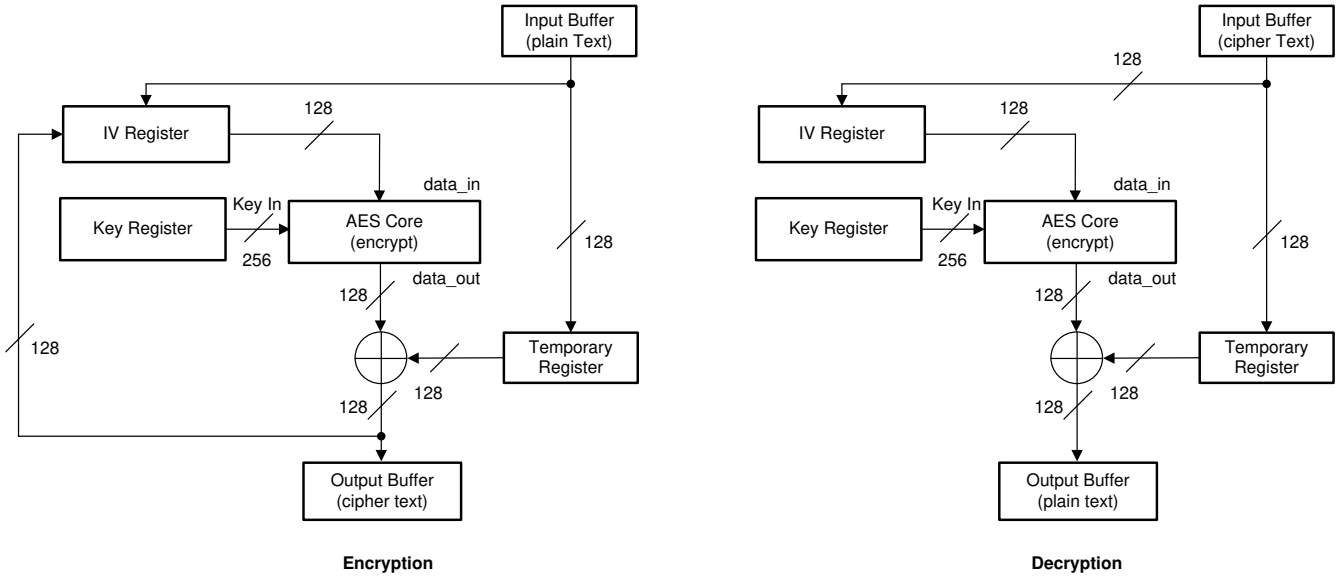

Figure 31-8. AES - CFB Feedback Mode

31.2.8 F8 Mode

Figure 31-9 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

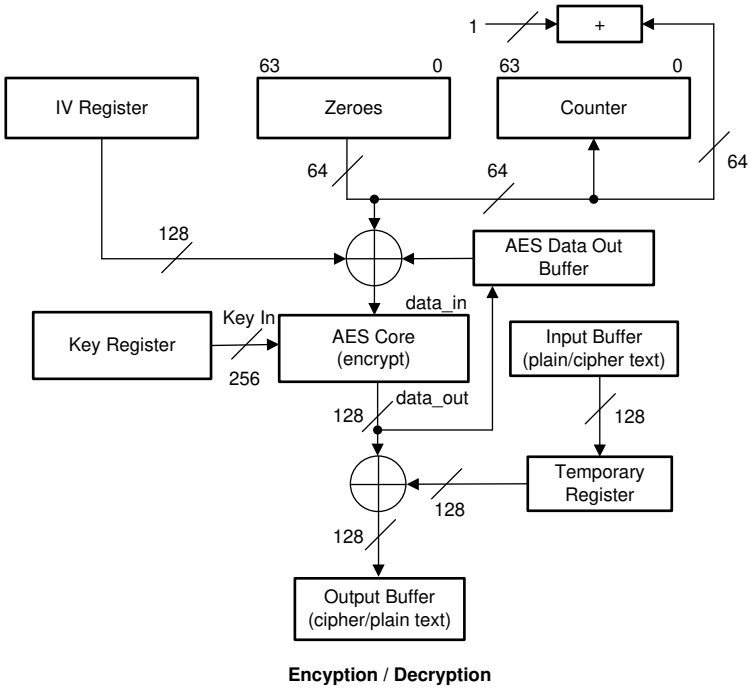

Figure 31-9. AES - F8 Mode

31.2.9 F9 Operation

Figure 31-10 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

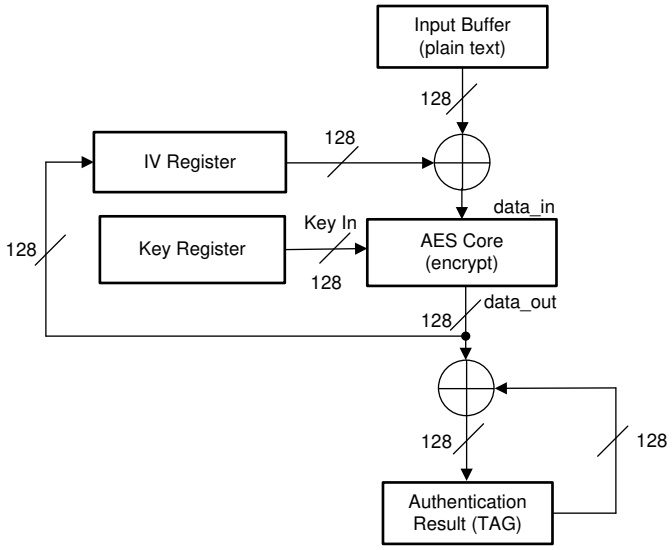

Figure 31-10. AES - F9 Operation

31.2.10 CBC-MAC Operation

Figure 31-11 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

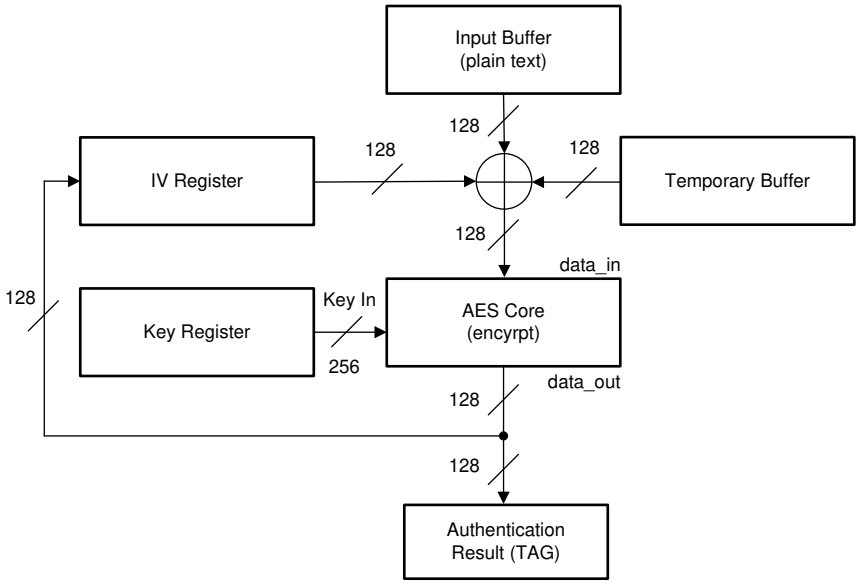

Figure 31-11. AES - CBC-MAC Authentication Mode

31.3 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

31.3.1 GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted or decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption, decryption, and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit-long vector and finally encrypt the authentication result.

31.3.2 CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. The authentication and encryption or decryption operations use the cryptographic core; these operations are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption or decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

31.3.3 Hardware Requests

The AES module can assert a DMA request for context in, context out, input data, or output data read. The AES DMA Interrupt Mask (AES_DMAIM) register can be set to generate interrupts during the following events:

- Context In DMA request (Cin)
- Context Out DMA request (Cout)
- Data In DMA request (Din)
- Data Out DMA request (Dout)

The AES module can be programmed to assert an interrupt when the DMA has completed the last transfer.

If context and data transfers are to be handled through software, then the AES Interrupt Enable (AES_IRQENABLE) register can be used to enable interrupt triggering when context out, context in, data in, or data out is ready. The AES Interrupt Status (AES_IRQSTATUS) register indicates when an interrupt is triggered, as listed in Table 31-3.

Table 31-3. Interrupts and Events

Event	Description
AES_IRQSTATUS[3]: CONTEXT_OUT	Context output interrupt
AES_IRQSTATUS[2]: DATA_OUT	Data output interrupt
AES_IRQSTATUS[1]: DATA_IN	Data input interrupt
AES_IRQSTATUS[0]: CONTEXT_IN	Context input interrupt

31.4 AES Module Programming Guide

31.4.1 AES Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES module.

31.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and associated modules.

1. Configure the DMA Trigger Source corresponding to AES. For more information, refer to the *Direct Memory Access (DMA)* chapter.
2. Specify the size of the keys by programming the KEY_SIZE bit field in the AES_CTRL register.
3. Load the AES Key 1 (AES_KEY1_n) register.
4. Load the AES Key 2 (AES_KEY2_n) register if it is used by the configuration mode.
5. Configure the AES for the appropriate encryption or decryption mode (see Section 31.4.1.2).
6. Select encryption or decryption by programming the DIRECTION bit in the AES Control (AES_CTRL) register.

31.4.1.2 AES Operating Modes Configuration

The following sections list the initialization subsequences for the available encryption and decryption modes:

Subsequence: Initialize CCM AES Core Mode

The steps to initialize CCM mode follow:

1. Define the width of the length field and the length of the authentication field by programming the CCM_L and CCM_M bit fields in the AES_CTRL register.
2. Enable counter mode by setting the CTR bit in the AES_CTRL register.
3. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES_AUTH_LENGTH) register.
4. Select the IV counter by programming the CTR_WIDTH field in the AES_CTRL register.
5. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize GCM AES Core Mode

The steps to enable GCM mode follow:

1. Enable counter mode by setting the CTR bit in the AES_CTRL register.
2. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES_AUTH_LENGTH) register.
3. Select the IV counter by programming the CTR_WIDTH field in the AES_CTRL register.
4. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CBC-MAC AES Core Mode

The steps to initialize CBC-MAC mode follow:

1. Enable CBC-MAC mode by setting the CBCMAC bit in the AES_CTRL register.
2. Select encryption mode by setting the DIRECTION bit in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize F9 AES Core Mode

The steps to configure the AES for F9 mode follow:

1. Enable F9 mode by setting the F9 bit in the AES_CTRL register.
2. Set the key size to 128 bits by programming the KEY_SIZE field to 0x1 in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize F8 AES Core Mode

The steps to configure the AES for F8 mode follow:

1. Enable F8 mode by setting the F8 bit in the AES_CTRL register.
2. Select the counter width by programming the CTR_WIDTH field in the AES_CTRL register.
3. Set the key size to 128 bits by setting the KEY_SIZE field to 0x1 in the AES_CTRL register.
4. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize XTS AES Core Mode

The steps to configure XTS mode follow:

1. Enable XTS mode by configuring the XTS field in the AES_CTRL register.
2. If the XTS field in the AES_CTRL register indicates that the AAD length is required, load the AAD length in the AES_AUTH_LENGTH register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CFB AES Core Mode

The steps to initialize the AES code for CFB mode follow:

1. Enable CFB mode by setting the CFB bit in the AES_CTRL register.
2. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize ICM AES Core Mode

The steps to initialize the AES code for ICM mode follow:

1. Enable ICM mode by setting the ICM bit in the AES_CTRL register.
2. Configure for a 16-bit counter by programming the CTR_WIDTH field to 0x0 in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CTR AES Core Mode

The steps to initialize CTR mode follow:

1. Enable CTR mode by setting the CTR bit in the AES_CTRL register.
2. Select counter width by programming the CTR_WIDTH in the AES_CTRL register.
3. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

Subsequence: Initialize CBC AES Core Mode

The steps to configure CBC mode follow:

1. Enable CBC mode by setting the MODE bit in the AES_CTRL register.
2. Load the AES Initialization Vector Input n (AES_IV_IN_n) registers.

31.4.1.3 AES Mode Configurations

AES Polling Mode

Main Sequence: AES Polling Mode – Figure 31-12 shows AES polling mode. The registers used in AES polling mode follow:

- AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_OUT_0) registers
- AES Control (AES_CTRL) register
- AES Hash Tag Out 0 (AES_TAG_OUT_0) register

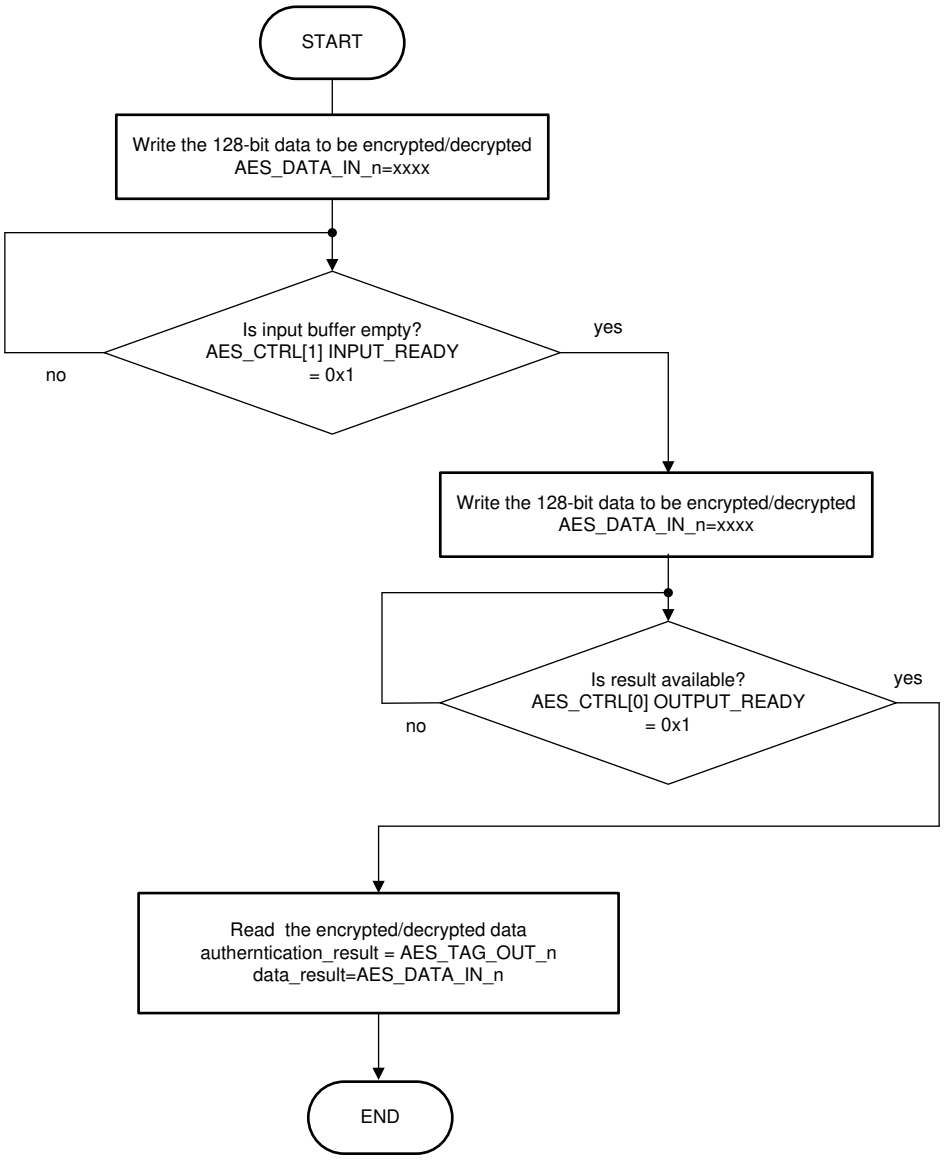

Figure 31-12. AES Polling Mode

AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts

1. First, initialize the device by following the initialization sequences described in Section 31.4.1.1 and Section 31.4.1.2.
2. When the device has been initialized, the application can enable the AES module interrupts through the AES Interrupt Enable (AES_IRQENABLE) register.
3. Load the input buffers, AES_DATA_IN_OUT_n, with data.

Note

If the application uses interrupt mode, an interrupt is generated for each block of processed data. To support larger data flow, DMA access mode must be used and the bits in the AES_IRQENABLE register must be cleared.

AES DMA Mode

When AES DMA mode is enabled, the AES_IRQENABLE register must be cleared. To enable the DMA to transfer data, follow these steps:

1. When the AES module is initialized, configure DMA sources and channels. Refer to the *Direct Memory Access (DMA)* chapter for the associated AES sources.
2. Configure the corresponding DMA enable and request bits in the AES System Configuration (AES_SYSCONFIG) register.

The input buffer registers, AES_DATA_IN_OUT_n, are now loaded.

31.4.1.4 AES Events Servicing

Interrupt Servicing

This section describes the event servicing of the module. Figure 31-13 shows the AES interrupt service. The registers used during event servicing follow:

- AES_IRQSTATUS
- AES_KEY1_n
- AES_KEY2_n
- AES_IV_IN_n
- AES_DATA_IN_OUT_n
- AES_TAG_OUT_n
- AES_IRQENABLE

31.5.3 AES Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/aes

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

31.5.3.1 AES ECB Encryption Example

FILE: aes_ex1_ecb_encrypt.c

This example encrypts block cipher-text using AES128 in ECB mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections

- None

Watch Variables

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.2 AES ECB De-cryption Example

FILE: aes_ex2_ecb_decrypt.c

This example de-crypts block cipher-text using AES128 in ECB mode. It does the de-cryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.3 AES GCM Encryption Example

FILE: aes_ex3_gcm_encrypt.c

This example encrypts block cipher-text using AES128 in GCM mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.4 AES GCM Decryption Example

FILE: aes_ex4_gcm_decrypt.c

This example decrypts block cipher-text using AES128 in GCM mode. It does the decryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.5 AES CBC Encryption Example

FILE: aes_ex5_cbc_encrypt.c

This example encrypts block cipher-text using AES128 in CBC mode. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections
- None

Watch Variables
- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.6 AES CBC De-cryption Example

FILE: aes_ex6_cbc_decrypt.c

This example de-crypts block cipher-text using AES128 in CBC mode. It does the de-cryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections

- None

Watch Variables

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.5.3.7 AES CMAC Authentication Example

FILE: aes_ex7_cmac_auth.c

This example encrypts block cipher-text using AES128 and AES256 in CMAC mode and authenticates the result. It does the encryption first without uDMA and then with uDMA. The results are checked after each operation.

External Connections

- None

Watch Variables

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

31.6 AES Registers

This Section describes the AES Registers.

31.6.1 AES Base Address Table

Table 31-6. AES Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
AesaRegs	AES_REGS	AESA_BASE	0x0004_2000	YES	YES	-	YES
AesaSsRegs	AES_SS_REGS	AESA_SS_BASE	0x0004_2C00	YES	YES	-	YES

31.6.2 AES_REGS Registers

Table 31-7 lists the memory-mapped registers for the AES_REGS registers. All register offset addresses not listed in Table 31-7 should be considered as reserved locations and the register contents should not be modified.

Table 31-7. AES_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	AES_KEY2_6	XTS Second Key or CBC-MAC Third Key		Go
4h	AES_KEY2_7	XTS Second Key or CBC-MAC Third Key		Go
8h	AES_KEY2_4	XTS/CCM Second Key or CBC-MAC Third Key		Go
Ch	AES_KEY2_5	XTS Second Key or CBC-MAC Third Key		Go

8Ch	AES_IRQSTATUS	Interrupt Status		Go
90h	AES_IRQENABLE	Interrupt Enable		Go
94h	AES_DIRTY_BITS	Accessed / Dirty Bits		Go

Complex bit access types are encoded to fit into small table cells. Table 31-8 shows the codes that are used for access types in this section.

Table 31-8. AES_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

31.6.2.1 AES_KEY2_6 Register (Offset = 0h) [Reset = 00000000h]

AES_KEY2_6 is shown in Figure 31-14 and described in Table 31-9.

Return to the Summary Table.

Table 31-16. AES_KEY2_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	KEY	R-0/W	0h	Key Data This register contains the 32-bit key data for the AES module. Initial key for XTS operations For a Host write operation, these registers must be written with the 128, 192 or 256-bit key for a subsequent AES operation. The key size equals the AES_KEY1 size. For a Host write operation, these registers must be written with the new values to be subsequently transferred to the AES Engine. OR Pre-calculated CBC-MAC second key (K2), used to perform a final XOR operation on the last input data block. OR Hash key, can be calculated internal or written via these registers. Only used for GHASH (GCM) modes. For a Host write operation, these registers must be written with the new values to be subsequently transferred to the AES Engine. OR These 128-bits are used to store the CKKM / IKKM value for f8 OR These 128-bits are used to store the CKKM / IKKM value for f9 Reset type: PER.RESET

31.6.2.9 AES_KEY1_6 Register (Offset = 20h) [Reset = 00000000h]

AES_KEY1_6 is shown in Figure 31-22 and described in Table 31-17.

Return to the Summary Table.

Table 31-25. AES_IV_IN_OUT_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	0h	For a Host write operation, these registers must be written with the new 128-bit IV to be subsequently transferred to the AES Engine. For a Host read operation, these registers contain the latest 128-bit IV output by the AES Engine. This value is incremented with 0x1, after first use when a new data block is submitted to the engine if CTR/ICM mode is selected. OR For XTS mode, this register must be written with the tweak location i of the data unit or (intermediate) tweak value (Tj), For a Host read operation, the IV_OUT register holds the next tweak value that is used for the next data block provided via the DATA_IN registers. This value can be re-used for continuation with the next block. It must be provide together with a 'j' of '0' via the IV_IN registers. OR For f8 this field must be written with zeroes. OR (In case of GCM) For a Host write operation, these registers must be written with the new 128-bit IV to be subsequently transferred to the AES Engine. For a Host read operation, these registers contain the latest 128-bit IV output by the AES Engine. Note that bits [127:96] of the IV represent the initial counter value (which is '1' for GCM) and must therefore be initialized to 0x01000000. This value is incremented with 0x1, after first use when a new data block is submitted to the engine. OR For CCM this field must be written with A0, this value constist of the concatenation of: A0-flags (5-bits of zero and 3-bits 'L'), Nonce and counter value. 'L' must be a copy from the 'L' value of the AES_CTRL register. This 'L' indicates the width of the Nonce and counter. The loaded counter must be initialized to zero. The total width of A0 is 128-bit. Reset type: PER.RESET

LENGTH																															
R-0/W-0h																															

Table 31-30. AES_C_LENGTH_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LENGTH	R-0/W	0h	Bits [60:0] of the crypto length registers (LSW and MSW) store the cryptographic data length in bytes for all modes. Once processing with this context is started, this length decrements to zero. Data lengths up to (2^{61} - 1) bytes are allowed. For GCM, any value up to 2^{36} - 32 bytes can be used. This is because a 32-bit counter mode is used the maximum number of 128-bit blocks is 2^{32} - 2, resulting in a maximum number of bytes of 2^{36} - 32. A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data the authentication length is specified in the AES_AUTH_LENGTH register below. All modes must have a length > 0. For the combined modes, it is allowed to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is allowed to program zero to the length field in that case the length is assumed infinite. All data must be byte (8-bit) aligned for stream cipher modes bit aligned data streams are not supported by the AES Engine. For block cipher modes, the data length must be programmed in multiples of the block cipher size, 16 bytes. For a Host read operation, these registers return all-zeroes. Reset type: PER.RESET

31.6.2.23 AES_C_LENGTH_1 Register (Offset = 58h) [Reset = 00000000h]

AES_C_LENGTH_1 is shown in Figure 31-36 and described in Table 31-31.

Return to the Summary Table.

AUTH																															
R-0/W-0h																															

Table 31-32. AES_AUTH_LENGTH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	AUTH	R-0/W	0h	Bits [31:0] of the authentication length register store the authentication data length in bytes for combined modes only (GCM or CCM) Supported AAD-lengths for CCM are from 0 to (2^{16} - 2^{8}) bytes. For GCM any value up to (2^{32} - 1) bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS this register is optionally used to load 'j'. Loading of 'j' is only required if 'j' != 0. 'j' is a 28-bit value and must be written to bits [31-4] of this register. 'j' represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a 'j' for each new data block within a unit. Note that it is possible to start with a 'j' unequal to zero refer to Table 4 for more details. For a Host read operation, these registers return all-zeroes. Reset type: PER.RESET

31.6.2.25 AES_DATA_IN_OUT_0 Register (Offset = 60h) [Reset = 00000000h]

AES_DATA_IN_OUT_0 is shown in Figure 31-38 and described in Table 31-33.

2	RESERVED	R/W1S	0h	Reserved
1	S_DIRTY	R/W1S	0h	AES Dirty Bit This bit must be written to a 1 to clear. Value Description 0 No AES registers have been written. 1 Indicates when any of the AES_x registers have been written (except for the AES_DIRTYBITS register). Reset type: PER.RESET
0	S_ACCESS	R/W1S	0h	AES Access Bit This bit must be written to a 1 to clear. Value Description 0 No AES registers have been read. 1 Indicates when any of the AES_x registers have been read (except for the AES_DIRTYBITS register). Reset type: PER.RESET

31.6.3 AES_SS_REGS Registers

Table 31-47 lists the memory-mapped registers for the AES_SS_REGS registers. All register offset addresses not listed in Table 31-47 should be considered as reserved locations and the register contents should not be modified.

Table 31-47. AES_SS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
4h	AES_GLB_INT_FLG	AES Global Interrupt Flag Register		Go
8h	AES_GLB_INT_CLR	AES Global Interrupt Clear Register		Go

Complex bit access types are encoded to fit into small table cells. Table 31-48 shows the codes that are used for access types in this section.

Table 31-48. AES_SS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

31.6.3.1 AES_GLB_INT_FLG Register (Offset = 4h) [Reset = 00000000h]

AES_GLB_INT_FLG is shown in Figure 31-52 and described in Table 31-49.

Return to the Summary Table.

The AES_GLB_INT_FLG register contains the current status of the AES interrupt

Chapter 32

Embedded Pattern Generator (EPG)

This chapter describes the Embedded Pattern Generator (EPG) module.

32.1 Introduction

The Embedded Pattern Generator (EPG) module is a customizable pattern and clock generator that can serve many test and application scenarios that require a simple pattern generator or a periodic clock generator. The EPG module can also be used to capture an incoming serial stream of data.

32.1.1 Features

Features of the EPG module are:

- Clock generation:
  - Independent clock generation and clock division
  - Synchronous clock generation with programmable offsets
- Pattern generation:
  - Independent serial data stream generation
  - Serial data stream and the associated clock generation
  - Ability to skew clock with respect to serial data
  - Synchronous data stream with programmable offset with respect to one another
  - Can generate waveforms for loopback test of communication peripherals
  - Useful as diagnostics test if not already built-in

The EPG output signals are connected to GPIOs or other peripherals inside the device. The EPG inputs act as shift register inputs to capture incoming serial data streams. This allows the EPG to be configured as a custom serial module. The EPG is also capable of generating interrupts that are used to supply the pattern generators with new data or signal the completion of a generated pattern.

32.1.2 EPG Block Diagram

Figure 32-1 shows the EPG overview block diagram.

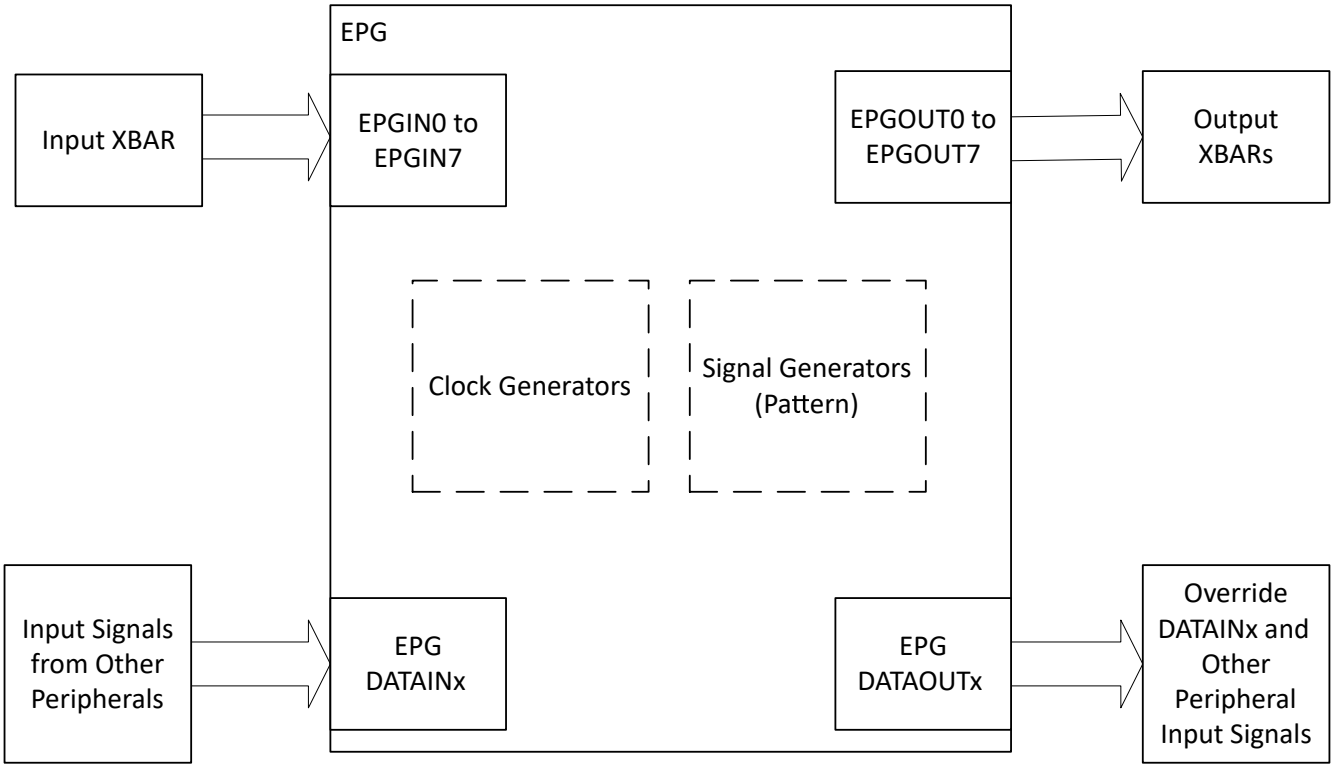

Figure 32-1. EPG Overview Block Diagram

Figure 32-2 shows the EPG block diagram.

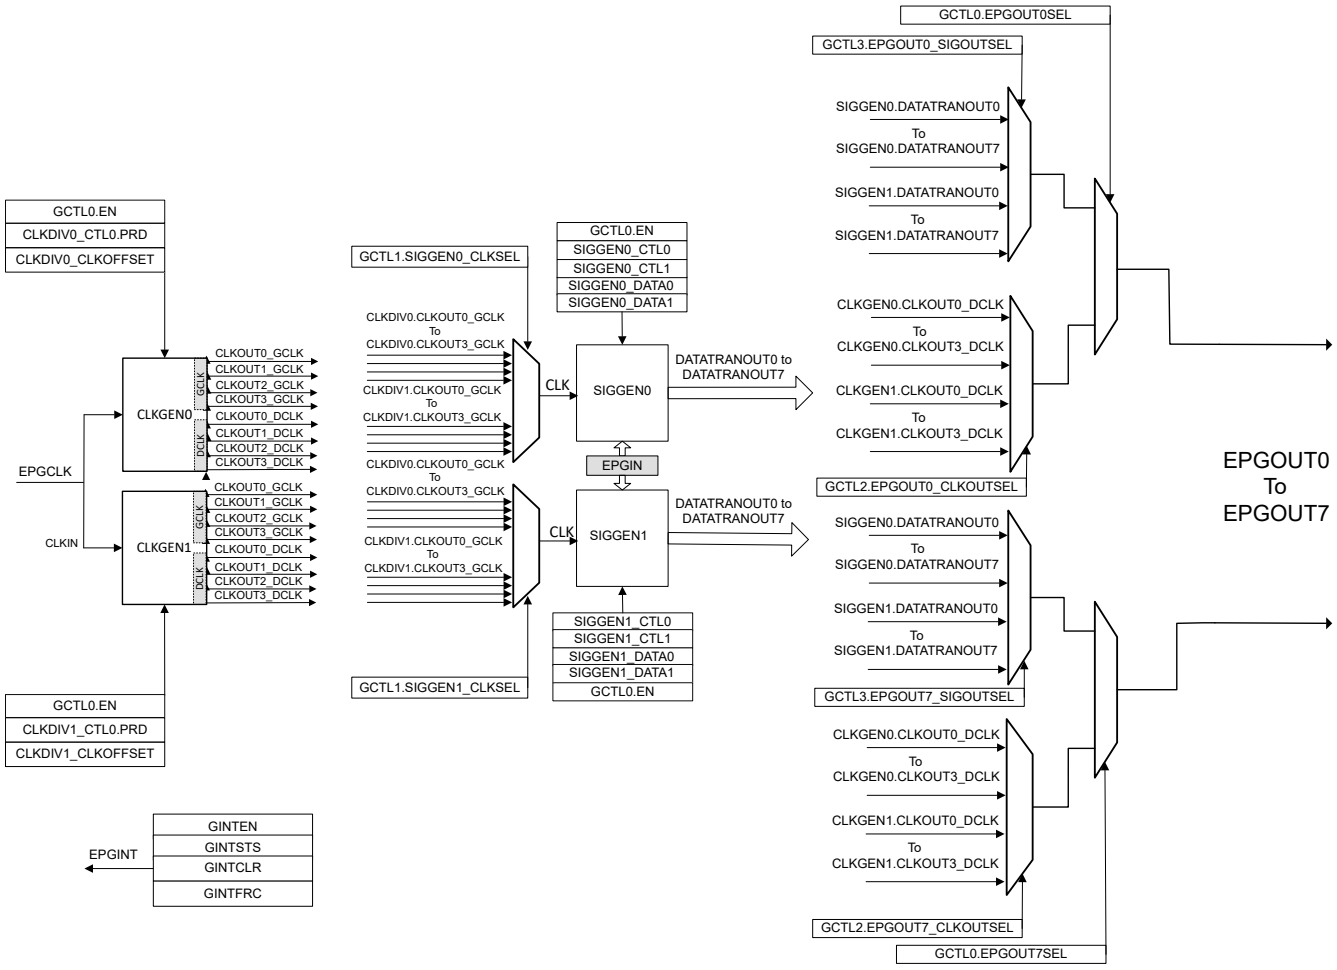

Figure 32-2. EPG Detailed Block Diagram

Note

The number of available EPGx SIGGEN modules for each device can be different. This diagram shows an EPG with 2 SIGGEN modules (SIGGEN0 and SIGGEN1). Refer to the EPG_REGS register description to see how many SIGGEN modules are available for a specific device.

The EPG input clock (EPGCLK) is sourced from PERx.SYSCLK.

32.2 Clock Generator Modules

The clock generator modules use the EPG input clock and generate four output clocks, see Figure 32-3. Each of the four output clocks (CLKOUT0 to CLKOUT3) has a DCLK and a GCLK version. The EPG clock division results in a gated, GCLK, version of the EPG input clock which are named CLKOUT0_GCLK to CLKOUT3_GCLK. The other version, DCLK (CLKOUT0_DCLK to CLKOUT3_DCLK), have the same period but with an approximately 50% duty cycle. The clock generation takes place using the divider settings CLKDIVx_CTL0.PRD, and clock offset settings CLKDIVx_CLK.CLKyOFFSET. The RUNCLOCK signal generated by the clock stop logic determines when the clock generation is started and stopped.

The clock divider counter is a simple up counter, which has a period determined by CLKDIVx_CTL0.PRD. This divider counter begins counting when RUNCLOCK is set. The CLKOUT0 to CLKOUT4 GCLKs are gated versions of the CLKIN (EPG input clock). The clock gates are enabled when the counter value matches the corresponding clock offsets. In the case where RUNCLOCK is cleared, the clock gates are disabled and the counter is set to zero.

Note

The CLKDIVx_CTL0.PRD register can only be written when GCTL0.EN is 0.

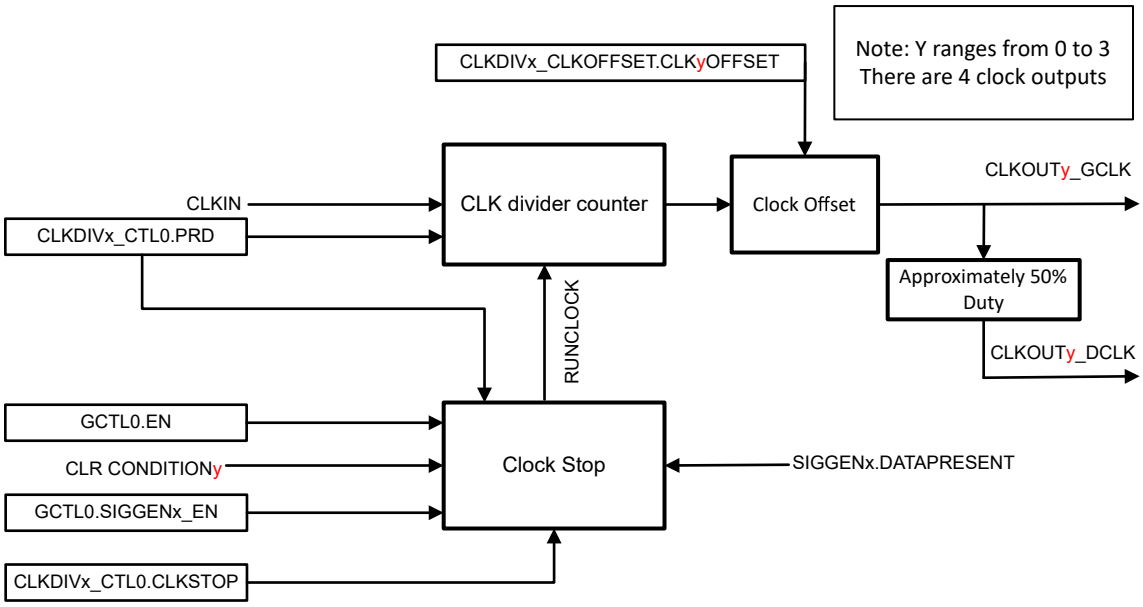

Figure 32-3. EPG Clock Generator

32.2.1 DCLK (50% duty cycle clock)

The CLKOUTy_DCLK is generated by setting the clock output for half the clock divider period. When CLKDIVx_CTL0.PRD is set to zero, CLKOUTy_DCLK is the same as the input clock.

32.2.2 Clock Stop

Figure 32-4 shows how the Clock Stop module sets and clears the RUNCLOCK signal.

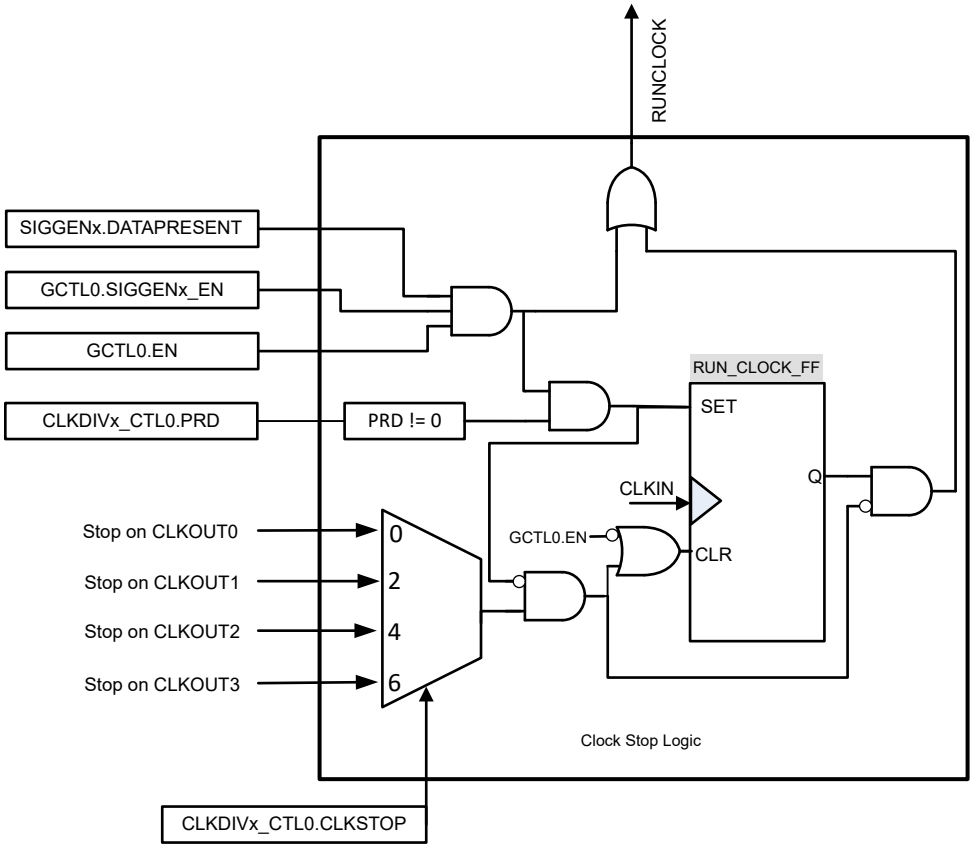

Figure 32-4. EPG Clock Stop

In signal generator modes, GCTL0.SIGGENx_EN bit is cleared when BIT_LENGTH shifts (or rotates) is completed. This makes sure that data is not shifted out. In addition, clock generation (generation of CLKOUT0 to CLKOUT3) also is stopped to make sure that sampling of input data does not continue after BIT_LENGTH shifts when GCTL0.SIGGENx_EN is cleared to 0.

The RUNCLOCK signal has to be high for the clock generation circuitry to be active. When GCTL0.SIGGENx_EN is cleared, the clock generation can be selected to stop on the falling edge of CLKOUT0 to CLKOUT3.

The clock stop module operates as follow:

- RUNCLOCK is asserted as soon as both GCTL0.SIGGENx_EN and GCTL0.EN are set.
- RUN_CLOCK_FF is set when both GCTL0.SIGGENx_EN and GCTL0.EN are set and CLKDIVx_CTL0.PRD is not zero.
- When GCTL0.SIGGENx_EN is cleared, RUN_CLOCK_FF is not cleared immediately. This makes sure that RUNCLOCK remains set and the clock generation circuitry remains enabled.
- When SIGGENx.DATA0 and SIGGENx.DATA1 are not filled with data before the next shift sequence (repeat shift modes) and signal generator is waiting for data to be written, clocks are stopped.
- The RUN_CLOCK_FF can be cleared on the falling edge of CLKOUT0 to CLKOUT3 based on the configuration of CLKSTOP field.
- Clearing GCTL0.EN clears RUN_CLOCK_FF unconditionally.

32.3 Signal Generator Module

The signal generator module is the main component of the EPG and generates the data stream that follows custom patterns. Figure 32-5 shows the main components. This module has 8 output ports DATATRANOUT0 to DATATRANOUT7. The two registers SIGGENx_DATA1 and SIGGENx_DATA0 constitute a 64-bit bus named DATA[63:0]. DATATRANIN[63:0], which is used for all the data transform operations, can be DATA[63:0] or bit reversed DATA (when SIGGENx_CTL0.BRIN bit is set). The DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0 to DATATRANIN7 when the signal generator is not in BIT_BANG mode. In BIT_BANG mode, DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0, DATATRANIN8, and DATATRANIN16 to DATATRANIN56.

In addition to generating data outputs, one of the 8 EPGIN inputs can act as data input to SIGGENx_DATAy registers. In Figure 32-5, the EPGIN_MUX block illustrates the mechanism used to capture the input data stream. This enables one to capture a data input stream using EPG module.

Data transformation is done on the DATATRANIN bus, and is determined by the configured mode (SIGGENx_CTL0.MODE), provided GCTL0.EN and GCTL0.SIGGENx_EN are both set. If either of these enable bits are 0, then the data output of the transform block is the same as the input. The transformed output is bit reversed when SIGGENx_CTL0.BROUT bit is set. Conditions under which the DATA active register (SIGGENx_DATA0_ACTIVE and SIGGENx_DATA1_ACTIVE) are:

- Loaded from SIGGENx_DATA1 and SIGGENx_DATA0
- Directly updated on a memory mapped write to SIGGENx_DATA1 and SIGGENx_DATA0
- Holds the current data

Table 32-1. SIGGENx Active Register Loading

Condition	SIGGENx_DATA1_ACTIVE DATA ACTIVE Register [63:32]	SIGGENx_DATA0_ACTIVE DATA ACTIVE Register [31:0]
Memory mapped write to SIGGENx_DATA0 register and GCTL0.SIGGENx_EN is 0	No updates	Updated with the value written to SIGGENx_DATA0 register
Memory mapped write to SIGGENx_DATA1 register and GCTL0.SIGGENx_EN is 0.	Updated with the value written to SIGGENx_DATA1 register	No updates
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Either SIGGENx_DATA0 or SIGGENx_DATA1 has been updated	Copy SIGGENx_DATA1 register content	Copy SIGGENx_DATA0 register content
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Both SIGGENx_DATA0 and SIGGENx_DATA1 have been updated	Copy SIGGENx_DATA1 register contents	Copy SIGGENx_DATA0 register contents
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has been updated	Hold the current value, no shifts	Hold the current value, no shifts
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has not been updated	Hold the current value, no shifts	Hold the current value, no shifts
All other conditions	Updates based on current mode of operation	Updates based on current mode of operation

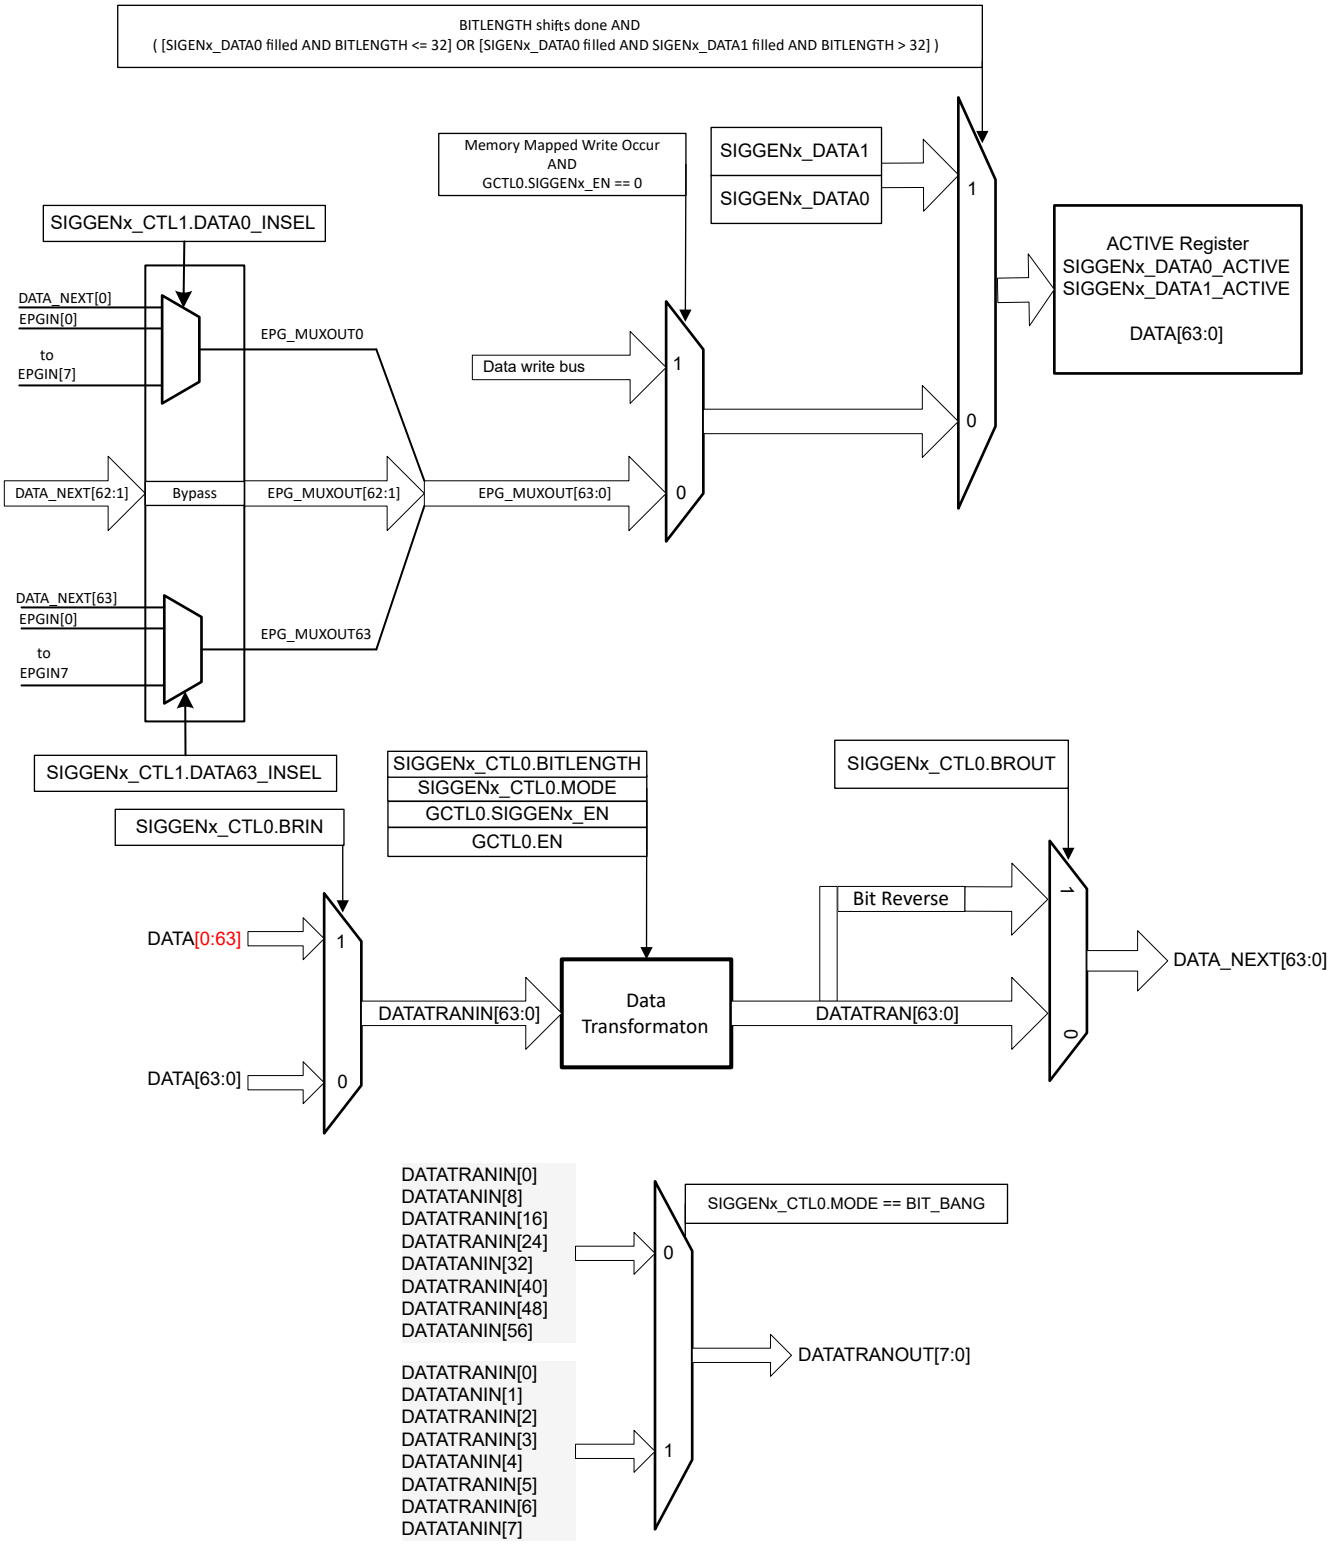

Figure 32-5. EPG Signal Generator Detailed Overview

Following are the possible data transformations:

Bit-bang mode: In this mode, DATATRAN[63:0] is the same as DATATRANIN[63:0].

Shift right once mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift right repeat mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 32-1.

Rotate right once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[0],DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate right repeat: This mode is same as rotate right once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Shift left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift left repeat mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 32-1.

Rotate left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],DATATRANIN[63]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate left repeat: This mode is same as rotate left once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Note

SIGGENx_CTL0.MODE and SIGGENx_CTL.BITWIDTH must only be updated when GCTL0.SIGGENx_EN is 0.

32.4 EPG Peripheral Signal Mux Selection

EPG DATAINx signals are connected to input signal sources from other peripherals. The EPG DATAINx signal sources are listed in Table 32-2.

Table 32-2. EPG Data Input Connections

EPG Data Connection (DATAINx)	Peripheral Input Signal
0	MCANA_RX
1	MCANB_RX
2	LINA_RX
3-3	Reserved
4	FSIRXA_D0

54	ECAP2

Table 32-2. EPG Data Input Connections (continued)

EPG Data Connection (DATAINx)	Peripheral Input Signal
55-59	Reserved
60	SRAM_REPAIR_FCLK*
61	SRAM_REPAIR_FCLRZ*
62	SRAM_REPAIR_DATA_OUT*

EPGOUT0 to EPGOUT7 can override peripheral input signals connected to DATAINx. For example, the peripheral CAN RX input signal can be overwritten by EPGOUTx. DATAINx can be passed to DATAOUTx untouched, if EPG is not required, or the DATAINx can be replaced with EPGOUTy (y = x%8). The EPGMXSEL0 and EPGMXSEL1 registers must be configured to select the source of the DATAOUTx signals. Also, EPGOUTx signals can be connected to GPIOs through the Output XBARs and CLB Output XBARs, while EPGINx signals can be connected to the Input XBARs.

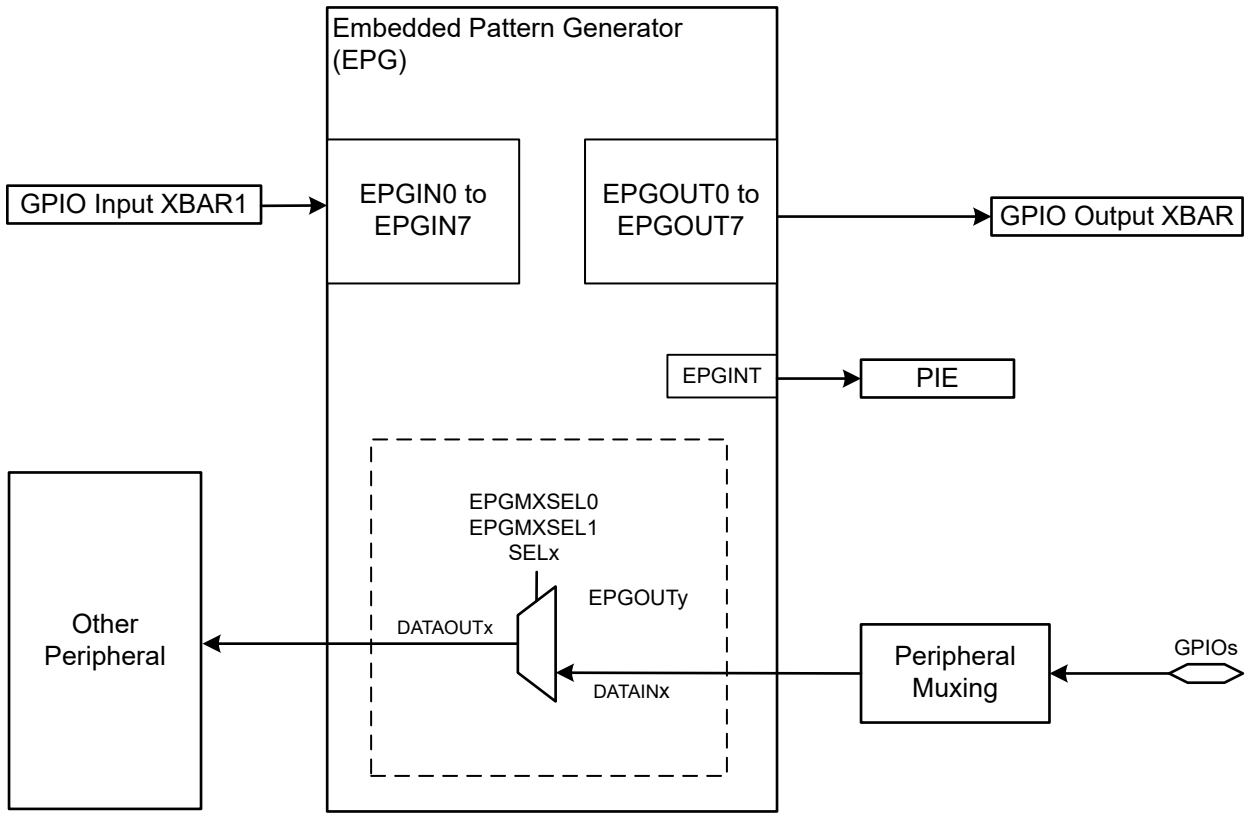

Figure 32-6. EPG Peripheral Signal Muxing

Table 32-3. EPG Input Connections

Index	Signal
0	INPUTXBAR13
1	INPUTXBAR14
2	INPUTXBAR15
3	INPUTXBAR16

0	OUTPUTXBAR.G30.3
1	OUTPUTXBAR.G31.3
2	CLBOUTPUTXBAR.G30.3
3	CLBOUTPUTXBAR.G31.3

32.5 Application Software Notes

The following points are important considerations when utilizing the EPG:

- SIGGENx_CTL0.MODE and SIGGENx_CTL0.BITLENGTH can only be written to when SIGGENx_CTL0.EN is 0
- CLKDIVx_CTL0.PRD register can be written, when GCTL0.EN is 0
- GCTL0.EN can be enabled before GCTL0.SIGGENx_EN

32.6 EPG Example Use Cases

This section provides example register configurations for different EPG use cases.

Note

Some examples can require more than one SIGGEN module. Check the device registers or data sheet for the number of available SIGGEN modules.

32.6.1 EPG Example: Synchronous Clocks with Offset

Example 32-1 register configuration generates 4 clocks, all synchronous to one another with edges offset by 2 clock cycles. In Example 32-1, a clock divide value of 12 is used.

Example 32-1. Synchronous Clocks with Offset Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
EPGMXSEL0.SEL2	0x1	Select EPGOUT2 to drive DATAOUT[2]
EPGMXSEL0.SEL3	0x1	Select EPGOUT3 to drive DATAOUT[3]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL0.EPGOUT2SEL	0x0	Selects signal mux output on EPGOUT2
GCTL0.EPGOUT3SEL	0x0	Selects signal mux output on EPGOUT3
GCTL3.EPGOUT0_SIGOUTSEL	0x0	Select SIGGEN0.OUT[0] on EPGOUT0
GCTL3.EPGOUT1_SIGOUTSEL	0x1	Select SIGGEN0.OUT[1] on EPGOUT1
GCTL3.EPGOUT2_SIGOUTSEL	0x2	Select SIGGEN0.OUT[2] on EPGOUT2
GCTL3.EPGOUT3_SIGOUTSEL	0x3	Select SIGGEN0.OUT[3] on EPGOUT3
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x0	Divide by 1
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0xC	Configure bit length to 12 to get a divide-by-12 clock.
SIGGEN0_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode to generate a periodic waveform.
SIGGEN0_DATA0[11:0]	0000 0111 1110	Initialize the 12 bits to 6 ones and 6 zeroes, which makes sure of a 50% duty cycle clock.
SIGGEN0_DATA0[27:16]	0001 1111 1000	Create a 2-cycle offset with respect to first clock.
SIGGEN0_DATA1[11:0]	0111 1110 0000	Create a 4-cycle offset with respect to first clock.
SIGGEN0_DATA1[27:16]	1111 1000 0001	Create a 6-cycle offset with respect to first clock.

32.6.2 EPG Example: Serial Data Bit Stream (LSB first)

Example 32-2 register configuration shifts out a data word, the data rate is set to divide by 8 and the LSB is shifted out first. After 32 shifts are completed, an interrupt is generated for further sequencing.

Example 32-2. Serial Data Bit Stream (LSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

32.6.3 EPG Example: Serial Data Bit Stream (MSB first)

Example 32-3 register configuration shifts out a data word, the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

Example 32-3. Serial Data Bit Stream (MSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

32.7 EPG Interrupt

EPG interrupt can be generated on “BIT_LENGTH" shifts or rotates, or “BIT_LENGTH/2” shifts or rotates. Interrupts can be generated in any of the signal generator modes.

The GINTSTS, GINTEN, GINTCLR, and GINTFRC registers are used to configure the EPG interrupt, as shown in Figure 32-7.

32.8.2 EPG Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/epg

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

32.8.2.1 EPG Generating Synchronous Clocks

FILE: epg_ex1_generate_clocks.c

This example shows how to generate 2 synchronous clocks with edges being offset by 2 clock cycles. It configures Signal Generator to shift a periodic data. Generated Clock has period EPG CLOCK/6.

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

Watch Variables

- sigGenActiveData - Active Data of signal generator transform output

32.8.2.2 EPG Generating Two Offset Clocks

FILE: epg_ex7_generate_two_offset_clocks.c

This example generates two offset clocks using the CLKGEN (CLKDIV) modules. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

32.8.2.3 EPG Generating Two Offset Clocks With SIGGEN

FILE: epg_ex8_generate_two_offset_clocks_with_siggen.c

This example generates two offset clocks using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

32.8.2.4 EPG Generate Serial Data

FILE: epg_ex9_generate_serial_data.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

32.8.2.5 EPG Generate Serial Data Shift Mode

FILE: epg_ex10_generate_serial_data_shift_mode.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module in SHIFT mode. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

32.9 EPG Registers

This Section describes the EPG Registers.

32.9.1 EPG Base Address Table

Table 32-6. EPG Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
Epg1Regs	EPG_REGS	EPG1_BASE	0x0005_EC00	YES	-	-	YES
Epg1MuxRegs	EPG_MUX_REGS	EPG1MUX_BASE	0x0005_ECD0	YES	-	-	YES

32.9.2 EPG_REGS Registers

Table 32-7 lists the memory-mapped registers for the EPG_REGS registers. All register offset addresses not listed in Table 32-7 should be considered as reserved locations and the register contents should not be modified.

Table 32-7. EPG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GCTL0	EPG Global control register 0		Go
2h	GCTL1	EPG Global control register 1		Go
4h	GCTL2	EPG Global control register 2		Go
6h	GCTL3	EPG Global control register 3		Go
8h	EPGLOCK	EPG LOCK Register		Go
Ah	EPGCOMMIT	EPG COMMIT register		Go
Ch	GINTSTS	EPG Global interrupt status register.		Go
Eh	GINTEN	EPG Global interrupt enable register.		Go
10h	GINTCLR	EPG Global interrupt clear register.		Go
12h	GINTFRC	EPG Global interrupt force register.		Go
18h	CLKDIV0_CTL0	Clock divider 0's control register 0		Go
1Eh	CLKDIV0_CLKOFFSET	Clock divider 0's clock offset value		Go
24h	CLKDIV1_CTL0	Clock divider 1's control register 0		Go
2Ah	CLKDIV1_CLKOFFSET	Clock divider 1's clock offset value		Go
30h	SIGGEN0_CTL0	Signal generator 0's control register 0		Go
32h	SIGGEN0_CTL1	Signal generator 0's control register 1		Go
38h	SIGGEN0_DATA0	Signal generator 0's data register 0		Go
3Ah	SIGGEN0_DATA1	Signal generator 0's data register 1		Go
3Ch	SIGGEN0_DATA0_ACTIVE	Signal generator 0's data active register 0		Go
3Eh	SIGGEN0_DATA1_ACTIVE	Signal generator 0's data active register 1		Go
50h	REVISION	IP Revision tie-off value		Go

Complex bit access types are encoded to fit into small table cells. Table 32-8 shows the codes that are used for access types in this section.

Table 32-8. EPG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 32-8. EPG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

32.9.2.1 GCTL0 Register (Offset = 0h) [Reset = 00000000h]

GCTL0 is shown in Figure 32-8 and described in Table 32-9.

Return to the Summary Table.

Table 32-29. REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	This identifies the scheme revision ID register type implemented for this module Reset type: SYSRSn
29-28	RESERVED	R-0	0h	Reserved
27-16	FUNC	R	1h	Functional Release Number Reflects software-compatability. If there is no software compatability, a unique func number is assigned for compatible modules, the same number is maintained. Reset type: SYSRSn
15-11	RESERVED	R	1h	Reserved
10-8	MAJOR	R	0h	Major Revision Number Represents major changes to the module (e.g. entirely new features are added/changed). The major revision number for this module. Reset type: SYSRSn
7-6	CUSTOM	R	0h	Custom Module Number Indicates a special version of the module. May not be supported by standard software. Reset type: SYSRSn
5-0	MINOR	R	1h	Minor Revision Number Represents minor changes to the module (e.g. enhancements to existing features). The minor revision number for this module. Reset type: SYSRSn

32.9.3 EPG_MUX_REGS Registers

Table 32-30 lists the memory-mapped registers for the EPG_MUX_REGS registers. All register offset addresses not listed in Table 32-30 should be considered as reserved locations and the register contents should not be modified.

Table 32-30. EPG_MUX_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	EPGMXSEL0	EPG Mux select register 0		Go
Ch	EPGMXSELLOCK	EPG Mux select register lock		Go
Eh	EPGMXSELCOMMIT	EPG Mux select register commit		Go

Complex bit access types are encoded to fit into small table cells. Table 32-31 shows the codes that are used for access types in this section.

Table 32-31. EPG_MUX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

32.9.3.1 EPGMXSEL0 Register (Offset = 0h) [Reset = 00000000h]

EPGMXSEL0 is shown in Figure 32-29 and described in Table 32-32.

Return to the Summary Table.

EPG Mux select register 0

Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from April 5, 2024 to September 23, 2024 (from Revision A (April 2024) to Revision B (September 2024))	Page
• Changed Section 3.11.1.4	142
• Added Section 4.7.1.1	617
• Changed starting address in Section 5.7.8	667
• Added Chapter 8	1051
• Changed DACB_OUT to CMPSS1_DACL in Figure 14-1	1914
• Changed DACB_OUT to CMPSS1_DACL in Figure 14-2	1914
• Changed DACB_OUT to CMPSS1_DACL in Table 14-1	1914
• Changed DACB_OUT to CMP1_DACL in Table 14-4	1922
• Changed DACB_OUT to CMP1_DACL in Table 14-5	1922
• Changed INTSEL1N2.INT1SEL values in Figure 15-21	1998
• Added Section 15.9	2008
• Added Note in Section 19.4.5	2401
• Changed Figure 20-4	2664
