About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that can be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you would expect to see for certain technology areas.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

TI Glossary	This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at www.ti.com.

Additionally, the *TMS320C28x DSP CPU and Instruction Set Reference Guide* and the *TMS320C28x Floating Point Unit and Instruction Set Reference Guide* must be used in conjunction with this TRM.

Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Chapter 1

C2000™ Microcontrollers Software Support

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

1.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in Table 1-1.

Table 1-1. C2000Ware Root Directories

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDs. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: www.ti.com/c2000.

1.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

1.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: www.ti.com/ccstudio

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

1.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: dev.ti.com

Chapter 2

C28x Processor

This chapter contains a short description of the C28x processor and extended instruction sets.

Further information can be found in the following documents:

- *TMS320C28x CPU and Instruction Set Reference Guide*

2.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the *TMS320C28x CPU and Instruction Set Reference Guide*.

2.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while the CPU writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

2.4 Floating-Point Unit (FPU)

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

2.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in Table 2-1.

Table 2-1. TMU Supported Instructions

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32 RaH,RbH	a = b * 2pi	2/3
DIV2PIF32 RaH,RbH	a = b / 2pi	2/3
DIVF32 RaH,RbH,RcH	a = b/c	5
SQRTF32 RaH,RbH	a = sqrt(b)	5
SINPUF32 RaH,RbH	a = sin(b*2pi)	4
COSPUF32 RaH,RbH	a = cos(b*2pi)	4
ATANPUF32 RaH,RbH	a = atan(b)/2pi	4
QUADF32 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

Exponent instruction IEXP2F32 and logarithmic instruction LOG2F32 have been added to support computation of floating-point power function for the nonlinear proportional integral derivative control (NLPID) component of the C2000 Digital Control Library. These two added instructions reduce the power function calculations from a typical of 300 cycles using library emulation to less than 10 cycles.

No changes have been made to existing instructions, pipeline, or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out the operations.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

2.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5D 6DCB
- CRC32 polynomial1 = 0x04C1 1DB7
- CRC32 polynomial2 = 0x1EDC 6F41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to 3 cycles when using a custom polynomial.

For more information, see the *TMS320C28x Extended Instruction Sets Technical Reference Manual*.

Chapter 3

System Control and Interrupts

The system-level functionality of this microcontroller configures the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

3.1 Introduction

System-level configuration is controlled by a group of submodules that are collectively referred to as the system control module. The system control module provides the following capabilities:

- System-level resets, including power-on and brownout resets
- Clock source selection and PLL configuration
- Missing clock detection
- Clock-gating low-power modes
- Peripheral interrupt handling
- Non-maskable interrupts for certain fault conditions
- Three 32-bit timers
- Windowed watchdog timer, which can generate an interrupt or a reset
- RAM initialization, write protection, and controller control
- Flash memory ECC, wait state, and cache configuration
- Dual-zone code security module

3.1.2 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by LOCK registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

3.1.3 EALLOW Protection

Some registers in the system are protected from spurious CPU writes by the EALLOW protection mechanism. This uses the special CPU instructions EALLOW and EDIS to enable and disable access to protected registers. The current protection state is given by the EALLOW bit in the CPU ST1 register, as shown in Table 3-1.

Register protection is enabled by default at startup. While protected, all writes to protected registers by the CPU are ignored. Only CPU reads, JTAG reads, and JTAG writes are allowed. If protection is disabled by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

Writes to the clock configuration and peripheral clock enable registers can be disabled until the next reset by writing to special lock registers.

Table 3-1. Access to EALLOW-Protected Registers

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed(1)	Allowed	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden by way of the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio™ IDE interface.

3.2 Power Management

The TMS320F28P55x MCU supports both internal generation of the 1.2V rail for single-supply operation or externally supplied 1.2V into the device. The internal VREG is controlled using the VREGENZ pin: if enabled, the 1.2V rail is generated by the device; if disabled, the 1.2V rail is supplied from an external source. For more details, see *TMS320F28P55x Real-Time Microcontrollers*.

3.3 Device Identification and Configuration Registers

The device identification registers and configuration registers provide information on the part number, product family, revision, pin count, qualification status, and feature availability of the device.

All of the device information is part of the DEV_CFG_REGS space. The identification registers are PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID_REGS. The 256 bits are separated into these registers:

- UID_PSRAND0-4: 160 bits of pseudo-random data
- UID_UNIQUE: 64-bit unique data; the value in this register is unique across all devices in the same PARTIDH
- UID_CHECKSUM: 32-bit Fletcher checksum of UID_PSRAND0-4 and UID_UNIQUE and calculated as either little-endian or big-endian during factory testing

3.4 Resets

This section explains the types and effects of the different resets on this device.

3.4.1 Reset Sources

Table 3-2 summarizes the various reset signals and the effect on the device.

Table 3-2. Reset Signals

Reset Source	CPU Core Reset (C28x, FPU, VCU)	Peripherals Reset	JTAG / Debug Logic Reset	IOs	$\overline{\text{XRS}}$ Output
POR	Yes	Yes	Yes	Hi-Z	Yes
BOR	Yes	Yes	Yes	Hi-Z	Yes
$\overline{\text{XRS}}$ Pin	Yes	Yes	No	Hi-Z	-
$\overline{\text{WDRS}}$	Yes	Yes	No	Hi-Z	Yes
$\overline{\text{NMIWDRS}}$	Yes	Yes	No	Hi-Z	Yes
$\overline{\text{SYSRS}}$ (Debugger Reset)	Yes	Yes	No	Hi-Z	No
$\overline{\text{SCCRESET}}$	Yes	Yes	No	Hi-Z	No
SIMRESET.$\overline{\text{XRS}}$	Yes	Yes	No	Hi-Z	Yes
SIMRESET.$\overline{\text{CPU1RS}}$	Yes	Yes	No	Hi-Z	No

The resets can be divided into two groups:

- Chip-level resets ($\overline{\text{XRS}}$, POR, BOR, $\overline{\text{WDRS}}$, SIMRESET.$\overline{\text{XRS}}$, and $\overline{\text{NMIWDRS}}$), which reset all or almost all of the device.
- System resets ($\overline{\text{SYSRS}}$, SIMRESET.$\overline{\text{CPU1RS}}$, and $\overline{\text{SCCRESET}}$), which reset a large subset of the device but maintain some system-level configuration.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain the state across multiple resets. The bits can only be cleared by a power-on reset (POR) or by writing ones to the RESCCLR register. Some are cleared by the boot ROM as part of the start-up routines.

Many peripheral modules have individual resets accessible through the SOFTPRESx registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After any reset, the CPU begins execution from address 0x3FFFC0 (the reset vector), which is in the boot ROM. After running the boot ROM code, the CPU typically branches to the start of the Flash memory at address 0x80000. For more information on controlling the boot process, see Chapter 4 .

Note

After a POR, the boot ROMs clear the M0/M1, LSx, GSx, and message RAMs to make sure that the memories contain valid ECC or parity.

3.4.2 External Reset ($\overline{\text{XRS}}$)

The external reset ($\overline{\text{XRS}}$) is the main chip-level reset for the device and resets the CPU, all peripherals and I/O pin configurations, and most of the system control registers. There is a dedicated open-drain pin for $\overline{\text{XRS}}$. This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The $\overline{\text{XRS}}$ is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever $\overline{\text{XRS}}$ is driven low for any reason. This bit is then cleared by the boot ROM.

3.4.3 Simulate External Reset (SIMRESET.$\overline{\text{XRS}}$)

In some cases, the user can need to simulate the external reset ($\overline{\text{XRS}}$) in software. This can be done using software by setting XRSn bit to 1 in SIMRESET register. This toggles the $\overline{\text{XRS}}$ pin and resets the full device (just like an external reset).

After this reset, the SIMRESET_XRSn and XRSn bits in the RESC register are set. Software can read these bits to know the cause of reset and clear the status by writing a 1 into corresponding bits in RESCCLR register.

3.4.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{\text{XRS}}$ pin is held low for the duration of the POR. In most applications, $\overline{\text{XRS}}$ is held low long enough to reset other system ICs, but some applications can require a longer pulse. In these cases, the $\overline{\text{XRS}}$ pin can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{\text{XRS}}$ does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), and the X1 clock counter register (X1CNT). A POR also resets the debug logic used by the JTAG port.

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

3.4.5 Brown-Out Reset (BOR)

The brown-out reset (BOR) is an internal supply voltage supervisor (SVS) circuit that monitors the VDDIO supply for glitches or supply interruptions. If the VDDIO supply voltage drops below operational voltage range, this circuit forces the XRSn pin low until the fault is removed and the supply voltage returns to the minimum operational voltage. A BOR resets everything in the same manner as a POR reset.

The BOR circuit is enabled by default and is always active during power up or after any type of reset. To disable the BOR circuit, set the BORLVMONDIS bit in the VMONCTL register.

3.4.6 Debugger Reset ($\overline{\text{SYSRS}}$)

During development, it is sometimes necessary to reset the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, the CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio™ IDE. This reset ($\overline{\text{SYSRS}}$) resets the CPU, the peripherals, many system control registers (including the clock gating and LPM configuration), and all I/O pin configurations.

The $\overline{\text{SYSRS}}$ does not reset the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see Section 3.4.4).

3.4.7 Simulate CPU Reset (SIMRESET)

In some cases, you can simulate the CPU reset ($\overline{\text{SYSRS}}$) in software. This can be done by setting the CPU1RSn bit to 1 in the SIMRESET register by CPU1 software. This toggles CPU1.SYSRS signals, resetting the CPU (just like the debugger reset).

After this reset, the SIMRESET_CPU1RSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.4.8 Watchdog Reset ($\overline{\text{WDRS}}$)

The device has a watchdog timer that can optionally trigger a reset if it is not serviced by the CPU within a user-specified amount of time. This watchdog reset ($\overline{\text{WDRS}}$) produces an $\overline{\text{XRS}}$ that lasts for 512 INTOSC1 cycles.

After a watchdog reset, the WDRSn and XRSn bits in RESC are set.

3.4.9 NMI Watchdog Reset ($\overline{\text{NMIWDRS}}$)

The device has a non-maskable interrupt (NMI) module that detects hardware errors in the system. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This NMI watchdog reset ($\overline{\text{NMIWDRS}}$) produces an $\overline{\text{XRS}}$ that lasts for 512 INTOSC1 cycles.

After an NMI watchdog reset, the NMIWDRSn and XRSn bits in RESC are set.

3.4.10 DCSM Safe Code Copy Reset ($\overline{\text{SCCRESET}}$)

The device has a dual-zone code security module (DCSM) that blocks read access to certain areas of the Flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. This security reset ($\overline{\text{SCCRESET}}$) is similar to a $\overline{\text{SYSRS}}$. However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

3.5 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in Section 3.6. Software interrupts and emulation interrupts are not covered in this chapter (see the *TMS320C28x CPU and Instruction Set Reference Guide*).

3.5.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause the current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until the interrupt is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

3.5.2 Interrupt Architecture

The C28x CPU has 14 peripheral interrupt lines. Two of the interrupts (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining 12 interrupts are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to 16 peripheral interrupts into each CPU interrupt line and also expands the vector table to allow each interrupt to have an ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages: the peripheral, the PIE, and the CPU. Each stage has enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

Figure 3-1 shows the interrupt architecture for this device.

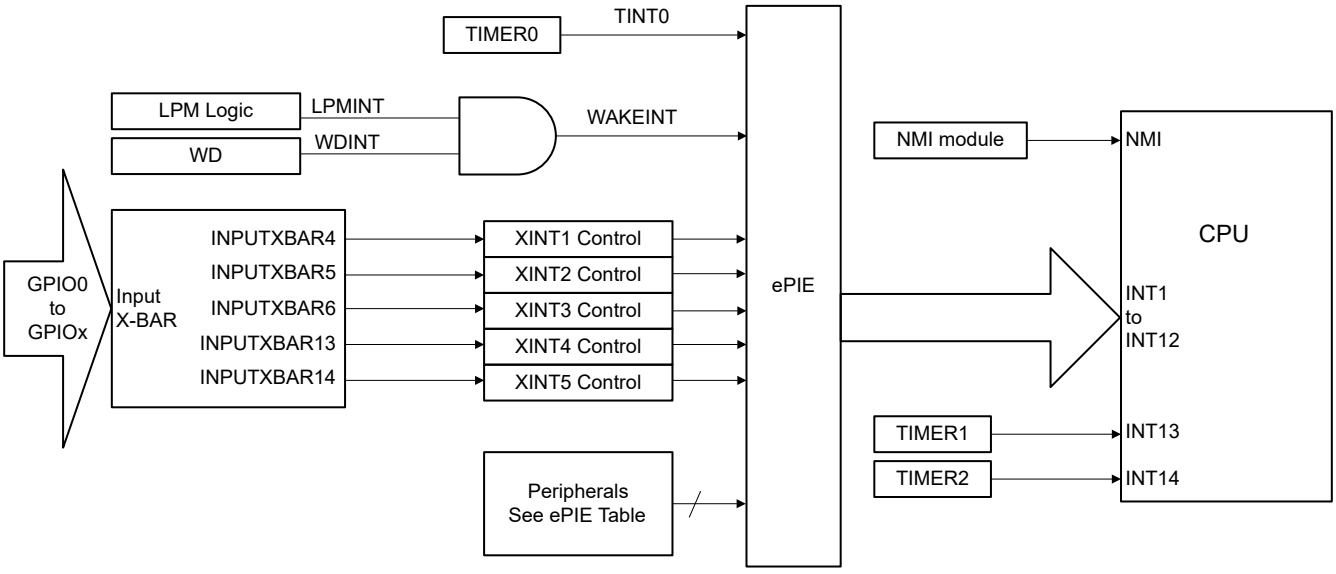

Figure 3-1. Device Interrupt Architecture

3.5.2.1 Peripheral Stage

Each peripheral has a unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral can use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt is generated.

3.5.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to the associated CPU interrupt. Each PIE group has one 8-bit enable register (PIEIERx), one 8-bit flag register (PIEIFRx) , and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, the CPU fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition does not happen unless software changes the state of the PIE while an interrupt is propagating. Section 3.5.4 contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

3.5.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of the interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC and CLRC instructions. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is set, the next instruction in the pipeline runs with interrupts disabled. No software delays are needed.

3.5.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

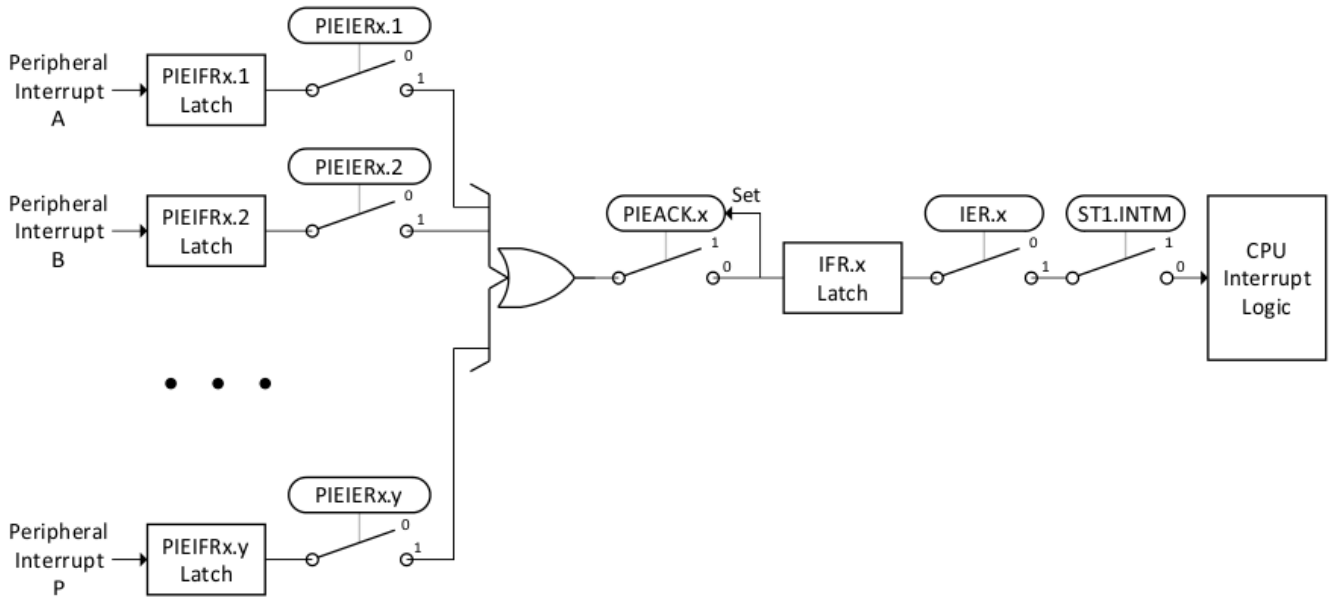

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), the interrupt triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves the context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

3.5.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

3.5.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in Section 3.5.8. Note that the vector table is EALLOW-protected.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be found in Section 3.5.8.
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

3.5.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the __interrupt keyword. For information on this keyword, see the Keywords section of the *TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide*. For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the *TMS320C28x CPU and Instruction Set Reference Guide*.

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU does not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

3.5.4.3 Disabling Interrupts

To disable all interrupts, set the CPUs global interrupt mask using DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction executes with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, the interrupt signal can reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

The PIEIFR bits must never be cleared in software since the read/modify/write operation can cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR only contains a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to the original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

3.5.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts using software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at software-dl.ti.com/C2000/docs/c28x_interrupt_nesting/html/index.html.

3.5.4.5 Vector Address Validity Check

The ePIE vector table memory is protected using a parity check. Upon each vector fetch from the ePIE, a parity check is performed. If a parity failure occurs during vector fetch, the ePIE returns either a user defined error handler routine (if PIEVERRADDR is defined with a non 0x003FFFFF value), or the default boot ROM handler at address 0x3FFFBE. The ePIE also sends trip signals to the EPWMs.

The parity check only returns the error handler value if the failure occurs during vector fetch. Parity errors during data read is handled by the memory controller module and logged by UCERRFLG register in MEMORY_ERROR_REGS. The address that caused the error is located in the UCCPUREADDR register. If the error address logged is between 0xD00 to 0xDFF, then the error is a PIE parity error. Additionally, a parity error during vector fetch does not flag an uncorrectable error NMI.

3.5.5 PIE Channel Mapping

Table 3-3 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel is the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

Note

Cells that are empty are Reserved.

Table 3-3. PIE Channel Mapping

3.5.6 PIE Interrupt Priority

3.5.6.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 is serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 is serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 that is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU services channel 1.2 and channel 1.3 is still left pending. Using the steps from the Interrupt Entry Sequence (Section 3.5.3), channel 1.2 interrupt can happen as late as step 10 (the CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and the channel is still serviced ahead of channel 1.3.

3.5.6.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in the respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 is serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence (Section 3.5.3).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence (Section 3.5.3).

1. As the CPU reaches step 10 (the CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 is serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 is serviced ahead of channels 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only specified if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence (Section 3.5.3) is not executing.

3.5.7 System Error

SYS_ERR consolidate several sources of interrupts (see Figure 3-3). These sources set the respective bit in the SYS_ERR_INT_FLG register. Any set bit in the SYS_ERR_INT_FLG register also sets the global interrupt (GINT) bit. The GINT bit has to be cleared before any SYS_ERR interrupt is generated. If the GINT bit is cleared with the source flags still set, another SYS_ERR interrupt is fired; therefore, it is recommended to clear the source flags before clearing the GINT bit.

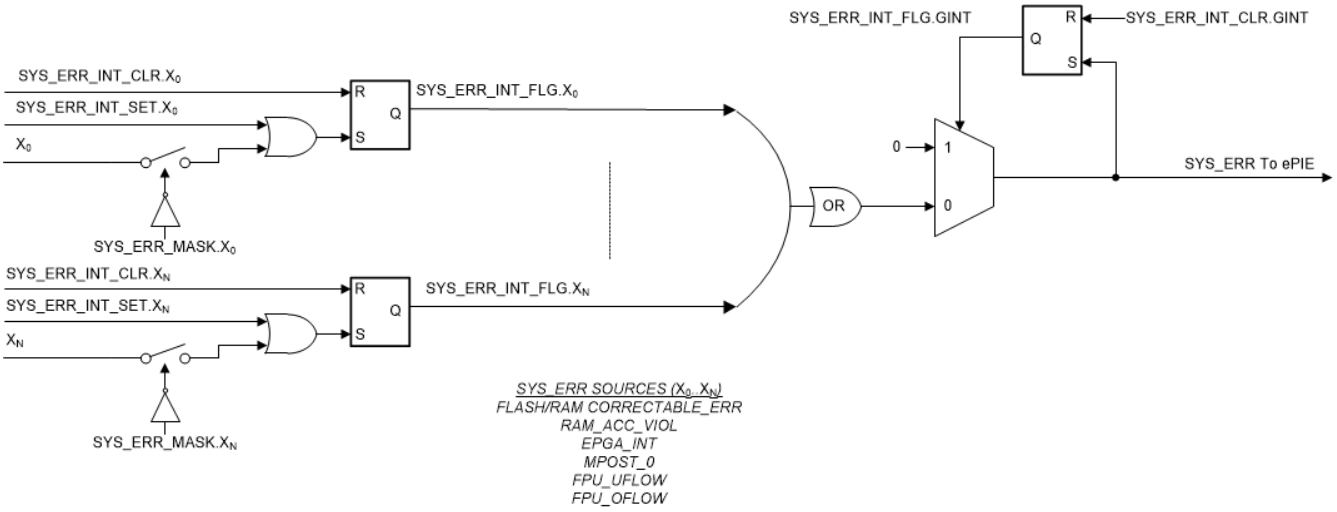

Figure 3-3. System Error

3.5.8 Vector Tables

Table 3-4 shows the CPU interrupt vector table. The vectors for INT1–INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table. All vectors are EALLOW-protected.

Table 3-5 shows the PIE vector table.

Table 3-4. CPU Interrupt Vectors

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority

3.6 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

3.6.1 Configuring and Using NMIs

An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if the count reaches the value in the NMIWDPRD register, the counter triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register can also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

3.6.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

3.6.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

3.6.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and an NMI is fired to the CPU. For more information on missing clock detection, see Section 3.7.12.1.

3.6.3.2 RAM Uncorrectable Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read triggers an NMI. This applies to CPU and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see Section 3.11.1.9.

3.6.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt.

3.6.3.4 Software-Forced Error

There is a special NMI source that can only be triggered by writing to the SWERR bit in the NMIFLGFRC register. Since the SWERR flag is never set by a real hardware fail, it can be used to implement a self-test mode for the NMI subsystem.

3.6.3.5 ERAD NMI

The ERAD module can generate NMI based on different events. This is configurable in the GLBL_NMI_CTL register.

3.6.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, the CPU generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has a vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the *TMS320C28x DSP CPU and Instruction Set Reference Guide*.

Note

A RAM fetch access violation triggers an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU handles the ITRAP first.

3.6.5 ERRORSTS Pin

The ERRORSTS pin is an 'always output' pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared. Figure 3-4 shows the functionality of the ERRORSTS pin.

The ERRORSTS pin is tri-stated until the chip power rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up can connect an external pull-down on this pin.

Following enhancement has been made on this device for ERRORSTS pin logic:

- Polarity of Error pin has been made configurable through the ERRORCTL register (default setting is active-low polarity).
- To enable testing of the Error pin, capability to force and clear the Error pin from software has been provided.
- Additional sources of Error have been added to ERRORSTS:
  - CPU1 Watchdog reset
  - Error on a PIE vector fetch

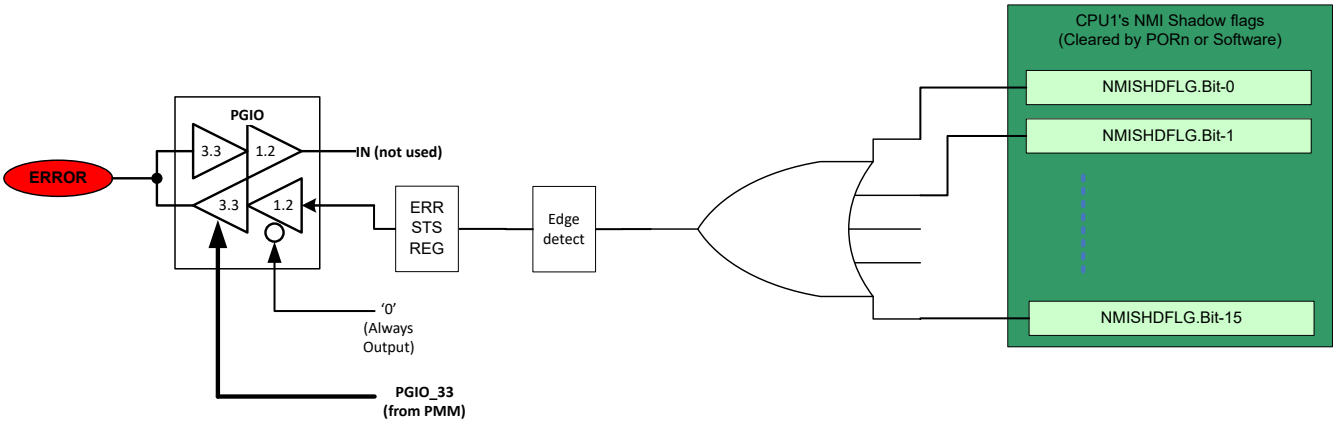

Figure 3-4. ERRORSTS Pin Diagram

3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-5 and Figure 3-6 provide an overview of the device's clocking system.

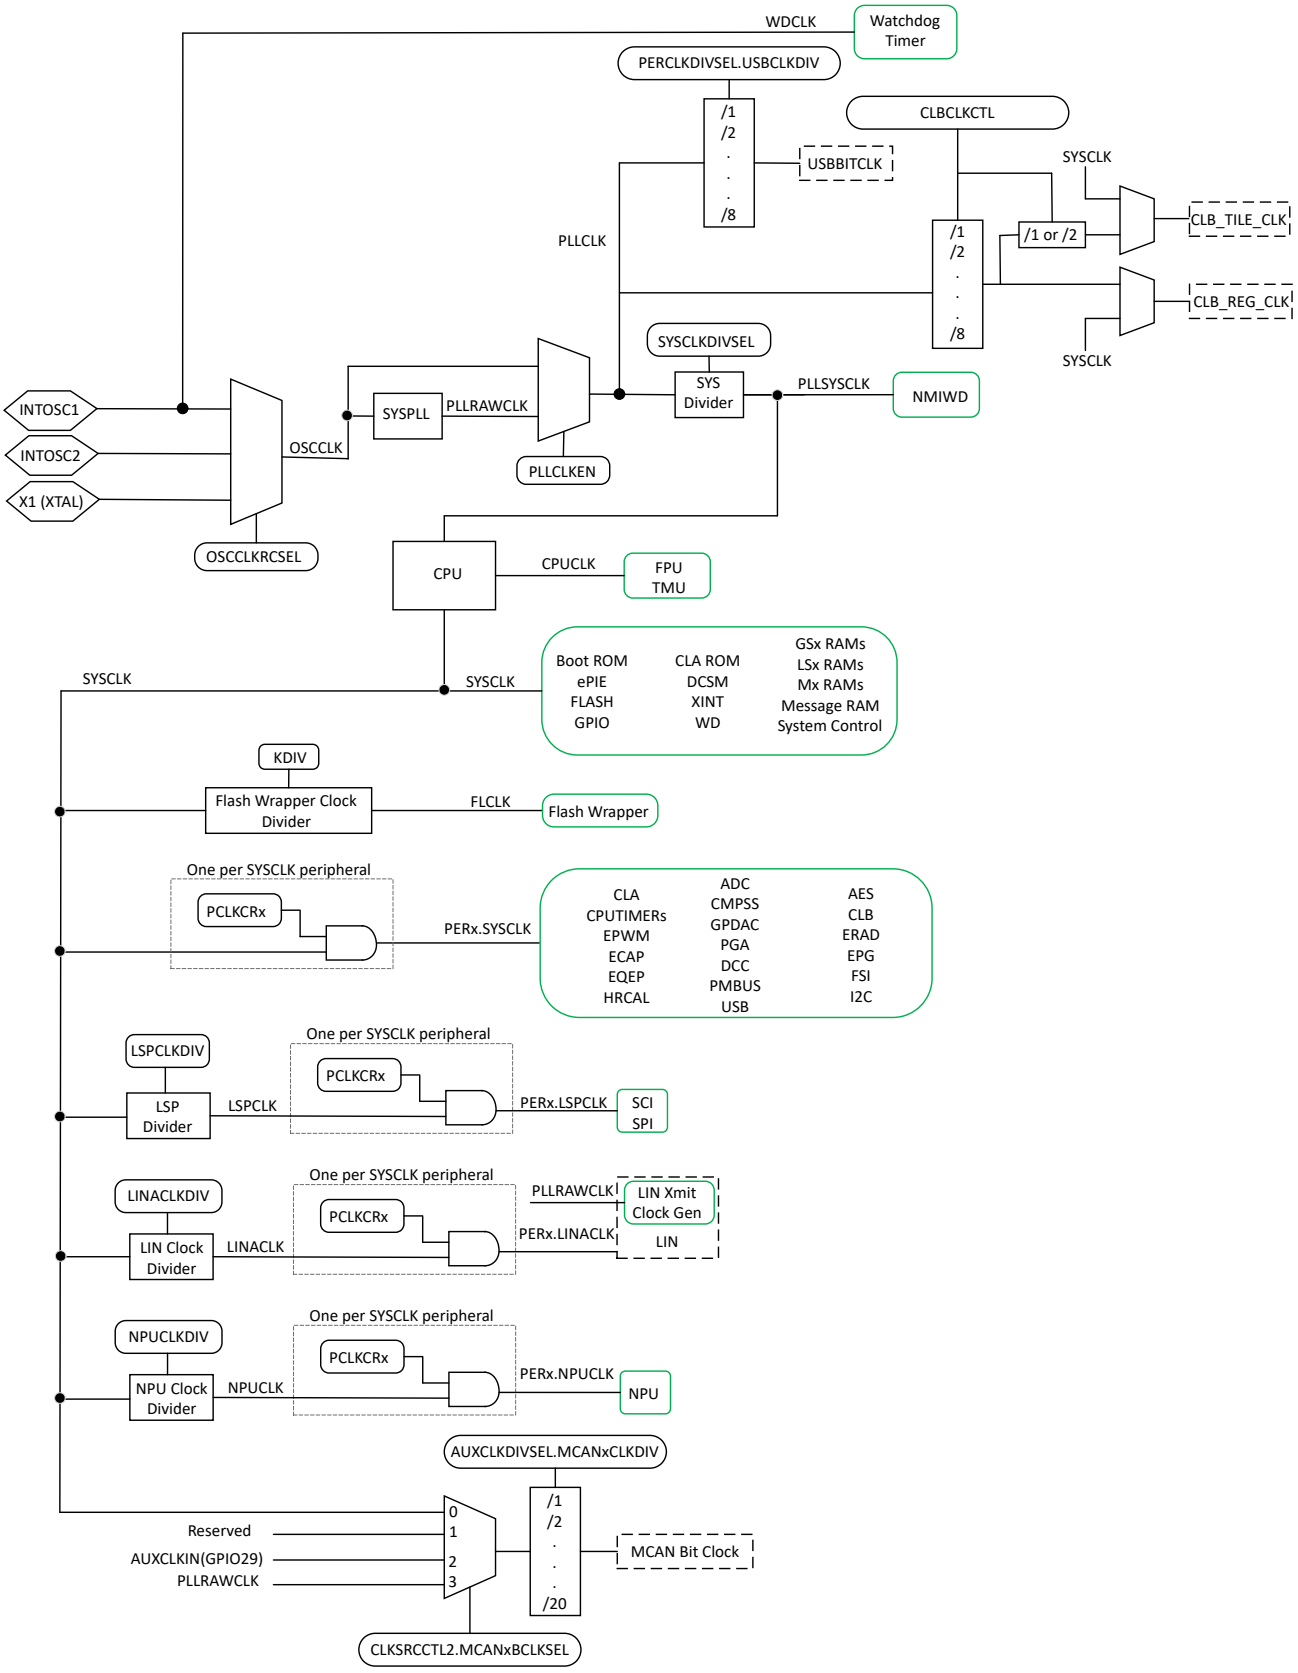

Figure 3-5. Clocking System

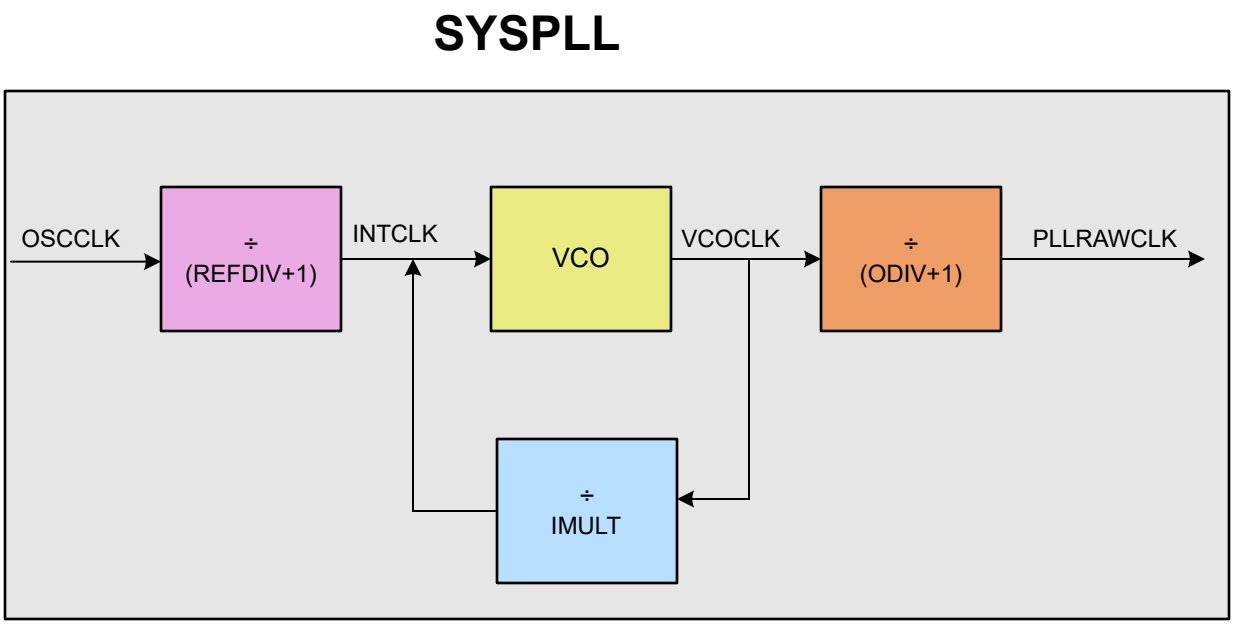

Figure 3-6. System PLL

$$f_{PLLRAWCLK} = \frac{f_{OSCCLK}}{(REFDIV + 1)} \times \frac{IMULT}{(ODIV + 1)} \quad (1)$$

3.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. INTOSC2 is used to run the boot ROM and can be used as the system clock source for the application. Note that the INTOSC2 frequency tolerance is too loose to meet the timing requirements for CAN. Use of the CAN modules requires an external oscillator. When INTOSC2 is used as the system clock source, GPIO19 (X1) and GPIO18 (X2) are available as GPIO pins.

3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 can also be manually selected as the system clock source for debug purposes.

3.7.1.3 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO29 (AUXCLKIN). This must be a single-ended 3.3V external clock as shown in Figure 3-7 and can be used as the clock source for MCAN. Frequency limits and timing requirements are found in the *TMS320F28P55x Real-Time Microcontrollers Data Sheet*. The external clock can be connected directly to the GPIO29 pin.

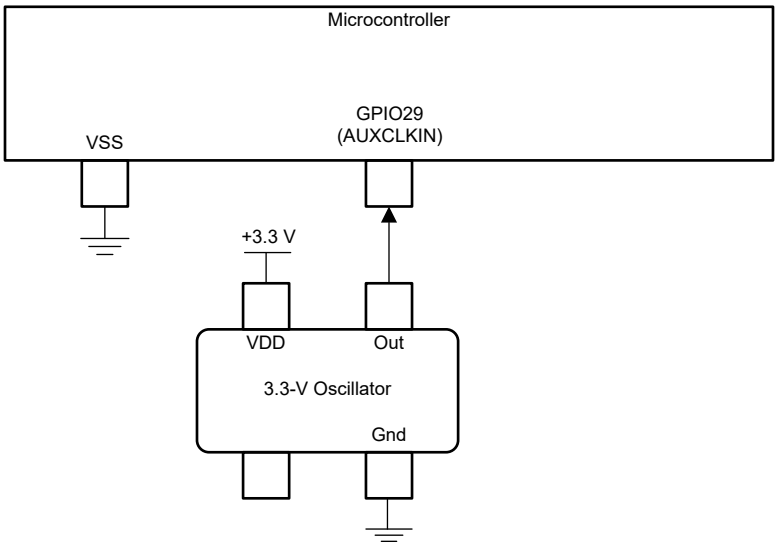

Figure 3-7. AUXCLKIN

3.7.1.4 External Oscillator (XTAL)

The device supports an external clock source (XTAL), which can be used as the main system and CAN bit clock source. Frequency limits and timing requirements can be found in the *TMS320F28P55x Real-Time Microcontrollers Data Sheet*. External clock sources use the X1/GPIO19 and X2/GPIO18 pins. After power-up, the X1 and X2 pin functionality can be enabled by following the procedure in Section 3.7.6.

Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal can be connected to X1, as shown in Figure 3-8.

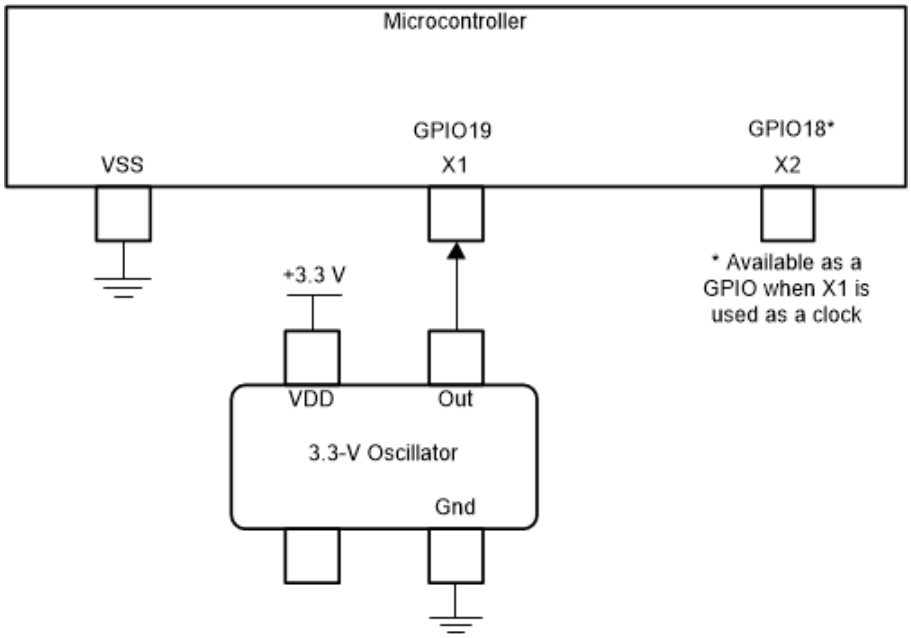

Figure 3-8. Single-ended 3.3V External Clock

- An external crystal. The crystal can be connected across X1 and X2 with the load capacitors connected to VSS as shown in Figure 3-9.

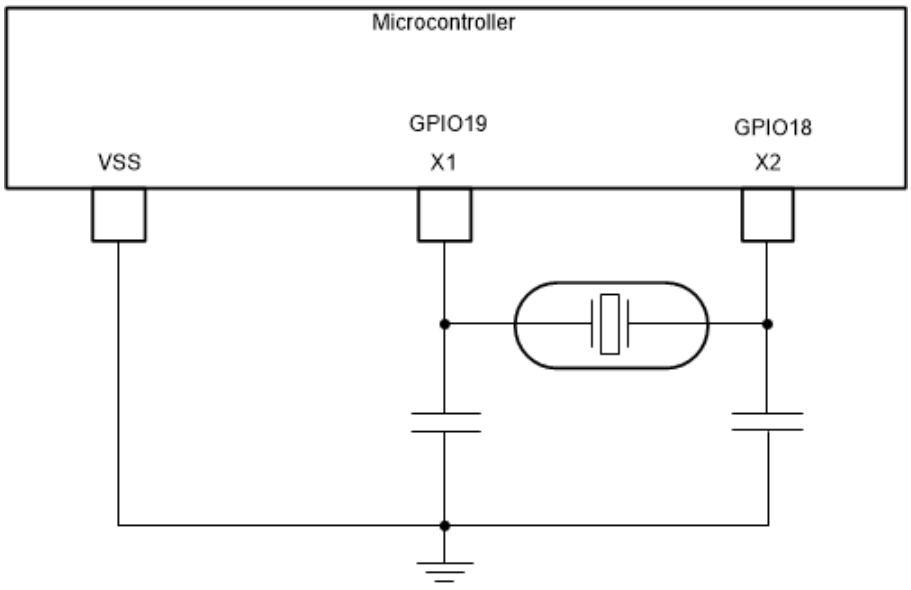

Figure 3-9. External Crystal

- An external resonator. The resonator can be connected across X1 and X2 with the ground connected to VSS as shown in Figure 3-10.

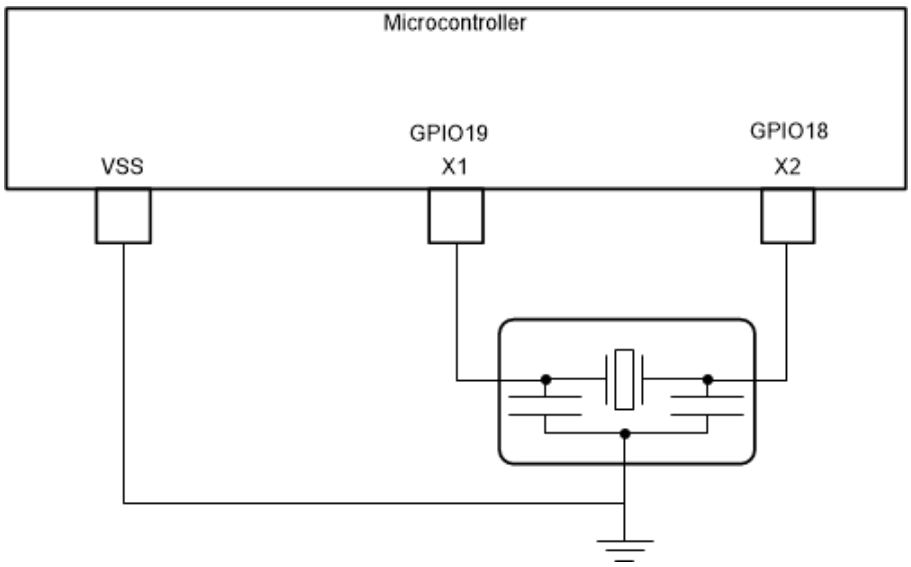

Figure 3-10. External Resonator

Table 3-6. ALT Modes

XTALCR Bit[1]		Operating Mode	GPIO19 Available on X1?	GPIO18 Available on X2?
OSCOFF	SE			
0	0	Crystal Mode: Quartz crystal connected to X1/X2	No	No
0	1	Single-Ended Mode: External clock on X1	No	Yes
1	0	Oscillator off	Yes	Yes
1	1	Single-Ended Mode: External clock on X1[2]	No	Yes

(1) OSCOFF and SE determine the ALT mode of GPIO18 and GPIO19.
(2) There is an approximately 1Kohm pull-down on X1 in this mode, external single-ended clock must be able to drive this load.

3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK can be used directly or applied through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference. PLLRAWCLK is the output of the PLL voltage-controlled oscillator (VCO). For configuration instructions, see Section 3.7.6.

3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

3.7.3.1 System Clock (PLLSYSCLK)

The NMI watchdog timer has a clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

3.7.3.2 CPU Clock (CPUCLK)

The CPU has a clock (CPUCLK) that is used to clock the CPU and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or HALT mode.

3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each peripheral clock has independent clock gating that is controlled by the PCLKCRx registers.

Note

The application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals when using PCLKCRx.

3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI and SPI modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed using the LOSPCP register. Each SCI and SPI module's clock (PERx.LSPCLK) can be gated independently using the PCLKCRx registers.

3.7.3.5 USB Bit Clock

The USB module requires a fixed 60MHz clock for bit sampling. When the PLLSYSCLK equals 150MHz, the PLLCLK output is 300MHz, which can be divided down evenly by 5 to achieve the 60MHz requirement.

USB clock tolerances are very tight. As stated in section 7.1.11 of the *USB 2.0 specification*, low-speed devices (1.50 b/s) have a tolerance of ±1.5% , while high-speed devices (12.000Mb/s) have a tolerance of ±0.25%. Typically these tolerances are achieved by using an external crystal or resonator as the clock source for the device.

3.7.3.6 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of SYSCLK) can not be precise, the bit clock can also be connected to the AUXCLKIN path using the CLKSRCCTL2 register. There is an independent selection for each CAN module.

To maintain correct operation, the frequency of the CAN bit clock must be less than or equal to the SYSCLK frequency.

3.7.3.7 CLB Clock

Both the CLB registers and CLB tiles can be clocked directly from SYSCLK domain. There is additional option to divide down PLLCLK directly and feed to one or both of the above depending on the system need.

3.7.3.8 LIN Clock

To give further granularity for the LIN module, an additional divider from SYSCLK can be implemented before the clock reaches the LIN peripheral.

3.7.3.9 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but can also be connected to INTOSC1, INTOSC2, or XTAL using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a non-SYSCLK source is used, the source must be divided down to no more than half the SYSCLK frequency.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of SYSCLK.

3.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, which can be GPIO16, GPIO18, or GPIO71. GPIO16 has digital input and output functionality; so, to use it for monitoring XCLKOUT, the register GPAAMSEL should be set to 0. The available clock sources are PLLSYSCLK, PLLRAWCLK, SYSCLK, INTOSC1, INTOSC2, and XTAL.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect GPIO16 or GPIO18 to mux channel 11 using the GPIO configuration registers.

3.7.5 Clock Connectivity

Table 3-7 shows the clock connections sorted by the clock domain and Table 3-8 shows the clock connections sorted by the module name.

Table 3-7. Clock Connections Sorted by Clock Domain

3.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but can provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. What types of external oscillators or clock sources are available?

If CAN is required, an external clock source with a precise frequency must be used as a reference clock;.otherwise, use only INTOSC2 and avoid the need for more external components.

3.7.7 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO19 and GPIO18. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. 1ms is the typical wait time but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Repeat steps 3-4 three additional times.
5. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF). Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCR register. If it's set, the oscillator has not finished powering up, and more time is required:
   a. Clear the missing clock status by writing a 1 to MCDCR.MCLKCLR.
   b. Repeat steps 2-7. Do not reset the device. Doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
   c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
8. If MCDCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

3.7.7.1 X1/X2 Precondition Circuit

The GPIO19/18 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. ClkCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. ClkCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. ClkCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE_DELAY_US(1);
5. ClkCfgRegs.XTALCR.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. ClkCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

3.7.8 Using an External Oscillator

The procedure for using an external oscillator connected to the X1 pin is similar to the procedure for using a crystal or resonator:

1. Clear the XTALCR.OSCOFF bit.
2. Set the XTALCR.SE bit to enable single-ended mode.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF).
5. Repeat steps 3 and 4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCR register. If the bit is set, either the external oscillator or the device has failed.
8. If MCLKSTS is clear, the switch to the external clock is a success. The system clock is now derived from XTAL.

3.7.9 Choosing PLL Settings

The equation shown in Figure 3-6 can be used to configure the PLL.

- IMULT is the integer value of the multiplier
- REFDIV is the reference divider for the OSCCLK
- ODIV is the output divider of the PLLRAWCLK
- PLLSYSCLKDIV is the system clock divider

For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the *TMS320F28P55x Real-Time Microcontrollers Data Sheet*.

Note

The system clock frequency (PLLSYSCLK) can not exceed the limit specified in the *TMS320F28P55x Real-Time Microcontrollers Data Sheet*. This limit does not allow for oscillator tolerance.

3.7.10 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN]. Allow at least 60 NOP instructions for this to take effect.
2. Power down the PLL by writing to SYSPLLCTL1.PLLEN = 0 and allow at least 60 NOP instructions for this to take effect.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. Allow at least 300 NOP instructions for this to take effect.
4. Set the system clock divider to /1 to make sure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This automatically enables the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the *TMS320F28P55x Real-Time Microcontrollers Data Sheet*.
6. Wait for PLL to lock by polling for lock status bit to go high, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to Chapter 9 for more information on the configuration and usage.
8. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN].

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 60 CPU clock cycles delay is needed after bypassing PLL, SYSPLLCTL1.PLLCLKEN = 0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLLEN = 0.
4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. The DCC can be used to check the validity of the PLL clock. This feature is included as part of SysCtl_setClock() function inside C2000Ware.

3.7.11 SYS PLL Bypass

If the application requires the PLL clock to be bypassed from the system, configure SYSPLLCTL1.PLLCLKEN=0. It takes up to 60 CPU clock cycles before the bypass is effective. In the meantime if PLLSYSCLKDIV is reduced to a lower value (for example from /2 to /1 or /4 to /2), the device can be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 60 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from PLLCLKEN=1 to PLLCLKEN=0.

3.7.12 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used. Table 3-9 lists the details.

Table 3-9. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.

3.7.12.1 Missing Clock Detection

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and does not perform any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or is not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason, or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDCR register (by making the MCLKOFF bit 1)
6. If the circuit ever detects a missing OSCCLK, the following occurs:
   - The MCDSTS flag is set
   - The MCDSCNT counter is frozen to prevent further missing clock detection
   - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD.
   - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (New, System Clock Frequency = INTOSC1 Freq 10MHz)/SYSDIV). In the meantime when the clock switches to INTOSC1, the System runs on PLL limp Clock.
   - SYSPLLMULT.IMULT is zeroed out automatically in this case.
   - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
   - PLLRAWCLK going to the system is switched to INTOSC1 automatically
7. If the MCLKCLR bit is written (this is a W=1 bit), MCDSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit to re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR, and re-lock the PLL.
8. The MCD is enabled at power up.

Figure 3-11 shows the missing clock logic functional flow.

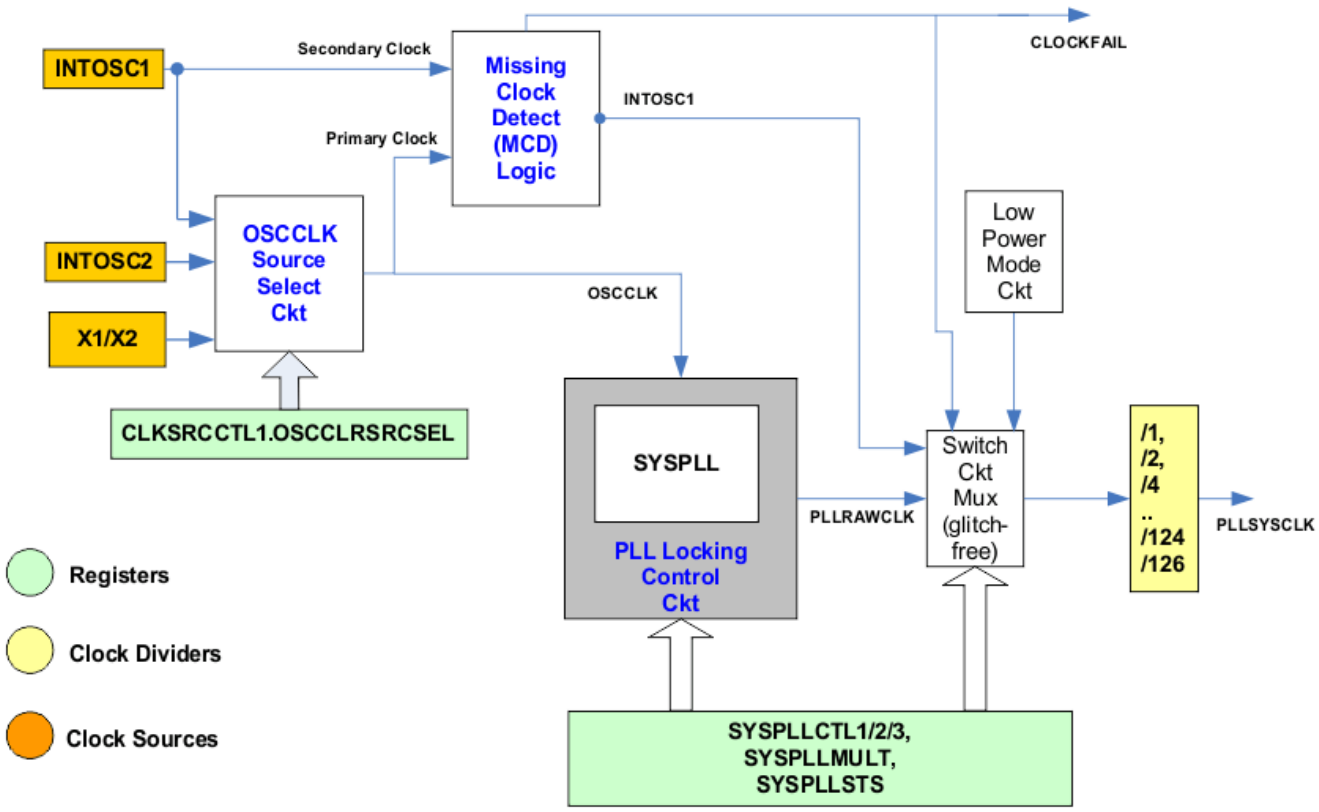

Figure 3-11. Missing Clock Detection Logic

Note

On a complete clock failure when OSCCLK is dead, it can take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated
- OSCCLK is switched to INTOSC1
- PWM Trip happens

3.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU timers (TIMER0/1/2) shown in Figure 3-12.

Timer0 and Timer1 can be used in user applications. Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then Timer2 can be used in the application. timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-13.

The general operation of a CPU timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every (TPR[TDDRH:TDDR] + 1) SYSCLK cycles, where TDDRH:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.16 are used to configure the timers.

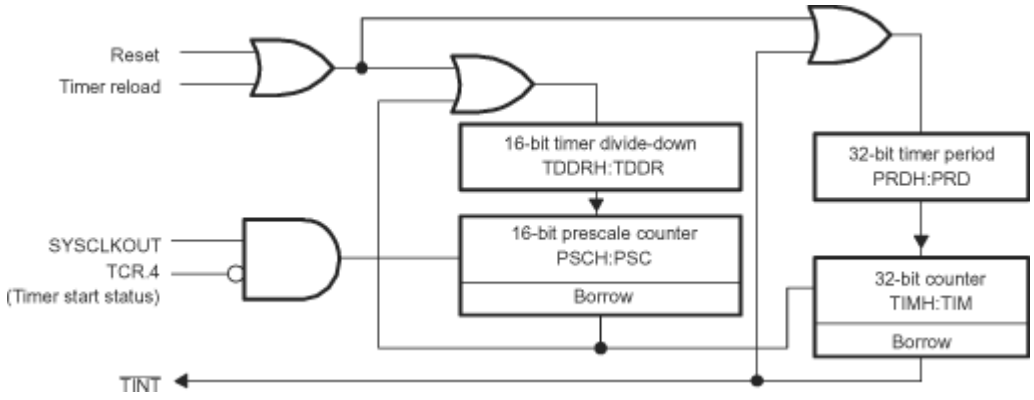

Figure 3-12. CPU Timers

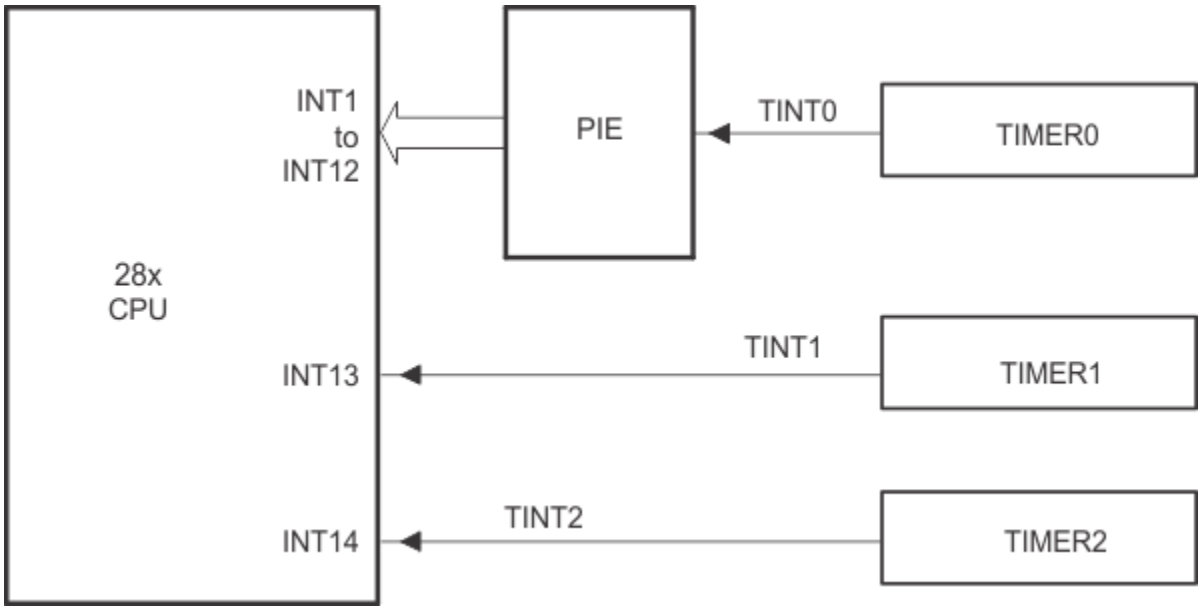

A. The timer registers are connected to the memory bus of the C28x processor.
B. The CPU timers are synchronized to SYSCLKOUT.

Figure 3-13. CPU Timer Interrupt Signals and Output Signal

3.9 Watchdog Timer

The watchdog module consists of an 8-bit counter sourced from a prescaled clock (WDCLK, which is connected to INTOSC1). When the counter reaches the maximum value, the module generates an output pulse 512 WDCLKs wide. This pulse can generate an interrupt or a reset. The CPU must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled.

The counter's clock is divided down from WDCLK by two dividers. The prescaler is adjustable from /1 to /64 in powers of two. The pre-divider defaults to /512 for backwards compatibility, but is adjustable from /2 to /4096 in powers of two. This allows a wide range of timeout values for safety-critical applications.

Figure 3-14 shows the various functional blocks within the watchdog module.

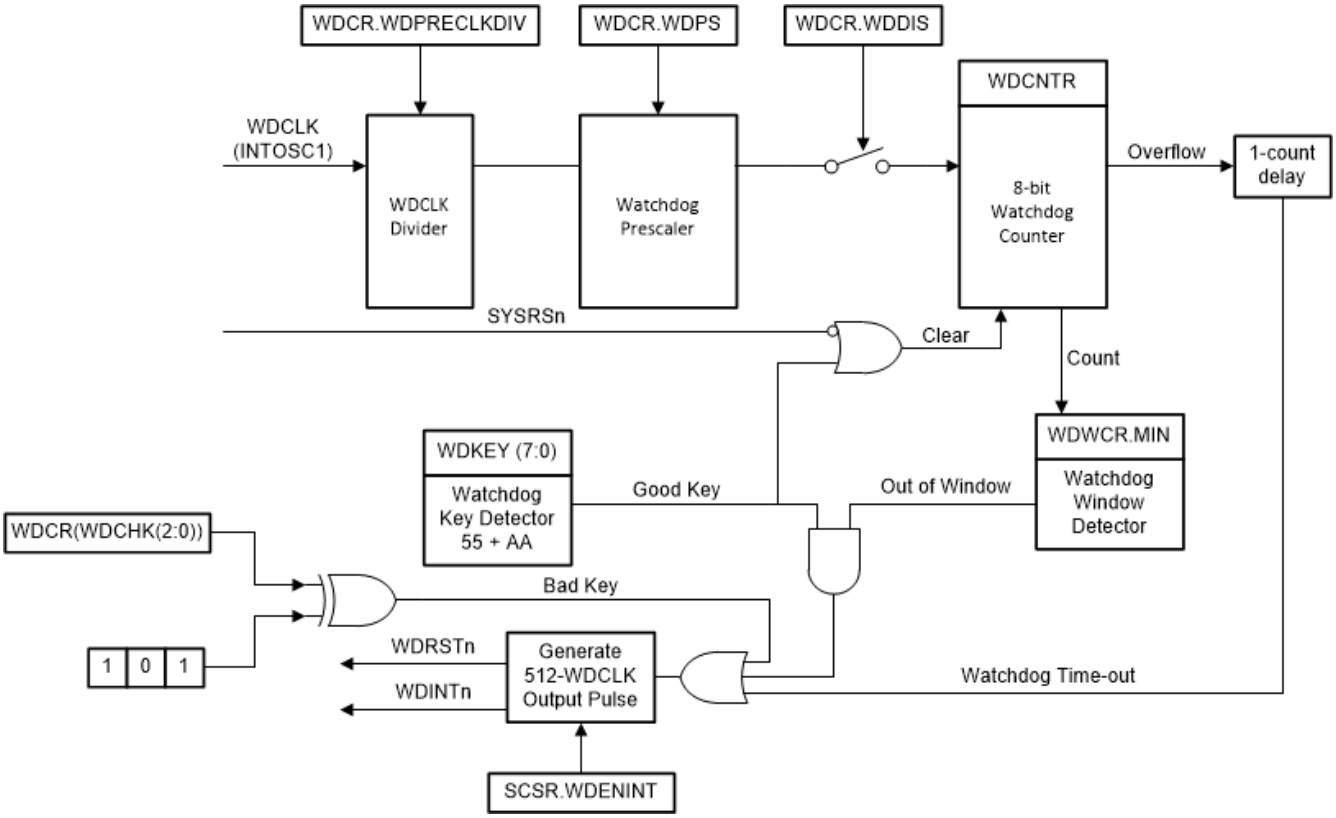

Figure 3-14. Watchdog Timer Module

3.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

The first action that enables the WDCNTR to be reset is shown in Step 3 in Table 3-10. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program can clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

Table 3-10. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

3.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

3.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal pulls the device reset ($\overline{\text{XRS}}$) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the counter asserts an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 INTOSC1 cycles. The falling edge of $\overline{\text{WDINT}}$ triggers a WAKEINT interrupt in the PIE, if the interrupt is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while $\overline{\text{WDINT}}$ is active does not produce a duplicate interrupt.

  To avoid unexpected behavior, software must not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active immediately resets the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active causes a duplicate interrupt, if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

3.9.4 Watchdog Operation in Low-Power Modes

Note

If the watchdog interrupt is used to wake-up from an IDLE low-power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE mode. The $\overline{\text{WDINT}}$ signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt triggers a WAKE interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

In HALT mode, the internal oscillators and watchdog timer are kept active if the user sets CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

3.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended	When the CPU is suspended, the watchdog clock (WDCLK) is suspended.
Run-Free Mode	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode	When the CPU is in real-time run-free mode, the watchdog operates as normal.

3.10 Low-Power Modes

This device has HALT, IDLE, and STANDBY as clock-gating low-power modes.

All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the *TMS320C28x CPU and Instruction Set Reference Guide*.

Low-power modes must not be entered into while a Flash program or erase operation is ongoing. Entering HALT stops all CPU and peripheral activities. This includes active transmissions and control algorithms. When preparing to enter HALT mode, the application must make sure that the system is prepared to enter a period of inactivity.

Before entering HALT mode, check the value of the GPIODAT register of the pin selected for HALT wake-up (GPIOLPMSEL0/1) prior to entering the low-power mode to make sure that the wake event has not already been asserted.

3.10.1 Clock-Gating Low-Power Modes

IDLE and HALT modes on this device are similar to those on other C28x devices. Table 3-11 describes the effect on the system when any of the clock-gating low-power modes are entered.

Table 3-11. Effect of Clock-Gating Low-Power Modes on the Device

Modules/ Clock Domain	IDLE	STANDBY	HALT
SYSCLK	Active	Gated	Gated
CPUCLK	Gated	Gated	Gated
Clock to modules connected to PERx.SYSCLK	Active	Gated	Gated
WDCLK	Active	Active	Gated if CLKSRCCTL1.WDHALTI = 0
PLL	Powered	Powered	Software must power down PLL before entering HALT.
INTOSC1	Powered	Powered	Powered down if CLKSRCCTL1.WDHALTI = 0
INTOSC2	Powered	Powered	Powered down if CLKSRCCTL1.WDHALTI = 0
Flash(1)	Powered	Powered	Powered
XTAL(2)	Powered	Powered	Powered

(1) The Flash module is not powered down by hardware in any LPM. The Flash module can be powered down using software if required by the application. For more information, see the *Flash Module* chapter.
(2) The XTAL is not powered down by hardware in any LPM. The XTAL can be powered down using software by setting the XTALCR.OSCOFF bit to 1. This can be done at any time during the application if the XTAL is not required.

3.10.2 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

The CPU resumes normal operations upon any enabled interrupt event.

3.10.3 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU's SYSCLK. The watchdog however, is left active. STANDBY is best suited for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO can be configured to wake up the CPU when the GPIOs are driven active low. Upon wake up, the CPU receives the WAKEINT interrupt if configured.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from STANDBY mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block.

The CPU is now out of STANDBY mode and can resume normal execution.

3.10.4 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks.

Unlike on other C2000™ devices, HALT mode does not automatically power down the XTAL upon HALT entry. Additionally, if the XTAL is not powered on, waking up from HALT mode does not automatically power on the XTAL. The XTALCR.OSCOFF bit has been added to power on and off the XTAL circuitry when not needed through application software.

For applications that require minimal power consumption during HALT mode, application software can power off the XTAL prior to entering HALT. If the OSCCLK source is configured to be XTAL, the application can first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

Each GPIO can be configured to wake up the system from HALT. No other wake up option is available. However, the watchdog timer can still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wake up, the CPU receives a WAKEINT interrupt.

To enter HALT mode:

1. Enable the WAKEINT interrupt in the PIE.
2. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
3. Set CLKSRCCTL1.WDHALTI to 1 to keep the watchdog timer active and INTOSC1 and INTOSC2 powered up in HALT.
4. Set CLKSRCCTL1.WDHALTI to 0 to disable the watchdog timer and power down INTOSC1 and INTOSC2 in HALT.
5. Execute the IDLE instruction to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system begins executing the WAKEINT ISR. After HALT wake up, ISR execution resumes where execution left off.

Note

Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), the PLL must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device never wakes up.

To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5µs. This activates the WAKEINT PIE interrupt.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL.
3. Wait 16µs plus 1024 OSCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

3.11 Memory Controller Module

On this device, the RAMs have different characteristics. These are:

- Dedicated to the CPU: M0 and M1 RAMs
- Shared between the CPU and CLA: LSx RAMs
- Shared between the CPU, DMA, and NPU: GSx RAMs
- Used to send and receive messages between the processors: MSG RAMs

All these RAMs are highly configurable to achieve control for write access and fetch access from different peripherals. All dedicated RAMs are enabled with the ECC feature (both data and address) and shared RAMs are enabled with the parity feature (both data and address). Some of the dedicated memories are secure memory as well. Refer to Chapter 5 for more details. Each RAM has a controller that takes care of the access protection and security related checks and ECC/Parity features for that RAM. Figure 3-15 shows the configuration of these RAMs.

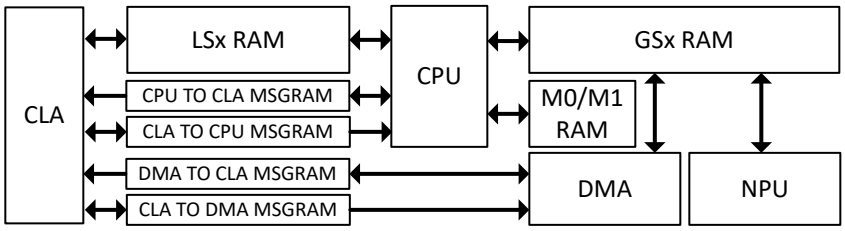

Figure 3-15. Memory Architecture

3.11.1 Functional Description

This section further defines and discusses the dedicated and shared RAMs on this device.

3.11.1.1 Dedicated RAM (Mx RAM)

This device has two dedicated RAM blocks: M0 and M1. M0 and M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories.

All dedicated RAMs have the ECC feature.

3.11.1.2 Local Shared RAM (LSx RAM)

Local shared RAMs (LSx RAMs) are secure memories and have ECC. These memories are shared between the CPU and CLA but are by default dedicated to the CPU only. CLA access can be enabled by configuring MSEL_LSx bit field in the LSxMSEL register.

Further, when these memories are shared between the CPU and CLA, the user can choose to use these memories as CLA program memory by configuring the CLAPGM_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. Table 3-12 shows the LSx RAM features.

Table 3-12. Local Shared RAM

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Read Emulation Write	LSx memory is CLA1 program memory

3.11.1.3 Global Shared RAM (GSx RAM)

RAM blocks that are accessible from the CPU and DMA are called global shared RAMs (GSx RAMs). Table 3-13 shows the features of the GSx RAM.

Table 3-13. Global Shared RAM

CPU (Fetch)	CPU (Read)	CPU (Write)	CPU.DMA (Read)	CPU.DMA (Write)	NPU (Read)	NPU (Write)
Yes	Yes	Yes	Yes	Yes	Yes	Yes

The shared RAM has different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers.

Access protection configuration for the GSx RAM block can be locked by the user to prevent further updates to this bit field. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once a configuration is committed for a particular GSx RAM block, the configuration can not be changed further until CPU.$\overline{\text{SYSRS}}$ is issued.

3.11.1.4 CAN Message RAM

Note

Control of the CAN message RAMs can only be given to the CPU if the MCAN module is not used by the system. The reset source for the MCANRAMACC register is PORSn (Power On Reset) and not XRSn. This is to align the behavior with other CPU controlled RAMs. It is not recommended to change the MCANRAMACC bit once the bit is set, as the contents of the RAM are not compatible with the MCAN module. Even if the MCAN module is only used for boot purposes, it is not recommended to change the ownership to the CPU.

Each MCAN module has 4KB of message RAM embedded locally and exclusively accessible by the MCAN module.

In systems that do not use one or both MCAN modules, there is the ability to re-assign the RAM to the CPU memory domain in data space only. The MCANRAMACC register in the Section 3.16.11 provides control of each MCAN instance RAM assignment individually. Once set, the MCAN module has no access to these RAMs. If the MCAN module is used at all in the system, it is not recommended to allocate this RAM to the CPU.

The C28x is a 16-bit word based CPU, as such the addressable memory is reduced to 2KB in size as shown in Table 3-14.

Table 3-14. Addressable Memory Range for MCAN Message RAMs

MCANRAMACC	MCANA Memory Addresses	MCANB Memory Addresses
0 (owned by MCAN)	0x58000-0x58FFF	0x5A000-0x5AFFF
1 (owned by C28x)	0x58000-0x587FF	0x5A000-0x5A7FF

3.11.1.5 CLA-CPU Message RAM

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

3.11.1.6 CLA-DMA Message RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the "CLA to DMA MSGRAM." The DMA has read and write access to the "DMA to CLA MSGRAM." The CLA and DMA both have read access to both MSGRAMs.

3.11.1.7 Access Arbitration

For a shared RAM, multiple accesses can happen at any given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and alternating scheme is followed to arbitrate multiple access at any given time.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 3-16 represents the arbitration scheme on local shared memories.

Figure 3-17 represents the arbitration scheme on global shared memories

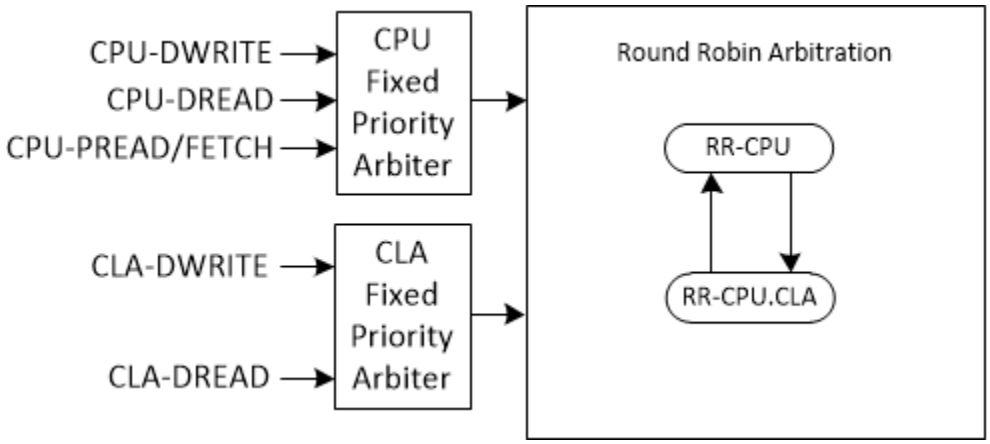

Figure 3-16. Arbitration Scheme on Local Shared Memories

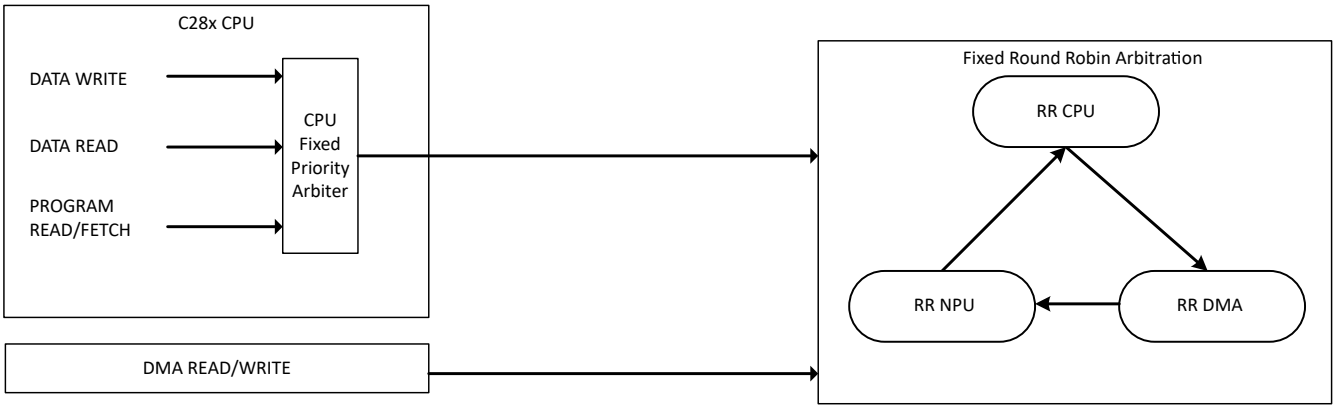

Figure 3-17. Arbitration Scheme on Global Shared Memories

3.11.1.8 Access Protection

All RAM blocks except for M0/M1 have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual controllers. There is no protection for read accesses, hence reads are always allowed from all the controllers which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

Note

For debug accesses, all the protections are disabled.

3.11.1.8.1 CPU Fetch Protection

Fetch accesses from the CPU can be protected by setting the FETCHPROTx bit of the specific register to 1. If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

If a fetch protection violation occurs, the violation results in an ITRAP for the CPU. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU fetch access violation address register.

3.11.1.8.2 CPU Write Protection

Write accesses from the CPU can be protected by setting the CPUWRPROTx bit of the specific register to 1. If write access is done by a CPU to memory where the write is protected, a write protection violation occurs.

If a write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

3.11.1.8.3 CPU Read Protection

If a read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

3.11.1.8.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-controller access violation.

If a CLA fetch protection violation occurs, the violation results in a MSTOP. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the CPU if enabled in the interrupt enable register.

3.11.1.8.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-controller access violation.

If a CLA write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the CPU if enabled in the interrupt enable register.

3.11.1.8.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-controller access violation.

If a CLA read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the CPU if enabled in the interrupt enable register.

3.11.1.8.7 DMA Write Protection

Write accesses from the DMA can be protected by setting the DMAWRPROTx bit of a specific register to 1. If a write access is done by the DMA to protected memory, a write protection violation occurs.

If a write access is made to a dedicated or shared memory by a DMA, and DMAWRPROTx is set to 1 for that memory, the write is called a DMA write protection violation.

A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

Note 1: All access protections are ignored during debug accesses. Write access to a protected memory go through when the write is done using the debugger, irrespective of the write protection configuration for that memory.

Note 2: Access protection is not implemented for M0 and M1 memories.

3.11.1.8.8 NPU Write Protection

Write accesses from the NPU module can be protected by setting the NPUWRPROTx bit of a specific register to 1. If a write access is done by the NPU module to protected memory, a write protection violation occurs.

If a write access is made to a dedicated or shared memory by the NPU module, and NPUWRPROTx is set to 1 for that memory, the write is called a NPU write protection violation.

A flag gets set in the NPU access violation flag register, and the memory address where the violation happened gets latched in the NPU fetch access violation address register. These are dedicated registers for each subsystem.

Note 1: All access protections are ignored during debug accesses. Write access to a protected memory go through when the write is done using the debugger, irrespective of the write protection configuration for that memory.

3.11.1.9 Memory Error Detection, Correction, and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs support error correction code (ECC) protection and the shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECDED). The parity scheme used is even parity. ECC/Parity covers the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bits of data, there are three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

3.11.1.9.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then the correct data is given back as read data. The correct data is also written back into the memory to prevent a double-bit error due to another single-bit error at the same memory address.

3.11.1.9.2 Error Handling

For each correctable error, the count in the correctable error count register increments by one. When the value in this count register becomes equal to the value configured in the correctable error threshold register, an interrupt is generated to the CPU, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into a register and a flag also gets set in a status register.

If there are uncorrectable errors, an NMI gets generated for the CPU. In this case also, the address for which the error occurred gets latched into a register, and a flag gets set in a status register.

Table 3-15 summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

Table 3-15. Error Handling in Different Scenarios

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes - CPU Read Error Address Register Data returned to CPU is incorrect	NMI for CPU access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPU Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Data read from PIE memory	Parity error	Yes - PIE Parity Error sets bit in MEM_CFG_REGS	Bit set in MEM_CFG_REGS
Reads	Address	Address error	Yes - CPU Read Address Error Register Data returned to CPU is incorrect	NMI to CPU for CPU access

Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

3.11.1.10 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications need to make sure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error can be injected into data.

Note

The memory map for ECC/Parity bits and data bits are the same. The user must choose a different test mode to access ECC/Parity bits. In test mode, all access to memories (data as well as ECC/Parity) can be done as 32-bit access only.

Table 3-16 and Table 3-17 show the bit mapping for the ECC/Parity bits when the bits are read in RAMTEST mode using the respective addresses.

Table 3-16. Mapping of ECC Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 3-17. Mapping of Parity Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

3.11.1.11 RAM Initialization

To make sure that a read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and the respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to 1 for the specific RAM block in INIT registers. To check the status of RAM initialization, software must poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access can be made to that RAM memory block.

Note

None of the hosts must access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization does not happen correctly.

3.12 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application can not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable the watchdog), there is a difference in how the application behaves with the debugger and without the debugger.

Common tasks performed by the gel files (but not boot-ROM):

- On Reset:
  - Disable Flash ECC on some devices.
    - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
  - Disable Watchdog
  - Enable CLA clock
  - Select real-time mode or C28x mode
- On Restart:
  - Select real-time mode or C28x mode
  - Clear IER and IFR
- On Target Connect:
  - Select real-time mode or C28x mode

For more information, see *C2000 MCU JTAG Connectivity Debug*.

3.12.1 JTAG Noise and TAP_STATUS

The TAP_STATUS register reflects the status of the JTAG TAP at any given time. Normally when no JTAG is connected to the device, the status can be IDLE. In some cases with excessive PCB noise, there can be unwanted TMS and TCK toggles that take JTAG out of the IDLE state. When persistent, this can ultimately lead to unwanted activation of the JTAG Boundary Scan or some other JTAG mode that can interfere with the intended application. To avoid this scenario, place strong enough pull resistors on the board to prevent noise from activating JTAG. As a debug tool, the TAP_STATUS register can be polled by the application code to detect if this is a cause of device disturbance. The SOFTPRES40[JTAG_nTRST] register can also be used to reset the JTAG TAP through software. Use this reset register with caution, as this prevents connecting a debugger unless the code qualifies writes to this register with some other GPIO state or other means to distinguish between noise and debugger accesses.

The TAP_CONTROL register can be used to disable the TAP state machine's control of the device. Using the TAP_CONTROL register can help to prevent noise from activating JTAG.

3.13 Live Firmware Update

This device includes hardware hooks to streamline firmware updates. These hardware hooks enable seamless switching from the old firmware to the new firmware without resetting the application.

This section discusses the Live Firmware Update (LFU) and the hardware features present on the device to support LFU.

3.13.1 LFU Background

End equipment like Server Power Supply (PSU) are high availability systems that need to have minimum downtime, even during firmware upgrades. Firmware upgrades are essential to add additional functionality, enhance performance and fix software bugs/vulnerabilities. LFU helps update firmware while the application is running, thus eliminating downtime (with respect to critical real-time interrupts) and also providing a more cost-effective alternative compared to manually updating firmware.

LFU has traditionally been implemented in the C2000 family of MCUs using software-only techniques. This impacts LFU switchover time, which is the time to switchover to new firmware once the transition has begun.

User application code initiates this transition, typically by jumping to an entry point in the new firmware. There, a compiler provided initialization routine specific to LFU is called. This initializes user-specified data variables. When execution arrives in main() of the new application, user application code performs minimal initialization to get the new application running.

3.13.2 LFU Switchover Steps

A simplified representation of the LFU switchover is shown in Figure 3-18 and is described in the following steps:

1. In typical systems, a host – typically a PC or another MCU, initiates the LFU (depicted as LFU Request) on the application MCU (in this case, the C2000 MCU) that is executing the real-time control application. This initiates the Flash Program sequence in the application MCU. This runs as a background process even as the application MCU continues executing firmware (depicted as Firmware - 1).
2. Since the compiler can move existing PIE vectors and function pointers to new locations between firmware versions, PIE vectors or function pointers can get added or removed between firmware versions. User application code needs to manage these properly and efficiently during LFU. In the absence of Flash remapping (where different Flash memory banks can be mapped to the same address), PIE vector table remapping, that is “swapping” and RAM memory block swapping are features supported on the device. Without swapping, user application code needs to individually update each PIE vector and each function pointer, adding valuable cycles to the LFU switchover time. With swapping, prior to LFU switchover, user application code can populate a different PIE vector table (depicted as PIE Swap Memory Update) and a different LS RAM region (depicted as LSx Swap Memory Update).
3. When complete (depicted as LFU Switchover – waiting for appropriate time), user application code initiates the transition to new firmware. Once the compiler LFU initialization routine completes and transfers execution to the new application (depicted as Firmware – 2), user application code needs to perform necessary initialization before the new application can begin running. Since PIE vectors and function pointers have already been populated in the “swap” locations, all that is required is a PIE vector table swap and LSx RAM Memory Swap (depicted as PIE Vector Swap, LSx Memory Swap).

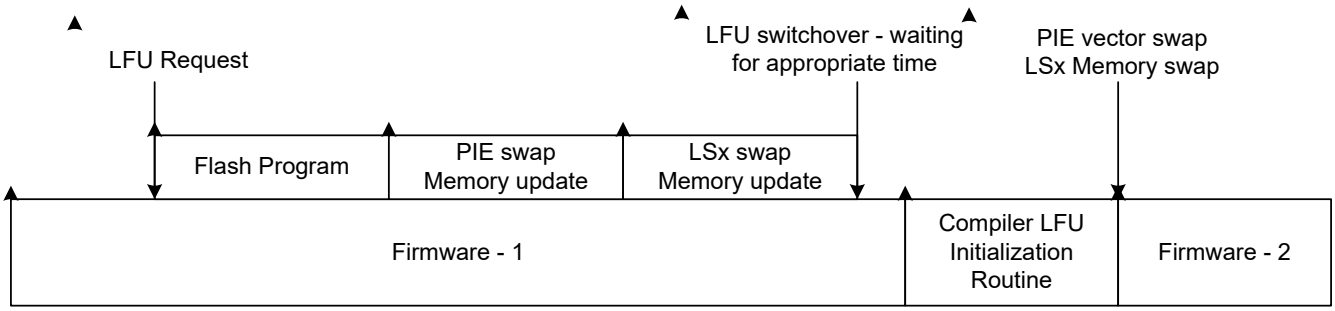

Figure 3-18. Simplified LFU Representation

3.13.3 Device Features Supporting LFU

The new hardware capabilities implemented in the device to support LFU are:

1. Multi-Bank Flash
2. PIE Vector Table Swap
3. LS0/LS1 RAM Memory Swap

3.13.3.1 Multi-Bank Flash

The device has up to five Flash banks, the maximum bank size is 256KB, with support for 128KB and 64KB banks based on the device part number (see the *TMS320F28P55x Real-Time Microcontrollers Data Sheet* for this information). With multiple banks, you can Program/Erase a bank while other banks are in read mode.

3.13.3.2 PIE Vector Table Swap

The device contains an additional PIE vector table, in addition to the typical PIE vector table that is present. This allows PIE vector addresses for the new firmware to be populated prior to the LFU switchover. During LFU switchover, a simple swap operation which activates the PIE vector swap table and deactivates the previously active PIE vector table is initiated by user application code, and this operation takes just 1 CPU clock cycle. To initiate the swap, user application code sets LFUConfig.PieVectorSwap = 1. The PIE vector table swap features are also implemented on a redundant PIE vector table implemented for safety. Therefore, to implement PIE vector table swap, the sizes of PIE vector memory and redundant PIE vector memory are both doubled.

The changes are summarized in Figure 3-19. In this device, there exists a duplicate PIE RAM mapped to a different memory address. There are now two physical PIE vector RAM memories – PIE-1 and PIE-2. By default, PIE-1 is *active*, and mapped to addresses 0x0000_0D00-0x0000_0EFF. PIE-2 is *inactive*, and mapped to addresses 0x0100_0900-0x0100_0AFF.

When user application code initiates a PIE vector table swap by setting LFUConfig.PieVectorSwap = 1, PIE-2 *becomes active*, and is mapped to addresses 0x0000_0D00-0x0000_0EFF. PIE-1 *becomes inactive*, and is mapped to addresses 0x0100_0900-0x0100_0AFF.

Note that the PIE vector RAM active addresses are always 0x0000_0D00-0x0000_0EFF. The inactive addresses are always 0x0100_0900-0x0100_0AFF. As mentioned above, prior to the LFU switchover, user application code needs to write to the inactive addresses with the PIE vector locations corresponding to the new firmware.

The register bit LFUStatus.PieVectorSwap provides the status of Pie Vector Swap.

The PIE vector RAM utilizes a parity scheme to detect address and data errors.

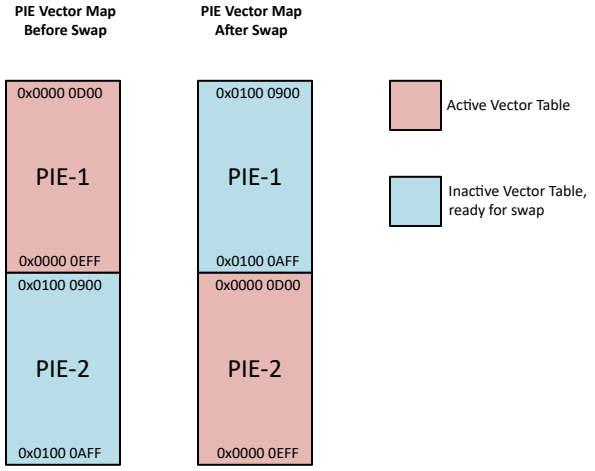

Figure 3-19. PIE Vector Table Swap

3.13.3.3 LS0/LS1 RAM Memory Swap

Similar to PIE Vector Table Swap, LS0 and LS1 physical RAM memory blocks can also be swapped. The memory architecture is similar to PIE vector table swap, and is shown in Figure 3-20. By default, physical Block 1 is assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 2 is assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1). By configuring LFUConfig.LS01Swap = 1, user application code can execute a swap, where physical Block 2 is now assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 1 is now assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1).

If physical memory Block 1 contains function pointers for the current firmware, the same relative locations in physical memory Block 2 can be populated with function pointers for the new firmware prior to LFU switchover. During LFU switchover, a simple swap operation is initiated by user application code, and this operation takes just 1 CPU clock cycle. This allows user application code to always have function pointers in LS0, yet have two different physical blocks that can map to the LS0 address range.

For example, if current firmware contains 10 function pointers present at the start of Block 1 (LS0 address space). If the new firmware contains the same 10 function pointers that now need to be updated, user application code can place these at the start of Block 2 (LS1 address space) prior to LFU switchover. During LFU switchover, user application code executes a LS0/LS1 RAM memory swap, where the physical RAM block previously mapped to the LS1 address space can now be mapped to the LS0 address space, and hence can be used seamlessly for function pointer addressing for the new firmware.

The register bit LFUStatus.LS01Swap provides the status of LS0/LS1 RAM memory swap.

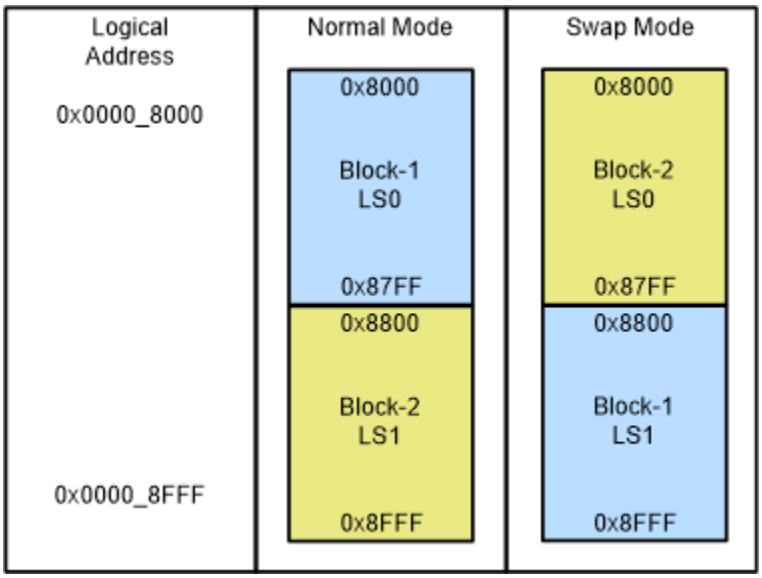

Figure 3-20. LS0/LS1 RAM Memory Swap

Additional points pertaining to LS0/LS1 RAM memory swap are:

1. LFU registers can be accessed from both CPU and CLA.
2. Only LS0 and LS1 blocks can be swapped. LS2 to LS7 blocks cannot be swapped.
3. LS0 and LS1 blocks have parity protection. Address parity is computed based on the physical address and hence the address does not change based on the memory swap.
4. A number of LSx RAM registers are available to the user application code to configure options such as select (LSxMSEL.MSEL_LS0, LSxMSEL.MSEL_LS1), fetch protect (LSxACCPROT0.FETCHPROT_LS0, LSxACCPROT0.FETCHPROT_LS1), write protect (LSxACCPROT0.CPUWRPROT_LS0, LSxACCPROT0.CPUWRPROT_LS1), CLA program memory LSxCLAPGM.CLAPGM_LS0, LSxCLAPGM.CLAPGM_LS1). These register bits indicate the status of the memory block that is deemed as LS0 (CPU address 0x8000 to 0x87FF) and LS1 (CPU address 0x8800 to 0x8FFF) at any point of time. When a LS0/LS1 RAM memory swap occurs, the corresponding control/status bits also automatically swap.
5. Service all pending errors (access violation and parity) associated with the memory before initiating a LS0/LS1 RAM memory swap.
6. LS0/LS1 RAM memory swap shall be initiated only after completion of RAM initialization for both LS0 and LS1 memories (LSxINITDONE.INITDONE_LS0 = 1 and LSxINITDONE.INITDONE_LS1 = 1).

7. LS0/LS1 RAM memory swap shall not be initiated when RAM-test (LSxTEST.TEST_LS0 = 1 or LSxTEST.TEST_LS1 = 1) is in progress for LS0 or LS1 blocks.
8. With DCSM security on the device, in general, LS0 and LS1 RAM blocks can be assigned to different security zones. However, with LS0/LS1 RAM memory swaps, different physical RAM blocks can get mapped to the same address space. Application software shall therefore make sure that both LS0 and LS1 have the same security settings (for example, zone, EXE protection), if there is a plan to implement LS0/LS1 RAM memory swap. Hardware logic is implemented on the device to prevent swap of LS0 and LS1 if the blocks have different security configurations.
9. To prevent security vulnerabilities, LS0/LS1 RAM memory swap is not allowed if the memory swap is initiated by code from a different zone. For example:
   - if LS0 and LS1 are part of Zone1, the swap is not allowed if the code that initiates the swap resides in Zone2 or unsecure zone
   - if LS0 and LS1 are part of Zone2, the swap is not allowed if the code that initiates the swap resides in Zone1 or unsecure zone
   - if LS0 and LS1 are part of the same zone that is unsecure, the swap is allowed in all cases irrespective of where the code that initiates the swap resides
   - if LS0 and LS1 are part of the same zone and is unlocked, the swap can be initiated from code residing anywhere (including from the debugger)
10. Once the swap is initiated, the swap happens in the next cycle, subject to the swap meeting the security requirements previously mentioned. After initiation of a swap, application software shall check if the swap was correctly configured by checking the LFUStatus.LS01Swap status register. Consistency between LFUStatus.LS01Swap and LFUConfig.LS01Swap helps determine if the swap was correctly configured. If LFUStatus.LS01Swap does not match LFUConfig.LS01Swap, LFUConfig.LS01Swap needs to be cleared by user application code.

3.13.3.3.1 Applicability to CLA LFU

The device does not support a swap table for the CLA task vectors (MVECTs). CLA LFU is implemented typically on the CPU side, where the MVECTs are updated sequentially at an appropriate time. The techniques for when to update the MVECTs are described in the LFU system reference design guide, but noted here that the approach is different from the CPU PIE vector table case, where a simple single cycle swap achieves the switch to the new PIE vector table.

For the LS0/LS1 RAM memory swap feature to be useful for CLA LFU switchover, two conditions need to be satisfied:

- CLA code has to fit into a single LSx block. The MVECT table contains CLA task vectors, whose addresses correspond to locations in the LSx block. For example, if the current firmware CLA code is present in LS0, MVECTs point to various locations in LS0. If the new firmware CLA code is present in LS1, MVECTs point to various locations in LS1.
- When switching over from current to new firmware, the MVECTs need to be updated, unless the MVECTs reside at the same relative location in both LS0 and LS1. If that is the case, then simply swapping LS0/LS1 RAM memory blocks effectively updates the MVECT table, without the need to sequentially update the MVECTs.

3.13.4 LFU Switchover

After the new firmware has been programmed to Flash, the user application code needs to determine when appropriate to switchover to the new firmware. The techniques to determine this difference between real-time critical firmware running on the CPU and CLA and these techniques are beyond the scope of this document. The techniques are described in the LFU system reference design guide.

The device supports two register bits that can be set or reset to indicate that LFU switchover is in progress on the CPU (LFUConfig.LFU_CPU) and CLA (LFUConfig.LFU_CLA1). These bits do not impact any hardware logic on the device. For example, LFUConfig.LFU_CPU can be set by user application code at the start of switchover, and then tested in the initialization code in main(). This can enable only LFU switchover specific initialization to be performed (for example, PIE vector table swap, LS0/LS1 RAM memory swap), while bypassing all other initialization that typically happens after a device reset.

3.13.5 LFU Resources

The following are additional LFU resources available:

- *Live Firmware Update Without Device Reset on C2000™ MCUs User's Guide*
- *Live Firmware Update With Device Reset on C2000™ MCUs User's Guide*
- *Live Firmware Update Reference Design with C2000™ Real-Time MCUs*

3.14 System Control Register Configuration Restrictions

Memory-mapped registers in the system control operate on INTOSC1 clock domain. Any CPU writes to these registers requires a delay in between subsequent writes; otherwise, a second write can be lost. The application needs to take this into consideration and add a delay in terms of the number of NOP instructions after every write to the registers listed in Table 3-18. The formula to compute the delay between subsequent writes:

Delay (in SYSCLK cycles) = 3 × (F_{SYSCLK} ÷ $F_{INTOSC1}$) + 9

For Example: for SYSCLK = 100MHz

Delay (in SYSCLK cycles) = 3 × (100MHz ÷ 10MHz) + 9 = 39 SYSCLK cycles

3.15.8 SYSCTL Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.8.1 Missing clock detection (MCD)

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (150Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 150Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

3.15.8.2 XCLKOUT (External Clock Output) Configuration

FILE: sysctl_ex2_xclkout_config.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8. Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO16 using an oscilloscope.

3.15.9 TIMER Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.9.1 CPU Timers

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt. In order to migrate the project within syscfg to any device, click the swtich button under the device view and select your
corresponding device to migrate, saving the project will auto-migrate your project settings.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.9.2 CPU Timers

FILE: timer_ex1_cputimers_sysconfig.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.15.10 MEMCFG Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/memcfg

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.10.1 Correctable & Uncorrectable Memory Error Handling

FILE: memcfg_ex1_error_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable & uncorrectable memory errors has been demonstrated. Correctable memory errors & violations can generate SYS_INT interrupt to CPU while uncorrectable errors lead to NMI generation.

External Connections

- None

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

3.15.11 INTERRUPT Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/interrupt

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.11.1 External Interrupts (ExternalInterrupt)

FILE: interrupt_ex1_external.c

This program sets up GPIO0 as XINT1 and GPIO1 as XINT2. Two other GPIO signals are used to trigger the interrupt (GPIO10 triggers XINT1 and GPIO11 triggers XINT2). The user is required to externally connect these signals for the program to work properly.

XINT1 input is synced to SYSCLKOUT.

XINT2 has a long qualification - 6 samples at 510*SYSCLKOUT each.

GPIO16 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope.

Each interrupt is fired in sequence - XINT1 first and then XINT2

External Connections

- Connect GPIO10 to GPIO0. GPIO0 will be assigned to XINT1
- Connect GPIO11 to GPIO1. GPIO1 will be assigned to XINT2

Monitor GPIO16 with an oscilloscope. GPIO16 will be high outside of the ISRs and low within each ISR.

Watch Variables

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

3.15.11.2 Multiple interrupt handling of I2C, SCI & SPI Digital Loopback

FILE: interrupt_ex2_with_i2c_sci_spi_loopback.c

This program is used to demonstrate how to handle multiple interrupts when using multiple communication peripherals like I2C, SCI & SPI Digital Loopback all in a single example. The data transfers would be done with FIFO Interrupts.

It uses the internal loopback test mode of these modules. Both the TX and RX FIFOs and their interrupts are used. Other than boot mode pin configuration, no other hardware configuration is required.

A stream of data is sent and then compared to the received stream. The sent data looks like this for I2C and SCI:
0000 0001
0001 0002
0002 0003

....
00FE 00FF
00FF 0000
etc..
The sent data looks like this for SPI:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

External Connections

- None

Watch Variables

- *sDatai2cA* - Data to send through I2C
- *rDatai2cA* - Received I2C data
- *rDataPoint* - Used to keep track of the last position in the receive I2C stream for error checking
- *sDataspiA* - Data to send through SPI
- *rDataspiA* - Received SPI data
- *rDataPointspiA* - Used to keep track of the last position in the receive SPI stream for error checking
- *sDatasciA* - SCI Data being sent
- *rDatasciA* - SCI Data received
- *rDataPointA* - Keep track of where we are in the SCI data stream. This is used to check the incoming data

3.15.11.3 CPU Timer Interrupt Software Prioritization

FILE: interrupt_ex3_sw_prioritization.c

This examples demonstrates the software prioritization of interrupts through CPU Timer Interrupts. Software prioritization of interrupts is achieved by enabling interrupt nesting.

In this device, hardware priorities for CPU Timer 0, 1 and 2 are set as timer 0 being highest priority and timer 2 being lowest priority. This example configures CPU Timer0, 1, and 2 priority in software with timer 2 priority being highest and timer 0 being lowest in software and prints a trace for the order of execution.

For most applications, the hardware prioritizing of the interrupts is sufficient. For applications that need custom prioritizing, this example illustrates how this can be done through software.User specific priorities can be configured in sw_prioritized_isr_level.h header file.

To enable interrupt nesting, following sequence needs to followed in ISRs. *Step 1:* Set the global priority: Modify the IER register to allow CPU interrupts with a higher user priority to be serviced. Note: at this time IER has already been saved on the stack. *Step 2:* Set the group priority: (optional) Modify the appropriate PIEIERx register to allow group interrupts with a higher user set priority to be serviced. Do NOT clear PIEIER register bits from another group other than that being serviced by this ISR. Doing so can cause erroneous interrupts to occur. *Step 3:* Enable interrupts: There are three steps to do this: a. Clear the PIEACK bits b. Wait at least one cycle c. Clear the INTM bit. *Step 4:* Run the main part of the ISR *Step 5:* Set INTM to disable interrupts. *Step 6:* Restore PIEIERx (optional depending on step 2) *Step 7:* Return from ISR

Refer to below link on more details on Interrupt nesting in C28x devices:
<C2000Ware>\docs\c28x_interrupt_nesting\html\index.html

External Connections

- None

Watch Variables

- traceISR - shows the order in which ISRs are executed.

3.15.11.4 EPWM Real-Time Interrupt

FILE: interrupt_ex4_epwm_realtime_interrupt.c

This example configures the ePWM1 Timer and increments a counter each time the ISR is executed. ePWM interrupt can be configured as time critical to demonstrate real-time mode functionality and real-time interrupt capability.

The example uses 2 LEDs - LED1 is toggled in the main loop and LED2 is toggled in the EPWM Timer Interrupt. FREE_SOFT bits and DBGIER.INT3 bit must be set to enable ePWM1 interrupt to be time critical and operational in real time mode after halt command

How to run the example?
- Add the watch variables as mentioned below and enable Continuous Refresh.
- Enable real-time mode (Run->Advanced->Enable Silicon Real-time Mode)
- Initially, the DBGIER register is set to 0 and the EPWM emulation mode is set to EPWM_EMULATION_STOP_AFTER_NEXT_TB (FREE_SOFT = 0)
- When the application is running, you will find both LEDs toggling and the watch variables EPwm1TimerIntCount, EPwm1Regs.TBCTR getting updated.
- When the application is halted, both LEDs stop toggling and the watch variables remain constant. EPWM counter is stopped on debugger halt.
- To enable EPWM counter run during debugger halt, set emulation mode as EPWM_EMULATION_FREE_RUN (FREE_SOFT = 2). You will find EPwm1Regs.TBCTR is running, but EPwm1TimerIntCount remains constant. This means, the EPWM counter is running, but the ISRs are not getting serviced.
- To enable real-time interrupts, set DBGIER.INT3 = 1 (EPWM1 interrupt is part of PIE Group 3). You will find that the EPwm1TimerIntCount is incrementing and the LED starts toggling. The EPWM ISR is getting serviced even during a debugger halt.

For more details, watch this video : *C2000 Real-Time Features*

External Connections
- None

Watch Variables
- EPwm1TimerIntCount - EPWM1 ISR counter
- EPwm1Regs.TBCTR.TBCTR - EPWM1 Time Base counter
- EPwm1Regs.TBCTL.FREE_SOFT - Set this to 2 to enable free run
- DBGIER.INT3 - Set to 1 to enable real time interrupt

3.15.12 LPM Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/lpm

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.12.1 Low Power Modes: Device Idle Mode and Wakeup using GPIO

FILE: lpm_ex1_idlewake_gpio.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using XINT1 which triggers on a falling edge of GPIO0.

The GPIO0 pin must be pulled from high to low by an external agent for wakeup. GPIO0 is configured as an XINT1 pin to trigger an XINT1 interrupt upon detection of a falling edge.

Initially, pull GPIO0 high externally. To wake device from IDLE mode by triggering an XINT1 interrupt, pull GPIO0 low (falling edge). The wakeup process begins as soon as GPIO0 is held low for the time indicated in the device datasheet.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the external interrupt ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.12.2 Low Power Modes: Device Idle Mode and Wakeup using Watchdog

FILE: lpm_ex2_idlewake_watchdog.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using watchdog timer.

The device wakes up from the IDLE mode when the watchdog timer overflows, triggering an interrupt. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.12.3 Low Power Modes: Device Standby Mode and Wakeup using GPIO

FILE: lpm_ex3_standbywake_gpio.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode and then wakes up the device from STANDBY using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. Initially, pull GPIO0 high externally. To wake device from STANDBY mode, pull GPIO0 low for at least (2+QUALSTDBY), OSCLKS, then pull it high again.

The example then wakes up the device from STANDBY using GPIO0. GPIO0 wakes the device from STANDBY mode when a low pulse (signal goes high->low->high)is detected on the pin. This pin must be pulsed by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.12.4 Low Power Modes: Device Standby Mode and Wakeup using Watchdog

FILE: lpm_ex4_standbywake_watchdog.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode then wakes up the device from STANDBY using watchdog timer.

The device wakes up from the STANDBY mode when the watchdog timer overflows triggering an interrupt. In the ISR, the GPIO1 is pulled low. the GPIO1 is toggled to indicate the device is out of STANDBY mode. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.12.5 Low Power Modes: Halt Mode and Wakeup using GPIO

FILE: lpm_ex5_haltwake_gpio.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl_turnOffOsc(SYSCTL_OSCSRC_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse.The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.12.6 Low Power Modes: Halt Mode and Wakeup

FILE: lpm_ex6_haltwake_gpio_watchdog.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl_turnOffOsc(SYSCTL_OSCSRC_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse.The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

In this example, the watchdog timer is clocked, and is configured to produce watchdog reset as a timeout mechanism.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.13 WATCHDOG Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

3.15.13.1 Watchdog

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a wakeup interrupt using the watchdog. By default the example will generate a Wake interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections

- None.

Watch Variables

- wakeCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

3.16 SYSCTRL Registers

This Section describes the SYSCTRL Registers.

3.16.1 SYSCTRL Base Address Table

3.16.2 CPUTIMER_REGS Registers

Table 3-27 lists the memory-mapped registers for the CPUTIMER_REGS registers. All register offset addresses not listed in Table 3-27 should be considered as reserved locations and the register contents should not be modified.

Table 3-27. CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		Go
2h	PRD	CPU-Timer, Period Register		Go
4h	TCR	CPU-Timer, Control Register		Go
6h	TPR	CPU-Timer, Prescale Register		Go
7h	TPRH	CPU-Timer, Prescale Register High		Go

Complex bit access types are encoded to fit into small table cells. Table 3-28 shows the codes that are used for access types in this section.

Table 3-28. CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

3.16.2.1 TIM Register (Offset = 0h) [Reset = 0000FFFFh]

TIM is shown in Figure 3-21 and described in Table 3-29.

Return to the Summary Table.

CPU-Timer, Counter Register

Figure 3-21. TIM Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-29. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

3.16.2.2 PRD Register (Offset = 2h) [Reset = 0000FFFFh]

PRD is shown in Figure 3-22 and described in Table 3-30.

Return to the Summary Table.

CPU-Timer, Period Register

Figure 3-22. PRD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-30. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

3.16.2.3 TCR Register (Offset = 4h) [Reset = 0001h]

TCR is shown in Figure 3-23 and described in Table 3-31.

Return to the Summary Table.

CPU-Timer, Control Register

Figure 3-23. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED	
R/W1C-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R-0h	
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 3-31. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 3-31. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

3.16.2.4 TPR Register (Offset = 6h) [Reset = 0000h]

TPR is shown in Figure 3-24 and described in Table 3-32.

Return to the Summary Table.

CPU-Timer, Prescale Register

Figure 3-24. TPR Register

15	14	13	12	11	10	9	8
PSC							
R-0h							
7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

Table 3-32. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

3.16.2.5 TPRH Register (Offset = 7h) [Reset = 0000h]

TPRH is shown in Figure 3-25 and described in Table 3-33.

Return to the Summary Table.

Table 3-36. PIECTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

3.16.3.2 PIEACK Register (Offset = 1h) [Reset = 0000h]

PIEACK is shown in Figure 3-27 and described in Table 3-37.

Return to the Summary Table.

Acknowledge Register
When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.
Writes of 0 are ignored.

3.16.3.3 PIEIER1 Register (Offset = 2h) [Reset = 0000h]

PIEIER1 is shown in Figure 3-28 and described in Table 3-38.

Return to the Summary Table.

Interrupt Group 1 Enable Register
These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).
Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.
Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.3.4 PIEIFR1 Register (Offset = 3h) [Reset = 0000h]

PIEIFR1 is shown in Figure 3-29 and described in Table 3-39.

Return to the Summary Table.

Interrupt Group 1 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.3.11 PIEIER5 Register (Offset = Ah) [Reset = 0000h]

PIEIER5 is shown in Figure 3-36 and described in Table 3-46.

Return to the Summary Table.

Interrupt Group 5 Enable Register
These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).
Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.
Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.3.12 PIEIFR5 Register (Offset = Bh) [Reset = 0000h]

PIEIFR5 is shown in Figure 3-37 and described in Table 3-47.

Return to the Summary Table.

Interrupt Group 5 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.3.19 PIEIER9 Register (Offset = 12h) [Reset = 0000h]

PIEIER9 is shown in Figure 3-44 and described in Table 3-54.

Return to the Summary Table.

Interrupt Group 9 Enable Register
These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).
Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.
Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.3.20 PIEIFR9 Register (Offset = 13h) [Reset = 0000h]

PIEIFR9 is shown in Figure 3-45 and described in Table 3-55.

Return to the Summary Table.

Interrupt Group 9 Flag Register
These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).
When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.
NOTE: PIE IFR flags can be written to create software interrupts.
The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

Complex bit access types are encoded to fit into small table cells. Table 3-63 shows the codes that are used for access types in this section.

Table 3-63. NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.4.1 NMICFG Register (Offset = 0h) [Reset = 0000h]

NMICFG is shown in Figure 3-52 and described in Table 3-64.

Return to the Summary Table.

R-0h							
7	6	5	4	3	2	1	0
NMIWDCNT							
R-0h							

Table 3-68. NMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the SYSCLKOUT rate. Reset type: SYSRSn

3.16.4.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in Figure 3-57 and described in Table 3-69.

Return to the Summary Table.

3.16.5 XINT_REGS Registers

Table 3-76 lists the memory-mapped registers for the XINT_REGS registers. All register offset addresses not listed in Table 3-76 should be considered as reserved locations and the register contents should not be modified.

Table 3-76. XINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XINT1CR	XINT1 configuration register		Go
1h	XINT2CR	XINT2 configuration register		Go
2h	XINT3CR	XINT3 configuration register		Go
3h	XINT4CR	XINT4 configuration register		Go
4h	XINT5CR	XINT5 configuration register		Go
8h	XINT1CTR	XINT1 counter register		Go
9h	XINT2CTR	XINT2 counter register		Go
Ah	XINT3CTR	XINT3 counter register		Go

Complex bit access types are encoded to fit into small table cells. Table 3-77 shows the codes that are used for access types in this section.

Table 3-77. XINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.5.1 XINT1CR Register (Offset = 0h) [Reset = 0000h]

XINT1CR is shown in Figure 3-64 and described in Table 3-78.

Return to the Summary Table.

Table 3-83. XINT1CTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.5.7 XINT2CTR Register (Offset = 9h) [Reset = 0000h]

XINT2CTR is shown in Figure 3-70 and described in Table 3-84.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.6 SYNC_SOC_REGS Registers

Table 3-86 lists the memory-mapped registers for the SYNC_SOC_REGS registers. All register offset addresses not listed in Table 3-86 should be considered as reserved locations and the register contents should not be modified.

Table 3-86. SYNC_SOC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SYNCSELECT	Sync Input and Output Select Register	EALLOW	Go
2h	ADCSOCOUTSELECT	External ADCSOC Select Register	EALLOW	Go
4h	SYNCSOCLOCK	SYNCSEL and EXTADCSOC Select Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-87 shows the codes that are used for access types in this section.

Table 3-87. SYNC_SOC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.6.1 SYNCSELECT Register (Offset = 0h) [Reset = E003FFFFh]

SYNCSELECT is shown in Figure 3-72 and described in Table 3-88.

Return to the Summary Table.

3.16.8 LFU_REGS Registers

Table 3-99 lists the memory-mapped registers for the LFU_REGS registers. All register offset addresses not listed in Table 3-99 should be considered as reserved locations and the register contents should not be modified.

Table 3-99. LFU_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	LFUConfig	LFU configuration Register	EALLOW	Go
2h	LFUStatus	LFU Configuration Status Register		Go
1Ch	LFU_LOCK	LFU Lock Configuration		Go
1Eh	LFU_COMMIT	LFU Commit Configuration		Go

Complex bit access types are encoded to fit into small table cells. Table 3-100 shows the codes that are used for access types in this section.

Table 3-100. LFU_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.8.1 LFUConfig Register (Offset = 0h) [Reset = 00000000h]

LFUConfig is shown in Figure 3-81 and described in Table 3-101.

Return to the Summary Table.

3.16.9.47 MCUCNFLOCK Register (Offset = 1F8h) [Reset = 00000000h]

MCUCNFLOCK is shown in Figure 3-131 and described in Table 3-153.

Return to the Summary Table.

Lock bit for MCUCNFx registers
The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed
Note:
Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

Complex bit access types are encoded to fit into small table cells. Table 3-155 shows the codes that are used for access types in this section.

Table 3-155. CLK_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-155. CLK_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.10.1 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 00000000h]

CLKCFGLOCK1 is shown in Figure 3-132 and described in Table 3-156.

Return to the Summary Table.

Lock bit for CLKCFG registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

3	RESERVED	R/W	0h	Reserved
2	RESERVED	R-0	0h	Reserved

Table 3-157. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT[13:0] register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete.. Notes: [1] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. Reset type: XRSn

3.16.10.3 CLKSRCCTL2 Register (Offset = Ah) [Reset = 00000000h]

CLKSRCCTL2 is shown in Figure 3-134 and described in Table 3-158.

Complex bit access types are encoded to fit into small table cells. Table 3-175 shows the codes that are used for access types in this section.

Table 3-175. CPU_SYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.11.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 00000000h]

CPUSYSLOCK1 is shown in Figure 3-150 and described in Table 3-176.

Return to the Summary Table.

Lock bit for CPUSYS registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

3.16.12 SYS_STATUS_REGS Registers

Table 3-222 lists the memory-mapped registers for the SYS_STATUS_REGS registers. All register offset addresses not listed in Table 3-222 should be considered as reserved locations and the register contents should not be modified.

Table 3-222. SYS_STATUS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
10h	SYS_ERR_INT_FLG	Status of interrupts due to multiple different errors in the system.		Go
12h	SYS_ERR_INT_CLR	SYS_ERR_INT_FLG clear register		Go
14h	SYS_ERR_INT_SET	SYS_ERR_INT_FLG set register	EALLOW	Go
16h	SYS_ERR_MASK	SYS_ERR_MASK register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-223 shows the codes that are used for access types in this section.

Table 3-223. SYS_STATUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.12.1 SYS_ERR_INT_FLG Register (Offset = 10h) [Reset = 00000000h]

SYS_ERR_INT_FLG is shown in Figure 3-196 and described in Table 3-224.

Return to the Summary Table.

Status of interrupts due to multiple different errors in the system.

1AEh	AESA_AC	AES Controller Access Control Register	EALLOW	Go
1FEh	PERIPH_AC_LOCK	Lock Register to stop Write access to peripheral Access register.	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-229 shows the codes that are used for access types in this section.

Table 3-229. PERIPH_AC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.13.1 ADCA_AC Register (Offset = 0h) [Reset = 000000FFh]

ADCA_AC is shown in Figure 3-200 and described in Table 3-230.

Return to the Summary Table.

Based on control settings allows Full, Protected Read, No Access to perpheral from corresponding connected Controller.

Complex bit access types are encoded to fit into small table cells. Table 3-280 shows the codes that are used for access types in this section.

Table 3-280. MEM_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.14.1 DxLOCK Register (Offset = 0h) [Reset = 00000000h]

DxLOCK is shown in Figure 3-249 and described in Table 3-281.

Return to the Summary Table.

3.16.15 ACCESS_PROTECTION_REGS Registers

Table 3-316 lists the memory-mapped registers for the ACCESS_PROTECTION_REGS registers. All register offset addresses not listed in Table 3-316 should be considered as reserved locations and the register contents should not be modified.

Table 3-316. ACCESS_PROTECTION_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	NMAVFLG	Non-Controller Access Violation Flag Register		Go
2h	NMAVSET	Non-Controller Access Violation Flag Set Register	EALLOW	Go
4h	NMAVCLR	Non-Controller Access Violation Flag Clear Register	EALLOW	Go
6h	NMAVINTEN	Non-Controller Access Violation Interrupt Enable Register	EALLOW	Go
8h	NMCPURDAVADDR	Non-Controller CPU Read Access Violation Address		Go
Ah	NMCPUWRAVADDR	Non-Controller CPU Write Access Violation Address		Go
Ch	NMCPUFAVADDR	Non-Controller CPU Fetch Access Violation Address		Go
Eh	NMDMAWRAVADDR	Non-Controller DMA Write Access Violation Address		Go
10h	NMCLA1RDAVADDR	Non-Controller CLA1 Read Access Violation Address		Go
12h	NMCLA1WRAVADDR	Non-Controller CLA1 Write Access Violation Address		Go
14h	NMCLA1FAVADDR	Non-Controller CLA1 Fetch Access Violation Address		Go
1Ch	NMDMARDAVADDR	Non-Controller DMA Read Access Violation Address		Go
20h	MAVFLG	Controller Access Violation Flag Register		Go
22h	MAVSET	Controller Access Violation Flag Set Register	EALLOW	Go
24h	MAVCLR	Controller Access Violation Flag Clear Register	EALLOW	Go
26h	MAVINTEN	Controller Access Violation Interrupt Enable Register	EALLOW	Go
28h	MCPUFAVADDR	Controller CPU Fetch Access Violation Address		Go
2Ah	MCPUWRAVADDR	Controller CPU Write Access Violation Address		Go
2Ch	MDMAWRAVADDR	Controller DMA Write Access Violation Address		Go
3Ah	NMNPURDAVADDR	Non-Controller NPU Read Access Violation Address		Go
3Ch	NMNPUWRAVADDR	Non-Controller NPU Write Access Violation Address		Go

Complex bit access types are encoded to fit into small table cells. Table 3-317 shows the codes that are used for access types in this section.

Table 3-317. ACCESS_PROTECTION_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write

Table 3-317. ACCESS_PROTECTION_REGS Access Type Codes (continued)

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.15.1 NMAVFLG Register (Offset = 0h) [Reset = 00000000h]

NMAVFLG is shown in Figure 3-284 and described in Table 3-318.

Return to the Summary Table.

3.16.16 MEMORY_ERROR_REGS Registers

Table 3-339 lists the memory-mapped registers for the MEMORY_ERROR_REGS registers. All register offset addresses not listed in Table 3-339 should be considered as reserved locations and the register contents should not be modified.

Table 3-339. MEMORY_ERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	UCERRFLG	Uncorrectable Error Flag Register		Go
2h	UCERRSET	Uncorrectable Error Flag Set Register	EALLOW	Go
4h	UCERRCLR	Uncorrectable Error Flag Clear Register	EALLOW	Go
6h	UCCPUREADDR	Uncorrectable CPU Read Error Address		Go
8h	UCDMAREADDR	Uncorrectable DMA Read Error Address		Go
Ah	UCCLA1READDR	Uncorrectable CLA1 Read Error Address		Go
10h	UCNPUREADDR	Uncorrectable NPU Read Error Address		Go
1Ch	FLUCERRSTATUS	Flash read uncorrectable ecc err status		Go
1Eh	FLCERRSTATUS	Flash read correctable ecc err status		Go
20h	CERRFLG	Correctable Error Flag Register		Go
22h	CERRSET	Correctable Error Flag Set Register	EALLOW	Go
24h	CERRCLR	Correctable Error Flag Clear Register	EALLOW	Go
26h	CCPUREADDR	Correctable CPU Read Error Address		Go
28h	CDMAREADDR	Correctable DMA Read Error Address		Go
2Ah	CCLA1READDR	Correctable CLA1 Read Error Address		Go
2Eh	CERRCNT	Correctable Error Count Register		Go
30h	CERRTHRES	Correctable Error Threshold Value Register	EALLOW	Go
32h	CEINTFLG	Correctable Error Interrupt Flag Status Register		Go
34h	CEINTCLR	Correctable Error Interrupt Flag Clear Register	EALLOW	Go
36h	CEINTSET	Correctable Error Interrupt Flag Set Register	EALLOW	Go
38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-340 shows the codes that are used for access types in this section.

Table 3-340. MEMORY_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 3-340. MEMORY_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.16.1 UCERRFLG Register (Offset = 0h) [Reset = 00000000h]

UCERRFLG is shown in Figure 3-305 and described in Table 3-341.

Return to the Summary Table.

3.16.17 TEST_ERROR_REGS Registers

Table 3-362 lists the memory-mapped registers for the TEST_ERROR_REGS registers. All register offset addresses not listed in Table 3-362 should be considered as reserved locations and the register contents should not be modified.

Table 3-362. TEST_ERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU_RAM_TEST_ERROR_STS	Ram Test: Error Status Register		Go
2h	CPU_RAM_TEST_ERROR_STS_CLR	Ram Test: Error Status Clear Register		Go
4h	CPU_RAM_TEST_ERROR_ADDR	Ram Test: Error address register		Go

Complex bit access types are encoded to fit into small table cells. Table 3-363 shows the codes that are used for access types in this section.

Table 3-363. TEST_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.17.1 CPU_RAM_TEST_ERROR_STS Register (Offset = 0h) [Reset = 00000000h]

CPU_RAM_TEST_ERROR_STS is shown in Figure 3-326 and described in Table 3-364.

Return to the Summary Table.

Chapter 4

ROM Code and Peripheral Booting

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

4.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for the CPU core, including the boot procedure. This chapter also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See Table 4-1 for details on available boot features for the C28x CPU. Additionally, Table 4-2 shows the sizes of the various ROMs on the device.

For details on the security APIs provided, refer to Section 4.7.10.

Various tables are provided in ROM for use in software library, refer to Section 4.7.7 for more details.

Table 4-1. Boot System Overview

Boot Feature	CPU
Initial boot process	Device reset
Boot mode selection	GPIOs
Boot modes supported	Flash boot Secure Flash boot Firmware update (FWU) Flash boot RAM boot
Peripheral boot loaders supported	Parallel IO SCI / Wait CANFD I2C SPI USB

Table 4-2. ROM Memory

ROM	CPU Size
Unsecure boot ROM	80KB
Secure ROM	16KB
CLA data ROM	8KB

Expert Materials

- *C2000 Software Controlled Firmware Update Process Application Report*

4.2 Device Boot Sequence

Table 4-3 describes the general boot ROM procedure each time the CPU core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to Section 4.7.12 for more details.

Table 4-3. Device Boot ROM Sequence

Step	CPU Action
1	Initialize the device C28x CPU and M0/M1 RAM configuration
2	Initialize the device to use stack addressing mode, initialize DP to lower 64k and clear overflow mode bit
3	Trims are loaded from OTP and device configuration registers are programmed
4	On POR, all CPU RAMs (including GSxRAMs) are initialized. Boot continues once the 2KB RAMs are initialized.
5	Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed.
6	If enabled, the MPOST POR memory test is run. The original clock frequency is NOT restored post MPOST execution.
7	Pull-ups are enabled on unbonded IOs
8	Device calibration is performed, setting the analog trims. Then resets are handled and RAM is checked for initialization completion.
9	The boot mode GPIO pins are polled to determine the boot mode to run. Boot loader is executed based on boot mode/configurations. Refer to Figure 4-1 for a flow chart of the boot sequences.
10	After the application is loaded, the watchdog is enabled before executing application

4.3 Device Boot Modes

This section explains the default boot modes, as well as all the available boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

4.3.1 Default Boot Modes

Table 4-4 shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

Table 4-4. Device Default Boot Modes

Boot Mode	GPIO24 (Default boot mode select pin 1)	GPIO32 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait Boot(1)	0	1
CAN(MCAN-NONFD)	1	0
Flash (USB)(2)	1	1

(1) SCI boot mode is used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.
(2) If the default Flash entry address is not programmed, the boot mode switches to USB Boot for those devices that include the USB peripheral. On devices without a USB, the action is to enter the ITRAP ISR if the default Flash entry address is not programmed. The switch to USB boot is only supported for the default Flash entry address option and not all entry address options.

Refer to Section 4.7.8.1 for functional details of the boot modes.

Refer to Section 4.7.9 for GPIOs used for selecting the boot modes.

Refer to Section 4.4 for details of boot configurations.

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, MCANA, and so on). Whenever these boot modes are referred to in this chapter, such as SCI boot, the boot mode is actually referring to the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boot modes.

4.3.2 Custom Boot Modes

Once the user programs a custom boot table in user OTP, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN_CONFIG location in user OTP. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. You can also customize the boot definition table and indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of user OTP. Table 4-5 shows the options for various boot modes.

Table 4-5. Custom Boot Modes

Boot Mode Number	Boot Modes
0	Parallel
1	SCI / Wait
2	CAN (MCAN-NONFD)
3	Flash
4	Wait
5	RAM
6	SPI
7	I2C
8	CAN-FD (MCAN-FD)
9	USB(If Applicable)
10	Secure Flash
11	FWU Flash

4.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from **zero** boot mode select pins up to **three** boot mode select pins as well as from **one** configured boot mode up to **eight** configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: **Two** BMSPs are required to select between **three** boot mode options)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default that is disabled). Refer to Section 4.4.1 for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0=Boot to Flash, BOOTDEF1=CAN Boot, BOOTDEF2=SCI Boot; all other BOOTDEFx are left as default/nothing). Refer to Section 4.4.2 for all the details on setting up and configuring the custom boot mode table.

Additionally, Section 4.4.3 provides some example use cases on how to configure the BMSPs and custom boot tables.

4.4.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins are customized by the user, by programming the BOOTPIN-CONFIG location (refer to Table 4-6) in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-OTP-BOOTPIN-CONFIG or Z2-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG/Z2-OTP-BOOTPIN-CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use **zero**, **one**, **two** or **three** boot mode select pins as needed.

Note

When using Z2-OTP-BOOTPIN-CONFIG, the configurations programmed in this location take priority over the configurations in Z1-OTP-BOOTPIN-CONFIG. It is recommended to use Z1-OTP-BOOTPIN-CONFIG first and then if OTP configurations need to be altered, switch to using Z2-OTP-BOOTPIN-CONFIG.

Table 4-6. BOOTPIN-CONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description.
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description.
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x0 = GPIO0 0x01 = GPIO1, and so on. Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode.

Note

The following GPIOs cannot be used as a BMSP. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

- GPIO36, GPIO38, GPIO39
- GPIO82 to GPIO210, GPIO216 to GPIO223, GPIO225, GPIO229
- GPIO231 to GPIO235, GPIO237 to GPIO241, GPIO243 to GPIO246
- GPIO248 to GPIO252, and GPIO254

Table 4-7. Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled Boot as defined by the values of BMSP0 and BMSP1

Note

When decoding the boot mode, BMSP0 is the least-significant bit and BMSP2 is the most-significant bit of the boot table index value. It is recommended when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 are selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

4.4.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options. The 64-bit location is located in user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to Section 4.4.3 for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Note

The locations Z2-OTP-BOOTDEF-LOW and Z2-OTP-BOOTDEF-HIGH is used instead of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations when Z2-OTP-BOOTPIN-CONFIG is configured. Refer to Section 4.4.1 for more details on BOOTPIN_CONFIG usage.

Table 4-8. BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	[3:0] BOOT_DEF0 Mode	Set the boot mode number from Section 4.3.2. Any unsupported boot mode causes the device to either go to wait boot (debugger connected) or boot to Flash (standalone).
		[7:4] BOOT_DEF0 Options	Set alternate / additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to Section 4.7.9 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description.
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

4.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

4.4.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.9 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
   - Refer to Section 4.7.2 for the available Flash entry points.

Table 4-9. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

4.4.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.9 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 4-10. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

4.4.3.3 Three Boot Mode Select Pins

This use case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
   - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.9 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
   - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
   - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
   - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.

Table 4-11. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	Wait Boot - Alt (0x24)
3	SPI - Alt3 (0x66)
4	Flash Boot - Alt2 (0x43)
5, 6, 7	Not used in this example

4.5 Device Boot Flow Diagrams

This section details the boot flow diagrams for standalone and emulation boot flows.

4.5.1 Boot Flow

Upon reset, the CPU follows the boot flow shown in Figure 4-1. Depending on whether a JTAG debugger is connected to the device, the CPU either continues booting following the emulation boot flow or the standalone boot flow.

Note

BOR follows same flow as POR.

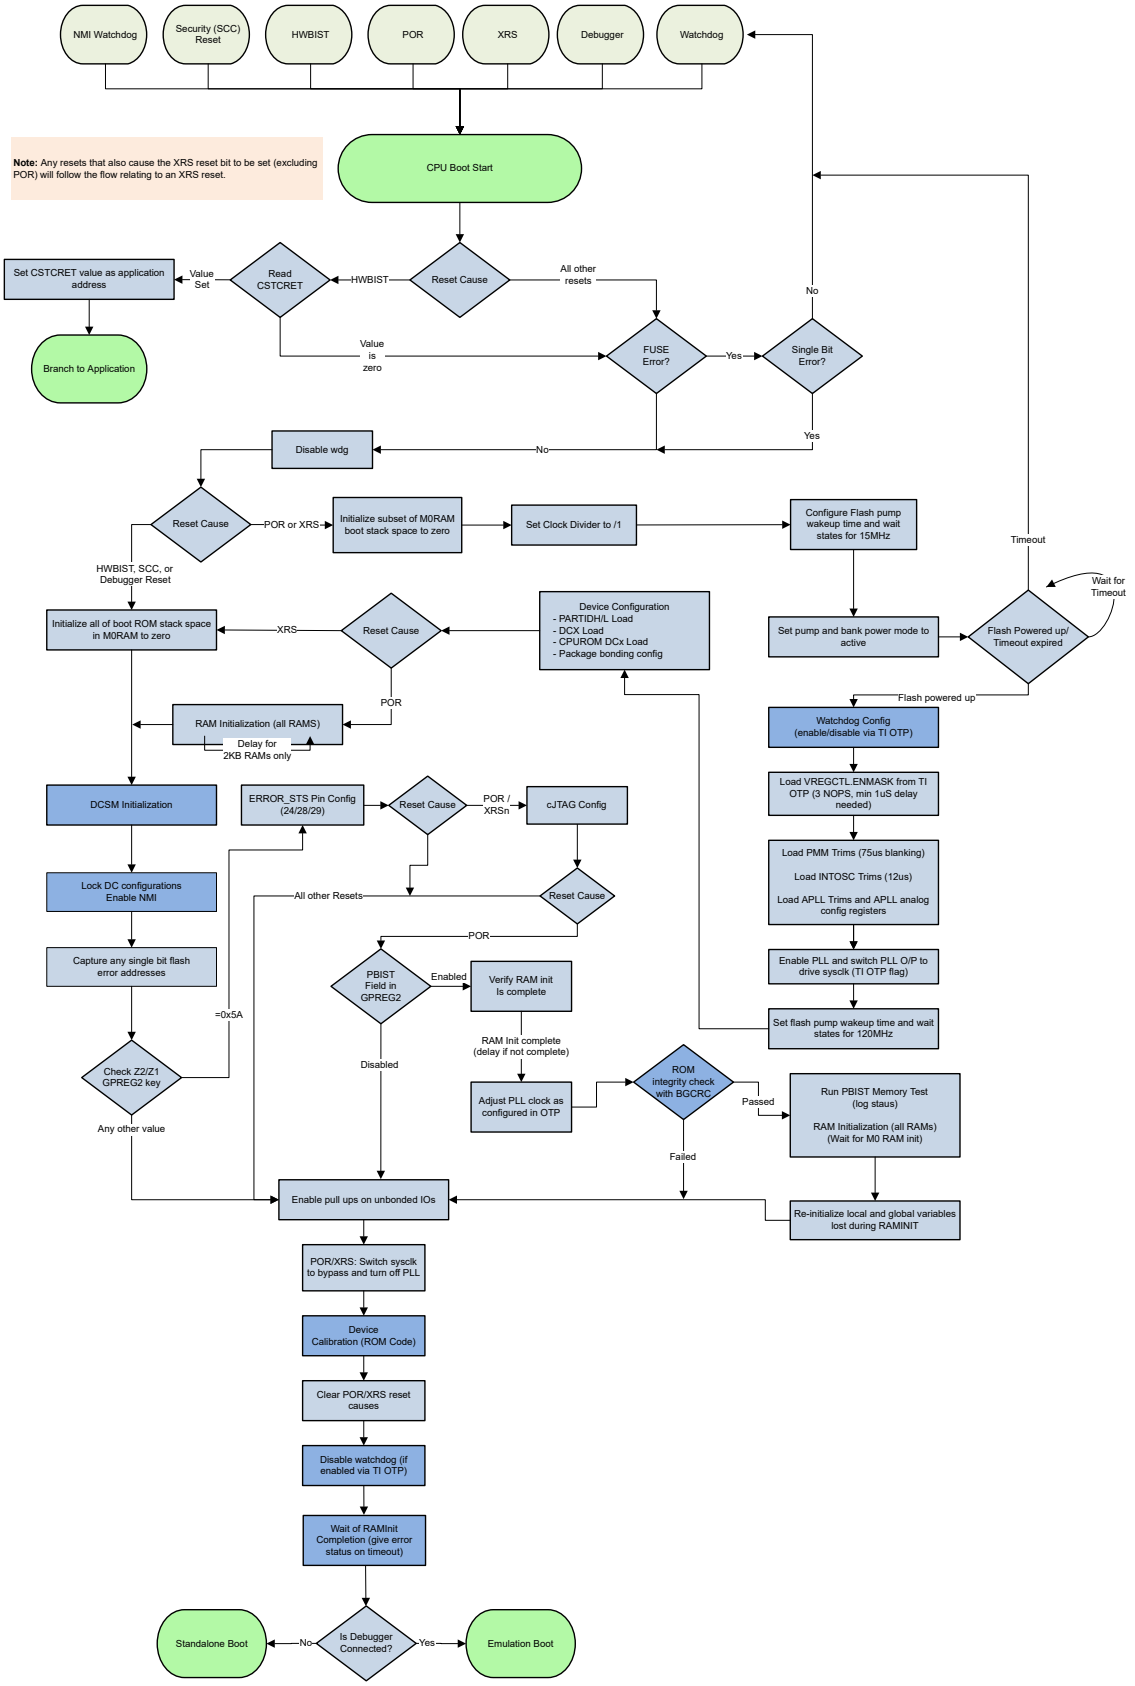

Figure 4-1. Device Boot Flow

4.5.2 Emulation Boot Flow

Figure 4-2 shows the emulation boot flow when JTAG debugger is connected.

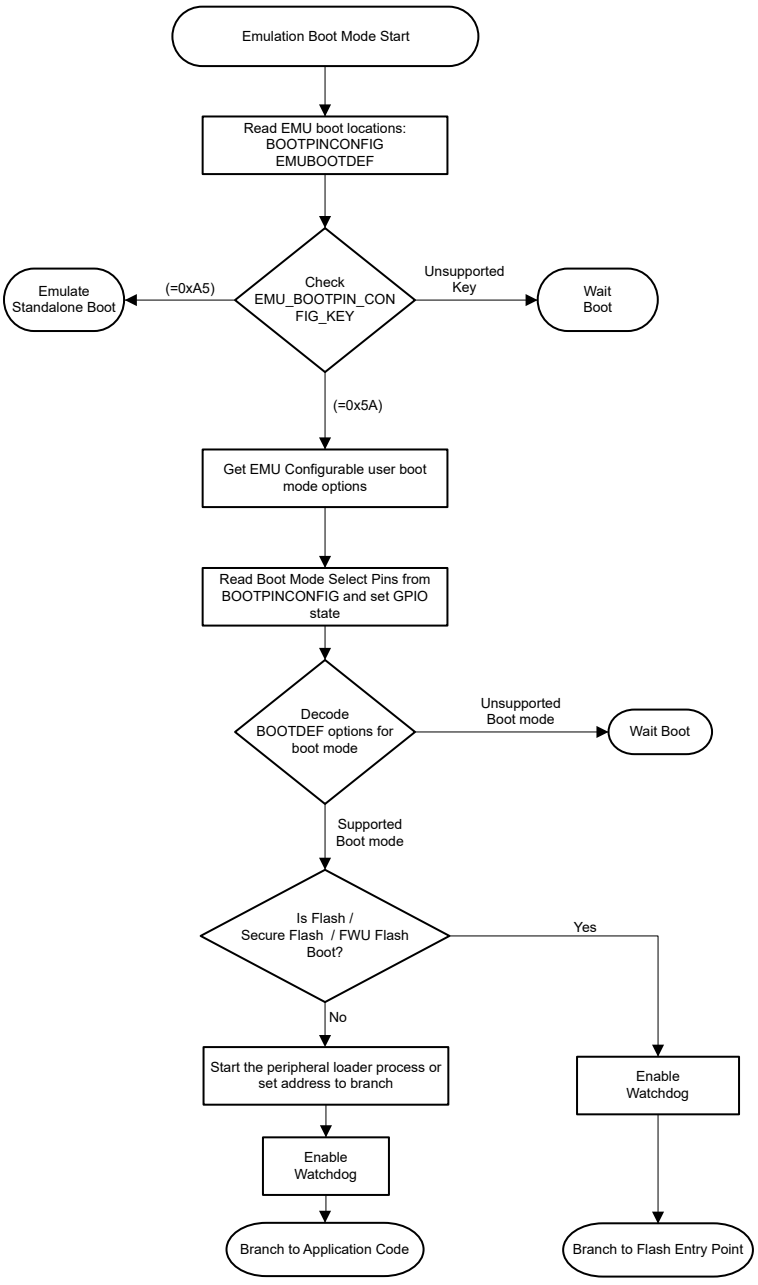

Figure 4-2. Emulation Boot Flow

4.5.3 Standalone Boot Flow

Figure 4-3 shows the standalone boot flow when no JTAG debugger is connected to the device.

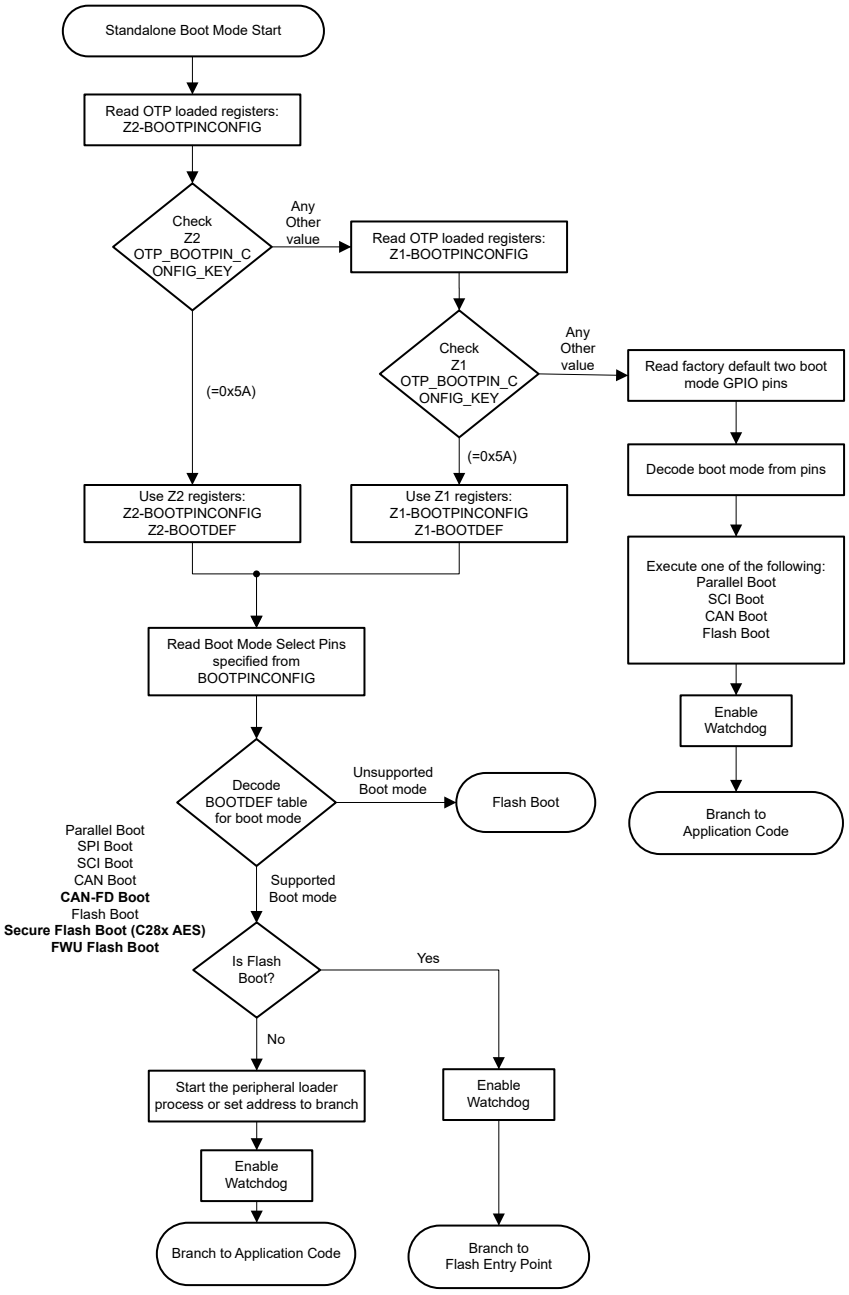

Figure 4-3. CPU Standalone Boot Flow

4.6 Device Reset and Exception Handling

4.6.1 Reset Causes and Handling

Table 4-12 explains the actions each boot ROM performs upon reset for a specific reset cause.

Table 4-12. Boot ROM Reset Causes and Actions

Reset Source	Boot ROM Action
Power-On Reset (POR)	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. Lock PLL and use PLL if configured to do so 5. RAM Initialization 6. Continue default boot flow
External Reset ($\overline{\text{XRS}}$) Includes: • Watchdog Reset ($\overline{\text{WDRS}}$) • NMI Watchdog Reset ($\overline{\text{NMIWDRS}}$) • Simulate External Reset (SIMRESET.$\overline{\text{XRS}}$)	1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. Lock PLL and use PLL if configured to do so 5. Clear boot stack 6. Continue default boot flow
Secure Copy Code Reset ($\overline{\text{SCCRESET}}$)	1. No change to CLK dividers or RAM 2. Clear boot stack 3. Continue default boot flow
Simulate CPU Reset (SIMRESET)	1. No change to CLK dividers or RAM 2. Clear boot stack 3. Continue default boot flow
Debugger Reset ($\overline{\text{SYSRS}}$)	1. No change to CLK dividers or RAM 2. Clear boot stack 3. Continue default boot flow

4.6.2 Exceptions and Interrupts Handling

Table 4-13 explains the actions boot ROM performs if any exceptions occur during boot. The exception handling philosophy in most cases, is to log the error and continue booting to reach the application.

Table 4-13. Boot ROM Exceptions and Actions

Exception Event Source	Boot ROM Action	Event Logged
Clock Fail	Clear the NMI flag and continue to boot	Yes
RAM Uncorrectable Error ROM Parity Error	Perform RAM initialization and reset the device	Yes(1)
Flash Uncorrectable Error	Reset the device	Yes
System Debug (ERAD) NMI	Clear the NMI flag and continue to boot	Yes
RL NMI (CLB)	Clear the NMI flag and continue to boot	Yes
ITRAP Exception	Record memory address of where the illegal instruction was executed and let device reset	Yes
Unsupported PIE Interrupts	Ignore and continue to boot	No
OVF (Over Voltage Fault)	Not in the scope of boot code, let the device reset	No
Software Error	Software Self-test Error (SW writes to the NMI FLAG). Not in the scope of the boot code, let the device reset	No

(1) A RAM uncorrectable error or ROM parity error clears the boot status information stored in RAM because a RAM initialization is performed to attempt to correct the error. Since the boot status information is erased, this exception can be identified in that a NMIWD reset occurred and all the RAMs are erased.

4.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

4.7.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. Table 4-14 details these locations. For bit field configuration details for BOOTPIN-CONFIG and BOOTDEF, see Section 4.4.1 and Section 4.4.2.

Additionally, the boot ROM supports boot configurations from DCSM zone 1 and zone 2 registers. Zone 2 configurations supercede zone 1 configurations, so it is recommended to use zone 1 configurations and use zone 2 as a secondary option.

Table 4-14. Boot ROM Registers

Boot Flow	Register Name	Boot ROM Name	Register Address	User OTP Address
Emulation	-	EMU-BOOTPIN-CONFIG	0x0000 0D00	-
	-	EMU-GPREG2	0x0000 0D02	-
	-	EMU-BOOTDEF-LOW	0x0000 0D04	-
	-	EMU-BOOTDEF-HIGH	0x0000 0D06	-
Standalone (Using Z1)	Z1-GPREG1	Z1-OTP-BOOTPIN-CONFIG	0x0005 F008	0x0007 8008
	Z1-GPREG2	Z1-OTP-BOOT-GPREG2	0x0005 F00A	0x0007 800A
	Z1-GPREG3	Z1-OTP-BOOTDEF-LOW	0x0005 F00C	0x0007 800C
	Z1-GPREG4	Z1-OTP-BOOTDEF-HIGH	0x0005 F00E	0x0007 800E
Standalone (Using Z2)	Z2-GPREG1	Z2-OTP-BOOTPIN-CONFIG	0x0005 F088	0x0007 8208
	Z2-GPREG2	Z2-OTP-BOOT-GPREG2	0x0005 F08A	0x0007 820A
	Z2-GPREG3	Z2-OTP-BOOTDEF-LOW	0x0005 F08C	0x0007 820C
	Z2-GPREG4	Z2-OTP-BOOTDEF-HIGH	0x0005 F08E	0x0007 820E

4.7.1.1 Flash Write Protection

The Z1 GPREG2 register in OTP can selectively enable and disable write protection for selected Flash sectors in Flash banks 0 and 2. When the selected bits are programmed to a value of 0, the corresponding sectors can no longer be erased or programmed. This capability allows the user to create immutable Flash regions and along with the DCSM security module can be used to realize new secure code functions, including authentication algorithms.

Table 4-15 explains how the bit field values from the user configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2 or Z2-OTP-BOOT-GPREG2, are decoded by boot ROM.

Note

Z1-GPREG2 shares ECC with Z1-GPREG1, so users must program both these locations at the same time in User OTP.

Table 4-15. DCSM Z1 GPREG2 Bit Fields

Bit	Name	Description	Boot ROM Action
31:24	Key	Write 0x5A to indicate to the boot ROM code that the bits in this register are valid.	If user sets to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.
23(2)	WPROT_BANK2_SEC_28_31	Write Protect Flash Bank 2 Sectors 28-31	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
22(2)	WPROT_BANK2_SEC_24_27	Write Protect Flash Bank 2 Sectors 24-27	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
21(2)	WPROT_BANK2_SEC_20_23	Write Protect Flash Bank 2 Sectors 20-23	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
20(2)	WPROT_BANK2_SEC_16_19	Write Protect Flash Bank 2 Sectors 16-19	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
19(2)	WPROT_BANK2_SEC_12_15	Write Protect Flash Bank 2 Sectors 12-15	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
18(2)	WPROT_BANK2_SEC_8_11	Write Protect Flash Bank 2 Sectors 8-11	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
17(2)	WPROT_BANK2_SEC_0_7	Write Protect Flash Bank 2 Sectors 0-7	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
16(2)	Reserved	Reserved	No Action
15(2)	WPROT_BANK0_SEC_28_31	Write Protect Flash Bank 0 Sectors 28-31	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
14(2)	WPROT_BANK0_SEC_24_27	Write Protect Flash Bank 0 Sectors 24-27	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
13(2)	WPROT_BANK0_SEC_20_23	Write Protect Flash Bank 0 Sectors 20-23	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
12(2)	WPROT_BANK0_SEC_16_19	Write Protect Flash Bank 0 Sectors 16-19	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
11(2)	WPROT_BANK0_SEC_12_15	Write Protect Flash Bank 0 Sectors 12-15	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
10(2)	WPROT_BANK0_SEC_8_11	Write Protect Flash Bank 0 Sectors 8-11	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
9(2)	WPROT_BANK0_SEC_0_7	Write Protect Flash Bank 0 Sectors 0-7	0: Flash sectors cannot be erased or programmed 1: Flash sectors can be erased or programmed
8:7	MPOST(1)	0x0 = Run MPOST with PLL disabled (10MHz internal oscillator) 0x1 = Run MPOST with PLL enabled for 150MHz 0x2 = Run MPOST with PLL enabled for 75MHz 0x3 = Disable MPOST	When configured to a valid value, MPOST POR memory self-test runs on all device memories
6:4	ERROR_STS_PIN configuration	0x0 – GPIO24, MUX Option 13 0x1 – GPIO28, MUX Option 13 0x2 – GPIO29, MUX Option 13 0x3 – ERROR_STS function disabled 0x4 – GPIO55, MUX Option 9 0x5 – GPIO64, MUX Option 13 0x6 – GPIO73, MUX Option 13 0x7 – ERROR_STS function disabled (default)	This indicates which GPIO pin is supposed to be used as ERROR_PIN and boot ROM configures the mux the pin. The ERROR_STS pin mux configuration is locked by the boot ROM, but is not committed.
3:0	CJTAGNODEID	CJTAGNODEID[3:0]	Boot ROM takes this values and programs the lower 4 bits of the CJTAGNODEID register.

(1) If MPOST is configured to run with PLL enabled and the PLL fails to lock, then the MPOST run is skipped. This does not apply, if MPOST is configured to use INTOSC2 with PLL disabled.
(2) Bits 23:9 are only present on Z1 GPREG2 and are reserved for Z2 GPREG2

4.7.1.2 MPOST Configuration

Two separate OTP locations determine if MPOST (Memory Power On Self Test) runs after a Power on Reset (POR) event. The first is the Z1/Z2 GPREG2 that is part of the Z1/Z2 OTP. The second is the Z1/Z2 DIAG location that is part of the Zone Select Block of the OTP. While both locations are in the OTP, and are write once only, the DIAG register is duplicated along with the other locations if the Link-Pointer is incremented.

Table 4-15 explains how the bit field values from the user configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2 or Z2-OTP-BOOT-GPREG2, are decoded by boot ROM.

Note

Z1-GPREG2 shares ECC with Z1-GPREG1, so users can program both these locations at the same time in User OTP.

Table 4-16 explains how the bit field values from the user configurable DCSM OTP location, Z1-DIAG or Z2-DIAG, are decoded by the boot ROM.

Table 4-16. DCSM Z1/Z2 DIAG Bit Fields

Bit	Name	Description	Boot ROM Action
31:6	Reserved	Reserved	No Action
5:4	MPOST_EN	0x0 - Disable MPOST 0x1 - Enable MPOST 0x2 - Disable MPOST 0x3 - Disable MPOST	Value of 1 along with correct value in GPREG2 allows MPOST to run after POR event. All other values disable MPOST.
3:0	Reserved	Reserved	No Action

4.7.2 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 4-17 gives the entry point addresses for Flash boot mode.

Table 4-18 gives the entry point addresses for RAM boot mode.

Table 4-17. Flash Entry Point Addresses

Option	BOOTDEFx Value	Flash Sector	Address	Devices Supported
0	0x03	Bank 0 Sector 0	0x0008 0000	All
1	0x23	Bank 0 Sector 32	0x0008 8000	All
2	0x43	Bank 2 Sector 0	0x000C 0000	All
3	0x63	Bank 2 Sector 32	0x000C 8000	All
4	0x83	Bank 4 Sector 0	0x0010 0000	Device Dependent

Table 4-18. RAM Entry Point Address

Option	BOOTDEFx Value	RAM Entry Point	Package Supported
0	0x05	0x0000 0000	All

4.7.3 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and does not branch to the user application code. The device can enter wait boot mode either through manually being set or because of some issue during boot up. Using wait boot mode is recommended when using a debugger to avoid any JTAG issues. There is an ESTOP provided for debugging during Wait boot.

Table 4-19. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Device Supported
0 (default)	0x04	Enabled	All
1	0x24	Disabled	All

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons. Table 4-20 details the address ranges that the CPU PC register value falls between if the CPU has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- The emulation BOOTPIN_CONFIG key is not equal to 0xA5 or 0x5A.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

Table 4-20. Wait Point Addresses

Address Range	Description
0x3F B8B9-0x3F B8C0	In Wait Boot Mode
0x3F C7D0-0x3F C7D8	In SCI Boot waiting on autobaud lock
0x3F EDFE-0x3F EEC8	In NMI Handler
0x3F EEC9-0x3F EEF9	In ITRAP ISR
0x3F CB96-0x3F CB9A	In Parallel boot waiting for control signal

4.7.4 Secure Flash Boot

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, calculate the golden CMAC tag based on the 16KB Flash memory range and store the CMAC tag along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. When authentication fails, the device is reset.

For the available secure Flash boot entry address options, refer to Section 4.7.2.

For generating the secure Flash golden CMAC tag for CPU, refer to the *TMS320C28x Assembly Language Tools User's Guide* within section "Using Secure Flash Boot on TMS320F2838x Devices" for instructions.

Note

Both the CMAC golden signature and CMAC key are stored in the most-significant double format, but each 32-bit section is in little-endian format.

Key: 2B7E 1516 28AE D2A6 ABF7 1588 09CF 4F3C

(MSB is 2B and LSB is 3C)

CMACKEY0 = 0x2B7E 1516

CMACKEY1 = 0x28AE D2A6

CMACKEY2 = 0xABF7 1588

CMACKEY3 = 0x09CF 4F3C

Make sure that the Flash sector that encompasses the configured Flash entry point and the first 16KB of Flash is assigned to Zone 1 for the core setup for secure Flash boot.

Recommended to use device JTAGLOCK when using secure Flash boot.

APIs for CMAC calculation and authentication is provided as part of ROM. Details are available in Section 4.7.10

Table 4-21. Secure Flash Tag and Key Details

Name	Address	Details
CMAC Golden Tag (128-bit)	**CPU:** *Flash Entry Point Address* + 0x2	Located in Flash, offset from the entry point address, by 2 words (CPU). When CMAC calculations are performed, the golden tag location in memory is considered all 0xF. Refer to Example 4-1 for an example regarding linker configuration on CPU. Lower memory contains the tag most-significant word (MSW) and higher memory contains the least-significant word (LSW). **Example (on CPU):** Tag = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF Address 0x0 = 0x0011 2233 Address 0x2 = 0x4455 6677 Address 0x4 = 0x8899 AABB Address 0x6 = 0xCCDD EEFF
CMAC 128-Bit Key	0x0007 8018	Located in CPU Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3) CMACKEY0 contains the key MSW and CMACKEY3 contains the LSW. **Example:** Key = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF CMACKEY0 = 0x0011 2233 CMACKEY1 = 0x4455 6677 CMACKEY2 = 0x8899 AABB CMACKEY3 = 0xCCDD EEFF
Address Range for CMAC Calculation		Start: Flash Entry Point Address End: Flash Entry Point Address + 16KB

Table 4-22. Secure Flash Entry Point Addresses

Option	BOOTDEFx Value	Flash Sector	Address	Devices Supported
0	0x0A	Bank 0 Sector 0	0x0008 0000	All
1	0x2A	Bank 0 Sector 32	0x0008 8000	All
2	0x4A	Bank 2 Sector 0	0x000C 0000	All
3	0x6A	Bank 2 Sector 32	0x000C 8000	All
4	0x83	Bank 4 Sector 0	0x0010 0000	Device Dependent

Table 4-23. Secure Flash Authentication Failure Actions

CPU	Action on Failed Authentication
C28x CPU	1. Emulation only - Halt debugger (ESTOP) 2. Wait in endless loop (for device reset due to a watchdog reset)

Table 4-24. Secure Flash on all CPUs Recommended Flow

Step	Action
1	Secure Flash boot CPU
2	Any Flash beyond the first 16KB from the entry point that is planned for use can be authenticated by the user using a different CMAC golden tag embedded at an address somewhere within the already authenticated 16KB of Flash.

Example 4-1. Secure Flash CPU1 Linker File Example

```
MEMORY
{
/* Code Start branch to _c_int00 */
BEGIN : origin = 0x80000, length = 0x0002
/* User calculated golden CMAC tag for Flash Sector 0 */
GOLDEN_CMAC_TAG : origin = 0x80002, length = 0x0008
/* Flash Sector 0 containing application code */
FLASH_SECTOR_0 : origin = 0x8000A, length = 0x1FF6
.
.
.
}
```

4.7.5 Firmware Update (FWU) Flash Boot

Firmware Update (FWU) boot mode is required to handle the FWU feature. In this boot mode, the boot loader reads the version number from images present in multiple banks and identifies the latest image. The boot ROM then hands off the execution to the application with the latest version. To support FWU boot mode each Flash bank containing an application image needs a few fields as shown in Table 4-25.

Table 4-25. FWU Application Image Format

Image Address Offset	Content
0x0	Application entry point (32-bit)
0xA	Key (32-bit) Valid Key = 0x5A5A 5A5A
0xC	Firmware version number (32-bit)

Application entry point: This is the code execution start address of the image stored in Flash.

Key: This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A 5A5A. In case all the banks have invalid keys, an error is flagged in the boot_status variable and the program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

Firmware version number: This 32-bit field is the version number of the firmware or application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with the lower version number is the latest application. If all valid images have the same version number, then bank-0 (or the lowest numbered bank) is chosen.

For example, if bank-0 has invalid **Key** and bank-1 and bank-2 have valid keys, then the one having the lowest **Firmware version number** is selected for boot. If both are the same, then bank-1 is selected.

Table 4-26 shows the entry points for FWU boot mode.

Table 4-26. FWU Entry Point Addresses

Option	BOOTDEFx Value	Bank 0	Bank 2
0	0x0B	0x0008 0000	0x000C 0000
1	0x2B	0x0008 8000	0x000C 8000

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

4.7.6 Memory Maps

4.7.6.1 Boot ROM Memory Maps

Table 4-27 details the ROM memory map.

Table 4-27. Boot ROM Memory Map

Memory	Origin Address	Length (Words) - TBD
Boot Code	0x0F AC8C	0x4F74
ROM Signature	0x3F 8000	0x0002
Version	0x3F 8002	0x0004
IQmath Tables	0x3F 8006	0x1674
FPU32 Fast Tables	0x3F 967A	0x081A
FPU32 Twiddle Tables	0x3F 9E94	0x0DF8
Interrupt Handlers	0x3F FC00	0x020E
RTS Lib	0x3F FF0E	0x01A8
CRC Table	0x3F FFB6	0x0008
Vector Table	0x3F FFBE	0x0042

Table 4-28 details the secure ROM memory map.

Table 4-28. Secure ROM Memory Map

Memory	Origin Address	Length
Zone 1 Secure-Copy / CRC Code	0x3F 4C00	0x0600
Zone 1 Secure Flash Boot	0x3F 4000	0x0C00
Zone 2 Secure-Copy / CRC Code	0x3F 5600	0x05F0
Reserved	0x3F 5BF0	0x0010

4.7.6.2 CLA Data ROM Memory Maps

Table 4-29 details the CLA data ROM memory map.

Note

Load refers to the memory addresses where the C28x CPU can view the data. **Run** refers to the CLA memory addresses that the CLA uses to access the data.

Table 4-29. CLA Data ROM Memory Map

Memory	Origin Address	Length (Words)
FFT Tables (Load)	0x0100 1070	0x0800
Data (Load)	0x0100 1870	0x078A
Version (Load)	0x0100 1FFA	0x0006
FFT Tables (Run)	0x0000 F070	0x0800
Data (Run)	0x0000 F870	0x078A
Version (Run)	0x0000 FFFA	0x0006

4.7.6.3 Reserved RAM Memory Maps

Table 4-30 details memory usage in RAM that is reserved for the boot ROM to use. These memory sections can be reserved in the user application.

Table 4-30. Reserved RAM Memory Map

Memory	Description	Origin Address	Length (Words)
RAM	Boot Status, Boot Mode, MPOST Status, Boot Stack	0x0000 0002	0x01BE

4.7.7 ROM Tables

Table 4-31 details the boot ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

Table 4-31. ROM Symbol Tables

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F28P55xCPU_BootROM_Symbols	Under */libraries/boot_rom* in C2000Ware
FPU32 Tables	F28P55xCPU_BootROM_Symbols	
IQmath	F28P55xCPU_IQMathROM_Symbols	

4.7.8 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

4.7.8.1 Boot Modes

Table 4-32 lists the available boot modes that do not involve a peripheral boot loader.

Table 4-32. Boot Mode Availability

Boot Mode	CPU Support
Flash Boot	C28x CPU
RAM Boot	C28x CPU
Wait Boot	C28x CPU
Secure Flash Boot	C28x CPU
FWU Flash Boot	C28x CPU

4.7.8.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to Section 4.7.2 for all the available Flash address options.

4.7.8.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to Section 4.7.2 for all the available RAM address options.

4.7.8.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in Section 4.7.3.

Table 4-33. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Enabled	All
1	0x24	Disabled	All

4.7.8.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to Section 4.8.1.

4.7.8.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as shown in Figure 4-4.

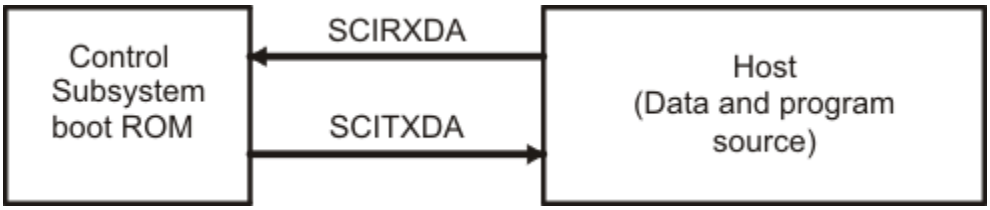

Figure 4-4. Overview of SCI Bootloader Operation

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echoes back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100 kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

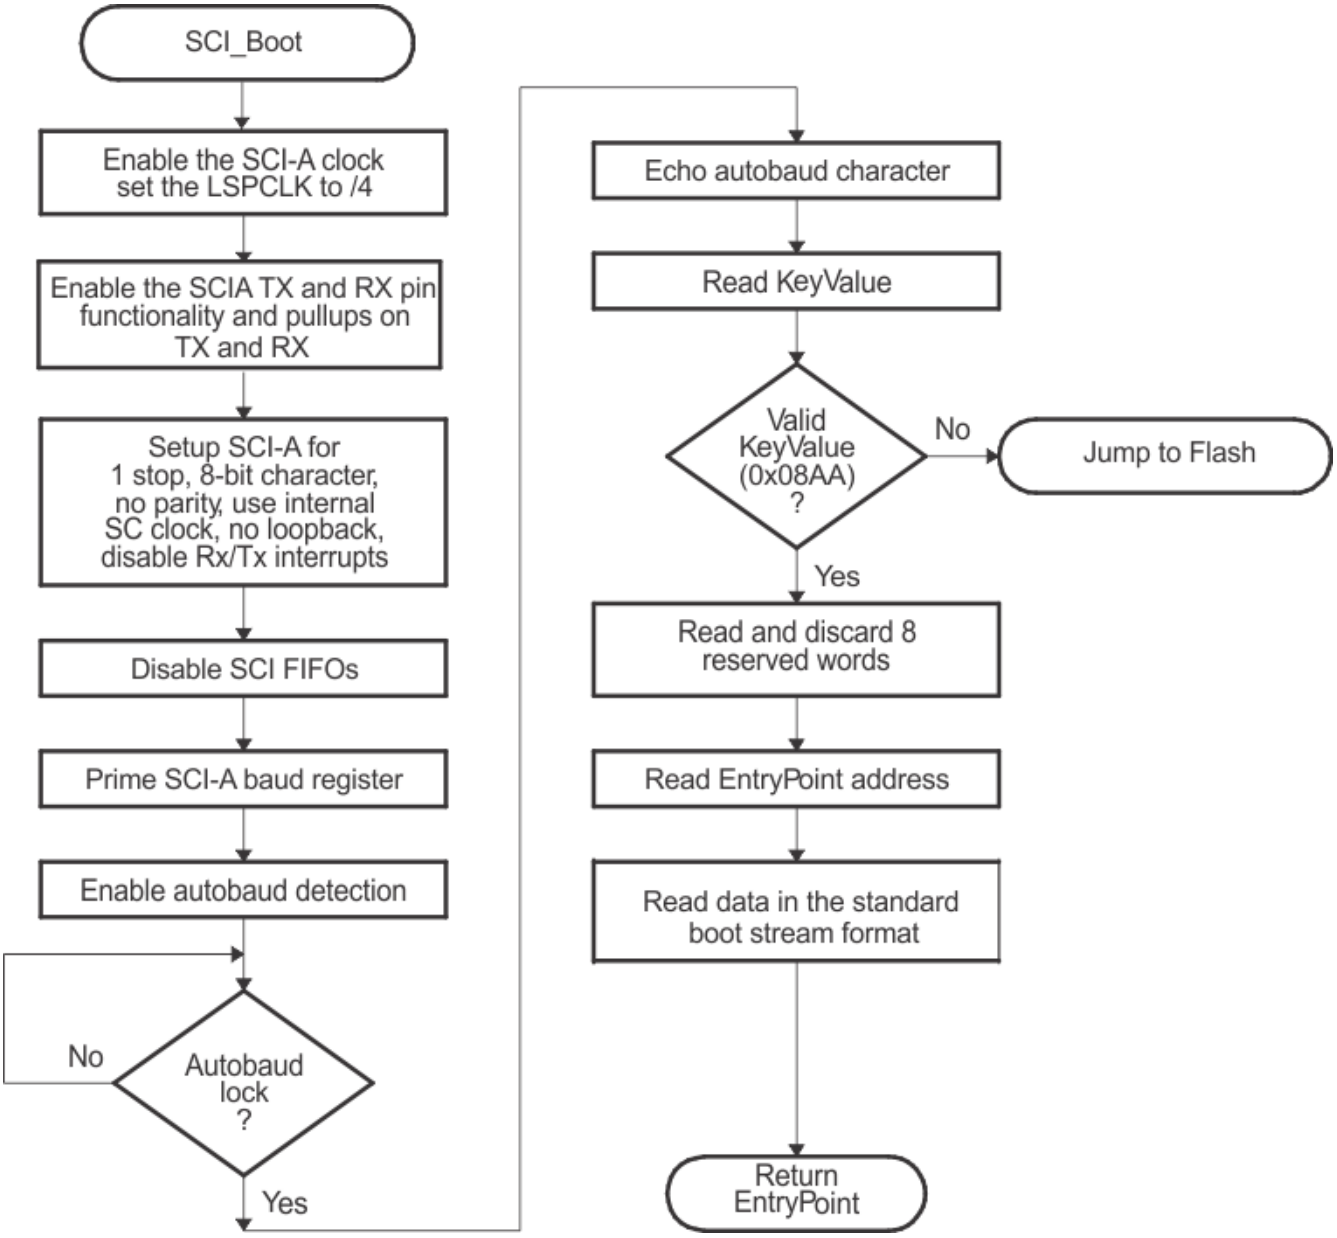

Figure 4-5. Overview of SCI Boot Function

4.7.8.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in Figure 4-6. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

Figure 4-6. Overview of SPI Bootloader Operation

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK controller mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the peripheral mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, you can specify a change in baud rate or low-speed peripheral clock. Table 4-34 shows the 8-bit data stream used by the SPI.

Table 4-34. SPI 8-Bit Data Stream

n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence is:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from Table 4-45, is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least-significant byte of this word is the byte read first and the most-significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

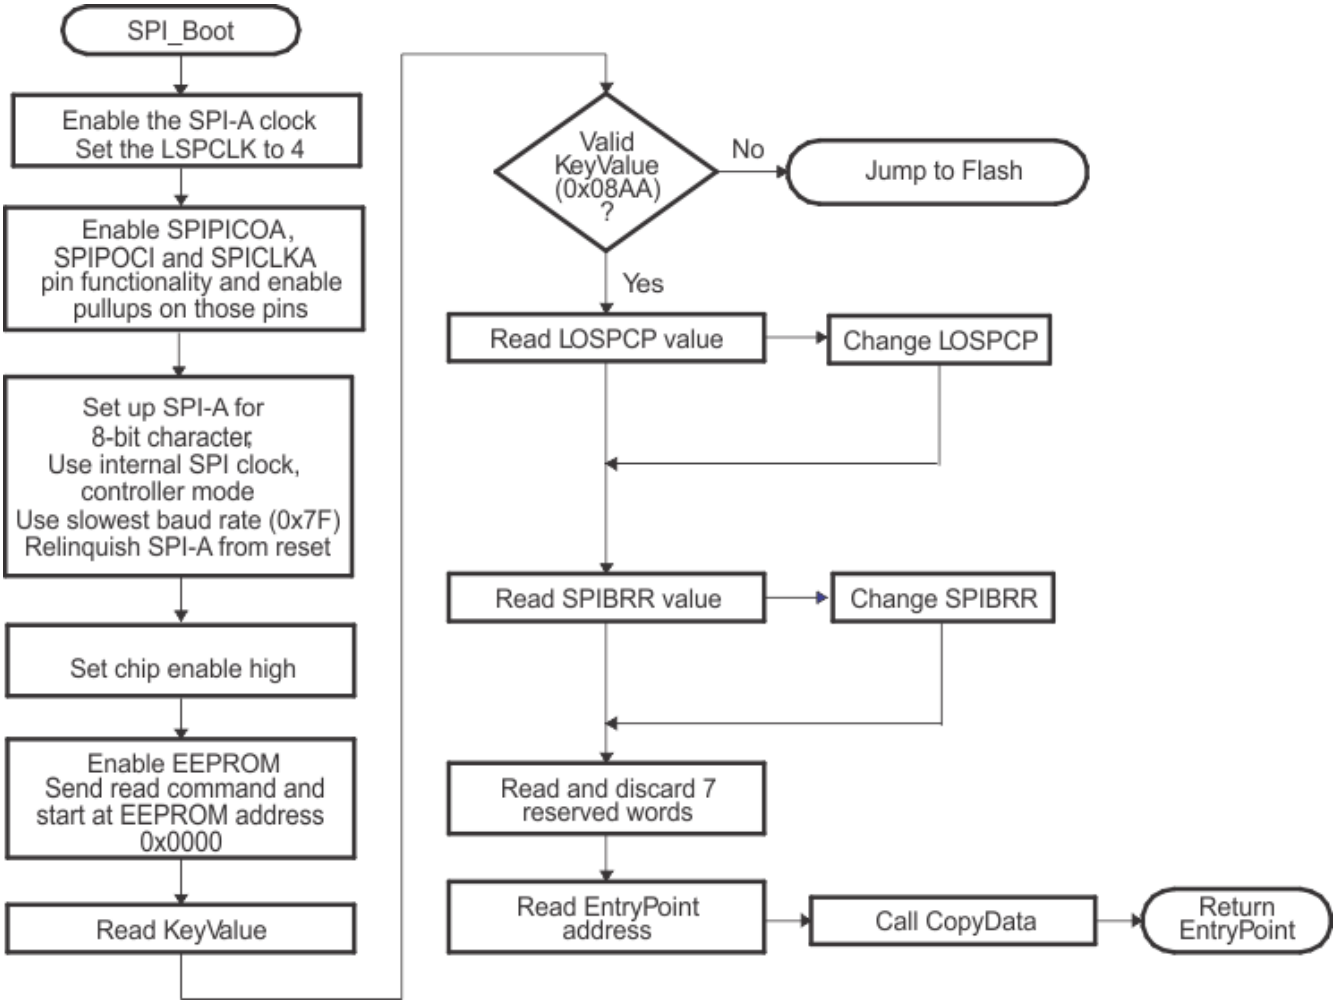

Figure 4-7. Data Transfer from EEPROM Flow

4.7.8.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in Figure 4-8. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

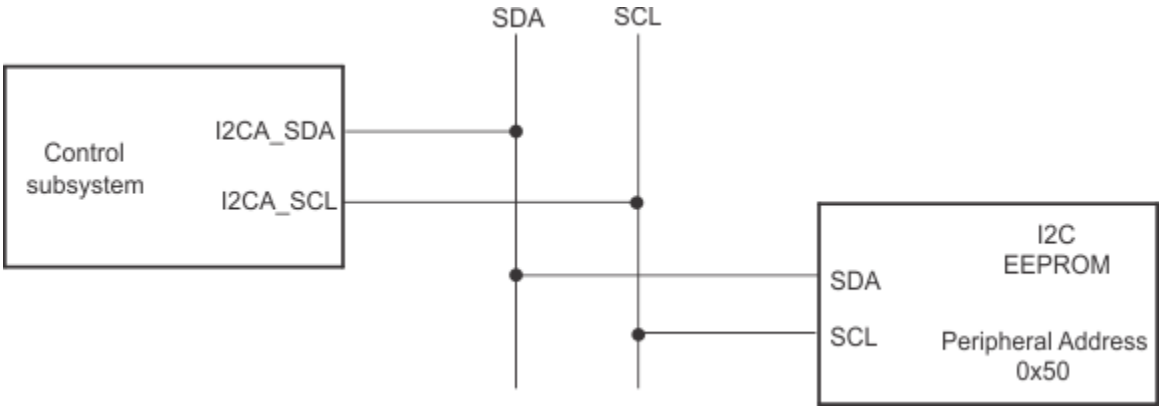

Figure 4-8. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the peripheral mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at peripheral address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and peripheral signals are not checked. Therefore, no other controller is allowed to control the bus during this initialization phase. If the application requires another controller during I2C boot mode, that controller must be configured to hold off sending any I2C messages until the application software signals that the controller is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C_Get Word). If a non-acknowledgment is received during the data read messages, the I2C bus hangs. Table 4-35 shows the 8-bit data stream used by the I2C.

The I2C EEPROM protocol required by the I2C bootloader is shown in Figure 4-10 and Figure 4-11. The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in Figure 4-10. All subsequent reads are shown in Figure 4-11 and are read two bytes at a time.

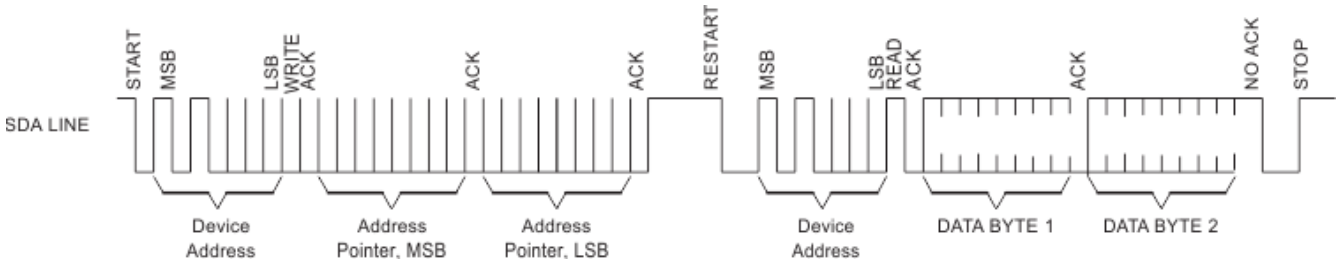

Figure 4-10. Random Read

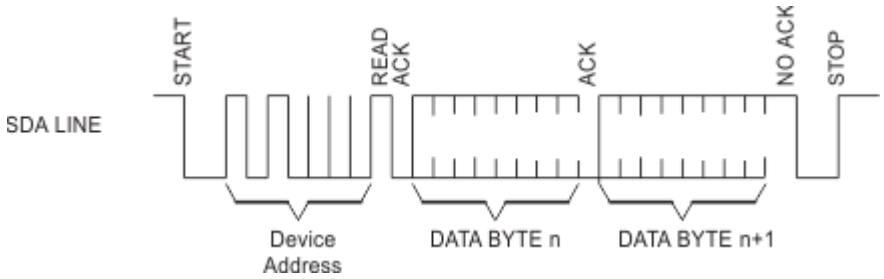

Figure 4-11. Sequential Read

4.7.8.2.4 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from host to C28x internal memory. Each value is 8-bits long and follows the same data flow as outlined in Figure 4-12.

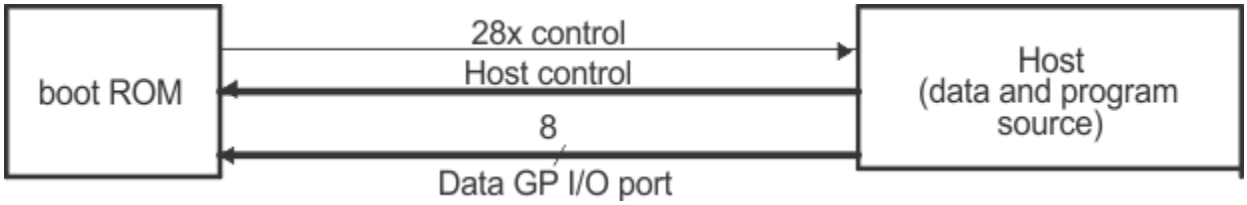

Figure 4-12. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and C28x control lines. The handshake protocol shown in Figure 4-13 must be used to successfully transfer each word using GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the controller subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The 8-bit data stream is shown in Table 4-36.

Table 4-36. Parallel GPIO Boot 8-Bit Data Stream

Bytes		GPIO[D0:D7] (Byte 1 of 2)	GPIO[D0:D7] (Byte 2 of 2)	Description
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	00	00	8 reserved words (words 2 to 9)

29	30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...				...
...				Data for this section.
...				...
.		BB	AA	Last word of the first block of the source being loaded = 0xAABB
.		NN	MM	Block size of the 2nd block to load = 0xMMNN words
.		BB	AA	Destination address of second block Addr[31:16]
.		DD	CC	Destination address of second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
...				…
n	n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that the device is ready to begin data transfer by pulling the C28x control pin low. The host load then initiates the data transfer by pulling the control pin low. The complete protocol is shown in Figure 4-13.

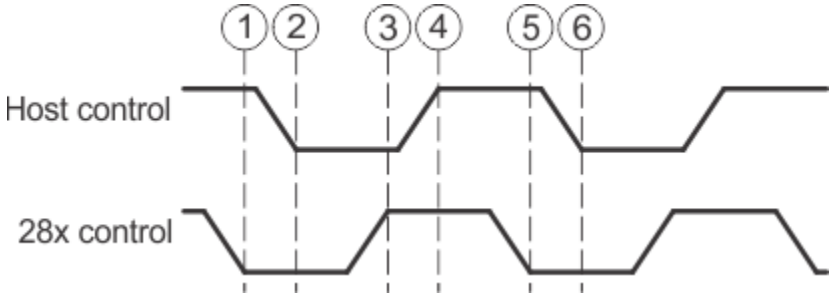

Figure 4-13. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling the control pin high.
4. The bootloader waits until the host acknowledges the device by pulling the host control pin high.
5. The device again indicates the device is ready for more data by pulling the control pin low.

This process is repeated for each data value to be sent.

Figure 4-14 shows an overview of the Parallel GPIO bootloader flow.

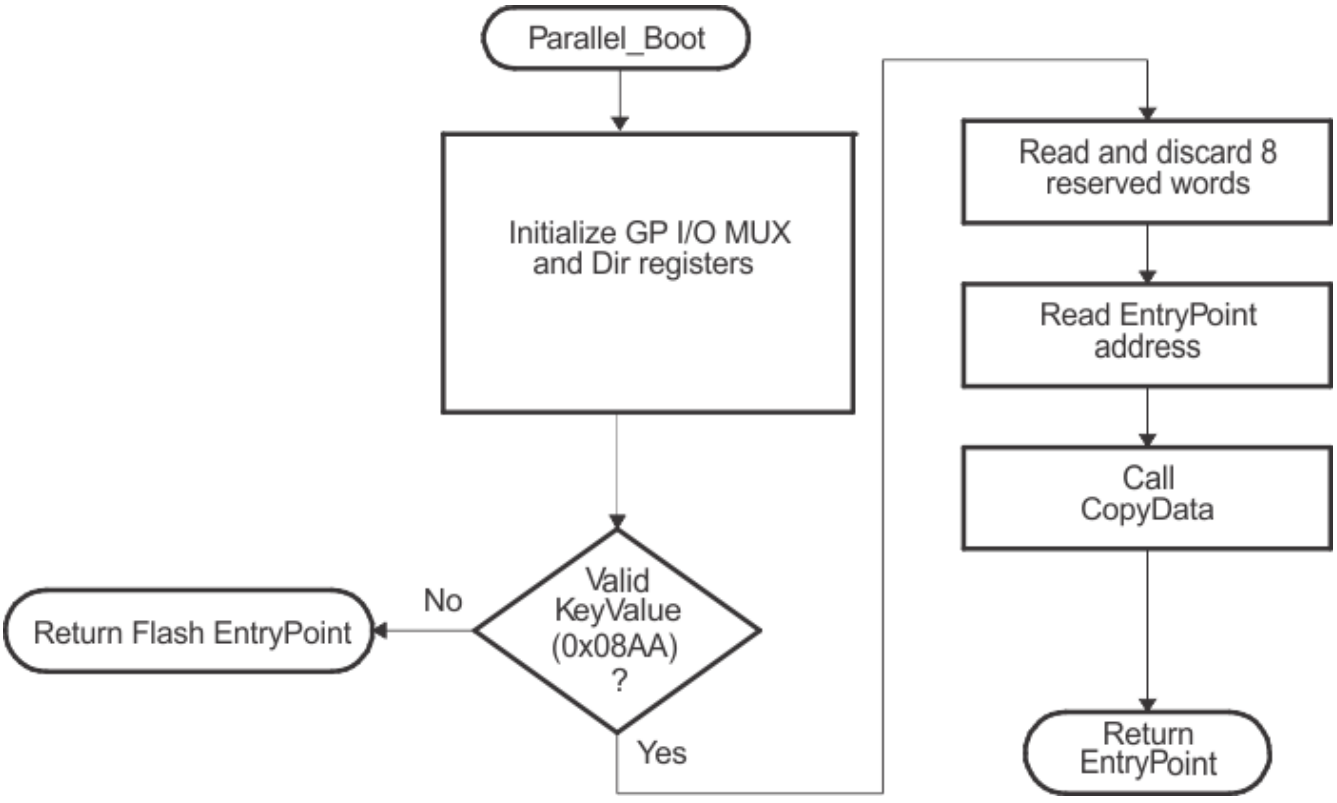

Figure 4-14. Overview of Parallel GPIO Boot Function

Figure 4-15 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host waits for the device and the device waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

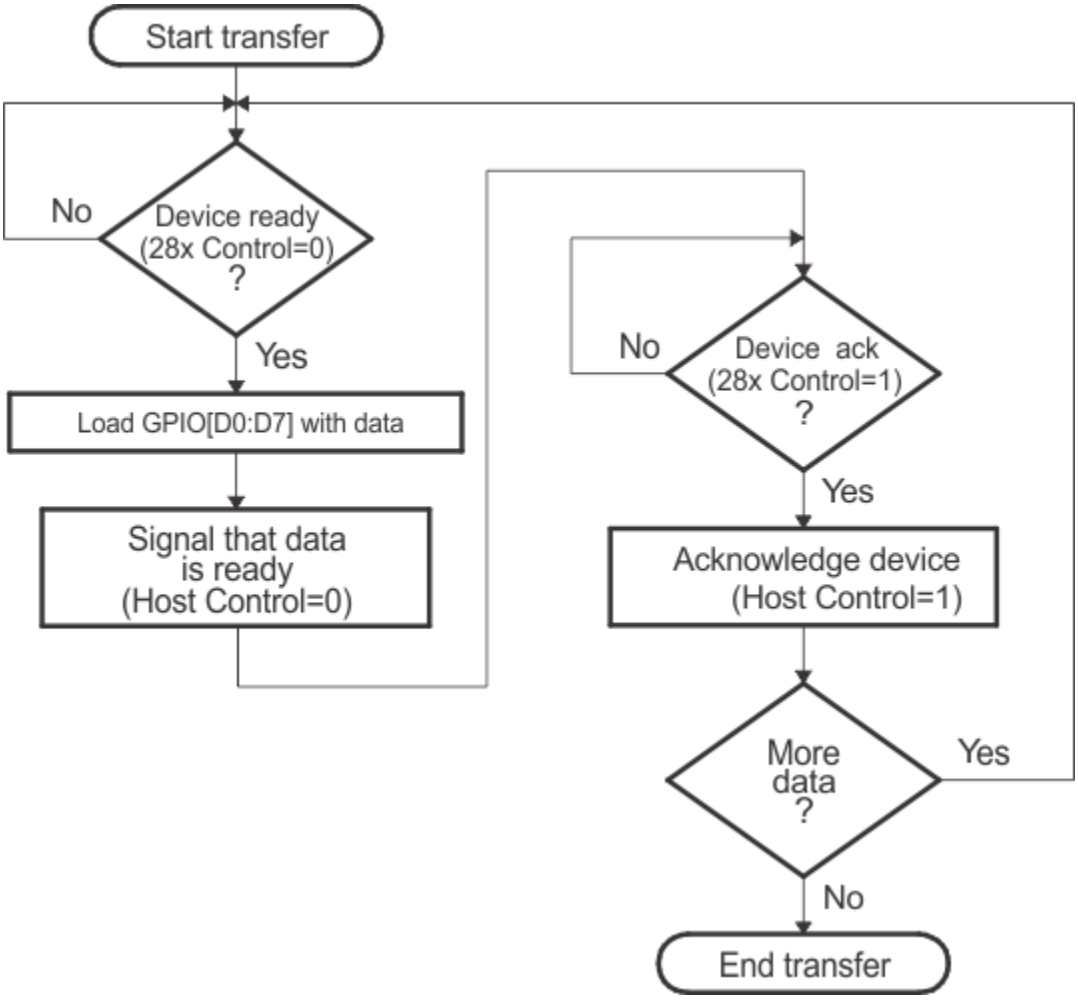

Figure 4-15. Parallel GPIO Mode - Host Transfer Flow

Figure 4-16 shows the flow used to read a single word of data from the parallel port. The 8-bit routine, shown in Figure 4-16, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with D7 in bit position 7 and D6 in bit position 6 as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

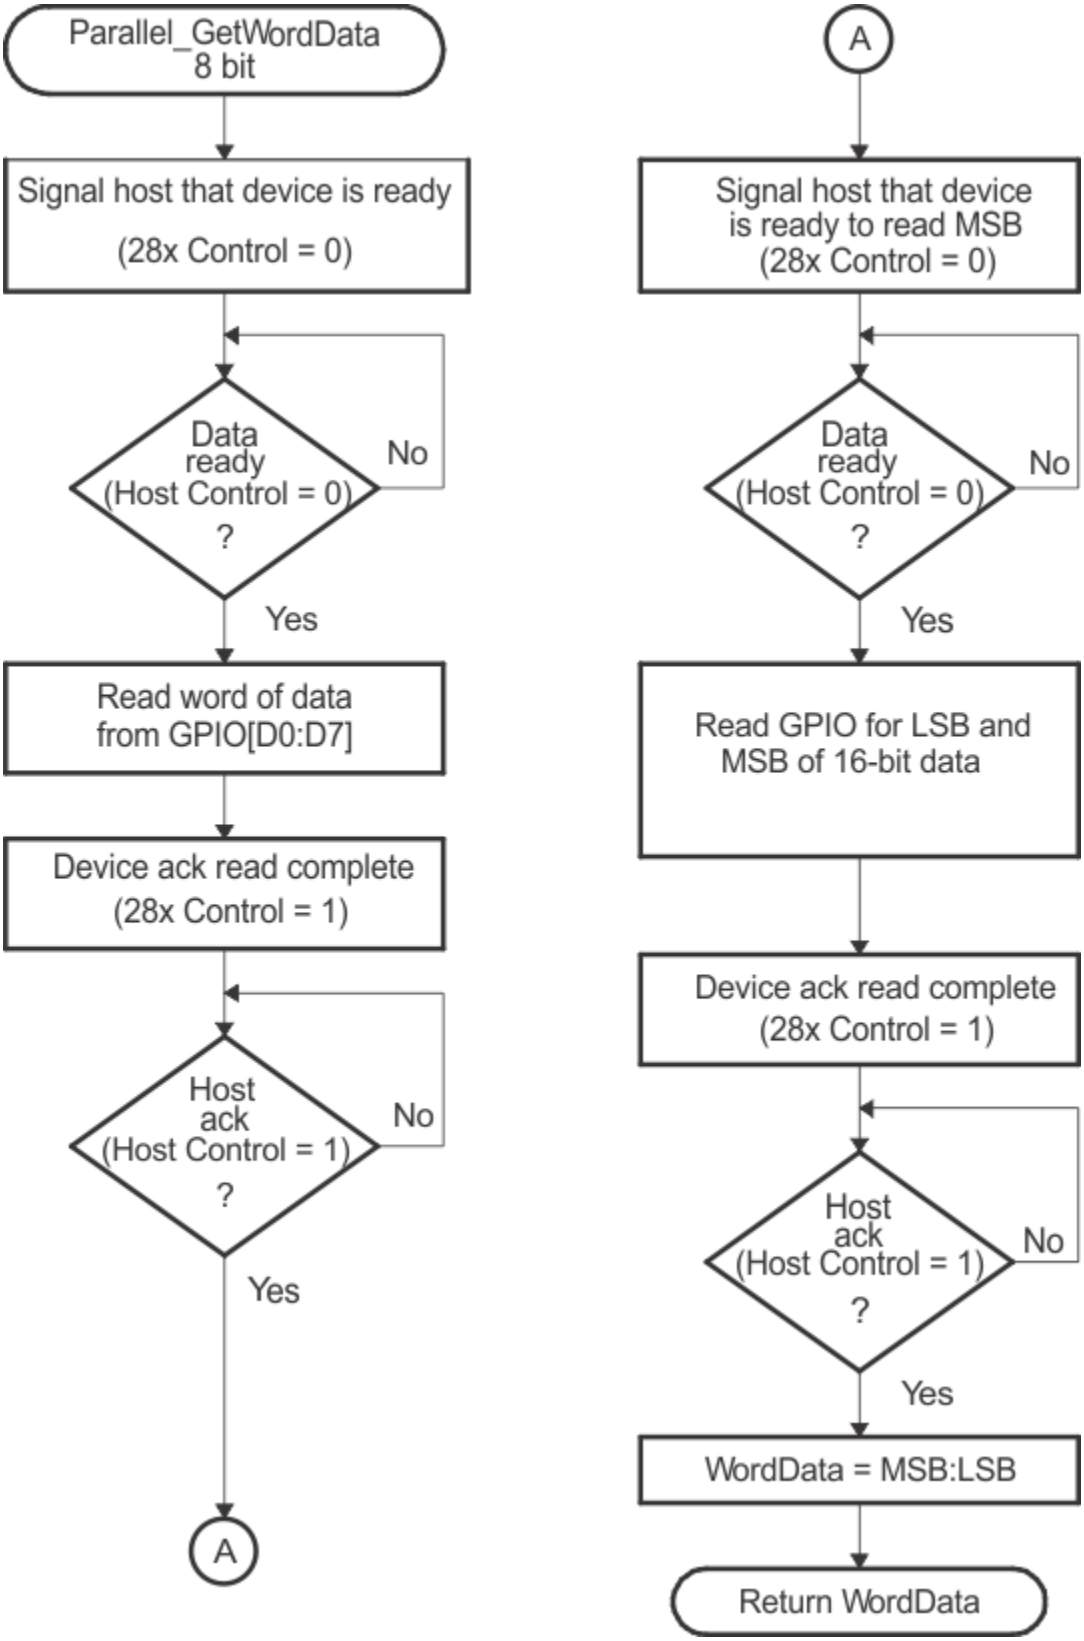

Figure 4-16. 8-Bit Parallel GetWord Function

4.7.8.2.5 CAN Boot Mode (MCAN in non-FD mode)

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in Figure 4-17. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

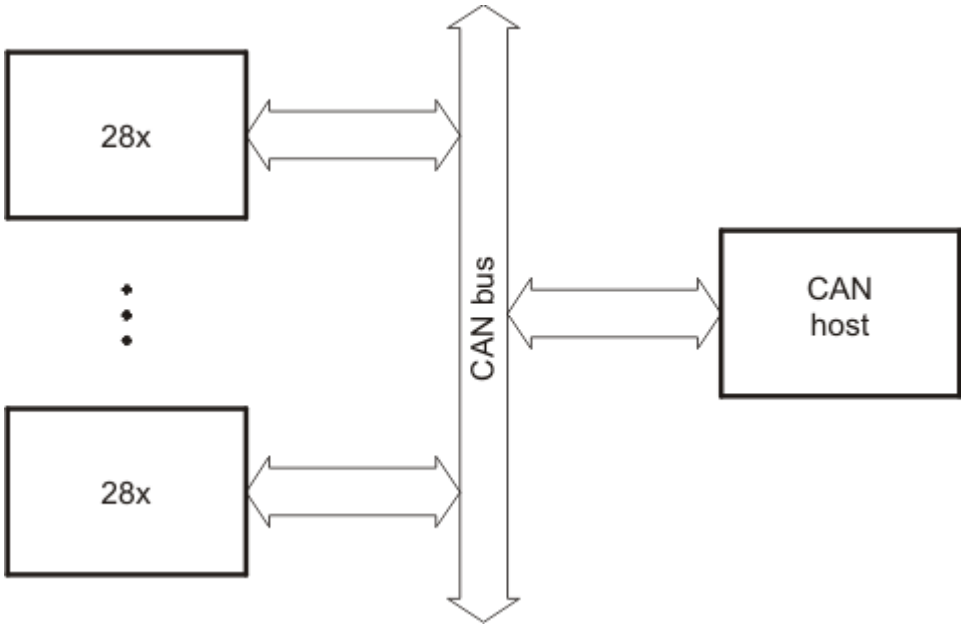

Figure 4-17. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in Table 4-37.

Table 4-37. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCLK	Bit Rate
20MHz	10MHz	100kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Note

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host can transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in Table 4-38.

Table 4-38. CAN 8-Bit Data Stream

4.7.8.2.6 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows same bootloader execution flow as Section 4.7.8.2.5. The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The bootloader uses a fixed 64-byte payload size and default bit rate of 1Mbps for nominal phase and 2Mbps for data phase. Bit data timing can be optionally reconfigured after receiving first data segment. The CAN-FD bootloader supports the same debug boot mode and GPIO option-0 as CAN bootloader.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN-FD host can transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN-FD bootloader is identical to the CAN bootloader. The data sequence for the CAN-FD bootloader is shown in Table 4-39.

Table 4-39. CAN-FD 8-Bit Data Stream

Bytes		Byte 1 of 2	Byte 2 of 2	Description

4.7.8.2.7 USB Boot Mode

Figure 4-18 illustrates the flow for USB boot mode. In USB boot mode, the device enumerates with vendor ID 0x1CBE and product ID 0x00FF. The device descriptor and interface descriptor both show the class as 0xFF (vendor-specific), the subclass as 0x00, and the protocol as 0x00. After enumeration, the device waits for data. Data can be sent using bulk OUT transfers to endpoint 1. The data is interpreted as a series of 8-bit bytes in the standard data stream format described in Section 4.8.1, shown in Table 4-40. No reserved bytes are used. Once the data transfer is complete (block size of 0x0000 sent), the device disconnects from the USB bus, allowing other software to make use of the module if desired.

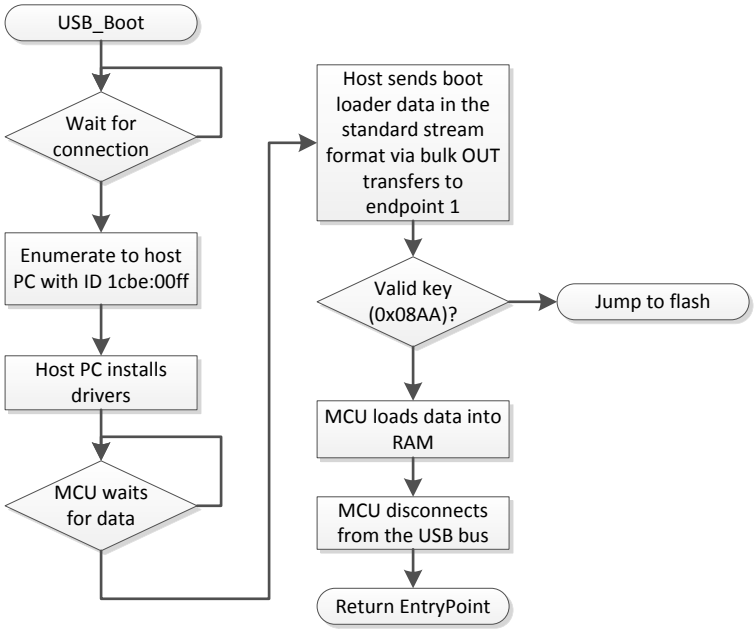

Figure 4-18. USB Boot Flow

n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

Implementing PC-side USB software is not trivial. It is recommended to use the TI-provided tools and drivers to load data in USB boot mode. Hex and binary files for loader tools can be generated from COFF (.out) files using the hex2000 tool. To produce a plain binary file in the boot loader format, use the following command line:

hex2000 -boot -b Program_to_Load.out -o Binary_Loader_Data.dat

For more information on hex2000, see the *TMS320C28x Assembly Language Tools User's Guide*.

Note

INTOSC2 must be enabled before invoking the USB boot loader. If INTOSC2 is not enabled, the boot loader hangs. A debugger reset or SCC reset does not enable INTOSC2, if INTOSC2 has been disabled by the application.

4.7.9 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT_DEF memory location located at Z1-OTP-BOOTDEF-LOW/ Z2-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH/ Z2-OTP-BOOTDEF-HIGH. Refer to Section 4.4.2 on how to configure BOOT_DEF. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Table 4-41. SCI Boot Options

Option	BOOTDEF Value	SCITXDA GPIO	SCIRXDA GPIO	Packages Supported
0 (default)	0x01	GPIO29	GPIO28	All
1	0x21	GPIO16	GPIO17	All
2	0x41	GPIO8	GPIO9	64 pin/80 pin/100 pin/ 128 pin
3	0x61	GPIO2	GPIO3	All
4	0x81	GPIO16	GPIO3	All

Table 4-42. CAN Boot Options

Option	BOOTDEF Value	CANTXA GPIO	CANRXA GPIO
0 (default)	0x02	GPIO4	GPIO5
1	0x22	GPIO1	GPIO0
2	0x42	GPIO13	GPIO12

Note: CAN boot modes are implemented with the MCAN module in "non-FD" mode.

Table 4-43. CAN-FD Boot Options

Option	BOOTDEFx Value	CANTXA GPIO	CANRXA GPIO
0	0x08	GPIO4	GPIO5
1	0x28	GPIO1	GPIO0
2	0x48	GPIO13	GPIO12

Note: These GPIOs are muxed with analog functions, AGPIO share pins. If the system is using these as analog pins during normal operation, extra circuitry needs to be used to support the use of these as boot pins.

4.7.10 Secure ROM Function APIs

There are a few functions that are available within Secure ROM to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

Note

The application must disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28x) while the program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset fires (RSN if from C28x). The consequence of this is if an NMI or ITRAP or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset is fired to the subsystem.

The **secure copy code zone 1 and zone 2 functions** allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

Table 4-48. Secure Copy Code Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	uint16_t **SecureCopyCodeZ1**(uint32_t size, uint16_t *dst, uint16_t *src) uint16_t **SecureCopyCodeZ2**(uint32_t size, uint16_t *dst, uint16_t *src)	*size* : The number of 16-bit words to copy *dst* : The destination memory address in EXEONLY RAM *src* : The source memory address in EXEONLY Flash	0xXXXX : Returns the number of 16-bit words copied 0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash and/or RAM are not set to EXEONLY; Error occurred during data copy

The **secure CRC calculation zone 1 and zone 2 functions** allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

Table 4-49. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	uint16_t **SecureCRCCalcZ1**(uint16_t len_id, uint16_t *dst, uint16_t *src) uint16_t **SecureCRCCalcZ2**(uint16_t size, uint16_t *dst, uint16_t *src)	*len_id* : A number from 1 to 8 which corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words *dst* : The destination memory address for resulting CRC *src* : The source memory address to begin CRC calculation	0xXXXX : Returns the number of 16-bit words CRC'd 0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone; On CM, CRCLOCK is enabled

The **CMAC calculate and compare function** allows to calculate CMAC signature of a Flash memory block and compare against a golden signature. This is used in the secure boot mode to authenticate the boot image.

Table 4-50. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	uint32_t **CPU1BROM_calculateCMAC**(uint32_t startAddress, uint32_t endAddress, uint32_t signatureAddress)	**startAddress**: Starting address of memory for which CMAC has to be calculated **endAddress**: Ending address of memory for which CMAC has to be calculated **signatureAddress**: Address of location where golden CMAC signature is stored	**0xFFFF FFFFU**: Calculated CMAC signature did not match golden signature (fail) **0xA5A5 A5A5U**: Memory range provided is not aligned to 128-bit boundary or length is zero **0xE1E1 E1E1U**: AES Engine timed out **0x0000 0000U**: No Error

4.7.11 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR and XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

Note

CPU performs clock configurations during boot up. If the PLL is used during the boot process, the PLL is bypassed by the boot ROM code before branching to the user application.

Table 4-51. CPU Boot Clock Sources

Source	Frequency	Description
INTOSC2	10MHz	Default clock source
INTOSC1	10MHz	Set as clock source if missing clock is detected at power up or right after device reset.
SYSPLL	150MHz, 75MHz	Enabled optionally as part of main boot flow or as part of MPOST POR memory test boot flow. PLL is bypassed and disabled after memory test has completed. See more details regarding enabling MPOST POR memory test in Section 4.7.1.2.

Table 4-52. CPU Clock State After Boot

Reset Source	Clock State
POR/XRS	1. Using INTOSC2 2. System clock divider set to /1
All other Resets	Maintain clocks setup before device reset.

4.7.12 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

4.7.12.1 Booting Status

Boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, you can clear the status before performing a debugger device reset to view the latest boot ROM actions reflected in the status.

Table 4-53. Boot Status Address

Description	Address
Boot ROM Status	0x0000 0002

Table 4-54. Boot Status Bit Fields

Value	Description
0x8000 0000	HWBIST reset is handled successfully
0x2000 0000	EFuse Single Bit Error
0x1000 0000	FWU Flash Boot Error
0x0800 0000	Flash Verification Error
0x0400 0000	DCSM initialization LP Error
0x0200 0000	DCSM Initialization Invalid LP
0x0100 0000	SYSPLL enabled successfully
0x0080 0000	HWBIST NMI occurred
0x0040 0000	Missing clock NMI occurred
0x0020 0000	RAM Uncorrectable Error NMI occurred
0x0010 0000	Flash Uncorrectable Error NMI occurred
0x0008 0000	RL NMI occurred
0x0004 0000	ERAD NMI occurred
0x0002 0000	Boot ROM detected a PIE mismatch
0x0001 0000	Boot ROM detected an ITRAP
0x0000 8000	Boot ROM has completed running
0x0000 2000	Boot ROM handled POR
0x0000 1000	Boot ROM handled XRS
0x0000 0800	Boot ROM handled all the resets
0x0000 0400	POR memory test has completed
0x0000 0200	DCSM initialization has completed
0x0000 0100	RAM Initialization Complete
0x0000 000C	FWU boot has started
0x0000 000B	Wait boot has started
0x0000 000A	CAN-FD boot has started
0x0000 0009	CAN boot has started
0x0000 0008	I2C boot has started
0x0000 0007	SPI boot has started
0x0000 0006	SCI boot has started
0x0000 0005	RAM boot has started
0x0000 0004	Parallel boot has started
0x0000 0003	Secure Flash boot has started
0x0000 0002	Flash boot has started
0x0000 0001	Boot ROM has started running

4.7.12.2 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow, the boot mode value is written to RAM. Additionally when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the *C2000™ Memory Power-On Self-Test (M-POST) Application Report*.

Table 4-55. Boot Mode and MPOST Status Addresses

Description	Address
Boot Mode	0x0000 0004
MPOST POR Memory Test Result	0x0000 0006

4.7.13 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in Table 4-56. Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0119” represents “01/19” or “January 2019”.

Table 4-56. Boot ROM Version Information

Contents	Address
Revision Number	0x003F 8044
Revision Date	0x003F 8045
Build Number	0x003F 8046

4.8 Application Notes for Using the Bootloaders

4.8.1 Bootloader Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

Table 4-57 and Example 4-2 show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to Section 4.8.2 for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to indicate to the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8- and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA; for a 16-bit data stream, the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to the bootloader. If a bootloader does not use these values, then the values are reserved for future use and the bootloader simply reads the value and then discards the value. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size is 0x000A to indicate 10 16-bit words.

The next two words indicate to the loader the destination address of the block of data. Following the size and address is the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine, which cleans up and exits. Execution then continues at the entry point address as determined by the input data stream contents.

Table 4-57. LSB/MSB Loading Sequence in 8-Bit Data Stream

Byte		Contents	
		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program. Otherwise another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

Example 4-2. Data Stream Structure 8-bit

```
AA 08       ; 0x08AA 8bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00       ; 0x0005 First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 First block is loaded starting at 0x3F9010
01 00       ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00       ; 0x0002 - 2nd block consists of 2 16bit words
3F 00 00 80 ; 0x003F8000 2nd block is loaded starting at 0x3F8000
00 77       ; Data loaded = 0x7700 0x7625
25 76
00 00       ; 0x0000 Size of 0 indicates end of data stream
After load has completed, the following memory values are initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000
```

4.8.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in Section 4.8.1. The hex conversion utility tool, included with the C28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in Example 4-3.

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) differs from one specific application to another and some additional conversion can be required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.** This creates the object files that is then used by the linker to create a single output file.
2. **Link the file.** The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options can be useful:
   - The linker -m option can be used to generate a map file. This map file shows all of the sections that were created, the location in memory, and the length. The map file can be useful to check this file to make sure that the initialized sections are where you expect them.
   - The linker -w option configures the linker to show, if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called .TI.ramfunc.
3. **Run the hex conversion utility.** Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the *TMS320C28x Assembly Language Tools User's Guide* and the *TMS320C28x Optimizing C/C++ Compiler User's Guide* for more information on the compiling and linking process.

Table 4-58 summarizes the hex conversion utility options available for the bootloader. See the *TMS320C28x Assembly Language Tools User's Guide* for a detailed description of the hex2000 operations used to generate a boot table. Updates are made to support the I2C boot. See the Codegen release notes for the latest information.

Table 4-58. Boot Loader Options

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally _c_int00 unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the eight least-significant bits and can be set to maintain an I2C module clock of 7 to 12MHz.
-i2cclkh value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cclkl value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

Example 4-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
Where:
- boot  Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN
        uses the same data format as the GPIO in 8bit mode.
- a     Select ASCII-Hex as the output format.
```

4.9 Software

4.9.1 BOOT Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/boot

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

Chapter 5

Dual Code Security Module (DCSM)

This chapter explains the dual code security module.

5.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device and prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. The DCSM also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory can be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE.

The CSM has dual-zone security, Zone1 (Z1) and Zone2 (Z2).

5.1.1 DCSM Related Collateral

Getting Started Materials

- *C2000 DCSM Security Tool Application Report*
- *C2000 Unique Device Number Application Report*
- *Enhancing Device Security by Using JTAGLOCK Feature Application Report*
- *Secure BOOT On C2000 Device Application Report*

5.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has a dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has a dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, the USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the bank's USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

Table 5-1 shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

The security of each zone is provided by a 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in Section 5.7.4.

There are three types of accesses:

- **Data/program reads:** Data reads to secure memory are always blocked unless the program is executing from a memory that belongs to the same zone. Data reads to unsecure memory are always allowed. Table 5-2 shows the levels of security.
- **JTAG access:** JTAG accesses are always blocked when a memory is secure.
- **Instruction fetches (calls, jumps, code executions, ISRs):** Instruction fetches are never blocked.

CAUTION

Never program any other values in these fields. Failing any of these conditions for a RAM block/ Flash sector makes that RAM block/Flash sector inaccessible.

Table 5-1. RAM/Flash Status

Zone 1 GRABRAMx/GRABSECTx Bits	Zone 2 GRABRAMx/GRABSECT Bits	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11(2)	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11(1)	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure
11(1)	11(2)	RAM block/Flash Sector is unsecure
11	11	RAM block/Flash Sector inaccessible if either of the zone is secure (CSM passwords are programmed). Never leave these values default (11), if CSM passwords are programmed for even one zone.

(1) Zone1 must be unsecure. Assumption in this case is that the user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by the user, hence, Zone1 is always unsecure.
(2) Zone2 must be unsecure. Assumption in this case is that the user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by the user, hence, Zone2 is always unsecure.

Table 5-2. Security Levels

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

5.2.1 CSM Passwords

Unlike earlier C2000™ devices, on this device ALL_1 value (0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL_1 from USER OTP, the device is in BLOCKED state. Due to this reason, TI programs a few bits in the second 32-bit password value (ZxOTP_CSMPSWD1) in every zone select block of each zone with value 0. The default value for this password location is chosen in a manner that the respective ECC value remains ALL_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See Table 5-3 for ZxOTP_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user is able to change this value by flipping the bits that are 1 to 0 but leaving the bits that are already programmed by TI as 0. BOOTROM code writes the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers, which means the zone cannot be unlocked using PMF, see the password match flow described in Section 5.7.2. Therefore, the user can never use ALL_0 as password. A password of ALL_0 prevents debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Table 5-3. Default Value of ZxOTP (Programmed by TI)

Zone Select Block	Zone1 USER OTP		Zone2 USER OTP	
	Address	Value	Address	Value
JLM_ENABLE (JTAGLOCK)	0x0007 8006	0xFFFF 000F	NA	NA
PSWDLOCK	0x0007 8010	0xFB7F FFFF	0x0007 8210	0x1F7F FFFF
CRCLOCK	0x0007 8012	0x7FFF FFFF	0x0007 8212	0x3FFF FFFF
JTAGPSWDH0	0x0007 8014	0x4BFF FFFF	NA	NA
JTAGPSWDH1	0x0007 8016	0x3FFF FFFF	NA	NA
Zone_Select_Block0	0x0007 8022 (CSMPSWD1)	0x4D7F FFFF	0x0007 8222 (CSMPSWD1)	0x1F7F FFFF
Zone_Select_Block0	0x0007 803E (JTAGPSWDL1)	0x2BFF FFFF	NA	NA

5.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected trips the ECSL and breaks the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This disables the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU starts running and can execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL trips and causes the emulator connection to be broken.

The answer to this problem is to use the Wait Boot Mode boot option. In this mode, the CPU is in a loop and does not jump to the user application code. Using this BOOTMODE, you can connect to CCS and debug the code.

5.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

5.2.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

5.2.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone’s PSWDLOCK field with any value other than 1111 (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations are not secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a new device, the value for password lock fields for all zones at the PSWDLOCK location in OTP is 1111, which means the password for all zones is unlocked.

Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone unsecure by running through PMF, user must program PSWDLOCK locations to lock the password before sending the device in field.

5.2.6 JTAGLOCK

Sometimes you want to disable the JTAG access on a device to avoid any debug access to the device. This can be done by using the JTAGLOCK feature on this device. You need to follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time).

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of Z1 USER OTP header and JTAGPSWDL is part of Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. Code Composer Studio has an integrated tool that you need to use to unlock the JTAGLOCK on device.
2. After programming the JTAG passwords, you need to enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP_JLM_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

5.2.7 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists that holds the configuration related to zone's security. The following are user programmable configurations:

- ZxOTP_LINKPOINTER1
- ZxOTP_LINKPOINTER2
- ZxOTP_LINKPOINTER3
- Z1OTP_JLM_ENABLE
- ZxOTP_GPREG1
- ZxOTP_GPREG2
- ZxOTP_GPREG3
- ZxOTP_GPREG4
- ZxOTP_PSWDLOCK
- ZxOTP_CRCLOCK
- Z1OTP_JTAGPSWDH
- Z1OTP_CMACKEY
- ZxOTP_CSMPSWD0
- ZxOTP_CSMPSWD1
- ZxOTP_CSMPSWD2
- ZxOTP_CSMPSWD3
- ZxOTP_GRABSECT1
- ZxOTP_GRABSECT2
- ZxOTP_GRABSECT3
- ZxOTP_GRABRAM1
- ZxOTP_EXEONLYSECT1
- ZxOTP_EXEONLYSECT2
- ZxOTP_EXEONLYRAM1
- Z1OTP_JTAGPSWDL

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- ZxOTP_CSMPSWD0
- ZxOTP_CSMPSWD1
- ZxOTP_CSMPSWD2
- ZxOTP_CSMPSWD3
- ZxOTP_GRABSECT1
- ZxOTP_GRABSECT2
- ZxOTP_GRABSECT3
- ZxOTP_GRABRAM1
- ZxOTP_EXEONLYSECT1
- ZxOTP_EXEONLYSECT2
- ZxOTP_EXEONLYRAM1
- Z1OTP_JTAGPSWDL

The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP_JLM_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a 1 can be flipped by the user to 0, but 0 can not be flipped to 1 (no erase operation for OTP), the most-significant bit position in the resolved link pointer that is 0, defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in Figure 5-1, the final link pointer value becomes All_1 (0xFFFF_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Selected ZSB	Zone1 ZSB Address	Zone2 ZSB Address
32xxxxxxxxxxxxxxxxx11111111111111	ZSB1	0x78020	0x78220
32xxxxxxxxxxxxxxxxx11111111111110	ZSB2	0x78040	0x78240
32xxxxxxxxxxxxxxxxx11111111111100	ZSB3	0x78060	0x78260

Figure 5-2. Location of Zone-Select Block Based on Link-Pointer

CAUTION

USER OTP is ECC protected. Program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and replacing the device can be possible.

5.2.8 C Code Example to Get Zone Select Block Addr for Zone1

```
unsigned long LinkPointer;
unsigned long *Zone1SelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-sigificant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        Zone1SelBlockPtr = (unsigned long *)(0x78000 + ((bitpos + 2)*32));
    }
    Else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    Zone1SelBlockPtr = (unsigned long *)0x78020;
}
```

5.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has a dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has a 128-bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and conversely. Before programming any secure Flash sector, either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory that belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

5.4 Secure Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for ZONE1 to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

5.5 SecureCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCUCRC, GCRC) or software. In some safety-critical applications, the user can calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address can be modulo the number of words (based on length_id) for which the CRC needs to be calculated.
- The destination address can belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

Note

The user must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

5.6 CSM Impact on Other On-Chip Resources

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT_ROM and OTP is accessible to the user.

The following steps are required by CPU after reset (any type of reset) to initialize the security on device.

Security Initialization

- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP_JLM_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP_GPREG1, Z1OTP_GPREG2, Z1OTP_GPREG3, Z1OTP_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_CRCLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDH0, Z1OTP_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP_GPREG1, Z2OTP_GPREG2, Z2OTP_GPREG3, Z2OTP_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP_CRCLOCK in Z2 OTP
- Read to memory map register of Z1_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP_GRABSECT1, Z1OTP_GRABSECT2, Z1OTP_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP_GRABRAM1
- Dummy read to address location of Z1OTP_EXEONLYSECT1, Z1OTP_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDL0, Z1OTP_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP_GRABSECT1, Z2OTP_GRABSECT2, Z2OTP_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP_GRABRAM1
- Dummy read to address location of Z2OTP_EXEONLYSECT1, Z2OTP_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYRAM1 in Z2 OTP

Note

Security Initialization is done by BOOTROM code on all the resets (as part of device initialization) that assert SYSRSn. This is not part of user application code.

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS IDE), the security initialization can occur in an incorrect order locking the device down. To avoid this, do not keep a memory window with USER OTP address opened in the debugger (CCS IDE) when performing a reset.

5.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password must be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (using JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

5.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio™ IDE). This is the most common environment during the design phase of a product.
- Flash programming using TI Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming that uses the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
  In addition to the above, access to secure memory contents can be required in situations such as:
  - Using the on-chip bootloader to load code or data into secure SRAM or to erase and program the Flash.
  - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code can compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. Section 5.7.2 explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

5.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. Figure 5-3 shows how PMF helps to initialize the security logic registers and disable security logic.

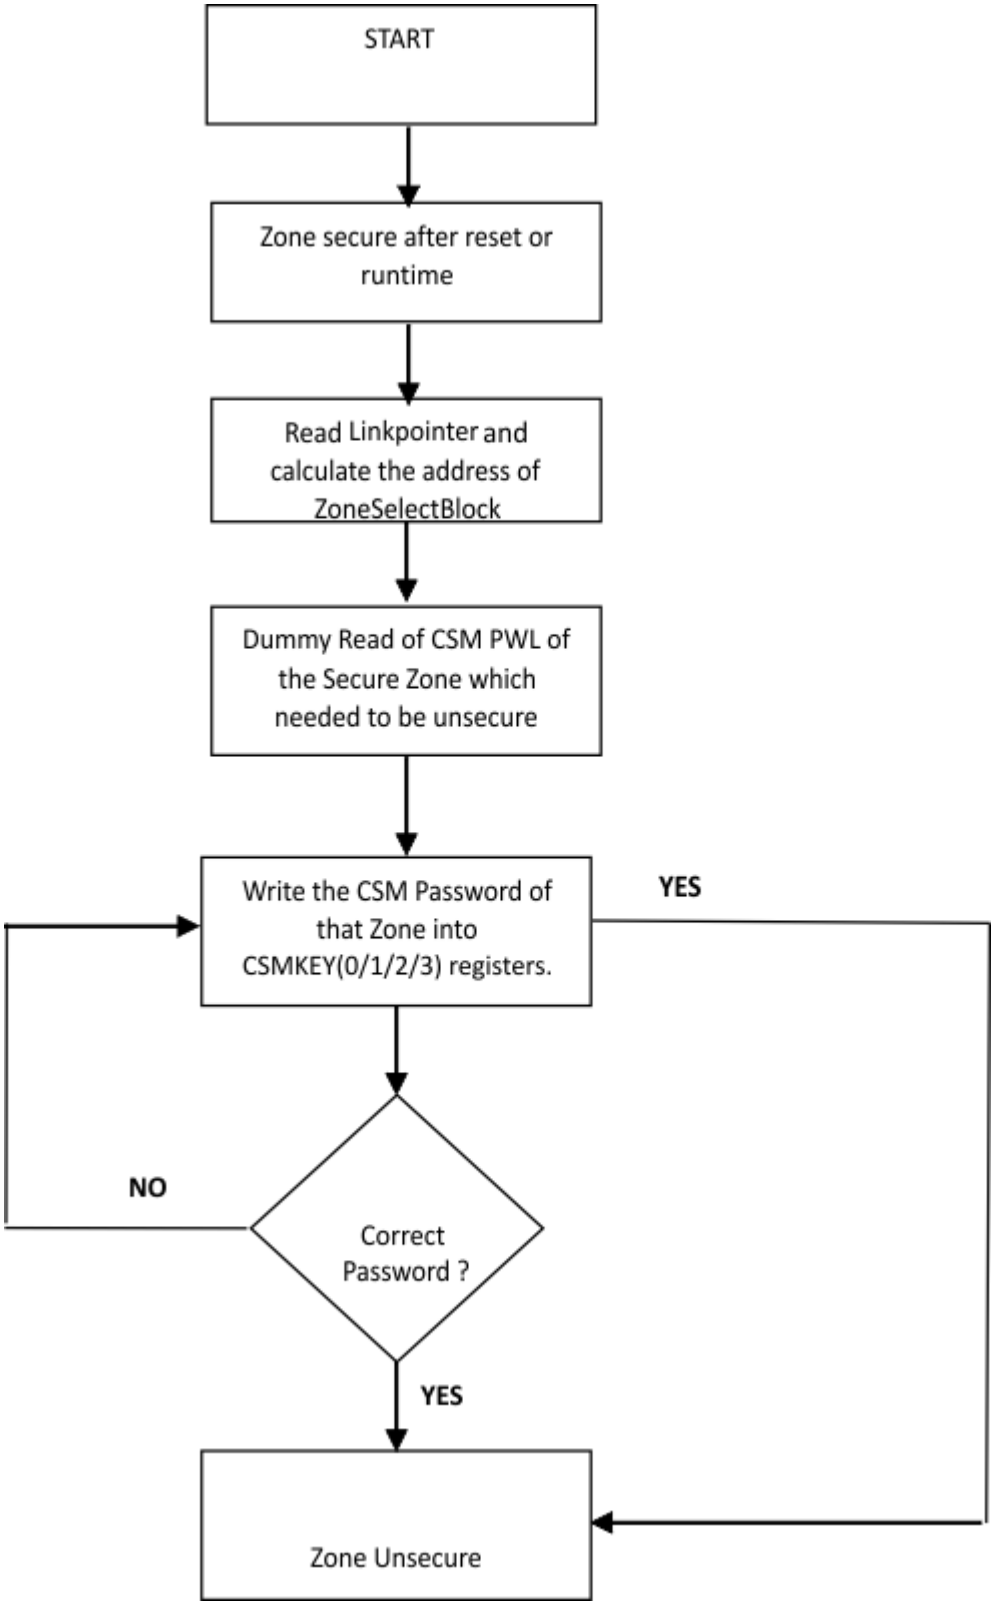

Figure 5-3. CSM Password Match Flow (PMF)

5.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F090; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default Zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the CSLPWL,
// then the CSM becomes unsecure. If this password does not match,
// then the zone remains secure.
// An example password of: // 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F094
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F096
```

5.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

5.7.5 Environments That Require ECSL Unlocking

The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and can halt while the main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of CCS (JTAG).

5.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. Figure 5-4 shows how the PMF helps to initialize the security logic registers and disable security logic.

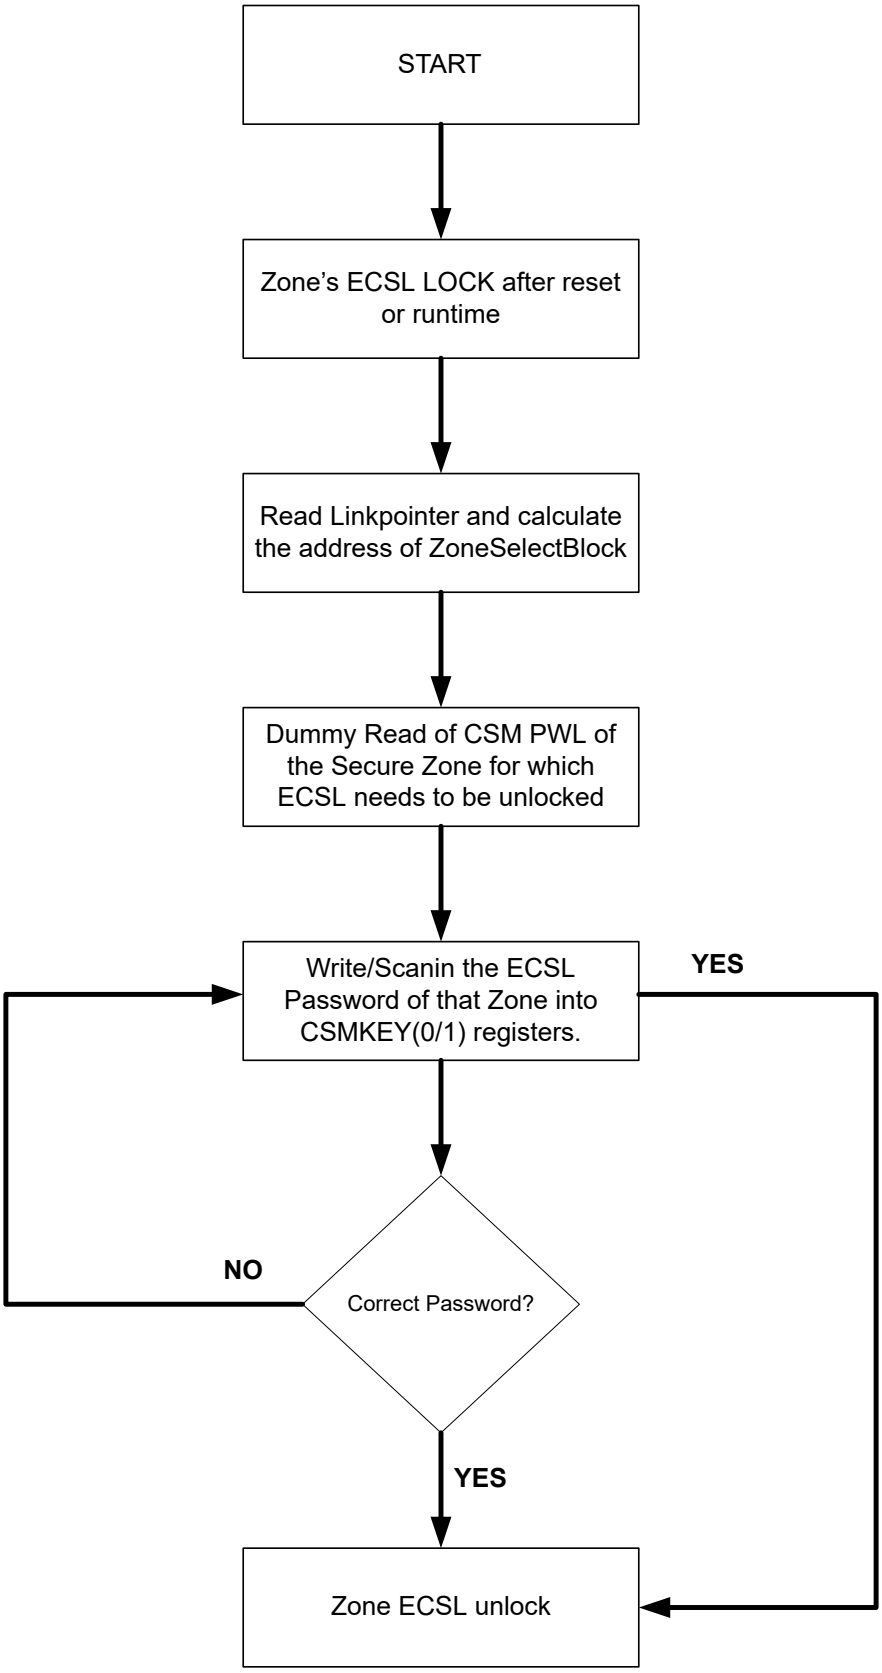

Figure 5-4. ECSL Password Match Flow (PMF)

5.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled can have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

1. Perform a dummy read of CSM password locations of that Zone.
2. Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
3. If the password is correct, the ECSL gets disabled; otherwise, the ECSL stays enabled.

5.7.7.1 C Code Example to Disable ECSL for C28x Zone1

```
volatile long int *ECSL = (volatile int *)0x5F090; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the CSMPWL,
// then ECSL gets disabled. If this password does not match,
// then the zone remains secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
```

5.7.8 Device Unique ID

TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x72168. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

5.8.2 DCSM Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcsm

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

5.8.2.1 Empty DCSM Tool Example

FILE: dcsm_security_tool.c

This example is an empty project setup for DCSM Tool and Driverlib development. For guidance refer to: *C2000 DCSM Security Tool*

5.9 DCSM Registers

This Section describes the DCSM Registers.

5.9.1 DCSM Base Address Table

Table 5-5. DCSM Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
DcsmZ1Regs	DCSM_Z1_REGS	DCSM_Z1_BASE	0x0005_F000	YES	-	-	YES
DcsmZ2Regs	DCSM_Z2_REGS	DCSM_Z2_BASE	0x0005_F080	YES	-	-	YES
DcsmCommonRegs	DCSM_COMMON_REGS	DCSMCOMMON_BASE	0x0005_F0C0	YES	-	-	YES
DcsmZ1OtpRegs	DCSM_Z1_OTP	DCSM_Z1OTP_BASE	0x0007_8000	YES	-	-	-
DcsmZ2OtpRegs	DCSM_Z2_OTP	DCSM_Z2OTP_BASE	0x0007_8200	YES	-	-	-

5.9.2 DCSM_Z1_REGS Registers

Table 5-6 lists the memory-mapped registers for the DCSM_Z1_REGS registers. All register offset addresses not listed in Table 5-6 should be considered as reserved locations and the register contents should not be modified.

Table 5-6. DCSM_Z1_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	Z1_LINKPOINTER	Zone 1 Link Pointer		Go
2h	Z1_OTPSECLOCK	Zone 1 OTP Secure Lock		Go
4h	Z1_JLM_ENABLE	Zone 1 JTAGLOCK Enable Register		Go
6h	Z1_LINKPOINTERERR	Link Pointer Error		Go
8h	Z1_GPREG1	Zone 1 General Purpose Register-1		Go
Ah	Z1_GPREG2	Zone 1 General Purpose Register-2		Go
Ch	Z1_GPREG3	Zone 1 General Purpose Register-3		Go
Eh	Z1_GPREG4	Zone 1 General Purpose Register-4		Go
10h	Z1_CSMKEY0	Zone 1 CSM Key 0		Go
12h	Z1_CSMKEY1	Zone 1 CSM Key 1		Go
14h	Z1_CSMKEY2	Zone 1 CSM Key 2		Go
16h	Z1_CSMKEY3	Zone 1 CSM Key 3		Go
18h	Z1_CR	Zone 1 CSM Control Register		Go
1Ah	Z1_GRABSECT1R	Zone 1 Grab Flash Status Register 1		Go
1Ch	Z1_GRABSECT2R	Zone 1 Grab Flash Status Register 2		Go
1Eh	Z1_GRABSECT3R	Zone 1 Grab Flash Status Register 3		Go
20h	Z1_GRABRAM1R	Zone 1 Grab RAM Status Register 1		Go
26h	Z1_EXEONLYSECT1R	Zone 1 Execute Only Flash Status Register 1		Go
28h	Z1_EXEONLYSECT2R	Zone 1 Execute Only Flash Status Register 2		Go
2Ah	Z1_EXEONLYRAM1R	Zone 1 Execute Only RAM Status Register 1		Go
2Eh	Z1_JTAGKEY0	JTAG Unlock Key Register 0		Go
30h	Z1_JTAGKEY1	JTAG Unlock Key Register 1		Go
32h	Z1_JTAGKEY2	JTAG Unlock Key Register 2		Go
34h	Z1_JTAGKEY3	JTAG Unlock Key Register 3		Go
36h	Z1_CMACKEY0	Secure Boot CMAC Key Status Register 0		Go
38h	Z1_CMACKEY1	Secure Boot CMAC Key Status Register 1		Go
3Ah	Z1_CMACKEY2	Secure Boot CMAC Key Status Register 2		Go
3Ch	Z1_CMACKEY3	Secure Boot CMAC Key Status Register 3		Go
3Eh	Z1_DIAG	Diagnostics Configuration Register		Go

Complex bit access types are encoded to fit into small table cells. Table 5-7 shows the codes that are used for access types in this section.

Table 5-7. DCSM_Z1_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		

Table 5-7. DCSM_Z1_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value

5.9.2.1 Z1_LINKPOINTER Register (Offset = 0h) [Reset = FFFFC000h]

Z1_LINKPOINTER is shown in Figure 5-5 and described in Table 5-8.

Return to the Summary Table.

Zone 1 Link Pointer

Figure 5-5. Z1_LINKPOINTER Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		LINKPOINTER													
R-0003FFFFh																		R-0h													

Table 5-8. Z1_LINKPOINTER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0003FFFFh	Reserved
13-0	LINKPOINTER	R	0h	This is resolved Link-Pointer value which is generated by looking at the three physical Link-Pointer values loaded from OTP Reset type: SYSRSn

5.9.2.2 Z1_OTPSECLOCK Register (Offset = 2h) [Reset = 00000001h]

Z1_OTPSECLOCK is shown in Figure 5-6 and described in Table 5-9.

Return to the Summary Table.

Zone 1 OTP Secure Lock

Figure 5-6. Z1_OTPSECLOCK Register

31	30	29	28	27	26	25	24

R-0h				R-0h			
7	6	5	4	3	2	1	0
PSWDLOCK				RESERVED			JTAGLOCK
R-0h				R-0h			R-1h

Table 5-9. Z1_OTPSECLOCK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-12	RESERVED	R	0h	Reserved
11-8	CRCLOCK	R	0h	Value in this field gets loaded from Z1_CRCLOCK[3:0] when a read is issued to address location of Z1_CRCLOCK in OTP. 1111 : VCU has ability to calculate CRC on secure memories. Other Value : VCU doesn't have ability to calculate CRC on secure memories. Reset type: XRSn
7-4	PSWDLOCK	R	0h	Value in this field gets loaded from Z1_PSWDLOCK[3:0] when a read is issued to address location of Z1_PSWDLOCK in OTP. 1111 : CSM password locations in OTP are not protected and can be read from debugger as well as code running from anywhere. Other Value : CSM password locations in OTP are protected and can't be read without unlocking CSM of that zone. Reset type: XRSn
3-1	RESERVED	R	0h	Reserved
0	JTAGLOCK	R	1h	Reflects the state of the JTAGLOCK feature. 0 : JTAG is not locked 1 : JTAG is locked Reset type: PORESETn

5.9.2.3 Z1_JLM_ENABLE Register (Offset = 4h) [Reset = 0000000Fh]

Z1_JLM_ENABLE is shown in Figure 5-7 and described in Table 5-10.

Return to the Summary Table.

Zone 1 JTAGLOCK Enable Register

Figure 5-7. Z1_JLM_ENABLE Register

31	30	29	28	27	26	25	24

R-0-0h				R-Fh			

Table 5-10. Z1_JLM_ENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R-0	0h	Reserved
3-0	Z1_JLM_ENABLE	R	Fh	Zone1 JLM_ENABLE register. The value in this field gets loaded from Z1OTP_JLM_ENABLE[3:0] when a read is issued to address location of Z1OTP_JLM_ENABLE in OTP. If Z1OTP_JLM_ENABLE[31:0] is equal to all ones during the load, the JTAGLOCK is not bypassed (is enabled). If the value of Z1OTP_JLM_ENABLE[31:0] is not all ones during the load, the JTAGLOCK is governed as follows by the Z1_JLM_ENABLE bits: 1111 : JTAG/Emulation access is allowed (JTAGLOCK is not enabled) Other values: JTAGLOCK is governed by the JTAGKEY==JTAGPSWD match condition Reset type: PORESETn

5.9.2.4 Z1_LINKPOINTERERR Register (Offset = 6h) [Reset = 00000000h]

Z1_LINKPOINTERERR is shown in Figure 5-8 and described in Table 5-11.

Return to the Summary Table.

Link Pointer Error

Figure 5-8. Z1_LINKPOINTERERR Register

Table 5-51. Z2_GRABSECT1R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-24	GRAB_B1_SECT31_4	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
23-22	GRAB_B1_SECT3	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
21-20	GRAB_B1_SECT2	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
19-18	GRAB_B1_SECT1	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
17-16	GRAB_B1_SECT0	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
15-14	GRAB_B0_SECT127_96	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn

Table 5-51. Z2_GRABSECT1R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-12	GRAB_B0_SECT95_64	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
11-10	GRAB_B0_SECT63_32	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
9-8	GRAB_B0_SECT31_4	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
7-6	GRAB_B0_SECT3	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
5-4	GRAB_B0_SECT2	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn
3-2	GRAB_B0_SECT1	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn

Table 5-51. Z2_GRABSECT1R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	GRAB_B0_SECT0	R	0h	Value in this field gets loaded from the equivalent bit field when a read is issued to the active ZSB address location of Z2_GRABSECT1 in the SECURITY sector. 00 : Invalid. Sectors are inaccessible. 01 : Request to allocate thes sectors to Zone2. 10 : No request for these sectors. 11 : No request for these sectors when this zone is UNLOCKED. Else these sectors are inaccessible if this zone is LOCKED. Reset type: SYSRSn

5.9.3.14 Z2_GRABSECT2R Register (Offset = 1Ch) [Reset = 00000000h]

Z2_GRABSECT2R is shown in Figure 5-47 and described in Table 5-52.

Return to the Summary Table.

5.9.4 DCSM_COMMON_REGS Registers

Table 5-58 lists the memory-mapped registers for the DCSM_COMMON_REGS registers. All register offset addresses not listed in Table 5-58 should be considered as reserved locations and the register contents should not be modified.

Table 5-58. DCSM_COMMON_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	Go
8h	SECTSTAT1	Flash Sectors Status Register 1		Go
Ah	SECTSTAT2	Flash Sectors Status Register 2		Go
Ch	SECTSTAT3	Flash Sectors Status Register 3		Go
10h	RAMSTAT1	RAM Status Register 1		Go
18h	SECERRSTAT	Security Error Status Register		Go
1Ah	SECERRCLR	Security Error Clear Register		Go
1Ch	SECERRFRC	Security Error Force Register		Go
1Eh	DENYCODE	Flash Authorization Denial Code		Go
28h	UID_UNIQUE_31_0	Unique Identification Number Low		Go
2Ah	UID_UNIQUE_63_32	Unique Identification Number High		Go
2Ch	PARTIDH	Part Identification High Register		Go
2Eh	PERSEM1	Peripheral Semaphore Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 5-59 shows the codes that are used for access types in this section.

Table 5-59. DCSM_COMMON_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
Reset or Default Value		
-n		Value after reset or the default value

5.9.4.1 FLSEM Register (Offset = 0h) [Reset = 00000000h]

FLSEM is shown in Figure 5-53 and described in Table 5-60.

Return to the Summary Table.

31-0	Z2OTP_CRCLOCK	R	FFFFFFFFh	Zone2 CRC lock location in USER OTP. Note: When this value is loaded into DCSM, if the value is 32-bit all-1s, VCU will not have ability to calculate CRC on secured memory content.. Before shipping parts to customers, TI would change the value of this location in such a way that the ECC field remains all-1s and also LSB 4-bits remain 4'b1111. Reset type: N/A

Chapter 6

Flash Module

This chapter describes the Flash module.

6.1 Introduction to Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of Flash. This section also includes information on Flash and OTP power modes, how to improve Flash performance by enabling the Flash prefetch/cache mode, and the SECDED safety feature.

6.1.1 FLASH Related Collateral

Foundational Materials

- [FAQ] FAQ for Flash ECC usage in C2000 devices - Includes ECC test mode, Linker ECC options:
- [FAQ] FAQ on Flash API usage for C2000 devices
- [FAQ] Flash - How to modify an application from RAM configuration to Flash configuration?
- [FAQ] How can we improve the Flash tool performance?
- [FAQ] TI C2000 Device Programming Tools and Services

6.1.2 Features

Features of Flash memory include:

- Up to five Flash banks (refer to device data sheet for the number and size of Flash banks);
- One Flash Wrapper controlling up to five Flash banks (Bank0, 1, 2, 3, 4);
- Program or erase one Flash bank while simultaneously reading another Flash bank;
- 128-bit wide Flash programming;
- Configurable Flash programming options, with ECC support;
- Multiple sectors, with the ability to erase individual/specific sectors while leaving others programmed;
- User-programmable locations in user-configurable DCSM OTP (also referred to as USER OTP), for configuring security, OTP boot mode and boot mode selection pins (if the user is unable to use factory-default boot mode select pins);
- Code prefetch mechanism and data cache for enhanced performance;
- Configurable wait states to achieve the best performance at a given clock frequency;
- Safety Features:
  - SECDED: Single-error correction and double-error detection is supported;
  - Address bits are included in ECC;
  - Test mode to check the health of ECC logic;
- Integrated Flash program and erase state machine in the Flash Wrapper:
  - Simple Flash API algorithms;
  - Fast erase and program times (refer to the device data sheet for details);

6.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin. TI recommends performing a debug reset and restart after programming the code into Flash using CCS.
- Flash API Library - a set of software peripheral functions to erase/program Flash
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS is required.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

6.1.4 Default Flash Configuration

The following are Flash module configuration settings at power-up:

- Flash Bank and Pump are powered up on device reset.
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled

During the boot process, the boot ROM performs a dummy read of the Code Security Module (CSM) password locations in the OTP. This read is performed to unlock a new device that has no password stored in the device, so that Flash programming or loading of code into CSM-protected SRAM can be performed. On devices with a password, this read has no effect and the device remains locked.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD_INTF_CTRL register, to achieve optimum system performance. Software that configures Flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from Flash memory.

Note

Before initializing wait-states, turn off the pre-fetch and data caching in the FRD_INTF_CTRL register.

6.2 Flash Bank, OTP, and Pump

This device includes up to five Flash banks. In addition, there is one-time programmable Flash memory (OTP) in each Flash bank. Flash and OTP are uniformly mapped in both program and data memory space.

There are two OTP regions. The first OTP region, TI-OTP, contains manufacturing information, trims, Flash operation settings, and other device data. TI-OTP can be read by the user application, but TI-OTP cannot be programmed or erased. The second OTP region, USER-OTP, is primarily used for programming device security (DCSM module) settings. USER-OTP can be programmed only once and cannot be erased afterwards. For information on the memory-map, Flash bank sizes, TI-OTP, USER-OTP, and corresponding ECC locations, refer to the device data sheet.

The *Location of Zone-Select Block Based on Link-Pointer* figure in the *Dual Code Security Module (DCSM)* chapter shows the user-programmable OTP locations in CPU1 USER-OTP. For more information on the functionality of these fields, refer to the *ROM Code and Peripheral Booting* chapter and the *Dual Code Security Module (DCSM)* chapter.

6.3 Flash Wrapper

The CPU interfaces with the Flash wrapper, which interfaces with the Flash banks and the pump (see Figure 6-1). The Flash wrapper has the following primary features:

- Provides a simple interface for software to program or erase the Flash memory.
- Provides an interface for the CPU to read Flash data, including data caching and prefetch features.
- Performs ECC error checking and correction, and generates interrupts when an error is detected.
- Provides the capability to prevent unwanted bank program or erase operations.

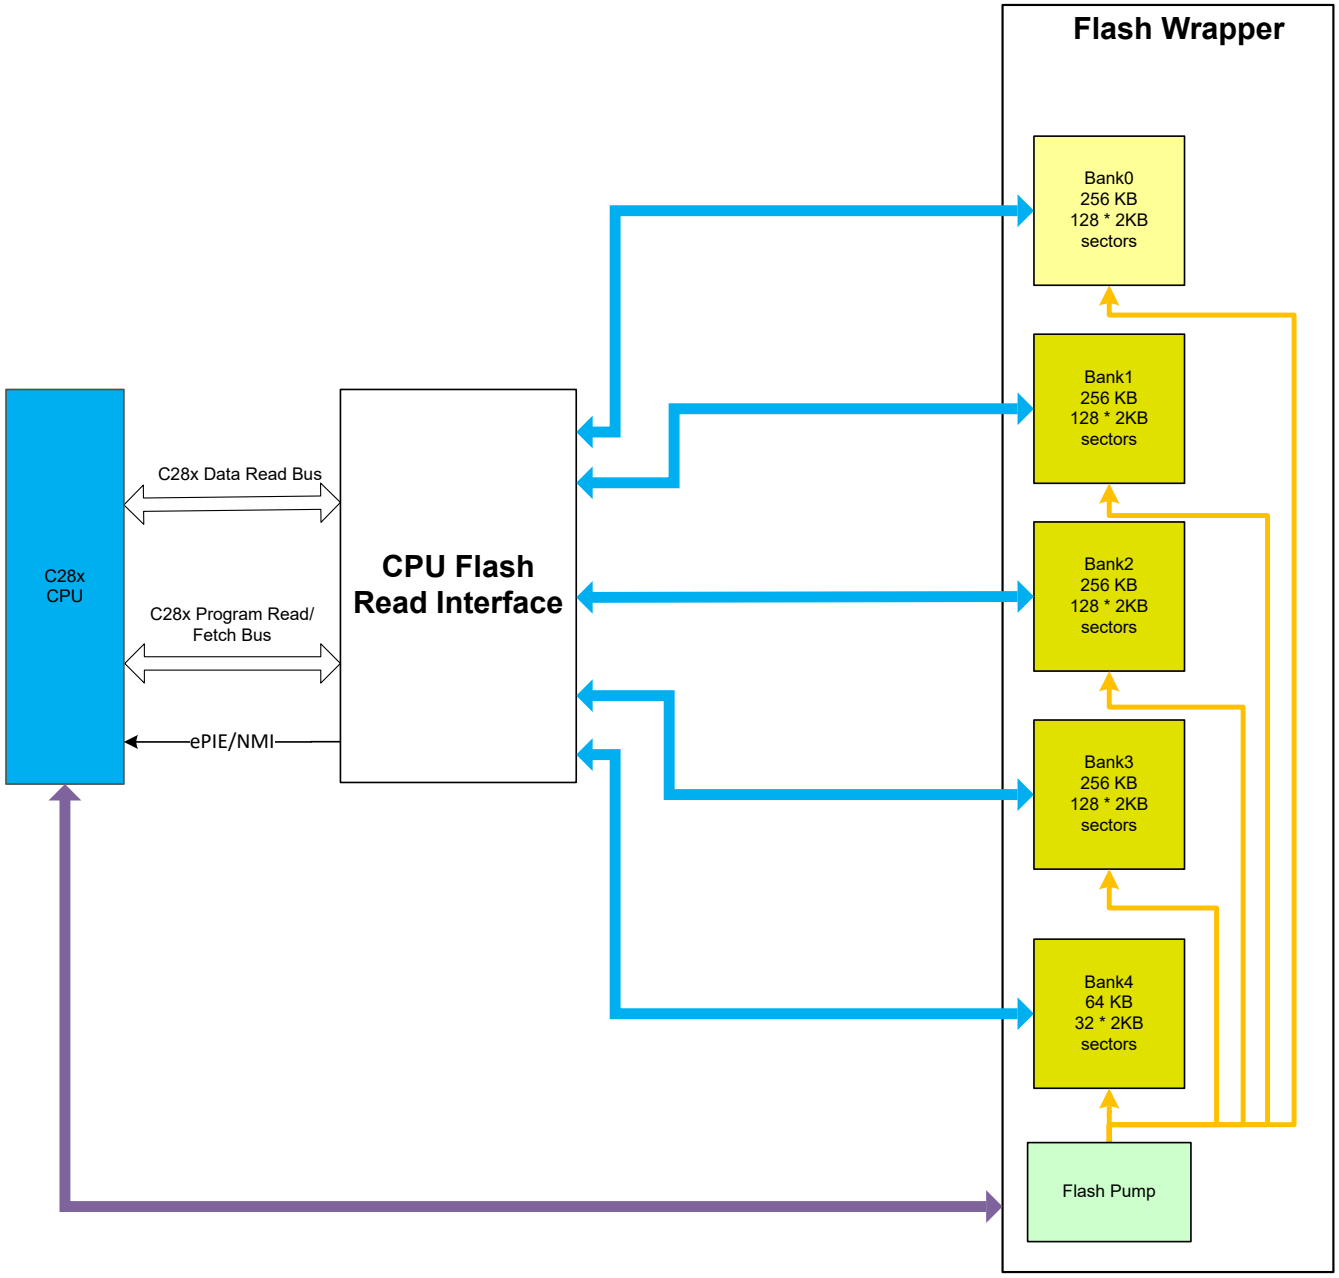

Figure 6-1. Flash Interface Block Diagram

6.4 Flash and OTP Memory Performance

Flash read or instruction fetch accesses can be classified either as a Flash access (access to an address location in Flash), or an OTP access (access to an address location in OTP).

When the CPU performs an access to a Flash memory address, data is returned after (RWAIT+1) SYSCLK cycles.

For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait states, and is configured using the RWAIT field in the FRDCNTL register. At reset, RWAIT defaults to a worst-case wait state count (15), and therefore must be initialized to the appropriate number of wait states to improve performance, based on the CPU clock frequency and the access time of the Flash. The Flash supports zero-wait accesses when RWAIT is set to zero, when the CPU clock frequency is low enough to accommodate the Flash access time.

For a given system clock frequency, configure RWAIT using the following formula:

For C28x Flash Bank: RWAIT = ceiling[(SYSCLK/FCLK)-1]

where SYSCLK is the system operating frequency for CPU1, and FCLK is the clock frequency for Flash.

FCLK must be ≤ $FCLK_{max}$, the allowed maximum Flash clock frequency at RWAIT = 0.

If RWAIT results in a fractional value when calculated using the above formula, round up RWAIT to the nearest integer.

Note

When programming the FRDCNTL register, be sure to avoid writing values to bits other than the RWAIT field as described in the register description. Overwriting reserved register fields can result in errors or unpredictable behavior.

6.5 Flash Read Interface

This section provides details about the data read modes to access Flash bank/OTP and the configuration registers that control the read interface. In addition to a standard read mode, the Flash wrapper has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

6.5.1 C28x-Flash Read Interface

6.5.1.1 Standard Read Mode

Standard read mode is the default Flash read mode after reset. In this mode, the code prefetch mechanism and data cache are disabled. When standard read mode is active, every read access to Flash is decoded by the Flash wrapper to fetch the data from the addressed location, and the data is returned after RWAIT+1 cycles (except User OTP).

Flash data buffers associated with the prefetch mechanism and data cache are bypassed in standard read mode; therefore, every access to the Flash/OTP is used by the CPU immediately, and every access creates a unique Flash bank access.

Standard read mode is the recommended mode for lower system frequency operation, where RWAIT can be set to zero to provide single-cycle access operation. The Flash wrapper can operate at higher frequencies using standard read mode, at the expense of adding wait states. At higher system frequencies, it is recommended to enable the data cache and prefetch mechanisms to improve performance. Refer to the device data sheet to determine the maximum Flash frequency allowed in standard read mode (that is, maximum Flash clock frequency with RWAIT = 0, $FCLK_{MAX}$).

6.5.1.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from contiguous memory addresses, except when a discontinuity occurs. Usually, the portion of the code that resides in contiguous address locations makes up the majority of the application code, and is referred to as linear code. To improve the performance of linear code execution, a Flash prefetch mechanism has been implemented. Figure 6-2 illustrates how this mode functions.

The prefetch mechanism does a look-ahead prefetch on linear address increments, starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. To enable prefetch mode, set the PREFETCH_EN bit in the FRD_INTF_CTRL register, or call the `Flash_enablePrefetch()` driverlib function.

Each instruction fetch from the Flash or OTP reads out 128 bits. The starting address of the access from Flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. When Flash prefetch mode is enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the Flash bank there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time to process these instructions, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 128 bits. The Flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash or OTP is improved significantly.

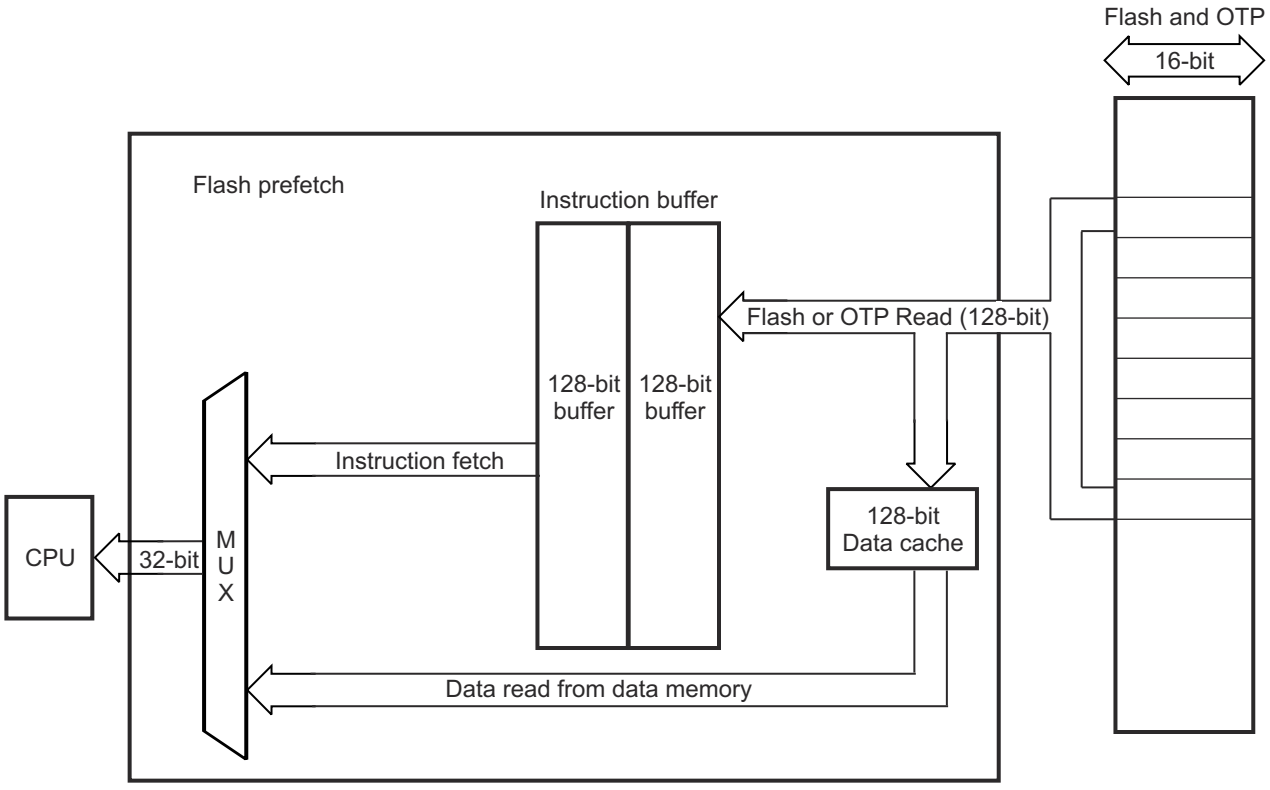

Figure 6-2. Flash Prefetch Mode

The Flash prefetch is aborted only when there is a code discontinuity caused by executing an instruction such as a branch, function call, or loop. When this occurs, the prefetch mechanism is aborted, and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the Flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the Flash and OTP, the prefetch is aborted, and begins again only when the code branches back into the Flash or OTP. The Flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch mechanism and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When such a read happens, the prefetch buffer is bypassed, but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read is stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

6.5.1.3 Data Cache

In addition to the prefetch mechanism, a data cache of 128-bits wide has been implemented to improve data space read performance. This data cache is separate from the instruction prefetch buffer, and is used for data reads only. Whenever a data read access is performed by the CPU to a Flash bank address, if the data located at that address is not presently loaded into the data cache, then the Flash wrapper reads 128 bits of data from the Flash bank and stores the data in the data cache. This data is eventually sent to the CPU for processing. The starting address of the Flash bank access is automatically aligned to a 128-bit boundary, such that the requested address location is within the 128 bits to be read from the bank.

The data cache is disabled by default at reset. To enable the data cache, set the DATA_CACHE_EN bit in the FRD_INTF_CTRL register, or call the `Flash_enableCache()` driverlib function. Note that the data cache gets bypassed when RWAIT is set to zero.

Note

The data cache does not get updated on a debugger access, or when a read to the ECC memory-mapped region is performed.

6.5.1.4 Flash Read Operation

There are a few important points to keep in mind when using Flash or OTP memory:

- Reads of USER OTP locations are hardwired for 9 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to Flash or OTP memory addresses are ignored, and complete within a single cycle. Flash memory can only be modified by issuing program or erase commands, using the Flash API.
- When a security zone is in the locked state, and the respective password lock bits are not all ones, then:
  - Data reads to Zx-CSMPSWD return zero;
  - Program space reads to Zx-CSMPSWD return zero; and
  - Program fetches to Zx-CSMPSWD return zero.
- When the Code Security Module (CSM) is secured, reads to Flash or OTP memory addresses from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns zero.
- The arbitration scheme in the Flash wrapper prioritizes CPU accesses in the fixed priority order of data space read (highest priority), program space read, and program fetches/program prefetches (lowest priority).
- When Flash state machine is activated for erase or program operations, the contents of the prefetch buffer and data cache are automatically flushed.

Note

ECC checks are performed on data read from Flash before the data is stored in the prefetch buffer or data cache. Once data has entered the cache or buffer, there are no further ECC checks performed.

6.6 Flash Erase and Program

Flash memory can be programmed either by using the CCS Flash plug-in or by using the UniFlash application. If these methods are not feasible in an application, the Flash API can be used. The Flash memory can be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

The recommended flow for programming Flash is:
Erase → Program → Verify

6.6.1 Erase

When the target Flash is erased, the Flash reads as all 1s. This state is called 'blank.' The erase function must be executed before programming. The user cannot skip erase on sectors that read as 'blank' because these sectors can require additional erasing due to marginally erased bits columns. The FSM provides an Erase Sector command to erase the target sector. The erase function erases the data and the ECC together. Bank erase is also supported in this device.

6.6.2 Program

The Flash wrapper provides a command to program the Flash and User OTP. This command is also used to program ECC check bits.

Note

The main array Flash programming must be aligned to 64-bit address boundaries, and each 64-bit word can only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128-bit address boundaries and each 128-bit word can only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP can be programmed together and can be programmed one bit at a time as required by the DCSM operation.
- The DCSM Zx-LINKPOINTER3 values in the DCSM OTP can be programmed one bit at a time as required by the DCSM operation.

To avoid exceeding data retention capability limits, do not perform more than 4 program operations on the same Flash word line before performing an erase operation. Each Flash word line consists of sixteen 128-bit words (256 bytes). This limit is especially important to observe when writing to one-time-programmable/non-erasable Flash regions, such as the User OTP.

6.6.3 Verify

After programming, the user must perform verify using API function Fapi_doVerify(). This function verifies the Flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default), catches single-bit errors, double-bit errors, and address errors whenever the CPU reads/fetches from a Flash address.

6.7 Error Correction Code (ECC) Protection

There are two ECC blocks (ECC64_H and ECC64_L) inside the Flash Read Interface. These ECC blocks correct single-bit Flash read errors, and can detect uncorrectable errors of two or more bits. The ECC blocks are also capable of detecting address errors. The ECC blocks operate using eight user-calculated ECC check bits associated with each 64-bit wide data word and the corresponding 128-bit memory-aligned address. Users must program these ECC check bits into ECC memory space, along with Flash data during the Flash programming operation. Refer to the device data sheet for the Flash/OTP ECC memory-map.

The ECC bits for a given Flash address and 64-bit data word can be calculated using the Flash API; however, TI recommends using the AutoEccGeneration option available in the Flash Plugin or API to auto-calculated and program ECC bits. The Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with the Code Composer Studio™ IDE, uses the Flash API to generate and program ECC data.

Figure 6-3 illustrates the ECC logic inputs and outputs.

During an instruction fetch or a data read operation, the 19 most-significant address bits (the three least-significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of Flash banks/ECC memory-map area, pass through the ECC logic, and the eight check bits are produced in ECC block. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the ECC block to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- A non-correctable error (double bit data error or address error) occurred

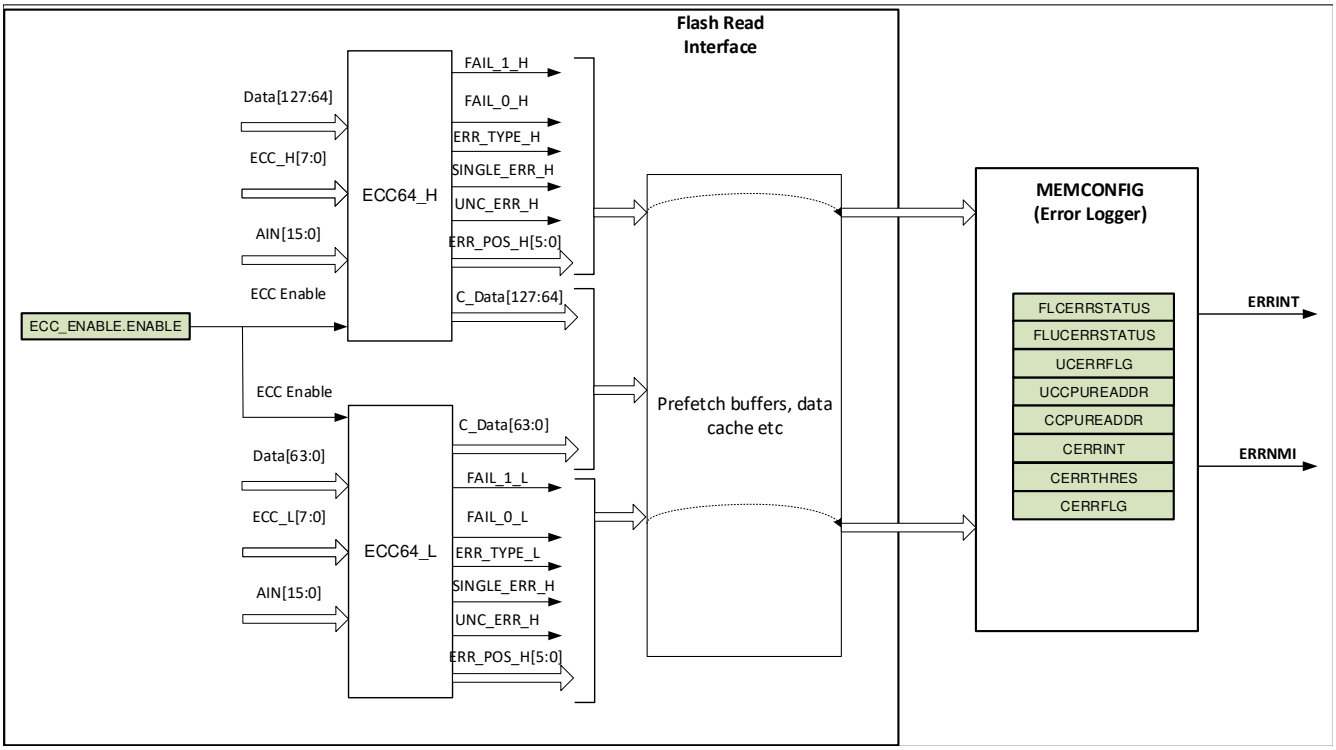

Figure 6-3. ECC Logic Inputs and Outputs

A single-bit error in the address field is considered to be a non-correctable error.

Note

Since ECC is calculated for an entire 64-bit data word, a non 64-bit read such as a byte read or a half-word read still forces the entire 64-bit data word to be read and calculated, even though only the byte or half-word is actually used by the CPU.

The ECC feature is enabled by default at reset, and can be enabled or disabled by writing to the ECC_ENABLE register. ECC logic is automatically bypassed when the 64 data bits and associated ECC bits fetched from the bank are either all ones or all zeros.

6.7.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in Flash data or in ECC data, then the error is considered as a single-bit data error. The SECDED module detects and corrects single-bit errors, if any, in the 64-bit Flash data or eight ECC check bits read from the Flash/ECC memory map before the read data is provided to the CPU.

When SECDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the single-bit error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the address of the lower 64-bit word is captured in the SINGLE_ERR_ADDR_LOW register. If the single-bit error occurs in the upper 64 bits of the 128-bit data word, then the address of the upper 64-bit word is captured in the SINGLE_ERR_ADDR_HIGH register.
- Whether the error occurred in data bits or ECC bits: the ERR_TYPE_L and ERR_TYPE_H bit fields in the ERR_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64 bits, or the upper 64 bits respectively, of a 128-bit memory-aligned Flash data word.
- Bit position at which the error occurred: the ERR_POS_L and ERR_POS_H bit fields in the ERR_POS register indicate the bit position of the error in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned Flash data word.
- Whether the corrected value is 0 (FAIL_0_L, FAIL_0_H flags in ERR_STATUS register).
- Whether the corrected value is 1 (FAIL_1_L, FAIL_1_H flags in ERR_STATUS register).
- A single bit error counter that increments on every single bit error occurrence (ERR_CNT register) until a user-configurable threshold (see ERR_THRESHOLD) is met.
- A flag that gets set when one or more single-bit errors occurs after ERR_CNT equals ERR_THRESHOLD (SINGLE_ERR_INT_FLG flag in the ERR_INTFLG register).

When the ERR_CNT value equals ERR_THRESHOLD+1, and a single bit error occurs, the Flash module sets the SINGLE_ERR_INT flag and generates an interrupt signal. To enable propagation of the generated interrupt pulse to the CPU, the user application must enable the FLASH_CORRECTABLE_ERROR channel in the C28 Peripheral Interrupt Expansion module (PIE). The interrupt signal remains high until the application clears the SINGLE_ERR_INTFLG flag by writing to the SINGLE_ERR_INTCLR bit in the ERR_INTCLR register. The Flash module cannot generate any further FLASH_CORRECTABLE_ERROR interrupt signals to the PIE/CPU until SINGLE_ERR_INTFLG is cleared, as this is an edge-based interrupt.

When multiple single-bit errors have been detected by ECC logic, the contents of the Flash ECC registers reflect the most recent ECC error. When multiple single-bit errors have been detected, both FAIL_0_L and FAIL_1_L (or FAIL_0_H and FAIL_1_H) can be set, indicating that single-bit fail0/fail1 occurred in different 64-bit aligned addresses.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash data word causes the single-bit error flag to get set, if there is a single-bit error in both or in either the lower 64 or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

6.7.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data or ECC. When the ECC logic finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the uncorrectable error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the lower 64-bit memory-aligned address is captured in the UNC_ERR_ADDR_LOW register. If the uncorrectable error occurs in the upper 64 bits of a 128-bit memory-aligned Flash data word, the upper 64-bit memory-aligned address is captured in the UNC_ERR_ADDR_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC_ERR_L and UNC_ERR_H flags in the ERR_STATUS register indicate the uncorrectable error occurrence in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned Flash data word.
- A flag is set indicating that an uncorrectable error interrupt is generated (UNC_ERR_INTFLG in ERR_INTFLG register).

When an uncorrectable error occurs, the Flash module sets the UNC_ERR_INTFLG bit and generates an uncorrectable error interrupt. This uncorrectable error interrupt generates a non-maskable interrupt (NMI), if enabled, in the CPU. If an uncorrectable error interrupt flag is not cleared by writing to the UNC_ERR_INTCLR bit in the ERR_INTCLR register, the Flash module cannot generate new uncorrectable interrupt signals, as this is an edge-based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash word causes the uncorrectable error flag to get set, and an uncorrectable error interrupt/NMI to occur, when there is a uncorrectable error in both or in either the lower 64 bits or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

6.7.3 Mechanism to Check the Correctness of ECC Logic

To make sure the correctness of the ECC logic, a redundant ECC logic block for each of the ECC64_L and ECC64_H checkers is used. Each 64-bit ECC checker block and the corresponding redundant checker block receive the same inputs. The output of each 64-bit checker block is bitwise XORed with the output of the corresponding redudnant checker block; a non-zero output from this comparison generates an uncorrectable error (UNC_ERR) signal. This redundancy makes sure that any fault in ECC logic circuits can be detected and trigger an NMI.

A mechanism has been added to enable self-testing of the ECC logic for additional diagnostic coverage. To use this mechanism, configure the ECC_TEST_EN field in the FECC_CTRL register. A value of 01 in ECC_TEST_EN injects a single-bit error into the redundant ECC logic upon a Flash read access, and a value of 11 injects a double-bit error upon a Flash read access. This causes an output comparison failure. In this mode, the diagnostic outputs of each of the high and low comparators (DIAG_H and DIAG_L) are captured in the FLUCERRSTATUS Memconfig register.

Note

When ECC self-test is enabled and CPU issues a read access to the Flash, ECC errors are captured in the data cache and prefetch buffers. TI recommends that application software disables caching while performing diagnostic checks.

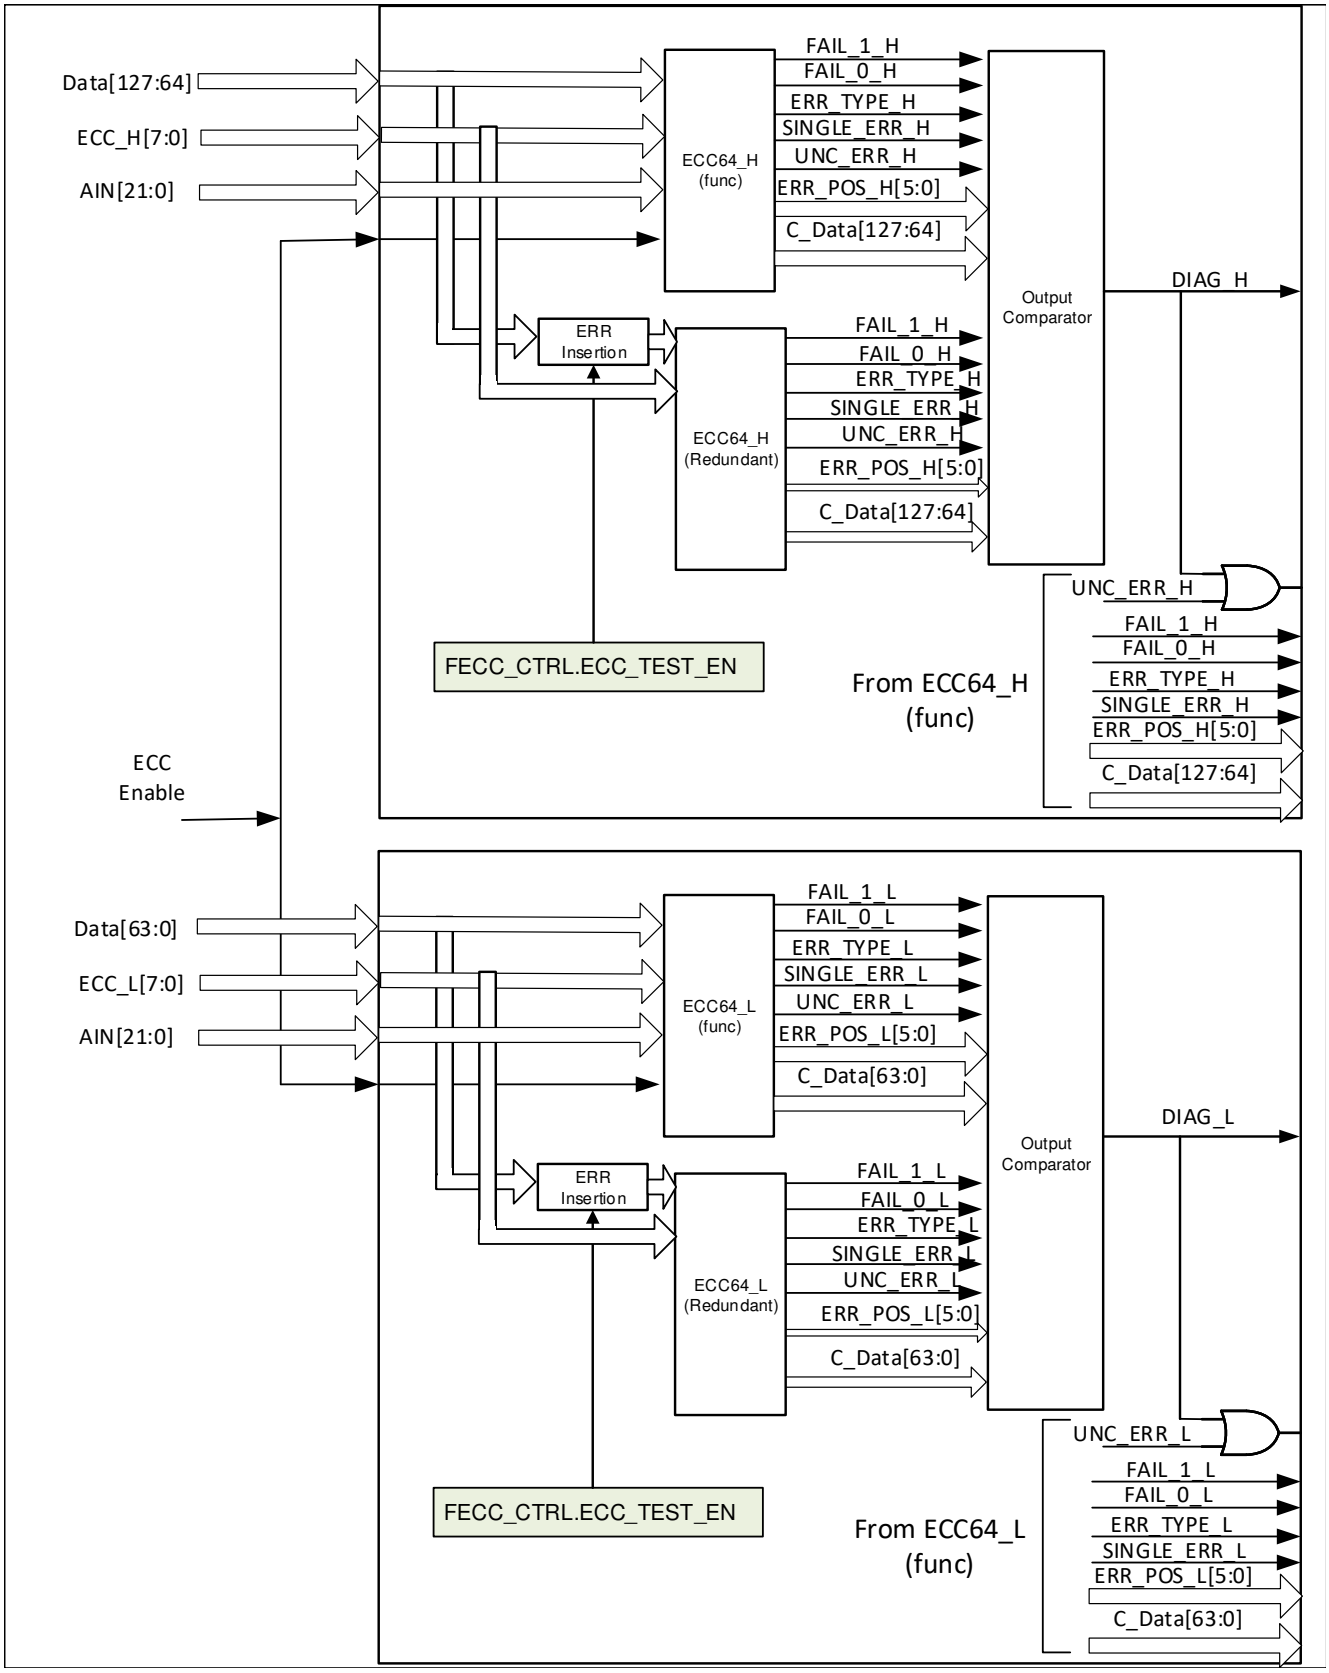

Figure 6-4. Testing ECC Logic

6.8 Reserved Locations Within Flash and OTP

When allocating code and data to Flash and OTP memory, keep the following reserved locations in mind:

- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in Flash for real-time operating system usage and a boot-to-Flash entry point. A boot-to-Flash entry point is reserved for an entry-into-Flash branch instruction. When the boot-to-Flash boot option is used, the boot ROM jumps to this address in Flash. If you program a branch instruction here, that redirects code execution to the entry point of the application.

6.9 Migrating an Application from RAM to Flash

To migrate an existing application that is configured to run from RAM to a Flash-based linker configuration, follow these steps:

1. Replace the RAM linker command file with a Flash linker command file. For examples of Flash-based linker command files, see the `device_support\<device>\common\cmd` directory.
2. When modifying the Flash-based linker command file, be sure to map any initialized sections to Flash memory regions.
3. Make sure the boot mode pins are configured for Flash boot. This tells the boot ROM to redirect execution to the application programmed into Flash memory after boot code execution is complete. For more information on boot mode configuration, see *Detailed Description* > *Device Boot Modes* in the device data sheet.
4. When the device is configured for Flash boot, the boot ROM redirects execution to the Flash entry point location (defined as `BEGIN` in TI-provided Flash linker command files) at the end of boot code execution. Make sure there is a branch instruction at the Flash entry point to your code initialization (for example, `_c_int00`) function. In the C2000Ware examples, the entry point code is specified in the `codestartbranch.asm` file.
5. To achieve best performance for Flash execution, configure the Flash wait states as per the device operating clock frequency, as specified in the device data sheet. In addition, enable prefetch mode and data cache mode. Calling the `Flash_initModule()` driverlib function achieves these steps. Note that code that initializes the Flash module must execute from a RAM location. This is accomplished by assigning the Flash initialization function to the `.TI.ramfunc` section. In the linker command file, map this section to Flash for load, and RAM for execution. The example cmd files provided in C2000Ware show how to do this correctly.
6. For any functions that require 0- or 1-wait state performance, be sure to map to RAM for execution in the linker command file, similar to the Flash initialization function. The `.TI.ramfunc` section in the TI-provided Flash linker command files accomplishes this purpose.
7. Align all code and data sections to 128-bit address boundaries when mapping to Flash memory, using the `ALIGN` directive in the linker command file.
8. For EABI executable formats, define all uninitialized sections mapped to RAM as NOINIT sections (using the directive "`type=NOINIT`") in the linker command file.
9. Be sure to program ECC bits correctly for the Flash application image. Keep the AutoEccGeneration option enabled in the Code Composer Studio Flash Plugin or UniFlash GUI.

6.10 Procedure to Change the Flash Control Registers

During Flash configuration, no accesses to the Flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown below for any code that modifies the Flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the Flash configuration code (that writes to Flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the Flash configuration cannot execute from the Flash or OTP and must reside in RAM.
3. Execute the Flash configuration code (located in RAM) that writes to Flash control registers like FRDCNTL, FRD_INTF_CTRL, and so on.
4. At the end of the Flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function that resides in RAM or Flash/OTP and continue execution.

6.11.2 FLASH Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/flash

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

6.11.2.1 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly

FILE: flashapi_128bit_programming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

External Connections

- None.

Watch Variables

- None.

6.11.2.2 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly

FILE: flashapi_512bit_programming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

External Connections

- None.

Watch Variables

- None.

6.12 FLASH Registers

This Section describes the FLASH Registers.

6.12.1 FLASH Base Address Table

Table 6-2. FLASH Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
Flash0CtrlRegs	FLASH_CTRL_REGS	FLASH0CTRL_BASE	0x0005_F800	YES	-	-	YES
Flash0EccRegs	FLASH_ECC_REGS	FLASH0ECC_BASE	0x0005_FB00	YES	-	-	YES

6.12.2 FLASH_CTRL_REGS Registers

Table 6-3 lists the memory-mapped registers for the FLASH_CTRL_REGS registers. All register offset addresses not listed in Table 6-3 should be considered as reserved locations and the register contents should not be modified.

Table 6-3. FLASH_CTRL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	FRDCNTL	Flash Read Control Register	EALLOW	Go
4h	FLPROT	Flash program/erase protect register	EALLOW	Go
180h	FRD_INTF_CTRL	Flash Read Interface Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 6-4 shows the codes that are used for access types in this section.

Table 6-4. FLASH_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.12.2.1 FRDCNTL Register (Offset = 0h) [Reset = 0F000F00h]

FRDCNTL is shown in Figure 6-5 and described in Table 6-5.

Return to the Summary Table.

Chapter 7

Control Law Accelerator (CLA)

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

7.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

7.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating-point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.
- Task trigger mechanisms:
  - C28x CPU using the IACK instruction
  - Task1 to Task8: trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

7.1.3 Block Diagram

Figure 7-1 is a block diagram of the CLA.

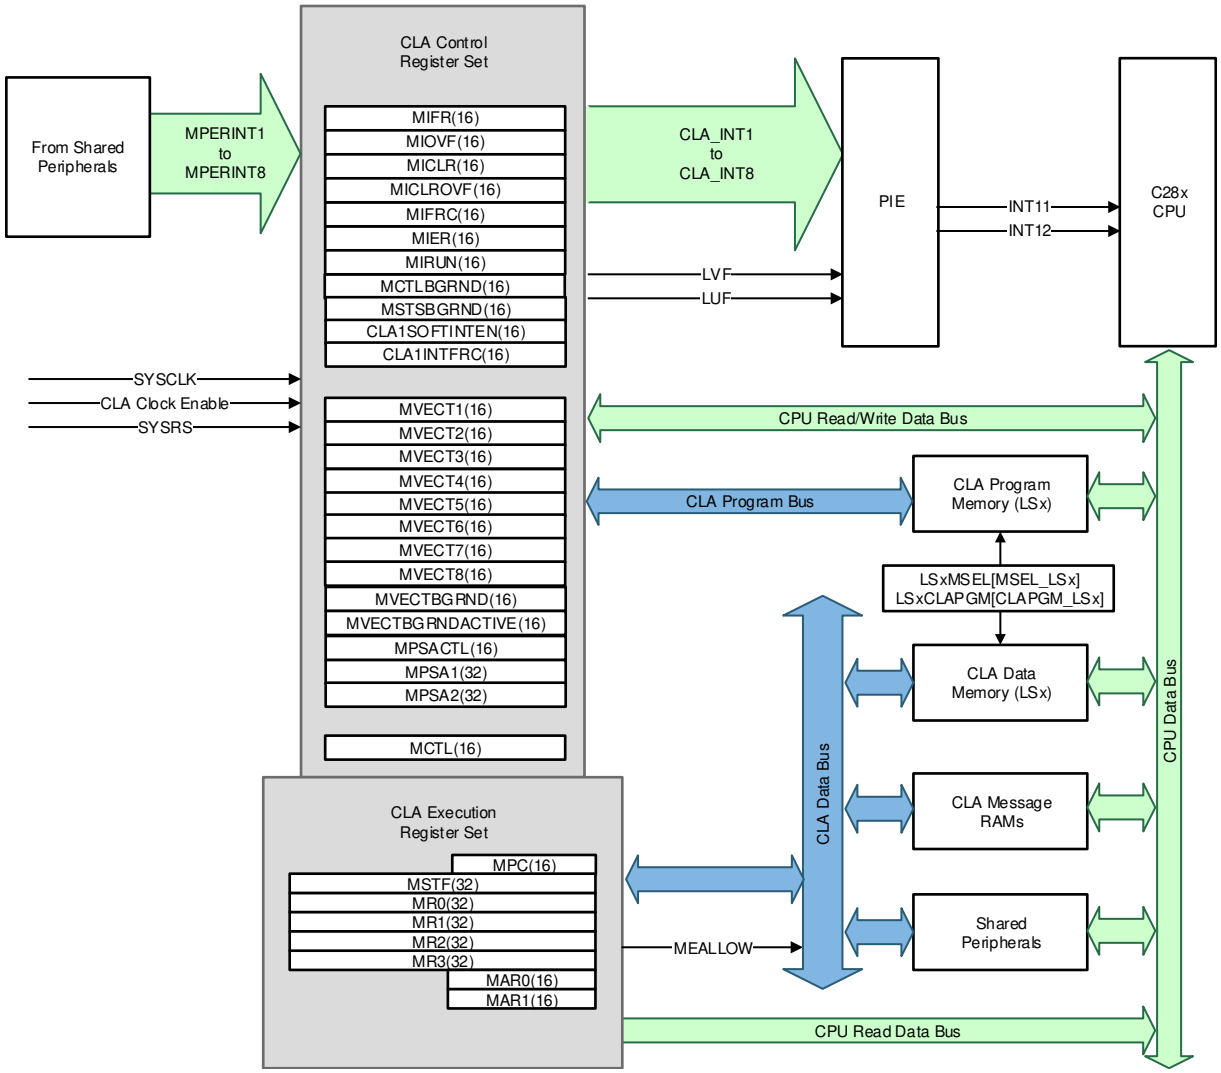

Figure 7-1. CLA Block Diagram

7.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

7.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter.

- **CLA Program Memory**

  The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

  Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:
  1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
  2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit.

  When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

  All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

  Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

  Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:
  1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
  2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. The value of this bit at reset is 0.

  When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

  There are two memory blocks for data sharing and communication between the CLA and the CPU . The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.
  - **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
  - **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

7.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

  The CLA program bus has an access range of 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of blocks. This number is device-dependent and can be described in the data sheet.

- **CLA Data Read Bus**

  The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

  The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

7.2.3 Shared Peripherals and EALLOW Protection

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in Section 7.5.

7.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain the priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

  Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in Table 7-1.

  For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

  CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

  The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

  Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

  The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has a fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task in enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

7.3 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure occurs. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

7.3.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU or CLA and DMA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
  The following accesses are allowed:
  - CPU reads
  - CLA data reads and writes
  - CPU debug reads and writes

  The following accesses are ignored:
  - CPU writes
- CPU to CLA Message RAM:
  The following accesses are allowed:
  - CPU reads and writes
  - CLA reads
  - CPU debug reads and writes

  The following accesses are ignored:
  - CLA writes

7.3.2 CLA Program Memory

The behavior of the program memory depends on the state of the MMEMCFG[PROGE] bit. This bit controls whether the memory is mapped to CLA space or CPU space.

- **MMEMCFG[PROGE] == 0**

  In this case, the memory is mapped to the CPU. The CLA is halted and no tasks can be incoming.
  - Any CLA fetch is treated as an illegal opcode condition as described in Section 7.4.4. This condition does not occur, if the proper procedure is followed to map the program memory.
  - CLA reads and writes cannot occur
  - The memory block behaves as any normal RAM block mapped to CPU memory space.

  Priority of accesses are (highest priority first):
  1. CPU data write, program write, debug write
  2. CPU data read, program read, debug read
  3. CPU fetch, program read

- **MMEMCFG[PROGE] == 1**

  In this case, the memory block is mapped to CLA space. The CPU can only make debug accesses.
  - CLA reads and writes cannot occur
  - CLA fetches are allowed
  - CPU fetches return 0 that is an illegal opcode and causes an ITRAP interrupt.
  - CPU data reads and program reads return 0
  - CPU data writes and program writes are ignored

  Priority of accesses are (highest priority first):
  1. CLA fetch
  2. CPU debug write
  3. CPU debug read

Note

Because the CLA fetch has higher priority than CPU debug reads, there is a possibility for the CLA to permanently block debug accesses if the CLA is executing in a loop. This can occur when initially developing CLA code due to a bug. To avoid this issue, the program memory returns all 0x0000 for CPU debug reads (ignore writes) when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access can be performed.

7.3.3 CLA Data Memory

There are independent data memory blocks. The behavior of the data memory depends on the state of the MMEMCFG[RAM0E] MMEMCFG[RAM1E] bits. These bits determine whether the memory blocks are mapped to CLA space or CPU space.

- **MMEMCFG[RAMxE] == 0**

  In this case the memory block is mapped to the CPU.
  - CLA fetches cannot occur to this block.
  - CLA reads return 0.
  - CLA writes are ignored.
  - The memory block behaves as any normal RAM block mapped to the CPU memory space.

  Priority of accesses are (highest priority first):
  1. CPU data write/program write/debug access write
  2. CPU data read/debug access read
  3. CPU fetch/program read

- **MMEMCFG[RAMxE] == 1**

  In this case the memory block is mapped to CLA space. The CPU can make only debug accesses.
  - CLA fetches cannot occur to this block.
  - CLA read and CLA writes are allowed.
  - CPU fetches return 0
  - CPU data reads and program reads return 0.
  - CPU data writes and program writes are ignored.

  Priority of accesses are (highest priority first):
  1. CLA data write
  2. CPU debug write
  3. CPU debug read
  4. CLA read

7.3.4 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

7.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

7.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in Section 7.7, or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the **.sect** assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

7.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. **Copy CLA code into the CLA program RAM:** The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
2. **Initialize CLA data RAM, if necessary:** Populate the CLA data RAM with any required data coefficients or constants.
3. **Configure the CLA registers:** Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
   - **Enable the CLA peripheral clock using the assigned PCLKCRn register:** The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
   - **Populate the CLA task interrupt vectors:**
     - MVECT1 to MVECT8
   - **Select the task interrupt sources:** For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt.
   - **Enable IACK to start a task from software, if desired:** To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit.
   - **Map CLA data RAM to CLA space, if necessary:**
   - **Map CLA program RAM to CLA space:**
4. **Initialize the PIE vector table and registers:** When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
5. **Enable CLA tasks/interrupts:** Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
6. **Initialize other peripherals:** Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

   The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

7.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

7.4.3.1 Breakpoint Support (MDEBUGSTOP)

1. **Insert a breakpoint in CLA code**

   Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUGSTOP instruction as needed.

   If CLA breakpoints are not enabled, then the MDEBUGSTOP instruction is ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUGSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the __mdebugstop() intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.
2. **Enable CLA breakpoints**

   Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.
3. **Start the task**

   There are three ways to start the task:
   a. The peripheral can assert an interrupt,
   b. The main CPU can execute an IACK instruction, or
   c. The user can manually write to the MIFRC register in the debugger window

   When the task starts, the CLA executes instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUGSTOP instruction.

4. **Single-step the CLA code**

   Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

   Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

   Note

   A CLA fetch has higher priority than CPU debug reads. For this reason, the CLA to permanently block CPU debug accesses if the CLA is executing in a loop is possible. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

   If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

   There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

   - **MPC halts at or after the MSTOP with a task already pending**

     If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
   - **MPC halts at or after the MSTOP with no task pending**

     In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

     Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

     This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

5. **Disable CLA breakpoints, if desired**

   In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

7.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, the CLA behaves as follows:

- The CLA halts with the illegal opcode in the D2 phase of the pipeline as if a breakpoint. This occurs whether CLA breakpoints are enabled or not.
- The CLA issues the task-specific interrupt to the PIE.
- The MIRUN bit for the task remains set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in Section 7.4.5.

7.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using $\overline{\text{XRS}}$ or the debugger). In this case, all CLA configuration and execution registers can be set to the default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start.

7.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

7.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage is stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage is stalled.

7.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

  In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in Table 7-2. In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in Table 7-3.

  This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

Table 7-2. Write Followed by Read - Read Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

Table 7-3. Write Followed by Read - Write Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	
						I5	I4	
							I5	

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

  Referring to Example 7-1, the following applies to delayed conditional instructions:
  - **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
  - **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
  - **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

  For a more detailed description, refer to the description for MBCNDD, MCCNDD, and MRCNDD.

Example 7-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD

```
  <Instruction 1>    ; I1 Last instruction that can affect flags for
                     ;     the branch, call or return operation
  <Instruction 2>    ; I2 Cannot be stop, branch, call or return
  <Instruction 3>    ; I3 Cannot be stop, branch, call or return
  <Instruction 4>    ; I4 Cannot be stop, branch, call or return
  <branch/call/ret>  ; MBCNDD, MCCNDD or MRCNDD
                     ; I5-I7: Three instructions after are always
                     ; executed whether the branch/call or return is
                     ; taken or not
  <Instruction 5>    ; I5 Cannot be stop, branch, call or return
  <Instruction 6>    ; I6 Cannot be stop, branch, call or return
  <Instruction 7>    ; I7 Cannot be stop, branch, call or return
  <Instruction 8>    ; I8
  <Instruction 9>    ; I9
  ....
```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

  The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to Example 7-1. To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

- **Loading MAR0 or MAR1**

  A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to Example 7-2, the following applies when loading the auxiliary registers:
  - **I1 and I2:** The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
  - **I3:** Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
  - **I4:** Starting with the 4th instruction MAR0 or MAR1 has the new value.

Example 7-2. Code Fragment for Loading MAR0 or MAR1

```
; Assume MAR0 is 50 and #_X is 20

   MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
   <Instruction 1>   ; I1 uses the old value of MAR0 (50)
   <Instruction 2>   ; I2 uses the old value of MAR0 (50)
   <Instruction 3>   ; I3 Cannot use MAR0
   <Instruction 4>   ; I4 uses the new value of MAR0 (20)
   <Instruction 5>   ; I5 uses the new value of MAR0 (20)
   ....
```

7.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

From a CLA perspective, the pipeline activity is shown in Table 7-4 for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

Table 7-4. ADC to CLA Early Interrupt Response

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
$Conversion_{(Cycle\ 1)}$	Interrupt Received								
$Conversion_{(Cycle\ 2)}$	Task Startup								
$Conversion_{(Cycle\ 3)}$	Task Startup								
$Conversion_{(Cycle\ 4)}$	$I_{(Cycle\ 4)}$	$I_{(Cycle\ 4)}$							
$Conversion_{(Cycle\ 5)}$	$I_{(Cycle\ 5)}$	$I_{(Cycle\ 5)}$	$I_{(Cycle\ 4)}$						
$Conversion_{(...)}$	...	...	...	...	...	...	...		
$Conversion_{(Cycle\ N-6)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$	$I_{(Cycle\ N-9)}$	$I_{(Cycle\ N-10)}$	$I_{(Cycle\ N-11)}$		
$Conversion_{(Cycle\ N-5)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$	$I_{(Cycle\ N-9)}$	$I_{(Cycle\ N-10)}$		
$Conversion_{(Cycle\ N-4)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$	$I_{(Cycle\ N-9)}$		
$Conversion_{(Cycle\ N-3)}$	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$	$I_{(Cycle\ N-8)}$		
$Conversion_{(Cycle\ N-2)}$	**Read RESULT**	**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$	$I_{(Cycle\ N-7)}$		
$Conversion_{(Cycle\ N-1)}$			**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$	$I_{(Cycle\ N-6)}$		
$Conversion_{(Cycle\ N-0)}$				**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$	$I_{(Cycle\ N-5)}$		
Conversion Complete					**Read RESULT**	$I_{(Cycle\ N-3)}$	$I_{(Cycle\ N-4)}$		
RESULT Latched						**Read RESULT**	$I_{(Cycle\ N-3)}$		
RESULT Available							**Read RESULT**		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is (N-2) - 4 = N-6.

7.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

Example 7-3. Math Operation with Parallel Load

```
;  MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
;  MADDF32 is a 1 cycle operation
;  MMOV32 is a 1 cycle operation
         MADDF32    MR0,  MR1, #2     ; MR0 = MR1 + 2,
      || MMOV32   MR1,  @Val           ; MR1 gets the contents of Val
                                       ; <-- MMOV32 completes here (MR1 is valid)
                                       ; <-- DDF32 completes here (MR0 is valid)
         MMPYF32 MR0, MR0, MR1         ; Any instruction, can use MR1 and/or MR0
```

Example 7-4. Multiply with Parallel Add

```
;  MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
;  MMPYF32 is a 1 cycle operation
;  MADDF32 is a 1 cycle operation
     MMPYF32 MR0, MR1, MR3         ; MR0 = MR1 * MR3
 ||  MADDF32 MR1, MR2, MR0         ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
                                   ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
     MMPYF32 MR1, MR1, MR0         ; Any instruction, can use MR1 and/or MR0
```

7.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

  Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

  Note

  If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

  Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

  Note

  If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

  The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

7.6.2 CLA Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cla

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

7.6.2.1 CLA arcsine(x) using a lookup table (cla_asin_cpu01)

FILE: cla_asin_ls8_9.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag cla_background_task is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS0)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

7.6.2.2 CLA arcsine(x) using a lookup table (cla_asin_cpu01)

FILE: cla_ex1_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag cla_background_task is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS1)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM

  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

Watch Variables
- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

7.6.2.3 CLA arctangent(x) using a lookup table (cla_atan_cpu01)

FILE: cla_ex2_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag cla_background_task is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation
- CLA1 Math Tables (RAMLS1)
  - CLAatan2Table - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fNum - Numerator of sample input
  - fDen - Denominator of sample input

Watch Variables
- fVal - Argument to task 1
- fResult - Result of arctan(fVal)

7.6.2.4 CLA background nesting task

FILE: cla_ex3_background_nesting_task.c

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag cla_background_task is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

7.6.2.5 Controlling PWM output using CLA

FILE: cla_ex4_pwm_control.c

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual

use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

External Connections

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

- duty

7.6.2.6 Just-in-time ADC sampling with CLA

FILE: cla_ex5_adc_just_in_time.c

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched.The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :- -ADC acquisition cycles programmed = 10 SYSCLKS -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCLKS -CLA task trigger to first instruction in Fetch delay = 4 -Let the interrupt offset value be 'x' -The code inside CLA control task before ADC read takes below cycles : Setting up profiling gpio : 3 cycles Pre-processing : 13 cycles Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. : x + 4 + 16 = 40 : x = 20

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality , observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (293 ns) based on the above calculation.

External Connections

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1 3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto fs / 10 = 100 KHz for observing continuous duty variations
- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

Watch Variables

7.6.2.7 Optimal offloading of control algorithms to CLA

FILE: cla_ex6_cpu_offloading.c

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the

PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system_OFF" is set to 1. The system gets enabled again once "system_OFF" is restored back to 0. By default system_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops. User-configurable pre-defined symbol "run_loop1_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For run_loop1_cla == 0 i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For run_loop1_cla == 1 i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU)= ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intutive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be 1.0(0.2 + 0.8) but will get saturated to 0.9(the maximum value defined). Similarly if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

External Connections

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V 0.8 3.3V 3.3V 0.1

Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

7.6.2.8 Handling shared resources across C28x and CLA

FILE: cla_ex7_shared_resource_handling.c

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100Khz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA

do read-modify -write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase_shift_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase_shift_ON" is set to 1.

External Connections

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

7.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

7.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction presents the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x instructions; the source operands are always on the right and the destination operands are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the CLA are given in Table 7-6.

Table 7-6. Operand Nomenclature

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	Auxiliary register 0
MAR1	Auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

Table 7-7. INSTRUCTION dest, source1, source2 Short Description

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in Section 7.5
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed the CLA data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

7.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown Table 7-8.

Table 7-8. Addressing Modes

Addressing Mode	'addr' Opcode Field Encode[1]	Description
@dir	**0000**	**Direct Addressing Mode** Example 1: MMOV32 MR1, @_VarA Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all In this case, the 'mmmm mmmm mmmm mmmm' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU. For example, @_VarA populates the address of the variable VarA. and @_EPwm1Regs.CMPA.all populates the address of the CMPA register.
***MAR0[#imm16]++**	**0001**	**MAR0 Indirect Addressing with 16-bit Immediate Post Increment**
***MAR1[#imm16]++**	**0010**	**MAR1 Indirect Addressing with 16-bit Immediate Post Increment** addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16. Example 1: MMOV32 MR0, *MAR0[2]++ Example 2: MMOV32 MR1, *MAR1[-2]++ For a post increment of 0, the assembler accepts both *MAR0 and *MAR0[0]++. The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFE. If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in Table 7-9.

Table 7-9. Shift Field Encoding

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	....
32	1111

For instructions that use MRx (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to Table 7-10.

Table 7-10. Operand Encoding

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

Table 7-11 shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

Table 7-11. Condition Field Encoding

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

7.7.3 Instructions

The instructions are listed alphabetically.

Instruction Set Summary

MABSF32 MRa, MRb

32-Bit Floating-Point Absolute Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
        else {MRa =  MRb};
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MABSF32 MR0, MR0  ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0  ; MR0 = 5.0 (0x40A00000)
MABSF32 MR0, MR0  ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0  ; MR0 = 0.0
MABSF32 MR0, MR0  ; MR0 = 0.0 ZF = 1, NF = 0
```

See also

MNEGF32 MRa, MRb {, CNDF}

MADD32 MRa, MRb, MRc

32-Bit Integer Add

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
       MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
       MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
       MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFF9)
       MADD32 MR3, MR0, MR1 ; A + B
       MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFC)
       MMOV32 @_y2, MR3     ; Store y2
       MSTOP                ; end of task
```

MADDF32 MRa, #16FHi, MRb

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
  MADDF32 MR0, #2.0, MR1    ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
  MADDF32 MR2, #-2.5, MR3   ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
  MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
   MMOV32 MR0,@M1       ; Load MR0 with M1
   MMOV32 MR1,@X1       ; Load MR1 with X1
   MMPYF32 MR1,MR1,MR0  ; Multiply M1*X1
|| MMOV32 MR0,@B1       ; and in parallel load MR0 with B1

32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
_Cla1Task2:
   MMOV32   MR0, @_A         ; Load MR0 with A
   MMOV32   MR1, @_B         ; Load MR1 with B
   MMPYF32  MR1, MR1, MR0    ; Multiply A*B
|| MMOV32   MR0, @_C         ;     and in parallel load MR0 with C
   MADDF32  MR1, MR1, MR0    ; Add (A*B) to C
|| MMOV32   @_Y2, MR1        ;     and in parallel store A*B
   MMOV32   @_Y3, MR1        ; Store the A*B + C

32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

Bitwise AND

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

Description

Bitwise AND of MRb with MRc.

```
MRa(31:0) = MRb(31:0) AND MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ   MR0,    #0x5555  ; MR0 = 0x5555AAAA
MMOVXI   MR0,    #0xAAAA
MMOVIZ   MR1,    #0x5432  ; MR1 = 0x5432FEDC
MMOVXI   MR1,    #0xFEDC

MBCNDD 16BitDest {, CNDF}

Branch Conditional Delayed

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MBCNDD 16BitDest {, CNDF} (continued)

Branch Conditional Delayed

Pipeline

The MBCNDD instruction alone is a single-cycle instruction. As shown in Table 7-12, 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to Table 7-12 and Table 7-13, the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```

MRCNDD CNDF

MCCNDD 16BitDest {, CNDF}

Call Conditional Delayed

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

Description

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

Flags

This instruction does not modify flags in the MSTF register.

MCCNDD 16BitDest {, CNDF} (continued)

Call Conditional Delayed

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MCCNDD instruction alone is a single-cycle instruction. As shown in Table 7-14, 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in Table 7-14 and Table 7-15, the instructions before and after MCCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MCMP32 MRa, MRb

32-Bit Integer Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to MCMPF32.

Note

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag --cla_signed_compare_workaround enables this workaround.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa ==    MRb) {ZF=1; NF=0;}
If(MRa >  MRb) {ZF=0; NF=0;}
If(MRa <  MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
    MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFF9)
    MCMP32 MR2, MR2 ; NF = 0, ZF = 1
    MCMP32 MR0, MR1 ; NF = 1, ZF = 0
    MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

MCMP32 MRa, MRb (continued)

32-Bit Integer Compare for Equal, Less Than or Greater Than

See also

MADD32 MRa, MRb, MRc
MSUB32 MRa, MRb, MRc

MCMPF32 MRa, MRb

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb)   {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
    MMOVIZ    MR1, #-2.0  ; MR1 = -2.0 (0xC0000000)
    MMOVIZ    MR0, #5.0   ; MR0 = 5.0 (0x40A00000)
    MCMPF32   MR1, MR0    ; ZF = 0, NF = 1
    MCMPF32   MR0, MR1    ; ZF = 0, NF = 0
    MCMPF32   MR0, MR0    ; ZF = 1, NF = 0
```

See also

MMAXF32 MRa, MRb
MMINF32 MRa, #16FHi
MMINF32 MRa, MRb

MCMPF32 MRa, #16FHi

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

Description

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

Pipeline

This is a single-cycle instruction

Example 1

```
; Behavior of ZF and NF flags for different comparisons
  MMOVIZ      MR1, #-2.0  ; MR1 = -2.0 (0xC0000000)
  MMOVIZ      MR0, #5.0   ; MR0 = 5.0 (0x40A00000)
  MCMPF32     MR1, #-2.2  ; ZF = 0, NF = 0
  MCMPF32     MR0, #6.5   ; ZF = 0, NF = 1
  MCMPF32     MR0, #5.0   ; ZF = 1, NF = 0
```

MDEBUGSTOP

Debug Stop Task

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000
```

Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction.

Flags

This instruction does not modify flags in the MSTF register.

MEALLOW

Enable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000
```

Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
   .cdecls C,LIST,"CLAShared.h"
   ...
_Cla1Task1:
   ...
   MEALLOW                          ; Allow CLA write access
   MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
   MEDIS                            ; Disallow CLA write access
   ...
   ...
   MSTOP
```

MEDIS

MEDIS

Disable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000
```

Description

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
   .cdecls C,LIST,"CLAShared.h"
   ...
_Cla1Task1:
   ...
   MEALLOW                          ; Allow CLA write access
   MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
   MEDIS                            ; Disallow CLA write access
   ...
   ...
   MSTOP
```

MEINVF32 MRa, MRb

32-Bit Floating-Point Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

Description

This operation generates an estimate of 1/X in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MEINVF32 MRa, MRb (continued)

32-Bit Floating-Point Reciprocal Approximation

Example

```
; Calculate Num/Den using a Newton-Raphson algorithum for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
_Cla1Task1:
    MMOV32 MR1, @_Den       ; MR1 = Den
    MEINVF32 MR2, MR1       ; MR2 = Ye = Estimate(1/Den)
    MMPYF32 MR3, MR2, MR1   ; MR3 = Ye*Den
    MSUBF32 MR3, #2.0, MR3  ; MR3 = 2.0 - Ye*Den
    MMPYF32 MR2, MR2, MR3   ; MR2 = Ye = Ye*(2.0 - Ye*Den)
    MMPYF32 MR3, MR2, MR1   ; MR3 = Ye*Den
 || MMOV32 MR0, @_Num       ; MR0 = Num
    MSUBF32 MR3, #2.0, MR3  ; MR3 = 2.0 - Ye*Den
    MMPYF32 MR2, MR2, MR3   ; MR2 = Ye = Ye*(2.0 - Ye*Den)
 || MMOV32 MR1, @_Den       ; Reload Den To Set Sign
    MNEGF32 MR0, MR0, EQ    ; if(Den == 0.0) Change Sign Of Num
    MMPYF32 MR0, MR2, MR0   ; MR0 = Y = Ye*Num
    MMOV32 @_Dest, MR0      ; Store result
    MSTOP                   ; end of task
```

MEISQRTF32 MRa, MRb

32-Bit Floating-Point Square-Root Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

Description

This operation generates an estimate of 1/sqrt(X) in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MEISQRTF32 MRa, MRb (continued)

32-Bit Floating-Point Square-Root Reciprocal Approximation

Example

```
; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
    MMOV32 MR0, @_x          ; MR0 = X
    MEISQRTF32 MR1, MR0      ; MR1 = Ye = Estimate(1/sqrt(X))
    MMOV32 MR1, @_x, EQ      ; if(X == 0.0) Ye = 0.0
    MMPYF32 MR3, MR0, #0.5   ; MR3 = X*0.5
    MMPYF32 MR2, MR1, MR3    ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2    ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2   ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2    ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR2, MR1, MR3    ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2    ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2   ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2    ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR0, MR1, MR0    ; MR0 = Y = Ye*X
    MMOV32 @_y, MR0          ; Store Y = sqrt(X)

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1000 0000
```

Description

Convert the 16-bit signed integer in MRb to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32(MRb);
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ      MR0, #0x0000    ; MR0(31:16) = 0.0 (0x0000)
MMOVXI      MR0, #0x0004    ; MR0(15:0) = 4.0 (0x0004)
MI16TOF32   MR1, MR0        ; MR1 = MI16TOF32 (MR0) = 4.0 (0x40800000)
MMOVIZ      MR2, #0x0000    ; MR2(31:16) = 0.0 (0x0000)
MMOVXI      MR2, #0xFFFC    ; MR2(15:0) = -4.0 (0xFFFC)
MI16TOF32   MR3, MR2        ; MR3 = MI16TOF32 (MR2) = -4.0 (0xC0800000)
MSTOP
```

MI16TOF32 MRa, mem16

Convert 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location to be converted

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 00aa addr
```

Description

Convert the 16-bit signed integer indicated by the mem16 pointer to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction:

Example

```
; Assume A = 4 (0x0004)
;        B = -4 (0xFFFC)
   MI16TOF32 MR0, @_A ; MR0 = MI16TOF32(A) = 4.0 (0x40800000)
   MI16TOF32 MR1, @_B ; MR1 = MI16TOF32(B) = -4.0 (0xC0800000
```

MI32TOF32 MRa, mem32

Convert 32-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 01aa addr
```

Description

Convert the 32-bit signed integer indicated by mem32 to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI32TOF32[mem32];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Given X, M and B are IQ24 numbers:
; X = IQ24(+2.5) = 0x02800000
; M = IQ24(+1.5) = 0x01800000
; B = IQ24(-0.5) = 0xFF800000
;
; Calculate Y = X * M + B
;
; Convert M, X, and B from IQ24 to float
;

MLSL32 MRa, #SHIFT

Logical Shift Left

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

Description

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
;       x2 = (int32)64
;       b2 = (int32)-128
;
; Calculate:
;       m2 = m2*2
;       x2 = x2*4
;       b2 = b2*8
;
_Cla1Task3:
   MMOV32 MR0, @_m2    ; MR0 = 32 (0x00000020)
   MMOV32 MR1, @_x2    ; MR1 = 64 (0x00000040)
   MMOV32 MR2, @_b2    ; MR2 = -128 (0xFFFFFF80)
   MLSL32 MR0, #1      ; MR0 = 64 (0x00000040)
   MLSL32 MR1, #2      ; MR1 = 256 (0x00000100)
   MLSL32 MR2, #3      ; MR2 = -1024 (0xFFFFFC00)
   MMOV32 @_m2, MR0    ; Store results
   MMOV32 @_x2, MR1
   MMOV32 @_b2, MR2
   MSTOP               ; end of task
```

MLSR32 MRa, #SHIFT

Logical Shift Right

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

Description

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA   ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0       ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0       ; MR2 = 0xAAAA5555
MASR32 MR1, #1        ; MR1 = 0xD5552AAA
MLSR32 MR2, #1        ; MR2 = 0x55552AAA
MASR32 MR1, #1        ; MR1 = 0xEAAA9555
MLSR32 MR2, #1        ; MR2 = 0x2AAA9555
MASR32 MR1, #6        ; MR1 = 0xFFAAAA55
MLSR32 MR2, #6        ; MR2 = 0x00AAAA55
```

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32

32-Bit Floating-Point Multiply and Accumulate with Parallel Move

Operands

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

Description

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

MMACF32 and MMOV32 complete in a single cycle.

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

32-Bit Floating-Point Multiply and Accumulate with Parallel Move

Example 1

```
; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E

MMAXF32 MRa, MRb

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

Description

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb)  {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ   MR0, #5.0  ; MR0 =  5.0  (0x40A00000)
MMOVIZ   MR1, #-2.0 ; MR1 = -2.0  (0xC0000000)
MMOVIZ   MR2, #-1.5 ; MR2 = -1.5  (0xBFC00000)
MMAXF32   MR2, MR1  ; MR2 = -1.5, ZF = NF = 0
MMAXF32   MR1, MR2  ; MR1 = -1.5, ZF = 0, NF = 1
MMAXF32   MR2, MR0  ; MR2 =  5.0, ZF = 0, NF = 1
MAXF32   MR0, MR2   ; MR2 =  5.0, ZF = 1, NF = 0
```

MMAXF32 MRa, MRb (continued)

32-Bit Floating-Point Maximum

Example 2

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store the value in Result
;

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0)  {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #5.0  ; MR0 =  5.0  (0x40A00000)
MMOVIZ    MR1, #4.0  ; MR1 =  4.0  (0x40800000)
MMOVIZ    MR2, #-1.5 ; MR2 = -1.5  (0xBFC00000)
MMAXF32   MR0, #5.5  ; MR0 =  5.5, ZF = 0, NF = 1
MMAXF32   MR1, #2.5  ; MR1 =  4.0, ZF = 0, NF = 0
MMAXF32   MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32   MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

32-Bit Floating-Point Minimum

Operands

MRa	floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0100 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is smaller, then load the value into MRa.

```
if(MRa > #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMINF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0)   {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ   MR0, #5.0   ; MR0 =  5.0  (0x40A00000)
MMOVIZ   MR1, #4.0   ; MR1 =  4.0  (0x40800000)
MMOVIZ   MR2, #-1.5  ; MR2 = -1.5  (0xBFC00000)
MMINF32  MR0, #5.5   ; MR0 =  5.0, ZF = 0, NF = 1
MMINF32  MR1, #2.5   ; MR1 =  2.5, ZF = 0, NF = 0
MMINF32  MR2, #-1.0  ; MR2 = -1.5, ZF = 0, NF = 1
MMINF32  MR2, #-1.5  ; MR2 = -1.5, ZF = 1, NF = 0
```

MMOV16 MARx, MRa, #16I

Load the Auxiliary Register with MRa + 16-bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

Description

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = MRa(15:0) + #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
  MMOV16 MAR0, MR0, #_X        ; Load MAR0 with address of X (20) + MR0 (10)
  <Instruction 1>         ; I1 Uses the old value of MAR0 (50)
  <Instruction 2>         ; I2 Uses the old value of MAR0 (50)
  <Instruction 3>         ; I3 Cannot use MAR0
  <Instruction 4>         ; I4 Uses the new value of MAR0 (30)
  <Instruction 5>         ; I5
```

MMOV16 MARx, MRa, #16I (continued)

MMOV16 MARx, mem16

Load MAR1 with 16-bit Value

Operands

MARx	CLA auxiliary register MAR0 or MAR1
mem16	16-bit destination memory accessed using one of the available addressing modes

Opcode

```
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR0, mem16)
MSW: 0111 0110 0000 addr
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR1, mem16)
MSW: 0111 0110 0100 addr
```

Description

Load MAR0 or MAR1 with the 16-bit value pointed to by mem16. Refer to the Pipeline section for important information regarding this instruction.

```
MAR1 = [mem16];
```

Flags

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50 and @_X is 20
MMOV16 MAR0, @_X    ; Load MAR0 with the contents of X (20)
<Instruction 1>     ; I1 Uses the old value of MAR0 (50)
<Instruction 2>     ; I2 Uses the old value of MAR0 (50)
<Instruction 3>     ; I3 Cannot use MAR0
<Instruction 4>     ; I4 Uses the new value of MAR0 (20)
<Instruction 5>     ; I5
....
```

Move 16-Bit Floating-Point Register Contents to Memory

Example

```
; This task logs the last NUM_DATA_POINTS
; ADCRESULT1 values in the array VoltageCLA
;
; When the last element in the array has been
; filled, the task goes back to the
; the first element.
;
; Before starting the ADC conversions, force
; Task 8 to initialize the ConversionCount to zero
;
; The ADC is set to sample (acquire) for 15 SYSCLK cycles
; or 75ns. After the capacitor has captured the analog
; value, the ADC triggers this task early.
; It takes 10.5 ADCCLKs to complete a conversion,
; the ADCCLK being SYSCLK/4
;   T_sys = 1/200MHz = 5ns
;   T_adc = 4*T_sys  = 20ns
; The ADC takes 10.5 * 4 or 42 SYSCLK cycles to complete
; a conversion. The ADC result register can be read on the
; 36th instruction after the task begins.

MMOV32 mem32, MRa

Move 32-Bit Floating-Point Register Contents to Memory

Operands

MRa	floating-point register (MR0 to MR3)
mem32	32-bit destination memory accessed using one of the available addressing modes

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 11aa addr
```

Description

Move from MRa to 32-bit memory location indicated by mem32.

```
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected.

Pipeline

This is a single-cycle instruction.

MMOV32 mem32, MRa (continued)

Move 32-Bit Floating-Point Register Contents to Memory

Example

```
; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3;
; Result = A + B + C + D + E

MMOV32 mem32, MSTF

MMOV32 mem32, MSTF

Move 32-Bit MSTF Register to Memory

Operands

MSTF	Floating-point status register
mem32	32-bit destination memory

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr
```

Description

Copy the CLA floating-point status register, MSTF, to memory.

```
[mem32] = MSTF;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

Example

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
 MMOV32 @_temp, MSTF ; D2|   |
MNOP                 ; R1|F1| MCCNDD is fetched
MNOP                 ; R2|F2|
MNOP                 ; E |D1|
MCCNDD _bar, UNC     ; W |D2| old RPC written to memory,
                     ;   |  | RPC updated with MPC+1
MNOP                 ;   |R1|
MNOP                 ;   |R2|
MNOP                 ;   |E | execution branches to _bar
```

MMOV32 mem32, MRa

MMOV32 MRa, mem32 {, CNDF}

Conditional 32-Bit Move

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

Description

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31);
  ZF = 0;
  if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
  else No flags modified;
```

MMOV32 MRa, mem32 {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A! = B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A
    MMOV32    MR1, @_B
    MCMPF32   MR0, MR1
    MMOV32    MR2, @_M1, EQ  ; if A == B, MR2 = M1
                             ;     Y = M1*X
    MMOV32    MR2, @_M2, NEQ ; if A! = B, MR2 = M2
                             ;     Y = M2*X
    MMOV32    MR3, @_X
    MMPYF32   MR3, MR2, MR3  ; Calculate Y
    MMOV32    @_Y, MR3       ; Store Y
    MSTOP                    ; end of task
```

Conditional 32-Bit Move

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Optional condition

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000
```

Description

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = MRb;
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
 {
   NF = MRa(31); ZF = 0;
   if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

MMOV32 MRa, MRb {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```
; Given: X = 8.0
;        Y = 7.0
;        A = 2.0
;        B = 5.0
; _ClaTask1
    MMOV32   MR3, @_X      ; MR3 = X = 8.0
    MMOV32   MR0, @_Y      ; MR0 = Y = 7.0
    MMAXF32  MR3, MR0      ; ZF = 0, NF = 0, MR3 = 8.0
    MMOV32   MR1, @_A, GT  ; true, MR1 = A = 2.0
    MMOV32   MR1, @_B, LT  ; false, does not load MR1
    MMOV32   MR2, MR1, GT  ; true, MR2 = MR1 = 2.0
    MMOV32   MR2, MR0, LT  ; false, does not load MR2
    MSTOP
```

MMOV32 MSTF, mem32

Move 32-Bit Value from Memory to the MSTF Register

Operands

MSTF	CLA status register
mem32	32-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0000 addr
```

Description

Move from memory to the CLA's status register MSTF. This instruction is most useful when nesting function calls (using MCCNDD).

```
MSTF = [mem32];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Loading the status register can overwrite all flags and the RPC field. The MEALLOW field is not affected.

Pipeline

This is a single-cycle instruction.

```

See also

MMOV32 MRa, mem32 {,CNDF}

MMOVF32 MRa, #32F

Load the 32-Bits of a 32-Bit Floating-Point Register

Operands

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex
```

MRa	CLA floating-point destination register (MR0 to MR3)
#32F	Immediate float value represented in floating-point representation

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating- point format), use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

Example

```
MMOVF32 MR1, #3.0     ; MR1 = 3.0 (0x40400000)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0     ; MR2 = 0.0 (0x00000000)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265  ; MR3 = 12.625 (0x41443D71)
                      ; Assembler converts this instruction as
                      ; MMOVIZ MR3, #0x4144
                      ; MMOVXI MR3, #0x3D71
```

MMOVF32 MRa, #32F (continued)

Load the 32-Bits of a 32-Bit Floating-Point Register

See also

MMOVIZ MRa, #16FHi
MMOVXI MRa, #16FLoHex
MMOVI32 MRa, #32FHex

MMOVI16 MARx, #16I

Load the Auxiliary Register with the 16-Bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000
```

Description

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

  The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.
- **I3**

  Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.
- **I4**

  Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```
;  Assume MAR0 is 50 and #_X is 20

I6	I6	I5	I4	I3	I2	I1	MMOVI16	

MMOVI32 MRa, #32FHex

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

Operands

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOVI32 to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOVI32 to MMOVIZ and MMOVXI instructions.

MMOVI32 MRa, #32FHex (continued)

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

Example

```
MOVI32   MR1, #0x40400000 ; MR1 = 0x40400000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR1, #0x4040
MOVI32  MR2, #0x00000000  ; MR2 = 0x00000000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR2, #0x0
MOVI32  MR3, #0x40004001  ; MR3 = 0x40004001
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR3, #0x4000
                          ; MMOVXI MR3, #0x4001
MOVI32  MR0, #0x00004040  ; MR0 = 0x00004040
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR0, #0x0000
                          ; MMOVXI MR0, #0x4040
```

MMOVIZ MRa, #16FHi

Load the Upper 16-Bits of a 32-Bit Floating-Point Register

Operands

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

Description

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0)  = 0;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
     MMOVIZ    MR0, #0xBFC0      ; MR0 = 0xBFC00000 (1.5)
     MMOVIZ    MR1, #-1.5        ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
     MMOVIZ    MR2, #0x4049      ; MR2 = 0x40490000
     MMOVXI    MR2, #0x0FDB      ; MR2 = 0x40490FDB
```

MMOVZ16 MRa, mem16

Load MRx with 16-Bit Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

Description

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0)== 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

MMOVXI MRa, #16FLoHex

Move Immediate Value to the Lower 16-Bits of a Floating-Point Register

Operands

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

Description

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

Flags

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
    MMOVIZ      MR0,#0x4049   ; MR0 = 0x40490000
    MMOVXI      MR0,#0x0FDB   ; MR0 = 0x40490FDB
```

MMPYF32 MRa, #16FHi, MRb

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; Same as example 2 but #16FHi is represented in float
    MMOVIZ    MR3, #2.0       ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, #3.0, MR3 ; MR0 = 3.0 * MR3 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0        ; Save the result in variable X
```

Example 2

```
; Same as example 1 but #16FHi is represented in Hex
    MMOVIZ    MR3, #2.0          ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, #0x4040, MR3 ; MR0 = 0x4040 * MR3 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0           ; Save the result in variable X
```

MMPYF32 MRa, MRb, #16FHi

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
;Same as example 2 but #16FHi is represented in float
    MMOVIZ    MR3, #2.0        ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, MR3, #3.0   ; MR0 = MR3 * 3.0 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0         ; Save the result in variable X
```

Example 2

```
;Same as example 1 but #16FHi is represented in Hex
    MMOVIZ    MR3, #2.0          ; MR3 = 2.0 (0x40000000)
    MMPYF32   MR0, MR3, #0x4040  ; MR0 = MR3 * 0x4040 = 6.0 (0x40C00000)
    MMOV32    @_X, MR0           ; Save the result in variable X
```

MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

Opcode

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

Description

Multiply the contents of two floating-point registers with parallel addition of two registers.

```
MRa = MRb * MRc;
MRd = MRe + MRf;
```

Restrictions

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

Pipeline

Both MMPYF32 and MADDF32 complete in a single cycle.

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32

32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRa	CLA floating-point destination register for MMOV32 (MR0 to MR3) MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source of MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0000 ffee ddaa addr
```

Description

Multiply the contents of two floating-point registers and load another.

```
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MMPYF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

Both MMPYF32 and MMOV32 complete in a single cycle.

Example 1

```
; Given M1, X1, and B1 are 32-bit floating point
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
    MMOV32     MR0, @M1        ; Load MR0 with M1
    MMOV32     MR1, @X1        ; Load MR1 with X1
    MMPYF32    MR1, MR1, MR0   ; Multiply M1*X1
||  MMOV32     MR0, @B1        ; and in parallel load MR0 with B1
    MADDF32    MR1, MR1, MR0   ; Add M*X1 to B1 and store in MR1
    MMOV32     @Y1, MR1        ; Store the result
    MSTOP                      ; end of task
```

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

32-Bit Floating-Point Multiply with Parallel Move

Example 2

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) * C
;
_Cla1Task2:
    MMOV32    MR0, @A         ; Load MR0 with A
    MMOV32    MR1, @B         ; Load MR1 with B
    MMPYF32   MR1, MR1, MR0   ; Multiply A*B
||  MMOV32    MR0, @C         ; and in parallel load MR0 with C
    MMPYF32   MR1, MR1, MR0   ; Multiply (A*B) by C
||  MMOV32    @Y2, MR1        ; and in parallel store A*B
    MMOV32    @Y3, MR1        ; Store the result
    MSTOP                     ; end of task
```

MMPYF32 MRd, MRe, MRf ||MMOV32 mem32, MRa

32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for MMPYF32 (MR0 to MR3)
MRe	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of MMOV32.
MRa	CLA floating-point source register for MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0100 ffee ddaa addr
```

Description

Multiply the contents of two floating-point registers and move from memory to register.

```
MRd = MRe * MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

MMPYF32 and MMOV32 both complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) * C
;
_Cla1Task2:
     MMOV32    MR0, @A         ; Load MR0 with A

Opcode

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0100 0000
```

Description

Multiply the contents of two floating-point registers with parallel subtraction of two registers.

```
MRa = MRb * MRc;
MRd = MRe - MRf;
```

Restrictions

The destination register for the MMPYF32 and the MSUBF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MSUBF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MSUBF32 generates an overflow condition.

Pipeline

MMPYF32 and MSUBF32 both complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A - B)
;
_Cla1Task2:
     MMOV32   MR0, @A          ; Load MR0 with A
     MMOV32   MR1, @B          ; Load MR1 with B
     MMPYF32  MR2, MR0, MR1    ; Multiply (A*B)
||   MSUBF32  MR3, MR0, MR1    ; and in parallel Sub (A-B)

MNEGF32 MRa, MRb{, CNDF}

Conditional Negation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Condition tested

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000
```

Description

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

Pipeline

This is a single-cycle instruction.

MNEGF32 MRa, MRb{, CNDF} (continued)

Conditional Negation

Example 1

```
; Show the basic operation of MNEGF32
;
     MMOVIZ    MR0, #5.0       ; MR0 = 5.0 (0x40A00000)

```

MOR32 MRa, MRb, MRc

Bitwise OR

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1000 0000
```

Description

Bitwise OR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) OR MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI    MR0, #0xAAAA
MMOVIZ    MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI    MR1, #0xFEDC
                       ; 0101 OR 0101 = 0101 (5)
                       ; 0101 OR 0100 = 0101 (5)
                       ; 0101 OR 0011 = 0111 (7)
                       ; 0101 OR 0010 = 0111 (7)
                       ; 1010 OR 1111 = 1111 (F)
                       ; 1010 OR 1110 = 1110 (E)
                       ; 1010 OR 1101 = 1111 (F)
                       ; 1010 OR 1100 = 1110 (E)

MRCNDD {CNDF}

Return Conditional Delayed

Operands

CNDF	Optional condition

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf
```

Description

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC = RPC;
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MRCNDD instruction is a single-cycle instruction. As shown in Table 7-19, 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

MRCNDD {CNDF} (continued)

Return Conditional Delayed

Referring to the following code fragment and the pipeline diagrams in Table 7-19 and Table 7-20, the instructions before and after MRCNDD have the following properties:

```
;
;
<Instruction 1>    ; I1 Last instruction that can affect flags for
                   ; the MCCNDD operation
<Instruction 2>    ; I2 Cannot be stop, branch, call or return
<Instruction 3>    ; I3 Cannot be stop, branch, call or return
<Instruction 4>    ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ  ; Call to func if not eqal to zero
                   ; Three instructions after MCCNDD are always
                   ; executed whether the call is taken or not
<Instruction 5>    ; I5 Cannot be stop, branch, call or return
<Instruction 6>    ; I6 Cannot be stop, branch, call or return
<Instruction 7>    ; I7 Cannot be stop, branch, call or return
<Instruction 8>    ; I8 The address of this instruction is saved
                   ; in the RPC field of the MSTF register.
                   ; Upon return this value is loaded into MPC
                   ; and fetching continues from this point.
<Instruction 9>    ; I9
<Instruction 10>   ; I10
....
....
_func:
<Destination 1>    ; d1 Can be any instruction
<Destination 2>    ; d2

MSTOP
....
```

- **d4**
  - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
  - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
  - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MSETFLG FLAG, VALUE

Set or Clear Selected Floating-Point Status Flags

Operands

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

Opcode

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

Pipeline

This is a single-cycle instruction.

Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSTFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

MSTOP

Stop Task

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000
```

Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MSTOP (continued)

Stop Task

Pipeline

This is a single-cycle instruction. Table 7-21 shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a MBCNDD, MCCNDD, or MRCNDD instruction.

Table 7-21. Pipeline Activity for MSTOP

Instruction	F1	F2	D1	D2	R1	R2	E	W

MDEBUGSTOP

MSUB32 MRa, MRb, MRc

32-Bit Integer Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
;
Calculate Y2 = A - B - C
;
_Cla1Task3:
   MMOV32   MR0, @_A          ; MR0 = 1 (0x00000001)
   MMOV32   MR1, @_B          ; MR1 = 2 (0x00000002)
   MMOV32   MR2, @_C          ; MR2 = -7 (0xFFFFFFF9)
   MSUB32   MR3, MR0, MR1     ; A + B
   MSUB32   MR3, MR3, MR2     ; A + B + C = 6 (0x0000006)
   MMOV32   @_y2, MR3         ; Store y2
   MSTOP                      ; End of task
```

32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

Description

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
_Cla1Task5:
   MMOV32    MR0, @_A      ; Load MR0 with A
   MMOV32    MR1, @_B      ; Load MR1 with B
   MADDF32   MR0, MR1, MR0 ; Add A + B
|| MMOV32    MR1, @_C      ;   and in parallel load C
   MSUBF32   MR0, MR0, MR1 ; Subtract C from (A + B)
   MMOV32    @Y,  MR0      ; (A+B) - C
   MSTOP                   ; end of task
```

MSUBF32 MRa, #16FHi, MRb

32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

Description

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

32-Bit Floating-Point Subtraction with Parallel Move

Operands

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

Description

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

Example

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

MSWAPF MRa, MRb {, CNDF}

Conditional Swap

Operands

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

Opcode

```
LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000
```

Description

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode[1]	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF[2]	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

Pipeline

This is a single-cycle instruction.

    MNOP                         ; Always executed
    MSTOP                        ; End of task
```

MTESTTF CNDF

Test MSTF Register Flag Condition

Operands

CNDF	Condition to test based on MSTF flags

Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode(1)	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF(2)	Unconditional with flag modification	None

(1) Values not shown are reserved.
(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

Pipeline

This is a single-cycle instruction.

MTESTTF CNDF (continued)

Test MSTF Register Flag Condition

Example

```
; if (State == 0.1)
;    RampState = RampState || RAMPMASK
; else if (State == 0.01)
;    CoastState = CoastState || COASTMASK
; else
;    SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:
   MMOV32    MR0, @_State
   MCMPF32   MR0, #0.1         ; Affects flags for 1st MBCNDD (A)
   MCMPF32   MR0, #0.01        ; Check used by 2nd MBCNDD (B)
   MTESTTF   EQ                ; Store EQ flag in TF for 2nd MBCNDD (B)
   MNOP
   MBCNDD    _Skip1, NEQ       ; (A) If State != 0.1, go to Skip1
   MMOV32    MR1, @_RampState  ; Always executed
   MMOVXI    MR2, #RAMPMASK    ; Always executed
   MOR32     MR1, MR2          ; Always executed
   MMOV32    @_RampState, MR1  ; Execute if (A) branch not taken

   MMOV32    @_CoastState, MR1 ; Execute if (B) branch not taken
   MSTOP                       ; end of task if (B) branch not taken
_Skip2:
   MMOV32 @_SteadyState, MR3   ; Executed if (B) branch taken
   MSTOP
```

MUI16TOF32 MRa, mem16

Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

Description

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1110 0000
```

Description

Convert an unsigned 16-bit integer to a 32-bit floating-point value. When converting float32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[MRb];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVXI MR1, #0x800F ; MR1(15:0) = 32783 (0x800F)
MUI16TOF32 MR0, MR1 ; MR0 = UI16TOF32 (MR1(15:0))
                    ; = 32783.0 (0x47000F00)
```

MXOR32 MRa, MRb, MRc

Bitwise Exclusive Or

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000
```

Description

Bitwise XOR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) XOR MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555   ; MR0 = 0x5555AAAA
  MMOVXI MR0, #0xAAAA
  MMOVIZ MR1, #0x5432   ; MR1 = 0x5432FEDC
  MMOVXI MR1, #0xFEDC
  ; 0101 XOR 0101 = 0000 (0)
  ; 0101 XOR 0100 = 0001 (1)
  ; 0101 XOR 0011 = 0110 (6)
  ; 0101 XOR 0010 = 0111 (7)
  ; 1010 XOR 1111 = 0101 (5)
  ; 1010 XOR 1110 = 0100 (4)
  ; 1010 XOR 1101 = 0111 (7)
  ; 1010 XOR 1100 = 0110 (6)
  MXOR32 MR2, MR1, MR0  ; MR3 = 0x01675476
```

7.8 CLA Registers

This section describes the CLA Registers.

7.8.1 CLA Base Address Table

Table 7-22. CLA Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
Cla1onlyRegs	CLA_ONLY_REGS	CLA1_ONLY_BASE	0x0000_0C00	-	-	YES	-
Cla1SoftintRegs	CLA_SOFTINT_REGS	CLA1_SOFTINT_BASE	0x0000_0CE0	-	-	YES	-
Cla1Regs	CLA_REGS	CLA1_BASE	0x0000_1400	YES	-	-	-

7.8.2 CLA_ONLY_REGS Registers

Table 7-23 lists the memory-mapped registers for the CLA_ONLY_REGS registers. All register offset addresses not listed in Table 7-23 should be considered as reserved locations and the register contents should not be modified.

Table 7-23. CLA_ONLY_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	Go
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	Go
C2h	_MPSA1	CLA PSA1 Register	EALLOW	Go
C4h	_MPSA2	CLA PSA2 Register	EALLOW	Go
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 7-24 shows the codes that are used for access types in this section.

Table 7-24. CLA_ONLY_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.8.2.1 _MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in Figure 7-2 and described in Table 7-25.

Return to the Summary Table.

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 7-2. _MVECTBGRNDACTIVE Register

7.8.3 CLA_SOFTINT_REGS Registers

Table 7-31 lists the memory-mapped registers for the CLA_SOFTINT_REGS registers. All register offset addresses not listed in Table 7-31 should be considered as reserved locations and the register contents should not be modified.

Table 7-31. CLA_SOFTINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 7-32 shows the codes that are used for access types in this section.

Table 7-32. CLA_SOFTINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0000h]

SOFTINTEN is shown in Figure 7-8 and described in Table 7-33.

Return to the Summary Table.

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

7.8.3.2 SOFTINTFRC Register (Offset = 2h) [Reset = 0000h]

SOFTINTFRC is shown in Figure 7-9 and described in Table 7-34.

Return to the Summary Table.

Writing a value of 1 in a bit will generate the corresponding task interrupt.This register is only accessible by the CLA (not the CPU).

Complex bit access types are encoded to fit into small table cells. Table 7-36 shows the codes that are used for access types in this section.

Table 7-36. CLA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 7-36. CLA_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.8.4.1 MVECT1 Register (Offset = 0h) [Reset = 0000h]

MVECT1 is shown in Figure 7-10 and described in Table 7-37.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Figure 7-10. MVECT1 Register

Table 7-37. MVECT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

7.8.4.2 MVECT2 Register (Offset = 1h) [Reset = 0000h]

MVECT2 is shown in Figure 7-11 and described in Table 7-38.

Return to the Summary Table.

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Figure 7-11. MVECT2 Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R-0/W1S-0h	R-0/W1S-0h

Table 7-45. MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	IACK Operation Enable Bit: Writing a '1' to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of '1' will set respective MIFR bit). At reset, this feature is disabled. This feature enables the C28 CPU to efficiently trigger a task. Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register. Reset type: SYSRSn 0h (R/W) = The CLA ignores the IACK instruction. (default) 1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software. Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1 IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2
1	SOFTRESET	R-0/W1S	0h	Soft Reset Bit: Writing a '1' to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of '0' are ignored and reads always return a '0'. Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.
0	HARDRESET	R-0/W1S	0h	Hard Reset Bit: Writing a '1' to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of '0' are ignored and reads always return a '0'. Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.

7.8.4.10 _MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in Figure 7-19 and described in Table 7-46.

Return to the Summary Table.

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

Figure 7-19. _MVECTBGRNDACTIVE Register

7.8.4.15 MIFR Register (Offset = 20h) [Reset = 0000h]

MIFR is shown in Figure 7-24 and described in Table 7-51.

Return to the Summary Table.

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.
The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

7.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0000h]

MIOVF is shown in Figure 7-25 and described in Table 7-52.

Return to the Summary Table.

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

7.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0000h]

MIFRC is shown in Figure 7-26 and described in Table 7-53.

Return to the Summary Table.

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

7.8.4.18 MICLR Register (Offset = 23h) [Reset = 0000h]

MICLR is shown in Figure 7-27 and described in Table 7-54.

Return to the Summary Table.

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

7.8.4.19 MICLROVF Register (Offset = 24h) [Reset = 0000h]

MICLROVF is shown in Figure 7-28 and described in Table 7-55.

Return to the Summary Table.

Overflow flag bits in the MIOVF register are latched until manually cleared using the MICLROVF register. Writing a 1 to a MICLROVF bit will clear the corresponding bit in the MIOVF register. Writes of 0 are ignored and reads always return 0.

7.8.4.20 MIER Register (Offset = 25h) [Reset = 0000h]

MIER is shown in Figure 7-29 and described in Table 7-56.

Return to the Summary Table.

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

7.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0000h]

MIRUN is shown in Figure 7-30 and described in Table 7-57.

Return to the Summary Table.

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task competes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

7.8.4.25 _MSTF Register (Offset = 2Eh) [Reset = 00000000h]

_MSTF is shown in Figure 7-34 and described in Table 7-61.

Return to the Summary Table.

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:
- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLSR32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

Chapter 8

Neural-network Processing Unit (NPU)

This chapter describes the features and operation of the Neural-network Processing Unit, used to improve the efficiency of machine learning inferencing.

8.1 Introduction

The Neural-network Processing Unit (NPU) can support intelligent inferencing running pre-trained models. Capable of 600–1200MOPS (Mega Operations Per Second) with example model support for ARC fault detection or Motor Fault detection, the NPU provides up to 10x Neural Network (NN) inferencing cycle improvement versus a software only based implementation. Load and train models with tools from TI: Model Composer GUI or TI's command-line Modelmaker tool for an advanced set of capabilities. Both of these options automatically generate source code for the C28x, eliminating the need to manually write code.

Figure 8-1shows the toolchain and steps to add NPU support to a project, starting with importing or using existing models from TI, training the models, generating the associated software libraries, and integrating into an existing Code Composer Studio™ IDE project.

Chapter 9

Dual-Clock Comparator (DCC)

This chapter describes the Dual-Clock Comparator (DCC) module.

9.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

9.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

9.1.2 Block Diagram

Figure 9-1 shows how the DCC connects to the rest of the system. Figure 9-2 shows the main concept of the DCC module.

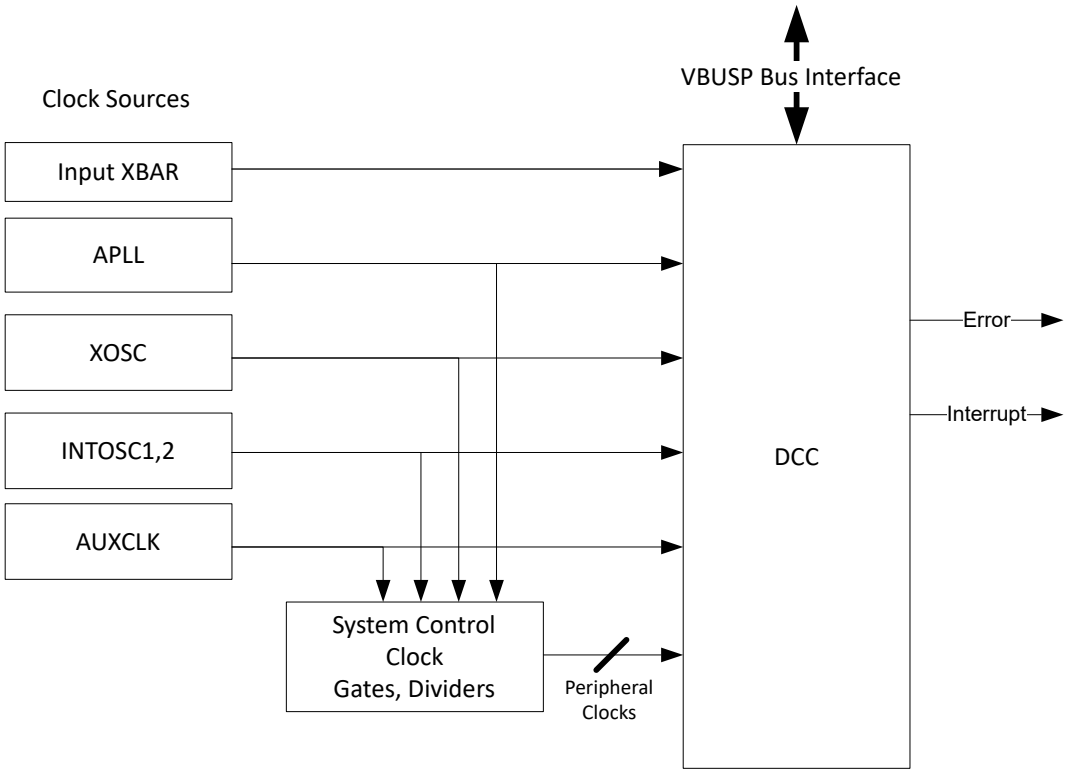

Figure 9-1. DCC Module Overview

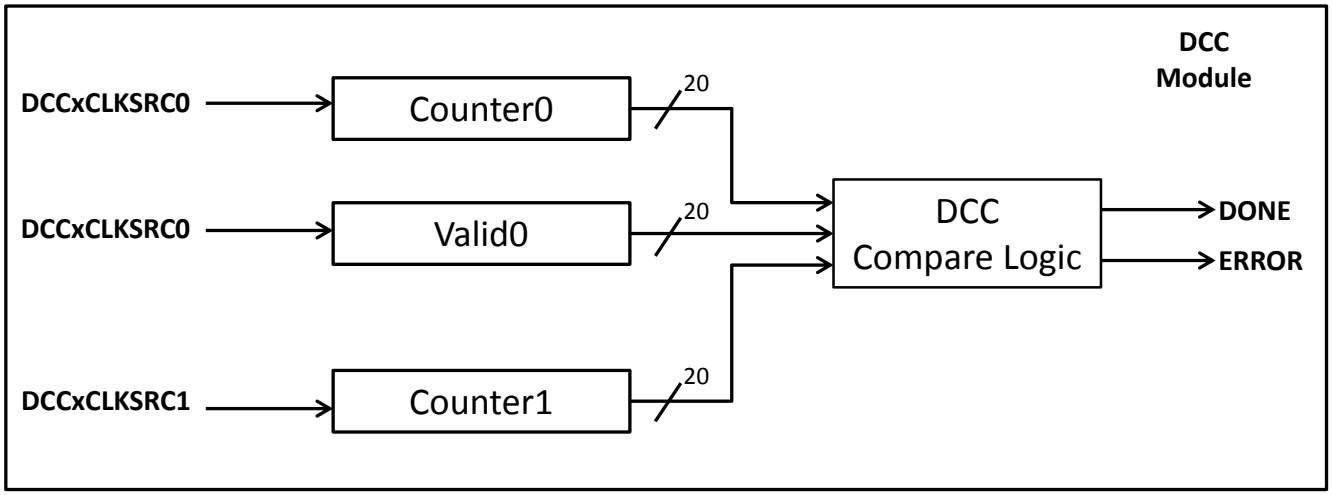

Figure 9-2. DCC Operation

9.2 Module Operation

As shown in Figure 9-2, DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with the user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

9.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 (Fclk1 × Counter0 = Fclk0×Counter1). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
  - If Fclk1 > Fclk0, then Async. Error (in Clock0 cycles) = 2 + 2 × (Fsysclk/Fclk0)
  - If Fclk1 < Fclk0, then Async. Error (in Clock0 cycles) = 2 × (Fclk0/Fclk1) + 2 × (Fsysclk/Fclk0)
  - If Fclk1 is unknown, then Async. Error (in Clock0 cycles) = 2 + 2 × (Fsysclk/Fclk0)
- Digitization Error = 8 Clock0 cycles

DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

Window (in Clock0 Cycles) = (DCC Error)/(0.01 × Tolerance)

For example, if DCC Error is 10 and the tolerance desired is ±0.1%, then:

Window (in Clock0 Cycles) = 10/(0.01 × 0.1) = 10000

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example, ±1%) can be accounted for and factored into the counter configuration. The formula is:

Frequency Error Allowed (in Clock0 Cycles) = Window × (Allowable Frequency Tolerance (in %) / 100)

Total Error (in Clock0 Cycles) = DCC Error + Frequency Error Allowed

The following equations are used to configure counter values:

Counter0 (DCCCNTSEED0) = Window - Total Error

Valid0 (DCCVALIDSEED0) = 2 × Total Error

Counter1 (DCCCNTSEED1) = Window × (Fclk1/Fclk0)

Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

Tolerance (%) = (100 × DCC Error × (Fclk1/Fclk0)) / 1048575

9.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10MHz, PLL output frequency is 100MHz, SYSCLK is 100MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in Section 9.2.1, calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the PIE. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the PIE whenever this DCC error is indicated. Refer to the PIE Channel Mapping table in the *System Control and Interrupts* chapter to determine the channel mapping of the DCC Interrupt.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

Example-2: Measuring AUXCLKIN frequency

Another example of single-shot mode is to measure the frequency of AUXCLKIN (unknown frequency) using INTOSC1 (10MHz) as the reference clock and SYSCLK is 10MHz. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as INTOSC1 (10MHz), and Clock1 source for Counter1 as AUXCLKIN.
- Now configure counter values using equations in Section 9.2.1. For tolerance = ±0.1%, Total Error = 10 clock0 cycles; Window = 10000 clock0 cycles; Counter0 = 9990; Valid0 = 20. Since Clock1 frequency (Fclk1) is unknown, the Counter1 value can be set to the maximum value, 1048575 (0xFFFFF).
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- Since Counter1 is set to the maximum value, 1048575, the counter does not expire when Counter0 and Valid0 have expired. This generates an error that is expected and the application ignores this error and uses Counter1 values to compute the frequency of Clock1 (Fclk1).
- Knowing the frequency of Clock0 (INTOSC1), Fclk0 = 10MHz, and using Equation 2, the frequency of AUXCLKIN, Fclk1, can be measured:

$$Fclk1 = \frac{Fclk0 \times (1048575 - Meas.Counter1)}{(Counter0 + Valid0)} = \frac{10 \times (1048575 - Meas.Counter1)}{(9990 + 20)} \quad (2)$$

9.2.3 Continuous Monitoring Mode

In this mode, the DCC is used by the application to make sure that two clock signals maintain the correct frequency ratio. Suppose the application wants to make sure that the PLL output signal always maintains a fixed frequency relationship with the XTAL:

- In this case, the application can use the XTAL as the Clock0 signal (for Counter0 and Valid0) and the PLL output as the Clock1 (for Counter1).
- The seed values of Counter0, Valid0 and Counter1 are selected based on the equations defined in Section 9.2.1 such that if the actual frequencies of Clock0 and Clock1 are equal to the expected frequencies, then the Counter1 reaches zero during the count down of the Valid0 counter.
- If the Counter1 reaches zero during the count down of the Valid0 counter, then all the counters (Counter0, Valid0, Counter1) are reloaded with the initial seed values.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters must get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected or Clock0 is slower than expected. This condition includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This condition includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

9.2.4 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0, and Counter1 all reach 0 without any error.

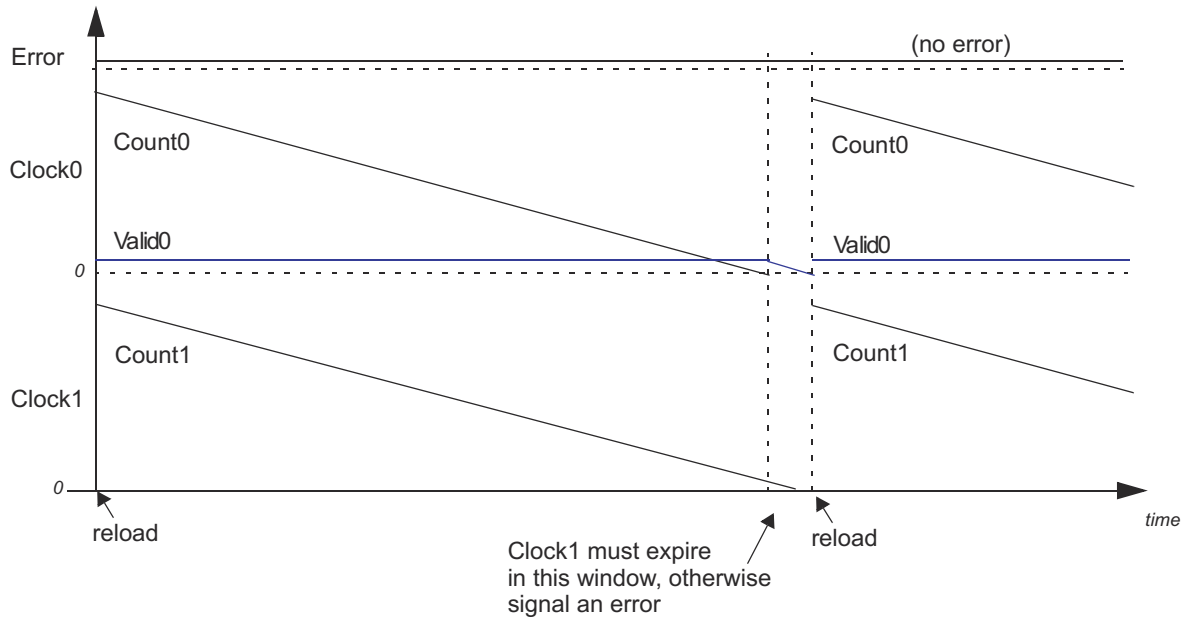

Figure 9-3. Counter Relationship

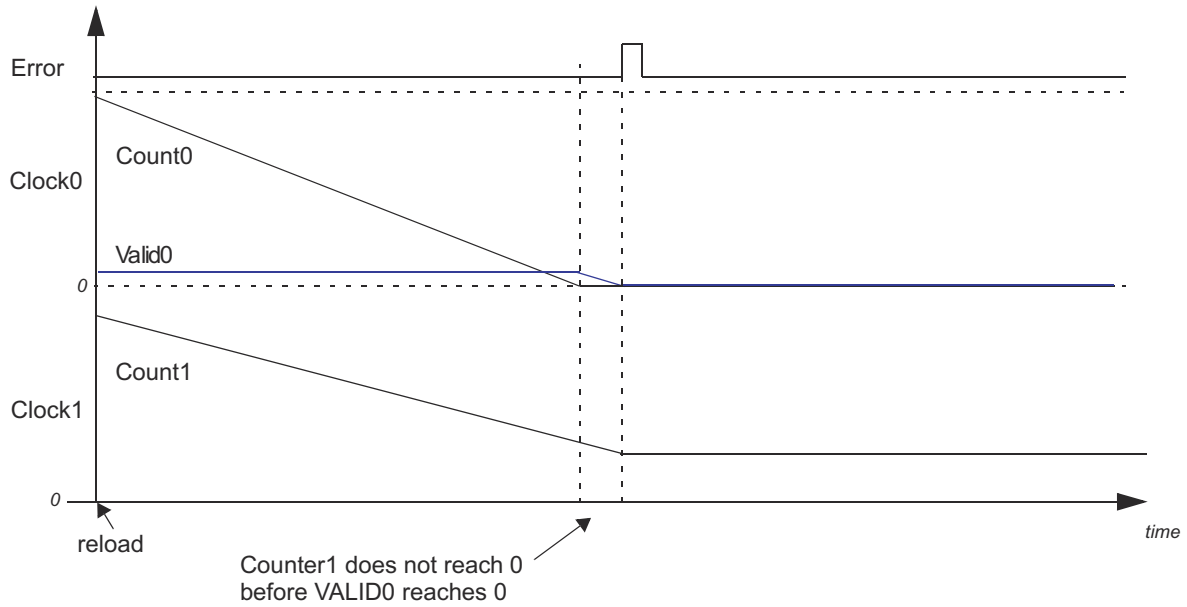

Figure 9-4. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

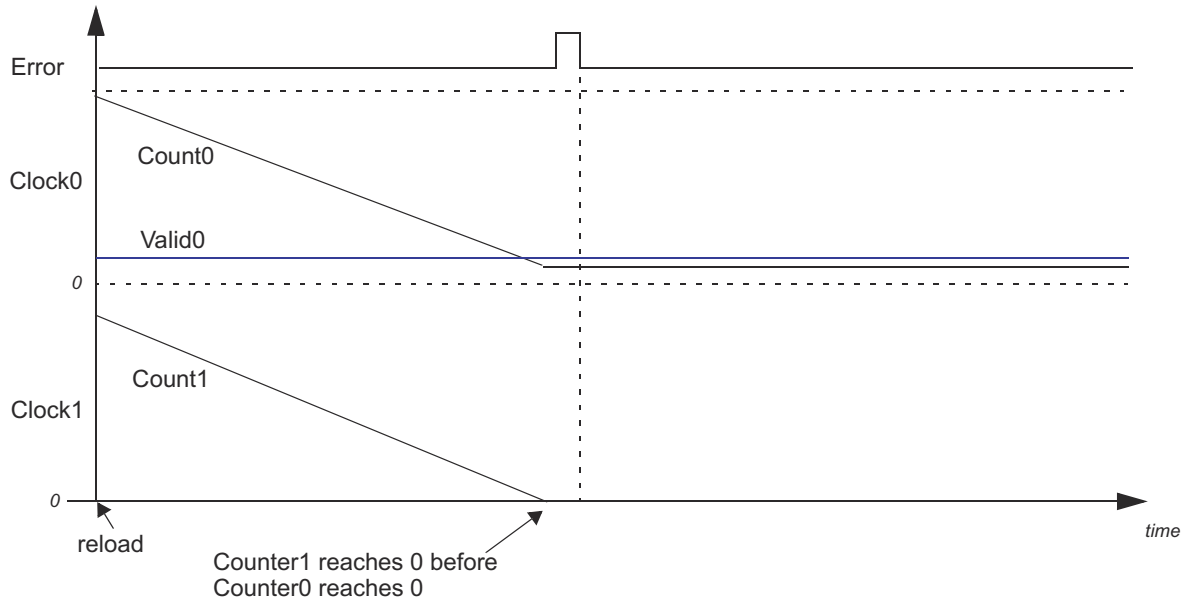

Figure 9-5. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

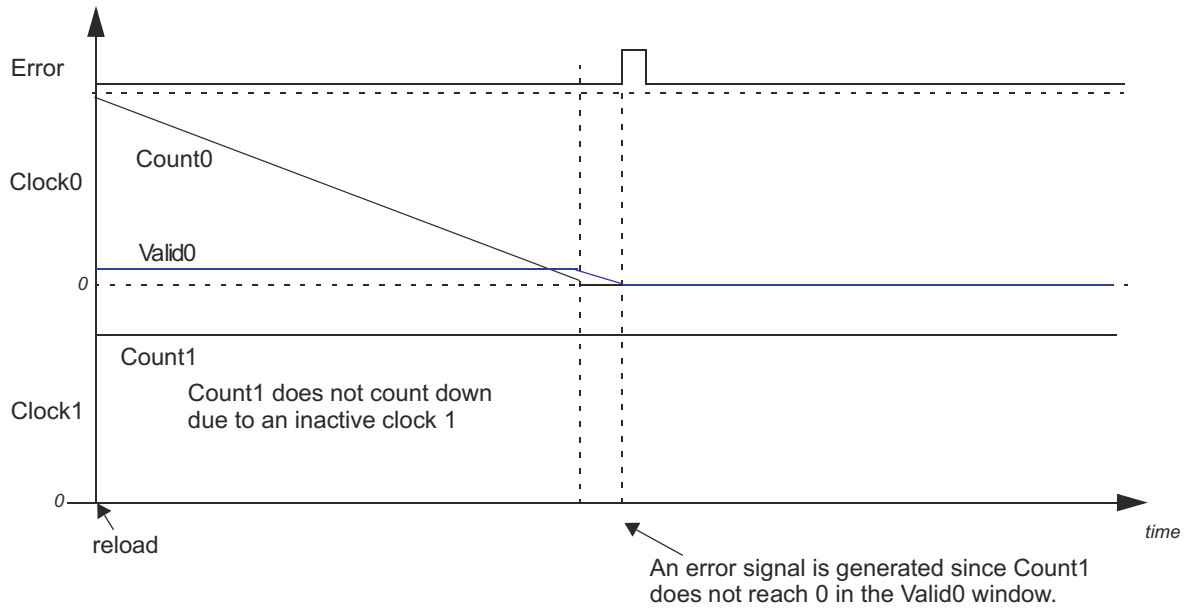

Figure 9-6. Clock1 Not Present - Results in an Error and Stops Counting

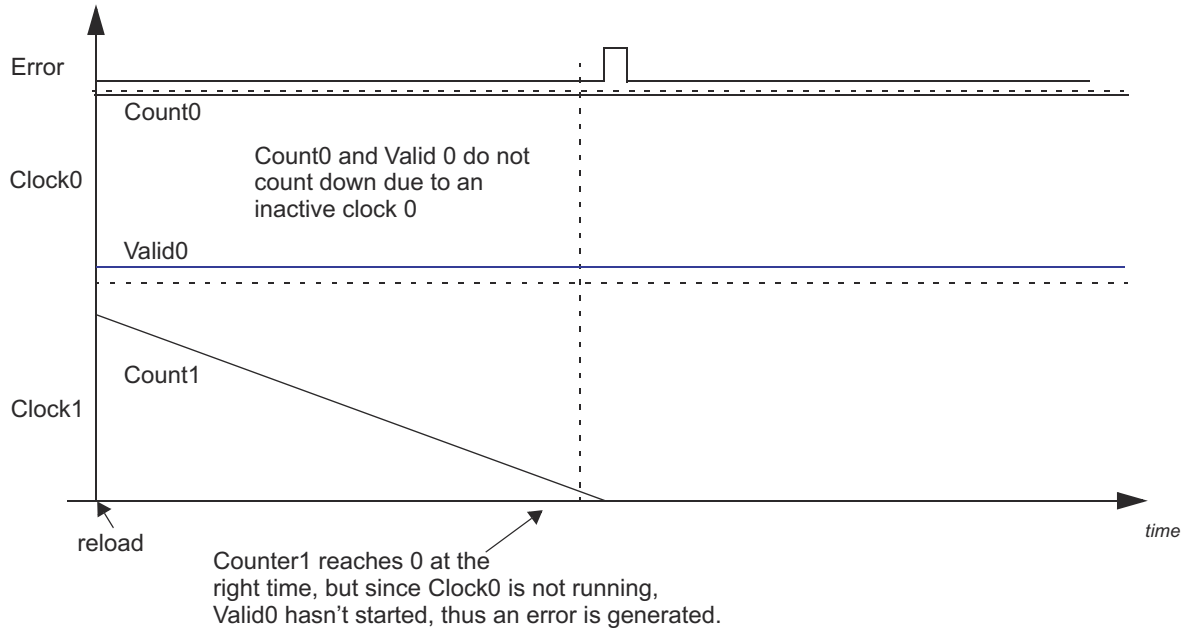

Figure 9-7. Clock0 Not Present - Results in an Error and Stops Counting

9.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided DCCGCTRL.DONENA = 1.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided DCCGCTRL.ERRENA = 1.

Interrupts generated by DONE or ERROR events are ORed and flagged as a SYS_ERR interrupt. Refer to the PIE Channel Mapping table in the *System Control and Interrupts* chapter to determine the interrupt channel mapping. The application interrupt service routine needs to check the status flag inside the DCCSTATUS register to determine whether the interrupt is due to ERROR or DONE.

DCC Error interrupts can also be configured as a Non-Maskable Interrupt (NMI) by enabling the CLKFAILCFG.DCCx_ERROR_EN flag.

9.4.2 DCC Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

9.4.2.1 DCC Single shot Clock measurement

FILE: dcc_ex2_single_shot_measurement.c

This program demonstrates Single Shot measurement of the INTOSC2 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 0 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of the clock1 needs to be measured an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *result* - Status if the INTOSC2 clock measurement completed successfully.
- *meas_freq1* - measured clock frequency, in this case for INTOSC2.

9.4.2.2 DCC Single shot Clock verification

FILE: dcc_ex1_single_shot_verification.c

This program uses the XTAL clock as a reference clock to verify the frequency of the PLLRAW clock.

The Dual-Clock Comparator Module 0 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 150Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock verification

9.4.2.3 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock_syscfg.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 150Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

9.4.2.4 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 150Mhz). The clock0 and clock1 seed are set to achieve a window of 400us. Seed is the value that gets loaded into the Counter. For the sake of demo a slight variance is given to clock1 seed value to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

9.4.2.5 DCC Detection of clock failure

FILE: dcc_ex4_clock_fail_detect.c

This program demonstrates clock failure detection on continuous monitoring of the PLL Clock in the system using XTAL as the osc clock source. Once the oscillator clock fails, it would trigger a DCC error interrupt, causing the decrement/ reload of counters to stop. In this examples, the clock failure is simulated by turning off the XTAL oscillator. Once the ISR is serviced, the osc source is changed to INTOSC1 and the PLL is turned off.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 150Mhz). Seed is the value that gets loaded into the Counter.

In the current example, the XTAL is expected to be a Resonator running in Crystal mode which is later switched off to simulate the clock failure. If an SE Crystal is used, you will need to physically disconnect the clock on the board. Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the clock failure detection

9.5 DCC Registers

This Section describes the DCC Registers.

9.5.1 DCC Base Address Table

Table 9-2. DCC Base Address Table

Complex bit access types are encoded to fit into small table cells. Table 9-4 shows the codes that are used for access types in this section.

Table 9-4. DCC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 00005555h]

DCCGCTRL is shown in Figure 9-8 and described in Table 9-5.

Return to the Summary Table.

Starts / stops the counters. Clears the error signal.

Chapter 10

General-Purpose Input/Output (GPIO)

The GPIO module controls the device's digital and analog I/O multiplexing, which uses shared pins to maximize application flexibility. The pins are named by the general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. The input signals can be qualified to remove unwanted noise.

10.1 Introduction

Up to twelve independent peripheral signals are multiplexed on a single GPIO-enabled pin in addition to the CPU-controlled I/O capability. Each pin output can be controlled by either a peripheral or one of the CPU controllers.

- CPU1
- CPU1.CLA

There are up to 8 possible I/O ports:

- Port A consists of GPIO0-GPIO31
- Port B consists of GPIO32-GPIO63
- Port C consists of GPIO64-GPIO95
- Port D consists of GPIO96-GPIO127
- Port E consists of GPIO128-GPIO159
- Port F consists of GPIO160-GPIO191
- Port G consists of GPIO192-GPIO223
- Port H consists of GPIO224-GPIO255

Note

Some GPIO and I/O ports can be unavailable on particular devices. See the *GPIO Registers* section for available GPIO and I/O ports.

The analog signals on this device are multiplexed with digital inputs and outputs. Some of these analog IO (AIO) pins do not have digital output capability. Others of these pins are analog pins capable of full digital input and output capability (AGPIO). Analog pins with AIO (digital input only) capability contain "AIO" signals in the Pin Attributes table of the device data sheet. Analog pins with full input and output capability (AGPIO pins) contain "GPIO" signals in the Pin Attributes table of the device data sheet. AGPIO pins also have pin names with both analog signals and GPIO in the name.

Figure 10-1 shows the GPIO logic for a single pin.

There are two key features to note in Figure 10-1. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, for both CPUs and CLAs to read the physical state of the pin independent of CPU controlling and peripheral muxing is possible. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all controllers and peripherals. However, the peripheral muxing, CPU muxing, and pin options can only be configured by CPU1. Table 10-1 provides details of GPIO registers accessible by different controllers.

Note

In open-drain mode, the GPIO does not drive the pin high, the GPIO can only pull the pin low. Instead, use an external pull-up to the bus voltage to drive the high level. When open-drain mode is enabled, the value in the GPyDAT register still controls the pin state. Writing a value of 1 turns off the driver to allow the external pull-up to control the pin; writing a value of 0 pulls the pin to ground. The open-drain configuration is automatically used by peripherals such as I2C and PMBus (no need to enable open-drain mode locally). This mode can also be set manually by writing to the GPyODR register and can be used when there are multiple nodes on the same net to avoid the pin contention that a push-pull driver can cause.

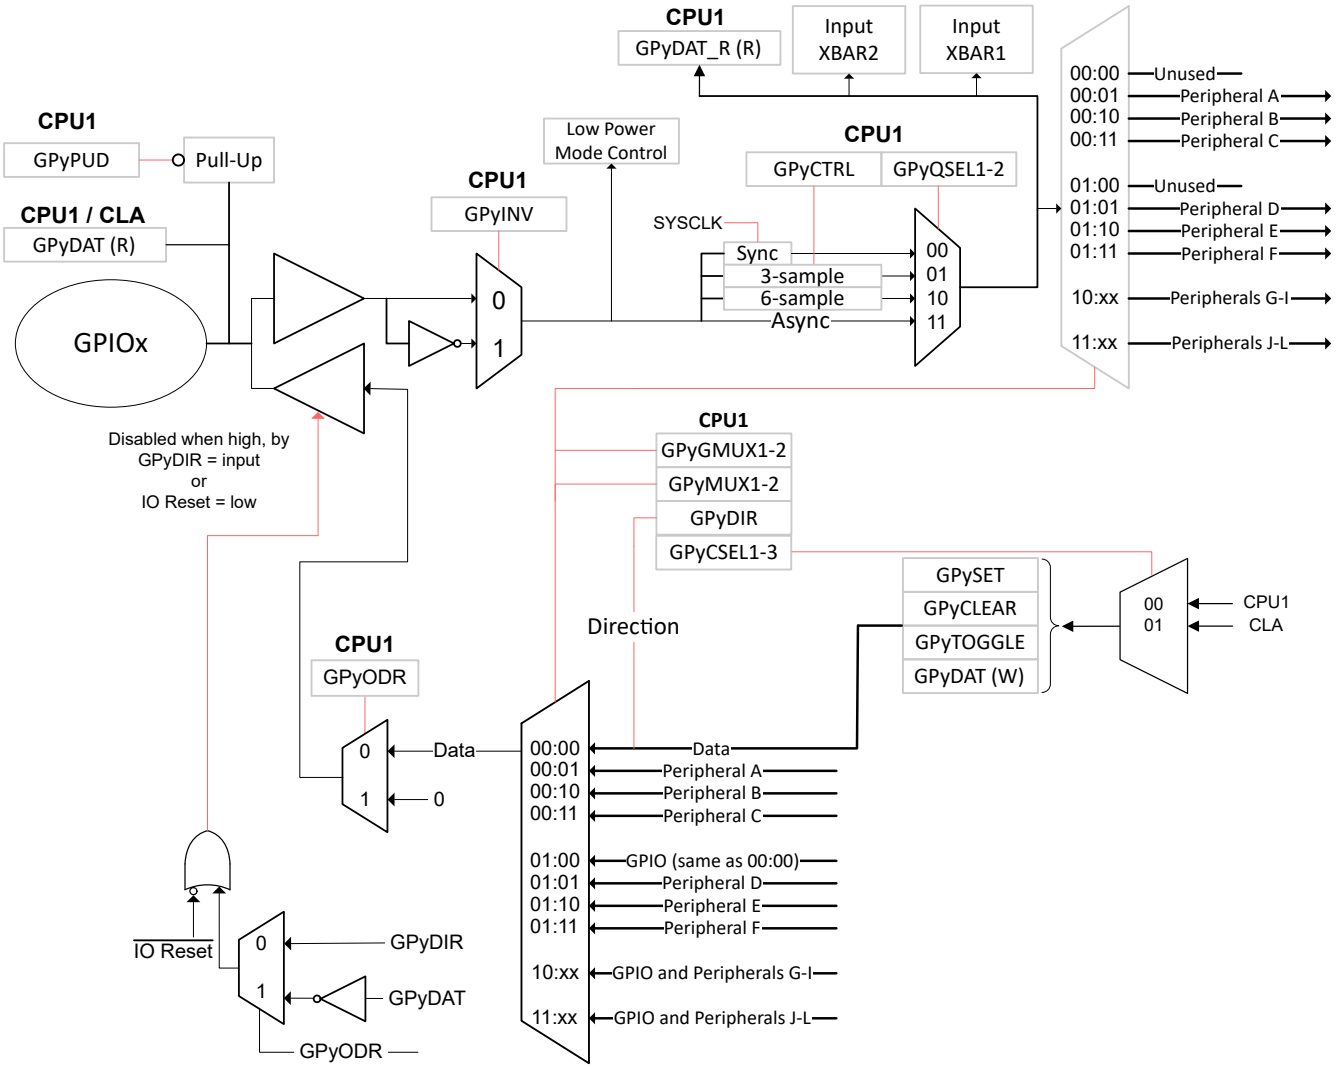

Figure 10-1. GPIO Logic for a Single Pin

Table 10-1. GPIO access by different controllers

Register Type	Function	CPU	CLA	DMA	Comments
GPIO_CTRL	Peripheral muxing, Pull Control ,etc.	Yes	NO	NO	
GPIO_DATA	GPIODAT, SET, CLEAR, TOGGLE, and pin status, etc.	Yes	Yes	NO	Based on GPxCSEL configuration.
GPIO_DATA_READ	Read back of GPIODAT register	Yes	Yes	NO

10.2 Configuration Overview

I/O pin configuration consists of several steps:

1. **Plan the device pin-out:** Make a list of all required peripherals for the application. Using the peripheral mux information in the device data sheet, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU and CLA.

   Once the peripheral muxing has been chosen, implement the mux by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals, with the exception of GPIO35 and GPIO37.
2. **(Optional) Enable internal pullup resistors:** To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. Pullups can be used to keep input pins in a known state when there is no external signal driving them.
3. **Select input qualification:** If the pin is used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK, with the exception of GPIO35 and GPIO37. For an explanation of input qualification, see Section 10.6.
4. **Select the direction of any general-purpose I/O pins:** For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.

   The GPyDAT_R register can be used to read what value was written to the GPyDAT register.
5. **Select low-power mode wake-up sources:** GPIOs 0-63 can be used to wake the system up from low power modes. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. For more information on low-power modes and GPIO wake-up, see the Low-Power Modes section in the *System Control and Interrupts* chapter.
6. **Select external interrupt sources:** Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and the polarity must be configured using the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *Crossbar (X-BAR)* chapter.

10.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

10.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. Table 10-2 shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOCTRLx from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

Table 10-2. AGPIO Configuration

AGPIOCTRLx.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
0	**1**	**-** (1)	**-** (1)
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

The general schematic of analog subsystem with AGPIO implementation is illustrated in Figure 10-2. The combinations of use cases for a specific analog input pin need special consideration are shown in Table 10-3. The AGPIO analog pin path contains an extra series switch of 53Ω. This creates a low capacitance isolated node shared by the ADC and CMPSS Comparator as shown in Figure 10-2. This node can be disturbed when the ADC samples the channel (depending on the prior voltage stored on the ADC sample and hold capacitor), and this disturbance can cause a false CMPSS event of up to 50ns. As shown in Table 10-3, special considerations or workarounds need to be used for the combination of CMPSS Input, ADC Sampling, and AGPIO. To accommodate this potential disturbance the following workarounds can be implemented:

1. Use a different pin (that is AIO pin type) for analog channels which need both ADC and CMPSS together.
2. Use the CMPSS Digital Filter with a setting of 50ns or greater, which filters the temporary disturbance.
3. Precondition the sample and hold capacitor of the ADC so the disturbance does not cause a false trip. For example, perform a dummy read of a 3.3V connection from a different channel on the ADC immediately before the impacted channel is read so the disturbance is in the positive direction, away from the false trip. The opposite dummy read of a 0V signal can be used if the false trip is inverted in polarity.

Table 10-3. The Combinations of Use Cases for a Specific Analog Input Pin

Function Used on a Specific Analog Pin	Component Used				
CMPSS Comparator Input	Yes	-	Yes	-	Yes
ADC Sampling	Yes	Yes	-	Yes	Yes
AGPIO Analog Pin Type	Yes	Yes	Yes	-	-
AIO Analog Pin Type	-	-	-	Yes	Yes
Result	**Workaround needed**	**No special analysis or workaround needed**			

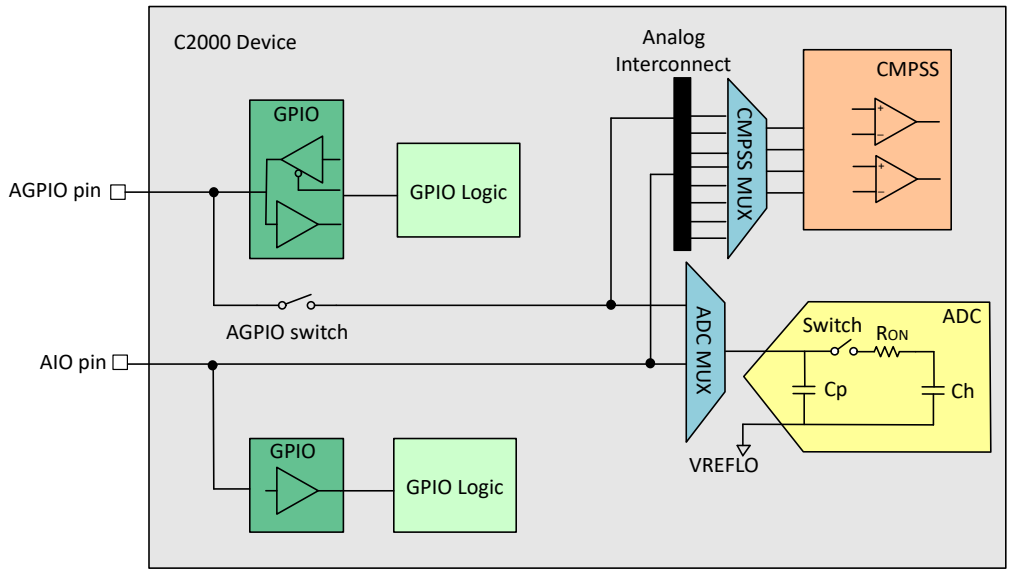

Figure 10-2. Analog Subsystem Block Diagram with AGPIO Implementation

10.5 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using the following registers.

- **GPyDAT Registers**

  Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general-purpose output (GPIO output), the pin is also driven either low or high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin.

  When using the GPyDAT register to change the level of an output pin, be cautious to not accidentally change the level of another pin. For example, to change the output latch level of GPIOA0 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

  The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This can pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

  If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) reads the old value and writes the value back.

```
GpioDataRegs.GPADAT.bit.GPIO1 = 1;  //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1;  //I2 also a read-modify-write of GPADAT
                                    //GPADAT gets the old value of GPIO1 due to the delay
```

  The second instruction waits for the first to finish the write due to the write-followed-by-read protection on this peripheral frame. There is some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction reads the old value of GPIO1 (0) and writes the value back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

  One answer is to put some NOPs between instructions. A better answer is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bits that are currently in the process of changing.

- **GPyDAT_R Registers**

  The GPyDAT_R registers are read only registers that return the value written to the GPyDAT registers instead of pin status. Writes to these registers have no effect.

- **GPySET Registers**

  The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register sets the output latch high and the corresponding pin is driven high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPyCLEAR Registers**

  The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general-purpose output, then writing a 1 to the corresponding bit in the clear register clears the output latch and the pin is driven low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPyTOGGLE Registers**

  The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register pulls the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register pulls the pin low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

10.6 Input Qualification

The input qualification scheme has been designed to be very flexible. Select the type of input qualification for each GPIO pin by configuring the GPyQSEL1 and GPyQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronized to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

10.6.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I^2C. In addition, the ePWM trip zone ($\overline{TZn}$) signals can function independent of the presence of SYSCLKOUT.

Note

Using input synchronization when the peripheral performs the synchronization can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

10.6.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, a SYSCLKOUT period of delay is needed for the input to the device to be changed. No further qualification is performed on the signal.

10.6.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. Figure 10-3 and Figure 10-4 show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

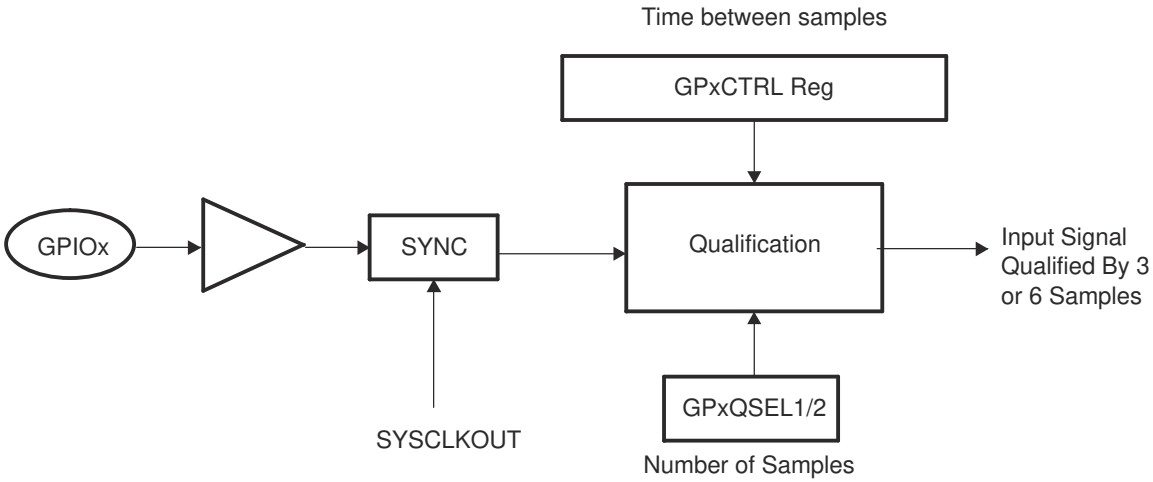

Figure 10-3. Input Qualification Using a Sampling Window

Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal is sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register. The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPACTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPACTRL[QUALPRD1]. Table 10-4 and Table 10-5 show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 10-4. Sampling Period

	Sampling Period
If GPxCTRL[QUALPRDn] = 0	$1 \times T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	$2 \times$ GPxCTRL[QUALPRDn] $\times T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Table 10-5. Sampling Frequency

	Sampling Frequency
If GPxCTRL[QUALPRDn] = 0	$f_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	$f_{SYSCLKOUT} \times 1 \div (2 \times$ GPxCTRL[QUALPRDn])
	Where $f_{SYSCLKOUT}$ is the frequency of SYSCLKOUT

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

Example: Maximum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0

then the sampling frequency is $f_{SYSCLKOUT}$

If, for example, $f_{SYSCLKOUT}$ = 60MHz

then the signal is sampled at 60MHz or one sample every 16.67ns.

Example: Minimum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0xFF (255)

then the sampling frequency is $f_{SYSCLKOUT} \times 1 \div (2 \times$ GPxCTRL[QUALPRDn])

If, for example, $f_{SYSCLKOUT}$ = 60MHz

then the signal is sampled at 60MHz × 1 ÷ (2 × 255) (117.647kHz) or one sample every 8.5µs.

Number of samples:

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPyQSEL1, GPyQSEL2) registers. When three or six consecutive cycles are the same, then the input change is passed through to the device.

Total Sampling-Window Width:

The sampling window is the time during which the input signal is sampled as shown in Figure 10-4. By using the equation for the sampling period, along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling-window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling-window width is two sampling-periods wide where the sampling period is defined in Table 10-4. Likewise, for a six-sample window, the sampling-window width is five sampling-periods wide. Table 10-6 and Table 10-7 show the calculations used to determine the total sampling-window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

Table 10-6. Case 1: Three-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	2 × $T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	2 × 2 × GPxCTRL[QUALPRDn] × $T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Table 10-7. Case 2: Six-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	5 × $T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	5 × 2 × GPxCTRL[QUALPRDn] × $T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Note

The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input must be held stable for a time greater than the sampling-window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period + $T_{SYSCLKOUT}$.

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the data sheet.

Example Qualification Window:

For the example shown in Figure 10-4, the input qualification has been configured as follows:

- GPxQSEL1/2 = 1,0. This indicates a six-sample qualification.
- GPxCTRL[QUALPRDn] = 1. The sampling period is $t_w(SP) = 2 \times$ GPxCTRL[QUALPRDn] $\times T_{SYSCLKOUT} = 2 \times T_{SYSCLKOUT}$.

This configuration results in the following:

- The width of the sampling window is:

  $t_w(IQSW) = 5 \times t_w(SP) = 5 \times 2 \times$ GPxCTRL[QUALPRDn] $\times T_{SYSCLKOUT} = 5 \times 2 \times T_{SYSCLKOUT}$

- If, for example, $T_{SYSCLKOUT}$ = 16.67ns, then the duration of the sampling window is:

  Sampling period, $t_w(SP) = 2 \times T_{SYSCLKOUT} = 2 \times 16.67ns = 33.3ns$

  Sampling window, $t_w(IQSW) = 5 \times t_w(SP) = 5 \times 33.3ns = 166.7ns$

- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to a single additional sampling period and SYSCLK period is required to detect a change in the input signal. For this example:

  $t_w(IQSW) + t_w(SP) + T_{SYSCLKOUT} = 166.7ns + 33.3ns + 16.67ns = 216.7ns$

- In Figure 10-4, the glitch (A) is shorter then the qualification window and is ignored by the input qualifier.

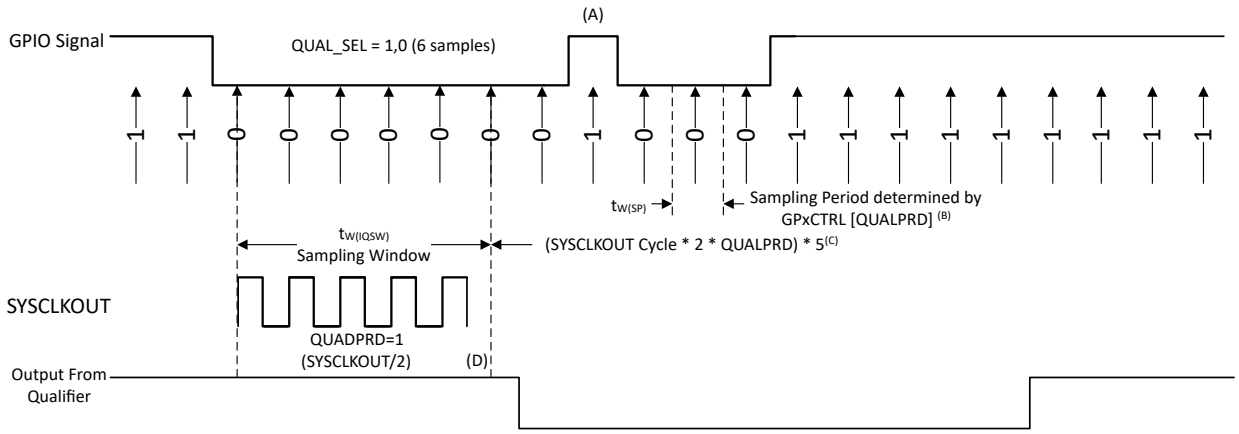

Figure 10-4. Input Qualifier Clock Cycles

- **A.** This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 0x00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value 'n', the qualificiation sampling period is 2n SYSCLKOUT cycles (i.e. at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).
- **B.** The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.

- **C.** the qualification block can take either 3 or 6 samples. The QUAL_SEL Register selects which samples mode is used.
- **D.** In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, a 13-SYSCLKOUT-wide pulse ensures reliable recognition.

10.7 USB Signals

The USB module on this device has an internal physical layer transceiver (PHY). The I/O signals are not normal digital signals, and as a result, the signals do not connect to the pins through the normal GPIO mux path. Instead, a special analog mux is used. To connect the USB signals to the device pins, set the GPyAMSEL bits appropriately. See the data sheet for which GPIOs are associated with the USB signals USBDM and USBDP. See Section 10.12 for correct GPyAMSEL register bits to set. Do not enable pullups or any other special pin option when using the USB signals.

10.8 PMBUS and I2C Signals

To support a wider range of PMBUS and I2C IO levels, certain GPIOs on this device have configurable V_{IH} minimum thresholds and configurable current sinking capabilities.

- PMBUS_IO_MODESEL register configures the V_{IH} threshold of the GPIO
- PMBUS_IO_DRVSEL register configures the current sinking capability of the GPIO

Note

The PMBUS_IO_MODESEL and PMBUS_IO_DRVSEL registers apply to the entire GPIO, not just the PMBUS module. Any peripheral or module in the given GPIO's mux is able to utilize the customizable V_{IH} threshold and current sinking capability.

The list of GPIOs that have these capabilities, and the configurable levels for these GPIOs are available in the PMBUS_IO_MODESEL and PMBUS_IO_DRVSEL registers.

10.9 GPIO and Peripheral Muxing

10.9.1 GPIO Muxing

Up to twelve different peripheral functions are multiplexed to each pin along with a general-purpose input/output (GPIO) function. This allows you to choose the peripheral mix and pinout that works best for your particular application. Refer to Table 10-8 for muxing combinations and definitions.

Table 10-8. GPIO Muxed Pins

10.9.2 Peripheral Muxing

For example, multiplexing for the GPIO6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO6 is configured as either a general-purpose digital I/O or one of several different peripheral functions. An example of GPyGMUX and GPyMUX selection and options for a single GPIO are shown in Table 10-9.

Note

The following table is for example only. Refer to the device data sheet to check the availability of GPIO6 on this device. If GPIO6 is available, the functions mentioned in the table may not match the actual functions available. See Section 10.9.1 for correct list of GPIOs and corresponding mux options for this device.

Table 10-9. GPIO and Peripheral Muxing

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin Functionality
00	00	GPIO6
00	01	Peripheral 1
00	10	Peripheral 2
00	11	Peripheral 3
01	00	GPIO6
01	01	Peripheral 4
01	10	Peripheral 5
01	11	
10	00	GPIO6
10	01	
10	10	Peripheral 6
10	11	Peripheral 7
11	00	GPIO6
11	01	Peripheral 8
11	10	Peripheral 9
11	11	Peripheral 10

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and must not be used.

CAUTION

If a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode is selected, the state of the pin is undefined and the pin is driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see the data sheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin by way of the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs p, q, or r (where p, q, and r are example GPIO numbers), depending on individual system requirements. An example of this is shown in Table 10-10.

Note

The following table is for example only. Bit ranges cannot correspond to OUTPUTXBAR1 on this device. See Section 10.9.1 for correct list of GPIOs and corresponding mux options for this device.

If none or more then one of the GPIO pins is configured as peripheral input pins, then that GPIO is set to a hard-wired default value.

Table 10-10. Peripheral Muxing (Multiple Pins Assigned)

GMUX Configuration	MUX Configuration	
Choice 1: GPIOp	GPyGMUX1[5:4] = 01	GPyMUX1[5:4] = 01
or Choice 2: GPIOq	GPyGMUX2[17:16] = 00	GPyMUX2[17:16] = 01
or Choice 3: GPIOr	GPyGMUX1[7:6] = 01	GPyMUX1[7:6] = 01

10.10 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user must always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above V_{ih} or below V_{il}
- Input mode with GPIO internal pullup enabled
- Output mode

On devices with lesser pin count packages, pull-ups on unbonded GPIOs are by default enabled to prevent floating inputs. The user must take care to avoid disabling these pullups in the application code.

On devices with larger pin count packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE/C2000Ware that users can call to enable the pullup on any unbonded GPIO for the package in use. This function, GPIO_EnabledUnbondedIOPullups(), resides in the (Device)_Sysctrl.c file and is called by default from InitSysCtrl(). The user must take care to avoid disabling these pullups in the application code.

10.11.2 GPIO Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/gpio

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

10.11.2.1 Device GPIO Setup

FILE: gpio_ex1_setup.c

Configures the device GPIO into two different configurations This code is verbose to illustrate how the GPIO could be setup. In a real application, lines of code can be combined for improved code size and efficiency.

This example only sets-up the GPIO. Nothing is actually done with the pins after setup.

In general:

- All pullup resistors are enabled. For ePWMs this may not be desired.
- Input qual for communication ports (CAN, SPI, SCI, I2C) is asynchronous
- Input qual for Trip pins (TZ) is asynchronous
- Input qual for eCAP and eQEP signals is synch to SYSCLKOUT
- Input qual for some I/O's and __interrupts may have a sampling window

10.11.2.2 Device GPIO Toggle

FILE: gpio_ex2_toggle.c

Configures the device GPIO through the sysconfig file. The GPIO pin is toggled in the infinite loop. In order to migrate the project within syscfg to any device, click the swtich button under the device view and select your corresponding device to migrate, saving the project will auto-migrate your project settings.

: This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example.

10.11.2.3 Device GPIO Interrupt

FILE: gpio_ex3_interrupt.c

Configures the device GPIOs through the sysconfig file. One GPIO output pin, and one GPIO input pin is configured. The example then configures the GPIO input pin to be the source of an external interrupt which toggles the GPIO output pin.

10.11.2.4 External Interrupt (XINT)

FILE: gpio_ex4_aio_external_interrupt.c

In this example AIO pins are configured as digital inputs. Two other GPIO signals (connected externally to AIO pins) are toggled in software to trigger external interrupt through AIO225 and AIO231 (AIO225 assigned to XINT1 and AIO231 assigned to XINT2). The user is required to externally connect these signals for the program to work properly. Each interrupt is fired in sequence: XINT1 first and then XINT2.

- GPIO5 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope. *External Connections*
- Connect GPIO0 to AIO225. AIO225 will be assigned to XINT1
- Connect GPIO1 to AIO231. AIO231 will be assigned to XINT2
- GPIO5 can be monitored on an oscilloscope

Watch Variables

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

10.11.3 LED Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/led

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

10.12 GPIO Registers

This Section describes the GPIO Registers.

10.12.1 GPIO Base Address Table

Table 10-12. GPIO Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	Pipeline Protected
Instance	Structure						
GpioCtrlRegs	GPIO_CTRL_REGS	GPIOCTRL_BASE	0x0000_7C00	YES	-	-	YES
GpioDataRegs	GPIO_DATA_REGS	GPIODATA_BASE	0x0000_7F00	YES	-	YES	YES
GpioDataReadRegs	GPIO_DATA_READ_REGS	GPIODATAREAD_BASE	0x0000_7F80	YES	-	YES	YES

10.12.2 GPIO_CTRL_REGS Registers

Table 10-13 lists the memory-mapped registers for the GPIO_CTRL_REGS registers. All register offset addresses not listed in Table 10-13 should be considered as reserved locations and the register contents should not be modified.

Table 10-13. GPIO_CTRL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPACTRL	GPIO A Qualification Sampling Period Control (GPIO0 to 31)	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 10-14 shows the codes that are used for access types in this section.

Table 10-14. GPIO_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.12.2.1 GPACTRL Register (Offset = 0h) [Reset = 00000000h]

GPACTRL is shown in Figure 10-5 and described in Table 10-15.

Return to the Summary Table.

GPIO A Qualification Sampling Period Control (GPIO0 to 31)

Table 10-16. GPAQSEL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	GPIO15	R/W	0h	Select input qualification type for GPIO15: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
29-28	GPIO14	R/W	0h	Select input qualification type for GPIO14: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
27-26	GPIO13	R/W	0h	Select input qualification type for GPIO13: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
25-24	GPIO12	R/W	0h	Select input qualification type for GPIO12: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
23-22	GPIO11	R/W	0h	Select input qualification type for GPIO11: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
21-20	GPIO10	R/W	0h	Select input qualification type for GPIO10: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

Table 10-16. GPAQSEL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-18	GPIO9	R/W	0h	Select input qualification type for GPIO9: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
17-16	GPIO8	R/W	0h	Select input qualification type for GPIO8: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
15-14	GPIO7	R/W	0h	Select input qualification type for GPIO7: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
13-12	GPIO6	R/W	0h	Select input qualification type for GPIO6: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
11-10	GPIO5	R/W	0h	Select input qualification type for GPIO5: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
9-8	GPIO4	R/W	0h	Select input qualification type for GPIO4: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
7-6	GPIO3	R/W	0h	Select input qualification type for GPIO3: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
5-4	GPIO2	R/W	0h	Select input qualification type for GPIO2: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
3-2	GPIO1	R/W	0h	Select input qualification type for GPIO1: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

Table 10-16. GPAQSEL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	GPIO0	R/W	0h	Select input qualification type for GPIO0: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

10.12.2.3 GPAQSEL2 Register (Offset = 4h) [Reset = 00000000h]

GPAQSEL2 is shown in Figure 10-7 and described in Table 10-17.

Return to the Summary Table.

GPIO A Qualifier Select 2 Register (GPIO16 to 31)
Input qualification type:
0,0 Sync
0,1 Qualification (3 samples)
1,0 Qualification (6 samples)
1,1 Async (no Sync or Qualification)

10.12.2.4 GPAMUX1 Register (Offset = 6h) [Reset = 00000000h]

GPAMUX1 is shown in Figure 10-8 and described in Table 10-18.

Return to the Summary Table.

GPIO A Mux 1 Register (GPIO0 to 15)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 10-8. GPAMUX1 Register

10.12.2.6 GPADIR Register (Offset = Ah) [Reset = 00000000h]

GPADIR is shown in Figure 10-10 and described in Table 10-20.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

Figure 10-10. GPADIR Register

10.12.2.7 GPAPUD Register (Offset = Ch) [Reset = FFFFFFFFh]

GPAPUD is shown in Figure 10-11 and described in Table 10-21.

Return to the Summary Table.

GPIO A Pull Up Disable Register (GPIO0 to 31)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.12.2.8 GPAINV Register (Offset = 10h) [Reset = 00000000h]

GPAINV is shown in Figure 10-12 and described in Table 10-22.

Return to the Summary Table.

GPIO A Input Polarity Invert Registers (GPIO0 to 31)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

10.12.2.9 GPAODR Register (Offset = 12h) [Reset = 00000000h]

GPAODR is shown in Figure 10-13 and described in Table 10-23.

Return to the Summary Table.

GPIO A Open Drain Output Register (GPIO0 to GPIO31)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.12.2.10 GPAAMSEL Register (Offset = 14h) [Reset = FF7FFFFFh]

GPAAMSEL is shown in Figure 10-14 and described in Table 10-24.

Return to the Summary Table.

GPIO A Analog Mode Select register (GPIO0 to GPIO31)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, the corresponding bits in these registers dont have any affect.

10.12.2.17 GPALOCK Register (Offset = 3Ch) [Reset = 00000000h]

GPALOCK is shown in Figure 10-21 and described in Table 10-31.

Return to the Summary Table.

GPIO A Lock Configuration Register (GPIO0 to 31)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

10.12.2.22 GPBMUX1 Register (Offset = 46h) [Reset = 00000CC0h]

GPBMUX1 is shown in Figure 10-26 and described in Table 10-36.

Return to the Summary Table.

GPIO B Mux 1 Register (GPIO32 to 47)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

10.12.2.24 GPBDIR Register (Offset = 4Ah) [Reset = 00000000h]

GPBDIR is shown in Figure 10-28 and described in Table 10-38.

Return to the Summary Table.

GPIO B Direction Register (GPIO32 to 63)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

10.12.2.25 GPBPUD Register (Offset = 4Ch) [Reset = FFFFFFFFh]

GPBPUD is shown in Figure 10-29 and described in Table 10-39.

Return to the Summary Table.

GPIO B Pull Up Disable Register (GPIO32 to 63)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.12.2.27 GPBODR Register (Offset = 52h) [Reset = 00000000h]

GPBODR is shown in Figure 10-31 and described in Table 10-41.

Return to the Summary Table.

GPIO B Open Drain Output Register (GPIO32 to GPIO63)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.12.2.28 GPBAMSEL Register (Offset = 54h) [Reset = FFFFFDFFh]

GPBAMSEL is shown in Figure 10-32 and described in Table 10-42.

Return to the Summary Table.

GPIO B Analog Mode Select register (GPIO32 to GPIO63)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

10.12.2.36 GPBCR Register (Offset = 7Eh) [Reset = 00000000h]

GPBCR is shown in Figure 10-40 and described in Table 10-50.

Return to the Summary Table.

GPIO B Lock Commit Register (GPIO32 to 63)
GPIO Configuration Lock Commit for GPIO:
1: Locks changes to the bit in GPyLOCK register which controls the same pin
0: Bit in the GPyLOCK register which controls the same pin can be changed

10.12.2.40 GPCMUX1 Register (Offset = 86h) [Reset = 00000000h]

GPCMUX1 is shown in Figure 10-44 and described in Table 10-54.

Return to the Summary Table.

GPIO C Mux 1 Register (GPIO64 to 79)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 10-44. GPCMUX1 Register

10.12.2.42 GPCDIR Register (Offset = 8Ah) [Reset = 00000000h]

GPCDIR is shown in Figure 10-46 and described in Table 10-56.

Return to the Summary Table.

GPIO C Direction Register (GPIO64 to 95)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

10.12.2.43 GPCPUD Register (Offset = 8Ch) [Reset = FFFFFFFFh]

GPCPUD is shown in Figure 10-47 and described in Table 10-57.

Return to the Summary Table.

GPIO C Pull Up Disable Register (GPIO64 to 95)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.12.2.44 GPCINV Register (Offset = 90h) [Reset = 00000000h]

GPCINV is shown in Figure 10-48 and described in Table 10-58.

Return to the Summary Table.

GPIO C Input Polarity Invert Registers (GPIO64 to 95)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

10.12.2.45 GPCODR Register (Offset = 92h) [Reset = 00000000h]

GPCODR is shown in Figure 10-49 and described in Table 10-59.

Return to the Summary Table.

GPIO C Open Drain Output Register (GPIO64 to GPIO95)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.12.2.46 GPCAMSEL Register (Offset = 94h) [Reset = 00000000h]

GPCAMSEL is shown in Figure 10-50 and described in Table 10-60.

Return to the Summary Table.

GPIO C Analog Mode Select register (GPIO64 to GPIO95)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

10.12.2.56 GPGMUX2 Register (Offset = 188h) [Reset = 00000000h]

GPGMUX2 is shown in Figure 10-60 and described in Table 10-70.

Return to the Summary Table.

GPIO G Mux 2 Register (GPIO208 to 223)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

10.12.2.57 GPGDIR Register (Offset = 18Ah) [Reset = 00000000h]

GPGDIR is shown in Figure 10-61 and described in Table 10-71.

Return to the Summary Table.

GPIO G Direction Register (GPIO192 to 223)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

10.12.2.58 GPGPUD Register (Offset = 18Ch) [Reset = FFFFFFFFh]

GPGPUD is shown in Figure 10-62 and described in Table 10-72.

Return to the Summary Table.

GPIO G Pull Up Disable Register (GPIO192 to 223)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.12.2.60 GPGODR Register (Offset = 192h) [Reset = 00000000h]

GPGODR is shown in Figure 10-64 and described in Table 10-74.

Return to the Summary Table.

GPIO G Open Drain Output Register (GPIO92 to 223)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.12.2.61 GPGAMSEL Register (Offset = 194h) [Reset = 00FF0000h]

GPGAMSEL is shown in Figure 10-65 and described in Table 10-75.

Return to the Summary Table.

GPIO G Analog Mode Select register (GPIO192 to 223)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

10.12.2.64 GPGLOCK Register (Offset = 1BCh) [Reset = 00000000h]

GPGLOCK is shown in Figure 10-68 and described in Table 10-78.

Return to the Summary Table.

GPIO G Lock Configuration Register (GPIO192 to 223)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

10.12.2.71 GPHDIR Register (Offset = 1CAh) [Reset = 00000000h]

GPHDIR is shown in Figure 10-75 and described in Table 10-85.

Return to the Summary Table.

GPIO H Direction Register (GPIO224 to 255)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

10.12.2.72 GPHPUD Register (Offset = 1CCh) [Reset = FFFFFFFFh]

GPHPUD is shown in Figure 10-76 and described in Table 10-86.

Return to the Summary Table.

GPIO H Pull Up Disable Register (GPIO224 to 255)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.12.2.74 GPHODR Register (Offset = 1D2h) [Reset = 00000000h]

GPHODR is shown in Figure 10-78 and described in Table 10-88.

Return to the Summary Table.

GPIO H Open Drain Output Register (GPIO224 to GPIO255)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.12.2.75 GPHAMSEL Register (Offset = 1D4h) [Reset = FFFFFFFFh]

GPHAMSEL is shown in Figure 10-79 and described in Table 10-89.

Return to the Summary Table.

GPIO H Analog Mode Select register (GPIO224 to GPIO255)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

10.12.3 GPIO_DATA_REGS Registers

Table 10-98 lists the memory-mapped registers for the GPIO_DATA_REGS registers. All register offset addresses not listed in Table 10-98 should be considered as reserved locations and the register contents should not be modified.

Table 10-98. GPIO_DATA_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT	GPIO A Data Register (GPIO0 to 31)		Go
2h	GPASET	GPIO A Data Set Register (GPIO0 to 31)		Go
4h	GPACLEAR	GPIO A Data Clear Register (GPIO0 to 31)		Go
6h	GPATOGGLE	GPIO A Data Toggle Register (GPIO0 to 31)		Go
8h	GPBDAT	GPIO B Data Register (GPIO32 to 63)		Go
Ah	GPBSET	GPIO B Data Set Register (GPIO32 to 63)		Go
Ch	GPBCLEAR	GPIO B Data Clear Register (GPIO32 to 63)		Go
Eh	GPBTOGGLE	GPIO B Data Toggle Register (GPIO32 to 63)		Go
10h	GPCDAT	GPIO C Data Register (GPIO64 to 95)		Go
12h	GPCSET	GPIO C Data Set Register (GPIO64 to 95)		Go
14h	GPCCLEAR	GPIO C Data Clear Register (GPIO64 to 95)		Go
16h	GPCTOGGLE	GPIO C Data Toggle Register (GPIO64 to 95)		Go
30h	GPGDAT	GPIO G Data Register (GPIO192 to 223)		Go
32h	GPGSET	GPIO G Data Set Register (GPIO192 to 223)		Go
34h	GPGCLEAR	GPIO G Data Clear Register (GPIO192 to 223)		Go
36h	GPGTOGGLE	GPIO G Data Toggle Register (GPIO192 to 223)		Go
38h	GPHDAT	GPIO H Data Register (GPIO224 to 255)		Go
3Ah	GPHSET	GPIO H Data Set Register (GPIO224 to 255)		Go
3Ch	GPHCLEAR	GPIO H Data Clear Register (GPIO224 to 255)		Go
3Eh	GPHTOGGLE	GPIO H Data Toggle Register (GPIO224 to 255)		Go

Complex bit access types are encoded to fit into small table cells. Table 10-99 shows the codes that are used for access types in this section.

Table 10-99. GPIO_DATA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 10-99. GPIO_DATA_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.12.3.1 GPADAT Register (Offset = 0h) [Reset = 00000000h]

GPADAT is shown in Figure 10-88 and described in Table 10-100.

Return to the Summary Table.

GPIO A Data Register (GPIO0 to 31)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

10.12.3.2 GPASET Register (Offset = 2h) [Reset = 00000000h]

GPASET is shown in Figure 10-89 and described in Table 10-101.

Return to the Summary Table.

GPIO A Data Set Register (GPIO0 to 31)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

10.12.3.5 GPBDAT Register (Offset = 8h) [Reset = 00000000h]

GPBDAT is shown in Figure 10-92 and described in Table 10-104.

Return to the Summary Table.

GPIO B Data Register (GPIO32 to 63)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

10.12.3.13 GPGDAT Register (Offset = 30h) [Reset = 00000000h]

GPGDAT is shown in Figure 10-100 and described in Table 10-112.

Return to the Summary Table.

GPIO G Data Register (GPIO192 to 223)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

10.12.3.15 GPGCLEAR Register (Offset = 34h) [Reset = 00000000h]

GPGCLEAR is shown in Figure 10-102 and described in Table 10-114.

Return to the Summary Table.

GPIO G Data Clear Register (GPIO192 to 223)
Writing a 1 will force GPIO0 output data latch to 0.
Writes of 0 are ignored.
Always reads back a 0.

10.12.3.17 GPHDAT Register (Offset = 38h) [Reset = 00000000h]

GPHDAT is shown in Figure 10-104 and described in Table 10-116.

Return to the Summary Table.

GPIO H Data Register (GPIO224 to 255)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

10.12.3.18 GPHSET Register (Offset = 3Ah) [Reset = 00000000h]

GPHSET is shown in Figure 10-105 and described in Table 10-117.

Return to the Summary Table.

GPIO H Data Set Register (GPIO224 to 255)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

10.12.4 GPIO_DATA_READ_REGS Registers

Table 10-120 lists the memory-mapped registers for the GPIO_DATA_READ_REGS registers. All register offset addresses not listed in Table 10-120 should be considered as reserved locations and the register contents should not be modified.

Table 10-120. GPIO_DATA_READ_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT_R	GPIO A Data Read Register		Go
2h	GPBDAT_R	GPIO B Data Read Register		Go
4h	GPCDAT_R	GPIO C Data Read Register		Go
Ch	GPGDAT_R	GPIO G Data Read Register		Go
Eh	GPHDAT_R	GPIO H Data Read Register		Go

Complex bit access types are encoded to fit into small table cells. Table 10-121 shows the codes that are used for access types in this section.

Table 10-121. GPIO_DATA_READ_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.12.4.1 GPADAT_R Register (Offset = 0h) [Reset = 00000000h]

GPADAT_R is shown in Figure 10-108 and described in Table 10-122.

Return to the Summary Table.

GPIO A Data Read Register.

Chapter 11

Crossbar (X-BAR)

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of three X-BARs:

- Input X-BAR
- Output X-BAR
- ePWM X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR brings external signals “in” to the device. The Output X-BAR takes internal signals “out” of the device to a GPIO. The ePWM X-BAR takes signals to the ePWM modules.

11.1 Input X-BAR and CLB Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in Figure 11-1 and Table 11-1. For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT_XBAR_REGS register definitions in the *XBAR Registers* section.

Note

All input sources to the generic XBAR can be active high.

The minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required), SYSCLK for Output XBAR, and CLB Output XBAR is 3 ticks of the respective clocks.

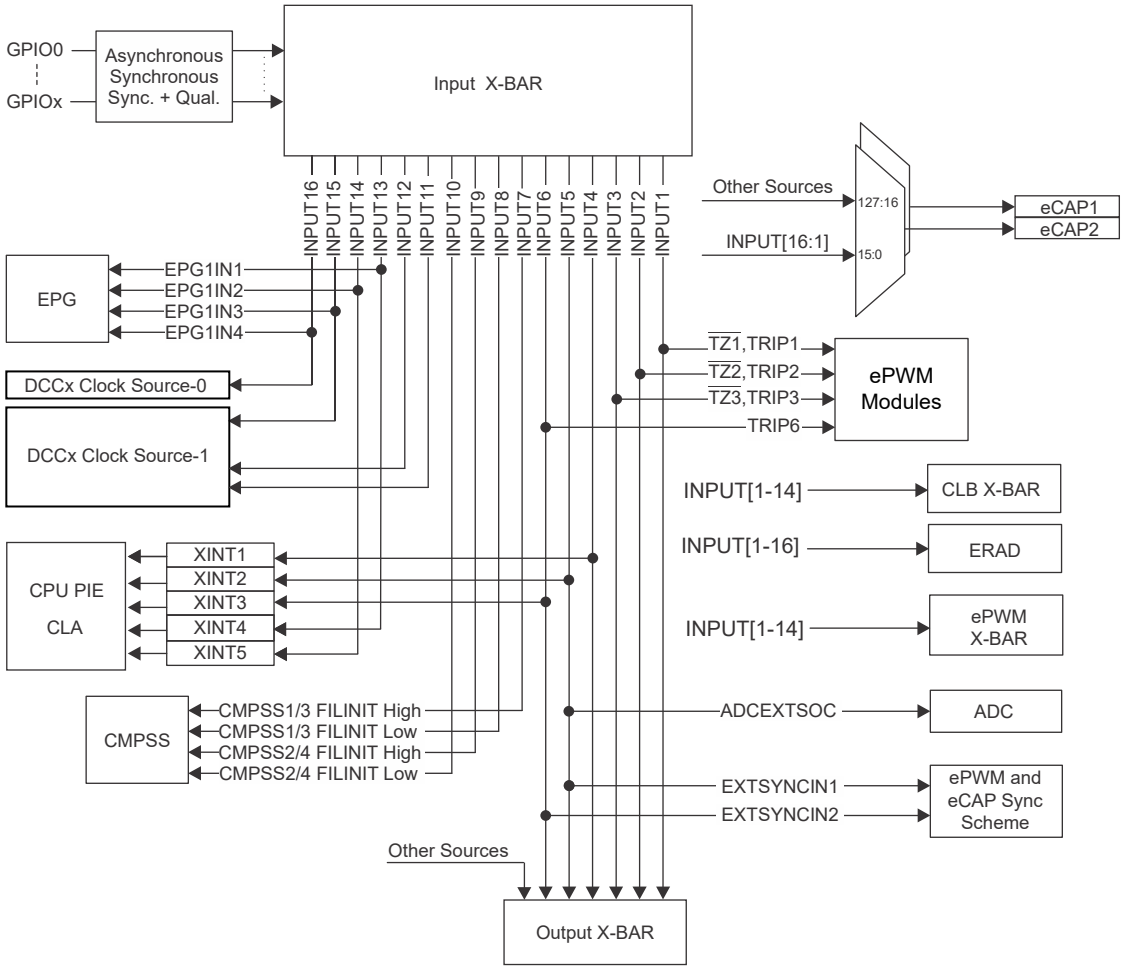

Figure 11-1. Input X-BAR

Note

INPUTXBARx, INPUTXBAR_INPUTx, and INPUTx (when referenced in the context of Input X-BAR) are equivalent in all C2000 software and documentation.

Table 11-1. Input X-BAR Destinations

Input	ECAP	EPWM XBAR	CLB XBAR	OUTPUT XBAR	EPWM TRIP	ERAD	CPU XINT	ADC SOC	EPWM / ECAP SYNC	CMPSS	DCCx	EPG
INPUTXBAR1	Yes	Yes	Yes	Yes	TZ1, TRIP1	Yes						
INPUTXBAR2	Yes	Yes	Yes	Yes	TZ2, TRIP2	Yes						
INPUTXBAR3	Yes	Yes	Yes	Yes	TZ3, TRIP3	Yes						
INPUTXBAR4	Yes	Yes	Yes	Yes		Yes	XINT1

INPUTXBAR10	Yes	Yes	Yes			Yes				CMPSS2/4. EXT_FILTIN_L		
INPUTXBAR11	Yes	Yes	Yes			Yes					CLK1	
INPUTXBAR12	Yes	Yes	Yes			Yes					CLK1	
INPUTXBAR13	Yes	Yes	Yes			Yes	XINT4					EPGAIN1
INPUTXBAR14	Yes	Yes	Yes			Yes	XINT5					EPGAIN2
INPUTXBAR15	Yes					Yes					CLK1	EPGAIN3
INPUTXBAR16	Yes					Yes					CLK0	EPGAIN4

11.1.1 CLB Input X-BAR

The CLB Input X-BAR is architecturally identical to the Input X-BAR. The only difference is the destination for each INPUTx. The destination for each INPUTx is only the CLB Tiles as shown in Table 11-2. This allows for GPIOs to be accessed by the CLB tiles without using the combination of Input X-BAR and CLB X-BAR.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

Table 11-2. CLB Input X-BAR Destinations

Input	CLB	EPWM XBAR	DCCx
CLBINPUTXBAR1	Yes		
CLBINPUTXBAR2	Yes		
CLBINPUTXBAR3	Yes		
CLBINPUTXBAR4	Yes

11.2 ePWM , CLB, and GPIO Output X-BAR

This section describes the ePWM , CLB, and GPIO Output X-BAR. Remember that the minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required), SYSCLK for Output XBAR, and CLB Output XBAR is 3 ticks of the respective clocks.

11.2.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 11-2 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

11.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. Figure 11-2 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 11-3. Select up to one signal per mux for each TRIPx output. Select the inputs to ePWM X-BAR using the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. To pass any signal through to the ePWM, enable the signal using the TRIPxMUXENABLE register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the TRIPOUTINV register.

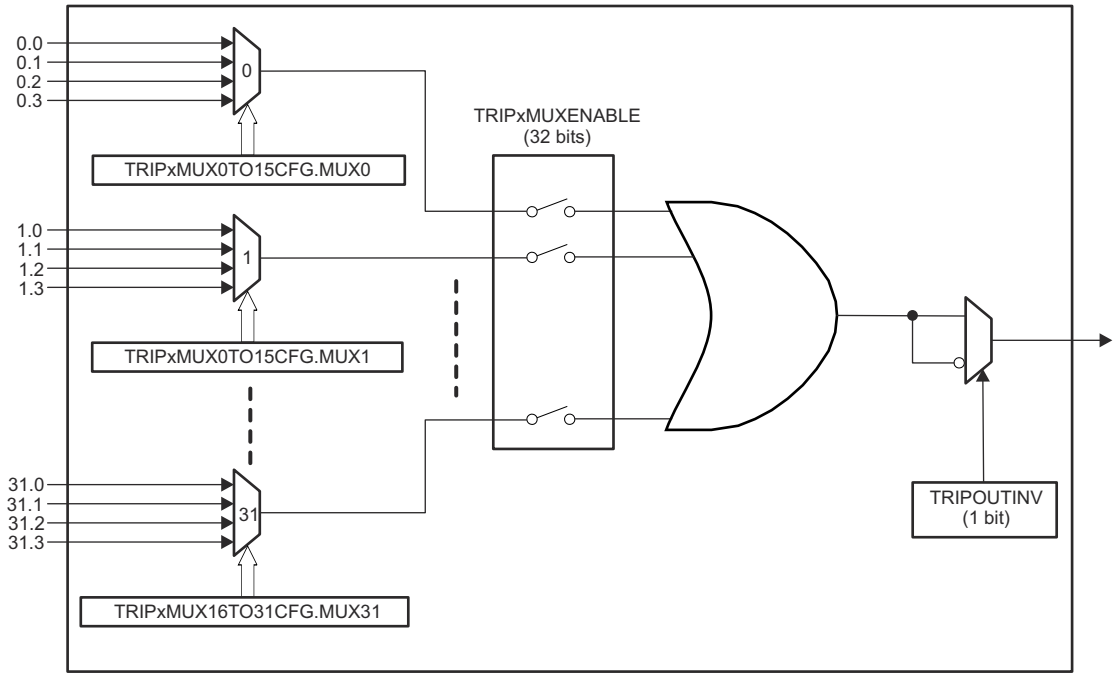

Figure 11-2. ePWM X-BAR Architecture - Single Output

Note

Do not use "Reserved" signals in your application.

11.2.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. Figure 11-3 shows the architecture of the CLB X-BAR. Note that the architecture of the CLB X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

11.2.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. Figure 11-3 represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing Table 11-4. Select up to one signal per mux (31 total muxes) for each AUXSIGx output. Select the inputs to each mux using the AUXSIGxMUX0TO15CFG and AUXSIGxMUX16TO31CFG registers. To pass any signal through to the CLB, enable the mux in the AUXSIGxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective AUXSIGx signal on the CLB. To optionally invert the signal, use the AUXSIGOUTINV register.

11.2.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 11-5 shows the architecture of the GPIO Output X-BAR. The X-BAR contains eight outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single input or a logical-OR of many inputs.

11.2.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has eight outputs that are routed to the GPIO module. Figure 11-5 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs. Note that the architecture of the Output X-BAR (with the exception of the output latch) is similar to the architecture of the ePWM X-BAR.

First, determine the signals that can be passed to the GPIO by referencing Table 11-5. Select up to one signal per mux (32 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux using the OUTPUTxMUX0TO15CFG and OUTPUTxMUX16TO31CFG registers. To pass any signal through to the GPIO, enable the mux in the OUTPUTxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective OUTPUTx signal on the GPIO module. To optionally invert the signal, use the OUTPUTINV register. The final output is only recognized on the GPIO if the proper OUTPUTx muxing options are selected using the GPIO registers.

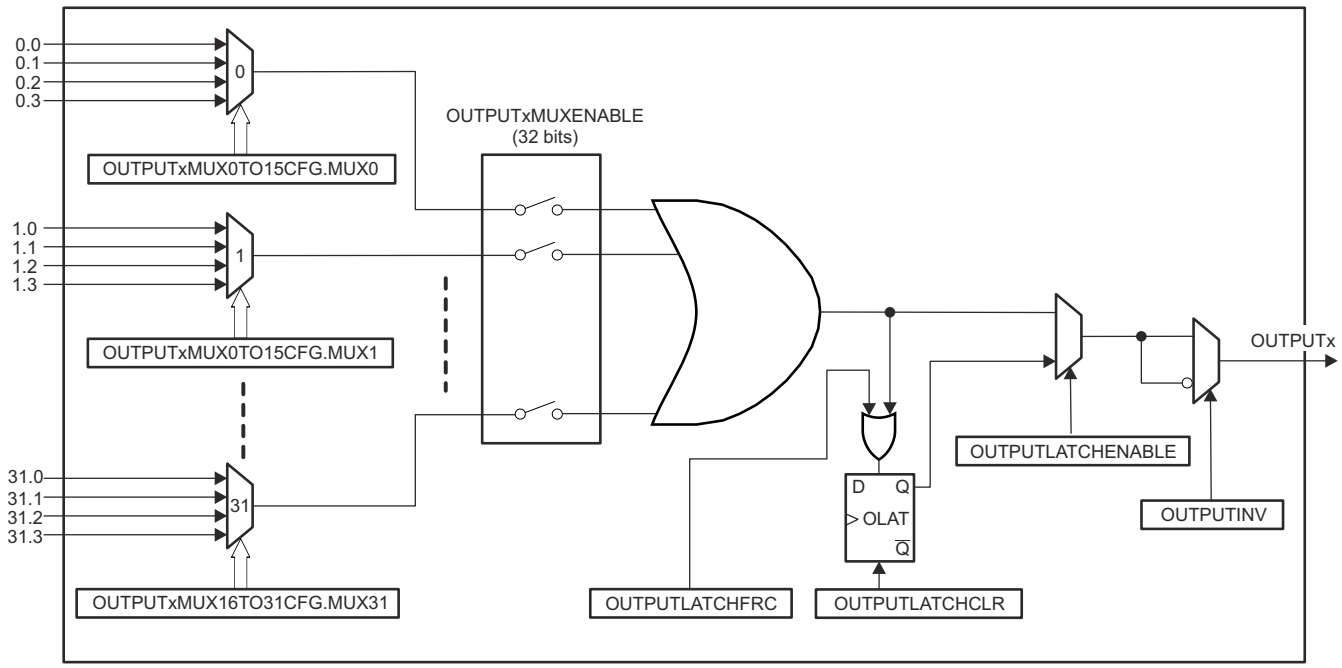

Figure 11-5. GPIO Output X-BAR Architecture

Note

Do not use "Reserved" signals in your application.

11.2.4 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See Figure 11-6 for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLRx register.

Note

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

Complex bit access types are encoded to fit into small table cells. Table 11-13 shows the codes that are used for access types in this section.

Table 11-13. INPUT_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.4.2.1 INPUT1SELECT Register (Offset = 0h) [Reset = FFFEh]

INPUT1SELECT is shown in Figure 11-7 and described in Table 11-14.

Return to the Summary Table.

11.4.3 XBAR_REGS Registers

Table 11-31 lists the memory-mapped registers for the XBAR_REGS registers. All register offset addresses not listed in Table 11-31 should be considered as reserved locations and the register contents should not be modified.

Table 11-31. XBAR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XBARFLG1	X-Bar Input Flag Register 1		Go
2h	XBARFLG2	X-Bar Input Flag Register 2		Go
4h	XBARFLG3	X-Bar Input Flag Register 3		Go
6h	XBARFLG4	X-Bar Input Flag Register 4		Go
8h	XBARCLR1	X-Bar Input Flag Clear Register 1		Go
Ah	XBARCLR2	X-Bar Input Flag Clear Register 2		Go
Ch	XBARCLR3	X-Bar Input Flag Clear Register 3		Go
Eh	XBARCLR4	X-Bar Input Flag Clear Register 4		Go

Complex bit access types are encoded to fit into small table cells. Table 11-32 shows the codes that are used for access types in this section.

Table 11-32. XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.4.3.1 XBARFLG1 Register (Offset = 0h) [Reset = 00000000h]

XBARFLG1 is shown in Figure 11-24 and described in Table 11-33.

Return to the Summary Table.

Table 11-33. XBARFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	CMPSS3_CTRIPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	CMPSS3_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	CMPSS2_CTRIPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	CMPSS2_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	CMPSS1_CTRIPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	CMPSS1_CTRIPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

11.4.3.2 XBARFLG2 Register (Offset = 2h) [Reset = 00000000h]

XBARFLG2 is shown in Figure 11-25 and described in Table 11-34.

Return to the Summary Table.

17	ECAP2_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 11-34. XBARFLG2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	ECAP1_OUT	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	INPUT14	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	INPUT13	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	INPUT12	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	INPUT11	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
11	INPUT10	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	INPUT9	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	INPUT8	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 11-34. XBARFLG2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	INPUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	ADCSOCB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	ADCSOCA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	INPUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	INPUT5	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	INPUT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	INPUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	INPUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 11-34. XBARFLG2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	INPUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: Corresponding Input was triggered 0: Corresponding Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

11.4.3.3 XBARFLG3 Register (Offset = 4h) [Reset = 00000000h]

XBARFLG3 is shown in Figure 11-26 and described in Table 11-35.

Return to the Summary Table.

3Eh	TRIPLOCK	ePWM XBAR Configuration Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 11-42 shows the codes that are used for access types in this section.

Table 11-42. EPWM_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

Table 11-42. EPWM_XBAR_REGS Access Type Codes (continued)

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.4.4.1 TRIP4MUX0TO15CFG Register (Offset = 0h) [Reset = 00000000h]

TRIP4MUX0TO15CFG is shown in Figure 11-32 and described in Table 11-43.

Return to the Summary Table.

Table 11-50. TRIP8MUX16TO31CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	MUX31	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux31: 00 : Select .0 input for Mux31 01 : Select .1 input for Mux31 10 : Select .2 input for Mux31 11 : Select .3 input for Mux31 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29-28	MUX30	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux30: 00 : Select .0 input for Mux30 01 : Select .1 input for Mux30 10 : Select .2 input for Mux30 11 : Select .3 input for Mux30 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27-26	MUX29	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux29: 00 : Select .0 input for Mux29 01 : Select .1 input for Mux29 10 : Select .2 input for Mux29 11 : Select .3 input for Mux29 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25-24	MUX28	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux28: 00 : Select .0 input for Mux28 01 : Select .1 input for Mux28 10 : Select .2 input for Mux28 11 : Select .3 input for Mux28 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23-22	MUX27	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux27: 00 : Select .0 input for Mux27 01 : Select .1 input for Mux27 10 : Select .2 input for Mux27 11 : Select .3 input for Mux27 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21-20	MUX26	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux26: 00 : Select .0 input for Mux26 01 : Select .1 input for Mux26 10 : Select .2 input for Mux26 11 : Select .3 input for Mux26 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-50. TRIP8MUX16TO31CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-18	MUX25	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux25: 00 : Select .0 input for Mux25 01 : Select .1 input for Mux25 10 : Select .2 input for Mux25 11 : Select .3 input for Mux25 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17-16	MUX24	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux24: 00 : Select .0 input for Mux24 01 : Select .1 input for Mux24 10 : Select .2 input for Mux24 11 : Select .3 input for Mux24 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15-14	MUX23	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux23: 00 : Select .0 input for Mux23 01 : Select .1 input for Mux23 10 : Select .2 input for Mux23 11 : Select .3 input for Mux23 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13-12	MUX22	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux22: 00 : Select .0 input for Mux22 01 : Select .1 input for Mux22 10 : Select .2 input for Mux22 11 : Select .3 input for Mux22 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11-10	MUX21	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux21: 00 : Select .0 input for Mux21 01 : Select .1 input for Mux21 10 : Select .2 input for Mux21 11 : Select .3 input for Mux21 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX20	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux20: 00 : Select .0 input for Mux20 01 : Select .1 input for Mux20 10 : Select .2 input for Mux20 11 : Select .3 input for Mux20 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7-6	MUX19	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux19: 00 : Select .0 input for Mux19 01 : Select .1 input for Mux19 10 : Select .2 input for Mux19 11 : Select .3 input for Mux19 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX18	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux18: 00 : Select .0 input for Mux18 01 : Select .1 input for Mux18 10 : Select .2 input for Mux18 11 : Select .3 input for Mux18 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-50. TRIP8MUX16TO31CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	MUX17	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux17: 00 : Select .0 input for Mux17 01 : Select .1 input for Mux17 10 : Select .2 input for Mux17 11 : Select .3 input for Mux17 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX16	R/W	0h	Select Bits for EPWM-XBAR TRIP8 Mux16: 00 : Select .0 input for Mux16 01 : Select .1 input for Mux16 10 : Select .2 input for Mux16 11 : Select .3 input for Mux16 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.9 TRIP9MUX0TO15CFG Register (Offset = 10h) [Reset = 00000000h]

TRIP9MUX0TO15CFG is shown in Figure 11-40 and described in Table 11-51.

Return to the Summary Table.

ePWM XBAR Mux Configuration for TRIP9

Bit	Field	Type	Reset	Description
31-30	MUX15	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux15: 00 : Select .0 input for Mux15 01 : Select .1 input for Mux15 10 : Select .2 input for Mux15 11 : Select .3 input for Mux15 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29-28	MUX14	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux14: 00 : Select .0 input for Mux14 01 : Select .1 input for Mux14 10 : Select .2 input for Mux14 11 : Select .3 input for Mux14 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27-26	MUX13	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux13: 00 : Select .0 input for Mux13 01 : Select .1 input for Mux13 10 : Select .2 input for Mux13 11 : Select .3 input for Mux13 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25-24	MUX12	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux12: 00 : Select .0 input for Mux12 01 : Select .1 input for Mux12 10 : Select .2 input for Mux12 11 : Select .3 input for Mux12 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23-22	MUX11	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux11: 00 : Select .0 input for Mux11 01 : Select .1 input for Mux11 10 : Select .2 input for Mux11 11 : Select .3 input for Mux11 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21-20	MUX10	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux10: 00 : Select .0 input for Mux10 01 : Select .1 input for Mux10 10 : Select .2 input for Mux10 11 : Select .3 input for Mux10 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-57. TRIP12MUX0TO15CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-18	MUX9	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux9: 00 : Select .0 input for Mux9 01 : Select .1 input for Mux9 10 : Select .2 input for Mux9 11 : Select .3 input for Mux9 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17-16	MUX8	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux8: 00 : Select .0 input for Mux8 01 : Select .1 input for Mux8 10 : Select .2 input for Mux8 11 : Select .3 input for Mux8 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15-14	MUX7	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux7: 00 : Select .0 input for Mux7 01 : Select .1 input for Mux7 10 : Select .2 input for Mux7 11 : Select .3 input for Mux7 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13-12	MUX6	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux6: 00 : Select .0 input for Mux6 01 : Select .1 input for Mux6 10 : Select .2 input for Mux6 11 : Select .3 input for Mux6 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11-10	MUX5	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux5: 00 : Select .0 input for Mux5 01 : Select .1 input for Mux5 10 : Select .2 input for Mux5 11 : Select .3 input for Mux5 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX4	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux4: 00 : Select .0 input for Mux4 01 : Select .1 input for Mux4 10 : Select .2 input for Mux4 11 : Select .3 input for Mux4 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7-6	MUX3	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux3: 00 : Select .0 input for Mux3 01 : Select .1 input for Mux3 10 : Select .2 input for Mux3 11 : Select .3 input for Mux3 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX2	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux2: 00 : Select .0 input for Mux2 01 : Select .1 input for Mux2 10 : Select .2 input for Mux2 11 : Select .3 input for Mux2 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-57. TRIP12MUX0TO15CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	MUX1	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux1: 00 : Select .0 input for Mux1 01 : Select .1 input for Mux1 10 : Select .2 input for Mux1 11 : Select .3 input for Mux1 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX0	R/W	0h	Select Bits for EPWM-XBAR TRIP12 Mux0: 00 : Select .0 input for Mux0 01 : Select .1 input for Mux0 10 : Select .2 input for Mux0 11 : Select .3 input for Mux0 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.16 TRIP12MUX16TO31CFG Register (Offset = 1Eh) [Reset = 00000000h]

TRIP12MUX16TO31CFG is shown in Figure 11-47 and described in Table 11-58.

Return to the Summary Table.

ePWM XBAR Mux Configuration for TRIP12

Table 11-59. TRIP4MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-59. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-59. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-59. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-59. TRIP4MUXENABLE Register Field Descriptions (continued)

3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of Mux0 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.18 TRIP5MUXENABLE Register (Offset = 22h) [Reset = 00000000h]

TRIP5MUXENABLE is shown in Figure 11-49 and described in Table 11-60.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP5

Figure 11-49. TRIP5MUXENABLE Register

31	30	29	28	27	26	25	24

Table 11-60. TRIP5MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-60. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-60. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-60. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-60. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.19 TRIP7MUXENABLE Register (Offset = 24h) [Reset = 00000000h]

TRIP7MUXENABLE is shown in Figure 11-50 and described in Table 11-61.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP7

Table 11-61. TRIP7MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-61. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-61. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-61. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-61. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.20 TRIP8MUXENABLE Register (Offset = 26h) [Reset = 00000000h]

TRIP8MUXENABLE is shown in Figure 11-51 and described in Table 11-62.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP8

Table 11-62. TRIP8MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-62. TRIP8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-62. TRIP8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-62. TRIP8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-62. TRIP8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.21 TRIP9MUXENABLE Register (Offset = 28h) [Reset = 00000000h]

TRIP9MUXENABLE is shown in Figure 11-52 and described in Table 11-63.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP9

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-63. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-63. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-63. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-63. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.22 TRIP10MUXENABLE Register (Offset = 2Ah) [Reset = 00000000h]

TRIP10MUXENABLE is shown in Figure 11-53 and described in Table 11-64.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP10

Table 11-64. TRIP10MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux31 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux30 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux29 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux28 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-64. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux27 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux26 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux25 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux24 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-64. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-64. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 11-64. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11.4.4.23 TRIP11MUXENABLE Register (Offset = 2Ch) [Reset = 00000000h]

TRIP11MUXENABLE is shown in Figure 11-54 and described in Table 11-65.

Return to the Summary Table.
