

BQ2980, BQ2982

JAJSEG2K - OCTOBER 2017 - REVISED JULY 2024

BQ298xyz シングルセル・リチウムイオン/リチウムポリマー・バッテリの高 速/フラッシュ充電用、ハイサイド NFET ドライバ内蔵の電圧/電流/温度プ ロテクタ

1 特長

- 電圧保護
 - 過電圧 (OV):±10mV
 - 低電圧 (UV):±20mV
- 電流保護:
 - 充電時の過電流 (OCC):±1mV
 - 放電時の過電流 (OCD):±1mV
 - 故電時の短絡 (SCD):±5mV
- 温度保護
 - 過熱 (OT)
- その他の機能:
 - 最低 1mΩ の検知抵抗 (R_{SNS}) をサポート
 - ハイサイド保護
 - 高 Vgs FET ドライブ
 - 0V 充電 (BQ2980 のみ)
 - FET オーバーライド制御用の CTR ピンによりシス テム リセット / シャットダウンを実現
 - 4 外付け PTC サーミスタを使った第2の OT 保護を 目的として CTR を構成可能
- 消費電流:
 - 通常モード:4μA
 - シャットダウン モード:0.1µA 以下
- パッケージ:
 - 8pin X2QFN: 1.50 × 1.50 × 0.37mm

2 アプリケーション

- スマートフォン
- タブレット
- パワーバンク
- ウェアラブル

3 概要

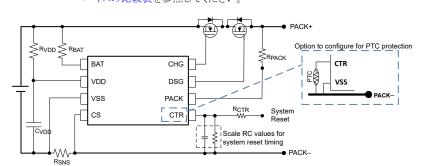

BQ298xyz ファミリは、内蔵のチャージ ポンプ FET ドライ バによって、1 シリーズ リチウムイオン / リチウムポリマー バッテリの使用時にハイサイドの 1 次バッテリ セルを保護 し、セル電圧範囲全体で安定した Rdson を実現できま す。システムの熱性能の向上に向けて、高精度な BQ298x では最小 $1m\Omega$ の検知抵抗を使用できます。

またホスト制御により FET ドライバをオーバーライドするよ うに CTR ピンを構成し、システム リセットまたはシャットダ ウン機能を実装することも可能です。あるいは、内蔵され ているダイ温度センサに加えて、外付けの正温度係数 (PTC) サーミスタに接続するように CTR ピンを構成し、 FET OT 保護を実現することもできます。 BQ2980xy デバ イスはゼロボルト (OV) 充電をサポートしていますが、 BQ2982xy デバイスはこの機能を無効にしています。

製品情報

部品番号 (1)	パッケージ	本体サイズ (公称)
BQ2980xy	X2QFN	1.50mm × 1.50mm × 0.37mm
BQ2982xy X2QFN		1.50mm × 1.50mm × 0.37mm

利用可能なすべてのパッケージについては、注文情報およびデ バイスの比較表を参照してください。

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
Supply voltage	VDD	-0.3	6	V
	PACK	-0.3	24	
Input voltage	BAT	-0.3	6	V
Input voltage	CS	-0.3	0.3	v
	CTR	-0.3	5	
Output valtage	CHG	-0.3	20	V
Output voltage	DSG	-0.3	20	v
Storage temperature, T _{stg}		-55	150	°C

⁽¹⁾ Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

6.2 ESD Ratings

			VALUE	UNIT
V	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±1000	V
V _(ESD)	Liectiostatic discharge	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±250	v

- 1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

			MIN	MAX	UNIT

6.6 Typical Characteristics

7 Detailed Description

7.1 Overview

The BQ298xyz devices are high-side single-cell protectors designed to improve thermal performance by reducing power dissipation across the protection FETs. This is achieved with high-side protection with a built-in charge pump to provide higher Vgs to the FET gate voltage to reduce FET Rdson. Additionally, the device supports as low as a $1-m\Omega$ sense resistor with $\pm 1-mV$ accuracy, resulting in lower heat dissipation at the sense resistor without compromising current accuracy.

The BQ298x device implements a CTR pin that allows external control to open the power FETs, as well as shut down the device for low power storage. Optionally, the CTR pin can be configured to connect to a PTC and be used for overtemperature protection.

7.1.1 Device Configurability

表 7-1 provides guidance on possible configurations of the BQ2980 and BQ2982 devices.

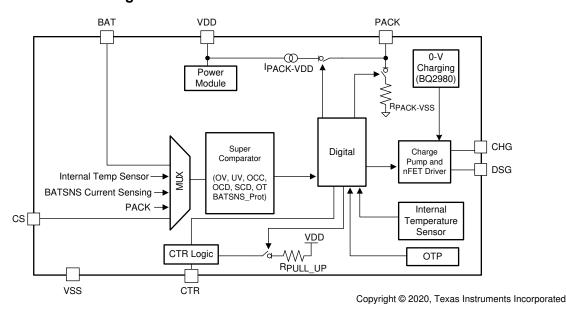

注

Texas Instruments preprograms devices: Devices are not intended to be further customized by the customer.

表 7-1. Device Configuration Range

	STEP DELAY RECOVERY DESCRIPTION							
	FAULT	RANGE	STEP SIZE	UNIT	DELAY SELECTION	CHG, DSG STATUS	(Non-Configurable)	
ov	Overvoltage	3750 – 5200	50	mV	0.25, 1, 1.25, 4.5 s	CHG OFF	(200-mV hysteresis AND charger removal) OR (below OV threshold AND discharge load is detected)	
		2200 –			20, 96, 125,	Option 1: UV_SHUT enable The device goes into SHUTDOWN.	(200-mV hysteresis AND discharge load is removed before device shuts down) OR (above UV threshold AND charger connection)	
UV	Undervoltage	3000	50	mV	20, 90, 123, 144 ms	Option 2: UV_SHUT disable DSG off, power consumption drops to I _{FETOFF} , and the device does not shut down.	(200-mV hysteresis) OR (above UV threshold AND charger connection)	
осс	Overcurrent in Charge	-644	2	mV	8, 16, 20, 48 ms	CHG OFF	Detect a charger removal (V _{BAT} – V _{PACK}) > 100-mV typical

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Overvoltage (OV) Status

The device detects an OV fault when $V_{BAT} > V_{OVP}$ (OV threshold) during charging. If this condition exists for longer than the OV delay (t_{OVP}), the CHG output is driven to V_{FETOFF} to turn off the CHG FET.

The OV status is released and the CHG output rises to HIGH, that is, $V_{CHG} = VDD \times (1 + A_{FETON})$, if one of the following conditions occurs:

- When V_{BAT} is < $(V_{OVP} V_{OVP_HYS})$ and the charger is removed or
- When V_{BAT} is < V_{OVP} and a discharge load is detected.

The device detects the charger is removed if $(V_{PACK} - V_{BAT}) < 100$ -mv typical. To detect if a load is attached, the device checks if $(V_{BAT} - V_{PACK}) > 400$ -mv typical.

7.3.2 Undervoltage (UV) Status

The device detects a UV fault when the battery voltage measured is below the UV threshold (V_{UVP}). If this condition exists for longer than the UV delay (t_{UVP}), the DSG output is driven to V_{FFTOFF} to turn off the DSG FET.

The device includes a UV_SHUT option which may be enabled during factory configuration. If this option is enabled, during the UV fault state the device goes into SHUTDOWN mode to preserve the battery. In SHUTDOWN mode, the BQ2980 will drive the CHG output to the PACK voltage, putting the device into ZVCHG mode (the BQ2982 does not enable this ZVCHG mode). That means, the CHG FET can be turned on if a charger is connected and both VDD and PACK meet the ZVCHG turn-on conditions (see $\frac{1}{2}$ 7.3.9 for more details). The PACK pin is internally pulled to VSS through $R_{PACK-VSS}$. This is to determine if the charger is disconnected on the PACK+ terminal before shutting down the device. It is also to ensure the device does not falsely wake up from SHUTDOWN mode due to noise.

The UV status is released and the DSG output rises to HIGH, that is, $V_{DSG} = VDD \times (1 + A_{FETON})$, if one of the following conditions occurs:

- When V_{BAT} is > (V_{UVP} + V_{UVP} HYS) and the discharge load is removed or
- When V_{BAT} is > V_{UVP} and a charger is connected.

The device detects that the charger is attached if $(V_{PACK} - V_{BAT}) > 700$ -mV typical. To detect for load removal, the device checks if $(V_{BAT} - V_{PACK}) < 400$ -mV typical.

If the UV_SHUT option is disabled, during a UV fault DSG is turned off and the device does not go into SHUTDOWN. The power consumption is reduced to I_{FETOFF}. The PACK pin is still internally pulled to VSS through R_{PACK-VSS}. To recover UV with this option, one of the following conditions must occur:

- When V_{BAT} is > (V_{UVP} + V_{UVP} HYS) or
- When V_{BAT} is > V_{UVP} and a charger is connected.

7.3.3 Overcurrent in Charge (OCC) Status

The BQ298xyz device detects a current fault by monitoring the voltage drop across an external sense resistor (R_{SNS}) between the CS and VSS pins. The device detects an OCC fault when ($V_{CS} - VSS$) < OCC threshold ($-V_{OC}$). If this condition exists for longer than the OCC delay (t_{OC}), the CHG output is driven to V_{FETOFF} to turn off the CHG FET.

The OCC status is released and the CHG output rises to HIGH, that is $V_{CHG} = VDD \times (1 + A_{FETON})$, if $(V_{BAT} - V_{PACK}) > 100$ mV, indicating a charger is removed.

7.3.4 Overcurrent in Discharge (OCD) and Short Circuit in Discharge (SCD) Status

The BQ298xyz device detects a current fault by monitoring the voltage drop across an external sense resistor (R_{SNS}) between the CS and VSS pins. The device applies the same method to detect OCD and SCD faults and applies the same recovery scheme to release the OCD and SCD faults.

The device detects an OCD fault when $(V_{CS} - VSS) > OCD$ threshold $(+V_{OC})$. If this condition exists for longer than the OCD delay (t_{OC}) , the DSG output is driven to V_{FETOFF} to turn off the DSG FET. The SCD detection is similar to OCD, but uses the SCD threshold (V_{SCD}) and SCD delay (t_{SCD}) time.

During an OCD or SCD state, the device turns on the recovery detection circuit. An internal current sink ($I_{PACK-VDD}$) is connected between the PACK and VDD pins, and the device consumes I_{OC_REC} during the OCD and SCD fault until recovery is detected.

The OCD or SCD status is released and the DSG output rises to HIGH, that is $V_{DSG} = VDD \times (1 + A_{FETON})$, if $(V_{BAT} - V_{PACK}) < 400$ mV, indicating a discharge load is removed.

7.3.5 Overtemperature (OT) Status

The device has a built-in internal temperature sensor for OT protection. The sensor detects OT when the internal temperature measurement is above the internal overtemperature threshold (T_{OT}). If this condition exists for longer than the OT delay (t_{OT}), both CHG and DSG outputs are driven to V_{FETOFF} to turn off the CHG and DSG FETs.

The OT state is released and the CHG and DSG outputs rise to HIGH, that is V_{CHG} and $V_{DSG} = VDD \times (1 + A_{FETON})$, if the internal temperature measurement falls below $(T_{OT} - T_{OT\ HYS})$.

7.3.6 Charge and Discharge Driver

The device has a built-in charge pump to support high-side protection using an NFET. When the drivers are on, the CHG and DSG pins are driven to the VDD × (1 + A_{FETON}) voltage level. This means the Vgs across the CHG or DSG FET is about (VDD × A_{FETON}). When the drivers are turned off and VDD \geq V_{0INH} , the CHG and/or DSG output is driven to V_{FETOFF}.

The charge pump requires VDD > V_{DRIVER_SHUT} to operate. When VDD falls below V_{DRIVER_SHUT} - $V_{DRIVER_SHUT_HYS}$, the DSG output is off. The CHG output can be turned on in BQ2980 if the ZVCHG charging condition is met. See $\frac{1}{2}$ 7.3.9 for more details.

7.3.7 CTR for FET Override and Device Shutdown

The CTR pin is an active-high input pin, which can be controlled by the host system to turn off both CHG and DSG outputs momentarily to reset the system, shut down the system for low-power storage, or as a necessary shutdown if the host detects a critical system error.

The CTR pin uses a 4.5-s timer (same specification tolerance as the t_{OVP} delay 4.5-s option) to differentiate a reset and shutdown signal. CHG and DSG are off when $V_{CTR} > CTR V_{IH}$ for $> 200 \mu s$. Counting from the start of

Copyright © 2024 Texas Instruments Incorporated

資料に関するフィードバック(ご意見やお問い合わせ) を送信

11

 $V_{CTR} > V_{IH}$, if V_{CTR} drops below V_{IL} within 3.6 s, CHG and DSG simply turn back on. If CTR remains HIGH for > 5.4 s, the device enters SHUTDOWN mode.

With this timing control, the system designer can use an RC circuit to implement either a host-controlled power-on-reset or a system shutdown.

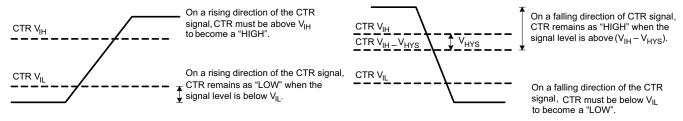

図 7-1. CTR Level in Rising and Falling Direction

注

- CTR shuts down the device only when V_{CTR} is HIGH for > 5.4 s AND when there is no OV or OT fault present.
- The CTR V_{IH} level is the voltage level at which the CTR pin is considered HIGH in the positive direction as voltage increases. There is a minimum hysteresis designed into the logic level; therefore, as voltage decreases, CTR is considered HIGH at the (V_{IH} – V_{HYS}) level.
- The FET override and the shutdown functions are not available if the CTR pull-up is enabled. See セクション 7.3.8 for details.

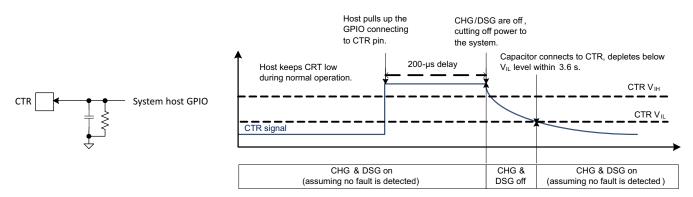

図 7-2. System Reset Function Implementation

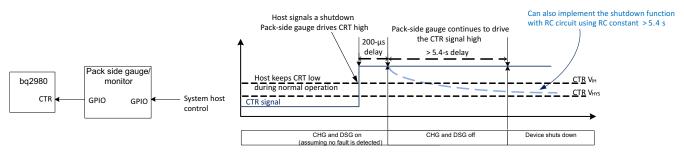

図 7-3. Potential System- Controlled Shutdown Implementation

7.3.8 CTR for PTC Connection

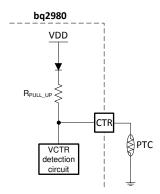

If any of the CTR pull-up resistors are selected, the device assumes a PTC is connected to the CTR pin. There are three internal pull-up options: 1.5 M Ω , 5 M Ω , or 8 M Ω . The internal pull-up allows a PTC to be connected

English Data Sheet: SLUSCS3

between the CTR pin and VSS. This turns the CTR pin to detect an overtemperature fault through an external PTC, as shown in \boxtimes 7-4.

Copyright © 2017, Texas Instruments Incorporated

図 7-4. Connecting PTC to CTR Pin for Overtemperature Protection

When any of the CTR internal pull-up resistors are selected (factory configured), an active-high signal ($V_{CTR} > CTR V_{IH}$) on CTR turns off both CHG and DSG outputs, but it does not shut down the device.

As temperature goes up, the PTC resistance increases and when the voltage divided by the internal R_{PULL_UP} and the R_{PTC} is > CTR V_{IH} , the CHG and DSG outputs are turned off. As temperature falls and the PTC resistance decreases, the CHG and DSG outputs turn back on when $(V_{CTR} < CTR \ V_{IL})$.

7.3.9 ZVCHG (0-V Charging)

ZVCHG (0-V charging) is a special function that allows charging a severely depleted battery that is below the FET driver charge pump shutdown voltage (V_{DRIVER_SHUT}). The BQ2980 has ZVCHG enabled, while the BQ2982 device has it disabled.

In BQ2980, if $V_{BAT} > V_{OINH}$ and VDD < V_{DRIVER_SHUT} - $V_{DRIVER_SHUT_HYS}$ and the charger voltage at PACK+ is > V_{OCHGR} , then the CHG output will be driven to the voltage of the PACK pin, allowing charging. ZVCHG mode in the BQ2980 is exited when $V_{BAT} > V_{DRIVER_SHUT}$, at which point the charge pump is enabled, and CHG transitions to being driven by the charge pump. In the BQ2982, ZVCHG is entirely disabled, so charging is disabled whenever VDD < V_{DRIVER_SHUT} - $V_{DRIVER_SHUT_HYS}$.

For BQ2980 and BQ2982, when the voltage on VDD is below V_{0INH} , the CHG output becomes high impedance, and any leakage current flowing through the CHG FET may cause this voltage to rise and reenable charging. If this is undesired, a high impedance resistor can be included between the CHG FET gate and source to overcome any leakage and ensure the FET remains disabled in this case. This resistance should be as high as possible while still ensuring the FET is disabled, since it will increase the device operating current when the CHG driver is enabled. Because gate leakage is typically extremely low, a gate-source resistance of 50 M Ω to 100 M Ω may be sufficient to overcome the leakage.

7.4 Device Functional Modes

7.4.1 Power Modes

7.4.1.1 Power-On-Reset (POR)

The device powers up in SHUTDOWN mode, assuming a UV fault. To enter NORMAL mode, both V_{BAT} and V_{PACK} must meet the UV recovery requirement. In summary, if UV_SHUT is enabled, $(V_{BAT} > V_{UVP})$ and V_{PACK} detecting a charger connection are required to enter NORMAL mode. If UV_SHUT is disabled, $(V_{BAT} > V_{UVP})$ and $(V_{PACK} >$ the minimum value of VDD) are required to enter NORMAL mode. See $\frac{1}{2}$ 7.4.1.4 for more details.

Copyright © 2024 Texas Instruments Incorporated

資料に関するフィードバック(ご意見やお問い合わせ)を送信

During the ZVCHG operation mode (only available in BQ2980), the CHG pin is internally connected to PACK when the device is in SHUTDOWN mode. If both V_{BAT} and V_{PACK} meet the ZVCHG condition (see $\frac{1}{2}\sqrt{2}$) 7.3.9 for details), CHG is on, even if UV recovery conditions are not met.

7.4.1.2 NORMAL Mode

In NORMAL mode, all configured protections are active. No fault is detected, and both CHG and DSG drivers are enabled. For the BQ298x device, if none of the internal CTR pull-up resistor options is selected, V_{CTR} must be < CTR V_{II} for CHG and DSG to be on.

7.4.1.3 FAULT Mode

If a protection fault is detected, the device enters FAULT mode. In this mode, the CHG or DSG driver is pulled to V_{FETOFF} to turn off the CHG or DSG FETs.

7.4.1.4 SHUTDOWN Mode

This mode is the lowest power-consumption state of the device, with both CHG and DSG turned off.

The two conditions to enter SHUTDOWN mode are as follows:

- Undervoltage (UV): If the device is configured with UV_SHUT enabled, when UV protection is triggered, the device enters SHUTDOWN mode. See セクション 7.3.2 for details.
- CTR control: When CTR is HIGH for > 5.4 s, the device enters SHUTDOWN mode. See セクション 7.3.7 for details.

注

If the internal CTR pull-up is enabled, a HIGH at CTR does not activate the shutdown process. This is because when the internal pull-up is enabled, the CTR pin is configured for use with an external PTC for overtemperature protection, and the CTR functionality is disabled.

8 Application and Implementation

Application Information Disclaimer

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Test Circuits for Device Evaluation

1. Test Power Consumption (Test Circuit 1)

This setup is suitable to test for device power consumption at different power modes. VS1 is a voltage source that simulates a battery cell. VS2 is used to simulate a charger and load under different power mode conditions.

I1 is a current meter that monitors the device power consumption at different modes. I2 is a current meter that monitors the PACK pin current. The I_{PACK} current is insignificant in most operation modes. If a charger is connected (VS2 has a positive voltage), but the device is still in SHUTDOWN mode, I2 reflects the I_{PACK} current drawing from the charger due to the internal $R_{PACK-VSS}$ resistor.

2. Test CHG and DSG Voltage and Status (Test Circuit 2)

This setup is suitable to test V_{CHG} and V_{DSG} levels or monitor the CHG and DSG status at different operation modes. It is not suitable to measure power consumption of the device, because the meters (or scope

Copyright © 2024 Texas Instruments Incorporated

probes) connected to CHG and/or DSG increase the charge pump loading beyond the normal application condition. Therefore, the current consumption of the device under this setup is greatly increased.

3. Test for Fault Protection (Test Circuit 3)

This setup is suitable to test OV, UV, OCD, OCD, and SCD protections.

Voltage protection:

Adjust VS1 to simulation OV and UV. TI recommends having 0 V on VS3 during the voltage test to avoid generating multiple faults. Adjust VS2 to simulate the charger/load connection or disconnection. Combine with test circuit 1 to monitor power consumption, or combine with test circuit 2 to monitor CHG and DSG status.

Test example for OV fault and OV recovery by charger removal:

- a. Adjust both VS1 and VS2 > OVP threshold.
- b. As the device triggers for OVP and CHG is open, VS2 can be set to a maximum expected charger voltage as if in an actual application when CHG is open, and charger voltage may regulate to the maximum setting.
- To test for OV recovery, adjust VS1 below (V_{OVP} V_{OVP_Hys}). Reduce the VS2 voltage so that (VS2 VS1) < 100 mV (to emulate removal of a charger).

Current protection:

Similar to the voltage protection test, adjust VS3 to simulate OCC, OCD, and SCD thresholds. Use VS2 to simulate a charger/load status. TI recommends setting VS1 to the normal level to avoid triggering multiple faults.

注

It is normal to observe CHG or DSG flipping on and off if VS2 is not set up properly to simulate a charger or load connection/disconnection, especially when the voltage source is used to simulate fault conditions. It is because an improper VS2 setting may mislead the device to sense a recovery condition immediately after a fault protection is triggered.

4. Test for CTR Control (Test Circuit 4)

This setup is suitable to test for CTR control. Adjust VS4 above or below the CTR V_{IH} or V_{IL} level. Combine with test circuit 1 to observe the power consumption, or combine with test circuit 2 to observe the CHG and DSG status.

8.1.2 Test Circuit Diagrams

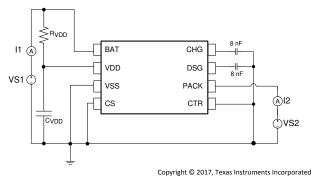

図 8-1. Test Circuit 1

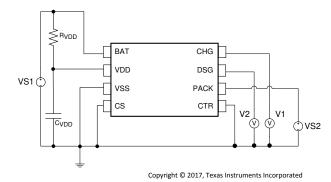

図 8-2. Test Circuit 2

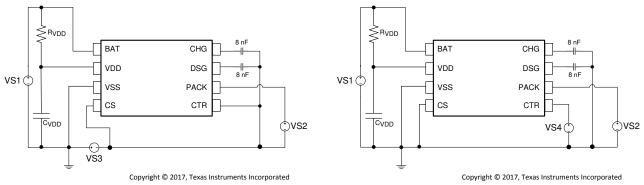

図 8-3. Test Circuit 3

図 8-4. Test Circuit 4

8.1.3 Using CTR as FET Driver On/Off Control

Normally, CTR is not designed as a purely on/off control of the FET drivers, because there is a timing constriction on the pin. The following is a list of workarounds to implement the CTR as an on/off switch to the FET drivers.

1. Switching CTR from high to low with less than 3.6 s:

If the application only requires turning off the FET drivers in < 3.6 s, then the CTR pin can simply be viewed as an on/off switch of the FET drivers. That means, after the CTR pin is pulled high, the application will pull the CTR pin back low in < 3.6 s.

2. Applying a voltage on PACK to prevent the device from entering SHUTDOWN mode:

When the CTR pin is be pulled high for > 3.6 s, there is a chance the device may go into SHUTDOWN mode. If the CTR pin is high for > 5.4 s, the device will be in SHUTDOWN mode. For applications that may use the CTR to keep the FET drivers off for > 3.6 s, the workaround is to keep V_{PACK} within the VDD recommended operating range while the CTR is pulled high to prevent the device from entering SHUTDOWN mode. The device is forced to stay in NORMAL mode with this method.

Because the PACK pin is also connected to the PACK terminal, the system designer should have a blocking diode to protect the GPIO (that controls the CTR pin) from high voltage.

During the time CTR is high voltage on PACK must be applied. Otherwise, device will enter SHUTDOWN mode

When CTR is pulled high (FETs off), the system ensures:

- 1. Voltage on PACK is applied before pulling CTR high or
- 2. Voltage on PACK is applied within 3.6 s after CTR is pulled high.

When CTR is pulled low (FET on), the system ensures: Voltage on PACK is still applied before pulling CTR low.

図 8-5. PACK Voltage Timing with Switching CTR as On/Off Control of FET Drivers

8.2 Typical Applications

8.2.1 BQ298x Configuration 1: System-Controlled Reset/Shutdown Function

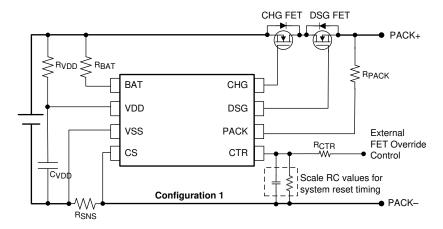

図 8-6. BQ298x Reference Schematic Configuration 1

8.2.1.1 Design Requirements

For this design example, use the parameters listed $\frac{1}{2}$ 8-1.

	24		IIIIICIIaca	Compon	ent delection
	PARAMETER	TYP	MAX	UNIT	COMMENT
R _{PACK}	PACK resistor	_	2	kΩ	This resistor is used to protect the PACK pin from a reserve charging current condition.
R _{VDD}	VDD filter resistor	_	300	Ω	
C _{VDD}	VDD filter capacitor	0.1	1	μF	
R _{BAT}	BAT resistor (for safety. To limit current if BAT pin is shorted internally)	20	_	Ω	This resistor limits current if the BAT pin is shorted to ground internally. BAT is used for voltage measurement for OV and UV. A larger resistor value can impact the voltage measurement accuracy.
R _{CTR}	CTR resistor (optional for ESD)	100	_	Ω	This is optional for ESD protection and is highly dependent on the PCB layout.

表 8-1. Recommended Component Selection

8.2.1.2 Detailed Design Procedure

- Determine if a CTR for FET override or an improved voltage measurement function is required in the battery pack design.
- See 🗵 8-6 for the schematic design.
- Check the cell specification and system requirement to determine OV and UV levels.
- Define the sense resistor value and system requirement to determine OCC, OCD, and SCD levels. For example, with a 1-mΩ sense resistor and OCC, OCD, and SCD, the requirement is 6 A, 8 A, and 20 A, respectively. The OCC threshold should be set to 6 mV, the OCD threshold should be at 8 mV, and the SCD threshold should be at 20 mV.
- Determine the required OT protection threshold. The OT fault turns off the CHG and the DSG, so the threshold must account for the highest allowable charge and discharge temperature range.
- When a decision is made on the various thresholds, search for whether a device configuration is available or contact the local sales office for more information.

8.2.1.3 Selection of Power FET

The high-side driver of the BQ298x device limits the Vgs below 8 V with a 4.4-V battery cell. This means the device can work with a power FET with an absolute maximum rating as low as ±8 V Vgs, which is common in smartphone applications.

17

Additionally, TI highly recommends using a low gate leakage FET around 6-V to 7-V Vgs range. The power FET on the BQ298x evaluation module has the following typical gate leakage. TI recommends selecting a similar gate leakage FET for the design.

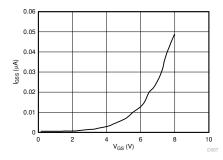

図 8-7. Power FET (on BQ2980 EVM) Gate Leakage Versus Vgs

8.2.1.4 Application Curves

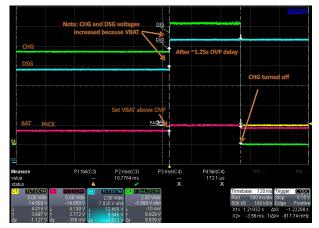

図 8-8. Overvoltage (OV) Protection

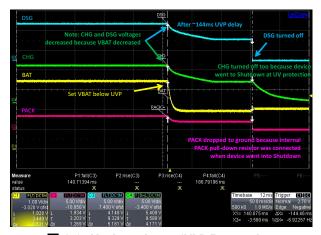

図 8-9. Undervoltage (UV) Protection

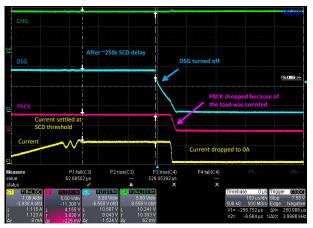

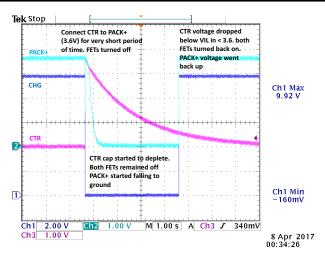

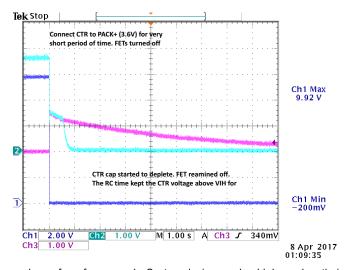

図 8-10. Short Circuit (SCD) Protection

The RC values used in this example are for reference only. System designers should depend on their pull-up voltage and RC tolerance to add any additional margin. TI also recommends users keep the delay time below 3.6 s, if possible, for the reset function.

図 8-11. Setup CTR for System Reset (Using 5 MΩ and 1 μF RC)

The RC values used in this example are for reference only. System designers should depend on their pull-up voltage and RC tolerance to add any additional margin. TI also recommends users keep the delay time below 5.4 s, if possible, for the shutdown function.

図 8-14. BQ298x Reference Schematic Configuration 3

9 Power Supply Recommendations

The device supports single-cell li-ion and li-polymer batteries of various chemistries with a maximum VDD below 5.5 V.

10 Layout

10.1 Layout Guidelines

- Place the components to optimize the layout. For example, group the high-power components like cell pads, PACK+ and PACK- pads, power FETs, and R_{SNS} together, allowing the layout to optimize the power traces for the best thermal heat spreading.
- 2. Separate the device's VSS and low-power components to a low-current ground plane. Both grounds can meet at R_{SNS}.
- 3. Place the VDD RC filter close to the device's VDD pin.

10.2 Layout Example

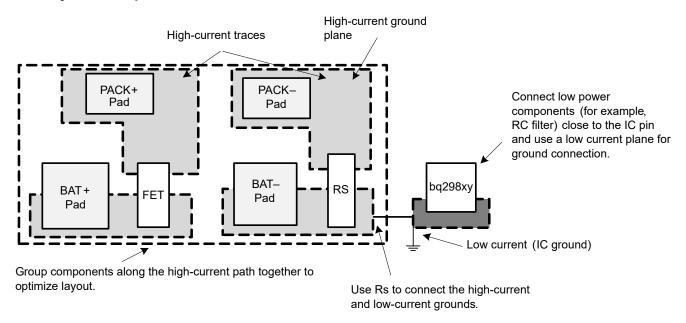

図 10-1. Component Placement and Grounding Pattern Example

PACKAGE OPTION ADDENDUM

www.ti.com 1-Jun-2024

Orderable Device	Status	Package Type	Package Drawing	Pins	Package Qty	Eco Plan	Lead finish/ Ball material	MSL Peak Temp	Op Temp (°C)	Device Marking (4/5)	Samples
							(6)				
BQ298218RUGR	ACTIVE	X2QFN	RUG	8	3000	RoHS & Green	NIPDAU	Level-1-260C-UNLIM	-40 to 85	82 18	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead finish/Ball material Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

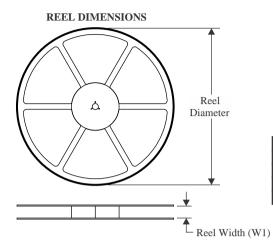

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

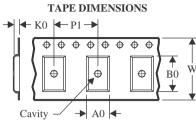

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

- B. This drawing is subject to change without notice.
 C. QFN (Quad Flatpack No-Lead) package configuration.
 D. This package complies to JEDEC MO-288 variation X2ECD.

RUG (R-PQFP-N8)

- NOTES: A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Publication IPC-7351 is recommended for alternate designs.
 - D. Customers should contact their board fabrication site for minimum solder mask web tolerances between signal pads.
 - E. Maximum stencil thickness 0,127 mm (5 mils). All linear dimensions are in millimeters.
 - F. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
 - G. Side aperture dimensions over-print land for acceptable area ratio > 0.66. Customer may reduce side aperture dimensions if stencil manufacturing process allows for sufficient release at smaller opening.
