DLPC410 DMD デジタル・コントローラ

1 特長

- 次の DLP®チップで動作
  - DLP650LNIR、DLP7000、DLP7000UV、DLP9500、DLP9500UV DMD
  - DLPA200 DMD マイクロミラー・ドライバ
  - DLPR410 構成 PROM
- 高速の DMD パターン速度を実現
  - 最高 32kHz の 1 ビット・バイナリ・パターン速度
  - 最高 4kHz の 8 ビット・モノクロ・パターン速度
- 400MHz の入力データ・クロック速度
- 64 ビット、2xLVDS データバス・インターフェイスによる入出力
- ランダム行および LOAD4 DMD アドレッシングをサポート
- 各種のユーザー定義プロセッサや FPGA に適合

2 アプリケーション

- 産業用
  - ダイレクト・イメージング・リソグラフィ
  - 3D 印刷 (SLA および SLS)
  - 3D マシン・ビジョン
  - ロボティクスおよび検査システム用の 3D スキャナ
  - 動的なグレイスケール・レーザー・マーキングおよびコーディング
  - 産業用印刷
  - 高速プロジェクションおよび高度な画像処理
  - 切除および修復システム
  - マイクロスコープ

3 概要

DLPC410 は、DLP650LNIR、DLP7000、DLP7000UV、DLP9500、DLP9500UV の 5 つの DMD に対応するデジタル・コントローラです。アプリケーションの電子回路と DMD とを接続するための、便利で高速なデータおよび制御インターフェイスです。DLPC410 は、DMD マイクロミラー・クロック・パルス (リセット) およびタイミング情報を、DLPA200 DMD マイクロミラー・ドライバに提供します。このデバイスは、DLPR410 の PROM に格納されたファームウェアを使って構成されます。

このファミリのチップセットは、シングル、デュアル、クワッド、およびグローバル・リセットのオプションを選択でき、最高 48 ギガビット/秒 (Gbps) のピクセル・データ速度に対応できます。さらに、ランダム行アドレッシングと LOAD4 機能も用意されています。このファミリのチップは多くの場合、高いスループットとピクセル単位で正確な制御を必要とする、ダイレクト・イメージング・リソグラフィ、3D 印刷、レーザー・マーキング・システムなどの UV および NIR システムの設計に使用されます。

製品情報(1)

型番	パッケージ	本体サイズ (公称)
DLPC410	FCBGA (676)	27.00mm×27.00mm

(1) 利用可能なすべてのパッケージについては、このデータシートの末尾にある注文情報を参照してください。

4 改訂履歴

資料番号末尾の英字は改訂を表しています。その改訂履歴は英語版に準じています。

Revision E (January 2019) から **Revision F** に変更 **Page**

- Modified functions for TP4-TP31 ... 15
- Corrected DLP650LNIR Bus A Pixel Mapping ... 38
- Corrected DLP650LNIR Bus A Pixel Mapping ... 39
- Corrected DLP650LNIR Bus B Pixel Mapping ... 40
- Corrected DLP650LNIR Bus B Pixel Mapping ... 41
- Removed ECP2M calibration feedback pins ... 62
- Removed ECP2M DLPA200 Init Status pin ... 62
- Removed ECP2M DMD Init Status pin ... 62
- Adjusted pinouts of DMD OK Status bits ... 62
- Adjusted pinouts of DMD OK Status bits ... 63
- Removed the ECP2_M TP20 referring to AA18 instead ... 63

Revision D (December 2018) から **Revision E** に変更 **Page**

- 変更 $\overline{\text{ARST}}$ description that was incorrectly described in DLPS024 Revision D. ... 48

Revision C (December 2015) から **Revision D** に変更 **Page**

- サポートされる DMD (複数) に新しい DLP650LNIR を追加 ... 1
- 入力データ・クロック速度を 400MHz のみに変更 ... 1
- 最新の市場に合わせて「アプリケーション」一覧を更新 ... 1
- 概略回路図を変更し、新しい DLP650LNIR を追加 ... 1
- Changed pin DDC_SPARE_0 to $\overline{\text{LOAD4}}$ ... 16
- Removed 200MHz - new revision tested at 400MHz only ... 21
- Re-organization of *Detailed Description* for flow, clarity, and readability ... 23

- Added DLP650LNIR functional block diagram 24
- Updated DLP7000 functional block diagram (no technical changes) 25
- Updated DLP9500 functional block diagram (no technical changes) 26
- Added new DLP650LNIR DMD Characteristics to 表 2 28
- Added DLP650LNIR DMD to Row Addressing and 表 11 41
- Re-worded the Block Operations section for clarity. 45
- Added new DLP650LNIR DMD Characteristics 48
- Added/edited LOAD4 sections, enabled by DLPR410A 49
- Removed reference to 200 MHz input data clock. 49
- Added the DLP650LNIR and its block load time to 表 16 51
- Added 表 17 54
- Combined Application Example Diagrams to encompass all DLPC410 supported DMDs 60
- Added DLP650LNIR to Detailed Design procedure section 61
- Added 図 25 - DLP650LNIR window transmittance 61
- Changed "Generate Data" to "Present Data to DLPC410" 63
- 変更 "DLPC410 DMD data signals" to "LVDS data bus differential pairs" 66
- TI 型番 2510440-001 への参照を削除 77
- Discovery チップセットのデータシートを削除、DLP650LNIR のデータシートを追加、他のデバイス名を訂正 78

Revision B (June 2013) から Revision C に変更 **Page**

- 「*ESD 定格*」表、「*機能説明*」セクション、「*デバイスの機能モード*」セクション、「*アプリケーションと実装*」セクション、「*電源に関する推奨事項*」セクション、「*レイアウト*」セクション、「*デバイスおよびドキュメントのサポート*」セクション、「*メカニカル、パッケージ、および注文情報*」セクション 追加 1
- ドキュメント全体を通して Discovery 4100 への参照を削除し、DLPR4101 を削除 1
- 「*特長*」と「*概要*」に DLP7000UV と DLP9500UV を 追加 1
- Added note - Xlilinx System Monitor analog supply & ground - "must be connected to ground" (AVDD_0 & AVSS_0) 7
- Changed "DAD A" descriptions to "DLPA200 number 1" and "DAD B" descriptions to "DLPA200 number 2" 7
- Reversed DDC_B*nn*_VR pairs pullups / pulldowns (for *nn* =12, 15, and 16)) 8
- Changed Pin # C22 name from DDC_B11_VRP (duplicate) to DDC_B15_VRP 8
- Added "Not used" to description for DMD_B_RESET and $\overline{\text{DMD\_B\_SCPEN}}$ 14
- Added TP14 and TP17 note - Xilinx Temperature Diode 14
- Added "in Reference Design" to ECP2 Mictor pin notes 14
- Changed ECP2 pin description from "Not Defined" to "Not Used" 14
- Added ECP2_M_TP[3:29] descriptions and active state 15
- Deleted duplicate pin numbers M13 and M14 16
- Changed Description from "DMD Power" to "DMD Power Good indicator" 16
- Changed duplicate pin name from RSVD_0 to RSVD_1 17
- Updated pin description for SCPDI and SCPDO 17
- Changed STEPVCC to connect to ground, active "Hi" to "-", and clock to "-" 17
- Changed Description from "JTAG Data Clock" to "JTAG Data" 17
- Changed pin names for VCCO_*n*_*n* pins to list each pin separately 18
- Added note about Xilinx System Monitor differential pins (VN_0 & VP_0) and reference voltage (VREFN_0 & VREFP_0) 18
- Changed Description from "DMD Reset Watchdog" to "DMD Mirror Clocking Pulse Watchdog" 19
- Deleted duplicate pin numbers in "UNUSED" pin list 19
- Updated the functional block diagrams 25
- Moved DLP7000 / DLP7000UV and DLP9500 / DLP9500UV Example Block Diagrams from Functional Block

Diagram section to Typical Application Section 26
- 削除 the "Step DMD SRAM Memory Voltage" and "Load 4" Enhanced Functionality (with DLPR4101 PROM only)" sections..... 48
- Updated the embedded example block diagrams..... 60
- 追加 DLP7000UV and DLP9500UV well suited for direct imaging lithography, 3D printing, and UV applications 61
- 追加 Debugging Guidelines section..... 61
- 変更 maximum differential trace length from 100 to 150 matching Table 13. 66
- 追加 DLP7000UV および DLP9500UV 関連のドキュメントを 78

Revision A (September 2012) から **Revision B** に変更 **Page**

- 「特長」の「最高 32kHz の 1 ビット・バイナリ・パターン速度」を「最高 32kHz の 1 ビット・バイナリ・パターン速度 (DLPR4101 とともに使用した場合は最高 48kHz)」に 変更..... 1
- 追加 Section "Load 4" Enhanced Functionality (with DLPR4101 PROM only) 49
- 追加 DLPR410 に DLPR4101 を..... 78

2012年8月発行のものから更新 **Page**

- デバイスを「製品プレビュー」から「量産」に変更..... 1

5 概要（続き）

DLP ベースの電子機器ソリューションでは、DLPC410 の入力ポートから、投影される画像まで、画像データはすべてデジタルです。画像はデジタル形式を維持し、アナログ信号に変換されることはありません。DLPC410 はデジタル入力画像を処理し、DMD の画像に必要とされる形式にデータを変換します。その後で DMD は、各ピクセル・ミラーに対してバイナリ・パルス幅変調 (PWM) を使用して光を制御します。

DLPC410 は、DLP650LNIR、DLP7000、DLP7000UV、DLP9500、DLP9500UV DMD を制御する DMD デジタル・コントローラです (図 4、図 5、図 6 を参照)。DLPC410 を使用すると、開発者は DMD に簡単にアクセスでき、マイクロミラーを高速に独立して制御できます。各 DMD ソリューションで必要なチップセット・コンポーネントについては、表 1 を参照してください。

表 1. DLPC410 のデバイス構成

DMD	DMD マイクロミラー・ドライバ	DMD デジタル・コントローラ
DLP9500 DLP 0.95 1080p 2xLVDS Type A DMD	各 2 つの DLPA200	DLPC410 (+ DLPR410 構成 PROM)
DLP9500UV DLP 0.95 UV 1080p 2xLVDS Type A DMD	各 2 つの DLPA200	
DLP7000 DLP 0.7 XGA 2xLVDS Type A DMD	各 1 つの DLPA200	
DLP7000UV DLP 0.7 UV XGA 2xLVDS Type A DMD	各 1 つの DLPA200	
DLP650LNIR 0.65 NIR WXGA S450 DMD	各 1 つの DLPA200	

DLPC410 の機能と動作の信頼性を確保するには、表 1 に記載されている他のコンポーネントと組み合わせて使用する必要があります。チップセットのコンポーネントの詳細については、*表 26* のデータシートを参照してください。

DDC_DIN_A12_DPN	C23	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_A	DDR	Data A bit 12 Input (Neg)
DDC_DIN_A12_DPP	B24	I	LVDS_25_I		-	DDC_DCLK_A	DDR	Data A bit 12 Input (Pos)
DDC_DIN_A13_DPN	C24	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_A	DDR	Data A bit 13 Input (Neg)
DDC_DIN_A13_DPP	D24	I	LVDS_25_I		-	DDC_DCLK_A	DDR	Data A bit 13 Input (Pos)
DDC_DIN_A14_DPN	A25	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_A	DDR	Data A bit 14 Input (Neg)
DDC_DIN_A14_DPP	B25	I	LVDS_25_I		-	DDC_DCLK_A	DDR	Data A bit 14 Input (Pos)
DDC_DIN_A15_DPN	C26	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_A	DDR	Data A bit 15 Input (Neg)
DDC_DIN_A15_DPP	B26	I	LVDS_25_I		-	DDC_DCLK_A	DDR	Data A bit 15 Input (Pos)
DDC_DIN_B0_DPN	A12	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 0 Input (Neg)
DDC_DIN_B0_DPP	A13	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 0 Input (Pos)
DDC_DIN_B1_DPN	B12	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 1 Input (Neg)
DDC_DIN_B1_DPP	C13	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 1 Input (Pos)
DDC_DIN_B2_DPN	D10	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 2 Input (Neg)
DDC_DIN_B2_DPP	D11	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 2 Input (Pos)
DDC_DIN_B3_DPN	C12	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 3 Input (Neg)
DDC_DIN_B3_DPP	C11	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 3 Input (Pos)
DDC_DIN_B4_DPN	A10	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 4 Input (Neg)
DDC_DIN_B4_DPP	B11	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 4 Input (Pos)
DDC_DIN_B5_DPN	D9	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 5 Input (Neg)
DDC_DIN_B5_DPP	C9	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 5 Input (Pos)
DDC_DIN_B6_DPN	B10	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 6 Input (Neg)
DDC_DIN_B6_DPP	B9	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 6 Input (Pos)
DDC_DIN_B7_DPN	A8	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 7 Input (Neg)
DDC_DIN_B7_DPP	A9	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 7 Input (Pos)
DDC_DIN_B8_DPN	D6	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 8 Input (Neg)
DDC_DIN_B8_DPP	D5	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 8 Input (Pos)
DDC_DIN_B9_DPN	C7	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 9 Input (Neg)
DDC_DIN_B9_DPP	C6	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 9 Input (Pos)
DDC_DIN_B10_DPN	B6	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 10 Input (Neg)
DDC_DIN_B10_DPP	B5	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 10 Input (Pos)
DDC_DIN_B11_DPN	D4	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 11 Input (Neg)
DDC_DIN_B11_DPP	D3	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 11 Input (Pos)
DDC_DIN_B12_DPN	B4	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 12 Input (Neg)
DDC_DIN_B12_DPP	C4	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 12 Input (Pos)
DDC_DIN_B13_DPN	C3	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 13 Input (Neg)
DDC_DIN_B13_DPP	C2	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 13 Input (Pos)
DDC_DIN_B14_DPN	A3	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 14 Input (Neg)
DDC_DIN_B14_DPP	A2	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 14 Input (Pos)
DDC_DIN_B15_DPN	B2	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_B	DDR	Data B bit 15 Input (Neg)
DDC_DIN_B15_DPP	B1	I	LVDS_25_I		-	DDC_DCLK_B	DDR	Data B bit 15 Input (Pos)
DDC_DIN_C0_DPN	E20	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 0 Input (Neg)
DDC_DIN_C0_DPP	E21	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 0 Input (Pos)
DDC_DIN_C1_DPN	F20	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 1 Input (Neg)
DDC_DIN_C1_DPP	G20	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 1 Input (Pos)
DDC_DIN_C2_DPN	H19	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 2 Input (Neg)
DDC_DIN_C2_DPP	J19	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 2 Input (Pos)
DDC_DIN_C3_DPN	E23	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 3 Input (Neg)
DDC_DIN_C3_DPP	E22	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 3 Input (Pos)
DDC_DIN_C4_DPN	F23	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 4 Input (Neg)
DDC_DIN_C4_DPP	F22	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 4 Input (Pos)
DDC_DIN_C5_DPN	G22	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 5 Input (Neg)
DDC_DIN_C5_DPP	G21	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 5 Input (Pos)
DDC_DIN_C6_DPN	J20	I	LVDS_25	100 Ω across pair (not terminated in the DLPC410)	-	DDC_DCLK_C	DDR	Data C bit 6 Input (Neg)
DDC_DIN_C6_DPP	J21	I	LVDS_25_I		-	DDC_DCLK_C	DDR	Data C bit 6 Input (Pos)

7 Specifications

注

The information contained in the following sections has been adapted from the Xilinx XC5VLX30 data sheet. For any information beyond what is listed here, consult the Xilinx XC5VLX30 data sheet. Where appropriate, DLPC410 specific values have been substituted in place of generic parameters.

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

			MIN	MAX	UNIT
ELECTRICAL					
	Supply voltage (2)	V_{CCINT}	–0.5	1.05	V
		V_{CCO}	–0.5	3.45	V
		V_{CCAUX}	2.35	2.625	V
V_I	Input voltage (3)	2.5 V	–0.75	V_{CCO} + 0.5	V
V_O	Output voltage(4)	2.5 V	–0.3	V_{CCO} + 0.3	V
ENVIRONMENTAL					
T_A	Operating free-air temperature(5)		0	85	°C
T_{stg}	Storage temperature		–65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) All voltage values are with respect to GND.
(3) Applies to external input and bidirectional buffers.
(4) Applies to external output and bidirectional buffers.
(5) Maximum Ambient Temperature may be further limited by the device's power dissipation (which is data and configuration dependent), air flow and resultant junction temperature.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins(1)	2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins(2)	400	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
V_{CCINT}	1-V Supply voltage, core logic		0.95	1.00	1.05	V
V_{CCO}	2.5-V Supply voltage, I/O		1.14	2.50	3.45	V
V_{CCAUX}	2.5-V Supply voltage, I/O		2.375	2.500	2.625	V
V_I	Input voltage	2.5-V CMOS	0		V_{CCO}	V
		2.5-V LVDS	0.3		2.2	
V_O	Output voltage	2.5-V CMOS	0		V_{CCO}	V
		2.5-V LVDS	0.825		1.675	
T_J	Operating junction temperature(1)		0		125	°C
P_D	Continuous total power dissipation			2.7	2.8	W

(1) Thermal analysis and design should be carefully considered to ensure that the junction temperature is maintained within the above specifications.

7.4 Electrical Characteristics

over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
V_{IH}	High-level Input voltage	2.5-V CMOS	1.7			V
V_{IL}	Low-level Input voltage	2.5-V CMOS			0.7	V
V_{OH}	High-level output voltage	2.5-V Interface	V_{CCO}-.4			V
		2.5-V LVDS		1.38		
V_{OL}	Low-level output voltage	2.5-V Interface			0.4	V
		2.5-V LVDS		1.03		
C_I	Input capacitance	2.5-V Interface		8		pF
		2.5-V LVDS		8		
I_{CCINT}	Supply voltage range, core supply			300		mA
I_{CCO}	Supply voltage range, I/O supply			850		mA

7.5 Timing Requirements

(see (1))

			MIN	NOM	MAX	UNIT
f_{cd}	Clock frequency, DCLKIN_n (2)		395	400	400	MHz
f_{cr}	Clock frequency, CLK_R			50		MHz
t_c	Cycle time, DCLKIN_n		2.5	2.5	2.53	ns
$t_{w(H)}$	Pulse duration, high	50% to 50% reference points (signal)	1.25	1.25	1.27	ns
$t_{w(L)}$	Pulse duration, low	50% to 50% reference points (signal)	1.25	1.25	1.27	ns
t_t	Transition time, $t_t = t_f / t_r$	20% to 80% reference points (signal)			.6	ns
t_{jp}	Period Jitter DCLKIN_n (3)			150		ps
t_{SK}	Skew, DIN_A(15-0) to DCLKIN_A		–150		150	ps
	Skew, DIN_B(15-0) to DCLKIN_B		–150		150	
	Skew, DIN_C(15-0) to DCLKIN_C		–150		150	
	Skew, DIN_D(15-0) to DCLKIN_D		–150		150	
	Skew, DVALID_n to DCLKIN_n↑		–150		150	
	Skew, BLK_MD BLK_AD to DCLKIN_n↑ (4)		–150		150	
	Skew, ROWMD or ROWAD to DCLKIN_n↑ (4)		–150		150	
	Skew, STEPVCC to DCLKIN↑ (4)		–150		150	

(1) It is recommended that the COMP_DATA, NS_FLIP and $\overline{\text{RST2BLK}}$ flags be set to one value and not adjusted during normal system operation.
(2) Preferred DCLKIN_n duty cycle = 50%
(3) This is the deviation in period from ideal period due solely to high frequency jitter.
(4) First edge of DIN*, ROW*, BLK* and STEPVCC should be synchronous to DVALID rising edge

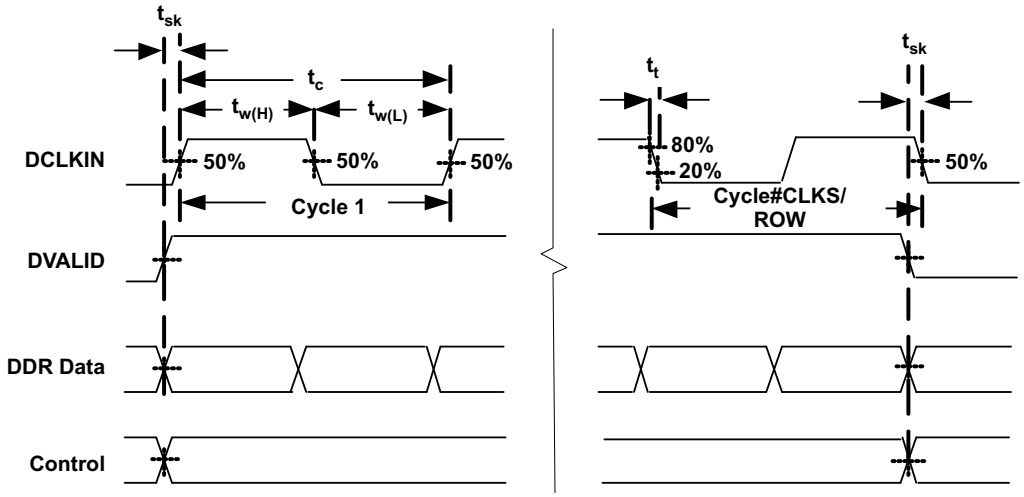

図 2. Input Interface Timing

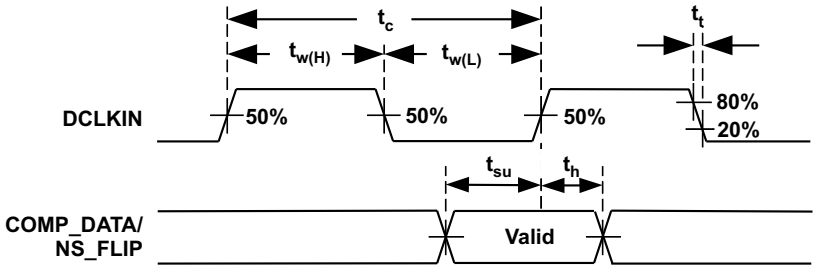

図 3. Control Timing

注

Dynamic changes to NS_FLIP and COMP_DATA during normal operation is not recommended.

8 Detailed Description

8.1 Overview

The DLPC410 DMD Digital Controller enables customers to stream binary pattern data to the DLP650LNIR, DLP7000(UV), or DLP9500(UV) DMD for very high speed binary pattern imaging applications. The DLPC410 receives customer input binary pattern data on a row by row basis and passes the pattern data to the connected DMD. Concurrent with the receipt of data, the DLPC410 captures the customer requested ROW mode and ROW address which determines if row loading starts at the top (or bottom) of the DMD and increments (or decrements) to the next row for the next Row Cycle, or if a specific row address is specified for loading the next pattern data. Each DMD micromirror is individually configurable through this data loading process which enables precise, predictable control of each and every micromirror in the DMD Micromirror array.

The DLPC410 also receives customer input control information instructing the DLPC410 to command the DLPA200 device(s) to generate the Mirror Clocking Pulses (MCPs) to the DMD – these MCPs are necessary for the DMD micromirrors to transition from their current state to their new state, the new state being determined by the new data just loaded into the DMD. A feedback signal from the DLPC410 frames the MCP such that the customer knows the MCP request has been received by the DLPC410 and when the MCP is completed.

The DLPC410 supports multiple MCP modes of operation. The DMD Micromirror arrays are arranged into horizontal Reset Blocks – there are typically 16 horizontal Reset Blocks per DMD where each Reset Block receives a single MCP to initiate the Micromirror state change. DMD blocks can be Reset one at a time or all at once. In certain modes, adjacent blocks of 2 or of 4 Reset Blocks can be Reset at the same time. This flexibility provides great advantages to optimizing the time certain DMD blocks are in certain states, which in turn can provide speed advantages or extend DMD illumination windows (the duration for which a solid state illuminator should be illuminating).

Behind the scenes, the DLPC410 also communicates directly with the control logic of the DMD to read part type and status information and to configure the DMD for proper operation. The DLPC410 is always paired with the DLPR410 PROM as the DLPR410 provides the configuration bit stream which configures the DLPC410 to be a DMD Digital Controller. The DLPC410 also drives one DMD at a time, and that DMD could require either one or two DLPA200 devices depending on the DMD type. For further information, refer to 表 11 or the individual DMD datasheets (links can be found in 表 26).

8.3 Feature Description

8.3.1 DLPC410 Binary Pattern Data Path

The DLPC410 receives binary pattern input data from the customer application formatted specifically for display on one of the DLPC410 compatible DMDs. This data is captured on a row by row basis using specific data formats with multiple signals which frame the data and provided control information from the customer defining where in the DMD the data is destined. The DLPC410 then sends the pattern data to the DMD and uses the received control information to decode and provide the correct control information to the DMD and other DLP components.

8.3.1.1 DIN_A, DIN_B, DIN_C, DIN_D Input Data Buses

The DLPC410 has four differential 16-bit input data buses (A/B/C/D). Which of these input data bus signals are used at any given time is specific to the DMD connected to the DLPC410 in the system. The data buses are 2xLVDS double-data-rate (DDR) buses which can transfer data at 800 MHz data rates per input. Data should be synchronous and edge aligned with the input clocks for each specific data bus (A, B, C, or D). Depending on the design, skewing the clock to data relationship may cause a problem. For timing constraints for the input data clock to either the input data and/or DVALID, refer to *Timing Requirements*

Feature Description (continued)

8.3.1.2 DCLKIN Input Clocks

DCLKIN is the differential input clock for each DLPC410 input data bus. There are four input clocks, one for each bus (A/B/C/D). DCLKIN is a 400 MHz clock to the DMD which should be synchronous and edge aligned with all data and control signals for that specific bus (A, B, C, or D). Depending on the design, skewing the clock to data relationship may cause a problem. For timing constraints for the input data clock to either the input data and/or DVALID, refer to *Timing Requirements*. Care should be take to keep clock jitter of these signals to a minimum.

8.3.1.3 DVALID Input Signals

The DVALID signal is a differential input signal, one for each input data bus (A/B/C/D), which indicates that data being presented to the DLPC410 is valid. DVALID assertion latches the following types of data into the DLPC410 for decoding or passing information to the DMD:

- Binary pattern data on input data buses A/B/C/D
- Row Mode
- Row Address
- Block Mode
- Block Address
- $\overline{\text{RST2BLK}}$ signal

DVALID and all other inputs listed above should be synchronous to DCLKIN. DVALID can be asserted in one of the three following ways:

- DVALID can frame (remain active) individual DMD row loads with breaks between rows.
- DVALID can frame continuous DMD block loads of multiple rows with breaks between blocks
- DVALID can frame (remain active) the entire DMD device load (all rows) without any breaks.

If the DVALID frames individual blocks or the entire DMD, ensure that block and row controls are adjusted at the proper locations in the data stream. See section *DLPC410 Initialization and Training* for further information.

注

After an active DVALID signal transitions inactive (low), DVALID should only transition to active again on even number of clocks later, i.e. 2, 4, 6, etc.

8.3.1.4 DOUT_A, DOUT_B, DOUT_C, DOUT_D Output Data Buses

The DLPC410, having captured the incoming pattern data on its input data buses, provides this data on an equivalent number of output data buses. The DLPC410 has four differential 16-bit output data buses (A/B/C/D), which are aligned to its input data buses. Which of these input data bus signals are used at any given time is specific to the DMD connected to the DLPC410 in the system. The data buses are 2xLVDS double-data-rate (DDR) buses which can transfer data at 800 MHz data rates per output. Data should be synchronous and edge aligned with the output clocks for each specific data bus (A, B, C, or D). Depending on the design, skewing the clock to data relationship may cause a problem. For timing constraints for the output data clock to the output data, refer to *Timing Requirements*.

8.3.1.5 DCLKOUT Output Clocks

DCLKOUT is the differential output clock for each DLPC410 output data bus. There are four output data clocks, one for each bus (A/B/C/D) to the DMD. DCLKOUT is a 400 MHz clock to the DMD which should be synchronous and edge aligned with all data and control signals for that specific bus (A, B, C, or D). Depending on the design, skewing the clock to data relationship may cause a problem. For timing constraints for the output data clocks to either the output data and/or SCTRL signals, refer to *Timing Requirements*.

Feature Description (continued)

8.3.1.6 SCTRL Output Signals

The SCTRL signal is a differential output signal to the DMD which provides DMD control information. There are four SCTRL differential pair signals, one for each bus (A/B/C/D). The control information is generated internally to the DLPC410 and is specific to the connected DMD. Data should be synchronous and edge aligned with the output clocks for each specific data bus (A, B, C, or D). Depending on the design, skewing the clock to SCTRL relationship may cause a problem. For timing constraints for the output data clock to the SCTRL signals, refer to *Timing Requirements*.

8.3.1.7 Supported DMD Bus Sizes

The DLPC410 supports the 2xLVDS Data Bus DMD types as shown in 表 11.

表 2. DMD Row Sizes, Bus Widths, and Row Lengths

TYPE	PIXELS PER ROW	INPUT / OUTPUT BUSS	NO. OF DATA LINES	CLOCKS PER ROW
DLP650LNIR DMD	1280	A[15,13,11,9,7,5,3,1] B[15,13,11,9,7,5,3,1]	16	40
DLP7000 and DLP7000UV DMDs	1024	A[15:0] B[15:0]	32	16
DLP9500 and DLP9500UV DMDs	1920 (2048)	A[15:0] B[15:0] C[15:0] D[15:0]	64	16

8.3.1.8 Row Cycle definition

A Row Cycle relates to specific number of input data clocks it takes for the customer to send one row of input binary pattern data to one row of the DMD. DVALID starts the Row Cycle by transitioning to an active (logic '1') state. The row cycle ends after the appropriate number of clock cycles per row are applied. Any input data on the DIN input data buses should be appropriately provided during the Row Cycle. 表 2 shows the number of input data clocks needing to populate one row of the DMD using the number of data lines identified in the table. Other Row and Block related signals are captured at the start of a row cycle and will be discussed later.

There is also a unique row cycle called a No-Op Row Cycle which does not provide any valid input data nor any valid block command. It is typically used to do nothing except provide the DLPC410 and DMD time to perform internal actions already in process. The No-Op Row Cycle is discussed in No-Op Row Cycle Description.

8.3.1.9 DLP9500 and DLP9500UV Input Data Formatting

図 7 details one Row Cycle of input data formatting for the DLP9500 and DLP9500UV DMDs. For brevity, only two data bits of all four 16 bit data bus (A/B/C/D) signals are shown, but there is enough information presented to allow extrapolation to all data bus signals not shown.

表 3, 表 4, 表 5, and 表 6 show how each pixel of the DLP9500 and DLP9500UV DMDs maps to individual data bus inputs and input clock edges within each row cycle. Because these DMDs are actually 2048 pixels per row with only 1920 micromirrors per row, no visible data is loaded for the first clock cycle for A and B data and for the last clock cycle for C and D data for each row load operation. This only applies to the DLP9500 and DLP9500UV. For readability purposes, input buses DIN_A, DIN_B, DIN_C, and DIN_D are abbreviated as D_A, D_B, D_C, and D_D. DCLKIN has been shortened to DCLK.

8.3.1.10 DLP7000 and DLP7000UV Input Data Bus

図 8 details one row cycle of input data formatting for the DLP7000 and DLP7000UV DMDs. For brevity, only two data bits of both 16 bit data bus (A/B) signals are shown, but there is enough information presented to allow extrapolation to data bus signals not shown.

表 7 and 表 8 show how each pixel of the DLP7000 and DLP7000UV DMDs maps to individual data bus inputs and input clock edges within each row load operation.

注

In the following charts, for readability purposes input buses DIN_A, DIN_B are abbreviated as D_A, D_B. DCLKIN has been shortened to DCLK.

8.3.1.11 DLP650LNIR Input Data Bus

図 9 details one row cycle of input data formatting for the DLP650LNIR DMD. For brevity, only two data bits of both 8 bit data bus (A/B) signals are shown, but there is enough information presented to allow extrapolation to data bus signals not shown.

表 9 and 表 10 show how each pixel of the DLP650LNIR DMD maps to individual data bus inputs and input clock edges within each row load operation.

注

In the following charts, for readability purposes input buses DIN_A, DIN_B are abbreviated as D_A, D_B. DCLKIN has been shortened to DCLK.

Since showing the entire 40 clock row cycle would make this chart unreadable, the chart has been broken in the middle. However, there is enough information available to allow extrapolation of the missing data.

8.3.2 Data Bus Operations

8.3.2.1 Row Addressing

The DIN (input data), DCLKIN (input data clock), and DVALID (data valid) signals enable the DLPC410 to capture one row of customer input data and send that data to the DMD. For the DMD to know specifically to which row the data will be applied, the ROW_MD(1:0) (row mode), the ROW_AD(10:0) (row address), and the NS_FLIP (North/South Flip) signal inputs must be presented to the DLPC410 inputs during each row cycle. 表 11 shows the number of rows for each DMD supported by the DLPC410.

表 11. DMD Row and Columns

TYPE	COLUMNS	ROWS	CLOCKS PER ROW	NO. OF DATA LINES
DLP650LNIR DMD	1280	800	40	16
DLP7000 and DLP7000UV DMDs	1024	768	16	32
DLP9500 and DLP9500UV DMDs	1920 (2048)(1)	1080	16	64

(1) The DLP9500 and DLP9500UV DMDs have 2048 memory cells per row . There are 64 bits at the beginning of each row and 64 bits at the end of each row which do not have corresponding DMD micromirrors. These 128 memory cells must be loaded with data but the data content can be arbitrary and will not affect the 1920 physical micromirrors within that row.

DMD data is loaded into the DMD SRAM pixels one row of data at a time. The DLP9500 and DLP9500UV require pattern data input to all four input data buses (A,B,C,D) while the DLP650LNIR, DLP7000 and DLP7000UV require pattern data to be input to two input data buses (A,B). The DLP650LNIR uses only the odd data bus pins of input buses A and B. The DMD input data buses are provided by the following DLPC410 outputs:

- DDC_DCLKOUT - high speed 2xLVDS data clock out to DMD
- SCTRL - high speed control bus to DMD
- DDC_DOUT[X:Y] - 2xLVDS data bus where X and Y depend on the DMD.

These signals are all output from the DLPC410 and are listed in *Pin Configuration and Functions*. Data and control from the DLPC410 are clocked into the DMD on both the rising and falling edges of the DDR data clocks: DDC_DCLKOUT_[A, B] for the 2 input bus DMDs and DDC_DCLKOUT_[A, B, C, D] for the 4 input bus DMDs. Data loading does not cause mirror state changes - mirrors transition to the next state only when a Mirror Clocking Pulse (Reset) operation is performed.

The row load length in clocks can be determined by the following equation: number row clocks = number of pixels per row / (total data buses bit width × 2 edges per clock). The "2 edges per clock" in the denominator is a direct results of the Dual Data Rate (DDR) nature of the DMD input data bus. This equation yields the results shown in 表 11

The DMD incorporates single row write operations using a row address counter that has different modes of operation. These modes are dependent on the state of the ROW_MD, ROW_AD, and NS_FLIP input signals. As shown in 表 12, ROW_MD(1:0) determines the row mode for a given Row Cycle, and, when ROW_MD = "10", then ROW_AD(10:0) selects the customer supplied single row address. ROW_MD and ROW_AD must be asserted and deasserted synchronously with DVALID and must be valid synchronous to the beginning of the data as shown in 図 10. If only one specific mode will be utilized in a customer system application, it is certainly acceptable to leave these values at their same desired input levels for as long as desired.

Row address orientation depends on the North/South Flip Flag (NS_FLIP) input to the DLPC410. This input controls if the DMD starting row address starts at the top of the DMD (Row 0) and increments downward, or from the bottom of the DMD (last row) and decrements upward.

The row address counter does not automatically wrap-around when using the increment row address pointer instructions. For example, after the final row is addressed, the row address pointer must be set to row 0.

表 12. Row Modes and Row Addresses

ROW_MD(1:0)	ROW_AD(10:0)(1)	NS_FLIP(2)	ACTION
"00"	"xxxxxxxxxxx"	"x"	**Row No-Op** (No data write)
"01"	"xxxxxxxxxxx"	0	**Increment** internal row address by '1' - write concurrent data into that row
"01"	"xxxxxxxxxxx"	1	**Decrement** internal row address by '1' - write concurrent data into that row
"10"	ROW_AD(10:0)	"x"	**Set Random** row address as specified on ROW_AD(10:0) inputs - write concurrent data into that row.
"11"	"xxxxxxxxxxx"	0	**Set First** row address (DMD Row 0) and write concurrent data into that row
"11"	"xxxxxxxxxxx"	1	**Set Last** row address (DMD last row) - write concurrent data into that row (Last row = 767 for DP7000, 799 for DLP650LNIR, 1079 for DLP9500)

(1) "xxxxxxxxxxx" and "x" are don't care situations.
(2) It is recommended NS_FLIP remain constant throughout the loading of the DMD and not change on a row cycle basis.

8.3.2.2 Single Row Write Operation

Once initialization is complete (INIT_ACTIVE = 0) the user is free to send data and control information to the DLPC410. When the user asserts the DVALID signal for the LVDS input buses, the DLPC410 samples the customer supplied binary input pattern data (DIN) as well as the Row Mode, Row Address, Block Mode, Block Address, and other control information. The DLPC410 then sends pattern data synchronously to the DMD along with row address and control information. The row cycle period is defined by the Clocks per Row in 表 11 and is synchronous with DVALID as shown in 図 10. If DVALID is removed midway in a Row Cycle, the DLPC410 continues loading data regardless of data validity until the internal row cycle counter reaches the terminal count of Clocks/Row for that DMD.

図 10 is an example of a single Row Cycle for the DLP7000 DMD. A total of 32 bits of input data are presented to the DLPC410 on each clock edge (16 bits on Bus A + 16 bits on Bus B) . An entire line must be written for data to be latched into DMD memory and it requires 16 DDR clock cycles to write a single row of 1024 bits.

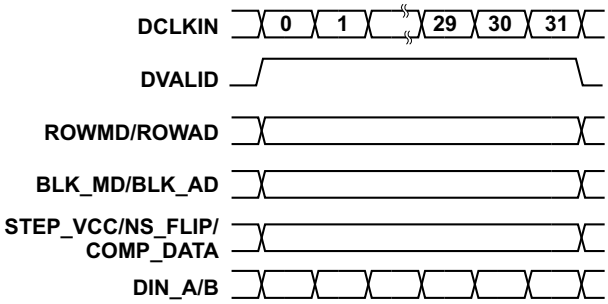

図 10. Single Row Write Operation (DLP7000 DMD)

8.3.2.3 No-Op Row Cycle Description

A Row No-Op is a row cycle in which setting ROW_MD = "00" commands the DLPC410 that within the current row cycle, no **Row Write** operation is to be performed. A Block No-Op is a row cycle in which BLK_MD = "00" commands the DLPC410 that within the current row cycle no **Block** Operation is to be performed. Row No-Ops can be inserted when only block operations are desired, Block No-ops can be inserted when only Row Write operations are desired, or both Row No-Ops and Block No-Ops can be performed at the same time when neither type of operation is desired (as shown in 図 11). No-Ops are frequently inserted in the stream of data and commands when delays are desired to complete on-going operations to avoid violating delay requirements.

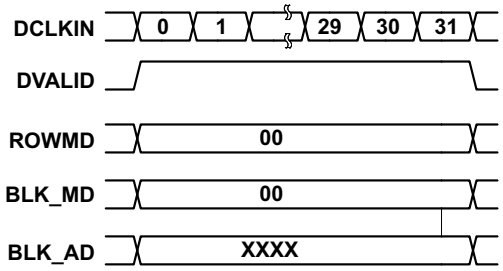

図 11. No-Op Row Cycle (DLP7000 example)

8.3.3 DMD Block Operations

Previous sections have described in detail how to send binary pattern data through the DLPC410 Controller to the connected DMD. Although the data loading process involves loading the specified data into the SRAM cells in the DMD array, this loading of data does not change the physical state of the DMD Micromirrors. The state of the mirrors can only be changed (or left the same if the data under the mirrors is unchanged) when a Mirror Clocking Pulse (Reset) is applied to the DMD MBRST pins from the DLPA200.

A sequence of Mirror Clocking Pulses (Resets) begins by asserting a row cycle with BLK_MD and BLK_AD as described in 表 14. Shortly after the row cycle, RST_ACTIVE output to the customer transitions to logic '1' for approximately 4.5 µs indicating a Mirror Clocking Pulse operation is in progress. During this time, no additional Mirror Clocking Pulses may be initiated until RST_ACTIVE returns to logic '0'.

RST_ACTIVE does not return to logic '0' unless:

- data load row cycles are issued to other DMD blocks as in 図 15 or,
- No-Op row cycles are provided to the DLPC410 to enable MCP or Block Clear operations to continue

This is accomplished by asserting DVALID while holding ROWMD = “00” and BLKMD = “00” for the pre-requisite number of CLKS per ROW (表 11) clock cycles, as in 図 11. If no other blocks need to be loaded then continuous No-Op row cycles are applied as in 図 11 .

8.3.3.1 Mirror Clocking Pulse (MCP)

A Mirror Clocking Pulse is an analog voltage waveform provided to the DMD from the DLPA200 DMD Micromirror Driver. This waveform times the electrostatic forces which cause each micromirror to transition to its next state. This next state is determined by the data in the SRAM cell beneath each pixel. If the data has changed, the micromirror will rotate its position 24 degrees to the opposite state. If the data is unchanged, the mirror will remain in the same state. The DLPC410 instructions the DLPA200 to apply Mirror Clocking Pulses to the DLPA200 based on instructions from the user.

注

A Mirror Clocking Pulse (MCP) is often referred to as a "Reset" operation.

8.3.3.2 Reset Active (RST_ACTIVE)

RST_ACTIVE is an output from the DLPC410 to indicate to the user that a user requested Reset (MCP) has been accepted by the DLPC410. Shortly after the user requests a Reset (MCP) by asserting the appropriate Block Control signals defined in DMD Block Control Signals, RST_ACTIVE output to the user will transition to logic '1' for approximately 4.5 µs indicating a Mirror Clocking Pulse operation is in progress. While RST_ACTIVE is logic '1', no additional Mirror Clocking Pulse requests may be initiated by the user until RST_ACTIVE returns to logic '0'. RST_ACTIVE is synchronized to a version of DCLKIN. As such, circuits in the application FPGA should consider this signal asynchronous and use standard synchronization techniques to assure reliable registering of this signal.

注

After a Mirror Clocking Pulse or Clear command is given, RST_ACTIVE may not be asserted until up to 60ns after the command. During this time, no other command should be given.

8.3.3.3 DMD Block Control Signals

The DMD micromirrors and their corresponding SRAM pixels are organized into horizontal rows where data is loaded one row at a time. DMD Blocks are defined as a group of sequential rows of mirrors. Each mirror block is measured in groups of [ROWS per BLK] as described in 表 11. DMD blocks are typically numbered from 0 to 15 with 0 being the block at the top of the DMD (row 0) and 15 being the block at the bottom of the DMD.

表 13. DMD Block Characteristics

DMD TYPE	COLUMNS	ROWS	BLOCKS	ROWS PER BLOCK
DLP650LNIR DMD	1280	800	16	50
DLP7000 and DLP7000UV DMDs	1024	768	16	48
DLP9500 and DLP9500UV DMDs	1920	1080	15	72

8.3.3.3.1 Block Mode - BLK_MD1:0)

The Block Mode signals define the type of block operation the user would like to take place. The allowed operations which can be requested are defined in 表 14. These signals work along side the RST2BLK and the Block Address signals to provide the gamut of Block Operations that enable DMD mirrors to update to their next used desired state. These signals should be setup synchronously with the start of a row cycle.

8.3.3.3.2 Block Address - BLK_AD(3:0)

The Block Address signals help to specify which block or group of blocks will be acted upon in a user issued Block Operation. They work with the RST2BLK and Block Mode signals to indicate which block or group of blocks will see a Reset (MCP). These signals should be setup synchronously with the start of a row cycle.

8.3.3.3.3 Reset 2 Blocks - $\overline{\text{RST2BLK}}$

The Reset 2 Blocks ($\overline{\text{RST2BLK}}$) signal helps to signify a multiple block operation is requested by the user, where, depending on the state of $\overline{\text{RST2BLK}}$, either two blocks or 4 blocks will be Reset together. The specific blocks to be Reset will then be determined by the Block Mode and Block Address. This signal should be setup synchronously with the start of a row cycle.

注

$\overline{\text{RST2BLK}}$ needs to be kept low during initialization for proper setup of the system.

8.3.3.4 DMD Block Operations

Once a portion or all of the DMD is loaded with new data, the user typically requests a Block Operation to be performed. This operation causes the DLPC410 to initiate one of the many block related activities to a block or group of blocks to the DMD. Available Block operations are:

- **Block No-Op** - user requests via BLK_MD(1:0) = "00" that no block operations are to take place in this row cycle. This is typically the case for row cycles used for data loading purposes only without any block operations.
- **Block Clear Request** - user requests a single block to be cleared causing all SRAM cells within that block to be reset to logic '0'.
- **Single Block Reset Request** - user requests a single DMD block be provided a Reset (MCP) signal to cause the micromirrors within that block to update to their new values.
- **Dual Block Reset Request** - user requests two sequential DMD blocks be provided Reset (MCP) signals to cause the micromirrors within those blocks to update to their new values.
- **Quad Block Reset Request** - user requests four sequential DMD blocks be provided Reset (MCP) signals to cause the micromirrors within those blocks to update to their new values.
- **Global Reset Request** - user requests all DMD blocks be provided Reset (MCP) signals to cause all DMD micromirrors to update to their new values.
- **DMD Park (Float) Request** - user requests all DMD micromirrors be provided special Parking Reset (MCP) signals causing the micromirrors within those blocks to relax to their unbiased state. This request is intended to place the micromirrors in the Parked state prior to power removal (shutdown).

Mirror blocks are addressed using the Block Address (BLK_AD[3:0]) signals for application of either a Mirror Clocking Pulse (Reset) or a Memory Clear operation by asserting the block control signals of 表 14 at the start of each row data load. $\overline{\text{RST2BLK}}$, Block Mode (BLK_MD[1:0]), and BLK_AD[3:0] define the requested operation as shown in 表 14 and designate which mirror block or mirror blocks are issued a Mirror Clocking Pulse or are Cleared. The number of DMD blocks and BLOCKS/ROW is unique to each DMD - refer to the individual DMD data sheets for DMD block definition.

表 14. Block Control Signals and Operations

$\overline{\text{RST2BLK}}$	BLK_MD(1:0)	BLK_AD(3:0)	OPERATION	OPERATION TYPE
x	00	xxxx	None	Block No-OP
x	01	0000	Clear block 00	Block Clear Request(1)(2)
x	01	0001	Clear block 01	
x	01	0010	Clear block 02	
x	01	0011	Clear block 03	
x	01	0100	Clear block 04

0	11	0010	Reset blocks 04-05	
0	11	0011	Reset blocks 06-07	
0	11	0100	Reset blocks 08-09	
0	11	0101	Reset blocks 10-11	
0	11	0110	Reset blocks 12-13	
0	11	0111	Reset blocks 14-15	
1	11	000x	Reset blocks 00-03	Quad Block Reset Request
1	11	001x	Reset blocks 04-07	
1	11	010x	Reset blocks 08-11	
1	11	011x	Reset blocks 12-15	
x	11	10xx	Reset blocks 00-15	Global Reset Request
x	11	11xx	Float blocks 00-15	DMD Park Request

(1) Each Block Clear operation for DLP650LNIR and DLP7000(UV) DMDs will clear all SRAM cells of one DMD block (reset to '0') within one row cycle duration.
(2) Each Block Clear operation for DLP9500(UV) DMDs must be followed by two No-Op row cycles. To clear one DMD Block, one Block Clear Request row cycle followed by two consecutive No Op row cycles are required. In total, 15 Block Clear Request row cycles and 30 No-Ops are required to clear the entire 15 block DMD array.

Block operations cause the DMD micromirrors to transition to their next state. Some notes and restrictions regarding block operations are:

- A Block No-Op row cycle causes no new block operations to occur. Block No-Op row cycles can be used to provide extended time for a previous operation.
- The Block Clear operation resets all SRAM pixels in the designated block to logic zero during the current row cycle.
- It is not necessary to Clear a block if it will be reloaded with new data (just like a normal memory cell).
- It is not possible to Clear a block while writing to a different block.
- It is possible to issue a Mirror Clocking Pulse to a block while data loading a different block.
- The DLP9500 and DLP9500UV DMDs have 15 blocks (block 0 – block 14). Block operations on block 15 have no function for this DMD.
- $\overline{\text{RST2BLK}}$ should be set to one value and not adjusted during normal system operation. A change in $\overline{\text{RST2BLK}}$ is not immediately effective and will require more than one row load cycle to complete.

8.3.3.4.1 Global Reset (MCP) Consideration

A Global Reset (BLK_MD = 11 and BLK_AD = 10XX) is an operation which Resets (MCP) all DMD blocks at the same time. The Global Reset duration is the same as the Single, Dual, and Quad Block Reset (MCP). In addition to requiring a No-Op row cycle to initiate the Global Reset, row cycles (either No-Op row cycles or data loading row cycles) are required to continually be provided to complete the Global Reset operation. If continual provision of row cycles is not provided, the customer interface monitoring RST_ACTIVE may never see RST_ACTIVE transition back low to indicate the Reset is complete. Customers should always provide valid row cycles, either No-Ops or data loading row cycles. To know when the reset operation is complete, customers can either monitor RST_ACTIVE high-to-low transition, or use a counter to know when at least a 4.5 µs period has expired from the start of the Global Reset. From that point on, the customer also needs to count the mirror settling time of the DMD to expire prior to loading the next data into the DMD.

注

Reset (MCP) operations to a specific block or consecutive blocks of the DMD are also referred to "Block Resets" or just "Reset" operations. This is because they are physically "resetting" the micromirrors of the block to their next physical positions based on the underlying data.

注

(DLP9500 and DLP9500UV DMDs Only) To clear one Mirror Clocking Pulse (Reset) Group in the DMD Block, one Clear command followed by two consecutive No Operation commands (No-Ops) are required. Therefore, 15 total Block Clear commands and 30 total No-Ops commands are required to clear the entire DMD array.

8.3.4 Other Data Control Inputs

It is recommended that the Complement and Flip flags be set to one value and not adjusted during normal system operation. These controls are asserted through a different mechanism than the input data bus and row controls, hence their effect is asynchronous and cannot be expected to take effect immediately upon assertion.

8.3.4.1 Complement Data

By setting the COMP_DATA flag high, the user is able to command the DMD to internally complement its data inputs prior to loading the data into the mirror array. At least 0.6 ms is needed for the signal to be loaded. This signal should not be used to invert data on a row basis. When used with the “Clear” command, the mirrors are still set to zero regardless of the COMP_DATA bit. The COMP_DATA signal should be kept low during initialization to ensure proper setup of the system.

8.3.4.2 North/South Flip

NS_FLIP allows the user to specify the loading direction of rows in the DMD when used with ROWMD = “01”. This control has no effect if ROWMD = “10”.

Row Addressing and 表 12 describe the effect of N/S flip. If NS_FLIP is set, this does not reverse the direction of Mirror Clocking Pulse groups (blocks). For example, the normal case is to Mirror Clocking Pulse blocks 0 – 15 in order. When NS_FLIP is set, the order of block Mirror Clocking Pulses must be reversed to 15 – 0.

The NS_FLIP signal should be kept low during initialization to ensure proper setup of the system.

8.3.5 Miscellaneous Control Inputs

8.3.5.1 $\overline{\text{ARST}}$

$\overline{\text{ARST}}$ is an active low, asynchronous reset. This reset can be sourced from a voltage supervisor or from the customer interface. Be aware that the chipset will not operate correctly if all DLPC410 power supplies are not in range at the time this reset is released.

8.3.5.2 CLKIN_R

The reference clock, CLKIN_R, supplied from an oscillator must be 50 MHz. This is required for precise timing used to perform the DMD Mirror Clocking Pulse (Reset). This clock should be valid prior to releasing $\overline{\text{ARST}}$.

8.3.5.3 DMD_A_RESET

DMD_A_RESET is an active low reset to the DMD. This signal is deasserted as appropriate at the end of system initialization.

8.3.5.4 Watchdog Timer Enable ($\overline{\text{WDT\_ENABLE}}$)

The DLPC410 contains a watchdog timer that initiates a global DMD Mirror Clocking Pulse in the event that the DMD has not received any Mirror Clocking Pulse by the user within the last 10 seconds. This auto-generated Mirror Clocking Pulse function is to provide Mirror Clockling Pulses to the DMD mirrors to prevent long term landed mirrors in the event the input data and source control has been inadvertently disrupted. This capability can be user disabled by setting $\overline{\text{WDT\_ENABLE}}$ to logic '1'. Note that the global DMD Mirror Clocking Pulse generated by the watch dog timer is asynchronous to any/all activity on the DMD input data bus - therefore there is no guarantee as to the validity of the data displayed on the DMD once this pulse occurs, at least until new data is subsequently loaded and displayed.

8.3.6 Miscellaneous Status Outputs

8.3.6.1 INIT_ACTIVE

The INIT_ACTIVE signal ins an output which indicates that the DMD, Digital Micromirror Driver, and the Digital Controller are in an initialization state after power is applied. During this initialization period, the DLPC410 is calibrating the data interface, initializing the DMD, and DLPA200(s). When this signal goes low, the system has completed initialization. See the section on System initialization

8.3.6.2 DMD_Type(3:0)

The DLPC410 only supports the DMDs indicated in 表 15.At power-up, the DLPC410 checks the DMD signature. If the DLPC410 finds the DMD is not supported, it will not allow the user to display data on the DMD and indicated that the DMD is unsupported.

DMD_TYPE(3:0) is an output from the DLPC410 to the user FPGA which will indicate to the user which DMD is connected to the DLPC410, or in another case, the DMD is not supported or a DMD is not properly connected.

表 15. DMD Characteristics

DMD_TYPE(3:0)	DMD Reported
0000	DLP9500 and DLP9500UV DMDs
0001	DLP7000 and DLP7000UV DMDs
0111	DLP650LNIR DMD
1111	Unsupported DMD / No DMD

8.3.6.3 DDC_VERSION(3:0)

These four pins identify the version of the DLPC410 determined by the contents of DLPR410. If a problem is encountered which encourages you to contact a Texas Instruments representative, please provide the version number along with the detailed information of the problem. See the DLPR410 datasheet (DLPS027) for the version number reported on these pins.

8.3.6.4 LED0

The LED0 signal is typically connected to an LED to show that the DLPC410 is operating normally. The signal is 1 Hz with 50% duty cycle, otherwise known as the heartbeat.

8.3.6.5 LED1

The LED1 signal is typically connected to an LED indicator to show the status of system initialization and the status of the clock circuits. The LED1 signal is asserted only when system initialization is complete and clock circuits are initialized. Logically, these signals are ANDed together to show an indication of the health of the system. If the Phase Locked Loop (PLL) connected to the data clock and the DMD clock are functioning correctly after system initialization, the LED will be illuminated.

8.3.6.6 DLPA200 Control Signals

Coordinating the operation of the DLPA200 with the DMD is one of the primary functions of the DLPC410. During system initialization, the DLPC410 releases the reset pin (DAD_INIT) and communicates with the DLPA200 via a serial bus to configure the device. Once this is complete, the high voltage output pins are enabled to prepare for command execution. As the DLPC410 is commanded to load data and perform Mirror Clocking Pulses, the DAD_ADDR address, DAD_MODE mode, DAD_SEL select and DAD_STROBE strobe signals are asserted as appropriate to cause the Mirror Clocking Pulses. The operation of these signals are managed by the DLPC410 and, besides board layout and good design practices, should be of little concern to the end user.

8.3.6.7 ECM2M_TP_ (31:0)

These are reserved signals for test signal output. Do not drive these signals.

8.4 Device Functional Modes

The DLPC410 has one basic function which is to receive customer data at the inputs of the DLPC410 and deliver that data and any appropriate DMD control information to the DMD for displaying of binary patterns at very high speeds. The *Feature Description* section describes how binary pattern data is loaded into the DMD and ultimately where that data is displayed on the DMD. The following subsections describe the different display modes of operation of the DMD as enabled by the DLPC410.

8.4.1 DLPC410 Initialization and Training

8.4.1.1 Initialization

The INIT_ACTIVE signal indicates that the DMD, Digital Micromirror Driver, and the Digital Controller are in an initialization state after power is applied. During this initialization period, the DLPC410 is calibrating the data interface, initializing the DMD, and DLPA200(s). When this signal goes low, the system has completed initialization. System initialization takes approximately 220 ms to complete. Data and command row cycles must not be presented to the DLPC410 during the initialization. INIT_ACTIVE should be considered an asynchronous feedback signal to the user. Standard synchronization techniques should be applied. After initialization is complete, a delay of at least 64 DCLKIN clocks (on all input data buses being used) should be observed before the first DVALID is asserted on those data buses to ensure a clean start up process.

注

Note: NS_FLIP, COMP_DATA, and $\overline{\text{RST2BLK}}$ signals should be kept low ('0') during initialization to ensure proper system setup.

8.4.1.2 input Data Interface (DIN) Training Pattern

The DLPC410 detects the phase differences between the ½ speed clock (used in the customer device driving the LVDS data) and the internally generated ½ speed data clocks and automatically corrects their alignment. This is done by the customer FPGA supplying a simple repeating pattern on all of the data inputs while the INIT_ACTIVE output of the DLPC410 is high/active. The details of the training pattern are described below.

This is a simple block diagram of the training pattern insertion logic.

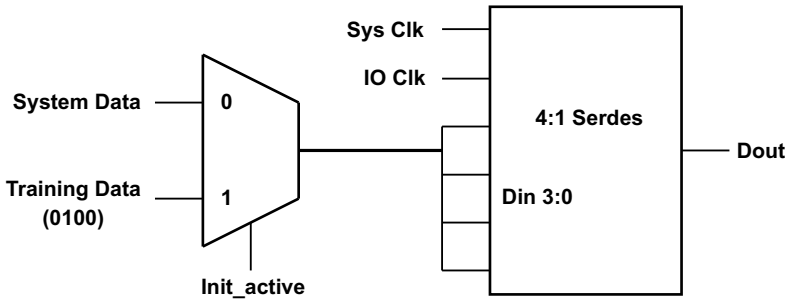

図 12. Block Diagram of Training Pattern Logic

The expected training pattern is 0100. In 図 13 the data input to the 4:1 SERDES cells is captured on the rising edge of the ½ speed system clock. The output latency shown is based on the documentation for the Xilinx SERDES cells. Individual implementation may vary depending on the type of cells, technology, and design technique used.

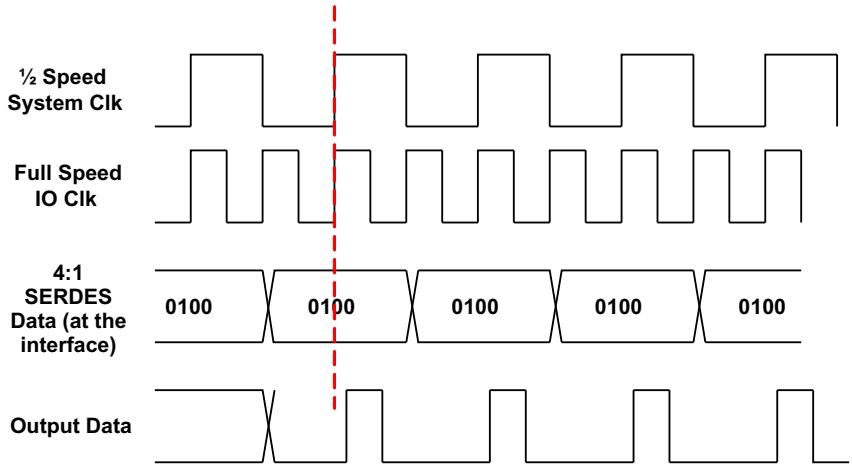

図 13. Training Pattern Alignment

注

In Xilinx FPGAs (due to the construction of the ISERDES and OSERDES cells) a pattern of 0010 needs to be applied to the output/transmitting SERDES cells data pins (D1 = 0, D2 = 0, D3 = 1, D4 = 0) in order to receive a result of 0100 (Q1 = 0, Q2 = 1, Q3 = 0, Q4 = 0) at the input/receiving SERDES cell.

The patterns should be applied on all of the input data and DVALID pins. In this respect, the interface is treated as a 17 bit interface with DVALID being the 17th data bit. The receiving logic in the DLPC410 will shift the data until the correct pattern is seen at the inputs. The SERDES cells align the incoming data with the ½ speed system clock (derived from the full speed data clock). This allows DLPC410 to correctly align the DVALID signal and the incoming data and will contribute to a more robust interface. It is important that the training pattern is applied to the DVALID and data inputs of the DLPC410 before reset to the device is deasserted, as training commences immediately on the deassertion of reset. The INIT_ACTIVE signal is asserted while the device is held in reset in order to help facilitate this behavior.

8.4.2 DLPC410 Operational Modes

The following modes of operation are frequently used operational modes enabling customers to update DMD data and to control how, where, and how long their binary patterns are displayed on the DMD. Customers frequently pick the mode which provides the best performance and simplicity for their specific system. Combinations of these modes can also be used.

8.4.2.1 Single Block Mode

A single block of DMD memory cells can be updated by providing successive row cycles with valid data (DVALID) to the DLPC410 until the desired amount of data is presented. Since different DMDs have different row and block sizes (and therefore different number of clocks per row or per block), the amount of time it takes to load a block of DMD data will be different for each DMD. Leveraging 表 11 and 表 13, we can calculate the single block load time for each DMD by the following equation: Block Load Time = Clock Period × number CLKS per ROW × number ROWS per BLK. The results are shown in 表 16 for DLPC410 supported DMDs.

表 16. DMD Block Load Time (400 MHz DMD Clock)

DMD	DMD BLOCK LOAD TIME
DLP650LNIR	5.00 µsec
DLP7000 / DLP7000UV	1.92 µsec
DLP9500 / DLP9500UV	2.88 µsec

Once the block is loaded with data, a Block Reset (MCP) for that block must be initiated. This can be performed by providing a row cycle with BLKMD = "10" and with BLK_AD(3:0) equal to the block just loaded. Upon initiation of the Block Reset, RST_ACTIVE will transition high for approximately 4.5 µs indicating a Reset operation is taking place and that no additional Reset Requests will be accepted during that time. In the case of wanting to reload the same block with new data, one must wait for the 12.5 µs (RST_ACTIVE (4.5 µs) + the micromirror settling time (8 µs)) before the reload of the same block can start. Waiting this time allows for the DMD micromirrors in that block to settle to a stable state prior to reloading the memory cells underneath with new data. 図 14 shows a single block load, Mirror Clocking Pulse and reload sequence with the 8 µs periods indicating micromirror settling times.

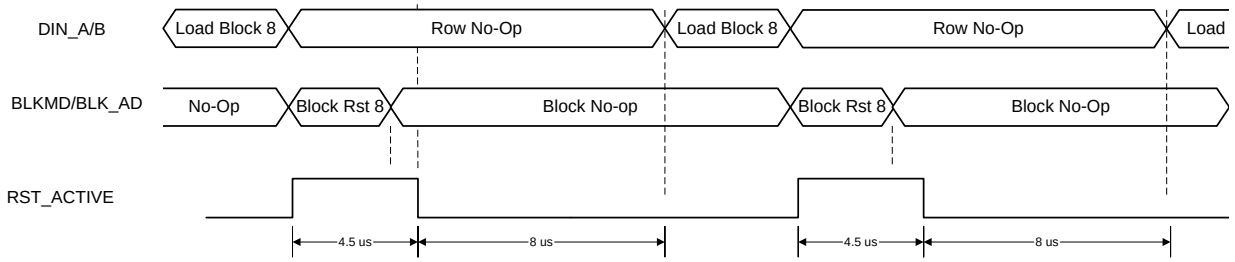

図 14. Block Load, Reset, and Same Block Reload

Although 図 14shows that one must wait for the mirror settling time of the current block (Block=8 in this case) to complete before reloading data into the same block (8), it is possible to load data to a different block while waiting for Block 8 to settle. However, it must be a block which is not currently being Reset nor which has micromirrors which are still settling. This method is used in the Phased Mode of operation described in *Single Block Phased Mode* .

注

The RST_ACTIVE and micromirror settling times indicated in this example are typical for many DMDs. See each individual DMD data sheet for more information on the micromirror switching and settling times.

注

Customers do not have to load the entire block at one time unless specifically directed. The DLPC410 supports individual row loads and partial block loads. Customers can use ROW_AD(10:0) to load one (or more) specific Row Addresses within any block. These loading modes are defined in 表 12. Care must be taken to ensure all RST_ACTIVE time plus DMD mirror settling times are taken into account prior to re-loading any rows in the same block once a Reset has been requested.

8.4.2.2 Single Block Phased Mode

Single Block Phased Mode is best described as "phasing" the data load operation with the Block Reset operation. The major advantages of Phased Modes (Single, Dual, and Quad) in general are the idea of not having to wait for the micromirror settling time duration to complete prior to the next block reset, and for not having to wait for the Reset Request to complete prior to loading more data. In the example of 図 15, Block 15 is loaded with data while the Reset operation is taking place for Block 14 (Rst 14). The Reset Request (BLKMD and BLK_AD) for Block 14 needs to be one row cycle in duration minimum but can be extended to additional row cycles. Subsequent row cycles containing a valid Reset Request will be ignored until RST_ACTIVE goes low. Therefore, BLKMD and BLK_AD should transition from a Reset Request to a Block No-Op while RST_ACTIVE is still asserted as once RST_ACTIVE de-asserts there is the likelihood of an undesired Reset Request to be generated on the same block.

In 図 15, Block 0 is issued a Block Reset concurrently with data being loaded into the next block (1). The Row Cycles of the Block 1 data loading capture the Reset Request for Block 0, and provide continued Row Cycles for the duration of both the Block Load and the Block Reset. Note that the loading of block 1 does not need to wait for the mirror settling time of Block 0. This is repeated until the last block is Reset (which might also contain loading the next Block 0 data). Since the DLP650LNIR block load time is already longer than the RST_ACTIVE time, full utilization of its bandwidth is readily achieved in a single block phased mode.

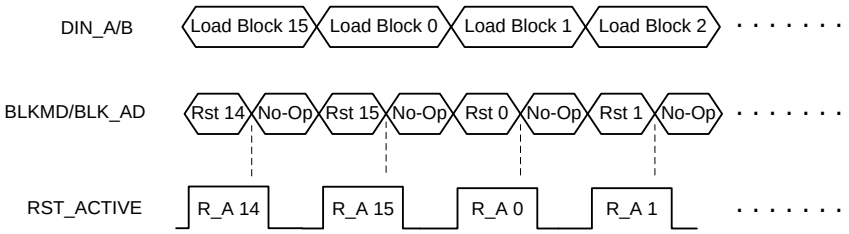

図 15. Single Block Phased Mode with Longer Block Load Times

Depending on the DMD type, the RST_ACTIVE duration of 4.5us may be longer than a single block load time. For example, the sequence shown in図 16 shows that when the Block Load time is shorter than RST_ACTIVE, one should include Row No-Ops to create a delay until the current RST_ACTIVE transitions low. Once RST_ACTIVE transitions low, the first row cycle of the next block data load can occur while also providing the Reset Request for the previously loaded block. At least one row cycle minimum must be completed to initiate the Reset Request and the next Reset Request must wait until the data is loaded and RST_ACTIVE transitions low.

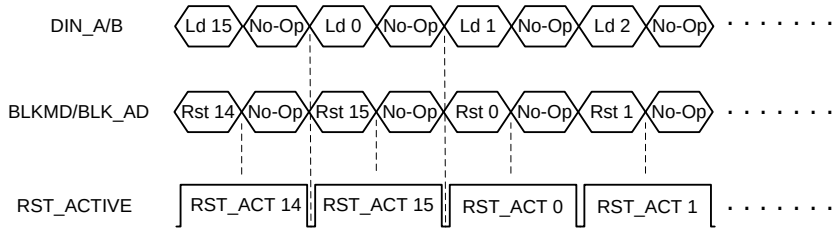

図 16. Single Block Phased Mode with Short Block Load TIme

図 17 is nearly the same as Figure 16 except that the data loading of each block is timed such that it completes loading the block just about the same time the RST_ACTIVE signal goes low. Row No-Op cycles are used to provide the Reset Requests instead of data load row cycles. The benefit of this would be the delayed loading of data could provide more time for the customer application data processing upstream. In both cases, the next block Reset Request cannot be initiated until the previous Reset Request has completed.

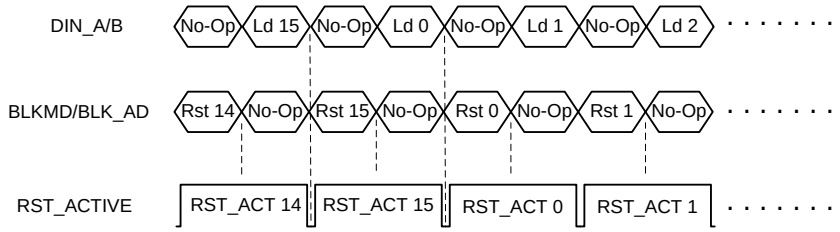

図 17. 2nd Single Block Phased Mode with Short Block Load TIme

8.4.2.3 Dual Block Mode

Dual Block Mode can help to avoid the required delays (via No-Ops) encountered in a Single Phased Mode where the load time is less than the Reset duration. In the case of the DLP9500 DMD with a block load time of 2.88 μs, loading two blocks (2 × 2.88 = 5.76 μs) takes more time than the Reset duration (4.5 μs) so once the data is loaded, a Dual Block Reset Request can be issued immediately (instead of waiting for RST_ACTIVE) to the two blocks by setting RST2BLK to “0” and BLK_MD to “11” and the appropriate address in BLK_AD. This method is indicated in 図 18.

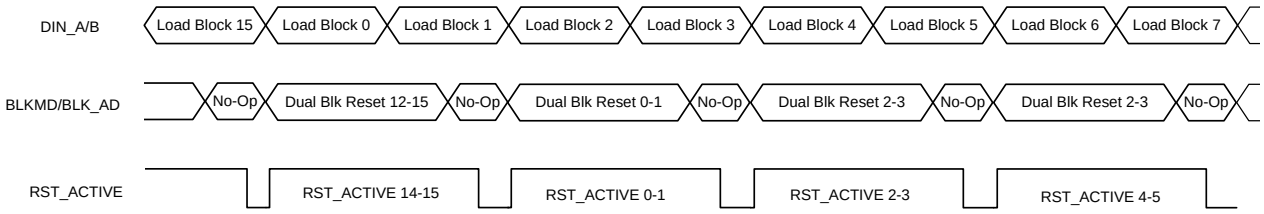

図 18. Dual Block Mode

8.4.2.4 Quad Block Mode

Quad Block mode is very similar to Dual Block mode but in Quad Block Mode, 4 Blocks are loaded with data and then Reset. In the case of the DLP7000 DMD with a block load time of 1.92 μs, the loading of two blocks would still be less than the 4.5 μs required for the Reset to complete so No-Ops would be required. To avoid inserting No-Ops is this case, loading four blocks (4 × 1.92 = 7.68 μs) is longer than the RST_ACTIVE duration (4.5 μs) so once loaded, the 4 blocks can immediately be issued a Reset Request by settingRST2BLK to “1”, BLK_MD to “11”, and setting the appropriate BLK_AD address in the first row cycle of the next data block load.

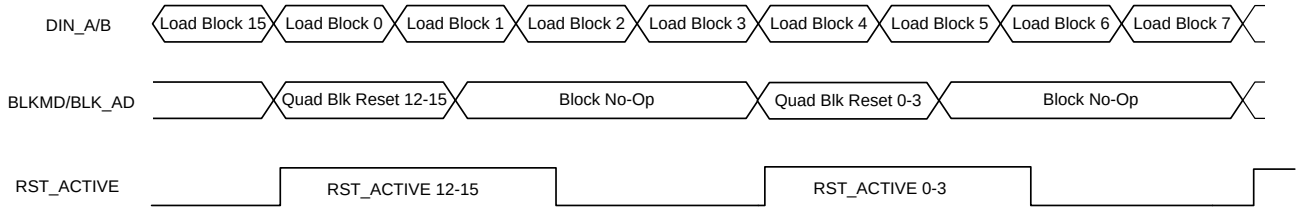

図 19. Quad Block Mode

Quad Block mode tends to offer customers the fastest full-DMD pattern rates combined with the largest solid state illuminations windows. Pattern rates for Single Block Phased and Dual Block Phased modes can sometimes be as fast as Quad Block rates, but the illumination windows can be smaller or even negative, thereby requiring delays between patterns to widen the illumination windows for solid state illuminators. These added delays will decrease the resulting pattern rates.

8.4.2.5 Global Mode

One of the simplest and most frequently utilized modes, the Global Mode involves loading the entire DMD with new pattern data and then issuing a Global Reset to update all DMD mirrors at the same time. Loading the entire DMD with data involves loading every row of every block. The time it takes to load the DMD is the block load time × the number of blocks for that specific DMD. 表 17 shows the fastest DMD load times for DLPC410 supported DMDs.

表 17. DMD Load Times (Entire DMD)

DMD	DMD LOAD TIME (400 MHz Clock)
DLP650LNIR	80.0 μsec
DLP7000 / DLP7000UV	30.7 μsec
DLP9500 / DLP9500UV	43.2 μsec

The Global Mode case is shown in 図 20. Following the loading of all rows in the device, a Row No-Op row cycle with a Global Reset Request must be issued to initiate the Reset Pulse and No-Ops should continue until ready to load the DMD again. If the global Reset Pulse is asserted prior to loading all rows of the device, rows which were not updated will show old data. Global mode is similar to Single Block Mode in that the mirror settling time must be taken into account prior to reloading the DMD data after a Reset Request is provided. This additional delay makes the Global Mode of operation inherently slower. However, if speed is not as important in a customer application, Global mode is great for its simplicity of DMD loading and Resetting.

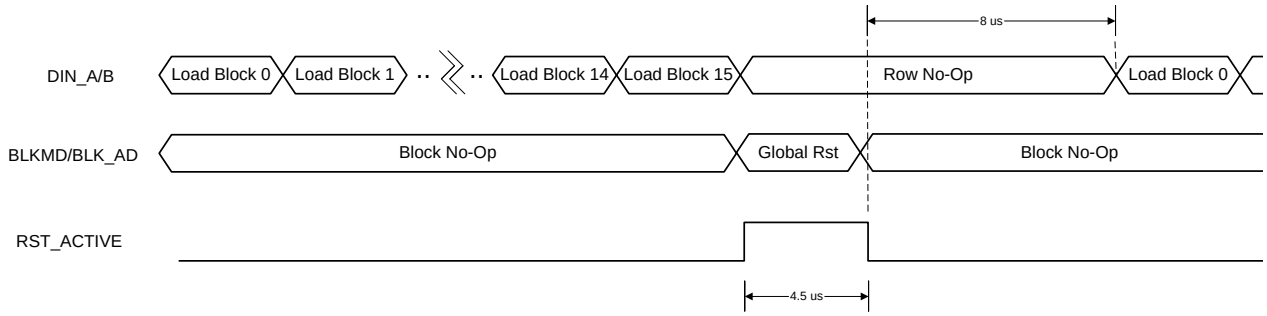

図 20. Full Device Load with Global Reset

8.4.2.6 DMD Park Mode

Park Mode places the DMD in a state where the micromirrors are not biased to either the plus or the minus side, but are instead floating in an unbiased and uncontrolled state. Hence, this is also referred to as Mirror Float mode. Parking (floating) the DMD mirrors should be performed when powering down the DMD to avoid leaving a static image on the DMD during down time or storage. The mirror can be Parked in one of two ways:

1. PWR_FLOAT input pin (recommended method) : asserting this input to the DLPC410 will cause the DLPC410 to automatically Park the mirrors in preparation for power removal. This operation is independent of any activity on the input data bus or Block operations. It is often best to drive this pin from both a power supervisor circuit which provides immediate DMD parking upon detecting input power removal, and from a programmable/controllable output from the customer application FPGA or processor.
2. DMD Park (Float Blocks 0-15) operation per 表 14: A mirror float sequence begins with a row cycle with assertion of the proper BLK_MD and BLK_AD as described in 表 14. Following the row cycle, the DMD releases the tension under each mirror so that all mirrors relax to a relatively flat position. The float operation takes approximately 3 µs to complete, during which time RST_ACTIVE is asserted.

注

Park the DMD only when DC power is going to be removed from the DMD. Recovery from a PWR_FLOAT input pin assertion requires either a DLPC410 logic reset or a complete power cycle.

8.4.2.7 DMD Idle Mode

When not powering down the DMD yet it is desired to place the system in an idle (non-functioning) state, regardless of end application, all DMDs benefit from continuously operating the DMD near 50% landed on/off duty cycle. This requires customers to understand how they can provide the DMD a sequence of patterns which approximate a 50/50 duty cycle without interfering with normal operation of their system. See section 3 (Duty Cycle Considerations) in application note DLPA052 - *System Design Considerations Using TI DLP® Technology down to 400 nm*. Also see

- DLPA060 - *System Design Considerations Using TI DLP® Technology in UVA*, and
- DLPA104 - *DLP® High-Power NIR Thermal Design Guide*

for additional information.

8.4.3 LOAD4 Functionality (enabled with DLPR410A)

The DLPR410A PROM enables a new LOAD4 feature for the DLPC410 and attached DMD. The LOAD4 capability enables the DMD to load 4 rows for every row of data provided by the DLPC410, thereby reducing the number of rows to be transferred to 1/4 of the total of DMD rows, and the pattern load time to ¼ the total of row cycles, all at the expense of vertical resolution (1/4). Faster global binary pattern rates at the expense of vertical addressable resolution may make sense for certain applications like shutter/chopper solutions and vertical structured light patterns. LOAD4 reduces data load time only and does not reduce the “Mirror Clocking Pulse” and “Settling Time” durations.

8.4.3.1 Enabling LOAD4

LOAD4 is enabled by setting the DLPC410 input signal "$\overline{\text{LOAD4}}$" to a logic '0'. When not using LOAD4, this input should driven or pulled up to logic '1'.

注

The $\overline{\text{LOAD4}}$ pin on the DLPC410 was previously defined as "DDC_SPARE_0" pin. DLPC410 referenceschematics may still show this signal as DDC_SPARE_0 even though the DLPR410A enables the LOAD4 capability using this pin. LOAD4 capability is available starting with the DLPR410A and is not available with the DLPR410.

8.4.3.2 Loading Data with LOAD4

LOAD4 enables the attached DMD to load four rows of the same data for every one row of provided pattern data. “Automatic Increment” mode and “Row Address” mode can be used as before, however the largest addressable row will be the Vertical Resolution (VRes) of the attached DMD divided by four. For example, using LOAD4 the XGA DMD will have 1024/4 = 256 addressable rows (0 . . . 255). The addressable vertical resolution is reduced by four, although the physical mirror resolution remains unchanged.

“Automatic Increment” address mode will automatically increment the Row Address input by one (or decrement by one for N/S flip). The Row Address input will be re-mapped as shown in the next section.

8.4.3.3 Row Mapping with LOAD4

The DMD row addresses are re-mapped per 表 18.

表 18. LOAD4 Row Address Mapping

Row Address Input	Physical Rows loaded on DMD
0	0, 1, 2, 3
1	4, 5, 6, 7
2	8, 9, 10, 11
3	12, 13, 14, 15
. . .	. . .
N	4N, 4N+1, 4N+2, 4N+3
. . .	. . .
(VRes/4) -1	VRes-4, VRes-3, VRes-2, VRes-1

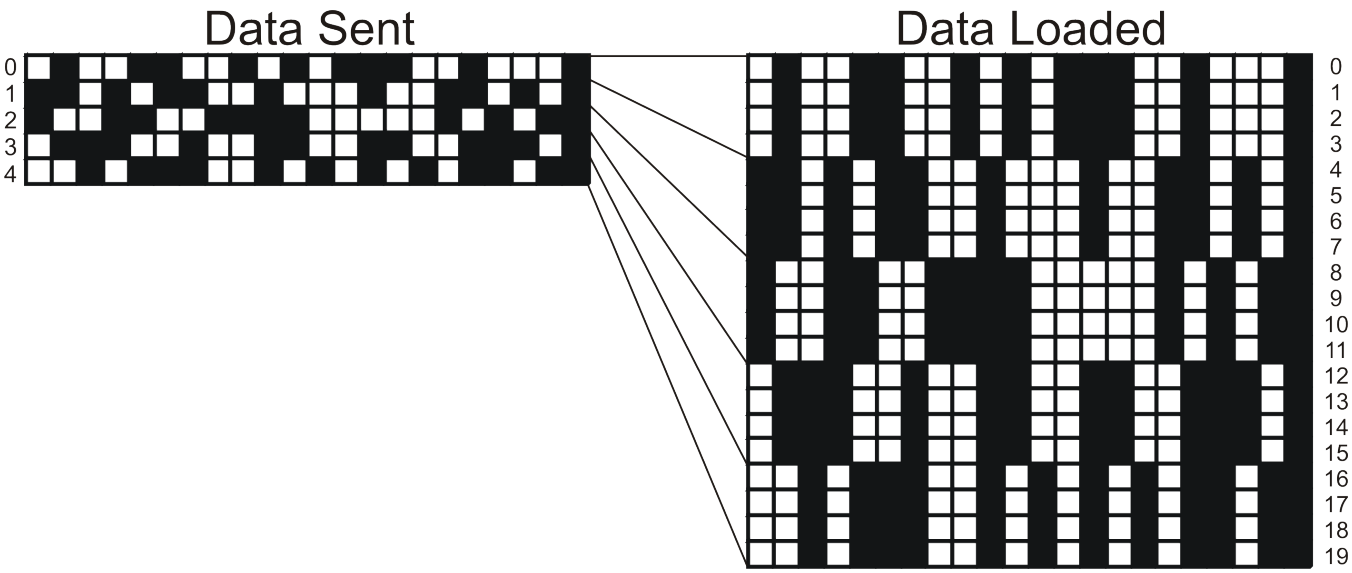

図 21. LOAD4 Row Address Mapping

8.4.3.4 Using Block Clear with LOAD4

While LOAD4 is enabled, Block Clear operations will be ignored. To use LOAD4 followed by Block Clear operations, simply de-assert $\overline{\text{LOAD4}}$ at the beginning of the Reset request(s) preceding the Block Clear request(s). Re-assert $\overline{\text{LOAD4}}$ at the beginning of the Reset request(s) preceding the next desired LOAD4 operation. This will ensure that the DLPC410 Controller has sufficient time to disable or enable LOAD4 before data is loaded or Block Clear(s) are requested.

8.4.3.5 Timing Requirements for LOAD4

LOAD4 functionality is primarily intended to be used with Global Resets. However, It is possible to use a subset of the DMD array including Block Resets. The driving software/hardware MUST ensure that the average “Reset” (MCP) rate does not exceed an average rate of 50,000 MCPs/sec as this is the specification limit of the DLPA200 Micromirror Driver device (see . The driving software/hardware MUST also ensure that the “Mirror Settling Time” is not violated for any Block.

Average rate means averaged over 2-3 Load/Clear cycles. For example if a pattern is loaded and displayed with a Mirror Clocking Pulse followed by a Block Clear and a Mirror Clocking Pulse the “on” display time is very short. However, If the next pattern is loaded and displayed immediately, the average MCP rate may be exceeded, depending on the DMD and the number of Blocks in use. Therefore idle time must be added in the Load or Block Clear cycle to ensure an average MCP rate of 50,000 MCPs/sec or lower. Typically the smallest pattern display time is desired so that the time is added during the Load cycle rather than the Block Clear cycle so that the “off” time is extended, not the pattern display time.

8.4.3.6 Global Binary Pattern Rate increases using LOAD4

表 19 shows the improvements in binary pattern rates for the DLPC410 supported DMDs when using LOAD4 enhanced functionality of the DLPR410A PROM. When using solid state illuminators (which can be switched on and off quickly), the illumination window is the period of time between when a solid state illuminator can be turned on after the micromirrors have settled to when the micromirrors start to transition to their next state (after the load and a Reset). This illumination window is typically equal to the DMD load time. When the DMD load time is long (without LOAD4) there is a longer allowed illumination window for the application. As one moves to using LOAD4 but yet keeps the illumination window unchanged, the illumination window becomes a higher percentage of pattern period, and more the limiter of the maximum binary pattern rate.

表 19. DMD Block Load Time at 400MHz DMD Clock

DMD	Global Frame Rate (without LOAD4)	Global Frame Rate (with LOAD4 mode)
DLP650LNIR	11k binary patterns/sec	30k binary patterns/sec
DLP7000	23k binary patterns/sec	48k binary patterns/sec
DLP9500	18k binary patterns/sec	42k binary patterns/sec

8.4.3.7 Special LOAD4 considerations

Take precautions when using LOAD4 mode with the DLP650LNIR DMD, or similar DMDs where the number of rows per reset block is not evenly divisible by 4. In the case of the DLP650LNIR, the number of rows per block for this DMD is 50 rows which is not evenly divisible by 4. Therefore, loading the last two rows of an even number block (n = 0,2,4,...14) concurrently loads the first two rows in the subsequent odd number block (n+1). Conversely, to address and load an odd block using LOAD4, the last two rows of the preceding even number block will be loaded first, else the first two rows of the odd block will not be loaded with new data.

8.5 Programming

The DLPC410 has no software interfaces and is therefore not programmable from a software perspective. All operational modes involve externally applied hardware signals.

9 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The DLP650LNIR, DLP7000, DLP7000UV, DLP9500, and DLP9500UV devices require they be coupled with the DLPC410 controller to provide a reliable solution for many different applications. The DMDs are spatial light modulators which reflect incoming light from an illumination source to one of two directions, with the primary direction being into a projection collection optic. Each application is derived primarily from the optical architecture of the system and the format of the data coming into the DLPC410. Applications of interest include industrial, medical, and intelligent display.

9.1.1 Device Description

The DLPC410 Controller based chipsets offer developers a convenient way to design a wide variety of industrial, medical, and advanced display applications by delivering maximum flexibility in formatting and sequencing customer binary pattern data for display as projected light patterns from DMDs of varying resolutions.

These chipsets include the following components:

DLPC410 DMD Digital Controller

- Captures 2xLVDS input pattern data plus control from the user.
- Provides data and additional control to the DMD for high speed binary pattern display.
- Commands the DLPA200 to generate Resets Pulses (MCP) with highly specific timing.
- Supports random DMD row addressing, clear operations, and LOAD4 capability.

DLPR410 Configuration PROM

- Contains DLPC410 Controller power up configuration information.

DLPA200 DMD Micromirror Driver

- Creates Reset Pulses (MCP) to the DMD to initiate mirror transitions to the next state.

DMD: Digital Micromirror Device, a 2-dimensional array of aluminum micromirrors

- DMD micromirrors tilt +12 degrees and -12 degrees to steer light in one of two directions.
- DLP650LNIR DMD: 0.65-inch array diagonal, 1280 x 800 micromirror array, WXGA resolution.
- DLP7000(UV) DMDs: 0.7-inch array diagonal, 1024 x 768 micromirror array, XGA resolution.
- DLP9500(UV) DMDs: 0.95-inch array diagonal, 1920 x 1080 micromirror array, 1080p resolution.

Reliable function and operation of the DLP650LNIR, DLP7000, DLP7000UV, DLP9500, and DLP9500UV DMDs require the DMDs to be used in conjunction with the components listed in 表 1. This document describes the proper integration and use of the chipset components.

The DLPC410 chipset can be combined with a user programmable Application FPGA (not included) to create high performance systems.

9.2 Typical Application

A typical embedded system application using the DLPC410 controller is shown in 図 22. The DLPC410, the DMD, and their associated DLP components do not specifically determine the application in which the components are used - customer applications and use cases may vary widely, from Digital Image Lithography to 3D Printing to 3D Scanners using Structured Light. The DMD is capable of being used with multiple illumination source types, from Lasers and LEDs to wide band wavelength mercury halide lamps. The DLPC410 supported DMDs cover applications utilizing ultraviolet (UV), visible, and/or near-infrared (NIR) wavelengths. The duration of each binary pattern displayed on the DMD is totally under control of the Applications Processor. The displayed patterns could be strictly binary patterns or could be bit weight exposures of varying durations representing

Typical Application (continued)

encoded PWM-based gray scales. The timing of the micromirrors and the illumination sources are controlled at the discretion of a Customer Applications Processor and in many solid state cases, provide best performance when source illuminators are synchronous to the commanded DMD micromirror transitions. The speed, diversity, programmability, and flexibility of the DLPC410 building blocks provide an electro-optical cornerstone for customers to build upon to create applications limited only by customer ingenuity.

In 図 22, the MBRST 2 signals and the C, D LVDS Data buses are shown with dashed lines to indicate that some DMDs do not require these signals to be used. TI's Reference Design and Evaluation Modules leverage a DLPC410 Controller Board which supports all 5 of the DLPC410 supported DMDs. The performance differences for each application are determined by which DMD Board is plugged into the Controller Board. This provides a single DLPC410 design platform which can then be used for multiple customer SKUs within an application platform for product segmentation purposes.

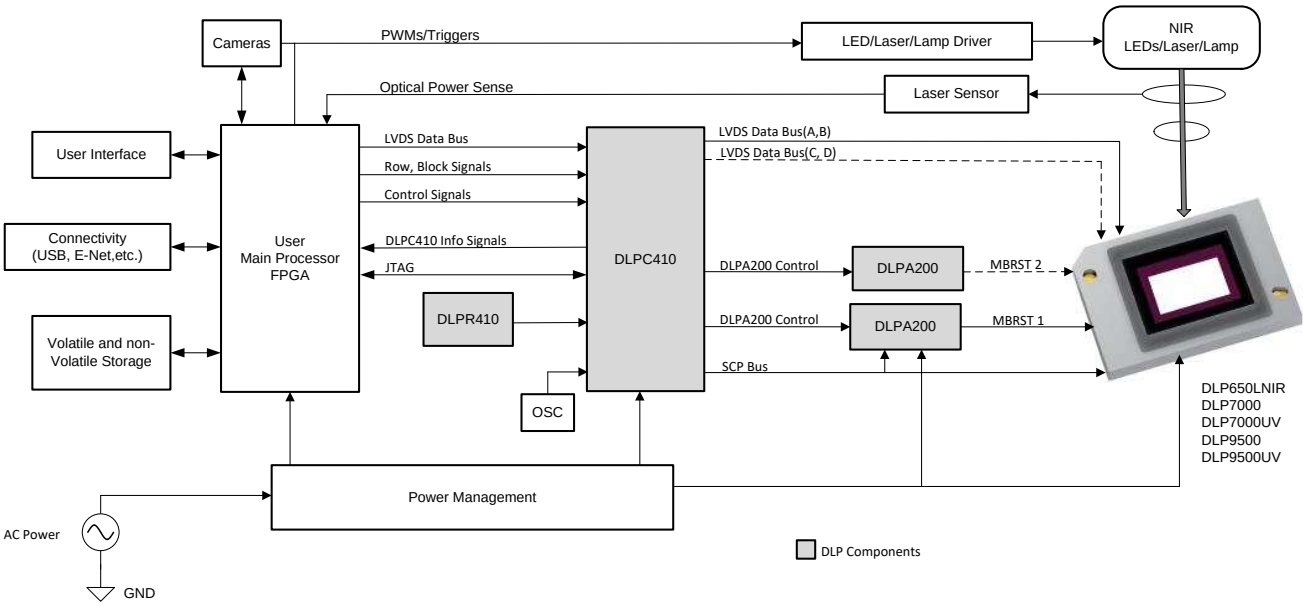

図 22. DLPC410 Application Example Block Diagram

9.2.1 Design Requirements

All applications using the DLP650LNIR, DLP7000(UV) or DLP9500(UV) DMDs require the DLPC410 Controller, DLPR410 PROM, and one or two DLPA200 Micromirror Drivers for proper operation. The chipset has several system interfaces and requires some support circuitry. The following interfaces and support circuitry for the DLPC410 are required:

- DLPC410 Application System Interfaces to the customer electronics and software:
  - Input LVDS Data Buses A, B, C, D
  - Row Address to specify DMD row to load
  - Block address and Block Mode to specify which DMD block(s) to "Reset" (MCP)
  - RST_ACTIVE feedback to indicated a "Reset" is in progress
  - Miscellaneous control inputs
  - Miscellaneous feedback signals
  - Power Supply inputs
- DLPC410 to other DLP Component Interfaces
  - Output LVDS Data Buses A, B, C, D to DMD
  - Output control signals (SCP bus) to DMD
  - Output commands to DLPA200 for MCP generation

Typical Application (continued)

9.2.2 Detailed Design Procedure

The DLP7000 and DLP9500 DMD are designed to be operated by the DLPC410 controller and are well suited for visible light applications requiring fast, spatially programmable light patterns using the micromirror array. In addition the DLP7000UV and DLP9500UV are well suited for direct imaging lithography, 3D printing applications, and other applications requiring ultraviolet light (UVA). The DLP650LNIR DMD is optimal for high power Near-Infrared light (NIR) applications like 3D additive manufacturing (SLS), marking and coding, and FPD repair and ablation. See the block diagrams in *Functional Block Diagrams* to see the connections between the DLP650LNIR, DLP7000 / DLP7000UV or DLP9500 / DLP9500UV DMD, the DLPC410 digital controller, the DLPR410 Configuration PROM, and the DLPA200 DMD micromirror drivers. Layout guidelines should be followed for reliability.

9.2.3 Application Curves

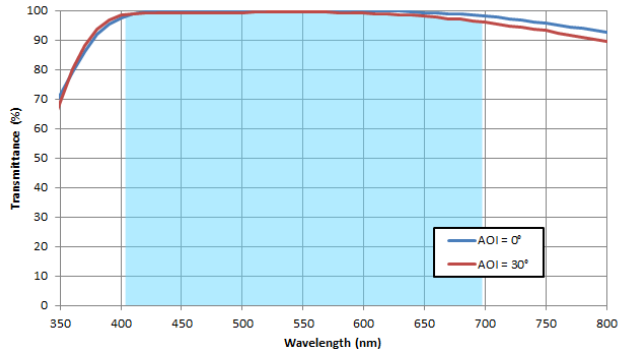

図 23. DLP7000 and DLP9500 Transmittance (Visible Window)

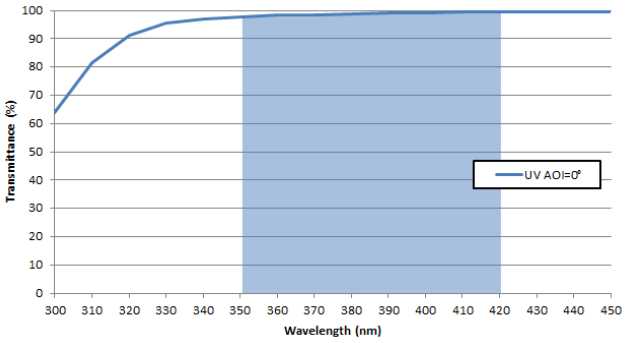

図 24. DLP7000UV and DLP9500UV Transmittance (UV Window)

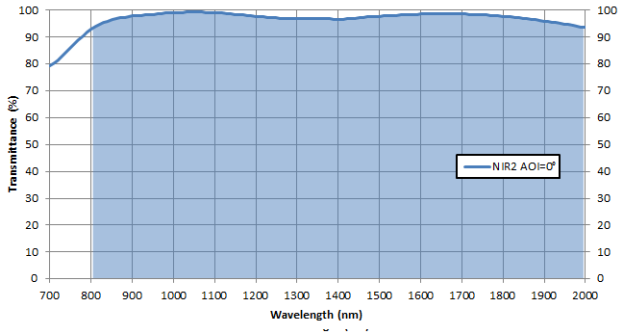

図 25. DLP650LNIR Transmittance (NIR2 Window)

9.3 Initialization Setup

9.3.1 Debugging Guidelines

Prior to checking the DLPC410 signals, make sure the reference clock to the DLPC410 is running at 50 MHz. Check that DONE_DDC (pin K10) signal is asserted indicating the DLPR410 PROM has correctly programmed the DLPC410 FPGA.

9.3.2 Initialization

Initialization will automatically start after $\overline{\text{ARST}}$ (pin AC13) is deasserted. The initialization process includes the following components in the order presented here:

1. Calibration
2. DLPA200 number 1 Initialization (all DMDs)

Initialization Setup (continued)

3. DMD Initialization
4. DLPA200 number 2 Initialization (DLP9500 & DLP9500UV only)
5. Command Sequence

9.3.2.1 Calibration

Calibration is done on each of the data (DDC_DIN) and DVALID signal pairs using the training pattern as specified in *input Data Interface (DIN) Training Pattern*. When calibration is successful, the Initialization will move on to initializing the first DLPA200.

注

The training pattern going into the SERDES on the transmit side is different than the pattern on the receive SERDES. On the receive side the value should be “0100”. However, this could translate to “0010” on the transmit side. Please see *input Data Interface (DIN) Training Pattern* for more information. An improper training pattern could cause the part to not perform the commands correctly.

9.3.2.2 DLPA200 Number 1 Initialization

The DLPC410 will initialize the first DLPA200 (number 1) regardless of connected DMD type. The DLPC410 output DAD_A_SCPEN (pin AE3) signal will assert indicating that the DLPC410 is ready to communicate with DLPA200 number 1. Signaling should be seen on SCPCLK (pin AB15), SCPDO (pin AA15 - SCP output from the DLPC410) and SCPDI (pin AA15 - SCP input to the DLPC410) traces. Be sure that the direction of the SCP input and output signals are connected correctly.

When DLPA200 Number 1 initialization is complete, check V_{BIAS}, V_{RESET}, and V_{OFFSET} voltage values on the DLPA200 number 1 and compare against the DLPA200 data sheet specifications for the particular DMD being used with the DLPC410.

9.3.2.3 DMD Initialization

During DMD initialization, the DLPC410 output DMD_A_SCPEN (pin AB14) signal will assert indicating that the DLPC410 is ready to communicate to the DMD. Signaling can be seen on SCPCLK (pin AB15), SCPDO (pin AA15 - SCP output from the DLPC410) and SCPDI (pin AA15 - SCP input to the DLPC410) lines. Be sure that the direction of the SCP input and output signals are connected correctly.

9.3.2.3.1 DMD Device ID Check

If the DLPC410 has successfully initialized the DMD, the four DMD_TYPE(3:0) pins (AA17, AC16, AB17, and AD15)) will provide the DMD type as identified by the DLPC410. The possible DMD_TYPE values are shown in 表 15. DMD_TYPE(3:0) will return "1111" if the DMD is not attached or not recognized.

注

Only the DMDs listed in 表 1 are supported by the DLPC410. The DLPC410 will not function for unsupported DMDs or when a DMD is not installed.

9.3.2.3.2 DMD Device OK

The signals ECP2_M_TP11 (pin AA10) and ECP2_M_TP12 (pin Y10) indicate the status of the DMD buses:

表 20. DMD Device OK Status

ECP2_M_TP12 (PIN Y10 - A/B SIDE)	ECP2_M_TP13 (PIN AC11 - C/D SIDE)	NOTE
0	0	DMD not supported or not initialized

表 20. DMD Device OK Status (continued)

ECP2_M_TP12 (PIN Y10 - A/B SIDE)	ECP2_M_TP13 (PIN AC11 - C/D SIDE)	NOTE
1	0	A/B side is attached and initialized. (Expected for DLP650LNIR, DLP7000, DLP7000 UV DMDs but indicates a problem with C/D side connection if DMD is DLP9500 or DLP9500UV)
0	1	Invalid output
1	1	All buses (A/B and C/D) are attached and initialized (DLP9500, DLP9500UV only)

9.3.2.4 DLPA200 Number 2 Initialization

The DLPC410 will only initialize the second DLPA200 (number 2) when it detects a DLP9500 or DLP9500UV DMD is connected. The DLPC410 output DAD_B_SCPEN (pin AB19) signal will assert indicating that the DLPC410 is ready to communicate with DLPA200 number 2. Signaling should be seen on SCPCLK (pin AB15), SCPDO (pin AA15 - SCP output from the DLPC410) and SCPDI (pin AA15 - SCP input to the DLPC410) traces. Be sure that the direction of the SCP input and output signals are connected correctly.

When DLPA200 Number 2 initialization is complete, check V_{BIAS}, V_{RESET}, and V_{OFFSET} voltage values on the DLPA200 number 2 and compare against the DLPA200 data sheet specifications for the DLP9500 or DLP9500UV DMD.

9.3.2.5 Command Sequence Initialization

The last portion of the initialization process involves a series of commands sent from the DLPC410 to the DMD. During this step, check the output of the DLPA200(s). One should expect to see several Mirror Clocking Pulse waveforms indicating the DLPA200(s) is (are) initialized correctly.

This will complete the initialization process. When the initialization process starts, the INIT_ACTIVE ouput signal (pin AA18) will assert (go high) indicating that the initialization sequence is in process. At the end of the initialization sequence, if the initialization is successful, the INIT_ACTIVE ouput signal (pin AA18) will deassert (go low) indicating that the initialization process is complete.

注

Initialization complete indicates that the initialization sequence of the DLPC410 has completed, but does not ensure that each step was completed correctly, only that it finished. For example the initialization of a DLPA200 may complete, but if the voltages set are incorrect further investigation is needed to uncover the reason.

9.3.3 Image Display Issues

There are three steps to displaying an image on the DMD, each of which can cause an image to fail to display correctly or in some case not at all. These steps are:

1. Present Data to DLPC410 – Pattern data generated by the users device.
2. Load Data to the DMD – The DLPC410 loads data into the attached DMD CMOS memory array.
3. Issue Reset (MCP) – A Reset pulse (MCP) is issued to block(s) to change the state of the micromirrors based on the data loaded in step two. See *Mirror Clocking Pulse (MCP)* .

9.3.3.1 Present Data to DLPC410

If there is a problem with the image displayed, one of the first places to check is the data being presented to the DLPC410. This data is generated by customer application hardware/software and is then presented to the inputs of the DLPC410. If the data is formatted incorrectly or the control information is incorrect, the DLPC410 may not properly receive the data. Please see *Row Addressing* for a description of how to send data to the DLPC410.

9.3.3.2 Load Data to DMD

After data and commands are sent to the DLPC410, the DLPC410 processes the information and passes it to the DMD. If there is no image displayed, first check the data output and SCTRL lines of the DLPC410 to see if there is data coming out. Data output (DDC_DOUT...) and DDC_SCTRL pins can be found in the *Pin Configuration and Functions*.

PWR_FLOAT (pin AC17) will prevent the data from coming out of the DLPC410 if asserted. Check to make sure that it is at logic level 0.

A *Float blocks 00-15* command will also prevent data from the DLPC410. Please see the last entry of 表 14.

9.3.3.3 Mirror Clocking Pulse

For a new image to appear on the DMD, Mirror Clocking Pulses must be received for the DMD block or blocks that have received new data. Check DAD_A_STROBE (pin AF3) and DAD_B_STROBE (pin AB20) [if applicable] for pulses to verify that requests for mirror clocking pulses are being sent to the DLPA200(s). Also check the DLPA200(s) output is enabled by checking that DAD_OE (pin AF5) is low.

10 Power Supply Recommendations

10.1 Power Down Operation

For correct operation of the DMD, the following power down procedure must be executed. Prior to power removal, assert PWR_FLOAT and allow approximately 300 µs for the procedure to complete. This procedure will assure the mirrors are in a flat state, similar to the float operation. Following this procedure, the power can be safely removed.

To restart after assertion of PWR_FLOAT the DLPC410 must be reset ($\overline{\text{ARST}}$ low then high) or power must be cycled.

11 Layout

11.1 Layout Guidelines

The DLPC410 is part of a chipset that is controls a DLP650LNIR, DLP7000 / DLP7000UV or DLP9500 / DLP9500UV DMD in conjunction with the DLPA200 driver(s). These guidelines are targeted at designing a PCB board with these components.

11.1.1 Impedance Requirements

Signals should be routed to have a matched impedance of 50 Ω ±10% except for LVDS differential pairs (DMD_DAT_Xnn, DMD_DCKL_Xn, and DMD_SCTRL_Xn), which should be matched to 100 Ω ±10% across each pair.

11.1.2 PCB Signal Routing

When designing a PCB board for the DLP650LNIR, DLPC7000 / DLP7000UV or DLP9500 / DLP9500UV controlled by the DLPC410 in conjunction with the DLPA200(s), the following are recommended:

Signal trace corners should be no sharper than 45°. Adjacent signal layers should have the predominate traces routed orthogonal to each other. TI recommends that critical signals be hand routed in the following order: DDR2 Memory, DMD (LVDS signals), then DLPA200 signals.

TI does not recommend signal routing on power or ground planes.

TI does not recommend ground plane slots.

High speed signal traces should not cross over slots in adjacent power and/or ground planes.

表 21. Important Signal Trace Constraints

SIGNAL	CONSTRAINTS
LVDS (DMD_DAT_xnn, DMD_DCKL_xn, and DMD_SCTRL_xn)	P-to-N data, clock, and SCTRL: <10 mils (0.25 mm); Pair-to-pair <10 mils (0.25 mm); Bundle-to-bundle <2000 mils (50 mm, for example DMD_DAT_Ann to DMD_DAT_Bnn) Trace width: 4 mil (0.1 mm) Trace spacing: In ball field – 4 mil (0.11 mm); PCB etch – 14 mil (0.36 mm) Maximum recommended trace length <6 inches (150 mm)

表 22. Power Trace Widths and Spacing

SIGNAL NAME	MINIMUM TRACE WIDTH	MINIMUM TRACE SPACING	LAYOUT REQUIREMENTS
GND	Maximize	5 mil (0.13 mm)	Maximize trace width to connecting pin as a minimum
P2P5V, P1P0V	50 mil (1.3 mm)	10 mil (0.25 mm)	Create mini planes and connect to devices as necessary with multiple vias
P2P5V, P1P0V	30 mil (0.76 mm) - stub width	10 mil (0.25 mm)	Stub width to connecting IC pins; maximize width when possible

11.1.3 Fiducials

Fiducials for automatic component insertion should be 0.05-inch copper with a 0.1-inch cutout (antipad). Fiducials for optical auto insertion are placed on three corners of both sides of the PCB.

11.1.4 PCB Layout Guidelines

A target impedance of 50 Ω for single ended signals and 100 Ω between LVDS signals (P/N) is specified for all signal layers.

11.1.4.1 DMD Interface

The digital interface from the DLPC410 to the DMD are LVDS signals that run at clock rates up to 400 MHz. DDR Data is clocked into the DMD on both the rising and falling edge of the clock, so the data rate is 800 MHz. The LVDS signals should have 100-Ω differential impedance. The differential signals should be matched but kept as short as possible. Parallel termination at the LVDS receiver is in the DMD; therefore, on board termination is not necessary.

11.1.4.1.1 Trace Length Matching

The require precise length matching. LVDS data bus differential pairs should have an impedance of 100 Ω (with 5% tolerance). It is important that the propagation delays are matched. The maximum differential pair uncoupled length is 150 mils with a relative propagation delay of ±25 mil between the p and n. Matching all signals exactly will maximize the channel margin. The signal path through all boards, flex cables and internal DMD routing must be considered in this calculation.

11.1.4.2 DLPC410 DMD Decoupling

General decoupling capacitors for the DMD should be distributed around the PCB and placed to minimize the distance from IC voltage and ground pads. Each decoupling capacitor (0.1 µF recommended) should have vias directly to the ground and power planes. Via sharing between components (discreet or integrated) is discouraged. The power and ground pads of the DMD should be tied to the voltage and ground planes with their own vias.

11.1.4.2.1 Decoupling Capacitors

Decoupling capacitors should be placed to minimize the distance from the decoupling capacitor to the supply and ground pin of the component. It is recommended that the placement of and routing for the decoupling capacitors meet the following guidelines:

- The supply voltage pin of the capacitor should be located close to the device supply voltage pin(s). The decoupling capacitor should have vias to ground and voltage planes. The device can be connected directly to the decoupling capacitor (no via) if the trace length is less than 0.1 inch. Otherwise, the component should be tied to the voltage or ground plane through separate vias.
- The trace lengths of the voltage and ground connections for decoupling capacitors and components should be less than 0.1 inch to minimize inductance.
- The trace width of the power and ground connection to decoupling capacitors and components should be as wide as possible to minimize inductance.
- Connecting decoupling capacitors to ground and power planes through multiple vias can reduce inductance and improve noise performance.
- Decoupling performance can be improved by utilizing low ESR and low ESL capacitors.

11.1.4.3 VCC and VCC2

The VCC pins of the DMD should be connected directly to the DMD VCC plane. Decoupling for the VCC should be distributed around the DMD and placed to minimize the distance from the voltage and ground pads. Each decoupling capacitor should have vias directly connected to the ground and power planes. The VCC and GND pads of the DMD should be tied to the VCC and ground planes with their own vias.

The VCC2 voltage can be routed to the DMD as a trace. Decoupling capacitors should be placed to minimize the distance from the VCC2 and ground pads of the DMD. Using wide etch from the decoupling capacitors to the DMD connection will reduce inductance and improve decoupling performance.

11.1.4.4 DMD Layout

See the respective sections in this data sheet for package dimensions, timing and pin out information.

11.1.4.5 DLPA200

The DLPA200 generates the micromirror clocking pulses for the DMD. The DMD-drive outputs from the DLPA200 should be routed with minimum trace width of 11 mil and a minimum spacing of 15 mil. The VCC and VCC2 traces from the output capacitors to the DLPA200 should also be routed with a minimum trace width and spacing of 11 mil and 15 mil, respectively. See the DLPA200 customer data sheet for mechanical package and layout information.

11.2 Layout Example

For LVDS (and other differential signal) pairs and groups, it is important to match trace lengths. In the area of the dashed lines, 図 26 shows correct matching of signal pair lengths with serpentine sections to maintain the correct impedance.

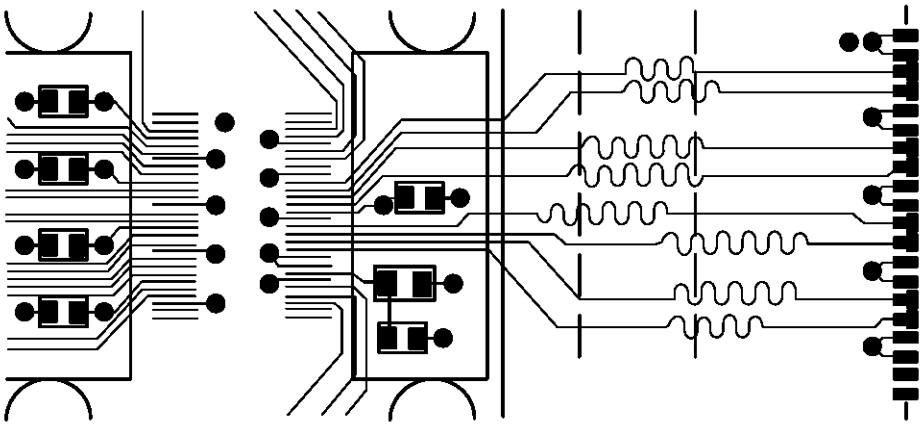

図 26. Mitering LVDS Traces to Match Lengths

11.3 DLPC410 Chipset Connections

The following tables list the signal connections between components of the Chipset when used with the DLP650LNIR DMD, the DLP7000 / DLP700UV DMD, and with the DLP9500 / DLP9500UV DMD. These tables do not include power, ground, pull-up, pull-down, termination, or any other connection requirements. Please see the Pin Functions table in the respective data sheet of each chipset component for connection requirements.

E2E is a trademark of Texas Instruments.
DLP is a registered trademark of Texas Instruments.

12.5 静電気放電に関する注意事項

これらのデバイスは、限定的なESD（静電破壊）保護機能を内 蔵しています。保存時または取り扱い時は、MOSゲートに対す る静電破壊を防止するために、リード線同士をショートさせて おくか、デバイスを導電フォームに入れる必要があります。

12.6 Glossary

SLYZ022 — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

13 メカニカル、パッケージ、および注文情報

以降のページには、メカニカル、パッケージ、および注文に関する情報が記載されています。この情報は、そのデバイスについて利用可能な最新のデータです。このデータは予告なく変更されることがあり、ドキュメントが改訂される場合もあります。本データシートのブラウザ版を使用されている場合は、画面左側の説明をご覧ください。

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
DLPC410ZYR	ACTIVE			676	1	TBD	Call TI	Call TI	0 to 85		Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

重要なお知らせと免責事項
