概要

LM2903B-Q1 デバイスは、業界標準の LM2903-Q1 コンパレータ・ファミリの次世代バージョンです。この次世代ファミリは、小さいオフセット電圧、高い電源電圧への対応、小さい消費電流、小さい入力バイアス電流、小さい伝搬遅延、優れた 2kV の ESD 性能などの特長と、そのまま置き換えることができる利便性を兼ね備えており、コストの制約が厳しい用途で大きな価値を提供します。

すべてのデバイスは、広い電圧範囲にわたって動作するように設計された 2 つの独立した電圧コンパレータで構成されています。デュアル電源でも、2 つの電源間の差分が 2V ~ 36V の範囲内であり、VCC が入力同相電圧より 1.5V 以上高ければ、動作可能です。出力は、他のオープン・コレクタ出力に接続できます。

LM2903-Q1 と LM2903B-Q1 は、AEC-Q100 グレード 1 の温度範囲 (-40°C ~ +125°C) で認定済みです。LM2903E-Q1 はグレード 0 の拡張温度範囲 (-40°C ~ +150°C) で認定済みです。

4 Detailed Description

4.1 Overview

The LM2903-Q1 family is a dual comparator with the ability to operate up to 36 V on the supply pin. This standard device has proven ubiquity and versatility across a wide range of applications. This is due to its very wide supply voltages range (2 V to 36 V), low I_q and fast response.

This device is AEC-Q100 qualified and can operate over a wide temperature range of -40°C to 125°C (LM2903-Q1 and LM2903B-Q1) or -40°C to 150°C (LM2903E-Q1).

The open-drain output allows the user to configure the output's logic low voltage (V_{OL}) and can be utilized to enable the comparator to be used in AND functionality.

The "B" versions add dedicated ESD protections on all the pins for improved ESD performance as well as improved negative input voltage handling. Please see Application Note [SNOAA35](#) for more information

4.2 Functional Block Diagram

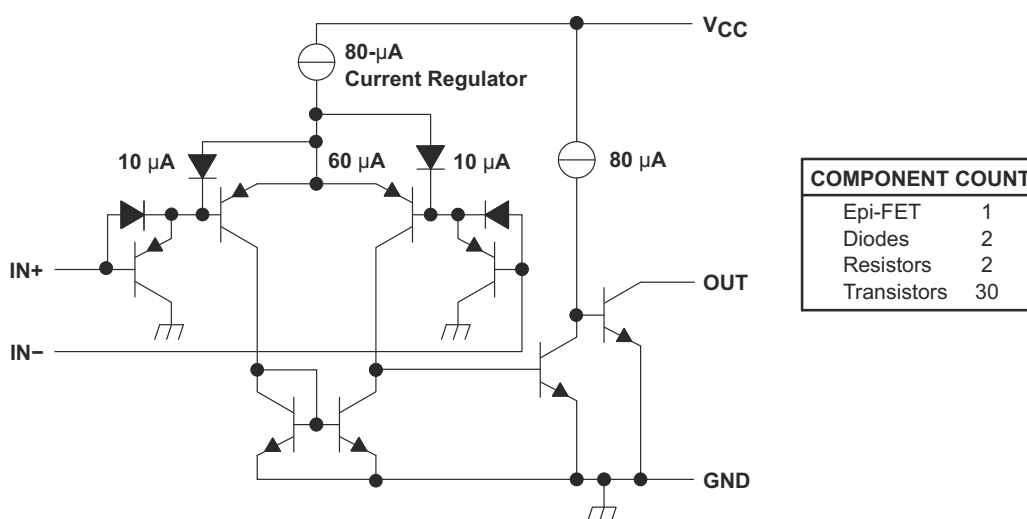

FIG 4-1. Schematic (Each Comparator)

4.3 Feature Description

LM2903-Q1 family consists of a PNP darlington pair input, allowing the device to operate with very high gain and fast response with minimal input bias current. The input Darlington pair creates a limit on the input common mode voltage capability, allowing LM2903-Q1 to accurately function from ground to $V_{CC}-1.5\text{V}$ differential input. This enables much head room for modern day supplies of 3.3 V and 5.0 V.

The output consists of an open drain NPN (pull-down or low side) transistor. The output NPN will sink current when the negative input voltage is higher than the positive input voltage and the offset voltage. The V_{OL} is resistive and will scale with the output current. Please see FIG 3-3 in the [セクション 3.15](#) section for V_{OL} values with respect to the output current.

4.4 Device Functional Modes

4.4.1 Voltage Comparison

The LM2903-Q1 family operates solely as a voltage comparator, comparing the differential voltage between the positive and negative pins and outputting a logic low or high impedance (logic high with pull-up) based on the input differential polarity.

5 Application and Implementation

5.1 Application Information

LM2903-Q1 will typically be used to compare a single signal to a reference or two signals against each other. Many users take advantage of the open drain output to drive the comparison logic output to a logic voltage level to an MCU or logic device. The wide supply range and high voltage capability makes LM2903Q1 optimal for level shifting to a higher or lower voltage.

5.2.1 Design Requirements

For this design example, use the parameters listed in 表 5-1 as the input parameters.

表 5-1. Design Parameters

Logic Supply Voltage	2 V to 36 V
Output Current (R_{PULLUP})	1 μ A to 20 mA
Input Overdrive Voltage	100 mV

5.2.2 Detailed Design Procedure

When using LM2903-Q1 family in a general comparator application, determine the following:

- Input Voltage Range
- Minimum Overdrive Voltage
- Output and Drive Current
- Response Time

5.2.2.1 Input Voltage Range

When choosing the input voltage range, the input common mode voltage range (V_{ICR}) must be taken in to account. If temperature operation is above or below 25°C the V_{ICR} can range from 0 V to $V_{CC}-2.0$ V. This limits the input voltage range to as high as $V_{CC}-2.0$ V and as low as 0 V. Operation outside of this range can yield incorrect comparisons.

Below is a list of input voltage situation and their outcomes:

1. When both IN- and IN+ are both within the common mode range:
 - a. If IN- is higher than IN+ and the offset voltage, the output is low and the output transistor is sinking current
 - b. If IN- is lower than IN+ and the offset voltage, the output is high impedance and the output transistor is not conducting
2. When IN- is higher than common mode and IN+ is within common mode, the output is low and the output transistor is sinking current
3. When IN+ is higher than common mode and IN- is within common mode, the output is high impedance and the output transistor is not conducting
4. When IN- and IN+ are both higher than common mode, see Section 2 of [Application Design Guidelines for LM339, LM393, TL331 Family Comparators Including the New B-versions](#)

5.2.2.2 Minimum Overdrive Voltage

Overdrive Voltage is the differential voltage produced between the positive and negative inputs of the comparator over the offset voltage (V_{IO}). In order to make an accurate comparison the Overdrive Voltage (V_{OD}) should be higher than the input offset voltage (V_{IO}). Overdrive voltage can also determine the response time of the comparator, with the response time decreasing with increasing overdrive. [Figure 5-2](#) and [Figure 5-3](#) show positive and negative response times with respect to overdrive voltage.

5.2.2.3 Output and Drive Current

Output current is determined by the load/pull-up resistance and logic/pull-up voltage. The output current will produce a output low voltage (V_{OL}) from the comparator. In which V_{OL} is proportional to the output current. Use [Figure 3-5](#) to determine V_{OL} based on the output current.

The output current can also effect the transient response. More will be explained in the next section.

5.2.2.4 Response Time

The transient response can be determined by the load capacitance (C_L), load/pull-up resistance (R_{PULLUP}) and equivalent collector-emitter resistance (R_{CE}).

- The positive response time (T_P) is approximately $T_P \sim R_{PULLUP} \times C_L$
- The negative response time (T_N) is approximately $T_N \sim R_{CE} \times C_L$
 - R_{CE} can be determine by taking the slope of [Figure 3-5](#) in it's linear region at the desired temperature, or by dividing the V_{OL} by I_{out}

5.2.3 Application Curves

The following curves were generated with 5 V on V_{CC} and V_{Logic} , $R_{PULLUP} = 5.1 \text{ k}\Omega$, and 50 pF scope probe.

5-2. Response Time for Various Overdrives (Positive Transition)

5-3. Response Time for Various Overdrives (Negative Transition)

5.3 Power Supply Recommendations

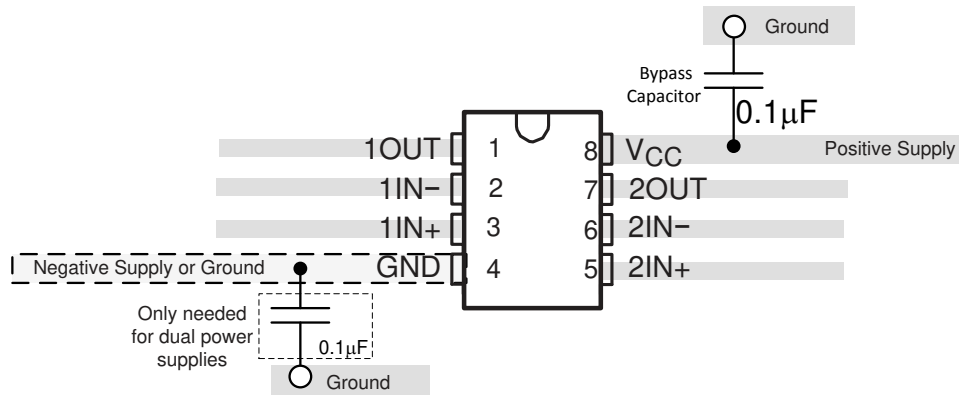

For fast response and comparison applications with noisy or AC inputs, it is recommended to use a bypass capacitor on the supply pin to reject any variation on the supply voltage. This variation can eat into the comparator's input common mode range and create an inaccurate comparison.

5.4 Layout

5.4.1 Layout Guidelines

For accurate comparator applications without hysteresis it is important maintain a stable power supply with minimized noise and glitches, which can affect the high level input common mode voltage range. In order to achieve this, it is best to add a bypass capacitor between the supply voltage and ground. This should be implemented on the positive power supply and negative supply (if available). If a negative supply is not being used, do not put a capacitor between the IC's GND pin and system ground.
