

TPS63810 および TPS63811 - I²C インターフェイス付き 2.5A 昇降圧コンバータ

1 特長

- 入力電圧範囲: 2.2V~5.5V
- 出力電圧範囲: 1.8V~5.2V
 - 動作中およびシャットダウン中に I²C で設定可能
 - VSEL ピンで 2 つのプリセット出力電圧を切り替え可能
- 出力電流
 - $V_I \geq 2.5V$, $V_O = 3.3V$ で最大 2.5A
 - $V_I \geq 2.8V$, $V_O = 3.5V$ で最大 2.5A
- 全負荷範囲にわたって高効率を実現
 - 低い動作時静止電流: 13 μ A
 - 自動パワーセーブ・モードと強制 PWM モード (I²C で設定可能)
- ピーク電流モード昇降圧アーキテクチャ
 - 降圧、昇降圧、昇圧動作間の遷移を定義済み
 - 順方向および逆方向電流動作
 - あらかじめ出力にバイアスを印加した状態で起動
- 安全で堅牢な動作を実現する機能
 - ソフトスタート内蔵
 - 過熱保護および過電圧保護
 - シャットダウン時に負荷を完全に切断
 - 順方向および逆方向の電流制限
- 2 つのデバイス・オプション
 - TPS63810: 出力電圧を事前設定済み (3.3V, 3.45V)
 - TPS63811: 起動前に出力電圧を設定
- 20mm² 未満のソリューション・サイズ、わずか 4 つの外付け部品

2 アプリケーション

- システム・プリレギュレータ (スマートフォン、タブレット、トラッキング / テレマティクス、EPOS、TWS イヤホン、医療用補聴器)
- ポイント・オブ・ロード・レギュレーション (TOF カメラ・センサ、ポート / ケーブル・アダプタおよび dongle)
- 熱電デバイスの電源 (TEC、光モジュール)
- ブロードバンド・ネットワーク無線または SoC 電源 (IoT、ホーム・オートメーション、EPOS)

3 概要

TPS63810 および TPS63811 は、I²C を介して完全にプログラム可能な高効率、大出力電流の昇降圧コンバータです。入力電圧に応じて自動的に昇圧モード、降圧モード、革新的な 4 サイクル昇降圧モード (入力電圧が出力電圧とほぼ等しい場合) で動作します。

モード間の遷移は定義されたスレッシュホールドで行い、出力電圧リップルを減らすためモード間の不要なトグルは行いません。

I²C を介して 2 つのレジスタで出力電圧を設定し、アクティブにする出力電圧レジスタを VSEL ピンで選択します。これにより、動的な電圧スケールリングをサポートできます。動作中に出力電圧レジスタを変更する (VSEL ピンを切り替える) と、定義されたプログラム可能なランプ・レートで遷移します。

7.1 Absolute Maximum Ratings

over operating junction temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
V _I	Input voltage (VIN, LX1, LX2, VOUT, SCL, SDA, EN, VSEL) ⁽²⁾	-0.3	6	V
	Input voltage for less than 10 ns (LX1, LX2) ⁽²⁾	-3	9	V
T _J	Operating junction temperature	-40	150	°C
T _{stg}	Storage temperature	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to network ground terminal, unless otherwise noted.

7.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

8 Detailed Description

8.1 Overview

The TPS63810 and TPS63811 devices are high-efficiency buck-boost converters. Each device uses four switches to maintain synchronous power conversion under all operating conditions, so that the device achieves high efficiency power conversion over a wide range of input voltages and output currents. The device automatically switches between buck, boost, and buck-boost operation as required by the operating conditions. The device operates as a true buck converter when $V_I > V_O$ and as a true boost converter when $V_I < V_O$. When $V_I \approx V_O$, the device operates in a 4-cycle buck-boost mode. The RMS current through the switches and the inductor is thus kept to a minimum, minimizing switching and conduction losses. Controlling the switches this way lets the converter achieve high efficiency over the whole input voltage range.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Control Scheme

The device automatically selects the best switching scheme for the operating conditions. To make sure of stable operation, the selection logic includes hysteresis (see [Figure 3](#)).

Figure 3. Switching Scheme Selection

Feature Description (continued)

8.3.1.1 Buck Operation

When $V_I > V_O$, the device switches like a buck converter:

- Q1 is the switch.
- Q2 is the rectifier.
- Q3 is permanently off.
- Q4 is permanently on.

See [Figure 4](#). During buck operation, one switching cycle comprises two phases: on–off.

Figure 4. Buck Switch Configuration

8.3.1.2 Boost Operation

When $V_I < V_O$, the device switches like a boost converter:

- Q1 is permanently on.
- Q2 is permanently off.
- Q3 is the switch.
- Q4 is the rectifier.

See [Figure 5](#). During boost operation, one switching cycle comprises two phases: on–off.

Figure 5. Boost Switch Configuration

8.3.1.3 Buck-Boost Operation

When $V_I \approx V_O$, all four transistors switch continuously (see [Figure 6](#)). During buck-boost operation, one switching cycle comprises four phases: on–commutate–off–commutate.

Feature Description (continued)

图 6. Buck-Boost Switch Configuration

8.3.2 Control Scheme

The device uses a constant off-time, peak-current-mode control scheme where an outer voltage control loop generates the demand signal for an inner current control loop. During the on-time, the inner current control loop monitors the inductor current, and when the inductor current equals the demand signal from the error amplifier, the on-time stops and the next part of the switching cycle starts.

The off-time is a function of V_I and V_O and the operating mode (buck, boost, or buck-boost) of the converter.

Feature Description (continued)

Figure 9. Peak Current Control – Buck-Boost Operation with $V_1 > V_O$

Figure 10. Peak Current Control – Buck-Boost Operation with $V_1 = V_O$

During PWM operation, current can flow in the reverse direction (from output to input). In this case, the error amplifier provides a negative peak current target. Note that the average reverse current is greater (more negative) than the peak current (see [Figure 11](#) and [Figure 12](#)).

Figure 11. Reverse Peak Current Control – Buck and Boost Operation

Feature Description (continued)

⊠ 12. Reverse Peak Current Control – Buck-Boost Operation, with $V_1 > V_O$

8.3.3 Power-Save Mode Operation (PSM)

To increase efficiency across a wide range of operating conditions, the device automatically changes from pulse-width modulation (PWM) at medium and high output currents to pulse-frequency modulation (PFM) at low output currents.

- During PWM operation, the device switches continuously and adjusts the duty cycle of each switching cycle to regulate the output voltage.
- During PFM operation, the device switches in bursts of a few switching cycles, separated by periods when the device does not switch (see ⊠ 13). PFM operation increases efficiency at low output currents because when the device does not switch, there are no switching losses and most of the internal circuitry is disabled, which reduces quiescent power consumption. A comparator with hysteresis compares the output voltage of the error amplifier to a predefined PFM threshold voltage. When the output voltage of the error amplifier is greater than the burst threshold voltage, the device starts switching. When the output voltage of the error amplifier is less than the burst threshold voltage, the device stops switching. This scheme automatically adjusts the frequency and the duration of the switching bursts to regulate the output voltage. During PFM operation, the output voltage ripple can be higher and the transient response is not as good as during PWM operation (see 表 1).

To enable power-save mode, clear the FPWM bit in the Control register to 0.

⊠ 13. Pulse-Frequency Modulation

表 1. Forced-PWM versus Power-Save Mode Performance Comparison

PERFORMANCE PARAMETER	BEST OPERATING MODE
Low-power efficiency	Power-Save Mode (PSM)
Medium- and high-power efficiency	No difference
DC Output voltage accuracy	Forced-PWM
Transient response	Forced-PWM
Output voltage ripple	Forced-PWM

8.3.4 Forced-PWM Operation (FPWM)

During forced-PWM operation, the device uses PWM for all operating conditions. Forced-PWM operation has lower output voltage ripple and better transient response than power-save mode operation, but lower efficiency at low output currents (see 表 1).

Note that the device inhibits forced-PWM operation during start-up (that is, until the converter output has reached power-good for the first time).

To enable forced-PWM operation, set the FPWM bit in the Control register to 1.

8.3.5 Ramp-PWM Operation (RPWM)

If Ramp-PWM operation is enabled, the device operates in forced-PWM when it ramps from one output voltage to another during dynamic voltage scaling. This function is useful if you want the device to operate in power-save mode, but you want to make sure that dynamic voltage scaling ramps the output voltage up and down in a controlled way. If the device operates in power-save mode and Ramp-PWM is disabled, the device cannot always control the ramp from a higher output voltage to a lower output voltage, because in power-save mode the device cannot sink current (see 图 14).

To enable Ramp-PWM operation, set the RAMP bit in the Control register to 1. To disable Ramp-PWM operation, clear the RAMP bit in the Control register to 0.

图 14. Ramp-PWM Operation

8.3.6 Device Enable (EN)

The EN pin enables and disables the device.

- When the EN pin is high, the device is enabled.
- When the EN pin is low, the device is disabled.

You can also use the ENABLE bit in the Control register to enable and disable the output of the converter (see the Register Map).

表 2. Device Enable Truth Table

ENABLE PIN (EN)	ENABLE BIT	DEVICE STATE	OUTPUT STATE
0	X	Device in Shutdown	Output Discharge Active
1	0	Programming Interface Active	Output Discharge Active
1	1	Device Active	Output Enabled

8.3.7 Undervoltage Lockout (UVLO)

The device has an undervoltage lockout function that disables the device when the supply voltage is too low for correct operation.

8.3.8 Soft Start

To minimize inrush current and output voltage overshoot during start-up, the device has a soft-start function. At turn on, the switch current limit ramps gradually to its maximum value and the device starts up in a controlled way. The gradual increase of the current limit generates the smallest inrush current for no-load conditions. It is also possible to start into a high load as long as the load does not exceed the device current limit.

The rise time of the output voltage changes with the application circuit and the operating conditions. The output voltage rise time increases if the following occurs:

- The output capacitance is large.
- The load current is large.
- The device operates in boost mode.

See the [Application and Implementation](#) section for output voltage rise times in a typical application.

⊠ 15. Device Start-Up

8.3.9 Output Voltage Control

The device can generate output voltages from 1.8 V to 5.2 V with a resolution of 25 mV. To set the output voltage, you must first program the RANGE bit in the Control register to select the output voltage range:

- When RANGE = 0, you can program the output voltage from 1.8 V to 4.975 V.
- When RANGE = 1, you can program the output voltage from 2.025 V to 5.2 V.

When you have selected the output voltage range, you can program the VOUT1 register and VOUT2 register to set the output voltage:

- When RANGE = 0, $V_O = (VOUT[6:0] \times 0.025) + 1.8$ V
- When RANGE = 1, $V_O = (VOUT[6:0] \times 0.025) + 2.025$ V

VOUT[6:0] is the 7-bit value in the VOUT1 register or VOUT2 register, whichever is active.

The VSEL pin selects which VOUT register is active:

- When VSEL = low, the VOUT1 register sets the output voltage.
- When VSEL = high, the VOUT2 register sets the output voltage.

注

To prevent output voltage transients, TI recommends that you do not change the output voltage range while the converter is in operation. Instead, clear the ENABLE bit in the Control register to 0 to disable the DC/DC converter before you change the RANGE bit.

8.3.9.1 Dynamic Voltage Scaling

The device has a dynamic voltage scaling (DVS) function which lets you change the output voltage in a controlled way during operation. Figure 16 shows a simplified block diagram of the DVS function. The VSEL pin controls a multiplexer which selects either the VOUT1 register or the VOUT2 register to control the set voltage. The ramp control block detects when the target output voltage is different from the actual output voltage and ramps the output voltage to the target voltage in 25-mV steps. You can use the 2-bit SLEW parameter in the Control register to select one of four slew rates from 0.5 V/ms to 10 V/ms.

The device starts a DVS ramp when you change the logic level on the VSEL pin or program to a new value in the active VOUT register.

Figure 16. Dynamic Voltage Scaling Block Diagram

Note that if you change the contents of the active VOUT register or change the state of the VSEL pin during start-up (that is, before the end of the soft start), the converter uses the new value immediately and does not ramp gradually to the final value.

Figure 17 shows the timing diagram when you use the VSEL pin to change between the output voltage values in the VOUT1 and VOUT2 registers.

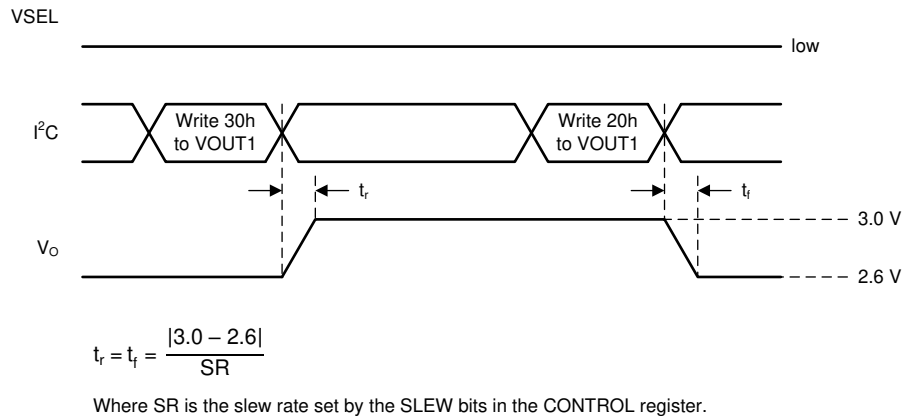

$$t_r = t_f = \frac{|V_{O(1)} - V_{O(2)}|}{SR}$$

Where

- $V_{O(1)}$ is the output voltage set by the VOUT1 register
- $V_{O(2)}$ is the output voltage set by the VOUT2 register
- SR is the slew rate set by the SLEW bits in the CONTROL register

Figure 17. DVS Timing Diagram Using the VSEL Pin

8.3.10 Protection Functions

8.3.10.1 Input Voltage Protection (IVP)

Under certain operating conditions, current can flow from the output of the device to the input. For example, this can occur during dynamic voltage scaling when the output ramps down to a lower voltage and the VOUT pin sinks current from the output capacitor. Under such conditions, if the voltage source supplying the device cannot sink current, the voltage on the VIN pin can rise uncontrollably.

To make sure the input voltage stays within the permitted range, the device stops switching if the voltage on the VIN pin is greater than 5.7 V. The device automatically starts to switch again when the voltage on the VIN pin is less than 5.7 V.

The device sets the \overline{PG} bit in the Status register when an input overvoltage event occurs. The device clears the \overline{PG} bit if the Status register is read when the power-not-good condition no longer exists.

8.3.10.2 Current Limit Mode and Overcurrent Protection

The device has a clamp circuit which limits the peak inductor current in the event of an overload. The exact value of the output current during an overload changes with the operating conditions (V_I and V_O) and the switching mode (buck, buck-boost, or boost) – see [FIG 52](#).

Overloads increase the power dissipation in the device, which increases its temperature. If the device becomes too hot, the thermal shutdown function turns off the converter. When the device cools down, the thermal shutdown function automatically turns on the converter again. Thus, under a permanent overload condition, the device can periodically turn on and off, as it cools down and then heats up.

8.3.10.3 Thermal Shutdown

The device has a thermal shutdown function which turns off the converter if the junction temperature is greater than 150°C. The device automatically turns on the converter again when the junction temperature is less than 130°C. You can still use the I²C interface to read and write to the registers when the device is in an overtemperature condition.

When the device detects an overtemperature condition, it sets the TSD bit in the Status register to 1. The device clears the TSD bit to 0 if you read the Status register when the junction temperature of the device is less than 130°C.

8.3.11 Power Good

The device has a power-good function which indicates if the output of the DC/DC converter is in regulation or not. The device detects a power-good condition when the output voltage is greater than 95% of its nominal value and detects a power-not-good condition when the output voltage is less than 90% of its nominal value.

When a power-not-good condition occurs, the device sets the \overline{PG} bit in the Status register to 1. The device clears the \overline{PG} bit to 0 if you read the Status register when a power-good condition exists.

8.3.12 Load Disconnect

During device shutdown, the input is disconnected from the output. This prevents any current flow from the output to the input or from the input to the output.

8.3.13 Output Discharge

The device actively discharges the output when the EN pin is low or the ENABLE bit is set to zero.

8.4 Device Functional Modes

The device has two functional modes: off and on. The device enters the on mode when the voltage on the VIN pin is higher than the UVLO threshold and a high logic level is applied to the EN pin. The device enters the off mode when the voltage on the VIN pin is lower than the UVLO threshold or a low logic level is applied to the EN pin.

8.5 Programming

8.5.1 Serial Interface Description

I²C is a 2-wire serial interface developed by Philips Semiconductor, now NXP Semiconductors (see [NXP Semiconductors, UM10204 – I²C-Bus Specification and User Manual](#)). The bus consists of a data line (SDA) and a clock line (SCL) with pullup structures. When the bus is idle, both SDA and SCL lines are pulled high. All the I²C-compatible devices connect to the I²C bus through open-drain I/O pins, SDA, and SCL. A master device, usually a microcontroller or a digital signal processor, controls the bus. The master is responsible for generating the SCL signal and device addresses. The master also generates specific conditions that indicate the START and STOP of data transfer. A slave device receives and transmits data on the bus under control of the master device.

The device works as a slave and supports the following data transfer modes, as defined in the I²C-Bus Specification:

- Standard-mode (100 kbps)
- Fast-mode (400 kbps)
- Fast-mode Plus (1 Mbps)

The interface adds flexibility to the power supply solution, enabling most functions to be programmed to new values, depending on the instantaneous application requirements. Register contents remain intact as long as supply voltage remains above 2.1 V.

The data transfer protocol for standard and fast modes is exactly the same, therefore, it is referred to as F/S-mode in this document. The device supports 7-bit addressing; 10-bit addressing and general call address are not supported. The device 7-bit address is 75h (1110101b).

To make sure that the I²C function in the device is correctly reset, it is recommended that the I²C master initiates a STOP condition on the I²C bus after the initial power up of SDA and SCL pullup voltages.

Programming (continued)

8.5.2 Standard-, Fast-, and Fast-Mode Plus Protocol

The master initiates a data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in [Figure 20](#). All I²C-compatible devices recognize a start condition.

Figure 20. START and STOP Conditions

The master then generates the SCL pulses and transmits the 7-bit address and the read/write direction bit, R/W, on the SDA line. During all transmissions, the master ensures that data is valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse (see [Figure 21](#)). All devices recognize the address sent by the master and compare it to their internal fixed addresses. Only the slave device with a matching address generates an acknowledge (see [Figure 22](#)) by pulling the SDA line low during the entire high period of the ninth SCL cycle. Upon detecting this acknowledge, the master knows that communication link with a slave has been established.

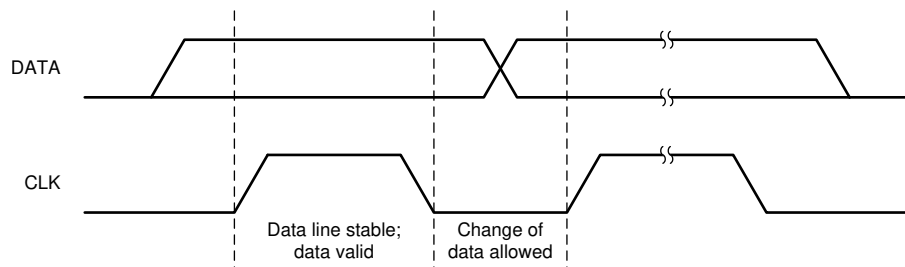

Figure 21. Bit Transfer on the Serial Interface

The master generates further SCL cycles to either transmit data to the slave (R/W bit 1) or receive data from the slave (R/W bit 0). In either case, the receiver needs to acknowledge the data sent by the transmitter. An acknowledge signal can either be generated by the master or by the slave, depending on which one is the receiver. 9-bit valid data sequences consisting of 8-bit data and 1-bit acknowledge can continue as long as necessary.

To signal the end of the data transfer, the master generates a stop condition by pulling the SDA line from low to high while the SCL line is high (see [Figure 20](#)). This releases the bus and stops the communication link with the addressed slave. All I²C-compatible devices must recognize the stop condition. Upon the receipt of a stop condition, all devices know that the bus is released and they wait for a start condition followed by a matching address.

Attempting to read data from register addresses not listed in this section results in 00h being read out.

Programming (continued)

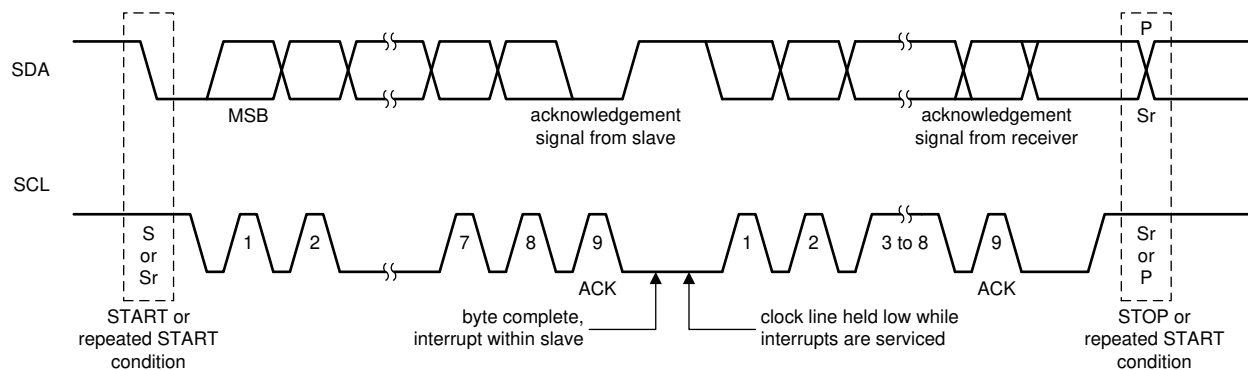

Figure 23. Bus Protocol

8.5.3 I²C Update Sequence

A single update requires the following:

- A start condition
- A valid I²C slave address
- A register address
- A data byte

To acknowledge the receipt of each byte, the device pulls the SDA line low during the high period of a single clock pulse. The device performs an update on the falling edge of the acknowledge signal that follows the last byte.

9 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The TPS63810 and TPS63811 devices are high efficiency, high current buck-boost converters, suitable for applications where the input voltage is higher, lower, or equal to the output voltage. The maximum peak current in the switches is limited to a typical value of 6 A.

9.2 Typical Applications

9.2.1 1.8-V to 5.2-V Output Smartphone Power Supply

图 31. Typical Application Schematic

9.2.1.1 Design Requirements

This example uses the design parameters listed in 表 8.

表 8. Design Parameters

DESIGN PARAMETER	SYMBOL	EXAMPLE VALUE
Input voltage	V_I	2.5 V to 4.8 V
Output voltage	V_O	1.8 V to 5.2 V
Output current	I_O	2 A
I ² C bus voltage	V_{BUS}	3.3 V
I ² C bus capacitance	C_b	100 pF
I ² C bus speed		Fast-mode (400 kHz)

9.2.1.2 Detailed Design Procedure

9.2.1.2.1 Input Capacitor Selection

TI recommends a minimum input capacitance (including DC bias effects) of 5 μF . A 10- μF , 10-V ceramic capacitor is suitable for typical applications. If the input supply is located more than a few centimeters from the converter, you may need to add additional bulk capacitance (a 47- μF electrolytic or tantalum capacitor is a typical choice).

The output capacitance does not have an upper limit; you can make it as big as you want.

9.2.1.2.2 Inductor Selection

TI recommends you use the TPS63810 device with 0.47- μH inductors. For high efficiencies, use an inductor with a low DC resistance (DCR) and low core losses.

The saturation current of the inductor must be greater than the maximum inductor current in your application. To include sufficient margin for worst-case and transient operating conditions, TI recommends you use an inductor with saturation current that is at least 20% higher than the maximum inductor current in your application. The maximum current in the inductor occurs when the device operates in boost mode and the following is true:

- The input voltage is at its minimum value.
- The output voltage is at its maximum value.
- The output current is at its maximum value.

To calculate the maximum inductor current, first use [式 1](#) to calculate the maximum duty cycle during boost operation (which is when the maximum inductor current occurs).

$$D = \frac{V_O - V_I}{V_O}$$

where

- D is the duty cycle
- V_I is the input voltage
- V_O is the output voltage

(1)

$$D = \frac{5\text{ V} - 2.5\text{ V}}{5\text{ V}} = 0.5$$

Next, use [式 2](#) to calculate the maximum inductor current.

$$I_{LM} = \frac{I_O}{\eta(1-D)} + \frac{DV_I}{2fL}$$

where

- I_{LM} is the peak inductor current
- I_O is the output current
- η is the converter efficiency (use the value from the application curves or assume 90%)
- D is the duty cycle (calculated with [式 1](#))
- V_I is the input voltage
- f is the switching frequency (assume 2 MHz)
- L is the inductance (use 0.47 μH)

(2)

$$I_{LM} = \frac{2\text{ A}}{(0.9)(1-0.5)} + \frac{(0.5)(2.5\text{ V})}{(2)(2\text{ MHz})(0.47\text{ }\mu\text{H})} = 5.1\text{ A}$$

To include enough margin for transient conditions, TI recommends you use an inductor with a saturation current rating at least 20% higher than the calculated maximum current. In this example, TI recommends an inductor with a saturation current of at least 6.1 A.

9.2.1.2.3 Output Capacitor Selection

TI recommends a minimum output capacitance (including DC bias effects) of 16 μF . Two 22- μF , 10-V ceramic capacitors are suitable for typical applications with $V_O \leq 3.6\text{ V}$. For $V_O > 3.6\text{ V}$, three 22- μF or two 47- μF ceramic capacitors are suitable. If you want to minimize switching noise on the output, connect a small ceramic capacitor (100 nF is a typical value) in parallel to the two main output capacitors and place it closest to the VOUT pin. Smaller capacitors have lower parasitic inductance and are more effective at filtering high frequencies than the two main output capacitors.

The output capacitance does not have an upper limit, however, very large values of output capacitance make the transient response of the converter slower.

It is important that the effective capacitance is given according to the recommended value in [Recommended Operating Conditions](#). In general, consider DC bias effects resulting in less effective capacitance. The choice of the output capacitance is mainly a trade-off between size and transient behavior as higher capacitance reduces transient response overshoot and undershoot and increases transient response time. [表 9](#) lists possible output capacitors.

9.2.1.2.4 I²C Pullup Resistor Selection

Refer to the [NXP Semiconductors, UM10204 – I²C-Bus Specification and User Manual](#) for the specifications relevant to your application.

Use [式 3](#) to calculate the maximum permitted pullup resistor value for the bus speed used in the application.

$$R_P(\text{max}) = \frac{t_r}{0.8473 \times C_b}$$

where

- t_r is the maximum permitted rise time (300 ns for Fast-mode)
 - C_b is the capacitive load on each bus line
- (3)

$$R_P(\text{max}) = \frac{300\text{ ns}}{0.8473 \times 100\text{ pF}} = 3.541\text{ k}\Omega$$

If you do not know what the bus capacitance is in your application, start with a 1-k Ω pullup resistor and measure the rise time with an oscilloscope. Use [式 3](#) to calculate the bus capacitance and thus the maximum permitted pullup resistor.

Use [式 4](#) to calculate the minimum permitted pullup resistor value for different bus speeds.

$$R_P(\text{min}) = \frac{V_{\text{BUS}} - V_{\text{OL}}}{I_{\text{OL}}}$$

where

- V_{BUS} is the I²C bus pullup voltage
 - V_{OL} is the low-level output voltage (0.4 V)
 - I_{OL} is the low-level output current (3 mA for Fast-mode)
- (4)

$$R_{\text{P}}(\text{min}) = \frac{3.3 \text{ V} - 0.4 \text{ V}}{3 \text{ mA}} = 967 \Omega$$

A pullup resistor value of 3.3 k Ω meets both of these requirements.

10 Power Supply Recommendations

The device is designed to operate with a DC supply voltage in the range 2.2 V to 5.5 V. If the input supply is more than a few centimeters from the device, TI recommends adding some bulk capacitance to the ceramic bypass capacitors. A 47- μ F electrolytic capacitor is a typical selection for the bulk capacitance.

11 Layout

11.1 Layout Guidelines

Correct PCB layout is necessary to obtain the full performance from the device. TI recommends to follow these basic principles:

- Place input and output capacitors close to the device to minimize the input and output loop areas.
- If you combine different-sized capacitors to make up the total input capacitance, place the smallest capacitor closest to the device. The same applies to the output capacitance.
- Keep PCB traces short and wide to minimize parasitic resistance and inductance.
- Use the following PCB layer stack (or something similar):
 - Layer 1 (top): All components and all power traces
 - Layer 2 (inner): Signals
 - Layer 3 (inner): Signals
 - Layer 4 (bottom): Ground plane

Figure 56 shows an example of the PCB layout used for all of the measurement data in [Application Curves](#).

13 メカニカル、パッケージ、および注文情報

以降のページには、メカニカル、パッケージ、および注文に関する情報が記載されています。この情報は、そのデバイスについて利用可能な最新のデータです。このデータは予告なく変更されることがあり、ドキュメントが改訂される場合もあります。本データシートのブラウザ版を使用されている場合は、画面左側の説明をご覧ください。

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
