UCC23513-Q1 4A ソース、5A シンク、5.7kV$_{RMS}$ 強化絶縁、フォトカプラ互換、シングル・チャネル絶縁型ゲート・ドライバ

1 特長

- 車載アプリケーション向けに AEC-Q100 認証済み
- フォトカプラ互換入力付きの 5.7kV$_{RMS}$ シングル・チャネル絶縁型ゲート・ドライバ
- 光絶縁型ゲート・ドライバに対して、ピン互換でドロップイン・アップグレード可能
- 4.5A ソース / 5.3A シンクのピーク出力電流
- 最大 33V の出力ドライバ電源電圧
- 8V (B) または 12V の VCC UVLO を選択可能
- レール・ツー・レール出力
- 伝搬遅延時間:105ns 以下
- 部品間遅延ばらつき:25ns 以下
- パルス幅歪み:35ns 以下
- 同相過渡耐性 (CMTI):150kV/µs 以上
- 絶縁バリアの寿命:50 年超
- 入力段で 13V の逆極性電圧を扱えるためインターロックをサポート可能
- 沿面距離と空間距離が 8.5mm を超える、ストレッチ SO-6 パッケージ
- 動作時の接合部温度、T_J:–40℃～+150℃
- 機能安全対応
  - 機能安全システムの設計に役立つ資料を利用可能
- 安全関連の認定
  - DIN V VDE V0884-11: 2017-01 に準拠した強化絶縁耐圧:8000V$_{PK}$ (進行中)
  - UL 1577 に準拠した絶縁耐圧:5.7kV$_{RMS}$ (1 分間)

2 アプリケーション

- EV 用トラクション・インバータ
- オンボード充電器および DC 充電ステーション
- HVAC (エアコン)
- 暖房器具
- 産業用モータ制御ドライブ

3 概要

UCC23513-Q1 ドライバは、IGBT、MOSFET、SiC MOSFET 用の、フォトカプラ互換、シングル・チャネル絶縁型ゲート・ドライバです。ソース 4.5A、シンク 5.3A のピーク電流を出力でき、5.7kV$_{RMS}$ の 絶縁定格を持っています。電源電圧範囲が 33V と高いため、バイポーラ電源を使用して IGBT および SiC パワー FET を効果的に駆動できます。UCC23513-Q1 は、ローサイドとハイサイドの両方のパワー FET を駆動でき、フォトカプラ・ベースのゲート・ドライバに比べて性能と信頼性を大幅に向上させると同時に、回路設計とレイアウト設計の両方でピン互換性を維持しています。同相過渡耐性 (CMTI) が高く、伝搬遅延時間が短く、パルス幅歪みが小さいという特長があります。厳密なプロセス制御により、部品間スキューも小さくなっています。入力段はダイオード・エミュレーション (e-diode) であり、フォトカプラ・ゲート・ドライバで使われている従来型 LED に比べて、長期的な信頼性と優れた経時特性を実現します。高性能でありかつ信頼性が高いため、トラクション・インバータ、オンボード・チャージャ、DC 充電ステーション、車載 HVAC、暖房システムなど、車載用モータ駆動に理想的です。高い温度で動作するため、従来のフォトカプラでは対応できなかったアプリケーションで活用する機会が広がります。

5 Pin Configuration and Function

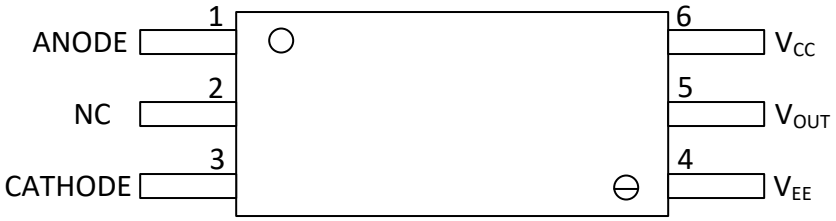

図 5-1. UCC23513-Q1 Package SO-6 Top View

Pin Functions

PIN		TYPE(1)	DESCRIPTION
NAME	NO.		
ANODE	1	I	Anode
CATHODE	3	I	Cathode
NC	2	-	No Connection
V_{CC}	6	P	Positive output supply rail
V_{EE}	4	P	Negative output supply rail
V_{OUT}	5	O	Gate-drive output

(1) P = Power, G = Ground, I = Input, O = Output

6 Specifications

6.1 Absolute Maximum Ratings

Over operating free air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
Average Input Current	$I_{F(AVG)}$	-	25	mA
Peak Transient Input Current	$I_{F(TRAN)}$ <1us pulse, 300pps		1	A
Reverse Input Voltage	$V_{R(MAX)}$		14	V
Output supply voltage	$V_{CC} – V_{EE}$	-0.3	35	V
Output signal voltage	$V_{OUT} – V_{CC}$		0.3	V
Output signal voltage	$V_{OUT} – V_{EE}$	-0.3		V
Junction temperature	T_J (2)	-40	150	°C
Storage temperature	T_{stg}	-65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) To maintain the recommended operating conditions for T_J, see the *Thermal Information Section*.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002(1)	±4000	V
		Charged-device model (CDM), per AEC Q100-011	±1500	

(1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

Over operating free-air temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
V_{CC}	Output Supply Voltage ($V_{CC} – V_{EE}$)	UCC23513-Q1 (12-V UVLO Version)	14		33	V
		UCC23513B-Q1 (8-V UVLO Version)	10		33	V
I_F (ON)	Input Diode Forward Current (Diode "ON")		7		16	mA
V_F (OFF)	Anode voltage - Cathode voltage (Diode "OFF")		-13		0.9	V
T_J	Junction temperature		-40		150	°C
T_A	Ambient temperature		-40		125	°C

6.4 Thermal Information

THERMAL METRIC(1)		UCC23513-Q1 SO6 6 Pins	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	126	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	66.1	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	62.8	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	29.6	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	60.8	°C/W

(1) For more information about traditional and new thermal metrics, see the http://www.ti.com/lit/SPRA953 application report.

6.5 Power Ratings

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
P_D	Maximum power dissipation on input and output(1)	V_{CC} = 20 V, I_F= 10mA 10-kHz, 50% duty cycle, square wave,180-nF load, T_A=25°C			750	mW
P_{D1}	Maximum input power dissipation(2)				10	mW
P_{D2}	Maximum output power dissipation				740	mW

(1) Derate at 6 mW/°C beyond 25°C ambient temperature
(2) Recommended maximum P_{D1} = 40mW. Absolute maximum P_{D1} = 55mW

6.6 Insulation Specifications

PARAMETER		TEST CONDITIONS	SPECIFICATION	UNIT
CLR	External clearance(1)	Shortest terminal-to-terminal distance through air	>8.5	mm
CPG	External Creepage(1)	Shortest terminal-to-terminal distance across the package surface	>8.5	mm
DTI	Distance through the insulation	Minimum internal gap (internal clearance)	>17	µm
CTI	Comparative tracking index	DIN EN 60112 (VDE 0303-11); IEC 60112	>600	V
	Material Group	According to IEC 60664-1	I

V_{ISO}	Withstand isolation voltage	$V_{TEST} = V_{ISO} = 5700\ V_{RMS}$, t = 60 s (qualification), $V_{TEST} = 1.2 \times V_{ISO} = 6840\ V_{RMS}$, t = 1 s (100% production)	5700	V_{RMS}

(1) Creepage and clearance requirements should be applied according to the specific equipment isolation standards of an application. Care should be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed-circuit board do not reduce this distance. Creepage and clearance on a printed-circuit board become equal in certain cases. Techniques such as inserting grooves, ribs, or both on a printed-circuit board are used to help increase these specifications.
(2) This coupler is suitable for *safe electrical insulation* only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
(3) Testing is carried out in air or oil to determine the intrinsic surge immunity of the isolation barrier.
(4) Apparent charge is electrical discharge caused by a partial discharge (pd).
(5) All pins on each side of the barrier tied together creating a two-pin device.

6.8 Safety Limiting Values

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_S	Safety input, output, or supply current	R_{qJA} = 126°C/W, V_I = 15 V, T_J = 150°C, T_A = 25°C			50	mA
		R_{qJA} = 126°C/W, V_I = 30 V, T_J = 150°C, T_A = 25°C			25	
P_S	Safety input, output, or total power	R_{qJA} = 126°C/W, T_J = 150°C, T_A = 25°C			750	mW
T_S	Maximum safety temperature(1)				150	°C

(1) The maximum safety temperature, T_S, has the same value as the maximum junction temperature, T_J , specified for the device. The I_S and P_S parameters represent the safety current and safety power respectively. The maximum limits of I_S and P_S should not be exceeded. These limits vary with the ambient temperature, T_A. The junction-to-air thermal resistance, R_{qJA}, in the Thermal Information table is that of a device installed on a high-K test board for leaded surface-mount packages. Use these equations to calculate the value for each parameter: $T_J = T_A + R_{qJA} \times P$, where P is the power dissipated in the device. $T_{J(max)} = T_S = T_A + R_{qJA} \times P_S$, where $T_{J(max)}$ is the maximum allowed junction temperature. $P_S = I_S \times V_I$, where VI is the maximum supply voltage.

6.9 Electrical Characteristics

Unless otherwise noted, all typical values are at T_A = 25°C, V_{CC}–V_{EE}= 15V, V_{EE}= GND. All min and max specifications are at recommended operating conditions (T_J = -40C to 150°C, $I_{F(on)}$= 7 mA to 16 mA, V_{EE}= GND, V_{CC}= 15 V to 30 V, $V_{F(off)}$= –5V to 0.8V)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
INPUT						
I_{FLH}	Input Forward Threshold Current Low to High	V_{OUT} > 5 V, Cg = 1 nF	1.5	2.8	4	mA
V_F	Input Forward Voltage	I_F =10 mA	1.8	2.1	2.4	V

$UVLO_R$	Under Voltage Lockout VCC rising	V_{CC_Rising}, I_F=10 mA	7.8	8.5	9.2	V
$UVLO_F$	Under Voltage Lockout VCC falling	$V_{CC\_Falling}$, I_F=10 mA	7.05	7.75	8.45	V
$UVLO_{HYS}$	UVLO Hysteresis			0.75		V

6.10 Switching Characteristics

Unless otherwise noted, all typical values are at T_A = 25°C, V_{CC}-V_{EE}= 30 V, V_{EE}= GND. All min and max specifications are at recommended operating conditions (T_J = -40 to 150°C, $I_{F(ON)}$= 7 mA to 16 mA, V_{EE}= GND, V_{CC}= 15 V to 30 V, $V_{F(OFF)}$= –5V to 0.8V)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
t_r	Output-signal Rise Time	Cg = 1nF F_{SW} = 20 kHz, (50% Duty Cycle) VCC=15V			28	ns
t_f	Output-signal Fall Time				25	ns
t_{PLH}	Propagation Delay, Low to High			70	105	ns
t_{PHL}	Propagation Delay, High to Low			70	105	ns
t_{PWD}	Pulse Width Distortion $\lvert t_{PHL} - t_{PLH} \rvert$				35	ns
$t_{sk(pp)}$	Part-to-Part Skew in Propagation Delay Between any Two Parts(1)	Cg = 1nF F_{SW} = 20 kHz, (50% Duty Cycle) VCC=15V, I_F=10mA			25	ns
t_{UVLO_rec}	UVLO Recovery Delay	V_{CC} Rising from 0V to 15V		20	30	µs
$CMTI_H$	Common-mode Transient Immunity (Output High)	I_F = 10 mA, V_{CM} = 1500 V, V_{CC}= 30 V, T_A= 25°C	150			kV/µs
$CMTI_L$	Common-mode Transient Immunity (Output Low)	V_F = 0 V, V_{CM} = 1500 V, V_{CC}= 30 V, T_A= 25°C	150			kV/µs

(1) $t_{sk(pp)}$ is the magnitude of the difference in propagation delay times between the output of different devices switching in the same direction while operating at identical supply voltages, temperature, input signals and loads ensured by characterization.

7 Parameter Measurement Information

7.1 Propagation Delay, Rise Time and Fall Time

図 7-1 shows the propagation delay from the input forward current I_F, to V_{OUT}. This figures also shows the circuit used to measure the rise (t_r) and fall (t_f) times and the propagation delays t_{PDLH} and t_{PDHL}.

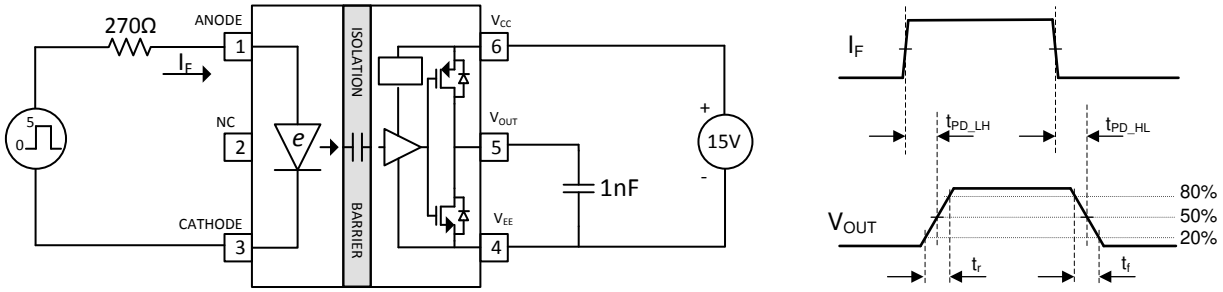

図 7-1. I_F to V_{OUT} Propagation Delay, Rise Time and Fall Time

7.2 I_{OH} and I_{OL} testing

図 7-2 shows the circuit used to measure the output drive currents I_{OH} and I_{OL}. A load capacitance of 180nF is used at the output. The peak dv/dt of the capacitor voltage is measured in order to determine the peak source and sink currents of the gate driver.

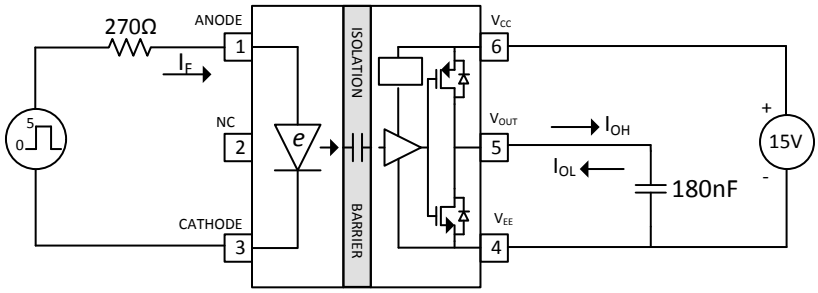

図 7-2. I_{OH} and I_{OL}

7.3 CMTI Testing

図 7-3 is the simplified diagram of the CMTI testing. Common mode voltage is set to 1500V. The test is performed with I_F = 6mA (VOUT= High) and I_F = 0mA (V_{OUT} = LOW). The diagram also shows the fail criteria for both cases. During the application on the CMTI pulse with I_F = 6mA, if V_{OUT} drops from VCC to ½VCC it is considered as a failure. With I_F= 0mA, if V_{OUT} rises above 1V, it is considered as a failure.

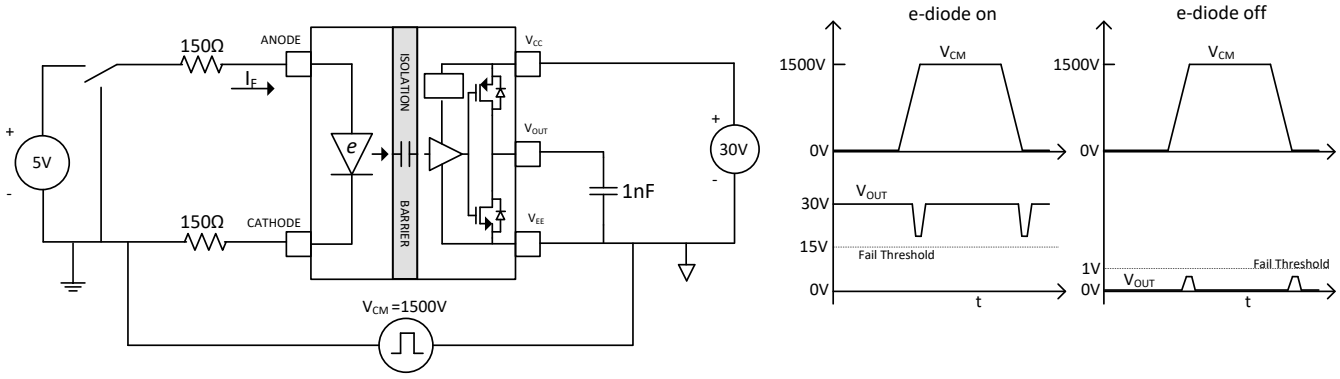

図 7-3. CMTI Test Circuit for UCC23513

8 Detailed Description

8.1 Overview

UCC23513-Q1 is a single channel isolated gate driver, with an opto-compatible input stage, that can drive IGBTs, MOSFETs and SiC FETs. It has 4A peak output current capability with max output driver supply voltage of 33V. The inputs and the outputs are galvanically isolated. UCC23513-Q1 is offered in an industry standard 6 pin (SO6) package with >8.5mm creepage and clearance. It has a working voltage of 1500-V_{RMS}, reinforced isolation rating of 5.7-kV_{RMS} for 60s and a surge rating of 8-kV_{PK}. It is pin-to-pin compatible with standard opto isolated gate drivers. While standard opto isolated gate drivers use an LED as the input stage, UCC23513-Q1uses an emulated diode (or "e-diode") as the input stage which does not use light emission to transmit signals across the isolation barrier. The input stage is isolated from the driver stage by dual, series HV SiO_2 capacitors in full differential configuration that not only provides reinforced isolation but also offers best-in-class common mode transient immunity of > 150 kV/us. The e-diode input stage along with capacitive isolation technology gives UCC23513-Q1 several performance advantages over standard opto isolated gate drivers. They are as follows:

1. Since the e-diode does not use light emission for its operation, the reliability and aging characteristics of UCC23513-Q1 are naturally superior to those of standard opto isolated gate drivers.
2. Higher ambient operating temperature range of 125°C, compared to only 105°C for most opto isolated gate drivers
3. The e-diode forward voltage drop has less part-to-part variation and smaller variation across temperature. Hence, the operating point of the input stage is more stable and predictable across different parts and operating temperature.
4. Higher common mode transient immunity than opto isolated gate drivers
5. Smaller propagation delay than opto isolated gate drivers
6. Due to superior process controls achievable in capacitive isolation compared to opto isolation, there is less part-to-part skew in the prop delay, making the system design simpler and more robust
7. Smaller pulse width distortion than opto isolated gate drivers

The signal across the isolation has an on-off keying (OOK) modulation scheme to transmit the digital data across a silicon dioxide based isolation barrier (see 図 8-1). The transmitter sends a high-frequency carrier across the barrier to represent one digital state and sends no signal to represent the other digital state. The receiver demodulates the signal after advanced signal conditioning and produces the output through a buffer stage. The UCC23513-Q1 also incorporates advanced circuit techniques to maximize the CMTI performance and minimize the radiated emissions from the high frequency carrier and IO buffer switching. 図 8-2 shows conceptual detail of how the OOK scheme works.

8.2 Functional Block Diagram

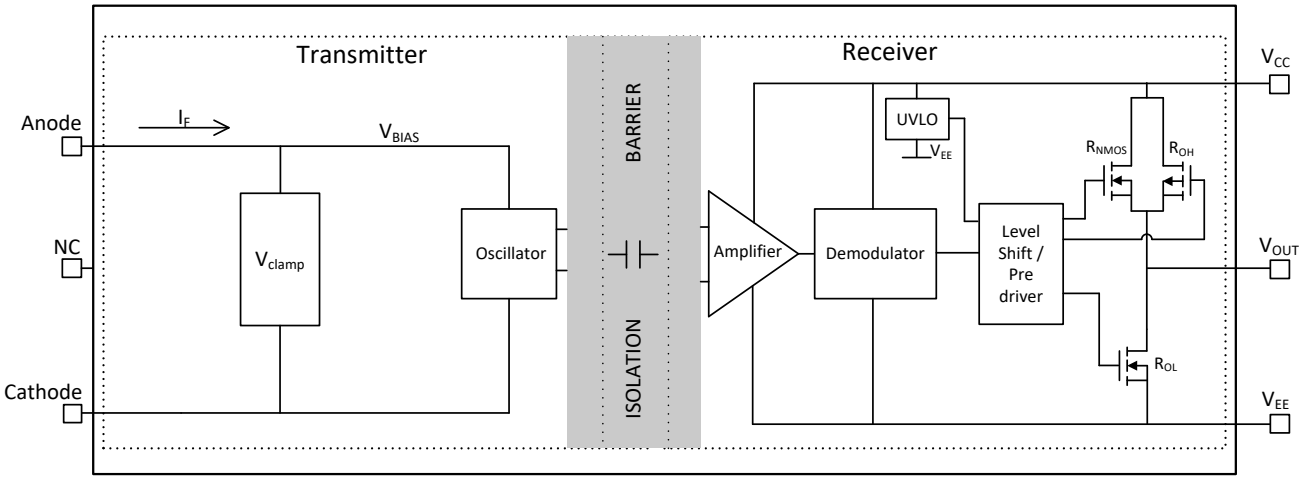

図 8-1. Conceptual Block Diagram of a Isolated Gate Driver with an Opto Emulated Input Stage (SO6 pkg)

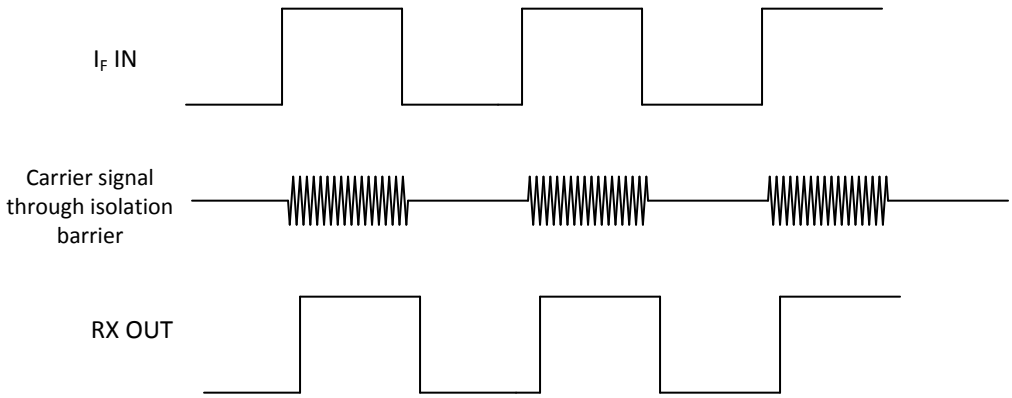

図 8-2. On-Off Keying (OOK) Based Modulation Scheme

8.3 Feature Description

8.3.1 Power Supply

Since the input stage is an emulated diode, no power supply is needed at the input.

The output supply, V_{CC}, supports a voltage range from 14V to 33V. For operation with bipolar supplies, the power device is turned off with a negative voltage on the gate with respect to the emitter or source. This configuration prevents the power device from unintentionally turning on because of current induced from the Miller effect. The typical values of the V_{CC} and V_{EE} output supplies for bipolar operation are 15V and -8V with respect to GND for IGBTs, and 20V and -5V for SiC MOSFETs.

For operation with unipolar supply, the V_{CC} supply is connected to 15V with respect to GND for IGBTs, and 20V for SiC MOSFETs. The V_{EE} supply is connected to 0V.

8.3.2 Input Stage

The input stage of UCC23513-Q1 is simply the e-diode and therefore has an Anode (Pin 1) and a Cathode (Pin 3). Pin 2 has no internal connection and can be left open or connected to ground. The input stage does not have a power and ground pin. When the e-diode is forward biased by applying a positive voltage to the Anode with respect to the Cathode, a forward current I_F flows into the e-diode. The forward voltage drop across the e-diode is 2.1V (typ). An external resistor should be used to limit the forward current. The recommended range for the forward current is 7mA to 16mA. When I_F exceeds the threshold current I_{FLH}(2.8mA typ.) a high frequency signal is transmitted across the isolation barrier through the high voltage SiO_2 capacitors. The HF signal is detected by the receiver and V_{OUT} is driven high. See セクション 9.2.2.1 for information on selecting the input resistor. The dynamic impedance of the e-diode is very small(<1.0Ω) and the temperature coefficient of the e-diode forward voltage drop is <1.35mV/°C. This leads to excellent stability of the forward current I_F across all operating conditions. If the Anode voltage drops below V_{F_HL} (0.9V), or reverse biased, the gate driver output is driven low. The reverse breakdown voltage of the e-diode is >15V. So for normal operation, a reverse bias of up to 13V is allowed. The large reverse breakdown voltage of the e-diode enables UCC23513-Q1 to be operated in interlock architecture (see example in 図 8-3) where V_{SUP} can be as high as 12V. The system designer has the flexibility to choose a 3.3V, 5.0V or up to 12V PWM signal source to drive the input stage of UCC23513-Q1 using an appropriate input resistor. The example shows two gate drivers driving a set of IGBTs. The inputs of the gate drivers are connected as shown and driven by two buffers that are controlled by the MCU. Interlock architecture prevents both the e-diodes from being "ON" at the same time, preventing shoot through in the IGBTs. It also ensures that if both PWM signals are erroneously stuck high (or low) simultaneously, both gate driver outputs will be driven low.

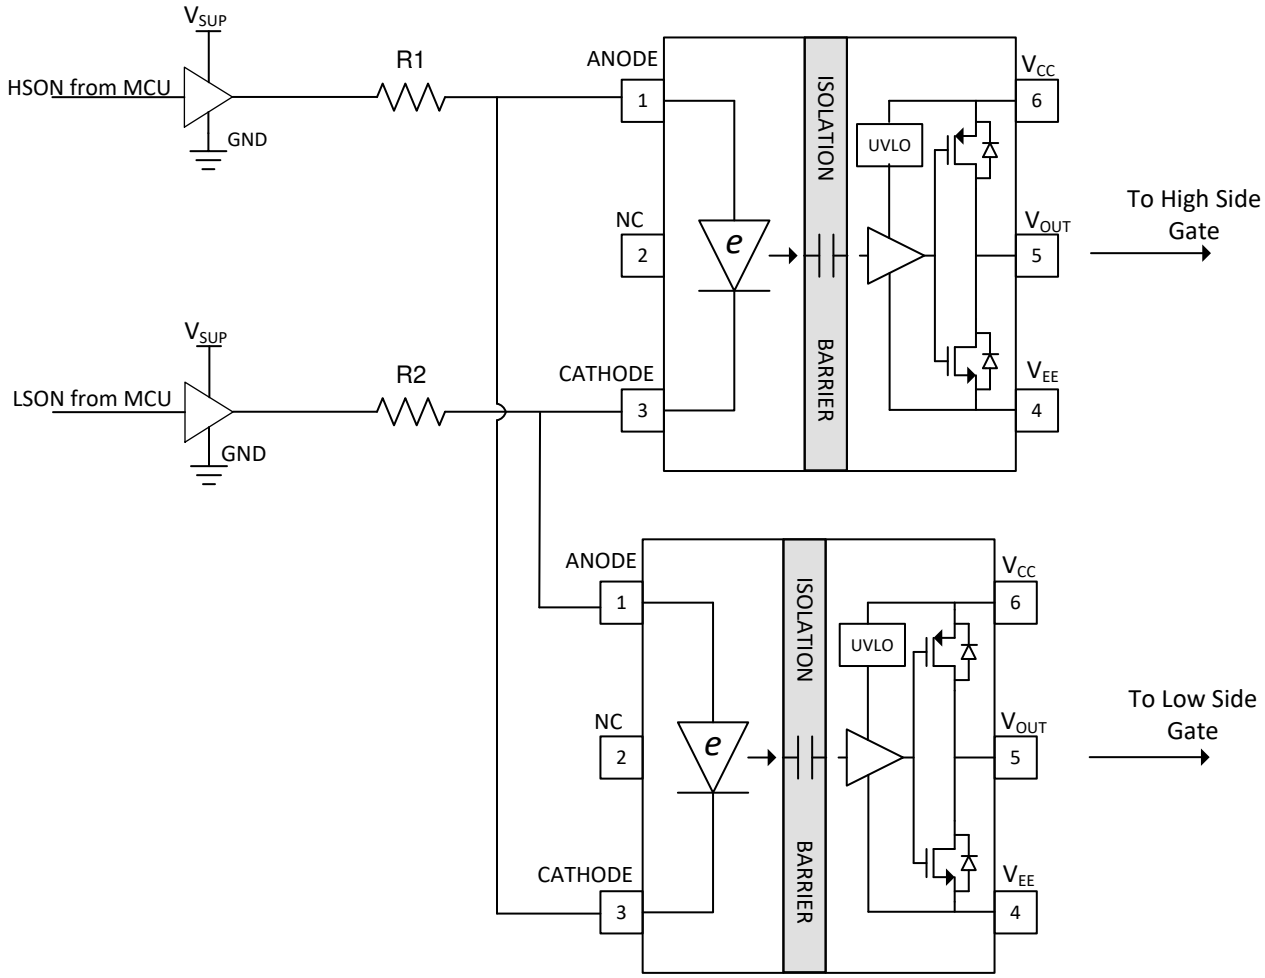

図 8-3. Interlock

8.3.3 Output Stage

The output stages of the UCC23513-Q1 family feature a pullup structure that delivers the highest peak-source current when it is most needed which is during the Miller plateau region of the power-switch turnon transition (when the power-switch drain or collector voltage experiences dV/dt). The output stage pullup structure features a P-channel MOSFET and an additional pull-up N-channel MOSFET in parallel. The function of the N-channel MOSFET is to provide a brief boost in the peak-sourcing current, enabling fast turnon. Fast turnon is accomplished by briefly turning on the N-channel MOSFET during a narrow instant when the output is changing states from low to high. The on-resistance of this N-channel MOSFET (R_{NMOS}) is approximately 5.1 Ω when activated.

表 8-1. UCC23513-Q1 On-Resistance

R_{NMOS}	R_{OH}	R_{OL}	UNIT
5.1	9.5	0.40	Ω

The R_{OH} parameter is a DC measurement and is representative of the on-resistance of the P-channel device only. This parameter is only for the P-channel device because the pullup N-channel device is held in the OFF state in DC condition and is turned on only for a brief instant when the output is changing states from low to high. Therefore, the effective resistance of the UCC23513-Q1 pullup stage during this brief turnon phase is much lower than what is represented by the R_{OH} parameter, yielding a faster turn on. The turnon-phase output resistance is the parallel combination R_{OH} || R_{NMOS}.

The pulldown structure in the UCC23513-Q1 is simply composed of an N-channel MOSFET. The output voltage swing between V_{CC} and V_{EE} provides rail-to-rail operation because of the MOS-out stage which delivers very low dropout.

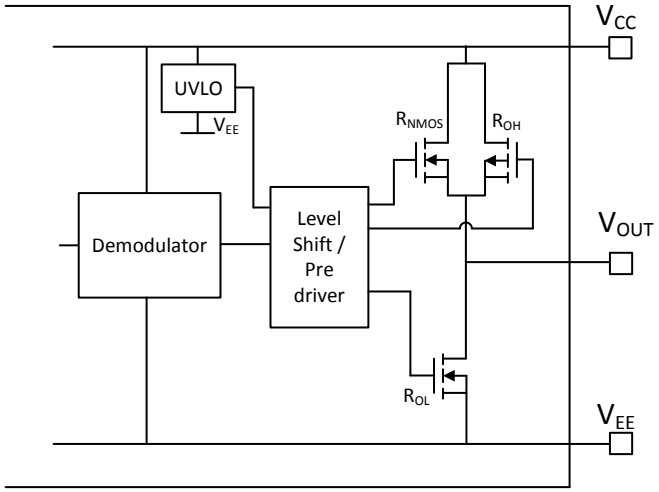

図 8-4. Output Stage

8.3.4 Protection Features

8.3.4.1 Undervoltage Lockout (UVLO)

UVLO function is implemented for V_{CC} and V_{EE} pins to prevent an under-driven condition on IGBTs and MOSFETs. When V_{CC} is lower than $UVLO_R$ at device start-up or lower than $UVLO_F$ after start-up, the voltage-supply UVLO feature holds the effected output low, regardless of the input forward current as shown in 表 8-2. The V_{CC} UVLO protection has a hysteresis feature ($UVLO_{hys}$). This hysteresis prevents chatter when the power supply produces ground noise which allows the device to permit small drops in bias voltage, which occurs when the device starts switching and operating current consumption increases suddenly.

When V_{CC} drops below $UVLO_F$, a delay, t_{UVLO_rec} occurs on the output when the supply voltage rises above $UVLO_R$ again.

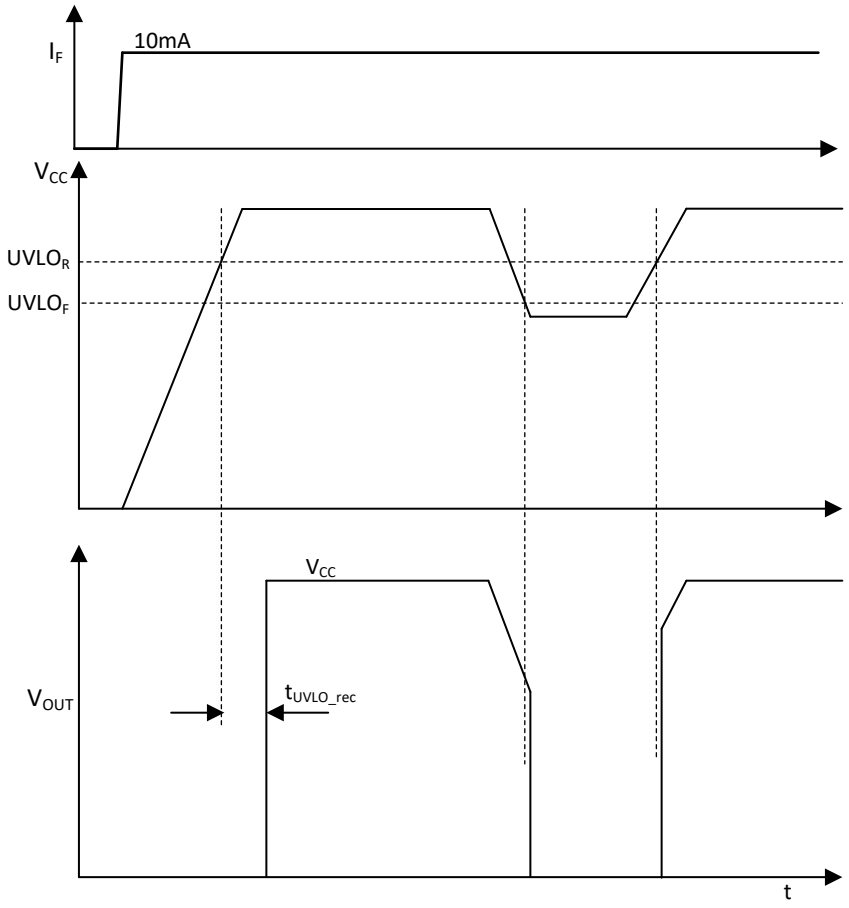

図 8-5. UVLO functionality

8.3.4.2 Active Pulldown

The active pull-down function is used to pull the IGBT or MOSFET gate to the low state when no power is connected to the V_{CC} supply. This feature prevents false IGBT and MOSFET turn-on by clamping V_{OUT} pin to approximately 2V.

When the output stage of the driver is in an unbiased condition (V_{CC} floating), the driver outputs (see 図 8-4) are held low by an active clamp circuit that limits the voltage rise on the driver outputs. In this condition, the upper PMOS & NMOS are held off while the lower NMOS gate is tied to the driver output through an internal 500-kΩ resistor. In this configuration, the lower NMOS device effectively clamps the output (V_{OUT}) to less than 2V.

8.3.4.3 Short-Circuit Clamping

The short-circuit clamping function is used to clamp voltages at the driver output and pull the output pin V_{OUT} slightly higher than the V_{CC} voltage during short-circuit conditions. The short-circuit clamping function helps protect the IGBT or MOSFET gate from overvoltage breakdown or degradation. The short-circuit clamping function is implemented by adding a diode connection between the dedicated pins and the V_{CC} pin inside the driver. The internal diodes can conduct up to 500-mA current for a duration of 10 µs and a continuous current of 20 mA. Use external Schottky diodes to improve current conduction capability as needed.

8.4 Device Functional Modes

表 8-2 lists the functional modes for UCC23513-Q1

表 8-2. Function Table for UCC23513-Q1 with VCC Rising

e-diode	VCC	V_{OUT}
OFF (I_F< I_{FLH})	0V - 33V	Low
ON (I_F> I_{FLH})	0V - $UVLO_R$	Low
ON ((I_F> I_{FLH})	$UVLO_R$ - 33V	High

表 8-3. Function Table for UCC23513-Q1 with VCC Falling

e-diode	VCC	V_{OUT}
OFF (I_F< I_{FLH})	0V - 33V	Low
ON (I_F> I_{FLH})	$UVLO_F$- 0V	Low
ON ((I_F> I_{FLH})	33V - $UVLO_F$	High

8.4.1 ESD Structure

図 8-6 shows the multiple diodes involved in the ESD protection components of the UCC23513-Q1 device. This provides pictorial representation of the absolute maximum rating for the device.

9 Application and Implementation

Note

以下のアプリケーション情報は、TI の製品仕様に含まれるものではなく、TI ではその正確性または完全性を保証いたしません。個々の目的に対する製品の適合性については、お客様の責任で判断していただくことになります。お客様は自身の設計実装を検証しテストすることで、システムの機能を確認する必要があります。

9.1 Application Information

UCC23513-Q1 is a single channel, isolated gate driver with opto-compatible input for power semiconductor devices, such as MOSFETs, IGBTs, or SiC MOSFETs. It is intended for use in applications such as motor control, industrial inverters, and switched-mode power supplies. It differs from standard opto isolated gate drivers as it does not have an LED input stage. Instead of an LED, it has an emulated diode (e-diode). To turn the e-diode "ON", a forward current in the range of 7mA to 16mA should be driven into the Anode. This will drive the gate driver output High and turn on the power FET. Typically, MCU's are not capable of providing the required forward current. Hence a buffer has to be used between the MCU and the input stage of UCC23513-Q1. Typical buffer power supplies are either 5V or 3.3V. A resistor is needed between the buffer and the input stage of the UCC23513-Q1 to limit the current. It is simple, but important to choose the right value of resistance. The resistor tolerance, buffer supply voltage tolerance and output impedance of the buffer, have to be considered in the resistor selection. This will ensure that the e-diode forward current stays within the recommended range of 7mA to 16mA. Detailed design recommendations are given in the セクション 9.1. The current driven input stage offers excellent noise immunity that is need in high power motor drive systems, especially in cases where the MCU cannot be located close to the isolated gate driver. UCC23513-Q1 offers best in class CMTI performance of >150kV/us at 1500V common mode voltages.

The e-diode is capable of 25mA continuous in the forward direction. The forward voltage drop of the e-diode has a very tight part to part variation (1.8V min to 2.4V max). The temperature coefficient of the forward drop is <1.35mV/°C. The dynamic impedance of the e-diode in the forward biased region is ~1Ω. All of these factors contribute in excellent stability of the e-diode forward current. To turn the e-diode "OFF", the Anode - Cathode voltage should be <0.8V, or I_F should be <I_{FLH}. The e-diode can also be reverse biased up to 13V (14V abs max) in order to turn it off and bring the gate driver output low. The large reverse breakdown voltage of the input stage provides system designers the flexibility to drive the input stage with 12V PWM signals without the need for an additional clamping circuit on the Anode and Cathode pin.

The output power supply for UCC23513-Q1 can be as high as 33V (35V abs max). The output power supply can be configured externally as a single isolated supply up to 33V or isolated bipolar supply such that V_{CC}-V_{EE} does not exceed 33V, or it can be bootstrapped (with external diode & capacitor) if the system uses a single power supply with respect to the power ground. Typical quiescent power supply current from V_{CC} is 1.2mA (max 2.2mA).

9.2 Typical Application

The circuit in 図 9-1, shows a typical application for driving IGBTs.

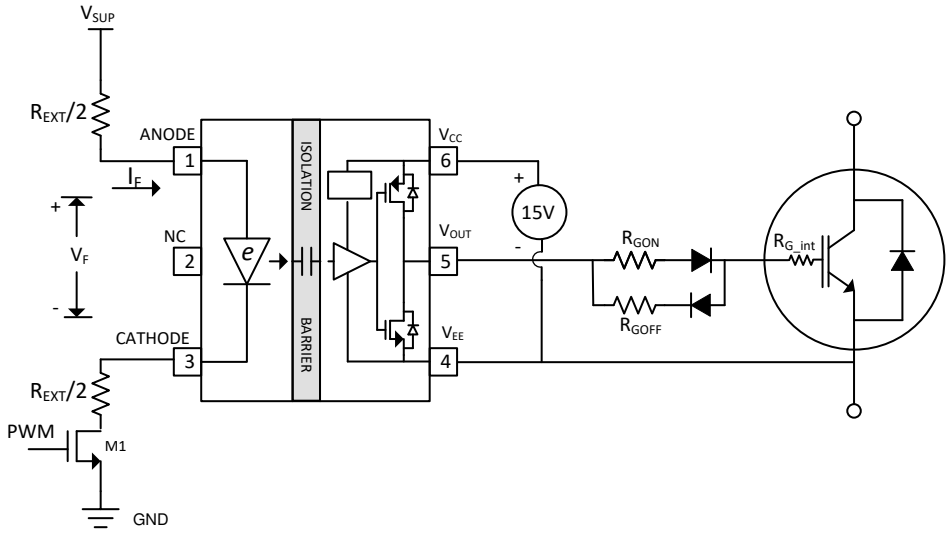

図 9-1. Typical Application Circuit for UCC23513-Q1 to Drive IGBT

9.2.1 Design Requirements

表 9-1 lists the recommended conditions to observe the input and output of the UCC23513-Q1 gate driver.

表 9-1. UCC23513-Q1 Design Requirements

PARAMETER	VALUE	UNIT
V_{CC}	15	V
I_F	10	mA
Switching frequency	8	kHz

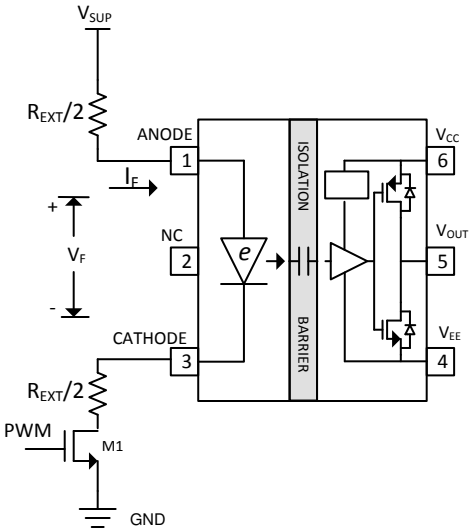
9.2.2 Detailed Design Procedure

9.2.2.1 Selecting the Input Resistor

The input resistor limits the current that flows into the e-diode when it is forward biased. The threshold current I_{FLH} is 2.8 mA typ. The recommended operating range for the forward current is 7 mA to 16 mA (e-diode ON). All the electrical specifications are guaranteed in this range. The resistor should be selected such that for typical operating conditions, I_F is 10 mA. Following are the list of factors that will affect the exact value of this current:

1. Supply Voltage V_{SUP} variation
2. Manufacturer's tolerance for the resistor and variation due to temperature
3. e-diode forward voltage drop variation (at I_F=10 mA, V_F= typ 2.1 V, min 1.8 V, max 2.4 V, with a temperature coefficient < 1.35 mV/°C and dynamic impedance < 1 Ω)

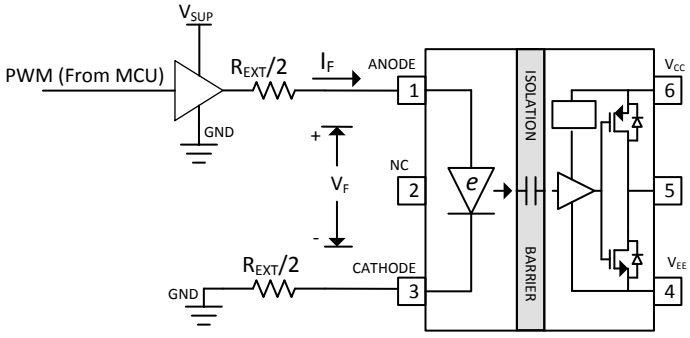
See 図 9-2 for the schematic using a single NMOS and split resistor combination to drive the input stage of UCC23513-Q1. The input resistor can be selected using the equation shown.



$$R_{EXT} = \frac{V_{SUP} - V_F}{I_F} - R_{M1}$$

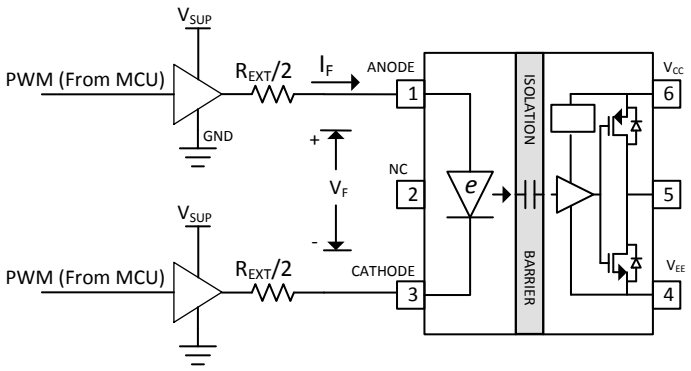
図 9-2. Configuration 1: Driving the input stage of UCC23513-Q1 with a single NMOS and split resistors

Driving the input stage of UCC23513-Q1 using a single buffer is shown in 図 9-3 and using 2 buffers is shown in 図 9-4



$$R_{EXT} = \frac{V_{SUP} - V_F}{I_F} - R_{OH\_buf}$$

図 9-3. Configuration 2: Driving the input stage of UCC23513-Q1 with one Buffer and split resistors



$$R_{EXT} = \frac{V_{SUP} - V_F}{I_F} - (R_{OH\_buf} + R_{OL\_buf})$$

図 9-4. Configuration 3: Driving the input stage of UCC23513-Q1 with 2 buffers and split resistors

表 9-2 shows the range of values for R_{EXT} for the 3 different configurations shown in 図 9-2, 図 9-3 and 図 9-4.The assumptions used in deriving the range for R_{EXT} are as follows:

1. Target forward current I_F is 7mA min, 10mA typ and 16mA max
2. e-diode forward voltage drop is 1.8V to 2.4V
3. V_{SUP} (Buffer supply voltage) is 5V with ±5% tolerance
4. Manufacturer's tolerance for R_{EXT} is 1%
5. NMOS resistance is 0.25Ω to 1.0Ω (for configuration 1)
6. R_{OH}(buffer output impedance in output "High" state) is 13Ω min, 18Ω typ and 22Ω max
7. R_{OL}(buffer output impedance in "Low" state) is 10Ω min, 14Ω typ and 17Ω max

表 9-2. R_{EXT} Values to Drive The Input Stage

	R_{EXT} Ω		
Configuration	Min	Typ	Max
Single NMOS and R_{EXT}	218	290	331
Single Buffer and R_{EXT}	204	272	311
Two Buffers and R_{EXT}	194	259	294

9.2.2.2 Gate Driver Output Resistor

The external gate-driver resistors, $R_{G(ON)}$ and $R_{G(OFF)}$ are used to:

1. Limit ringing caused by parasitic inductances and capacitances
2. Limit ringing caused by high voltage or high current switching dv/dt, di/dt, and body-diode reverse recovery
3. Fine-tune gate drive strength, specifically peak sink and source current to optimize the switching loss
4. Reduce electromagnetic interference (EMI)

The output stage has a pull up structure consisting of a P-channel MOSFET and an N-channel MOSFET in parallel. The combined peak source current is 4.5 A Use 式 1 to estimate the peak source current as an example.

$$I_{OH} = \min\left[4.5A, \frac{V_{CC} - V_{GDF}}{(R_{NMOS}||R_{OH} + R_{GON} + R_{GFET_{INT}})}\right] \quad (1)$$

where

- R_{GON} is the external turnon resistance.

- R_{GFET_Int} is the power transistor internal gate resistance, found in the power transistor data sheet. We will assume 0Ω for our example
- I_{OH} is the peak source current which is the minimum value between 4.5A, the gate-driver peak source current, and the calculated value based on the gate-drive loop resistance.
- V_{GDF} is the forward voltage drop for each of the diodes in series with R_{GON} and R_{GOFF}. The diode drop for this example is 0.7 V.

In this example, the peak source current is approximately 1.7A as calculated in 式 2.

$$I_{OH} = \min\left[4.5A, \frac{15 - 0.7}{(5.1\Omega||9.5\Omega + 5\Omega + 0\Omega)}\right] = 1.72A \quad (2)$$

Similarly, use 式 3 to calculate the peak sink current.

$$I_{OL} = \min\left[5.3A, \frac{V_{CC} - V_{GDF}}{(R_{OL} + R_{GOFF} + R_{GFET_{INT}})}\right] \quad (3)$$

where

- R_{GOFF} is the external turnoff resistance.
- I_{OL} is the peak sink current which is the minimum value between 5.3A, the gate-driver peak sink current, and the calculated value based on the gate-drive loop resistance.

In this example, the peak sink current is the minimum of 5.3A and 式 4.

$$I_{OL} = \min\left[5.3A, \frac{15 - 0.7}{(0.4\Omega + 10\Omega + 0\Omega)}\right] = 1.38A \quad (4)$$

The diodes shown in series with each, R_{GON} and R_{GOFF}, in 図 9-1 ensure the gate drive current flows through the intended path, respectively, during turn-on and turn-off. Note that the diode forward drop will reduce the voltage level at the gate of the power switch. To achieve rail-to-rail gate voltage levels, add a resistor from the V_{OUT} pin to the power switch gate, with a resistance value approximately 20 times higher than R_{GON} and R_{GOFF}. For the examples described in this section, a good choice is 100 Ω to 200 Ω.

Note

The estimated peak current is also influenced by PCB layout and load capacitance. Parasitic inductance in the gate-driver loop can slow down the peak gate-drive current and introduce overshoot and undershoot. Therefore, TI strongly recommends that the gate-driver loop should be minimized. Conversely, the peak source and sink current is dominated by loop parasitics when the load capacitance (C_{ISS}) of the power transistor is very small (typically less than 1 nF) because the rising and falling time is too small and close to the parasitic ringing period.

9.2.2.3 Estimate Gate-Driver Power Loss

The total loss, P_G, in the gate-driver subsystem includes the power losses (P_{GD}) of the UCC23513-Q1 device and the power losses in the peripheral circuitry, such as the external gate-drive resistor.

The P_{GD} value is the key power loss which determines the thermal safety-related limits of the UCC23513-Q1 device, and it can be estimated by calculating losses from several components.

The first component is the static power loss, P_{GDQ}, which includes power dissipated in the input stage (P_{GDQ_IN}) as well as the quiescent power dissipated in the output stage (P_{GDQ_OUT}) when operating with a certain switching frequency under no load. P_{GDQ_IN} is determined by I_F and V_F and is given by 式 5. The P_{GDQ_OUT} parameter is measured on the bench with no load connected to V_{OUT} pin at a given V_{CC}, switching frequency,

and ambient temperature. In this example, V_{CC} is 15 V. The current on the power supply, with PWM switching at 10 kHz, is measured to be I_{CC} = 1.33 mA . Therefore, use 式 6 to calculate P_{GDQ_OUT}.

$$P_{GDQ\_IN} = \frac{1}{2} * V_F * I_F \tag{5}$$

$$P_{GDQ\_OUT} = V_{CC} * I_{CC} \tag{6}$$

The total quiescent power (without any load capacitance) dissipated in the gate driver is given by the sum of 式 5 and 式 6 as shown in 式 7

$$P_{GDQ} = P_{GDQ\_IN} + P_{GDQ\_OUT} = 10\ mW + 20mW = 30mW \tag{7}$$

The second component is the switching operation loss, P_{GDSW}, with a given load capacitance which the driver charges and discharges the load during each switching cycle. Use 式 8 to calculate the total dynamic loss from load switching, P_{GSW}.

$$P_{GSW} = V_{CC2} \times Q_G \times f_{SW} \tag{8}$$

where

- Q_G is the gate charge of the power transistor at V_{CC}.

So, for this example application the total dynamic loss from load switching is approximately 18 mW as calculated in 式 9.

$$P_{GSW} = 15\ V \times 120\ nC \times 10\ kHz = 18\ mW \tag{9}$$

Q_G represents the total gate charge of the power transistor switching 520 V at 50 A, and is subject to change with different testing conditions. The UCC23513-Q1 gate-driver loss on the output stage, P_{GDO}, is part of P_{GSW}. P_{GDO} is equal to P_{GSW} if the external gate-driver resistance and power-transistor internal resistance are 0 Ω, and all the gate driver-loss will be dissipated inside the UCC23513-Q1. If an external turn-on and turn-off resistance exists, the total loss is distributed between the gate driver pull-up/down resistance, external gate resistance, and power-transistor internal resistance. Importantly, the pull-up/down resistance is a linear and fixed resistance if the source/sink current is not saturated to 4.5A/5.3A, however, it will be non-linear if the source/sink current is saturated. Therefore, P_{GDO} is different in these two scenarios.

Case 1 - Linear Pull-Up/Down Resistor:

$$P_{GDO} = \frac{P_{GSW}}{2}\left[\frac{R_{OH}||R_{NMOS}}{R_{OH}||R_{NMOS} + R_{GON} + R_{GFET\_int}} + \frac{R_{OL}}{R_{OL} + R_{GOFF} + R_{GFET\_int}}\right] \tag{10}$$

In this design example, all the predicted source and sink currents are less than 4.5 A and 5.3 A, therefore, use 式 11 to estimate the UCC23513-Q1 gate-driver loss.

$$P_{GDO} = \frac{18\ mW}{2}\left[\frac{9.5\Omega||5.1\Omega}{9.5\Omega||5.1\Omega + 5.1\Omega + 0\Omega} + \frac{0.4\Omega}{0.4\Omega + 10\Omega + 0\Omega}\right] = 3.9\ mW \tag{11}$$

Case 2 - Nonlinear Pull-Up/Down Resistor:

$$P_{GDO} = f_{sw} \times \left[4.5A \times \int_{0}^{T_{R\_Sys}} (V_{CC} - V_{OUT}(t))dt + 5.3A \times \int_{0}^{T_{F\_Sys}} V_{OUT}(t)\,dt \right] \quad (12)$$

where

- $V_{OUT(t)}$ is the gate-driver OUT pin voltage during the turnon and turnoff period. In cases where the output is saturated for some time, this value can be simplified as a constant-current source (4.5 A at turnon and 5.3 A at turnoff) charging or discharging a load capacitor. Then, the $V_{OUT(t)}$ waveform will be linear and the T_{R_Sys} and T_{F_Sys} can be easily predicted.

For some scenarios, if only one of the pullup or pulldown circuits is saturated and another one is not, the P_{GDO} is a combination of case 1 and case 2, and the equations can be easily identified for the pullup and pulldown based on this discussion.

Use 式 13 to calculate the total gate-driver loss dissipated in the UCC23513-Q1 gate driver, P_{GD}.

$$P_{GD} = P_{GDQ} + P_{GDO} = 30mW + 3.9mW = 33.9mW \quad (13)$$

9.2.2.4 Estimating Junction Temperature

Use 式 14 to estimate the junction temperature (T_J) of UCC23513-Q1.

$$T_J = T_C + \Psi_{JT} \times P_{GD} \quad (14)$$

where

- T_C is the UCC23513-Q1 case-top temperature measured with a thermocouple or some other instrument.
- Ψ_{JT} is the junction-to-top characterization parameter from the table.

Using the junction-to-top characterization parameter (Ψ_{JT}) instead of the junction-to-case thermal resistance ($R_{\theta JC}$) can greatly improve the accuracy of the junction temperature estimation. The majority of the thermal energy of most ICs is released into the PCB through the package leads, whereas only a small percentage of the total energy is released through the top of the case (where thermocouple measurements are usually conducted). The $R_{\theta JC}$ resistance can only be used effectively when most of the thermal energy is released through the case, such as with metal packages or when a heat sink is applied to an IC package. In all other cases, use of $R_{\theta JC}$ will inaccurately estimate the true junction temperature. The Ψ_{JT} parameter is experimentally derived by assuming that the dominant energy leaving through the top of the IC will be similar in both the testing environment and the application environment. As long as the recommended layout guidelines are observed, junction temperature estimations can be made accurately to within a few degrees Celsius.

9.2.2.5 Selecting V_{CC} Capacitor

Bypass capacitors for V_{CC} is essential for achieving reliable performance. TI recommends choosing low-ESR and low-ESL, surface-mount, multi-layer ceramic capacitors (MLCC) with sufficient voltage ratings, temperature coefficients, and capacitance tolerances. A 50-V, 10-µF MLCC and a 50-V, 0.22-µF MLCC are selected for the C_{VCC} capacitor. If the bias power supply output is located a relatively long distance from the V_{CC} pin, a tantalum or electrolytic capacitor with a value greater than 10 µF should be used in parallel with C_{VCC}.

Note

DC bias on some MLCCs will impact the actual capacitance value. For example, a 25-V, 1-µF X7R capacitor is measured to be only 500 nF when a DC bias of 15-V_{DC} is applied.

9.2.3 Application Performance Plots

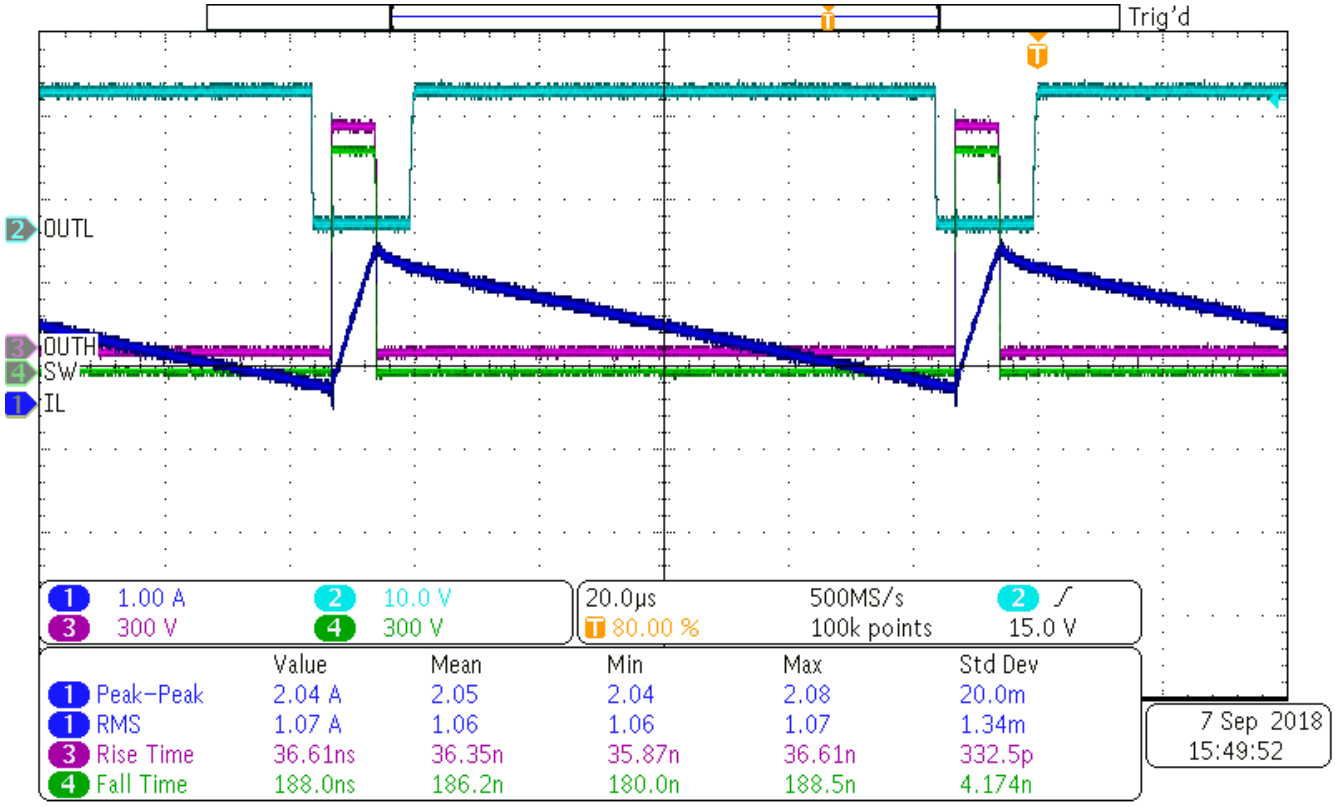


図 9-5. 1-A Load Performace Data

10 Power Supply Recommendations

The recommended input supply voltage (V_{CC}) for the UCC23513-Q1 device is from 14V to 33V. The lower limit of the range of output bias-supply voltage (V_{CC}) is determined by the internal UVLO protection feature of the device. V_{CC} voltage should not fall below the UVLO threshold for normal operation, or else the gate-driver outputs can become clamped low for more than 20 µs by the UVLO protection feature. The higher limit of the V_{CC} range depends on the maximum gate voltage of the power device that is driven by the UCC23513-Q1 device, and should not exceed the recommended maximum V_{CC} of 33 V. A local bypass capacitor should be placed between the V_{CC} and V_{EE} pins, with a value of 220-nF to 10-µF for device biasing. TI recommends placing an additional 100-nF capacitor in parallel with the device biasing capacitor for high frequency filtering. Both capacitors should be positioned as close to the device as possible. Low-ESR, ceramic surface-mount capacitors are recommended.

If only a single, primary-side power supply is available in an application, isolated power can be generated for the secondary side with the help of a transformer driver such as Texas Instruments' SN6501 or SN6505A. For such applications, detailed power supply design and transformer selection recommendations are available in *SN6501 Transformer Driver for Isolated Power Supplies* data sheet and *SN6505A Low-Noise 1-A Transformer Drivers for Isolated Power Supplies* data sheet.

11 Layout

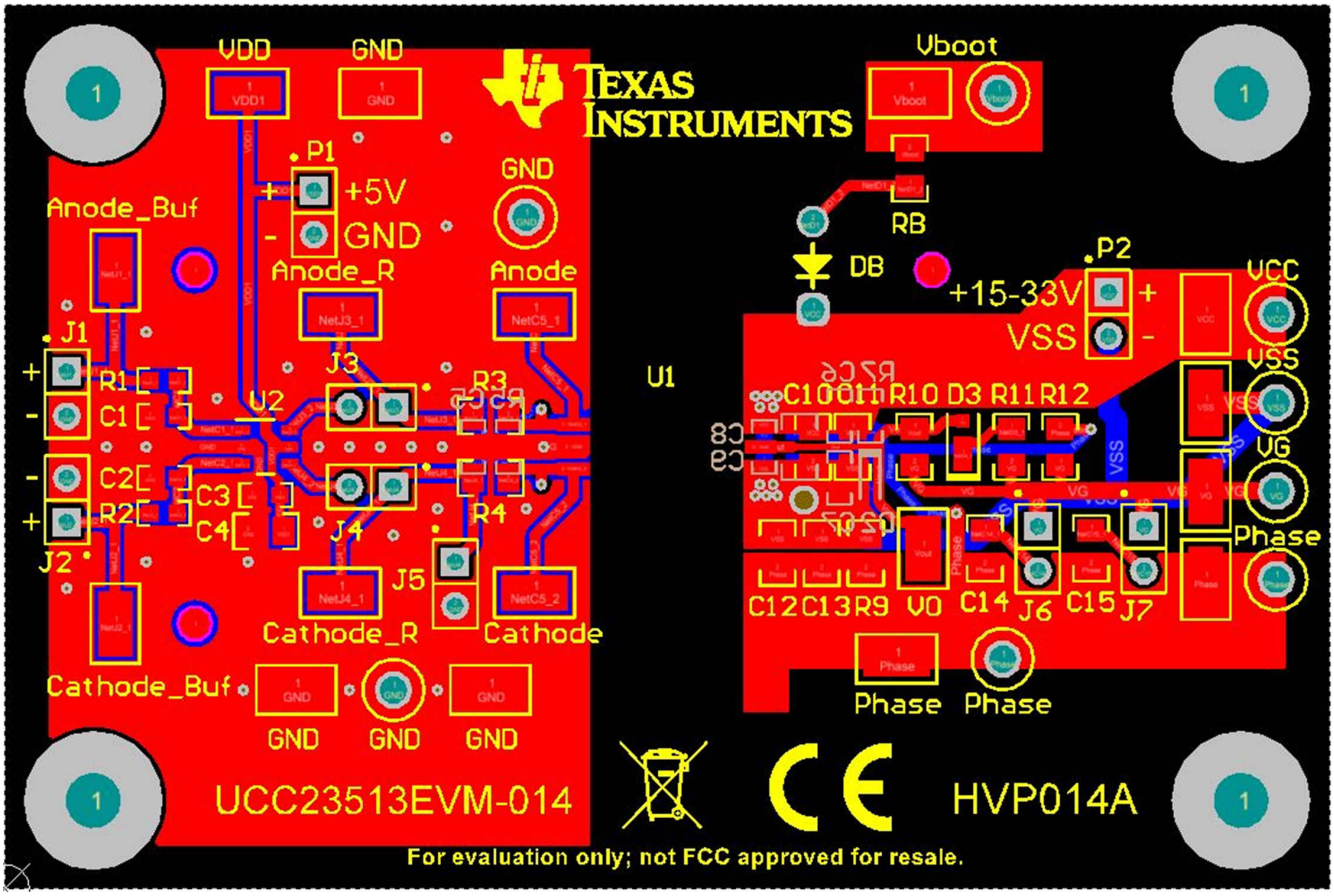
11.1 Layout Guidelines

Designers must pay close attention to PCB layout to achieve optimum performance for the UCC23513-Q1. Some key guidelines are:

- Component placement:
  - Low-ESR and low-ESL capacitors must be connected close to the device between the V_{CC} and V_{EE} pins to bypass noise and to support high peak currents when turning on the external power transistor.
  - To avoid large negative transients on the V_{EE} pins connected to the switch node, the parasitic inductances between the source of the top transistor and the source of the bottom transistor must be minimized.
- Grounding considerations:
  - Limiting the high peak currents that charge and discharge the transistor gates to a minimal physical area is essential. This limitation decreases the loop inductance and minimizes noise on the gate terminals of the transistors. The gate driver must be placed as close as possible to the transistors.
- High-voltage considerations:
  - To ensure isolation performance between the primary and secondary side, avoid placing any PCB traces or copper below the driver device. A PCB cutout or groove is recommended in order to prevent contamination that may compromise the isolation performance.
- Thermal considerations:
  - A large amount of power may be dissipated by the UCC23513-Q1 if the driving voltage is high, the load is heavy, or the switching frequency is high. Proper PCB layout can help dissipate heat from the device to the PCB and minimize junction-to-board thermal impedance (θ_{JB}).
  - Increasing the PCB copper connecting to the V_{CC} and V_{EE} pins is recommended, with priority on maximizing the connection to V_{EE}. However, the previously mentioned high-voltage PCB considerations must be maintained.
  - If the system has multiple layers, TI also recommends connecting the V_{CC} and V_{EE} pins to internal ground or power planes through multiple vias of adequate size. These vias should be located close to the IC pins to maximize thermal conductivity. However, keep in mind that no traces or coppers from different high voltage planes are overlapping.

11.2 Layout Example

図 11-1 shows a PCB layout example with the signals and key components labeled.



A. No PCB traces or copper are located between the primary and secondary side, which ensures isolation performance.

図 11-1. Layout Example

図 11-2 and 図 11-3 show the top and bottom layer traces and copper.

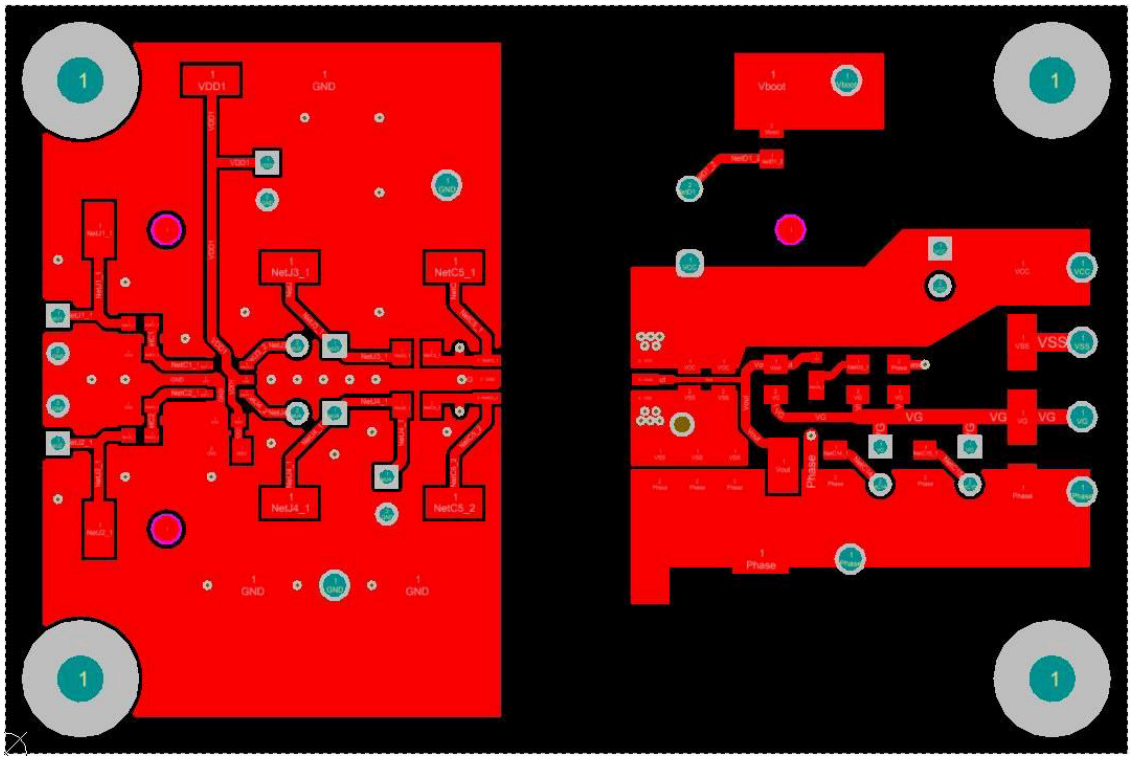


図 11-2. Top-Layer Traces and Copper

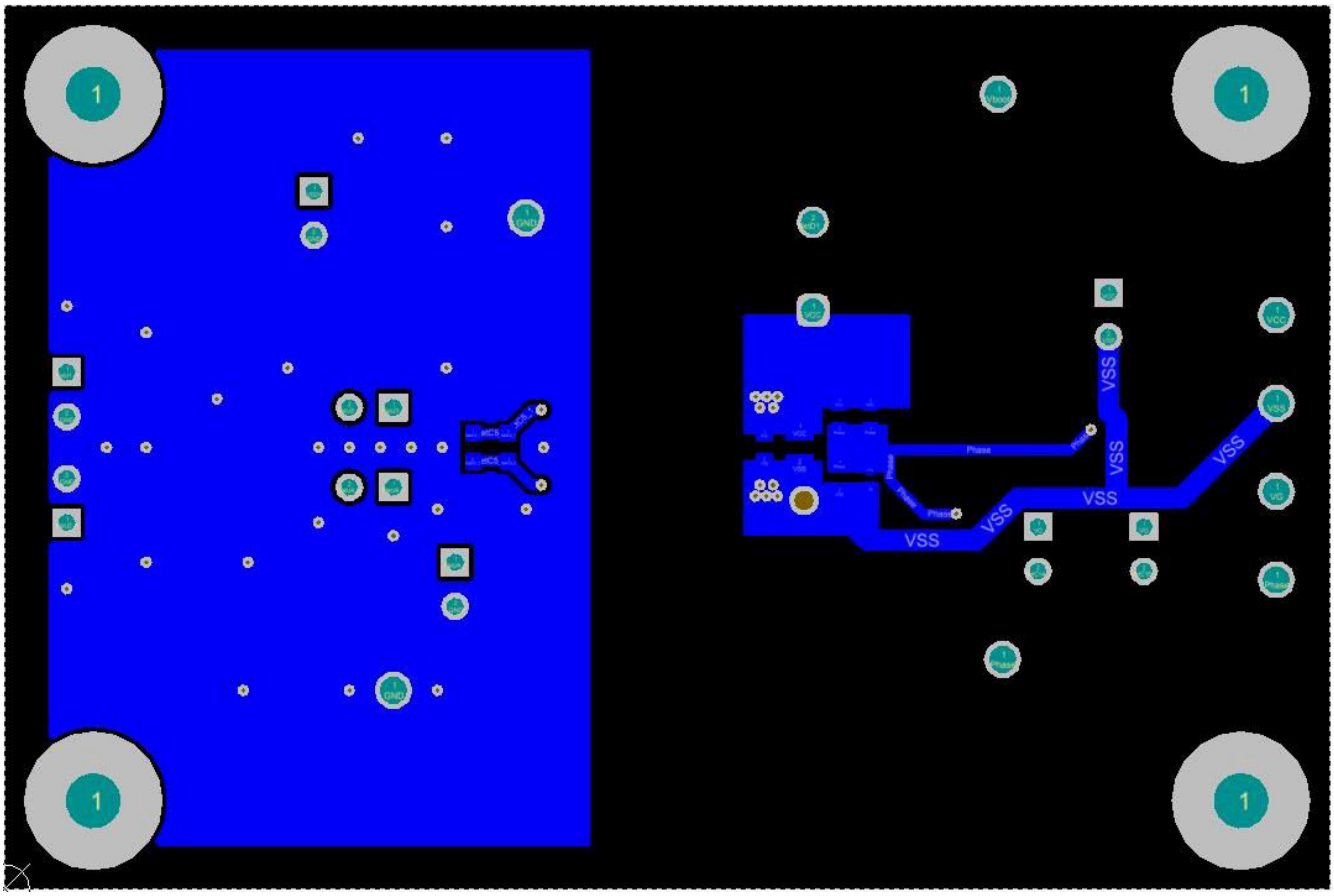

図 11-3. Bottom-Layer Traces and Copper (Flipped)

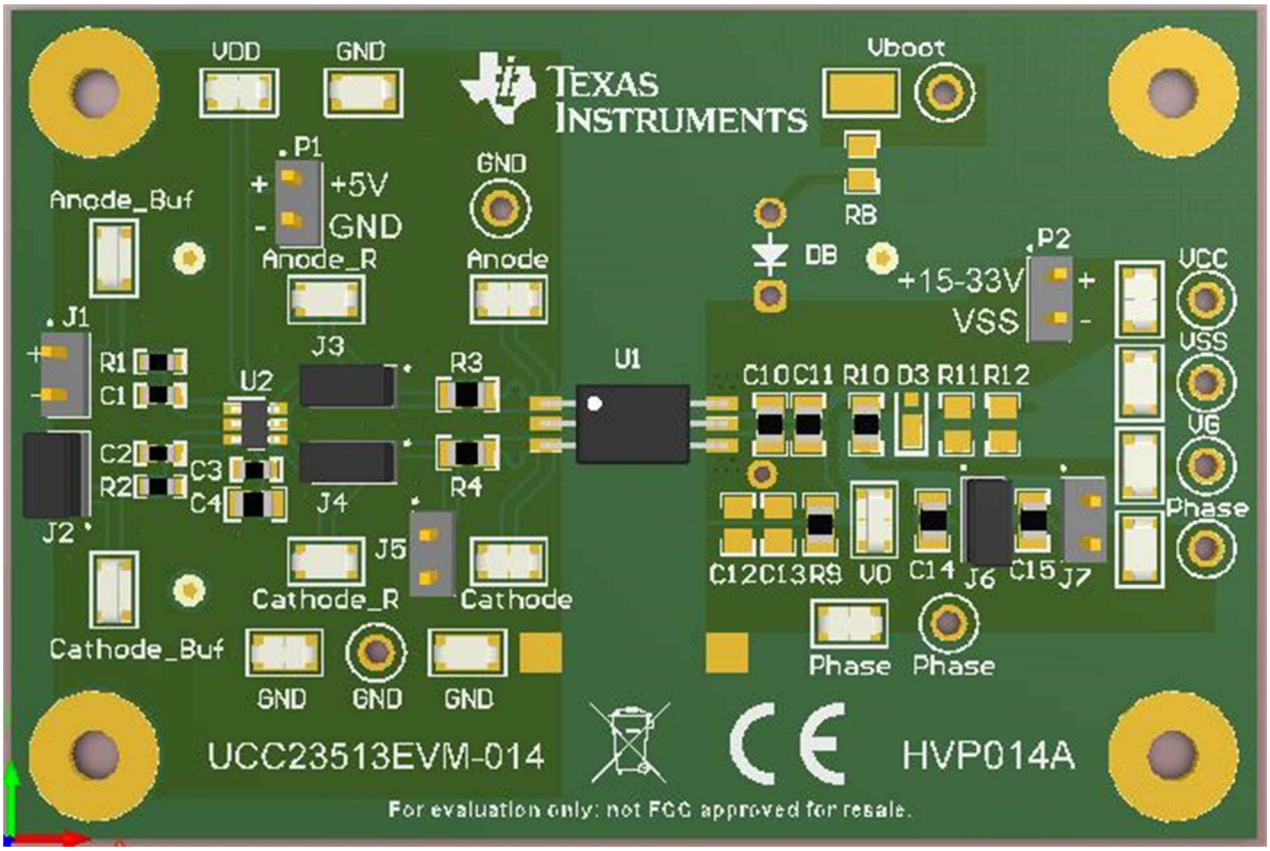
図 11-4 shows the 3D layout of the top view of the PCB.



A. The location of the PCB cutout between primary side and secondary sides ensures isolation performance.

図 11-4. 3-D PCB View

11.3 PCB Material

Use standard FR-4 UL94V-0 printed circuit board. This PCB is preferred over cheaper alternatives because of lower dielectric losses at high frequencies, less moisture absorption, greater strength and stiffness, and the self-extinguishing flammability-characteristics.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples

UCC23513QDWYRQ1	ACTIVE	SOIC	DWY	6	850	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 125	UC23513Q	Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

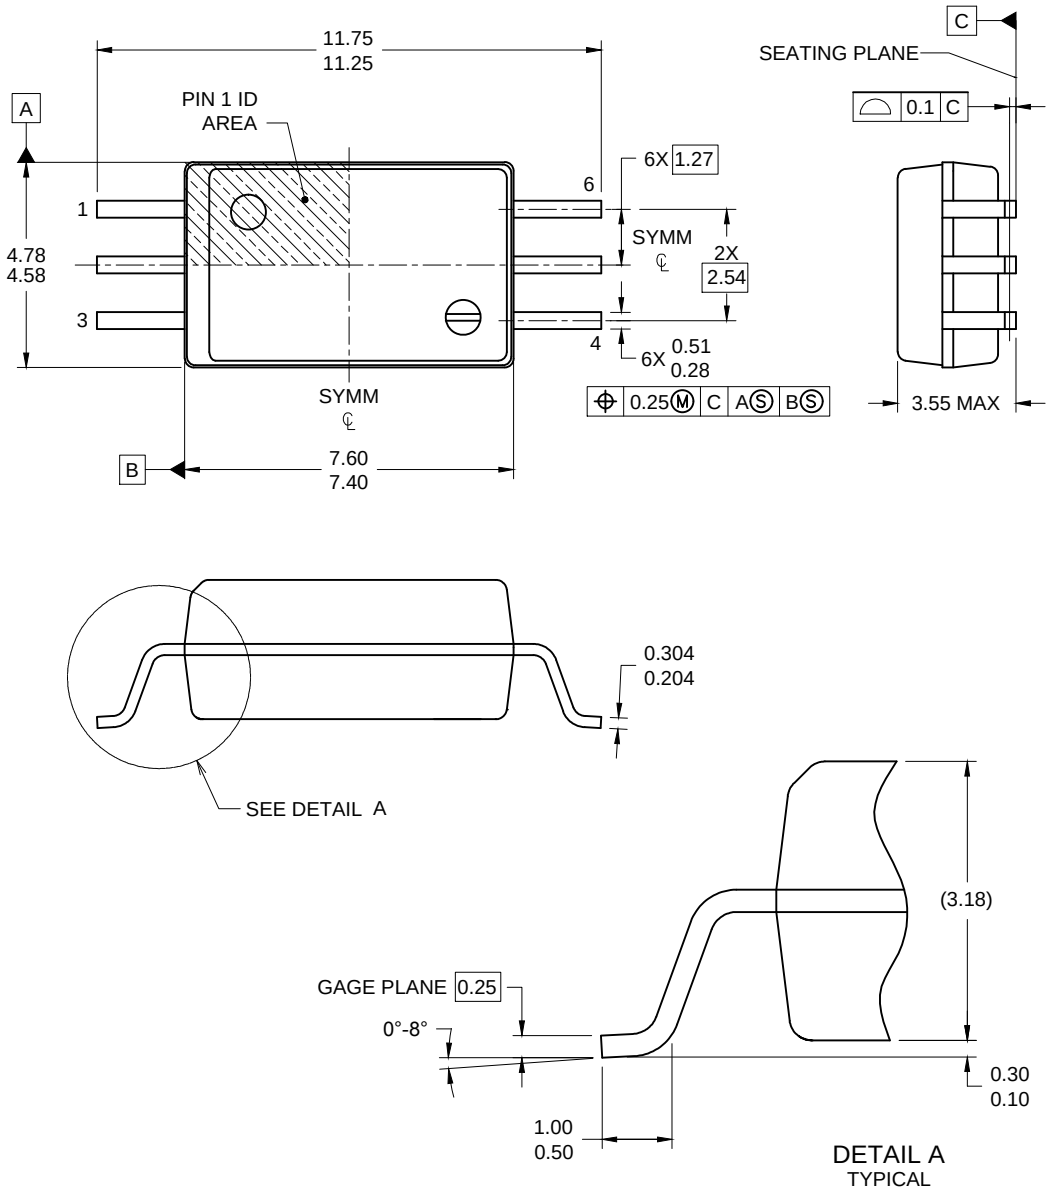
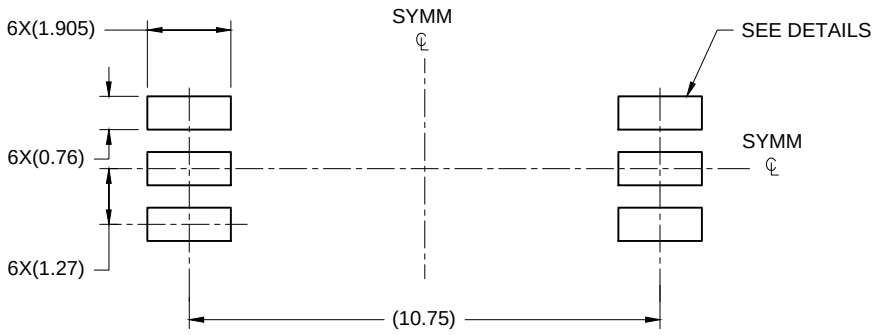
SOIC

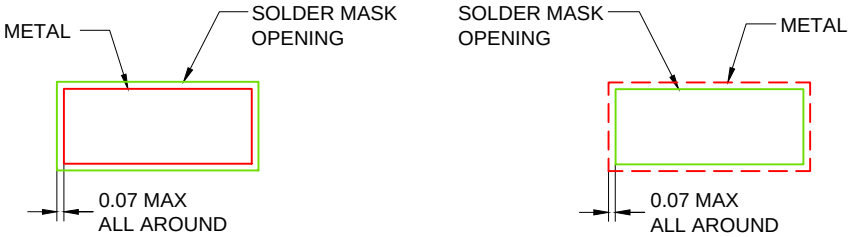


NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.70 per side.



LAND PATTERN EXAMPLE
SCALE:6X

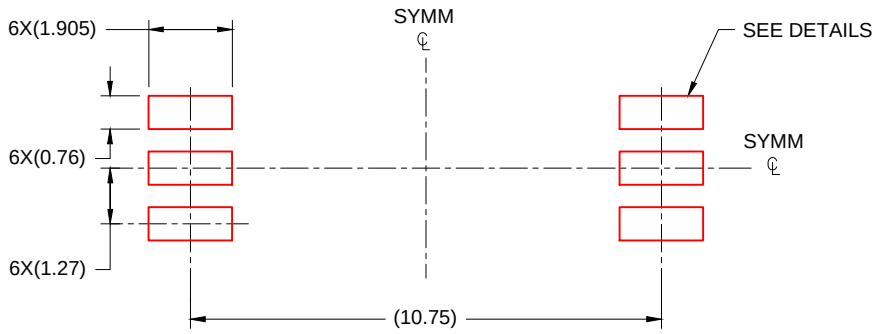


SOLDER MASK DETAAILS

4223977/A 01/2018

NOTES: (continued)

5. Publication IPC-7351 may have alternate designs.
6. Solder mask tolerances between and around signal pads can vary based on board fabrication site.



SOLDER PASTE EXAMPLE
BASED ON 0.125 mm THICK STENCIL
SCALE: 6X

4223977/A 01/2018

NOTES: (continued)

7. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
8. Board assembly site may have different recommendations for stencil design.

重要なお知らせと免責事項

TI は、技術データと信頼性データ (データシートを含みます)、設計リソース (リファレンス· デザインを含みます)、アプリケーションや設計に関する各種アドバイス、Web ツール、安全性情報、その他のリソースを、欠陥が存在する可能性のある「現状のまま」提供しており、商品性および特定目的に対する適合性の黙示保証、第三者の知的財産権の非侵害保証を含むいかなる保証も、明示的または黙示的にかかわらず拒否します。

これらのリソースは、TI 製品を使用する設計の経験を積んだ開発者への提供を意図したものです。(1) お客様のアプリケーションに適した TI 製品の選定、(2) お客様のアプリケーションの設計、検証、試験、(3) お客様のアプリケーションに該当する各種規格や、その他のあらゆる安全性、セキュリティ、規制、または他の要件への確実な適合に関する責任を、お客様のみが単独で負うものとします。

上記の各種リソースは、予告なく変更される可能性があります。これらのリソースは、リソースで説明されている TI 製品を使用するアプリケーションの開発の目的でのみ、TI はその使用をお客様に許諾します。これらのリソースに関して、他の目的で複製することや掲載することは禁止されています。TI や第三者の知的財産権のライセンスが付与されている訳ではありません。お客様は、これらのリソースを自身で使用した結果発生するあらゆる申し立て、損害、費用、損失、責任について、TI およびその代理人を完全に補償するものとし、TI は一切の責任を拒否します。

TI の製品は、TI の販売条件、または ti.com やかかる TI 製品の関連資料などのいずれかを通じて提供する適用可能な条項の下で提供されています。TI がこれらのリソースを提供することは、適用される TI の保証または他の保証の放棄の拡大や変更を意味するものではありません。

お客様がいかなる追加条項または代替条項を提案した場合でも、TI はそれらに異議を唱え、拒否します。
