JAJSS81I – SEPTEMBER 2008 – REVISED NOVEMBER 2023

UCC2742x-Q1、デュアル、4A、高速ローサイド MOSFET ドライバ、イネーブル付き

1 特長

- 車載アプリケーション用に認定済み
- 下記内容で AEC-Q100 認定済み:
  - デバイス温度グレード 1:-40℃～+125℃の周囲動作温度範囲
  - デバイス HBM ESD 分類レベル 2
  - デバイス CDM ESD 分類レベル C6
- 業界標準のピン配置
- ドライバ毎のイネーブル機能
- 高い電流駆動能力:±4A
- 独自のバイポーラおよび CMOS True Drive 出力段により、MOSFET のミラー スレッショルドで高電流を供給
- TTL および CMOS 互換の電源電圧から独立した入力
- 標準立ち上がり時間 20ns、標準立ち下がり時間 15ns (1.8nF 負荷時)
- 標準伝播遅延時間:25ns (入力立ち下がり時)、35ns (入力立ち上がり時)
- 電源電圧:4V～15V
- 2 つの出力を並列に使用することで、より高い駆動電流を実現可能
- 熱特性が強化された MSOP PowerPAD™ パッケージで供給
- -40℃～+125℃で仕様を規定

2 アプリケーション

- スイッチ・モード電源
- DC/DC コンバータ
- モーター・コントローラ
- ライン・ドライバ
- Class-D スイッチング・アンプ

3 概要

UCC2742x-Q1 ファミリのデバイスは、容量性負荷に大きなピーク電流を供給できる高速デュアル MOSFET ドライバです。デュアル反転ドライバとデュアル非反転ドライバの 2 つの標準ロジック・オプションが用意されています。標準の 8 ピン SOIC (D) パッケージで供給されます。熱特性が強化された 8 ピン PowerPAD Package MSOP パッケージ (DGN) によって熱抵抗が大幅に低減され、長期的な信頼性が向上しています。

本質的に貫通電流を最小限に抑える設計により、MOSFET のスイッチング遷移中のミラー プラトー領域で最も必要とされる 4A の電流を供給します。また、独自のバイポーラおよび MOSFET の並列ハイブリッド出力段により、低い電源電圧でも高効率の電流ソース/シンクを実現します。

UCC2742x-Q1 は、イネーブル (ENB) 機能によって、ドライバ アプリケーションの動作をよりきめ細かく制御できます。ENBA および ENBB は、業界標準ピン配置では未使用だったピン 1 および 8 に実装されています。これらのピンは、アクティブ ハイ ロジックでは内部で V_{DD} にプルアップされ、標準動作時にはオープンにできます。

製品情報

部品番号 (1)	パッケージ	本体サイズ (公称)
UCC2742x-Q1	SOIC (8)	4.90mm × 3.91mm
	MSOP PowerPAD (8) 搭載	3.00mm × 3.00mm

表 5-1. Pin Functions

PIN		I/O	DESCRIPTION
NO.	NAME		
1	ENBA	I	Enable input for the driver A with logic-compatible threshold and hysteresis. The driver output can be enabled and disabled with this pin. It is internally pulled up to V_{DD} with 100-kΩ resistor for active high operation. The output state when the device is disabled is low, regardless of the input state.
2	INA	I	Input A. Input signal of the A driver which has logic-compatible threshold and hysteresis. If not used, this input must be tied to either V_{DD} or GND. It must not be left floating.
3	GND	—	Common ground. This ground must be connected very closely to the source of the power MOSFET which the driver is driving.
4	INB	I	Input B. Input signal of the B driver which has logic-compatible threshold and hysteresis. If not used, this input must be tied to either V_{DD} or GND. It must not be left floating.
5	OUTB	O	Driver output B. The output stage is capable of providing 4-A drive current to the gate of a power MOSFET.
6	VDD	—	Supply voltage and the power input connection for this device.

7	OUTA	O	Driver output A. The output stage is capable of providing 4-A drive current to the gate of a power MOSFET.
8	ENBB	I	Enable input for the driver B with logic-compatible threshold and hysteresis. The driver output can be enabled and disabled with this pin. It is internally pulled up to V_{DD} with 100-kΩ resistor for active-high operation. The output state when the device is disabled is low, regardless of the input state.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1) (2)

			MIN	MAX	UNIT
V_{DD}	Supply voltage		–0.3	16	V
I_{OUT}	Output current	DC		0.3	A
		Pulsed, 0.5 µs		4.5	
V_{IN}	Input voltage	INA, INB	–5	6(3) or (V_{DD} + 0.3)(3)	V
V_{EN}	Enable voltage	ENBA, ENBB	–0.3	6(3) or (V_{DD} + 0.3)(3)	V
P_D	Power dissipation	T_A = 25°C (D package)		650	mW
		T_A = 25°C (DGN package)		3	W
T_J	Junction operating temperature		–55	150	°C
T_{stg}	Storage temperature		–65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) All voltages are with respect to GND. Currents are positive into, negative out of, the specified terminal.
(3) Whichever is larger.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002(1)	±2000	V
		Charged-device model (CDM), per AEC Q100-011	±1000	

(1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V_{DD}	Supply voltage	4	15	V
INA	Input voltage	–2	15	V
INB				
ENA	Enable voltage	0	15	V
ENB				
T_J	Operating junction temperature	–40	125	°C

6.7 Dissipation Ratings

PACKAGE	θ_{JC} (°C/W)	θ_{JA} (°C/W)	POWER RATING T_A = 70°C (mW)(1)
D (SOIC-8)	42	84 to 160(2)	344 to 655(2)
DGN (MSOP PowerPAD)(3)	11.9	63	873

(1) 125°C operating junction temperature is used for power rating calculations.
(2) The range of values indicates the effect of the PCB. These values are intended to give the system designer an indication of the best- and worst-case conditions. In general, the system designer should attempt to use larger traces on the PCB, where possible, to spread the heat away form the device more effectively.
(3) The PowerPAD is not directly connected to any leads of the package. However, it is electronically and thermally connected to the substrate which is the ground of the device.

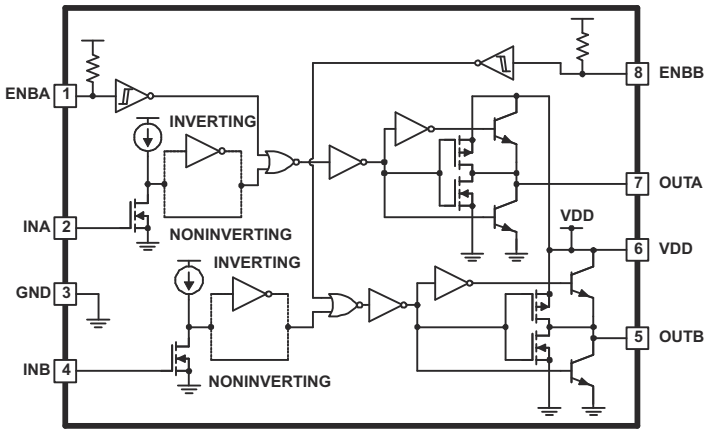
7 Detailed Description

7.1 Overview

The UCC2742x-Q1 family of high-speed dual MOSFET drivers can deliver large peak currents into capacitive loads. The UCC27423-Q1 offers these standard logic options: dual-inverting drivers, dual noninverting drivers, and one inverting, one noninverting driver. The thermally enhanced 8-pin PowerPAD MSOP package (DGN) drastically lowers the thermal resistance to improve long-term reliability. It is also offered in the standard 8-pin SOIC (D) package. Using a design that inherently minimizes shoot-through current, these drivers deliver 4 A of current where it is needed most at the Miller plateau region during the MOSFET switching transition. A unique Bipolar and MOSFET hybrid output stage in parallel also allows efficient current sourcing and sinking at low supply voltages.

7.2 Functional Block Diagram



7.3 Feature Description

7.3.1 Input Stage

The input thresholds have a 3.3-V logic sensitivity over the full range of V_{DD} voltages; yet it is equally compatible with 0 to V_{DD} signals. The inputs of UCC2742x-Q1 drivers are designed to withstand 500-mA reverse current without either damage to the IC for logic upset. The input stage of each driver must be driven by a signal with a short rise or fall time. This condition is satisfied in typical power supply applications, where the input signals are provided by a PWM controller or logic gates with fast transition times (< 200 ns). The input stages to the drivers function as a digital gate, and they are not intended for applications where a slow changing input voltage is used to generate a switching output when the logic threshold of the input section is reached. While this may not be harmful to the driver, the output of the driver may switch repeatedly at a high frequency.

Users should not attempt to shape the input signals to the driver in an attempt to slow down (or delay) the signal at the output. If limiting the rise or fall times to the power device is desired, limit the rise or fall times to the power device, then an external resistance can be added between the output of the driver and the load device, which is generally a power MOSFET gate. The external resistor may also help remove power dissipation from the device package, as discussed in the セクション 10.3.

7.3.2 Output Stage

Inverting outputs of the UCC2742x-Q1 are intended to drive external P-channel MOSFETs. Noninverting outputs of the UCC2742x-Q1 are intended to drive external N-channel MOSFETs.

Each output stage is capable of supplying ±4-A peak current pulses and swings to both V_{DD} and GND. The pullup and pulldown circuits of the driver are constructed of bipolar and MOSFET transistors in parallel. The peak output current rating is the combined current from the bipolar and MOSFET transistors. The output resistance is the $R_{DS(on)}$ of the MOSFET transistor when the voltage on the driver output is less than the saturation voltage of the bipolar transistor. Each output stage also provides a very low impedance to overshoot

and undershoot due to the body diode of the external MOSFET. This means that in many cases, external Schottky-clamp diodes are not required.

The UCC2742x-Q1 family delivers the 4-A gate drive where it is most needed during the MOSFET switching transition—at the Miller plateau region—providing improved efficiency gains. A unique bipolar and MOSFET hybrid output stage in parallel also allows efficient current sourcing at low supply voltages.

7.3.3 Enable

The UCC2742x-Q1 devices provide dual enable inputs for improved control of each driver channel operation. The inputs incorporate logic-compatible thresholds with hysteresis. They are internally pulled up to V_{DD} with 100-kΩ resistor for active-high operation. When ENBA and ENBB are driven high, the drivers are enabled; when ENBA and ENBB are low, the drivers are disabled. The default state of the enable pin is to enable the driver and, therefore, can be left open for standard operation. The output states when the drivers are disabled is low, regardless of the input state. See 表 7-1 for operation using enable logic.

Enable inputs are compatible with both logic signals and slowly-changing analog signals. They can be directly driven, or a power-up delay can be programmed with a capacitor between ENBA/ENBB and GND. ENBA and ENBB control input A and input B, respectively.

7.3.4 Parallel Outputs

The A and B drivers may be combined into a single driver by connecting the INA/INB inputs together and the OUTA/OUTB outputs together. Then, a single signal can control the paralleled combination as shown in 図 7-1.

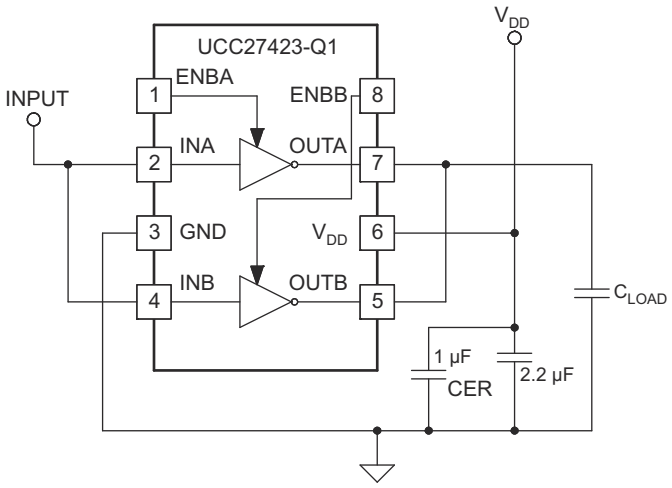


図 7-1. Parallel Outputs

7.3.5 Operational Waveforms and Circuit Layout

図 7-2 shows the circuit performance achievable with a single driver (half of the 8-pin IC) driving a 10-nF load. The input pulse width (not shown) is set to 300 ns to show both transitions in the output waveform. Note the linear rise and fall edges of the switching waveforms. This is due to the constant output current characteristic of the driver as opposed to the resistive output impedance of traditional MOSFET-based gate drivers.

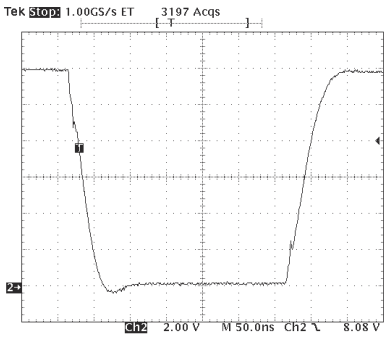

図 7-2. Pulse Response

In a power driver operating at high frequency, it is a significant challenge to get clean waveforms without much overshoot or undershoot and ringing. The low output impedance of these drivers produces waveforms with high di/dt. This tends to induce ringing in the parasitic inductances. Use the upmost care in the circuit layout. It is advantageous to connect the driver IC as close as possible to the leads. The driver IC layout has ground on the opposite side of the output, so the ground must be connected to the bypass capacitors and the load with copper trace as wide as possible. These connections must also be made with a small enclosed loop area to minimize the inductance.

7.3.6 V_{DD}

Although quiescent V_{DD} current is very low, total supply current is higher, depending on OUTA and OUTB current and the programmed oscillator frequency. Total V_{DD} current is the sum of quiescent V_{DD} current and the average OUT current. Knowing the operating frequency and the MOSFET gate charge (Q_g), average OUT current can be calculated from 式 1.

$$I_{OUT} = Q_g \times f \quad (1)$$

where

- f is frequency

For the best high-speed circuit performance, TI recommends two V_{DD} bypass capacitors to prevent noise problems. TI highly recommends using surface-mount components. A 0.1-µF ceramic capacitor must be located closest to the V_{DD} to ground connection. In addition, a larger capacitor (such as 1 µF) with relatively low ESR must be connected in parallel, to help deliver the high current peaks to the load. The parallel combination of capacitors must present a low impedance characteristic for the expected current levels in the driver application.

7.4 Device Functional Modes

With V_{DD} power supply in the range of 4 V to 16 V, the output stage is dependent on the states of the HI and LI pins. 表 7-1 shows the UCC2742x-Q1 truth table.

表 7-1. Input and Output Logic Table

ENBA	ENBB	INPUTS (V_{IN_L}, V_{IN_H})		UCC27423-Q1		UCC27424-Q1		UCC27425-Q1	
		INA	INB	OUTA	OUTB	OUTA	OUTB	OUTA	OUTB
H	H	L	L	H	H	L	L	H	L
H	H	L	H	H	L	L	H	H	H
H	H	H	L	L	H	H	L	L	L
H	H	H	H	L	L	H	H	L	H
L	L	X	X	L	L	L	L	L	L

Importantly, if INA and INB are not used, they must be tied to either VDD or GND; they must not be left floating.

8 Application and Implementation

注

以下のアプリケーション情報は、TI の製品仕様に含まれるものではなく、TI ではその正確性または完全性を保証いたしません。個々の目的に対する製品の適合性については、お客様の責任で判断していただくことになります。お客様は自身の設計実装を検証しテストすることで、システムの機能を確認する必要があります。

8.1 Application Information

High-frequency power supplies often require high-speed, high-current drivers such as the UCC2742x-Q1 family. A leading application is the need to provide a high-power buffer stage between the PWM output of the control IC and the gates of the primary power MOSFET or IGBT switching devices. In other cases, the driver IC is used to drive the power device gates through a drive transformer. Synchronous rectification supplies also have the need to simultaneously drive multiple devices which can present an extremely large load to the control circuitry.

Driver ICs are used when it is not feasible to have the primary PWM regulator IC directly drive the switching devices for one or more reasons. The PWM IC may not have the brute drive capability required for the intended switching MOSFET, limiting the switching performance in the application. In other cases, there may be a desire to minimize the effect of high-frequency switching noise by placing the high current driver physically close to the load. Also, newer ICs that target the highest operating frequencies may not incorporate onboard gate drivers at all. Their PWM outputs are only intended to drive the high impedance input to a driver such as the UCC2742x-Q1. Finally, the control IC may be under thermal stress due to power dissipation, and an external driver can help by moving the heat from the controller to an external package.

8.2 Typical Application

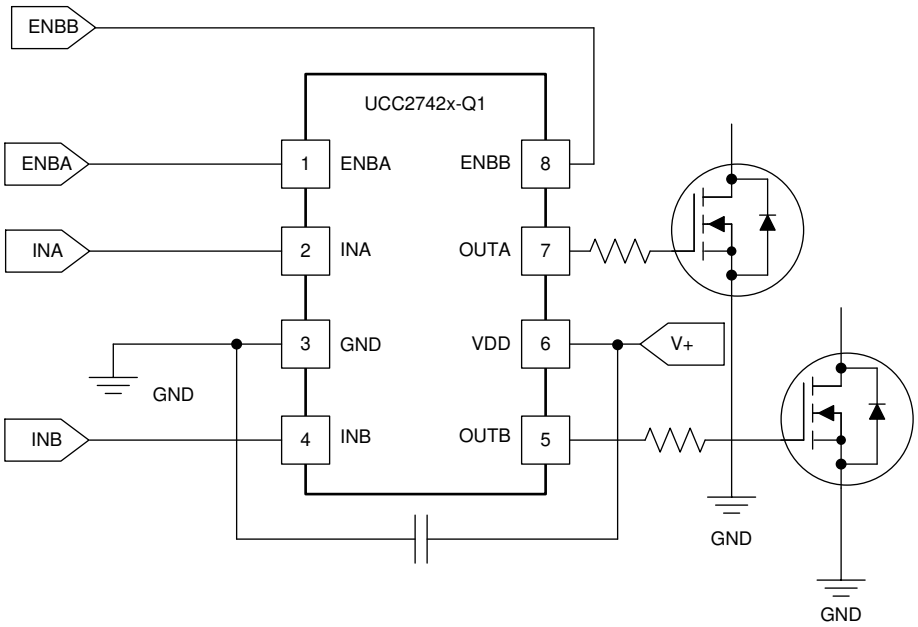

図 8-1. UCC2742x-Q1 Driving Two Independent MOSFETs

8.2.1 Design Requirements

To select proper device from UCC2742x-Q1 family, TI recommends first checking the appropriate logic for the outputs. The UCC27423-Q1 has dual inverting outputs, the UCC27424-Q1 has dual noninverting outputs, and the UCC27425-Q1 has an inverting channel A and noninverting channel B. Moreover, evaluate some

considerations to make the most appropriate selection. Among these considerations are V_{DD}, drive current, and power dissipation.

8.2.2 Detailed Design Procedure

8.2.2.1 Source and Sink Capabilities During Miller Plateau

Large power MOSFETs present a large load to the control circuitry. Proper drive is required for efficient, reliable operation. The UCC2742x-Q1 drivers have been optimized to provide maximum drive to a power MOSFET during the Miller plateau region of the switching transition. This interval occurs while the drain voltage is swinging between the voltage levels dictated by the power topology, requiring the charging and discharging of the drain-gate capacitance with current supplied or removed by the driver device.

Two circuits are used to test the current capabilities of the UCC2742x-Q1 driver. In each case, external circuitry is added to clamp the output near 5 V while the IC is sinking or sourcing current. An input pulse of 250 ns is applied at a frequency of 1 kHz in the proper polarity for the respective test. In each test, there is a transient period where the current peaked up and then settled down to a steady-state value. The noted current measurements are made at a time of 200 ns after the input pulse is applied, after the initial transient.

The circuit in 図 8-2 is used to verify the current sink capability when the output of the driver is clamped around 5 V, a typical value of gate-source voltage during the Miller plateau region. The UCC2742x-Q1 is found to sink 4.5 A at V_{DD} = 15 V and 4.28 A at V_{DD} = 12 V.

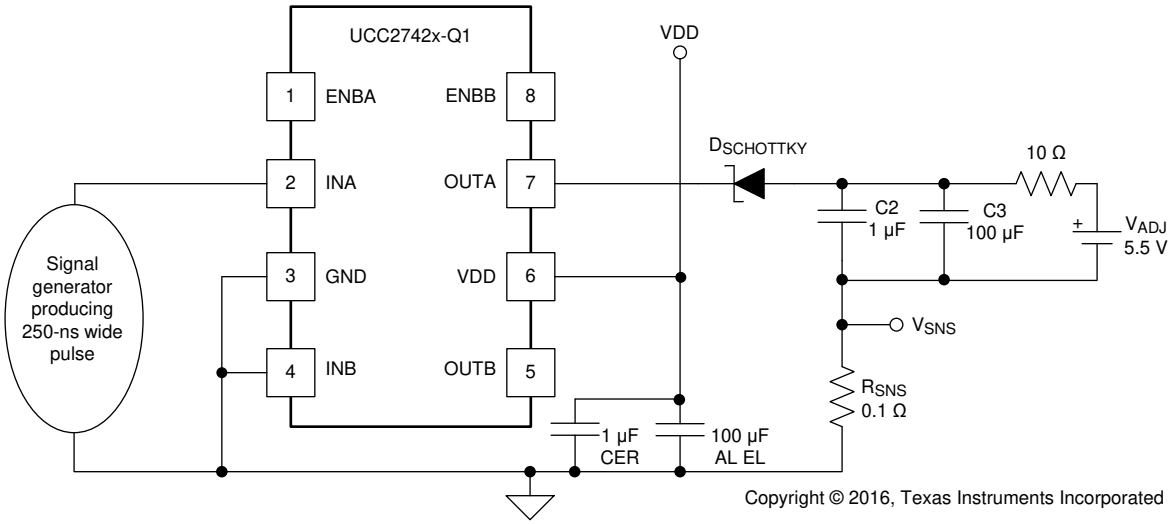

図 8-2. Current Sink Capability Test

The circuit show in 図 8-3 is used to test the current source capability with the output clamped around 5 V with a string of Zener diodes. The UCC2742x-Q1 is found to source 4.8 A at V_{DD} = 15 V and 3.7 A at V_{DD} = 12 V.

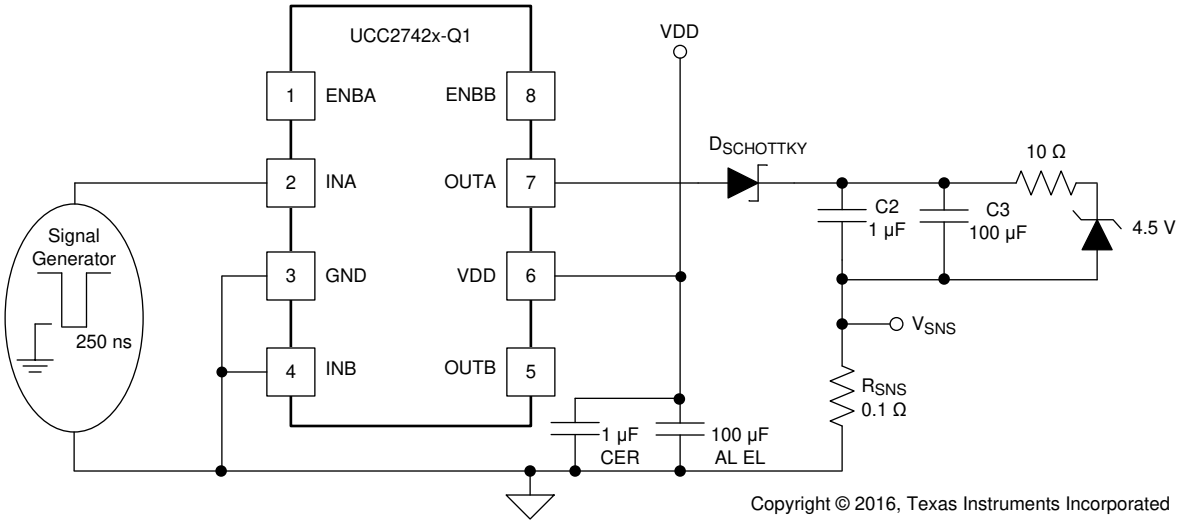

図 8-3. Current Source Capability Test

8.2.2.2 Drive Current and Power Requirements

The UCC2742x-Q1 family of drivers are capable of delivering 4 A of current to a MOSFET gate for a period of several hundred nanoseconds. High-peak current is required to turn the device ON quickly. Then, to turn the device OFF, the driver is required to sink a similar amount of current to ground. This repeats at the operating frequency of the power device. A MOSFET is used in this discussion because it is the most common type of switching device used in high frequency power conversion equipment.

Reference 1 in the *セクション 11.2.1* section discuss the current required to drive a power MOSFET and other capacitive-input switching devices. Reference 1 in includes information on the previous generation of bipolar IC gate drivers.

When a driver IC is tested with a discrete, capacitive load, it is a fairly simple matter to calculate the power that is required from the bias supply. The energy that must be transferred from the bias supply to charge the capacitor is given by 式 2.

$$E = \frac{1}{2}CV^2 \tag{2}$$

where

- C = load capacitor
- V = bias voltage (feeding the driver)

There is an equal amount of energy transferred to ground when the capacitor is discharged. This leads to a power loss given by 式 3.

$$P = CV^2 \times f \tag{3}$$

where

- f = switching frequency

This power is dissipated in the resistive elements of the circuit. Thus, with no external resistor between the driver and gate, this power is dissipated inside the driver. Half of the total power is dissipated when the capacitor is charged, and the other half is dissipated when the capacitor is discharged. An actual example using the conditions of the previous gate drive waveform should help clarify this.

With V_{DD} = 12 V, C_{LOAD} = 10 nF, and f = 300 kHz, the power loss can be calculated as 式 4.

$$P = 10\ nF \times (12\ V)^2 \times (300\ kHz) = 0.432\ W \quad (4)$$

With a 12-V supply, this would equate to a current of 式 5.

$$I = \frac{P}{V} = \frac{0.432\ W}{12\ V} = 36\ mA \quad (5)$$

The actual current measured from the supply was 0.037 A, and is very close to the predicted value. But, consider the I_{DD} current that is due to the IC internal consumption. With no load, the IC current draw is 0.0027 A. Under this condition, the output rise and fall times are faster than with a load. This could lead to an almost insignificant, yet measurable current due to cross-conduction in the output stages of the driver. However, these small current differences are buried in the high-frequency switching spikes, and are beyond the measurement capabilities of a basic lab setup. The measured current with 10-nF load is reasonably close to that expected.

The switching load presented by a power MOSFET can be converted to an equivalent capacitance by examining the gate charge required to switch the device. This gate charge includes the effects of the input capacitance plus the added charge needed to swing the drain of the device between the ON and OFF states. Most manufacturers provide specifications that provide the typical and maximum gate charge, in nC, to switch the device under specified conditions. Using the gate charge Q_g, one can determine the power that must be dissipated when charging a capacitor. This is done by using the equivalence $Q_g = C_{eff}V$ to provide the power loss in 式 6.

$$P = C \times V^2 \times f = V \times Q_g \times f \quad (6)$$

式 6 allows a power designer to calculate the bias power required to drive a specific MOSFET gate at a specific bias voltage.

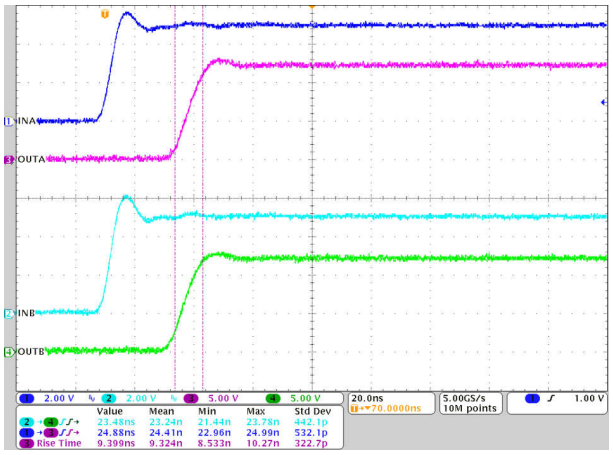
8.2.3 Application Curves

図 8-4 and 図 8-5 show rising and falling time and turnon and turnoff propagation delay testing waveform in room temperature for UCC27424-Q1, and waveform measurement data (see the bottom part of the waveform). Each channel, INA/INB/OUTA/OUTB, is labeled and displayed on the left hand of the waveforms.

The load capacitance testing condition is 1.8 nF, V_{DD} = 12 V, and f = 300 kHz.

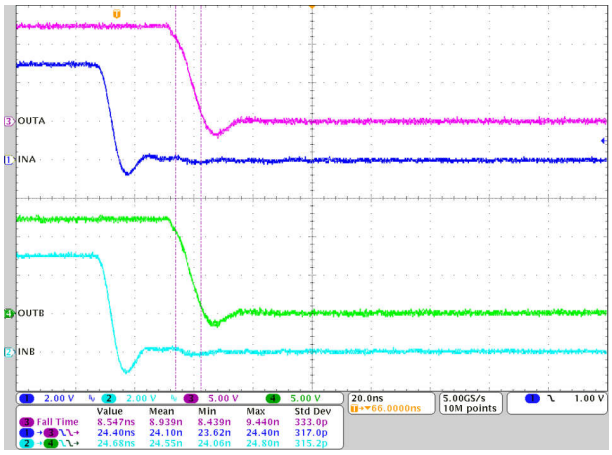
HI and LI share one same input from function generator; therefore, besides the propagation delay and rising or falling time, the difference of the propagation delay between HO and LO gives the propagation delay matching data.

Note the linear rise and fall edges of the switching waveforms. This is due to the constant output current characteristic of the driver as opposed to the resistive output impedance of traditional MOSFET-based gate drivers.



CL = 1.8 nF, V_{DD} = 12 V, f = 300 kHz

図 8-4. Rising Time and Turnon Propagation Delay



CL = 1.8 nF, V_{DD} = 12 V, f = 300 kHz

図 8-5. Falling Time and Turnoff Propagation Delay

9 Power Supply Recommendations

The recommended bias supply voltage range for UCC2742x-Q1 is from 4 V to 15 V. The upper end of this range is driven by the absolute maximum voltage rating of the V_{DD} (16 V). TI recommends keeping proper margin to allow for transient voltage spikes. A local bypass capacitor must be placed between the VDD and GND pins. And this capacitor must be placed as close to the device as possible. A low ESR, ceramic surface-mount capacitor is recommended. TI recommends using 2 capacitors across VDD and GND: a 100-nF ceramic surface-mount capacitor for high-frequency filtering placed very close to VDD and GND pin, and another surface-mount capacitor (220 nF to 10 µF) for IC bias requirements.

10 Layout

10.1 Layout Guidelines

Optimum performance of gate drivers cannot be achieved without taking due considerations during circuit board layout. The following points are emphasized:

1. Low ESR or ESL capacitors must be connected close to the IC between VDD and GND pins to support high peak currents drawn from VDD during the turnon of the external MOSFETs.
2. Grounding considerations:
   - The first priority in designing grounding connections is to confine the high peak currents that charge and discharge the MOSFET gates to a minimal physical area. This decreases the loop inductance and minimizes noise issues on the gate terminals of the MOSFETs. The gate driver must be placed as close as possible to the MOSFETs.
   - Star-point grounding is a good way to minimize noise coupling from one current loop to another. The GND of the driver is connected to the other circuit nodes such as source of power MOSFET and ground of PWM controller at one, single point. The connected paths must be as short as possible to reduce inductance.
   - Use a ground plane to provide noise shielding. Fast rise and fall times at OUT may corrupt the input signals during transition. The ground plane must not be a conduction path for any current loop. Instead the ground plane must be connected to the star-point with one single trace to establish the ground potential. In addition to noise shielding, the ground plane can help in power dissipation as well.
3. In noisy environments, tying inputs of an unused channel of the UCC2742x-Q1 device to VDD or GND using short traces in order to ensure that the output is enabled and to prevent noise from causing malfunction in the output may be necessary.
4. Separate power traces and signal traces, such as output and input signals.

10.2 Layout Example

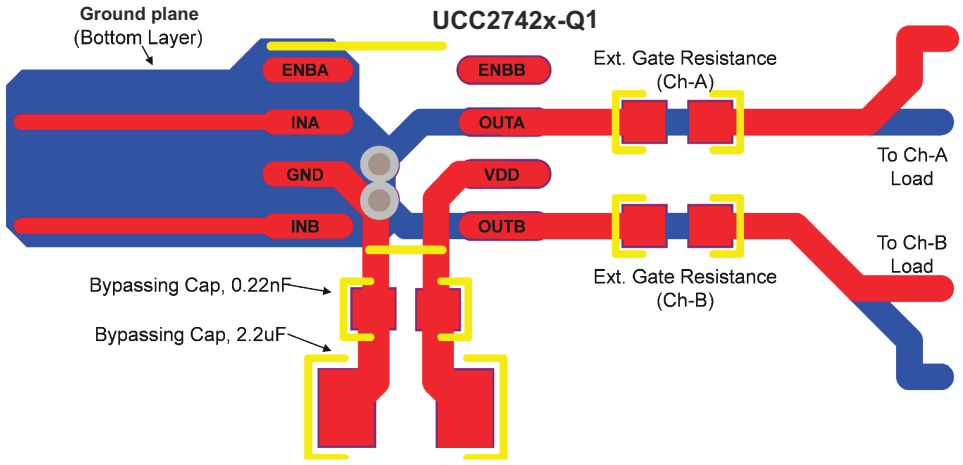


図 10-1. Recommended PCB Layout for UCC2742x-Q1

10.3 Thermal Considerations

The useful range of a driver is greatly affected by the drive power requirements of the load and the thermal characteristics of the IC package. For a power driver to be useful over a particular temperature range, the package must allow for the efficient removal of the heat produced while keeping the junction temperature within rated limits. The UCC2742x-Q1 family of drivers is available in three different packages to cover a range of application requirements.

As shown in the power dissipation rating table, the 8-pin SOIC (D) package has a power rating of around 0.5 W with T_A = 70°C. This limit is imposed in conjunction with the power derating factor also given in the セクション 6.7 table. Note that the power dissipation in our earlier example is 0.432 W with a 10-nF load, 12 V_{DD}, switched at 300 kHz. Thus, only one load of this size could be driven using the D package, even if the two onboard drivers are paralleled. The difficulties with heat removal limit the drive available in the older packages.

The 8-pin MSOP with PowerPAD (DGN) package significantly relieves this concern by offering an effective means of removing the heat from the semiconductor junction. As described in reference 2 of the セクション 11.2.1, the PowerPAD packages offer a leadframe die pad that is exposed at the base of the package. This pad is soldered to the copper on the PCB directly underneath the IC package, reducing the $R_{\theta\ JC(bot)}$ down to 5.9°C/W. Data is presented in reference 2 of セクション 11.2.1 to show that the power dissipation can be quadrupled in the PowerPAD configuration when compared to the standard packages. The PCB must be designed with thermal lands and thermal vias to complete the heat removal subsystem. This allows a significant improvement in heat sinking over that available in the D package, and is shown to more than double the power capability of the D package. Note that the PowerPAD is not directly connected to any leads of the package. However, it is electrically and thermally connected to the substrate which is the ground of the device.

11 Device and Documentation Support

12 Revision History

資料番号末尾の英字は改訂を表しています。その改訂履歴は英語版に準じています。

Changes from Revision H (October 2016) to Revision I (November 2023) **Page**

- Deleted top-side marking and T_A range from the Device Comparison Table. Refer to the Mechanical, Packaging, and Orderable Information for this information ... 3
- Changed ESD CDM rating value from ±1500 V to ±1000 V in ESD Ratings ... 6
- Changed input threshold voltage values, deleted V_{OH} output high level and V_{OL} output low level, changed output resistance high and output resistance low values and deleted Latch-up protection from Electrical Characteristics ... 8
- Changed UCC274323 to UCC27423 in 図 6-9, changed 図 6-27 and added -Q1 to part number in several graphs ... 11

Changes from Revision G (May 2016) to Revision H (October 2016) **Page**

- Changed the UCC27424-Q1 pinout drawing to show two, noninverting channels ... 4
- Changed the units of the capacitors in the *Parallel Outputs* figure from mF to µF ... 17

Changes from Revision F (September 2012) to Revision G (May 2016) **Page**

- 「ESD 定格」表、「機能説明」セクション、「デバイスの機能モード」セクション、「アプリケーションと実装」セクション、「電源に関する推奨事項」セクション、「レイアウト」セクション、「デバイスおよびドキュメントのサポート」セクション、「メカニカル、パッケージ、および注文情報」セクションを追加 ... 1
- 「特長」および「概要」セクションに MSOP パッケージの情報を追加 ... 1

Changes from Revision E (July, 2012) to Revision F (September, 2012) **Page**

- Changed the word terminal to pin per new standards ... 4
- Removed derating factor column in dissipation ratings table, and changed the θ_{JC} value from 4.7 to 11.9, the θ_{JA} value from 50–59 to 63, and the power rating T_A = 70°C (mW) value from 1370 to 873 for the DGN package. ... 10

13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

OTHER QUALIFIED VERSIONS OF UCC27423-Q1, UCC27424-Q1, UCC27425-Q1 :

- Catalog : UCC27423, UCC27424, UCC27425
- Enhanced Product : UCC27423-EP, UCC27424-EP

NOTE: Qualified Version Definitions:

- Catalog - TI's standard catalog product
- Enhanced Product - Supports Defense, Aerospace and Medical Applications
