WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

7.3.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 3). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 3) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

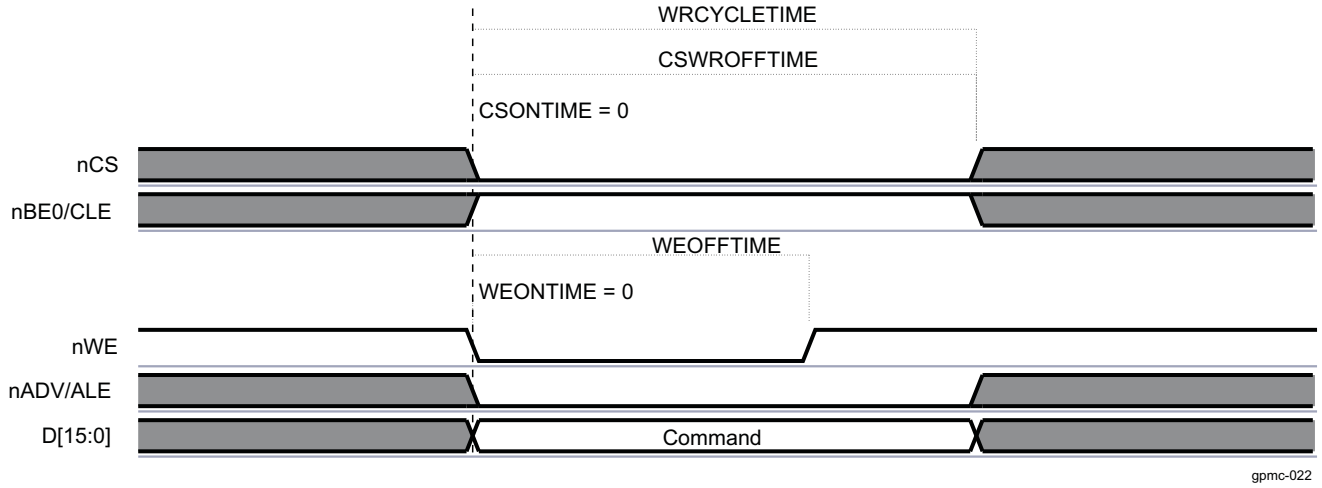
7.3.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 7-185 shows the NAND command latch cycle.

Figure 7-185. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

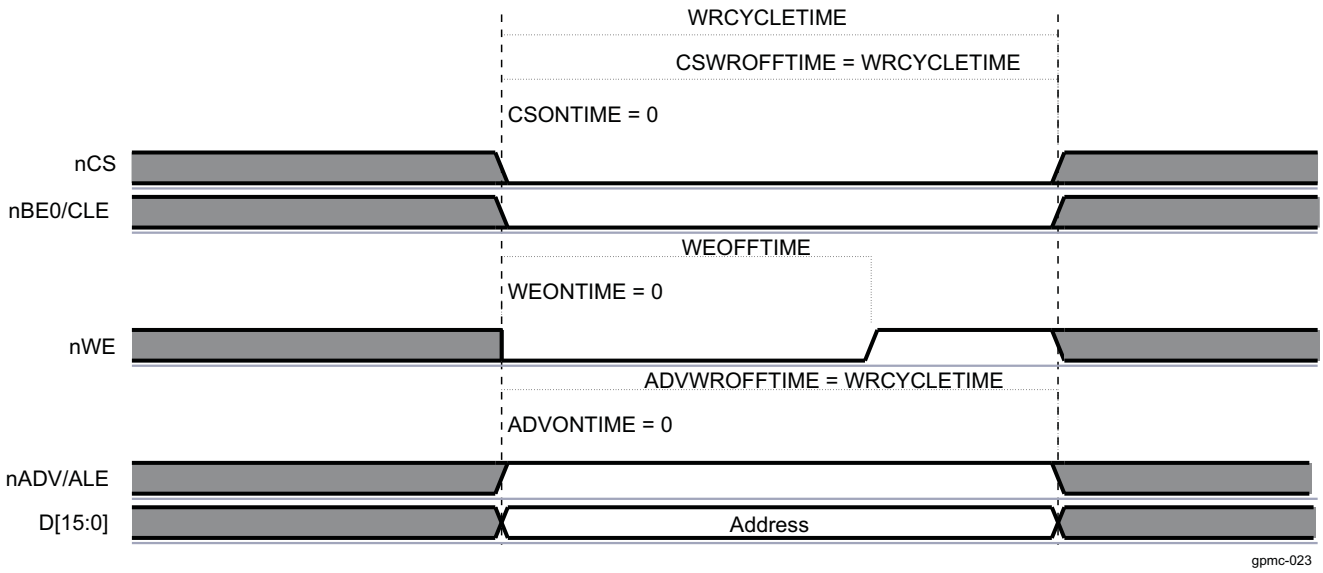
7.3.4.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 7-186 shows the NAND address latch cycle.

Figure 7-186. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

7.3.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 3) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

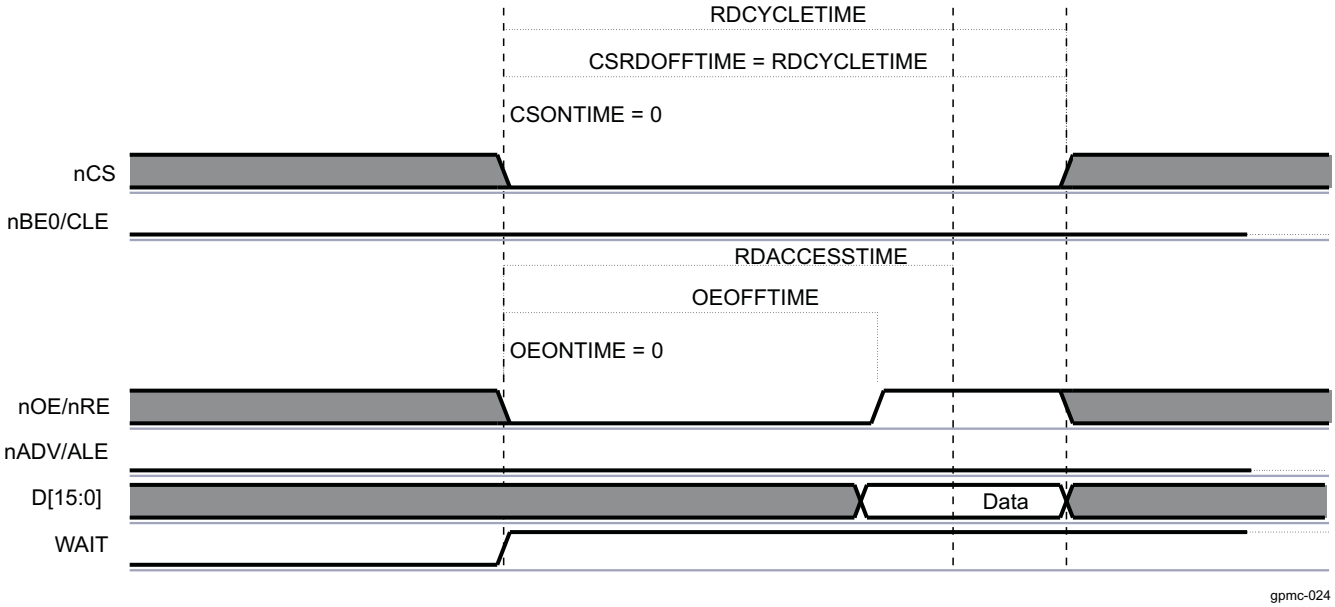
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 7-187 shows the NAND data read cycle.

Figure 7-187. NAND Data Read Cycle

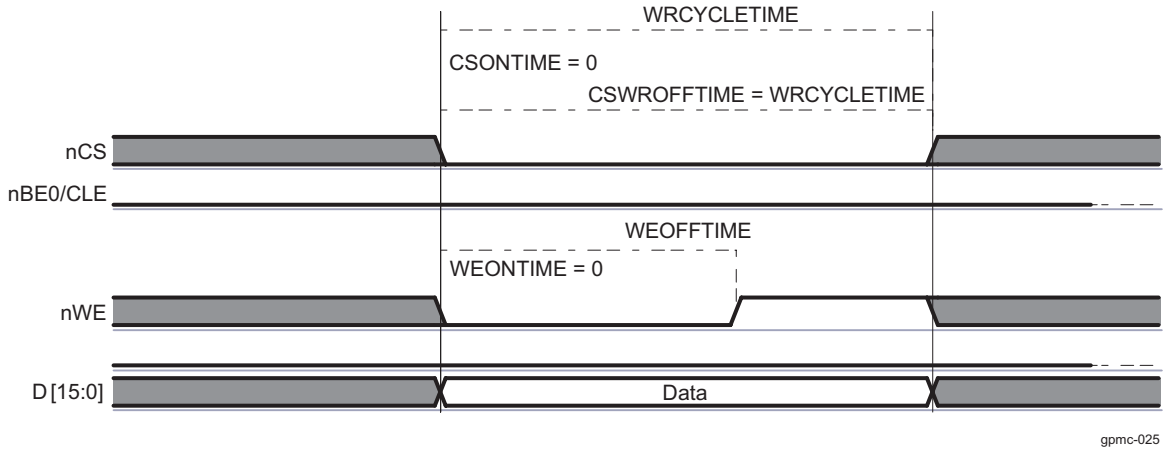


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 7-188 shows the NAND data write cycle.

Figure 7-188. NAND Data Write Cycle



7.3.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 7.3.4.12.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

7.3.4.12.1.7 Read and Write Access Size Adaptation

7.3.4.12.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

7.3.4.12.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

7.3.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

7.3.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

7.3.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for NAND device ready signal monitoring.

7.3.4.12.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

7.3.4.12.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

7.3.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

7.3.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 7-473 describes the ECC enable settings.

Table 7-473. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 7-473. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	00h–FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	00h–FFh	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

7.3.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 7-189 and Figure 7-190. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

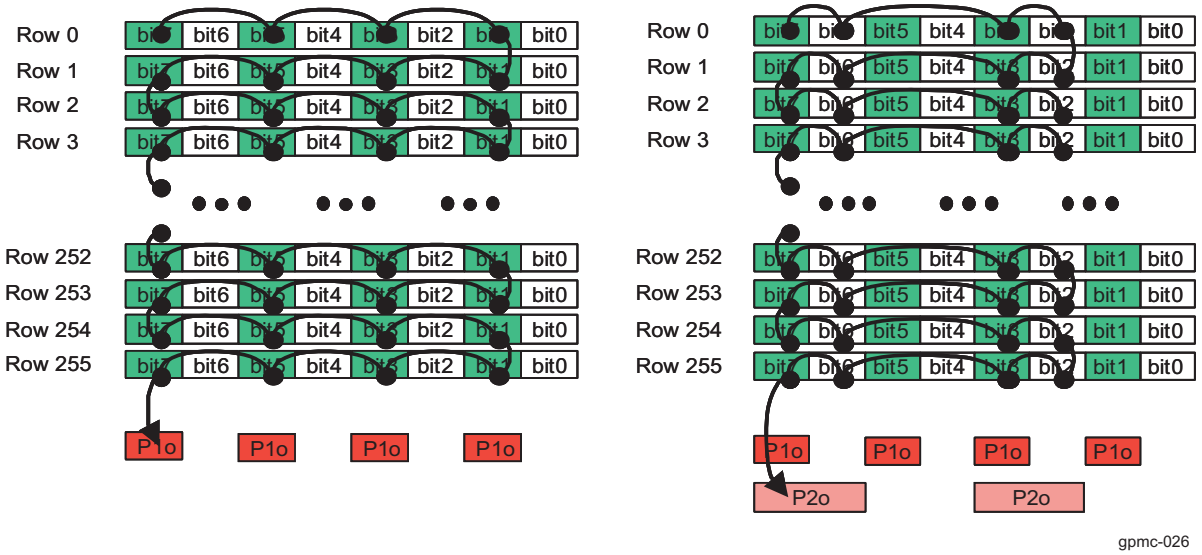
P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 7-189. Hamming Code Accumulation Algorithm (1/2)

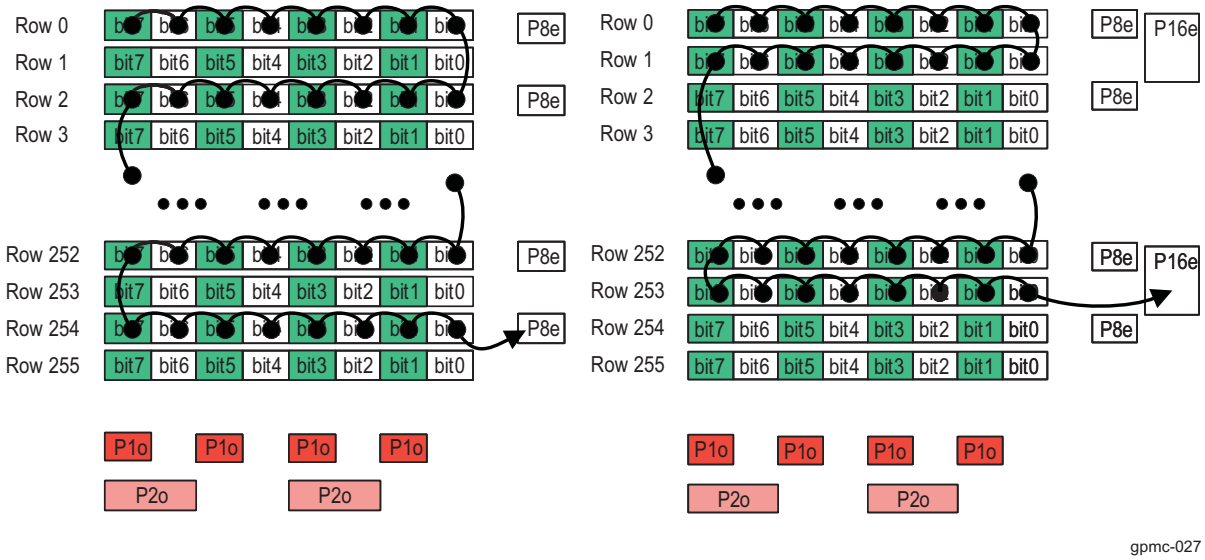


For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 7-190. Hamming Code Accumulation Algorithm (2/2)



Unused parity bits in the result registers are set to 0.

Figure 7-191 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 7-191. ECC Computation for a 256-Byte Data Stream (Read or Write)

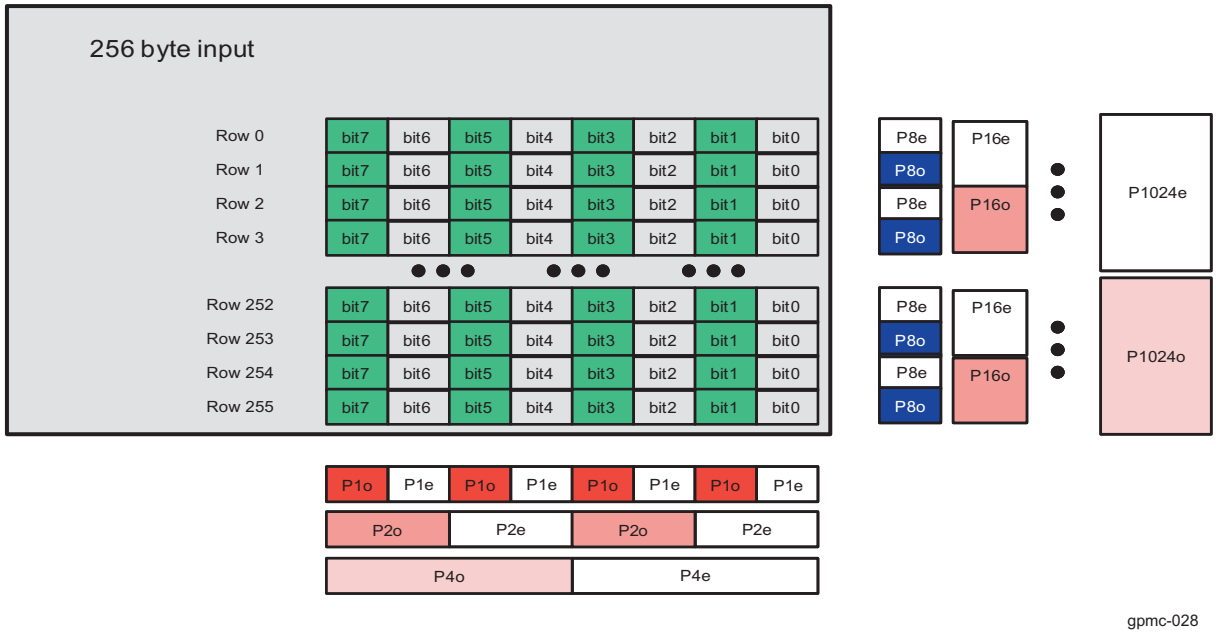


Figure 7-192 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

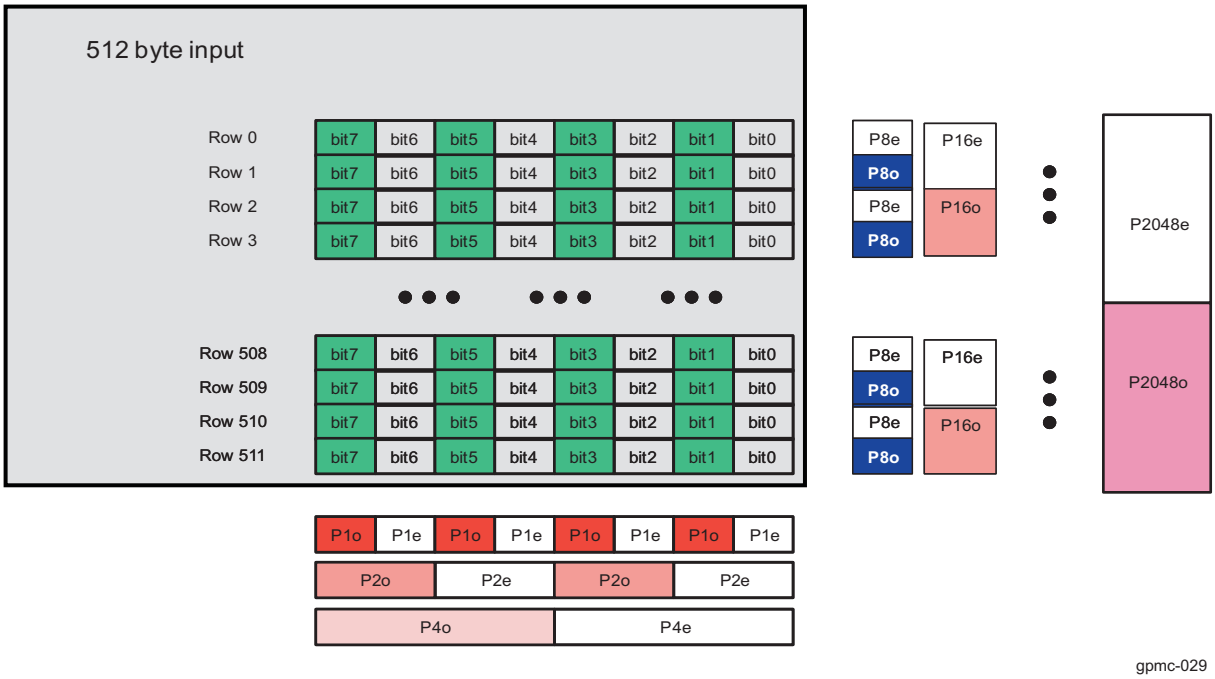
Figure 7-192. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

7.3.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

7.3.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

7.3.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 7-193 and Figure 7-194 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 7-193. 128 Word16 ECC Computation

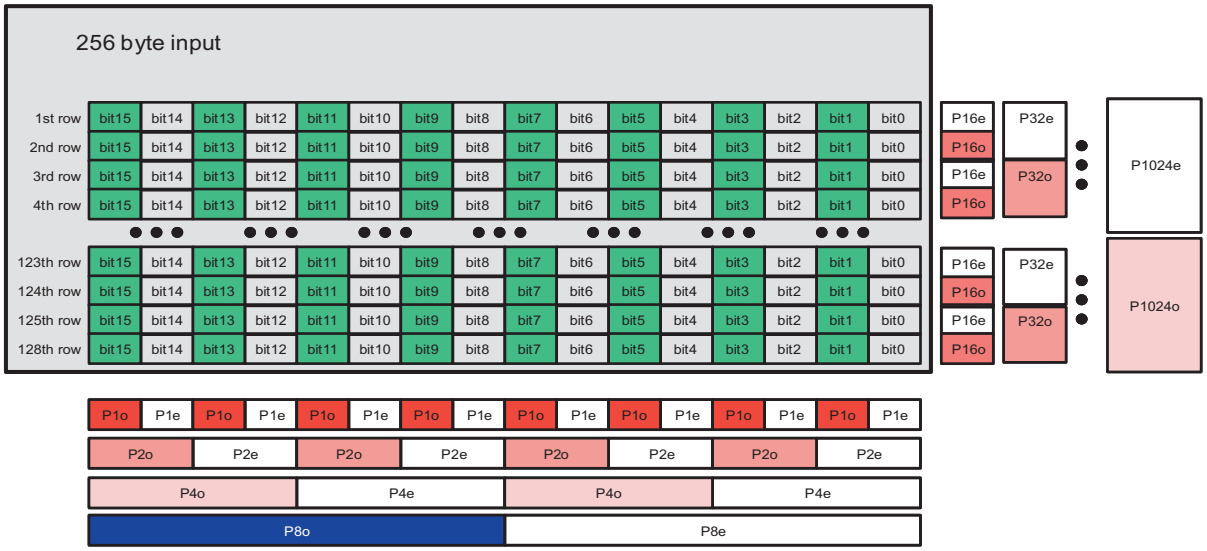


Figure 7-194. 256 Word16 ECC Computation

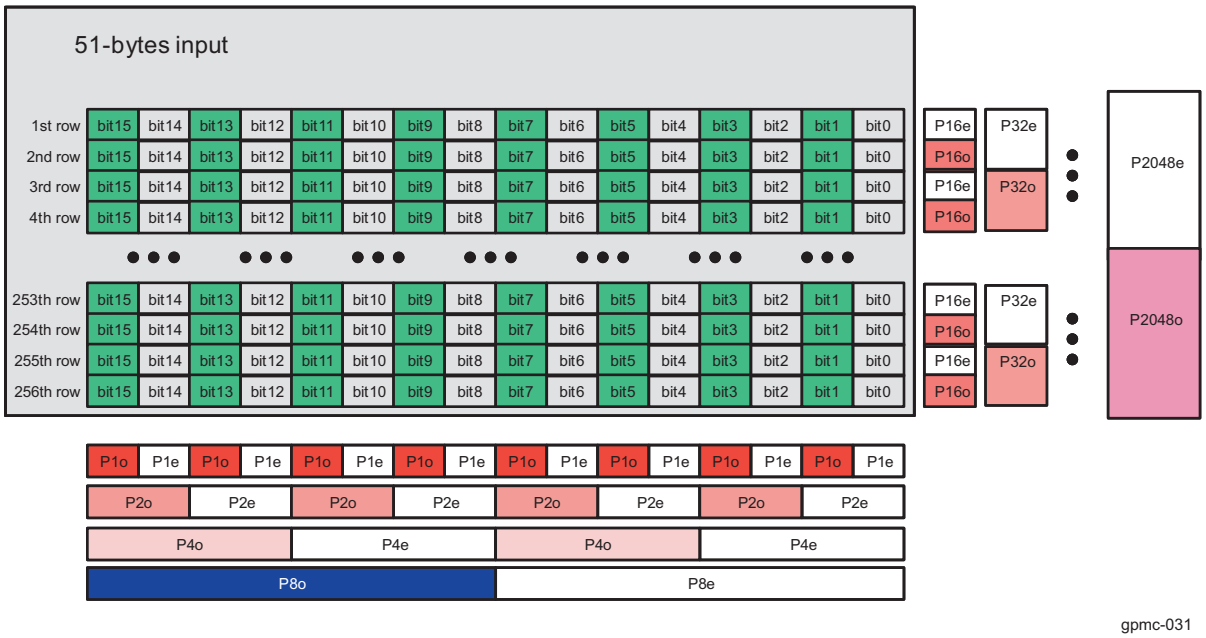


7.3.4.12.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

7.3.4.12.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy

accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.

- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

7.3.4.12.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 7-474.

Table 7-474. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 3):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

7.3.4.12.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + ... + b0 * x^{i}$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 7-475 and Table 7-476 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (200h), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and $M(2^{12}–1)$ of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 7-475. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
000h	(MSB) Byte 511 (1FFh)
001h	Byte 510 (1FEh)
...	...
1FFh	Byte 0 (0h) (LSB)

Table 7-476. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
000h	Byte 510 (1FEh)	(MSB) Byte 511 (1FFh)
002h	Byte 508 (1FCh)	Byte 509 (1FDh)
...	...	...
1FEh	Byte 0 (0h)	(LSB) Byte 1 (1h)

Table 7-477 through Table 7-482 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 7-477. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

Table 7-478. Misaligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S + 1) / 2 – 2	Nibble 2	Nibble 1
(S + 1) / 2 – 1	Nibble 0 (LSB)	

Table 7-479. Aligned Nibble Mapping of Message in 16-Bit NAND

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
S/2 – 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 – 2	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

Table 7-480. Misaligned Nibble Mapping of Message in 16-Bit NAND (1 Unused Nibble)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 1) / 2 – 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S + 1) / 2 – 2	Nibble 0 (LSB)		Nibble 2	Nibble 1

Table 7-481. Misaligned Nibble Mapping of Message in 16-Bit NAND (2 Unused Nibbles)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 2) / 2 – 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S + 2) / 2 – 2			Nibble 1	Nibble 0 (LSB)

Table 7-482. Misaligned Nibble Mapping of Message in 16-Bit NAND (3 Unused Nibbles)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 3) / 2 – 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

7.3.4.12.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

7.3.4.12.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 7.3.4.12.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

7.3.4.12.3.2.2.4 Manual Mode (0h)

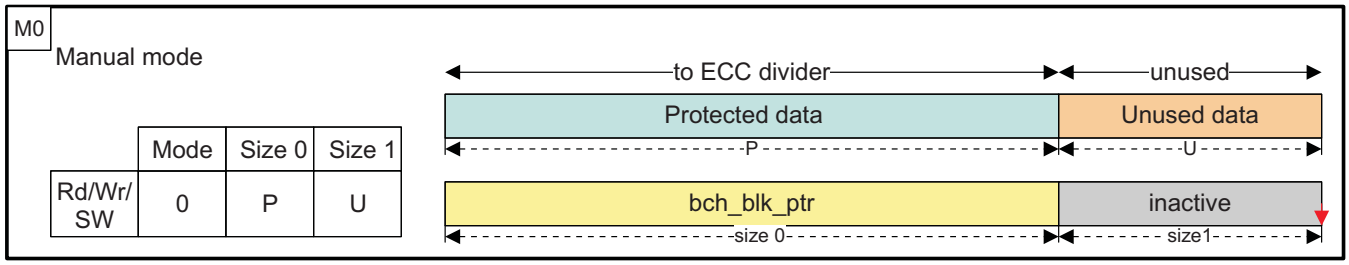
This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 = 5h
- GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1 = 3h

NOTE: In the following figures, size and size0 are the same parameter.

Figure 7-195. Manual Mode Sequence and Mapping



gpmc-032

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

7.3.4.12.3.2.2.5 Mode 1h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

7.3.4.12.3.2.2.6 Mode Ah (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

7.3.4.12.3.2.2.7 Mode 2h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

7.3.4.12.3.2.2.8 Mode 3h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

7.3.4.12.3.2.2.9 Mode 7h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

7.3.4.12.3.2.2.10 Mode 8h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

7.3.4.12.3.2.2.11 Mode 4h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)

  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

7.3.4.12.3.2.2.12 Mode 9h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

7.3.4.12.3.2.2.13 Mode 5h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

7.3.4.12.3.2.2.14 Mode Bh (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

7.3.4.12.3.2.2.15 Mode 6h

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

7.3.4.12.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 7.3.4.12.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 7-196 through Figure 7-198, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} – 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

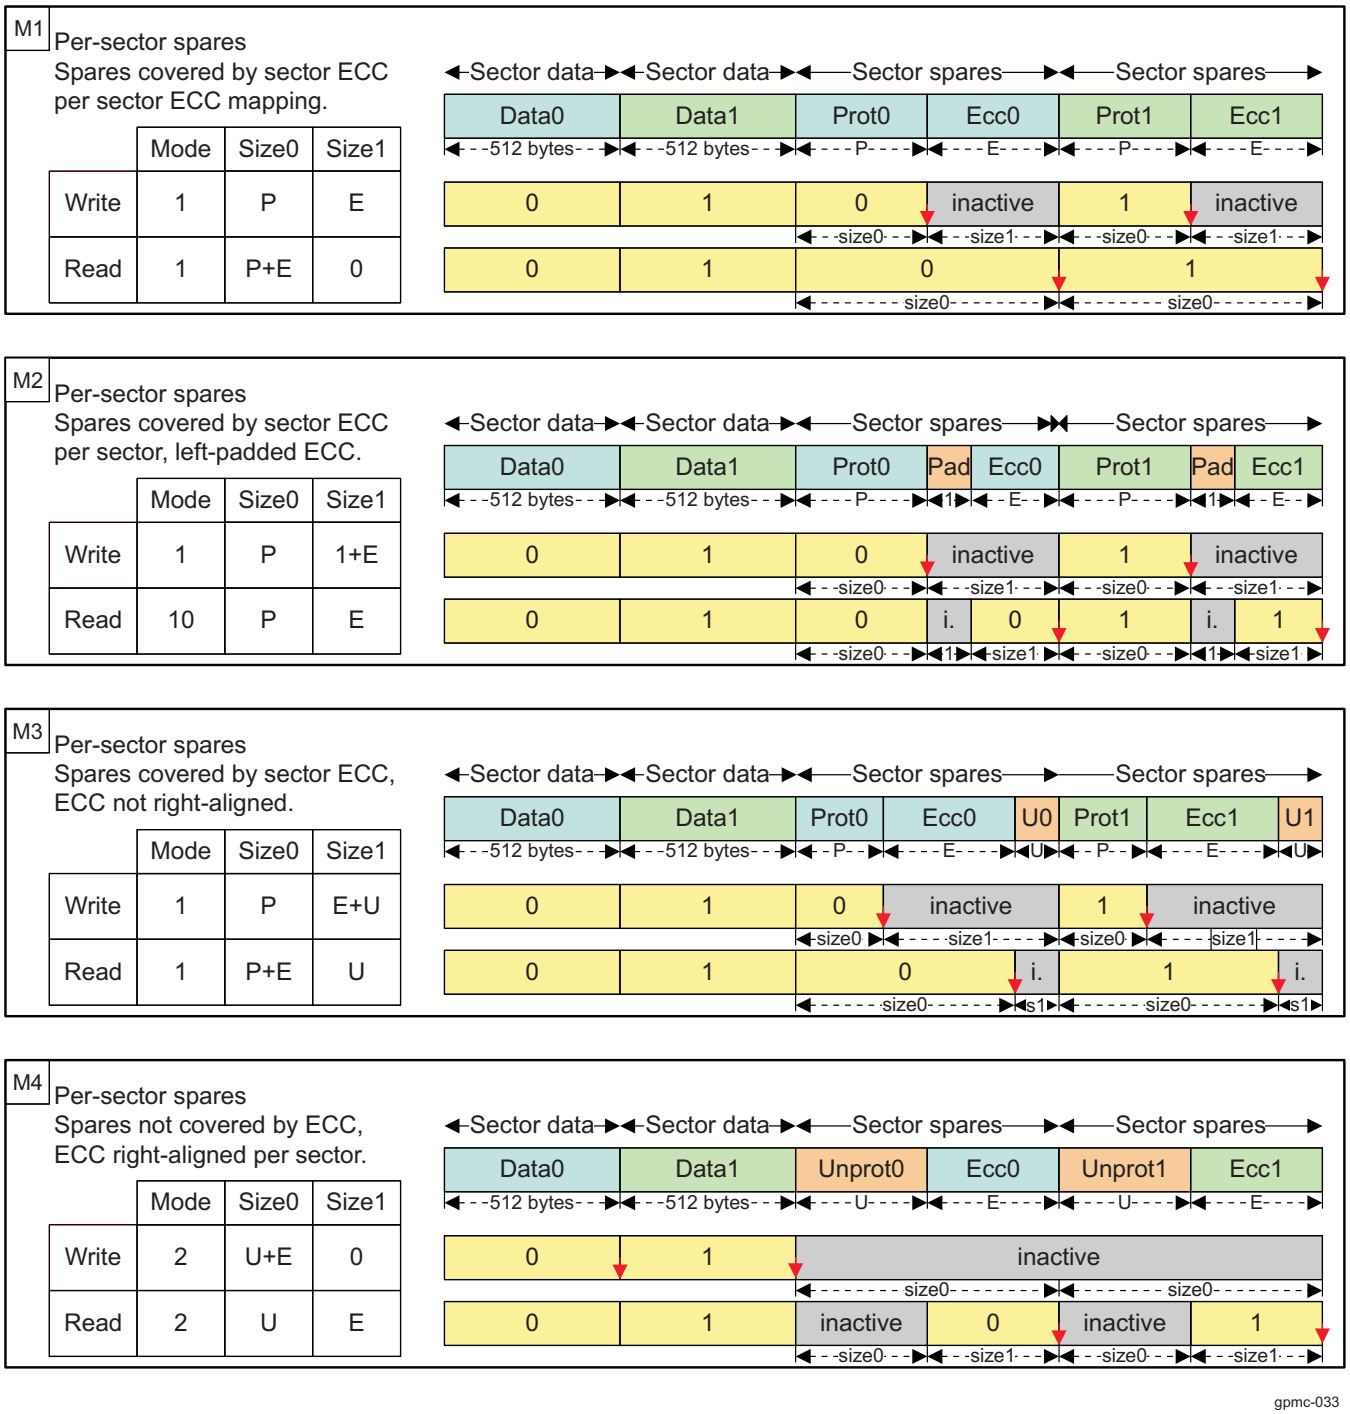
- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

7.3.4.12.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

Figure 7-196. NAND Page Mapping and ECC: Per-Sector Schemes

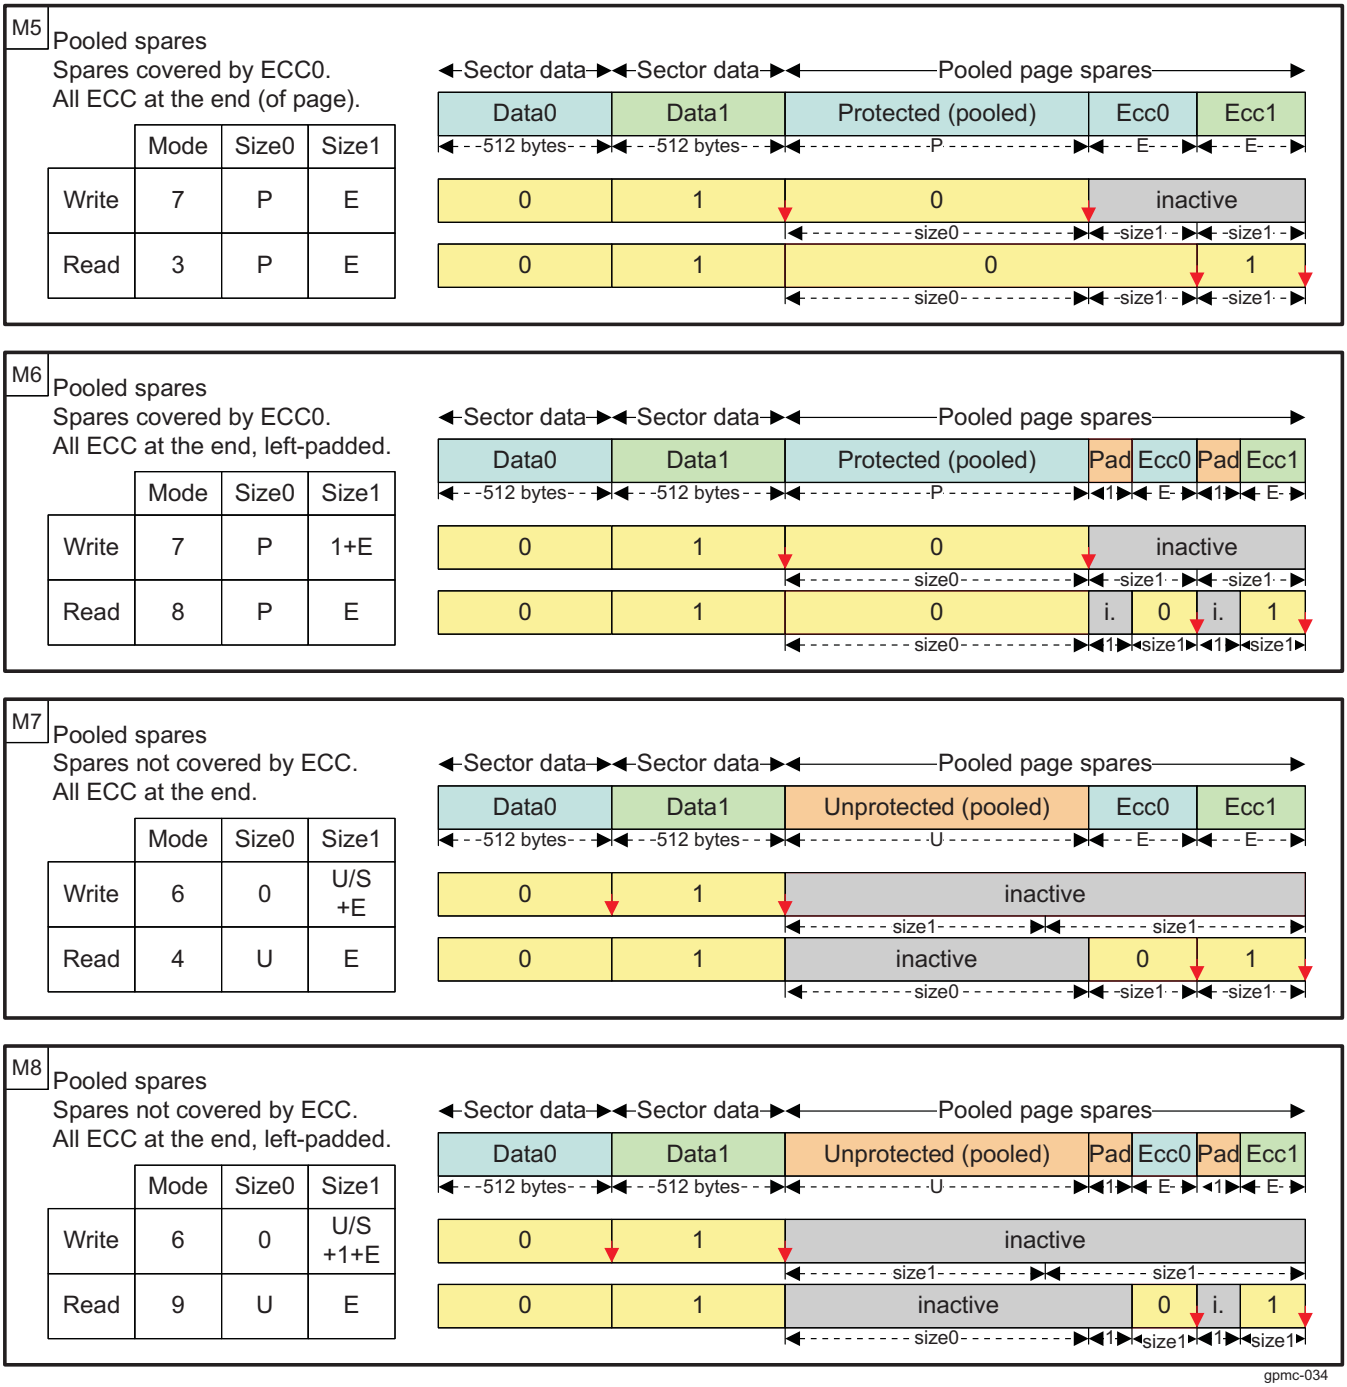


7.3.4.12.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

Figure 7-197. NAND Page Mapping and ECC: Pooled Spare Schemes

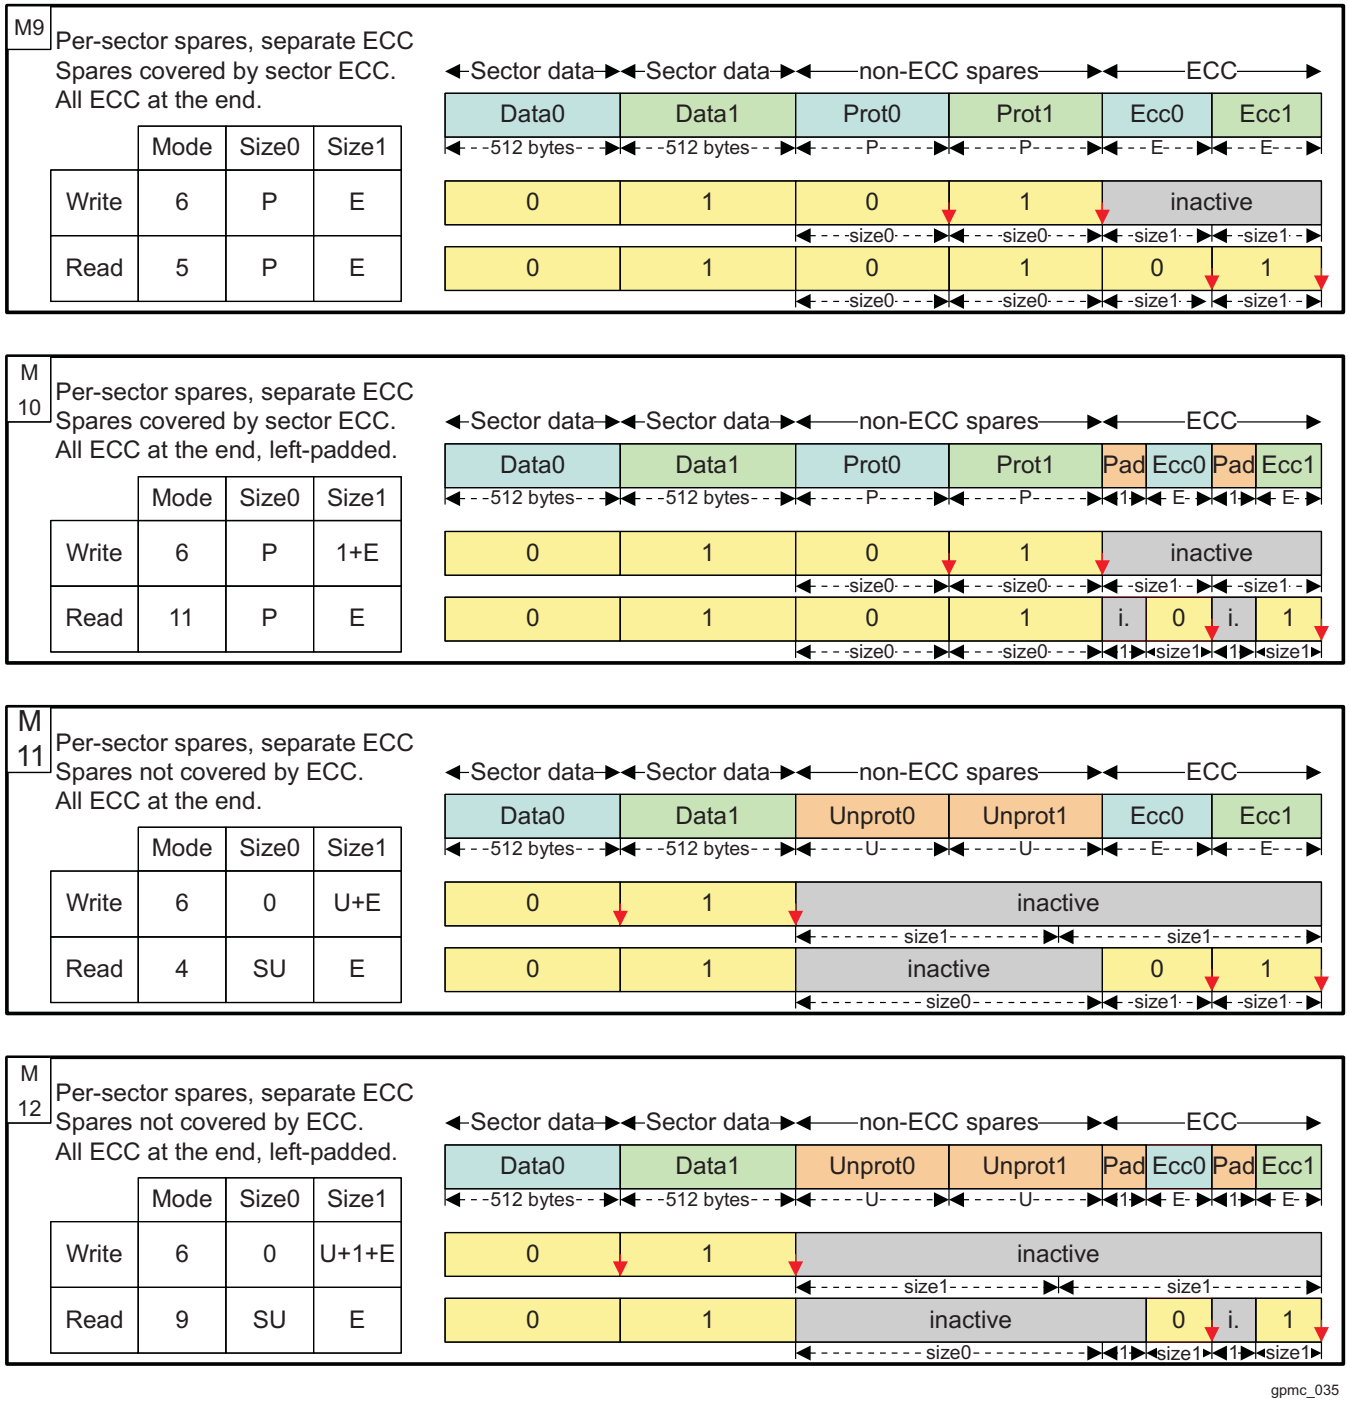


7.3.4.12.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

Figure 7-198. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC



7.3.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

7.3.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

7.3.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 7.3.4.12.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT bit field.

Table 7-483 describes the prefetch mode configuration.

Table 7-483. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1h)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 7.3.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

7.3.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

7.3.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 7-484 describes the write-posting configuration.

Table 7-484. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 7-484. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 7.3.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

7.3.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

7.3.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

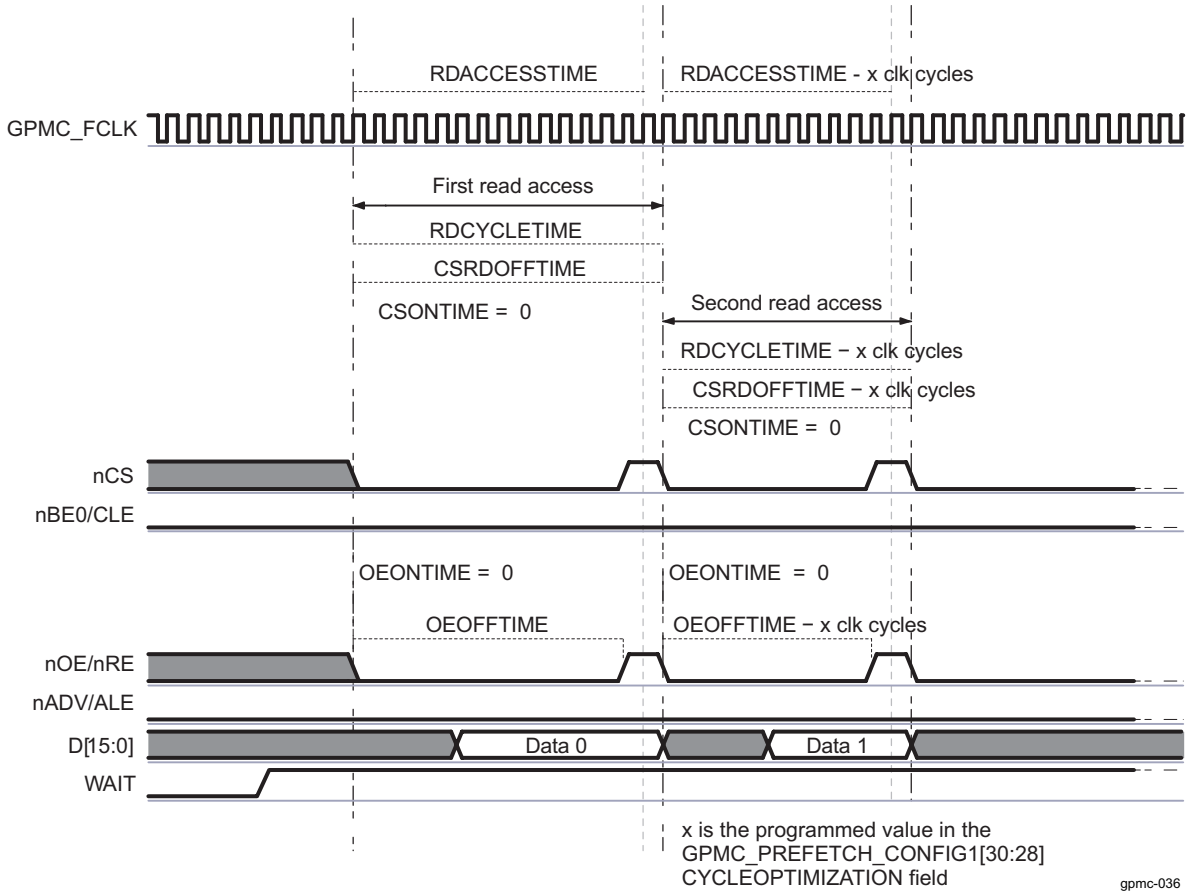
Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 3) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 7-199 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

Figure 7-199. NAND Read Cycle Optimization Timing Description



7.3.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

7.3.5 GPMC Basic Programming Model

7.3.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 7-200 and through Table 7-486 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

Figure 7-200. Programming Model Top-Level Diagram

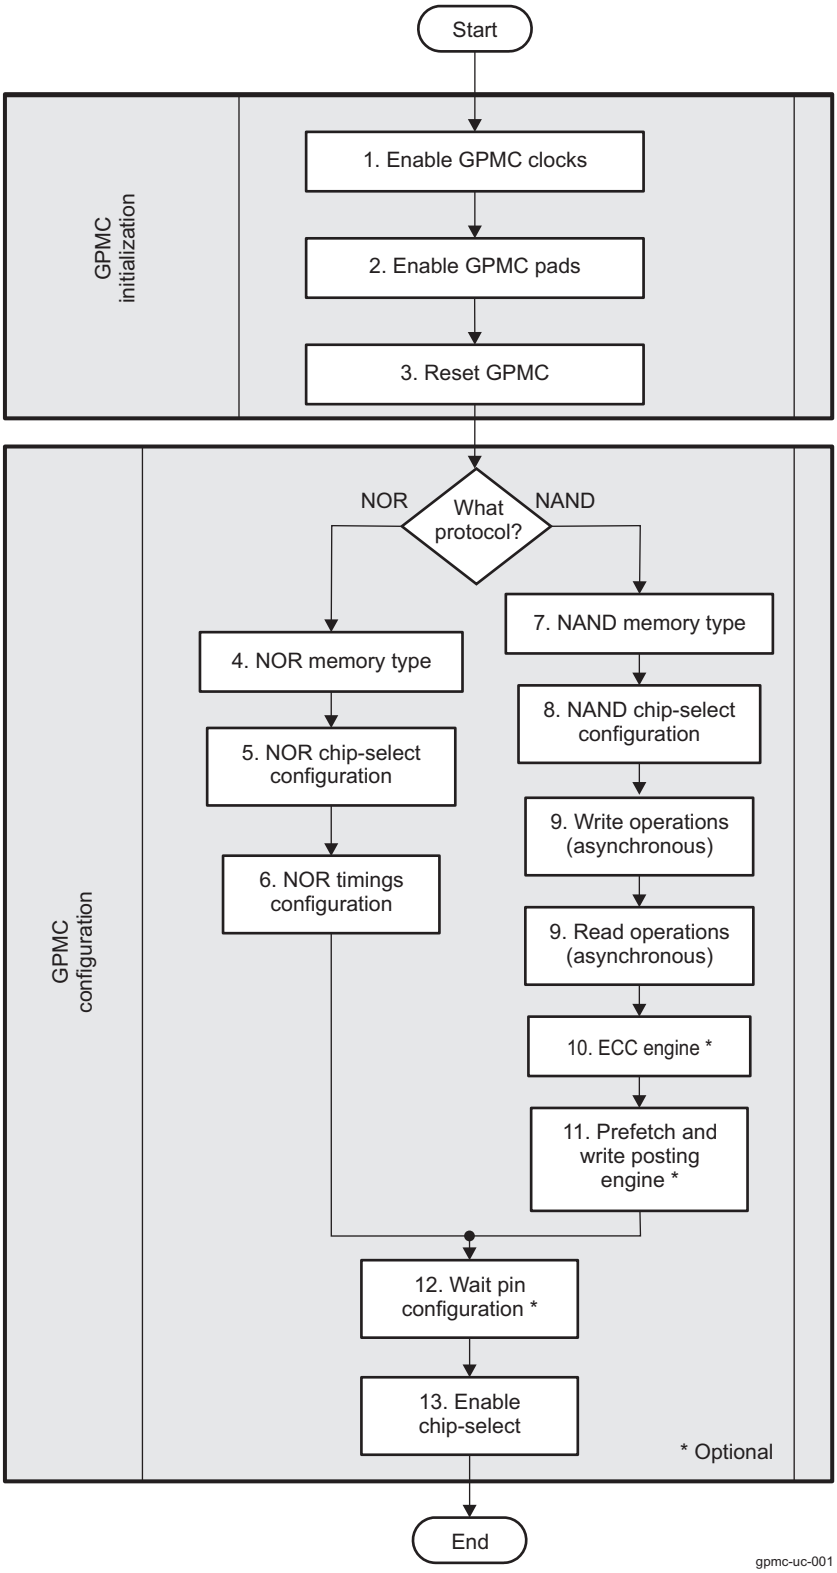


Table 7-485. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 7-488.
NOR Chip-Select Configuration	See Table 7-489.
NOR Timings Configuration	See Table 7-490.
WAIT Pin Configuration	See Table 7-498.
Enable Chip-Select	See Table 7-499.

Table 7-486. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 7-493.
NAND Chip-Select Configuration	See Table 7-494.
Write Operations (Asynchronous)	See Table 7-495.
Read Operations (Asynchronous)	See Table 7-495.
ECC Engine	See Table 7-496.
Prefetch and Write-Posting Engine	See Table 7-497.
WAIT Pin Configuration	See Table 7-498.
Enable Chip-Select	See Table 7-499.

7.3.5.2 GPMC Initialization

Table 7-515 describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 7-487. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG[1] SOFTRESET	1h
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	1h

7.3.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 7-488. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0h
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency (1).	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time (1).	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations (1).	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

Table 7-488. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

Table 7-489. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 7-490. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 7.3.5.6, *GPMC Timing Parameters*	

Table 7-491. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable WAIT pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable WAIT pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a WAIT pin monitoring time.	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input WAIT pin for the chip-select.	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

Table 7-492. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

7.3.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 7-493. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	2h
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0h
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 7.3.5.5, *Set Memory Access*.	x

Table 7-494. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 7-495. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 7.3.5.6, *GPMC Timing Parameters*.	

Table 7-496. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x (1)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 and [29-22] ECCSIZE1	x (2)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_CONFIG[6-4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	1h

(1) This parameter depends on the numbers of sectors in a page.
(2) Depends on the size of each sector in the NAND page

Table 7-497. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0h
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	1h
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	1h

Table 7-498. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

Table 7-499. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

7.3.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. Table 7-500 and Table 7-501 provide check lists for mode parameters and access type parameters, respectively.

Table 7-500. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0h	–	1h (1)	N/S	0h	–	1h	–
GPMC_CONFIG1_i	29	READTYPE	0h	–	0h (1)	N/S	1h	–	1h	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0h	- (1)	N/S	–	0h	–	1h
GPMC_CONFIG1_i	27	WRITETYPE	–	0h	- (1)	N/S	–	1h	–	1h

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

Table 7-501. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	0h	2h	1h

7.3.5.6 GPMC Timing Parameters

Figure 7-201 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 7-201. NOR Interfacing Timing Parameters Diagram

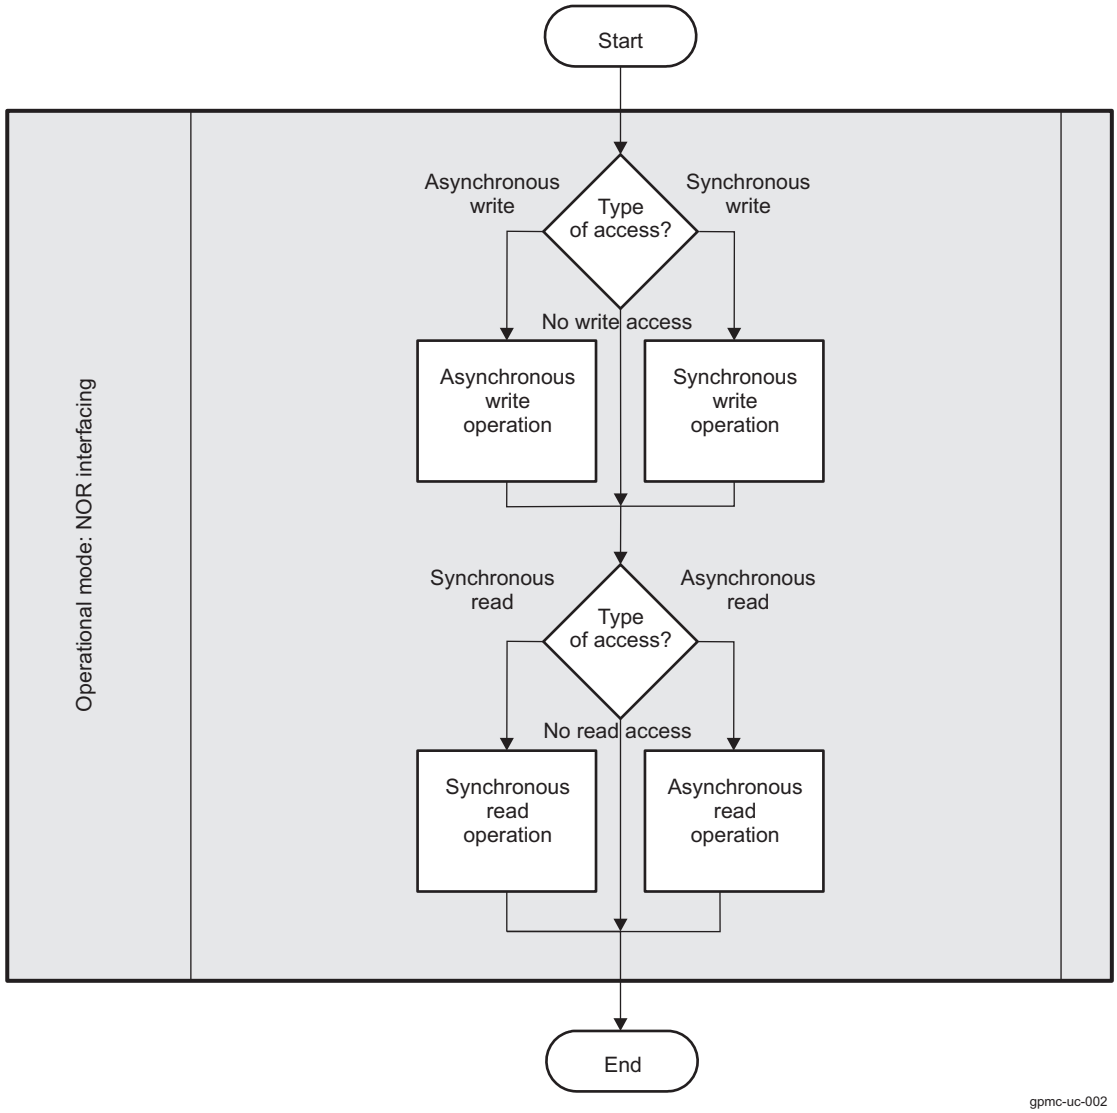

Table 7-502 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 7-502. Timing Parameters

			Asynchronous			Synchronous				Access Type		
Register	Bit	Name	Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address / Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y

GPMC_CONFIG7_i	6	CSVALID	y	y	y	y	y	y	y	y	y	y

7.3.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device Data Manual.

7.3.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 2h. Table 7-503 describes the NAND timing parameters.

Table 7-503. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BEn0_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15:0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15:0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BEn0_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15:0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device Data Manual.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((RdAccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

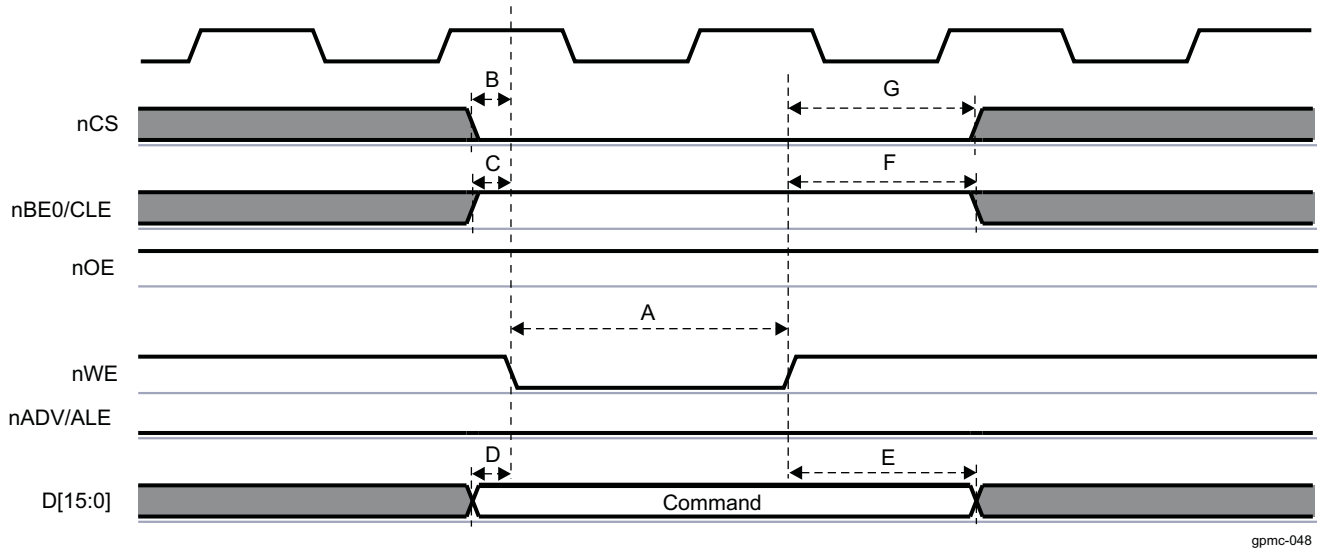
K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 7-202 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

Figure 7-202. NAND Command Latch Cycle Timing Simplified Example



7.3.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0h and when READTYPE or WRITETYPE are set to synchronous mode. Table 7-504 describes the synchronous NOR formulas.

Table 7-504. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_CS low
B	ns	Delay time – address bus valid to GPMC_CLK first edge
		Delay time – GPMC_BEn0_CLE/GPMC_BEn1 valid to GPMC_CLK first edge
C	ns	Pulse duration – GPMC_BEn0_CLE/GPMC_BEn1 low
D	ns	Delay time – GPMC_CLK rising edge to GPMC_BEn0_CLE/GPMC_BEn1 invalid
		Delay time – GPMC_CLK rising edge to GPMC_ADVn_ALE invalid
E	ns	Delay time – GPMC_CLK rising edge to GPMC_CS invalid
		Delay time – GPMC_CLK rising edge to GPMC_OEn_REn invalid
F	ns	Delay time – GPMC_CLK rising edge to GPMC_CS transition
G	ns	Delay time – GPMC_CLK rising edge to GPMC_ADVn_ALE transition
H	ns	Delay time – GPMC_CLK rising edge to GPMC_OEn_REn transition
I	ns	Delay time – GPMC_CLK rising edge to GPMC_WEn transition
J	ns	Delay time – GPMC_CLK rising edge to GPMC_AD data bus transition
		Delay time – GPMC_CLK rising edge to GPMC_BEn0_CLE/GPMC_BEn1 transition
K	ns	Pulse duration – GPMC_ADVn_ALE low
L	ns	Delay time – GPMC_WAIT invalid to first data latching GPMC_CLK edge

The configuration parameters are calculated through the following formulas. For more information, see the device Data Manual.

1. For single read accesses:

   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – RDACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – RDACCESSTIME) * GPMC_FCLK period

2. For burst read accesses (where n is the page burst access number):

   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSRDOFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period

3. For burst write accesses (where n is the page burst access number):

   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSWROFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period

4. For all accesses:

   For nCS falling edge (chip-select activated):

   - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 1h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 2h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in reading mode:

   - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 1h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 2h:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 2h:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For gpmc_nadv low pulse duration:

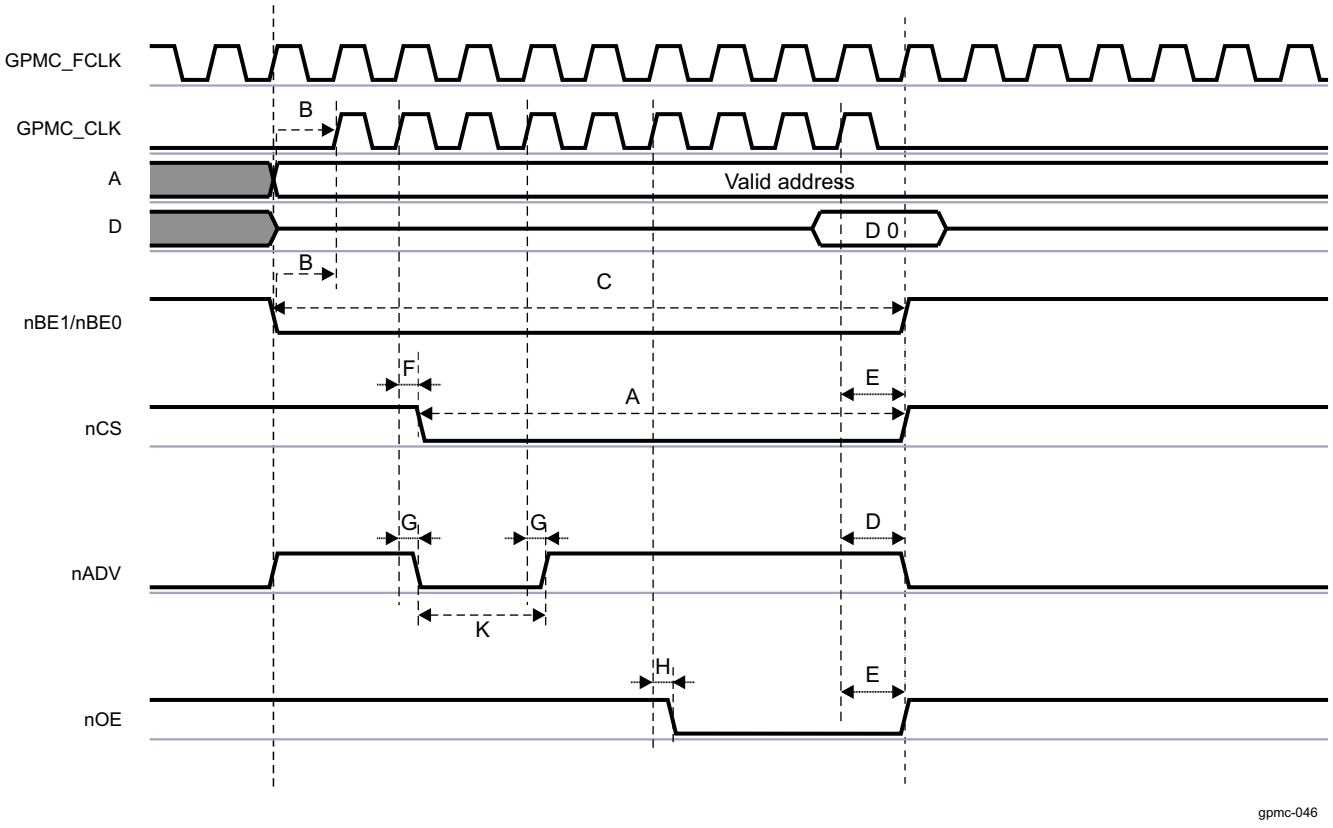
- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 7-203 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

Figure 7-203. Synchronous NOR Single Read Simplified Example



7.3.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0h and when READTYPE or WRITETYPE are set to asynchronous mode. Table 7-505 describes the asynchronous NOR formulas.

Table 7-505. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_CS low
B	ns	Delay time – GPMC_CS valid to GPMC_ADVn_ALE invalid
C	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
F	ns	Delay time – GPMC_CS valid to GPMC_WEn invalid
G	ns	Address invalid duration between two successive R/W accesses

Table 7-505. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
H	ns	Setup time – read data valid before GPMC_OEn_REn high
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn invalid (burst read)
J	ns	Delay time – address bus valid to GPMC_CS valid
		Delay time – data bus valid to GPMC_CS valid
		Delay time – GPMC_BEn0_CLE/GPMC_BEn1 valid to GPMC_CS valid
K	ns	Delay time – GPMC_CS valid to GPMC_ADVn_ALE valid
L	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
M	ns	Delay time – GPMC_CS valid to first data latching edge
N	ns	Pulse duration – GPMC_BEn0_CLE/GPMC_BEn1 valid time
O	ns	Delay time – GPMC_CS valid to GPMC_ADVn_ALE valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device Data Manual.

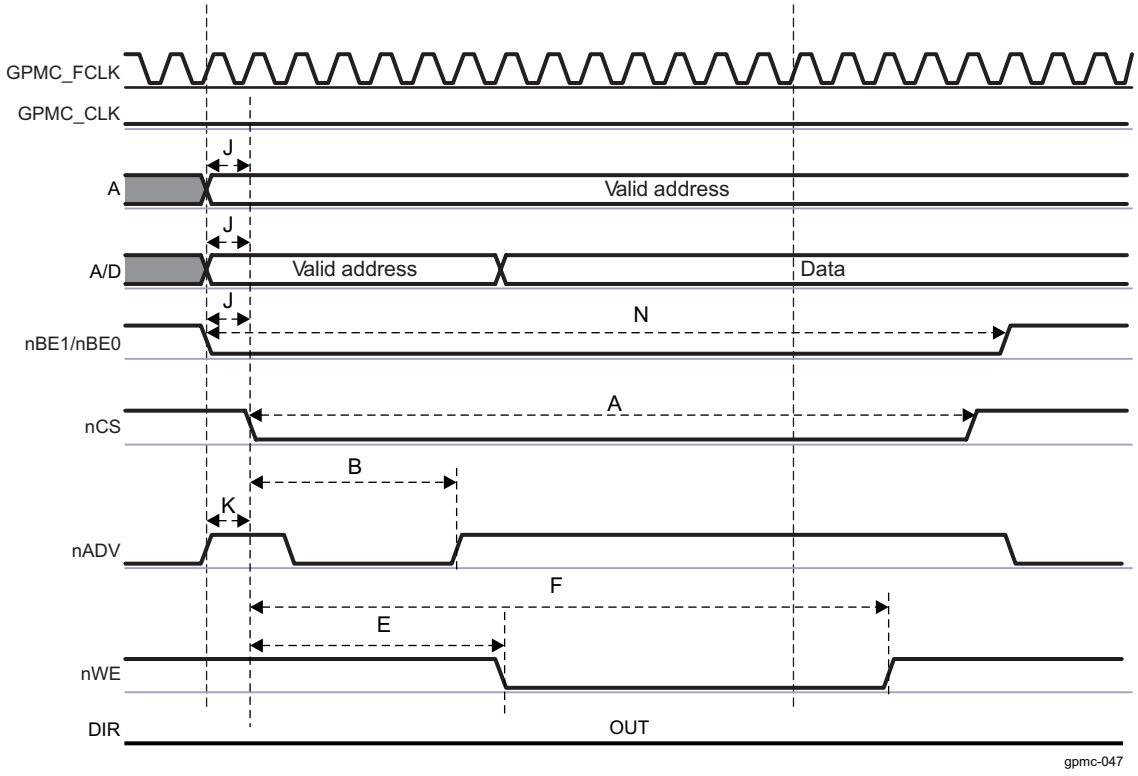
- GPMC_CS low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- GPMC_CS valid to GPMC_ADVn_ALE invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- GPMC_BEn0_CLE/GPMC_BEn1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 7-204 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

Figure 7-204. Asynchronous NOR Single Write Simplified Example



NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

7.3.6 GPMC Use Cases and Tips

7.3.6.1 How to Set GPMC Timing Parameters for Typical Accesses

7.3.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

7.3.6.1.2 Typical GPMC Setup

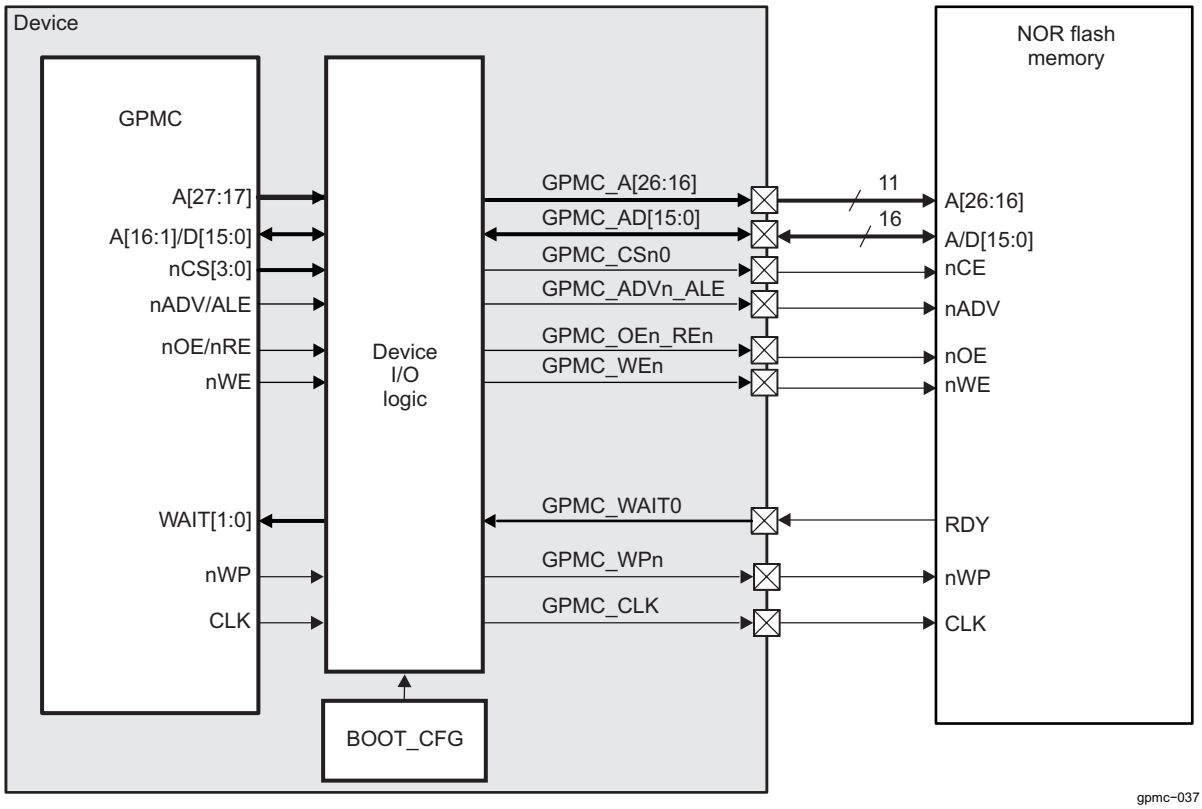
Table 7-506 lists some of the I/Os of the GPMC module.

Table 7-506. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[26:16]	O	Address
GPMC_AD[15:0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
GPMC_CSn[3:0]	O	Chip-selects
GPMC_ADVn_ALE	O	Address valid enable
GPMC_OEn_REn	O	Output enable (read access only)
GPMC_WEn	O	Write enable (write access only)
GPMC_WAIT[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 7-205 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 7-205. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

7.3.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

NOTE: The examples in Section 7.3.6.1.2.1 through Section 7.3.6.1.2.3 are based on a clock rate of 104 MHz. See the device Data Manual for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 7-507 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 7-508 shows how to calculate timings for the GPMC using the memory parameters.

Figure 7-206 shows the synchronous burst read access.

Table 7-507. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3

Table 7-507. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

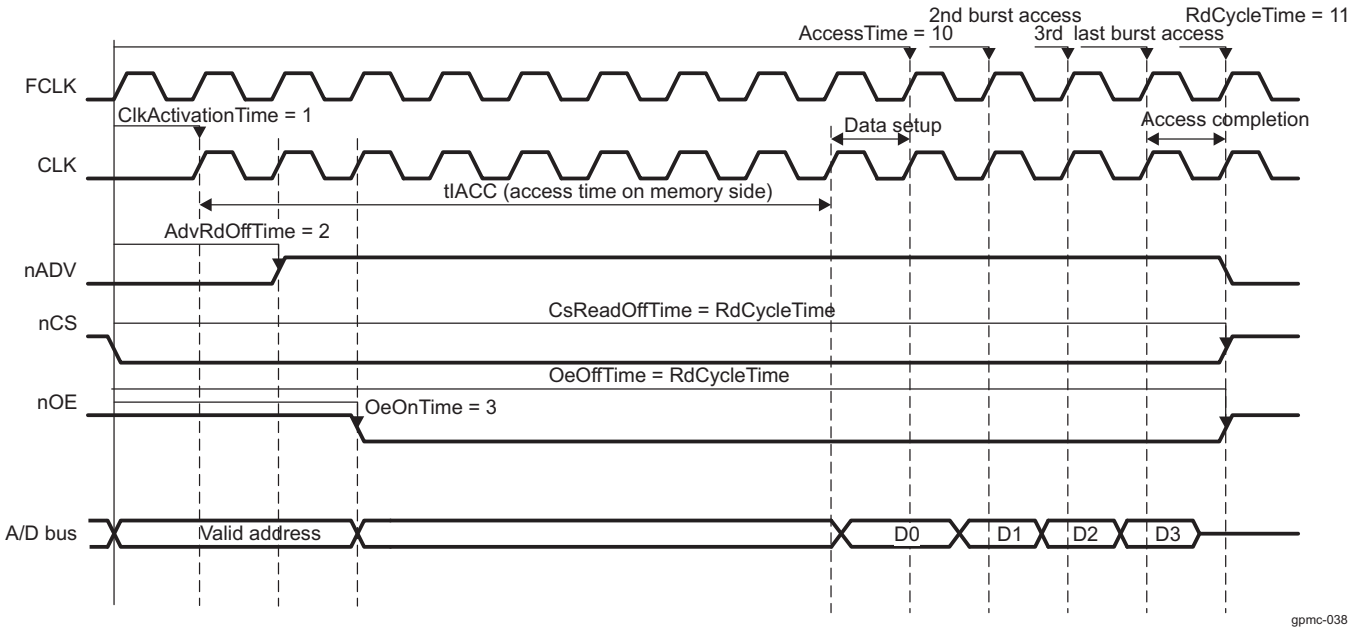
- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 7-508. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0h
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 1h
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	RDACCESSTIME = Ah
PageBurst RdAccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 1h
RdCycleTime	RdAccess time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = Bh
CsOnTime	tCES	0	0	CSONTIME = 0h
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = Bh
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0h
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 2h
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 3h
OeOffTime	RdCycleTime	–	11	OEOFFTIME = Bh

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

Figure 7-206. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



7.3.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 7-509 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 7-510 shows how to calculate timings for the GPMC using the memory parameters.

Figure 7-207 shows the asynchronous read access.

Table 7-509. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 7-509: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

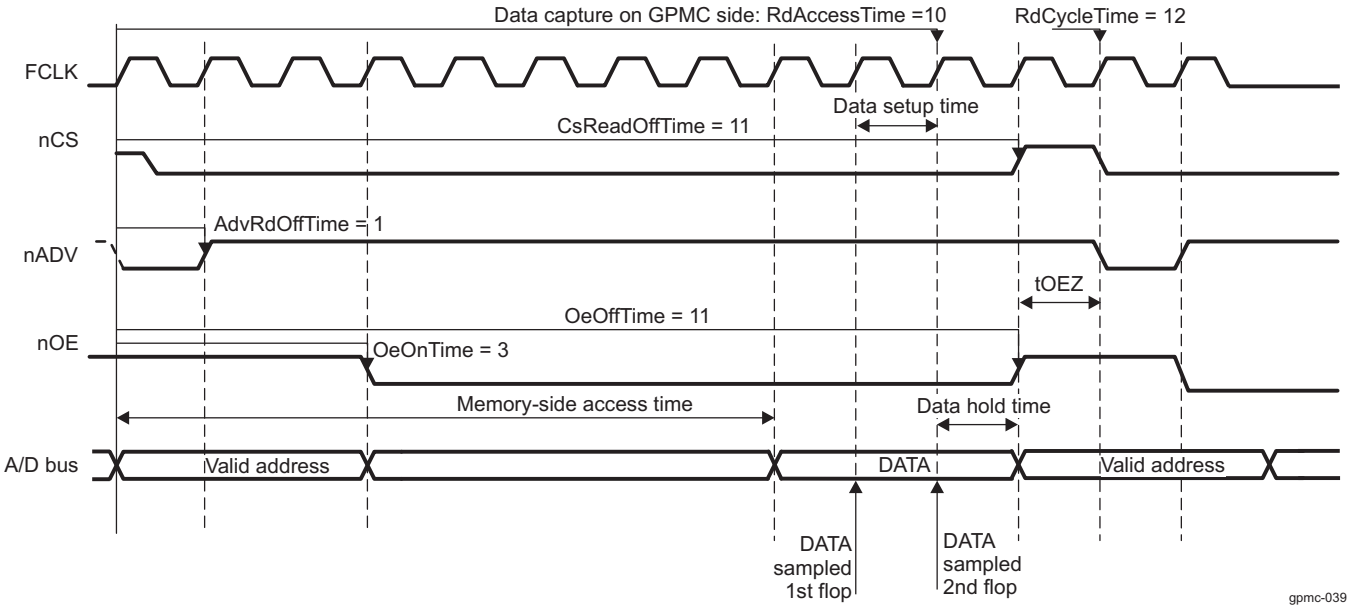
   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 7-510. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = Ah
PageBurstAccess Time	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = Ch
CsOnTime	tCAS	0	0	CSONTIME = 0h
CsReadOffTime	RdAccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = Bh
AdvOnTime	tAAVDS	3	1	ADVONTIME = 1h
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 01h
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 3h
OeOffTime	RdAccessTime + 1cycle	89, 615	11	OEOFFTIME = Bh

Figure 7-207. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



7.3.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 7-512 shows how to calculate timings for the GPMC using the memory parameters.

Table 7-511 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 7-208 shows the synchronous burst write access.

Table 7-511. AC Characteristics for Asynchronous Single Write (Memory Side)

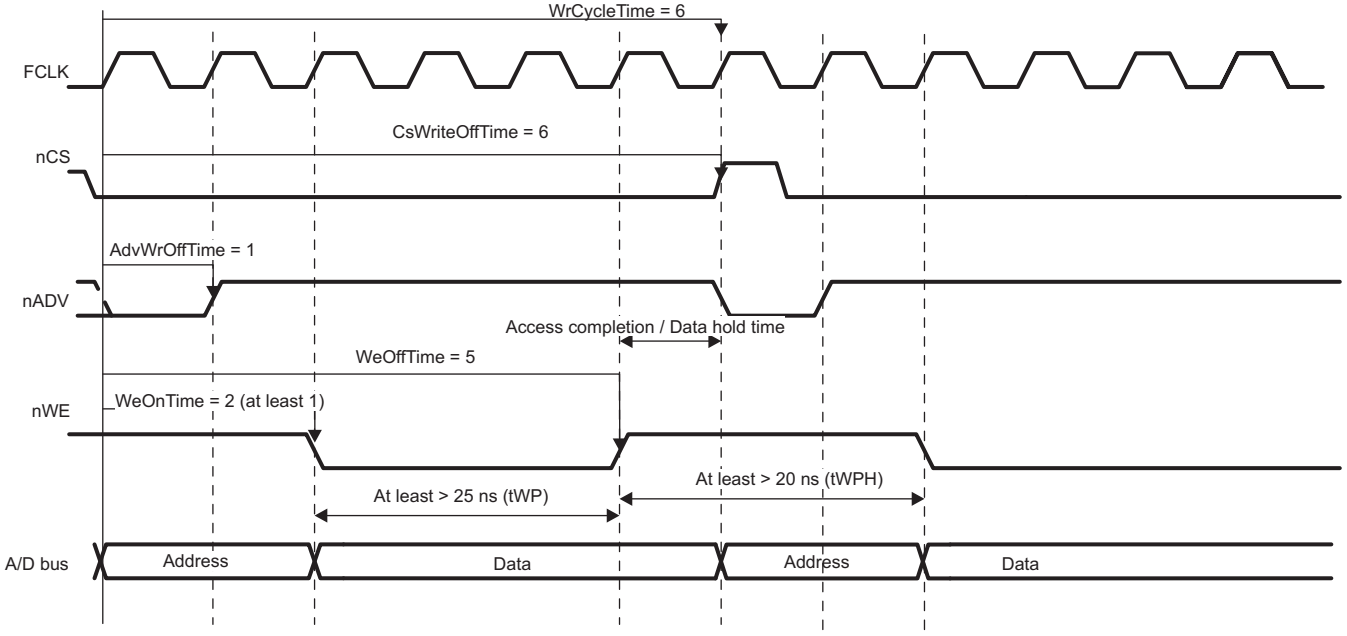
AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device Data Manual.

Table 7-512. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 6h
CsOnTime	tCAS	0	0	CSONTIME = 0h
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 6h
AdvOnTime	tAVSC	3	1	ADVONTIME = 1h
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 1h
WeOnTime	tCS	3	1	WEONTIME = 1h
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 5h

Figure 7-208. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)



7.3.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

7.3.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, and so on)
- 8- and 16-bit NAND flash devices

7.3.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 7-513. Supported Memory Interfaces

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash (1)	OneNAND	16-Bit NAND	8-Bit NAND

7.3.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 7-514 summarizes the NAND interface signals level applied to external device or memories.

Table 7-514. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H

(1) RE stands for rising edge; FE stands for falling edge

Table 7-514. NAND Interface Bus Operations Summary (continued)

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H [2]	H [2]	H [2]	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

[2] Can be nCE high, or WE and nRE high.

7.3.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 7-515 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 7-515. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

7.3.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

7.3.7 GPMC Registers

Table 7-517 lists the memory-mapped registers for the GPMC. All register offset addresses not listed in Table 7-517 should be considered as reserved locations and the register contents should not be modified.

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

Table 7-516. GPMC Instances

Instance	Base Address
GPMC	2181 8000h

Table 7-517. GPMC Registers

Offset	Acronym	Register Name	GPMC Physical Address	Section
0h	GPMC_REVISION	This register contains the IP revision code.	2181 8000h	Section 7.3.7.1
10h	GPMC_SYSCONFIG	Register related to module software reset and local power management.	2181 8010h	Section 7.3.7.2
14h	GPMC_SYSSTATUS	This register provides status information about the module, excluding the interrupt status information.	2181 8014h	Section 7.3.7.3
18h	GPMC_IRQSTATUS	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.	2181 8018h	Section 7.3.7.4
1Ch	GPMC_IRQENABLE	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.	2181 801Ch	Section 7.3.7.5
40h	GPMC_TIMEOUT_CONTROL	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter.	2181 8040h	Section 7.3.7.6
44h	GPMC_ERR_ADDRESS	The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.	2181 8044h	Section 7.3.7.7
48h	GPMC_ERR_TYPE	The GPMC_ERR_TYPE register stores the type of error when an error occurs.	2181 8048h	Section 7.3.7.8
50h	GPMC_CONFIG	The configuration register allows global configuration of the GPMC.	2181 8050h	Section 7.3.7.9

7.3.7.3 GPMC_SYSSTATUS Register (Offset = 14h) [reset = 0000000-h]

GPMC_SYSSTATUS is shown in Figure 7-211 and described in Table 7-525.

This register provides status information about the module, excluding the interrupt status information.

Table 7-524. GPMC_SYSSTATUS Instances

Instance	Physical Address

7.3.7.4 GPMC_IRQSTATUS Register (Offset = 18h) [reset = 0h]

GPMC_IRQSTATUS is shown in Figure 7-212 and described in Table 7-528.

This interrupt status register regroups all the status of the module internal events that can generate an interrupt.

Table 7-527. GPMC_IRQSTATUS Instances

7.3.7.5 GPMC_IRQENABLE Register (Offset = 1Ch) [reset = 0h]

GPMC_IRQENABLE is shown in Figure 7-213 and described in Table 7-531.

The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.

Table 7-579. GPMC_PREFETCH_CONFIG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R/W	0h	Write 0s for future compatibility. Read returns 0.
30-28	CYCLEOPTIMIZATION	R/W	0h	Define the number of GPMC_FCLK cycles to be subtracted from RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, WEOFFTIME 0h: 0 GPMC_FCLK cycle 1h: 1 GPMC_FCLK cycle ... 7h: 7 GPMC_FCLK cycles
27	ENABLEOPTIMIZEDACCESS	R/W	0h	Enables access cycle optimization 0h (R/W) = Access cycle optimization is disabled. 1h (R/W) = Access cycle optimization is enabled.
26-24	ENGINECSSELECTOR	R/W	0h	Selects the chip-select where Prefetch Postwrite engine is active 0h: CS0 1h: CS1 2h: CS2 3h: CS3 4h-7h: Reserved
23	PFPWENROUNDROBIN	R/W	0h	Enables the PFPW RoundRobin arbitration 0h (R/W) = Prefetch Postwrite engine round robin arbitration is disabled. 1h (R/W) = Prefetch Postwrite engine round robin arbitration is enabled.

Table 7-579. GPMC_PREFETCH_CONFIG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22-20	RESERVED	R/W	0h	Write 0s for future compatibility. Read returns 0s.
19-16	PFPWWEIGHTEDPRIO	R/W	0h	When an arbitration occurs between a DMA and a PFPW engine access, the DMA is always serviced. If the PFPWEnRoundRobin is enabled, 0h: The next access is granted to the PFPW engine. 1h: The next two accesses are granted to the PFPW engine. ..., Fh: The next 16 accesses are granted to the PFPW engine.
15	RESERVED	R/W	0h	Write 0s for future compatibility. Read returns 0.
14-8	FIFOTHRESHOLD	R/W	40h	Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request 00h: 0 byte 01h: 1 byte ... 40h: 64 bytes
7	ENABLEENGINE	R/W	0h	Enables the Prefetch Postwite engine 0h (R/W) = Prefetch Postwrite engine is disabled. 1h (R/W) = Prefetch Postwrite engine is enabled.
6	RESERVED	R/W	0h	Write 0s for future compatibility. Read returns 0.
5-4	WAITPINSELECTOR	R/W	0h	Select which wait pin edge detector should start the engine in synchronized mode 0h (R/W) = Selects Wait0 EdgeDetection 1h (R/W) = Selects Wait1 EdgeDetection 2h, 3h: Reserved
3	SYNCHROMODE	R/W	0h	Selects when the engine starts the access to chip-select 0h (R/W) = Engine starts the access to chip-select as soon as STARTENGINE is set 1h (R/W) = Engine starts the access to chip-select as soon as STARTENGINE is set AND wait to nonwait edge detection on the selected wait pin
2	DMAMODE	R/W	0h	Selects interrupt synchronization or DMA request synchronization 0h (R/W) = Interrupt synchronization is enabled. Only interrupt line is activated on FIFO threshold crossing. 1h (R/W) = DMA request synchronization is enabled. A DMA request protocol is used.
1	RESERVED	R/W	0h	Write 0s for future compatibility. Read returns 0.
0	ACCESSMODE	R/W	0h	Selects prefetch read or write-posting accesses 0h (R/W) = Prefetch read mode 1h (R/W) = Write-posting mode

7.4 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

NOTE: ELM is not supported on this family of devices.

7.4.1 ELM Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

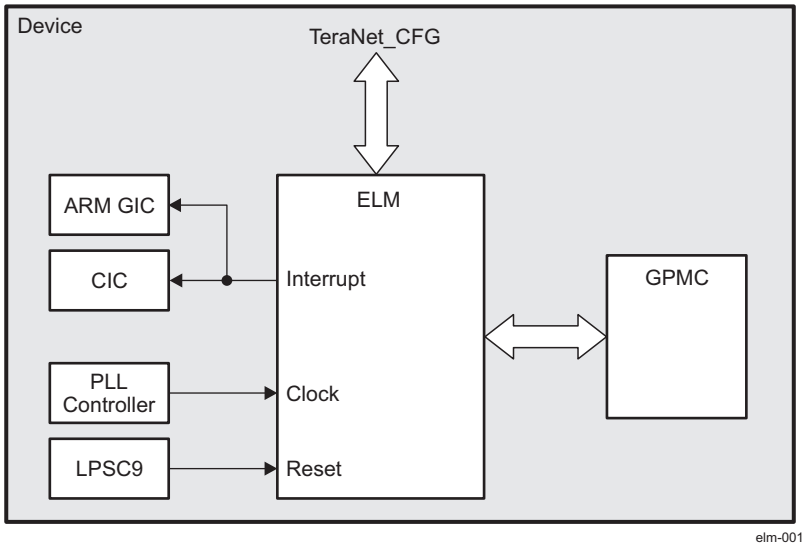
When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode.

Figure 7-245 shows the ELM overview.

Figure 7-245. ELM Overview



7.4.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 7-246 shows the integration of the ELM module in the device.

Figure 7-246. ELM Integration

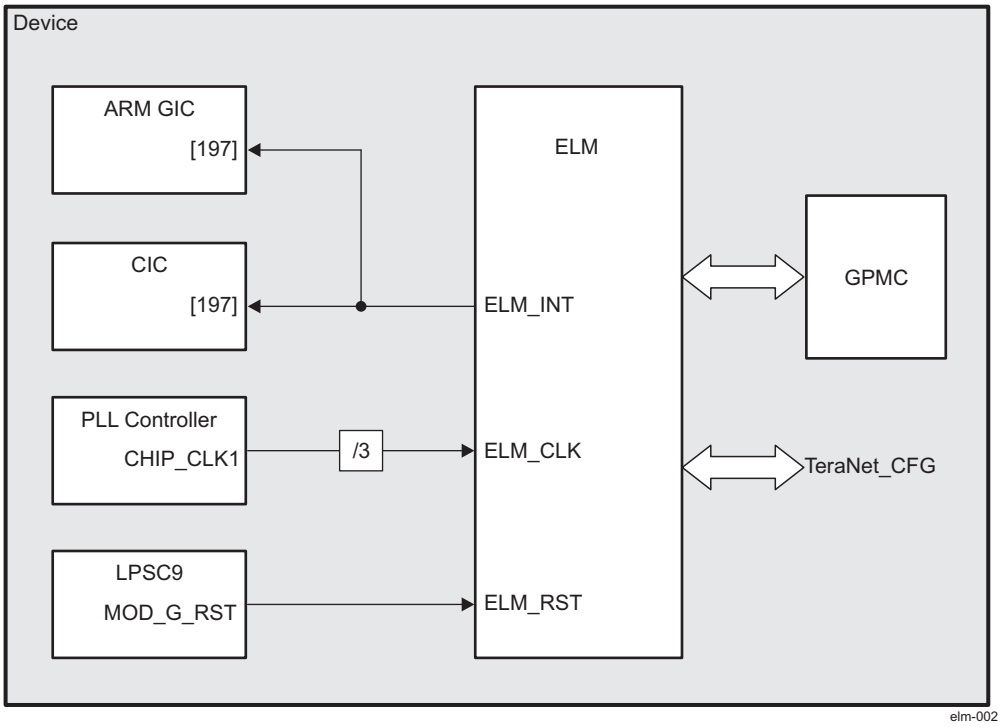


Table 7-626 through Table 7-628 summarize the integration of the ELM module in the device.

		ARM GIC	**CIC**	
ELM	ELM_INT	[197]	[197]	Error location process complete interrupt

NOTE: For more information about interrupts, see Section 7.4.3.3.

7.4.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

7.4.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

7.4.3.2 ELM Power Management

Table 7-629 describes the power-management features available to the ELM.

Table 7-629. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_CLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

7.4.3.3 ELM Interrupt Requests

Table 7-630 lists the event flags, and their masks, that can cause module interrupts asserting the ELM_INT signal.

Table 7-630. ELM Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

7.4.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26-16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 1h, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

7.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set to 0h.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION bit field, and so on.

Table 7-631 describes the ELM_LOCATION_STATUS_i value decoding.

Table 7-631. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

7.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

7.4.4 ELM Basic Programming Model

7.4.4.1 ELM Low-Level Programming Model

7.4.4.1.1 Processing Initialization

Table 7-632. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	1h
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	1h
Configure the slave interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
IF continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0h
Enable interrupt for syndrome polynomial i.	ELM_IRQENABLE[i] LOCATION_MASK_i	1h
ELSE (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	1h
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0h and ELM_IRQENABLE[8] PAGE_MASK = 1h	Set value
ENDIF		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	1h

7.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 7-633 and Table 7-634 describe the processing completion for continuous and page modes, respectively.

Table 7-633. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_INT interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	1h
IF the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0h
It is software dependant.		
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	1h
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		

Table 7-633. ELM Processing Completion for Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	1h

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0h) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 7-634. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_INT interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	1h
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
IF the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0h
It is software dependent.		
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	1h
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	1FFh

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 1h for all syndrome polynomials i used in the page).

7.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 7-635). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0A16ABE115E44F767BFB0D0980h.

Table 7-635. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	1h
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	1h
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	2h
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	1h
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	420h

Table 7-635. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQENABLE[0] LOCATION_MASK_0	1h
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	FB0D0980h
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	E44F767Bh
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	16ABE115h
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0000000Ah
Initiate the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	1h
Wait until process is complete for syndrome polynomial 0: ELM_INT is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	1h
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	1h
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	4h
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	1AFh
	ELM_ERROR_LOCATION_1_i (where i = 0)	426h
	ELM_ERROR_LOCATION_2_i (where i = 0)	775h
	ELM_ERROR_LOCATION_3_i (where i = 0)	D7Ch
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	1h

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0h contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 7-636 are given in decimal format.

Table 7-636. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24

Table 7-636. 16-Bit NAND Sector Buffer Address Map (continued)

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

7.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see Table 7-637). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = E8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EFh
- P1 = BAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EBh
- P2 = 69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189h
- P3 = 0h

Table 7-637. Use Case: Page Mode

Step	Register/Bit Field/Programming Model	Value
Reset the module	ELM_SYSCONFIG[1] SOFTRESET	1h
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	1h
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	2h
Define the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	2h
Define the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	420h
Set the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	1h
	ELM_PAGE_CTRL[1] SECTOR_1	1h
	ELM_PAGE_CTRL[2] SECTOR_2	1h
	ELM_PAGE_CTRL[3] SECTOR_3	1h
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	100h
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	E0B718EFh
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	A329AA05h

7.4.5.1 ELM_REVISION Register (Offset = 0h) [reset = 20h]

ELM_REVISION is shown in Figure 7-247 and described in Table 7-641.

This register contains the IP revision code.
(A write to or reset of this register has no effect.)

Interprocessor Communication

This chapter describes the Message Manager and Semaphore modules for the device.

Topic **Page**

8.1 Message Manager

This section describes the Message Manager module on the SoC.

8.1.1 Message Manager Overview

8.1.1.1 Introduction

The SoC implements a single instance of the Message Manager to provide inter-processor communication between the various processing units:

- Arm A15
- C66x DSP
- PMMC
- PRU-ICSS

The Message Manager is a hardware engine used for queuing messages in a secure and self-contained manner. There is no limitation on the message format or content. It is software responsibility to define the message format.

The Message Manager provides a multi-core safe message interface which allows multiple users (message senders and receivers) to access the queues without the need for any mutual exclusion. It also allows for secure and authorized access to the queues.

8.1.1.2 Key Features

The general features of the Message Manager module include:

- Provides hardware acceleration for pushing/popping messages to/from logical queues
- Supports the following SoC configuration:
  - 64 queues
  - Up to 128 pending messages
  - 64-byte messages
  - 32 proxies (single proxy per page)
- Support for highly-pipelined push/pop operations
- Support for self-contained mode with zero SW initialization
- Provides a secure front-end for the queues
- Provides flexible message allocation with ability to store the same message multiple times in different queues or multiple times in the same queue
- Queue depth limited only by the maximum number of messages
- Support for little-endian (LE) operation only

Monitoring and trace functions include:

- Provides hardware signals to monitor the empty status for all transmit source queues
- Provides ability to read Linking RAM contents for debug purposes
- Provides ability to generate an interrupt when there are no free entries in the Linking RAM
- Provides ability to generate an interrupt due to a proxy fault

8.1.2 Message Manager Integration

This section describes the module integration in the device, including information about clocks, resets, and hardware requests.

Figure 8-1 shows the Message Manager integration.

Figure 8-1. Message Manager Integration

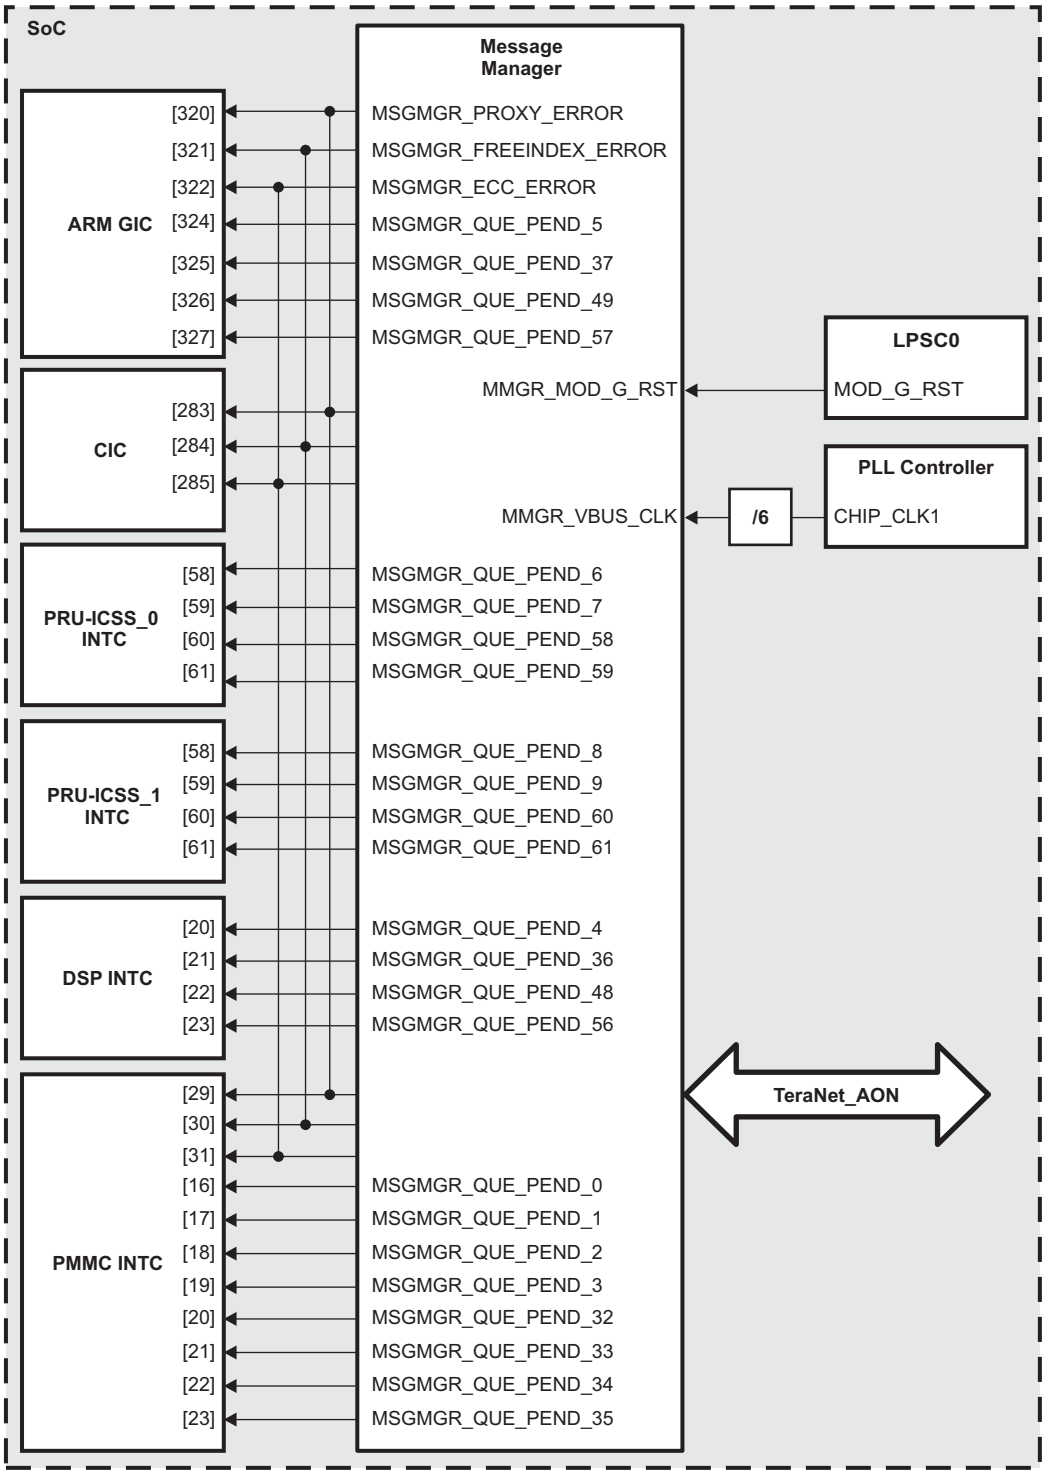

Table 8-1 through Table 8-3 summarize the integration of the module in the device.

8.1.3 Message Manager Functional Description

8.1.3.1 Basics and SoC Implementation

The Message Manager provides a standard API interface between the various hosts on the system. A host can be kernel, hypervisor or even user processes.

The Message Manager provides a set of queues that can be used to temporarily store and pass messages between the hosts. The messages are allocated and stored internally automatically and can be placed into any queue, regardless of the data contents. The data returned is exactly the same as the data inserted into the queues. For each queue there is a dedicated *queue pending* signal to indicate if the queue is empty or not.

The current Message Manager configuration supports 64-byte messages, 64 queues and it has buffer space to accommodate 128 pending messages.

Table 8-4 summarizes the SoC configuration of the Message Manager.

Table 8-4. Message Manager SoC Configuration

Parameter Name	Parameter Description	SoC Value	Comment
QCNT	Number of queues	64	64 queues
MAX_MSG_SIZE	Message size (in bytes)	80	64B message(1)
MAX_MESSAGES	Number of messages	128	128 messages
Q_PROXIES	Number of queue proxies per page	1	Single proxy per page

(1) Total message size includes: 16B control words + 64B actual message

The Message Manager provides one proxy region per host. The proxy is a module that provides atomic queue pushes across the cores in the device. The purpose of the proxy is to accept a queue write by a given core without allowing another core to inject its own push.

The trusted OS is responsible to configure the proxy region for each host. A total of 32 proxy regions are supported and each proxy region is aligned in size with MMU page (64KB).

Each proxy supports 64 virtual queue slots:

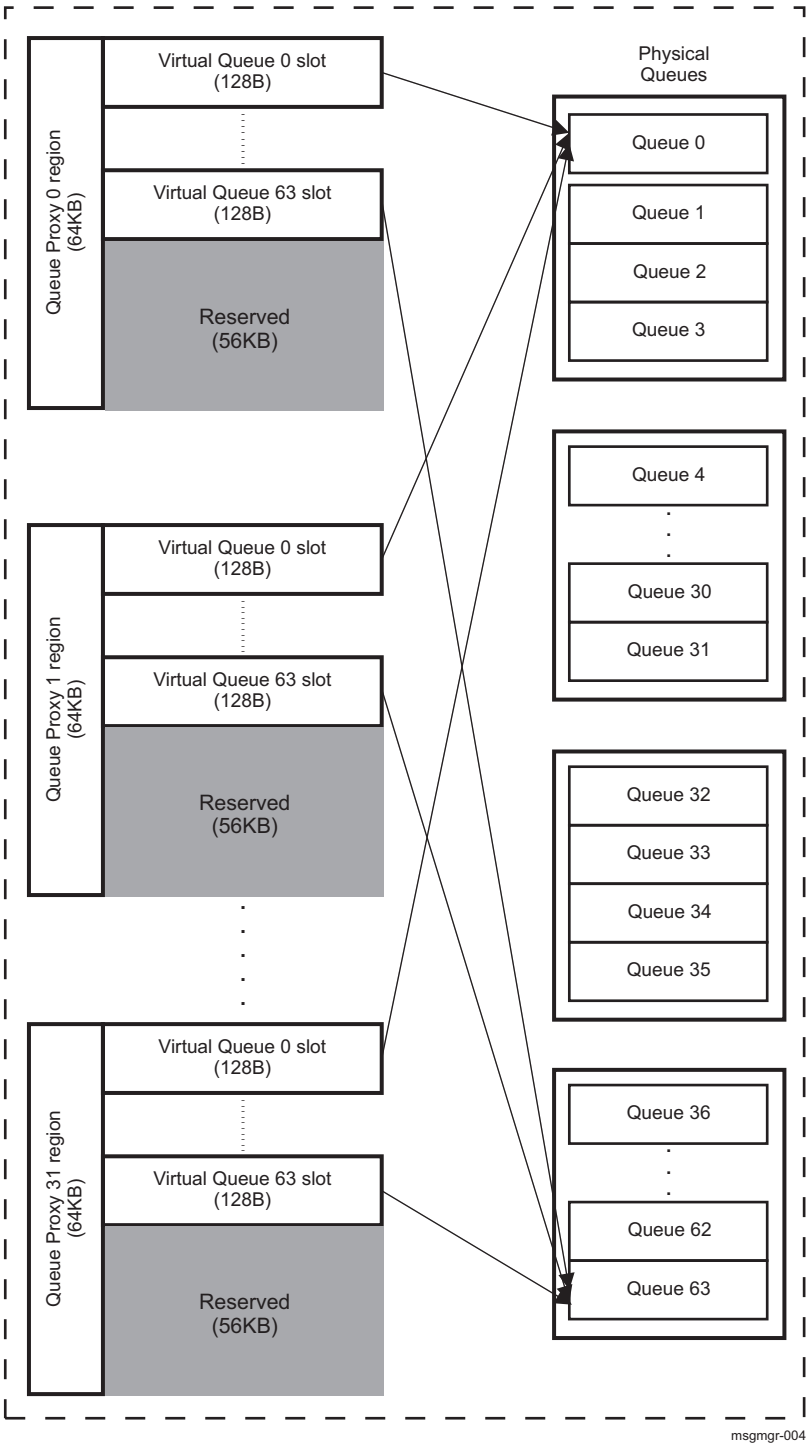
- Each virtual queue slot occupies 128B address space
- The same virtual queue slot in any proxy region is mapped to the same physical queue inside the Message Manager (that is, one-to-one mapping)
- Each virtual queue slot per proxy can be individually set access privilege to allow sending (write) or receiving (read) access.

NOTE: The actual size of each proxy region is 8KB. To align the proxy with a page size of 64KB, there is a 56KB reserved memory space.

A Memory Protection Unit (MPU_0) is placed in front of the Message Manager to protect the secure virtual queue region.

Figure 8-2 shows the proxy/queue mapping.

Figure 8-2. Message Manager Proxy/Queue Mapping



The SoC implementation supports a *single proxy per page* configuration and makes use of 9 of the 32 available pages/proxies. Proxies are assigned as shown in Table 8-5.

Table 8-5. Message Manager Proxy Assignment

Proxy	Usage
0	PMMC
1	DSP (non-secure)

8.1.3.2 Queue Access

A queue access is a simple read or write burst on the bus to a particular offset. A burst is required to keep the queue accesses coherent and atomic from other queue accesses. When a burst cannot be achieved by an endpoint itself, this is guaranteed by the corresponding proxy region instead.

Each queue has a dedicated address space, and these spaces are packed together to form all the queues, allowing the offset to indicate which queue is being accessed.

A write burst will add the data to the tail of the selected queue. The write burst does not need to cover the entire data size, and any unwritten bytes will be assumed to be their default values or 0s otherwise.

A read burst will find the head data item on the selected queue, and return the stored data, removing it from the queue. If the read burst does not cover the entire data size, then any unread bytes will be lost. If there is a read burst to an empty queue, the data returned will be all 0s.

See Section 8.1.3.5 for more details on queuing / dequeuing messages.

8.1.3.3 Queue Processing

The queue processing is handled by two components: the dispatcher and the engine. There are also three structures that store state about the queues and items: the queue state memory (Queue State RAM), storage memory (Queue Data RAM) and the link memory (Linking RAM). All the links within the queues are in terms of links to internal item storage and not any pointers included in the data. These link values are automatically allocated during writes.

8.1.3.3.1 Free Index Allocation

For every push (write burst) operation, the Message Manager needs to allocate an index to the message before pushing it to a queue. This index ranges from 0 to 127. The Message Manager allocates this index from a free index pool. On every pop (read burst), the index is returned back to the free index pool.

NOTE: An error interrupt (MSGMGR_FREEINDEX_ERROR) occurs when a push is attempted and all the storage items have already been allocated. This is something that SW should avoid, as the data written causing the error is lost.

8.1.3.3.2 Queue Dispatcher and Engine

The Queue Dispatcher decodes the queue access and forwards it to the engine. It also checks for hazards when the next queue access is to the same queue that is already being processed by an engine. In this case, it will stall the dispatch until all processing on that queue has been completed.

In other words, the Queue Dispatcher is responsible for scheduling the push and pop accesses to the queues. All operations to the queues are done in order. Maximum performance is achieved when back-to-back pop operations are done from multiple queues. A back-to-back pop from the same queue will be stalled until the Queue Engine has fetched the next linking index from the Linking RAM and updated the internal Queue State RAM.

The Queue Engine takes the queue access and the current queue state and performs the requested operation.

The following sequence of operations is automatically done for a push:

1. Get a free index from the free index pool
2. Write the queue contents in the Queue Data RAM using the free index as the address
3. Update the next index in the Linking RAM
4. Update the Queue State RAM for the corresponding queue via the write-back interface
5. Update any statistics/monitoring information (such as queue empty status)

The following sequence of operations is automatically done for a pop:

1. Read the head index from the Queue State RAM
2. Read the queue contents from the Queue Data RAM and return the data on the VBUSM interface

3. Read the next index from the Linking RAM and update the Queue State RAM via the write-back interface
4. Return the current head index back to the free index pool
5. Update any statistics/monitoring information (queue empty status)

8.1.3.3.3 Queue Memory (Queue State RAM)

The Message Manager uses a Queue State RAM (64x21-bit) to record the value of head index and entry count for each queue. When a push/pop operation is performed, the Message Manager updates the word corresponding to the queue number to reflect its new head index and entry count.

The Queue State RAM is available for debug inspection only (see Section 8.1.5.7).

8.1.3.3.4 Link Memory (Linking RAM)

The Message Manager uses a Linking RAM (128x7-bit) to store information about how the messages are logically connected to one another in the various queues. Each location in the Linking RAM corresponds to one message index and stores information about the next linking index.

The linking information for all messages is stored in a contiguous fashion in the Linking RAM. That is, the information for message index 0 is stored at Linking RAM entry 0, the information for message index 1 is stored at Linking RAM entry 1, etc.

The Linking RAM is available for debug inspection only (see Section 8.1.5.6).

8.1.3.3.5 Storage Memory (Queue Data RAM)

All data that is queued will be stored internally in the module in local storage (Queue Data RAM, 1024x64-bit).

8.1.3.4 Queue Protection

Queue protection is achieved via the Queue Virtualization Unit (QVU). The QVU is a method to provide the application SW with an access to the Message Manager resources with low overhead but still ensure the access protections provided by the kernel. Software always accesses the Message Manager via the QVU.

The QVU provides the following functions:

- Access policy checks configured for a given 64KB page of queues that are dedicated to a user process. A total of 32 pages are supported (but only 9 of them are used in this SoC; see)
- Supports default screen door settings to remove the need for SW initialization
- Acts as a proxy to the SW user processes accessing the Message Manager. A single proxy is provided for every page. This implies that there is a single owner of the proxy for every page and the owner is either a single master/core or a single thread on a master
- Flags an error if any SW access violates the page policy checks
- Provides a message bus interface to the Message Manager internal resources

An important consideration is using the proxy in a multitasking environment. The proxy cannot differentiate writes having different sources within the same core (such as multiple threads). Since the proxy cannot distinguish messages between different threads, a partial push to a given queue by *thread X* followed by a completion write to the same queue by *thread Y* will be regarded as a single message write to that queue. No error will be flagged in this case. It is up to software to ensure that the accesses to the same queue are not interleaved between threads.

The Message Manager will flag an error and not queue the messages for the page if the following conditions are true:

- A partial push to a queue was followed by a completion write to a different queue from the same page. The Message Manager will not the queue the current or subsequent messages to any queues accessed from that page until the error status bit has been cleared
- A partial push to a queue was followed by a partial push to a different queue from the same page

8.1.3.5 Passing Messages

The Message Manager provides the mechanism to queue messages in a multi-core safe method. The messages are arranged as a set of 32-bit memory-mapped registers (MMRs).

8.1.3.5.1 Queuing Messages

Messages are queued onto a logical queue by writing a burst of information to the appropriate Queue Data Registers (described in Section 8.1.5.9).

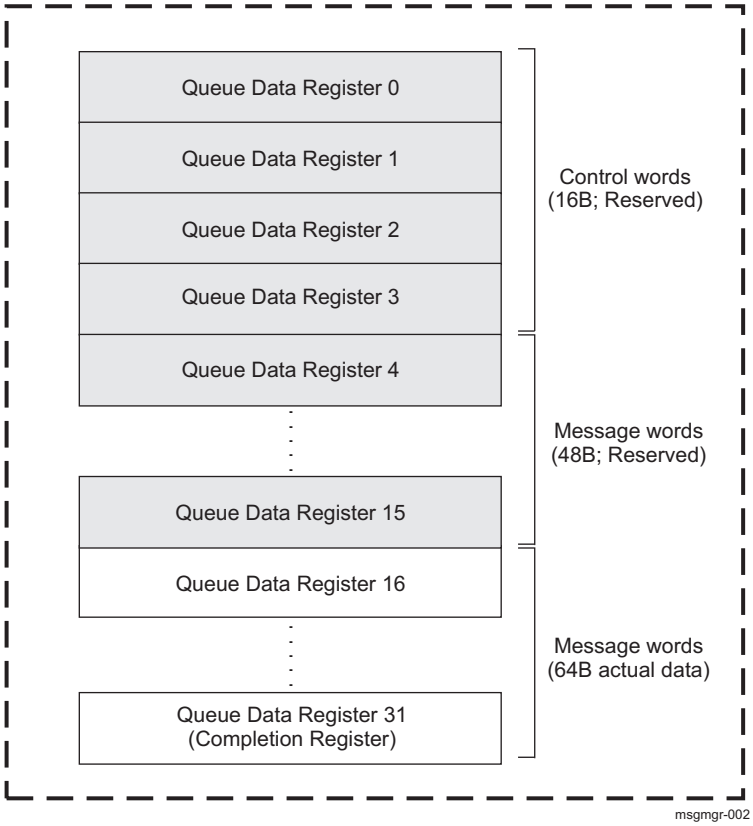
Figure 8-3 shows the message structure supported by the Message Manager. The current Message Manager implementation supports a 80B max message size which includes:

- **16B control words**: The control words are contained in Queue Data Registers 0–3. These registers are reserved for future use
- **64B actual message**: The actual message occupies one or more Queue Data Registers in the range 16–31

NOTE: Queue Data Registers 4–15 are reserved and an access to any of these registers will be ignored or return 0s.

Queue Data Register 31 is also called Completion Register because it must be written (or read) in oder to complete a push (or a pop). The value written in this register can be the last word in a message or simply a dummy write to trigger the push, in cases where the message is smaller than 64B. The push is completed only when a write is done to Queue Data Register 31.

Figure 8-3. Message Manager – Message Structure



With the exclusion of the control words, there is no restriction on the message content or format that is pushed into a queue. It is completely up to software to define the message protocol that the sender and the receiver can understand.

The Message Manager tracks the messages in a queue by an index. The index is a serial number assigned to each message that is internally allocated and deallocated by the Message Manager. To queue a message, the Message Manager allocates an index from its free index pool. The index is used to write the message into the Queue Data RAM. The queue push or pop is not complete until the Completion Register 31 is written or read.

Note that:

- The Message Manager will return stale data for the words that were not written in a message
- Any partial writes to a queue in a page will not be explicitly associated with that queue unless Queue Data Register 31 is written. In other words, if a partial push to a queue (e.g: *queue Y*) is followed by a push to Queue Data Register 31 in *queue X* from the same page, then the Message Manager will drop both messages and flag an error

Once the entire message is written, the Message Manager uses the physical index to link the queue message onto the message chain that is maintained for that logical queue by writing the linking information out to the Linking RAM. The Message Manager also updates the queue head and tail pointers. Since logical queues within the Message Manager are maintained using linked lists, queues cannot become full and no check for fullness is required before a message is queued.

8.1.3.5.2 Dequeuing Messages

Messages are dequeued from a logical queue by reading the corresponding Queue Data Registers. If the queue is empty, it returns a value of 0h. A read operation from an idle proxy will trigger a pop/dequeue from the head of a queue and will initiate an access to the Queue State RAM to get the head index which will then be used to read the contents from the Queue Data RAM. The Message Manager will then proceed to read the next link pointer in the Linking RAM and will stall any subsequent pop operations from the same queue until the next pointer has been read and loaded into the Queue State RAM.

Regardless of the message size, the proxy read operation is only completed if Queue Data Register 31 is read and any other reads are from the same message.

After the pop/dequeue operation, another proxy is free to read a message from the same queue and it will trigger another pop/dequeue to the queue which will return the next message on the queue. In this manner, two Users of the same queue will never read the same message.

NOTE: If the message queue is empty AND an user attempts to read any register != Queue Data Register 31, then the queue will not show the actual message when it arrives unless Queue Data Register 31 is read.

8.1.3.6 Interrupts

The Message Manager supports two kinds of interrupts/events:

- Error interrupts
- Queue pending events

The Message Manager will generate an error interrupt under the following conditions:

- When a proxy fault occurs due to either:
  - An access violating the queue read/write permissions, or
  - An access to a different queue than the current queue which has a partial message written
- When no free index is available in the linking RAM. This will only happen if more than 128 messages are queued. In this case, the Message Manager will ignore the access
- When there is an ECC-related error

The Message Manager also ouputs a group of queue pending signals (1 per queue) to indicate the empty status for each queue. When a given queue is not empty, the corresponding queue pending signal becomes active (asserted).

Table 8-7 shows the Message Manager interrupt types and their polarity.

Table 8-7. Message Manager Interrupt Types

Interrupt Name	Description	Type (At IP Boundary)
MSGMGR_PROXY_ERROR	Proxy error interrupt	Active-high PULSE
MSGMGR_FREEINDEX_ERROR	No free index available interrupt	Active-high PULSE
MSGMGR_ECC_ERROR	ECC error interrupt	Active-high PULSE
MSGMGR_QUE_PEND_[63:0]	Queue pending signals [63:0]	Active-high LEVEL

The Message Manager interrupt mapping is presented in Section 8.1.2.

The Message Manager registers related to the *proxy fault* and *no free index* interrupts are descibed in Section 8.1.5.4 and Section 8.1.5.5, respectively.

8.1.3.7 Power, Clock and Reset

The Message Manager resides in the ALWAYS_ON power domain (PD0).

The Message Manager runs on a single clock (CHIP_CLK1 / 6). All functional and VBUS operations are synchronized to this clock.

The Message Manager uses one hardware reset (LPSC0.MOD_G_RST). A hardware reset initializes all internal logic of the Message Manager and its configuration registers.

The Message Manager does not support a software reset at module level.

8.1.3.8 ECC Support

Error Correction Code (ECC) is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected, and double bit errors to be detected. Several memories within the Message Manager are ECC-protected by an ECC Wrapper which implements *Single Error Correction and Double Error Detection (SECDED)*:

- *Single Error Detection and Correction (SED/SEC)*: This logic detects and corrects a single bit error (1-bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC Wrapper also supports multiple options for partial word writes, such as read-modify-write (R-M-W) or multiple ECC code segments per word.
- *Double Error Detection (DED)*: This logic only detects (does not correct) double errors (2-bit errors per ECC word or per ECC data segment). If a double error is detected, the module can have unpredictable behavior and must be reset to guarantee correct behavior once again.

ECC Aggregator module (integrated inside the Message Manager) consolidates the ECC configuration and status bits for all the ECC-supported memories within the Message Manager. It provides a single End-of-Interrupt (EOI) handshake based interrupt to the host (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the various ECC Wrappers via their respective register set.

Table 8-8 lists the Message Manager memories that are ECC-protected along with the ECC attribute for each memory. Basic features for all the Message Manager memories are as follows:

- ECC-enabled RAMs have delayed write-back
- All control and status is handled by the ECC Aggregator

Table 8-8. Message Manager RAMs and ECC Options

RAM Wrapper Name	Data Width (bits)	Width with ECC (bits)	Depth	R-M-W
Queue Data RAM	64	8	1024	Y
Queue State RAM	21	6	64	N
Linking RAM	7	5	128	Y
Proxy Config RAM	32	7	128	Y

For more details on ECC Wrapper and ECC Aggregator, see Section 11.14.4.19.1, *ECC Wrapper and ECC Aggregator*.

The ECC-related registers of the Message Manager are described in Section 8.1.5.8.

8.1.4 Message Manager Programming Guidelines

8.1.4.1 Proxy Queue Page Configuration

The first step in using the Message Manager is to configure the proxy queue page. The purpose of the proxy queue is to facilitate masters' autonomous operations so there is no conflict (no race conditions) between multiple masters that try to send multiple messages to the same queue. The Message Manager has 32 proxy queues but in this SoC only 9 proxy queues are available (see Table 8-5 for the allocation of proxy queue to a host).

Each master CPU is assigned a single proxy queue, so if the CPU employed multiple threads, they all share the same proxy queue. Note that non-secure ARMSS and secure ARMSS are considered as two separate masters, and the same is true for the DSP as well.

Each proxy supports mapping of 64 queues and each queue can hold up to 32 values (4 bytes * 32 registers = 128 bytes). Thus, the size of each proxy is 8KB (4 bytes * 32 registers * 64 queues). To align the proxy with a page size of 64KB (10000h), 56KB of addressed memory is reserved.

Table 8-9 summarizes the base physical memory of the proxy queues.

Table 8-9. Proxy Queue Physical Memory

Proxy Number and Master	Start Address	End Address
Proxy 0, PMMC	02A0 0000h	02A0 1FFCh
Proxy 1, DSP non-secure	02A1 0000h	02A1 1FFCh
Proxy 2, A15 non-secure	02A2 0000h	02A2 1FFCh
Proxy 3, PRU-ICSS_0_PRU0 non-secure	02A3 0000h	02A3 1FFCh
Proxy 4, PRU-ICSS_0_PRU1 non-secure	02A4 0000h	02A4 1FFCh
Proxy 5, PRU-ICSS_1_PRU0 non-secure	02A5 0000h	02A5 1FFCh
Proxy 6, PRU-ICSS_1_PRU1 non-secure	02A6 0000h	02A6 1FFCh
Proxy 7, DSP secure	02A7 0000h	02A7 1FFCh
Proxy 8, A15 secure	02A8 0000h	02A8 1FFCh
Proxy 9 to 31	Reserved	Reserved

To open a proxy queue, the software must associate logical memory with the physical memory from above. Thus, A15 non-secure code will define a logical page that will be mapped into physical address 02A2 0000h, and the DSP non-secure code will configure logical address to physical address 02A1 0000h.

8.1.4.2 Sending a Message

To send a message to a destination, a master must do the following:

1. Choose the destination queue. Each message queue is connected to a destination. Example: if the message should go only to the DSP, the sender can choose either queue 4, or queue 36, or queue 48, or queue 56.
2. Next, the software should allocate the logical address of the destination queue that was chosen. This is done by adding the destination queue offset to the base address of the proxy queue. The offset of queue N from the base address of the proxy is 80h*N. Examples:
   - The sender is the non-secure DSP and the physical address of the proxy queue is 02A1 0000h that is mapped to the same logical address. The destination is A15 and the user chooses queue 5. The offset of queue 5 is 5*80h = 280h, so the first register of queue 5 for non-secure DSP is at location 02A1 0280h.
   - The sender is the secure A15 and the physical address of the proxy queue is 02A8 0000h that is mapped into same logical memory. The destination is PMMC and the user chooses queue 32. The offset of queue 32 is 32*80h = 1000h, so the first register of queue 32 for secure A15 is at location 02A8 1000h.
3. The master is ready to write the message to the proxy queue. However, the proxy queues are not protected from multiple writers to the same proxy, and multiple writers (or reader and writer

simultaneously) can cause conflicts. Thus, systems with multiple threads or multiple tasks must protect the proxy queue write operation when one thread (or task) starts writing and prevents other threads from accessing the proxy queue until the write operation is done. The software must define software semaphore or similar lock mechanism to ensure autonomous write operation to a proxy queue.

4. After the writer master secures the semaphore (or any other lock mechanism) for the proxy queue, it can start writing the message. The message is up to 64 bytes long and resides in registers 16 to 31 of the queue message. Registers 0 to 3 are the header registers that are populated by the Message Manager hardware and registers 4 to 15 are reserved. The queue proxy pushes the message into the queue only after register 31 is written, so even if the message is short, the writer must write a dummy value to register 31 in order to initiate the push operation.
5. The message protocol is the sole responsibility of the software. The hardware is indifferent of the payload structure as long as it occupies registers 16 to 31.
    1. The non-secure DSP from above wants to send 64 bytes message to A15 using queue 5. It will write the sixteen 32-bit values starting at address 02A1 02C0h – this is the offset of register 16 (40h) in the queue 5 of the non-secure DSP proxy page. The last 32-bit write will be at address 02A1 027Ch – this is the offset of register 31 (7Ch) in the queue 5 of the non-secure DSP proxy page. Writing to the last register will push the message into queue 5.
    2. The secure ARMSS from above wants to send 4 bytes message (e.g. 12345678h) to PMMC using queue 32. It will write the value 12345678h to address 02A8 1040h – this is the offset of register 16 (40h) in the queue 32 of the secure A15 proxy page. In order to push the message into queue 32, the register 31 must be written as well, so the secure A15 must write a dummy value (e.g. BADEFACEh) to address 02A8 107Ch – this is the offset of register 31 (7Ch) in the queue 32 of the secure A15 proxy page.
    3. Note: For a message that is longer than 64 bytes, the software is responsible for defining a disassemble and assemble protocol and code
6. The Message Manager has a limited capacity of 128 messages at any given time. Each message is assigned an index value from 0 to 127. After writing to register 31, the software must check and verify that there was an available index (via the MSGMGR_FREEINDEX_ERROR signal). It is software responsibility to ensure that no error occurs. If an error occurs, the message is not pushed into the queue and the process should be repeated.
7. The MSGMGR_FREEINDEX_ERROR signal can be set by any of the writing masters. In order to identify which master write set the MSGMGR_FREEINDEX_ERROR interrupt, the system must use a hardware based system semaphore. The semaphore block of this SoC has 64 semaphores and one of them should be dedicated to Message Manager operation. The algorithm of using the semaphore for sending a message is as follows:
    1. Just before writing to register 31, the master asks for a global hardware semaphore using a blocking function
    2. After the semaphore is granted, the master writes the last word of the message to register 31
    3. Next, the master reads the value of the interrupt status register into a volatile variable. The master repeats the read operation twice to give enough time for the hardware to set bit 0 in the register
    4. If bit 0 is not set, the master releases the semaphore
    5. If bit 0 is set, the master clears bit 0, releases the semaphore and resends the message one more time (that is, repeat steps *(a)* to *(e)*)
    6. A watchdog-like mechanism should indicate when error persists and interrupt the system
8. After finishing the send process, the thread must release the software semaphore

8.1.4.3 Receiving a Message

All queues in the Message Manager are pending queues. Table 8-3 shows what signal in the receiving host is set when there is a message in the corresponding queue. The software can configure the signal as an interrupt or the signal can be pulled periodically to look for messages.

1. Before starting run-time execution, the software should allocate the logical address of the RX queues in which messages may arrive. This is done by adding the RX queue offset to the base address of the proxy queue. The offset of queue N from the base address of the proxy is 80h*N. Examples:
    1. The non-secure DSP received queues are 4, 36, 48 and 56. The software must calculate the base

address of the proxy queue for each queue that may contain a message. For queue number 36, the base address of the proxy queue is: (80h*36 + 02A1 0000h = 02A1 1200h).

2. The non-secure A15 received queues are 5, 37, 49 and 57. The software must calculate the base address of the proxy queue for each queue that may contain a message. For queue number 37, the base address of the proxy queue is: (80h*37 + 02A2 0000h = 02A2 1280h).

2. As mentioned above, each receiver can use a polling scheme or interrupt based scheme to access the proxy queue
3. The master is ready to read the message from the proxy queue. However, the proxy queues are not protected from multiple read from the same proxy, and multiple readers (or reader and writer simultaneously) can cause conflicts. Thus, systems with multiple threads or multiple tasks must protect the proxy queue read operation when one thread (or task) starts reading and prevents other threads from accessing the proxy queue until the read operation is done. The software must define software semaphore or similar lock mechanism to ensure autonomous read operation from a proxy queue.
4. After the reader master secures the semaphore (or any other lock mechanism) for the proxy queue, it can start reading the message. The message is up to 64 bytes long and the reader must read the last 4 bytes in order to free the message and delete it from the queue. The reader must first read one or more registers (protocol dependent) starting in register 16, and then read register 31. After register 31 is read, the hardware will pop the message as described in Section 8.1.3.3.2. The offset addresses for reading are the same as described above (Section 8.1.4.2; step #2)
5. After the reader master reads register 31, it must release the software semaphore

8.1.5 Message Manager Registers

This section describes the memory-mapped registers associated with the Message Manager.

8.1.5.1 Message Manager Memory Regions

Table 8-10 lists the base address and block size for each of the Message Manager memory regions.

Table 8-10. Message Manager Memory Regions

Memory Region Name	Memory Region Base Address	Size
MSGMGR_PROXY_PAGE_CONFIG	0288 0000h	128KB
MSGMGR_PROXY_CONFIG	028A 0000h	128KB
MSGMGR_PROXY_GLOBAL_CONFIG	028C 0000h	4KB
MSGMGR_GLOBAL_CONFIG	028C 1000h	4KB
MSGMGR_LINKING_RAM_DEBUG	028C 2000h	4KB
MSGMGR_ECC_AGGR	028C 3000h	1KB
MSGMGR_QUEUE_STATE_DEBUG	028C 3400h	512B
MSGMGR_QUEUE_PROXY	02A0 0000h	2MB

8.1.5.2 MSGMGR_PROXY_PAGE_CONFIG Registers

Table 8-11 lists the memory-mapped registers for the MSGMGR_PROXY_PAGE_CONFIG region. All register offset addresses not listed in Table 8-11 should be considered as reserved locations and the register contents should not be modified.

Table 8-11. MSGMGR_PROXY_PAGE_CONFIG Registers

Offset	Acronym	Register Name	Physical Address	Section
0h	PAGE_PROXY_CFG_REG_0_0	Page 0 Proxy 0 Map Registers	0288 0000h	Section 8.1.5.2.1
1000h	PAGE_PROXY_CFG_REG_1_0	Page 1 Proxy 0 Map Registers	0288 1000h	Section 8.1.5.2.1
2000h to 1F000h	PAGE_PROXY_CFG_REG_2_0 to PAGE_PROXY_CFG_REG_31_0	Page 2–31 Proxy 0 Map Registers	0288 2000h to 0289 F000h	Section 8.1.5.2.1

8.1.5.2.1 PAGE_PROXY_CFG_REG_0_0 to PAGE_PROXY_CFG_REG_31_0 Register (Offset = Table 8-11) [reset = 0h]

PAGE_PROXY_CFG_REG_0_0 to PAGE_PROXY_CFG_REG_31_0 is shown in Figure 8-4 and described in Table 8-12.

This register holds the mapping of virtual proxy Q (0–31) in page N (0–31) to a physical proxy. The current configuration is such that each page is given a single proxy, which implies the following:

- Only virtual proxy 0 is used for each page; virtual proxies 1–31 are not used
- The mapping between virtual and physical proxies is as follows:
  - Virtual proxy 0 in page 0 --> physical proxy 0;
  - Virtual proxy 0 in page 1 --> physical proxy 1;
  - ...
  - Virtual proxy 0 in page 31 --> physical proxy 31;

Figure 8-4. PAGE_PROXY_CFG_REG_0_0 to PAGE_PROXY_CFG_REG_31_0 Register

Table 8-12. PAGE_PROXY_CFG_REG_0_0 to PAGE_PROXY_CFG_REG_31_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	PHYSICAL_PROXY	R	N	Physical proxy number for virtual proxy 0 (Virtual-to-physical mapping disabled; always N)

8.1.5.3 MSGMGR_PROXY_CONFIG Registers

Table 8-13 lists the memory-mapped registers for the MSGMGR_PROXY_CONFIG region. All register offset addresses not listed in Table 8-13 should be considered as reserved locations and the register contents should not be modified.

Table 8-13. MSGMGR_PROXY_CONFIG Registers

Offset	Acronym	Register Name	Physical Address	Section
0h to FCh	PROXY_QUEUE_CFG_REG_0_0 to PROXY_QUEUE_CFG_REG_0_63	Proxy 0 Queue 0–63 Config Registers	028A 0000h to 028A 00FCh	Section 8.1.5.3.1
0x1000 to 0x1FFFC	PROXY_QUEUE_CFG_REG_1_0 to PROXY_QUEUE_CFG_REG_31_63	Proxy 1-31 Queue 0–63 Config Registers	028A 1000h to 028B FFFCh	Section 8.1.5.3.1

8.1.5.3.1 PROXY_QUEUE_CFG_REG_0_0 to PROXY_QUEUE_CFG_REG_31_63 Register (Offset = Table 8-13) [reset = 0h]

PROXY_QUEUE_CFG_REG_0_0 to PROXY_QUEUE_CFG_REG_31_63 is shown in Figure 8-5 and described in Table 8-14.

This register holds the access permissions for Proxy 0–31, Queue 0–63. Disabling both the write and read permissions will disable the queue access for this proxy.

This register does not support byte enables and must be written as a full 32-bit access.

Figure 8-5. PROXY_QUEUE_CFG_REG_0_0 to PROXY_QUEUE_CFG_REG_31_63 Register

40h	PROXY_ERROR_STATUS_REG	Proxy Error Status Register	028C 0040h	Section 8.1.5.4.6

8.1.5.4.1 INTR_RAW_STATUS_SET_REG Register (Offset = 10h) [reset = 0h]

INTR_RAW_STATUS_SET_REG is shown in Figure 8-6 and described in Table 8-16.

The Interrupt Raw Status/Set register shows the raw interrupt status before enabling and allows setting the interrupt status. Each bit corresponds to an error associated with a given proxy.

This register is useful for software debugging.

Figure 8-6. INTR_RAW_STATUS_SET_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PROXY_ERROR

Table 8-16. INTR_RAW_STATUS_SET_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	PROXY_ERROR	R/W1S	0h	Each bit indicates an error associated with a given proxy. (Bit position [0] corresponds to proxy 0, bit position [1] corresponds to proxy 1, etc.) Write '1' to set the status for the associated proxy. Writing '0' has no effect.

8.1.5.4.2 INTR_ENABLED_STATUS_SET_REG Register (Offset = 18h) [reset = 0h]

INTR_ENABLED_STATUS_SET_REG is shown in Figure 8-7 and described in Table 8-17.

The Interrupt Enabled Status/Set register shows the interrupt enabled status and allows clearing the interrupt status. Each bit corresponds to an error associated with a given proxy.

Figure 8-7. INTR_ENABLED_STATUS_SET_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	PROXY_ERROR	R/W1C	0h	Each bit indicates an error associated with a given proxy. (Bit position [0] corresponds to proxy 0, bit position [1] corresponds to proxy 1, etc.) Write '1' to clear the status for the associated proxy. Writing '0' has no effect.

8.1.5.4.3 INTR_ENABLE_REG Register (Offset = 20h) [reset = 0h]

INTR_ENABLE_REG is shown in Figure 8-8 and described in Table 8-18.

The Interrupt Enable register allows setting the interrupt enable (that is, enable interrupt generation). Each bit corresponds to an error associated with a given proxy.

Figure 8-8. INTR_ENABLE_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	PROXY_ERROR	R/W1S	0h	Each bit corresponds to an error associated with a given proxy. (Bit position [0] corresponds to proxy 0, bit position [1] corresponds to proxy 1, etc.) Write '1' to set the enable for the associated proxy.

8.1.5.4.4 INTR_CLEAR_REG Register (Offset = 28h) [reset = 0h]

INTR_CLEAR_REG is shown in Figure 8-9 and described in Table 8-19.

The Interrupt Clear register allows clearing the interrupt enable (that is, disable interrupt generation). Each bit corresponds to an error associated with a given proxy.

Figure 8-9. INTR_CLEAR_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8.1.5.4.5 EOI_REG Register (Offset = 30h) [reset = 0h]

EOI_REG is shown in Figure 8-10 and described in Table 8-20.

The EOI register is used by software to write a vector associated with each interrupt to indicate that the interrupt has been serviced.

Figure 8-10. EOI_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8.1.5.4.6 PROXY_ERROR_STATUS_REG Register (Offset = 50h) [reset = 0h]

PROXY_ERROR_STATUS_REG is shown in Figure 8-11 and described in Table 8-21.

The Proxy Error Status register holds the proxy number and queue number for the first transfer that resulted in a proxy error.

Figure 8-11. PROXY_ERROR_STATUS_REG Register

Bit	Field	Type	Reset	Description
31-24	PROXY_NUM	R	0h	Indicates the proxy number associated with the queue access resulting in a proxy error • 0h = Proxy 0; • 1h = Proxy 1; • ... • 7Ch = Proxy 31; • 80h to FFh = Reserved;
23-0	QUEUE_NUM	R	0h	Indicates the queue number associated with the queue access resulting in a proxy error • 0h = Queue 0; • 1h = Queue 1; • ... • FCh = Queue 63; • 100h to FFFFFFh = Reserved;

8.1.5.5 MSGMGR_GLOBAL_CONFIG Registers

lists the memory-mapped registers for the MSGMGR_GLOBAL_CONFIG region. All register offset addresses not listed in should be considered as reserved locations and the register contents should not be modified.

Table 8-22. MSGMGR_GLOBAL_CONFIG Registers

Offset	Acronym	Register Name	Physical Address	Section
0h	REVISION_REG	Revision Register	028C 1000h	Section 11.13.5.2.3.1.1
10h	INTR_RAW_STATUS_SET_REG	Interrupt Raw Status/Set Register	028C 1010h	Section 8.1.5.5.2
14h	INTR_ENABLED_STATUS_SET_REG	Interrupt Enabled Status/Set Register	028C 1014h	Section 8.1.5.5.3
18h	INTR_ENABLE_REG	Interrupt Enable Register	028C 1018h	Section 8.1.5.5.4
1Ch	INTR_CLEAR_REG	Interrupt Clear Register	028C 101Ch	Section 8.1.5.5.5
20h	EOI_REG	End of Interrupt (EOI) Register	028C 1020h	Section 8.1.5.5.6

8.1.5.5.1 REVISION_REG Register (Offset = 0h) [reset = 0h]

REVISION_REG is shown in Figure 11-1055 and described in Table 11-2446.

The Revision register provides revision details of the module.

Figure 8-12. REVISION_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	REV	R	4E641900	TI internal data. Identifies revision of peripheral.

8.1.5.5.2 INTR_RAW_STATUS_SET_REG Register (Offset = 10h) [reset = 0h]

INTR_RAW_STATUS_SET_REG is shown in Figure 8-13 and described in Table 8-24.

The Interrupt Raw Status/Set register shows the raw interrupt status before enabling and allows setting the interrupt status. Bit position [0] indicates that there is no free index available. This should only happen if more than 128 messages are queued.

This register is useful for software debugging.

0	FREE_INDEX_ERROR	R/W1S	0h	Indicates that there is no free index available. Write '1' to set the status. Writing '0' has no effect.

8.1.5.5.3 INTR_ENABLED_STATUS_SET_REG Register (Offset = 14h) [reset = 0h]

INTR_ENABLED_STATUS_SET_REG is shown in Figure 8-14 and described in Table 8-25.

The Interrupt Enabled Status/Set register shows the interrupt enabled status and allows clearing the interrupt status. Bit position [0] indicates that there is no free index available. This should only happen if more than 128 messages are queued.

8.1.5.5.4 INTR_ENABLE_REG Register (Offset = 18h) [reset = 0h]

INTR_ENABLE_REG is shown in Figure 8-15 and described in Table 8-26.

The Interrupt Enable register allows setting the interrupt enable (that is, enable interrupt generation). Bit position [0] corresponds to the free index error interrupt.

8.1.5.5.5 INTR_CLEAR_REG Register (Offset = 1Ch) [reset = 0h]

INTR_CLEAR_REG is shown in Figure 8-16 and described in Table 8-27.

The Interrupt Clear register allows clearing the interrupt enable (that is, disable interrupt generation). Bit position [0] corresponds to the free index error interrupt.

8.1.5.5.6 EOI_REG Register (Offset = 20h) [reset = 0h]

EOI_REG is shown in Figure 8-17 and described in Table 8-28.

The EOI register is used by software to write a vector associated with each interrupt to indicate that the interrupt has been serviced.

Figure 8-17. EOI_REG Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8.1.5.6 MSGMGR_LINKING_RAM_DEBUG Registers

Table 8-29 lists the memory-mapped registers for the MSGMGR_LINKING_RAM_DEBUG region. All register offset addresses not listed in Table 8-29 should be considered as reserved locations and the register contents should not be modified.

Table 8-29. MSGMGR_LINKING_RAM_DEBUG Registers

Offset	Acronym	Register Name	Physical Address	Section
0h to 1FCh	NEXT_INDEX_REG_0 to NEXT_INDEX_REG_127	Linking RAM contents from 0 to 127	028C 2000h to 028C 21FCh	Section 8.1.5.6.1

8.1.5.6.1 NEXT_INDEX_REG_0 to NEXT_INDEX_REG_127 Register (Offset = 0h to 1FCh) [reset = 0h]

NEXT_INDEX_REG_0 to NEXT_INDEX_REG_127 is shown in Figure 8-18 and described in Table 8-30.

This register holds the contexts (next index) of Linking RAM Entry 0 to 127.

This register is intended to be used for debug purpose.

Figure 8-18. NEXT_INDEX_REG_0 to NEXT_INDEX_REG_127 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear bit; W1S = Write 1 to set bit; *-n* = value after reset

Table 8-38. ECC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0h	Force single/double-bit error on the next RAM read. Note: Takes effect only when ECC_ENABLE is set.
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted. Note: Takes effect only when ECC_ENABLE is set.
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted. Note: Takes effect only when ECC_ENABLE is set.
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes.
1	ECC_CHECK	R/W	1h	Enable ECC check. ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are 0.
0	ECC_ENABLE	R/W	1h	Enable ECC generation.

8.1.5.8.6 ECC_ERROR_CONTROL1 Register (Offset = 18h) [reset = 0h]

ECC_ERROR_CONTROL1 is shown in Figure 8-25 and described in Table 8-39.

Figure 8-25. ECC_ERROR_CONTROL1 Register

Table 8-41. ECC_ERROR_STATUS1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_ROW	R	0h	Indicates the row/address where the single or double-bit error occurred.
15-11	RESERVED	R	0h	Reserved
10	CLR_ECC_OTHER	R/W1C	0h	'1' indicates a successive single-bit error. Writing a '1' clears the status bit.
9	CLR_ECC_DED	R/W1C	0h	'1' indicates a pending double-bit error. Writing a '1' clears the status bit.
8	CLR_ECC_SEC	R/W1C	0h	'1' indicates a pending single-bit error. Writing a '1' clears the status bit.
7-3	RESERVED	R	0h	Reserved
2	ECC_OTHER	R/W1S	0h	'1' – Indicates that successive single-bit errors have occurred while a writeback is still pending. The software can also write a '1' to set the pending status and write a '1' to the corresponding clear bit to clear the status.
1	ECC_DED	R/W1S	0h	'1' – Indicates pending double-bit error status Since the double-bit error from the ECC logic is a pulsed interrupt, this is also a status set register. The software can also write a '1' to set the pending status and write a '1' to the corresponding clear bit to clear the status.
0	ECC_SEC	R/W1S	0h	'1' – Indicates pending single-bit error status Since the single-bit error from the ECC logic is a pulsed interrupt, this is also a status set register. The software can also write a '1' to set the pending status and write a '1' to the corresponding clear bit to clear the status.

8.1.5.8.9 ECC_ERROR_STATUS2 Register (Offset = 24h) [reset = 0h]

8.2 Semaphore Module

This chapter describes the operation of the Semaphore hardware module. The Semaphore module is accessible across all the cores on a multicore environment. The module supports up to 64 independent semaphores that help the application to implement shared-resource protection mechanism across multiple cores. Each of the semaphores can be accessed by the cores in direct, indirect, or combined modes.

8.2.1 Semaphore Overview

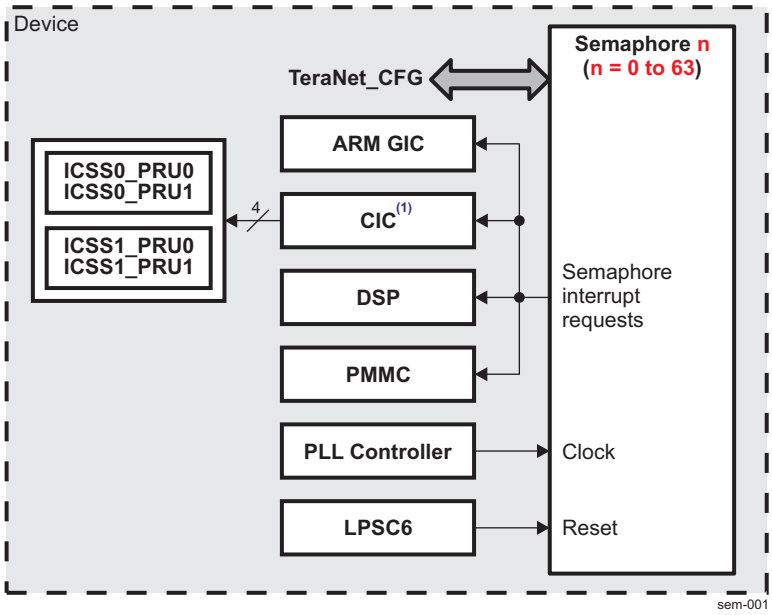
In a multicore environment where system resources must be shared it is important to control simultaneous accesses to the available resources. To ensure correct system operation, it is necessary to limit access to a resource by one and only one core at a time; that is, it is necessary to provide mutual exclusion for resources shared across multiple cores.

The Semaphore module provides a mechanism that applications can use to implement mutual exclusion of shared resources across multiple cores. The following CPU cores can be semaphore masters on this device:

- DSP C66x
- Arm Cortex-A15
- PMMC CPU
- ICSS0_PRU0
- ICSS0_PRU1
- ICSS1_PRU0
- ICSS1_PRU1

Figure 8-34 shows an overview of the Semaphore module.

Figure 8-34. Semaphore Module Overview



(1) The user may enable PRU-ICSS semaphore usage. This is possible by programming the CIC to route the appropriate events to one or more of the CIC outputs which are connected to the PRU-ICSS events inputs.

The Semaphore module supports the following features:

- Provides mutual exclusion for a shared resource
- A maximum of 16 semaphore masters (device cores)
- A maximum of 64 independent semaphores
- Semaphore request methods:
  - Direct request

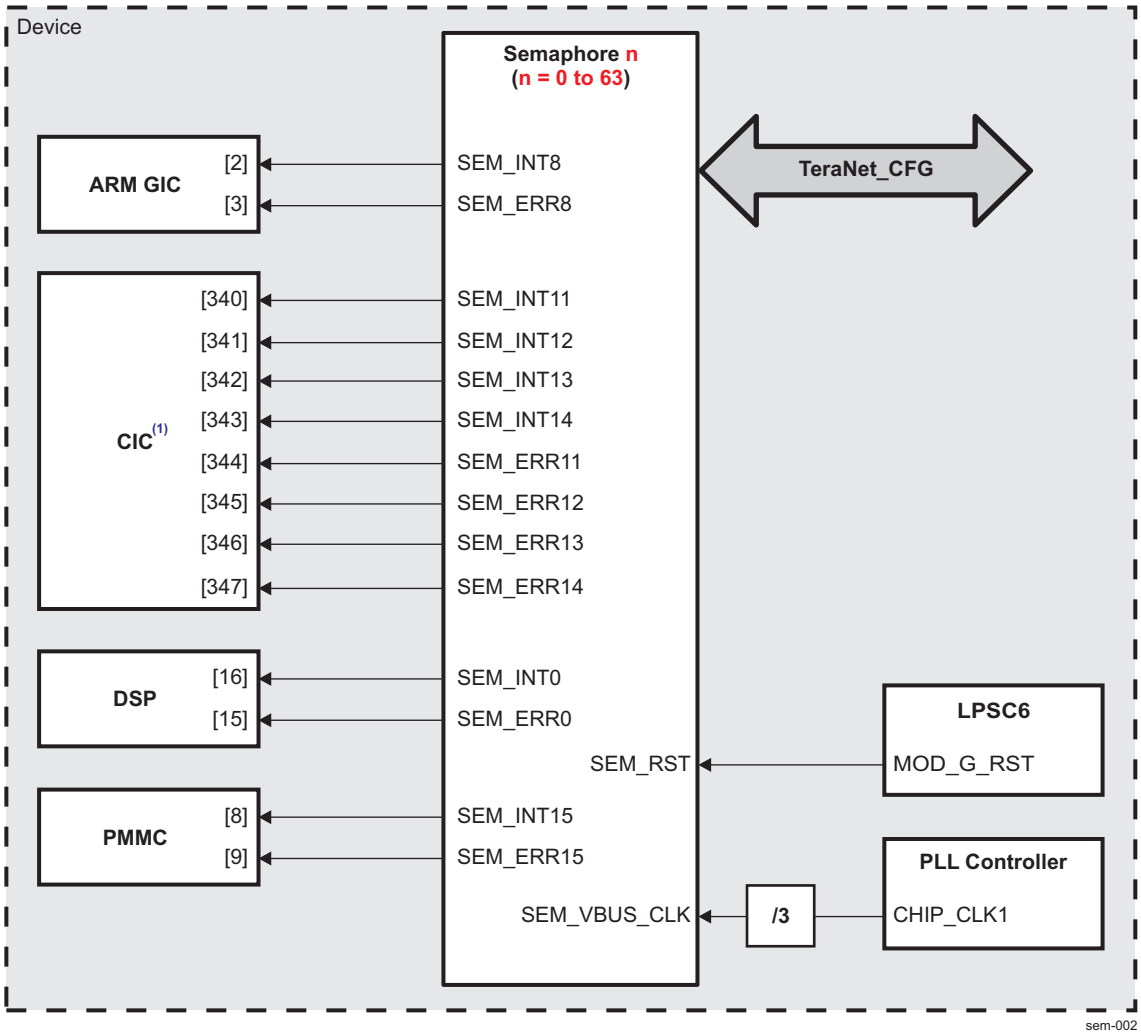
  - Indirect request
  - Combined request
- Endian independent
- Atomic semaphore access
- Lock-out mechanism for used semaphores
- Queued requests for used semaphores
- Semaphores access grant interrupt for queued requests
- Allows the application to check the status of any of the semaphores
- Error detection and interrupts

8.2.2 Semaphore Integration

This section describes the module integration in the device, including information about clocks, resets, and hardware requests.

Figure 8-35 shows the Semaphore module integration.

Figure 8-35. Semaphore Integration



(1) SEM_INT[14-11] and SEM_ERR[14-11] events are not routed directly to PRU-ICSS due to limited PRU-ICSS event availability. Instead these events are routed to the CIC. The user may enable PRU-ICSS semaphore usage by programming the CIC to route the appropriate events to one or more of the CIC outputs which are connected to the PRU-ICSS events inputs. For more information, see Chapter 9, *Interrupts*.

Table 8-49 through Table 8-51 summarize the integration of the module in the device.

Table 8-49. Semaphore Integration Attributes

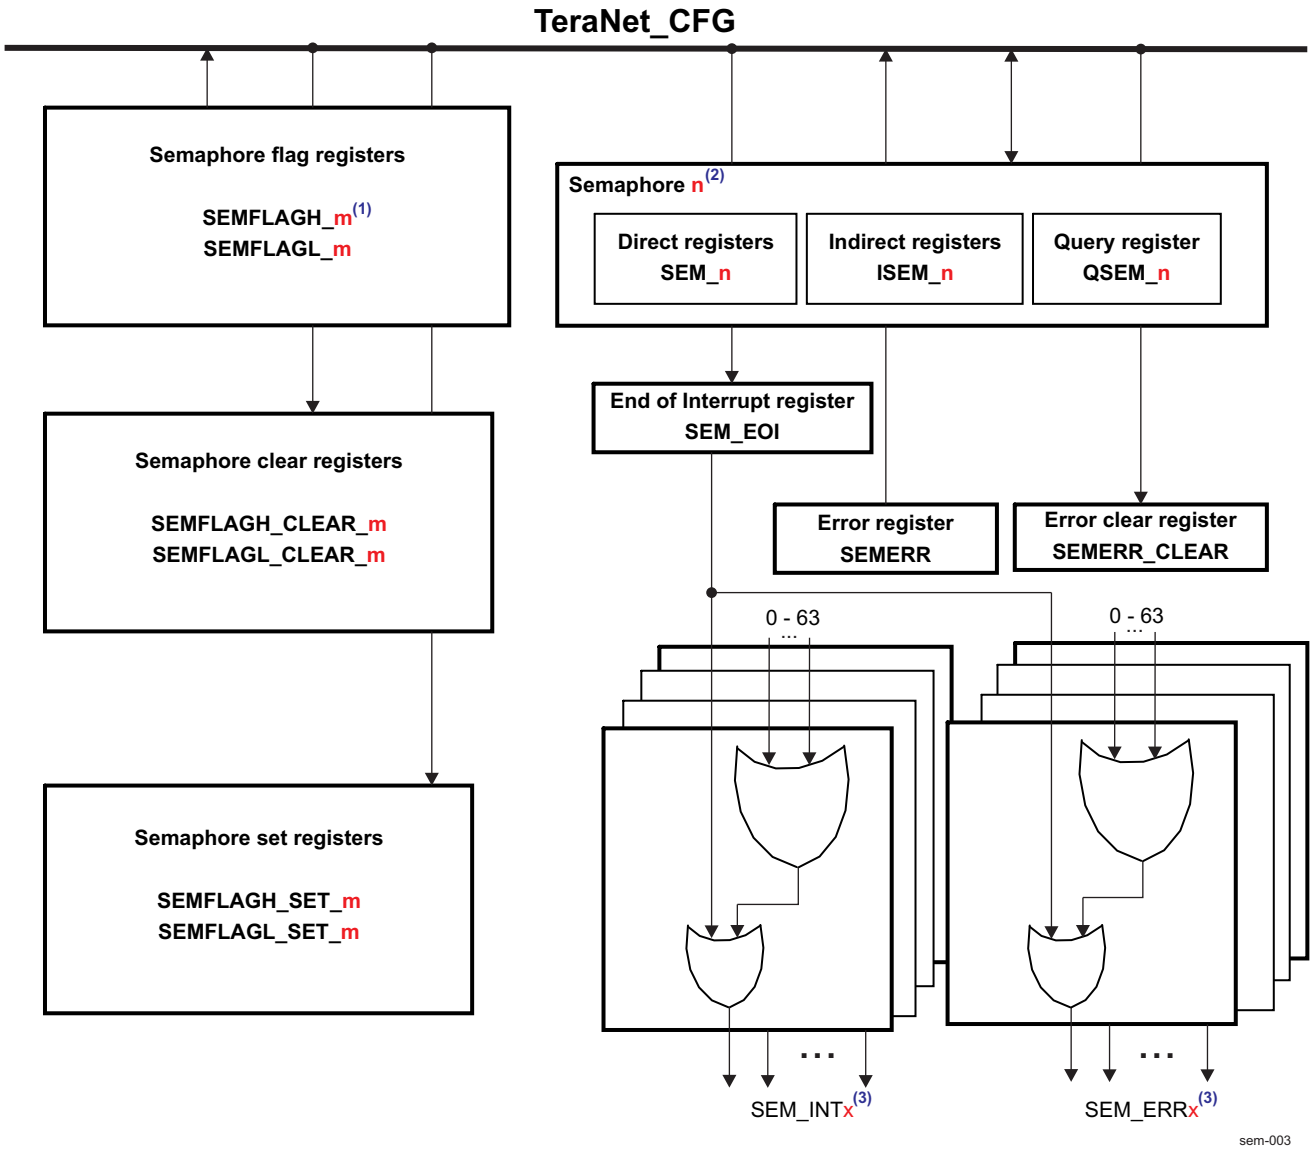
NOTE: For more information about Semaphore Grand and Error Interrupt Requests, see Section 8.2.3.3, *Interrupt Support*.

8.2.3 Semaphore Functional Description

8.2.3.1 Functional Block Diagram

Figure 8-36 shows the block diagram of the Semaphore module. The module supports up to 64 independent semaphores that can be accessed by all device cores (DSP C66x, Arm Cortex-A15, PMMC CPU, and the PRUs in the PRU-ICSS modules). The module generates two sets of interrupts: semaphore grant interrupt (SEM_INTx) and error interrupt (SEM_ERRx). In the figure, 'm' denotes the number of masters (device cores) available (maximum of 16) and 'n' denotes the number of semaphores (maximum of 64) available on a device.

Figure 8-36. Semaphore Module Block Diagram



(1) Number of Cores: m = 0 to 15

(2) Number of Semaphores: n = 0 to 63

(3) See Section 8.2.2, *Semaphore Integration*

The Semaphore module can be used as an arbiter to ensure mutual exclusivity when sharing resources over multiple cores in a multicore device. It provides up to 64 independent semaphores that can be acquired and released by the application.

Each of the semaphores is controlled by either reading from or writing to one of the three registers: SEM_n, ISEM_n, or QSEM_n. These three registers form a set and each semaphore is attached to one such set as shown in Figure 8-36. The Semaphore module can service requests using one of three methods: the direct request method, the indirect request method, or the combined request method. These three methods provide flexibility to the application to either implement a polling-based system or an interrupt-based callback mechanism for acquiring or locking a semaphore.

None of the semaphores on the module are mapped to any resource or module on the device. The application can choose to map any of the available semaphores to protect any resource. There is no support provided by the Semaphore module to store the semaphore to resource mapping information. The mapping information must be maintained by the software application.

8.2.3.2 Reset Considerations

8.2.3.2.1 Software Reset Considerations

The Semaphore module can be reset through software by writing to the SEM_RST_RUN[0] RESET bit. On reset, all semaphores are in 'FREE' state and all the errors cleared.

8.2.3.2.2 Hardware Reset Considerations

On reset, all semaphores are in 'FREE' state and all the errors cleared.

8.2.3.3 Interrupt Support

8.2.3.3.1 Interrupt Events and Requests

The Semaphore module can generate an interrupt to any of the cores on the device either to signal semaphore grant or an error. The module generates two sets of interrupts: semaphore grant (SEM_INTx) and error (SEM_ERRx) interrupts. Each set has the capability to interrupt any core m (m = 0 to 15) on the device. For more information about available semaphore masters (device cores) on this device, see Section 8.2.1, *Semaphore Overview*.

8.2.3.3.2 Error Generation and Handling

There are four types of errors the Semaphore module can generate:

- Already Free Error: This error is generated when an attempt is made to free a semaphore that is already free.
- Illegal Free Error: This error is generated when an attempt is made to free a semaphore by a core that is not the current owner.
- Already Own Error: This error is generated when a core attempts to acquire a semaphore that it already owns.
- Already Requested Error: This error is generated when a core attempts to acquire a semaphore for which it already has a pending request in the queue.

When an error is generated by the module, the SEMERR register is updated with the error code, semaphore number (n = 0 to 63) and the ID (m = 0 to 15) of the core that caused the error. Refer to Error Register (SEMERR) for a more detailed description.

The SEMERR register can be cleared by writing '1h' to the SEMERR_CLEAR[0] CLRERR bit.

NOTE: The SEMERR register is influenced by the SEMERR interrupt state. To capture and register errors continuously besides clearing the SEMERR register, the application must also reset the SEMERR interrupt state each time a new error is detected. Refer to the interrupt handling section for a description of the steps for resetting the interrupt (Section 8.2.3.3.3.2.1, *Servicing SEM_ERRx*).

8.2.3.3.3 Interrupts

The Semaphore module can generate two sets of interrupts (events):

- Semaphore Grant Interrupt (SEM_INTx)
- Semaphore Error Interrupt (SEM_ERRx)

Each set has independent lines capable of addressing any specific core on the device. See Section 8.2.2, *Semaphore Integration*.

8.2.3.3.3.1 Semaphore Grant Interrupt (SEM_INTx)

The SEM_INTx is generated whenever a pending request is granted for any of the semaphores. The interrupt is directed to the specific core that posted the original request. The bit marking the semaphore that was granted is set in either the SEMFLAGL_m (semaphore < 32) or the SEMFLAGH_m (semaphore >= 32) register corresponding to that core. Each time a SEM_INTx is generated, the SEM_INTx line to that core is disabled to prevent further semaphore interrupts from being generated.

8.2.3.3.3.1.1 Servicing SEM_INTx

Whenever SEM_INTx is received by a core, the following steps are performed by the application to clear the event and re-enable the interrupt:

1. Read the SEMFLAGL_m and/or the SEMFLAGH_m register to determine the semaphore that was granted.
2. Write '1h' to the SEMFLAGL_CLEAR_m or the SEMFLAGH_CLEAR_m register bit corresponding to the semaphore that was granted.

   This clears the corresponding bit in the flag register.
3. Write the core ID number to the End-of-Interrupt Register (SEM_EOI).

   This re-enables the SEM_INTx line to that core and enables the generation of further SEM_INTx interrupts.

8.2.3.3.3.2 Semaphore Error Interrupt (SEM_ERRx)

The SEM_ERRx interrupt is generated whenever an error condition is detected. Refer to Section 8.2.3.3.2, *Error Generation and Handling* for a more detailed description of the error conditions. The SEMERR register is updated with the error condition and core that caused the condition. Refer to the SEMERR register for a description of the fields. Each time a SEM_ERRx is generated, all the SEM_ERRx lines are disabled to prevent any further semaphore error interrupts from being generated.

8.2.3.3.3.2.1 Servicing SEM_ERRx

Whenever SEM_ERRx is received by a core, the following steps are performed by the application to clear the event and re-enable the error interrupts.

1. Read the SEMERR register to determine the error condition.
2. Clear the SEMERR register by writing '1h' to the SEMERR_CLEAR register.
3. Write '10h' to the SEM_EOI register to re-arm the semaphore error interrupts to all cores.

8.2.3.4 Emulation Considerations

During debug when using the emulator, the core or cores may be halted for debugging. During emulation halt, the debugger read to semaphore registers is ignored. That is, debugger read of semaphore registers like SEM_n or ISEM_n will not change the state of the semaphore peripheral.

However, during emulation halt, the debugger can always see the QSEM_n register to check the semaphore peripherals status.

8.2.3.5 Semaphore Request Methods

8.2.3.5.1 Direct Semaphore Request

Direct request is the simplest method used to request a semaphore. The request behaves as an atomic read and set operation. The result of a request is either to grant the semaphore to the requesting core or deny the request because the semaphore has already been granted to another core.

8.2.3.5.1.1 Issuing a Direct Request

A direct request is issued by reading the SEM_n[15-8] FREE8_15 field corresponding to the semaphore requested. As seen in Figure 8-36 there are up to 64 direct registers, one corresponding to each of the semaphores.

If the semaphore is free, the read of the SEM_n[15-8] FREE8_15 field returns '1h'; if the request is rejected, the read returns the ID of the core that currently owns the semaphore. See SEM_n register for a detailed description of the read value.

8.2.3.5.1.2 Interrupt Events

No semaphore grant (SEM_INTx) interrupts are generated when the direct request method is used. However, an error interrupt may be generated. For more information, about semaphore access errors, see Section 8.2.3.3.2, *Error Generation and Handling*.

8.2.3.5.2 Indirect Semaphore Request

The indirect request method acquires a semaphore with one request. If a semaphore was not free using the direct request method, the application has to keep trying until it is granted a semaphore. With the indirect method, the request for a semaphore is submitted to a queue. The request queue is processed sequentially by the Semaphore module on a 'first-in-first-out' basis. The semaphore is granted to the core whose request is at the top of the request queue and is marked busy until it is released, at which point the next request (if any) is processed.

8.2.3.5.2.1 Issuing an Indirect Request

An indirect request is issued by writing '0h' to the SEM_n[0] FREE0, ISEM_n[0] FREE0, or the QSEM_n[0] FREE0 bits corresponding to the semaphore requested. As shown in Figure 8-36, there are up to 64 sets of the three registers – one corresponding to each of the semaphores.

When a semaphore becomes available or is free, the semaphore is granted to the core that has its request at the top of the queue.

8.2.3.5.2.2 Interrupt Events

When a semaphore is granted to a core via a request made using the indirect method, a SEM_INTx interrupt to that core is generated.

8.2.3.5.3 Combined Semaphore Request

A combined semaphore request is a hybrid version of the direct and indirect methods. It behaves like a direct request if the semaphore is free; otherwise it behaves like an indirect request and posts a request in the queue.

8.2.3.5.3.1 Issuing an Indirect Request

A combined request is issued by reading the ISEM_n[15-8] FREE8_15 field corresponding to the semaphore being requested.

If the semaphore is free, it is granted to the core making the request and the read returns '1h'.

If the semaphore it is not free, the resulting read returns the ID of the core that currently owns the semaphore. A request for the semaphore is also posted to the queue for that semaphore. Refer to ISEM_n register for a detailed description of the read value. The semaphore is granted whenever the posted request is processed.

8.2.3.5.3.2 Interrupt Events

For a combined request where a semaphore is free at the time the request is made, a SEM_INTx interrupt is not generated when the semaphore is granted to the requestor. However, if it is posted to the request queue because the semaphore was not free at the time of request, a SEM_INTx interrupt is generated to that core when the semaphore is granted to it.

8.2.3.6 Releasing Semaphores

Whenever a core is finished using a shared resource, it must free the associated semaphore so that other processes waiting to use it can get access. To release a semaphore and set its state to 'FREE', the application must write '1h' to one of SEM_n[0] FREE, ISEM_n[0] FREE, or QSEM_n[0] FREE bits corresponding to that semaphore.

NOTE: A semaphore can be released only by a process that is running on the core that is currently its owner; any other core trying to release the semaphore will generate an error.

8.2.3.7 Querying Semaphore Status

It is reasonable that the application would need to check the status of a semaphore without acquiring it. The Semaphore module provides the ability to query the status of any of the semaphores.

To query the status of a semaphore, the application needs to read the QSEM_n[15-8] FREE8_15 field corresponding to the semaphore. The query returns information about whether the semaphore is free; if it is not free, the application returns the ID of the current owner.

8.2.4 Semaphore Registers

Table 8-53 lists the memory-mapped registers for the Semaphore module. All register offset addresses not listed in Table 8-53 should be considered as reserved locations and the register contents should not be modified.

Table 8-52. SEMAPHORE Instances

8.2.4.2 SEM_RST_RUN Register (Offset = 8h) [reset = 0h]

SEM_RST_RUN is shown in Figure 8-38 and described in Table 8-58.

This register contains the reset status of the semaphore module. This register is also used to soft reset the module.

Interrupts

Topic **Page**

9.1 Chip-level Interrupt Controller (CIC)

This chapter describes the Chip-level Interrupt Controller (CIC) present on the device.

9.1.1 CIC Overview

The SoC has many peripherals and a large number of event sources (interrupt or DMA). The use of events is completely dependent on a user's specific application, which drives a need for maximum flexibility in which event sources are used in the system. It is also completely up to software control as to how the events are serviced.

The SoC integrates the following event-servicing modules (hosts):

- Arm Subsytem (single Cortex-A15 CPU), also known as Arm CorePac
- DSP Subsystem (single C66x CPU), also known as C66x CorePac
- Industrial Communications Subsystems (PRU-ICSS_0 and PRU-ICSS_1)
- EDMA Controllers (EDMA_0 and EDMA_1)
- Power Management Micro Controller (PMMC)

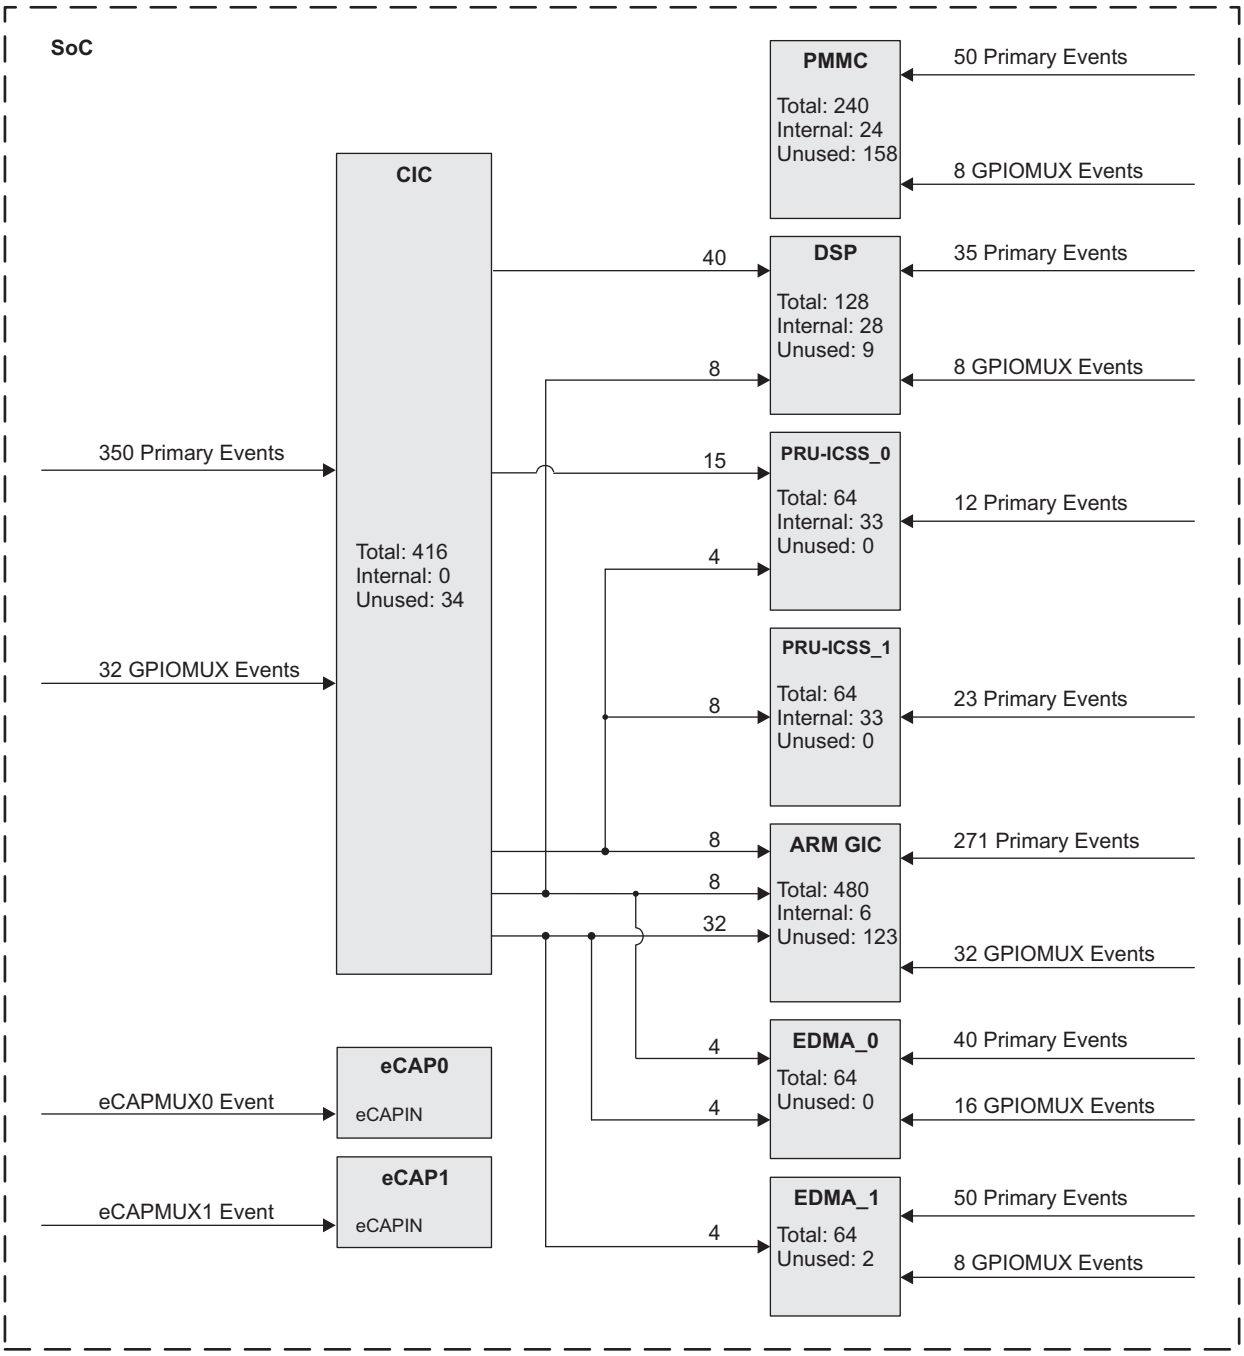
These hosts are capable of receiving events directly but the number of accepted events for each host is limited. To serve the large number of chip-level (system) event sources, the device instantiates a **Chip-level Interrupt Controller (CIC)**, which can be defined as a **system event router** – it aggregates the system events and routes them to the different hosts by using simple combination logic.

The CIC module has the following event input/output configuration for this SoC:

- 416 event inputs
- 104 event outputs

Figure 9-1 shows the SoC interrupt topology.

Figure 9-1. SoC Interrupt Topology



NOTE: This chapter covers only the functionality and interrupt mapping related to the CIC module. For functional description and interrupt mapping related to the different hosts shown on Figure 9-1 (and also GPIOMUX and eCAPMUX modules), see their respective chapters.

Some device modules have an interrupt that requires End-of-Interrupt (EOI) handshaking. The interrupt can be triggered by multiple conditions. After the host services the interrupt, the host needs to write a value into the EOI_VECTOR field in the corresponding EOI register (there is one such register for each peripheral and it is part of the module's register space) to acknowledge that it has cleared the interrupt condition before a new interrupt can be generated.

Table 9-1 shows the values that must be programmed in the corresponding module's EOI register.

Table 9-1. EOI Values

Module	EOI Value
MPU	0
TRACER	0
NSS_CDMA_STARVE	0
NSS_ESW_STAT_PEND0	1
NSS_ESW_STAT_PEND1	2
NSS_ESW_EVT_PEND	3
NSS_MDIO_LINK0	4
NSS_MDIO_LINK1	5
NSS_MDIO_USER0	6
NSS_MDIO_USER1	7

Additional event-generation features supported by the SoC are as follows:

- Inter-Processor Communication (IPC) – device cores can communicate with one another through inter-processor interrupts for core synchronization, allowing for direct notification from one core to another
- Non-Maskable Interrupt (NMI) generation to C66x DSP

For more details on these features, see Section 5.1, *Control Module (BOOT_CFG)*.

9.1.2 CIC Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Table 9-2 through Table 9-4 summarize the integration of the CIC module.

9.1.3 CIC Functional Description

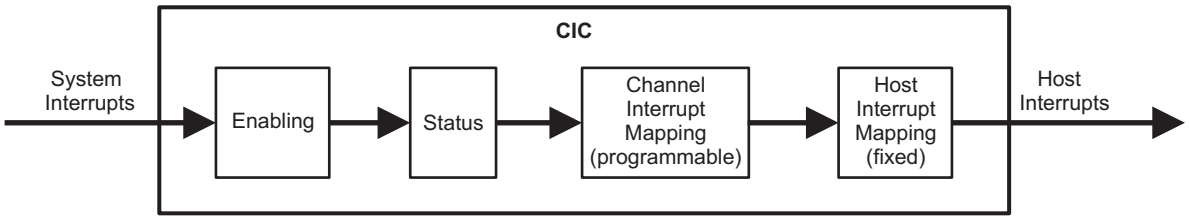
The CIC module controls the system interrupt mapping to the host interrupt interface. System interrupts are generated by device peripherals. System interrupts can be individual for a single core or can be shared by multiple cores.

The CIC receives the system interrupts and maps them to its internal channels. Channels are used to group interrupts together. These channels are then mapped onto the interrupt interfaces of the corresponding device hosts. The configuration of the CIC in the device has a fixed one-to-one mapping between channels and host interrupts.

The CIC encompasses several functions to process the system interrupts and prepare them for the host interface. These functions are:

- Enabling
- Status
- Channel mapping (programmable)
- Host interrupt mapping (fixed)

Figure 9-2. CIC Block Diagram



9.1.3.1 Interrupt Enabling

The first stage of the CIC is to enable the system interrupts based on programmed settings. Each system interrupt can be individually enabled or disabled by software. The system interrupts that are disabled will not generate any host interrupts.

The CIC receives 416 system interrupts at its inputs (see Section 9.2 for interrupt mapping).

9.1.3.2 Interrupt Status

The second stage of the CIC is to capture which system interrupts are pending. This status is captured into a status register that is readable by the system to identify the system interrupts that are pending and/or enabled. The pending status reflects whether the system interrupt occurred since the last time the status register bit was cleared. Each bit in the status register is individually clearable. Status is also cleared when the specific status is cleared. Software can also set interrupts without hardware triggering.

There are two kinds of status: *raw* status and *enabled* status. Raw status is the pending status of the system interrupt without regard to the enable bit for the system interrupt. Enabled status is the pending status of the system interrupts with the enable bits active. When the enable bit is inactive the enabled status will always be inactive. Only the enabled status will be used in later stages in the CIC, while raw status is provided for software or debug usage.

9.1.3.3 Channel Mapping

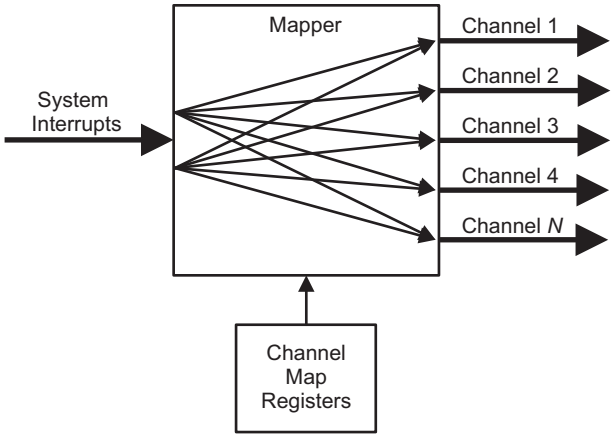
The third stage of the CIC is to map the system interrupts that have been enabled to CIC internal channels. Channels are used to group the system interrupts into a smaller number of interrupt inputs that can be provided to a host interface. When multiple system interrupts are mapped to the same channel, they are OR'd together so that when at least one is active, the output is active.

The CIC implements 104 internal channels.

Figure 9-3 shows the channel mapping function. Note that a system interrupt cannot be mapped to multiple channels but the connection is selected by the channel map value.

The mapping of the system interrupts to channels is programmable. Each system interrupt has a dedicated register to define its mapping.

Figure 9-3. Channel Mapping Block Diagram



9.1.3.4 Host Interrupt Mapping

The last stage of the CIC is host mapping. This stage maps the defined number of channels to the host interrupts.

The mapping of the channels to host interrupts is fixed (one-to-one mapping). Each channel has a dedicated register to define its host interrupt and the register is read-only.

9.1.3.5 Interrupt Service Sequence

One simple example of the interrupt service sequence is shown in Table 9-5. The interrupt service routine (ISR) executes when an interrupt is taken and services the pending interrupts before exiting.

Table 9-5. Interrupt Service Sequence

Step	Description	Example actions for C66x DSP
1	Receive the interrupt	Corresponding bit set in IFR register (by hardware) GIE bit cleared (by hardware) Execution from interrupt servicing table (IST) begins, entering to the ISR (by hardware) Corresponding bit cleared in IFR register (by hardware)
2	Disable the host interrupt	Disable the corresponding host interrupt output in the CIC Host Interrupt Enable Register
3	Determine the exact interrupt and clear the status of the system interrupt	Read the System Interrupt Status Enabled/Clear Register (for bit flags) Clear the system interrupt flag in CIC System Interrupt Status Clear Register and read back the register value.
4	Service the interrupt	Execute the user's code for servicing the interrupt
5	Re-enale the host interrupt	Enable the corresponding host interrupt output in the CIC Host Interrupt Enable Register
6	Return from interrupt	GIE bit set (by hardware) Return from ISR to the user's application

If the host can accept other host interrupts while processing the ISR then disabling all the host interrupts (in Step 2) would be suggested, assuming the ISR only wants to process one interrupt at a time. There is a global control bit (bit [0] in Global Enable Register) to enable/disable all the host interrupts to make the process easier (the individual host interrupt enables are maintained as well).

NOTE: When the CIC system interrupt flag is being cleared in ISR, if the same system interrupt happens again at the same cycle, the CIC system interrupt flag will not be cleared. By adding Step 2 (disabling the host interrupt) and Step 5 (re-enabling the host interrupt) in ISR will make sure to generate another interrupt to the host after exiting from the current ISR. So the new interrupt received during the ISR will not be missed. The dummy read in step 3 is added to make sure the system interrupt flag has been indeed cleared (writing to the register is completed) before further steps occur. It will prevent missed event as well.

9.1.4 CIC Registers

Table 9-7 lists the CIC configuration registers. All other register offset addresses not listed in Table 9-7 should be considered as reserved locations and the register contents should not be modified.

CIC Registers
• CIC Registers: [0]

9.1.4.9 CIC_RAW_STATUS_REG0 to CIC_RAW_STATUS_REG12 Register (Offset = 200h to 230h) [reset = 0h]

The System Interrupt Status Raw/Set Registers (Figure 9-12) show the pending raw status of the system interrupts. Software can write to the Status Set Registers to set a system interrupt without a hardware trigger. There are 13 registers (CIC_RAW_STATUS_REG0 to CIC_RAW_STATUS_REG12) used for the 416 system interrupts.

Table 9-32. CIC_RAW_STATUS_REG0 to CIC_RAW_STATUS_REG12 Instances

9.1.4.10 CIC_ENA_STATUS_REG0 to CIC_ENA_STATUS_REG12 Register (Offset = 280h to 2B0h) [reset = 0h]

The System Interrupt Status Enabled/Clear Registers (Figure 9-13) show the pending enabled status of the system interrupts. Software can write to the Status Clear Registers to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. There are 13 registers (CIC_ENA_STATUS_REG0 to CIC_ENA_STATUS_REG12) used for the 416 system interrupts.

9.1.4.15 CIC_ENABLE_HINT_REG0 to CIC_ENABLE_HINT_REG3 Register (Offset = 1500h to 150Ch) [reset = 0h]

The Host Interrupt Enable Registers (Figure 9-18) enable or disable individual host interrupts. These work separately from the global enables. There is one bit per host interrupt. These bits are updated when writing to the Host Interrupt Enable Index Set and Host Interrupt Enable Index Clear registers. There are 4 registers (CIC_ENABLE_HINT_REG0 to CIC_ENABLE_HINT_REG3) used for the 104 host interrupts.

9.2 Interrupt Sources

NOTE: This section covers only the mapping of system interrupts to CIC inputs. For information about interrupt mapping of other device hosts (Arm Subsystem, DSP Subsystem, etc), see their respective chapters.

NOTE: ELM is not supported on this family of devices.

Table 9-53 shows the system events mapping to CIC inputs.

Table 9-53. CIC Input Events Mapping

Event No.	Event Source Name	Description

Enhanced Direct Memory Access (EDMA) Controller

This chapter describes the Enhanced Direct Memory Access (EDMA) controllers in the device.

Topic **Page**

10.1 EDMA Overview

10.1.1 Introduction

The primary purpose of the Enhanced Direct Memory Access (EDMA) controller is to service user-programmed data transfers between two memory-mapped slave endpoints on the device.

Typical usage of the EDMA controller includes:

- Servicing software-driven paging transfers (e.g., data movement between external memory [such as SDRAM] and internal memory [such as DSP L2 SRAM])
- Servicing event-driven peripherals, such as a serial port
- Performing sorting or sub-frame extraction of various data structures
- Offloading data transfers from the main device CPUs, such as the C66x DSP CorePac or the Arm CorePac

The EDMA controller consists of two major principle blocks:

- EDMA Channel Controller
- EDMA Transfer Controller(s)

The **EDMA Channel Controller (EDMACC)** serves as the user interface for the EDMA controller. The EDMACC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMACC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TR) to the EDMA transfer controller.

The **EDMA Transfer Controller (EDMATC)** is responsible for data movement. The transfer request packets (TRP) submitted by the EDMACC contain the transfer context, based on which the transfer controller issues read/write commands to the source and destination addresses programmed for a given transfer.

There are two EDMA controllers present on this device:

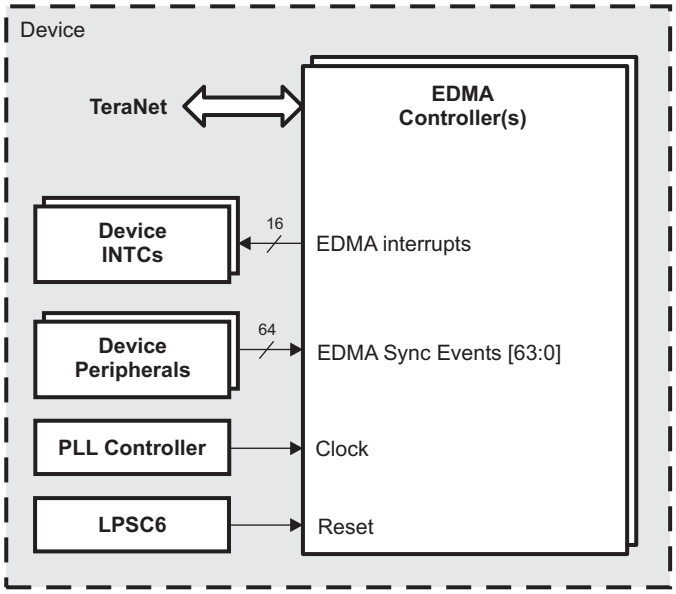
- **EDMA_0**, integrating:
  - 1 Channel Controller, referenced as: **EDMACC_0**
  - 2 Transfer Controllers, referenced as: **EDMACC_0_TC_0** (or **EDMATC_0**) and **EDMACC_0_TC_1** (or **EDMATC_1**)
- **EDMA_1**, integrating:
  - 1 Channel Controller, referenced as: **EDMACC_1**
  - 2 Transfer Controllers, referenced as: **EDMACC_1_TC_0** (or **EDMATC_2**) and **EDMACC_1_TC_1** (or **EDMATC_3**)

The two EDMA channel controllers (EDMACC_0 and EDMACC_1) are functionally identical. For simplification, the unified name **EDMACC** shall be regularly used throughout this chapter when referring to **EDMA Channel Controllers** functionality and features.

The four EDMA transfer controllers (EDMACC_0_TC_0, EDMACC_0_TC_1, EDMACC_1_TC_0 and EDMACC_1_TC_1) are functionally identical. For simplification, the unified name **EDMATC** shall be regularly used throughout this chapter when referring to **EDMA Transfer Controllers** functionality and features.

Figure 10-1 shows an overview of the EDMA controllers.

Figure 10-1. EDMA Controllers Overview



10.1.2 EDMA Controllers Features

Each **EDMACC** has the following features:

- Fully orthogonal transfer description
  - 3 transfer dimensions:
    - Array (multiple bytes)
    - Frame (multiple arrays)
    - Block (multiple frames)
  - Single event can trigger transfer of array, frame, or entire block
  - Independent indexes on source and destination
- Flexible transfer definition
  - Increment or constant addressing modes
  - Linking mechanism allows automatic PaRAM set update
  - Chaining allows multiple transfers to execute with one event
- 64 DMA channels
  - Channels triggered by either:
    - Event synchronization
    - Manual synchronization (CPU write to event set register)
    - Chain synchronization (completion of one transfer triggers another transfer)
  - Support for programmable DMA Channel to PaRAM mapping
- 8 Quick DMA (QDMA) channels
  - QDMA channels are triggered automatically upon writing to PaRAM set entry
  - Support for programmable QDMA channel to PaRAM mapping
- 512 PaRAM sets
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set
- 2 transfer controllers/event queues
  - 16 event entries per event queue
- Interrupt generation based on:

  - Transfer completion
  - Error conditions
- Debug visibility
  - Queue water marking/threshold
  - Error and status recording to facilitate debug
- Memory protection support
  - Proxied memory protection for TR submission
  - Active memory protection for accesses to PaRAM and registers

Each **EDMATC** has the following features:

- Supports 2-dimensional (2D) transfers with independent indexes on source and destination (EDMACC manages the 3rd dimension)
- Up to 4 in-flight transfer requests (TR)
- Programmable priority levels
- Support for increment or constant addressing mode transfers
- Interrupt and error support
- Supports only little-endian operation in this device
- Memory mapped register (MMR) bit fields are fixed position in 32-bit MMR

10.1.3 EDMA Controllers Configuration

Table 10-1 summarizes the configuration for each of the EDMA channel controllers present on the device.

Table 10-1. EDMA Channel Controllers Configuration

Parameter	EDMACC_0 Configuration	EDMACC_1 Configuration
Number of DMA channels (NUM_DMACH)	64	64
Number of QDMA channels (NUM_QDMACH)	8	8
Number of interrupt channels (NUM_INTCH)	64	64
Number of PaRAM set entries (NUM_PARAMENTRY)	512	512
Number of event queues (NUM_EVQUE)	2	2
Number of transfer controllers (NUM_TC)	2	2
Memory protection existence (MPEXIST)	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes

Table 10-2 summarizes the configuration of each of the EDMA transfer controllers present on the device.

Table 10-2. EDMA Transfer Controllers Configuration

Parameter	EDMACC_0_TC_0 Configuration	EDMACC_0_TC_1 Configuration	EDMACC_1_TC_0 Configuration	EDMACC_1_TC_1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	1024 bytes	1024 bytes	1024 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries	4 entries
Default burst size (DBS)	64 bytes	64 bytes	64 bytes	64 bytes

See Section 10.3 for functional details related to the EDMACC and EDMATC configuration parameters.

10.1.4 Terminology Used in This Chapter

Table 10-3 presents a brief explanation of some terms that are used in this chapter.

Table 10-3. EDMA Controller – Terms and Definitions

Term	Meaning
A-synchronized transfer	A transfer type where one dimension is serviced per synchronization event.
AB-synchronized transfer	A transfer type where two dimensions are serviced per synchronization event.
Chaining	A trigger mechanism in which a transfer can be initiated at the completion of another transfer or sub-transfer.
DMA channel	A channel that can be triggered by external, manual, and chained events. All DMA channels exist in the EDMACC.
DSP(s)	Digital signal processor(s).
Dummy set or dummy PaRAM set	A PaRAM set for which at least one of the count fields is equal to 0 and at least one of the count fields is nonzero. All of the count fields are cleared in a null PaRAM set.
Dummy transfer	A dummy set results in the EDMACC performing a dummy transfer. This is not an error condition. A null set results in an error condition.
EDMA channel controller(s) (EDMACC)	The EDMACC is the portion of the EDMA that is user-programmable. The EDMACC contains the parameter RAM (PaRAM), event processing logic, DMA/QDMA channels, and event queues. The EDMACC service events (external, manual, chained, and QDMA) and is responsible for submitting transfer requests to the transfer controllers (EDMATC) that perform the actual transfer.
EDMA programmer	Any entity on the chip that has read/write access to the EDMA registers and can program an EDMA transfer.
EDMA transfer controller(s) (EDMATC)	Transfer controllers are the transfer engines for the EDMA controller. They perform the read/writes, as dictated by the EDMACC's transfer requests.
Enhanced direct memory access (EDMA) controller	EDMA consists of the EDMA channel controller(s) (EDMACC) and the EDMA transfer controller(s) (EDMATC), referred to as EDMA in this document.
ITCCHEN	Intermediate transfer completion chaining enable.
ITCINTEN	Intermediate transfer completion interrupt enable.
Link parameter set	A PaRAM set that is used for linking.
Linking	The mechanism of reloading a PaRAM set with new transfer characteristics on completion of the current transfer.
Memory-mapped slaves	All on-chip memories, off-chip memories, and slave peripherals. These typically rely on the EDMA (or other master peripheral) to perform transfers to and from them.
Master peripherals	All peripherals that are capable of initiating read and write transfers to the system that may not solely rely on the EDMA for their data transfers.
Null set or null PaRAM	A PaRAM set that has all count fields cleared (except for the link field). A dummy PaRAM set has at set least one of the count fields nonzero.
Null transfer	A trigger event for a null PaRAM set results in the EDMACC performing a null transfer. This is an error condition. A dummy transfer is not an error condition.
Parameter RAM (PaRAM)	Programmable RAM that stores PaRAM sets that DMA channels, QDMA channels, and linking uses.
Parameter RAM (PaRAM) set	The PaRAM set is a 32-byte EDMA channel transfer definition. Each parameter set consists of eight words (that are four bytes each) that store the context for a DMA/QDMA/link transfer. A PaRAM set includes source address, destination address, counts, indexes, and options.
Parameter RAM (PaRAM) set entry	A PaRAM set entry occurs when one of the eight four-byte components of the parameter set.
QDMA channel	A channel that can be triggered when writing to the trigger word (TRWORD) of a PaRAM set. All QDMA channels exist in the EDMACC.
Slave end points	Slave end points are all on-chip memories, off-chip memories, and slave peripherals. Slave end points may rely on the EDMA to perform transfers to and from them.
SYNCDIM	Transfer synchronization dimension.
TCCHEN	Transfer complete chaining enable.
TCINTEN	Transfer complete interrupt enable.
Transfer request (TR)	A command for data movement that is issued from the EDMACC to the EDMATC. A TR includes source and destination addresses, counts, indexes, and options.
Trigger event	A trigger event is an action that causes the EDMACC to service the channel and to submit a transfer request to the EDMATC. Trigger events for the DMA channels include events that are triggered manually, externally, and by chain. Trigger events for QDMA channels include events that are triggered automatically and by link.

Table 10-3. EDMA Controller – Terms and Definitions (continued)

Term	Meaning
Trigger word	For QDMA channels, the trigger word specifies the PaRAM set entry that results in a QDMA trigger event when it is written. The trigger word is programmed via the QDMA channel map register (QCHMAP) and can point to any of the PaRAM set entries.
TR synchronization (sync) event	See Trigger event.

10.2 EDMA Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 10-2 and Figure 10-2 show the integration of the EDMA controllers on the device.

Figure 10-2. EDMA_0 Controller Integration

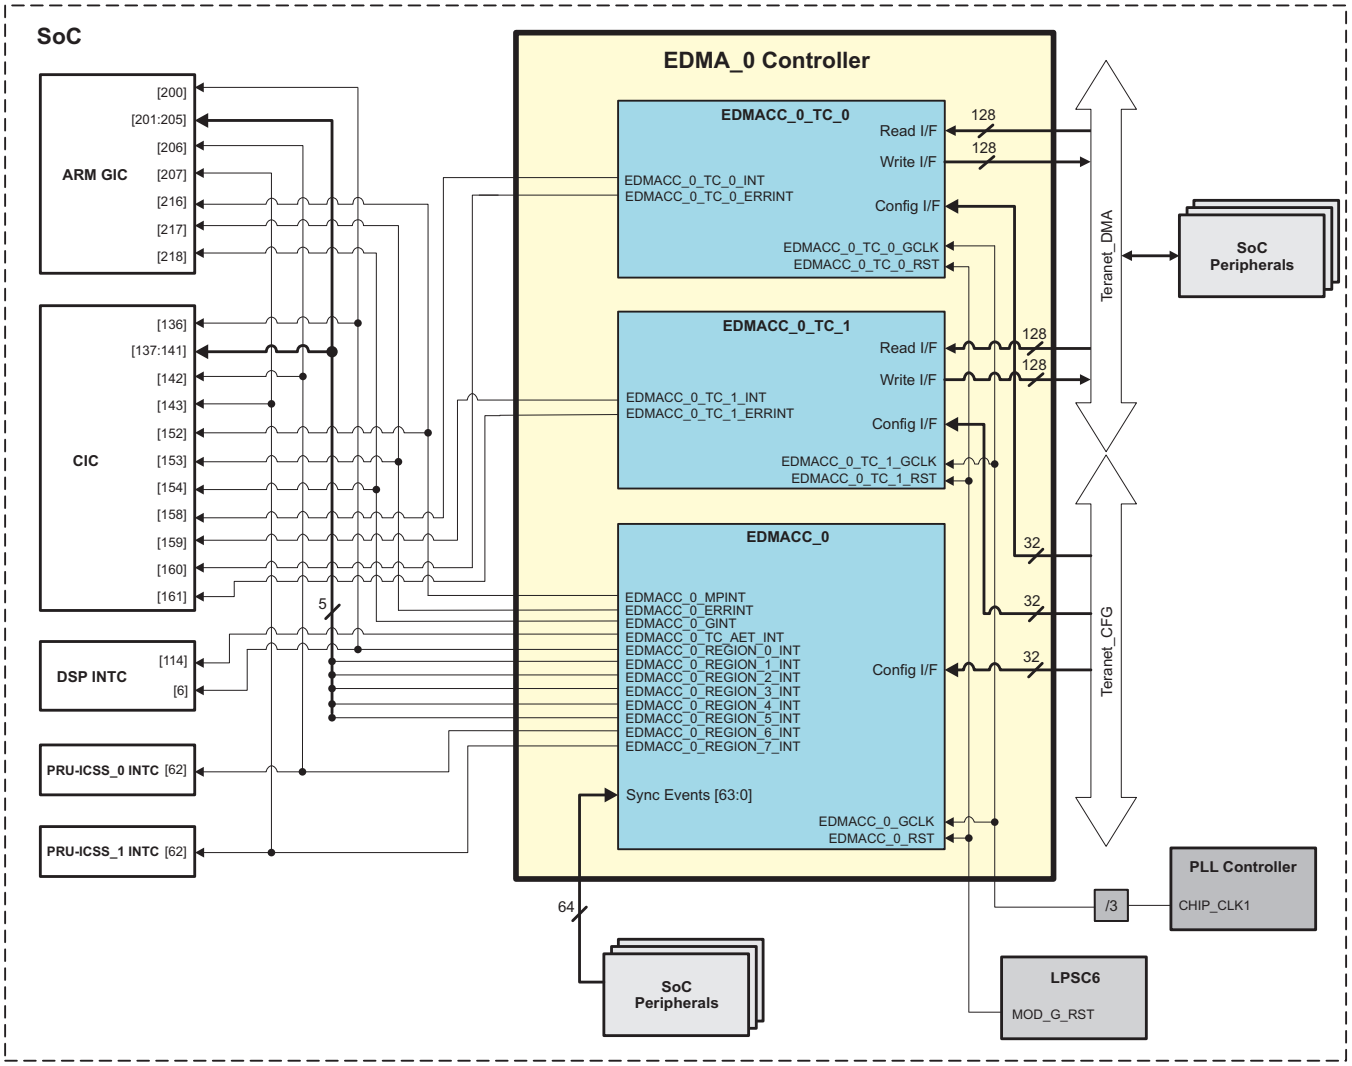


Figure 10-3. EDMA_1 Controller Integration

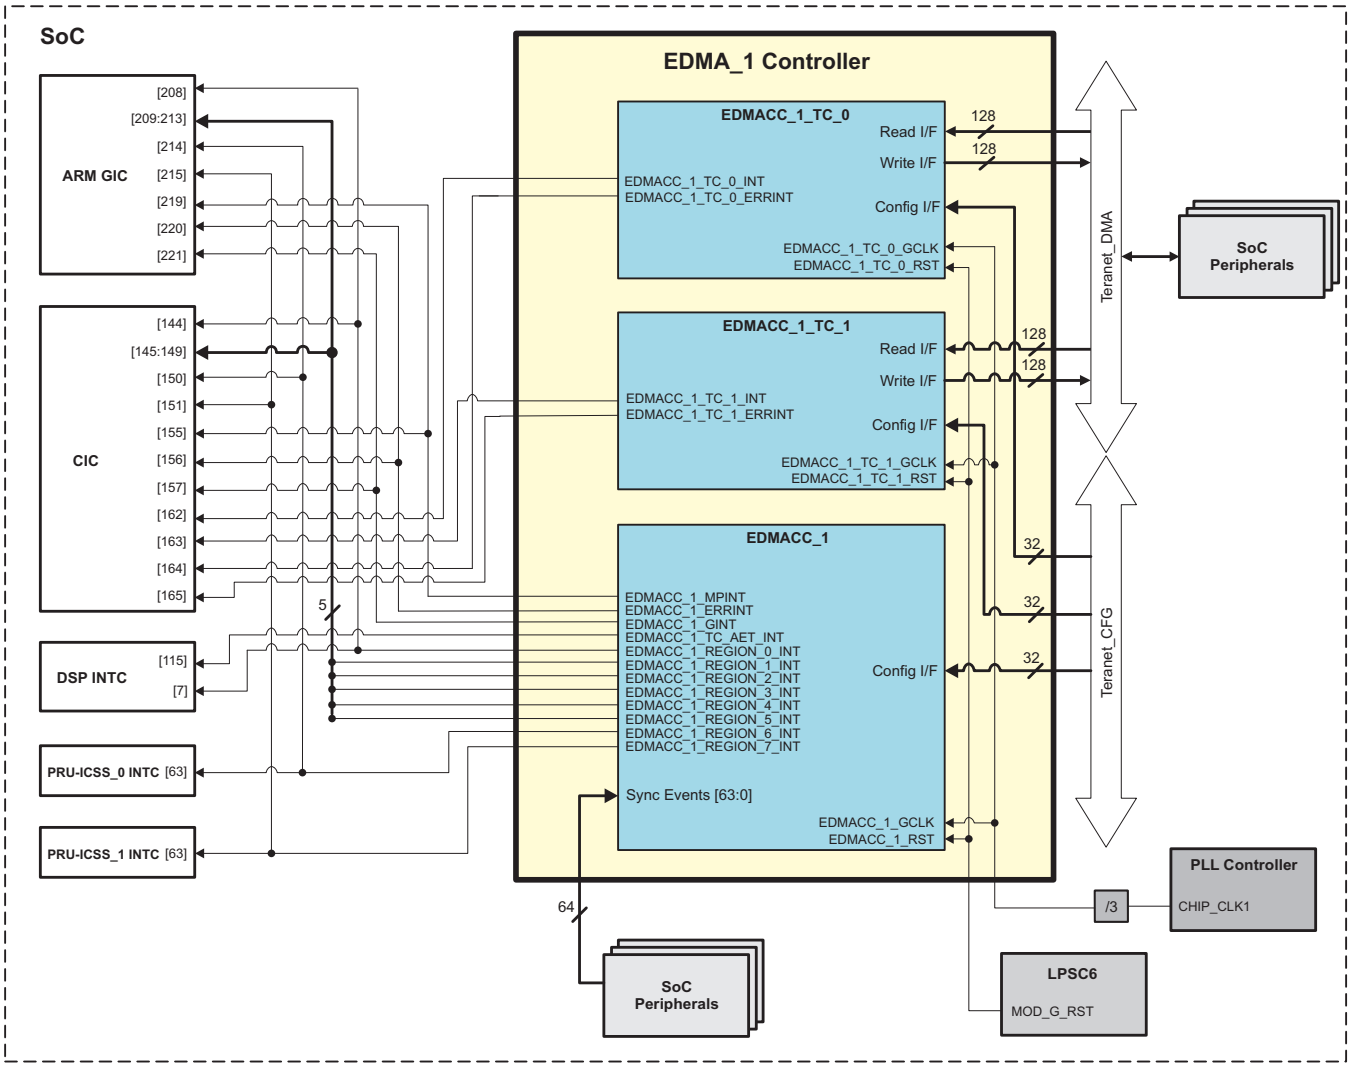

Table 10-4 through Table 10-6 summarize the integration of the EDMA controllers.

Table 10-4. EDMA Integration Attributes

Module Instance		Attributes		
		Power Domain	Module Domain	Interconnect
EDMA_0	EDMACC_0 EDMACC_0_TC_0 EDMACC_0_TC_1	PD5	LPSC6	TeraNet_DMA TeraNet_CFG
EDMA_1	EDMACC_1 EDMACC_1_TC_0 EDMACC_1_TC_1	PD5	LPSC6	TeraNet_DMA TeraNet_CFG

Table 10-5. EDMA Clocks and Resets

Clocks				
Module Instance	**Module Clock Name**	**Source Clock Name**	**Source**	**Description**
EDMACC_0	EDMACC_0_GCLK	CHIP_CLK1 / 3	PLL Controller	EDMA interface/functional clock. This clock is used for all interface and functional operations.
EDMACC_1	EDMACC_1_GCLK			
EDMACC_0_TC_0	EDMACC_0_TC_0_GCLK			
EDMACC_0_TC_1	EDMACC_0_TC_1_GCLK			
EDMACC_1_TC_0	EDMACC_1_TC_0_GCLK			
EDMACC_1_TC_1	EDMACC_1_TC_1_GCLK			
Resets				
Module Instance	**Module Reset Name**	**Source Reset Name**	**Source**	**Description**
EDMACC_0	EDMACC_0_RST	MOD_G_RST	LPSC6	EDMA hardware reset. See Section 10.3.17.
EDMACC_1	EDMACC_1_RST			
EDMACC_0_TC_0	EDMACC_0_TC_0_RST			
EDMACC_0_TC_1	EDMACC_0_TC_1_RST			
EDMACC_1_TC_0	EDMACC_1_TC_0_RST

10.2.1 EDMA Synchronization Events

The EDMA supports up to 64 DMA channels (per EDMACC instance) that can be used to service system peripherals and to move data between system memories. DMA channels can be triggered by synchronization events generated by system peripherals. Table 10-7 and Table 10-8 list the source of the synchronization event associated with each of the EDMACC DMA channels.

For more information about how EDMA events are enabled, captured, processed, prioritized, linked, chained, and cleared, see Section 10.3.

10.2.1.1 EDMACC_0 Synchronization Events

Table 10-7 lists the EDMACC_0 synchronization events.

Table 10-7. EDMACC_0 Synchronization Events

Event No.	Event Name	Description
0	TIMER_2_INTL	TIMER_2 low interrupt
1	TIMER_2_INTH	TIMER_2 high interrupt
2	TIMER_3_INTL	TIMER_3 low interrupt
3	TIMER_3_INTH	TIMER_3 high interrupt
4	SPI_0_XEVT	SPI_0 level 0 interrupt
5	SPI_0_REVT	SPI_0 level 1 interrupt
6	SPI_1_XEVT	SPI_1 level 0 interrupt
7	SPI_1_REVT	SPI_1 level 1 interrupt
8	I2C_0_XEVT	I2C_0 transmit event
9	I2C_0_REVT	I2C_0 receive event
10	QSPI_INT	QSPI interrupt
11	PMMCTBR_DMAINT	PMMC trace buffer DMA event
12	ARM_TBR_DMA	ARMSS trace buffer DMA event
14	TETB_HFULLINT0	TETB half-full flag
13	DBGTBR_DMAINT	System trace buffer DMA event

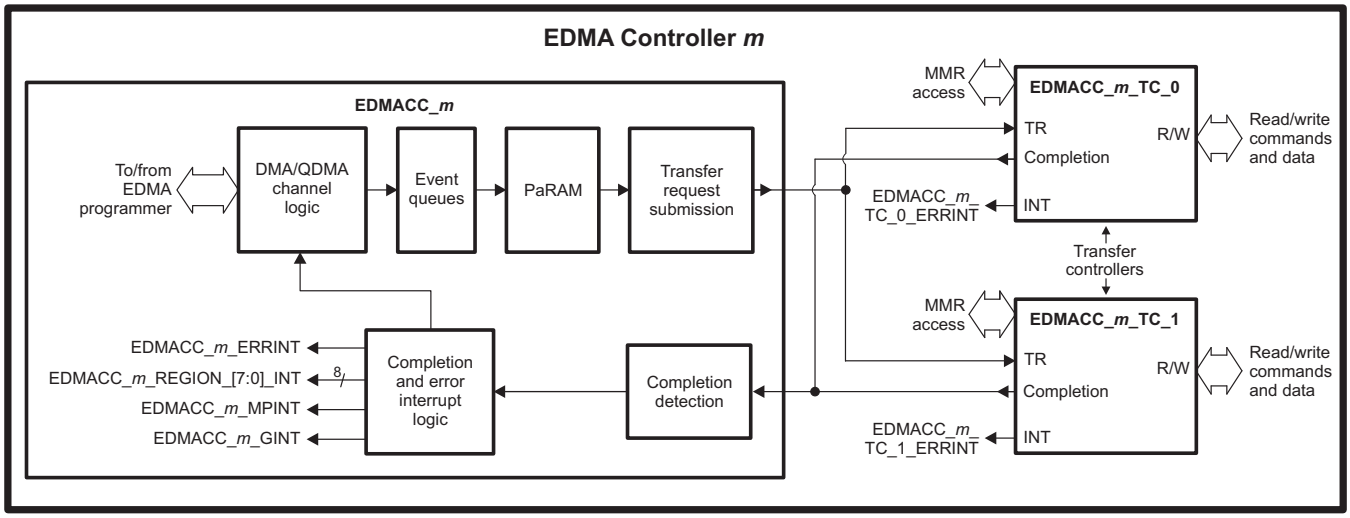
10.3 EDMA Functional Description

10.3.1 EDMA Controller Block Diagram

Figure 10-4 shows the EDMA controller block diagram.

Figure 10-4. EDMA Controller Block Diagram



NOTE: 'm' indicates the EDMACC instance number.

10.3.2 EDMA Channel Controller (EDMACC)

The EDMACC is responsible for scheduling, arbitrating, and issuing user-programmed transfers to the two EDMATCs associated with it.

Figure 10-5 shows a functional block diagram of the EDMACC. The main blocks of the EDMACC are:

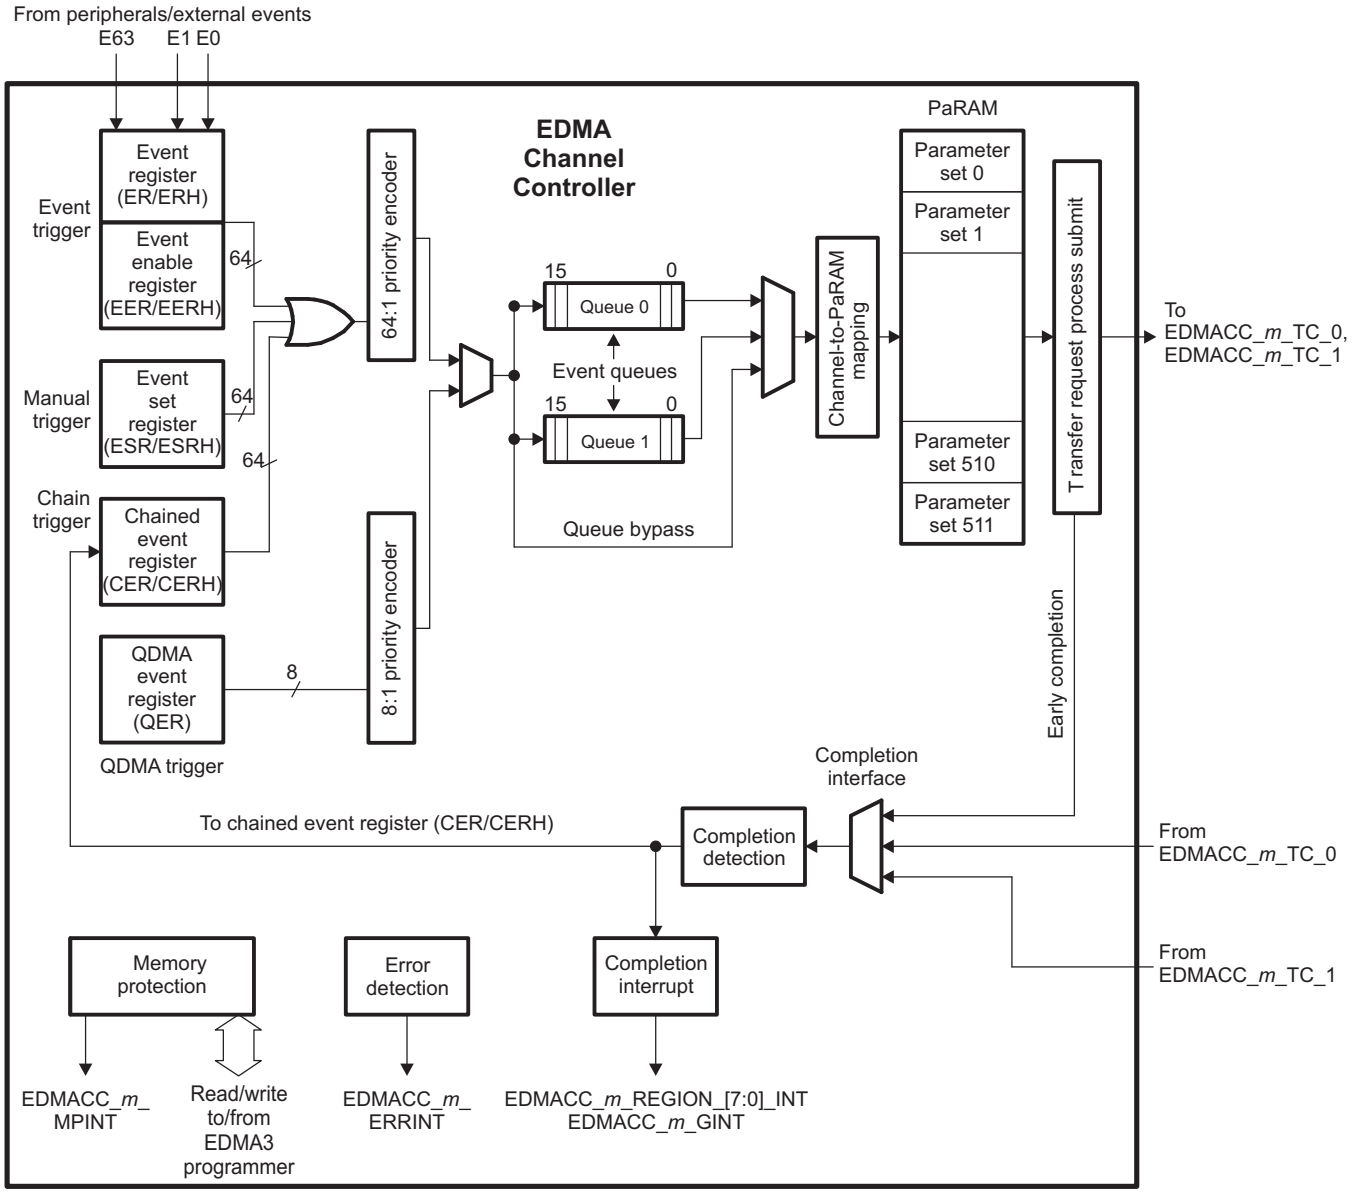
- **DMA/QDMA Channel Logic**: This block consists of logic that captures external system or peripheral events that can be used to initiate event triggered transfers. It also includes:
  - Registers that allow configuring the DMA/QDMA channels (queue mapping, PaRAM entry mapping).
  - All the registers for different trigger type (manual, external events, chained and auto-triggered) for enabling/disabling events, and monitor event status.
- **Parameter RAM (PaRAM)**: The PaRAM maintains parameter set entries for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets.
- **Event Queues**: Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Transfer Request Submission Logic**: This logic processes PaRAM sets based on a trigger event submitted to the event queue and submits a transfer request (TR) to the transfer controller associated with the event queue.
- **EDMA Event and Interrupt Processing Registers**: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion Detection**: This block detects completion of transfers by the EDMATC and/or slave peripherals. Completion of transfers can optionally be used to chain trigger new transfers or to assert interrupts. The logic includes the interrupt processing registers for enabling/disabling interrupt (to be sent to the CPU), interrupt status/clearing registers.
- **Memory Protection Registers**: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of

PaRAM.

Additional functions include the following:

- **Region Registers**: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions, which can be owned by unique EDMA programmers.
- **Debug Registers**: Debug registers allow debug visibility by providing registers to read the queue status, channel controller status, and missed event status.

Figure 10-5. EDMA Channel Controller Block Diagram



NOTE: 'm' indicates the EDMACC instance number.

The EDMACC includes two channel types: DMA channels and QDMA channels.

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and QDMA channel is how the transfers are triggered by the system. See Section 10.3.6.

A trigger event is necessary to initiate a transfer. For DMA channels, a trigger event may be due to an external event, manual write to the event set register, or chained event. QDMA channels are auto-triggered when a write is performed to the user-programmed trigger word. All such trigger events are logged into appropriate registers upon recognition. See Section 10.6.1.5 and Section 10.6.1.7.

Once a trigger event is recognized, the event type/channel is queued in the appropriate EDMACC event queue. The assignment of each DMA/QDMA channel to event queue is programmable. Each queue is 16 deep, so up to 16 events may be queued (on a single queue) in the EDMACC at an instant in time. Additional pending events mapped to a full queue are queued when event queue space becomes available. See Section 10.3.13.

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Each event in the event queue is processed in FIFO order. On reaching the head of the queue, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMATC (based on the event queue to the EDMATC association, Q0 goes to EDMATC0, and Q1 goes to EDMATC1). For more information, see Section 10.3.5.

The EDMATC receives the request and is responsible for data movement as specified in the transfer request packet (TRP), and other necessary tasks like buffering, ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMATC, see Section 10.3.3.

The user might choose to receive an interrupt or chain to another channel on completion of the current transfer, in which case the EDMATC signals completion to the EDMACC completion detection logic when the transfer is done. The user can alternately choose to trigger completion when a TR leaves the EDMACC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMACC interrupt registers, the completion interrupt generation logic is responsible for generating EDMACC completion interrupts to the CPU. For more information, see Section 10.3.7.

Additionally, the EDMACC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, see Section 10.3.11.4.

10.3.3 EDMA Transfer Controller (EDMATC)

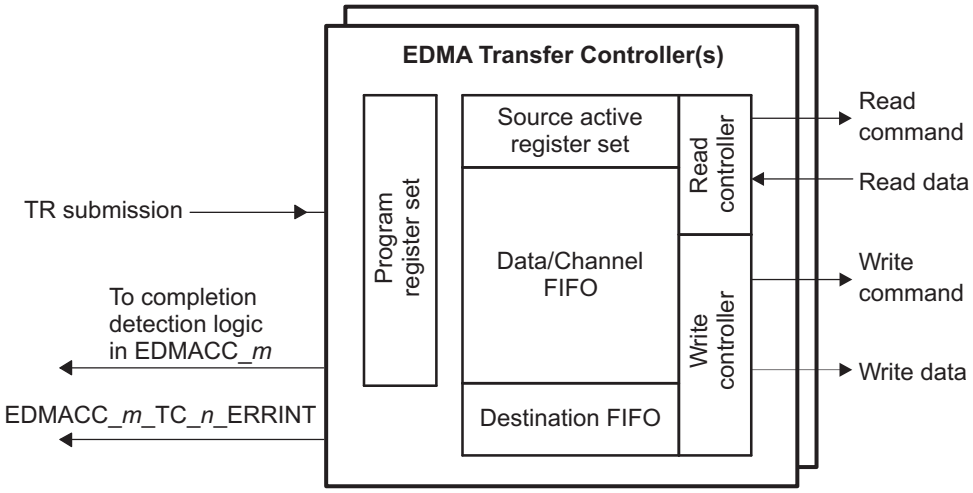
The EDMATC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port, and a write-only port.

Figure 10-6 shows a functional block diagram of the EDMA transfer controller (EDMATC). The main blocks of the EDMATC are:

- **DMA Program Register Set**: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or EDMACC programs the program register set, not the active register set. For typical standalone operation, the CPU programs the program register while the EDMATC services the active register set. The program register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- **DMA Source Active Register Set**: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.
- **Destination FIFO Register Set**: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- **Data/Channel FIFO**: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- **Read Controller/Read Interface**: The read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and available landing space in the channel FIFO.

- **Write Controller/Write Interface**: The write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- **Completion Interface**: Sends completion codes to the EDMACC when a transfer completes and generates interrupts and chained events in the EDMACC module (see Section 10.3.2 for more information on transfer completion reporting).
- **Configuration Port**: Slave interface that provides read/write access to program registers and read access to all memory-mapped EDMATC registers.

Figure 10-6. EDMA Transfer Controller Block Diagram



NOTE: 'm' indicates the EDMACC instance number, and 'n' indicates the EDMATC number.

When the EDMATC is idle and receives its first TR, the TR is received in the DMA program register set, where it transitions to the DMA source active set and the destination FIFO register set immediately. The source active register set tracks the commands for the source side of the transfers, and the destination FIFO register set tracks commands for the destination side of the transfer. The second TR (if pending from EDMACC) is loaded into the DMA program register set, ensuring it can start as soon as possible when the active transfer (the transfer in the source active set) is completed. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the read data. The number of read commands issued depends on the TR transfer size. The TC write controller starts issuing write commands as soon as sufficient data is read in the data FIFO for the write controller to issue optimally sized write commands following the rules for command fragmentation and optimization. For details on command fragmentation and optimization, see Section 10.3.14.1.2.

The DSTREGDEPTH parameter (fixed in design for a given transfer controller) determines the number of entries in the destination FIFO register set. The number of entries determines the amount of TR pipelining possible for a given TC. The write controller can manage the write context for the number of entries in the destination FIFO register set. This allows the read controller to go ahead and issue read commands for the subsequent TRs while the destination FIFO register set manages the write commands and data for the previous TR.

In summary, since the DSTREGDEPTH is fixed to 4 in this device, the read controller is able to process up to 4 TRs ahead of the write controller. However, the overall TR pipelining is also subject to the amount of free space in the data FIFO.

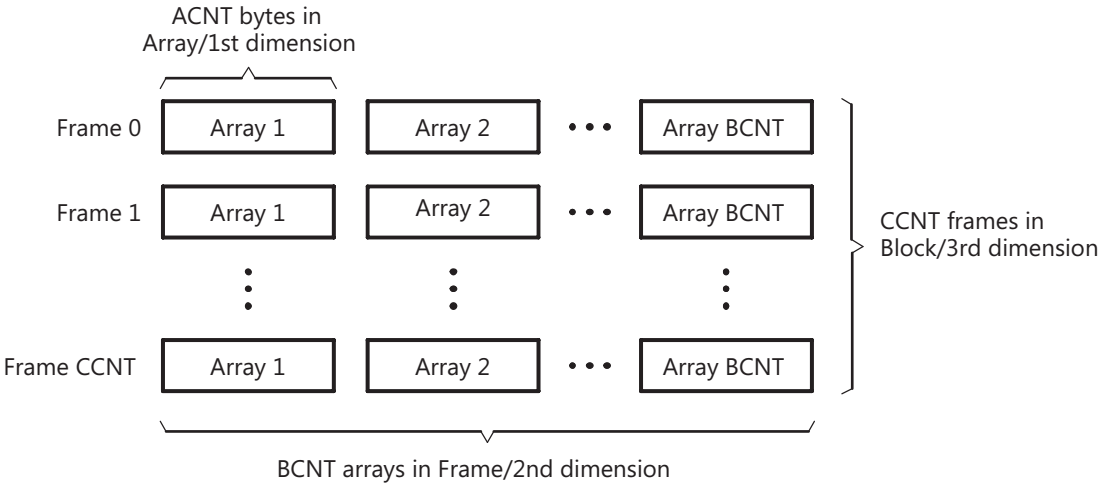
10.3.4 Types of EDMA Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 10-7 shows the three dimensions used by EDMA transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 10-7. Definition of ACNT, BCNT, and CCNT



10.3.4.1 A-Synchronized Transfers

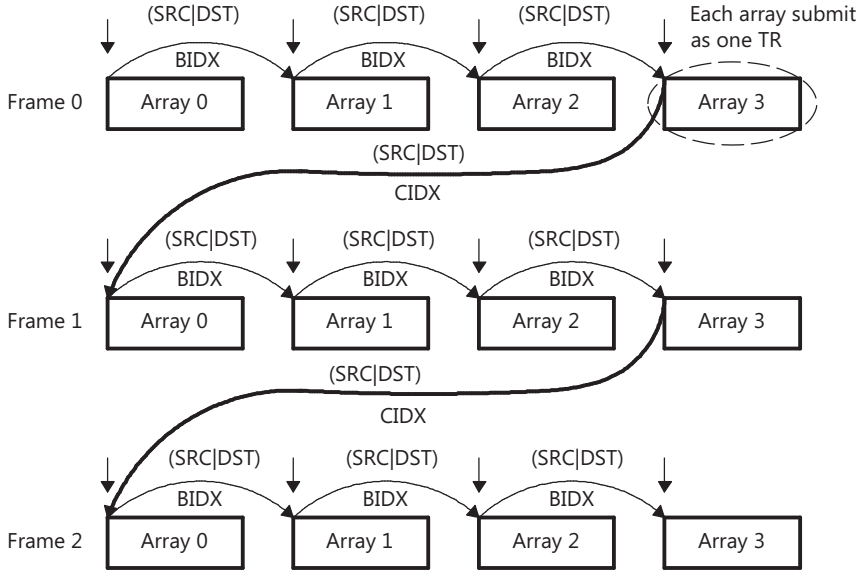
In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in Figure 10-8, where the start address of Array N is equal to the start address of Array N - 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 10-8, SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 10-8 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Section 10.3.5.6 for details on parameter set updates.

Figure 10-8. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



10.3.4.2 AB-Synchronized Transfers

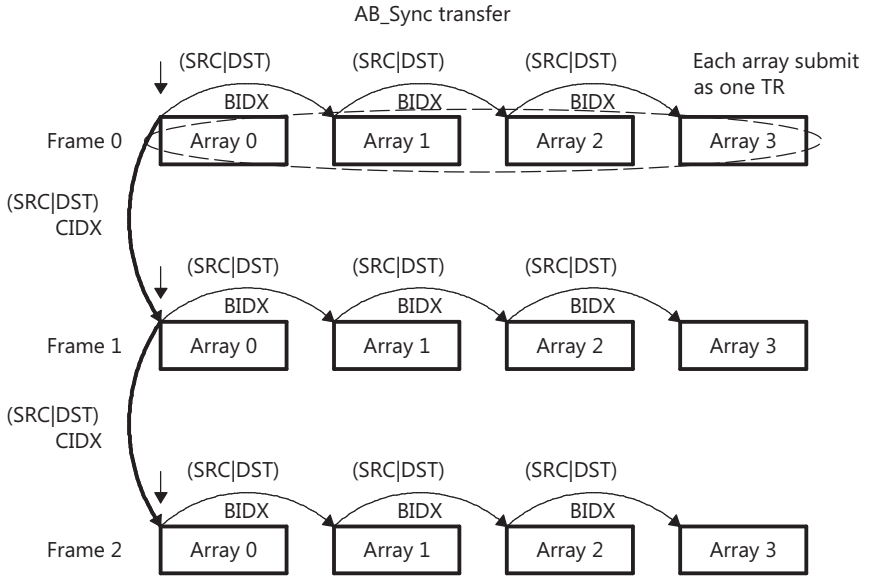
In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 10-9. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 10.3.5.6 for details on parameter set updates.

Figure 10-9 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 10-9. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



NOTE: ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

10.3.5 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM (PaRAM) table within the EDMACC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight 4-byte PaRAM set entries (32 bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and autoreloading (linking). The first 64 PaRAM sets are directly mapped to the DMA channels. The remaining PaRAM sets can be used for link entries or associated with QDMA channels. Additionally, if the DMA channels are not used, the PaRAM sets associated with the unused DMA channels can also be used for link entries or QDMA channels.

The contents of the PaRAM include the following:

- 512 PaRAM sets
- Any PaRAM entry can be used for DMA, QDMA, or link sets
- By default, all channels are mapped to PaRAM set 0. They should be re-mapped before use. See (DCHMAP registers) and (QCHMAP registers) for more information.

Table 10-9. EDMA Parameter RAM Contents

PaRAM Set Number[(1)]	Address Offset
0	4000h to 401Fh
1	4020h to 403Fh
2	4040h to 405Fh
3	4060h to 407Fh
4	4080h to 409Fh
5	40A0h to 40BFh
6	40C0h to 40DFh

(1) A PaRAM set can be configured for use with either DMA channel, QDMA channel, or as a reload link set.

Table 10-9. EDMA Parameter RAM Contents (continued)

PaRAM Set Number[1]	Address Offset
7	40E0h to 40FFh
8	4100h to 411Fh
9	4120h to 413Fh
...	...
64	4800h to 481Fh
65	4820h to 483Fh
...	...
126	4FC0h to 4FDFh
127	4FE0h to 4FFFh
...	...
254	5FC0h to 5FDFh

511	7FE0h to 7FFFh

10.3.5.1 PaRAM Set

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 10-10 and described in Table 10-10. Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 10-10. PaRAM Set

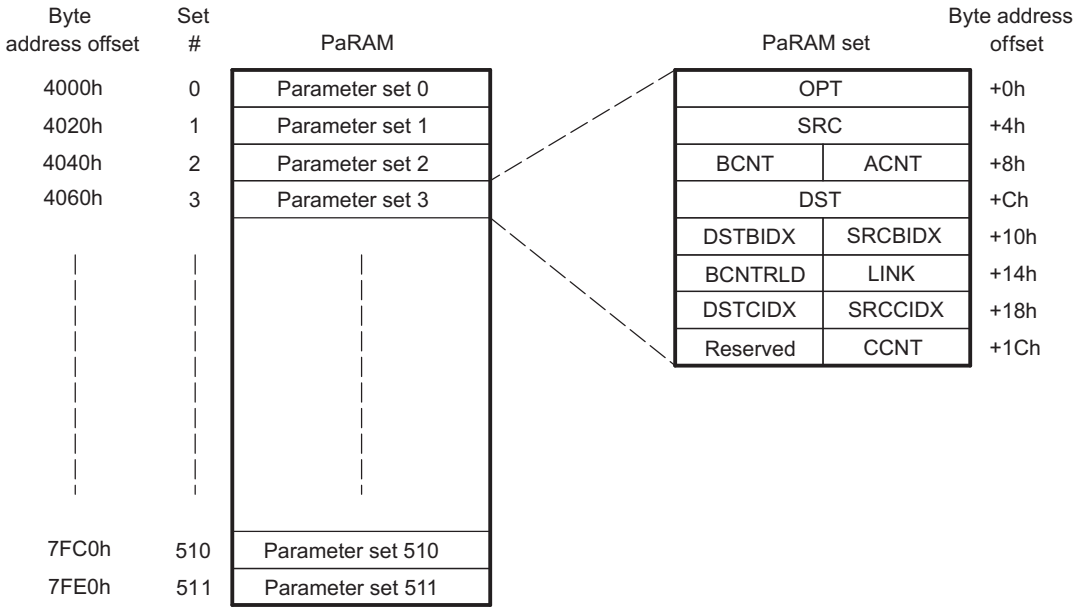

Table 10-10. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options	Transfer configuration options
4h	SRC	Channel Source Address	The byte address from which data is transferred

Table 10-10. EDMA Channel Parameter Description (continued)

Offset Address (bytes)	Acronym	Parameter	Description
8h [(1)]	ACNT	Count for 1st Dimension	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address	The byte address to which data is transferred
10h[(1)]	SRCBIDX	Source BCNT Index	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from -32 768 and 32 767.
	DSTBIDX	Destination BCNT Index	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from -32 768 and 32 767.
14h[(1)]	LINK	Link Address	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h[(1)]	SRCCIDX	Source CCNT Index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from -32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DSTCIDX	Destination CCNT index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from -32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	RSVD	Reserved	Reserved. Always write 0 to this bit; writing 1 to this bit is not supported and attempts to do so may result in undefined behavior.

(1) The parameter sets must be accessed as 32-bit words.

10.3.5.2 EDMA Channel PaRAM Set Entry Fields

10.3.5.2.1 Channel Options Parameter (OPT)

The 32-bit channel options parameter (OPT) specifies the transfer configuration options. The channel options parameter (OPT) is shown in Figure 10-11 and described in Table 10-11.

Figure 10-11. Channel Options Parameter (OPT)

31	30 28	27 24	23	22	21	20	19 18	17 16
PRIV	Reserved	PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved	TCC
R-0	R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

15 12	11	10 8	7 4	3	2	1	0
TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM
R/W-0			R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; -n = value after reset

Table 10-11. Channel Options Parameters (OPT) Field Descriptions

Bit	Field	Description
31	PRIV	Privilege level (supervisor versus user) for the host/DSP/DMA that programmed this PaRAM set. This value is set with the EDMA master's privilege value when any part of the PaRAM set is written. 0h = User level privilege 1h = Supervisor level privilege
30-28	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
27-24	PRIVID	Privilege identification for the external host/DSP/DMA that programmed this PaRAM set. This value is set with the EDMA master's privilege identification value when any part of the PaRAM set is written. Value = 0-Fh
23	ITCCHEN	Intermediate transfer completion chaining enable. 0h = Intermediate transfer complete chaining is disabled 1h = Intermediate transfer complete chaining is enabled When enabled, the chained event register (EDMACC_CER/EDMACC_CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in EDMACC_CER or EDMACC_CERH is the TCC value specified.
22	TCCHEN	Transfer complete chaining enable. 0h = Transfer complete chaining is disabled 1h = Transfer complete chaining is enabled When enabled, the chained event register (EDMACC_CER/EDMACC_CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in EDMACC_CER or EDMACC_CERH is the TCC value specified.
21	ITCINTEN	Intermediate transfer completion interrupt enable. 0h = Intermediate transfer complete interrupt is disabled 1h = Intermediate transfer complete interrupt is enabled When enabled, the interrupt pending register (EDMACC_IPR/EDMACC_IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in EDMACC_IPR or EDMACC_IPRH is the TCC value specified. To generate a completion interrupt to the DSP, the corresponding EDMACC_IER [TCC] / EDMACC_IERH [TCC] bit must be set.
20	TCINTEN	Transfer complete interrupt enable. 0h = Transfer complete interrupt is disabled 1h = Transfer complete interrupt is enabled When enabled, the interrupt pending register (EDMACC_IPR / EDMACC_IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in EDMACC_IPR or EDMACC_IPRH is the TCC value specified. To generate a completion interrupt to the DSP, the corresponding EDMACC_IER[TCC] / EDMACC_IERH [TCC] bit must be set.
19-18	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17-12	TCC	Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] /CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts. Value = 0-3Fh
11	TCCMODE	Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation. 0h = Normal completion: A transfer is considered completed after the data has been transferred. 1h = Early completion: A transfer is considered completed after the EDMACC submits a TR to the EDMATC. TC may still be transferring data when the interrupt/chain is triggered.

Table 10-11. Channel Options Parameters (OPT) Field Descriptions (continued)

Bit	Field	Description
10-8	FWID	FIFO Width. Applies if either SAM or DAM is set to constant addressing mode. 0h = FIFO width is 8-bit 1h = FIFO width is 16-bit 2h = FIFO width is 32-bit 3h = FIFO width is 64-bit 4h = FIFO width is 128-bit 5h = FIFO width is 256-bit 6h - 7h = Reserved
7-4	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	STATIC	Static set. 0h = Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers. 1h = Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.
2	SYNCDIM	Transfer synchronization dimension. 0h = A-synchronized. Each event triggers the transfer of a single array of ACNT bytes. 1h = AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.
1	DAM	Destination address mode. 0h = Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO. 1h = Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	Source address mode. 0h = Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO. 1h = Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

10.3.5.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, the user must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMATC will signal an error, if this rule is violated. See Section 10.3.14.3 for additional details.

10.3.5.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, the user must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMATC will signal an error, if this rule is violated. See Section 10.3.14.3 for additional details.

10.3.5.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K - 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMATC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer.

See Section 10.3.5.5 and Section 10.3.7.3 for details on dummy/null completion conditions.

10.3.5.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K - 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer.

See Section 10.3.5.5 and Section 10.3.7.3 for details on dummy/null completion conditions.

10.3.5.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K - 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer.

See Section 10.3.5.5 and Section 10.3.7.3 for details on dummy/null completion conditions.

10.3.5.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMACC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMACC decrements CCNT and uses the BCNTRLD value to re-initialize the BCNT value.

For AB-synchronized transfers, the EDMACC submits the BCNT in the TR and the EDMATC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

10.3.5.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between -32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (-1): the address offset from the beginning of an array to the beginning of the next array in a frame is -1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

10.3.5.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between -32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See Section 10.3.5.2.8 (SRCBIDX) for examples.

10.3.5.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between -32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-8), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 10-9).

10.3.5.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between -32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-8), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 10-9).

10.3.5.2.12 Link Address (LINK)

The EDMACC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMACC loads/reloads the next PaRAM set during linking.

The user must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMACC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if the user makes use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

The user should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMACC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 10.3.7 for details on terminating a transfer.

10.3.5.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMACC, the bit corresponding to the channel is set in the associated event missed register (EDMACC_EMR, EDMACC_EMRH, or EDMACC_QEMR). This bit remains set in the associated secondary event register (EDMACC_SER, EDMACC_SERH, or EDMACC_QSER). This implies that any future events on the same channel are ignored by the EDMACC and the user is required to clear the bit in EDMACC_SER, EDMACC_SERH, or EDMACC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. See and for more information on the EDMACC_SER and EDMACC_EMR registers, respectively.

10.3.5.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMACC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMACC_EMR, EDMACC_EMRH, or EDMACC_QEMR) and the secondary event register (EDMACC_SER, EDMACC_SERH, or EDMACC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. See and for more information on the EDMACC_SER and EDMACC_EMR registers, respectively.

10.3.5.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMACC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E *n*) in EDMACC_EMR to get set and the E *n* bit in EDMACC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 10-12 summarizes the conditions and effects of null and dummy transfer requests.

Table 10-12. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMACC_EMR/EDMACC_EMRH/EDMACC_QEMR is set	Yes	No
EDMACC_SER/EDMACC_SERH/EDMACC_QSER remains set	Yes	No
Link update (STATIC = 0 in OPT)	Yes	Yes
EDMACC_QER is set	Yes	Yes
EDMACC_IPR/EDMACC_IPRH EDMACC_CER/EDMACC_CERH is set using early completion	Yes	Yes

10.3.5.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMACC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See Table 10-13 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 10.3.5.7.

After the TR is read from the PaRAM (and is in process of being submitted to EDMATC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST
- AB-synchronized: CCNT, SRC, DST

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMATC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 10.3.14. For A-synchronized transfers, the EDMACC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMACC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMATC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMATC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

Table 10-13 shows the details of parameter updates that occur within EDMACC for A-synchronized and AB-synchronized transfers.

Table 10-13. Parameter Updates in EDMACC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	**BCNT > 1**	**BCNT == 1 && CCNT > 1**	**BCNT == 1 && CCNT == 1**	**N/A**	**CCNT > 1**	**CCNT == 1**
SRC	+= SRCBIDX	+= SRCCIDX	= Link.SRC	in EDMATC	+= SRCCIDX	= Link.SRC
DST	+= DSTBIDX	+= DSTCIDX	= Link.DST	in EDMATC	+= DSTCIDX	= Link.DST

Table 10-13. Parameter Updates in EDMACC (for Non-Null, Non-Dummy PaRAM Set) (continued)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	CCNT > 1	CCNT == 1
ACNT	None	None	= Link.ACNT	None	None	= Link.ACNT
BCNT	-= 1	= BCNTRLD	= Link.BCNT	in EDMATC	N/A	= Link.BCNT
CCNT	None	-= 1	= Link.CCNT	in EDMATC	-=1	= Link.CCNT
SRCBIDX	None	None	= Link.SRCBIDX	in EDMATC	None	= Link.SRCBIDX
DSTBIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
SRCCIDX	None	None	= Link.SRCBIDX	in EDMATC	None	= Link.SRCBIDX
DSTCIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
LINK	None	None	= Link.LINK	None	None	= Link.LINK
BCNTRLD	None	None	= Link.BCNTRLD	None	None	= Link.BCNTRLD
OPT (1)	None	None	= LINK.OPT	None	None	= LINK.OPT

(1) In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

NOTE: The EDMACC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. The user should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

10.3.5.7 Linking Transfers

The EDMACC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field (of the current parameter set). Linking only occurs when the STATIC bit in OPT is cleared to 0.

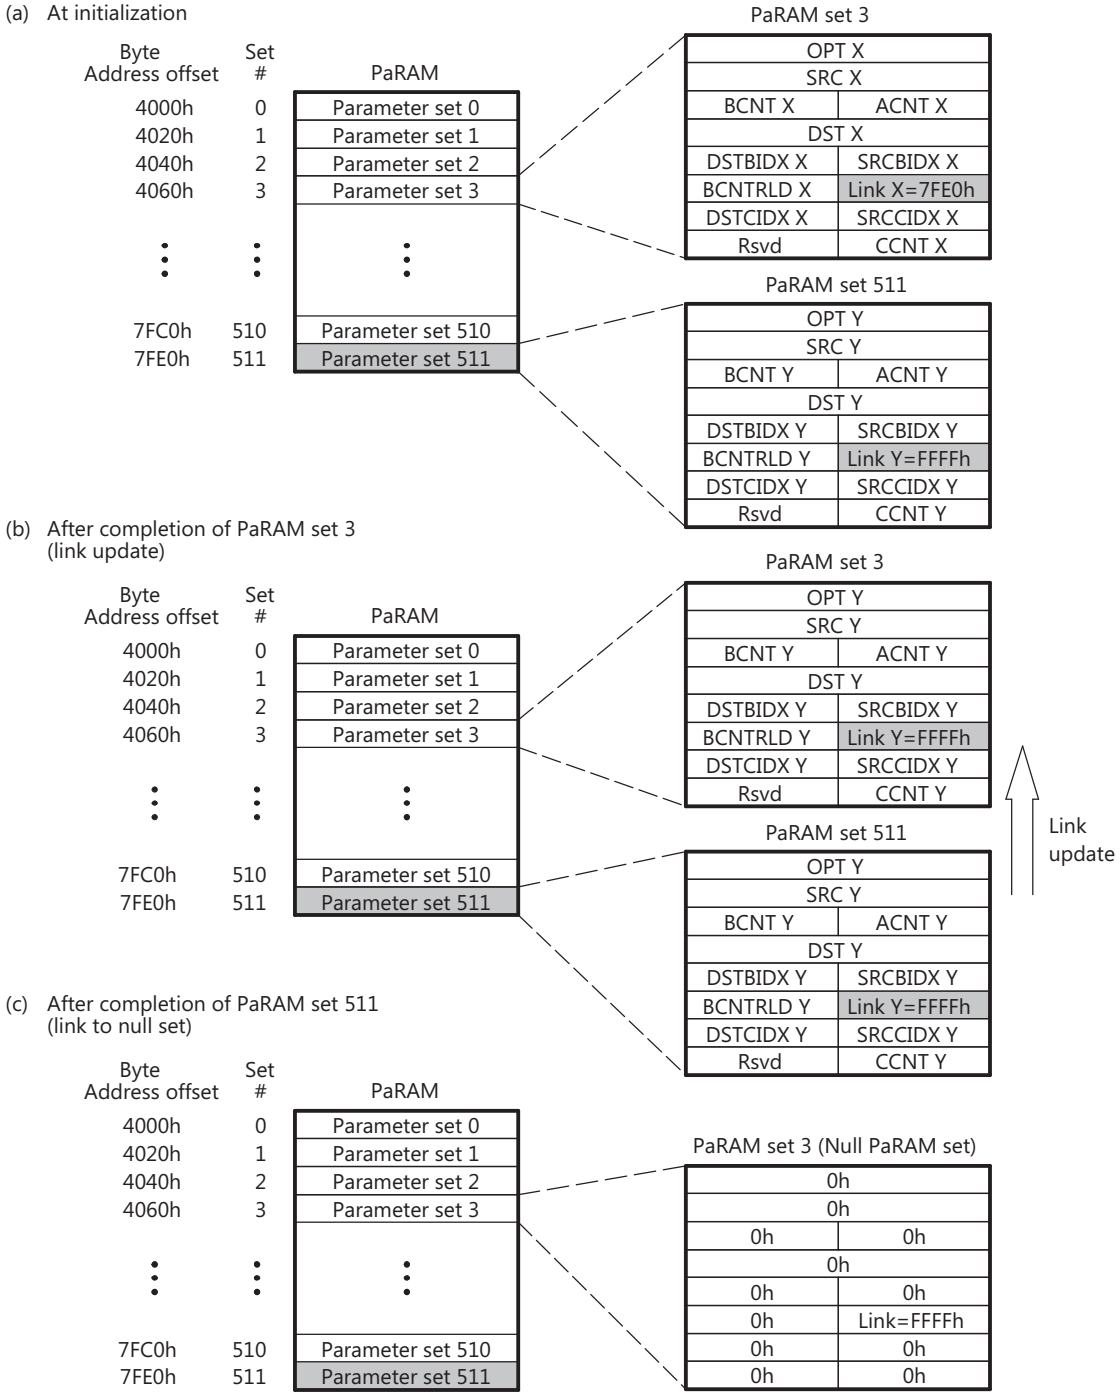
NOTE: A transfer (DMA or QDMA) should always be linked to another useful transfer. If it is required to terminate a transfer, the transfer should be linked to a NULL set. See Section 10.3.5.3.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all the transfers associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location pointed to by LINK is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. The EDMACC reads the entire PaRAM set (8 words) from the PaRAM set specified by LINK and writes all 8 words to the PaRAM set associated with the current channel. Figure 10-12 shows an example of a linked transfer.

Figure 10-12. Linked Transfer Example

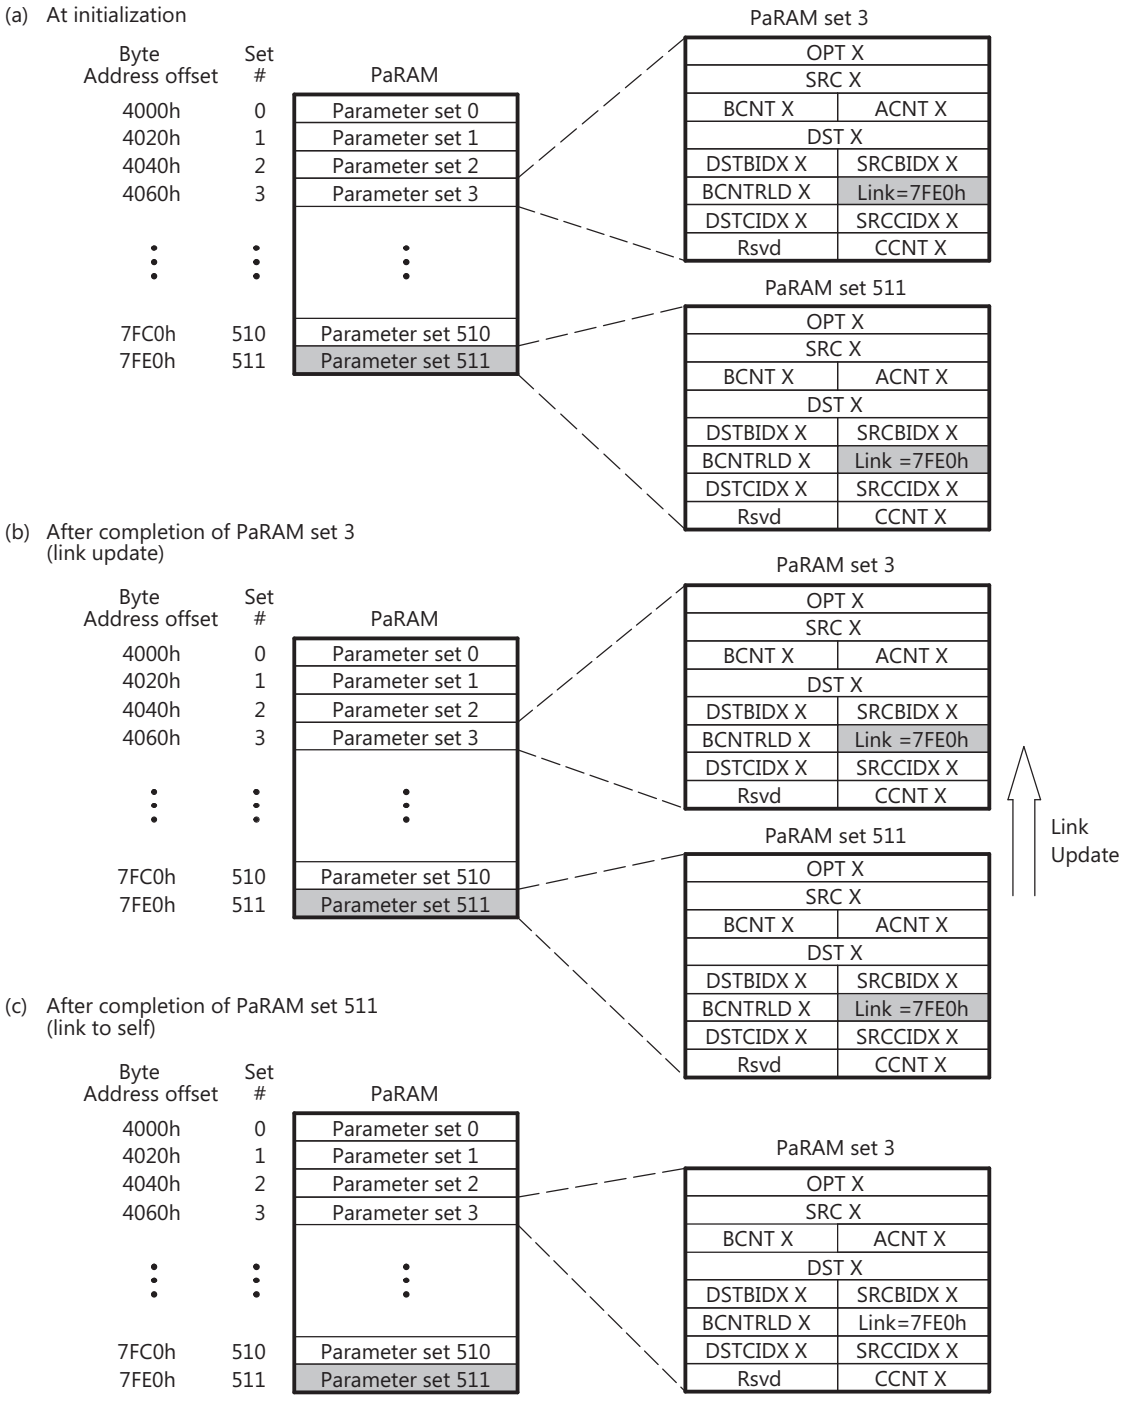


Any PaRAM set in the PaRAM can be used as a link/reload parameter set; however, it is recommended that the PaRAM sets associated with peripheral synchronization events (see Section 10.3.8) should only be used for linking if the synchronization event isolated with the channel mapped to that PaRAM set is disabled.

If a PaRAM set location is mapped to a QDMA channel (by QCHMAP *n*), then copying the link PaRAM set onto the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMACC_QER since a write to the trigger word was performed. This feature can be used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See Section 10.3.6.2.

Link-to-self transfers replicate the behavior of auto-initialization, which facilitates the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all the parameter set entries from another PaRAM set, which is initialized with values identical to the original PaRAM set. Figure 10-13 shows an example of a linked-to-self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked-to-self).

Figure 10-13. Link-to-Self Transfer Example



NOTE: If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed. The link updates performed internally by the EDMACC are atomic. This implies that when the EDMACC is updating a PaRAM set, accesses to PaRAM by other EDMA programmer's (for example, CPU configuration accesses) are not allowed. Also for QDMA, for example, if the first word of the PaRAM entry is defined as a trigger word, EDMACC logic assures that all 8 PaRAM words are updated before the new QDMA event can trigger the transfer for that PaRAM entry.

10.3.5.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set to 1 (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bit). The EDMACC does not recognize errors here, but the EDMATC asserts an error if this is not true. See Section 10.3.14.3.

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM = 0) by appropriately programming the count and indices values.

10.3.5.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if there are 16-bit data and 256 samples that must be transferred to a serial port, the user can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

10.3.6 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA channel controller. Transfers on DMA channels are initiated by three sources:

- **Event-triggered transfer request** (this is the most typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request**: The CPU manually triggers a transfer by writing 1 to the corresponding bit in the event set register (EDMACC_ESR/EDMACC_ESRH).
- **Chain-triggered transfer request**: A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources:

- **Auto-triggered transfer request**: Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests**: Writing to the trigger word triggers the transfer when linking occurs.

10.3.6.1 DMA Channel

10.3.6.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMACC_ER.E *n* = 1). If the corresponding event in the event enable register (EDMACC_EER) is enabled (EDMACC_EER.E *n* = 1), then the EDMACC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMATC and the E *n* bit in EDMACC_ER is cleared. At this point, a new event can be safely received by the EDMACC.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.5.3), then no transfer request (TR) is submitted and the corresponding E *n* bit in EDMACC_ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMACC_EMR.E *n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMACC_ER.E *n* = 1), regardless of the state of EDMACC_EER.E *n*. If the event is disabled when an external event is received (EDMACC_ER.E *n* = 1 and EDMACC_EER.E *n* = 0), the EDMACC_ER.E *n* bit remains set. If the event is subsequently enabled (EDMACC_EER.E *n* = 1), then the pending event is processed by the EDMACC and the TR is processed/submitted, after which the EDMACC_ER.E *n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMACC_ER.E *n* ! = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMACC_EMR.E *n* = 1).

The mapping of the peripheral/external events to the EDMA controller inputs (and DMA channels, respectively) is presented in Section 10.2.1.

10.3.6.1.2 Manually-Triggered Transfer Request

A DMA transfer is initiated by writing to the event set register (EDMACC_ESR) by the CPU (or any EDMA programmer). Writing 1 to an event bit in the EDMACC_ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EDMACC_EER.E *n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a NULL set) then the TR is submitted to the associated EDMATC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.5.3), then no transfer request (TR) is submitted and the corresponding E *n* bit in EDMACC_ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMACC_EMR.E *n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register (EDMACC_ESR.E *n* = 1) prior to the original being cleared (EDMACC_ESR.E *n* = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMACC_EMR.E *n* = 1).

10.3.6.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5-0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (EDMACC_CER) to be set (EDMACC_CER.E[TCC] = 1).

Once a bit is set in EDMACC_CER, the EDMACC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMATC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.5.3), then no transfer request (TR) is submitted and the corresponding En bit in EDMACC_CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMACC_EMR.E *n* = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by software before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (EDMACC_CER.E *n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EDMACC_EMR.E *n* = 1).

NOTE: Chained event registers (EDMACC_CER/EDMACC_CERH), event registers (EDMACC_ER/EDMACC_ERH), and event set registers (EDMACC_ESR/EDMACC_ESRH) operate independently. An event (E *n*) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

10.3.6.2 QDMA Channels

10.3.6.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (EDMACC_QER.E *n* = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (EDMACC_QER) when the following occurs:

- A CPU (or any EDMA programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP *n*)) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMACC_QEER.E *n* = 1).
- EDMACC performs a link update on a PaRAM set address that is configured as a QDMA channel matches QCHMAP *n* settings) and the corresponding channel is enabled via the QDMA event enable register (EDMACC_QEER.E *n* = 1).

Once a bit is set in EDMACC_QER, the EDMACC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMATC and the channel can be triggered again.

If a bit is already set in EDMACC_QER (EDMACC_QER.E *n* = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (EDMACC_QEMR.E *n* = 1).

10.3.6.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMACC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU-triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (EDMACC_ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or other EDMA programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows the user to initiate a linked list of QDMAs, so when EDMACC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

10.3.7 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 10-14 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 10-14. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at Time 0	Total # Transfers	Counts Prior to Final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	BCNT == 1 && CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	CCNT == 1

The user must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (EDMACC_CER[TCC]) and/or interrupt pending register (EDMACC_IPR[TCC]) is set. See Section 10.3.11 for details on interrupts and Section 10.3.10 for details on chaining.

The user can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See Section 10.3.10 for details on chaining (intermediate/final chaining) and Section 10.3.11 for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed.

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See Section 10.3.5.7 for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See Section 10.3.5.5.

There are three ways the EDMACC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

10.3.7.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

10.3.7.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

10.3.7.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set (Section 10.3.5.4) or null set (Section 10.3.5.3). In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (EDMACC_IPR/EDMACC_IPRH) or chained event register (EDMACC_CER/EDMACC_CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMACC generates the completion code).

10.3.8 Event, Channel, and PaRAM Mapping

Most of the DMA channels are tied to a specific hardware peripheral event, thus allowing transfers to be triggered by events from device peripherals or external hardware. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed. Each of the DMA channels has one specific event associated with it. For the synchronization events associated with each of the programmable DMA channels, see Section 10.2.1.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

10.3.8.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable. The DMA channel *n* mapping register (DCHMAP *n*) in the EDMACC provide programmability that allows the user to map the DMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 10-14 illustrates the use of DCHMAP. There is one DCHMAP register per channel.

10.3.8.2 QDMA Channel to PaRAM Mapping

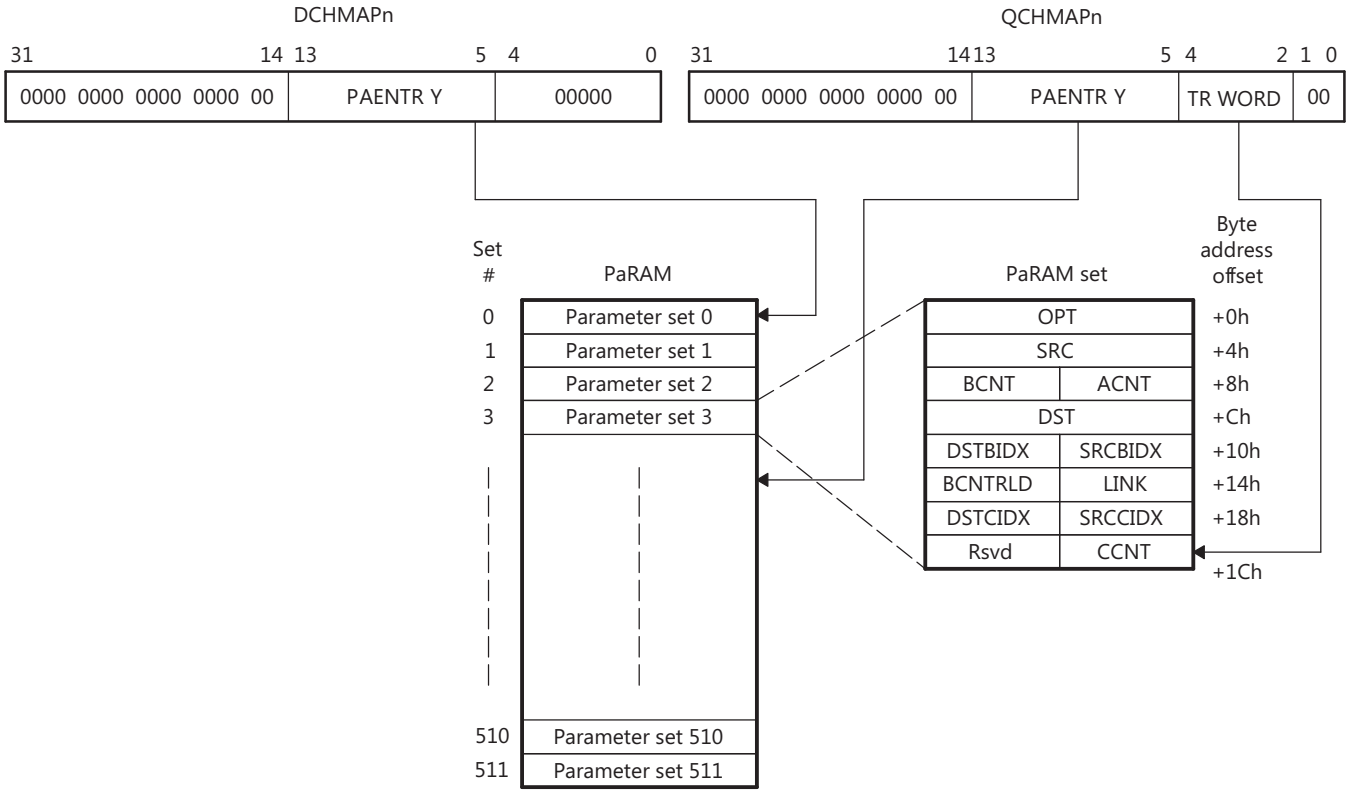
The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel *n* mapping register (QCHMAP *n*) in the EDMACC allows the user to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 10-14 illustrates the use of QCHMAP.

Additionally, QCHMAP allows the user to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the 8 words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMACC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel.

NOTE: By default, QDMA channels are mapped to PaRAM set 0. Care must be taken to appropriately remap PaRAM set 0 before it is used.

QDMA channel to PaRAM mapping is shown in Figure 10-14.

Figure 10-14. DMA/QDMA Channel to PaRAM Mapping



10.3.9 EDMA Channel Controller Regions

The EDMA channel controller (EDMACC) divides its address space into 8 regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

The user can design the application software to use regions or to ignore them altogether. The user can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in Section 10.3.12.

10.3.9.1 Region Overview

The EDMACC memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMACC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

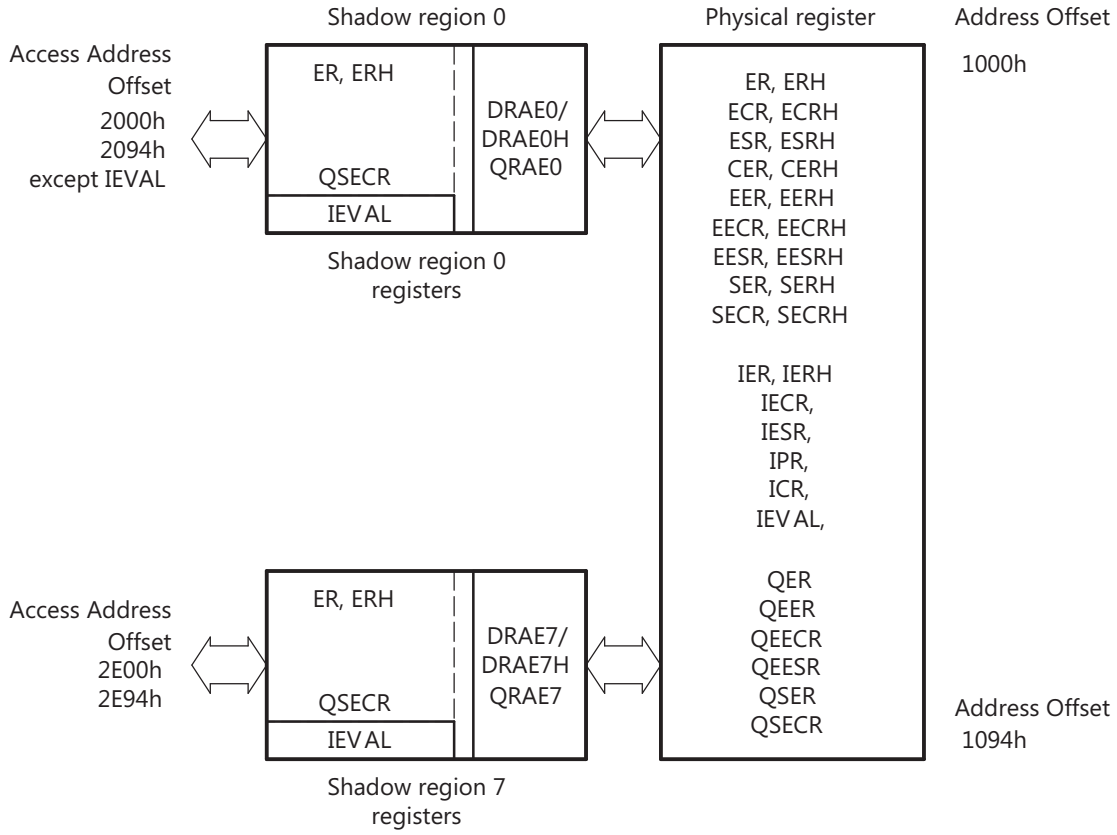
The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register (EDMACC_EER) is visible in the global region register space at offset 1020h, or region addresses at offset 2020h for region 0, 2220h for region 1, ... offset 2E20h for region 7.

Figure 10-15 illustrates the conceptual view of the regions.

Table 10-15. Shadow Region Registers

DRAE *m*	DRAEH *m*	QRAE *n*
EDMACC_ER	EDMACC_ERH	EDMACC_QER
EDMACC_ECR	EDMACC_ECRH	EDMACC_QEER
EDMACC_ESR	EDMACC_ESRH	EDMACC_QEECR
EDMACC_CER	EDMACC_CERH	EDMACC_QEESR
EDMACC_EER	EDMACC_EERH	
EDMACC_EECR	EDMACC_EECRH	
EDMACC_EESR	EDMACC_EESRH	
EDMACC_SER	EDMACC_SERH	
EDMACC_SECR	EDMACC_SECRH	
EDMACC_IER	EDMACC_IERH	
EDMACC_IECR	EDMACC_IECRH	
EDMACC_IESR	EDMACC_IESRH	
EDMACC_IPR	EDMACC_IPRH	
EDMACC_ICR	EDMACC_ICRH	
Register not affected by DRAE/DRAEH		
EDMACC_IEVAL		

Figure 10-15. Shadow Region Registers



10.3.9.2 Channel Controller Shadow Regions

For each EDMA shadow region (and associated memory-maps) there is a set of registers associated with the shadow region that allows association of the DMA/QDMA channels and interrupt completion codes to the region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels and TCC values to a region.

- DRAE*m* and DRAEH*m*: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels. These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA event registers and interrupt registers via the shadow region address map are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- QRAE*n*: One register exists for every region. The number of bits in each register matches the number of QDMA channels. These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMACC_QEER, the respective bit in QRAE must be set or writing into EDMACC_QEESR will not have the desired effect.
- MPPA*n* and EDMACC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of DMA/QDMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/QRAE registers. If exclusive access to any given channel/TCC code is required for a region, then only that region's DRAE/QRAE should have the associated bit set.

Example 10-1 illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 3 QDMA channels (1-3) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes.

Example 10-1. Resource Pool Division Across Two Regions

```
Region 0:

DRAEH, DRAE = FFFF 0000h, 0000 FFFFh
QRAE = 000 0001h

Region 1:

DRAEH, DRAE = 0000 FFFFh, FFFF 0000h
QRAE = 000 000Eh
```

10.3.9.3 Region Interrupts

In addition to the EDMACC global completion interrupt (EDMACC_*m*_GINT, where *m* denotes the EDMACC instance number), there is an additional completion interrupt (EDMACC_*m*_REGION_*n*_INT, where *n* denotes the shadow region number) that is associated with every shadow region. The DRAE associated with each shadow region acts as a secondary interrupt enable along with the interrupt enable register (EDMACC_IER) for the respective shadow region interrupts. See Section 10.3.11 for more information on EDMA interrupts.

10.3.10 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the user the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 10.3.5.7). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see Section 10.3.6.1.3 for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* needs to be programmed into the TCC bit of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the *last* transfer request of channel *m* is either submitted (early completion) or completed (normal completion).
- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every *intermediate* transfer request of channel *m* is either submitted (early completion) or completed (normal completion).
- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after *every* transfer request of channel *m* is either submitted (early completion) or completed (normal completion).

Table 10-16 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 10-16. Chain Event Triggers

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
TCCHEN = 1, ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
TCCHEN = 0, ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
TCCHEN = 1, ITCCHEN = 1	20 (Owing to a total of 60 TRs)	5 (Owing to a total of 5 TRs)

10.3.11 EDMA Interrupts

The EDMA interrupts are divided into 2 categories:

- Transfer completion interrupts
- Error interrupts

The transfer completion interrupts are listed in Table 10-17. The error interrupts are listed in Table 10-18.

Table 10-17. EDMA Transfer Completion Interrupts

Name	Description
EDMACC_*m*_GINT	EDMACC Global Transfer Completion Interrupt
EDMACC_*m*_REGION_0_INT	EDMACC Transfer Completion Interrupt Shadow Region 0
EDMACC_*m*_REGION_1_INT	EDMACC Transfer Completion Interrupt Shadow Region 1
EDMACC_*m*_REGION_2_INT	EDMACC Transfer Completion Interrupt Shadow Region 2
EDMACC_*m*_REGION_3_INT	EDMACC Transfer Completion Interrupt Shadow Region 3
EDMACC_*m*_REGION_4_INT	EDMACC Transfer Completion Interrupt Shadow Region 4
EDMACC_*m*_REGION_5_INT	EDMACC Transfer Completion Interrupt Shadow Region 5
EDMACC_*m*_REGION_6_INT	EDMACC Transfer Completion Interrupt Shadow Region 6
EDMACC_*m*_REGION_7_INT	EDMACC Transfer Completion Interrupt Shadow Region 7
EDMACC_*m*_TC_AET_INT	EDMACC Advanced Event Triggering (AET) Event

Table 10-18. EDMA Error Interrupts

Name	Description
EDMACC_*m*_ERRINT	EDMACC Error Interrupt
EDMACC_*m*_MPINT	EDMACC Memory Protection Interrupt
EDMACC_*m*_TC_*n*_ERRINT	EDMATC Error Interrupt

10.3.11.1 Transfer Completion Interrupts

The EDMACC is responsible for generating transfer completion interrupts to the CPU. The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all DMA/QDMA channels. The various control registers and bit fields facilitate EDMA interrupt generation.

For a given DMA/QDMA channel, the software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (EDMACC_IPR/EDMACC_IPRH). For example, if TCC = 10 0001b, EDMACC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 10.3.11.1.1 for details on enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completion), the corresponding bit in EDMACC_IPR/EDMACC_IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

The transfer completion code (TCC) can be programmed to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

NOTE: The TCC field in the channel options parameter (OPT) is a 6-bit field and can be programmed for any value between 0-64. For devices with 16/32 DMA channels, the TCC should have a value between 0 to 15/31 so that it sets the appropriate bits (0 to 15/31) in EDMACC_IPR (and can interrupt the CPU(s) on enabling the EDMACC_IER register bits (0-15/31)).

If the channel is used in the context of a shadow region and the user intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMACC_IER/EDMACC_IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

The user can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCINTEN = 1 in OPT) is enabled, the interrupt occurs after the *last* transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCINTEN = 1 in OPT) is enabled, the interrupt occurs after every *intermediate* transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCINTEN = 1, and ITCINTEN = 1 in OPT) are enabled, then the interrupt occurs after *every* transfer request of channel *m* is submitted or completed (depending on early or normal completion).

Table 10-19 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 10-19. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
TCINTEN = 1, ITCINTEN = 0	1 (Last TR)	1 (Last TR)
TCINTEN = 0, ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
TCINTEN = 1, ITCINTEN = 1	20 (All TRs)	5 (All TRs)

10.3.11.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external world, the interrupts must be enabled in the EDMACC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

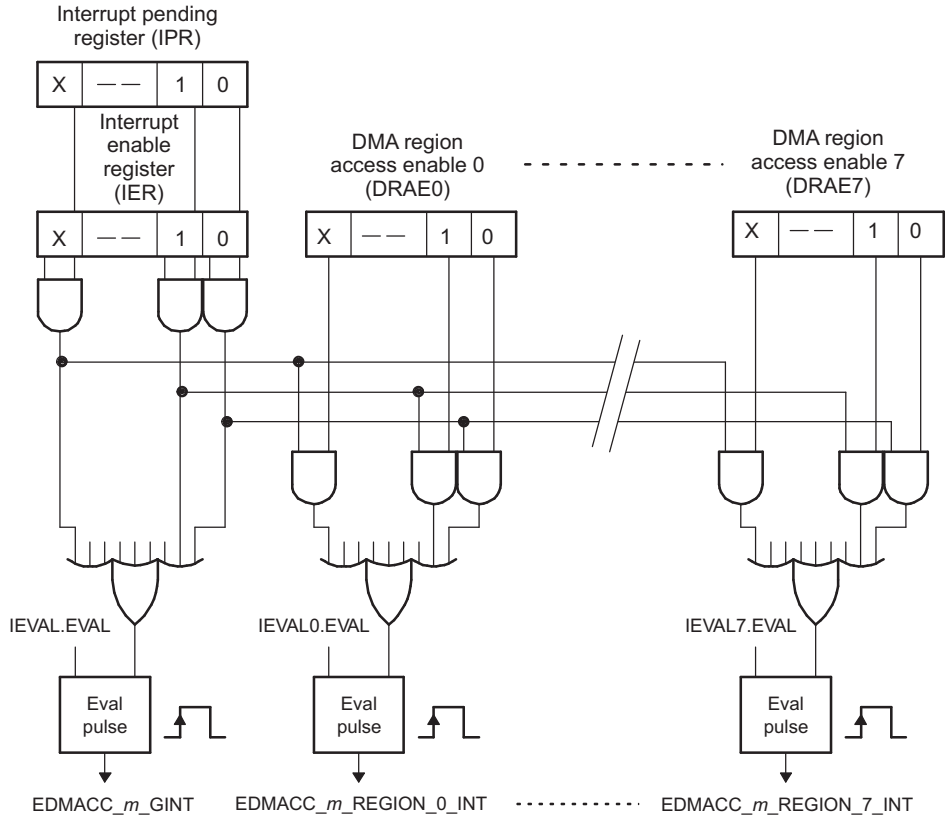
The EDMA channel controller has interrupt enable registers (EDMACC_IER/EDMACC_IERH) and each bit location in EDMACC_IER/EDMACC_IERH serves as a primary enable for the corresponding interrupt pending registers (EDMACC_IPR/EDMACC_IPRH).

All the interrupt registers (EDMACC_IER, EDMACC_IESR, EDMACC_IECR, and EDMACC_IPR) are either manipulated from the global DMA channel region, or by way of the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (EDMACC_IPR/EDMACC_IPRH) and single set of interrupt enable registers (EDMACC_IER/EDMACC_IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMACC_IER.

The region interrupt outputs are gated by EDMACC_IER and the specific DRAE/DRAEH associated with the region. See Figure 10-16.

Figure 10-16. Interrupt Diagram



For the EDMACC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMACC_m_REGION_0_INT: (EDMACC_IPR.E0 & EDMACC_IER.E0 & EDMACC_DRAE0.E0) | (EDMACC_IPR.E1 & EDMACC_IER.E1 & EDMACC_DRAE0.E1) | …|(EDMACC_IPR[H].E *n* & EDMACC_IER[H].E *n* & DRAE[H]0.E *n*)
- EDMACC_m_REGION_1_INT: (EDMACC_IPR.E0 & EDMACC_IER.E0 & EDMACC_DRAE1.E0) | (EDMACC_IPR.E1 & EDMACC_IER.E1 & EDMACC_DRAE1.E1) | …| (EDMACC_IPR[H].E *n* & EDMACC_IER[H].E *n* & DRAE[H]1.E *n*)
- EDMACC_m_REGION_2_INT: (EDMACC_IPR.E0 & EDMACC_IER.E0 & EDMACC_DRAE2.E0) | (EDMACC_IPR.E1 & EDMACC_IER.E1 & EDMACC_DRAE2.E1) | …|(EDMACC_IPR[H].E *n* & EDMACC_IER[H].E *n* & DRAE[H]2.E *n*)...
- Up to EDMACC_m_REGION_7_INT: (EDMACC_IPR.E0 & EDMACC_IER.E0 & EDMACC_DRAE7.E0) | (EDMACC_IPR.E1 & EDMACC_IER.E1 & EDMACC_DRAE7.E1) | …|(EDMACC_IPR[H].E *n* & EDMACC_IER[H].E *n* & DRAE[H]7.E *n*)

NOTE: The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.
Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, EDMACC_IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, the user must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMACC_IPRH bit that is set upon completion).

10.3.11.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMACC_IPR/EDMACC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMACC_ICR/EDMACC_ICRH). For example, a write of 1 to EDMACC_ICR.E0 clears a pending interrupt in EDMACC_IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in EDMACC_IPR/EDMACC_IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMACC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

10.3.11.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMACC_IPR/EDMACC_IPRH) as specified by the transfer completion codes. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMACC_IPR/EDMACC_IPRH, thereby enabling recognition of future interrupts. The EDMACC will only assert additional completion interrupts when all EDMACC_IPR/EDMACC_IPRH bits are cleared.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMACC_IPR/EDMACC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMACC_IPR/EDMACC_IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMACC completion interrupt are shown in Section 10.3.11.2.1 and Section 10.3.11.2.2.

The ISR routine in Section 10.3.11.2.1 is more exhaustive and incurs a higher latency.

10.3.11.2.1 Interrupt Servicing Example 1

Step 1. Read the interrupt pending register (EDMACC_IPR/EDMACC_IPRH).

Step 2. Perform the operations needed.

Step 3. Writes to the interrupt pending clear register (EDMACC_ICR/EDMACC_ICRH) to clear the corresponding EDMACC_IPR/EDMACC_IPRH bit(s).

Step 4. Reads EDMACC_IPR/EDMACC_IPRH again:

a. If EDMACC_IPR/EDMACC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

b. If EDMACC_IPR/EDMACC_IPRH is equal to 0, this should assure the user that all enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the EDMACC_IPR/EDMACC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt is generated as soon as the application exits the interrupt service routine.

Section 10.3.11.2.2 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

If it is desired to leave any enabled and pending (possibly lower priority) interrupts, it is required to force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (EDMACC_IEVAL).

10.3.11.2.2 Interrupt Servicing Example 2

Step 1. Enter ISR.

Step 2. Read EDMACC_IPR/EDMACC_IPRH.

Step 3. For the condition set in EDMACC_IPR/EDMACC_IPRH that the user desires to service, do the following:

a. Service interrupt as required by the application.

b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMACC after step 2).

Step 4. Read EDMACC_IPR/EDMACC_IPRH prior to exiting the ISR:

a. If EDMACC_IPR/EDMACC_IPRH is equal to 0, then exit the ISR.

b. If EDMACC_IPR/EDMACC_IPRH is not equal to 0, then set EDMACC_IEVAL so that upon exit of ISR, a new interrupt is triggered if any enabled interrupts are still pending.

NOTE: The EVAL bit must not be set when EDMACC_IPR/EDMACC_IPRH is read to be 0, to avoid generation of extra interrupt pulses.

10.3.11.3 Interrupt Evaluation Operations

The EDMACC has interrupt evaluate registers (EDMACC_IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMACC_IER/EDMACC_IERH) is still pending (EDMACC_IPR/EDMACC_IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. See Section 10.3.11.2.2 for the use of EDMACC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register (EDMACC_EEVAL) exists in the global region. Writing 1 to the EVAL bit in EDMACC_EEVAL causes the pulsing of the error interrupt if any pending errors are in EDMACC_EMR/EDMACC_EMRH, EDMACC_QEMR, or EDMACC_CCERR. See Section 10.3.11.4 for additional information regarding error interrupts.

NOTE: While using EDMACC_IEVAL for shadow region completion interrupts, the user should make sure that the EVAL operated upon is from that particular shadow region memory map.

10.3.11.4 Error Interrupts

The EDMACC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMACC error interrupt. If the EDMACC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMACC has a single error interrupt (EDMA_CC_*m*_ERRINT) that is asserted for all EDMACC error conditions. There are four conditions that cause the error interrupt to be pulsed:

- DMA missed events: for all DMA channels. DMA missed events are latched in the event missed registers (EDMACC_EMR/EDMACC_EMRH).
- QDMA missed events: for all QDMA channels. QDMA missed events are latched in the QDMA event missed register (EDMACC_QEMR).
- Threshold exceed: for all event queues. These are latched in EDMACC error register (EDMACC_CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of *n*-1, where *n* is the number of DMA channels supported by the EDMACC. This is also latched in the EDMACC error register (EDMACC_CCERR).

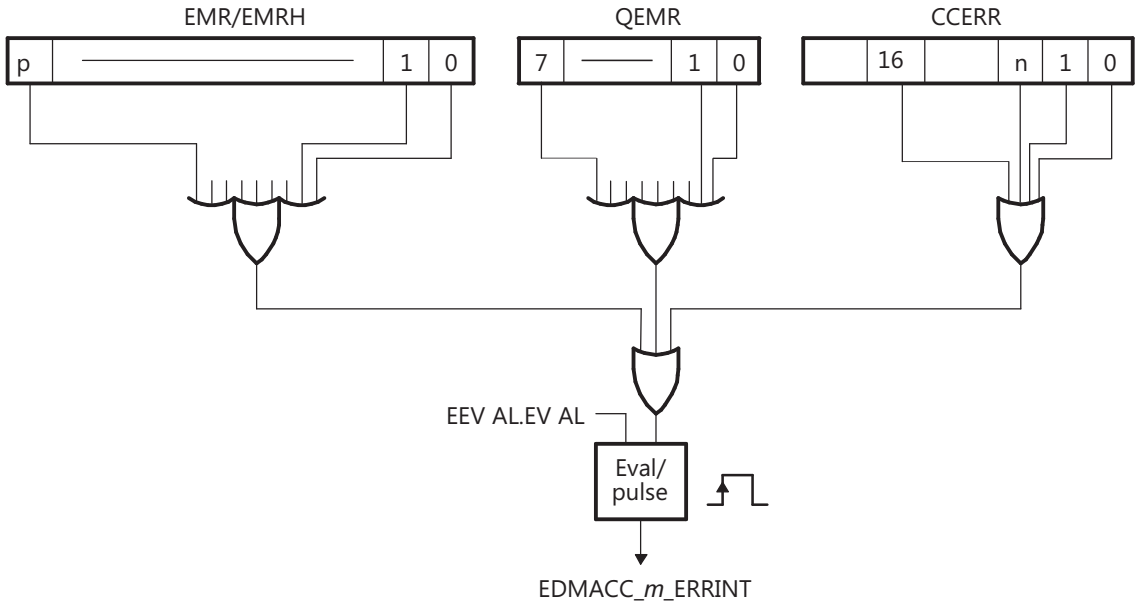
Figure 10-17 illustrates the EDMACC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_CC *m*_ERRINT is always asserted, as there are no enables for masking these error events. Similar to the transfer completion interrupts, the error interrupt also is pulsed only when the error interrupt condition transitions from a state where no errors are set to a state where at least one error bit is set. If additional error events are latched prior to the original error bits being cleared, the EDMACC does not generate additional interrupt pulses.

To reduce the burden on the software, similar to the interrupt evaluate register (EDMACC_IEVAL), there is an error evaluate register (EDMACC_EEVAL) that allows re-evaluation of pending set error events/bits. This can be used so that the CPU(s) does not miss any error events.

NOTE: It is a good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status). Additionally, it provides a good debug mechanism for unexpected error conditions.

Figure 10-17. Error Interrupt Operation



10.3.12 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

10.3.12.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA programmer) to the EDMACC registers (based on user-programmed permission characteristics). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMACC register map is divided into three categories:

- A global region
- A global channel region
- 8 shadow regions

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, see Table 10-15.

Each of the eight shadow regions has an associated MPPA register (MPPA *n*) that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (EDMACC_MPPAG). The EDMACC_MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, see Table 10-21.

See for the bit field descriptions of MPPA *n*. The MPPA *n* have a certain set of access rules.

Table 10-20 shows the accesses that are allowed or not allowed to the EDMACC_MPPAG and MPPA *n*.

Table 10-20. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 10-21 describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

Table 10-21. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect	Address Range for 512 PaRAM sets
EDMACC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMACC_MPPA0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPA1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPA2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPA3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPA4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPA5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPA6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
EDMACC_MPPA7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

Section 10.3.12.1.1 is an example of access denied to an EDMACC register. Write access to shadow region 7's event enable set register (EDMACC_EESR).

10.3.12.1.1 Access Denied to an EDMACC Register

Step 1. The original value of the event enable register (EDMACC_EER) at address offset 1020h is 0.

Step 2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).

Step 3. The C66x DSP, which has a privilege ID of 0, attempts to perform a user-level write access of a value of FF00 FF00h to shadow region 7's event enable set register (EDMACC_EESR) at address offset 2E30h. Note that the EDMACC_EER is a read-only register and the only way that the user can write to it is by writing to the EDMACC_EESR. Also remember that there is only one physical register for EDMACC_EER, EDMACC_EESR, etc. and that the shadow regions only provide to the same physical set.

Step 4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMACC_EER is not written to.

Table 10-22 illustrates the example above.

Table 10-22. Example Access Denied

Register (Address Offset)	Value	Description
EDMACC_EER (1020h)	0000 0000h	Initial value in EDMACC_EER.
EDMACC_EESR (2E30h)	FF00 FF00h	Value attempted to be written to shadow region 7's EDMACC_EESR. This is done by an EDMA programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (082Ch)	0000 04B0h	Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1.
	X	Access Denied
EDMACC_EER (1020h)	0000 0000h	Final value of EDMACC_EER

Section 10.3.12.1.2 is an example of access allowed to an EDMACC register.

10.3.12.1.2 Write access to shadow region 7's event enable set register (EDMACC_EESR)

Step 1. The original value of the event enable register (EDMACC_EER) at address offset 1020h is 0

Step 2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1)

Step 3. The C66x DSP, which has a privilege ID of 0, attempts to perform a user-level write of a value of ABCD 0123h to shadow region 7's event enable set register (EDMACC_EESR) at address offset 2E30h. Note that the EDMACC_EER is a read-only register and the only way that the user can write to it is by writing to the EDMACC_EESR. Also remember that there is only one physical register for EDMACC_EER, EDMACC_EESR, etc. and that the shadow regions only provide to the same physical set.

Step 4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.

Step 5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 9F00 0F00h.

Step 6. The value finally written to EDMACC_EER is 9F00 0F00h.

Table 10-23 illustrates the example above.

Table 10-23. Example Access Allowed

Register (Address Offset)	Value	Description
EDMACC_EER (1020h)	0000 0000h	Initial value in EDMACC_EER.
EDMACC_EESR (2E30h)	FF00 FF00h	Value attempted to be written to shadow region 7's EDMACC_EESR. This is done by an EDMA programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (082Ch)	0000 04B3h	Memory Protection Filter AID0 = 1, UW = 1, UR = 1, SW = 1, SR = 1.
	3	Access allowed.
	↓	
DRAE[7] (0378h)	9FF0 0FC2h	DMA Region Access Enable Filter
	↓	
EDMACC_EESR (2E30h)	9F00 0F00h	Value written to shadow region 7's EDMACC_EESR. This is done by an EDMA programmer with a privilege level of User and a Privilege ID of 0.
	↓	
EDMACC_EER (1020h)	↓	Final value of EDMACC_EER.
	9F00 0F00h	

10.3.12.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given EDMA programmer to have its permissions travel with the transfer through the EDMATC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (that is, user versus supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA programmer.

See the device Data Manual for the PRIVIDs that are associated with potential EDMA programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

For example, consider a parameter set that is programmed by a DSP in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an external memory page. The PRIV is 0 for user-level and the DSP has a PRIVID of 0.

The PaRAM set is shown in Figure 10-22.

Figure 10-18. PaRAM Set Content for Proxied Memory Protection Example

(a) EDMA Parameters

Parameter Contents	Parameter
0010 0007h	Channel Options Parameter (OPT)
1080 0000h	Channel Source Address (SRC)
0001h | 0004h	Count for 2nd Dimension (BCNT) | Count for 1st Dimension (ACNT)
8000 0000h	Channel Destination Address (DST)
0001h | 0001h	Destination BCNT Index (DSTBIDX) | Source BCNT Index (SRCBIDX)
0000h | FFFFh	BCNT Reload (BCNTRLD) | Link Address (LINK)
0001h | 1000h	Destination CCNT Index (DSTCIDX) | Source CCNT Index (SRCCIDX)
0000h | 0001h	Reserved | Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

31	30 28	27 24	23	22	21	20	19 18	17 16
0	000	0000	0	0	0	1	00	00
PRIV	Reserved	PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved	TCC

15 12	11	10 8	7 4	3	2	1	0
0000	0	000	0000	0	1	1	1
TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM

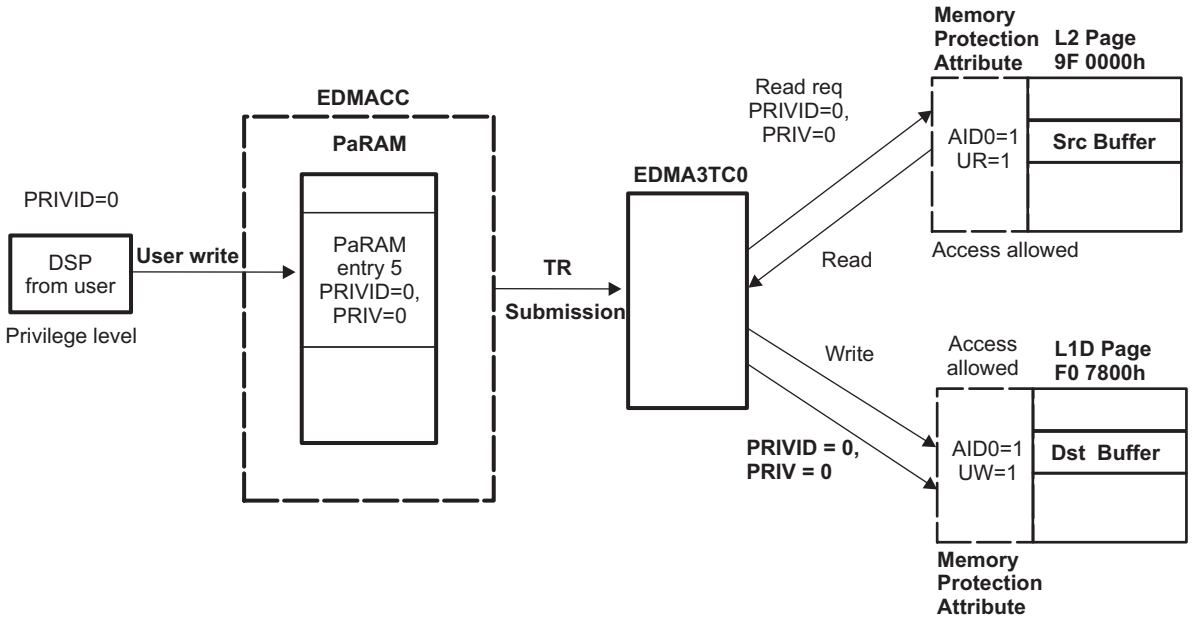
The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR, SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses with a PRIVID 0. For more information regarding how to set memory protection attributes for pages of memory in L2/L1D, see the TMS320C66x DSP CorePac User Guide (SPRUGW0).

Because the programmers privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 10-19 illustrates the propagation of PRIV and PRIVID at the boundaries (DSP, EDMACC, EDMATC, and slave memories).

Figure 10-19. Proxied Memory Protection Example



10.3.13 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMACC and the transfer request (TR) submission logic of the EDMACC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Q0, and Q1. By default, there is a one-to-one mapping between the queues and transfer controllers. Therefore, the transfer requests (TRs) associated with events in Q0 get submitted to EDMATC0. Similarly, transfer requests associated with events in Q1 get submitted to EDMATC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

A lower numbered queue has a higher de-queuing priority than a higher numbered queue. For example, Q0 has higher priority than Q1, if Q0 and Q1 both have at least one event entry and if both EDMATC0 and EDMATC1 can accept transfer requests, then the event in Q0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See Section 10.3.13.4 for system-level performance considerations. All the event entries in all the event queues are software readable (not writable) by accessing the event queue entry registers (Q *x*E *y*). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. See for a description of the bit fields in the queue event entry registers.

10.3.13.1 DMA/QDMA Channel to Event Queue Mapping

Each DMA channel and QDMA channel is independently programmed to map to a specific queue using the DMA queue number register (DMAQNUM *n*) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly in meeting real-time deadlines. See Section 10.3.13.4.

NOTE: If an event is ready to be queued and both the event queue and the EDMA transfer controller associated to the event queue are empty, then the event bypasses the event queue, and goes to the PaRAM processing logic and eventually to the transfer request submission logic for submission to the EDMATC. In this case, the event is not logged in the event queue status registers.

10.3.13.2 Queue RAM Debug Visibility

Each event queue has 16 entries. These 16 entries are managed in a circular FIFO manner. All event queue entries for all event queues are software readable by the event queue entry register (Q *x*E *y*). Additionally, for each queue there is a queue status register (QSTAT *n*).

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources.

Each of the 16 entries in the event queue are read using the EDMACC memory-mapped register. By reading the event queue, the user can see the history of the last 16 TRs that have been processed by the EDMA controller on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The event queue entry register (Q *x*E *y*) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for DMA/QDMA channels) that are in the queue or have been de-queued (passed through the queue).

The queue status register (QSTAT *n*) includes fields for the start pointer (STRTPTR) that provides the offset to the head entry of an event. It also includes a NUMVAL field that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR field may be used to index appropriately into the 16 event entries. The NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entries may be read to determine which events have already been de-queued and submitted to the associated transfer controller.

10.3.13.3 Queue Resource Tracking

The EDMACC event queue includes watermarking/threshold logic that allows the user to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The user can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (EDMACC_QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT *n*) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT *n* and the maximum number of entries (WM bit in QSTAT *n*).

If the queue usage is exceeded, this status is visible in the EDMACC registers: the QTHRXCD *n* bit in the channel controller error register (EDMACC_CCERR) and the THRXCD bit in QSTAT *n*, where *n* stands for the event queue number. Any bits that are set in EDMACC_CCERR also generate an EDMACC error interrupt.

10.3.13.4 Performance Considerations

The main TeraNet switch fabric arbitrates bus requests from all of the masters (like DSP core, Arm Cortex-A15, etc.) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the system crossbar are programmed using the queue priority register (EDMACC_QUEPRI). EDMACC_QUEPRI programs the priority of the event queues (or indirectly, TC *n*, because Q *n* transfer requests are submitted to TC *n*).

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMATC (dictated by the priority set using EDMACC_QUEPRI).

10.3.14 EDMA Transfer Controller Operation

The EDMA channel controller (EDMACC) is the user-interface of the EDMA module and the EDMA transfer controller (EDMATC) is the data movement engine of the EDMA module. The EDMACC submits transfer requests (TR) to the EDMATC and the EDMATC performs the data transfers dictated by the TR; thus, the EDMATC is a slave to the EDMACC.

10.3.14.1 Architecture Details

10.3.14.1.1 EDMATC Configuration

The parameters that determine the EDMATC configuration are:

- FIFOSIZE: Determines the size in bytes for the Data FIFO that is the temporary buffer for the in-flight data. The data FIFO is where the read return data read by the EDMATC read controller from the source endpoint is stored and subsequently written out to the destination endpoint by the EDMATC write controller.
- BUSBYTE: The width of the read and write data buses (in bytes) for the EDMATC read and write controller, respectively.
- Default Burst Size (DBS): The DBS is the maximum number of bytes per read/write command issued by a transfer controller.
- DSTREGDEPTH: This determines the number of Destination FIFO register set. The number of Destination FIFO register set for a transfer controller, determines the maximum number of outstanding transfer requests (TR pipelining).

All the above four parameters are fixed in design for the device (see section Section 10.1.3).

10.3.14.1.2 Command Fragmentation

The EDMATC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is tied-off to be 64 bytes for each EDMATC instance present on this device.

The EDMATC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMATC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS tie-off value.
- The first command of a 1D transfer is always issued so that subsequent commands align to the DBS tie-off value.

Example 10-2 shows the command fragmentation for a DBS of 64 bytes. In summary, if the ACNT value is larger than the DBS value, then the EDMATC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMATC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2. Table 10-24 summarizes conditions in which the optimizations are performed.

Example 10-2. Command Fragmentation (DBS = 64)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1. Cmd0 = 64 byte
   Write Controller: Because DSTBIDX != ACNT, it is not optimized.
   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT=128, BCNT = 1,SRCADDR = 63, DSTADDR = 513

   Read Controller: Read address is not aligned.
   Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command) Cmd1 = 64 bytes Cmd2 = 63 bytes
   Write Controller: The write address is also not aligned.
   Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command) Cmd1 = 64 bytes Cmd2 = 1 byte

Table 10-24. Read/Write Command Optimization Rules

ACNT DBS	ACNT is power of 2	BIDX = ACNT	BCNT 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

10.3.14.1.3 TR Pipelining and Data Ordering

The transfer controller(s) can issue back-to-back transfer requests (TR). The number of outstanding TRs for a EDMATC is limited by the number of destination FIFO register entries that is controlled by the DSTREGDEPTH parameter (fixed in design to a value of 4 entries for this device). TR pipelining refers to the ability of the EDMATC read controller to issue read commands for a subsequent TR, while the EDMATC write controller is still performing writes for the previous TR. Consider the case of 2 TRs (TR0 followed by TR1), because of TR pipelining, the EDMATC read controller can start issuing the read commands for TR1 as soon as the last read command for TR0 has been issued, meanwhile the write commands and write data for TR0 are tracked by the destination FIFO registers. In summary, the EDMATC read controller is able to process 4 TRs ahead of the write controller.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

It should be noted that back-to-back TRs are targeted to different end points even though the read return data for the two TRs might get returned out of order (that is, read data for TR1 might come in before read data for TR0), the transfer controller issues the write commands in order (that is, write commands for TR0 will be issued before write commands for TR1).

10.3.14.1.4 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMATC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMATC is controlled by the EDMATC_RDRATE register. The EDMATC_RDRATE register defines the number of cycles that the EDMATC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMATC consuming all available slave resources. The EDMATC_RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

10.3.14.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMATC and used by the EDMATC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

10.3.14.3 Error Generation

Similar to the channel controller, the transfer controllers are capable of detecting and reporting several error conditions. The EDMATC errors are generated, under three main conditions:

- BUSERR: The EDMATC read or write controllers detect an error signaled by the source or destination address. The additional details on the type of error is also recorded in the EDMATC_ERRDET register, which indicates whether it is a read error (source address errors) or write error (destination address error).
- MMRAERR: Attempt to read or write to an invalid/reserved addresses in the EDMACC/EDMATC memory map.
- TRERR: A transfer request packet is detected to be violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

The user can poll for the errors, as the status of the errors can be read from the EDMATC_ERRSTAT registers. Additionally, if the error bits are enabled in the EDMATC_ERREN register, a bit set in the EDMATC_ERRSTAT will cause the error condition to interrupt the CPU(s). The user can decide to enable/disable either or all error types.

10.3.14.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMATC status register (EDMATC_TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and the user must realize that there is a chance that the values read from the EDMATC status registers will be inconsistent since the EDMATC may change the values of these registers due to ongoing activities.

It is recommended that the user ensures no additional submission of TRs to the EDMATC in order to facilitate ease of debug.

10.3.14.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of 4 entries. The EDMATC maintains two important status details in EDMATC_TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

10.3.15 Event Dataflow

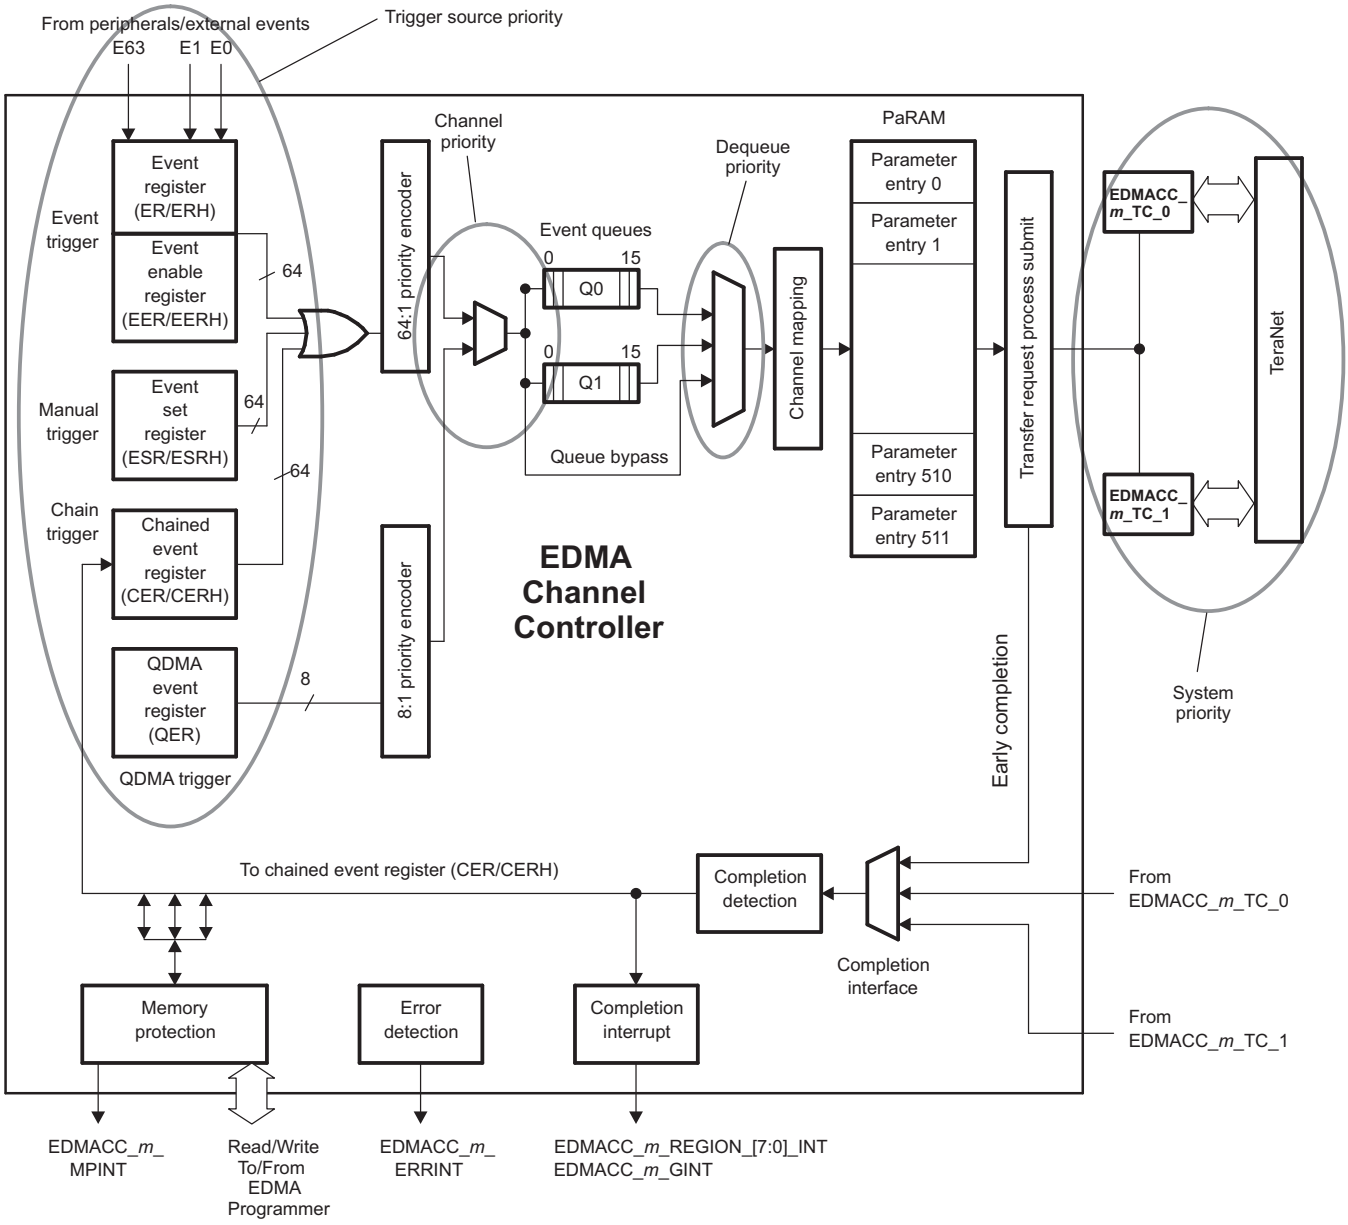
This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMACC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMACC_ER.E *n*/EDMACC_ERH.E *n* (or EDMACC_CER.E *n*/EDMACC_CERH.E *n*, EDMACC_ESR.E *n* /EDMACC_ESRH.E *n*, EDMACC_QER.E *n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the EDMACC_SER.E *n*/EDMACC_SERH.E *n* (or EDMACC_QSER.E *n*) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMACC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMACC clears the EDMACC_ER.E *n*/EDMACC_ERH.E *n* (or EDMACC_CER.E *n*/EDMACC_CERH.E *n*, EDMACC_ESR.E *n*/EDMACC_ESRH.E *n*, EDMACC_QER.E *n*) bit and the EDMACC_SER.E *n*/EDMACC_SERH.E *n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMACC_SER.E *n*/EDMACC_SERH.E *n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMACC immediately sets the interrupt pending register (EDMACC_IPR.I[TCC]/EDMACC_IPRH.I[TCC]-32).
5. If the TR was programmed for normal completion, the EDMACC sets the interrupt pending register (EDMACC_IPR.I[TCC]/EDMACC_IPRH.I[TCC]) when the EDMATC informs the EDMACC about completion of the transfer (returns transfer completion codes).
6. The EDMACC programs the associated EDMATC *n*'s Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the Dst FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMATC *n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMATC *n* then signals completion status to the EDMACC.

10.3.16 EDMA Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 10-20 shows the different places EDMA priorities come into play.

Figure 10-20. EDMA Prioritization



NOTE: 'm' indicates the EDMACC instance number.

10.3.16.1 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMACC_ER.E *n* = 1, EDMACC_ESR.E *n* = 1, EDMACC_CER.E *n* = 1), then the EDMACC always services these events in the following priority order: event trigger (via EDMACC_ER) is higher priority than chain trigger (via EDMACC_CER) and chain trigger is higher priority than manual trigger (via EDMACC_ESR).

This implies that if for channel 0, both EDMACC_ER.E0 = 1 and EDMACC_CER.E0 = 1 at the same time, then the EDMACC_ER.E0 event is always queued before the EDMACC_CER.E0 event.

10.3.16.2 Channel Priority

The DMA event registers (EDMACC_ER and EDMACC_ERH) captures all external/peripheral events connected to the EDMACC; likewise, the QDMA event register (EDMACC_QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

10.3.16.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM *n* and EDMACC_QDMAQNUM). For submission of a TR to the transfer controller, events need to be dequeued from the event queues. The lower numbered queue (Q0) has a higher dequeuing priority then the higher numbered queue (Q1). For example, if there are events in Q0 and Q1 and the respective transfer controllers (EDMATC0 and EDMATC1) are ready to receive the next TR from the EDMACC, then the transfer requests associated with events in Q0 will get submitted to EDMATC0 prior to any transfer requests associated with events in Q1 getting submitted to EDMATC1.

NOTE: At any given time, if there are outstanding events in both queues, when the transfer controller associated with Q0 (higher priority) queue is busy processing earlier transfer requests and the transfer controller associated with the higher numbered (lower priority) queue is idle, then the event in Q1 (lower priority) queue will de-queue first.

10.3.16.4 System (Transfer Controller) Priority

Every transfer controller has a programmable system priority (programmed via EDMACC_QUEPRI) (Figure 10-20) that is implemented when multiple masters in the system are vying for the same endpoint. The priority of the associated transfer request (TR) is further mitigated by the system priority setting of the transfer controller. This priority comes into play at the TeraNet when several masters are submitting requests to the main TeraNet.

The default priority for all TCs is the same (0 or highest priority to other masters). If an application requires the EDMA to service both real-time (urgent) and non-real-time transfers, it is recommended that this priority be changed.

10.3.17 EDMA Reset Considerations

A hardware reset initializes all internal logic of the EDMA controller (EDMACC and EDMATC) and the EDMA configuration registers. Note that the PaRAM memory contents are undefined after device reset and the user should not rely on parameters to be reset to a known state. The PaRAM set must be initialized to a desired value before it is used.

10.3.18 EDMA Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a serial port interface (SPI) is halted during an emulation access, the SPI stops generating the receive (REVT) or transmit (XEVT) events to the EDMA. From SPI point of view, the EDMA is suspended but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

10.4 EDMA Transfer Examples

The EDMACC performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

10.4.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal DSP L2 SRAM. A data block of 256 words residing at address 8000 0000h (external memory) needs to be transferred to internal address 0080 0000h (DSP L2 SRAM), as shown in Figure 10-21. Figure 10-22 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in DSP L2 SRAM. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 10-22 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The user may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 10-21. Block Move Example

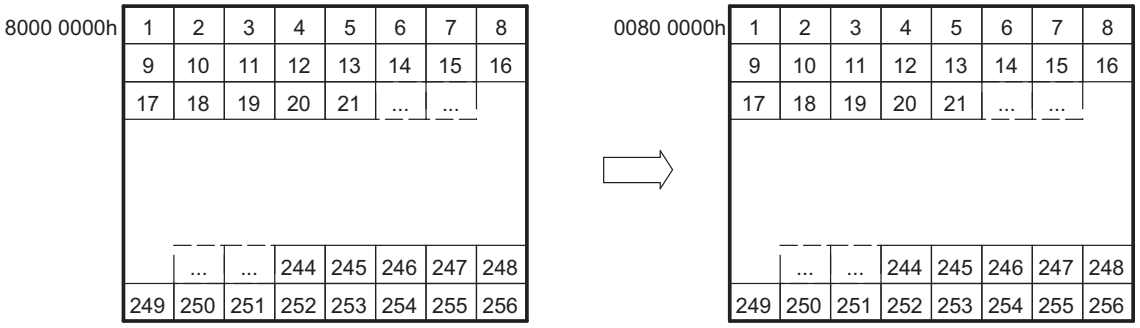


Figure 10-22. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents	Parameter
0010 0008h	Channel Options Parameter (OPT)
80000000h	Channel Source Address (SRC)
0001h | 0100h	Count for 2nd Dimension (BCNT) | Count for 1st Dimension (ACNT)
1080 0000h	Channel Destination Address (DST)
0000h | 0000h	Destination BCNT Index (DSTBIDX) | Source BCNT Index (SRCBIDX)
0000h | FFFFh	BCNT Reload (BCNTRLD) | Link Address (LINK)
0000h | 0000h	Destination CCNT Index (DSTCIDX) | Source CCNT Index (SRCCIDX)
0000h | 0001h	Reserved | Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

10.4.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the DSP to process. In this example, a 640×480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The DSP extracts a 16×12-pixel subframe of the image for processing. To facilitate more efficient processing time by the DSP, the EDMA places the subframe in internal L2 SRAM. Figure 10-23 shows the transfer of a subframe from external memory to L2. Figure 10-24 shows the parameters for this transfer.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 10-23. Subframe Extraction Example

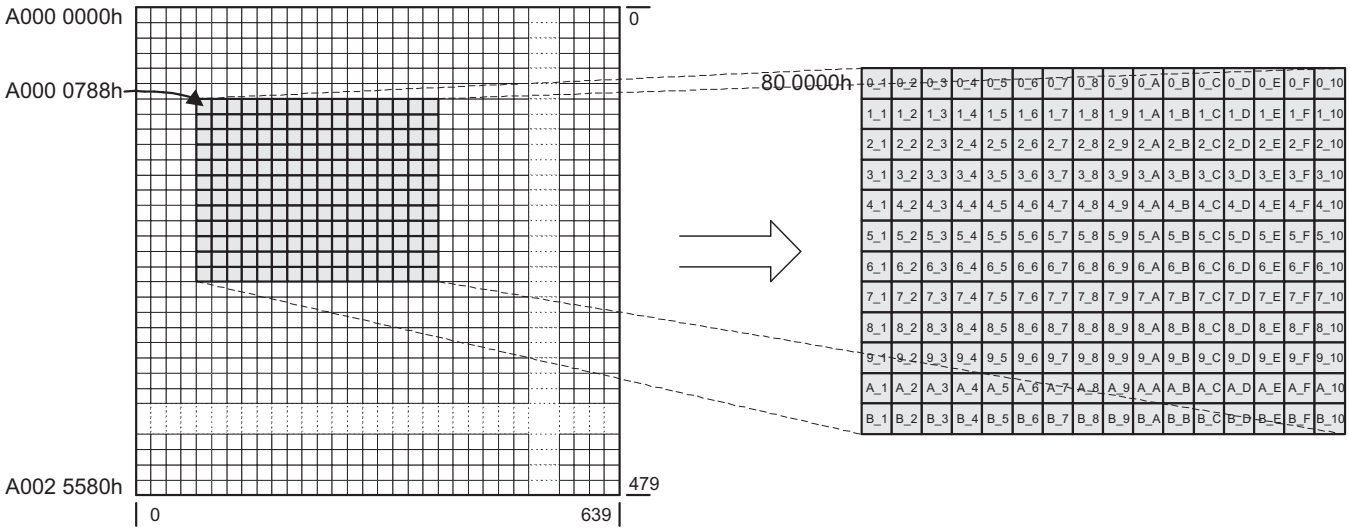

Figure 10-24. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

10.4.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on.

Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format. Figure 10-25 shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT – The user should program this to be the size in bytes of an element.
- BCNT – The user should program this to be the number of elements in a frame.
- CCNT – The user should program this to be the number of frames.
- SRCBIDX – The user should program this to be the size of the element or ACNT.
- DSTBIDX = CCNT × ACNT
- SRCCDX = ACNT × BCNT
- DSTCIDX = ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 10-26 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 10-25. Data Sorting Example

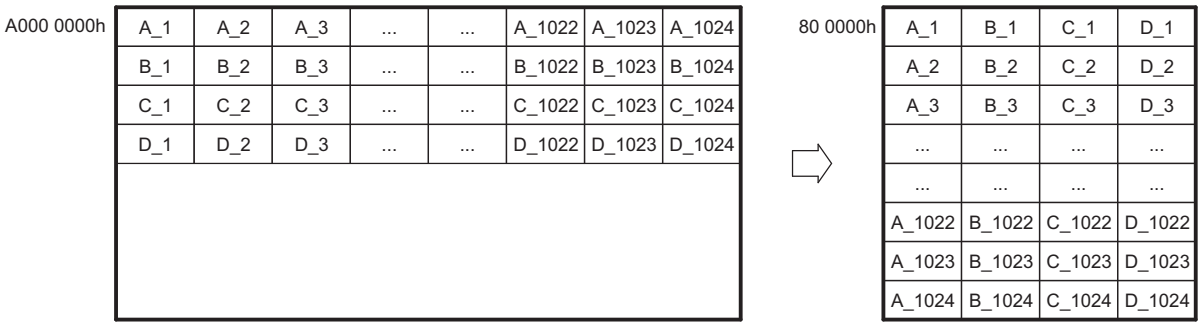

Figure 10-26. Data Sorting Example PaRAM Configuration

(a) EDMA Parameters

TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM

10.4.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of DSP operation, without requiring any DSP intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously.

The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EDMACC_EER). When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the DSP. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

10.4.4.1 Non-Bursting Peripherals

The non-bursting peripheral transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats. Figure 10-27 shows servicing incoming non-bursting peripheral data.

To transfer the incoming data stream to its proper location in L2 memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because a receive event (REVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 10-28 shows the parameters for this transfer. The source address of the EDMA channel is set to the data receive register address of the non-bursting peripheral, and the destination address is set to the start of the data block in L2. Because the address of data receive register is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 10-27. Servicing Incoming Non-Bursting Peripheral Data Example

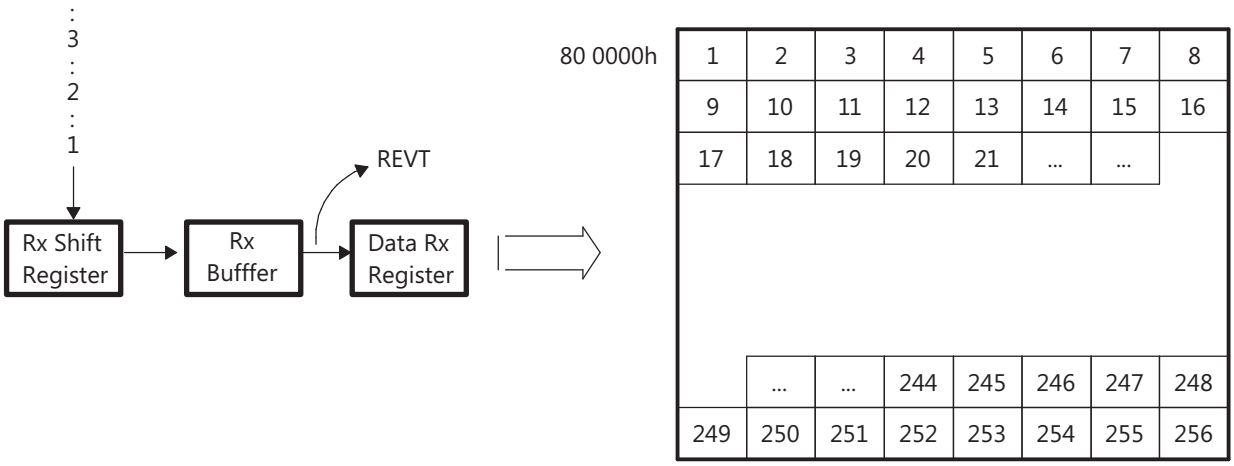

Figure 10-28. Servicing Incoming Non-Bursting Peripheral Data Example PaRAM Configuration

TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM

10.4.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the DSP for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the DSP.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640×480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. Figure 10-29 shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on EVTn, channel n must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 10-30 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment.

The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to 640×2.

Figure 10-29. Servicing Peripheral Burst Example

10.4.4.3 Continuous Operation

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the DSP. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, non-bursting peripheral is configured to transmit and receive data. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to L2 memory and from L2 memory to the serial port, as shown Figure 10-31.

The non-bursting peripheral generates REVT for every element received and generates XEVT for every element transmitted. To service the data streams, EDMA channels 12 and 13 must be set up for 1D-to-1D transfers with A-synchronization.

Figure 10-32 shows the parameter entries for the channel for these transfers. To service the non-bursting peripheral continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue. Figure 10-33 shows the reload parameters for the channel.

10.4.4.3.1 Receive Channel

EDMA channel 13 services the incoming data stream of non-bursting peripheral. The source address is set to that of the data receive register of the non-bursting peripheral, and the destination address is set to the first element of the data block.

Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 13 parameter set, the parameters located at the link address are loaded into the channel 13 parameter set and operation continues. This function continues throughout device operation until halted by the DSP.

10.4.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of non-bursting peripheral. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

10.4.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the DSP. Because the input and output buffers are continuously being filled/emptied, the DSP must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the DSP accesses it, and the DSP must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the DSP activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the DSP manipulates the data in the pong buffers. When both DSP and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 10-34 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 10-35 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 10-35). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 10-36). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 10-37). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

10.4.4.4.1 Synchronization with the DSP

To utilize the ping-pong buffering technique, the system must signal the DSP when to begin to access the new data set. After the DSP finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 13 fills an input buffer, the E13 bit in the interrupt pending register (EDMACC_IPR) is set; when channel 12 empties an output buffer, the E12 bit in EDMACC_IPR is set. The DSP must manually clear these bits. With the channel parameters set, the DSP polls EDMACC_IPR to determine when to switch. The EDMA and DSP could alternatively be configured such that the channel completion interrupts the DSP. By doing this, the DSP could service a background task while waiting for the EDMA to complete.

10.4.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

10.4.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signalled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 10-38 shows the EDMA setup and illustration for this example.

A GPIO event (in this example, mapped to EDMACC_0 input #48 via GPIOMUX48) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (EDMACC_CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining – not intermediate transfer complete chaining – sets the E8 bit in EDMACC_CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (EDMACC_IPR), which can generate an interrupt to the DSP, if the I8 bit in the interrupt enable register (EDMACC_IER) is set.

10.4.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 10-39 shows the EDMA setup and illustration of an example single large block transfer.

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The DSP starts the EDMA transfer by writing to the appropriate bit of the event set register (EDMACC_ESR.E25). The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 10-40 shows the EDMA setup and illustration of the broken up smaller packet transfers.

10.5 EDMA Debug/Programming Tips

10.5.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA controller. Table 10-25 provides some common issues and their probable causes and resolutions.

Table 10-25. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMACC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers (EDMACC_ER/EDMACC_ERH), make sure that the event is enabled in the Event Enable Registers (EDMACC_EER/EDMACC_EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (EDMACC_QEER). 2) Verify that the DMA or QDMA Secondary Event Register (EDMACC_SER/EDMACC_SERH/QSERH) bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., OPT.STATIC = 0, LINK = FFFFh), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMACC_QEMR and EDMACC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of Non-bursting peripheral, every time the data shifts out from the Data Transmit register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMACC_SER.Ex and EDMACC_EMR.Ex set, preventing further event prioritization. The user must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or the user must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (EDMACC_SER/EDMACC_SERH/EDMACC_QSER) and Event Missed Registers (EDMACC_EMR/EDMACC_EMRH/EDMACC_QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	The user must ensure the following: 1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1). 2) The interrupts are enabled in the EDMACC, via the Interrupt Enable Registers (EDMACC_IER/EDMACC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMACC_IPR/EDMACC_IPRH) before exiting the transfer completion interrupt service routine (ISR). For details on writing EDMA ISRs, see Section 10.3.11.1.2. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the EDMACC_IER/EDMACC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC = 63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMACC_IPRH.I63 (not EDMACC_IPR.I0).

10.5.2 Miscellaneous Programming/Debug Tips

Setting and Clearing Bits

For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (EDMACC_ER/EDMACC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMACC_ECR/EDMACC_ECRH). Similarly, the Event Enable Register (EDMACC_EER/EDMACC_EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EDMACC_EESR/EDMACC_EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EDMACC_EECR/EDMACC_EECRH).

Writing to Shadow Region Memory Maps

Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.

Shadow Region Completion Interrupts

When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts. For example, if EDMACC_DRAE0.E0 and EDMACC_DRAE1.E0 are both set, then on completion of a transfer that returns a TCC = 0, they will generate both shadow region 0 and 1 completion interrupts.

Programming a Non-Dummy Parameter Set

While programming a non-dummy parameter set, ensure the CCNT is not left to zero.

Ensuring Error Conditions are Not Missed

Enable the EDMACC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.

Breaking Up Transfers

Depending on the application, the user may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.

Chaining

In applications where a large transfer is broken into sets of small transfers using chaining or other methods, the user might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMACC internally signals completion when the TR is submitted to the EDMATC, potentially before any data has been transferred.

View Event Queue Entries

The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

10.5.3 Setting Up a Transfer

The following procedure provides a quick guide for the typical steps involved in setting up a transfer:

Step 1. Initiating a DMA/QDMA channel

a. Determine the type of channel (QDMA or DMA) to be used.

b. Channel mapping

i. If using a QDMA Channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.

ii. If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.

c. If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Table 10-15)

d. Determine the type of triggering used.

   i. If external events are used for triggering (DMA channels), enable the respective event in EDMACC_EER/EDMACC_EERH by writing into EDMACC_EESR/EDMACC_EESRH.

   ii. If QDMA Channel is used, enable the channel in EDMACC_QEER by writing into EDMACC_QEESR.

e. Queue setup

   i. If a QDMA channel is used, set up the EDMACC_QDMAQNUM to map the channel to the respective event queue.

   ii. If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.

Step 2. Parameter set setup
Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word. See Section 10.4 for parameter set field setups for different types of transfers. See the sections on chaining () and interrupt completion (Section 10.3.11) on how to set up final/intermediate completion chaining and/or interrupts.

Step 3. Interrupt setup

a. Enable the interrupt in the EDMACC_IER/EDMACC_IERH by writing into EDMACC_IESR/EDMACC_IESRH.

b. Ensure the EDMACC completion interrupt (this refers to either the global interrupt or the shadow region interrupt) is enabled properly in the device interrupt controller.

c. Set up the interrupt controller properly to receive the expected EDMA interrupt.

Step 4. Initiate transfer
This step is highly dependent on the event trigger source:

a. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMACC_ER transfer.

b. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.

c. Manually triggered transfers will be initiated by writes to the Event Set Registers (EDMACC_ESR/EDMACC_ESRH).

d. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

a. If the interrupts are enabled as mentioned in step 3 above, then the EDMACC will generate a completion interrupt to the DSP whenever transfer completion results in setting the corresponding bits in the interrupt pending register (EDMACC_IPR/EDMACC_IPRH). The set bits must be cleared in the EDMACC_IPR/EDMACC_IPRH by writing to corresponding bit in EDMACC_ICR/EDMACC_ICRH.

b. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMACC_IPR/EDMACC_IPRH. Again, the set bits in the EDMACC_IPR/EDMACC_IPRH must be manually cleared via EDMACC_ICR/EDMACC_ICRH before the next set of transfers is performed for the same transfer completion code values.

10.6 EDMA Registers

This section describes the memory-mapped registers associated with the EDMA controller.

10.6.1 EDMA Channel Controller (EDMACC) Registers

Table 10-26 lists the base address for each of the EDMACC module instances.

Table 10-27 lists the memory-mapped registers for the EDMA channel controller (EDMACC). All register offset addresses not listed in Table 10-27 should be considered as reserved locations and the register contents should not be modified.

Table 10-26. EDMACC Instances

Instance	Base Address
EDMACC_0	0270 0000h
EDMACC_1	0272 8000h

10.6.1.1 Global Registers

10.6.1.1.1 EDMACC_PID Register (Offset = 0h) [reset = 4001AB00h]

The peripheral identification register (EDMACC_PID) uniquely identifies the EDMACC and the specific revision of the EDMACC.

The EDMACC_PID is shown in Figure 10-41 and described in Table 10-29.

Table 10-28. EDMACC_PID Instances

Instance	Physical Address

EDMA Registers
• EDMA Channel Controller (EDMACC) Registers: [0]

10.6.1.1.4 EDMACC_QCHMAP0 to EDMACC_QCHMAP7 Register (Offset = 200h to 21Ch) [reset = 0h]

Each QDMA channel in EDMACC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map n register (QCHMAP *n*).

The QCHMAP *n* is shown in Figure 10-44 and described in Table 10-38.

NOTE: At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP *n* is programmed appropriately to point to a different PaRAM entry.

EDMA Registers
• EDMA Channel Controller (EDMACC) Registers: [0]

10.6.1.1.5 EDMACC_DMAQNUM0 to EDMACC_DMAQNUM7 Register (Offset = 240h to 25Ch) [reset = 0h]

The DMA channel queue number register (DMAQNUM *n*) allows programmability of the DMA channels in the EDMACC to submit its associated synchronization event to any event queue in the EDMACC. At reset, all channels point to event queue 0.

The DMAQNUM *n* is shown in Figure 10-45 and described in Table 10-41. shows the channels and their corresponding bits in DMAQNUM *n*.

NOTE: Because the event queues in EDMACC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM *n* for a particular DMA channel *n* also dictates which transfer controller is utilized for the data movement (or which EDMATC receives the TR request).

N refer to the number of DMA Channels (0 to 7).

10.6.1.1.7 EDMACC_QUETCMAP Register (Offset = 280h) [reset = 3210h]

The Queue-to-TC Mapping Register (EDMACC_QUETCMAP) defines the mapping between Event queue n and the TC number. By default, there is a one-to-one mapping between the Event queues and the Transfer Controllers. Therefore, the Transfer requests (TRs) associated with events in Q0 get submitted to TC0, TRs associated with events in Q1 get submitted to TC1, and so on. This register enables a change to the default mapping of the TC number that Event queue n TRs are submitted to. It is only used if TCs are not identical (e.g., TC0 FIFO is 512 bytes while TC1 FIFO is 1024 bytes).

CAUTION

Care must be taken while changing the default mapping in this register. User must ensure that the same TC number should never be assigned to multiple queues (i.e., TCNUMQn != TCNUMQm).

The Queue-to-TC Mapping Register (EDMACC_QUETCMAP) is shown in Figure 10-47 and described in Table 10-47.

10.6.1.1.8 EDMACC_QUEPRI Register (Offset = 284h) [reset = 0h]

The queue priority register (EDMACC_QUEPRI) allows you to change the priority of the individual queues and the priority of the transfer request (TR) associated with the events queued in the queue. It essentially governs the priority of the associated transfer controller(s) read/write commands with respect to the other bus masters in the device. You can modify the EDMATC priority to obtain the desired system performance.

The EDMACC_QUEPRI is shown in Figure 10-48 and described in Table 10-50.

10.6.1.1.9 EDMACC_EMR Register (Offset = 300h) [reset = 0h]

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EDMACC_EMR/EDMACC_EMRH). All trigger types are treated individually, that is, manual triggered (EDMACC_ESR/EDMACC_ESRH), chain triggered (EDMACC_CER/EDMACC_CERH), and event triggered (EDMACC_ER/EDMACC_ERH) are all treated separately. The EDMACC_EMR/EDMACC_EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EDMACC_EMR/EDMACC_EMRH bit is set (and all errors, including bits in other error registers (EDMACC_QEMR, EDMACC_CCERR) were previously cleared), the EDMACC generates an error interrupt. See for details on EDMACC error interrupt generation.

The EDMACC_EMR is shown in Figure 10-49 and described in Table 10-53.

10.6.1.1.10 EDMACC_EMRH Register (Offset = 304h) [reset = 0h]

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EDMACC_EMR/EDMACC_EMRH). All trigger types are treated individually, that is, manual triggered (EDMACC_ESR/EDMACC_ESRH), chain triggered (EDMACC_CER/EDMACC_CERH), and event triggered (EDMACC_ER/EDMACC_ERH) are all treated separately. The EDMACC_EMR/EDMACC_EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EDMACC_EMR/EDMACC_EMRH bit is set (and all errors, including bits in other error registers (EDMACC_QEMR, EDMACC_CCERR) were previously cleared), the EDMACC generates an error interrupt. See for details on EDMACC error interrupt generation.

The EDMACC_EMRH is shown in Figure 10-50 and described in Table 10-56.

10.6.1.1.11 EDMACC_EMCR Register (Offset = 308h) [reset = 0h]

Once a missed event is posted in the event missed registers (EDMACC_EMR/EDMACC_EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of DSP writes to the event missed clear registers (EDMACC_EMCR/EDMACC_EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EDMACC_EMR/EDMACC_EMRH; writing a 0 has no effect.

The EDMACC_EMCR is shown in Figure 10-51 and described in Table 10-59.

10.6.1.1.15 EDMACC_CCERR Register (Offset = 318h) [reset = 0h]

The EDMACC error register (EDMACC_CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (EDMACC_QWMTHRA). Additionally, EDMACC_CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMACC has exceeded the maximum allowed value of 63. If any bit in EDMACC_CCERR is set (and all errors, including bits in other error registers (EDMACC_EMR/EDMACC_EMRH, EDMACC_QEMR) were previously cleared), the EDMACC generates an error interrupt. See for details on EDMACC error interrupt generation. Once the error bits are set in EDMACC_CCERR, they can only be cleared by writing to the corresponding bits in the EDMACC error clear register (EDMACC_CCERRCLR).

The EDMACC_CCERR is shown in Figure 10-55 and described in Table 10-71.

10.6.1.1.17 EDMACC_EEVAL Register (Offset = 320h) [reset = 0h]

The EDMACC error interrupt is asserted whenever an error bit is set in any of the error registers (EDMACC_EMR/EDMACC_EMRH, EDMACC_QEMR, and EDMACC_CCERR). For subsequent error bits that get set, the EDMACC error interrupt is reasserted only when transitioning from an "all the error bits cleared" to "at least one error bit is set". Alternatively, a DSP write of 1 to the EVAL bit in the error evaluation register (EDMACC_EEVAL) results in reasserting the EDMACC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EDMACC_EEVAL is shown in Figure 10-57 and described in Table 10-77.

10.6.1.2 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAE *m* and DRAEH *m*) and the QDMA access enable registers (QRAE *m*). Where *m* is the number of shadow regions in the EDMACC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

10.6.1.2.1 EDMACC_DRAE0 Register (Offset = 340h) [reset = 0h]

The DMA region access enable register for shadow region *0* (EDMACC_DRAE0/EDMACC_DRAEH0) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region *0* view of the DMA channel registers. See the EDMACC register memory map (Table 10-27) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the EDMACC_DRAE0/EDMACC_DRAEH0 configuration determines completion of which DMA channels will result in assertion of the shadow region *0* DMA completion interrupt (see).

The EDMACC_DRAE0 is shown in Figure 10-58 and described in Table 10-80.

10.6.1.2.15 EDMACC_DRAE7 Register (Offset = 378h) [reset = 0h]

The DMA region access enable register for shadow region *7* (EDMACC_DRAE7/EDMACC_DRAEH7) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region *7* view of the DMA channel registers. See the EDMACC register memory map (Table 10-27) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the EDMACC_DRAE7/EDMACC_DRAEH7 configuration determines completion of which DMA channels will result in assertion of the shadow region *7* DMA completion interrupt (see).

The EDMACC_DRAE7 is shown in Figure 10-72 and described in Table 10-122.

Reads return the value from bit n and writes modify the state of bit N.

Table 10-129. Register Call Summary for EDMACC_QRAE0

EDMA Registers
• EDMA Channel Controller (EDMACC) Registers: [0]

10.6.1.3 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMACC logic are active once the event has been received by the EDMACC.

10.6.1.3.1 EDMACC_Q0E0 to EDMACC_Q3E15 Register (Offset = 400h to 4FCh) [reset = 0h]

The event queue entry registers (Q *x*E *y*) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMACC.

There are EDMACC_Q0E0 to Q0E15, Q1E0 to Q1E15, Q2E0 to Q2E15, and Q3E0 to EDMACC_Q3E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The Q *x*E *y* is shown in Figure 10-75 and described in Table 10-131.

18	QUEACTV2	R	0h	Queue 2 active. 0h = No events are queued in queue 2. 1h = At least one TR is queued in queue 2.
17	QUEACTV1	R	0h	Queue 1 active. 0h = No events are queued in queue 1. 1h = At least one TR is queued in queue 1.
16	QUEACTV0	R	0h	Queue 0 active. 0h = No events are queued in queue 0. 1h = At least one TR is queued in queue 0.
15-14	RESERVED	R	0h	Reserved
13-8	COMPACTV	R	0h	Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMACC will not service any new TRs until the count is less then 63 (or return a transfer completion code from a transfer controller, which would decrement the count). 0h = No completion requests outstanding. 1h-3Fh = Total of 1 completion request to 63 completion requests are outstanding.

Table 10-140. EDMACC_CCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-5	RESERVED	R	0h	Reserved
4	ACTV	R	0h	Channel controller active. Channel controller active is a logical-OR of each of the *ACTV bits. The ACTV bit remains high through the life of a TR. 0h = Channel is idle. 1h = Channel is busy.
3	WSTATACTV	R	0h	Write status interface active. 0h = Write status req is idle and write status FIFO is idle. 1h = Either the write status request is active or additional write status responses are pending in the write status FIFO.
2	TRACTV	R	0h	Transfer request active. 0h = Transfer request processing/submission logic is inactive. 1h = Transfer request processing/submission logic is active.
1	QEVTACTV	R	0h	QDMA event active. 0h = No enabled QDMA events are active within the EDMACC. 1h = At least one enabled QDMA event (EDMACC_QER) is active within the EDMACC.
0	EVTACTV	R	0h	DMA event active. 0h = No enabled DMA events are active within the EDMACC. 1h = At least one enabled DMA event (EDMACC_ER and EDMACC_EER, EDMACC_ESR, EDMACC_CER) is active within the EDMACC.

EDMA Registers • EDMA Channel Controller (EDMACC) Registers: [0]
Memory Protection • Active Memory Protection: [0]

10.6.1.5 DMA Channel Registers

The following sets of registers pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUM *n*) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. Note that high registers (reg_name_High) are applicable only when the EDMACC supports more than 32 DMA channels.

For example, the event register (EDMACC_ER) corresponds to DMA channel 0 through 31 and the event register high register (EDMACC_ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register.

The DMA channel registers are accessible via read/writes to the global address range. They also are accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAE *m*/DRAEH *m*). The registers are described in and the details for shadow region/global region usage is explained in .

10.6.1.5.1 EDMACC_ER Register (Offset = 1000h) [reset = 0h]

All external events are captured in the event register (EDMACC_ER/EDMACC_ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EDMACC_EER.E *n*/EDMACC_EERH.E *n* = 1), then the event is evaluated by the EDMACC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (EDMACC_ER.E *n*/EDMACC_ERH.E *n* = 0) once the corresponding events are prioritized and serviced. If EDMACC_ER.E *n*/EDMACC_ERH.E *n* are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EDMACC_EMR.E *n*/EDMACC_EMRH.E *n*), provided that the event was enabled (EDMACC_EER.E *n*/EDMACC_EERH.E *n* = 1).

Event *n* can be cleared by the DSP writing a 1 to corresponding event bit in the event clear register (EDMACC_ECR/EDMACC_ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EDMACC_EMR/EDMACC_EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

provides the type of synchronization events and the EDMACC channels associated to each of these external events.

The EDMACC_ERH is shown in Figure 10-85 and described in Table 10-161.

10.6.1.5.3 EDMACC_ECR Register (Offset = 1008h) [reset = 0h]

Once an event has been posted in the event registers (EDMACC_ER/EDMACC_ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EDMACC_EER/EDMACC_EERH) and the EDMACC submits a transfer request for the event to the EDMATC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EDMACC_EER/EDMACC_EERH), the DSP can clear the event by way of the event clear registers (EDMACC_ECR/EDMACC_ECRH).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMACC submits a transfer request for that event or the DSP clears the event by setting the corresponding bit in EDMACC_ECR/EDMACC_ECRH.

The EDMACC_ECR is shown in Figure 10-86 and described in Table 10-164.

EDMA Channel Controller Regions • Region Overview: [0]

10.6.1.5.5 EDMACC_ESR Register (Offset = 1010h) [reset = 0h]

The event set registers (EDMACC_ESR/EDMACC_ESRH) allow the DSP (EDMA programmers) to manually set events to initiate DMA transfer requests. DSP writes of 1 to any event set register (E *n*) bits set the corresponding bits in the registers. The set event is evaluated by the EDMACC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set registers operate independent of the event registers (EDMACC_ER/EDMACC_ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EDMACC_EER.E *n*/EDMACC_EERH.E *n*).

Once the event is set in the event set registers, it cannot be cleared by DSP writes, in other words, the event clear registers (EDMACC_ECR/EDMACC_ECRH) have no effect on the state of EDMACC_ESR/EDMACC_ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EDMACC_EMR/EDMACC_EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to EDMACC_ESR/EDMACC_ESRH allow the DSP to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the EDMACC_ESR.E *n*/EDMACC_ESRH.E *n* bit is already set and another DSP write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EDMACC_EMR.E *n*/EDMACC_EMRH.E *n* = 1).

The EDMACC_ESR is shown in Figure 10-88 and described in Table 10-170.

10.6.1.5.7 EDMACC_CER Register (Offset = 1018h) [reset = 0h]

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (EDMACC_CER/EDMACC_CERH). The set chained event is evaluated by the EDMACC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The E *n* bit is set (regardless of the state of EDMACC_EER.E *n*/EDMACC_EERH.E *n*) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMACC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the E *n* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EDMACC_EMR.E *n*/EDMACC_EMRH.E *n* = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EDMACC_EMR/EDMACC_EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The EDMACC_CER is shown in Figure 10-90 and described in Table 10-176.

10.6.1.5.9 EDMACC_EER Register (Offset = 1020h) [reset = 0h]

The EDMACC provides the option of selectively enabling/disabling each event in the event registers (EDMACC_ER/EDMACC_ERH) by using the event enable registers (EDMACC_EER/EDMACC_EERH). If an event bit in EDMACC_EER/EDMACC_EERH is set (using the event enable set registers, EDMACC_EESR/EDMACC_EESRH), it will enable that corresponding event. Alternatively, if an event bit in EDMACC_EER/EDMACC_EERH is cleared (using the event enable clear registers, EDMACC_EECR/EDMACC_EECRH), it will disable the corresponding event.

The event registers latch all events that are captured by EDMACC, even if the events are disabled (although EDMACC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMACC to process the already set event like any other new event. The EDMACC_EER/EDMACC_EERH settings do not have any effect on chained events (EDMACC_CER.E *n*/EDMACC_CERH.E *n* = 1) and manually set events (EDMACC_ESR.E *n*/EDMACC_ESRH.E *n* = 1).

The EDMACC_EER is shown in Figure 10-92 and described in Table 10-182.

10.6.1.5.15 EDMACC_SER Register (Offset = 1038h) [reset = 0h]

The secondary event registers (EDMACC_SER/EDMACC_SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMACC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (EDMACC_ESR.E *n*/EDMACC_ESRH.E *n* = 1, EDMACC_ER.E *n*/EDMACC_ERH.E *n* = 1, or EDMACC_CER.E *n*/EDMACC_CERH.E *n* = 1), which results in the setting of a corresponding event bit in EDMACC_SER/EDMACC_SERH (EDMACC_SER.E *n*/EDMACC_SERH.E *n* = 1), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in EDMACC_SER/EDMACC_SERH, the EDMACC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the EDMACC_SER bits, either the EDMACC hardware or the software (using EDMACC_SECR/EDMACC_SECRH) needs to clear the EDMACC_SER/EDMACC_SERH bits for the EDMACC to evaluate subsequent events (subsequent transfers) on the same channel. See for additional conditions that can cause the secondary event registers to be set.

The EDMACC_SERH is shown in Figure 10-99 and described in Table 10-203.

The secondary event register is used along with the event register high (EDMACC_ERH) to provide information on the state of an event. 0h = Event is not currently stored in the event queue. 1h = Event is currently stored in the event queue. Event submission/prioritization logic will not prioritize additional events.

10.6.1.6 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMACC completion interrupt to the DSP on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following set of registers is used for the transfer completion interrupt reporting/generating by the EDMACC. See for more details on EDMACC completion interrupt generation.

10.6.1.6.1 EDMACC_IER Register (Offset = 1050h) [reset = 0h]

Interrupt enable registers (EDMACC_IER/EDMACC_IERH) are used to enable/disable the transfer completion interrupt generation by the EDMACC for all DMA/QDMA channels. The EDMACC_IER/EDMACC_IERH cannot be written to directly. To set any interrupt bit in EDMACC_IER/EDMACC_IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (EDMACC_IESR/EDMACC_IESRH). Similarly, to clear any interrupt bit in EDMACC_IER/EDMACC_IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (EDMACC_IECR/EDMACC_IECRH).

The EDMACC_IER is shown in Figure 10-102 and described in Table 10-212.

EDMA Channel Controller Regions • Region Overview: [0]

10.6.1.6.7 EDMACC_IPR Register (Offset = 1068h) [reset = 0h]

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMATC (for normal completion) or the EDMACC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with TCC = *n* is detected by the EDMACC, then the corresponding bit is set in the interrupt pending register (EDMACC_IPR.I *n*, if N = 0 to 31; EDMACC_IPRH.I *n*, if N = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in EDMACC_IPR/EDMACC_IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (EDMACC_ICR/EDMACC_ICRH).

The EDMACC_IPR is shown in Figure 10-108 and described in Table 10-230.

10.6.1.6.11 EDMACC_IEVAL Register (Offset = 1078h) [reset = 0h]

The interrupt evaluate register (EDMACC_IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region EDMACC_IEVAL is not affected by the DMA/QDMA region access registers (DRAE *m*/DRAEH *m*, QRAE *n*/QRAEH *n*). EDMACC_IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the DSP.

The EDMACC_IEVAL is shown in Figure 10-112 and described in Table 10-242.

Table 10-241. EDMACC_IEVAL Instances

Instance	Physical Address

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	Reserved
1	SET	W	0h	Always write 0. Writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL	W	0h	Interrupt evaluate 0h = No effect. 1h = Causes EDMACC completion interrupt to be pulsed, if any enabled (EDMACC_IER *n*/EDMACC_IERH *n* = 1) interrupts are still pending (EDMACC_IPR *n*/EDMACC_IPRH *n* = 1). The EDMACC completion interrupt that is pulsed depends on which EDMACC_IEVAL is being exercised. For example, writing to the EVAL bit in EDMACC_IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt.

10.6.1.7 QDMA Registers

The following sets of registers control the QDMA channels in the EDMACC. The QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAE *n*/QRAEH *n*). details shadow region/global region usage.

10.6.1.7.1 EDMACC_QER Register (Offset = 1080h) [reset = 0h]

The QDMA event register (EDMACC_QER) channel *n* bit is set (E *n* = 1) when the DSP or any EDMA programmer (including EDMA) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAP *n*)) in the PaRAM entry associated with QDMA channel n (which is also programmed using QCHMAP *n*). The E *n* bit is also set when the EDMACC performs a link update on a PaRAM address that matches the QCHMAP *n* settings. The QDMA event is latched only if the QDMA event enable register (EDMACC_QEER) channel *n* bit is also enabled (EDMACC_QEER.E *n* = 1). Once a bit is set in EDMACC_QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMACC logic for an associated transfer request submission to the transfer controllers. See for additional conditions that can lead to the setting of EDMACC_QER bits.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (EDMACC_QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in EDMACC_QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMACC and submitted to the transfer controller. If the E *n* bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in EDMACC_QEMR (E *n* = 1).

The EDMACC_QER is shown in Figure 10-113 and described in Table 10-245.

10.6.1.7.2 EDMACC_QEER Register (Offset = 1084h) [reset = 0h]

The EDMACC provides the option of selectively enabling/disabling each channel in the QDMA event register (EDMACC_QER) by using the QDMA event enable register (EDMACC_QEER). If any of the event bits in EDMACC_QEER is set (using the QDMA event enable set register, EDMACC_QEESR), it will enable that corresponding event. Alternatively, if any event bit in EDMACC_QEER is cleared (using the QDMA event enable clear register, EDMACC_QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via EDMACC_QEER.

The EDMACC_QEER is shown in Figure 10-114 and described in Table 10-248.

10.6.1.7.3 EDMACC_QEECR Register (Offset = 1088h) [reset = 0h]

The QDMA event enable register (EDMACC_QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (EDMACC_QEECR) is used to disable events. Writes of 1 to the bits in EDMACC_QEECR clear the corresponding QDMA channel bits in EDMACC_QEER; writes of 0 have no effect.

The EDMACC_QEECR is shown in Figure 10-115 and described in Table 10-251.

10.6.1.7.5 EDMACC_QSER Register (Offset = 1090h) [reset = 0h]

The QDMA secondary event register (EDMACC_QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in EDMACC_QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in EDMACC_QSER, the EDMACC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the EDMACC_QSER bits, either the EDMACC hardware or the software (using EDMACC_QSECR) needs to clear the EDMACC_QSER bits for the EDMACC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of EDMACC_QSER and the required user actions to submit another QDMA transfer might be different. See for additional conditions that can cause the secondary event registers (EDMACC_QSER/EDMACC_SER) to be set.

The EDMACC_QSER is shown in Figure 10-117 and described in Table 10-257.

10.6.1.7.6 EDMACC_QSECR Register (Offset = 1094h) [reset = 0h]

The QDMA secondary event clear register (EDMACC_QSECR) clears the status of the QDMA secondary event register (EDMACC_QSER) and the QDMA event register (EDMACC_QER). DSP writes of 1 clear the corresponding set bits in EDMACC_QSER and EDMACC_QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (EDMACC_SECR) operation, which only clears the secondary event register (EDMACC_SER) bits and does not affect the event registers.

The EDMACC_QSECR is shown in Figure 10-118 and described in Table 10-260.

10.6.2.1 EDMATC_PID Register (Offset = 0h) [reset = 40000301h]

The peripheral identification register (EDMATC_PID) is a constant register that uniquely identifies the EDMATC and specific revision of the EDMATC. The EDMATC_PID is shown in Figure 10-119 and described in Table 10-266.

Table 10-265. EDMATC_PID Instances

Instance	Physical Address
EDMACC_0_TC_0 (EDMATC_0)	0276 0000h

Table 10-272. EDMATC_TCSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12-11	DFSTRTPTR	R	0h	Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries.
10-7	RESERVED	R	2h	Reserved
6-4	DSTACTV	R	0h	Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter. 0h = Destination FIFO is empty. 1h = Destination FIFO contains 1 TR. 2h = Destination FIFO contains 2 TRs. 3h = Destination FIFO contains 3 TRs. 4h = Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4) If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle. If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed. 5h - 7h = Reserved
3	RESERVED	R	0h	Reserved

Table 10-272. EDMATC_TCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	WSACTV	R	0h	Write status active. 0h = Write status is not pending. Write status has been received for all previously issued write commands. 1h = Write status is pending. Write status has not been received for all previously issued write commands.
1	SRCACTV	R	0h	Source active state. 0h = Source controller is idle. Source active register set contains a previously processed transfer request. 1h = Source controller is busy servicing a transfer request.
0	PROGBUSY	R	0h	Program register set busy. 0h = Program set idle and is available for programming by the EDMACC. 1h = Program set busy.

Table 10-284. EDMATC_ERRDET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17	TCCHEN	R	0h	Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
16	TCINTEN	R	0h	Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
15-14	RESERVED	R	0h	Reserved
13-8	TCC	R	0h	Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
7-4	RESERVED	R	0h	Reserved
3-0	STAT	R	0h	Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMATC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority. 0h = No error 1h - 7h = Read error 8h - Fh = Write error

10.6.2.5 EDMATC_RDRATE Register (Offset = 140h) [reset = 0h]

The EDMA transfer controller issues read commands at a rate controlled by the read rate register (EDMATC_RDRATE). The EDMATC_RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if EDMATC_RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads.

EDMATC_RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, EDMATC_RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMATC cycles.

The EDMATC_RDRATE is shown in Figure 10-127 and described in Table 10-290.

NOTE: It is expected that the EDMATC_RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the fly.

10.6.2.6 EDMATC Channel Registers

The EDMATC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO register. This section describes the registers and their functions. The program register set is programmed by the channel controller, and is for internal use. The other two sets are read-only and provided to facilitate advanced debug capabilities.

The number of destination FIFO register sets depends on the destination FIFO depth. Each TC has a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of the transfer controllers.

10.6.2.6.1 EDMATC_SAOPT Register (Offset = 240h) [reset = 0h]

The source active options register (EDMATC_SAOPT) is shown in Figure 10-128 and described in Table 10-293.

11.1 Audio Sample Rate Converter (ASRC)

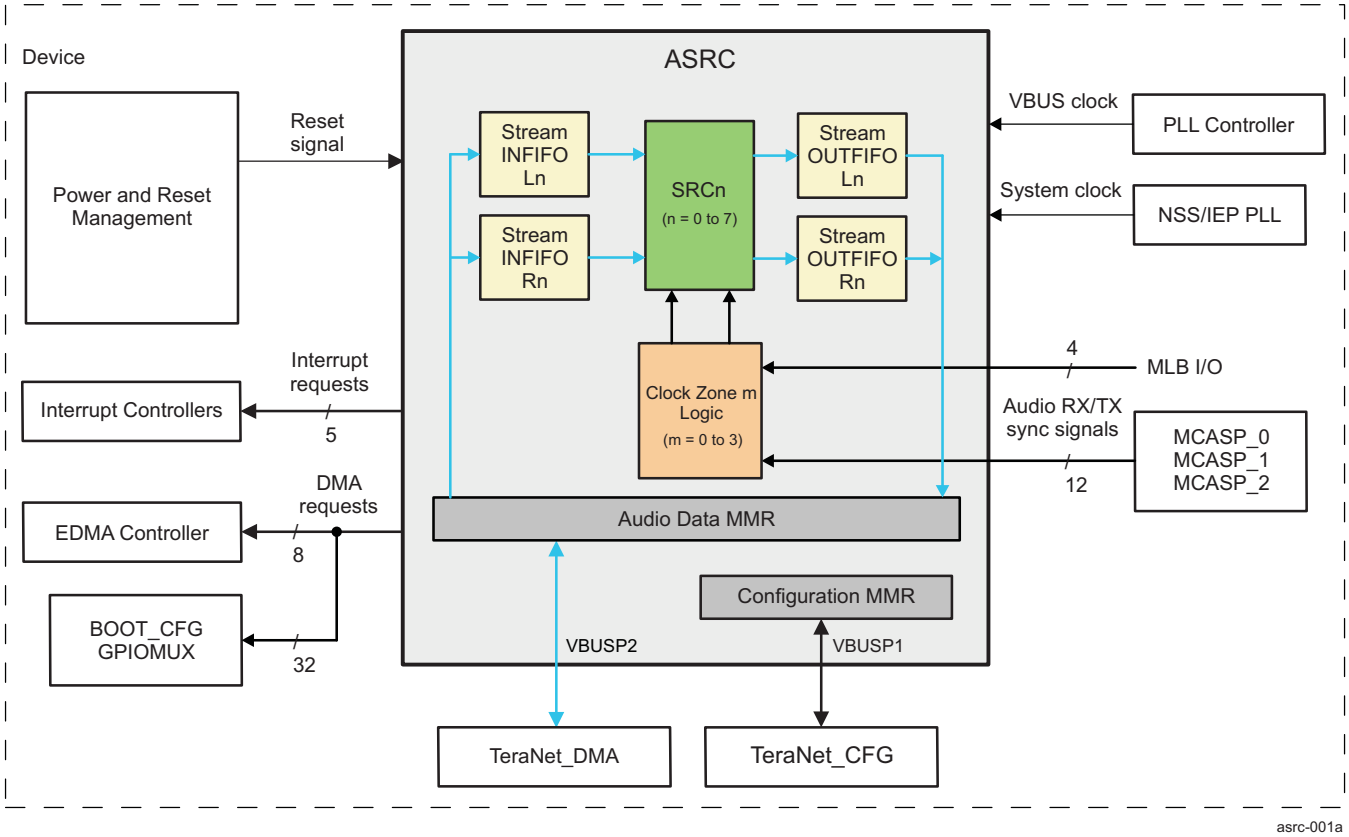
This section describes the asynchronous Audio Sample Rate Converter (ASRC) in the device.

11.1.1 ASRC Overview

The reception of many different audio sources and the transmission of these to different audio zones, may require different audio clocks. The asynchronous Audio Sample Rate Converter (ASRC) module takes samples from one clock zone and moves them to another, while maintaining a high signal to noise ratio to ensure that the output quality is sufficient to meet the requirements for various high-end algorithms.

Figure 11-1 is a simplified overivew diagram of the ASRC module implementation within the device.

Figure 11-1. ASRC Overview Diagram



The ASRC module supports the following main features:

- High performance Asynchronous Sample Rate Converter with 140dB Signal-to-Noise (SNR)
- Up to 8 input and output stereo streams (16 audio channels)
- 4 input and output clock zones
- Support for input and output audio sample rates from 8 kHz to 216 kHz
- Automatically sensing/detection of input sample frequencies
- Attenuation of sampling clock jitter
- 16-, 18-, 20-, 24-bit data input/output
- Input/output sampling ratios from 16:1 to 1:16
- 32-sample input and output FIFO for each channel with independently configurable thresholds
- Group mode, where multiple ASRC blocks use the same timing loop for input or output
- Linear phase FIR filter
- Controllable soft mute

- De-Emphasis supported for 48, 44.1 and 32 kHz sample rates
- Separate DMA events for input and output, for each channel and group
- Interrupts for input, output, and error for channels and groups of channels
- Channels belonging in an input/output clock zone may be configured and managed as a group or as individual streams

The ASRC module has the following main constrains:

- The ASRC output rate divided by input rate must be between 1/16 and 16
- Sample rate must be between 8 and 216 kHz

11.1.2 ASRC Integration

This section describes the ASRC integration in the device.

Figure 11-2. ASRC Integration Diagram

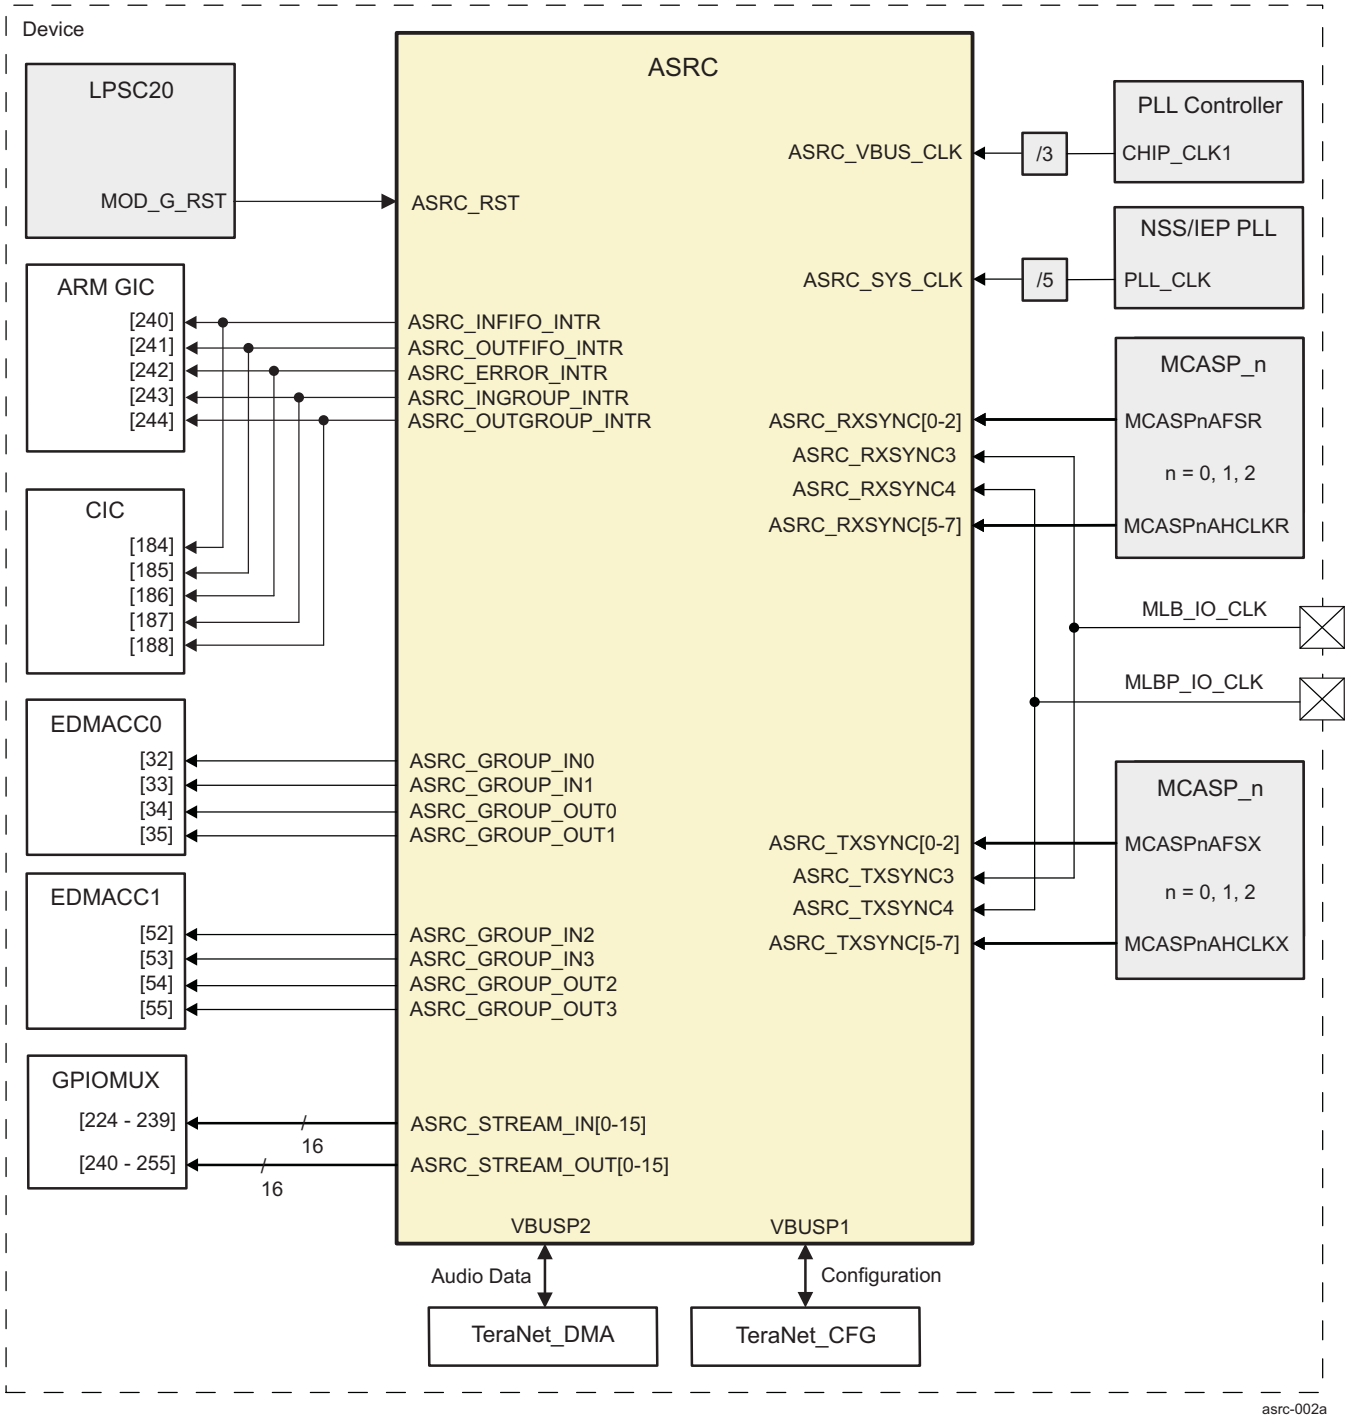


Table 11-3492 through Table 11-3494 summarize the integration of the module in the device.

Table 11-1. ASRC Integration Attributes

Module Instance	Attributes

11.1.3 ASRC Functional Description

11.1.3.1 ASRC Block Diagram and Implementation

The Asynchronous Audio Sample Rate Converter (ASRC) allows the movement of up to 8 audio stereo streams (16 audio channels) from one audio zone to another audio zone via 8 two-channel sample rate converters.

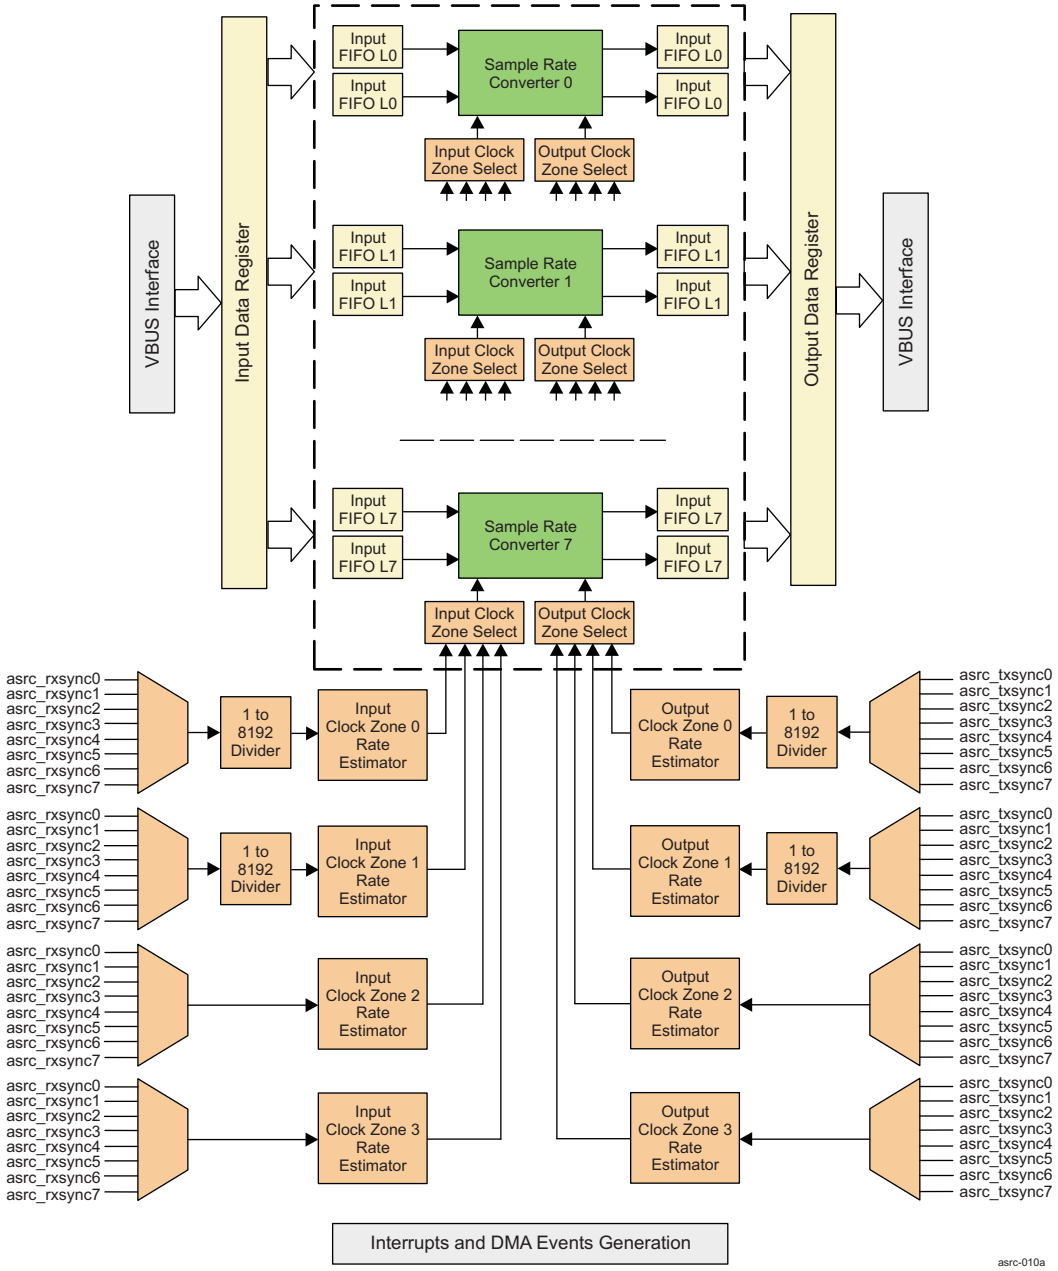
Each sample rate converter performs a digital audio sample rate conversion between input and output clock zone sample rates. The input and output clock zones can be individually selected for each sample rate converter in stream mode configuration. In group mode configuration, the sample rate converters that make up each group share the same input and output clock zone specifications. Each input and output channel is buffered by a 32-sample FIFO. The FIFO threshold values are programmed to a value between 1 and 16 samples.

The ASRC converts audio data between 4 input and 4 output clock zones. The clock zones provide a sample rate (Fs) input into clock rate estimators on the receive side and transmit side. Each ASRC receive and transmit clock zone input can come from one of 8 possible sources as shown in Figure 11-3. The input clocks and output clocks can have any frequency that is within the constraints specified in Section 11.1.1 and are completely asynchronous to each other.

The ASRC works by interpolating the input audio signals that are in the sequential domain of the source audio input clock. The input audio signal is interpolated up to 16x the input rate, then resampled at 16x the output rate, and then downsampled to the desired output clock frequency.

Figure 11-3 shows a simplified block diagram of ASRC module.

Figure 11-3. ASRC Block Diagram



The ASRC can handle multiple channels and switch between each channel as samples become available. The ASRC external interface is VBUS interface. One VBUS Interface is provided for configuration and status registers and another VBUS interface is dedicated for writing and reading audio samples. The ASRC also generate events when a configurable amount of output samples are ready. The ASRC implemets sample packer modules for processing the different streams as data becomes available.

The ASRC is a loosely coupled coprocessor to the main SoC DSP. Data is moved into the ASRC by device EDMA controller and an event is generated when another block of samples is completed for a given audio stream. In order to minimize the number of EDMA channels and events required, the ASRC also supports group events which are generated only when all of the selected Left and Right channels meet a pre-defined FIFO threshold. This permits a single EDMA transfer to perform the input and a single EDMA transfer to perform the output of all of the channels in the group.

As an alternative to EDMA moderated data input and output ASRC data transfers, the ASRC also supports input FIFO and output FIFO interrupts to permit a device processor to control the data transfers. The ASRC generates an error interrupt when a FIFO overflow and underflow error condition occurs.

The ASRC supports two modes of transferring data into the ASRC data inputs and from the ASRC data outputs:

- Group Mode, which enables all of the streams that are part of an input or output clock zone to be transferred using a single EDMA (each group is controlled by separate EDMA. Group mode is well suited for handing stereo or multichannel data from a single source.
- Stream Mode, which enables each stream to be transferred using a separate EDMA (each individual stream can be controlled by a separate EDMA). Stream mode is well suited for handing data from two or more isolated sources.

11.1.3.2 ASRC Data Rate and Traffic Behavior

The ASRC traffic and transaction behavior is a function of the input and output sample rates. The rate of the transactions is 4 bytes per sample. For example, if the input rate is 48 kHz, then the input data rate will be 192 KB/s. The traffic is bursty based upon the threshold size set in the ASRC_SRCFFCTRL_0 register.

The following must be considered:

- Output rate / Input rate ratio must be between 1/16 and 16
- Sample rate must be less than or equal to 216 kHz

11.1.3.3 ASRC Data Interface and Formats

NOTE: The only internal data format is of a 28-bit sample. Externally, the only format supported is a packed 24-bit samples into a 32-bit word, as described in this section.

Data is written to the ASCR and read from the ASRC using the VBUS interface. This interface has separate data register memory regions for Stream and Group input / output. Each region is used as based upon the mode (Group or Stream) that has been selected for each sample rate converter.

The ASRC data format is little endian, with up to 24-bit samples of data packed into 32-bit word.

ASRC supports 16-/18-/20-/24-bit audio data. ASRC understands audio data in the format dictated by Table 11-4, which holds true for both input and output channels.

Table 11-4. ASRC Data Packing at the SRC Interface

Sample Width	[31:24]	[23:8]	[7:6]	[5:4]	[3:0]
24-bit	8'h00	AudioData[23:0]			
20-bit	8'h00	AudioData[19:0]			4'h0
18-bit	8'h00	AudioData[17:0]		6'h00	
16-bit	8'h00	AudioData[15:0]	8'h00		

ASRC also supports automatic HW audio data alignment. Audio data alignment is active by default, but can be disabled via ASRC_SYSCONFIG[1] DATA_FORMAT_DISABLE register bit.

If auto data alignment feature is disabled, then data format for the audio samples at the VBUS interface can be seen in Table 11-5. For input audio samples packed into 32-bit VBUS packet, the most significant 8 bits [31:24] are always ignored by the ASRC internal engine. For output audio samples packed into 32-bit VBUS packet, the most significant 8 bits are always padded with 0's.

Table 11-5. ASRC Data Packing at the VBUS Interface When Auto Alignment is Disabled

Sample Width	[31:24]	[23:8]	[7:6]	[5:4]	[3:0]
24-bit	8'h00	AudioData[23:0]			
20-bit	8'h00	AudioData[19:0]			4'h0

Table 11-5. ASRC Data Packing at the VBUS Interface When Auto Alignment is Disabled (continued)

Sample Width	[31:24]	[23:8]	[7:6]	[5:4]	[3:0]
18-bit	8'h00	AudioData[17:0]		6'h00	
16-bit	8'h00	AudioData[15:0]	8'h00		

In case of automatic HW alignment is being used (this feature is selected by default), input audio samples packed into 32-bit VBUS packet must be LSB aligned. Input data format for the audio samples at the VBUS interface can be seen in Table 11-6.

Table 11-6. ASRC Input Data Packing at the VBUS Interface When Auto Alignment is Enabled

Sample Width	[31:24]	[23:20]	[19:18]	[17:16]	[15:0]
24-bit	xx	AudioData[23:0]			
20-bit	xx		AudioData[19:0]		
18-bit	xx			AudioData[17:0]	
16-bit	xx				AudioData[15:0]

In case of automatic HW alignment is being used, output audio samples will be packed into 32-bit VBUS packet. Audio data will be LSB aligned, little endian and sign extended 2's complement. Output data format for the audio samples at the VBUS interface can be seen in Table 11-7.

Table 11-7. ASRC Output Data Packing at the VBUS Interface When Auto Alignment is Enabled

Sample Width	[31:24]	[23:20]	[19:18]	[17:16]	[15:0]
24-bit	sign extend	AudioData[23:0]			
20-bit	sign extend		AudioData[19:0]		
18-bit	sign extend			AudioData[17:0]	
16-bit	sign extend				AudioData[15:0]

11.1.3.4 ASRC Clock Configuration

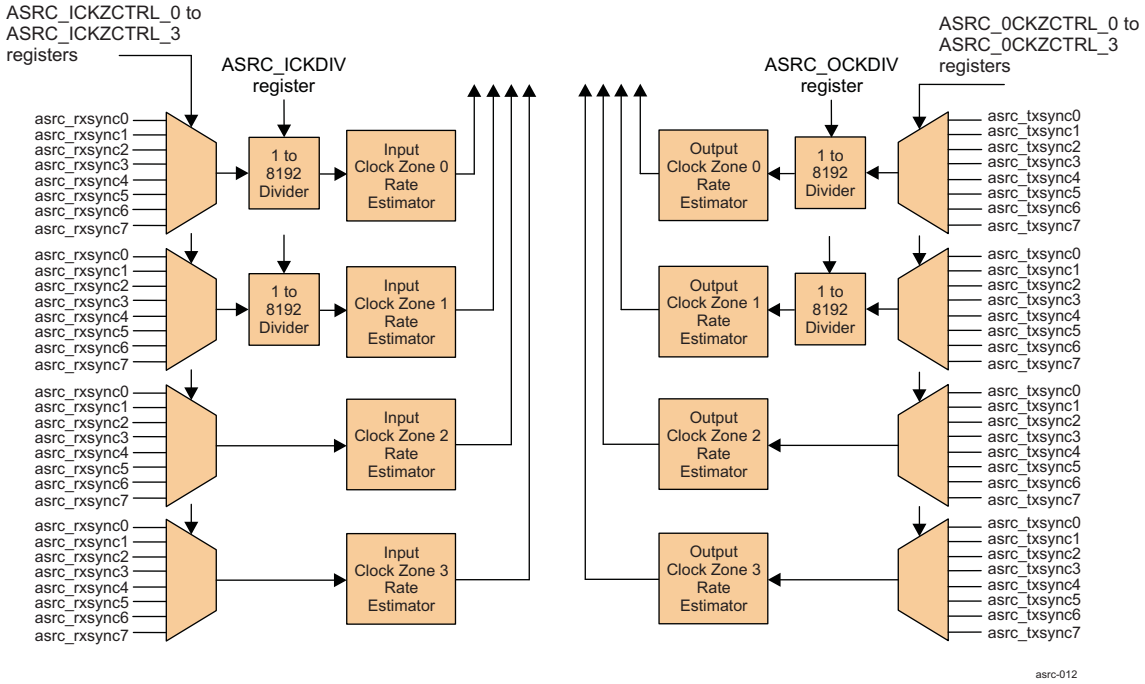
The ASRC_SYS_CLK is used for all filter processing in the module.

The ASRC_VBUS_CLK is used for VBUS interfaces.

There are four dividers present to divide the input audio sample rate clocks (ASRC_RXSYNC0-7 and ASRC_TXSYNC0-7). Two dividers are used for RX side and other two dividers are used for the TX side. The RX side dividers are working on the muxed ASRC_RXSYNC0-7 clocks. The TX side dividers are working on the muxed ASRC_TXSYNC0-7 clocks. The dividers are used for Clock Zone 0 and Clock Zone 1 only, on both RX and TX sides, and are controlled via ASRC_ICKDIV register (for RX side) and ASRC_OCKDIV register (for TX side).

The muxing of ASRC_RXSYNC0-7 clocks is controlled by [3-0] INPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT bit-field within ASRC_ICKZCTRL_0 to ASRC_ICKZCTRL_3 registers. The muxing of ASRC_TXSYNC0-7 clocks is controlled by [3-0] OUTPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT bit-field within ASRC_OCKZCNT_0 to ASRC_OCKZCNT_3 registers.

Figure 11-4. ASRC Input and Output Clock Zone Controls



11.1.3.5 ASRC Reset Configuration

The ASRC module is based on a single asynchronous reset that is synchronized to ASRC_SYS_CLK, ASRC_VBUS_CLK, and divider clocks (muxed version of TX and RX SYNC signals). The reset impacts configuration and processing information.

Additionally, each processing path enters a reset state when it is disabled, until the path is enabled with a new stream. This reset clears the data path and all memories associated with the path, when the new stream is started.

11.1.3.6 ASRC Power Management

Power management is accomplished using a standard clock stop protocol interface. When ASRC module is instructed to disable clocks for the internal clock domain, the internal clock network is shut down. This applies to the ASRC_SYS_CLK and ASRC_VBUS_CLK

Before a clock stop request is asserted at ASRC input, SW needs to confirm that ASRC is fully idle. HW will not check internal states to verify ASRC is idle. HW does check that no VBUSP transactions are ongoing before acknowledging the clock stop request.

11.1.3.7 ASRC Interrupts and Data Transfer Model

The ASRC can generate interrupt signals whenever interrupt condition is satisfied. These signals are exported on ASRC module boundary and can be used to trigger DMA transactions. There is a dedicated interrupt signal for audio samples write and for audio samples read, respectively.

All channels share common interrupt signals at the ASRC module boundary: infifo_intr and outfifo_intr, for write and read respectively. All groups also share common interrupt signals at the ASRC module boundary: ingrp_intr and outgrp_intr, for write and read respectively.

- In group mode, where more than one channels are part of one particular group, ingrp_intr and outgrp_intr need to be used, and infifo_intr and outfifo_intr need to be disabled accordingly.
- In stream mode, where a channel is working independently, infifo_intr and outfifo_intr need to be used.

For more details on interrupt descriptions, refer to Table 11-8. Software is aware of the configuration of each channel, whether it is a part of stream mode or group mode, and corresponding interrupts need to be disabled. If a channel is part of any group, then infifo_intr and outfifo_intr for that particular channel need to be disabled.

Table 11-8. ASRC Interrupts

Interrupt Event Name	Status Register	Set Register	Clear Register	Description
INFIFO_INTR	ASRC_IFIRQENSTS	ASRC_IFIRQENSET	ASRC_IFIRQENCLR	Interrupt indicating that one of the input FIFOs has enough space below the configured threshold.
OUTFIFO_INTR	ASRC_OFIRQENSTS	ASRC_OFIRQENSET	ASRC_OFIRQENCLR	Interrupt indicating that one of output FIFOs has enough data above the configured threshold.
INGROUP_INTR	ASRC_IGIRQENSTS	ASRC_IGIRQENSET	ASRC_IGIRQENCLR	Interrupt indicating that the one of the configured Group interrupts has all of the configured Input FIFOs below their respective threshold.
OUTGROUP_INTR	ASRC_OGIRQENSTS	ASRC_OGIRQENSET	ASRC_OGIRQENCLR	Interrupt indicating that one of the configured Group interrupts has all of the configured Output FIFOs above their respective threshold.
ERROR_INTR	ASRC_ERIRQENSTS	ASRC_ERIRQENSET	ASRC_ERIRQENCLR	Interrupt indicating one of the streams has received an error condition, FIFO overflow or underflow

11.1.3.7.1 Input FIFO Interrupts

Each channel has a dedicated input FIFO that is filled when an VBUS write (by a processor, EDMA, or DMA) occurs to that particular channel data register. The ASRC keeps tracks of the number of writes to the input FIFO and the number of reads that are sent into the processing path. The infifo interrupt will fire whenever the Input FIFO for the channel is below the threshold set in the ASRC_SRCFFCTRL_0[7:0] INFIFO_THRESHOLD register field. The interrupt will not be active until channel is enabled. Status for each FIFO can be checked in the ASRC_IFIRQENSTS status register. Once an INFIFO interrupt is fired, next interrupt will be generated only after INFIFO_THRESHOLD number of Audio RX Sync pulses has occured for that particular channel.

When the CPU is used to transfer data to ASRC, whenever an infifo_intr is triggered, SW needs to read the ASRC_IFIRQENSTS status register in order to determine which channels need to be serviced. Based on interrupt status register, software can trigger DMA to initiate transactions to channels. Data transfer will be in the same manner as described in Figure 11-5, *ASRC Stream Mode Audio Data Write for Channel N* with DMA triggered by software instead of infifo_evt event. After servicing the channel, SW needs to clear the interrupt for that particular channel.

11.1.3.7.2 Output FIFO Interrupts

Each channel has a dedicated output FIFO that is filled when the data path writes a sample to the output FIFO. The ASRC keeps tracks of the number of writes to the output FIFO and the number of reads that occur from the VBUS (by a processor, EDMA, or DMA). The outfifo interrupt will fire whenever the amount of available data matches the threshold set in the ASRC_SRCFFCTRL_0[23:16] OUTFIFO_THRESHOLD register field. Status for each FIFO can be checked in the ASRC_OFIRQENSTS status register. Once an OUTFIFO interrupt is fired, next interrupt will be generated only after OUTFIFO_THRESHOLD number of Audio RX Sync pulses has occured for that particular channel.

When the CPU is used to transfer data from ASRC, whenever an outfifo_intr is triggered, SW needs to read the ASRC_OFIRQENSTS status register and needs to determine which channel needs to be serviced. Based on interrupt status register software can trigger DMA to initiate transactions to channels. Data transfer will be in the same manner as described in Figure 11-6, *ASRC Stream Mode Audio Data Read for Channel N* with DMA triggered by software instead of outfifo_evt event. After servicing the channel SW needs to clear the interrupt for that particular channel.

11.1.3.7.3 Group Interrupts

The group interrupt is used to allow multiple stream DMA events to be tied together. That is, multiple channel inputs and outputs to be managed using a single DMA. A group is configured by writing to either the ASRC_IGRPSEL_0 to ASRC_IGRPSEL_3 registers for input groups, or the ASRC_OGRPSEL_0 to ASRC_OGRPSEL_3 registers for output groups. In the ASRC_IGRPSEL and ASRC_OGRPSEL registers there is a bit field for each channel. The group is determined by all the channels that have a 1 in them. When all of the selected streams in the input or output group are above the threshold, the corresponding group interrupt will fire. Once an ingrp_intr interrupt is fired, next interrupt will be generated only after INFIFO_THRESHOLD number of Audio RX Sync pulses has occured for all the channels of that group. Once an outgrp_intr interrupt is fired, next interrupt will be generated only after OUTFIFO_THRESHOLD number of Audio RX Sync pulses has occured for all the channels of that group.

When the CPU is used to transfer data to ASRC, whenever an ingrp_intr is triggered, SW needs to read the ASRC_IGIRQENSTS status register and needs to determine which group channels needs to be serviced. Based on interrupt status register, software can trigger DMA to initiate transactions to channels of that particular group. Data transfer will be in the same manner as described in Figure 11-7, *ASRC Group Mode Audio Data Write for Channels of Group N* with DMA triggered by software instead of ingrp_evt event. After servicing the channel, SW needs to clear the interrupt for that particular group.

When the CPU is used to transfer data from ASRC, whenever there is outgrp_intr is triggered, SW needs to read the ASRC_OGIRQENSTS status register and needs to determine which group channels needs to be serviced. Based on interrupt status register, software can trigger DMA to initiate transactions to channels of that particular group. Data transfer will be in the same manner as described in Figure 11-8, *ASRC Group Mode Audio Data Read from Channels of Group N* with DMA triggered by software instead of outgrp_evt event. After servicing the channel, SW needs to clear the interrupt for that particular group.

11.1.3.7.4 Error Interrupts

The error interrupt is used to signal a FIFO error condition. Below is a list of events that will cause the error interrupt to fire:

- Input FIFO overflow / underflow
- Output FIFO overflow / underflow

Overflow and underflow status for each SRC channel can be read through the ASRC_SRCFFCTRL_0 register. Clearing ERROR_INTR also clears the overflow/underflow status for that channel.

11.1.3.8 ASRC DMA Events and Data Transfer Model

The ASRC can be configured to generate individual EDMA events to initiate EDMA transfers for fillimg the input FIFOs in each operating mode, Group or Stream. Similarly, the ASRC is able to generate individual EDMA events to initiate EDMA transfers to empty the output FIFOs for each operating mode. Each event is triggered when the specific Group or Stream mode FIFO threshold condition has been met. The event generation is enabled on a group and stream basis. There are 4 group input events and 4 group output events. There are 16 stream input events and 8 stream output events (one for each input and output channel). The group and stream mode events are enabled when setting up the Stream or Group ASRC configuration

ASRC has individual event signals that generate pulse on ASRC external ports to trigger a DMA transaction. There are dedicated DMA events for audio samples write and read, respectively. Each channel/stream and each group has separate DMA event at the ASRC module boundary. The total number of events is determined by the number of channels and the number of groups. These events can be used to transfer the fixed block of data to ASRC.

- In group mode, where more than one channels are part of one particular group, ingrp_evt and

outgrp_evt for that group need to be used, and infifo_evt and outfifo_evt need to be ignored.

- In stream mode, where channel is working independently, infifo_evt and outfifo_evt for that channel need to be used.

Table 11-9 describes the DMA events, and provides mapping to ASRC boundary signals covered in Table 11-3494.

Table 11-9. ASRC DMA Events

DMA Event	Mapped to ASRC Boundary Signal	Number of Events	Description
infifo_evt[15:0]	ASRC_STREAM_IN[15:0]	16	The event will send out a pulse when the threshold for the input FIFO has fallen below the configured level. Once an INFIFO event is fired, next event will be generated only after ASRC_SRCFFCTRL_0[7:0] INFIFO_THRESHOLD number of Audio RX Sync pulses for that particular channel.
outfifo_evt[15:0]	ASRC_STREAM_OUT[15:0]	16	The event will send out a pulse when the threshold for the output FIFO has reached the configured level. Once an OUTFIFO event is fired, next event will be generated only after ASRC_SRCFFCTRL_0[23:16] OUTFIFO_THRESHOLD number of Audio RX Sync pulses for that particular channel.
ingrp_evt[3:0]	ASRC_GROUP_IN[3:0]	4	The event will send out a pulse when all input FIFOs in the configured group has fallen below their configured level. Once an INGROUP event is fired, next event will be generated only after INFIFO_THRESHOLD number of Audio RX Sync pulses for all the channels of that group.
outgrp_evt[3:0]	ASRC_GROUP_OUT[3:0]	4	The event will send out a pulse when all output FIFOs in the configured group has reached their configured level. Once an OUTGROUP event is fired, next event will be generated only after OUTFIFO_THRESHOLD number of Audio RX Sync pulses for all the channels of that group.

11.1.3.8.1 Stream Mode DMA Events

In stream mode, data transfer for channel number N is shown in Figure 11-5 and Figure 11-6.

Figure 11-5. ASRC Stream Mode Audio Data Write for Channel N

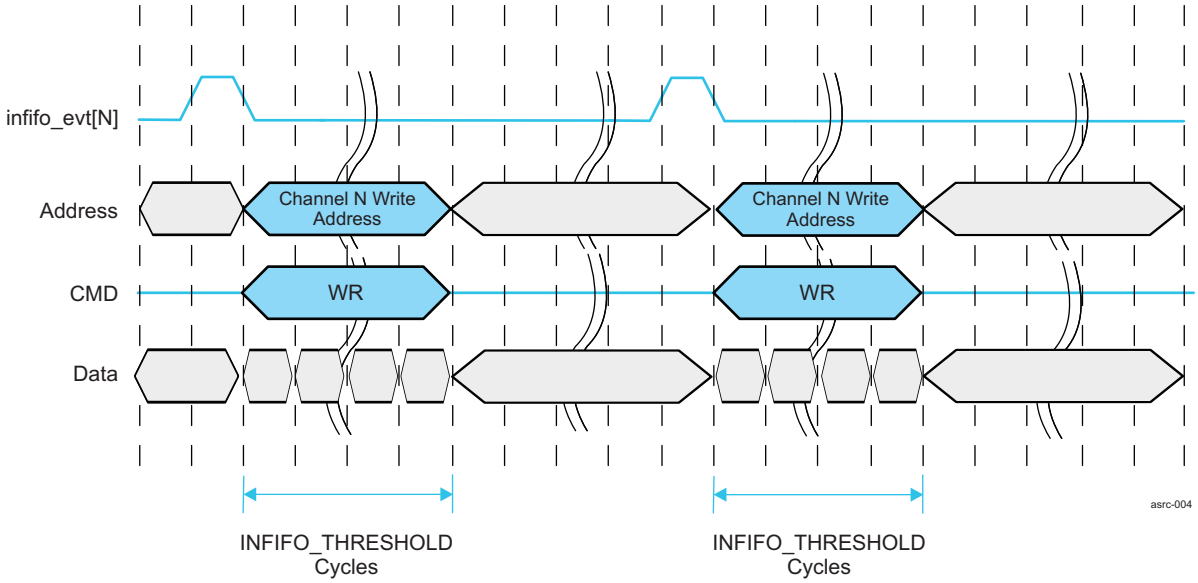


Figure 11-6. ASRC Stream Mode Audio Data Read for Channel N

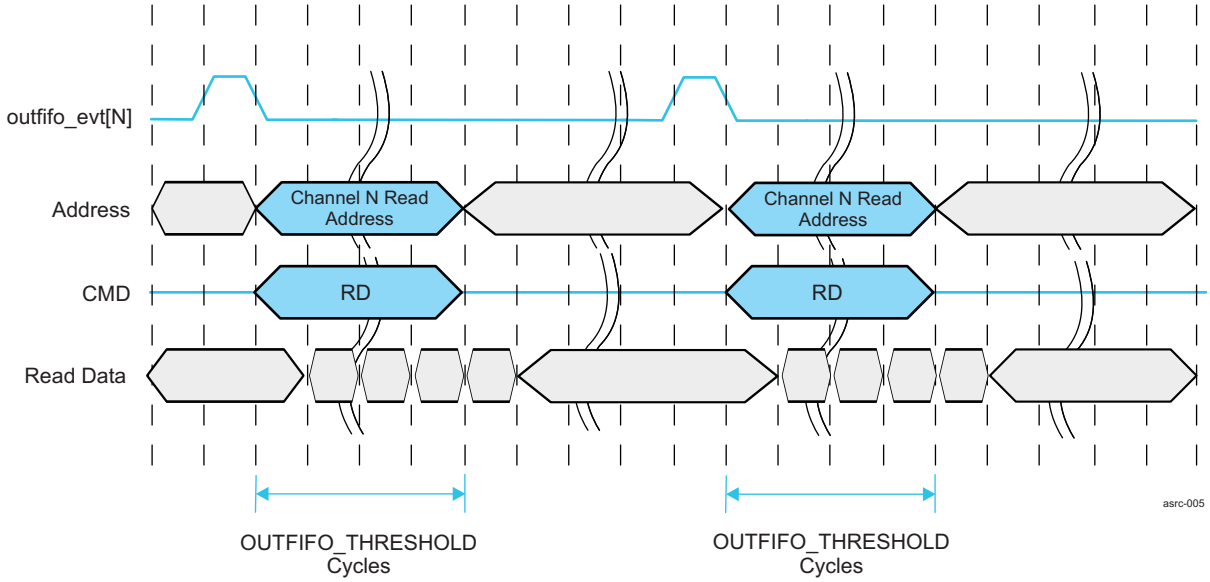

It is not required for the device EDMA to service an event in one cycle, as it may be busy with other transfers also. If EDMA channel is shared between more than one channels, then it can queue the events and service whenever it has the resources available.

For each infifo_evt[N], that is infifo event for channel N, ASRC ensures that there is space available for at least INFIFO_THRESHOLD number of samples in the INFIFO of that channel. This INFIFO_THRESHOLD value can be set in ASRC_SRCFFCTRL_0[7:0] INFIFO_THRESHOLD register bitfield of that channel.

For each outfifo_evt[N], that is outfifo event for channel N, ASRC ensures that there is at least OUTFIFO_THRESHOLD number of samples available in OUTFIFO of that channel. This OUTFIFO_THRESHOLD value can be set in ASRC_SRCFFCTRL_0[23:16] OUTFIFO_THRESHOLD register bitfield of that channel.

11.1.3.8.2 Group Mode DMA Events

In group mode data transfer for all the channels of group number N is shown in Figure 11-7 and Figure 11-8.

Figure 11-7. ASRC Group Mode Audio Data Write for Channels of Group N

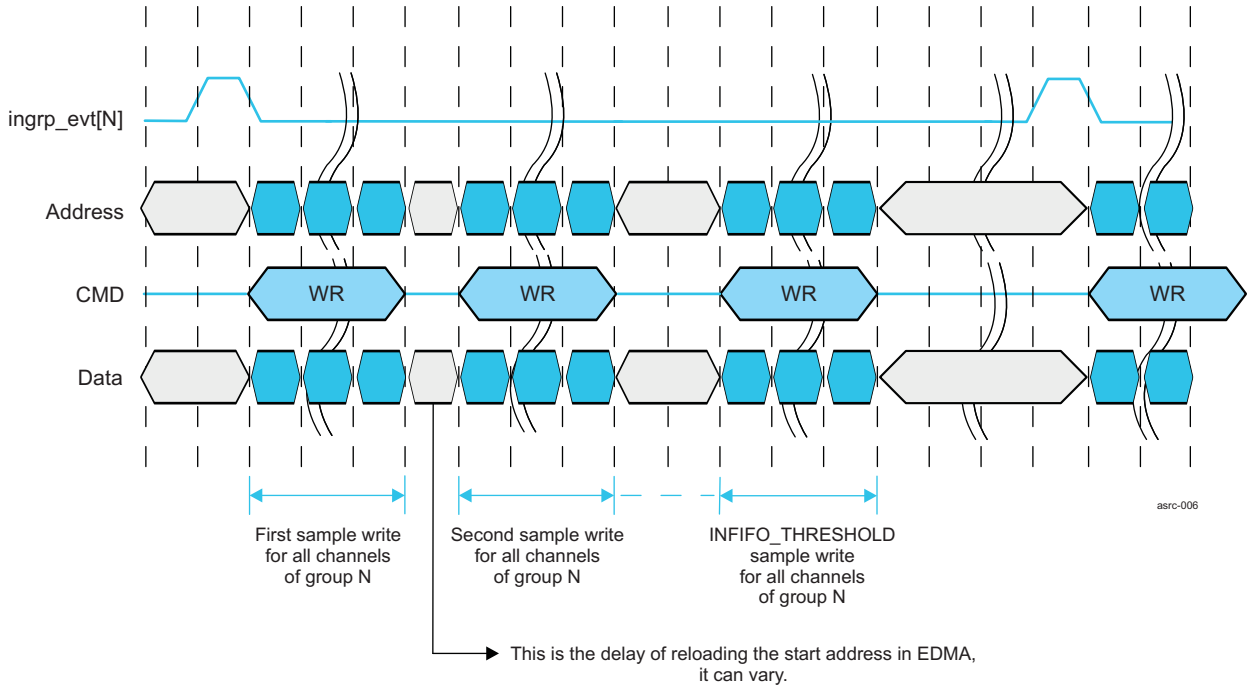

Figure 11-8. ASRC Group Mode Audio Data Read from Channels of Group N

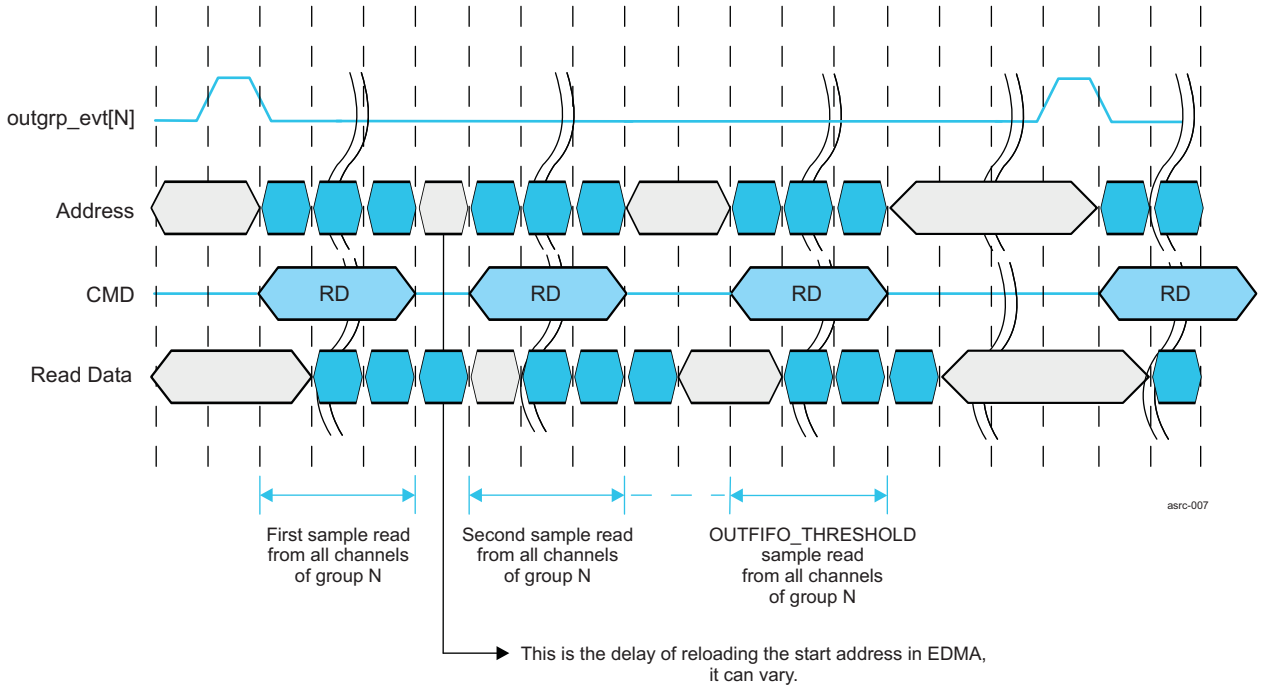


It is not required for the device EDMA to service an event in one cycle as it may be busy with other transfers also. If EDMA channel is shared between more than one channels or groups, then it can queue the events and service whenever it has the resources available.

For each ingrp_evt[N], that is infifo event for group N, ASRC ensures that there is space available for at least INFIFO_THRESHOLD number of samples in the INFIFO of all the channels of that group. This INFIFO_THRESHOLD value can be set in ASRC_GFFCTRL_0[7:0] INFIFO_THRESHOLD register bitfield of that particular group. In this mode one sample is written in each of the channels of that group. The EDMA will update the adress to follow the channel number sequence of that group. This step is repeated INFIFO_THRESHOLD number of times to fill in INFIFO_THRESHOLD number of samples in each channel of that particular group.

For each outgrp_evt[N], that is outfifo event for group N, ASRC ensures that there is at least OUTFIFO_THRESHOLD number of samples available in OUTFIFO of all the channels of that group. This OUTFIFO_THRESHOLD value can be set in ASRC_GFFCTRL_0[23:16] OUTFIFO_THRESHOLD register bitfield of that particular group. In this mode one sample is read from all the channels of that group. The EDMA will update the address to follow the channel number sequence of that group. This step is repeated OUTFIFO_THRESHOLD number of times to drain OUTFIFO_THRESHOLD number of samples from each channel of that particular group.

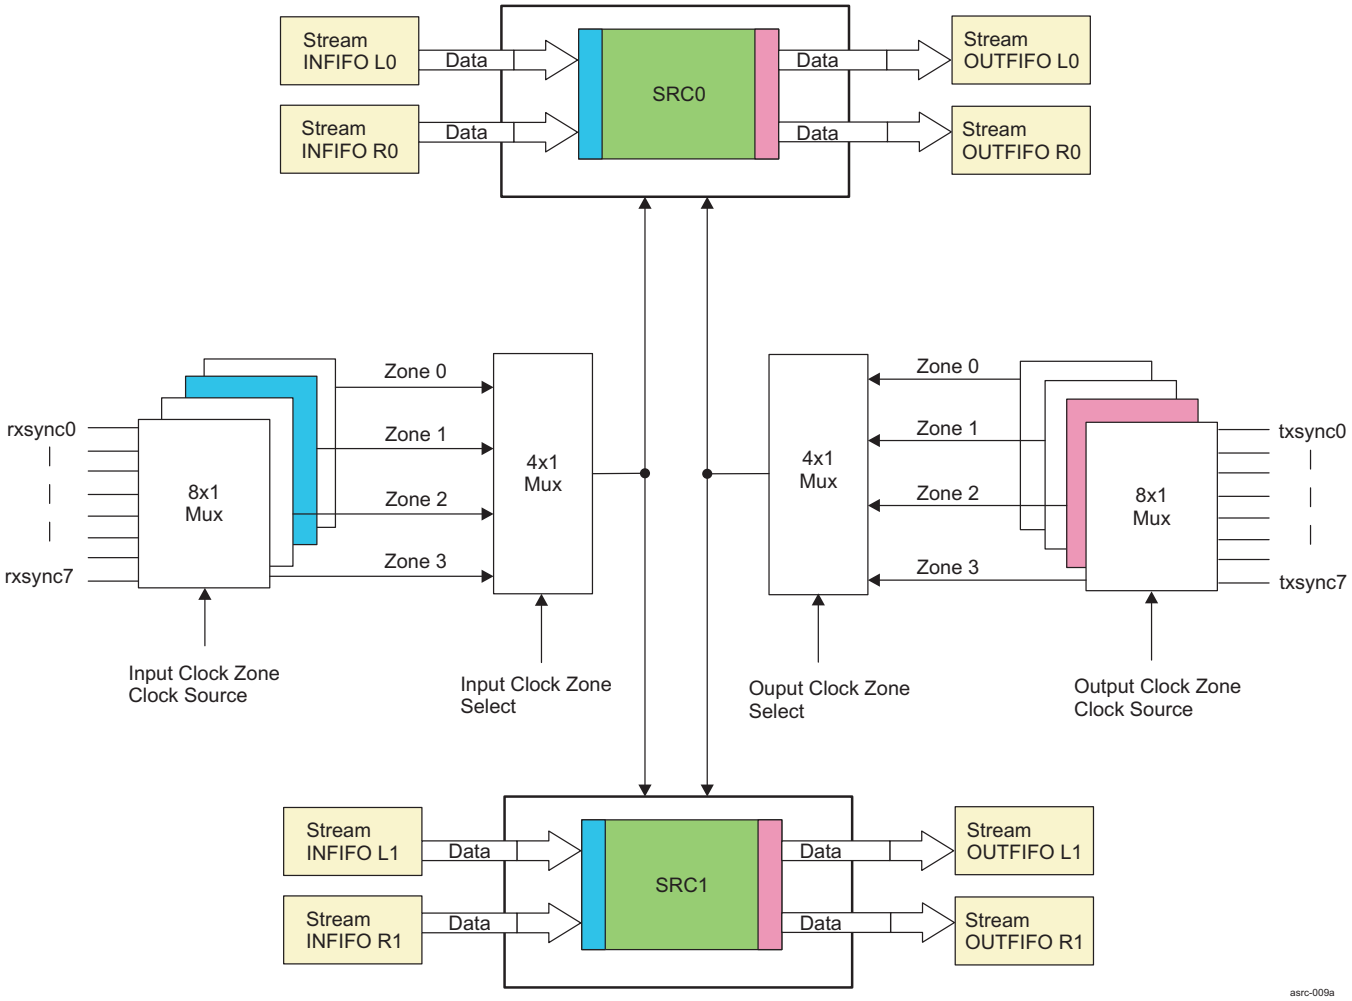
11.1.3.9 ASRC Group Mode Configuration

NOTE: Interleaving of audio data must be handled outside the ASRC module.

The ASRC supports 4 input and 4 output groups that can be configured. Each group can be composed of 1 to 16 channels. A stereo pair can only be assigned to one group. In group mode, a single INFIFO interrupt/event is triggered based upon status of Input FIFO status of all channels of the group. Similarly, a single OUTFIFO interrupt/event is triggered based upon status of Output FIFO status of all channels of the group. Each group can be controlled by separate EDMA.

Figure 11-9 shows and an example for group mode where all four input channels of SRC0 and SRC1 are part of input Clock Zone 1 and all four output channels are part of output Clock Zone 2.

Figure 11-9. ASRC Group Mode Example



The basic functionality of the ASRC follows the steps below for setting up a single group. For more details on programming model, refer to Section 11.1.3.9.1, *Group Mode Configuration Sequence*.

- Configure the Input and Output Clock Zone inputs to use one of the 8 possible input and output clock sources.
- Set the input and output channels.
- Configure INFIFO threshold and OUTFIFO threshold values.
- Configure Input and Output Word Length.
- Configure other conversion settings like de-emphasis, group delay, direct down conversion, output dither enable, and mute.
- Enable the conversion by enabling events or interrupts.

At this point, the ASRC automation starts. The ASRC clock zone input and output rate estimators will start estimation of the input and output sample rates. Once the estimation has settled, the ASRC will initiate input and output event or interrupt generation based upon the input and output FIFO status.

11.1.3.9.1 Group Mode Configuration Sequence

1. Configure Clock Zones:
   a. Program Input Clock Zone Clock Source and Loop Setup:
      - ASRC_ICKZCTRL_0[3-0] INPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT register bitfield
      - ASRC_ICKZCTRL_0[16-9] LOOP_SETUP register bitfield

b. Program Output Clock Zone Clock Source and Loop Setup
   - ASRC_OCKZCTRL_0[3-0] OUTPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT register bitfield
   - ASRC_OCKZCTRL_0[16-9] LOOP_SETUP register bitfield

2. Program Clock Zone 0 divider and Clock Zone 1 divider values (optional step, required if ASRC module dividers are being used):
   - ASRC_ICKDIV[13-0] CLOCK_ZONE0_DIVIDE
   - ASRC_ICKDIV[29-16] CLOCK_ZONE1_DIVIDE
   - ASRC_OCKDIV[13-0] CLOCK_ZONE0_DIVIDE
   - ASRC_OCKDIV[29-16] CLOCK_ZONE1_DIVIDE
3. Program Clock Zone 0 divider enable and Clock Zone 1 divider enable (optional step, required if ASRC module dividers are being used):
   - ASRC_ICKDIV[14] CLOCK_ZONE0_DIVIDE_EN
   - ASRC_ICKDIV[30] CLOCK_ZONE1_DIVIDE_EN
   - ASRC_OCKDIV[14] CLOCK_ZONE0_DIVIDE_EN
   - ASRC_OCKDIV[30] CLOCK_ZONE1_DIVIDE_EN
4. Program Input Group and Output Group Select Registers (select channels):
   - ASRC_IGRPSEL_0 to ASRC_IGRPSEL_3[...] CHANNEL_#_GROUP_ENABLE
   - ASRC_OGRPSEL_0 to ASRC_OGRPSEL_3[...] CHANNEL_#_GROUP_ENABLE
5. Program INFIFO threshold and OUTFIFO threshold values:
   - ASRC_GFFCTRL_0[7-0] INFIFO_THRESHOLD
   - ASRC_GFFCTRL_0[23-16] OUTFIFO_THRESHOLD
6. Program Output Word Length, Group Delay, De-emphasis Mode, Attenuation, Direct Down Sample, Mute, Dither Enable, Output Clock Zone Select and Input Clock Zone Select:
   - ASRC_GSRCCTRL_0[29-28] OUTPUT_WORD_LENGTH
   - ASRC_GSRCCTRL_0[27-26] GROUP_DELAY
   - ASRC_GSRCCTRL_0[25-24] DE_EMPHASIS_MODE
   - ASRC_GSRCCTRL_0[23-16] ATTENUATION
   - ASRC_GSRCCTRL_0[10] DIRECT_DOWN_SAMPLE
   - ASRC_GSRCCTRL_0[9] MUTE
   - ASRC_GSRCCTRL_0[8] DITHER_ENABLE
   - ASRC_GSRCCTRL_0[7-6] INPUT_WORD_LENGTH
   - ASRC_GSRCCTRL_0[5-3] OUTPUT_CLOCK_ZONE_SELECT
   - ASRC_GSRCCTRL_0[2-0] INPUT_CLOCK_ZONE_SELECT
7. Program Data Alignment Disable:
   - ASRC_SYSCONFIG[1] DATA_FORMAT_DISABLE
8. Program Channel Enable (channel enable will be effective, only if that particular channel is the part of a that particular group):
   - ASRC_GSRCCTRL_0[31-30] CHANNEL_ENABLE
9. Program DMA transfers:
   - Once the INGROUP_EVT event is triggered, a maximum block of ASRC_GFFCTRL_0[7-0] INFIFO_THRESHOLD audio samples can be written to the data register of each channel of that group. Once the OUTGROUP_EVT event is triggered, ASRC_GFFCTRL_0[23-16] OUTFIFO_THRESHOLD samples can be read from OUTPUT FIFO DATA registers (ASRC_GOFDATAL_0 and ASRC_GOFDATAR_0) of channel in the group. Events will not be triggered until Input Clock Recovery Loop and Output Clock Recovery Loop are settled. For this SW must check the status of bit [8] SETTLE in ASRC_ICKZCTRL_0 and ASRC_OCKZCTRL_0 registers, respectively.

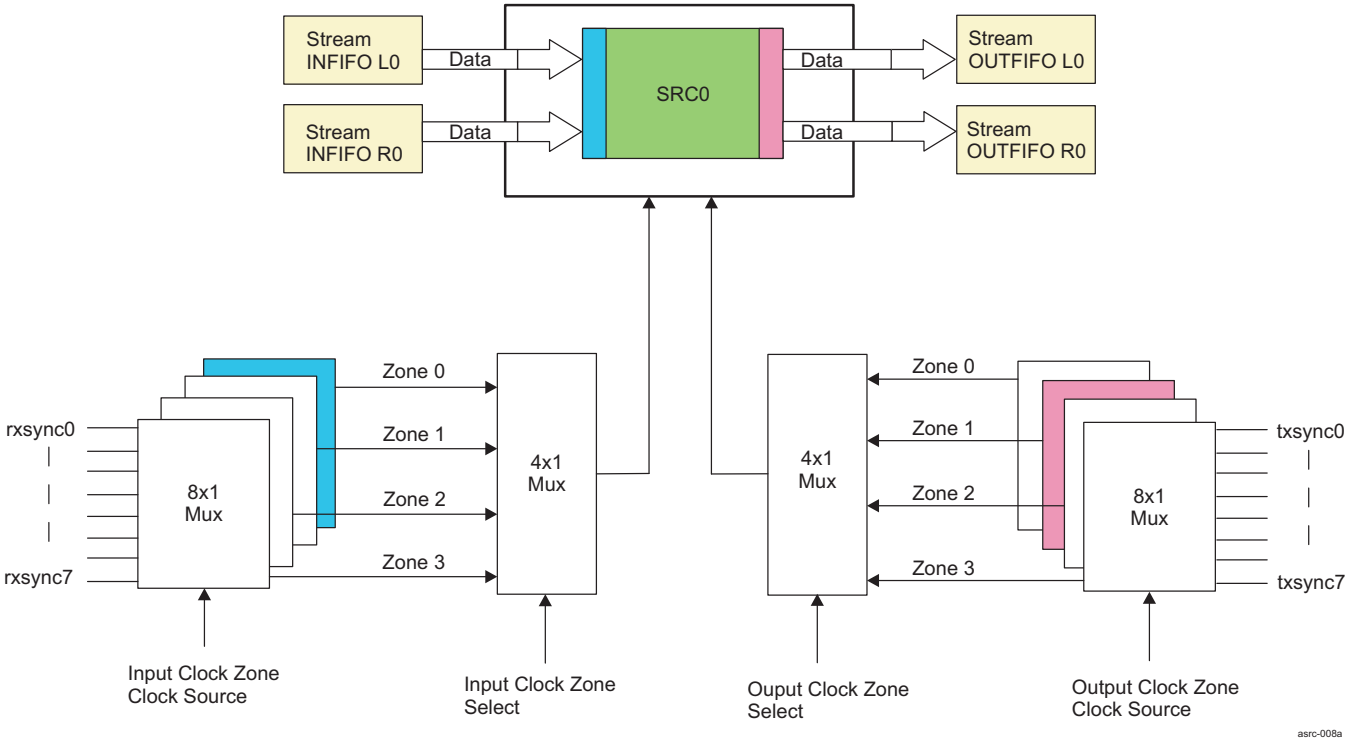
11.1.3.10 ASRC Stream Mode Configuration

NOTE: Interleaving of audio data must be handled outside the ASRC module.

In stream mode each stereo stream / channel can be controlled by a separate EDMA. Both channels of one SRC must be in same clock zone. User can process the audio samples by putting the sample in appropriate channel data register. In stream mode the individual channel FIFO interrupt / interrupts are not consolidated. In stream mode, a stereo pair is individually assigned to an input and output clock zone. A stereo pair is assigned even if only one channel is active. A stereo pair can only be part of one clock zone.

Figure 11-10 shows and an example for stream mode where the two input channels of SRC0 (which are part of input Clock Zone 0) are moved to output Clock Zone 1.

Figure 11-10. ASRC Stream Mode Example



The basic functionality of the ASRC in stream mode follows the steps below for setting up a single channel. For more details on programming model, refer to Section 11.1.3.10.1, *Stream Mode Configuration Sequence*.

- Configure the Input and Output Clock Zone inputs to use one of the 8 possible input and output clock sources.
- Set the input and output channels.
- Configure INFIFO threshold and OUTFIFO threshold values.
- Configure Input and Output Word Length.
- Configure other conversion settings like de-emphasis, group delay, direct down conversion, output dither enable, and mute.
- Enable the conversion by enabling events or interrupts.

At this point, the ASRC automation starts. The ASRC clock zone input and output rate estimators will start estimation of the input and output sample rates. Once the estimation has settled, the ASRC will initiate input and output event or interrupt generation based upon the input and output FIFO status.

11.1.3.10.1 Stream Mode Configuration Sequence

1. Configure Clock Zones:
   a. Program Input Clock Zone Clock Source and Loop Setup:
      - ASRC_ICKZCTRL_0[3-0] INPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT register bitfield
      - ASRC_ICKZCTRL_0[16-9] LOOP_SETUP register bitfield
   b. Program Output Clock Zone Clock Source and Loop Setup
      - ASRC_OCKZCTRL_0[3-0] OUTPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT register bitfield
      - ASRC_OCKZCTRL_0[16-9] LOOP_SETUP register bitfield
2. Program Clock Zone 0 divider and Clock Zone 1 divider values (optional step, required if ASRC module dividers are being used):
   - ASRC_ICKDIV[13-0] CLOCK_ZONE0_DIVIDE
   - ASRC_ICKDIV[29-16] CLOCK_ZONE1_DIVIDE
   - ASRC_OCKDIV[13-0] CLOCK_ZONE0_DIVIDE
   - ASRC_OCKDIV[29-16] CLOCK_ZONE1_DIVIDE
3. Program Clock Zone 0 divider enable and Clock Zone 1 divider enable (optional step, required if ASRC module dividers are being used):
   - ASRC_ICKDIV[14] CLOCK_ZONE0_DIVIDE_EN
   - ASRC_ICKDIV[30] CLOCK_ZONE1_DIVIDE_EN
   - ASRC_OCKDIV[14] CLOCK_ZONE0_DIVIDE_EN
   - ASRC_OCKDIV[30] CLOCK_ZONE1_DIVIDE_EN
4. Program INFIFO threshold and OUTFIFO threshold values:
   - ASRC_SRCFFCTRL_0[7-0] INFIFO_THRESHOLD
   - ASRC_SRCFFCTRL_0[23-16] OUTFIFO_THRESHOLD
5. Program Output Word Length, Group Delay, De-emphasis Mode, Attenuation, Direct Down Sample, Mute, Dither Enable, Output Clock Zone Select and Input Clock Zone Select:
   - ASRC_SRCCTRL_0[29-28] OUTPUT_WORD_LENGTH
   - ASRC_SRCCTRL_0[27-26] GROUP_DELAY
   - ASRC_SRCCTRL_0[25-24] DE_EMPHASIS_MODE
   - ASRC_SRCCTRL_0[23-16] ATTENUATION
   - ASRC_SRCCTRL_0[10] DIRECT_DOWN_SAMPLE
   - ASRC_SRCCTRL_0[9] MUTE
   - ASRC_SRCCTRL_0[8] DITHER_ENABLE
   - ASRC_SRCCTRL_0[7-6] INPUT_WORD_LENGTH
   - ASRC_SRCCTRL_0[5-3] OUTPUT_CLOCK_ZONE_SELECT
   - ASRC_SRCCTRL_0[2-0] INPUT_CLOCK_ZONE_SELECT
6. Program Data Alignment Disable (optional step, if desired):
   - ASRC_SYSCONFIG[1] DATA_FORMAT_DISABLE
7. Program Channel Enable:
   - ASRC_SRCCTRL_0[31-30] CHANNEL_ENABLE
8. Program DMA transfers:
   - Once the INFIFO_EVT event is triggered, a maximum block of ASRC_SRCFFCTRL_0[7-0] INFIFO_THRESHOLD audio samples can be written to the data register. If OUTFIFO_EVT event is triggered, then ASRC_SRCFFCTRL_0[23-16] OUTFIFO_THRESHOLD samples can be read from output data register. Events will not be triggered until Input Clock Recovery Loop and Output Clock Recovery Loop are settled. For this SW must check the status of [8] SETTLE bit in ASRC_ICKZCTRL_0 and ASRC_OCKZCTRL_0 registers, respectively.

The typical time that for an ASRC clock rate estimator to settle is proportionate to the clock rate that is input to the rate estimator. The typical setting time in ms is approximately 8850 / sample rate in kHz. A 192 kHz clock will typically settle in 46 ms.

11.1.3.11 ASRC Programming Ranges and Restrictions

The following programming ranges and restrictions are valid:

- The programmed values of [7-0] INFIFO_THRESHOLD and [23-16] OUTFIFO_THRESHOLD register bitfields should be within 1-32 range. This applies to ASRC_SRCFFCTRL_0 and ASRC_GFFCTRL_0 registers.
- Only the following settings for [16-9] LOOP_SETUP bit-field are allowed: 8'h00, 8'h40, 8'h80, 8'hC0. This applies to ASRC_ICKZCTRL_0 and ASRC_OCKZCTRL_0 registers.
- ASRC_IGRPSEL_0 to ASRC_IGRPSEL_3 and ASRC_OGRPSEL_0 to ASRC_OGRPSEL_3 registers should have same channels enabled for group number 0 to 3.

11.1.3.12 ASRC Registers Shadowing

ASRC module has no shadowing of registers. A stream must be disabled and a new stream enabled to change an active stream.

11.1.4 ASRC Registers

11.1.4.1 ASRC Configuration and Status Registers

Table 11-11 lists the memory-mapped registers for the ASRC configuration and status. All register address offsets not listed in Table 11-11 should be considered as reserved locations and corresponding register content should not be modified.

Table 11-10. ASRC Configuration and Status Instances

Instance	Physical Address
ASRC_0_CFG	021E 0000h

Table 11-11. ASRC Configuration and Status Registers

Table 11-22. ASRC_IFIRQRAW Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Always read as 0
15	CHANNEL_15_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 15 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
14	CHANNEL_14_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 14 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
13	CHANNEL_13_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 13 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
12	CHANNEL_12_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 12 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
11	CHANNEL_11_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 11 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
10	CHANNEL_10_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 10 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.

Table 11-22. ASRC_IFIRQRAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CHANNEL_9_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 9 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
8	CHANNEL_8_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 8 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
7	CHANNEL_7_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 7 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
6	CHANNEL_6_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 6 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
5	CHANNEL_5_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 5 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
4	CHANNEL_4_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 4 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
3	CHANNEL_3_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 3 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
2	CHANNEL_2_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 2 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
1	CHANNEL_1_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 1 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.
0	CHANNEL_0_INPUT_FIFO_THRESHOLD_RAW	R/W1S	0h	Channel 0 Input FIFO Threshold Interrupt. Read indicates raw status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will set status. Writing 0 has no effect.

Table 11-25. ASRC_IFIRQENSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Always read as 0
15	CHANNEL_15_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 15 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
14	CHANNEL_14_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 14 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
13	CHANNEL_13_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 13 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
12	CHANNEL_12_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 12 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
11	CHANNEL_11_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 11 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
10	CHANNEL_10_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 10 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect

Table 11-25. ASRC_IFIRQENSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CHANNEL_9_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 9 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
8	CHANNEL_8_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 8 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
7	CHANNEL_7_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 7 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
6	CHANNEL_6_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 6 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
5	CHANNEL_5_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 5 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
4	CHANNEL_4_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 4 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
3	CHANNEL_3_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 3 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
2	CHANNEL_2_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 2 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
1	CHANNEL_1_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 1 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect
0	CHANNEL_0_INPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 0 Input FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Input FIFO for this Channel is below the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect

Table 11-37. ASRC_OFIRQENSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Always read as 0
15	CHANNEL_15_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 15 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
14	CHANNEL_14_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 14 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
13	CHANNEL_13_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 13 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
12	CHANNEL_12_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 12 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
11	CHANNEL_11_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 11 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
10	CHANNEL_10_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 10 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.

Table 11-37. ASRC_OFIRQENSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CHANNEL_9_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 9 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
8	CHANNEL_8_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 8 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
7	CHANNEL_7_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 7 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
6	CHANNEL_6_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 6 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
5	CHANNEL_5_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 5 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
4	CHANNEL_4_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 4 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
3	CHANNEL_3_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 3 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
2	CHANNEL_2_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 2 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
1	CHANNEL_1_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 1 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.
0	CHANNEL_0_OUTPUT_FIFO_THRESHOLD_ENABLED	R/W1C	0h	Channel 0 Output FIFO Threshold Interrupt. Read indicates enabled status. This fires when the Output FIFO for this Channel is above the level set in the Configuration register. 0 = inactive. 1 = active. Writing 1 will clear status. Writing 0 has no effect.

Table 11-97. ASRC_SRCCTRL_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	CHANNEL_ENABLE	R/W	0h	Setting this enables the Channels of SRC0. The output FIFOs for the stream must be enabled before the input FIFOs. 00: No channel enabled 01: Only Right Channel enabled 10: Only Left Channel enabled 11: Both channels enabled Clearing this register will clear the data path.
29-28	OUTPUT_WORD_LENGTH	R/W	0h	These bits select the word length for the SRC0 output data. The word length reduction is performed by utilizing triangular PDF dithering. 0: 24 Bits (Default) 1: 20 Bits 2: 18 Bits 3: 16 Bits
27-26	GROUP_DELAY	R/W	0h	These bits select the interpolation filter group delay by configuring the number of samples which are pre-buffered prior to the re-sampler function. 0: 64 Samples (Default) 1: 32 Samples 2: 16 Samples 3: 8 Samples
25-24	DE_EMPHASIS_MODE	R/W	0h	These bits are utilized to enable or disable the digital de-emphasis filter manually. The de-emphasis filter is intended to process 50/15 s pre-emphasized audio material at the following input sampling rates. 0: De-Emphasis Disabled (Default) 1: De-Emphasis Enabled for fS = 48kHz 2: De-Emphasis Enabled for fS = 44.1kHz 3: De-Emphasis Enabled for fS = 32kHz
23-16	ATTENUATION	R/W	0h	These bits are utilized to configure the SRC digital output attenuation for the stream Output Attenuation (dB) = N 0.5, where N = Attenuation[7:0]DEC.
15-11	RESERVED	R	0h	Always read as 0
10	DIRECT_DOWN_SAMPLE	R/W	0h	This bit selects the mode of the decimation function, either true decimation filter or direct down-sampling without filtering. DDN Decimation Function 0 Decimation Filter (Default) 1 Direct Down Sampling Note: Direct down-sampling should only be used when the output sampling rate is higher than the input sampling rate. When the output sampling rate is equal to or lower than the input sampling rate, the Decimation Filter must be used in order to avoid aliasing.

Table 11-97. ASRC_SRCCTRL_0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	MUTE	R/W	0h	This bit enables or disables the SRC output soft mute function. 0: Mute Disabled (Default) 1: Mute enabled; output data set to all zeros.
8	DITHER_ENABLE	R/W	0h	This bit enables or disables the SRC filter s dithering. 0: Dithering Disabled (Default) 1: Dithering enabled
7-6	INPUT_WORD_LENGTH	R/W	0h	These bits select the word length for the SRC0 input data. 0: 24 Bits (Default) 1: 20 Bits 2: 18 Bits 3: 16 Bits
5-3	OUTPUT_CLOCK_ZONE_SELECT	R/W	0h	This selects the output clock zone for the stream0. It can select between the 4 external audio clock zones. Based on this number rate and stamp is passed to the Stream0 Sample rate converter from respective clock recovery loop. 00: This selects the Clock Recovery loop 0. 01: This selects the Clock Recovery loop 1. 10: This selects the Clock Recovery loop 2. 11: This selects the Clock Recovery loop 3. In this SoC other values are not valid.
2-0	INPUT_CLOCK_ZONE_SELECT	R/W	0h	This selects the input clock zone for the stream0. It can select between the 4 external audio clock zones. Based on this number rate and stamp is passed to the Stream0 Sample rate converter from respective clock recovery loop. 000: This selects the Clock Recovery loop 0. 001: This selects the Clock Recovery loop 1. 010: This selects the Clock Recovery loop 2. 011: This selects the Clock Recovery loop 3. In this SoC other values are not valid.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-160. ASRC_OCKZCTRL_0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Always read as 0
18	OVERRIDE_SETTLE_VALUE	R/W	0h	Value written to this field will be used as settle if override settle signal is set.
17	OVERRIDE_SETTLE	R/W	0h	This signal override the settle of output clock zone 0 clock recovery loop. 1'b1: value written to override settle value will be used. 1'b0: settle from clock recovery will be used.
16-9	LOOP_SETUP	R/W	0h	This is the setting for input clock recovery loop for zone 0 8 h00: Slow loop 8 h40: Medium1 loop 8 h80: Medium2 loop 8 hC0: Slow loop
8	SETTLE	R	0h	This signals sets to 1 when clock recovery loop is settled
7-4	LOOP_STATE	R	0h	Loop debug state
3-0	OUTPUT_CLOCK_ZONE_CLOCK_SOURCE_SELECT	R/W	0h	This selects the 8x1 and 2x1 mux structure for output clock zone 0. 1xxx: Clock comes from output clock gen 0 0000-0111: Selects txsync signal from 0-7

11.2 Controller Area Network Interface (DCAN)

This section describes the Controller Area Network (DCAN) module in the device.

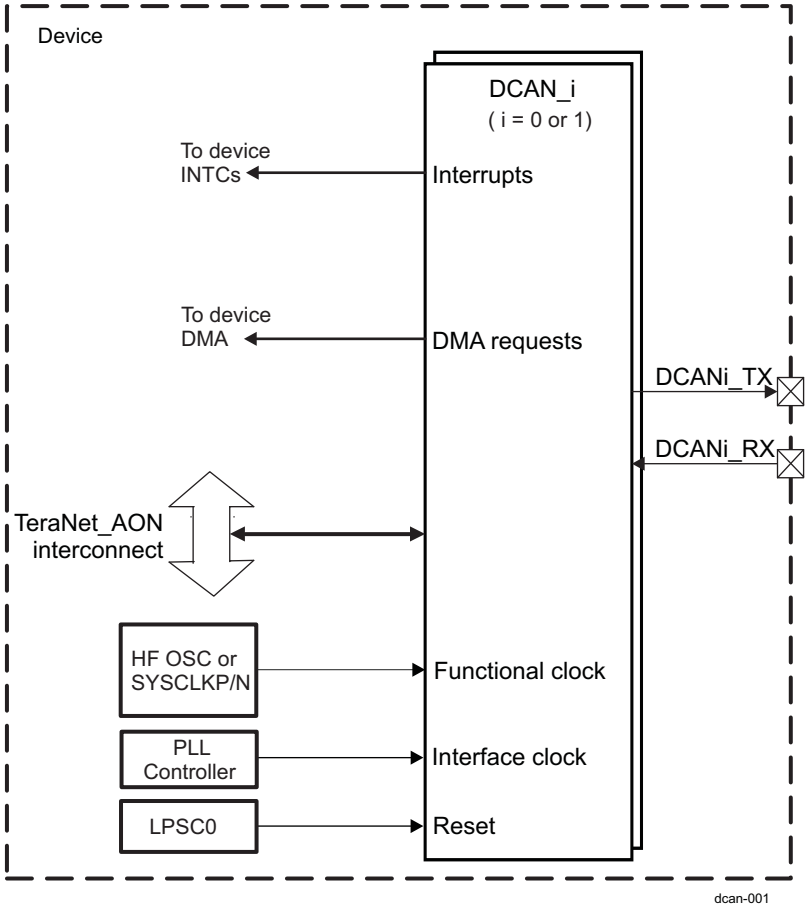
11.2.1 DCAN Overview

Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports two DCAN modules, referred to as DCAN_0 and DCAN_1, connecting to the CAN network through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification

Figure 11-73 shows the DCAN module highlights.

Figure 11-73. DCAN Overview



11.2.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation

- Software module reset
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM single error correction and double error detection mechanism (SECDED)
- Direct access to message RAM during test mode.
- Support for three interrupt lines: Level 0 and Level 1, and a separate ECC interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

11.2.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 11-74 shows an overview of a typical DCAN application.

Figure 11-74. DCAN Typical Application

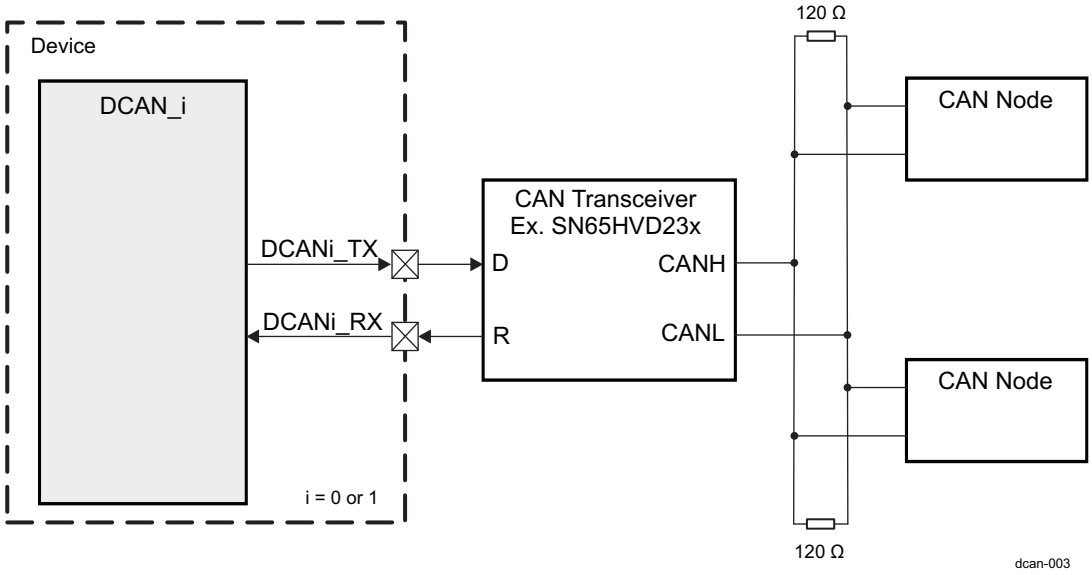


Table 11-202 describes the external signals of the DCAN module.

Table 11-202. DCAN I/O Description

Module Signal	Device Signal	I/O[1]	Description	Value at Reset
CAN_RX	DCANi_RX[2]	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	DCANi_TX[2]	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output
(2) i = 0 to 1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The BOOT_CFG registers assign the specific function to the device pads. For more information on BOOT_CFG settings, see Section 5.1.3.1.1, *Pad Configuration Registers* in Section 5.1, *Control Module (BOOT_CFG)*.

11.2.2.1 CAN Network Basics

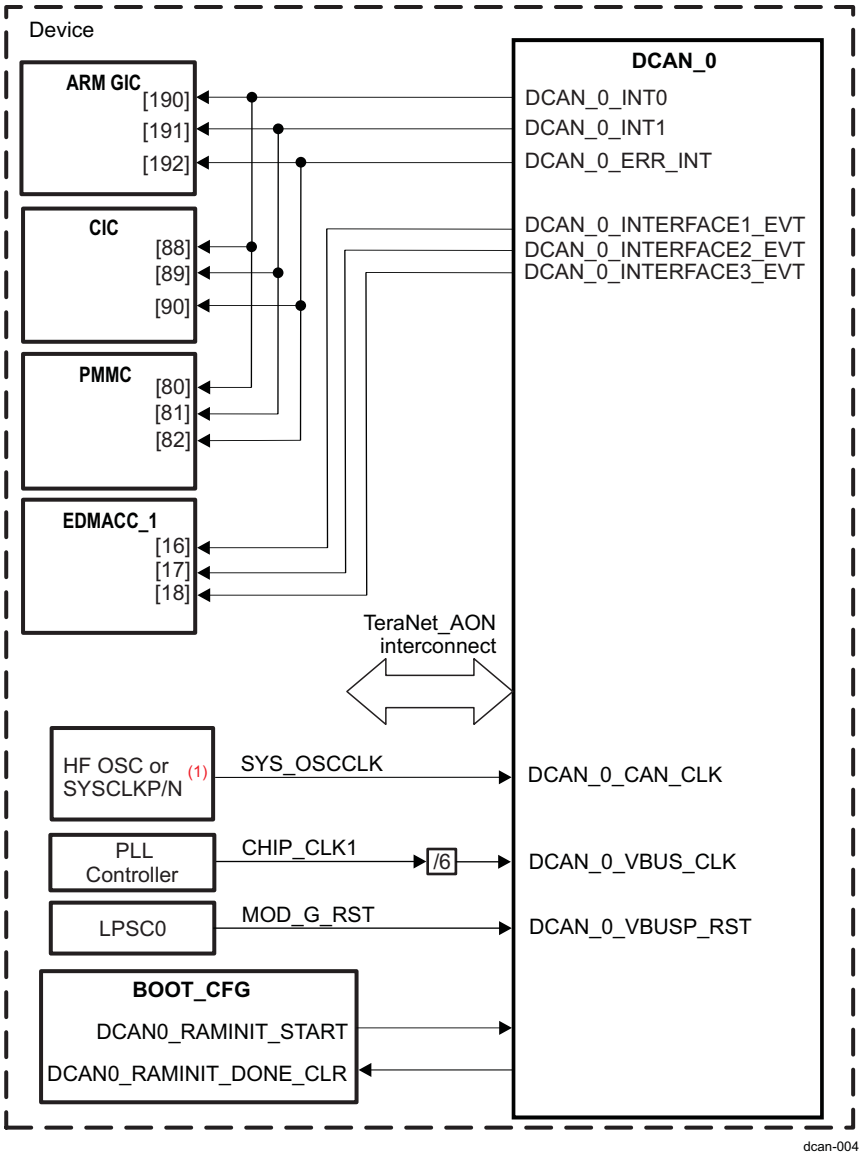
- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  - Recessive state (logic 0)
  - Dominant state (logic 1)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, and so forth).

- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field.

11.2.3 DCAN Integration

Figure 11-75 shows the integration of the DCAN_0 module in the device.

Figure 11-75. DCAN_0 Integration



(1) For more information see Section 5.4, *Clock Management*.

Figure 11-76 shows the integration of the DCAN_1 module in the device.

Figure 11-76. DCAN_1 Integration

DMA Requests					
Module Instance	**Event Name**	**Mapped To Input Event [Number]**			**Description**
		EDMACC_0		**EDMACC_1**	
DCAN_0	DCAN_0_INTERFACE1_EVT	–		[16]	DMA request for IF1 interface register
	DCAN_0_INTERFACE2_EVT	–		[17]	DMA request for IF2 interface register
	DCAN_0_INTERFACE3_EVT	–		[18]	DMA request for IF3 interface register
DCAN_1	DCAN_1_INTERFACE1_EVT	–		[19]	DMA request for IF1 interface register
	DCAN_1_INTERFACE2_EVT	–		[20]	DMA request for IF2 interface register
	DCAN_1_INTERFACE3_EVT	–		[21]	DMA request for IF3 interface register

NOTE: For the description of the interrupt source, see Section 11.2.4.2, *Interrupt Functionality*.

11.2.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

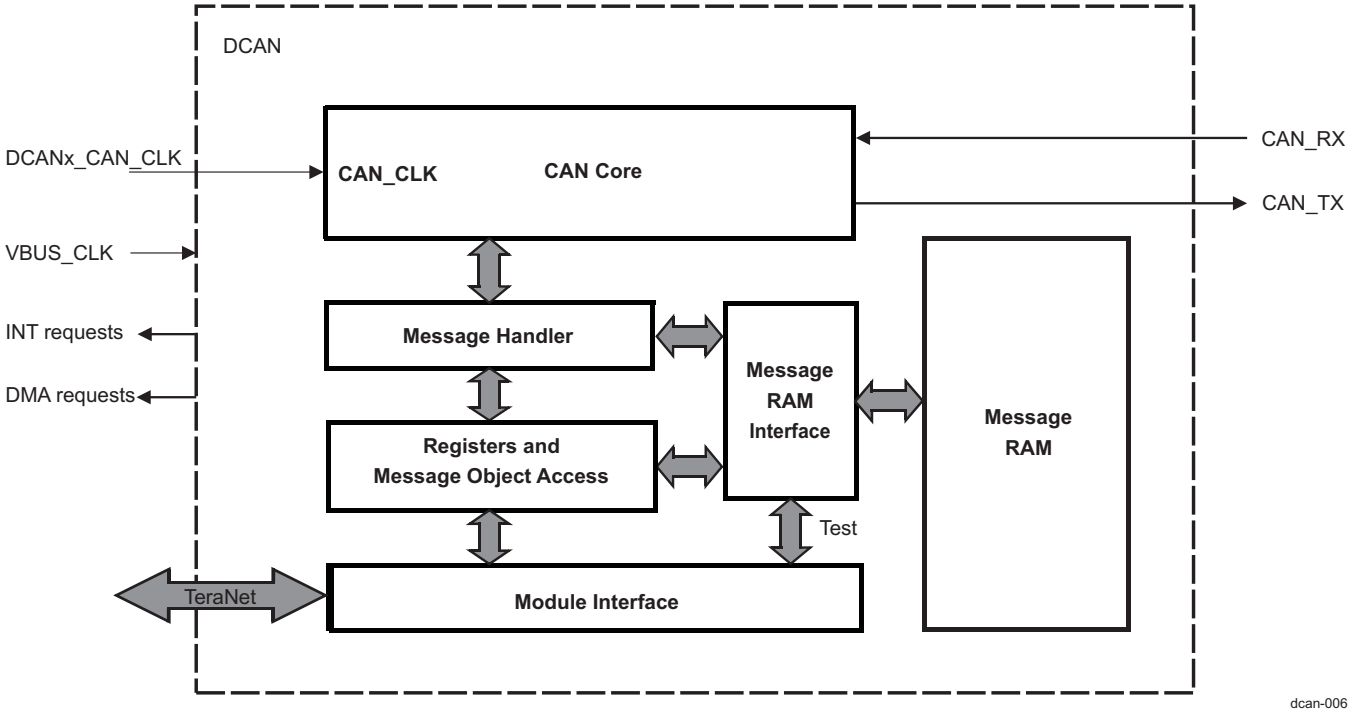
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 11-77 shows the DCAN block diagram and its features are described below.

Figure 11-77. DCAN Block Diagram



CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 11.2.4.8.12, *Reading From a FIFO Buffer*.

The interface registers have the same word-length as the message RAM.

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [VBUS_CLK]) and the peripheral asynchronous clock (functional clock [CAN_CLK]).

11.2.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (VBUS_CLK) as the general module clock source
- and the peripheral asynchronous clock (CAN_CLK) provided to the CAN core for generating the CAN bit timing.

NOTE: VBUS_CLK must always be higher or equal to CAN_CLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated VBUS_CLK has to be considered:

$f_{0,\ VBUS\_CLK} \pm \Delta f_{FM,\ VBUS\_CLK} \geq f_{CAN\_CLK}$

11.2.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the DCAN_CTL[1] IE0 and [17] IE1 bits, respectively. The interrupts are level triggered at the chip level.

DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 11-78, *Error and Status Change Interrupts* and Figure 11-79, *Message Objects Interrupts*).

The source of an interrupt can be determined by the interrupt identifiers DCAN_INT[15-0] INT0ID or bit field [23-16] INT1ID. When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN_INT[15-0] INT0ID or bit field [23-16] INT1ID again reaches zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN_ES). This interrupt has the highest priority. The software can update (reset) the status bits [9] WAKEUPPND, [4] RXOK, [3] TXOK and [2-0] LEC by reading DCAN_ES, but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID, respectively INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (DCAN_IF1CMD/DCAN_IF2CMD[19] CLRINTPND bit). When IntPnd is cleared, DCAN_INT will point to the next message object with a pending interrupt.

11.2.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in Section 11.2.4.11.1, *Structure of Message Objects*.

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN_INTMUX12 to DCAN_INTMUX78).

11.2.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

NOTE: Reading DCAN_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

11.2.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN_CTL[3] EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

Figure 11-78. Error and Status Change Interrupts

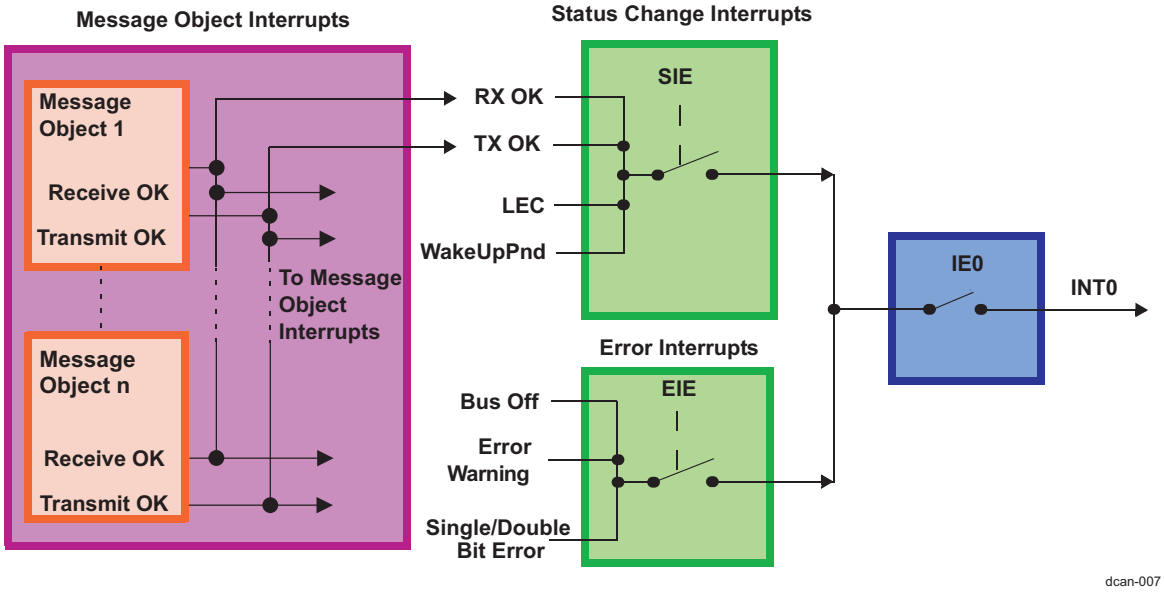


Figure 11-79. Message Objects Interrupts

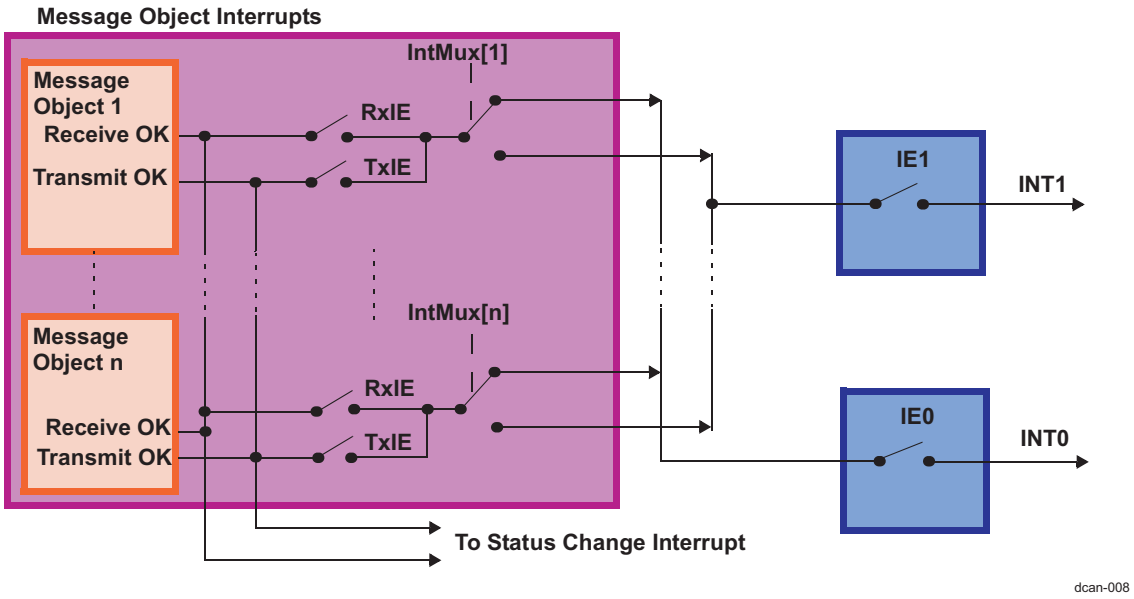


11.2.4.3 DMA Functionality

DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers (DCAN_IF1CMD, DCAN_IF2CMD).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see Section 11.2.4.10.2, *IF3 Register Set*.

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in DCAN_CTL.

11.2.4.4 Local Power-Down Mode

DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

11.2.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the DCAN_CTL[24] PDR bit (=1).

DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the DCAN_CTL[0] INIT bit to prevent any further CAN transfers, and it will also set the DCAN_ES[10] PDA bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 11.2.4.4.2, *Wakeup From Local Power Down*) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

11.2.4.4.2 Wakeup From Local Power Down

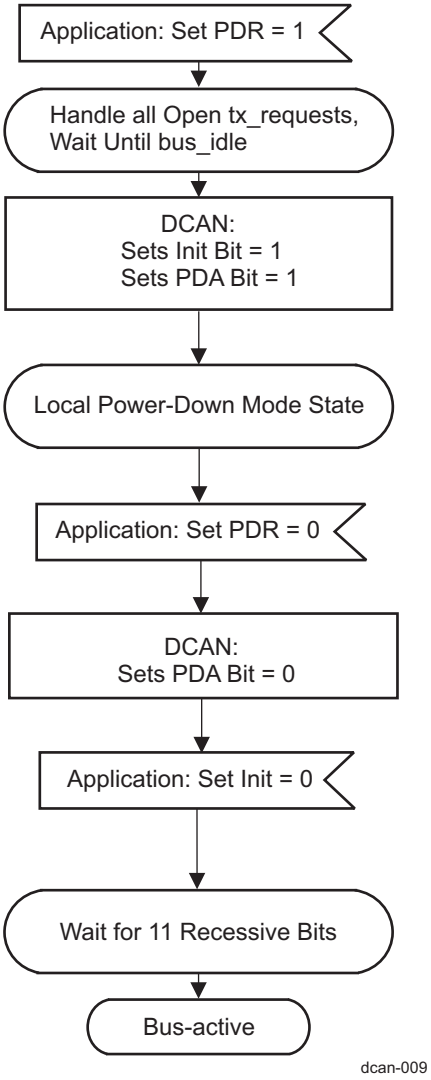
There is one way to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the DCAN_CTL[24] PDR bit and then clearing the DCAN_CTL[0] INIT.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

Figure 11-80 shows a flow diagram about entering and leaving local power-down mode.

Figure 11-80. Local Power-Down Mode Flow Diagram



11.2.4.5 SECDED Mechanism

The DCAN module provides a single error correction and double error detection (SECDED) mechanism to ensure data integrity of Message RAM data. For each message object (136 bits) in the Message RAM, 9 ECC bits will be calculated.

The ECC bits are stored in a dedicated RAM. They will be generated on write accesses and will be checked on read accesses.

The SECDED functionality can be enabled or disabled by DCAN_CTL[13-10] PMD bit field.

In case of disabled SECDED, the ECC bits will be left unchanged on write access to data area and no correction or check will be done on read access.

If SECDED is enabled, ECC bits will be automatically generated and checked. The ECC bits are memory mapped as described in Section 11.2.4.11.3, *ECC RAM*.

With the ECCMODE field in the DCAN_ECC_CS register the single bit error correction can be enabled or disabled (default: enabled).

NOTE: During RAM initialization, no SECDED check will be done, but if the PMD bit is set, the ECC bits will be generated.

11.2.4.5.1 Behavior on Single Bit Error

If a single bit error is detected with single bit error correction enabled, the correction will be done and the SEFLG in the DCAN_ECC_CS register will be set.

If single bit error correction is disabled and a single bit error is detected then the SEFLG in the DCAN_ECC_CS register and the the PER bit in the Error and Status register (DCAN_ES) will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

If single bit error correction is disabled and a single bit error is detected then the DCAN_n_ERR_INT signal (where n = 0 or 1) is generating a high pulse for one interface clock period.

The message object number where the single bit error has occurred will be indicated in the DCAN_ECC_SERR Register.

When single bit error correction is disabled the message object data can be read by the host CPU, independently of single bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the DCAN_ECC_SERR on single bit error.

11.2.4.5.2 Behavior on Double Bit Error

If a double bit error is detected, then the DEFLG in the DCAN_ECC_CS register and the PER bit in DCAN_ES will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset. The message object number will be indicated in the DCAN_PERR register.

Additionally the signal DCAN_n_ERR_INT signal (where n = 0 or 1) signalizes — by generating a high pulse for one interface clock period — the double bit error occurrence for the host CPU. The message object data can be read by the host CPU, independently of double bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the DCAN_PERR register on double bit error interrupt.

11.2.4.5.3 SECDED Testing

Testing of the SECDED mechanism can be implemented by using the diagnostic mode, which is enabled with the DCAN_ECCDIAG register. The following procedure can be used:

1. Disable SECDED using DCAN_CTL register. Enable diagnostic mode using the DCAN_ECCDIAG register.
2. Write to corrupt the data (in RDA mode) or ECC bits.
3. Enable SECDED and read data for which ECC is corrupted (either in RDA mode or via IFx registers).
4. Single bit error or double bit error flag will be set in the diagnostic status register (DCAN_ECCDIAG_STAT) and in the DCAN_ECC_CS register, accordingly. A double bit error or a single bit error with single bit error correction disabled also triggers the PER flag.
5. Disable diagnostic mode.

11.2.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit DCAN_CTL[8] IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by DCAN_CTL[16] INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 11.2.4.11.4, *Message RAM Representation in Debug/Suspend Mode*.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- DCAN_ES register (clear of status flags by read)
- DCAN_IF1CMD/DCAN_IF2CMD command registers (clear of [14] DMAACTIVE flag by read/write)

11.2.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1'.)

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

- In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.
- In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

11.2.4.7.1 Configuration of a Transmit Object for Data Frames

Table 11-206 shows how a transmit object can be initialized.

Table 11-206. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28-0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28-18]. In this case, ID[17-0] can be ignored.

The data length and data itself (DLC[3-0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28-0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 11.2.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

11.2.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

11.2.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 11-207 shows how a receive object for data frames can be initialized.

Table 11-207. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28-0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28-18]. In this case, ID[17-0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17-0] is set to '0'.

The data length code (DLC[3-0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28-0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to 'don't care', the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, and DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

11.2.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 11-208 shows how a receive object for remote frames can be initialized.

Table 11-208. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 11.2.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to '1.' The mask bits (Msk[28-0], UMask, MXtd, and MDir bits) may be set to 'must-match' or to 'don't care' to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 11.2.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28-0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to 'don't care' the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28-18]. In this case, ID[17-0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17-0] will be set to '0.'

The data length code (DLC[3-0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

11.2.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

11.2.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

11.2.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)

- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers.

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

11.2.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

11.2.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register (DCAN_MSGVAL12 to DCAN_MSGVAL78) and the TXRQST bits in the transmission request register (DCAN_TXRQ12 to DCAN_TXRQ78) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DCAN_CTL[5] DAR bit, the behavior of bits TXRQST and NEWDAT in the DCAN_IF1CMD/DCAN_IF2CMD register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

11.2.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN_IF1DATA/DCAN_IF2DATA) or IF1/IF2 Data B register (DCAN_IF1DATB/DCAN_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23-16] of the IF1/IF2 Command register (DCAN_IF1CMD/DCAN_IF2CMD) and then the number of the message object is written to bits [7-0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 11.2.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

11.2.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23-16] of the command register (DCAN_IF1CMD/DCAN_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23-16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

11.2.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

11.2.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the DCAN_INT to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

11.2.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'

  The remote frame is ignored, this message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

11.2.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23-16] and then the number of the message object to bits [7-0] MESSAGE_NUMBER of the command register (DCAN_IF1CMD/ DCAN_IF2CMD). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register (DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

11.2.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23-16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD).

11.2.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). Arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

11.2.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

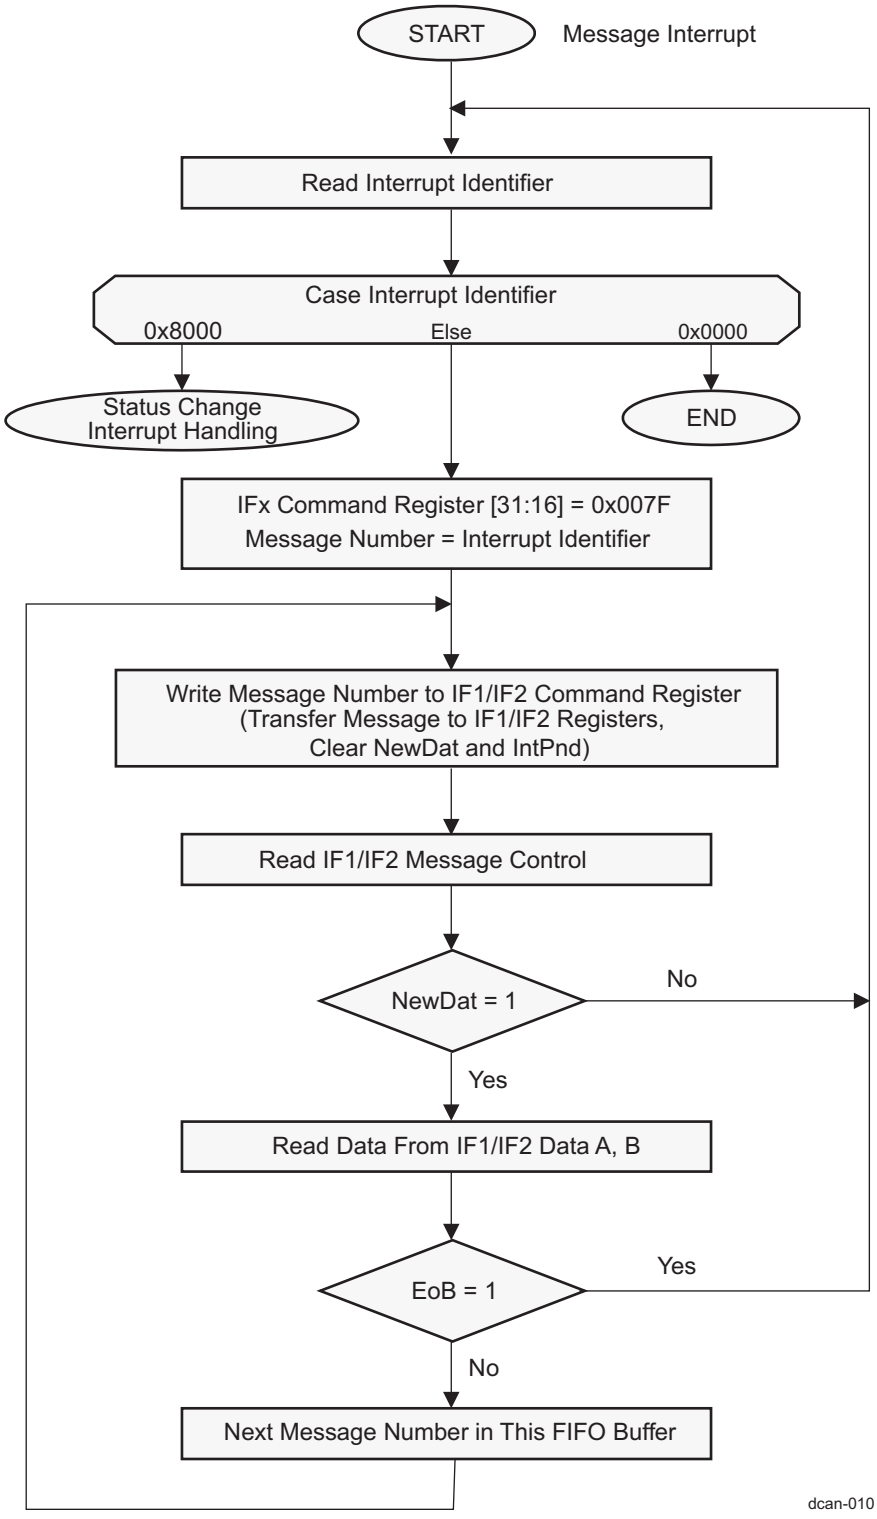
A FIFO buffer of length N will store N–1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 11-81.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 11-81. Software Handling of a FIFO Buffer (Interrupt Driven)



11.2.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of CAN bit synchronization inside CAN node and CAN nodes interaction on the CAN bus.

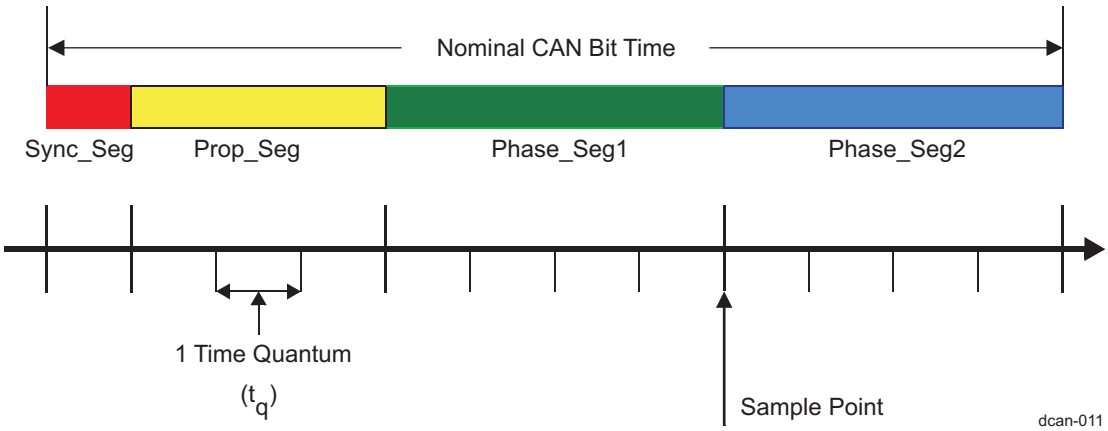
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of CAN network can be reduced significantly.

11.2.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 11-82):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 11-82. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 11-209 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 11-209. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization

Table 11-209. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

11.2.4.9.1.1 Synchronization Segment

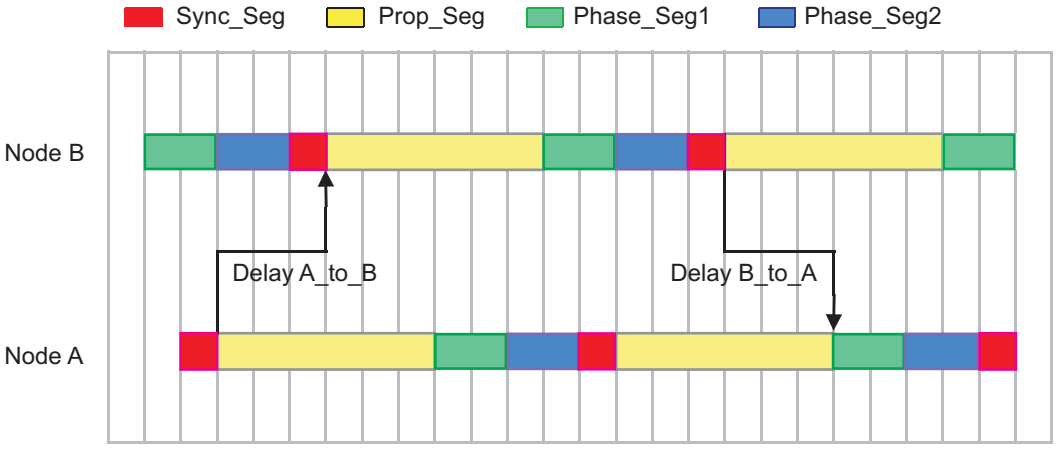
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

11.2.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 11-83 shows the phase shift and propagation times between two CAN nodes.

Figure 11-83. The Propagation Time Segment



Delay A_to_B ≥ node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg ≥ Delay A_to_B + Delay B_to_A

Prop_Seg ≥ 2 [max(node output delay + bus line delay + node input delay)]

dcan-012

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

11.2.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error — SJW) remains.

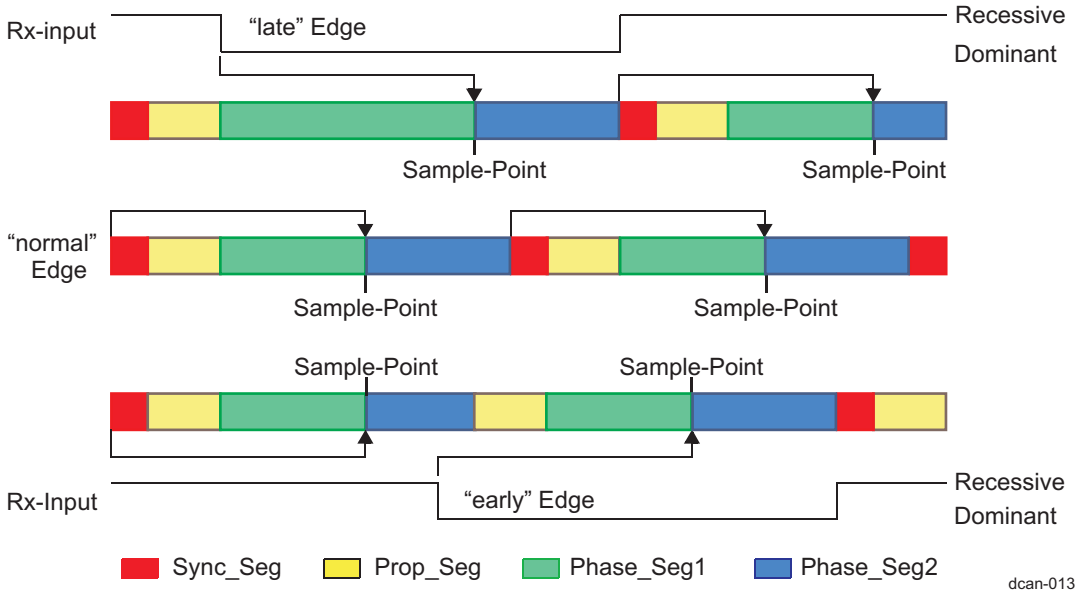
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 11-84 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 11-84. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

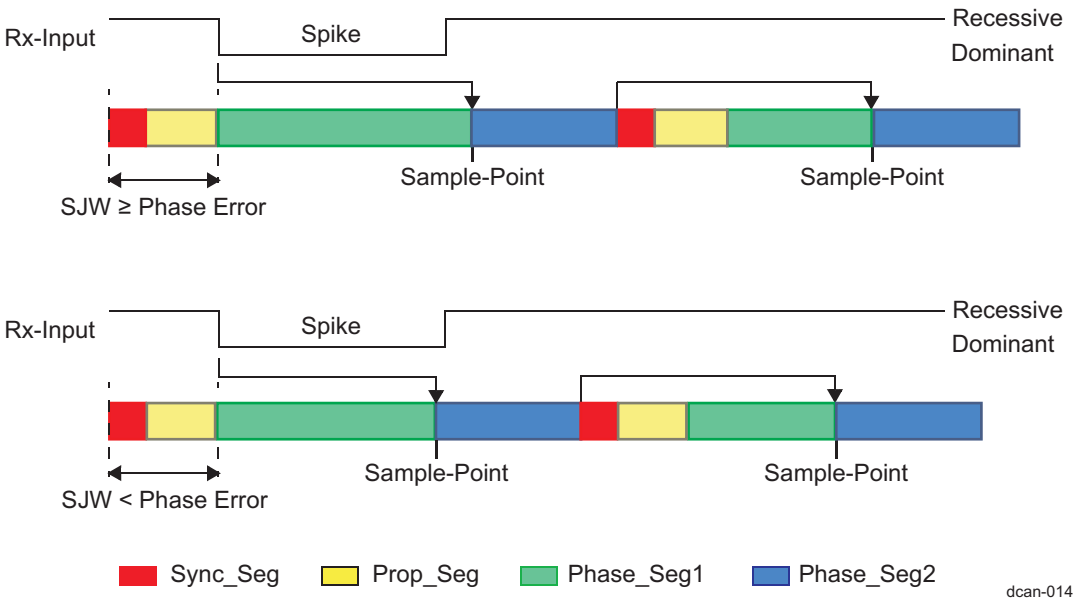
In these examples, the bit timing is seen from the point of view of the CAN implementation’s state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 11-85 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 11-85. Filtering of Short Dominant Spikes



11.2.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit\_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit\_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

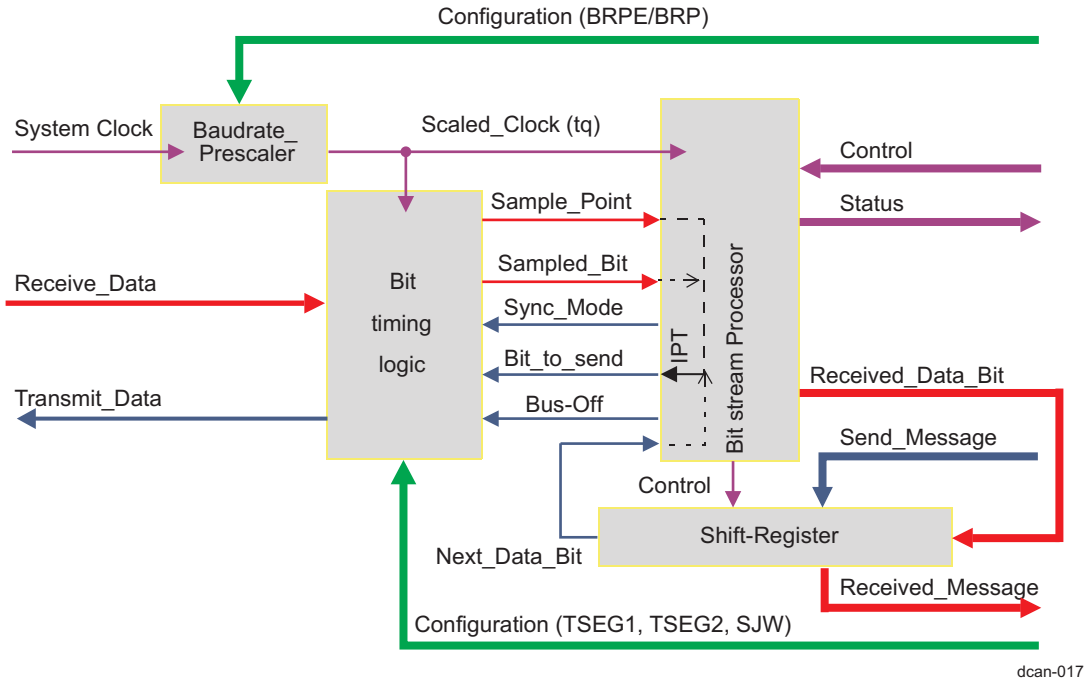
11.2.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in DCAN_BTR[14-0], additionally a baud rate prescaler extension of four bits (DCAN_BTR[19-16] BRPE) is provided.

- The sum of Prop_Seg and Phase_Seg1 is set in [11-8] TSEG1
- Phase_Seg2 in [14-12] TSEG2
- Synchronization JumpWidth in [7-6] SJW
- and baud rate prescaler [5-0] BRP (plus [19-16] BRPE).

Figure 11-86 shows the CAN protocol controller.

Figure 11-86. Structure of the CAN Core's CAN Protocol Controller



In DCAN_BTR register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1; n], values in the range of [0; n–1] are programmed. That way, for example, SJW (functional range of [1; 4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (DCAN_BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

11.2.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Table 11-210.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register (DCAN_BTR):

[14-12] TSEG2 = Phase_Seg2 - 1

[11-8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7-6] SJW = SynchronizationJumpWidth - 1

[5-0] BRP = Prescaler - 1

11.2.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of CAN_CLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 11-210. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	16 × 5.5 ns/m	88 ns	-
t_q	BRP/CAN_CLK	100 ns	1
t_{Sync_Seg}	1 × t_q (fixed)	100 ns	1
t_{Prop_Seg}	INT (2×delays + 1) = 8 × t_q	800 ns	8
t_{Seg1}	$t_{Prop\_Seg} + t_{Phase\_Seg1}$	1400 ns	14

Table 11-210. Example For Bit Timing (continued)

Parameter	Formula	Value	t_q
t_{Seg2}	bit time - ($_{Sync\_Seg}$ + t_{Seg1})	500 ns	5
t_{SJWmax}	MIN (4 × t_q, t_{Phase_Seg1})	400 ns	4

In this example, the bit timing register DCAN_BTR is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

11.2.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be left unchanged.

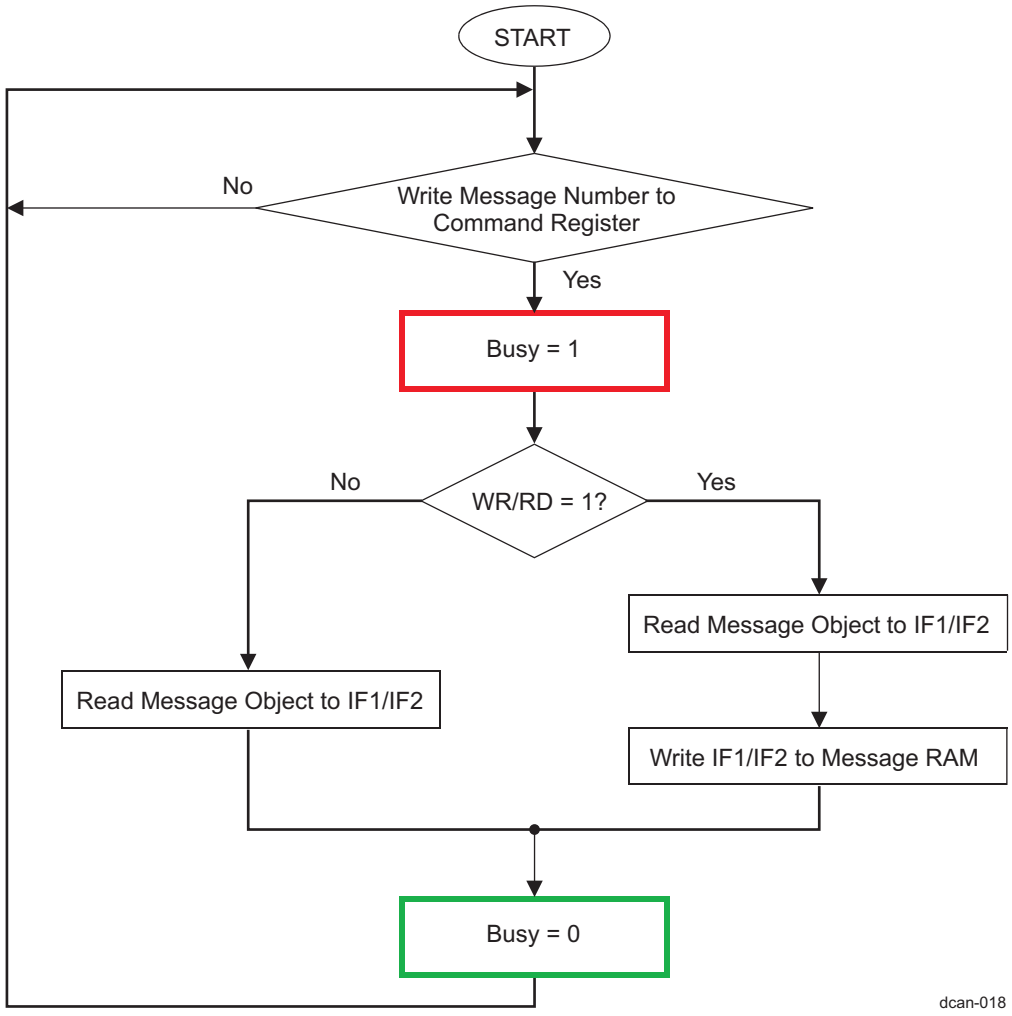
By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 11.2.4.11.1, *Structure of Message Objects*) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 11.2.5, *DCAN Registers*) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

11.2.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. DCAN_IF1CMD/DCAN_IF2CMD address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7-0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective DCAN_IF1CMD/DCAN_IF2CMD to 1. After the transfer has completed, the BUSY bit is set back to 0 (see Figure 11-87).

Figure 11-87. Data Transfer Between IF1/IF2 Registers and Message RAM



11.2.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (DCAN_IF3UPD12 to DCAN_IF3UPD78).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (DCAN_IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DCAN_CTL[20] DE3 = 1.

NOTE: The IF3 register set cannot be used for transferring data into message objects.

11.2.4.11 Message RAM

The DCAN message RAM contains message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see Section 11.2.4.11.4, *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see Section 11.2.4.11.5, *Message RAM Representation in Direct Access Mode*).

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

11.2.4.11.1 Structure of Message Objects

Table 11-211 shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 11-211. Structure of a Message Object

UMask	Msk[28-0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28-0]	Xtd	Dir	DLC[3-0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 11-212. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28-0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.
UMask		Use acceptance mask
	0	Mask bits (Msk[28-0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.

Table 11-212. Message Object Field Descriptions (continued)

Field Name	Value	Description
ID[28-0]		Message identifier
	ID[28-0]	29-bit (“extended”) identifier bits
	ID[28-18]	11-bit (“standard”) identifier bits
Msk[28-0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don’t care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit (“standard”) Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28-18]. For acceptance filtering, only these bits together with mask bits Msk[28-18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.

Table 11-212. Message Object Field Descriptions (continued)

Field Name	Value	Description
DLC[3-0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

11.2.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) × 20h

That is, message object 1 starts at offset 0020h; message object 2 starts at offset 0040h, and so forth.

NOTE: Because 0 is not a valid message object number, at offset 0000h is not located message object 0, but the last implemented: 64.

The base address for DCAN_0_DATA RAM is 0260 4000h and DCAN_1_DATA RAM is 0260 8000h.

Message object number 1 has the highest priority.

Table 11-213. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 11.2.4.11.4	RDA Mode, see Section 11.2.4.11.5
64 (last implemented)	0000h	1	Reserved	Data Bytes 4-7
	0004h	2	MXtd, MDir, Mask	Data Bytes 0-3
	0008h	3	Xtd, Dir, ID	ID[27-0], DLC
	000Ch	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0010h	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0014h	6	Data Bytes 7-4	-
1	0020h	1	Reserved	Data Bytes 4-7
	0024h	2	MXtd, MDir, Mask	Data Bytes 0-3
	0028h	3	Xtd, Dir, ID	ID[27-0], DLC
	002Ch	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0030h	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0034h	6	Data Bytes 7-4	-

Table 11-213. Message RAM Addressing in Debug/Suspend and RDA Modes (continued)

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 11.2.4.11.4	RDA Mode, see Section 11.2.4.11.5
2	0040h	1	Reserved	Data Bytes 4-7
	0044h	2	MXtd, MDir, Mask	Data Bytes 0-3
	0048h	3	Xtd, Dir, ID	ID[27-0], DLC
	004Ch	4	Ctrl	Mask, Xtd, Dir, ID[28]
	0050h	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	0054h	6	Data Bytes 7-4	-
…	…	…	…	…
63	07E0h	1	Reserved	Data Bytes 4-7
	07E4h	2	MXtd, MDir, Mask	Data Bytes 0-3
	07E8h	3	Xtd, Dir, ID	ID[27-0], DLC
	07ECh	4	Ctrl	Mask, Xtd, Dir, ID[28]
	07F0h	5	Data Bytes 3-0	Reserved, Ctrl, MXtd, MDir
	07F4h	6	Data Bytes 7-4	-

11.2.4.11.3 ECC RAM

On devices with SECDED implementation for the message RAM, the ECC bits are stored in a dedicated ECC RAM area which is memory mapped as follows:

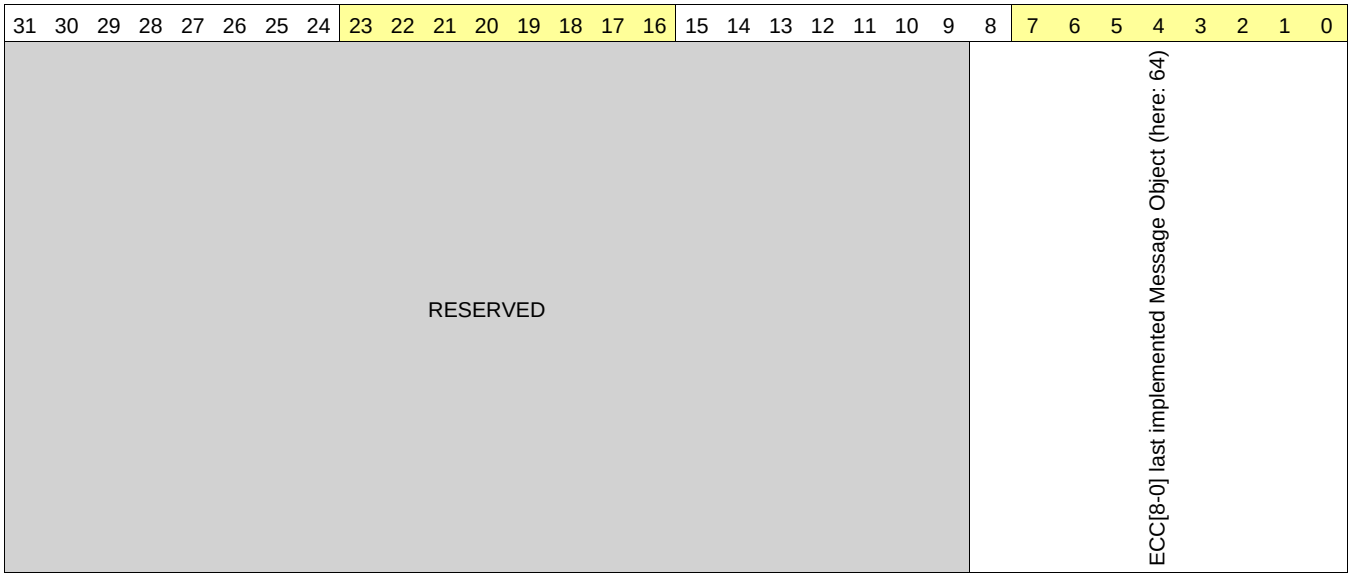
The location of the ECC bits for a particular message object in RAM is:

Message RAM base address + 1000h + (message object number) × 20h

NOTE: 0 is not a valid message object number. Therefore, at address 1000h, the ECC bits of the last implemented message object are located, that is, 64-th.

Table 11-214. ECC RAM Representation

Address	Msg RAM base + 0x1000



Address	Msg RAM base + 0x1020

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ECC[8-0] Message Object 1							

Address	Msg RAM base + 0x17E0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ECC[8-0] Message Object 63							

As shown in Table 11-214 the ECC bits for the last implemented Message Object (here: 64) are located at offset 0x1000; the ECC bits for Message Object 1 are located at offset 0x1020, and the ECC bits for Message Object 63 are located at offset 0x17E0.

The ECC RAM is only memory mapped if SECDED diagnostic mode is enabled.

11.2.4.11.4 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

11.2.4.11.5 Message RAM Representation in Direct Access Mode

When the DCAN_TEST[9] RDA bit is set while the DCAN module is in test mode (DCAN_CTL[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

11.2.4.12 CAN Operation

After hardware reset, the DCAN_CTL[0] INIT is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 11-88 illustrates the basic initialization flow for the CAN module.

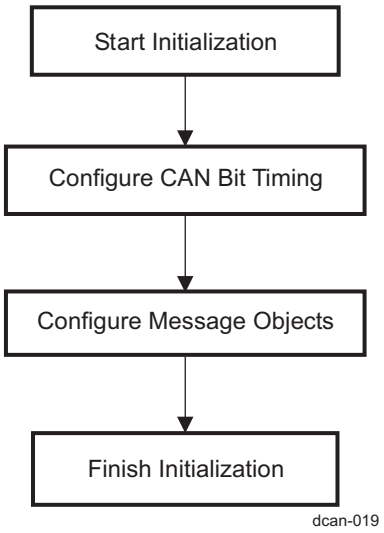
11.2.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

1. Configuration of the CAN bit timing.
2. Configuration of message objects.

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 11-88. CAN Module General Initialization Flow



11.2.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 11-89, *CAN Bit-Timing Configuration*.

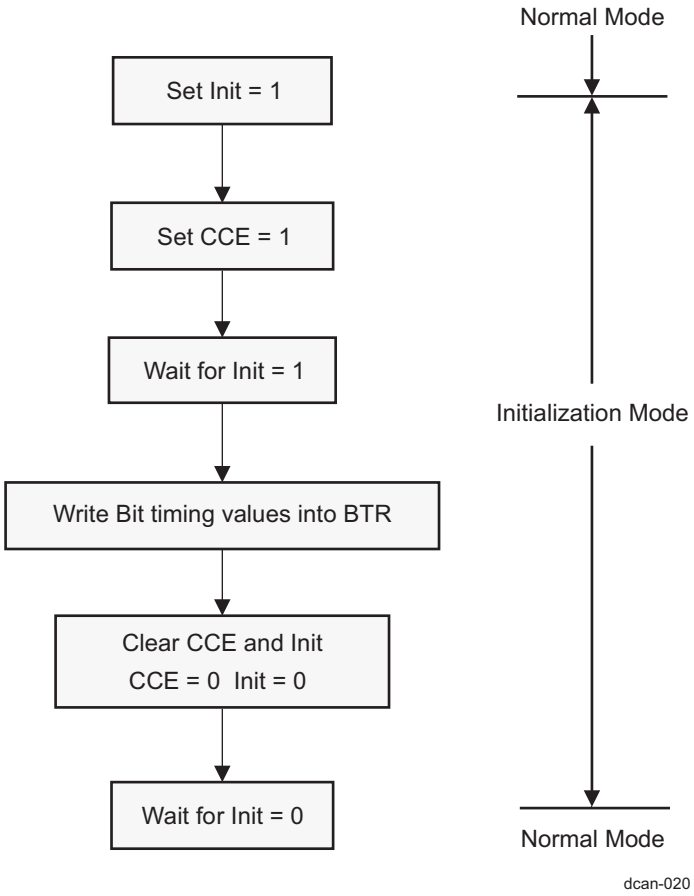
Step 1: Enter *initialization mode* (DCAN_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on hardware reset and during Bus-Off.

Figure 11-89. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable bit (DCAN_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into DCAN_BTR. See Section 11.2.4.9.2, *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the DCAN_BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the Initialization mode if any incorrect DCAN_BTR values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 11.2.4.12.1, *CAN Module Initialization*.

11.2.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM). For more details how to configuring the message objects, see Section 11.2.4.10, *Message Interface Register Sets*, for the interface register set (IFx) usage and see Section 11.2.4.11, *Message RAM* for the message object structure.

For more information regarding the procedure to configure the message objects, see Section 11.2.4.7, *Configuration of Message Objects Description*. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

11.2.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device BOOT_CFG module. Setting bit DCANx_RAMINIT_START to 1 (where x = 0 or 1), causes RAM initialization with zeros and sets ECC bits accordingly. Software must wait for the DCANx_RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on DCAN_RAMINIT register, see Section 5.1.4, *BOOT_CFG Registers*.

11.2.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and DCAN_CTL[0] INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (DCAN_CTL[1] IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The DCAN_INT register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled (DCAN_CTL[1] IE0 and [17] IE1 = 0).

The software may poll all MessageObject's NewDat and TxRqst bits in parallel from the DCAN_NWDAT_X and the DCAN_TXRQ_X registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (for example, when the identifier mask is used), the arbitration bits which are masked to 'don't care' may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

11.2.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO 11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DCAN_CTL[5] DAR = 1). Further details to this mode are provided in Section 11.2.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

11.2.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the DCAN_CTL[0] INIT bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit DCAN_CTL[9] ABO. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register (DCAN_ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

11.2.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the DCAN_CTL[7] TEST bit needs to be set to 1. This enables write access to the test register (DCAN_TEST).

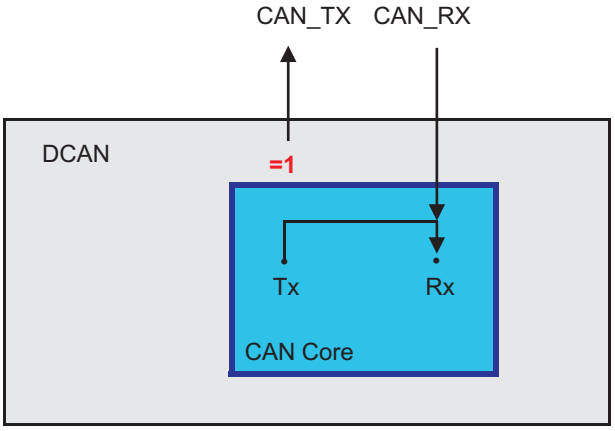
NOTE: It must be ensured by software that all message transfers are completed before entering test mode.

11.2.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 11-90 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 11-90. CAN Core in Silent Mode



11.2.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

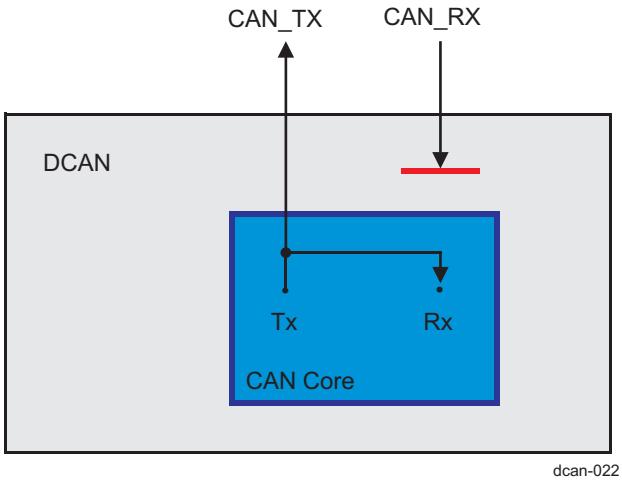
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 11-91 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit DCAN_TEST[4] LBACK to 1.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 11.2.4.12.3.3, *External Loopback Mode*.

Figure 11-91. CAN Core in Loopback Mode



11.2.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

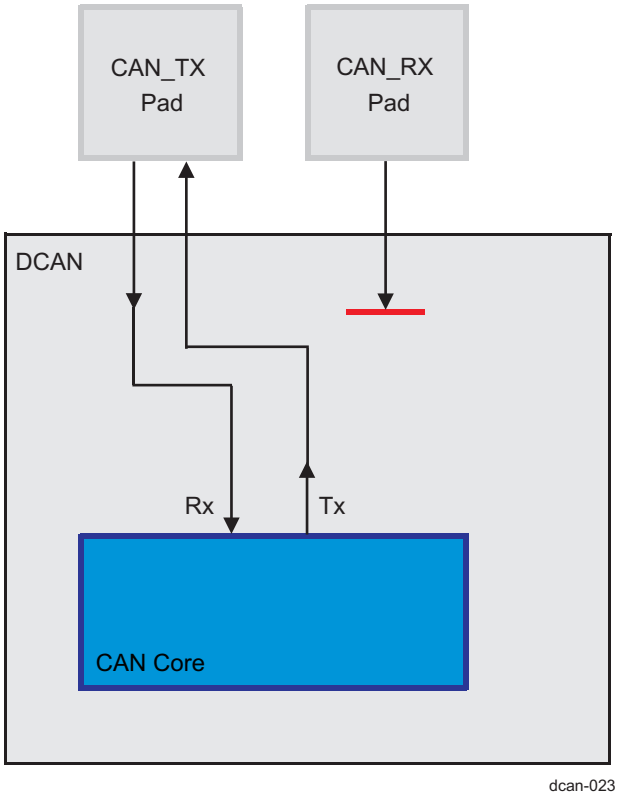
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit DCAN_TEST[8] EXL to 1.

Figure 11-92 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

Figure 11-92. CAN Core in External Loopback Mode

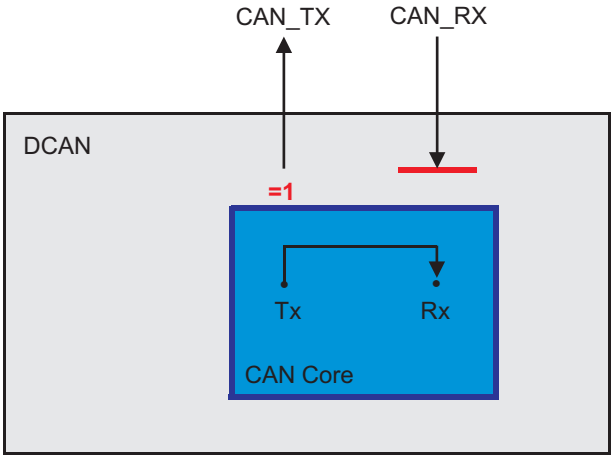


11.2.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits DCAN_TEST[4] LBACK and [3] SILENT at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 11-93 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Figure 11-93. CAN Core in Loop Back Combined With Silent Mode



11.2.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the DCAN_TEST[6-5] TX:

- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

11.2.5 DCAN Registers

Table 11-218 lists the memory-mapped registers for the DCAN. All register offset addresses not listed in Table 11-218 should be considered as reserved locations and the register contents should not be modified.

Table 11-217. DCAN Instances

Instance	Base Address
DCAN_0_DATA(1)	0260 4000h
DCAN_1_DATA(1)	0260 8000h
DCAN_0	0260 B200h
DCAN_1	0260 B400h

(1) Message RAM memory mapped space. See Section 11.2.4.11, *Message RAM* for more information.

NOTE: After hardware reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the DCAN_CTL is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

11.2.5.1 DCAN_CTL Register (Offset = 0h) [reset = 1401h]

DCAN_CTL is shown in Figure 11-94 and described in Table 11-220.

DCAN control register

NOTE: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 - 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES, enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

Table 11-220. DCAN_CTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
25	RESERVED	R	0h	
24	PDR	R/W	0h	Request for local low power-down mode 0h (R/W) = No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1h (R/W) = Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in Local Power-Down Mode).
23-21	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
20	DE3	R/W	0h	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled

Table 11-220. DCAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	DE2	R/W	0h	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
18	DE1	R/W	0h	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
17	IE1	R/W	0h	Interrupt line 1 enable 0h (R/W) = Disabled - Module interrupt INT1 is always low. 1h (R/W) = Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.
16	INITDBG	R/W	0h	Internal init state while debug access 0h (R/W) = Not in debug mode, or debug mode requested but not entered. 1h (R/W) = Debug mode requested and internally entered; the DCAN is ready for debug accesses.
15	SWR	R/W	0h	Software reset enable. Note: To execute software reset, the following procedure is necessary: 0h (R/W) = Normal Operation 1h (R/W) = Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one DCAN_i_VBUS_CLK (i = 0 or 1) clock cycle.
14	RESERVED	R	0h	This bit is always read as 0. Writes have no effect.
13-10	PMD	R/W	5h	ECC on/offOthers: function enabled. 5h (R/W) = function disabled
9	ABO	R/W	0h	Auto-Bus-On enable 0h (R/W) = The Auto-Bus-On feature is disabled 1h (R/W) = The Auto-Bus-On feature is enabled
8	IDS	R/W	0h	Interruption debug support enable 0h (R/W) = When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1h (R/W) = When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	TEST	R/W	0h	Test mode enable 0h (R/W) = Normal Operation 1h (R/W) = Test Mode
6	CCE	R/W	0h	Configuration change enable 0h (R/W) = The software has no write access to the configuration registers. 1h (R/W) = The software has write access to the configuration registers (when INIT bit is set).
5	DAR	R/W	0h	Disable automatic retransmission 0h (R/W) = Automatic retransmission of not successful messages enabled. 1h (R/W) = Automatic retransmission disabled.
4	RESERVED	R	0h	This bit is always read as 0. Writes have no effect.
3	EIE	R/W	0h	Error interrupt enable 0h (R/W) = Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1h (R/W) = Enabled - PER, BOFF and EWARN bits can generate an interrupt at INT0 line and affect the interrupt register.

Table 11-220. DCAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	SIE	R/W	0h	Status change interrupt enable 0h (R/W) = Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1h (R/W) = Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.
1	IE0	R/W	0h	Interrupt line 0 enable 0h (R/W) = Disabled - Module interrupt INT0 is always low. 1h (R/W) = Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.
0	INIT	R/W	1h	Initialization 0h (R/W) = Normal operation 1h (R/W) = Initialization mode is entered

- DCAN_BTR Register (Offset = Ch) [reset = 2301h]: [0]

11.2.5.2 DCAN_ES Register (Offset = 4h) [reset = 7h]

DCAN_ES is shown in Figure 11-95 and described in Table 11-223.

Error and Status Register
Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt.
Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value.
For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.

Table 11-222. DCAN_ES Instances

Instance	Physical Address

Table 11-223. DCAN_ES Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
10	PDA	R	0h	Local power-down mode acknowledge 0h (R) = DCAN is not in local power-down mode. 1h (R) = Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.
9	WAKEUPPND	R	0h	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0h (R) = No Wake Up is requested by DCAN. 1h (R) = DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.

Table 11-223. DCAN_ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	PER	R/W	0h	Single/Double bit error detected. This bit will be set on double bit errors and additionally on single bit errors if single bit error correction is disabled with the ECCMODE bitfield in DCAN_ECC_CS. 0h (R/W) = No effect 1h (R/W) = End of interrupt (EOI) for single/double error on DCAN_ERR_INT interrupt line
7	BOFF	R	0h	Bus-Off state 0h (R) = The CAN module is not bus-off state. 1h (R) = The CAN module is in bus-off state.
6	EWARN	R	0h	Warning state 0h (R) = Both error counters are below the error warning limit of 96. 1h (R) = At least one of the error counters has reached the error warning limit of 96.
5	EPASS	R	0h	Error passive state 0h (R) = On CAN Bus error, the DCAN could send active error frames. 1h (R) = The CAN core is in the error passive state as defined in the CAN Specification.
4	RXOK	R	0h	Received a message successfully. This bit will be reset if DCAN_ES register is read. 0h (R) = No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1h (R) = A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).
3	TXOK	R	0h	Transmitted a message successfully. This bit will be reset if DCAN_ES register is read. 0h (R) = No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1h (R) = A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.

Table 11-223. DCAN_ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	LEC	R	7h	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0h (R) = No error 1h (R) = Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 2h (R) = Form error: A fixed format part of a received frame has the wrong format. 3h (R) = Ack error: The message this CAN core transmitted was not acknowledged by another node. 4h (R) = Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5h (R) = Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6h (R) = CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 7h (R) = No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'

11.2.5.4 DCAN_BTR Register (Offset = Ch) [reset = 2301h]

DCAN_BTR is shown in Figure 11-97 and described in Table 11-229.

Bit timing register
This register is only writable if CCE and INIT bits in the DCAN_CTL are set.
The CAN bit time may be programmed in the range of 8 to 25 time quanta
The CAN time quantum may be programmed in the range of 1 to 1024 CAN_CLK periods.

Table 11-232. DCAN_INT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
23-16	INT1ID	R	0h	Interrupt 1 Identifier (indicates the message object with the highest pending interrupt)0x01-0x80: Number of message object which caused the interrupt. 0x81-0xFF: Unused. If several interrupts are pending,DCAN_INT will point to the pending interrupt with the highest priority. The INT1 interrupt line remains active until INT1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared. A message interrupt is cleared by clearing the message object's IntPnd bit. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0h (R) = No interrupt is pending
15-0	INT0ID	R	0h	Interrupt Identifier (the number here indicates the source of the interrupt)0x0001-0x0080: Number of message object which caused the interrupt. 0x0081-0x7FFF: Unused. 0x8001-0xFFFF: Unused. If several interrupts are pending,DCAN_INTwill point to the pending interrupt with the highest priority. The INT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0h (R) = No interrupt is pending 8000h (R) = DCAN_ES value is not 0x07.

11.2.5.6 DCAN_TEST Register (Offset = 14h) [reset = 0h]

DCAN_TEST is shown in Figure 11-99 and described in Table 11-235.

Test Register
For all test modes, the TEST bit in DCAN_CTL control register needs to be set to 1. If TEST bit is set, the RDA, EXL, TX1, TX0, LBACK and SILENT bits are writable. Bit RX monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when TEST bit is cleared.

11.2.5.7 DCAN_PERR Register (Offset = 1Ch) [reset = 0h]

DCAN_PERR is shown in Figure 11-100 and described in Table 11-238.

Parity Error Code Register
If a parity error is detected, the PER flag will be set in the DCAN_ES. This bit is not reset by the parity check mechanism; it must be reset by reading DCAN_ES. In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

11.2.5.12 DCAN_ECC_SERR Register (Offset = 30h) [reset = 0h]

DCAN_ECC_SERR is shown in Figure 11-105 and described in Table 11-253.

ECC Single Bit Error Code Register.
If an ECC single bit error is detected, the SEFLG flag will be set in the DCAN_ECC_CS. In addition, MESSAGE_NUMBER will indicate the memory area where the single bit error has been detected (message object number only).
If more than one word with an ECC single bit error was detected, the highest word number with an ECC single bit error error will be displayed.
After an ECC single bit error has been detected, the register will hold the last error code until power is removed.

DCAN Registers • DCAN_NWDAT_X Register (Offset = 98h) [reset = 0h]: [0] • DCAN Registers: [0]

11.2.5.20 DCAN_NWDAT12 Register (Offset = 9Ch) [reset = 0h]

DCAN_NWDAT12 is shown in Figure 11-113 and described in Table 11-277.

New Data Register
This register hold the NewDat bits of the implemented message objects. By reading out these bits, the software can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the software via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

- DCAN Registers: [0]

11.2.5.33 DCAN_MSGVAL78 Register (Offset = D0h) [reset = 0h]

DCAN_MSGVAL78 is shown in Figure 11-126 and described in Table 11-316.

Message Valid Register
These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the software can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the software via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission

11.2.5.34 DCAN_INTMUX12 Register (Offset = D8h) [reset = 0h]

DCAN_INTMUX12 is shown in Figure 11-127 and described in Table 11-319.

Interrupt Multiplexer Register
The IntMux flag determine for each message object, which of the two interrupt lines (INT0 or INT1) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in DCAN_CTL. The IntPnd bit of a specific message object can be set or reset by the software via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the INT0ID resp. INT1ID flags in the DCAN_INT register.

DCAN Functional Description • Message Object Interrupts: [0]
DCAN Registers • DCAN_INTMUX78 Register (Offset = E4h) [reset = 0h]: [0] • DCAN Registers: [0]

11.2.5.38 DCAN_IF1CMD Register (Offset = 100h) [reset = 1h]

DCAN_IF1CMD is shown in Figure 11-131 and described in Table 11-331.

IF1 Command Register
The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7-0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 DCAN_i_VBUS_CLK (i = 0 or 1) clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.
While BUSY bit is one, IF1/IF2 register sets are write protected.
For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.
If an invalid Message Number is written to bits [7-0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

31-24	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
23	WR_RD	R/W	0h	Write/Read 0h (R/W) = Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1h (R/W) = Direction = Write: Transfer direction is from the IF1 register set to the message object addressed by MESSAGE_NUMBER.

Table 11-331. DCAN_IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	MASK	R/W	0h	Access mask bits 0h (R/W) = Mask bits will not be changed 1h (R/W) = Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.
21	ARB	R/W	0h	Access arbitration bits 0h (R/W) = Arbitration bits will not be changed 1h (R/W) = Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.
20	CONTROL	R/W	0h	Access control bitsIf the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL will be ignored. 0h (R/W) = Control bits will not be changed 1h (R/W) = Direction = Write: The message control bits will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER.
19	CLRINTPND	R/W	0h	Clear interrupt pending bit 0h (R/W) = IntPnd bit will not be changed 1h (R/W) = Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).
18	TXRQST_NEWDAT	R/W	0h	Access transmission request bitNote: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL always reflect the status before resetting them. 0h (R/W) = Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1h (R/W) = Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object.
17	DATA_A	R/W	0h	Access Data Bytes 0-3Note: The duration of the message transfer is independent of the number of bytes to be transferred. 0h (R/W) = Data Bytes 0-3 will not be changed. 1h (R/W) = Direction = Write: The data bytes 0-3 will be transferred from the IF1 registerset to the message object addressed by the MESSAGE_NUMBER.
16	DATA_B	R/W	0h	Access Data Bytes 4-7Note: The duration of the message transfer is independent of the number of bytes to be transferred. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Write: The data bytes 4-7 will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER.
15	BUSY	R/W	0h	Busy flagThis bit is set to one after the message number has been written to bits [7-0] MESSAGE_NUMBER. IF1 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF1 register set and message RAM is in progress. 1h (R/W) = Transfer between IF1 register set and message RAM is in progress.

Table 11-331. DCAN_IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAACTIVE	R/W	0h	Activation of DMA feature for subsequent internal IF1 updateThe DMA request remains active until the first read or write to one of the IF1 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF1 activities. 1h (R/W) = DMA is requested after completed transfer between IF1 register set and message RAM.
13-8	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
7-0	MESSAGE_NUMBER	R/W	1h	Number of message object in message RAM which is used for data transfer0x01-0x80: Valid message numbers. 0x81-0xFF: Invalid message numbers. 0h (R/W) = Invalid message number

11.2.5.40 DCAN_IF1ARB Register (Offset = 108h) [reset = 0h]

DCAN_IF1ARB is shown in Figure 11-133 and described in Table 11-337.

IF1 arbitration register
The Arbitration bits ID[28-0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28-0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with XTD = 1, standard frames in message objects with XTD = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*
While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

Table 11-340. DCAN_IF1MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
15	NEWDAT	R/W	0h	New data 0h (R/W) = No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the software. 1h (R/W) = The message handler or the software has written new data into the data portion of this message object.
14	MSGLST	R/W	0h	Message lost (only valid for message objects with direction = receive) 0h (R/W) = No message lost since the last time when this bit was reset by the software. 1h (R/W) = The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	INTPND	R/W	0h	Interrupt pending 0h (R/W) = This message object is not the source of an interrupt. 1h (R/W) = This message object is the source of an interrupt. The Interrupt Identifier in DCAN_INT will point to this message object if there is no other interrupt source with higher priority.

Table 11-340. DCAN_IF1MCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	UMASK	R/W	0h	Use acceptance maskIf the UMASK bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. 0h (R/W) = Mask ignored 1h (R/W) = Use mask (Msk[28-0], MXtd, and MDir) for acceptance filtering
11	TXIE	R/W	0h	Transmit interrupt enable 0h (R/W) = IntPnd will not be triggered after the successful transmission of a frame. 1h (R/W) = IntPnd will be triggered after the successful transmission of a frame.
10	RXIE	R/W	0h	Receive interrupt enable 0h (R/W) = IntPnd will not be triggered after the successful reception of a frame. 1h (R/W) = IntPnd will be triggered after the successful reception of a frame.
9	RMTEN	R/W	0h	Remote enable 0h (R/W) = At the reception of a remote frame, TxRqst is not changed. 1h (R/W) = At the reception of a remote frame, TxRqst is set.
8	TXRQST	R/W	0h	Transmit request 0h (R/W) = This message object is not waiting for a transmission. 1h (R/W) = The transmission of this message object is requested and is not yet done.
7	EOB	R/W	0h	End of BlockNote: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1. 0h (R/W) = The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1h (R/W) = The message object is a single message object or the last message object in a FIFO Buffer Block.
6-4	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
3-0	DLC	R/W	0h	Data length code0-8: Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.

11.2.5.44 DCAN_IF2CMD Register (Offset = 120h) [reset = 1h]

DCAN_IF2CMD is shown in Figure 11-137 and described in Table 11-349.

IF2 Command Register
The IF2 Command Register (DCAN_IF2CMD) configure and initiate the transfer between the IF2 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7-0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 DCAN_i_VBUS_CLK (i = 0 or 1) clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.
While BUSY bit is one, IF1/IF2 register sets are write protected.
For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.
If an invalid Message Number is written to bits [7-0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
23	WR_RD	R/W	0h	Write/Read 0h (R/W) = Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1h (R/W) = Direction = Write: Transfer direction is from the IF2 register set to the message object addressed by MESSAGE_NUMBER.

Table 11-349. DCAN_IF2CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	MASK	R/W	0h	Access mask bits 0h (R/W) = Mask bits will not be changed 1h (R/W) = Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.
21	ARB	R/W	0h	Access arbitration bits 0h (R/W) = Arbitration bits will not be changed 1h (R/W) = Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.
20	CONTROL	R/W	0h	Access control bitsIf the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL/DCAN_IF2MCTL will be ignored. 0h (R/W) = Control bits will not be changed 1h (R/W) = Direction = Write: The message control bits will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER.
19	CLRINTPND	R/W	0h	Clear interrupt pending bit 0h (R/W) = IntPnd bit will not be changed 1h (R/W) = Direction = Write: This bit is ignored. Copying of IntPnd flag from IF2 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).
18	TXRQST_NEWDAT	R/W	0h	Access transmission request bitNote: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL/DCAN_IF2MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL/DCAN_IF2MCTL always reflect the status before resetting them. 0h (R/W) = Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1h (R/W) = Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object.
17	DATA_A	R/W	0h	Access Data Bytes 0-3Note: The duration of the message transfer is independent of the number of bytes to be transferred. 0h (R/W) = Data Bytes 0-3 will not be changed. 1h (R/W) = Direction = Write: The data bytes 0-3 will be transferred from the IF2 registerset to the message object addressed by the MESSAGE_NUMBER.
16	DATA_B	R/W	0h	Access Data Bytes 4-7Note: The duration of the message transfer is independent of the number of bytes to be transferred. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Write: The data bytes 4-7 will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER.
15	BUSY	R/W	0h	Busy flagThis bit is set to one after the message number has been written to bits [7-0] MESSAGE_NUMBER. IF2 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF2 register set and message RAM is in progress. 1h (R/W) = Transfer between IF2 register set and message RAM is in progress.

Table 11-349. DCAN_IF2CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAACTIVE	R/W	0h	Activation of DMA feature for subsequent internal IF2 update The DMA request remains active until the first read or write to one of the IF2 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF2 activities. 1h (R/W) = DMA is requested after completed transfer between IF2 register set and message RAM.
13-8	RESERVED	R	0h	These bits are always read as 0. Writes have no effect.
7-0	MESSAGE_NUMBER	R/W	1h	Number of message object in message RAM which is used for data transfer0x01-0x80: Valid message numbers. 0x81-0xFF: Invalid message numbers. 0h (R/W) = Invalid message number

• DCAN_IF2MSK Register (Offset = 124h) [reset = FFFFFFFFh]: [0] • DCAN Registers: [0]

11.2.5.46 DCAN_IF2ARB Register (Offset = 128h) [reset = 0h]

DCAN_IF2ARB is shown in Figure 11-139 and described in Table 11-355.

IF2 arbitration register
The Arbitration bits ID[28-0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28-0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with Xtd = 1, standard frames in message objects with Xtd = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*
While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

11.2.5.50 DCAN_IF3OBS Register (Offset = 140h) [reset = 0h]

DCAN_IF3OBS is shown in Figure 11-143 and described in Table 11-367.

IF3 Observation Register

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in *Structure of Message Objects*). The observation flags (Bits [4-0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.
NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12-8]).

11.2.5.56 DCAN_IF3UPD12 Register (Offset = 160h) [reset = 0h]

DCAN_IF3UPD12 is shown in Figure 11-149 and described in Table 11-385.

Update Enable Register
The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UPDEN flag is set. This means that an active NewDat flag of this message object (for example due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set
NOTE: IF3 Update enable should not be set for transmit objects.

Table 11-385. DCAN_IF3UPD12 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	IF3UPDEN	R/W	0h	IF3 Update Enabled (for 1-32 message objects) 0h (R/W) = Automatic IF3 update is disabled for this message object. 1h (R/W) = Automatic IF3 update is enabled for this message object. A message object is scheduled to be copied to IF3 register set, if NewDat flag of the message object is active.

Table 11-386. Register Call Summary for DCAN_IF3UPD12

DCAN Functional Description • IF3 Register Set: [0]
DCAN Registers • DCAN_IF3UPD12 Register (Offset = 160h) [reset = 0h]: [0] • DCAN Registers: [0]

11.2.5.57 DCAN_IF3UPD34 Register (Offset = 164h) [reset = 0h]

DCAN_IF3UPD34 is shown in Figure 11-150 and described in Table 11-388.

Update Enable Register
The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UPDEN flag is set. This means that an active NewDat flag of this message object (for example due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set
NOTE: IF3 Update enable should not be set for transmit objects.

Table 11-387. DCAN_IF3UPD34 Instances

11.3 Display Subsystem (DSS)

This section describes the Display Subsytem (DSS) in the device.

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

11.3.1 DSS Overview

The Display Subsystem (DSS) provides the logic to interface display peripherals. DSS includes a DMA engine as part of the integrated Display Controller (DISPC) module, which allows direct access to the frame buffer (system memory). Various pixel processing capabilities are supported, such as: color space conversion, filtering, scaling, among others.

The supported display interfaces (connections to external panel) are:

- One parallel interface, which can be used for MIPI® DPI 2.0, or BT-656 or BT-1120.
- One RFBI interface, supporting MIPI DBI 2.0.

The modules integrated in DSS are:

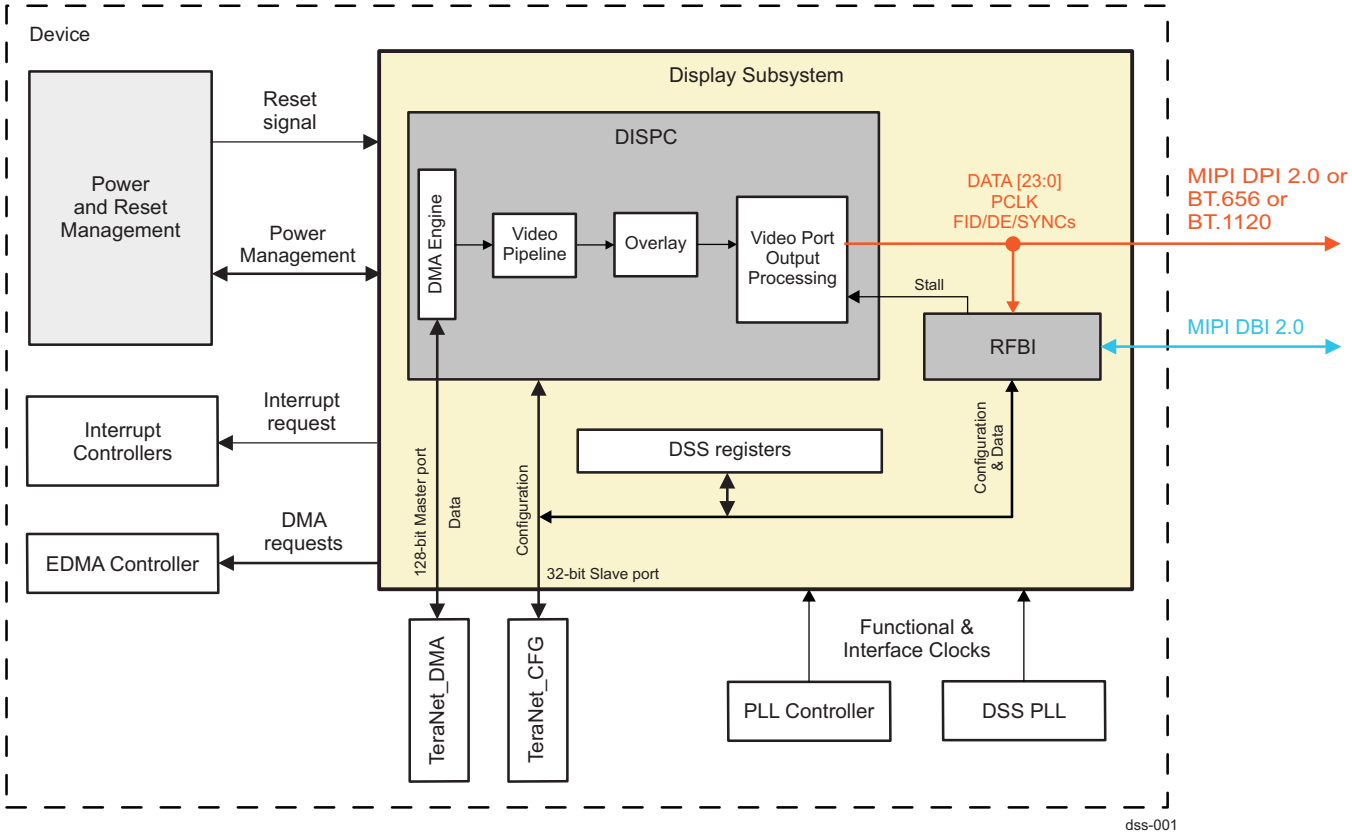
- Display Controller (DISPC), with the following main features
  - One Direct Memory Access (DMA) engine
  - One Video Pipeline (VID1), including VC1 Range Mapping Unit, Scaler, and Color Space Converter (CSC)
  - One Overlay Manager (OVR1)
  - Active Matrix color support for 12/16/18/24-bit (truncated or dithered encoded pixel values)
  - One Video Port (VP1) with programmable timing generator to support up to 148.5 MHz pixel clock video formats defined in CEA-861-E and VESA DMT standards
  - Supported maximum FrameBuffer width of 4096 for all pixel formats
  - Configurable output mode: progressive or interlaced
  - Selection between RGB and YUV422 output pixel formats (YUV422 only available when BT-656 or BT-1120 output mode is enabled on the parallel interface)
  - Stall Mode support for RFBI
- Remote Frame Buffer Interface (RFBI) module, with the following main features:
  - Access to RFB direct “ARMSS interface”
    - Sending commands and data to the RFB panel, received from DISPC or from ARMSS (through the 32-bit interconnect slave port)
    - Reading data/status from the RFB through the 32-bit interconnect slave port
  - RFB interface:
    - 8/9/12/16-bit data bus (for up to QVGA @30fps)
    - Two programmable configurations for two peripheral devices connected to the RFBI module
    - Tearing Effect control logic: Horizontal Synchronization (HSync) and Vertical Synchronization (VSync) embedded in a single signal (TE) or using two signals (HS+VS)
    - Programmable pixel memory and output formats

DSS provides two interfaces to SoC interconnect:

- One 128-bit master port (with MFLAG support). The DMA engine in DISPC uses this single master port to read data from SoC system memory.
- One 32-bit slave port. Used for configuration of the memory mapped registers inside DSS. It is further connected internally to DISPC and RFBI modules.

Figure 11-153 is a high-level overview of the display subsystem.

Figure 11-153. DSS Overview

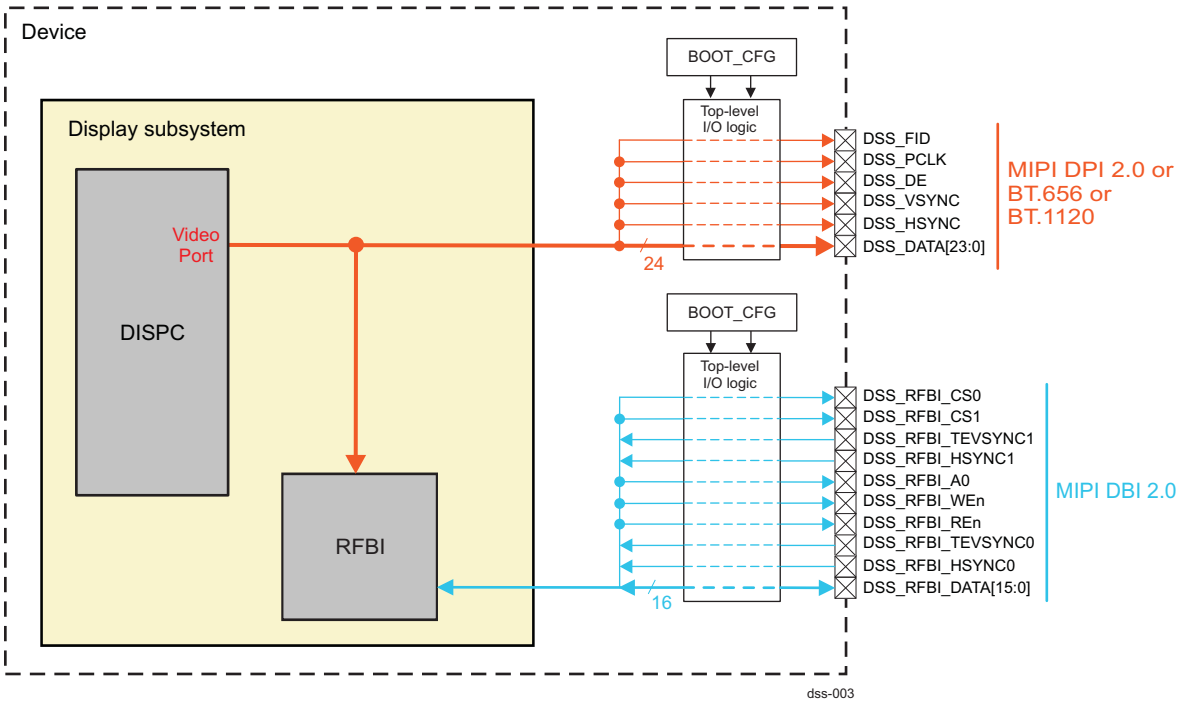


11.3.2 DSS Environment

This section describes the various interfaces handled by the display subsystem.

Figure 11-154 is a diagram of the DSS external connections.

Figure 11-154. DSS Environment



NOTE: The path from a module pin to SoC pad(s) is defined at SoC I/O logic level. The I/O logic maps the module signals to the different pads of the SoC and is programmable in the BOOT_CFG registers and dedicated module registers. For more information, see Section 5.1.3.1.1 *Pad Configuration Registers*.

CAUTION

The parallel interface and RFBI interface cannot be used simultaneously:

- When the DSS_DPI_CTRL[0] DPI_ENABLE is set to 0x1, the parallel output is enabled for usage.
- When the DSS_DPI_CTRL[0] DPI_ENABLE is set to 0x0, the parallel output is disabled. The output through RFBI module can be used, by enabling it via DSS_RFBI_CTRL[0] RFBI_ENABLE register bit.

11.3.2.1 DISPC Environment

The DISPC video port output (VP1) provides the required data and control signals to:

- Connect directly to device pads for MIPI DPI 2.0, or BT.656, or BT.1120 parallel interface support
- Connect to RFBI module for MIPI DBI 2.0 interface support (for more details, see Section 11.3.2.2, *RFBI Environment*)

In synchronous parallel interface configuration, the DISPC outputs data and control signals directly on device I/O pads: DATA[23:0] (data bus), HSYNC (horizontal synchronization signal), VSYNC (vertical synchronization signal), DE (data enable), FID (field identification, odd/even), and PCLK (pixel clock). The data and control signals can be provided directly to an external MIPI DPI 2.0 compatible LCD panel.

Table 11-396 describes the DISPC VP1 interface signals for direct connection to device pads for MIPI DPI 2.0, or BT.656 or BT.1120 parallel interface support.

Table 11-396. DISPC Video Port Signals for MIPI DPI 2.0, or BT.656 or BT.1120

Signal Name	Type[1]	Description
DSS_DATA[23:0]	O	Pixel data
DSS_PCLK	O	Pixel clock
DSS_VSYNC	O	Vertical synchronization. The frame synchronization pulse (vsync) toggles after all the lines in a frame are transmitted and a programmable number of line clock cycles has elapsed at the beginning and the end of each frame.
DSS_HSYNC	O	Horizontal synchronization. The line synchronization pulse (hsync) toggles after all pixels in a line are transmitted and a programmable number of pixel clock wait-states has elapsed at the beginning and the end of each line.
DSS_DE	O	Pixel data output-enable signal to indicate when data must be latched using the pixel clock.
DSS_FID	O	The FID signal indicates the output field identifier: • 0 means even • 1 means odd The FID signal is 0 when the progressive mode is selected for the VP output.

(1) I = Input, O = Output, I/O = Input/Output

11.3.2.1.1 DISPC VP1 Output and Data Formats

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations.

In the Active matrix display type, one pixel per pixel clock is displayed. The diagrams represent the configuration of assertion of the data on the rising edge of the pixel clock. It is possible to program the interface timing to output the data on the falling edge of the pixel clock.

Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.Figure 11-155 through Figure 11-158 show 12-, 16-, 18-, and 24-active matrix displays, respectively. The width of the data bus can be configured through DISPC_VP1_CONTROL[10-8] DATALINES register bitfield.

Figure 11-155. DISPC VP1 Pixel Data Color-12 Active Matrix

11.3.2.1.2 DISPC VP1 Active Marix Display Timing Diagrams

Figure 11-159 through Figure 11-162 show timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC directly drives these signals, which are related to the programmable fields listed in Table 11-397.

Table 11-397. DISPC VP1 Programmable Fields for Active Matrix Display

Name	Register	Description
PPL	DISPC_VP1_SIZE_SCREEN[11-0] PPL value + 1	Pixels per line
LPP	DISPC_VP1_SIZE_SCREEN[27-16] LPP value + 1	Lines per panel
HBP	DISPC_VP1_TIMING_H[31-20] HBP value + 1	Horizontal back porch
HFP	DISPC_VP1_TIMING_H[19-8] HFP value + 1	Horizontal front porch
HSW	DISPC_VP1_TIMING_H[7-0] HSW value + 1	Horizontal synchronization pulse width
VBP	DISPC_VP1_TIMING_V[31-20] VBP value	Vertical back porch
VFP	DISPC_VP1_TIMING_V[19-8] VFP value	Vertical front porch
VSW	DISPC_VP1_TIMING_V[7-0] VSW value + 1	Vertical synchronization pulse width
ALIGN	DISPC_VP1_POL_FREQ[18] ALIGN	Alignment between DISPC HSYNC and VSYNC assertion
ONOFF	DISPC_VP1_POL_FREQ[17] ONOFF	DISPC HSYNC and VSYNC pixel clock control
RF	DISPC_VP1_POL_FREQ[16] RF	DISPC HSYNC and VSYNC pixel clock edge control
IEO	DISPC_VP1_POL_FREQ[15] IEO	Invert output enable
IPC	DISPC_VP1_POL_FREQ[14] IPC	Invert DISPC PCLK
IHS	DISPC_VP1_POL_FREQ[13] IHS	Invert DISPC HSYNC
IVS	DISPC_VP1_POL_FREQ[12] IVS	Invert DISPC VSYNC

- Active matrix timing configuration 1:
  - DISPC_VP1_POL_FREQ[17] ONOFF = 0
  - DISPC_VP1_POL_FREQ[16] RF = 0

    The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.

– DISPC_VP1_POL_FREQ[15] IEO = 0
  The DE signal is active high.
– DISPC_VP1_POL_FREQ[14] IPC = 0
  The pixel data are driven on the rising edge of PCLK.
– DISPC_VP1_POL_FREQ[13] IHS = 0
  The HSYNC signal is active high.
– DISPC_VP1_POL_FREQ[12] IVS = 0
  The VSYNC signal is active high.
– DISPC_VP1_POL_FREQ[18] ALIGN = 0
  The VSYNC and HSYNC assertion is not aligned.

Figure 11-159. DISPC Active Matrix Timing Diagram of Configuration 1 (Start of Frame)

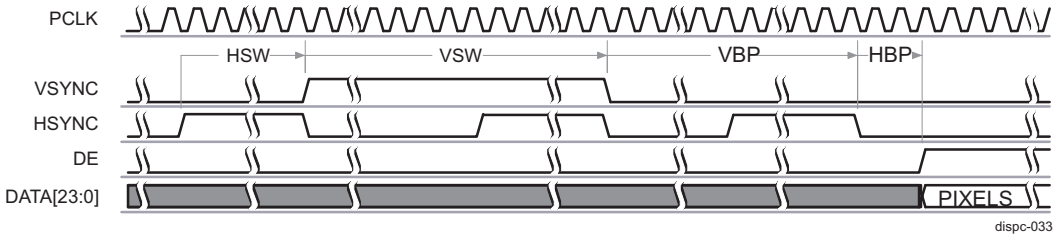

Figure 11-160. DISPC Active Matrix Timing Diagram of Configuration 1 (Between Lines)

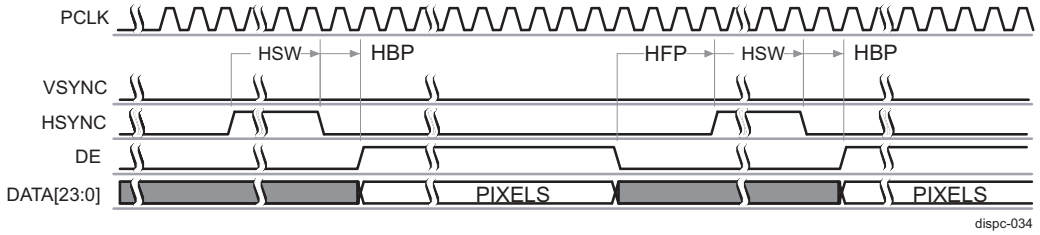

Figure 11-161. DISPC Active Matrix Timing Diagram of Configuration 1 (Between Frames)

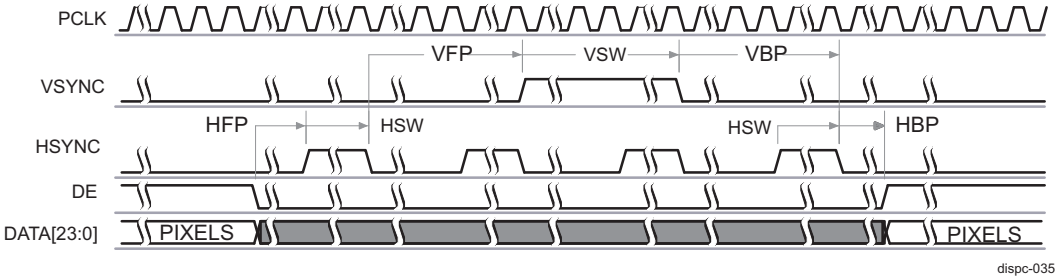

Figure 11-162. DISPC Active Matrix Timing Diagram of Configuration 1 (End of Frame)

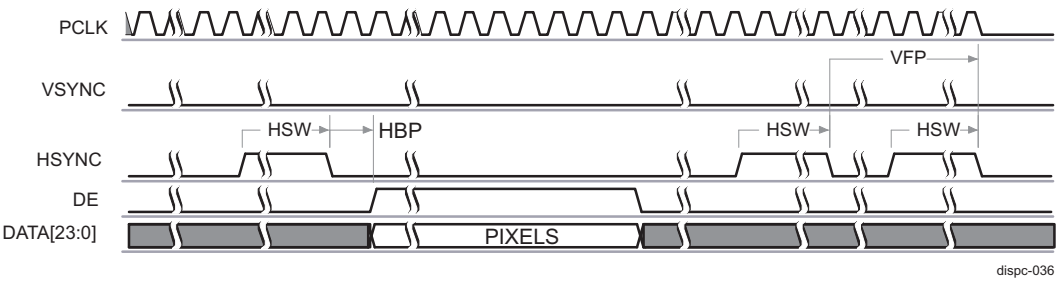

- Active matrix timing configuration 2:

– DISPC_VP1_POL_FREQ[17] ONOFF = 1
– DISPC_VP1_POL_FREQ[16] RF = 1
  The HSYNC and VSYNC signals are driven on the rising edge of PCLK.
– DISPC_VP1_POL_FREQ[15] IEO = 1
  The DE signal is active low.
– DISPC_VP1_POL_FREQ[14] IPC = 1
  The pixel data is driven on the falling edge of PCLK.
– DISPC_VP1_POL_FREQ[13] IHS = 1
  The HSYNC signal is active low.
– DISPC_VP1_POL_FREQ[12] IVS = 1
  The VSYNC signal is active low.
– DISPC_VP1_POL_FREQ[18] ALIGN = 0
  The VSYNC and HSYNC assertion is not aligned.

Figure 11-163. DISPC Active Matrix Timing Diagram of Configuration 2 (Start of Frame)

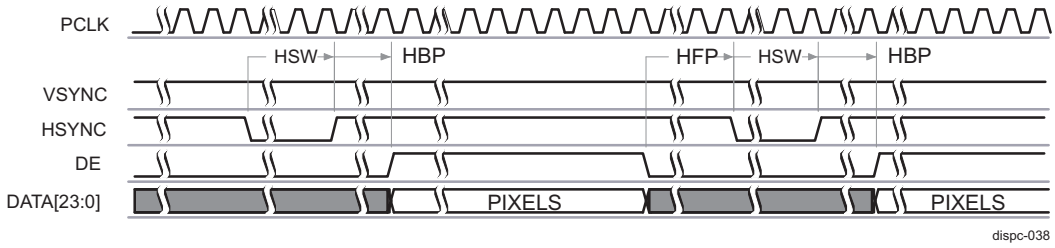

Figure 11-165. DISPC Active Matrix Timing Diagram of Configuration 2 (Between Frames)

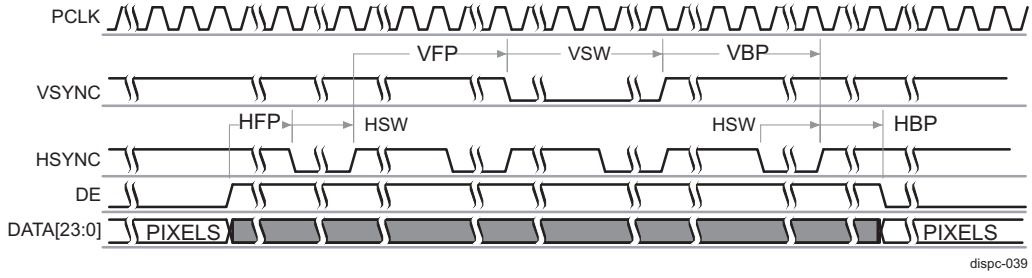

Figure 11-166. DISPC Active Matrix Timing Diagram of Configuration 2 (End of Frame)

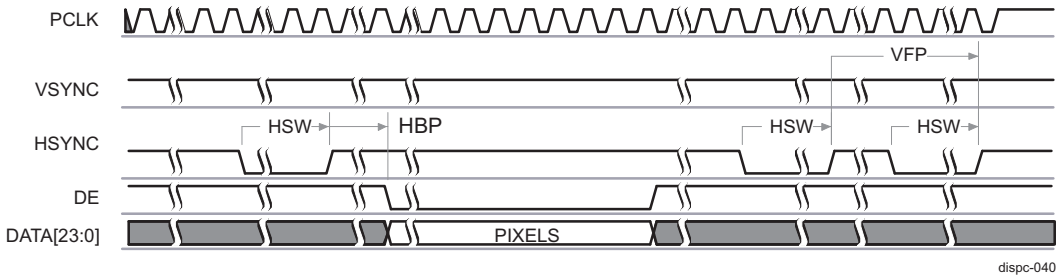

- Active matrix timing configuration 3:
  - DISPC_VP1_POL_FREQ[17] ONOFF = 1
  - DISPC_VP1_POL_FREQ[16] RF = 1
    The HSYNC and VSYNC signals are driven on the rising edge of PCLK.
  - DISPC_VP1_POL_FREQ[15] IEO = 0
    The DE signal is active high.
  - DISPC_VP1_POL_FREQ[14] IPC = 0
    The pixel data are driven on the rising edge of PCLK.
  - DISPC_VP1_POL_FREQ[13] IHS = 0
    The HSYNC signal is active high.
  - DISPC_VP1_POL_FREQ[12] IVS = 0
    The VSYNC signal is active high.
  - DISPC_VP1_POL_FREQ[18] ALIGN = 0
    The VSYNC and HSYNC assertion is not aligned.

11.3.2.2 RFBI Environment

In asynchronous RFBI configuration, the remote frame buffer (RFB) of the peripheral LCD panel is connected directly to the RFBI module of the device. RFBI controls the reads and writes to and from the RFB. The RFBI receives data from the DISPC video port, or from system memory (through the interconnect slave port), and generates the signals to control the LCD panel.

The RFBI module provides the necessary control signals to interface between the DISPC on one side and the LCD driver of the peripheral LCD panel on the other. The SoC ARMSS or DMA controller can read and write the encoded pixel values from/to the remote frame buffer inside the peripheral. In the forward direction from the SoC to the peripheral, the stream consists of commands, parameters, and pixels.

For the forward direction from the SoC to the LCD peripheral, the commands and parameters are provided using the RFBI interconnect slave port. The pixel data is provided either by:

- DISPC video port: DISPC uses its own DMA engine to read the system frame buffer, or
- SoC ARMSS or DMA controller, using the RFBI interconnect slave port

For the reverse direction from LCD peripheral to SoC, the data from the peripheral are transferred to system memory by the SoC ARMSS or DMA controller through the RFBI interconnect slave port. The ARMSS can also analyze directly the information received from the peripheral. In that case, there is not always access to the system memory when data are received from the peripheral (that is, status of the peripheral state: ON/OFF/IDLE).

The RFBI can manage only one LCD panel at a time, although a sequential configuration is also possible.

Table 11-398 describes the RFBI interface signals to/from a peripheral LCD panel.

Table 11-398. RFBI Interface Signals to/from Peripheral LCD

Signal Name	Type[1]	Description
DSS_RFBI_DATA[15:0]	I/O	RFBI I/O data

(1) I = Input; O = Output; I/O = Input/Output

Table 11-398. RFBI Interface Signals to/from Peripheral LCD (continued)

Signal Name	Type[1]	Description
DSS_RFBI_REn	O	Read access signal
DSS_RFBI_WEn	O	Write access signal
DSS_RFBI_A0	O	Command/data selection signal
DSS_RFBI_CS0	O	Chip-select (CS) signal for LCD panel 0
DSS_RFBI_CS1	O	Chip-select (CS) signal for LCD panel 1
DSS_RFBI_TEVSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 0)
DSS_RFBI_TEVSYNC1	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
DSS_RFBI_HSYNC0	I	HSYNC from LCD panel 0
DSS_RFBI_HSYNC1	I	HSYNC from LCD panel 1

- DSS_RFBI_DATA[15:0]: The pixel data comprises the RFBI pixel data (bits 15-0). A write/read command must be sent to the LCD panel to send/read the data.

  Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel.
- DSS_RFBI_REn: The read-enable signal indicates an ongoing read from the embedded memory in the LCD panel. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. The read is used to obtain status/data information from the LCD panel.
- DSS_RFBI_WEn: The write-enable signal indicates an ongoing write. The RFBI registers allow flexible behavior of the write signal (programmable off/on/cycle times and signal polarity).
- DSS_RFBI_A0: The signal is asserted to indicate its status: Command or Data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (RFBI_CMD/RFBI_READ/RFBI_STATUS/RFBI_PARAM/RFBI_DATA). The register in use by the hardware defines the status of DSS_RFBI_A0. The order of the writes/reads to RFBI registers RFBI_CMD/RFBI_READ/RFBI_STATUS/RFBI_PARAM/RFBI_DATA defines the transitions of RFBI_A0 signal.
- DSS_RFBI_CS0/CS1: The chip-select (CS) signals are asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. Two LCD panels can be connected at the same time to the RFBI module. When RFBI_REn or RFBI_WEn is on, the RFBI_CS0/CS1 signals must not be changed.

  To select the trigger mode, configure the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field (0x0: Internal trigger mode with the RFBI_CONTROL[4] ITE bit; 0x1: External trigger mode with the TE signal TEVSYNC; 0x2: External trigger mode with the TEVSYNC and HSYNC signals with the programmable line counter).
- DSS_RFBI_TEVSYNC0/TEVSYNC1 (used by RFBI only if RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE = 0x1 or 0x2; otherwise, this signal is ignored): Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel vertical synchronization (VSYNC) pulse signal. TE logic uses VSYNC as the synchronization signal to send the pixel to the LCD panel.
- DSS_RFBI_HSYNC0/HSYNC1 (used by RFBI only if RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE = 0x2, otherwise, this signal is ignored): The HSYNC pulse signals indicate to the RFBI when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two DSS_OCP_CLK cycles. TE logic uses HSYNC as a synchronization signal to send the pixel to the LCD panel.

11.3.2.2.1 RFBI Description of the Tearing Effect Pulse Signal

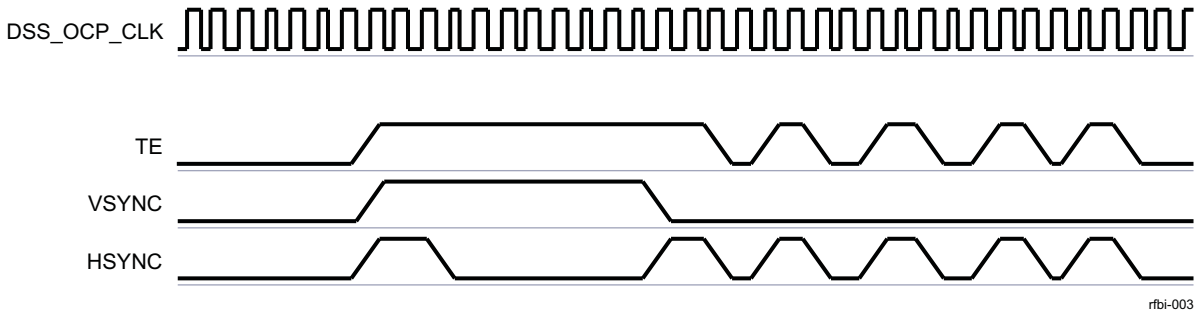
The TE signal can be generated externally by the RFBI depending on the value of the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field:

- TRIGGERMODE = 0x1: External trigger mode with the TE signal, which corresponds to the DSS_RFBI_TEVSYNC0 signal.

- TRIGGERMODE = 0x2: External trigger mode with the HSYNC/VSYNC signals. The HSYNC signal corresponds to the DSS_RFBI_HSYNC0 signal. The VSYNC signal corresponds to the DSS_RFBI_TEVSYNC0 signal.

The externally generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 11-171). The logical operation (OR or AND) depends on the polarity of the HSYNC and VSYNC signals. The VSYNC signal indicates to the RFBI when vertical synchronization occurs. The HSYNC signal indicates to the RFBI when horizontal synchronization occurs.

Figure 11-171. RFBI External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active High)



- The TE signal is connected to DSS_RFBI_TEVSYNC0 when the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field is set to 0x1.
- The HSYNC and VSYNC signals are connected to DSS_RFBI_HSYNC0 and DSS_RFBI_VSYNC0, respectively, when the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field is set to 0x2.

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the RFBI_VSYNC_WIDTH register. VSYNC is not triggered by an inactive-to-active edge.

HSYNC is detected based on the minimum pulse width defined by the RFBI_HSYNC_WIDTH register. HSYNC is not triggered by an inactive-to-active edge.

The signal is generated from external logic based on VSYNC and HSYNC of the LCD panel. The automatic trigger can be programmed based on the external RFBI_TE signal or use the RFBI_CONTROL[4] ITE bit to start data capture (internal trigger mode).

The polarity of the TE signal is programmable in the RFBI_CONFIG__0/RFBI_CONFIG__1 register. HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an OR-ed signal and active low for an AND-ed signal. The minimum pulse width of the signal is two DSS_OCP_CLK cycles. Hardware resets the line counter when VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

11.3.2.2.2 RFBI Transaction Timing Diagrams

Table 11-399 lists the programmable timing fields. Figure 11-172 through Figure 11-174 show timing diagrams of read/write transactions to the LCD panel for the RFBI. In these figures, the polarity 0 (active low) describes the DSS_RFBI_A0, DSS_RFBI_CS0/CS1, DSS_RFBI_REn, and DSS_RFBI_WEn signals.

Table 11-399. RFBI Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[3-0] CSONTIME bit field	RFBI_CS0/CS1 assertion time from start access time
CSOffTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[9-4] CSOFFTIME bit field	RFBI_CS0/CS1 deassertion time from start access time
WECycleTime	RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[5-0] WECYCLETIME bit field	The time when RFBI_A0 becomes valid until write cycle completion
WEOnTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[13-10] WEONTIME bit field	RFBI_WEn assertion delay time from start access time

Table 11-399. RFBI Programmable Timing Fields in RFBI Mode (continued)

Timing Name	Register Field	Description
WEOffTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[19-14] WEOFFTIME bit field	RFBI_WEn deassertion delay time from start access time
RECycleTime	RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[11-6] RECYCLETIME bit field	The time when RFBI_A0 becomes valid until read cycle completion
REOnTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[23-20] REONTIME bit field	RFBI_REn assertion delay time from start access time
REOffTime	RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[29-24] REOFFTIME bit field	RFBI_REn deassertion delay time from start access time
CSPulseWidth	RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[17-12] CSPULSEWIDTH bit field	The time when write cycle time or read cycle time completes

11.3.3 DSS Integration

This section describes the integration of DSS in the device, including information about clocks, resets, and hardware requests.

Figure 11-175 shows the integration of DSS in the device.

Figure 11-175. DSS Integration

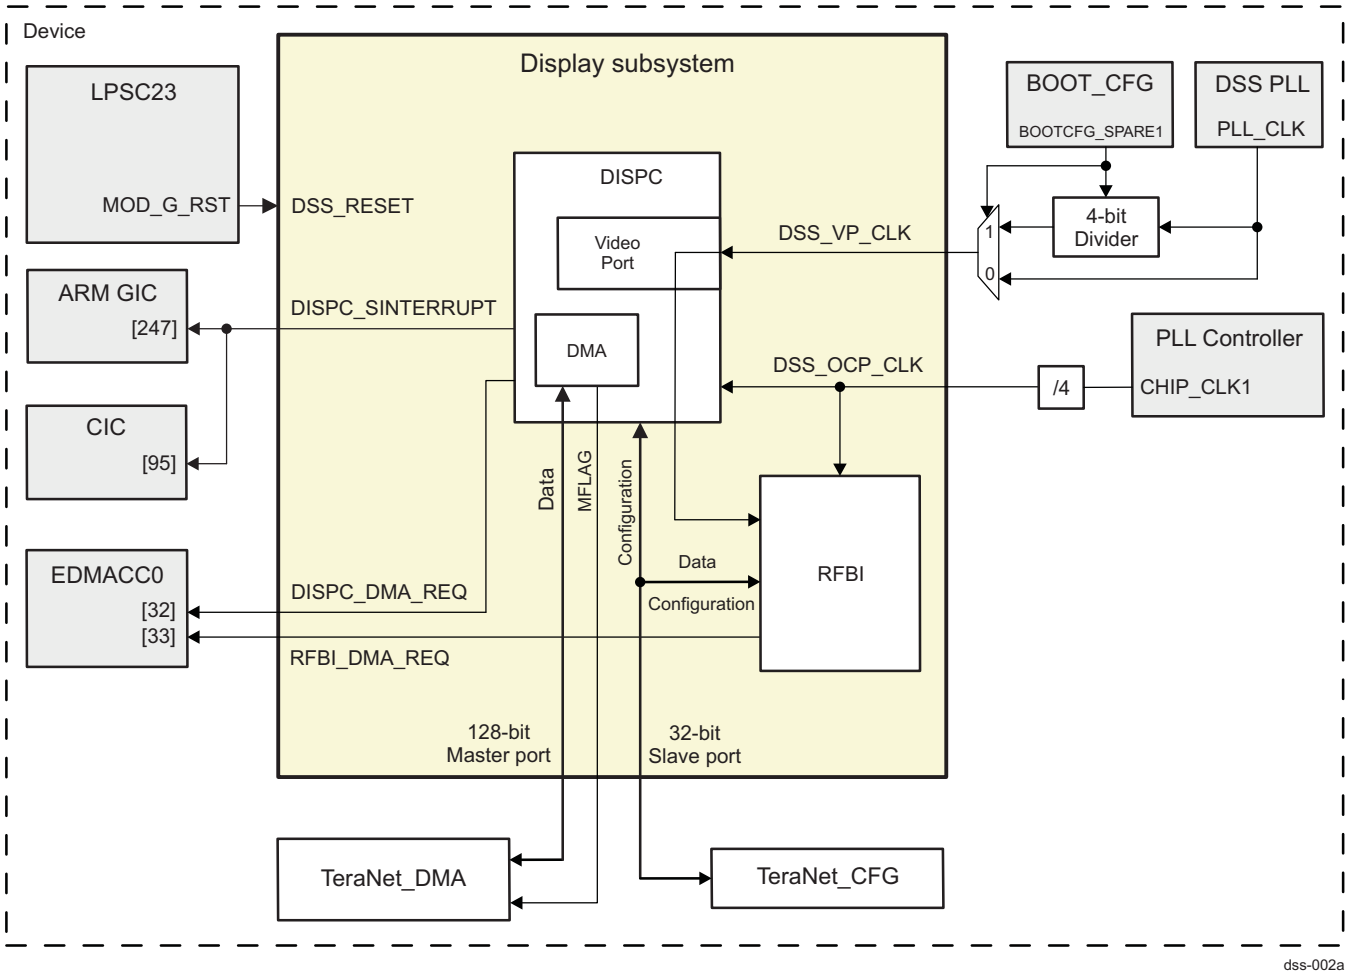

Table 11-400 summarizes the main integration attributes of DSS in the device.

Table 11-400. DSS Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
DSS	PD12	LPSC23	TeraNet_DMA: Connected to DSS 128-bit master port. Used for by DISPC DMA engine to read pixel data from system memory. TeraNet_CFG: Connected to DSS 32-bit slave port. Used for DSS, DISPC, and RFBI configuration, and data traffic via RFBI slave port.

NOTE: For more information on device and module level power management, see the corresponding sections within Chapter 5, *Device Configuration*.

For more information on device interconnects, see Section 3.1, *Interconnect*.

11.3.3.1 DSS Clocks and Resets

Table 11-401. DSS Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
DSS (DISPC and RFBI)	DSS_OCP_CLK	CHIP_CLK1 / 4	PLL Controller	Interconnect interface clock (for both DSS master port and slave port). Also the main functional clock (FCLK) inside the DISPC. Must be greater than DSS_VP_CLK for all supported display resolutions and refresh rates. RFBI module uses this clock when capturing data on the RFBI slave port data bus (through RFBI interconnect FIFO).
	DSS_VP_CLK	PLL_CLK / (4-bit clock divider value)	DSS PLL	DISPC video port (VP1) pixel clock. Its frequency is tied to the external LCD panel resolution and refresh rate. RFBI module uses this clock in order to capture the pixels from DISPC video port output, and for the generation of the STALL signal. The 4-bit clock divider value is controlled via BOOTCFG_SPARE1 register inside the device BOOT_CFG module.
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
DSS	DSS_RESET	MOD_G_RST	LPSC23	DSS asynchronous reset

The DSS is reset via a global HW reset signal (DSS_RESET), which is propagated to all DSS sub-modules.

Each DSS sub-module can also be reset by a corresponding SW reset on sub-module level.

The [0] DSS_RESETDONE and [7] RFBI_RESETDONE bits of DSS_SYSSTATUS register indicate the completion of the DSS reset following the HW reset, or after a SW reset of all its sub-modules.

NOTE: For more information on device reset and clock management, see the corresponding sections within Chapter 5, *Device Configuration*.

11.3.3.2 DSS Interrupt and DMA Requests

Table 11-402 shows the interrupt and DMA requests generated by the DISPC and RFBI modules.

Table 11-402. DSS Hardware Requests

Interrupt Requests				
Module Instance	**Event Name**	**Mapped To Input Event [Number]**		**Description**
		ARM GIC	**CIC**	
DISPC	DISPC_SINTERRUPT	[247]	[95]	DISPC interrupt
DMA Requests				
Module Instance	**Event Name**	**Mapped To Input Event [Number]**		**Description**
		EDMACC0		

Table 11-402. DSS Hardware Requests (continued)

DISPC	DISPC_DMA_REQ	[22]	Connected to DISPC line trigger DMA event. The line trigger signal is used for synchronization of a logical channel in the SoC DMA Controller, when performing data transfer. There is no real data received by the DISPC based on this DMA request. It can also be used to update a frame buffer base-address stored in the system memory.
RFBI	RFBI_DMA_REQ	[23]	RFBI FIFO DMA event. This signal is useful, if a SoC initiator (DMA controller) wants to do a direct pixel data transfer through RFBI, bypassing the DISPC.

NOTE: For more information on device interrupt controllers, see Chapter 9, *Interrupts*.

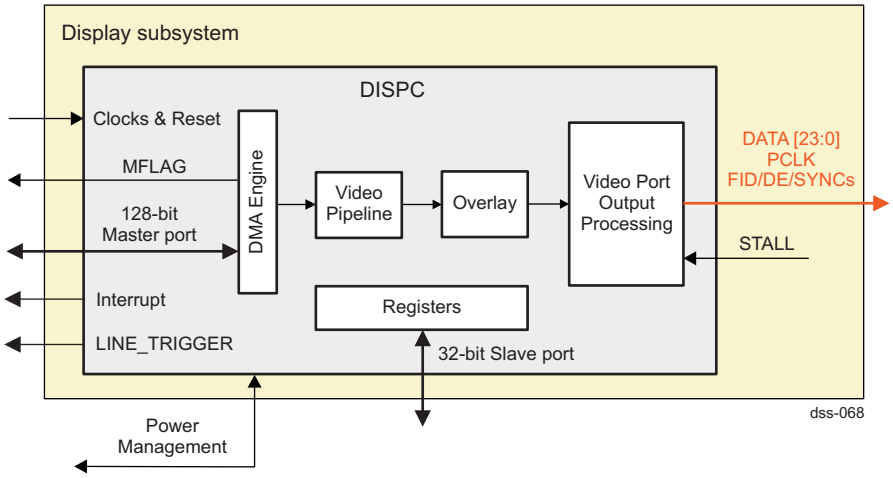
For more information on device DMA controllers, see Chapter 10, *Enhanced Direct Memory Access (EDMA) Controller*.

11.3.4 DSS Functional Description

11.3.4.1 DISPC Functional Description

11.3.4.1.1 DISPC Overview

Figure 11-176. DISPC Architecture Overview



The DISPC integrated within DSS is a fully scalable module capable of fetching pixel data from the device system memory through its single master port, performing various pixel processing, and then providing the processed pixels to an external display panel.

Several processes are configurable by the user in order to manage the video pipeline (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the vieo port output signals based on VESA DMT and CEA-861 standard.

The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the requests.

The DISPC video port output can be connected to display peripherals either directly (for MIPI DPI 2.0, or BT.656, or BT.1120 support), or through RFBI module for MIPI DBI 2.0 support.

NOTE: DISPC does not support any tiled frame buffer, nor any compressed frame buffer. The DISPC has no capability to support by itself rotation of the frame buffer.

11.3.4.1.2 DISPC Features

The DISPC provides the following features:

- One Video Pipeline (VID1):
  - Input pixel formats supported: ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555, ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, RGB24-888, ARGB32-2101010, ABGR32-2101010, ARGB48-12121212, RGBA48-12121212, ARGB64-16161616, RGBA64-16161616, RGB565-A8, BITMAP1, BITMAP2, BITMAP4, BITMAP8, YUV422-UYVY, YUV422-YUV2, YUV420-NV12, YUV420-NV21 and in addition RGBx, xRGB, xBGR, and BGRx pixel formats defined considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (e.g. ARGB->xRGB)
  - Premultiplied ARGB and RGBA formats
  - Programmable poly-phase filter:
    - Independent horizontal and vertical resampling. Upsampling up to x16, and downsampling down to 1/4
    - Maximum input width of 1280 pixels (32-bit) in 5-tap mode, and 2560 pixels (32-bit) in 3-tap

mode
- No limitation on the input height
- Supported pixel formats for scaling are all above listed formats, except BITMAP formats. The alpha channel is rescaled like the R, G and B color components. 16 phases with symmetrical coefficients are implemented.

– Programmable color space conversion from YUV4:2:2/YUV4:4:4, and YUV4:2:0 (after chroma upsampling through the scaler) into ARGB48-12121212.
– Programmable VC-1 range mapping
– Support for color look-up table (CLUT): 256 × 24-bit entries palette in RGB
– Up to 4K-by-4K frame buffer size

- One Video Port (VP1) output:
  – Up to 24 bits per pixel on the output interface, with selection between 12, 16, 18, or 24 bits
  – Programmable timing generator to support up to 150MHz pixel clock (PCLK) frequency for video formats defined in CEA-861-E and VESA-DMT standards
  – Programmable multiple cycles output format on 8/9/12/16-bit interface (TDM)
  – Configurable output mode: progressive or interlaced mode
  – Selection between RGB and YUV422 output pixel format (YUV4:2:2 only available when a BT mode is enabled)
- One Overlay Manager (OVR1):
  – Input pixel format: RGB48-12121212
  – Output pixel format: RGB48-12121212
  – Programmable background color
- Common:
  – Programmable 8-bit gamma curve support on VP1 output
  – Programmable color phase rotation (CPR)
- DMA (internal to the DISPC):
  – No support for rotation, flipping, mirroring, and memory fragmentation
  – Integrated buffers between DMA engine and VID1 pipeline
  – Programmable buffer thresholds
  – Support for MFLAG to indicate critical fullness of DMA buffer (close to underflow for video pipeline)
  – Region-Based support (same layer can display multiple windows)
- Advanced:
  – Self-refresh using the DMA buffers (outputting data on display only from the DMA buffer)

NOTE: The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations, related to the type of display or the processing done, apply:
- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory should consist of contiguous pixels.

11.3.4.1.3 DISPC Clock Configuration

The DISPC pixel clock (PCLK) for the Video Port (VP1) output is provided directly from the DSS_VP_CLK input clock. There is no internal DSS divisor on this clock. The PCLK transitions continuously as long as the VP1 is enabled and DISPC_VP1_CONFIG[0] PIXELGATED register bit is 0x0.

The DISPC internal functional clock (FCK_CLK) is provided by DSS_OCP_CLK. There is no internal divisor on this clock. It also acts as the interface clock for the DISPC master and slave ports.

The FCK_CLK has to be greater than the PCLK (that is, DSS_OCP_CLK must be greater than DSS_VP_CLK), in order for DISPC internal logic to function properly.

The minimum ratio between the PCLK frequency and FCK_CLK does not depend on the vertical scaling ratio. It is possible to rescale vertically between 16x and 0.25x with a clock ratio between functional clock and pixel clock of 1x. For the horizontal scaling, the minimum clock ratio does not depend on the video window width but on the display width. For example, downscaling a 1920 pixels wide video frame by 0.25 horizontally to 480 pixels and then displayed on a 1920 pixels wide screen, can be achieved by a FCK_CLK/PCLK ratio as low as 1.

The PCLK and FCK_CLK clocks are asynchronous. There is re-synchronization logic between internal logic and the VP1 output interface.

11.3.4.1.4 DISPC Software Reset

To perform a software reset on the DISPC, set the DISPC_SYSCONFIG[1] SOFTRESET bit to 0x1. The DISPC_SYSSTATUS[0] DISPC_FUNC_RESETDONE bit indicates that the software reset is complete when its value is 0x1. When the software reset completes, the DISPC_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the VP logic is indicated in the DISPC_SYSSTATUS[1] DISPC_VP1_RESETDONE bit.

11.3.4.1.5 DISPC Interrupt Requests

The interrupt line, DISPC_SINTERRUPT, indicates when one or more events are detected by the hardware. Each event is independently maskable by configuring the DISPC_IRQENABLE_SET register.

To check when a particular interrupt event occurs and to reset a particular event, the DISPC_IRQSTATUS register must be accessed. This register regroups the status of internal events in the module that generate an interrupt (Read 0: no interrupt occurred; Read 1: interrupt occurred; Write 1: status bit reset).

There are two level of interrupts. The first level, controlled by the DISPC_IRQENABLE_SET, DISPC_IRQENABLE_CLR, and DISPC_IRQSTATUS registers, is used to indicate common events and is also source for the second level of interrupts. The second level of interrupts consists of status and enable interrupt registers for the VID1 pipeline and the video port.

Table 11-403. DISPC Interrupts - First Level

Interrupt Name	Description
VP1_IRQ	At least one event of the Video Port 1 interrupt events occurred
VID1_IRQ	At least one event of the VID1 pipeline interrupt events occurred

The second level of interrupts for VID1 pipeline is controlled through the DISPC_VID1_IRQENABLE and DISPC_VID1_IRQSTATUS registers.

Table 11-404. DISPC Interrupts - Second Level - VID1 Pipeline

Interrupt Name	Description
VIDENDWINDOW_IRQ	End of the VID1 window: The DMA engine has fetched all the data from memory for the VID1 for the current frame.
VIDBUFFERUNDERFLOW_IRQ	VID1 DMA buffer underflow: The input VID1 DMA buffer goes underflow. Does not necessary means that the buffer is empty (out of order refill), but simply that the required pixel is not in yet.
VIDREGIONBASEDPIPESTART_IRQ	Video window started on overlay. Used for Region-based feature.
VIDREGIONBASEDPIPEEND_IRQ	Video window ended on overlay. Used for Region-based feature.

The second level of interrupts for VP1 ouput is controlled through the DISPC_VP1_IRQENABLE and DISPC_VP1_IRQSTATUS registers.

Table 11-405. DISPC Interrupts - Second Level - VP1 Output

Interrupt Name	Description
FRAMEDONE_IRQ	Frame Done for VP1 output. After disabling the VP1 output of the DISPC, the interrupt is set when the active frame related to the VP1 has completed.
VSYNC_IRQ	VSYNC for VP1 output: VSYNC interrupt for the VP1 has occurred at the end of the frame.
VSYNC_ODD_IRQ	VSYNC for odd field. VSYNC_ODD interrupt has occurred at the end of the frame (EVSYNC received and the field polarity is odd).
PROGRAMMEDLINENUMBER_IRQ	Programmed line number: The VP1 has reached the user programmed line number.
SYNCLOST_IRQ	Synchronization lost on VP1 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipeline with data (VP1 output).

11.3.4.1.6 DISPC DMA Requests

The DISPC DMA request signal, DISPC_DMA_REQ, is not a classical one, but rather a synchronization signal between the DISPC and device DMA controller. The device DMA controller is informed that a programmable number of lines are output on the VP1, and that the system memory can be updated. This request is related to the interrupt event PROGRAMMEDLINENUMBER_IRQ described in Table 11-405. This allows the device DMA controller channel to be synchronized with the internal DMA controller of the DISPC.

In other words, it allows synchronizing a system memory frame buffer update, based on the line of the frame buffer in system memory, which is scanned by the DISPC. The DISPC_DMA_REQ request is generated at a programmable line number defined in the DISPC_VP1_LINE_NUMBER[11-0] LINENUMBER bit field. This process allows an application to use a single frame buffer and to update it after a certain number of lines are read by the DISPC.

11.3.4.1.7 DISPC DMA Engine

The DISPC DMA engine:

- Requests and supplies data from system memory to the VID1 pipeline through the interconnect, based on the configuration of the DISPC and VID1 pipeline settings.
- Is fully programmable and fetches pixel data using 1D burst.

The VID1 pipeline has a dedicated buffer and a channel with independent settings. Table 11-406 lists the default size and allocation of the DMA buffer. The allocation is done in the DISPC_GLOBAL_BUFFER register.

Table 11-406. DISPC DMA Buffer Size

Pipeline	DMA Buffer Size
VID1	4 lines × 640 × 128 bits

11.3.4.1.7.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine:

- Calculates the pixel address
- Aligns the address
- Defines the burst structure:
  - Type of burst (1D only)
  - Length of the burst

The DMA engine generates scan addresses to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The ROW_INC register of VID1 pipeline allow to access a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW_INC can also be used to skip lines from the input frame. The byte address of each pixel in the frame buffer in the system memory is determined by:

Pixel address = Base address + x × bpp + (y × ((width × bpp) + increment))

where:

- Base address corresponds to the base address (for YUV–NV12 or YUV4:2:0-NV21 format) defined by:
  - DISPC_VID1_BA_0 to DISPC_VID1_BA_1[31-0] BA bit fields
  - DISPC_VID1_BA_UV_0 to DISPC_VID1_BA_UV_1[31-0] BA bit fields
- bpp corresponds to the number of bits per pixel defined by the DISPC_VID1_ATTRIBUTES[6-1] FORMAT bit field.
- width corresponds to the number of pixels per line defined by the DISPC_VID1_SIZE[11-0] SIZEX + 1 bit field.
- increment corresponds to the number of bytes to skip between two contiguous lines defined by the DISPC_VID1_ROW_INC[31-0] ROWINC – 1 bit field.
- x corresponds to the pixel position on the x-axis.
- y corresponds to the pixel position on the y-axis.

NOTE: For YUV420-NV12 or YUV420-NV21 format, the pixel values are defined in two buffers (Y and UV). The first one consists of Y values (8 bits for each Y sample). The second one consists of CbCr values (16 bits for each pair of CbCr samples). The base address of the Y buffers is defined in the DISPC_VID1_BA_0 to DISPC_VID1_BA_1[31-0] BA bit field. The base address of the UV buffers is defined in the DISPC_VID1_BA_UV_0 to DISPC_VID1_BA_UV_1[31-0] BA bit field.

In case of interlaced mode, DISPC_VID1_BA_0 and DISPC_VID1_BA_UV_0 registers define the base address of the even field, and DISPC_VID1_BA_1 and DISPC_VID1_BA_UV_1 registers define the base address of the odd field.

The number of bytes to skip between pixels and between lines are defined using DISPC_VID1_PIXEL_INC and DISPC_VID1_ROW_INC registers, respectivelly. They define the values to be used for the Y buffer. For the CbCr buffer, the HW calculates the corresponding values.

Table 11-407 summarizes the register settings for a simple access of a picture in the system memory.

Table 11-407. DISPC Register Settings for Accessing Image in Internal Memory

Registers	Value
DISPC_VID1_BA_0 to DISPC_VID1_BA_1	PBA, the physical base address of image in the memory
DISPC_VID1_BA_UV_0 to DISPC_VID1_BA_UV_1	PBA, the physical base address of UV buffers image in the memory
DISPC_VID1_PIXEL_INC	1 or other in pixel incremental value
DISPC_VID1_ROW_INC	1 or other in row incremental value

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values: 1x128-bit, 2x128-bit, 4x128-bit, or 8x128-bit. The default burst size at reset time is 8 × 128 bits. Because the burst size must be aligned to the burst boundary, in case of misalignment, the DMA engine may issue one or more smaller burst requests.

11.3.4.1.7.2 DISPC Read DMA Buffer

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffer is flushed according to the VP1 output associated with the VID1 pipeline. The DMA engine restarts fetching data from the memory through the device interconnect. Enabling or disabling the DISPC flushes the DMA buffer.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data to the device interconnect.

- When low threshold (set in the DISPC_VID1_BUF_THRESHOLD[15-0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the DISPC_VID1_BUF_THRESHOLD[31-16] BUFHIGHTHRESHOLD bit field) is reached, the DMA engine stops requesting encoded pixels.

NOTE: The following limitations on DISPC_VID1_BUF_THRESHOLD[15-0] BUFLOWTHRESHOLD must be considered:

- If VID1 scaler is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it
- If VID1 scaler is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes or the high threshold value. The preload ensures a minimum number of pixels present in the buffer. When the preload value is reached, the associated channel must start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DISPC_VID1_PRELOAD[11-0] PRELOAD bit field, the DISPC_VID1_BUF_THRESHOLD[19] BUFPRELOAD bit must be set to 0x0.

NOTE: When self-refresh mode is selected, meaning the data in the DMA buffer are used for multiple frames, and at the end of each frame, the DMA buffer is not flushed.

11.3.4.1.7.3 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffer.

The MFLAG mechanism is used when fullness of the DMA buffer is critical (close to underflow). The mechanism is implemented for all DMA buffer of VID1 pipeline.

Programmable buffer thresholds (hysteresis) are used to indicate when the local MFLAG signal is generated. The 1-bit MFLAG signal is generated in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

The threshold for VID1 pipeline corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT_MFLAG: High threshold.
  - For read access from the VID1 pipeline, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the DISPC_VID1_MFLAG_THRESHOLD[31-16] HT_MFLAG bit field
- LT_MFLAG: Low threshold.
  - For read access from the VID1 pipeline, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the DISPC_VID1_MFLAG_THRESHOLD[15-0] LT_MFLAG bit field

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < DISPC_VID1_MFLAG_THRESHOLD[15-0] LT_MFLAG, then MFLAG = 1
- If DISPC_VID1_MFLAG_THRESHOLD[15-0] LT_MFLAG < DMA read buffer fullness < DISPC_VID1_MFLAG_THRESHOLD[31-16] HT_MFLAG, then MFLAG = 1
- If DMA read buffer fullness > DISPC_VID1_MFLAG_THRESHOLD[31-16] HT_MFLAG, then MFLAG = 0

By default, the MFLAG mechanism is disabled (DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL bit field = 0x0), and the DSS MFLAG out band signal is low (de-asserted).

When the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL bit field is set to 0x2, the MFLAG mechanism is enabled, and the DSS MFLAG out band signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained previously in this section.

The DISPC_GLOBAL_MFLAG_ATTRIBUTE[2] MFLAG_START bit defines additional rules for the MFLAG mechanism:

- If the MFLAG_START bit is set to 0x0 (default value), then in the beginning of the frame when the DMA buffer is empty, the local MFLAG signal is kept at 0 until PRELOAD is reached (for more information on preloading, see Section 11.3.4.1.7.2, *DISPC Read DMA Buffer*. Then, based on the setting of the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL bit field, the MFLAG signal is generated.
- If the MFLAG_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL bit field defines the generation of the MFLAG signal.

NOTE: On SoC level, the DSS MFLAG signal is mapped to two transaction priorities, which can be configured via the INITIATOR_PRIORITY1 register within BOOT_CFG module. For more information, see Section 5.1.3.1.4, *TeraNet Priority Registers*.

11.3.4.1.7.4 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels in the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the DISPC_VID1_ROW_INC[31-0] ROWINC bit field.
- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 of 2 pixel data containers, up to 1 of 2047 pixel data containers, by setting the DISPC_VID1_PIXEL_INC[7-0] PIXELINC bit field to the number of pixel data containers to skip (n), multiplied by the size of a pixel data container (in bytes), +1.

The restriction to horizontal predecimation is that there is at least one useful pixel per 128-bit request. In that case, the DMA engine uses burst mode instead of singles to optimize the requests in terms of latency and SDRAM efficiency.

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

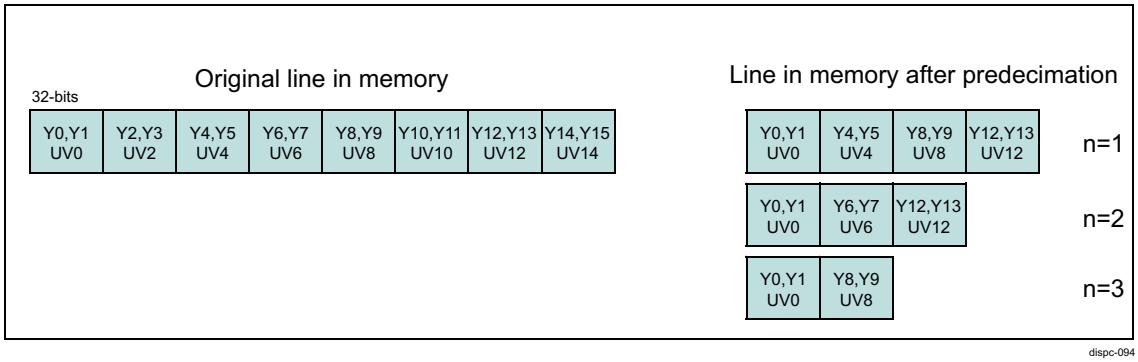
For RGB and YUV4:2:0 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXELINC bit field, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV4:2:2 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see Figure 11-177). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV4:2:2 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

Figure 11-177. DISPC YUV4:2:2 Predecimation



11.3.4.1.7.5 DISPC DMA Power Modes

11.3.4.1.7.5.1 DISPC DMA Low-Power Mode

The low power mode of the DISPC DMA is achieved by keeping the thresholds (bit-fields [31-16] BUFHIGHTHRESHOLD and [15-0] BUFLOWTHRESHOLD of DISPC_VID1_BUF_THRESHOLD register) farther apart. The farther they are there will be longer periods of idling on the DMA fetch interface resulting in lower power. The user needs to ensure a minimum value of BUFFER_LT, so that there is no underflow.

11.3.4.1.7.5.2 DISPC DMA Ultralow-Power Mode

In ultralow-power mode, the SoC interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. The SoC interconnect is not used to fetch new pixels for the following frames. The data in the DMA buffer are reused to display on the screen.

During the time in which the frames are fetched from the internal DMA buffer, MStandby is asserted, if the DISPC_SYSCONFIG[13-12] MIDLEMODE bit field is set to 0x2 (smart-standby mode).

Two ultralow-power modes can be entered manually or automatically:

- Self-refresh mode: Starting self-refresh mode is done manually by setting the DISPC_VID1_ATTRIBUTES[15] SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0.
- Automatic self-refresh mode: By setting the DISPC_VID1_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from off to on self-refresh mode is done by hardware after capturing the first frame. The hardware reflects the status of the self-refresh mode by setting the SELFREFRESH bit to 0x1, which means that the data are read inside the DMA buffer without accessing the interconnect and system memory during the frame. Setting the SELFREFRESH bit to 0x0 updates the DMA buffer.

11.3.4.1.8 DISPC Region-Based Mechanism

The region-based mechanism is used in order to display multiple windows using the same video pipeline. The reconfiguration of the pipeline is performed based on a synchronization signal (interrupt) from DISPC, which corresponds to the moment when the first pixel of the window is displayed in order to update the shadow registers of the layer. When all the pixels for the current window have been output, then the pipeline uses the new configuration provided through the shadow registers in order to display the new window re-using the same layer.

It is possible to display unlimited number of windows on the screen using same layer considering the following restriction: only one window horizontally per layer at a given time.

In order to enable the feature, SW needs to set to 0x1 the DISPC_VID1_ATTRIBUTES2[24] REGION_BASED register bit.

It is SW responsibility to handle the reconfiguration of the pipeline based on the different region-based interrupts. For more information, see Section 11.3.4.1.5, *DISPC Interrupt Requests*.

11.3.4.1.9 DISPC Memory Formats

The video pipeline supports various types of memory formats, listed in Table 11-408.

For BITMAP formats the nibble mode can be enabled by setting the DISPC_VID1_ATTRIBUTES[10] NIBBLEMODE bit to 0x1.

Table 11-408. DISPC Memory Formats Support

11.3.4.1.10 DISPC Video Pipeline

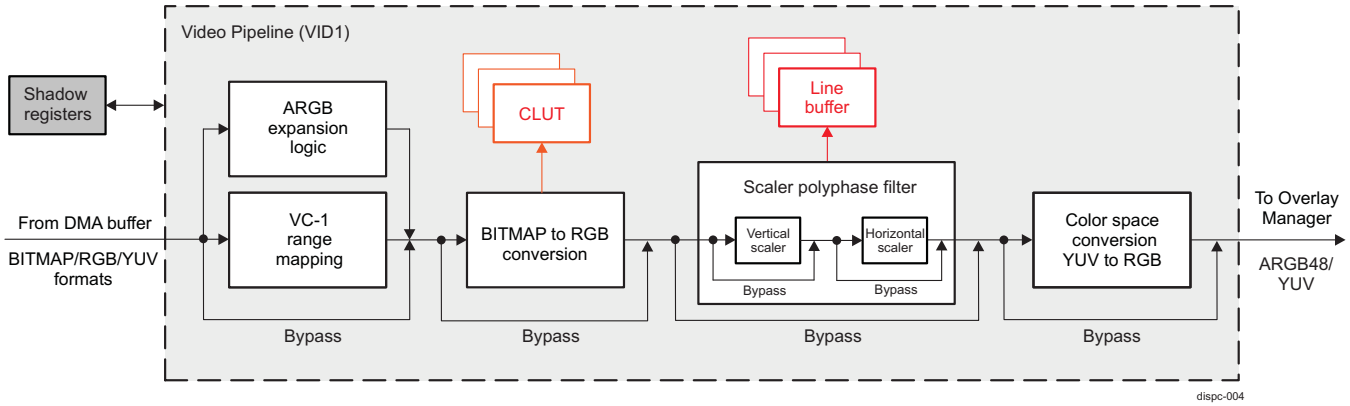
One video pipeline is available, VID1. The input of the video pipeline is connected to the video DMA buffer controller. The VID1 pixel output is always connected to the overlay manager (OVR1). The video pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, listed in Table 11-408.

The video pipeline consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter-based resizer unit (scaler);
- Color Space Conversion (CSC) unit (YUV to RGB);

Each processing block can be independently bypassed.

Figure 11-178. DISPC Video Pipeline Configuration



The 256-entry CLUT is used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format.

NOTE: For a BITMAP format data, scaling is not supported. Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21) the scaler unit up-samples the chrominance data using both vertical and horizontal polyphase filters.

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled, the resulting ARGB48 data is directly provided to VID1 pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

The video pipeline is enabled by setting the DISPC_VID1_ATTRIBUTES[0] ENABLE bit to 0x1.

11.3.4.1.10.1 DISPC VID1 Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

Table 11-409 shows how some of the ARGB formats supported by VID1 are remapped into ARGB48.

Table 11-409. DISPC VID1 Replication: ARGB Pixel Formats Remapping into ARGB48-12121212

Formats	A[11:0]	R[11:0]	G[11:0]	B[11:0]

11.3.4.1.10.2 DISPC VID1 VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before displaying. The unit is used primarily for YUV4:2:0-NV12 (NV21) pixel format, but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DISPC_VID1_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The VC-1 range mapping should be enabled only for 8 bits/component YUV input data.

The DISPC_VID1_ATTRIBUTES2[3:1] VC1_RANGE_Y and DISPC_VID1_ATTRIBUTES2[6:4] VC1_RANGE_CBCR bit fields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$Y_{out} = CLIP(((Y_{int} – 128) \times (VC1\_RANGE\_Y + 9) + 4) / 8) + 128)$

$C_b = CLIP(((C_b – 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$

$C_r = CLIP(((C_r – 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$

NOTE: The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

11.3.4.1.10.3 DISPC VID1 Color Look-Up Table (CLUT)

The video pipeline supports conversion of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB24 format through a Color Look-Up Table (CLUT).

The look-up table consists of 3 separate 256 x 8-bit memories and is indexed by the source BITMAP data. The table is loaded through direct register access by writing to DISPC_VID1_CLUT register.

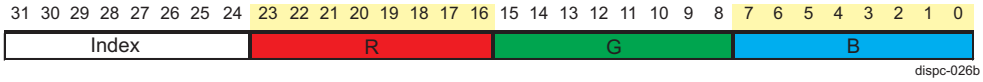
The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values using single access, or burst access in linear increment burst mode, into DISPC_VID1_CLUT register. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table (see Figure 11-179).
2. Loop to Step 1, if there is a new access to the CLUT register. The SW can access other registers between two accesses to the CLUT register.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under HW control.

The usage of the CLUT is activated when a BITMAP format is selected in the DISPC_VID1_ATTRIBUTES[6:1] FORMAT register bit-field.

Figure 11-179. DISPC VID1 CLUT Data Memory Organization



11.3.4.1.10.4 DISPC VID1 Chrominance Resampling

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV4:2:0 and YUV4:2:2 is shown in Figure 11-180 and Figure 11-181, respectively. The settings of the scaler unit to perform chrominance resampling are described in Section 11.3.4.1.10.5, *DISPC VID1 Scaler Unit*.

Figure 11-180. DISPC VID1 YUV4:2:0 to ARGB48 Using Scaler Unit for Resampling Chrominance

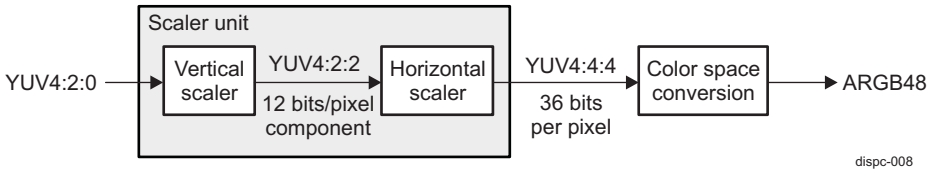


Figure 11-181. DISPC VID1 YUV4:2:2 to ARGB48 Using Scaler Unit for Resampling Chrominance

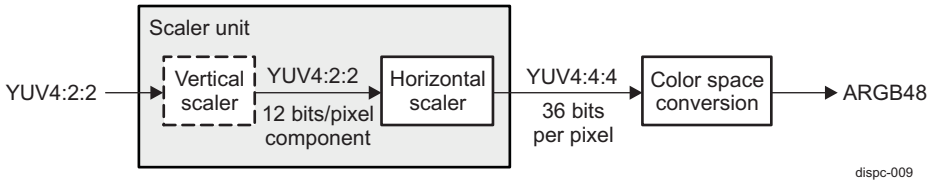


The vertical scaler is not a mandatory block for resampling chrominance of YUV4:2:2 data, as shown in Figure 11-181.

11.3.4.1.10.5 DISPC VID1 Scaler Unit

The video pipeline resizer unit (scaler) supports 8-bpc and 10-bpc source data, depending on the pixel format.

All video formats are supported, including formats with alpha channel. Alpha channel is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering.The filtering can be used for different processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

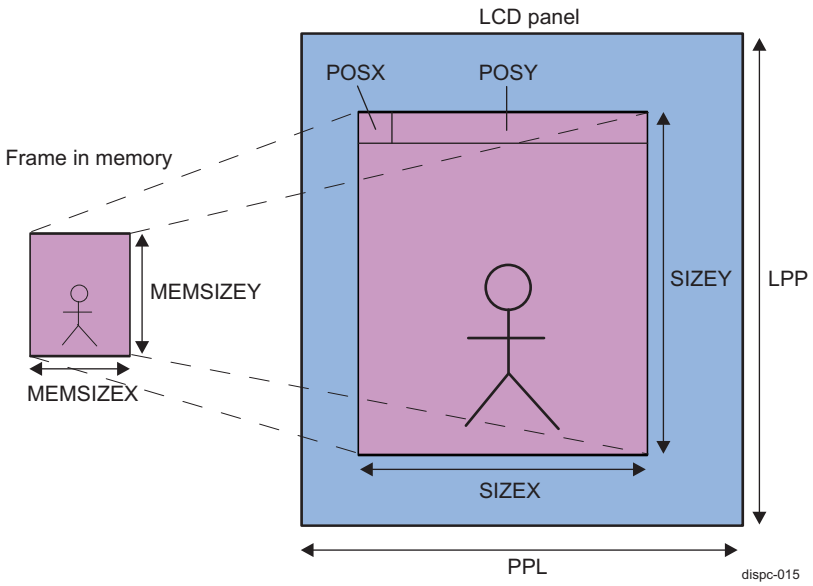
The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

NOTE: The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 11-182 shows an example of video up-sampling, with corresponding video window attributes.

Figure 11-182. DISPC Video Up-sampling



The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in DISPC_VID1_ATTRIBUTES [6-1] FORMAT bit-field
- Video window X-position in DISPC_VID1_POSITION [11-0] POSX bit-field
- Video window Y-position in DISPC_VID1_POSITION [27-16] POSY bit-field
- Video window width in DISPC_VID1_SIZE [11-0] SIZEX bit-field
- Video window height in DISPC_VID1_SIZE [27-16] SIZEY bit-field
- Video picture width in system memory (frame buffer) in DISPC_VID1_PICTURE_SIZE [11-0] MEMSIZEX bit-field
- Video picture height in system memory (frame buffer) in DISPC_VID1_PICTURE_SIZE [27-16]

MEMSIZEY bit-field

- For configuration of LPP and PPL parameters, see Section 11.3.4.1.12.7, *DISPC VP1 Timing Generator and Panel Settings*.

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

For RGB formats

$$Aout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Ain(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Rout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Gout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Gin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Bout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Bin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

For YUV formats

$$Yout(n) = \left(\sum_{i=-1}^{i=1} Cyi(\Phi y) \times Yin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Cbout(n) = \left(\sum_{i=-1}^{i=1} Cci(\Phi c) \times Cbin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Crout(n) = \left(\sum_{i=-1}^{i=1} Cci(\Phi c) \times Crin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-013

(1)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

For RGB formats

$$Aout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Ain(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Gout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Gin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Bout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Bin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

For YUV formats

$$Yout(n) = \left(\sum_{i=-2}^{i=2} Cyi(\Phi y) \times Yin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Cbout(n) = \left(\sum_{i=-2}^{i=2} Cci(\Phi c) \times Cbin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

$$Crout(n) = \left(\sum_{i=-2}^{i=2} Cci(\Phi c) \times Crin(n+i)\right) >> (Cwidth - (OutWidth - InWidth) - 1)$$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(2)

NOTE: The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV4:2:2 and YUV4:2:0.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of (see Table 11-410):

- Six lines of 1280 × 32 bits for 5-tap configuration
- Three lines of 2560 x 32 bits for 3-tap configuration

Table 11-410. DISPC VID1 Line Buffer Width for Scaler Unit

Vertical Taps	Maximum Input Width (Pixels)
3	2560
5	1280 (1)

(1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler, so that horizontal down-scaling can be supported with a minimum clock ratio equal to 1. The maximum output width is limited to 1280 pixels in order to be able to support clock ratio of 1 due to the 6th video line buffer.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing, the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has an 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

Figure 11-183 and Figure 11-184 show the scaler macro-architecture for components A, R, G, and B. Figure 11-185 and Figure 11-186 show the scaler macro-architecture for components Y, Cr, and Cb.

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VID1_ATTRIBUTES[11] FULLRANGE.

Figure 11-183. DISPC VID1 Macro-Architecture of the Horizontal Scaling for A, R, G, and B Components (5-tap Restriction)

15	DISPC_VID1_FIR_COEF_H12_15	DISPC_VID1_FIR_COEF_H12_15	DISPC_VID1_FIR_COEF_H0_1	DISPC_VID1_FIR_COEF_H12_1	DISPC_VID1_FIR_COEF_H12_1

NOTE: The Table 11-411 cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DISPC_VID1_FIR_COEF_V0_0 to DISPC_VID1_FIR_COEF_V0_8, and DISPC_VID1_FIR_COEF_V12_0 to DISPC_VID1_FIR_COEF_V12_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DISPC_VID1_FIR_COEF_H0_C_0 to DISPC_VID1_FIR_COEF_H0_C_8, and DISPC_VID1_FIR_COEF_H12_C_0 to DISPC_VID1_FIR_COEF_H12_C_15, and DISPC_VID1_FIR_COEF_V0_C_0 to DISPC_VID1_FIR_COEF_V0_C_8 and DISPC_VID1_FIR_COEF_V12_C_0 to DISPC_VID1_FIR_COEF_V12_C_15) .

The VID1 scaler unit vertical or/and horizontal sampling is selected by configuring the DISPC_VID1_ATTRIBUTES[8-7] RESIZEENABLE bit field.

A set of configurations must be valid before enabling the video up-sampling and down-sampling block.

The following fields define the configuration of the video up-sampling/down-sampling block for VID1 pipeline:

- Vertical upsampling and downsampling increments the value of the [23-0] FIRVINC bit field in DISPC_VID1_FIRV and DISPC_VID1_FIRV2 registers. The unsigned integer value range is 2^{23}. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left(\frac{MEMSIZEY+1}{SIZEY+1}\right) \quad (3)$$

dispc-066

- Horizontal upsampling and downsampling increments the value of the the [23-0] FIRHINC bit field in the DISPC_VID1_FIRH and DISPC_VID1_FIRH2 registers. The unsigned integer value range is 2^{23}. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left(\frac{MEMSIZEH+1}{SIZEH+1}\right)$$

dispc-067 (4)

- Vertical up/downsampling accumulator value, [23-0] VERTICALACCU bit field in DISPC_VID1_ACCUV_0 to DISPC_VID1_ACCUV_1 and DISPC_VID1_ACCUV2_0 to DISPC_VID1_ACCUV2_1 registers: The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_VID1_ACCUV_0 is used for progressive output, and for interlace output DISPC_VID1_ACCUV_0 and DISPC_VID1_ACCUV_1 registers are used. Similarly, DISPC_VID1_ACCUV2_0 and DISPC_VID1_ACCUV2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical upsampling and downsampling line buffer configuration DISPC_VID1_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value, [23-0] HORIZONTALACCU bit field in DISPC_VID1_ACCUH_0 to DISPC_VID1_ACCUH_1, and DISPC_VID1_ACCUH2_0 to DISPC_VID1_ACCUH2_1 registers: The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_VID1_ACCUH_0 is used for progressive output, and for interlace output the DISPC_VID1_ACCUH_0 and DISPC_VID1_ACCUH_1 registers are used. Similarly, DISPC_VID1_ACCUH2_0 and DISPC_VID1_ACCUH2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.

Table 11-412 lists the DISPC vertical and horizonatal accumulator values and phases.

Table 11-412. DISPC VID1 Vertical and Horizontal Accumulator Phases

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - The vertical upsampling and downsampling central coefficients are defined in the DISPC_VID1_FIR_COEF_V0_0 to DISPC_VID1_FIR_COEF_V0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four YUV, the vertical upsampling and downsampling central coefficients are set in DISPC_VID1_FIR_COEF_V0_C_0 to DISPC_VID1_FIR_COEF_V0_C_8 registers.
- Vertical upsampling and downsampling coefficients:
  - The vertical upsampling and downsampling coefficients are defined in the DISPC_VID1_FIR_COEF_V12_0 to DISPC_VID1_FIR_COEF_V12_15 registers. There are 16

registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.

  - Four YUV, the vertical upsampling and downsampling coefficients are set in DISPC_VID1_FIR_COEF_V12_C_0 to DISPC_VID1_FIR_COEF_V12_C_15 registers.

- Horizontal upsampling and downsampling central coefficients:
  - The horizontal upsampling and downsampling central coefficients are defined in the DISPC_VID1_FIR_COEF_H0_0 to DISPC_VID1_FIR_COEF_H0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four YUV, the horizontal upsampling and downsampling central coefficients are set in DISPC_VID1_FIR_COEF_H0_C_0 to DISPC_VID1_FIR_COEF_H0_C_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - The horizontal upsampling and downsampling coefficients are defined in the DISPC_VID1_FIR_COEF_H12_0 to DISPC_VID1_FIR_COEF_H12_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four YUV, the horizontal upsampling and downsampling coefficients are set in DISPC_VID1_FIR_COEF_H12_C_0 to DISPC_VID1_FIR_COEF_H12_C_15 registers.

11.3.4.1.10.6 DISPC VID1 CSC Unit - YUV to RGB

The CSC unit converts the video-encoded pixel values from YUV4:4:4 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFF).

In case of YUV4:2:0 or YUV4:2:2 formats, a chrominance resampling to YUV4:4:4 is performed before converting the YUV into RGB values (see Section 11.3.4.1.10.4, *DISPC VID1 Chrominance Resampling*). The YUV4:2:2 or YUV4:2:0 to YUV4:4:4 chrominance resampling is a pre-processing to the color space conversion.

Figure 11-187 and Figure 11-188 show the 3 × 3 11-bit coefficients used to convert from YUV4:4:4 into ARGB48. The value of A component is fixed at 0xFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. Table 11-413 summarizes the coefficients with their respective register bit fields.

Table 11-413. DISPC VID1 CSC - YUV to RGB Register Bitfield Settings

Coefficients	Bit Field Registers
R_Y	DISPC_VID1_CONV_COEF0[10-0] RY
R_{Cr}	DISPC_VID1_CONV_COEF0[26-16] RCR
R_{Cb}	DISPC_VID1_CONV_COEF1[10-0] RCB
G_Y	DISPC_VID1_CONV_COEF1[26-16] GY
G_{Cr}	DISPC_VID1_CONV_COEF2[10-0] GCR
G_{Cb}	DISPC_VID1_CONV_COEF2[26-16] GCB
B_Y	DISPC_VID1_CONV_COEF3[10-0] BY
B_{Cr}	DISPC_VID1_CONV_COEF3[26-16] BCR
B_{Cb}	DISPC_VID1_CONV_COEF4[10-0] BCB
G offset	DISPC_VID1_CONV_COEF5[31-19] GOFFSET
R offset	DISPC_VID1_CONV_COEF5[15-3] ROFFSET
B offset	DISPC_VID1_CONV_COEF6[15-3] BOFFSET

If the active range for the luminance samples (Y) is [256:3760] and [256:3840] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VID1_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [0:4095].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VID1_ATTRIBUTES[11] FULLRANGE.

Figure 11-187. DISPC VID1 YCbCr to RGB Registers (FULLRANGE = 0), 12-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

In Figure 11-187, the R, G, B offset values -256, -2048, -2048 are programmed via corresponding bit-fields in DISPC_VID1_CONV_COEF5 and DISPC_VID1_CONV_COEF6 registers (see Table 11-413, *DISPC VID1 CSC - YUV to RGB Register Bitfield Settings*).

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the range selection is done by setting the DISPC_VID1_ATTRIBUTES[11] FULLRANGE bit to 0x1. The values of R, G, and B output components are clipped to the range [0:4095].

Figure 11-188. DISPC VID1 YCbCr to RGB Registers (FULLRANGE = 1), 12-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

In Figure 11-188, the G and B offset values -2048 and -2048 are programmed via corresponding bit-fields in DISPC_VID1_CONV_COEF5 and DISPC_VID1_CONV_COEF6 registers (see Table 11-413, *DISPC VID1 CSC - YUV to RGB Register Bitfield Settings*).

11.3.4.1.11 DISPC Overlay Manager

DISPC implements a single Overlay Manager (OVR1) with output assigned to the Video Port (VP1) (see Figure 11-176, *DISPC Architecture Overview*).

Only background color (programmable constant background color) feature is available. The default solid background color is defined in DEFAULTCOLOR bit-fields of DISPC_OVR1_DEFAULT_COLOR and DISPC_OVR1_DEFAULT_COLOR2 registers.

The output of OVR1 is connected to VP1 Color Phase Rotation (CPR) block through the Gamma table.

11.3.4.1.12 DISPC Video Port Output

DISPC implemets a single video port output (VP1). It processes data received from Overlay Manager 1 (OVR1). The VP1 output path consist of several processing blocks (see Figure 11-189):

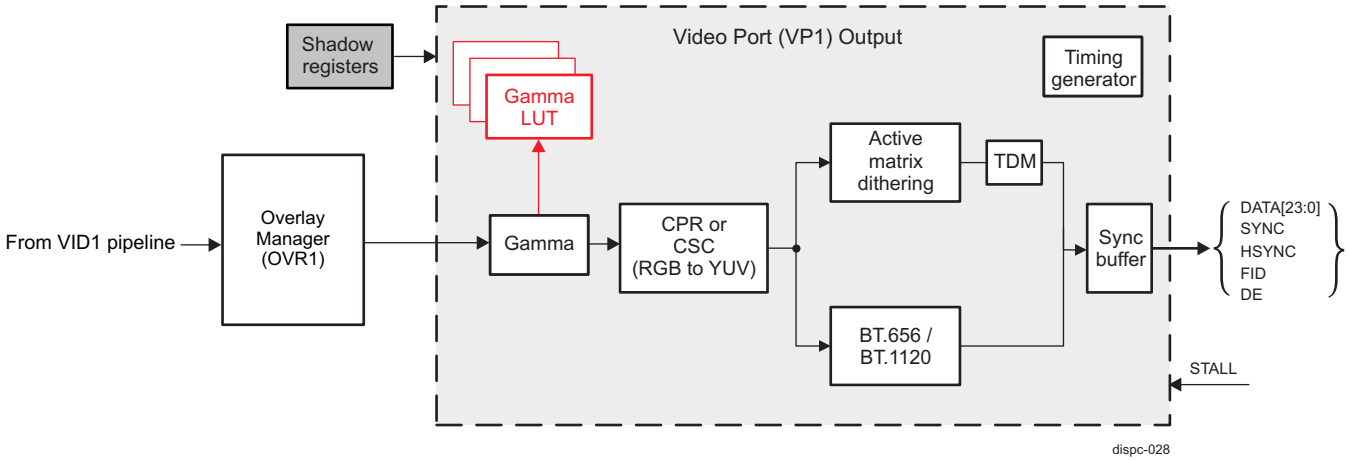
- Gamma correction unit
- Color phase rotation (CPR) (also used for RGB-to-YUV conversion)
- Active matrix dithering with TDM
- BT.656
- BT.1120
- Timing generator

The display subsystem supports active matrix display technology. The configuration of colors depends on the color depth:

- 24 bpp supports 16,777,216 colors.

- 18 bpp supports 262,144 colors.
- 16 bpp supports 65,536 colors.
- 12 bpp supports 4096 colors.

Figure 11-189. DISPC VP1 Output Architecture



NOTE: In BT.656 mode only bits 9 through 0 are used from DATA[23:0] data bus.

11.3.4.1.12.1 DISPC VP1 Gamma Correction Unit

When performing gamma correction, the selected encoded pixel values by the overlay manager from the video path are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 x 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software via the DISPC_VP1_GAMMA_TABLE register. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access).

The sequence to load the gamma table is:

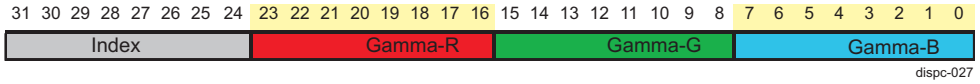
1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in streaming mode, into DISPC_VP1_GAMMA_TABLE register. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table.
2. Loop to Step 1, if there is a new access to the gamma table register. The SW can access other registers between two accesses to the gamma table register.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under HW control.

The usage of the gamma table is activated by setting DISPC_VP1_CONFIG[2] GAMMAENABLE register bit to 0x1.

Figure 11-190 describes the format of one of the gamma curve values in the memory.

Figure 11-190. DISPC Data Memory Organization for Gamma Mode in VP1 Output



NOTE: Because gamma registers are not 32-byte aligned, they cannot be accessed using EDMA constant mode addressing. For direct memory access to multiple words to/from these registers, the EDMA should be programmed to do multiple 4-byte accesses to the register address in increment mode (DAM/SAM = 0) by setting the appropriate ACNT=4 and BIDX=0x0.

11.3.4.1.12.2 DISPC VP1 Color Phase Rotation Unit

The Color Phase Rotation (CPR) unit can be used to correct the display output colorimetry in case of nonpure white backlight.

The CPR is enabled by setting the DISPC_VP1_CONFIG[15] CPR bit to 0x1. The coefficients are programmed in the following registers:

- Red 10-bit signed coefficients in DISPC_VP1_CPR_COEF_R
- Green 10-bit signed coefficients in DISPC_VP1_CPR_COEF_G
- Blue 10-bit signed coefficients in DISPC_VP1_CPR_COEF_B

The CPR logic is integrated after the overlay manager while using the gamma correction and before the spatial/temporal dithering. The CPR can be selected to correct the nonpure white backlight of the display module by using a programmable matrix to convert the 36-bit RGB pixel value into a new 30-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is processed by the equation shown in Figure 11-191. Table 11-414 lists all coefficients with their respective register bitfields for settings.

Figure 11-191. DISPC VP1 CPR Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} Rr & Rg & Rb \\ Gr & Gg & Gb \\ Br & Bg & Bb \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

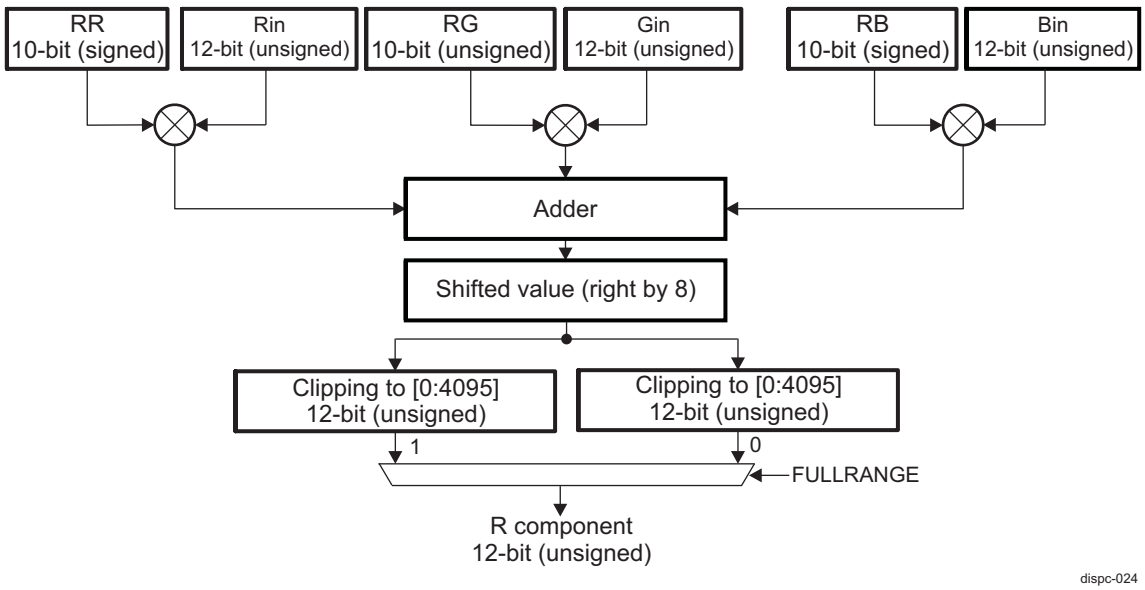
dispc-023

Table 11-414. DISPC VP1 CPR, or RGB to YUV Conversion Coefficients with Associated Register Bitfields

Registers	Bit Field	Color Phase Rotation	RGB to YUV
DISPC_VP1_CPR_COEF_R	RR	Rr	Yr
	RG	Rg	Yg
	RB	Rb	Yb
DISPC_VP1_CPR_COEF_G	GR	Gr	Cbr
	GG	Gg	Cbg
	GB	Gb	Cbb
DISPC_VP1_CPR_COEF_B	BR	Br	Crr
	BG	Bg	Crg
	BB	Bb	Crb

Figure 11-192 shows the CPR macro-architecture.

Figure 11-192. DISPC VP1 CPR Macro-Architecture



11.3.4.1.12.3 DISPC VP1 Color Space Conversion

The CPR block can be used to perform Color Space Conversion (CSC). Table 11-414 lists the associated coefficients with their respective register bit-fields. The CSC logic uses the CPR registers for the coefficients. Only the upper 10 bits of each color component are used for the CSC processing. The CSC processing is enabled by setting the DISPC_VP1_CONFIG[24] COLORCONVENABLE register bit to 0x1.

The color space conversion on the VP1 output can be selected in order to convert from 30-bit RGB to YUV444. The matrix is programmed through a set of nine 10-bit signed coefficients. The result is clipped to [64:940] for the luminance and [64:960] for the chrominance, when full-range equals zero (DISPC_VP1_CONFIG[25] FULLRANGE = 0).

Figure 11-193. DISPC VP1 CSC RGB to YUV Registers (FullRange=0)

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 64 \\ 512 \\ 512 \end{bmatrix}$$

dispc-098

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:1023], the values Y, Cb, and Cr are clipped to the range [0:1023]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full-range (DISPC_VP1_CONFIG[25] FULLRANGE = 1)

Figure 11-194. DISPC VP1 CSC RGB to YUV Registers (FullRange=1)

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 512 \\ 512 \end{bmatrix}$$

dispc-099

In order to provide YUV422 data to the BT-656 or BT-1120 blocks, the YUV444 format is converted to YUV422 by sub-sampling the chrominance values. The HW does this by averaging two-by-two the chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion is enabled.

11.3.4.1.12.4 DISPC VP1 BT.656 and BT.1120 Modes

The VP1 output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for VP1 ouput is done by setting DISPC_VP1_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bits, respectively

NOTE: It is not posssible to enable BT.656 and BT.1120 mode simultaneously on the same output.

Figure 11-195 shows signal mapping on DSS_DATA[23:0] data bus. Bits 9 to 0 are used in BT.656 mode (10-bit).

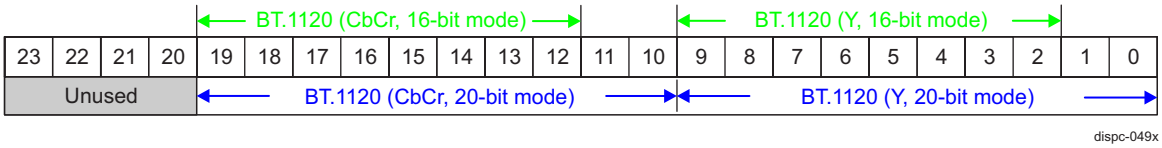
Figure 11-195. DISPC VP1 Data Mapping in BT.656 Mode

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

NOTE: For compatibility with existing 8-bit interfaces, the two LSB are ignored, and only bits [9-2] are used.

Figure 11-196 shows signal mapping on DSS_DATA[23:0] data bus for BT.1120 mode. Bits [19-10] (CbCr) and [9-0] (Y) are used in 20-bit mode. Bits [19-12] (CbCr) and [9-2] (Y) are used in 16-bit mode (YCbCr 4:2:2).

Figure 11-196. DISPC VP1 Data Mapping in BT.1120 Mode



VP1 supports progressive output for embedded syncs interface, when it is configured in BT.656/BT.1120 modes. For more information on timings configuration, see Section 11.3.4.1.12.7, *DISPC VP1 Timing Generator and Panel Settings*.

11.3.4.1.12.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY..). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

  The sequence in the BLANKING region of the data stream is therefore: *80h, 10h, 80h, 10h.....80h, 10h*

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see Section 11.3.4.1.12.7, *DISPC Timing Generator and Panel Settings*.

11.3.4.1.12.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes (FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in Figure 11-197, with the function of each bit described inTable 11-415.

Figure 11-197. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes

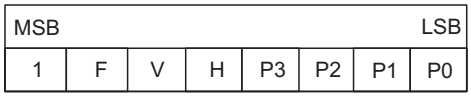


Table 11-415. DISPC BT Mode Bit Function

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V and H. This dependency is shown in Table 11-416.

Table 11-416. DISPC BT Mode Status of Protection Bits as F, V and H Vary

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0

Table 11-416. DISPC BT Mode Status of Protection Bits as F, V and H Vary (continued)

F	V	H	P3	P2	P1	P0
1	1	1	0	0	0	1

11.3.4.1.12.5 DISPC VP1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected to enhance the quality of the active matrix outputs. The dithering logic is integrated after the CPR and before the TDM. The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the display panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control. The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DISPC_VP1_CONTROL[31-30] SPATIALTEMPORALDITHERINGFRAMES bit field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, spatial and temporal processing are applied to the pixels. The spatial/temporal dithering logic is enabled by setting the DISPC_VP1_CONTROL[7] STDITHERENABLE bit to 0x1.

NOTE:

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus.

11.3.4.1.12.6 DISPC VP1 Multiple Cycle Output Format (TDM)

The pixels are formatted on one or multiple cycles (a maximum of three cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is selected through the DISPC_VP1_CONTROL[24-23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DISPC_VP1_DATA_CYCLE_0 register for the first cycle, the DISPC_VP1_DATA_CYCLE1 register for the second cycle, and the DISPC_VP1_DATA_CYCLE2 register for the third cycle. The interface data bus width, when TDM mode is enabled (DISPC_VP1_CONTROL[20] TDMENABLE = 1), can be 8, 9, 12, or 16 bits, configurable through the DISPC_VP1_CONTROL[22-21] TDMPARALLELMODE bit field.

When the TDM is disabled (DISPC_VP1_CONTROL[20] TDMENABLE = 0), the DISPC outputs the pixels using the conventional formats: active matrix display monochrome/color. When TDM is disabled, the interface data bus width is configured through the DISPC_VP1_CONTROL[10-8] DATALINES bit field.

When using TDM mode, only up to 24-bit per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

Figure 11-198 through Figure 11-201 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

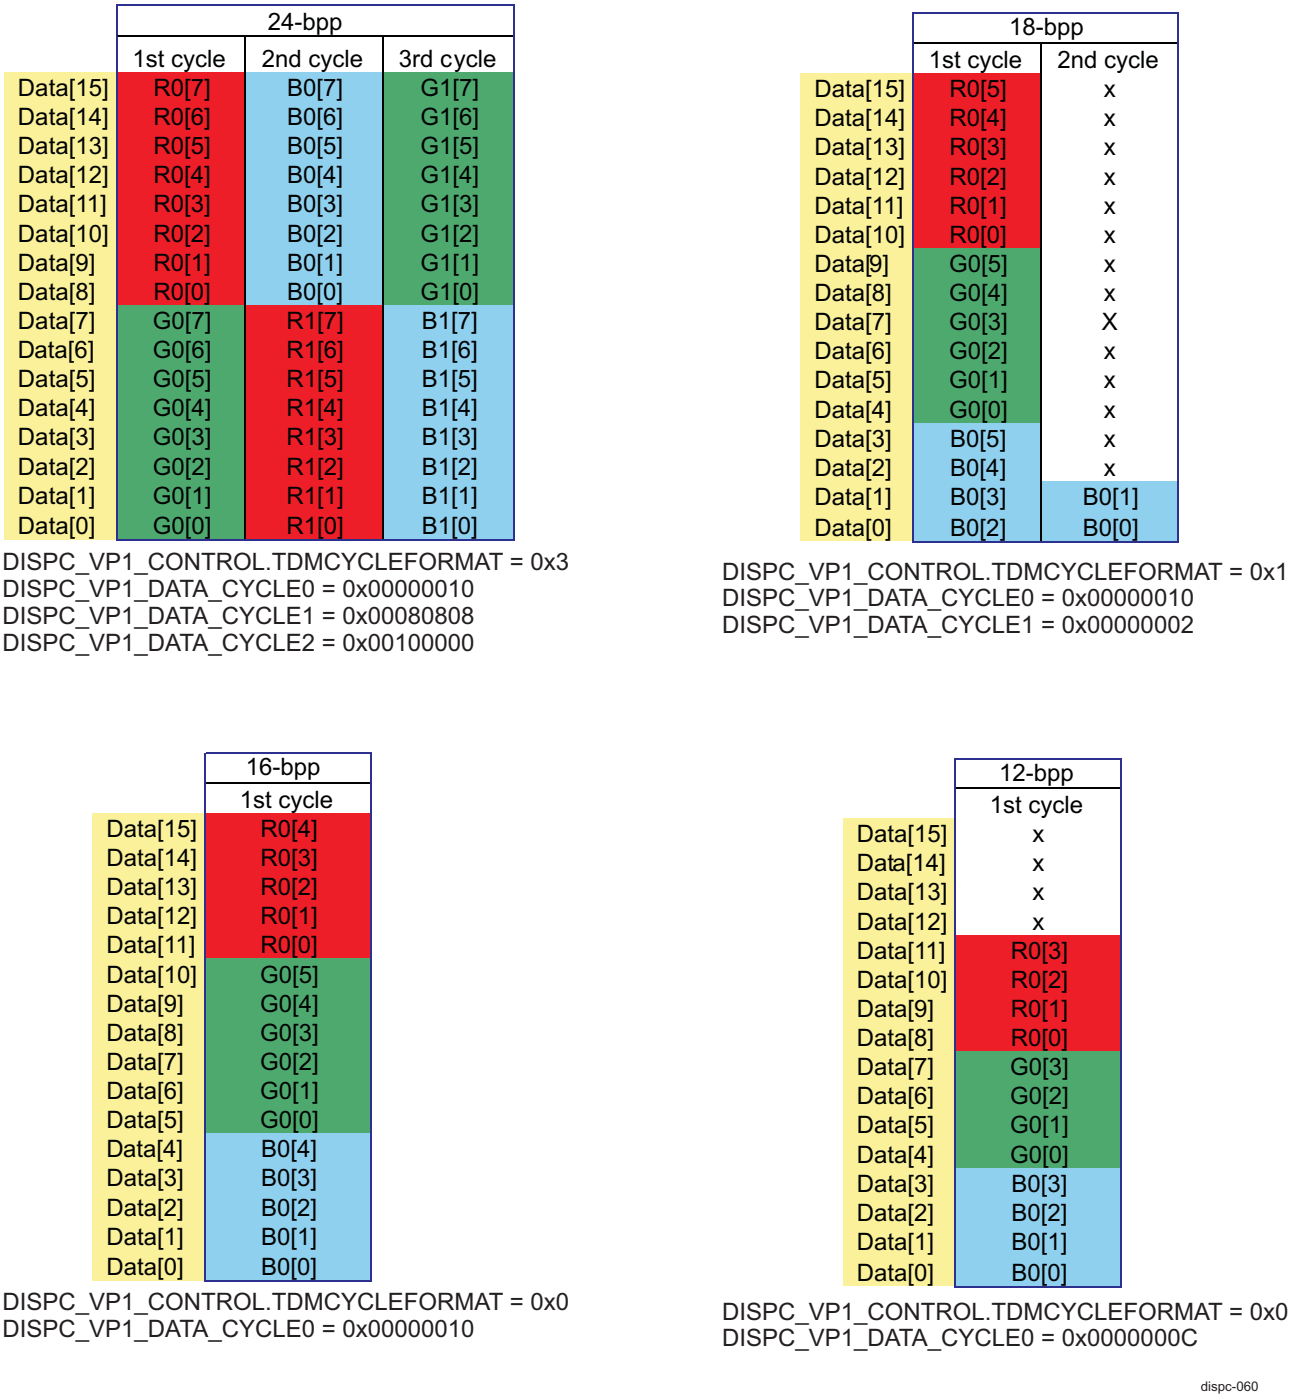
Figure 11-201. DISPC VP1 TDM 16-Bit Interface Settings



11.3.4.1.12.7 DISPC VP1 Timing Generator and Panel Settings

The VP1 output has a dedicated timing generator supporting progressive and interlaced mode.

The size of the display panel is defined by:

- Number of lines, DISPC_VP1_SIZE_SCREEN[27-16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_VP1_SIZE_SCREEN[11-0] PPL bit field, with a value from 1 to 4096

Standard HSYNC/VSYNC timing generation are programmable for VP1:

- Horizontal front porch is set in the DISPC_VP1_TIMING_H[19-8] HFP bit field.
- Horizontal back porch is set in the DISPC_VP1_TIMING_H[31-20] HBP bit field.
- Horizontal synchronization pulse width is set in the DISPC_VP1_TIMING_H[7-0] HSW bit field.
- Vertical front porch is set in the DISPC_VP1_TIMING_V[19-8] VFP bit field.
- Vertical back porch is set in the DISPC_VP1_TIMING_V[31-20] VBP bit field.
- Vertical synchronization pulse width is set in the DISPC_VP1_TIMING_V[7-0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DISPC_VP1_TIMING_H and DISPC_VP1_TIMING_V registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {DISPC_VP1_TIMING_V[3-0] VSW, DISPC_VP1_TIMING_H[7-0] HSW} bit fields; (up to 2048 bytes of horizontal blanking supported).
  - Vertical frame blanking No 1 is set in the DISPC_VP1_TIMING_V[19-8] VFP bit field.
  - Vertical frame blanking No 2 is set in the DISPC_VP1_TIMING_V[31-20] VBP bit field.
  - Number of lines is set in the DISPC_VP1_SIZE_SCREEN[27-16] LPP bit field
  - Number of pixels per line is set in the DISPC_VP1_SIZE_SCREEN[11-0] PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {DISPC_VP1_TIMING_V[3-0] VSW, DISPC_VP1_TIMING_H[7-0] HSW} bit fields; (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No 1 for Even Field is set in the DISPC_VP1_TIMING_H[19-8] HFP bit field.
  - Vertical field blanking No 2 for Even Field is set in the DISPC_VP1_TIMING_H[31-20] HBP bit field.
  - Vertical field blanking No 1 for Odd Field is set in the DISPC_VP1_TIMING_V[19-8] VFP bit field.
  - Vertical field blanking No 2 for Odd Field is set in the DISPC_VP1_TIMING_V[31-20] VBP bit field.
  - Number of lines per field (even) is set in the DISPC_VP1_SIZE_SCREEN[27-16] LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the DISPC_VP1_SIZE_SCREEN[15-14] DELTA_LPP bit field.
  - Number of pixels per line is set in the DISPC_VP1_SIZE_SCREEN[11-0] PPL bit field.

NOTE: The DELTA_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field shall be set to zero for YUV420 format.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DISPC_VP1_POL_FREQ[12] IVS, DISPC_VP1_POL_FREQ[13] IHS, and DISPC_VP1_POL_FREQ[15] IEO bits. These signals can be gated by setting the DISPC_VP1_CONFIG[7] VSYNCGATED and DISPC_VP1_CONFIG[6] HSYNCGATED bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the DISPC_VP1_POL_FREQ[18] ALIGN bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DISPC_VP1_POL_FREQ[14] IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DISPC_VP1_POL_FREQ[16] RF bit.

The timing generation of FID signal is defined by the DISPC_VP1_CONFIG[22] OUTPUTMODEENABLE bitfield. The selection can be changed only if the VP output is disabled.

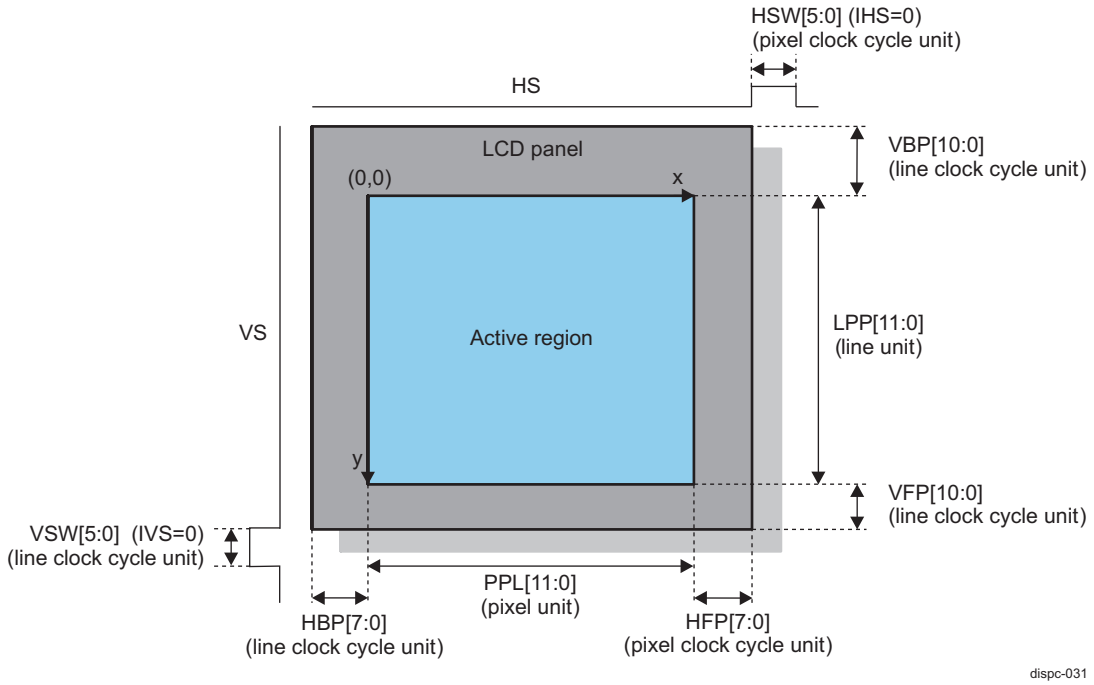
- 0x0 (default): Progressive mode (FID signal is inactive: low level)
- 0x1: Interlaced mode (FID signal transition from low to high and from high to low to indicate on the VP interface the field polarity and internally the FID to be used for the registers with dual value: one for odd field and another one for even field). The FID signal toggles on the rising edge of the VSW pulse.

When in interlaced mode, the DISPC_VP1_CONFIG[23] FIDFIRST bit indicates which field is output first:

- 0x0: Even field first (FID = 0)
- 0x1: Odd field first (FID = 1)

Figure 11-202 shows the timing values description.

Figure 11-202. DISPC VP1 Timing Values (Display Screen)

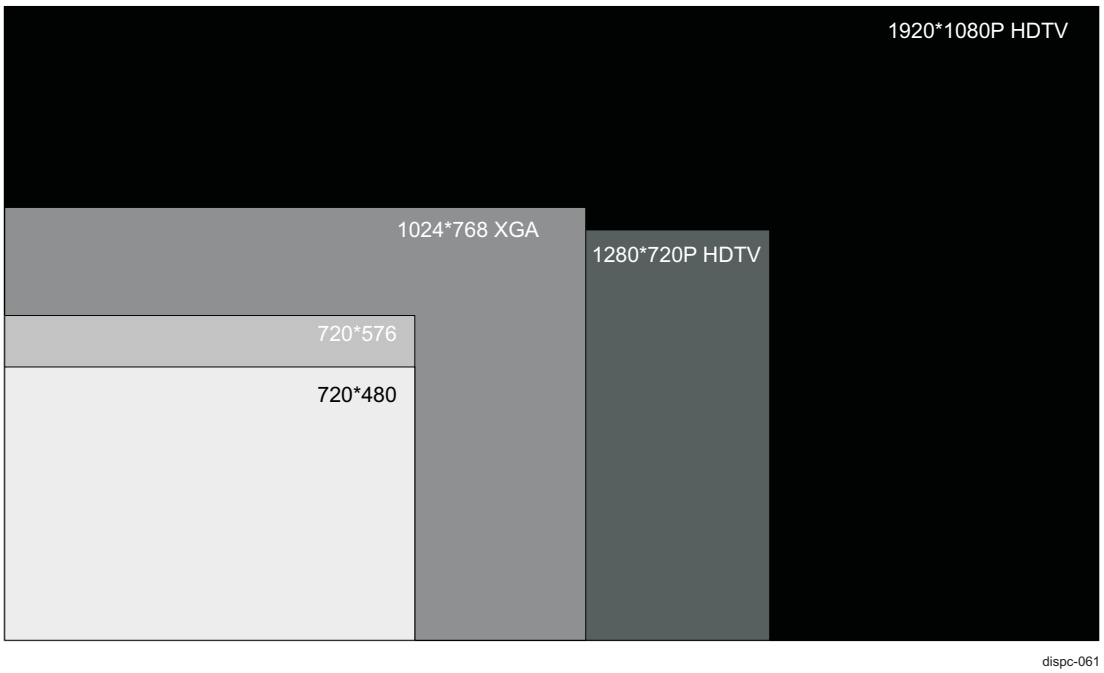


The pixel clock can be gated by setting the DISPC_VP1_CONFIG[5] PIXELCLOCKGATED bit to 0x1.

11.3.4.1.12.8 DISPC VP1 Configuration for TV Support

Figure 11-203 shows the TV formats supported.

Figure 11-203. DISPC Example TV Timing Formats



The size of a frame (field, if interlaced mode) is defined by the fields:

- Number of lines, DISPC_VP1_SIZE_SCREEN[27-16] LPP bit field, with a value from 1 to 4096

- Number of pixels per line, DISPC_VP1_SIZE_SCREEN[11-0] PPL bit field, with a value from 1 to 4096
- Delta size between odd/even field, DISPC_VP1_SIZE_SCREEN[15-14] DELTA_LPP bit field. This bit field controls only the output channel and not the size of the data field fetched from the frame buffer in memory.

The hold time of the pixels on the data bus is determined in clock cycles by the DISPC_VP1_CONTROL[16-14] HT bit field. The default value at reset time is 0x0 (one cycle).

- Table 11-417 indicates the DISPC_VP1_SIZE_SCREEN register values for PPL and LPP for each HD standard.

Table 11-417. DISPC VP1 PPL and LLP Value for HD Standard

Standards		Active Pixels/Line	Active Lines	Digital Clock DISPC_VP1_CONTROL [16-14] HT = 0x0	DISPC_VP1_SIZE_SCREEN Register Value
HDTV	720p	1280	720	74.25/74.125 MHz (60/59.99..frames/s)	0x02CF 04FF
	1080i	1920	540	74.25/74.125 MHz (60/59.99..frames/s)	0x021B 077F
	1080p	1920	1080	148.5/148.25 MHz (60/59.99..frames/s)	0x0437 077F

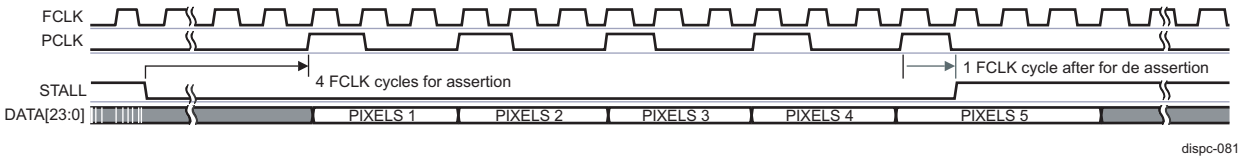
11.3.4.1.13 DISPC Stall Mode

Stall mode is used to indicate when the DISPC must stop sending data on the video port output interface to avoid an overflow on the interface level. Stall mode is available when the RFBI interfaces are used. The RFBI module asserts the stall signal to stop data output by the DISPC. It is deasserted by RFBI to indicate when new data must be output by the DISPC. Figure 11-204 shows the RFBI data stall mode activated.

Stall mode is selected by setting the DISPC_VP1_CONTROL[11] STALLMODE bit.

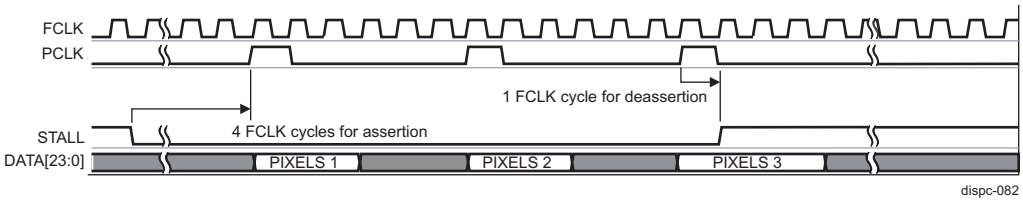
NOTE: The DISPC_VP1_CONTROL[5] GOBIT bit must not be set, but the DISPC configuration (DMA engine, VID1 pipeline) must be set before enabling the VP1 output by setting the DISPC_VP1_CONTROL[0] VPENABLE bit. In stall mode the VPENABLE bit initates the transfer.

Figure 11-204. DISPC RFBI Data Stall Signal Diagram



To avoid an underflow of the DMA buffer, the DMA buffer handshake must be enabled by setting the DISPC_VP1_CONFIG[16] BUFFERHANDCHECK bit. The fullness of the buffers associated to the VID1 pipeline used for the VP1 output is checked before providing data to the pipeline when the STALL signal is inactive. It prevents emptying the DMA buffer when the RFBI module requests data and there is not enough data in the DMA buffer of the DISPC. This feature must be enabled only when stall mode is used (the STALLMODE bit set to 0x1). When the DMA buffer handshake is activated, the pixel transfer to the RFBI module, outside a STALL period, can be stopped and restarted when there are enough data in the DMA buffer. The DMA buffer handshake ensures that the underflow does not occur for the VID1 pipeline associated with the VP1 output when RFBI interface is used. The rate of the data transfer to the RFBI is, then, fully dependent on the state of the DMA buffer. Figure 11-205 shows the RFBI data stall with FIFO handcheck mode activated.

Figure 11-205. DISPC RFBI Data Stall Signal Diagram with Handcheck



One STALL signal is generated by the RFBI. The RFBI module asserts the STALL signal when no more data must be output by the DISPC. STALL is deasserted to indicate when new data must be output by the DISPC.

11.3.4.1.14 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only 1 bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The DISPC_VP1_CONTROL[5] GOBIT bit enables the hardware to use the new configuration, for all shadow registers of the VID1 pipeline connected to the VP1 output.

11.3.4.2 RFBI Functional Description

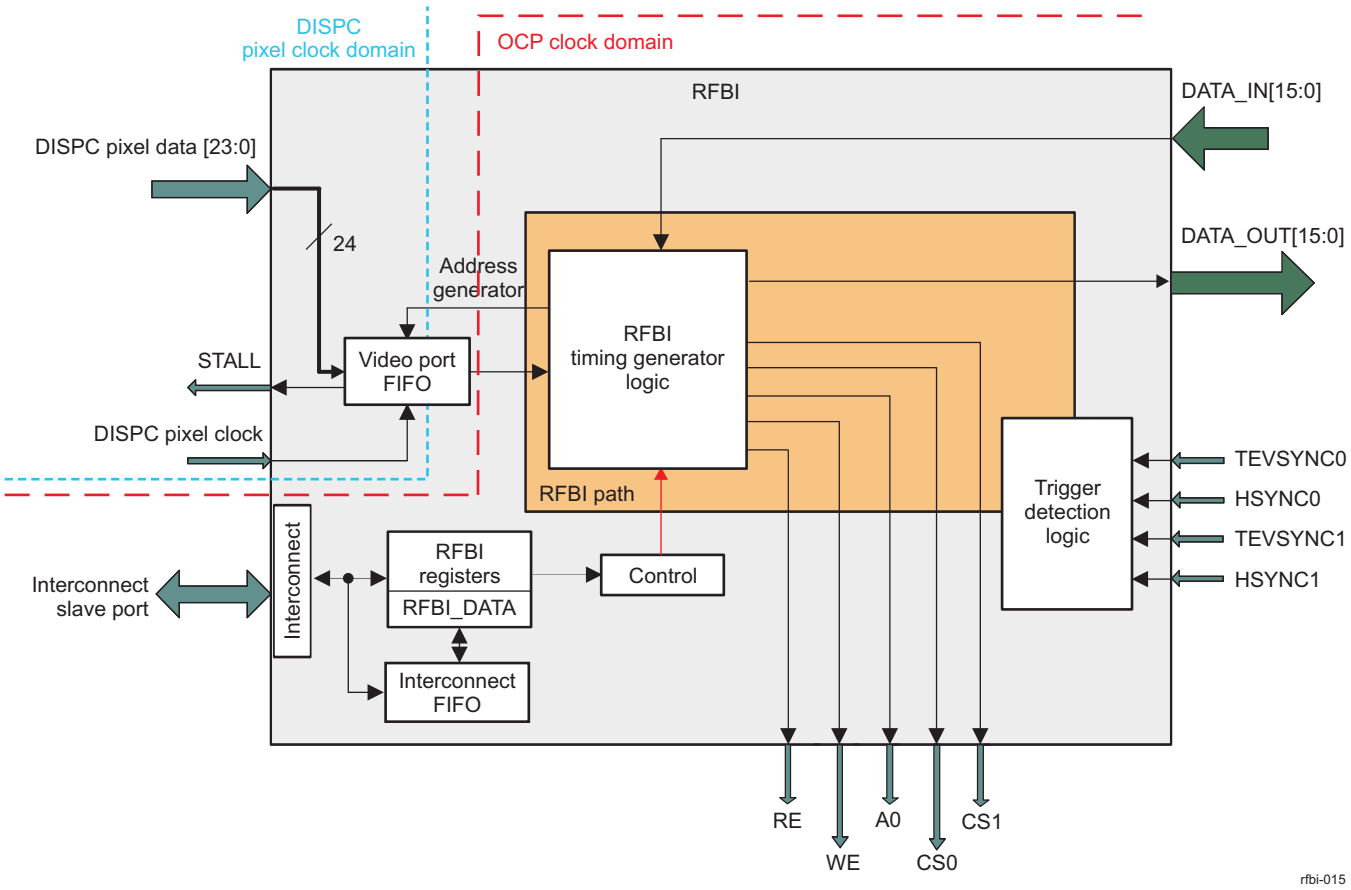
11.3.4.2.1 RFBI Block Diagram

The RFBI can capture the output pixel from the DISPC, or system memory, and send the data to the RFB in the LCD panel. The user application configures the RFBI, sends commands, reads data, and configures the DISPC to send data fetched from the system memory by the DISPC DMA engine. The commands/data are sent using an 8-, 9-, 12- or 16-bit parallel interface.

The DISPC can be configured to send the data in 12-, 16-, 18-, or 24-bpp format. In the RFBI video port FIFO, the encoded pixel values are in an LSB alignment independent of the endianness in system memory.

Figure 11-206 is an overview of the RFBI architecture.

Figure 11-206. RFBI Architecture Overview



11.3.4.2.2 RFBI Clock Configuration

For more information about the RFBI clocks, see Section 11.3.3, *DSS Integration*.

11.3.4.2.3 RFBI Software Reset

To perform a software reset, set the RFBI_SYSCONFIG[1] SOFTRESET bit to 1. The RFBI_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the RFBI_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing any RFBI operation.

11.3.4.2.4 RFBI Interrupt Requests

The RFBI does not generate interrupts, but DISPC interrupts must be properly configured, when DISPC is connected to the RFBI.

For more information on DISPC interrupts, see Section 11.3.4.1.5,*DISPC Interrupt Requests*.

11.3.4.2.5 RFBI DMA Requests

Table 11-418 lists event flags and their mask that can cause RFBI DMA requests.

Table 11-418. RFBI DMA Requests Events

DMA Request Name	DMA Request Mask	Description
RFBI_DMA_REQ	RFBI_CONTROL[7] DISABLE_DMA_REQ	DMA request used to transfer data from system memory (via SoC DMA controller) to the RFBI interconnect FIFO

11.3.4.2.6 RFBI Video Port FIFO

11.3.4.2.6.1 RFBI Video Port Description

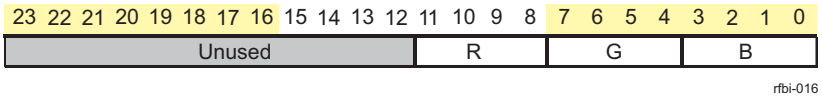
The input video port FIFO receives data from the DISPC at the pixel clock. The data in the video port FIFO are read by the RFBI and sent to the LCD panel. The video port FIFO is 24-bits wide and each pixel in 12-, 16-, 18-, and 24-bpp format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 11.3.4.2.9, *RFBI Output Parallel Modes*, provides examples of various output configurations based on the interface width (up to 16 bits) and pixel format output (up to 24 bits). Setting the RFBI_CONTROL[1] RFBIMODE bit to 0 directs the SoC ARMSS to send commands, parameters, and data from the input video port FIFO.

11.3.4.2.6.2 RFBI Input Formats

The encoded pixel formats supported at the RFBI input interface connected to the DISPC are: RGB12-444, RGB16-565, RGB18-666, and RGB24-888. This input data width is controlled by the RFBI_CONFIG__0/RFBI_CONFIG__1[6-5] DATATYPE bit field.

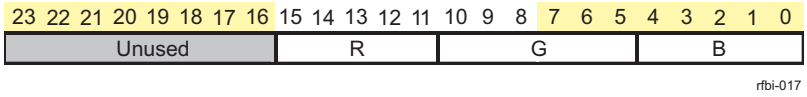
The following graphics describe the bit representation of each format in the video port FIFO. The output of the DISPC is aligned on the LSB of the interface. The pixels are then formatted in accordance with the configuration of the output interfaces (multiple cycles). For more information, see Section 11.3.4.2.9.1, *Cycle Mode Selection*.

- RGB12-444 format:



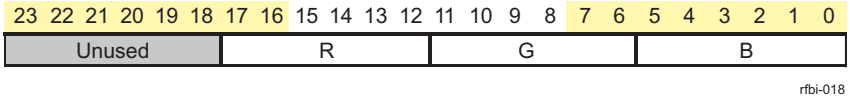
rfbi-016

- RGB16-565 format:



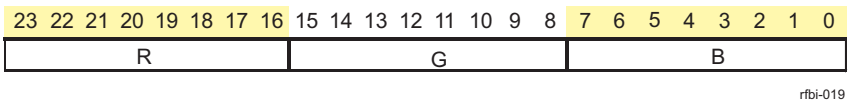
rfbi-017

- RGB18-666 format:



rfbi-018

- RGB24-888 format:



rfbi-019

NOTE: These pixel formats are also supported when data are provided from the slave port interconnect (for writing parameters).

11.3.4.2.6.3 RFBI Stall Mechanism

The internal STALL signal is generated by the RFBI video port FIFO to indicate when the DISPC must stop sending data on DISPC VP1 interface. This stall signal is used for DISPC VP1 output only when the DISPC is configured in stall mode. The stall mode is activated by setting the DISPC_VP1_CONTROL[11] STALLMODE bit.

NOTE: When the DISPC is configured in stall mode, the minimum transfer size is 1 byte.

The STALL signal allows the RFBI to reformat the data.

STALL is asserted when at least one of the following cases occurs:

- Default status when there is no data to capture from the DISPC
- High FIFO threshold reached
- End of transfer (number of data to output)
- RFBI reset
- RFBI_CONTROL[0] ENABLE bit reset to 0x0

STALL is deasserted when the RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occurs:

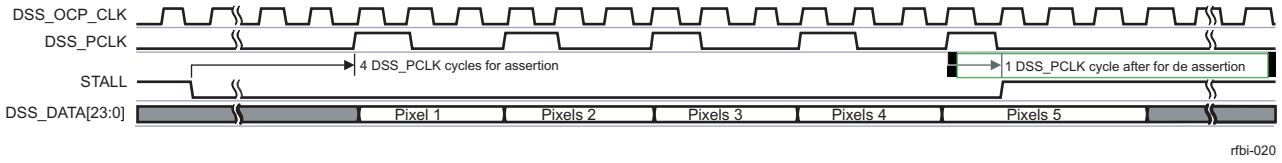
- Low FIFO threshold reached
- External TE occurs and the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field is set to 0x1 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- RFBI_CONTROL[4] ITE bit set to 0x1 by users (start of transfer, the FIFO pointers are reset, the FIFO is empty)

The RFBI asserts the STALL signal to stop data output by the DISPC. It is deasserted to indicate when new data must be output by the DISPC.

11.3.4.2.6.3.1 RFBI Data Stall Diagram without DISPC DMA Buffer Handshake

Figure 11-207 shows the RFBI data stall diagram when the DSS_OCP_CLK clock is 3 times faster than the pixel clock.

Figure 11-207. RFBI Data Stall Signal Diagram

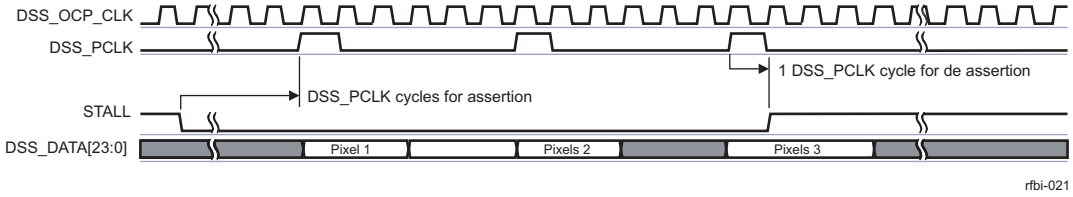


11.3.4.2.6.3.2 RFBI Data Stall Diagram with DISPC DMA Buffer Handshake

To avoid underflow of the DISPC DMA buffer, the DMA buffer handshake feature can be enabled by setting the DISPC_VP1_CONFIG[16] BUFFERHANDCHECK bit to 1. The fullness of the FIFOs associated with the VID1 pipeline used for the DISPC VP1 output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI requests data and there is not enough data in the DISPC DMA buffer. This feature must be enabled only when the stall mode is used (DISPC_VP1_CONTROL[11] STALLMODE bit set to 1).

When the DMA buffer handshake feature is activated, the pixel transfer to the RFBI during STALL inactivity period can be stopped (no PCLK pulse) and restarted when there is enough data in the DMA buffer. The DMA buffer handshake ensures that underflow cannot occur for the VID1 pipeline associated with the DISPC VP1 output in stall mode. Figure 11-208 shows the RFBI data stall with the DMA buffer handshake mode activated, and the DSS_OCP_CLK clock is 3 times faster than the pixel clock.

Figure 11-208. RFBI Data Stall Signal Diagram with Handshake



11.3.4.2.7 RFBI Interconnect FIFO

11.3.4.2.7.1 RFBI FIFO Description

The RFBI interconnect FIFO receives the data from DSS slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The address of the RFBI_DATA register should be used to access the interconnect FIFO. The interconnect FIFO is 32-bits wide. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA). The RFBI DMA request can be used to transfer data using the SoC DMA controller from system memory to the interconnect FIFO.

11.3.4.2.7.2 RFBI Using DMA Request with Interconnect FIFO

11.3.4.2.7.2.1 RFBI Threshold for DMA Request Generation

The RFBI_CONTROL[6-5] HIGHTHRESHOLD bit field defines the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register RFBI_DATA. The SoC DMA controller configuration regarding the size of the burst depends on the value of the RFBI_CONTROL[6-5] HIGHTHRESHOLD bit field. The supported values are 4 × 32, 8 × 32, and 16 × 32. For example, when 4 words of 32 bits are set for the threshold, the SoC DMA controller sends a burst of 4 × 32 bits only. The SoC DMA controller receives the DMA request and is in charge of providing the correct number of bytes.

11.3.4.2.7.2.2 RFBI Disabling DMA Request

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes slave port requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the slave port request.

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated and the threshold value is ignored.

NOTE: Software can access the RFBI_DATA location without using the DMA request and without programming the high threshold value.

11.3.4.2.7.2.3 RFBI Smart DMA Request Mode

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is reset (smart DMA mode disabled), the DMA request is asserted and deasserted depending on the interconnect FIFO space, even if MIdlereq is high in smart-idle mode and the entire burst gets error responses from the RFBI. The RFBI waits for a free entry in the interconnect FIFO to accept the burst request.

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is set (smart DMA mode enabled), the DMA request is deasserted after two DSS_OCP_CLK cycles, if it has been asserted for more than or equal to two DSS_OCP_CLK cycles and MIdlereq is high in smart-idle mode. If asserting time is less than two DSS_OCP_CLK cycles, no more burst requests are accepted even if space is available in the interconnect FIFO.

11.3.4.2.8 RFBI Timing Generator

11.3.4.2.8.1 RFBI Configuration Selection

The RFBI_CONTROL[3-2] CONFIGSELECT bit field selects the chip-select, CS0 or CS1, and corresponding configuration, 0 or 1.

The registers associated to the selected configuration are used to output the data to the LCD panel. If both CS0 and CS1 are selected, the configuration for the CS0 is used (except for the polarity of CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In Read mode, if both CS0 and CS1 are set, only CS0 is asserted in order to read data from the device connected on the CS0. In Write mode, with both CS0 and CS1 selected, the RFBI is able to write into the two devices at the same time.

Configuration 0 (with CS0 selected) uses the following registers:

- RFBI_CONFIG__0
- RFBI_ONOFF_TIME__0
- RFBI_CYCLE_TIME__0
- RFBI_DATA_CYCLE1__0
- RFBI_DATA_CYCLE2__0
- RFBI_DATA_CYCLE3__0

Configuration 1 (with CS1 selected) uses the following registers:

- RFBI_CONFIG__1
- RFBI_ONOFF_TIME__1
- RFBI_CYCLE_TIME__1
- RFBI_DATA_CYCLE1__1
- RFBI_DATA_CYCLE2__1
- RFBI_DATA_CYCLE3__1

11.3.4.2.8.2 RFBI Read/Write

Depending on the status of A0, WE, and RE signals (asserted or deasserted), the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WEn signal), RE (RFBI_REn signal), and CS (RFBI_CS0/CS1 signals) is programmable.

Table 11-419 describes the read/write function.

Table 11-419. RFBI Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WEn)	RE (RFBI_REn)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of CS cycle time, as defined in Table 11-420, is required to keep the RFBI_CS0/CS1 signals asserted between write transfers of multiple pixels.

Table 11-420 lists the minimum cycle time for RFBI_CS0/CS1, depending on the source of pixels (DISPC or RFBI slave port) and the cycle format (1pixel/cycle, 1pixel/2cycles, or 1pixel/3cycles).

Table 11-420. RFBI Minimum Cycle Time for CS/WE Always Asserted

RFBI Pixel Source	RFBI_CONFIG__0/ RFBI_CONFIG__1 [10-9] CYCLEFORMAT	RFBI_CONFIG__0/ RFBI_CONFIG__1 [8-7] PORTFORMAT	Minimum Cycle Time (in number of DSS_OCP_CLK cycles)
Slave port interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
DISPC video port output	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixel/3 cycles	N/A	6

11.3.4.2.8.3 RFBI State-Machine

The RFBI_A0, RFBI_REn, and RFBI_WEn signals are asserted and deasserted based on the register accessed (RFBI_CMD, RFBI_PARAM, RFBI_DATA, RFBI_READ, or RFBI_STATUS). When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the RFBI_DATA register only.

- Command register, RFBI_CMD

  Write one command at a time by writing through the slave port interconnect into the RFBI_CMD register. If the previous command is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new command is stalled.

- Parameter register, RFBI_PARAM

  Write one parameter at a time by writing in the RFBI_PARAM register.

  If the previous parameter is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new parameter is stalled.

- Data register, RFBI_DATA

  Write one or two pixels at a time by writing in the RFBI_DATA register.

  The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the RFBI_CONFIG__0/RFBI_CONFIG__1[8-7] PORTFORMAT bit field indicates the number of pixels for each slave port access to the register and the order of the pixels.

  If the previous data are not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, access is not stalled.

- Read/status register, RFBI_READ/RFBI_STATUS

  Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the RFBI_READ or RFBI_STATUS registers. In this case, the RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.

  When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the

appropriate command/parameters.

11.3.4.2.8.4 RFBI Timings

The timing registers can be accessed only when there is no transaction in progress (based on the value of the RFBI_CONTROL[3-2] CONFIGSELECT bit field). Granularity is defined using the RFBI_CONFIG__0/RFBI_CONFIG__1[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. See Table 11-421, *RFBI Timings Configuration*, for the configuration values of the timing bits.

- Chip-select assertion/deassertion time (CSOnTime/CSOffTime)

  RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[3-0] CSONTIME bit field

  The chip-select deassertion time from the start access time is programmable:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[9-4] CSOFFTIME bit field

  CAUTION

  Configuring RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[3-0] CSONTIME = [9-4] CSOFFTIME = 0 is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width (CSPulseWidth)

  The total chip-select pulse width is the time when write cycle time or read cycle time completes and is programmable:
  RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[17-12] CSPULSEWIDTH bit field

  It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

  – The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[19] RRENABLE bit: Read-to-read access
  – The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[20] WWENABLE bit: Write-to-write access
  – The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[18] RWENABLE bit: Read-to-write access
  – The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[21] WRENABLE bit: Write-to-read access

  By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select CS0 is activated by setting the RFBI_CONTROL[3-2] CONFIGSELECT bit field to 0x1.

- Access time

  Access time is the time delay between A0 assertion to data sampling before RE signal deassertion; access time is programmable:
  RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[27-22] ACCESSTIME bit field

  When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[29-24] REOFFTIME).

- Write-enable cycle time (WECycleTime)

  The total write-enable cycle time is the time when A0 becomes valid until write cycle completion; the write-enable cycle time is programmable:
  The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[5-0] WECYCLETIME bit field

- Write-enable assertion/deassertion time (WEOnTime/WEOffTime)

  The WE assertion delay time from start access time is programmable:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[13-10] WEONTIME bit field

  The WE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[19-14] WEOFFTIME bit field

- Read-enable cycle time (RECycleTime)

The total read-enable cycle time is the time when A0 becomes valid until read cycle completion; the read-enable cycle time is programmable:
The RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[11-6] RECYCLETIME bit field

- Read-enable assertion/deassertion time (REOnTime/REOffTime)

  The RE assertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[23-20] REONTIME bit field

  The RE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[29-24] REOFFTIME bit field

At cycle time completion (read access or write access), all control signals (RFBI_CS0/CS1, RFBI_WEn, and RFBI_REn) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to CS is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[17-12] CSPULSEWIDTH bit field = 0), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS0/CS1, RFBI_WEn, and RFBI_REn) stay asserted. This applies only to write-to-write access combination. In case of read-to-write, read-to-read, or write-to-read sequences, the RFBI_CS0/CS1, RFBI_WEn, and RFBI_REn signals are always deasserted.

Table 11-421 lists the configuration values for each timing bit.

Table 11-421. RFBI Timings Configuration

Timing Configuration Bits	Granularity[1]	
	One	Two
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[3-0] CSONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[9-4] CSOFFTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[17-12] CSPULSEWIDTH	0 to 63	0 to 126
RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[27-22] ACCESSTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[5-0] WECYCLETIME	3 to 63	4 to 126
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[13-10] WEONTIME	1 to 15	2 to 30
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[19-14] WEOFFTIME	2 to 63	2 to 126
RFBI_CYCLE_TIME__0/RFBI_CYCLE_TIME__1[11-6] RECYCLETIME	3 to 63	4 to 126
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[23-20] REONTIME	1 to 15	2 to 30
RFBI_ONOFF_TIME__0/RFBI_ONOFF_TIME__1[29-24] REOFFTIME	2 to 63	2 to 126

(1) Number of DSS_OCP_CLK cycles. The granularity can be configured using the RFBI_CONFIG__0/RFBI_CONFIG__1[4] TIMEGRANULARITY bit.

11.3.4.2.9 RFBI Output Parallel Modes

11.3.4.2.9.1 RFBI Cycle Mode Selection

In the following text and graphics RFBI_CONFIG refers to RFBI_CONFIG__0 or RFBI_CONFIG__1 registers. RFBI_DATA_CYCLE1 refers to RFBI_DATA_CYCLE1__0 and RFBI_DATA_CYCLE1__1 registers. RFBI_DATA_CYCLE2 refers to RFBI_DATA_CYCLE2__0 and RFBI_DATA_CYCLE2__1 registers. RFBI_DATA_CYCLE3 refers to RFBI_DATA_CYCLE3__0 and RFBI_DATA_CYCLE3__1 registers.

The RFBI_CONFIG__0/RFBI_CONFIG__1[10-9] CYCLEFORMAT bit field defines the number of cycles to output a pixel. The number of cycles determines the number of registers used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface. The data are formatted based on the configuration of the RFBI_DATA_CYCLE registers.

- One cycle: RFBI_CONFIG__0/RFBI_CONFIG__1[10-9] CYCLEFORMAT bit field = 0x00 and the RFBI_DATA_CYCLE1 registers
- Two cycles: RFBI_CONFIG__0/RFBI_CONFIG__1 [10-9] CYCLEFORMAT bit field = 0x01 and the RFBI_DATA_CYCLE1 and RFBI_DATA_CYCLE2 registers
- Three cycles: RFBI_CONFIG__0/RFBI_CONFIG__1[10-9] CYCLEFORMAT bit field = 0x10 and the RFBI_DATA_CYCLE1, RFBI_DATA_CYCLE2, and RFBI_DATA_CYCLE3 registers

Figure 11-209 through Figure 11-212 list the bits position of the pixel during the cycles for an 8-, 9-, and 16-bit parallel output, respectively.

Figure 11-210. RFBI 9-Bit Interface Settings

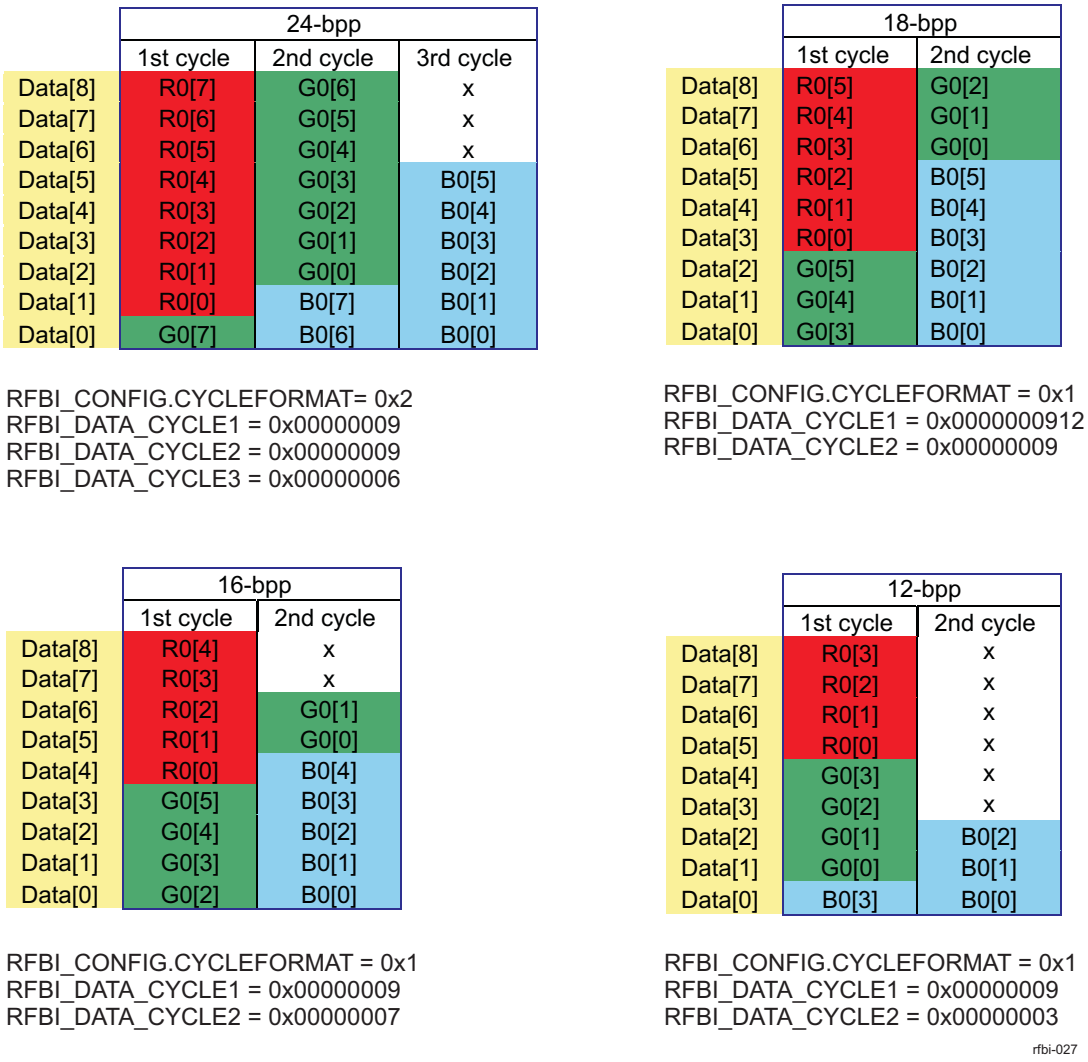

Figure 11-211. RFBI 12-Bit Interface Settings

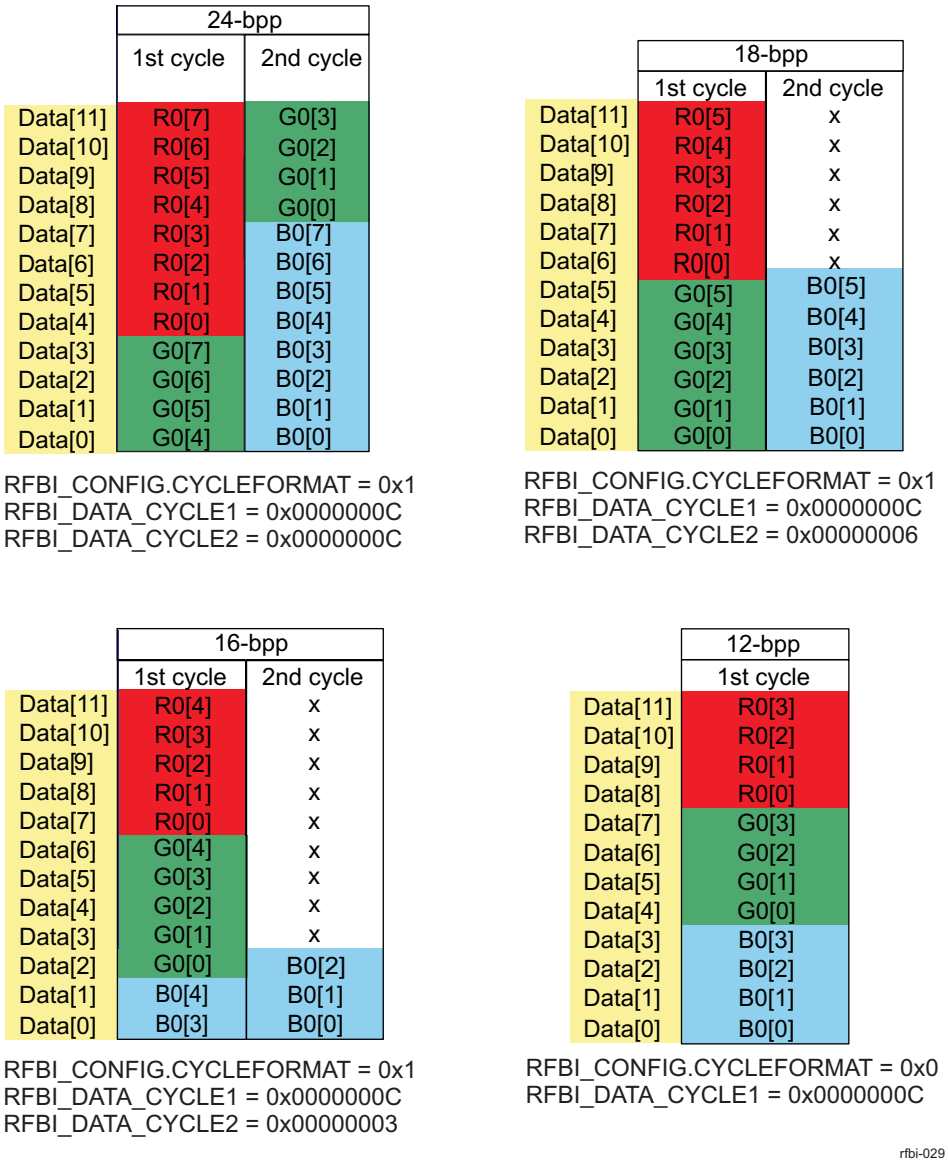

Figure 11-212. RFBI 16-Bit Interface Settings

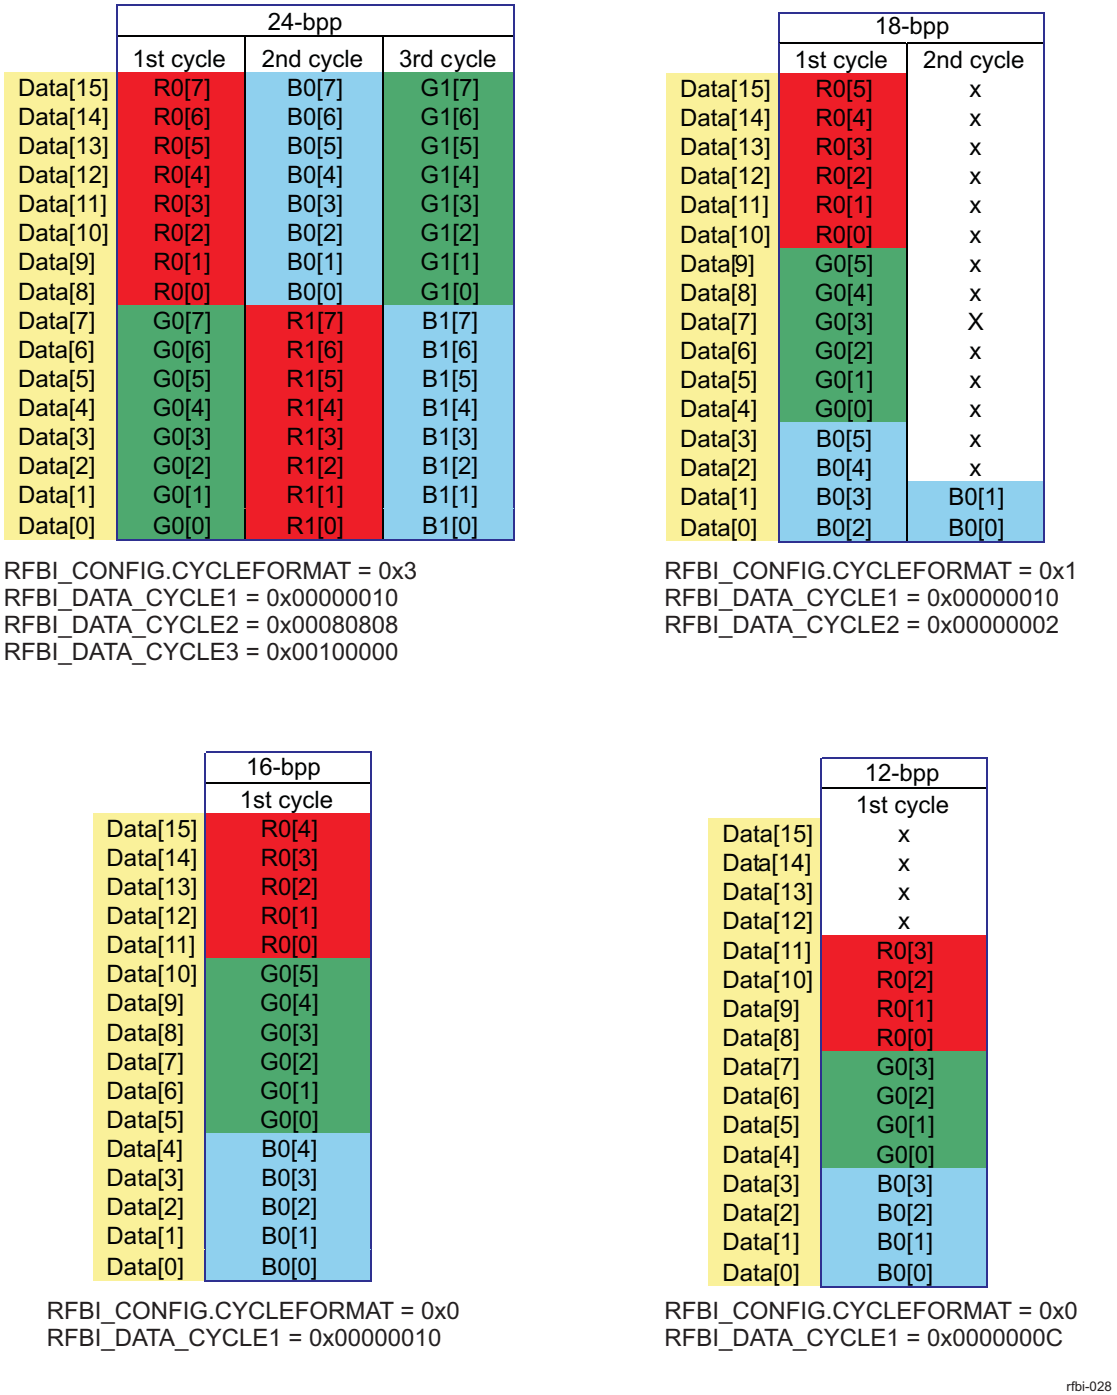

11.3.4.2.9.2 RFBI Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization). Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The RFBI_CONFIG__0/RFBI_CONFIG__1[12-11] UNUSEDBITS bit field is used.

11.3.4.2.9.3 RFBI Number of Pixels to Transfer

The RFBI_PIXEL_CNT[31-0] PIXELCNT bit field indicates the number of pixels to be transferred to the LCD panel. The value can be changed only when the RFBI_CONTROL[0] ENABLE bit is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the RFB. When the RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the RFBI_PIXEL_CNT register, and the current value in the register is a not 0 (the remaining number of pixels to transfer), the ongoing transfer is aborted.

11.3.4.2.10 RFBI Trigger Detection Logic

11.3.4.2.10.1 RFBI Trigger Mode

Setting the RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field configures the different trigger modes:

- Internal trigger mode with the internal programmable RFBI_CONTROL[4] ITE bit
- External trigger mode with the external TE signal (RFBI_TEVSYNC)
- External trigger mode with the external VSYNC/HSYNC signals

11.3.4.2.10.2 RFBI Internal Trigger Mode

Set the RFBI_CONTROL[4] ITE bit to start capturing the data from the DISPC. The DISPC must be configured in the RFBI mode to account for the STALL signal. Setting the trigger mode to external (RFBI_CONFIG__0/RFBI_CONFIG__1[3-2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the RFBI_CONTROL[4] ITE bit to be ignored. The chip-select CS0 must be selected (RFBI_CONTROL[3-2] CONFIGSELECT set to 0x1) when this bit is set by users.

11.3.4.2.10.3 RFBI External Trigger Mode

There are two external trigger modes:

- TE only: VSYNC and HSYNC are merged by logical OR operation and are detected through VSYNC and HSYNC pulse widths.
- HSYNC/VSYNC: This mode uses the two external signals, which are detected through VSYNC and HSYNC pulse widths.

11.3.4.2.10.3.1 RFBI Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines programmed by the user in the RFBI_LINE_NUMBER[10-0] LINENUMBER bit field (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

11.3.4.2.10.3.2 RFBI VSYNC Pulse Width (Minimum Value)

The RFBI_VSYNC_WIDTH[15-0] MINVSYNCPULSEWIDTH bit field defines the minimum number of DSS_OCP_CLK cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are OR-ed on the same signal, and is also used in HSYNC/VSYNC mode on the two separate input lines.

- The VSYNC pulse width must be equal to at least two DSS_OCP_CLK cycles when HSYNC is not present (TE trigger mode only).
- The VSYNC pulse width must be equal to at least four DSS_OCP_CLK cycles when HSYNC is present (TE trigger mode only).

11.3.4.2.10.3.3 RFBI HSYNC Pulse Width (Minimum Value)

The RFBI_HSYNC_WIDTH[15-0] MINHSYNCPULSEWIDTH bit field defines the minimum number of DSS_OCP_CLK cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are OR-ed on the same signal, and is also used in VSYNC/HSYNC mode on the separate two input lines. To be detected, the HSYNC/VSYNC pulse width must always be equal to at least two DSS_OCP_CLK cycles. See Table 11-422.

Table 11-422. RFBI Minimum Pulse Width (HSYNC/VSYNC)

Configuration Bits	TE Mode	HSYNC/VSYNC Mode
RFBI_HSYNC_WIDTH[15-0] MINHSYNCPULSEWIDTH field value	2	2
RFBI_VSYNC_WIDTH[15-0] MINVSYNCPULSEWIDTH field value	4	2

The pulse received by the RFBI must be at least two DSS_OCP_CLK cycles to be detected. For the TE mode, since the minimum value to differentiate VSYNC and HSYNC is two DSS_OCP_CLK cycles, the VSYNC pulse width must be at least four DSS_OCP_CLK cycles and the HSYNC pulse width must be at least two DSS_OCP_CLK cycles.

11.3.4.2.10.4 RFBI Hardware Status Features

Table 11-423 lists the RFBI hardware status features.

Table 11-423. RFBI Hardware Status Features

Feature	Type	Register/Bit Field	Description
Data pending	Status	RFBI_SYSSTATUS[9] BUSYRFBIDATA	It is set to 1 when some data are pending to be processed from the interconnect FIFO.
Slave port bus busy	Status	RFBI_SYSSTATUS[9] BUSY	It is set to 1 when the slave port bus is busy and access to some RFBI registers (RFBI_CMD, RFBI_STATUS, RFBI_PARAM, and RFBI_READ) is stalled.

11.3.5 DSS Registers

This section describes the DSS registers.

11.3.5.1 DSSUL_0_CFG Registers

Table 11-425 lists the memory-mapped registers for the DSSUL_0_CFG. All register offset addresses not listed in Table 11-425 should be considered as reserved locations and the register contents should not be modified.

This section describes the DSSUL_0_CFG instances registers.

Table 11-424. DSSUL_0_CFG Instances

Instance	Base Address
DSSUL_0_CFG	0254 0000h

Table 11-425. DSSUL_0_CFG Registers

Offset	Acronym	Register Name	DSSUL_0_CFG Physical Address	Section
0h	DSS_REVISION	This register contains the DSS revision number.	0254 0000h	Section 11.3.5.1.1
10h	DSS_SYSCONFIG	This register controls the various parameters of the OCP interface	0254 0010h	Section 11.3.5.1.2
14h	DSS_SYSSTATUS	This register provides status information about the module.	0254 0014h	Section 11.3.5.1.3
18h	DSS_RFBI_CTRL	This register contains control bits corresponding to the RFBI instance in DSS	0254 0018h	Section 11.3.5.1.4
1Ch	DSS_DPI_CTRL	This register contains control bits corresponding to the DPI interface in DSS	0254 001Ch	Section 11.3.5.1.5

11.3.5.2 DISPC_COMMON Registers

Table 11-445 lists the memory-mapped registers for the DISPC_COMMON. All register offset addresses not listed in Table 11-445 should be considered as reserved locations and the register contents should not be modified.

This section describes the DISPC_COMMON instances registers.

Table 11-444. DISPC_COMMON Instances

Instance	Base Address
DISPC_COMMON	0255 0000h

Table 11-445. DISPC_COMMON Registers

Offset	Acronym	Register Name	DISPC_COMMON Physical Address	Section
0h	DISPC_REVISION	This register contains the IP revision code	0255 0000h	Section 11.3.5.2.1
4h	DISPC_SYSCONFIG	This register allows to control various parameters of the OCP interface.	0255 0004h	Section 11.3.5.2.2
8h	DISPC_SYSSTATUS	This register provides status information about the module, excluding the interrupt status information.	0255 0008h	Section 11.3.5.2.3
20h	DISPC_IRQ_EOI	End Of Interrupt number	0255 0020h	Section 11.3.5.2.4
24h	DISPC_IRQSTATUS_RAW	Per-end of group (31 down to 0) internal signaling raw interrupt status vector, line #0. Raw status is set even if end of group (31 down to 0) interrupt is not enabled. Write 1 to set the (raw) status, mostly for debug.	0255 0024h	Section 11.3.5.2.5
28h	DISPC_IRQSTATUS	Per-end of group (31 down to 0) internal signaling 'enabled' interrupt status vector, line #0. Enabled status isn't set unless event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, i.e. even if not enabled).	0255 0028h	Section 11.3.5.2.6
2Ch	DISPC_IRQENABLE_SET	Per-end of group (31 down to 0) internal event interrupt enable bit vector, line #0. Write 1 to set (enable interrupt). Readout equal to corresponding _CLR register.	0255 002Ch	Section 11.3.5.2.7
30h	DISPC_IRQENABLE_CLR	See description of corresponding _SET register.	0255 0030h	Section 11.3.5.2.8
34h	DISPC_IRQWAKEEN	IRQ wake up register. **Note: Feature is not supported in this family of devices.**	0255 0034h	Section 11.3.5.2.9
40h	DISPC_GLOBAL_MFLAG_ATTRIBUTE	MFLAG control register	0255 0040h	Section 11.3.5.2.10
44h	DISPC_GLOBAL_BUFFER	The register configures the DMA buffers allocations to the pipeline.	0255 0044h	Section 11.3.5.2.11
48h	DISPC_BA0_FLIPIMMEDIATE_EN	**Note: Feature is not supported in this family of devices.**	0255 0048h	Section 11.3.5.2.12
4Ch	DISPC_DBG_CONTROL	DISPC debug bus control register.	0255 004Ch	Section 11.3.5.2.13
50h	DISPC_DBG_STATUS	DISPC debug status register.	0255 0050h	Section 11.3.5.2.14
54h	DISPC_CLKGATING_DISABLE	Register to control clock gating at DISPC sub-module level	0255 0054h	Section 11.3.5.2.15

11.3.5.2.1 DISPC_REVISION Register (Offset = 0h) [reset = 82h]

DISPC_REVISION is shown in Figure 11-219 and described in Table 11-447.

Return to Summary Table.

This register contains the IP revision code

Table 11-490. Register Call Summary for DISPC_CLKGATING_DISABLE

DISPC_COMMON Registers

- DISPC_COMMON Registers: [0]
- DISPC_CLKGATING_DISABLE Register (Offset = 54h) [reset = 0h]: [0]

11.3.5.3 DISPC_VID1 Registers

Table 11-492 lists the memory-mapped registers for the DISPC_VID1. All register offset addresses not listed in Table 11-492 should be considered as reserved locations and the register contents should not be modified.

This section describes the DISPC_VID1 instances registers.

Table 11-491. DISPC_VID1 Instances

Instance	Base Address
DISPC_VID1	0255 7000h

Table 11-492. DISPC_VID1 Registers

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
0h to 4h	DISPC_VID1_ACCUH_0 to DISPC_VID1_ACCUH_1	The register configures the resize accumulator init values for horizontal up/down-sampling of the video window (DISPC_VIDx_ACCU__0 & DISPC_VIDx_ACCU__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for ARGB and Y setting. Shadow register.	0255 7000h to 0255 7004h	Section 11.3.5.3.1
8h to Ch	DISPC_VID1_ACCUH2_0 to DISPC_VID1_ACCUH2_1	The register configures the resize accumulator init value for horizontal up/down-sampling of the video window (DISPC_VID#n_ACCU2__0 & DISPC_VID#n_ACCU2__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7008h to 0255 700Ch	Section 11.3.5.3.2
10h to 14h	DISPC_VID1_ACCUV_0 to DISPC_VID1_ACCUV_1	The register configures the resize accumulator init values for horizontal and vertical up/down-sampling of the video window (DISPC_VIDx_ACCU__0 & DISPC_VIDx_ACCU__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for ARGB and Y setting. Shadow register.	0255 7010h to 0255 7014h	Section 11.3.5.3.3

Table 11-492. DISPC_VID1 Registers (continued)

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
18h to 1Ch	DISPC_VID1_ACCUV2_0 to DISPC_VID1_ACCUV2_1	The register configures the resize accumulator init value for vertical up/down-sampling of the video window (DISPC_VID1_ACCU2__0 & DISPC_VID1_ACCU2__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7018h to 0255 701Ch	Section 11.3.5.3.4
20h	DISPC_VID1_ATTRIBUTES	The register configures the attributes of the video window. Shadow register.	0255 7020h	Section 11.3.5.3.5
24h	DISPC_VID1_ATTRIBUTES2	The register configures the attributes of the video window. Shadow register.	0255 7024h	Section 11.3.5.3.6
28h to 2Ch	DISPC_VID1_BA_0 to DISPC_VID1_BA_1	The register configures the base address of the video buffer for the video window (DISPC_VID1_BA__0 & DISPC_VID1_BA__1 for ping-pong mechanism with external trigger, based on the field polarity otherwise only DISPC_VID1_BA__0 is used). Shadow register.	0255 7028h to 0255 702Ch	Section 11.3.5.3.7
30h to 34h	DISPC_VID1_BA_UV_0 to DISPC_VID1_BA_UV_1	The register configures the base address of the UV buffer for the video window. (DISPC_VID1_BA_UV__0 & DISPC_VID1_BA_UV__1 for ping-pong mechanism with external trigger, based on the field polarity otherwise only DISPC_VID1_BA_UV__0 is used)). The register is also used to configure the RGB plane BA for RGB565A8 format Shadow register.	0255 7030h to 0255 7034h	Section 11.3.5.3.8
38h	DISPC_VID1_BUF_SIZE_STATUS	The register defines the Video buffer size for the video pipeline.	0255 7038h	Section 11.3.5.3.9
3Ch	DISPC_VID1_BUF_THRESHOLD	The register configures the video buffer associated with the video pipeline. Shadow register.	0255 703Ch	Section 11.3.5.3.10
40h	DISPC_VID1_CONV_COEF0	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7040h	Section 11.3.5.3.11
44h	DISPC_VID1_CONV_COEF1	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7044h	Section 11.3.5.3.12
48h	DISPC_VID1_CONV_COEF2	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7048h	Section 11.3.5.3.13

Table 11-492. DISPC_VID1 Registers (continued)

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
4Ch	DISPC_VID1_CONV_COEF3	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 704Ch	Section 11.3.5.3.14
50h	DISPC_VID1_CONV_COEF4	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7050h	Section 11.3.5.3.15
54h	DISPC_VID1_CONV_COEF5	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7054h	Section 11.3.5.3.16
58h	DISPC_VID1_CONV_COEF6	The register configures the color space conversion matrix coefficients for the video pipeline. Shadow register.	0255 7058h	Section 11.3.5.3.17
5Ch	DISPC_VID1_FIRH	The register configures the resize factor for horizontal up/down-sampling of the video window. It is used for ARGB and Y setting. Shadow register.	0255 705Ch	Section 11.3.5.3.18
60h	DISPC_VID1_FIRH2	The register configures the resize factor for horizontal up/down-sampling of the video window. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7060h	Section 11.3.5.3.19
64h	DISPC_VID1_FIRV	The register configures the resize factor for vertical up/down-sampling of the video window. It is used for ARGB and Y setting. Shadow register.	0255 7064h	Section 11.3.5.3.20
68h	DISPC_VID1_FIRV2	The register configures the resize factor for vertical up/down-sampling of the video window. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7068h	Section 11.3.5.3.21
6Ch to 8Ch	DISPC_VID1_FIR_COEF_H0_0 to DISPC_VID1_FIR_COEF_H0_8	The bank of registers configure the up/down-scaling coefficients for the horizontal resize of the video picture associated with the video window for the 16 phases It is used for ARGB and Y setting. Shadow register.	0255 706Ch to 0255 708Ch	Section 11.3.5.3.22

Table 11-492. DISPC_VID1 Registers (continued)

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
90h to B0h	DISPC_VID1_FIR_COEF_H0_C_0 to DISPC_VID1_FIR_COEF_H0_C_8	The bank of registers configure the up/down-scaling coefficients for the horizontal resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7090h to 0255 70B0h	Section 11.3.5.3.23
B4h to F0h	DISPC_VID1_FIR_COEF_H12_0 to DISPC_VID1_FIR_COEF_H12_15	The bank of registers configure the up/down-scaling coefficients for the horizontal resize of the video picture associated with the video window for the 16 phases It is used for ARGB and Y setting. Shadow register.	0255 70B4h to 0255 70F0h	Section 11.3.5.3.24
F4h to 130h	DISPC_VID1_FIR_COEF_H12_C_0 to DISPC_VID1_FIR_COEF_H12_C_15	The bank of registers configure the up/down-scaling coefficients for the horizontal resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 70F4h to 0255 7130h	Section 11.3.5.3.25
134h to 154h	DISPC_VID1_FIR_COEF_V0_0 to DISPC_VID1_FIR_COEF_V0_8	The bank of registers configure the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the 16 phases It is used for ARGB and Y setting. Shadow register.	0255 7134h to 0255 7154h	Section 11.3.5.3.26
158h to 178h	DISPC_VID1_FIR_COEF_V0_C_0 to DISPC_VID1_FIR_COEF_V0_C_8	The bank of registers configure the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 7158h to 0255 7178h	Section 11.3.5.3.27

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
17Ch to 1B8h	DISPC_VID1_FIR_COEF_V12_0 to DISPC_VID1_FIR_COEF_V12_15	The bank of registers configure the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the 16 phases It is used for ARGB and Y setting. Shadow register.	0255 717Ch to 0255 71B8h	Section 11.3.5.3.28
1BCh to 1F8h	DISPC_VID1_FIR_COEF_V12_C_0 to DISPC_VID1_FIR_COEF_V12_C_15	The bank of registers configure the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.	0255 71BCh to 0255 71F8h	Section 11.3.5.3.29
1FCh	DISPC_VID1_GLOBAL_ALPHA	The register defines the global alpha value for the video pipeline. Shadow register.	0255 71FCh	Section 11.3.5.3.30
200h	DISPC_VID1_IRQENABLE	This register allows to mask/unmask the module internal sources of interrupt, on an event-by-event basis	0255 7200h	Section 11.3.5.3.31
204h	DISPC_VID1_IRQSTATUS	This register regroups all the status of the module internal events that generate an interrupt. Write 1 to a given bit resets this bit	0255 7204h	Section 11.3.5.3.32
208h	DISPC_VID1_MFLAG_THRESHOLD	MFLAG thresholds for video pipelines. Shadow register.	0255 7208h	Section 11.3.5.3.33
20Ch	DISPC_VID1_PICTURE_SIZE	The register configures the size of the video picture associated with the video layer before up/down-scaling. Shadow register.	0255 720Ch	Section 11.3.5.3.34
210h	DISPC_VID1_PIXEL_INC	The register configures the number of bytes to increment between two pixels for the buffer associated with the video window. The register is used in order to perform low performance rotation. Shadow register.	0255 7210h	Section 11.3.5.3.35
214h	DISPC_VID1_POSITION	The register configures the position of the video window. Shadow register.	0255 7214h	Section 11.3.5.3.36
218h	DISPC_VID1_PRELOAD	The register configures the DMA buffer of the video pipeline. Shadow register.	0255 7218h	Section 11.3.5.3.37
21Ch	DISPC_VID1_ROW_INC	The register configures the number of bytes to increment at the end of the row for the buffer associated with the video window. Shadow register.	0255 721Ch	Section 11.3.5.3.38
220h	DISPC_VID1_SIZE	The register configures the size of the video window. Shadow register.	0255 7220h	Section 11.3.5.3.39

Table 11-492. DISPC_VID1 Registers (continued)

Offset	Acronym	Register Name	DISPC_VID1 Physical Address	Section
224h	DISPC_VID1_CLUT	The register configures the Color Look Up Table (CLUT) for VID pipeline. CLUT is used in conjunction with bitmap formats	0255 7224h	Section 11.3.5.3.40

11.3.5.3.1 DISPC_VID1_ACCUH_0 to DISPC_VID1_ACCUH_1 Register (Offset = 0h to 4h) [reset = 0h]

DISPC_VID1_ACCUH_0 to DISPC_VID1_ACCUH_1 is shown in Figure 11-234 and described in Table 11-494.

Return to Summary Table.

The register configures the resize accumulator init values for horizontal up/down-sampling of the video window (DISPC_VIDx_ACCU__0 DISPC_VIDx_ACCU__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for ARGB and Y setting. Shadow register.

Table 11-506. DISPC_VID1_ATTRIBUTES Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30	RESERVED	R	0h	Reserved
29	RESERVED	R	0h	Reserved
28	PREMULTIPLYALPHA	R/W	0h	The field configures the DISPC VID1 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. **Note: Feature is not supported in this family of devices.** 0h (R/W) = Non premultiplyalpha data color component 1h (R/W) = Premultiplyalpha data color component

Table 11-506. DISPC_VID1_ATTRIBUTES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27-25	ZORDER	R/W	0h	Z-Order defining the priority of the layer compared to others when overlaying. It is SW responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. **Note: Feature is not supported in this family of devices.** 0h (R/W) = Z-order 0: layer above solid background color and below layer with higher Z-order values. 1h (R/W) = Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 2h (R/W) = Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3 3h (R/W) = Z-order 3: layer above layers with z-order value of 0, 1 and 2 and below layer with z-order value of 4 4h (R/W) = Z-order 4: layer above layers with z-order value of 0, 1, 2 and 3 and below layer with z-order value of 5 5h (R/W) = Z-order 5: layer above all the other layers except cursor
24	SELFREFRESH	R/W	0h	Enables the self refresh of the video window from its own DMA buffer only. 0h (R/W) = The video pipeline accesses the interconnect to fetch data from the system memory. 1h (R/W) = The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video1 is used. It takes effect after the frame has been loaded in the DMA buffer.
23	ARBITRATION	R/W	0h	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. **Note: Feature is not supported in this family of devices.** 0h (R/W) = The video pipeline is one of the normal priority pipeline. 1h (R/W) = The video pipeline is one of the high priority pipeline.
22	DOUBLESTRIDE	R/W	0h	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV420 and 2D access 0h (R/W) = The CbCr stride value is equal to the Y stride. 1h (R/W) = The CbCr stride value is double to the Y stride.
21	VERTICALTAPS	R/W	0h	Video Vertical Resize Tap Number. The vertial poly-phase filter can be configured in 3-tap or 5-tap configuration. According to the number of taps, the maximum input picture width is double while using 3-tap compared to 5-tap. 0h (R/W) = 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit-fields for the 2 other taps coefficients do not need to be initialized. 1h (R/W) = 5 taps are used for the vertical filtering logic.
20	RESERVED	R	0h	Reserved
19	BUFPRELOAD	R/W	0h	Video Preload Value 0h (R/W) = H/W prefetches pixels up to the preload value defined in the preload register 1h (R/W) = H/W prefetches pixels up to high threshold value
18	RESERVED	R	0h	Write 0's for future compatibility. Reads return 0.
17	SELFREFRESHAUTO	R/W	0h	Automatic self refresh mode 0h (R/W) = The transition from SELFREFRESH <disabled> to <enabled> is controlled by SW. 1h (R/W) = The transition from SELFREFRESH <disabled> to <enabled> is controlled only by HW.

Table 11-506. DISPC_VID1_ATTRIBUTES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16-14	CHANNELOUT	R/W	0h	Video Channel Out configuration wr: immediate 0h (R/W) = OVR1 (VP1) Others = Reserved
13-12	RESERVED	R	0h	Reserved
11	FULLRANGE	R/W	0h	Color Space Conversion full range setting. 0h (R/W) = Limited range selected: 16 subtracted from Y before color space conversion 1h (R/W) = Full range selected: Y is not modified before the color space conversion
10	NIBBLEMODE	R/W	0h	Video Nibble mode (only for 1-, 2- and 4-bpp) 0h (R/W) = Nibble mode is disabled 1h (R/W) = Nibble mode is enabled
9	COLORCONVENABLE	R/W	0h	Enable the color space conversion. The HW does not enable/disable the conversion based on the pixel format. The bit-field shall be reset when the format is not YUV. 0h (R/W) = Disable Color Space Conversion YUV to RGB 1h (R/W) = Enable Color Space Conversion YUV to RGB
8-7	RESIZEENABLE	R/W	0h	Video Resize Enable 0h (R/W) = Disable both horizontal and vertical resize processing 1h (R/W) = Enable the horizontal resize processing 2h (R/W) = Enable the vertical resize processing 3h (R/W) = Enable both horizontal and vertical resize processing

11.3.5.3.19 DISPC_VID1_FIRH2 Register (Offset = 60h) [reset = 00200000h]

DISPC_VID1_FIRH2 is shown in Figure 11-252 and described in Table 11-548.

Return to Summary Table.

The register configures the resize factor for horizontal up/down-sampling of the video window. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.

DISPC_VID1 Registers • DISPC_VID1_FIR_COEF_V0_0 to DISPC_VID1_FIR_COEF_V0_8 Register (Offset = 134h to 154h) [reset = 0h]: [0] • DISPC_VID1 Registers: [0]

11.3.5.3.27 DISPC_VID1_FIR_COEF_V0_C_0 to DISPC_VID1_FIR_COEF_V0_C_8 Register (Offset = 158h to 178h) [reset = 0h]

DISPC_VID1_FIR_COEF_V0_C_0 to DISPC_VID1_FIR_COEF_V0_C_8 is shown in Figure 11-260 and described in Table 11-572.

Return to Summary Table.

The bank of registers configure the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.

Table 11-605. DISPC_VID1_ROW_INC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ROWINC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value (from -2^{31}-1 to 2^{31}) to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value 1+n*bpp means increment of n pixels. The value 1- (n+1)*bpp means decrement of n pixels.

Table 11-639. DISPC_VP1_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	FULLRANGE	R/W	0h	Color Space Conversion full range setting. 0h (R/W) = Limited range selected. 1h (R/W) = Full range selected.
24	COLORCONVENABLE	R/W	0h	Enable the color space conversion. It shall be reset when CPR bit-field is set to 0x1. 0h (R/W) = Disable Color Space Conversion RGB to YUV 1h (R/W) = Enable Color Space Conversion RGB to YUV
23	FIDFIRST	R/W	0h	Selects the first field to output in case of interlace mode. In case of progressive mode, the value is not used. 0h (R/W) = First field is even. 1h (R/W) = Odd field is first.
22	OUTPUTMODEENABLE	R/W	0h	Selects between progressive and interlace mode for the VP output. 0h (R/W) = Progressive mode selected. 1h (R/W) = Interlace mode selected.
21	BT1120ENABLE	R/W	0h	Selects BT-1120 format on the VP output. It is not posssible to enable BT656 and BT1120 at the same time on the same VP output. 0h (R/W) = BT-1120 is disabled. 1h (R/W) = BT-1120 is enabled.

Table 11-639. DISPC_VP1_CONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	BT656ENABLE	R/W	0h	Selects BT-656 format on the VP output. It is not posssible to enable BT656 and BT1120 at the same time on the same VP output. 0h (R/W) = BT-656 is disabled. 1h (R/W) = BT-656 is enabled.
19-17	RESERVED	R	0h	Write 0's for future compatibility. Reads return 0
16	BUFFERHANDSHAKE	R/W	0h	Controls the handshake between DMA buffer and STALL signal in order to prevent from underflow. The bit shall be set to 0 when the module is not in STALL mode. 0h (R/W) = Only the STALL signal (generated by RFBI) is used regardless of the DMA buffer fullness information in order to provide data to the RFBI module. 1h (R/W) = The STALL signal (generated by RFBI) is used in combination with the DMA buffer fullness information in order to provide data to the RFBI module only when it does not generated buffer underflow.
15	CPR	R/W	0h	Color Phase Rotation Control VP output). It shall be reset when ColorConvEnable bit-field is set to 1. Shadow bit-field. 0h (R/W) = Color Phase Rotation Disabled 1h (R/W) = Color Phase Rotation Enabled
14-9	RESERVED	R	0h	Write 0's for future compatibility. Reads return 0
8	EXTERNALSYNCEN	R/W	0h	Selects between external sync and internal sync mode for the VP output. 0h (R/W) = Internal sync mode selected 1h (R/W) = External sync mode selected.
7	VSYNCGATED	R/W	0h	VSYNC Gated Enabled (VP output) Shadow bit-field. 0h (R/W) = VSYNC Gated Disabled 1h (R/W) = VSYNC Gated Enabled
6	HSYNCGATED	R/W	0h	HSYNC Gated Enabled (VP output) Shadow bit-field. 0h (R/W) = HSYNC Gated Disabled 1h (R/W) = HSYNC Gated Enabled
5	PIXELCLOCKGATED	R/W	0h	Pixel Clock Gated Enabled (VP output) Shadow bit-field. 0h (R/W) = Pixel Clock Gated Disabled 1h (R/W) = Pixel Clock Gated Enabled
4	PIXELDATAGATED	R/W	0h	Pixel Data Gated Enabled (VP output) Shadow bit-field. 0h (R/W) = Pixel Data Gated Disabled 1h (R/W) = Pixel Data Gated Enabled
3	HDMIMODE	R/W	0h	Configures the timing generator in HDMI compatible mode to generate same timings as HDMI wrapper timings. **Note: Feature is not supported in this family of devices.** 0h (R/W) = Disable HDMI mode. 1h (R/W) = Enable HDMI mode timings: - vertical FSM starts with the VFP period (instead of VSYNC) - last frame ends with the last pixel of data state.
2	GAMMAENABLE	R/W	0h	Enable the gamma Shadow bit-field. 0h (R/W) = Gamma disabled 1h (R/W) = Gamma enabled
1	DATAENABLEGATED	R/W	0h	DE Gated Enable Shadow bit-field. 0h (R/W) = DE signal is not gated 1h (R/W) = DE signal is gated.
0	PIXELGATED	R/W	0h	Pixel Gated Enable Shadow bit-field. 0h (R/W) = Pixel clock always toggles (only in TFT mode) 1h (R/W) = Pixel clock only toggles when there is valid data to display. (only in TFT mode)

Table 11-640. Register Call Summary for DISPC_VP1_CONFIG

Table 11-642. DISPC_VP1_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	SPATIALTEMPORALDITHERINGFRAMES	R/W	0h	Spatial/Temporal dithering number of frames for the VP output. Shadow bit-field. 0h (R/W) = Spatial only 1h (R/W) = Spatial and temporal over 2 frames 2h (R/W) = Spatial and temporal over 4 frames 3h (R/W) = Reserved
29-27	RESERVED	R	0h	Write 0's for future compatibility. Reads return 0
26-25	TDMUNUSEDBITS	R/W	0h	State of unused bits (TDM mode only) for the VP output. Shadow bit-field. 0h (R/W) = low level (0) 1h (R/W) = high level (1) 2h (R/W) = unchanged from previous state 3h (R/W) = reserved
24-23	TDMCYCLEFORMAT	R/W	0h	Cycle format (TDM mode only) for the VP output. Shadow bit-field. 0h (R/W) = 1 cycle for 1 pixel 1h (R/W) = 2 cycles for 1 pixel 2h (R/W) = 3 cycles for 1 pixel 3h (R/W) = 3 cycles for 2 pixels

Table 11-642. DISPC_VP1_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22-21	TDMPARALLELMODE	R/W	0h	Output Interface width (TDM mode only) for the VP output. Shadow bit-field. 0h (R/W) = 8-bit parallel output interface selected 1h (R/W) = 9-bit parallel output interface selected 2h (R/W) = 12-bit parallel output interface selected 3h (R/W) = 16-bit parallel output interface selected
20	TDMENABLE	R/W	0h	Enable the multiple cycle format for the VP output. Shadow bit-field. 0h (R/W) = TDM disabled 1h (R/W) = TDM enabled
19-17	RESERVED	R	0h	Reserved
16-14	HT	R/W	0h	Hold Time for VP output. Shadow bit-field. Encoded value (from 1 to 8) to specify the number of external digital clock periods to hold the data (programmed value = value minus one)
13	RESERVED	R	0h	Reserved
12	RESERVED	R	0h	Reserved
11	STALLMODE	R/W	0h	STALL Mode for the VP output. Shadow bit-field. 0h (R/W) = Normal mode selected 1h (R/W) = STALL mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The VP output is disabled at the end of the transfer of the frame. The S/W has to re-enable the VP output in order to generate a new frame.
10-8	DATALINES	R/W	0h	Width of the data bus on VP output. Shadow bit-field. 0h (R/W) = 12-bit output aligned on the LSB of the pixel data interface 1h (R/W) = 16-bit output aligned on the LSB of the pixel data interface 2h (R/W) = 18-bit output aligned on the LSB of the pixel data interface 3h (R/W) = 24-bit output aligned on the LSB of the pixel data interface 4h (R/W) = 30-bit output aligned on the LSB of the pixel data interface 5h (R/W) = 36-bit output aligned on the LSB of the pixel data interface
7	STDITHERENABLE	R/W	0h	Spatial Temporal dithering enable for the VP output Shadow bit-field. 0h (R/W) = Spatial/Temporal dithering logic disabled 1h (R/W) = Spatial/Temporal dithering logic enabled
6	RESERVED	R	0h	Reserved
5	GOBIT	R/W	0h	GO Command for the VP output. It is used to synchronized the pipelines associated with the VP output. wr:immediate 0h (R/W) = The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the VP output using the user values. The hardware resets the bit when the update is completed. 1h (R/W) = The user has finished to program the shadow registers of the pipeline(s) associated with the VP output and the hardware can update the internal registers at the VFP start period
4	M8B	R/W	0h	Mono 8-bit mode of the primary LCD wr: VFP start period of primary LCD output 0h (R/W) = Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition. (only in Passive Mono 4-bit mode) 1h (R/W) = Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition. (only in Passive Mono 8-bit mode)

Table 11-642. DISPC_VP1_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	STN	R/W	0h	LCD Display type of the primary LCD wr: VFP start period of primary LCD output 0h (R/W) = Passive or STN display operation disabled. 1h (R/W) = Passive or STN display operation enabled. STN dither logic is enabled.
2	MONOCOLOR	R/W	0h	Monochrome/Color selection for the primary LCD wr: VFP start period of primary LCD output only) 0h (R/W) = Color operation enabled (STN mode only) 1h (R/W) = Monochrome operation enabled (STN mode only)
1	VPPROGLINENUMBERMODULO	R/W	0h	Enable the modulo of the line number interrupt generation 0h (R/W) = Disable modulo 1h (R/W) = Enable Modulo
0	VPENABLE	R/W	0h	Enable the video port output wr:immediate 0h (R/W) = VP output disabled (at the end of the frame when the bit is reset) 1h (R/W) = VP output enabled

Table 11-663. DISPC_VP1_IRQSTATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	ACBIASCOUNTSTATUS_IRQ	R/W1C	0h	AC BIAS transition counter has decremented to zero 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.
4	VPSYNCLOST_IRQ	R/W1C	0h	Synchronization Lost on VP output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with VP output. 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.
3	VPPROGRAMMEDLINENUMBER_IRQ	R/W1C	0h	Programmed Line Number. It indicates that the scan of the display has reached the programmed user line number. 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.
2	VPVSYNC_ODD_IRQ	R/W1C	0h	VSYNC for odd field from interlace mode only. 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.

Table 11-663. DISPC_VP1_IRQSTATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	VPVSYNC_IRQ	R/W1C	0h	Vertical Synchronization for VP output. It is used as VSYNC_EVEN in case of interlace mode. 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.
0	VPFRAMEDONE_IRQ	R/W1C	0h	Frame Done for VP. VP output has been disabled by user. All the data have been sent. 0h (R/W) = READS: Event is false. WRITES: Status bit unchanged. 1h (R/W) = READS: Event is true (pending). WRITES: Status bit is reset.

Table 11-675. DISPC_VP1_TIMING_H Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	HBP	R/W	0h	Horizontal Back Porch. Encoded value (from 1 to 4096) to specify the number of pixel clock periods to add to the beginning of a line transmission before the first set of pixels is output to the displaydisplay (program to value minus one). When in BT mode and interlaced, this field corresponds to the vertical field blanking No 2 for Even Field.
19-8	HFP	R/W	0h	Horizontal front porch. Encoded value (from 1 to 4096) to specify the number of pixel clock periods to add to the end of a line transmission before line clock is asserted display (program to value minus one). When in BT mode and interlaced, this field corresponds to the vertical field blanking No 1 for Even Field.
7-0	HSW	R/W	0h	Horizontal synchronization pulse width Encoded value (from 1 to 256) to specify the number of pixel clock periods to pulse the line clock at the end of each line display (program to value minus one). When in BT mode, this field corresponds to the LSB 8-bits of the 12-bit horizontal blanking(BT_HBLANK[11:0]= {VSW[3:0],HSW[7:0]}).

Table 11-676. Register Call Summary for DISPC_VP1_TIMING_H

Table 11-678. DISPC_VP1_TIMING_V Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	VBP	R/W	0h	Vertical back porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the beginning of a frame. When in BT mode and interlaced, this field corresponds to the vertical field blanking No 2 for Odd Field. When in BT and in progressive mode, this field corresponds to the Vertical frame blanking No 2 . before the first set of pixels is output to the display.
19-8	VFP	R/W	0h	Vertical front porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the end of each frame. When in BT mode and interlaced, this field corresponds to the vertical field blanking No 1 for Odd Field. When in BT and in progressive mode, this field corresponds to the Vertical frame blanking No 2 .
7-0	VSW	R/W	0h	Vertical synchronization pulse width Encoded value (from 1 to 256) to specify the number of line clock periods to pulse the frame clock (VSYNC) pin at the end of each frame after the end of frame wait (VFP) period elapses. Frame clock uses as VSYNC signal in active mode. When in BT mode, the lsb 4-bits of this field (VSW[3:0]) corresponds to the MSB 4-bits of the 12-bit horizontal blanking(BT_HBLANK= {VSW[3:0],HSW[7:0]}).

Table 11-689. RFBI_SYSSTATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved for module-specific status information. Read returns 0.
9	BUSYRFBIDATA	R	0h	Data are pending to be processed from internal FIFO. 0h (R) = No data pending 1h (R) = Some data are pending
8	BUSY	R	0h	OCP Slave port busy status bit 0h (R) = The access to the following register is not stall: RFBI_CMD, RFBI_STATUS, RFBI_PARAM, RFBI_READ. 1h (R) = The access to any of the following registers is stall: RFBI_CMD, RFBI_STATUS, RFBI_PARAM, RFBI_READ.
7-1	RESERVED	R	0h	Reserved for OCP socket status information. Read returns 0.
0	RESETDONE	R	1h	Internal reset monitoring. It can be used to determine when a HW reset is completed or when a SW reset is completed (software has set RFBI_SYSCONFIG.SOFTRESET to 1). 0h (R) = Internal module reset is on-going 1h (R) = Reset completed

Table 11-692. RFBI_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Write 0's for future compatibility. Reads returns 0.
8	SMART_DMA_REQ	R/W	0h	Smart DMA request 0h (R/W) = The dmareq is asserted and de-asserted depending on FIFO space even if MIdlereq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 1h (R/W) = The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and MIdlereq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the FIFO.
7	DISABLE_DMA_REQ	R/W	0h	Disable DMA request 0h (R/W) = The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register 1h (R/W) = The dmareq is disabled and the signal is not generated at all based on space in FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in FIFO to take requests
6-5	HIGHTHRESHOLD	R/W	0h	Defines the FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0h (R/W) = Size of the transfer of 4 words of 32-bit wide 1h (R/W) = Size of the transfer of 8 words of 32-bit wide 2h (R/W) = Size of the transfer of 16 words of 32-bit wide

Table 11-692. RFBI_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	ITE	R/W	0h	Internal Trigger 0h (R/W) = H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1h (R/W) = User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.
3-2	CONFIGSELECT	R/W	0h	Select the CS and configuration 0h (R/W) = No CS selected 1h (R/W) = CS0 selected and configuration #0 2h (R/W) = CS1 selected and configuration #1 3h (R/W) = CS0 and CS1 both selected (only the configuration for CS0 is used)
1	BYPASSMODE	R/W	1h	Bypass Mode 0h (R/W) = The bypass mode not selected 1h (R/W) = The bypass mode is selected
0	ENABLE	R/W	0h	Enable/Disable flag 0h (R/W) = Disable the RFBI module 1h (R/W) = Enable the RFBI module

11.4 Enhanced Capture (eCAP) Module

This section describes the Enhanced Capture (eCAP) module for the device.

11.4.1 eCAP Overview

11.4.1.1 Purpose of the eCAP Peripheral

The enhanced Capture (eCAP) module can be used for:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors.

11.4.1.2 eCAP Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the eCAP module can be configured as a single channel PWM output.

11.4.2 eCAP Environment

11.4.2.1 eCAP I/O Interface

Table 11-757 shows the device integrated eCAP subsystems interface signals to external devices.

Table 11-757. eCAP Subsystems I/O Signals

eCAP Modules Level Signal Name	Device Level Signal Name	I/O Type[1]	Description	Module Pin Reset Value

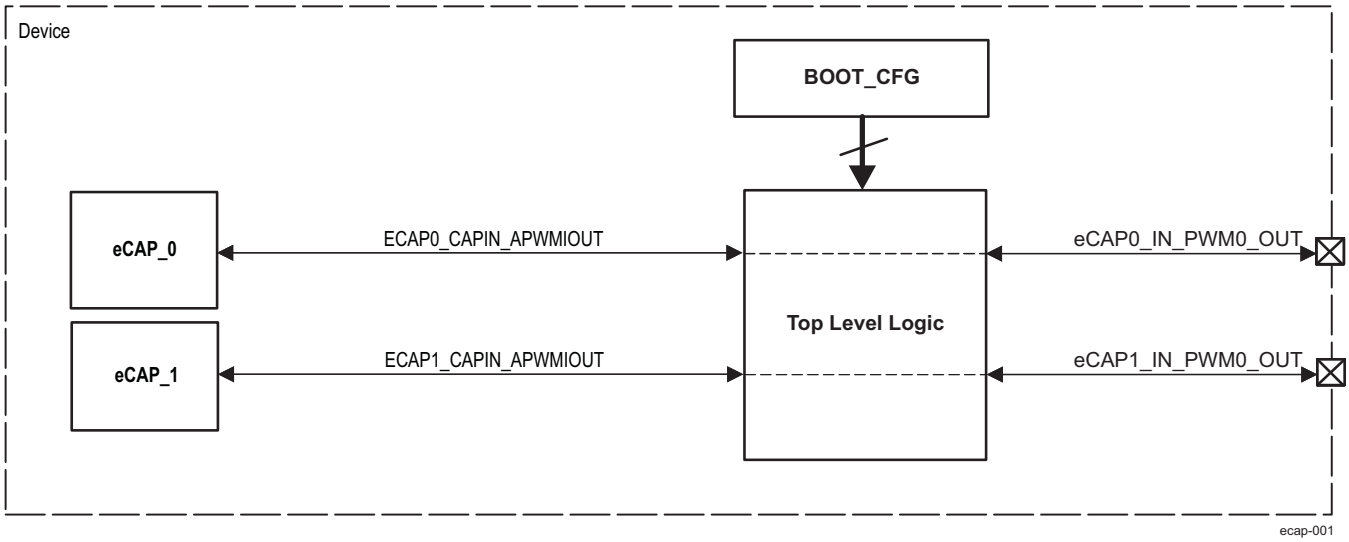
ECAP1_CAPIN_APWMOUT	eCAP1_IN_PWM1_OUT	I/O	eCAP_1 Capture input / PWM1 output	HiZ

(1) I = Input; O = Output

Figure 11-320. eCAP External Interface I/Os



11.4.3 eCAP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-437 shows the eCAP integration.

There are two instances of the Enhanced Capture (eCAP) module integrated in the device.

Figure 11-321. eCAP Integration

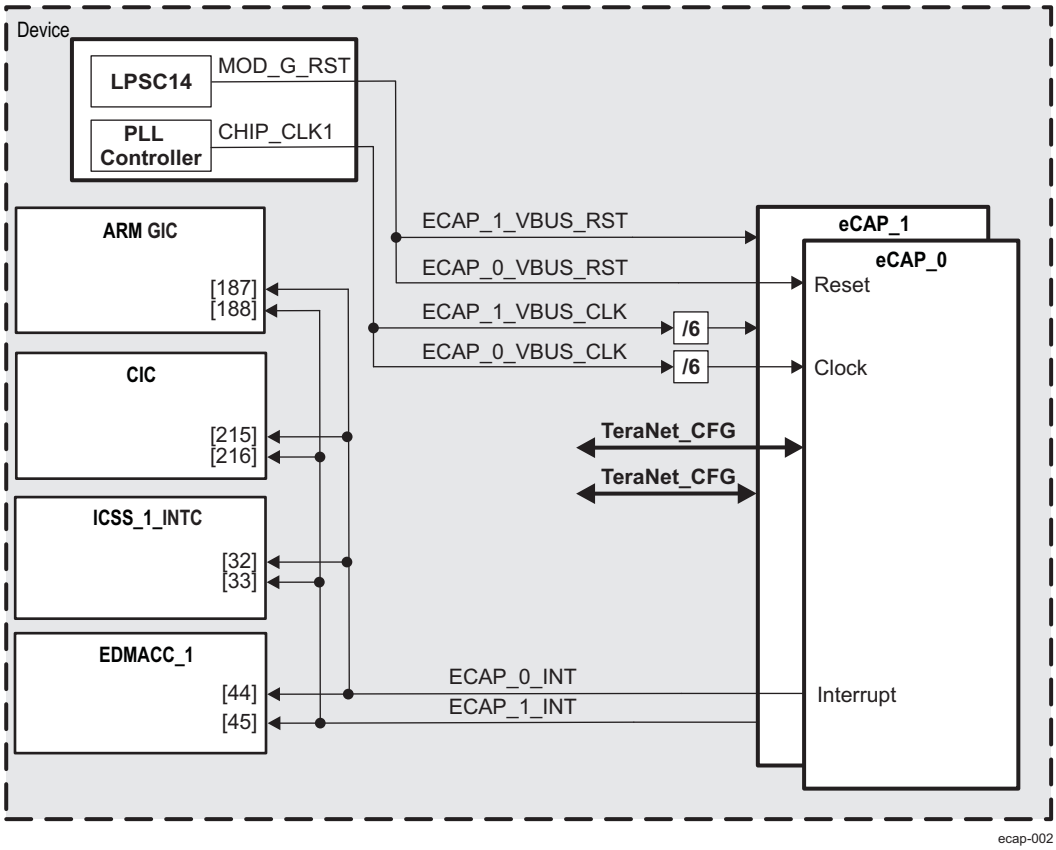


Table 11-924 through Table 11-926 summarize the integration of the module in the device.

Table 11-758. eCAP Integration Attributes

Module Instance	Attributes

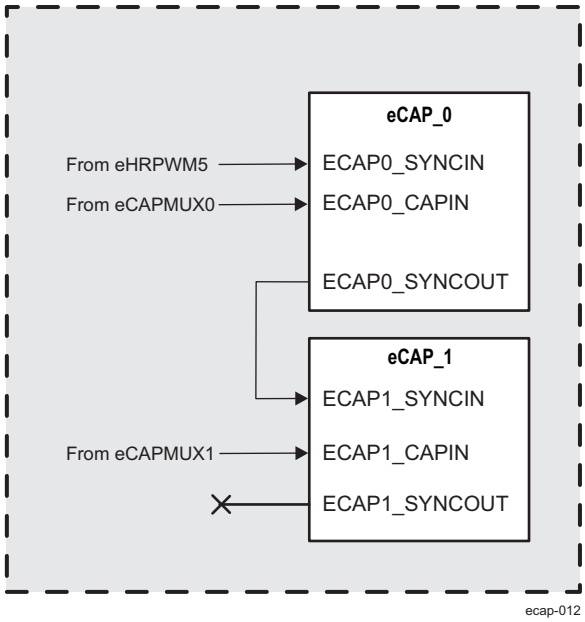
NOTE: For more information about interrupts, see Section 11.4.4.2.1.6, *eCAP Interrupt Control*.

11.4.3.1 Daisy-Chain Connectivity between eCAP Modules

The eCAP module is provided with input and output synchronisation signals allowing synchronisation with other modules or events. In the device, these signals are connected in a daisy-chain fashion as shown in Figure 11-322.

Figure 11-322. eCAP Daisy-Chain Connectivity



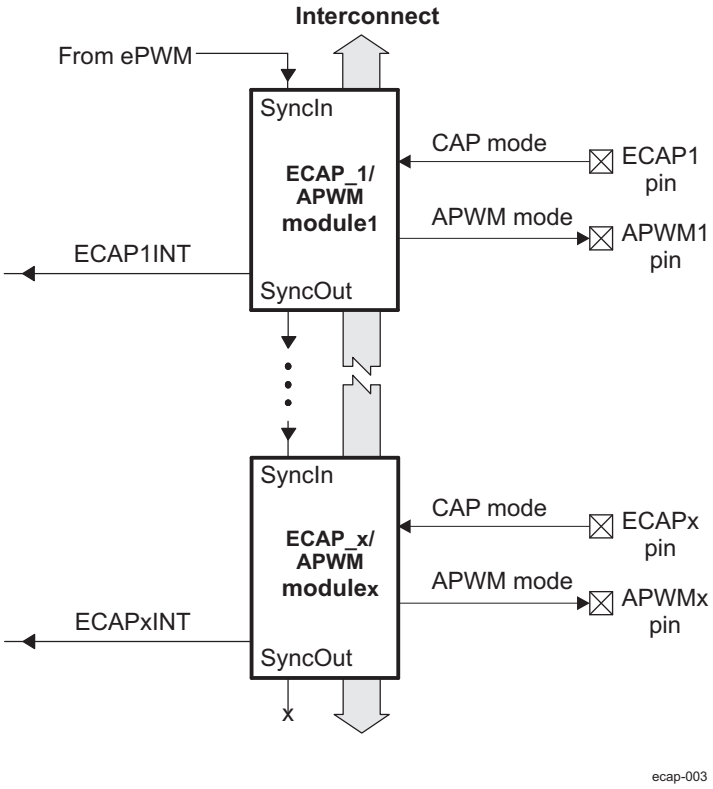
11.4.4 eCAP Functional Description

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32 events selection mapping capability to the input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4)
- 4-stage sequencer (Mod4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events.

Multiple identical eCAP modules can be contained in a system as shown in Figure 11-323. For actual number of eCAP modules integrated in the device, refer to the Section 11.6.3, *eCAP Integration*. The letter x within a signal or module name is used to indicate a generic eCAP instance on a device. For example, output interrupt request, ECAP1INT belongs to eCAP_1, ECAP2INT belongs to eCAP_2, and so forth.

Figure 11-323. Multiple eCAP Modules



11.4.4.1 eCAP Input Capture Events

The eCAP input capture events can be selected from 2 external eCAP input pins or 30 different internal events as selected through the eCAPMUX0 and eCAPMUX1 event muxes, using the ECAP_CAPEVT_CTL register in the BOOT_CFG module. Figure 11-324 shows the eCAP input events mapping.

Figure 11-324. eCAP Input Events

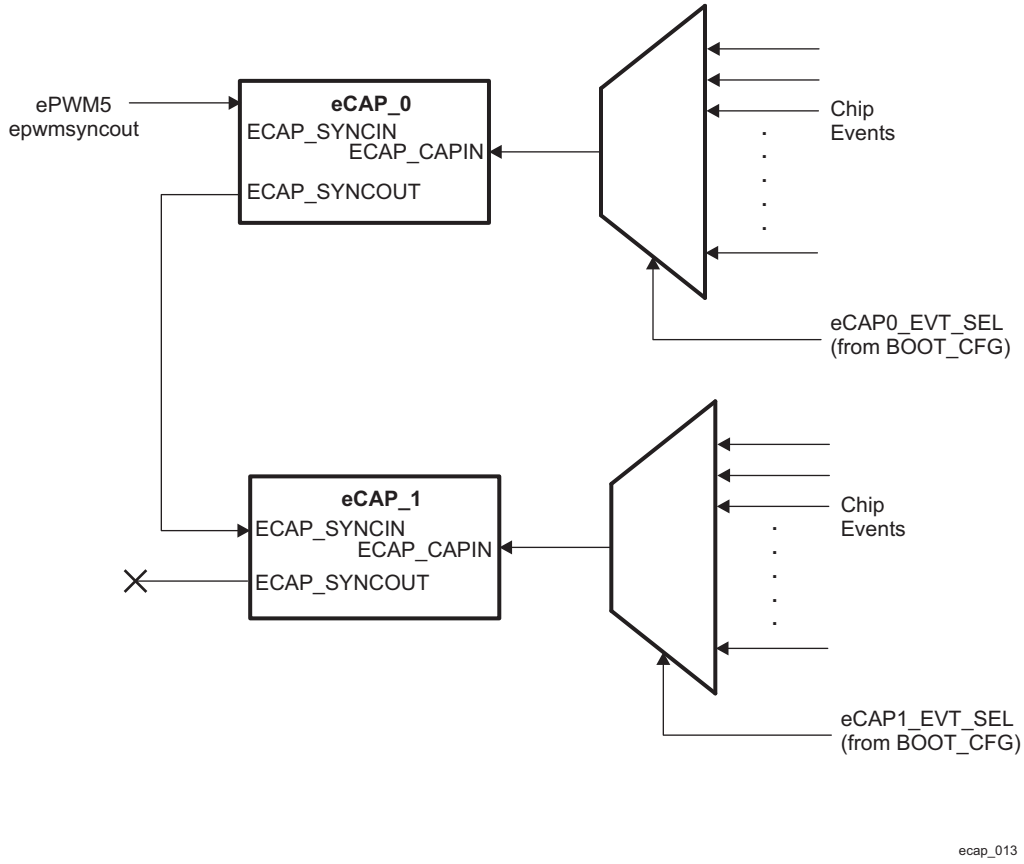


Figure 11-352 summarizes the input event mapping.

Table 11-761. eCAPMUX0 and eCAPMUX1 Input Event Mapping

Input event	Event Name	Description	Source
0	eCAP0_IN_PWM0_OUT	ECAP_0 input event from external pin	ePWM_0

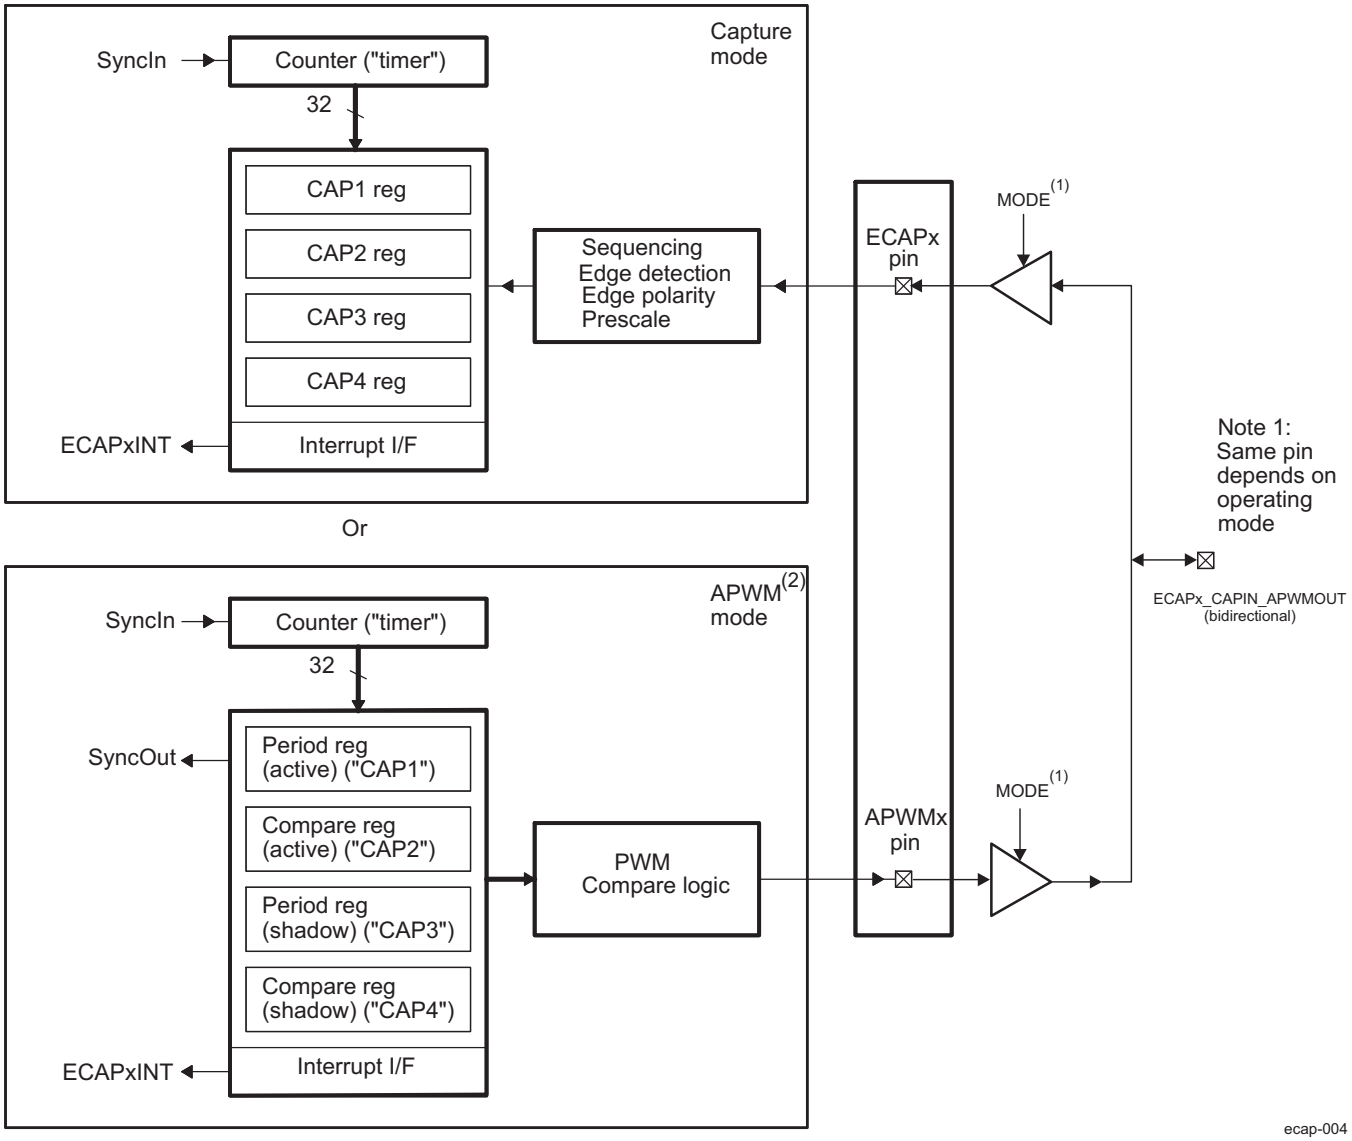
11.4.4.2 Capture and APWM Operating Modes

The eCAP module resources can be used to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers become the active period and compare registers, respectively, while PWMSS_ECAP_CAP3 and PWMSS_ECAP_CAP4 registers become the period and capture shadow registers, respectively. is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 11-325. Capture and APWM Modes of Operation



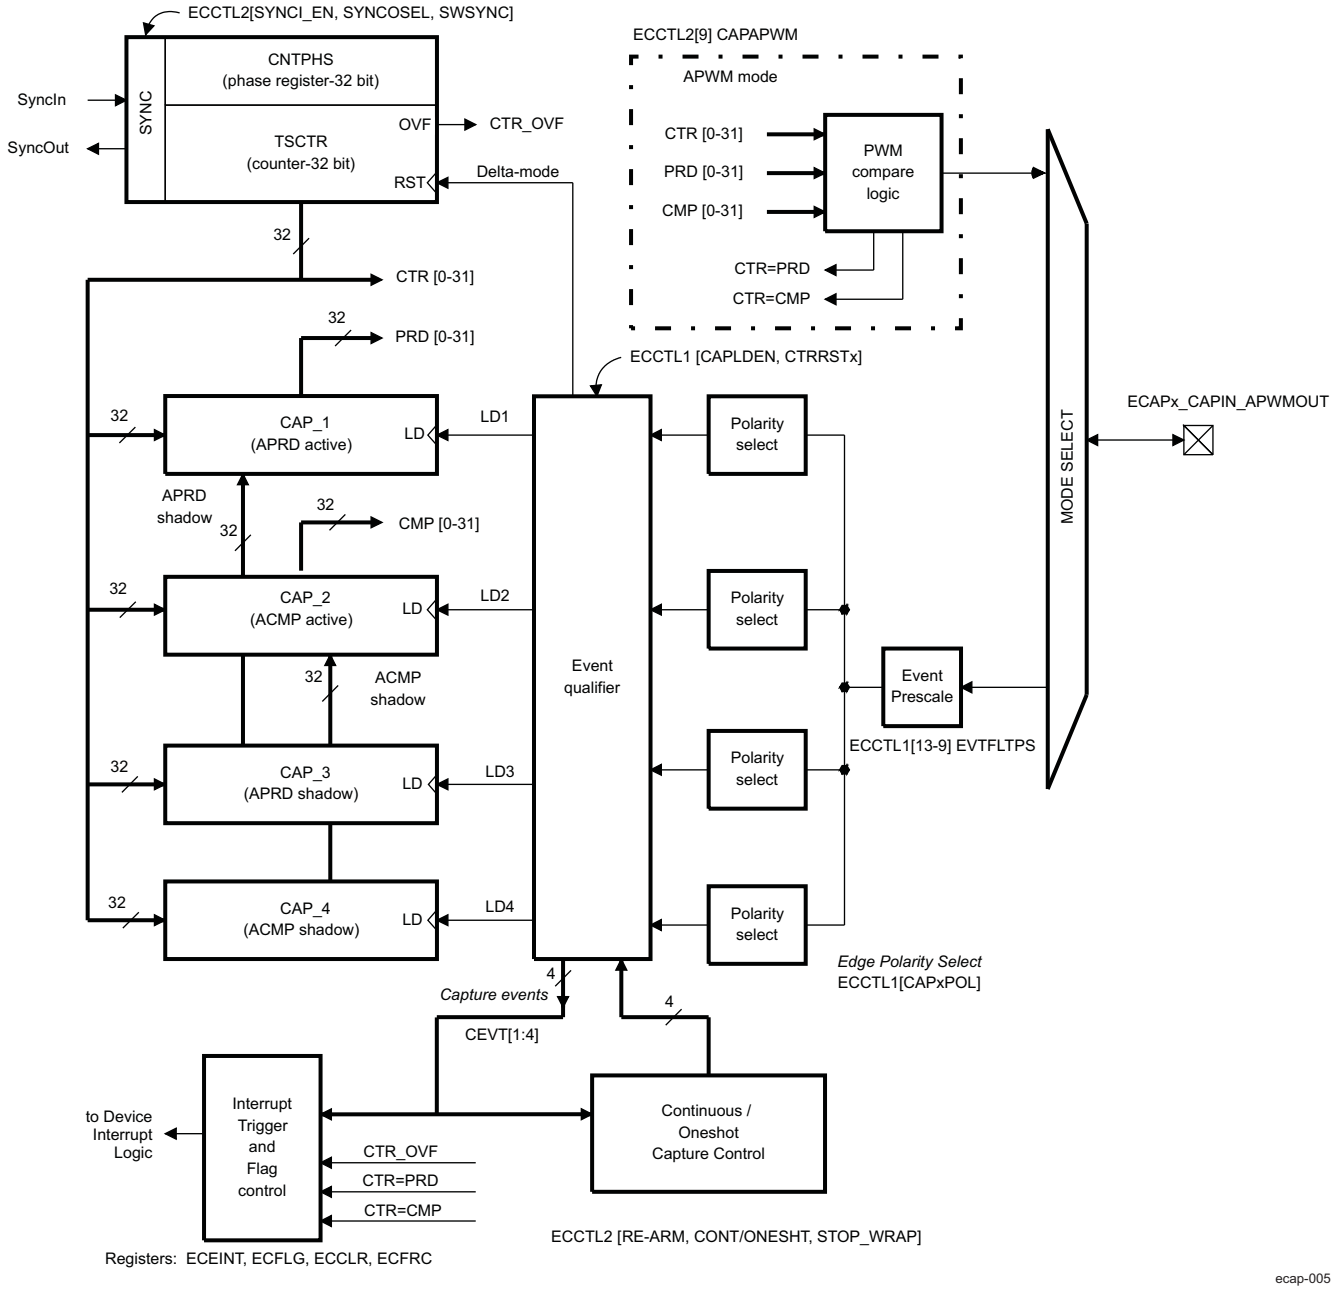
(1) A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.

(2) In APWM mode, writing any value to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 invokes the shadow mode.

11.4.4.2.1 eCAP Capture Mode Description

Figure 11-326 shows the various components that implement the capture function.

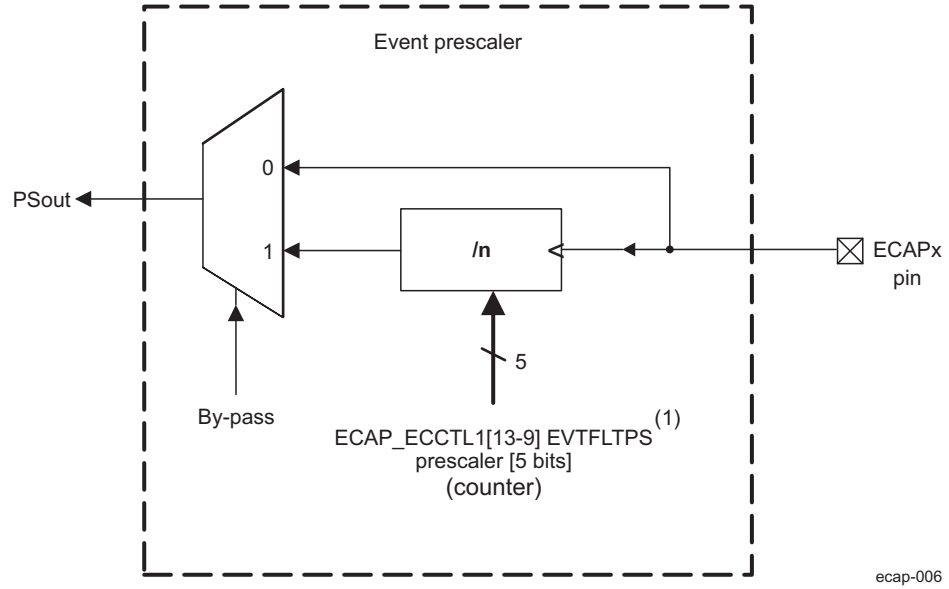
Figure 11-326. Capture Function Diagram



11.4.4.2.1.1 eCAP Event Prescaler

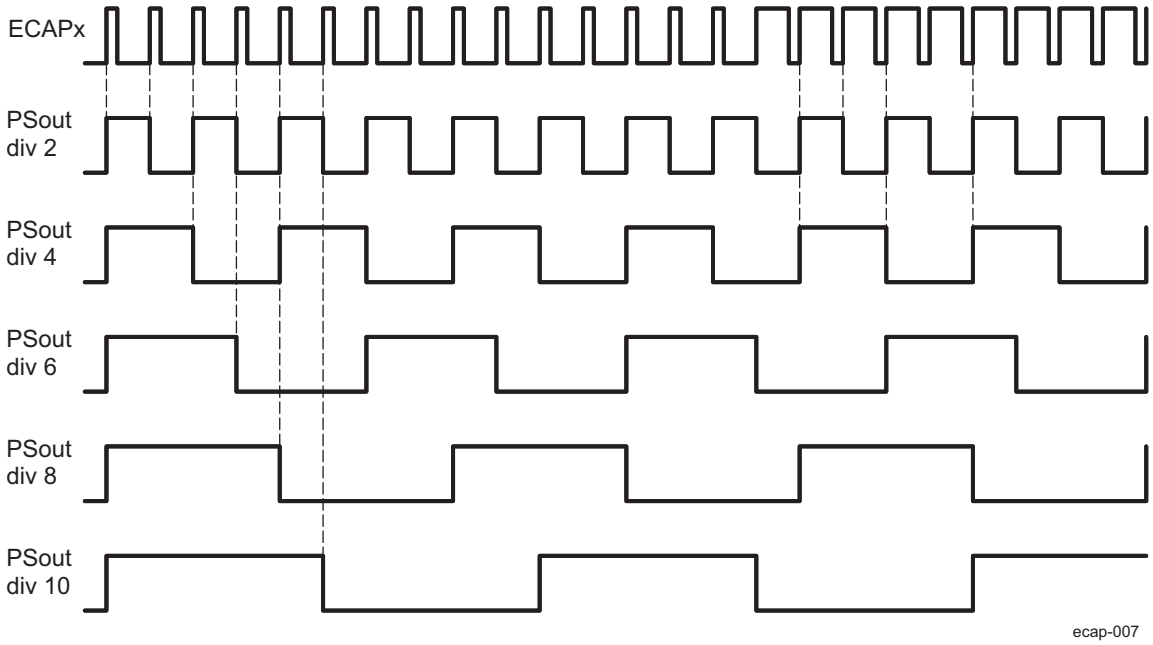
An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 11-327 shows a functional diagram and Figure 11-328 shows the operation of the prescale function.

Figure 11-327. Event Prescale Control



(1) When a prescale value of 1 is chosen (PWMSS_ECAP_ECCTL1[13-9] EVTFLTPS = 0b0000) the input capture signal by-passes the prescale logic completely.

Figure 11-328. Prescale Function Waveforms



11.4.4.2.1.2 eCAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Mod4 sequencer.
- The edge event is gated to its respective CAP*n* register by the Mod4 counter. The CAP*n* register is loaded on the falling edge.

11.4.4.2.1.3 eCAP Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events CEVT1 through CEVT4 (see register PWMSS_ECAP_ECEINT [4-1] field).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output; when equal the Mod4 counter stops and inhibits further loads of the PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4 registers. This occurs during one-shot operation.

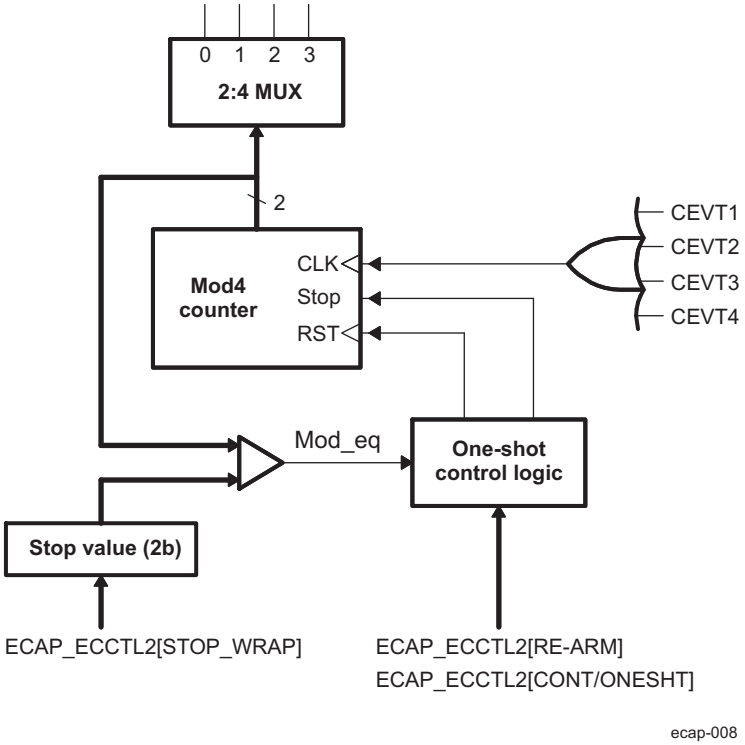
The continuous/one-shot block (Figure 11-329) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to PWMSS_ECAP_CAP1 through PWMSS_ECAP_CAP4 registers in a circular buffer sequence.

Figure 11-329. eCAP Continuous/One-shot Block Diagram



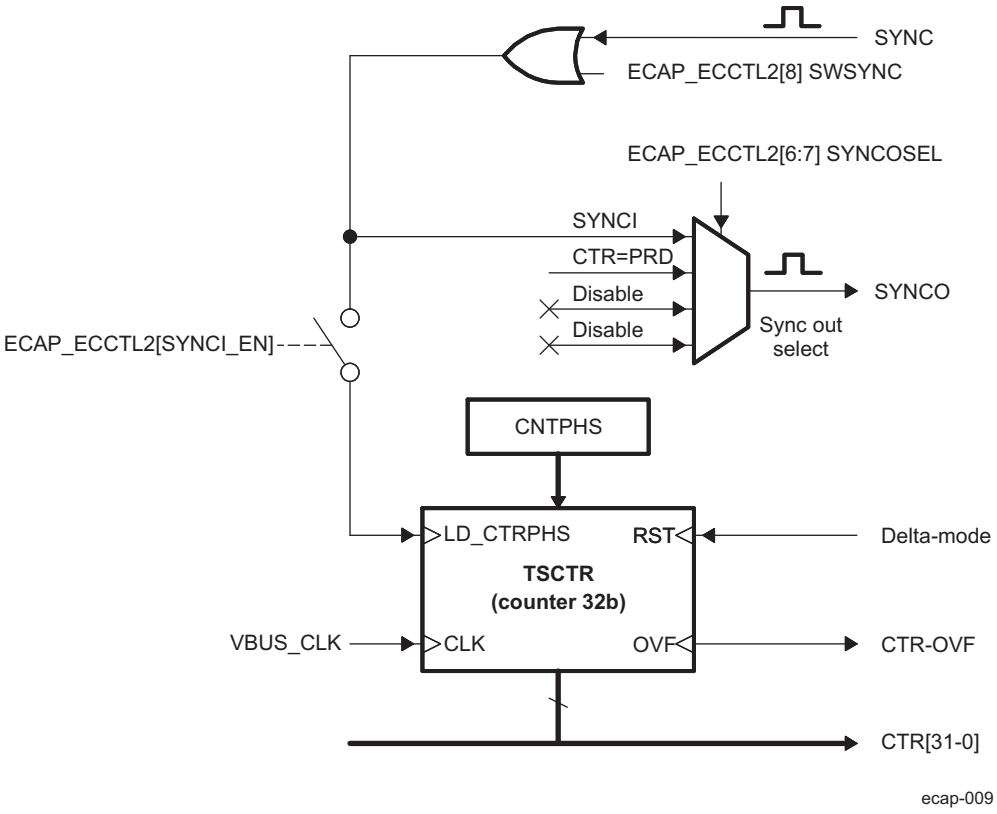
11.4.4.2.1.4 eCAP 32-Bit Counter and Phase Control

This counter (Figure 11-330) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1 through LD4 signals.

Figure 11-330. eCAP Counter and Synchronization Block Diagram



11.4.4.2.1.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit PWMSS_ECAP_ECCTL1[8] CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

PWMSS_ECAP_CAP3 and PWMSS_ECAP_CAP4 registers become the respective shadow registers (APRD and ACMP) for PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 during APWM operation.

11.4.4.2.1.6 eCAP Interrupt Control

An Interrupt can be generated on capture events CEVT1 through CEVT4, CNTOVF (see PWMSS_ECAP_ECEINT[5] CNTOVF bit) or APWM events (TSCNT = PRD, TSCNT = CMP). See Figure 11-331.

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP*n* module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (PWMSS_ECAP_ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (PWMSS_ECAP_ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit PWMSS_ECAP_ECFLG[0] INT. An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (PWMSS_ECAP_ECCLR) before any other interrupt pulses are generated. The interrupt force register (PWMSS_ECAP_ECFRC) can force an interrupt event. This is useful for test purposes.

11.4.4.2.1.7 eCAP Shadow Load and Lockout Control

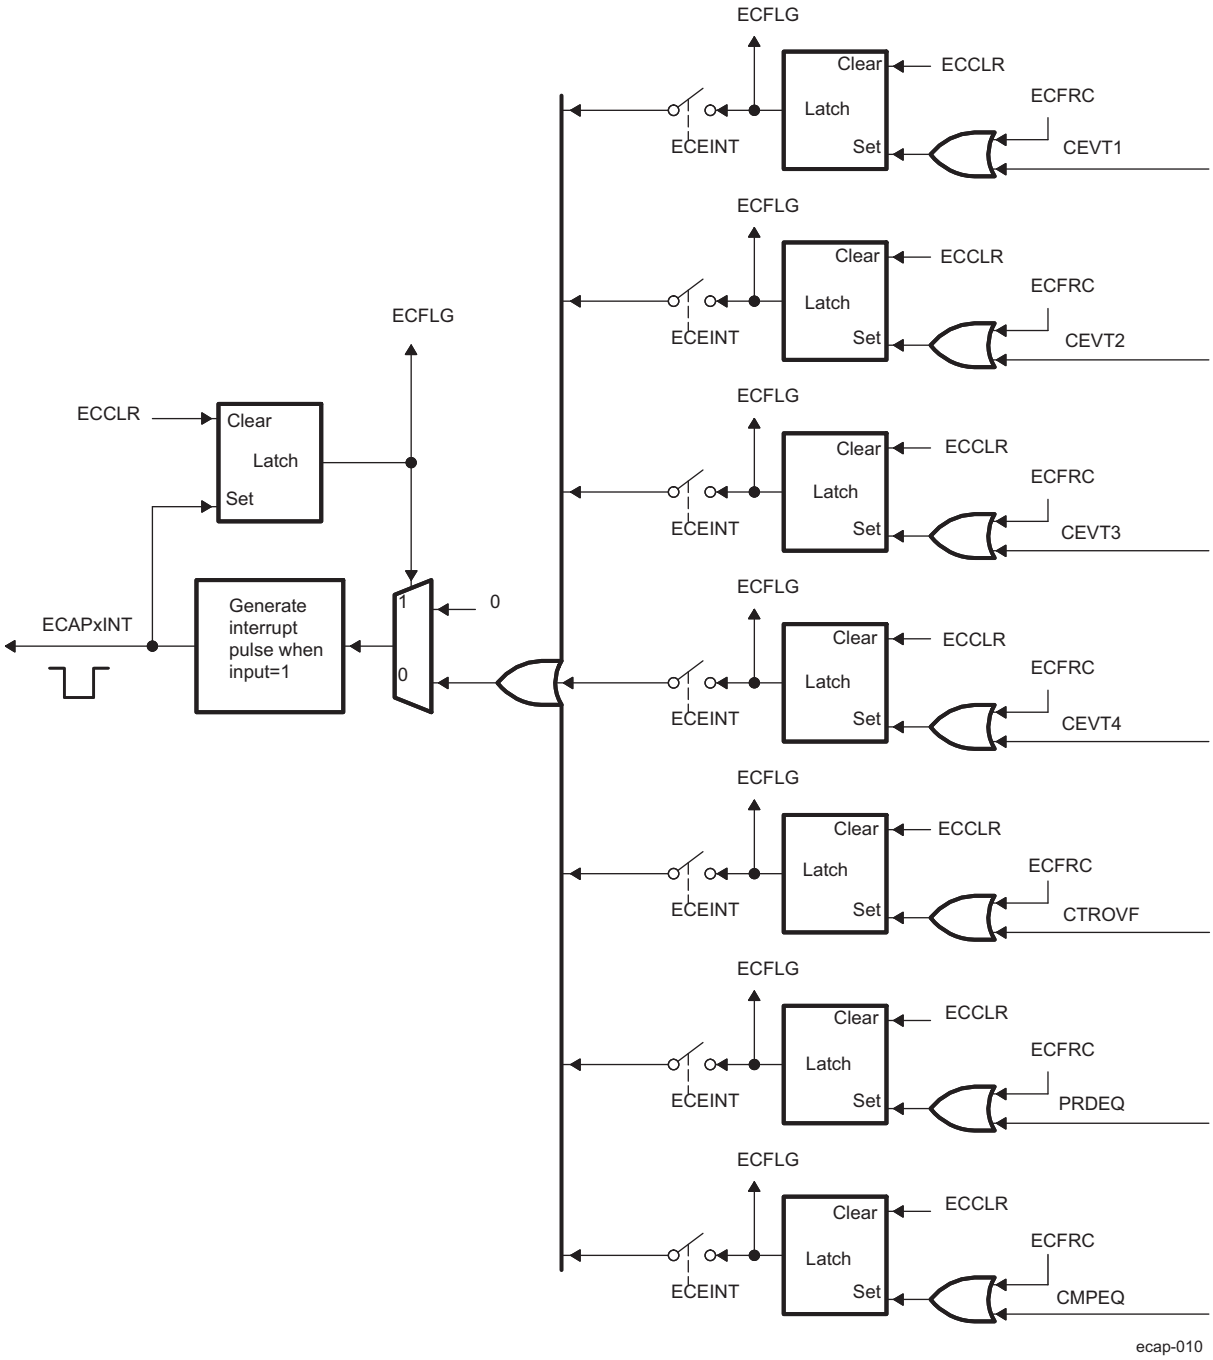
In capture mode, this logic inhibits (locks out) any shadow loading of PWMSS_ECAP_CAP1 or PWMSS_ECAP_CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to PWMSS_ECAP_CAP1 or PWMSS_ECAP_CAP2 immediately upon writing a new value.
- On period equal, CTR[31-0] = PRD[31-0]

NOTE: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (PWMSS_ECAP_ECCTL2[9] CAPAPWM == 0). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (PWMSS_ECAP_ECCTL2[9] CAPAPWM == 1). CNTOVF flag is valid in both modes.

Figure 11-331. Interrupts in eCAP Module

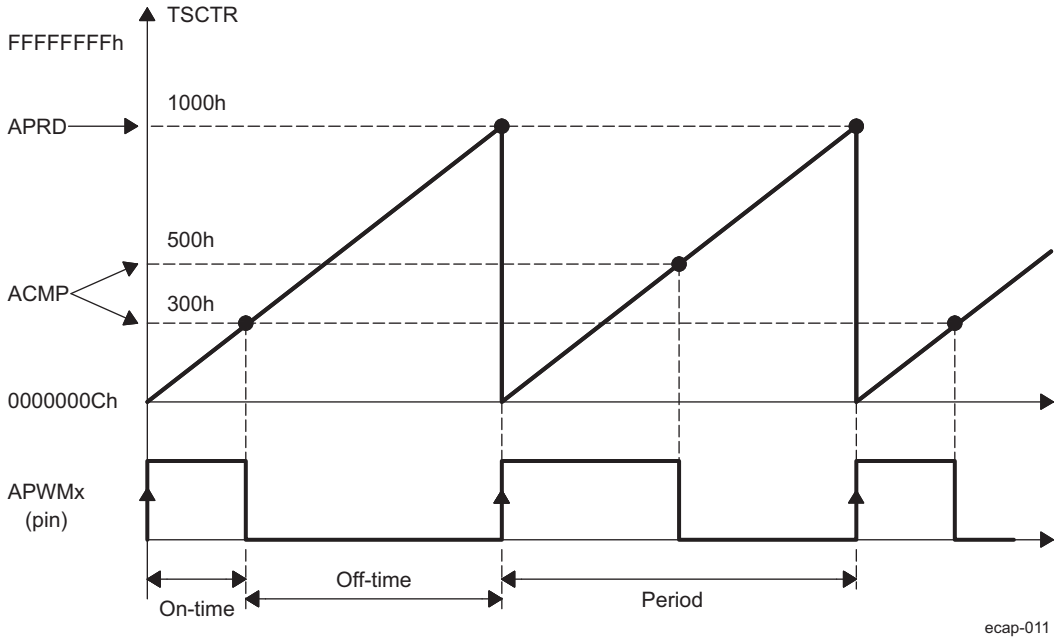


11.4.4.2.2 eCAP APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When PWMSS_ECAP_CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (PWMSS_ECAP_CAP3/4). The shadow register contents are transferred over to PWMSS_ECAP_CAP1/2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers will also write the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 will invoke the shadow mode.
- During initialization, SW must write the PRD and CMP values to the active registers. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, SW should use only shadow registers.

Figure 11-332. PWM Waveform Details Of eCAP APWM Mode Operation



The behavior of APWM active-high mode (APWMPOL == 0) is:

```
CMP = 0x00000000, output low for duration of period (0% duty)
CMP = 0x00000001, output high 1 cycle
CMP = 0x00000002, output high 2 cycles
CMP = PERIOD, output high except for 1 cycle (<100% duty)
CMP = PERIOD+1, output high for complete period (100% duty)
CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active-low mode (APWMPOL == 1) is:

```
CMP = 0x00000000, output high for duration of period (0% duty)
CMP = 0x00000001, output low 1 cycle
CMP = 0x00000002, output low 2 cycles
CMP = PERIOD, output low except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output low for complete period (100% duty)
CMP > PERIOD+1, output low for complete period
```

11.4.4.3 Summary of eCAP Functional Registers

Table 11-762 shows the eCAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

NOTE: In APWM mode, writing to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 invokes the shadow mode.

Table 11-762. eCAP Control and Status Functional Registers

RESERVED					APWMPOL	CAPAPWM	SWSYNC
R-0h					R/W-0h	R/W-0h	R/W-0h
7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCI_EN	TSCNTSTP	REARMRESET	STOPVALUE		CONTONESHT
R/W-0h		R/W-0h	R/W-0h	R/W-0h	R/W-3h		R/W-0h

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-780. PWMSS_ECAP_ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode 0h = Output is active high (Compare value defines high time) 1h = Output is active low (Compare value defines low time)
9	CAPAPWM	R/W	0h	CAP/APWM operating mode select **0h = ECAP module operates in capture mode. This mode forces the following configuration.** 1. Inhibits TSCNT resets via TSCNT = PRD event. 2. Inhibits shadow loads on PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers. 3. Permits user to enable PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4 register load. (d) ECAP input / APWM output pin operates as a capture input.
8	SWSYNC	R/W	0h	Software-forced Counter (TSCNT) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the TSCNT = PRD event. Note: Selection TSCNT = PRD is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful. 0h = Writing a zero has no effect. Reading always returns a zero 1h = Writing a one forces a TSCNT shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0b00. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select 0h = Select sync-in event to be the sync-out signal (pass through) 1h = Select TSCNT = PRD event to be the sync-out signal 2h = Disable sync out signal 3h = Disable sync out signal

Table 11-780. PWMSS_ECAP_ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SYNCI_EN	R/W	0h	Counter (TSCNT) Sync-In select mode 0h = Disable sync-in option 1h = Enable counter (TSCNT) to be loaded from PWMSS_ECAP_CNTPHS register upon either a SYNCI signal or a S/W force event.
4	TSCNTSTP	R/W	0h	Time Stamp (TSCNT) Counter Stop (freeze) Control 0h = TSCNT stopped 1h = TSCNT free-running
3	REARMRESET	R/W	0h	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0h = Has no effect (reading always returns a 0) 1h = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.
2-1	STOPVALUE	R/W	3h	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOPVALUE is compared to Mod4 counter and, when equal, the following two actions occur. (1) Mod4 counter is stopped (frozen). (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0h = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 1h = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 2h = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 3h = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
0	CONTONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) 0h = Operate in continuous mode 1h = Operate in one-shot mode

11.4.5.9 PWMSS_ECAP_ECEINT Register (Offset = 2Ch) [reset = 0h]

PWMSS_ECAP_ECEINT is shown in Figure 11-341 and described in Table 11-782.

eCAP Interrupt Enable Register.

11.5 Enhanced PWM (ePWM) Module

This chapter describes the Enhanced PWM (ePWM) module for the device.

11.5.1 ePWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In the further description the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWM_x instance. Thus, EPWM1A and EPWM1B belong to ePWM_1, EPWM2A and EPWM2B belong to ePWM_2, and so forth.

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given ePWM module functionality can be extended with the so called **High-Resolution Pulse Width modulator**. Refer to the Section 11.6.3, to determine which ePWM instances include the HRPWM feature. The HRPWM functionalities are described in Section 11.5.4.9.

As also described in Section 11.5.3.2, the ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the ePWM integration allows this synchronization scheme to be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other ePWM modules
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Allows events to trigger both CPU interrupts and ADC start of conversions
- Programmable event prescaling minimizes CPU overhead on interrupts
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 11-346. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in Figure 11-346. See Section 11.5.3.2 for the actual synchronization scheme implemented in the device. Each ePWM module consists of eight submodules and is connected within a system via the signals shown in Figure 11-347.

Figure 11-346. Multiple ePWM Modules

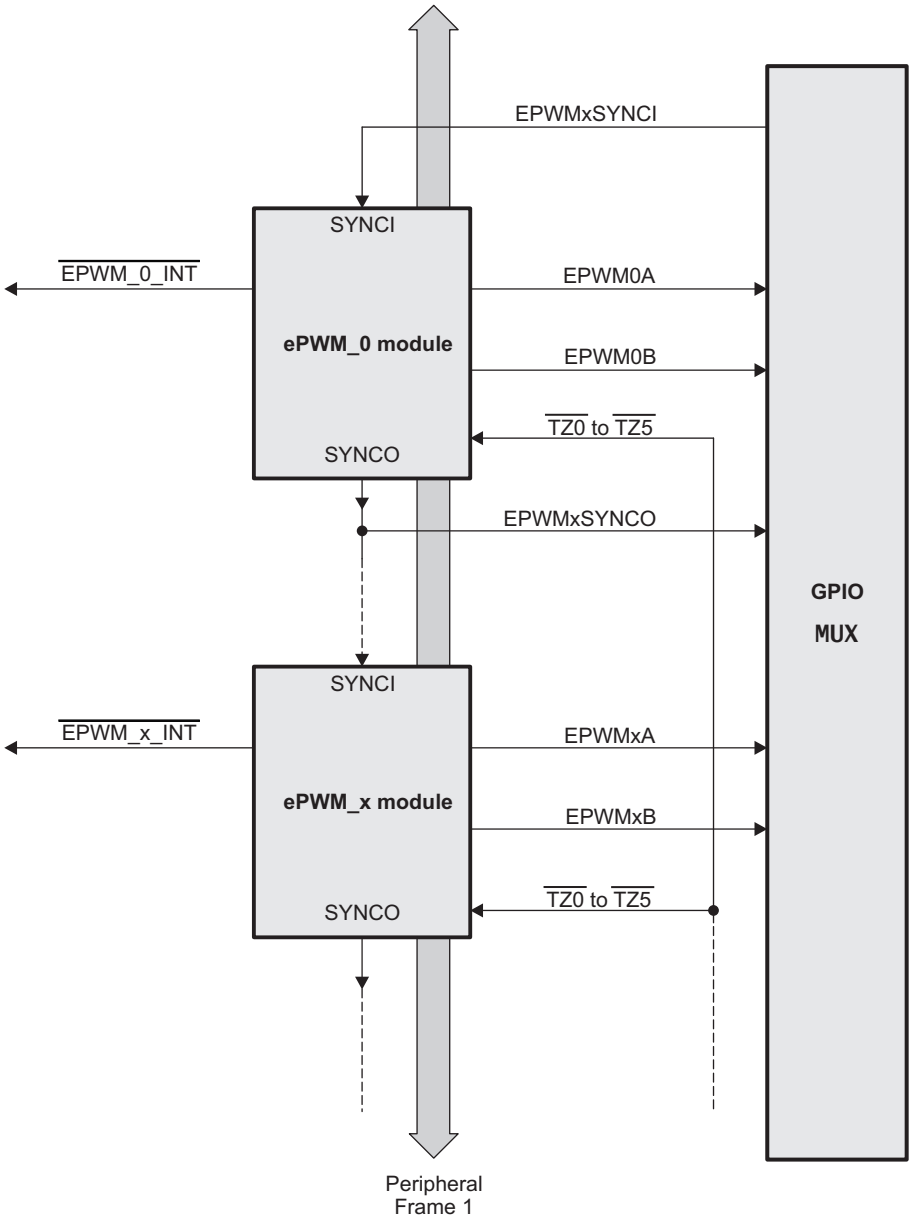

Figure 11-347. Submodules and Signal Connections for an ePWM Module

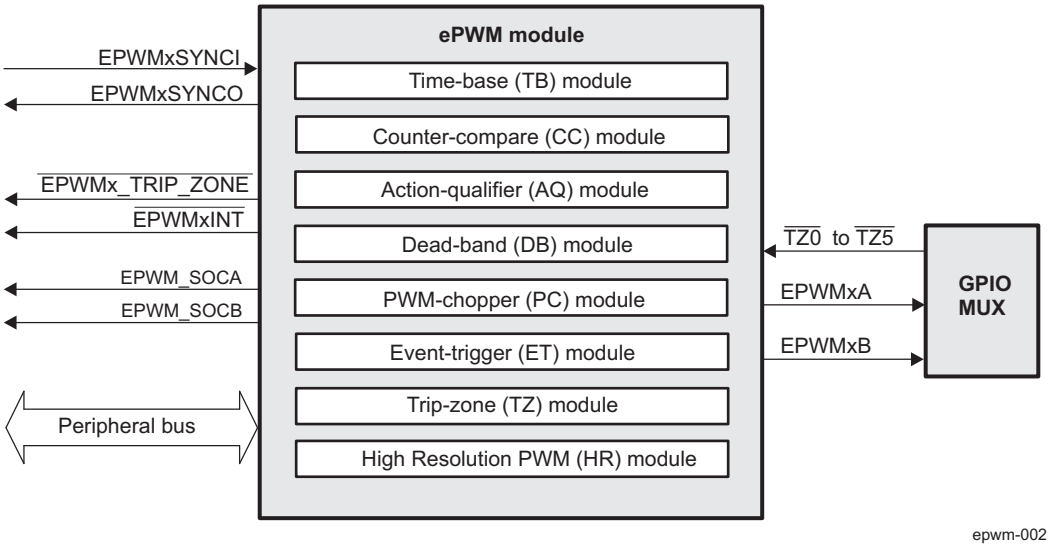

Figure 11-348 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for the device.
- **Trip-zone signals ($\overline{TZ0}$ to $\overline{TZ5}$).** These input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins for ePWM_0 (ePWM module 0) and ePWM_3. The ePWM_5 synchronization output (EPWM5SYNCO) is also connected to the input SyncIn of the first enhanced capture module (eCAP_0).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).** Each ePWM module has two ADC start of conversion signals (one for each sequencer). Any ePWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 11-348 also shows the key internal submodule interconnect signals. Each submodule is described in Section 11.5.4.

11.5.3 ePWM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-350 shows the ePWM integration.

There are 6 instances of the ePWM integrated in the device. Each of the Enhanced Pulse Width Modulator (ePWM) includes an Enhanced High Resolution Modulator (eHRPWM).

At system level the ePWM_0 through ePWM_5 integration features are listed below:

- A 32-bit slave configuration port on the TeraNet_CFG interconnect.
- A single functional clock from PLL_CONTROLLER shared between the 5 ePWM modules.
- 2 hardware events per ePWM, that is a total of 12 events. From these events each ePWM:
  - generates 2 interrupts to the device ARM_GIC, CIC and ICSS_1_INTC
  - generates 2 DMA requests, mapped to the device EDMACC_1
- A synchronization input/output daisy chain-like connection exists between the ePWM_0 trough ePWM_5. For more details, refer to Section 11.5.3.2, *Daisy-Chain Connectivity between ePWM Modules*.

Figure 11-350. ePWM Integration

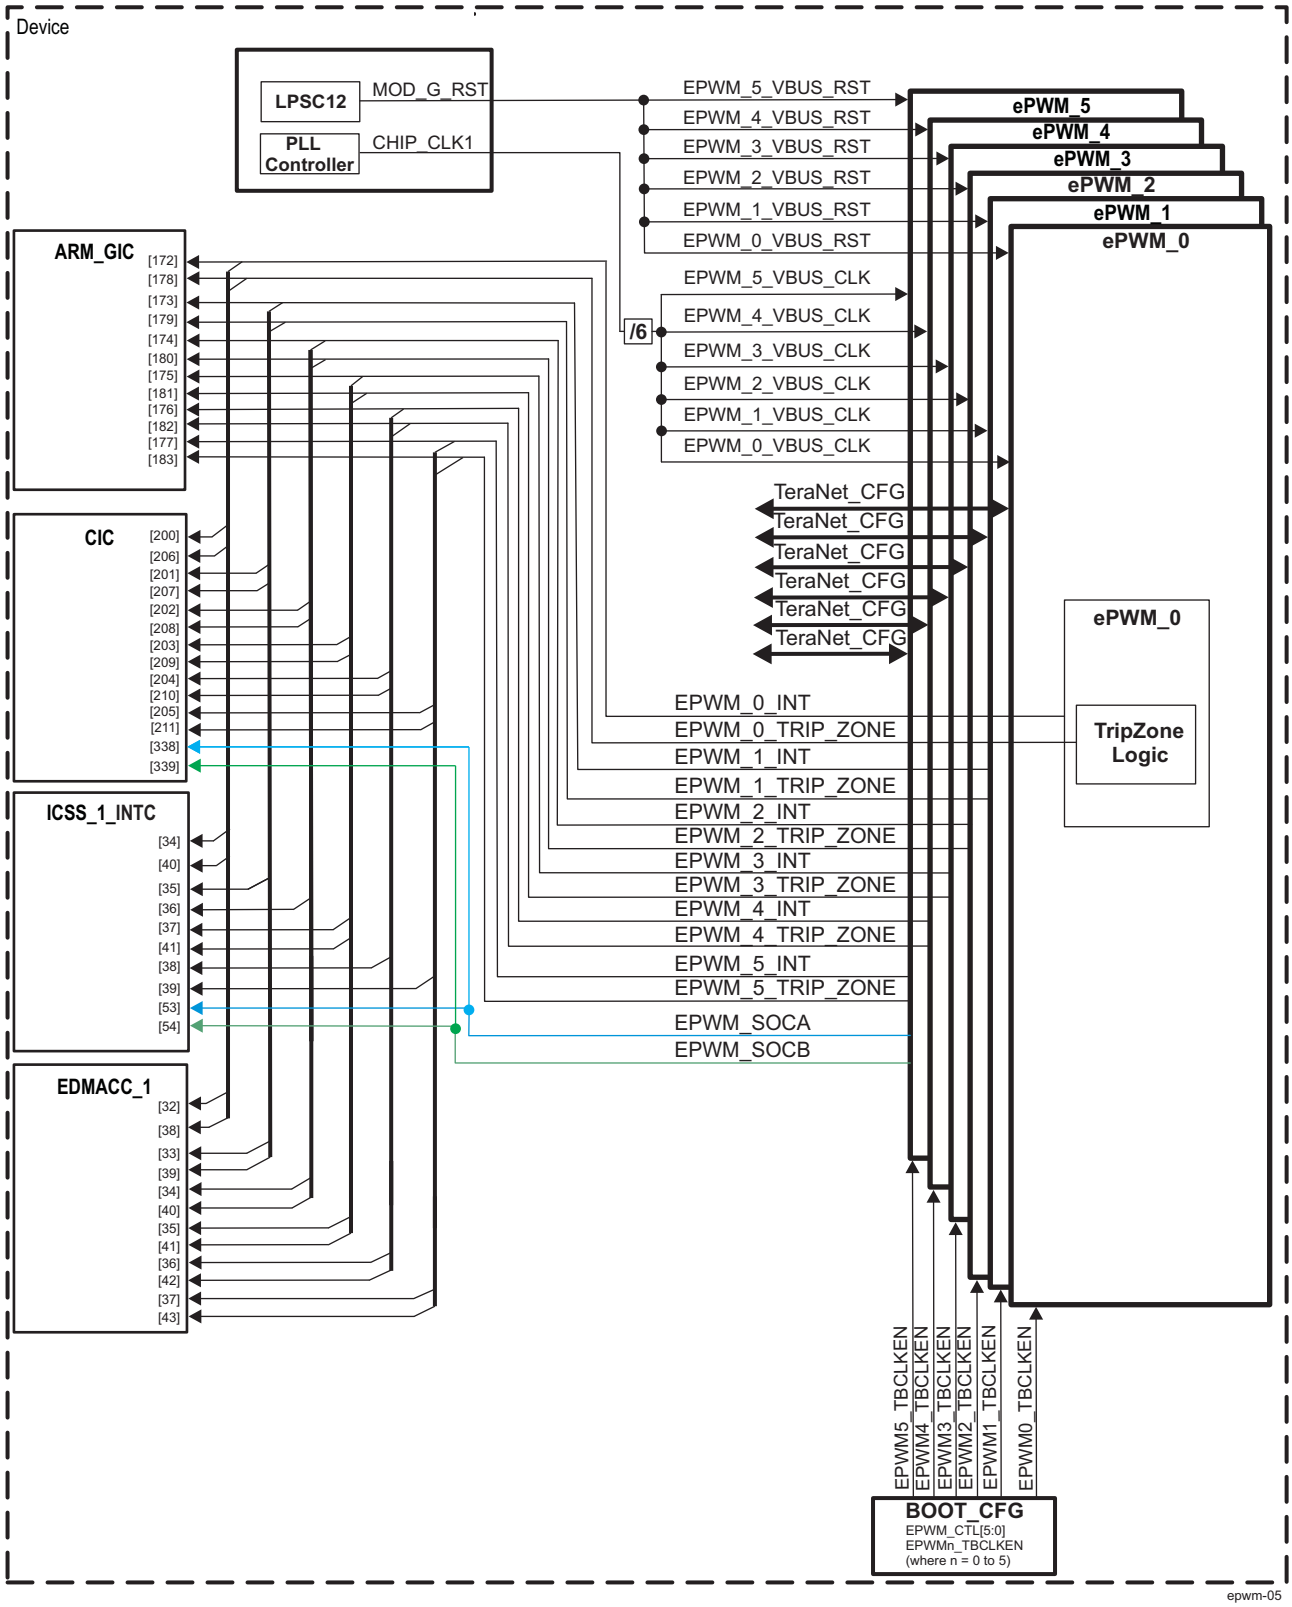

Table 11-924 through Table 11-3555 summarize the integration of the module in the device.

Table 11-792. ePWM Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
ePWM_0	PD5	LPSC12	TeraNet_CFG

ePWMx	EPWM_SOCA	–	[338]	[53]	Start of Conversion A event
ePWMx	EPWM_SOCB	–	[339]	[54]	Start of Conversion B event

DMA Requests

Module Instance	Event Name	Mapped To Input Event [Number]		Description
		EDMACC_0	EDMACC_1	
ePWM_0	EPWM_0_INT	–	[32]	ePWM_0 event to the EDMA_1
	EPWM_0_TRIP_ZONE	–	[38]	ePWM_0 Tripzone event to the EDMA_1
ePWM_1	EPWM_1_INT	–	[33]	ePWM_1 event to the EDMA_1
	EPWM_1_TRIP_ZONE	–	[39]	ePWM_1 Tripzone event to the EDMA_1
ePWM_2	EPWM_2_INT	–	[34]	ePWM_2 event to the EDMA_1
	EPWM_2_TRIP_ZONE	–	[40]	ePWM_2 Tripzone event to the EDMA_1
ePWM_3	EPWM_3_INT	–	[35]	ePWM_3 event to the EDMA_1
	EPWM_3_TRIP_ZONE	–	[41]	ePWM_3 Tripzone event to the EDMA_1
ePWM_4	EPWM_4_INT	–	[36]	ePWM_4 event to the EDMA_1
	EPWM_4_TRIP_ZONE	–	[42]	ePWM_4 Tripzone event to the EDMA_1
ePWM_5	EPWM_5_INT	–	[37]	ePWM_5 event to the EDMA_1
	EPWM_5_TRIP_ZONE	–	[43]	ePWM_5 Tripzone event to the EDMA_1

11.5.3.1 Device Specific ePWM Features

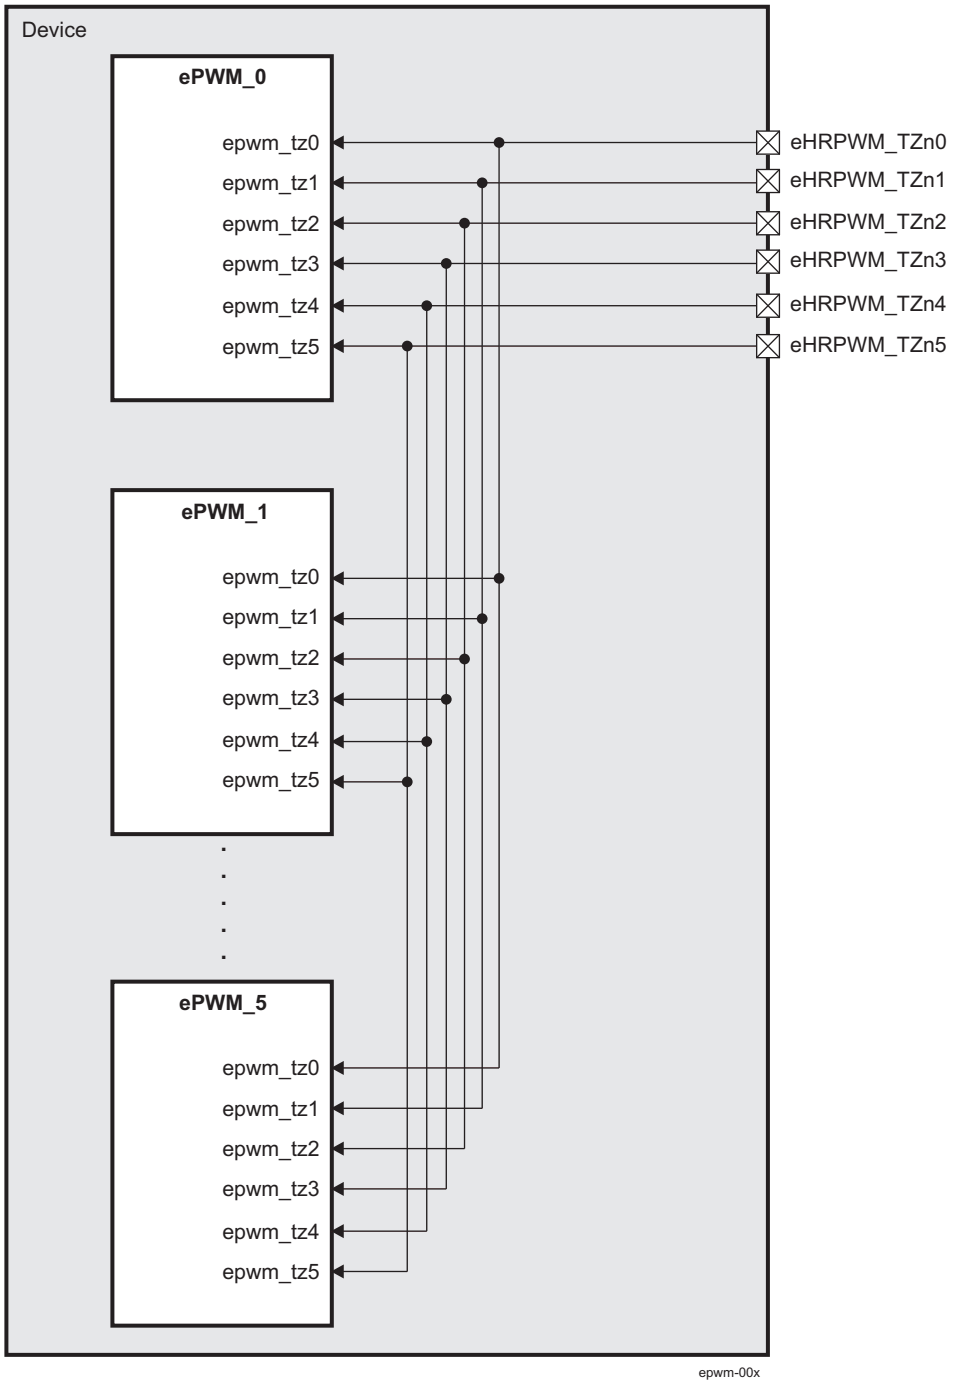
A High-Resolution PWM (HRPWM) modulator is added to each of the device ePWM modules.

NOTE: The HRPWM option applies only to the ePWMxA output channel. The ePWMxB channel has conventional capabilities. For more details on HRPWM features of ePWM modules refer to the Section 11.5.4.9.

The ePWM module interface has some restrictions in functionality as listed below:

- **For ePWM comparators — only the outputs (ehrpwmxA and ehrpwmxB, where x = 0 to 5) are available at chip level**
- **Each ePWM supports 6 tripzone event inputs and each of those inputs from all six of the ePWMs are tied to a common tripzone_input pin so that any ePWM can be triggered by any of the six tripzone inputs as shown in Figure 11-351.**

Figure 11-351. ePWM Tripzone Connectivity Detail



The ePWM functional interface signals which are NOT available to user are summarized in Table 11-927.

Table 11-795. Device Limitations for the ePWM Functional Interfaces

Module Interface	Signal	Description	Comment
ePWM_n (where n = 0 to 5 for the device)	EPWM_COMP_EPWMDCMAH	ePWM Comparator A input (HIGH)	Not available at chip boundary (can not be used)
	EPWM_COMP_EPWMDCMAL	ePWM Comparator A input (LOW)	
	EPWM_COMP_EPWMDCMBH	ePWM Comparator B input (HIGH)	
	EPWM_COMP_EPWMDCMBL	ePWM Comparator B input (LOW)	
	EPWM_TRIP_TZ_O[5:0]	ePWM Tripzone outputs	
	EPWM_TRIP_TZ_OEN[5:0]	ePWM Tripzone outputs enable	

NOTE: Only the SYNCI input and SYNCO output signals of ePWM_0 and ePWM_3 modules are available at chip-level. Respective names of the signals are: eHRPWM0_SYNCI and eHRPWM0_SYNCO (for ePWM_0) and eHRPWM3_SYNCI and eHRPWM3_SYNCO (for ePWM_3). For more information, see Section 11.5.2, *ePWM Environment*.

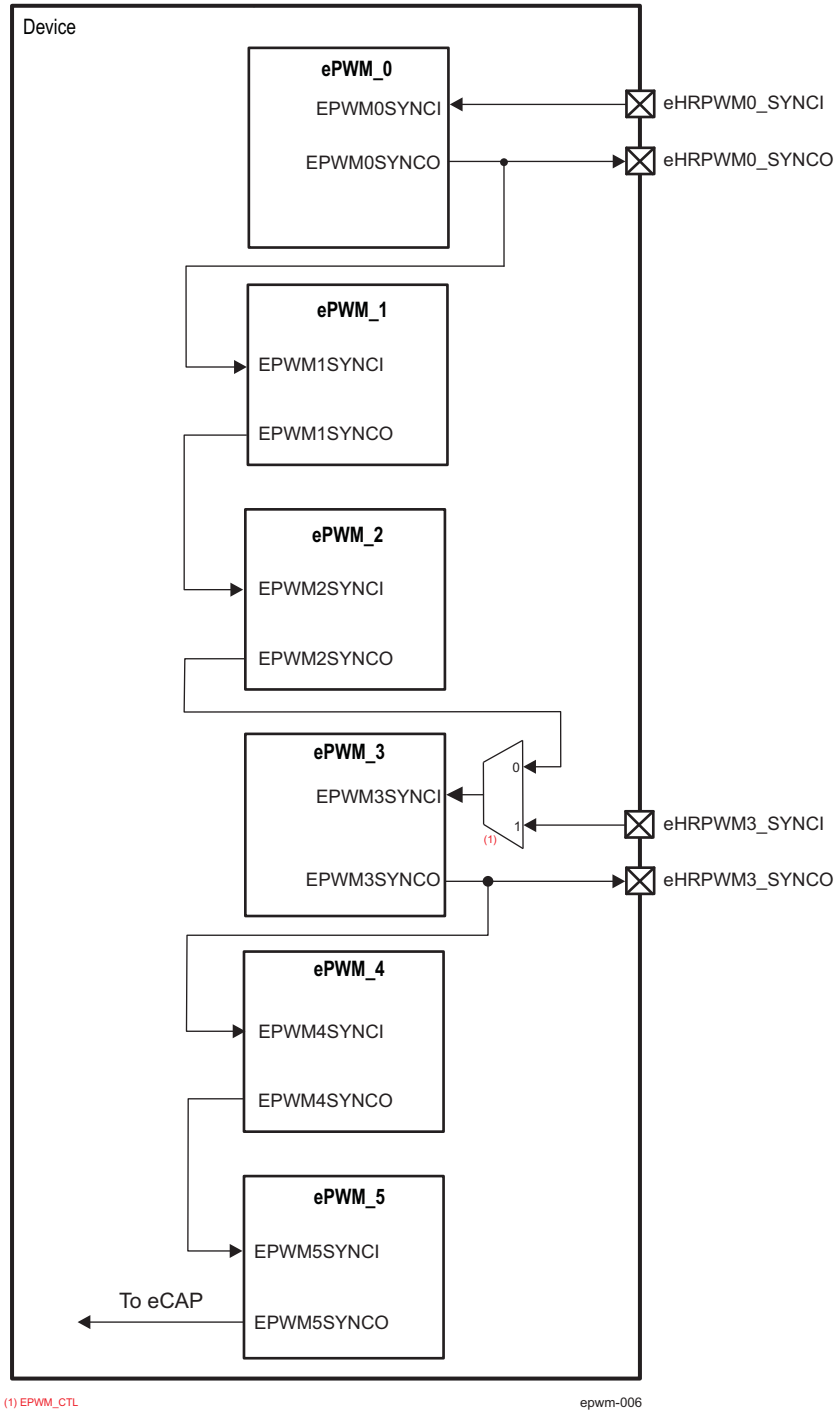
11.5.3.2 Daisy-Chain Connectivity between ePWM Modules

For synchronization to other modules or events ePWMs are provided with synchronization signals. In the device, these signals are connected in a daisy-chain fashion as shown in Figure 11-352. The ePWM_0 input synchronization signal is terminated at a device pad (eHRPWM0_SYNCI signal), such that device external sync events can be directly applied only to the ePWM_0 submodule. The ePWM_3 through ePWM_5 modules can be synchronized either to a separate external signal on the eHRPWM3_SYNCI pin (routed through the PRU-ICSS module) or to ePWM_2 output synchronization signal. The ePWM_3 input synchronization signal is selected using the corresponding EPWM3_SYNCSEL bit of the EPWM_CTL register in the BOOT_CFG module. A synchronization output is available from the ePWM_0 on the eHRPWM0_SYNCO output pin and from ePWM_3 on the eHRPWM3_SYNCO pin.

NOTE: The ePWM_0 EPWM0SYNCI signal (device eHRPWM0_SYNCI input signal) triggers the event of the ePWM_0 Phase Register being loaded into the Counter register (TBPHS -> TBCNT). This event is synchronous to the ePWM_0 **time-base clock** (TBCLK).

The ePWM_0 EPWM0SYNCO (device eHRPWM0_SYNCO output signal) is implicitly synchronous to the time-base clock, as this signal has a programmable source of event (in EPWM_TBCTL[5-4] SYNCOSEL) triggered synchronously to the ePWM_0 TBCLK.

Figure 11-352. Daisy-Chain Connectivity between ePWM Modules

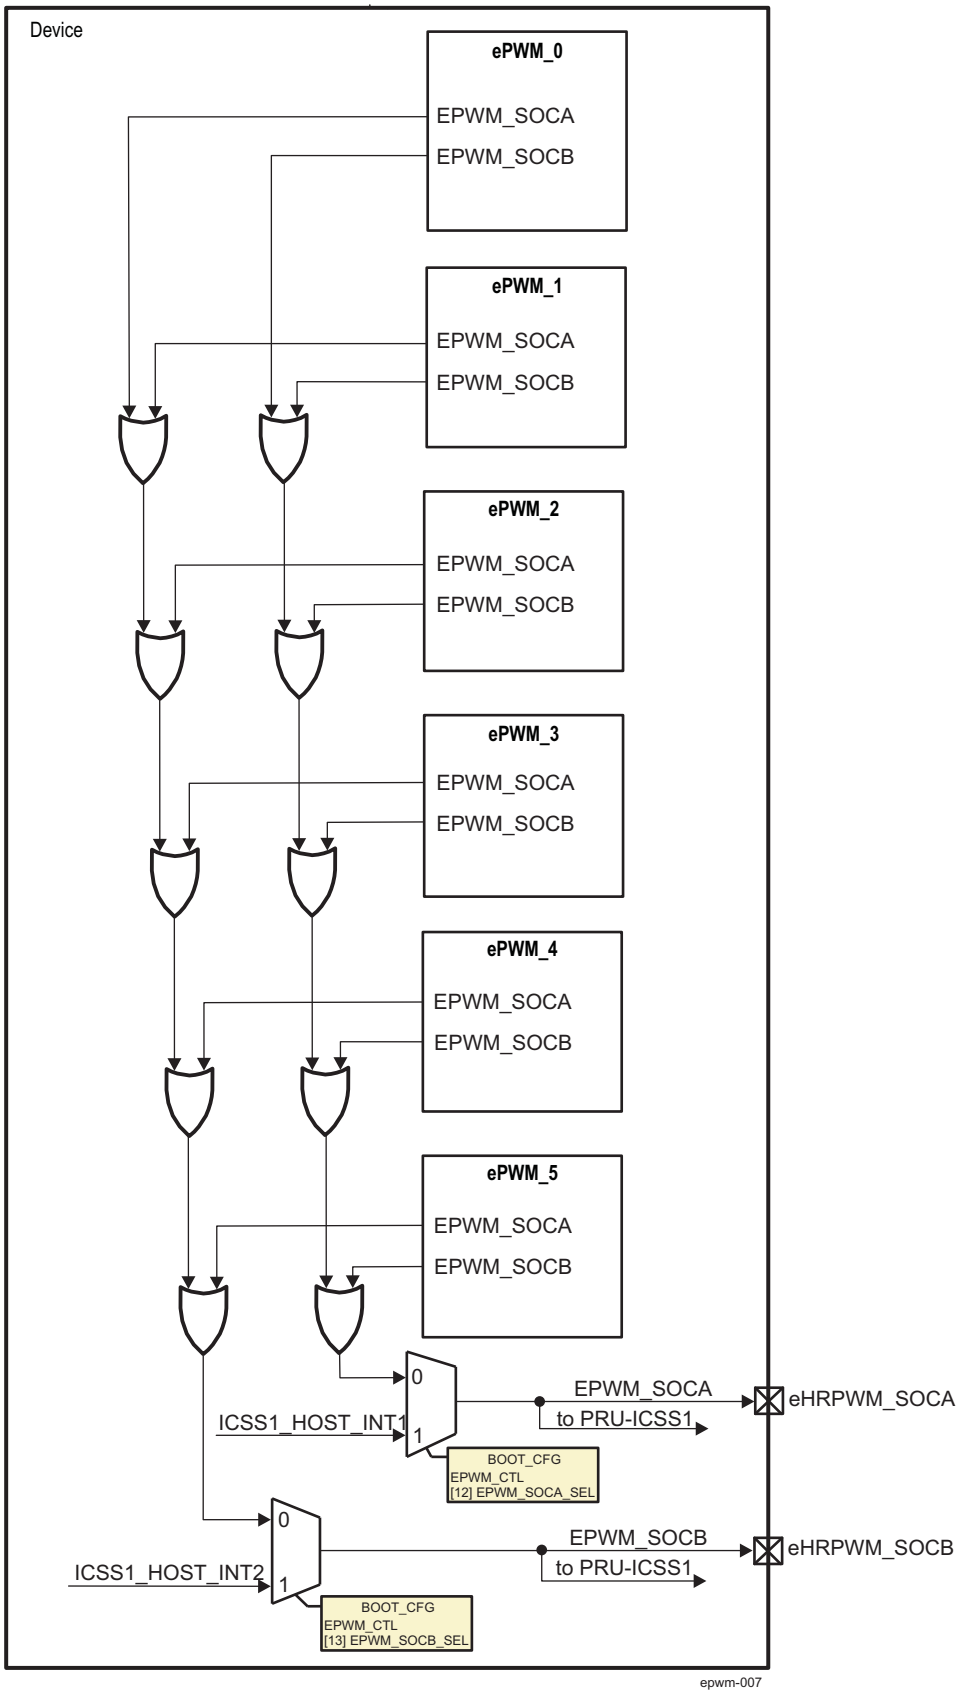


11.5.3.3 ADC start of conversion signals (EPWM_SOCA and EPWM_SOCB).

Each ePWM module provides start of conversion events (SOCA and SOCB), that can be used to start conversion of external ADC module. In this device all SOCA and all SOCB events are ORed together and hence any of the 6 ePWMs can initiate an ADC start of conversion. These events are then multiplexed with an PRU-ICSS1 host interrupts (ICSS1_HOST_INT1 or ICSS1_HOST_INT2), allowing either PRU-ICSS1 or ePWM_0 through ePWM_5 modules to trigger the SOCA/SOCB event pins (eHRPWM_SOCA and eHRPWM_SOCB). The EPWM_SOCA and EPWM_SOCB event output signals are also routed back to the PRU-ICSS1 module as interrupts as shown in Figure 11-353

NOTE: ICSS1_HOST_INT1 and ICSS1_HOST_INT2 interrupts are mapped to Host-3 and Host-4 of the PRU-ICSS Interrupt Controller.

Figure 11-353. Interconnectivity of ADC start of conversion



11.5.3.4 ePWM Modules Time Base Clock Gating

Each ePWM module has an EPWMTBCLKEN module input used to individually **enable / disable its ePWM time-base clock**. The ePWM time-base clock enable input comes from the EPWM_CTL register, as follows:

- ePWM_0 -> EPWM_CTL[0] EPWM0_TBCLKEN bit
- ePWM_1 -> EPWM_CTL[1] EPWM1_TBCLKEN bit
- ePWM_2 -> EPWM_CTL[2] EPWM2_TBCLKEN bit
- ePWM_3 -> EPWM_CTL[3] EPWM3_TBCLKEN bit
- ePWM_4 -> EPWM_CTL[4] EPWM4_TBCLKEN bit
- ePWM_5 -> EPWM_CTL[5] EPWM5_TBCLKEN bit.

This individual TBCLKEN control can be used to align the ePWM time base clock. EPWMn_TBCLKEN (where n = 0 to 5) bit set to 0b0, holds the TBCLK generation counter in its reset state. When EPWMn_TBCLKEN is set to 0b1, then the TBCLK generation counter is allowed to count.

11.5.4 ePWM Functional Description

8 submodules are included in each ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

11.5.4.1 ePWM Submodule Features

Table 11-796 lists the eight key submodules together with a list of their main configuration parameters.

Table 11-796. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (VBUS_CLK). • Configure the PWM time-base counter (TBCNT) frequency or period. • Time-base counter mode selection: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 11-796. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone pins. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to the trip-zone pin: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
High-Resolution PWM (HRPWM)	• Enable extended time resolution capabilities • Configure finer time granularity control or edge positioning

Some examples on various ePWM module configurations are shown below. These examples use the constant definitions shown in Example 11-1.

Example 11-1. Constant Definitions Used in the ePWM Code Examples

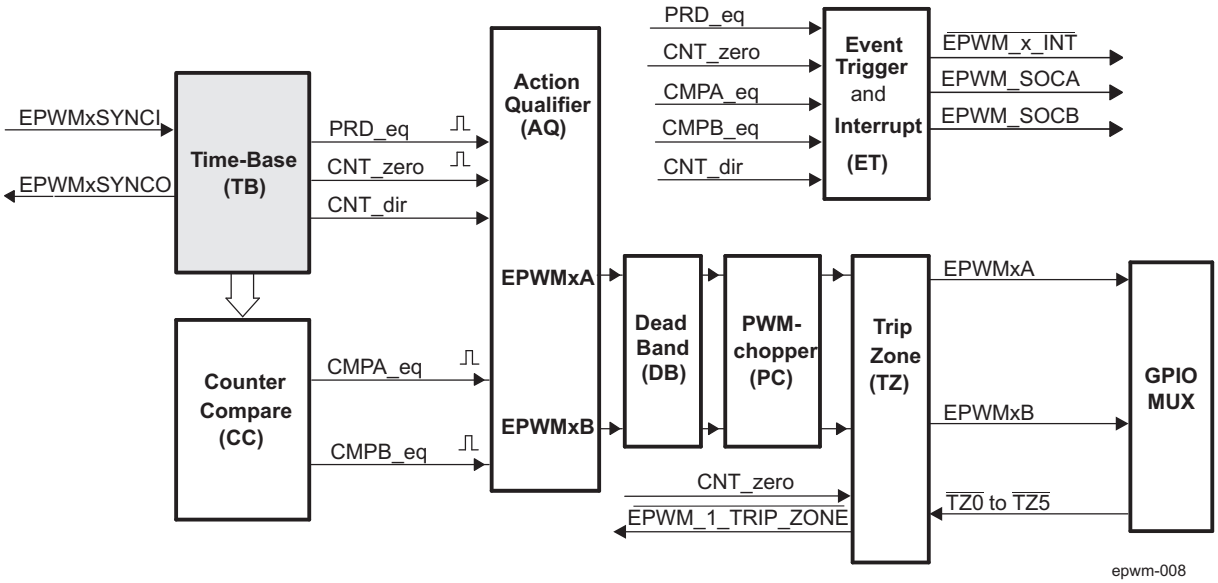
11.5.4.2 ePWM Time-Base (TB) Submodule

This section describes the Time-Base (TB) submodule in the PWM module.

11.5.4.2.1 Overview

Each ePWM module has its own time-base submodule that determines all of the timing events. Built-in synchronization logic allows the time-base of multiple ePWM modules (ePWMx) to work together as a single system. Figure 11-354 illustrates the time-base module's place within the ePWM.

Figure 11-354. ePWM Time-Base Submodule



TB module generates the period (or frequency) of the PWM output waveforms and consists of a 16-bit counter that can be configured for up, down or up and down counting. The time base for the counter is a pre-scaled version of the system clock (VBUS_CLK/n) which can be programmed for a pre-scale of 1, that is same as system clock.

TB module features:

- Specify the ePWMx time-base counter (TBCNT) frequency or period in the EPWM_TBCNT register to control how often events occur.
- Manage time-base synchronization with other ePWMx modules.
- Maintain a phase relationship with other ePWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - PRD_eq (Time-base counter (EPWM_TBCNT register) equal to the specified period in EPWM_TBPRD register (that is TBCNT = TBPRD)).
  - CNT_zero (Time-base counter equal to zero (TBCNT = 0000h)).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (VBUS_CLK). This allows the time-base counter to increment/decrement at a slower rate.

11.5.4.2.2 Controlling and Monitoring the ePWM Time-Base Submodule

Table 11-797 lists the registers used to control and monitor the time-base submodule.

Table 11-797. ePWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register (1)	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

(1) This register is available only on ePWM instances that include the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 11.6.3 to determine which ePWM instances include this feature.

Figure 11-355 shows the critical signals and registers of the time-base submodule. Table 11-798 provides descriptions of the key signals associated with the time-base submodule.

Figure 11-355. ePWM Time-Base Submodule Signals and Registers

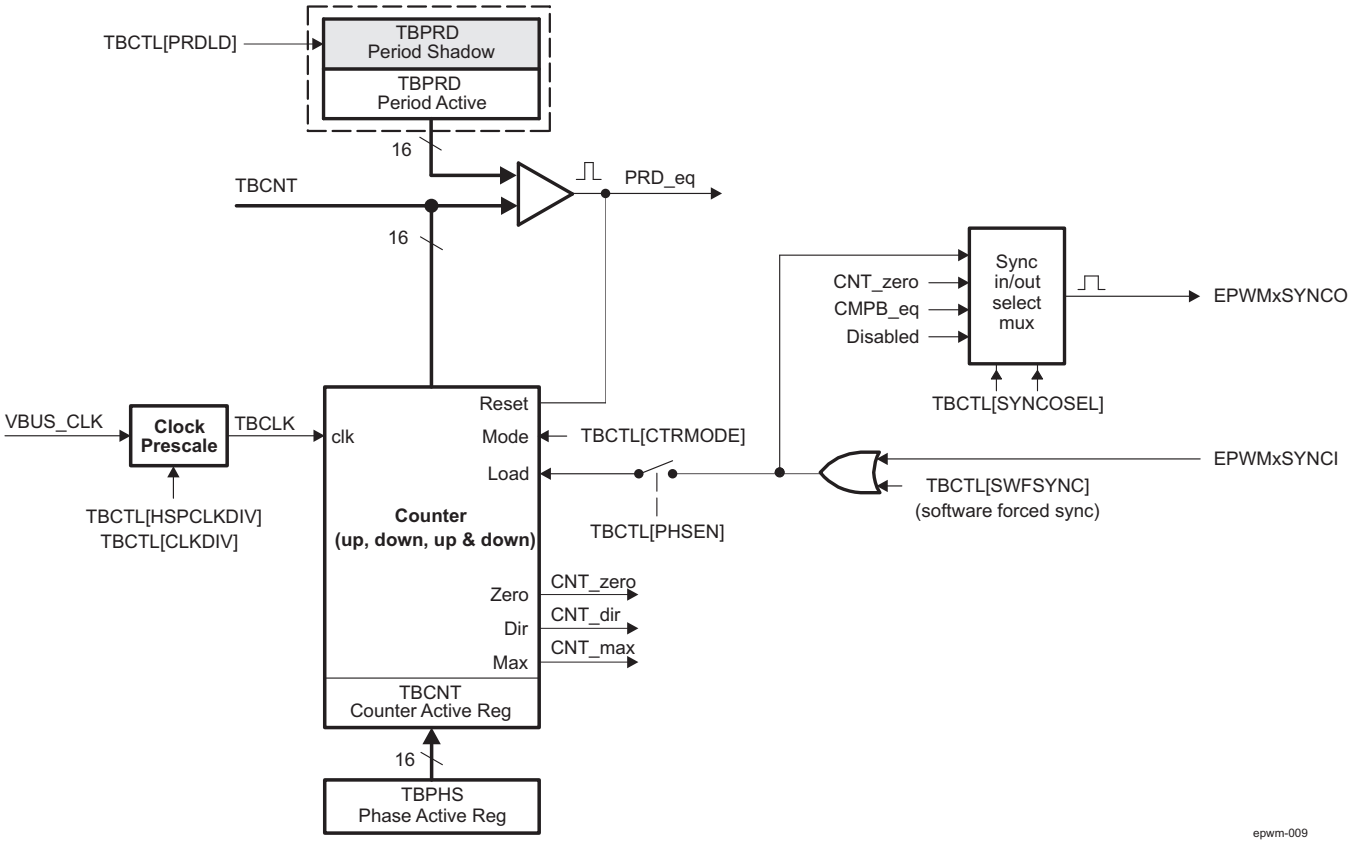


Table 11-798. ePWM Time-Base Submodule Key Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of another ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM_0) this signal comes from a device pin. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM_1 peripheral and the EPWM3SYNCI is generated (optional through internal multiplexer) by ePWM_2 or from a device pin. See Section 11.5.4.2.3.2 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. TBCNT = 0: The time-base counter (register EPWM_TBCNT) equal to zero (TBCNT = 0000h). 3. TBCNT = CMPB: The time-base counter (register EPWM_TBCNT) equal to the counter-compare B register — EPWM_CMPB (that is bitfield TBCNT = bitfield CMPB).
PRD_eq	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CNT_zero	Time-base counter equal to zero. This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CMPB_eq	Time-base counter equal to active counter-compare B register (TBCNT = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic.
CNT_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CNT_max	Time-base counter equal max value. (TBCNT = FFFFh) Generated event when the EPWM_TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock. This is a prescaled version of the system clock — VBUS_CLK and is used by all submodules within the ePWMn. This clock determines the rate at which time-base counter increments or decrements.

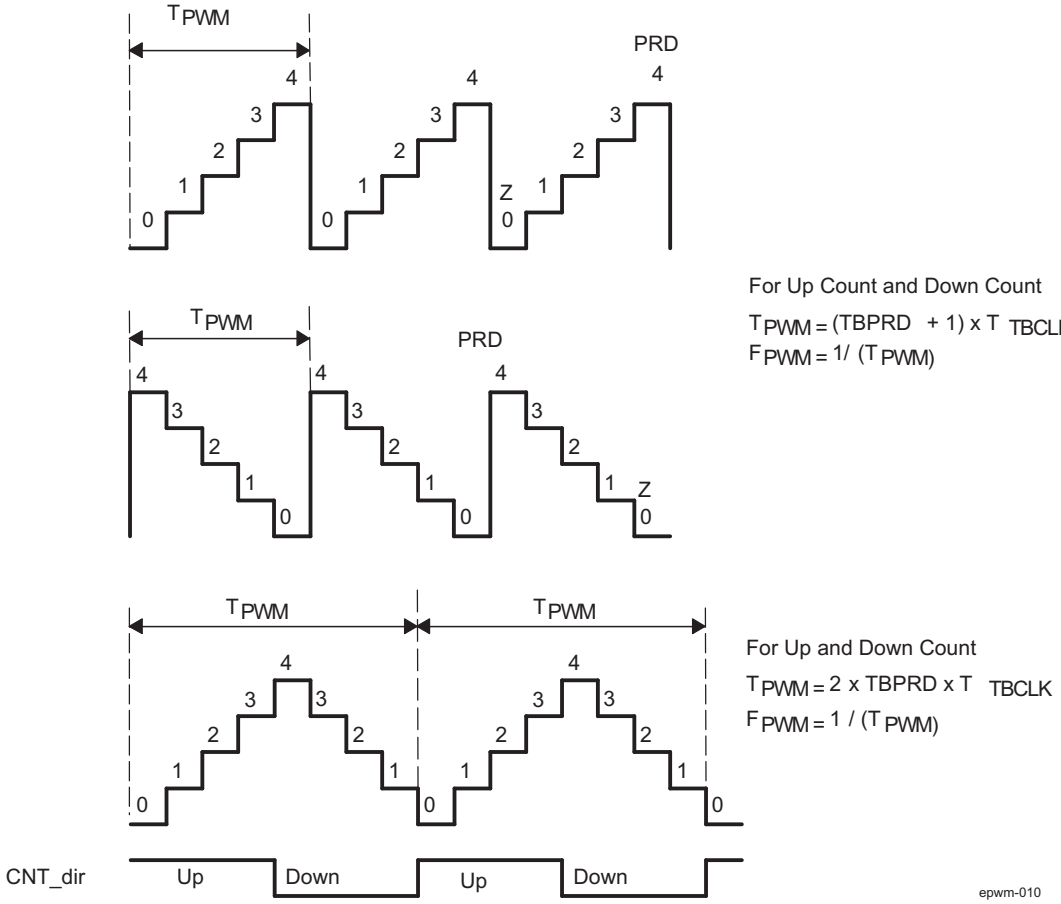
11.5.4.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (EPWM_TBPRD) register and the mode of the time-base counter. Figure 11-356 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM_TBPRD register bitfield TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VBUS_CLK).

The time-base counter has three modes of operation selected by the time-base control register (EPWM_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset back to the period value and it repeats this pattern.

Figure 11-356. ePWM Time-Base Frequency and Period



11.5.4.2.3.1 ePWM Time-Base Period Shadow Register

The time-base period register (EPWM_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

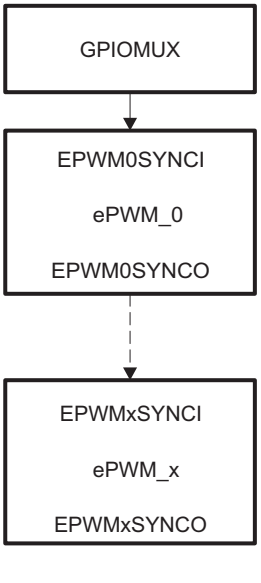
The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM_TBCTL[3] PRDLD bit. This bit enables and disables the EPWM_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM_TBPRD shadow register is enabled when EPWM_TBCTL[3] PRDLD = 0. Reads from and writes to the EPWM_TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM_TBPRD (Active) ← EPWM_TBPRD (shadow)) when the time-base counter (register (EPWM_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM_TBCTL[3] PRDLD = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

11.5.4.2.3.2 ePWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM_0) comes from an external pin. For the device ePWM environment sync pin details refer to the Section 11.5.2. The possible synchronization connections for the remaining ePWM modules is shown in Figure 11-357.

Figure 11-357. ePWM Time-Base Counter Synchronization Scheme 1



Each ePWM module can be configured to use or ignore the synchronization input. If the EPWM_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the ePWM module (register EPWM_TBCNT) will be automatically loaded with the phase register (EPWM_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM_TBPHS → EPWM_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the EPWM_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the EPWM_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See Figure 11-358 through Figure 11-361 for examples.

Clearing the EPWM_TBCTL[2] PHSEN bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, a master time-base (for example, ePWM_1) and downstream modules (ePWM_2–ePWM_x) can be set and they may elect to run in synchronization with the master.

11.5.4.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

As already described in the Section 11.5.3.4, EPWM0_TBCLKEN through EPWM5_TBCLKEN bits in the EPWM_CTL register of the device BOOT_CFG can be used to individually control or globally synchronize the time-base clocks of all enabled ePWM modules on a device. When all EPWMn_TBCLKEN (where n = 0 to 5) bits are set to 0b0, the time-base clocks of all ePWM_x (where x = 0 to 5) modules are stopped (default). When all EPWMn_TBCLKEN bits are simultaneously set in SW to 0b1, all ePWM_x modules time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM_TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set EPWMn_TBCLKEN = 0. This will stop the time-base clock within any enabled ePWM_x module.
3. Configure the prescaler values and desired ePWM modes per each involved ePWM_x.
4. Simultaneously set bits EPWMn_TBCLKEN to 0b1 (where n = 0 to 5) 1.

11.5.4.2.5 ePWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, Figure 11-358 to Figure 11-361 show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

Figure 11-358. ePWM Time-Base Up-Count Mode Waveforms

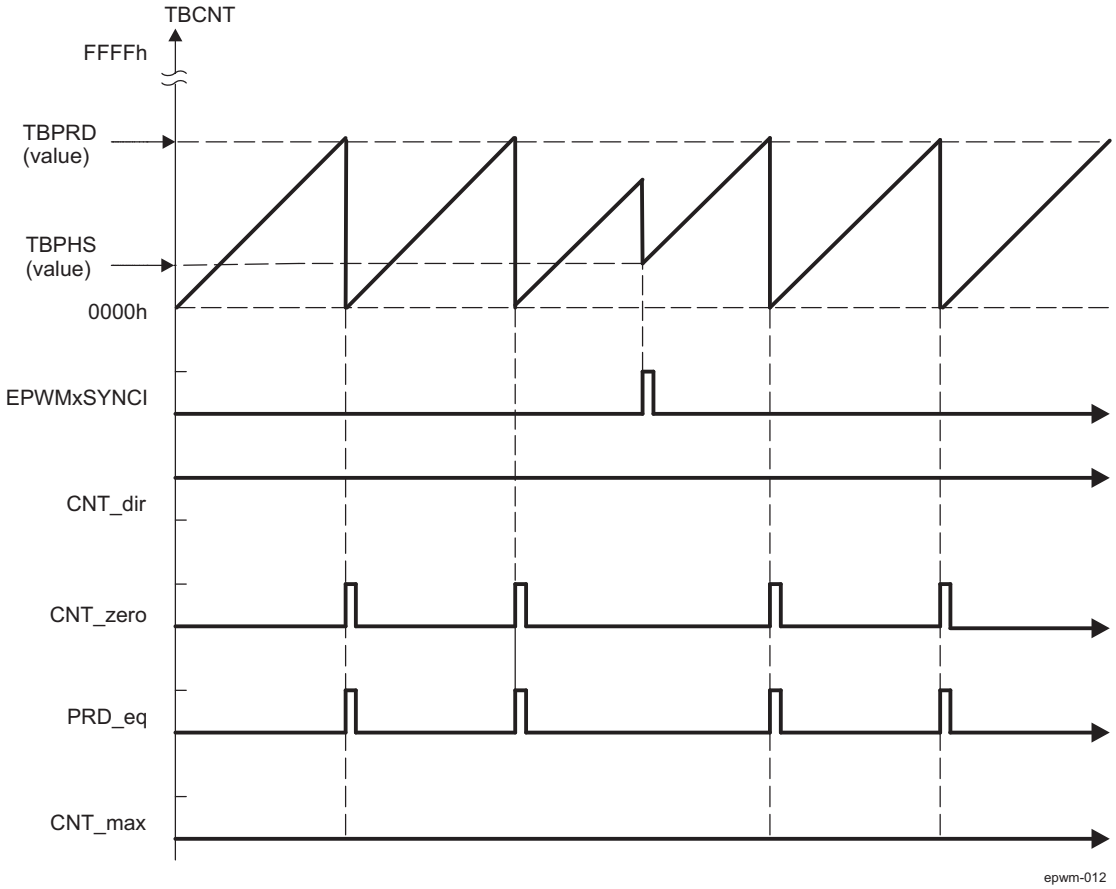


Figure 11-359. ePWM Time-Base Down-Count Mode Waveforms

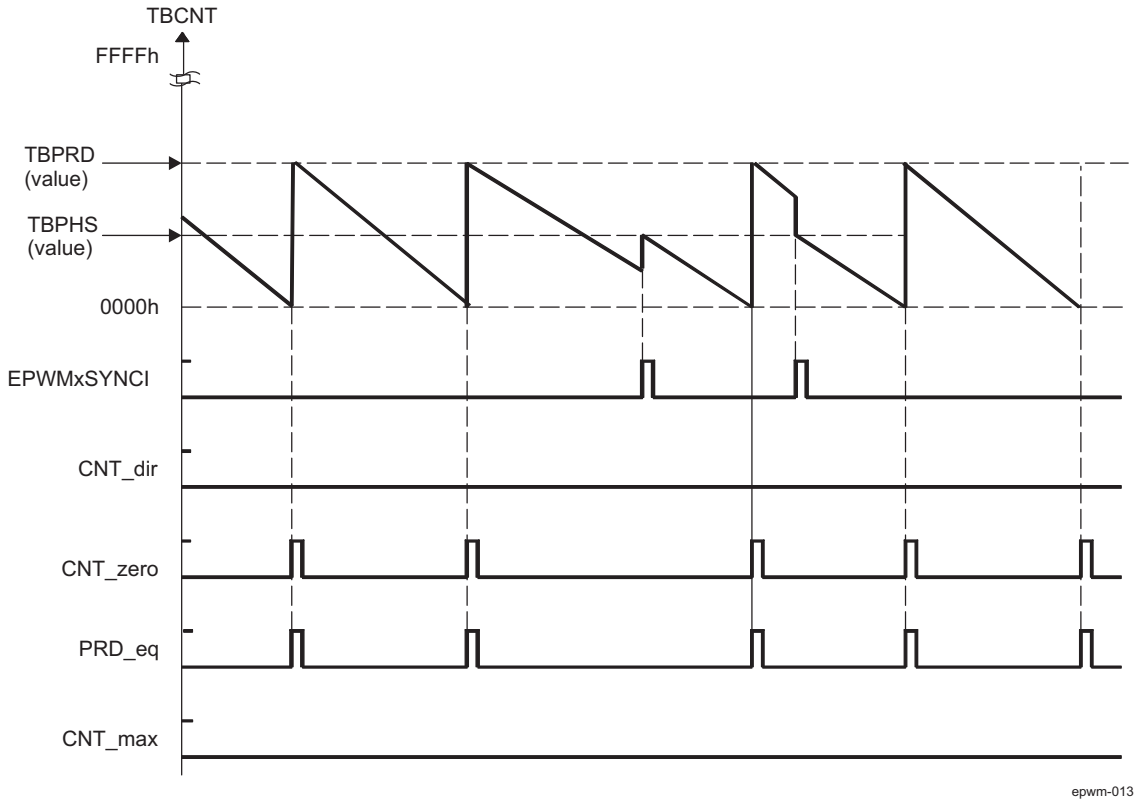

Figure 11-360. ePWM Time-Base Up-Down-Count Waveforms, EPWM_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event

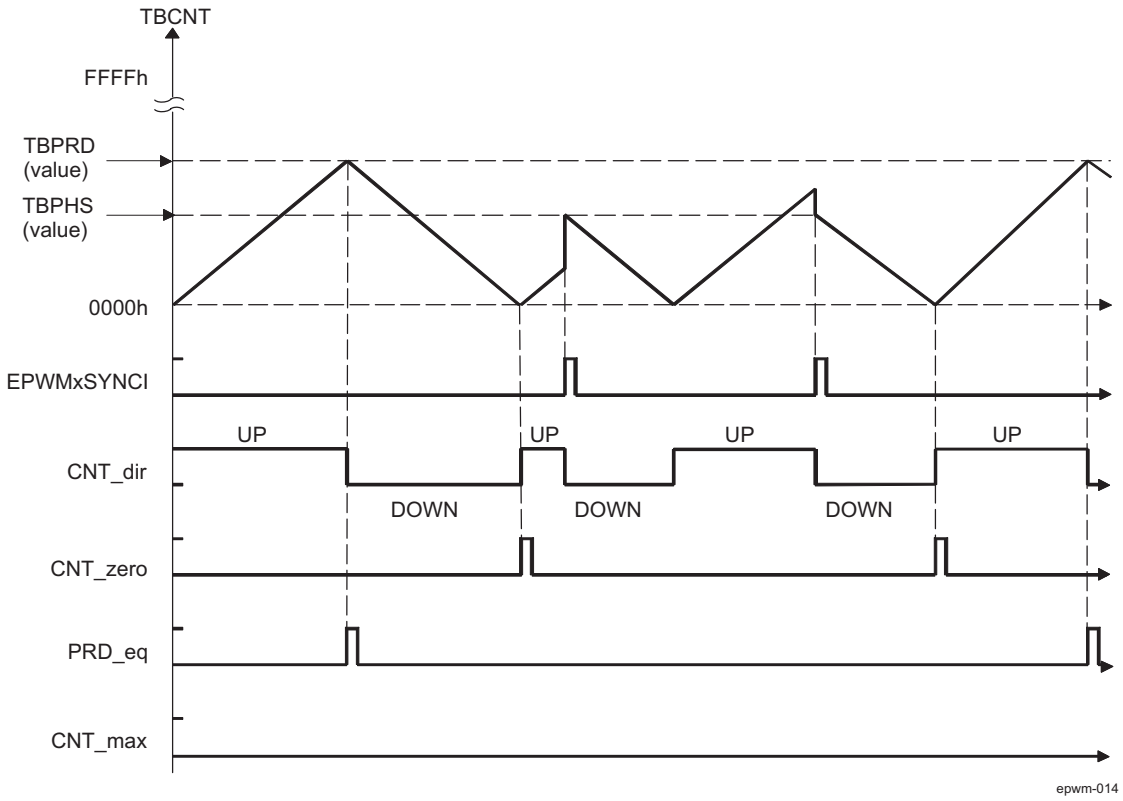

Figure 11-361. ePWM Time-Base Up-Down Count Waveforms, EPWM_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event

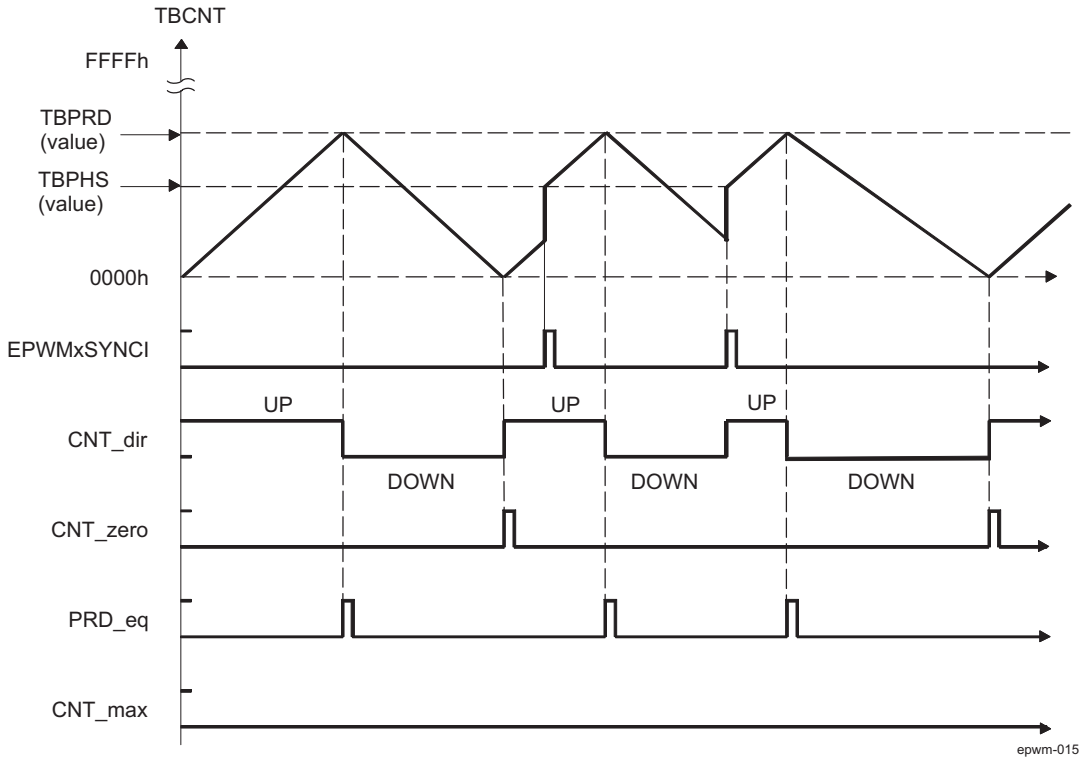


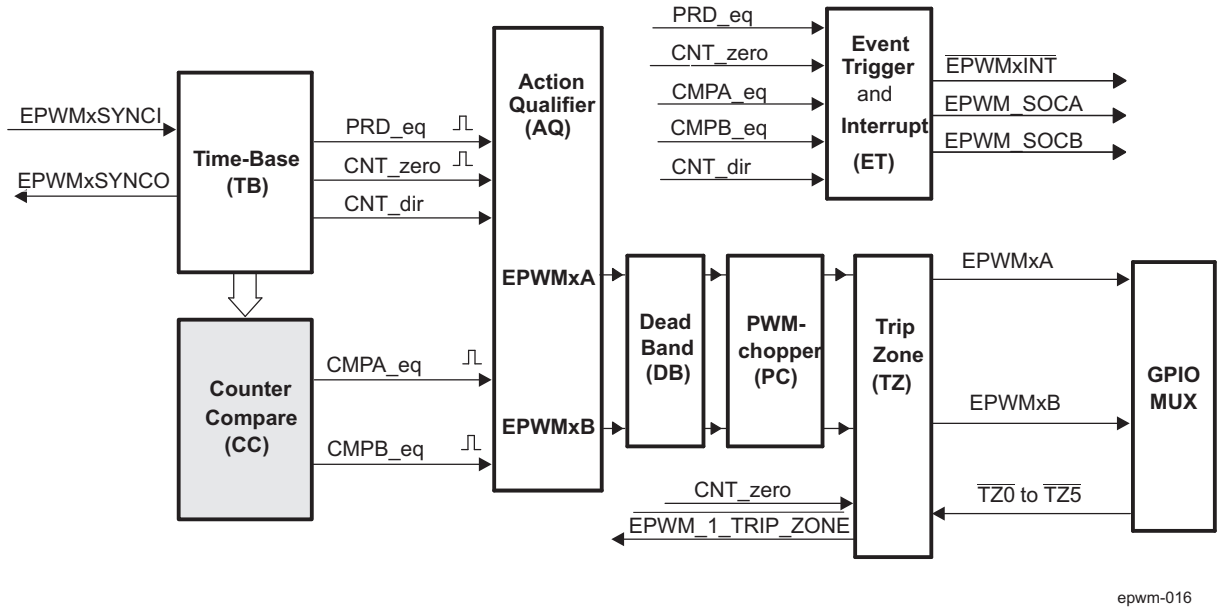
11.5.4.3 ePWM Counter-Compare (CC) Submodule

This section describes the Counter-Compare (CC) submodule in the PWM module.

11.5.4.3.1 Overview

Figure 11-362 illustrates the counter-compare submodule within the ePWM. Figure 11-363 shows the basic structure of the counter-compare submodule.

Figure 11-362. ePWM Counter-Compare Submodule



CC module features:

- Generates events based on programmable time stamps using the EPWM_CMPA and EPWM_CMPB registers
  - CMPA_eq (Time-base counter equals counter-compare A register (TBCNT = CMPA)).
  - CMPB_eq (Time-base counter equals counter-compare B register (TBCNT = CMPB)).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle.

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM_CMPA) and counter-compare B (EPWM_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

11.5.4.3.2 Controlling and Monitoring the ePWM Counter-Compare Submodule

Table 11-799 lists the registers used to control and monitor the counter-compare submodule. Table 11-800 lists the key signals associated with the counter-compare submodule.

Table 11-799. ePWM Counter-Compare Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register (1)	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on ePWM modules with the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 11.6.3 to determine which ePWM instances include this feature.

Figure 11-363. ePWM Counter-Compare Submodule Signals and Registers

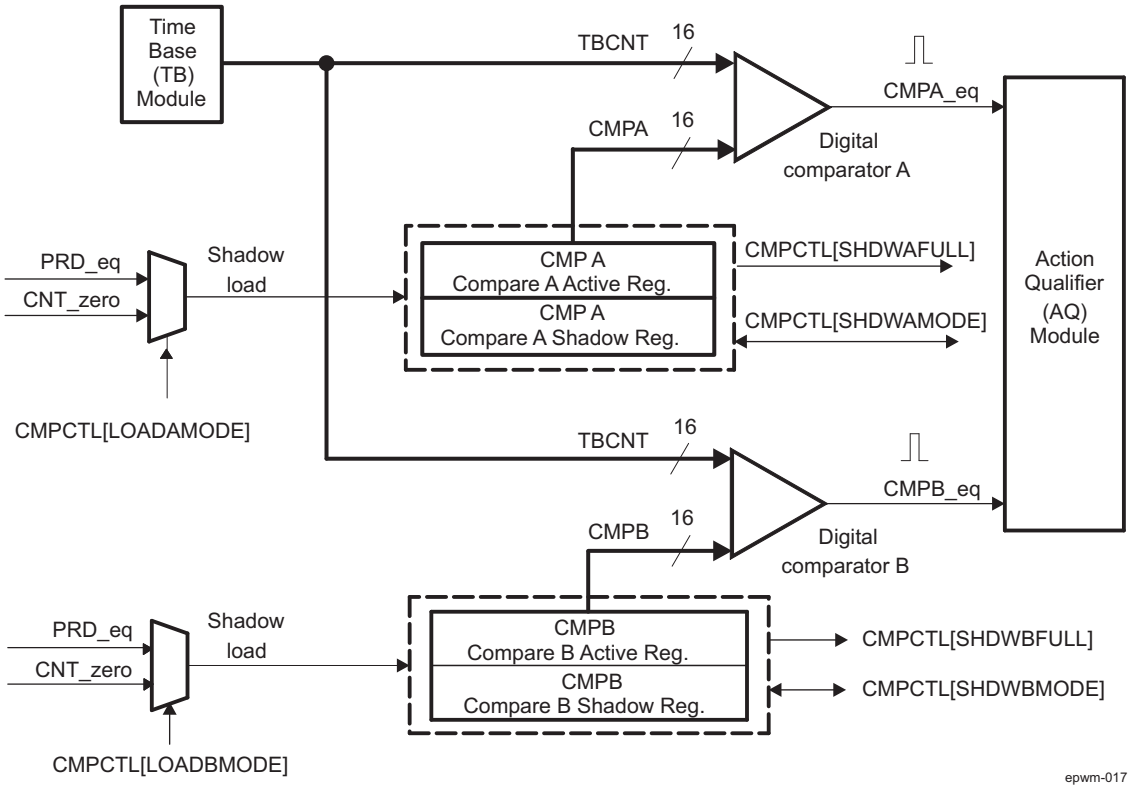


Table 11-800. ePWM Counter-Compare Submodule Key Signals

Signal	Description of Event	Register Bitfields Compared
CMPA_eq	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
PRD_eq	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

11.5.4.3.3 Operational Highlights for the ePWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CMPA: Time-base counter equal to counter-compare A register (EPWM_TBCNT = EPWM_CMPA).
2. CMPB: Time-base counter equal to counter-compare B register (EPWM_TBCNT = EPWM_CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to for more details.

The counter-compare registers EPWM_CMPA and EPWM_CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM_CMPCTL[4] SHDWAMODE and EPWM_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM_CMPA shadow register and EPWM_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Load Mode:**
  The shadow mode for the EPWM_CMPA is enabled by clearing the EPWM_CMPCTL[4] SHDWAMODE bit and the shadow register for CMPB is enabled by clearing the EPWM_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM_CMPA and EPWM_CMPB.

  If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

  – PRD_eq: Time-base counter equal to the period (TBCNT = TBPRD).
  – CNT_zero: Time-base counter equal to zero (TBCNT = 0000h)
  – Both PRD_eq and CNT_zero events occurrence

  Which of these three events will drive the counter compare module is specified by the EPWM_CMPCTL[1-0] LOADAMODE and EPWM_CMPCTL[3-2] LOADBMODE register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.
- **Immediate Load Mode:**
  If immediate load mode is selected (EPWM_CMPCTL[4] SHDWAMODE = 1 or EPWM_CMPCTL[6] SHDWBMODE = 1), then a read from or a write to the register will go directly to the active register.

Figure 11-364 and Figure 11-365 show Compare A and B Dual Shadow registers.

Figure 11-364. Compare A Dual Shadow register

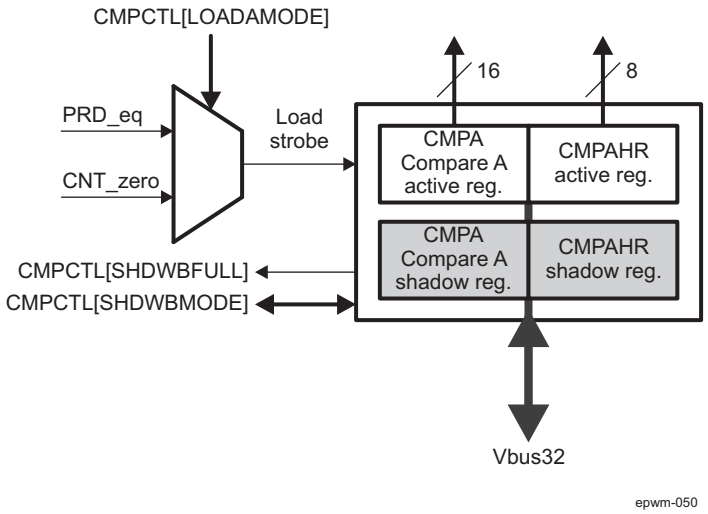

Figure 11-365. Compare B Dual Shadow register

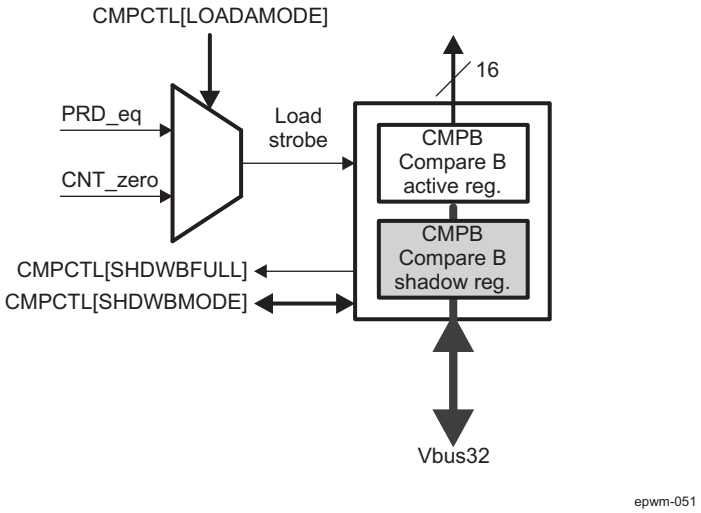


NOTE: In HRPWM mode the user must perform a single 32-bit write access to both the HRPWM_CMPAHR and EPWM_CMPA registers. Two 16-bit accesses are not allowed.

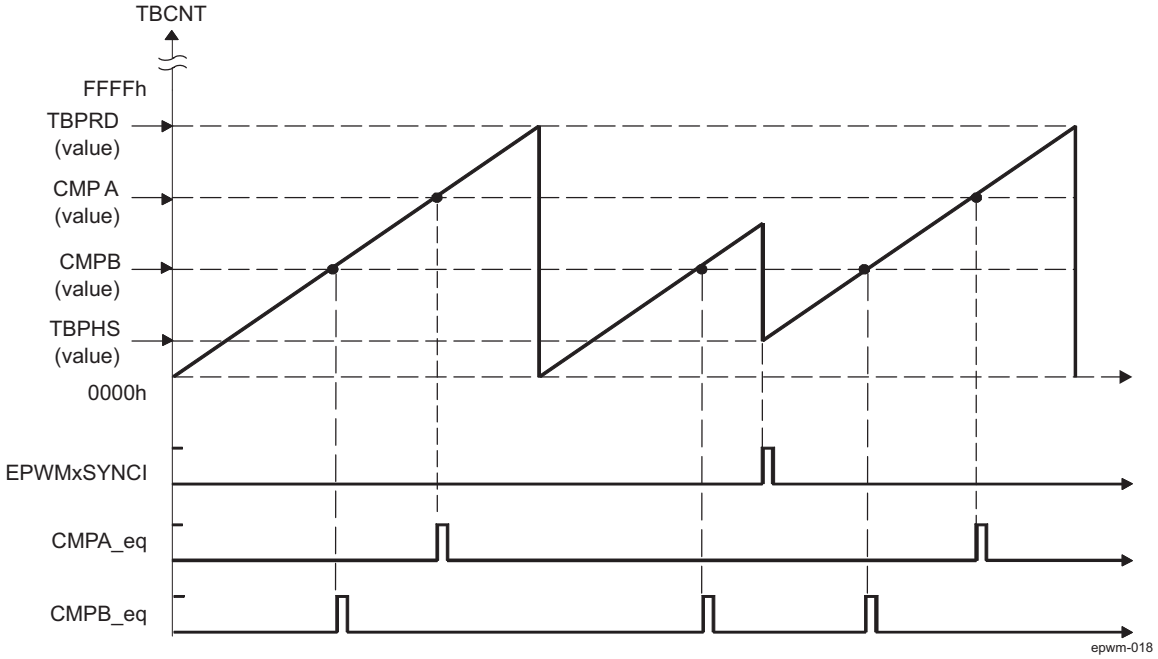
11.5.4.3.4 ePWM Counter-Compare Submodule Timing Waveforms

As described in Section 11.5.4.2, the Time Base (TB) module can be configured to operate in 3 distinct count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

The timing diagrams in Figure 11-366 to Figure 11-369 show how CMPA and CMPB events are generated in each of the 3 count modes and how the EPWMxSYNCI signal interacts.

Figure 11-366. ePWM Counter-Compare Event Waveforms in Up-Count Mode



NOTE: An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 11-367. ePWM Counter-Compare Events in Down-Count Mode

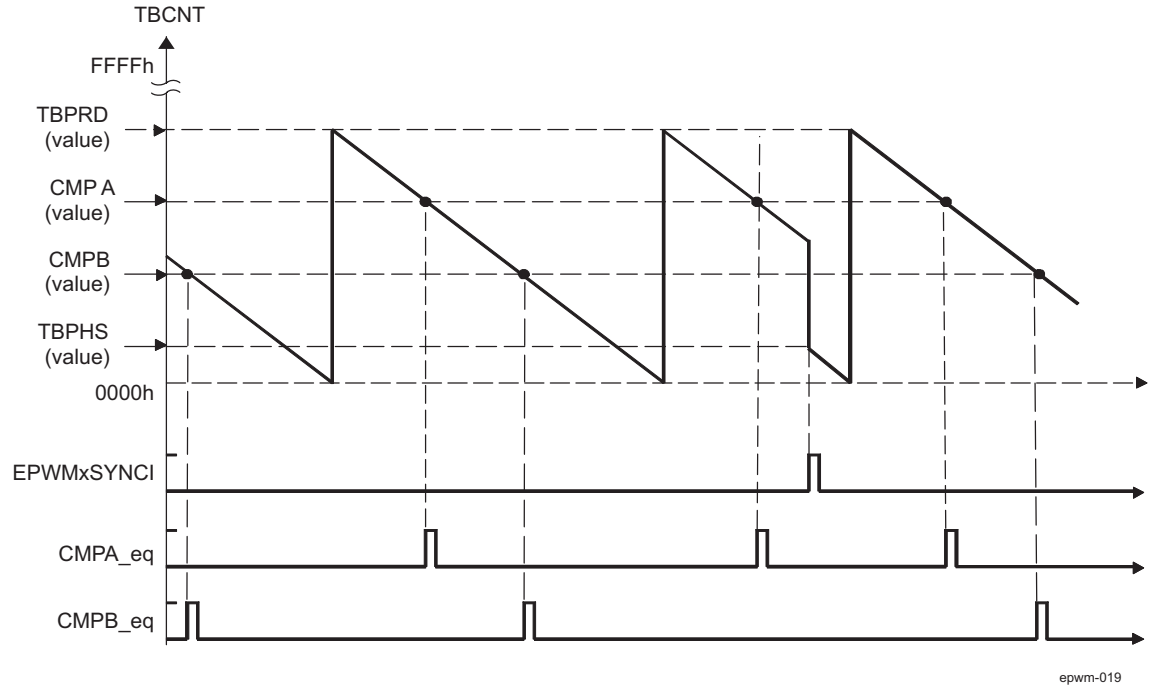


Figure 11-368. ePWM Counter-Compare Events in Up-Down-Count Mode, EPWM_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event

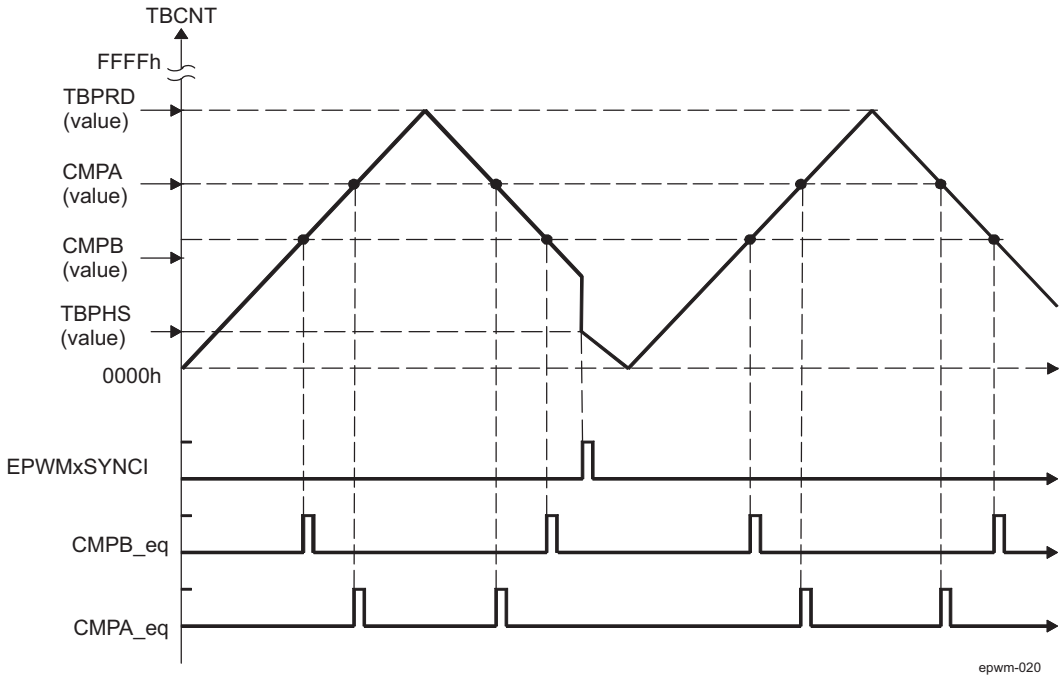

Figure 11-369. ePWM Counter-Compare Events in Up-Down-Count Mode, EPWM_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event

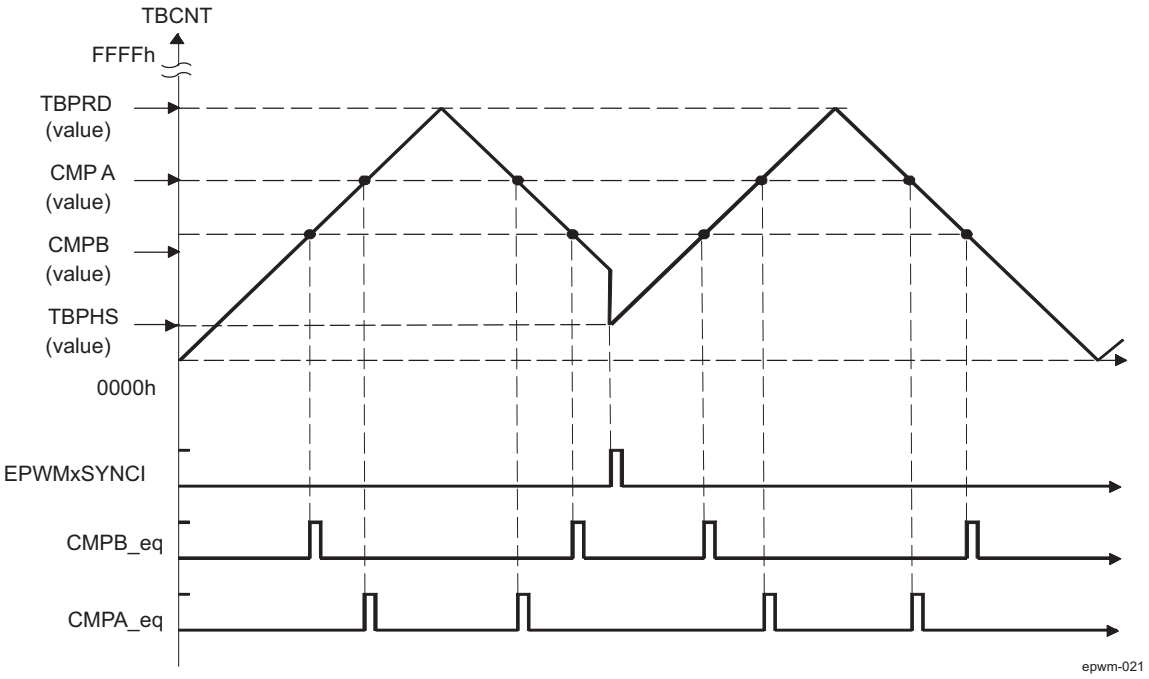


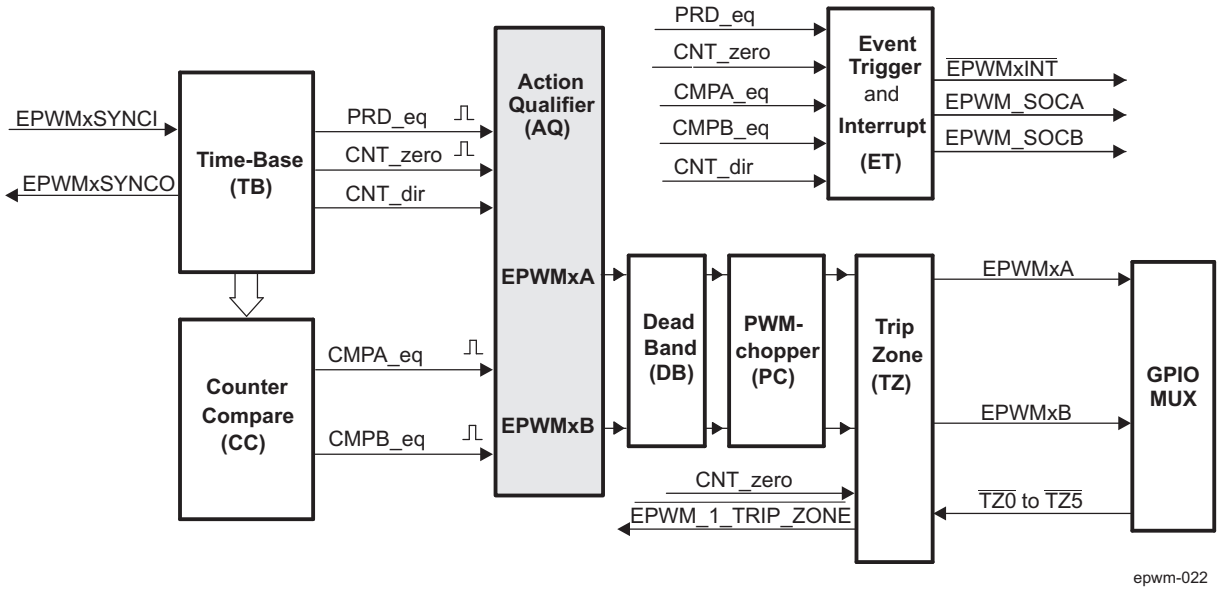
11.5.4.4 ePWM Action-Qualifier (AQ) Submodule

This section describes the Action-Qualifier (AQ) submodule in the PWM module.

11.5.4.4.1 Overview

Figure 11-370 shows the action-qualifier (AQ) submodule in the ePWM system. This submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 11-370. ePWM Action-Qualifier Submodule



AQ module features:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - PRD_eq: Time-base counter equal to the period (TBCNT = TBPRD)
  - CNT_zero: Time-base counter equal to zero (TBCNT = 0000h)
  - CMPA_eq: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CMPB_eq: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

11.5.4.4.2 Controlling and Monitoring the ePWM Action-Qualifier Submodule

Table 11-801 lists the registers used to control and monitor the action-qualifier submodule.

Table 11-801. ePWM Action-Qualifier Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers as shown in Figure 11-371. The possible input events are summarized again in Table 11-802.

Figure 11-371. ePWM Action-Qualifier Submodule Inputs and Outputs

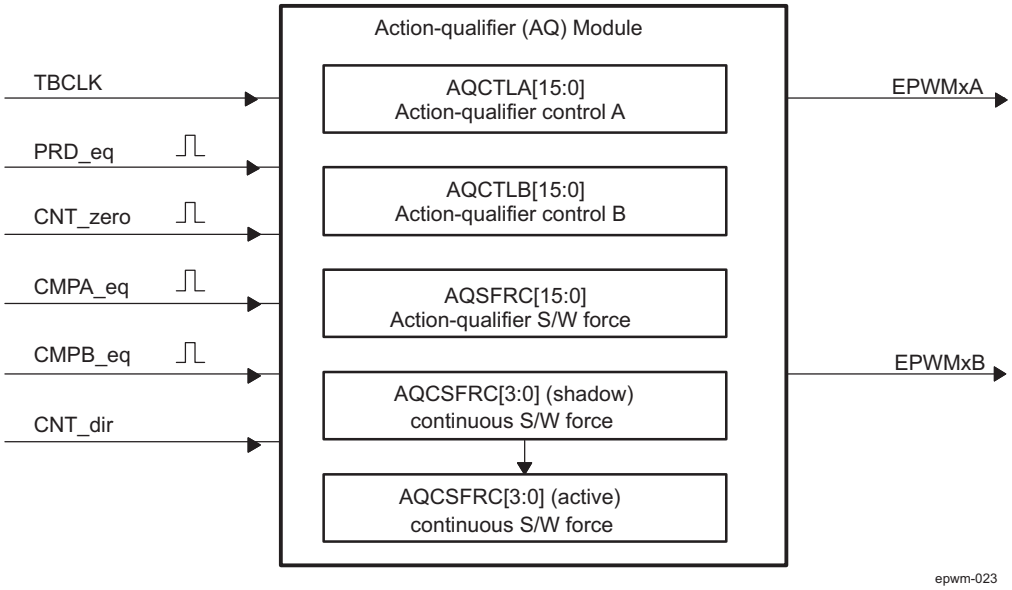


Table 11-802. ePWM Action-Qualifier Submodule Possible Input Events

Signal	Description	Register Bitfield Compared
PRD_eq	Time-base counter equal to the period value	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero	TBCNT = 0000h
CMPA_eq	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers EPWM_AQSFRC and EPWM_AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the Event_Trigger (ET) submodule description in Section 11.5.4.8 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in Figure 11-372. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 11-372. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW ×	Z ×	CA ×	CB ×	P ×	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

epwm-024

11.5.4.4.3 ePWM Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is: events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 11-803. A priority level 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

Table 11-803. ePWM Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) (1)	Counter equals CMPB on up-count (CBU) (1)
6 (Lowest)	Counter equals CMPA on down-count (CAD) (1)	Counter equals CMPA on up-count (CBU) (1)

(1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

Table 11-804 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 11-804. ePWM Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 11-805 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 11-805. ePWM Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 11-806.

Table 11-806. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

11.5.4.4.4 Waveforms for Common ePWM Configurations

NOTE: The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM_CMPA and EPWM_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place — either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If EPWM_CMPA / EPWM_CMPB is loaded on zero, then use EPWM_CMPA / EPWM_CMPB values greater than or equal to 1.
- If EPWM_CMPA / EPWM_CMPB is loaded on period, then use EPWM_CMPA / EPWM_CMPB values less than or equal to TBPRD - 1.

  This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50-0% asymmetric PWM use the following configuration: Load EPWM_CMPA / EPWM_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50-0% PWM duty.

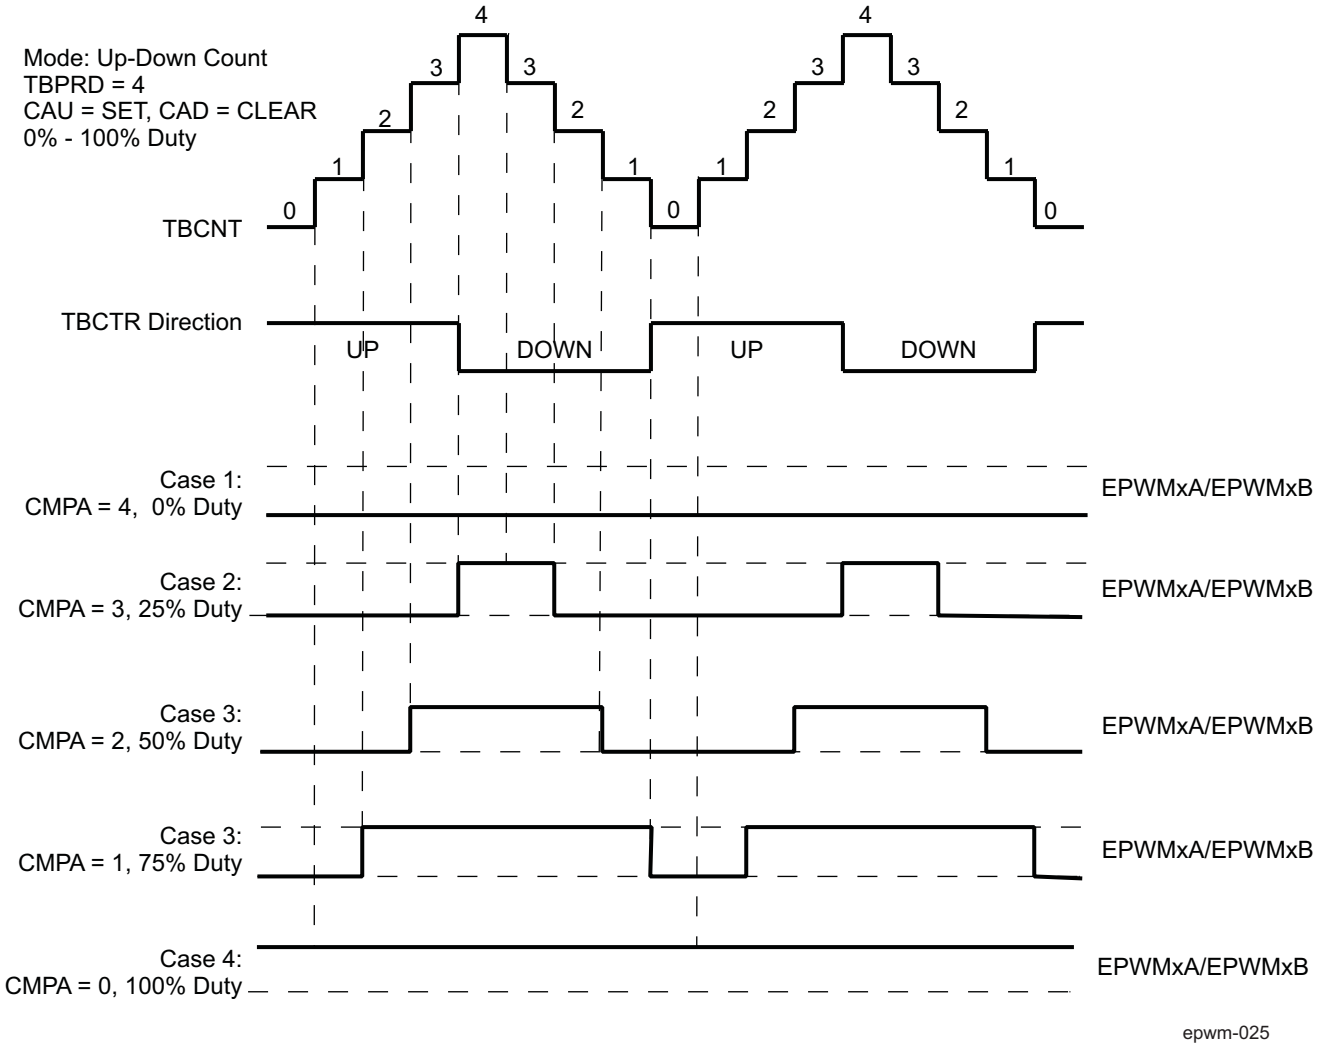
When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM_CMPA / EPWM_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 11-373 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When EPWM_CMPA = EPWM_TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if CMPA/CMPB is loaded on zero, then use CMPA/CMPB values greater than or equal to 1. If CMPA/CMPB is loaded on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 11-373. ePWM Up-Down-Count Mode Symmetrical Waveform

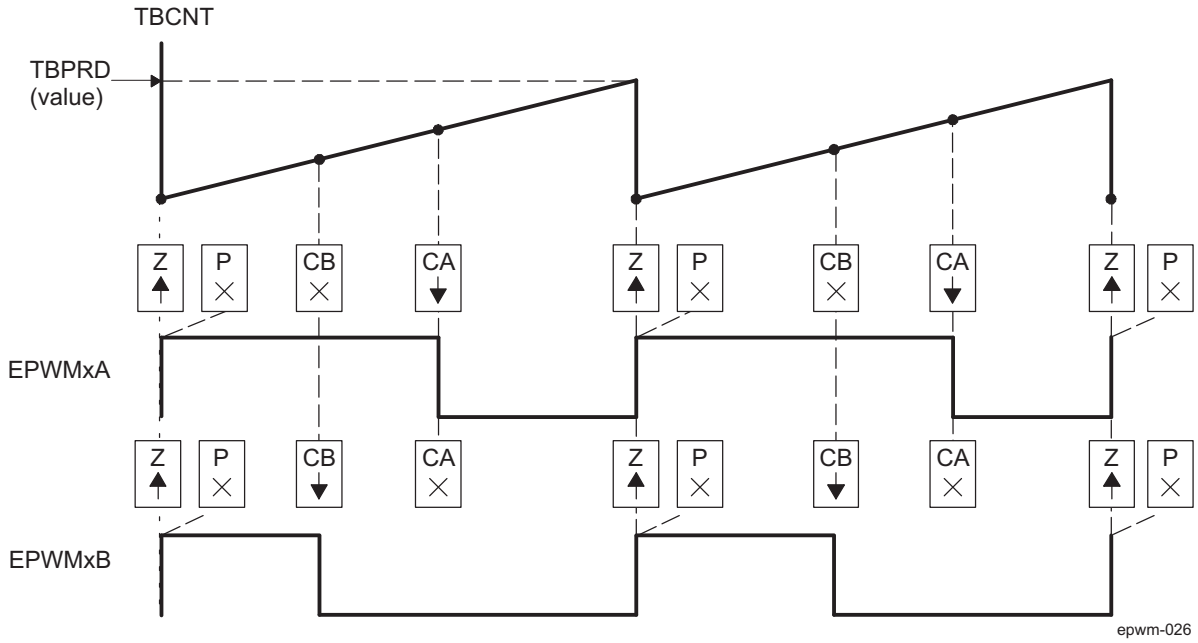


The PWM waveforms in Figure 11-374 through Figure 11-379 show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers (EPWM_TBPRD, EPWM_CMPA, and EPWM_CMPB). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Table 11-807 and Table 11-808 contains initialization and runtime register configurations for the waveforms in Figure 11-374.

Figure 11-374. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active High



(1) PWM period = (TBPRD + 1) × T_{TBCLK}

(2) Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

(3) Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

(4) The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.

(5) Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

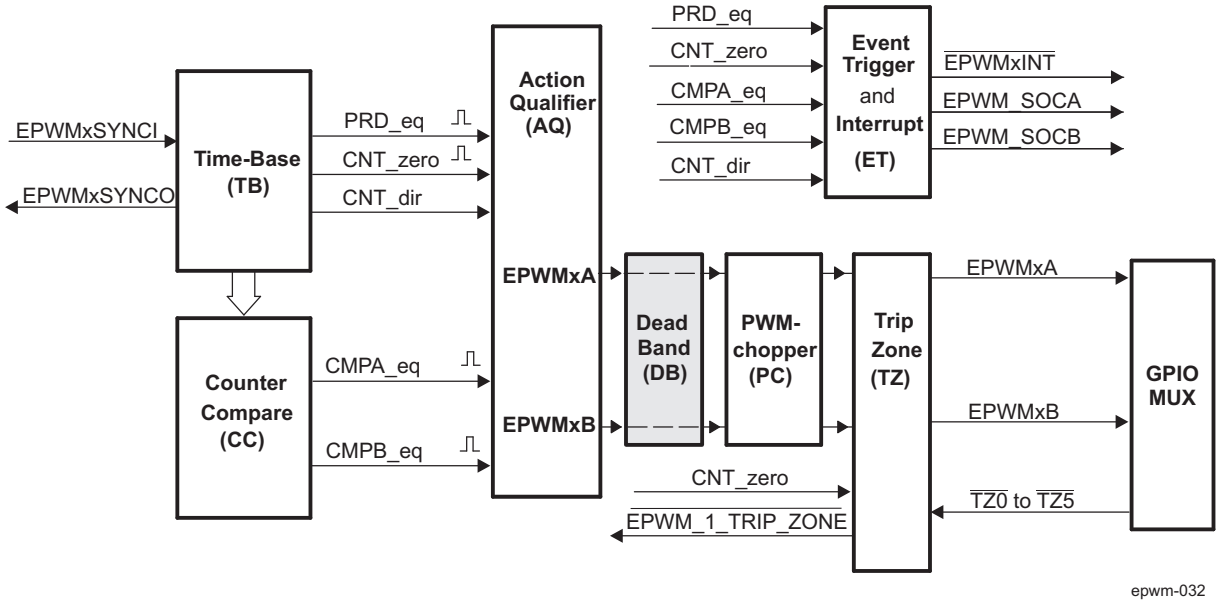
11.5.4.5 ePWM Dead-Band Generator (DB) Submodule

This section describes the Dead-Band Generator (DB) submodule in the PWM module.

11.5.4.5.1 Overview

Figure 11-380 illustrates the dead-band generator submodule within the ePWM module.

Figure 11-380. Dead-Band Generator Submodule



The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in Figure 11-380)

11.5.4.5.2 Controlling and Monitoring the ePWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 11-819. Dead-Band Generator Submodule Registers

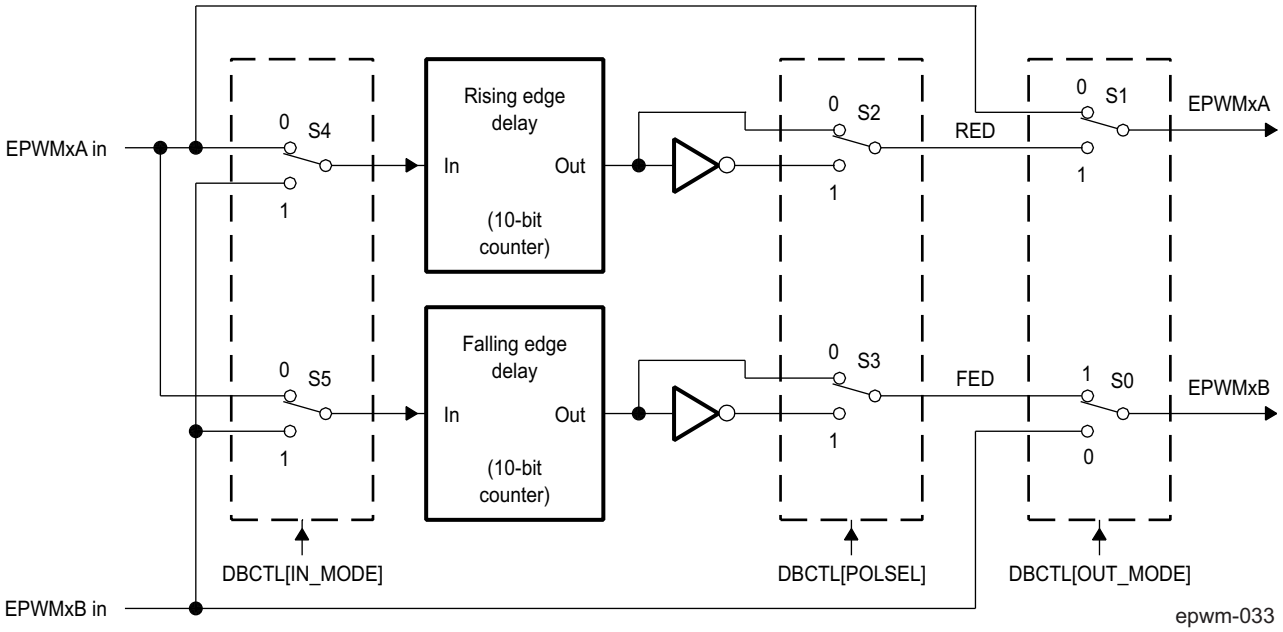
Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

11.5.4.5.3 Operational Highlights for the ePWM Dead-Band Generator Submodule

The dead-band submodule has two groups of independent selection options as shown in Figure 11-381.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM_DBCTL[5-4] IN_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM_DBCTL[1-0] OUT_MODE bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM_DBCTL[3-2] POLSEL) allows to be specified whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 11-381. Configuration Options for the ePWM Dead-Band Generator Submodule



Although all combinations are supported, not all are typical usage modes. Table 11-820 lists some classical dead-band configurations. These modes assume that the EPWM_DBCTL[5-4] IN_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 11-820 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows to be fully disabled the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 11-382. Note that to generate equivalent waveforms to Figure 11-382, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in Table 11-820 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

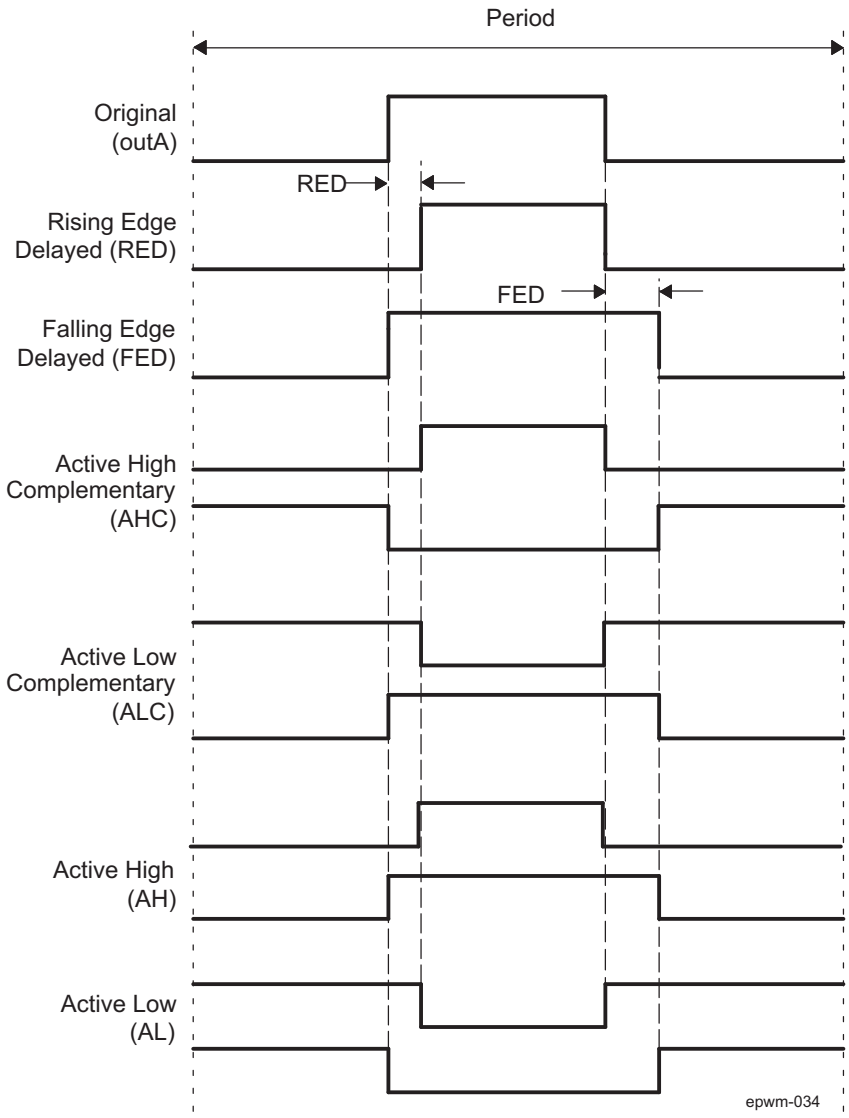
Table 11-820. Classical Dead-Band Operating Modes

		EPWM_DBCTL[3-2] POLSEL		EPWM_DBCTL[1-0] OUT_MODE	
Mode	Mode Description [1]	S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM_DBCTL[5-4] IN_MODE = 0b00. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN_MODE configuration.

Figure 11-382 shows waveforms for typical cases where 0% < duty < 100%.

Figure 11-382. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)



The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM_DBRED and EPWM_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formulas to calculate falling-edge-delay and rising-edge-delay are:

FED = EPWM_DBFED × T_{TBCLK}

RED = EPWM_DBRED × T_{TBCLK}

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VBUS_CLK.

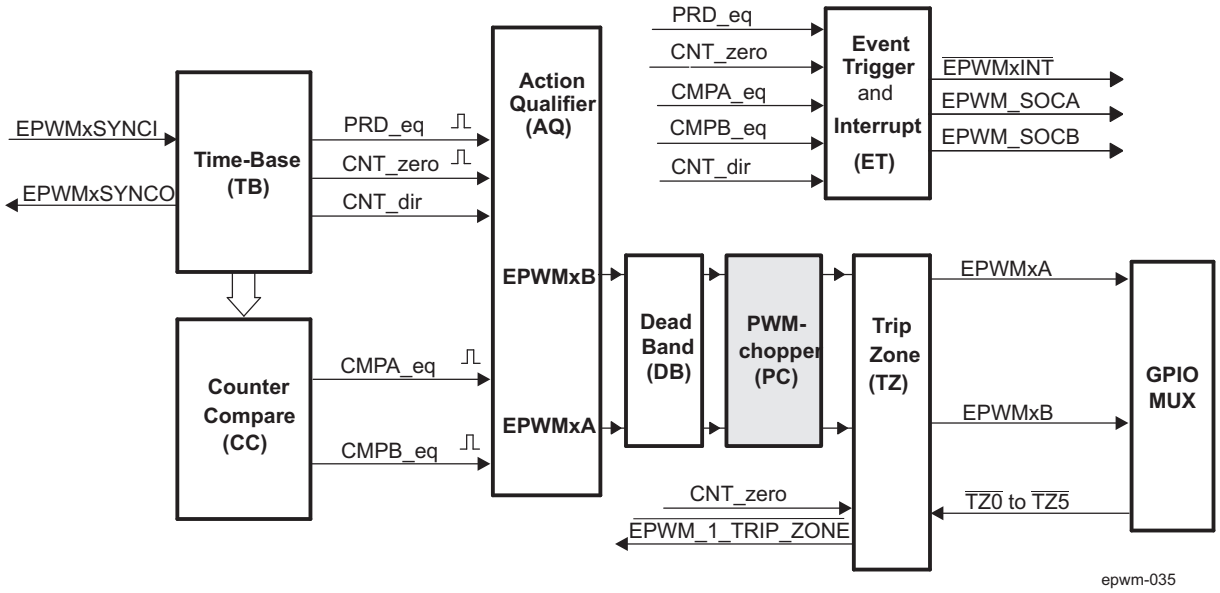
11.5.4.6 ePWM-Chopper (PC) Submodule

This section describes the PWM-Chopper (PC) submodule in the PWM module.

11.5.4.6.1 Overview

Figure 11-383 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if a pulse transformer-based gate drivers to control the power switching elements is needed.

Figure 11-383. PWM-Chopper Submodule



PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

11.5.4.6.2 Controlling the ePWM-Chopper Submodule

The ePWM-chopper submodule operation is controlled via the register in Table 11-821.

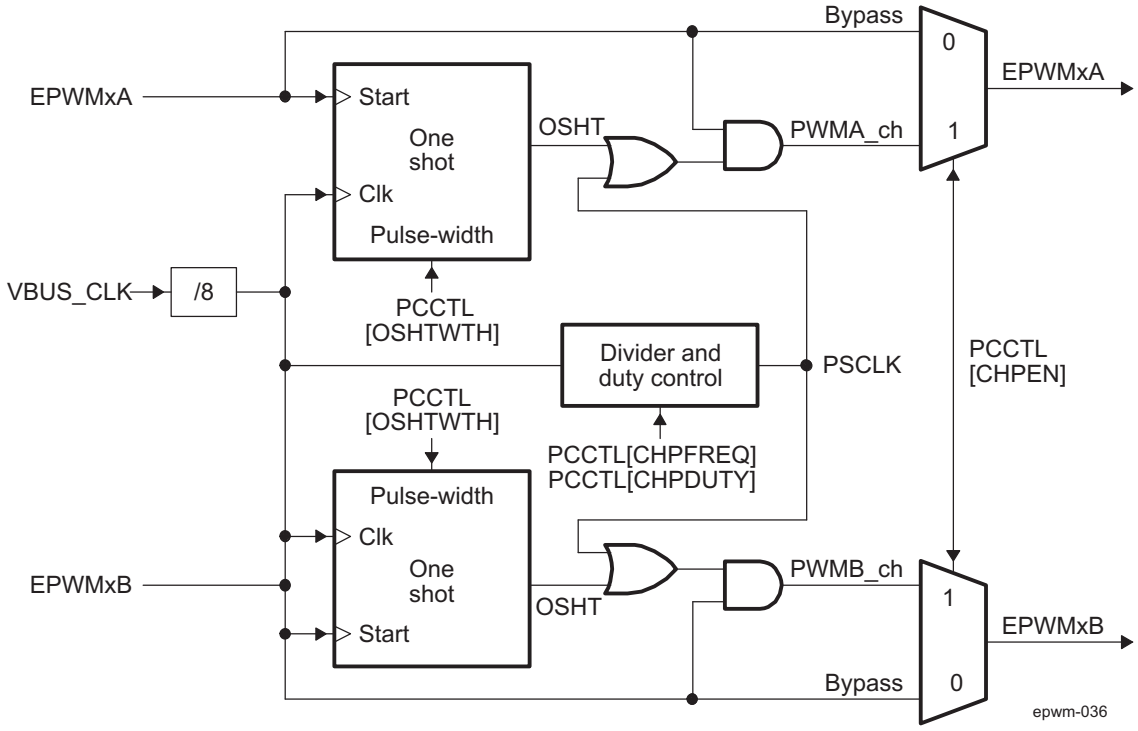
Table 11-821. ePWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

11.5.4.6.3 Operational Highlights for the ePWM-Chopper Submodule

Figure 11-384 shows the operational details of the ePWM-chopper submodule. The carrier clock is derived from VBUS_CLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

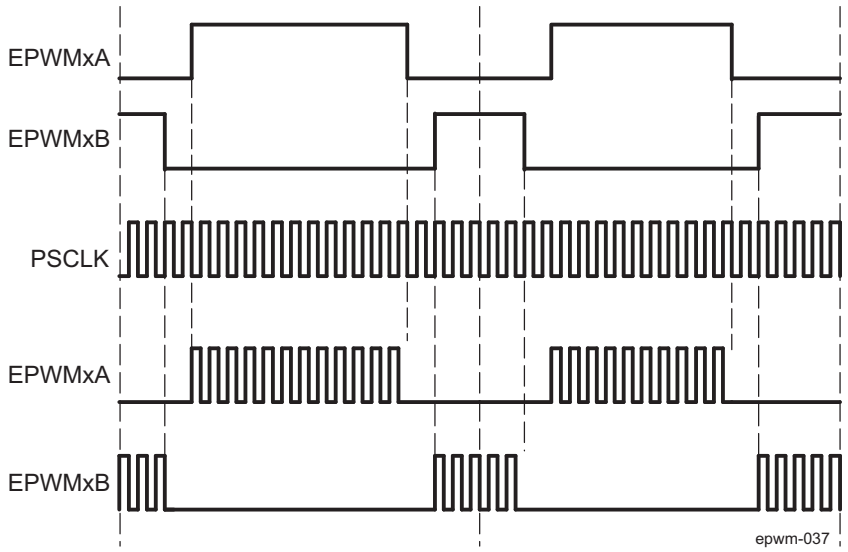
Figure 11-384. PWM-Chopper Submodule Signals and Registers



11.5.4.6.4 ePWM-Chopper Waveforms

Figure 11-385 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 11-385. Simple ePWM-Chopper Submodule Waveforms Showing Chopping Action Only



11.5.4.6.4.1 ePWM-Chopper One-Shot Pulse

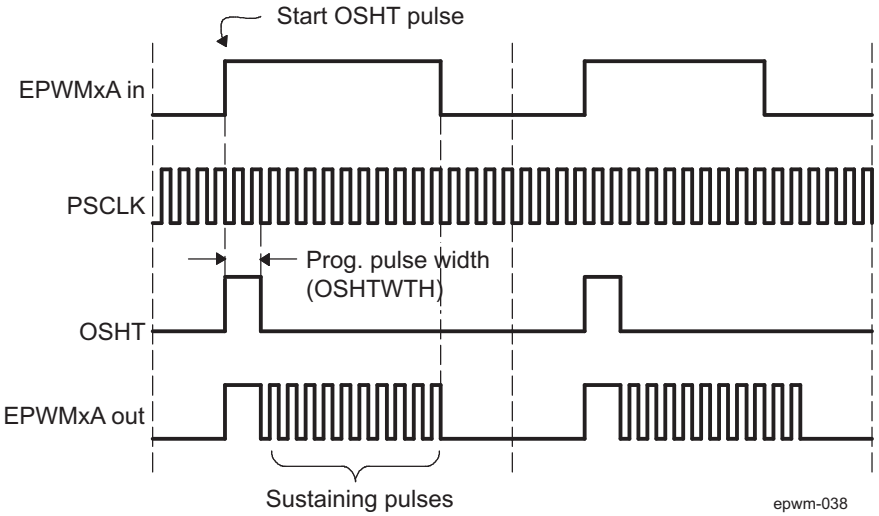
The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$T_{1stpulse} = T_{VBUS\_CLK} \times 8 \times OSHTWTH$

Where T_{VBUS_CLK} is the period of the system clock (VBUS_CLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 11-386 shows the first and subsequent sustaining pulses.

Figure 11-386. ePWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

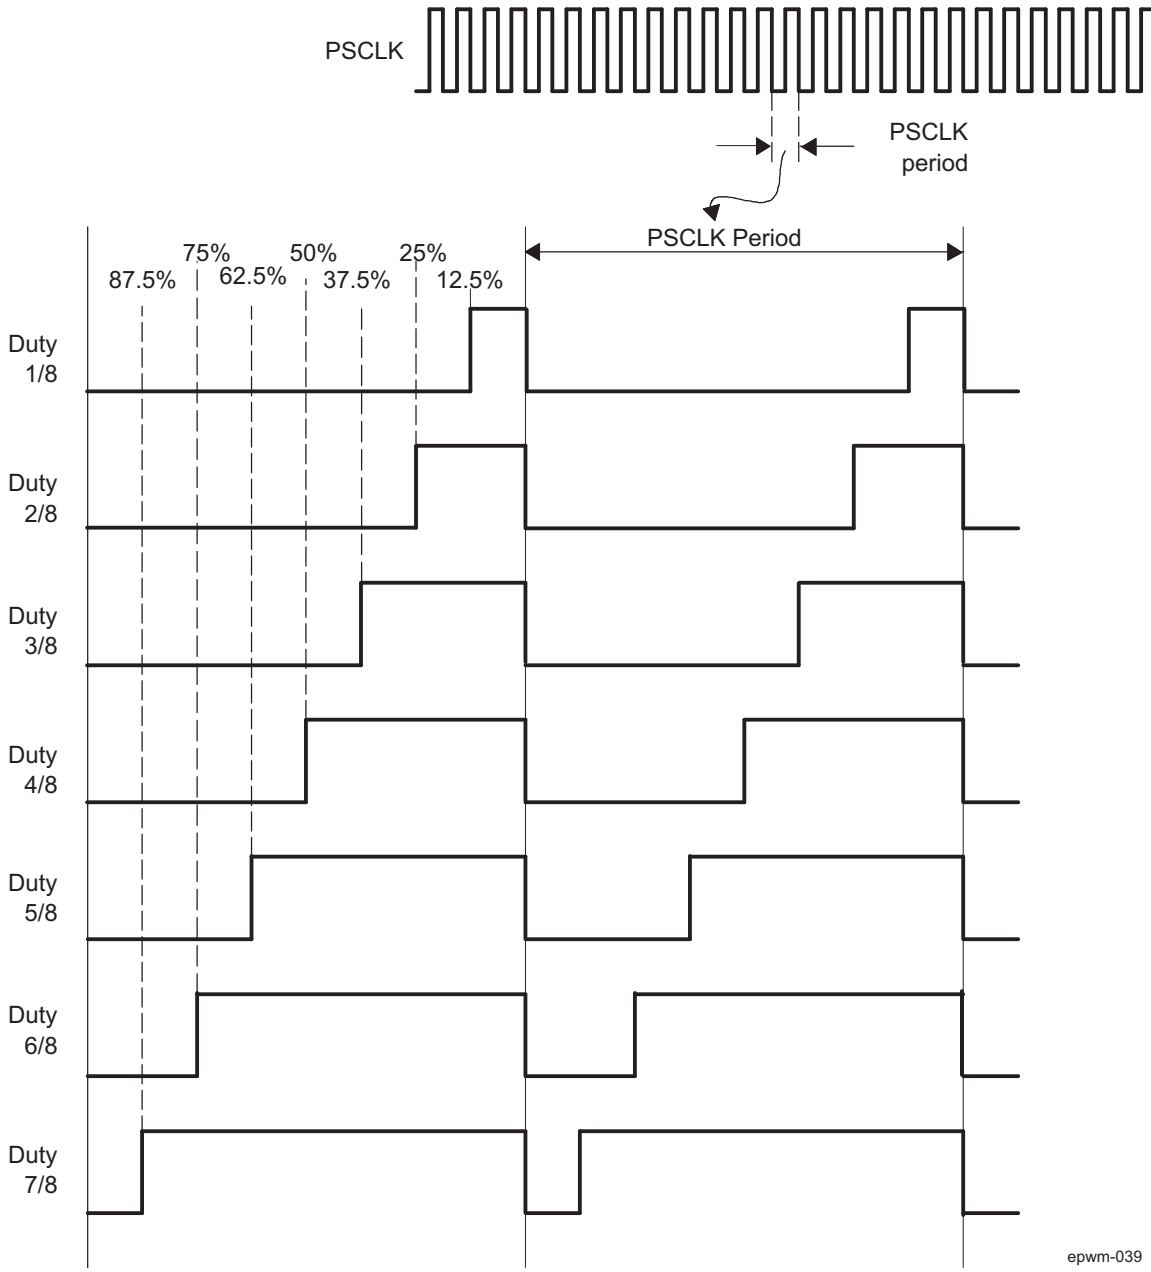


11.5.4.6.4.2 ePWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 11-387 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5 to 87.5%.

Figure 11-387. ePWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses



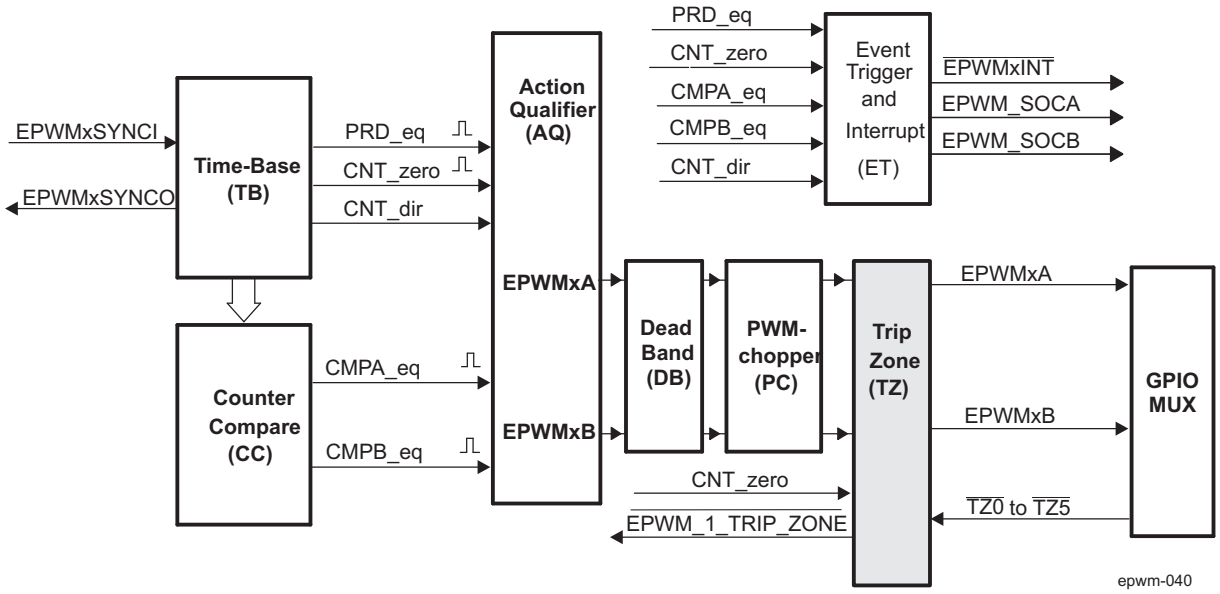
11.5.4.7 ePWM Trip-Zone (TZ) Submodule

This section describes the Trip-Zone (TZ) submodule in the PWM module.

11.5.4.7.1 Overview

Figure 11-388 shows how the trip-zone (TZ) submodule fits within the ePWM module. Each ePWM module is connected to six $\overline{TZ}$ signals ($\overline{TZ0}$ to $\overline{TZ5}$) that are sourced from the GPIO MUX. These signals indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur. See Section 11.6.3 to determine the number of trip-zone pins available for the device.

Figure 11-388. ePWM Trip-Zone Submodule



The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ0}$ to $\overline{TZ5}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

NOTE: For each ePWM_x module, 6 tripzone input events are supported ($\overline{EPWMx\_TRIP\_TZ[5:0]}$). Each tripzone input for all ePWM_x modules (where x = 0 to 5) are tied to a common tripzone input pin, so that any ePWM_x can be triggered by any of the six tripzone inputs.

11.5.4.7.2 Controlling and Monitoring the ePWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 11-822. ePWM Trip-Zone Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register(1)	24h	No
EPWM_TZCTL	Trip-Zone Control Register(1)	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register(1)	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register(1)	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register(1)	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register(1)	30h	No

(1) All trip-zone registers are EALLOW protected and can be modified only after executing the EALLOW instruction.

11.5.4.7.3 Operational Highlights for the ePWM Trip-Zone Submodule

The trip-zone signals at pin $\overline{TZ0}$ to $\overline{TZ5}$ is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular ePWM module is determined by the EPWM_TZSEL register for that specific ePWM module. The trip-zone signal may or may not be synchronized to the system clock (VBUS_CLK). A minimum of 1 VBUS_CLK low pulse on the $\overline{TZ0}$ to $\overline{TZ5}$ inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the $\overline{TZ0}$ to $\overline{TZ5}$ inputs.

The $\overline{TZ0}$ to $\overline{TZ5}$ inputs can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the EPWM_TZSEL[5-0] CBCk and EPWM_TZSEL[13-8] OSHTk bits (where k = 0 to 5 corresponds to the trip pin), respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 11-823 lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register.

  The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (EPWM_TBCNT bitfield TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM_TZFLG[1] CBC bit is cleared, then it will again be immediately set.
- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 11-823 lists the possible actions. In addition, the one-shot trip event flag (EPWM_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the EPWM_TZCTL[1-0] TZA and EPWM_TZCTL[3-2] TZB register bits. One of four possible actions, shown in Table 11-823, can be taken on a trip event.

Table 11-823. Possible Actions On an ePWM Trip Event

EPWM_TZCTL[1-0] TZA and/or EPWM_TZCTL[3-2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

Example of ePWM Trip-Zone Configurations

A one-shot trip event on $\overline{TZ0}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM_1 registers as follows:
  - EPWM_TZSEL[8] OSHT1 = 1: enables $\overline{TZ}$ as a one-shot event source for ePWM_1
  - EPWM_TZCTL[1-0] TZA = 2: EPWM1A will be forced low on a trip event.
  - EPWM_TZCTL[3-2] TZB = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM_2 registers as follows:
  - EPWM_TZSEL[8] OSHT1 = 1: enables $\overline{TZ}$ as a one-shot event source for ePWM_2
  - EPWM_TZCTL[1-0] TZA = 1: EPWM2A will be forced high on a trip event.
  - EPWM_TZCTL[3-2] TZB = 1: EPWM2B will be forced high on a trip event.

11.5.4.7.4 Generating ePWM Trip-Event Interrupts

Figure 11-389 and Figure 11-390 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 11-389. ePWM Trip-Zone Submodule Mode Control Logic

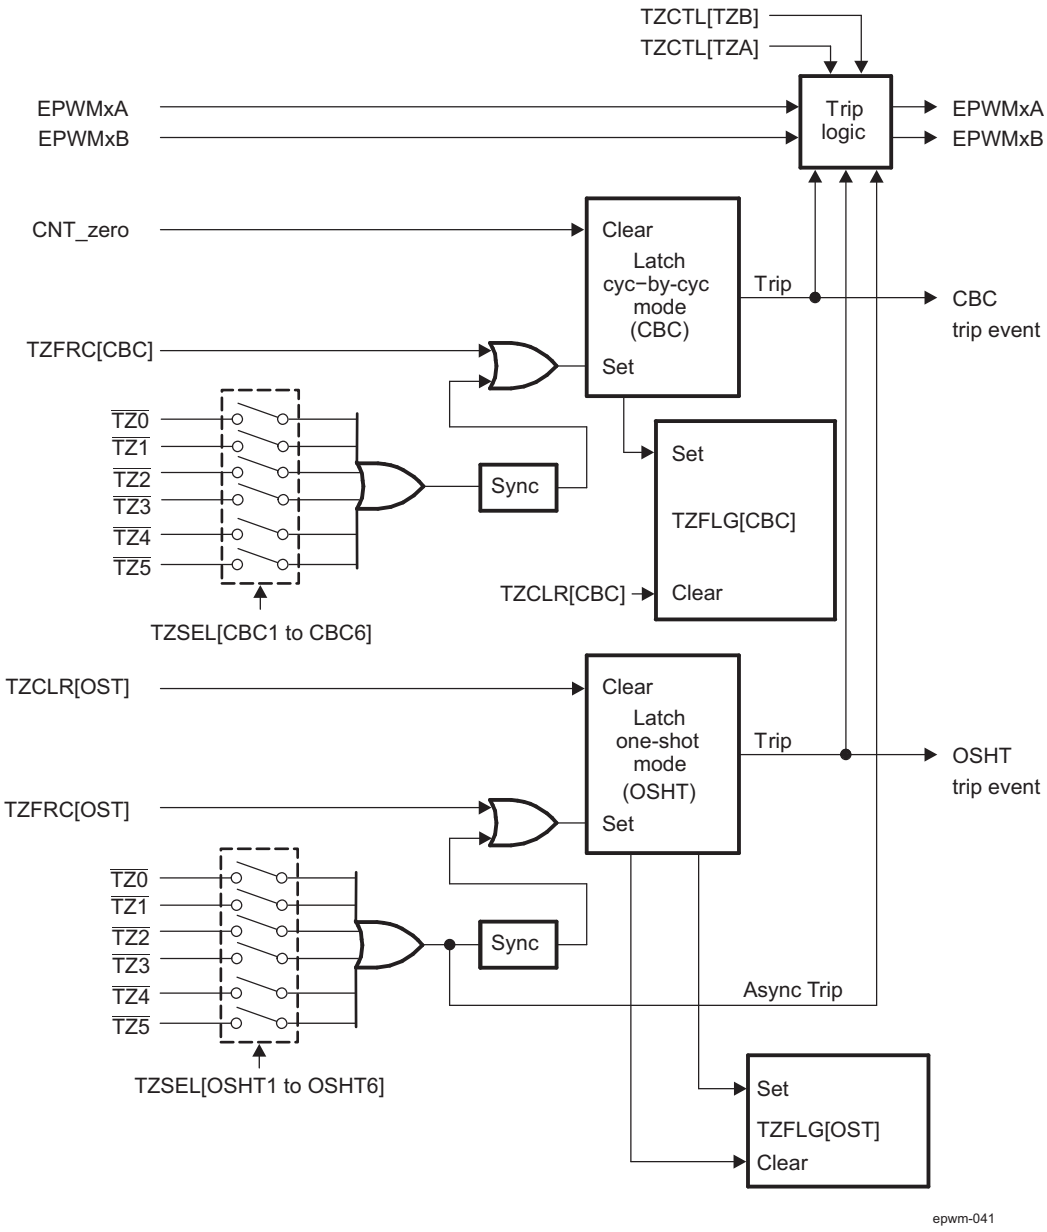


Figure 11-390. ePWM Trip-Zone Submodule Interrupt Logic

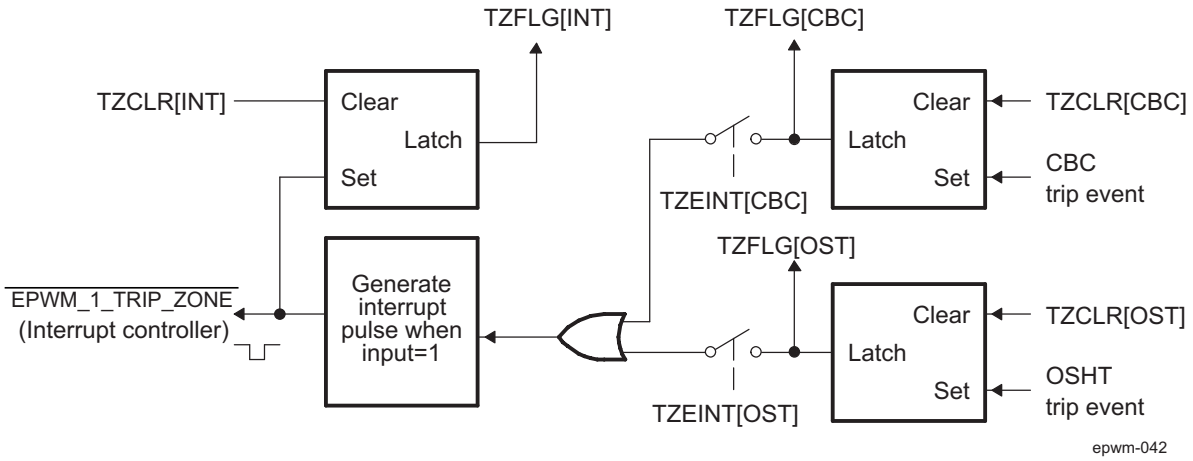


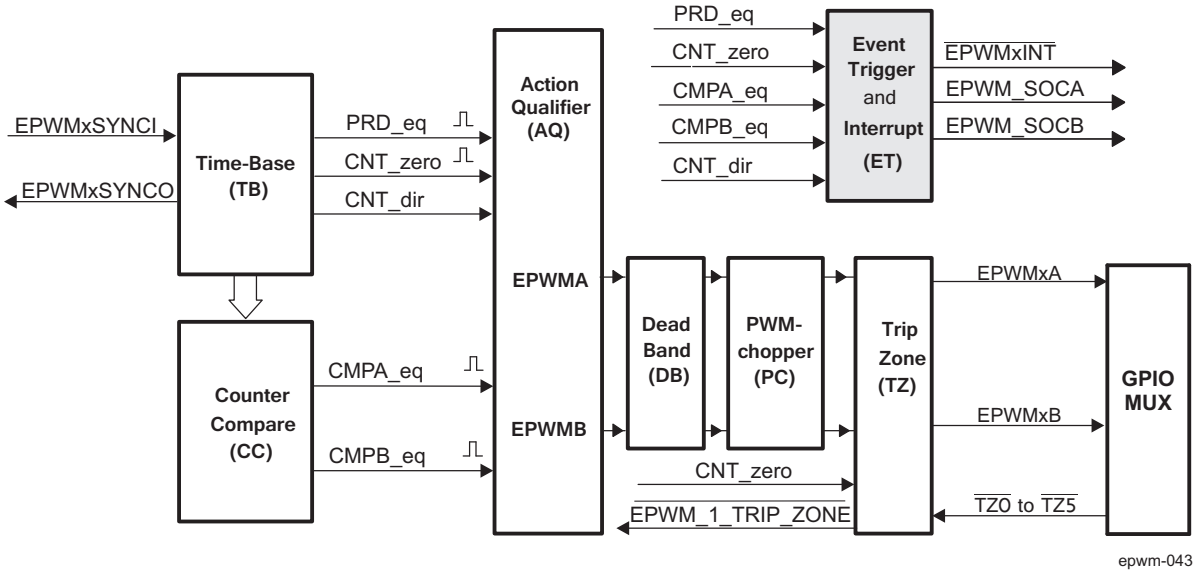
11.5.4.8 ePWM Event-Trigger (ET) Submodule

This section describes the Event-Trigger (ET) submodule in the PWM module.

11.5.4.8.1 Overview

Figure 11-391 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

Figure 11-391. ePWM Event-Trigger Submodule



The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event.
- Provides full visibility of event generation via event counters and flags

11.5.4.8.2 Controlling and Monitoring the ePWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 11-824:

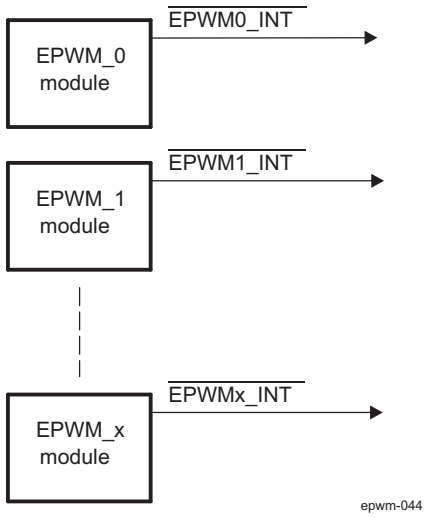
Table 11-824. ePWM Event-Trigger Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

11.5.4.8.3 Operational Overview of the ePWM Event-Trigger Submodule

Each ePWM module has one interrupt request line as shown in Figure 11-392. Mapping interrupt lines to device host interrupt controllers is device specific and is covered in the Section 11.6.3.

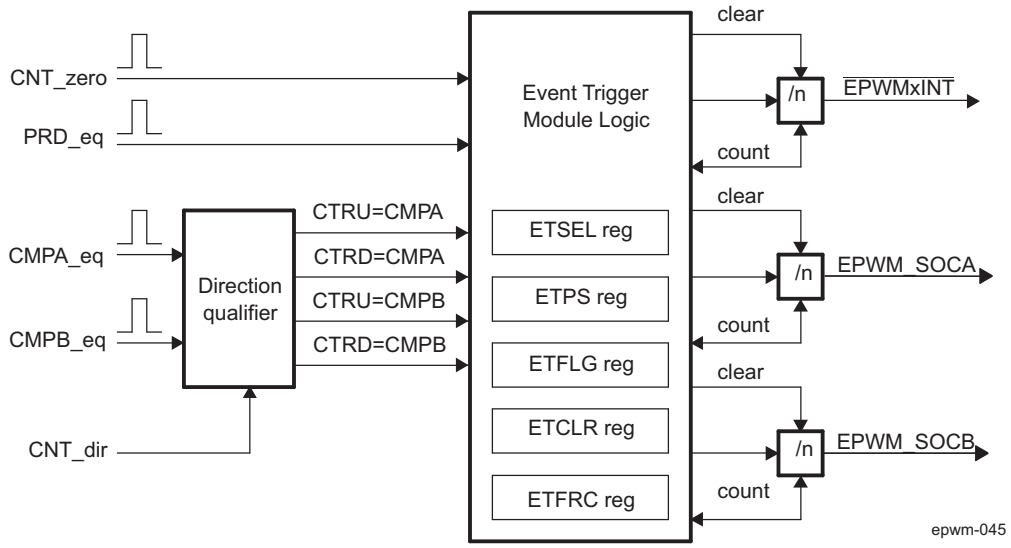
Figure 11-392. ePWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller



The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 11-393) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

Figure 11-393. ePWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs



- ETSEL — This selects which of the possible events will trigger an interrupt.
- ETPS — This programs the event prescaling options previously mentioned.
- ETFLG — These are flag bits indicating status of the selected and prescaled events.
- ETCLR — These bits allow to clear the flag bits in the EPWM_ETFLG register via software.
- ETFRC — These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in Figure 11-394.

Figure 11-394 shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM_ETPS[1-0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM_ETSEL[2-0] INTSEL) bits. The event can be one of the following:

- Time-base counter equal to zero (EPWM_TBCNT bitfield TBCNT = 0000h).
- Time-base counter equal to period (EPWM_TBCNT bitfield TBCNT = TBPRD value in EPWM_TBPRD active register).
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM_ETPS[3-2] INTCNT) register bits. That is, when the specified event occurs the EPWM_ETPS[3-2] INTCNT bits are incremented until they reach the value specified by EPWM_ETPS[1-0] INTPRD. When EPWM_ETPS[3-2] INTCNT = EPWM_ETPS[1-0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM_ETPS[3-2] INTCNT reaches EPWM_ETPS[1-0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM_ETSEL[3] INTEN = 1 and the interrupt flag is clear, EPWM_ETFLG[0] INT = 0, then an interrupt pulse is generated and the interrupt flag is set, EPWM_ETFLG[0] INT = 1, and the event counter is cleared EPWM_ETPS[3-2] INTCNT = 0. The counter will begin counting events again.
- If interrupts are disabled, EPWM_ETSEL[3] INTEN = 0, or the interrupt flag is set, EPWM_ETFLG[0] INT = 1, the counter stops counting events when it reaches the period value EPWM_ETPS[3-2] INTCNT = EPWM_ETPS[1-0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the EPWM_ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the EPWM_ETFRC[0] INT bit is also ignored.

Figure 11-394. ePWM Event-Trigger Interrupt Generator

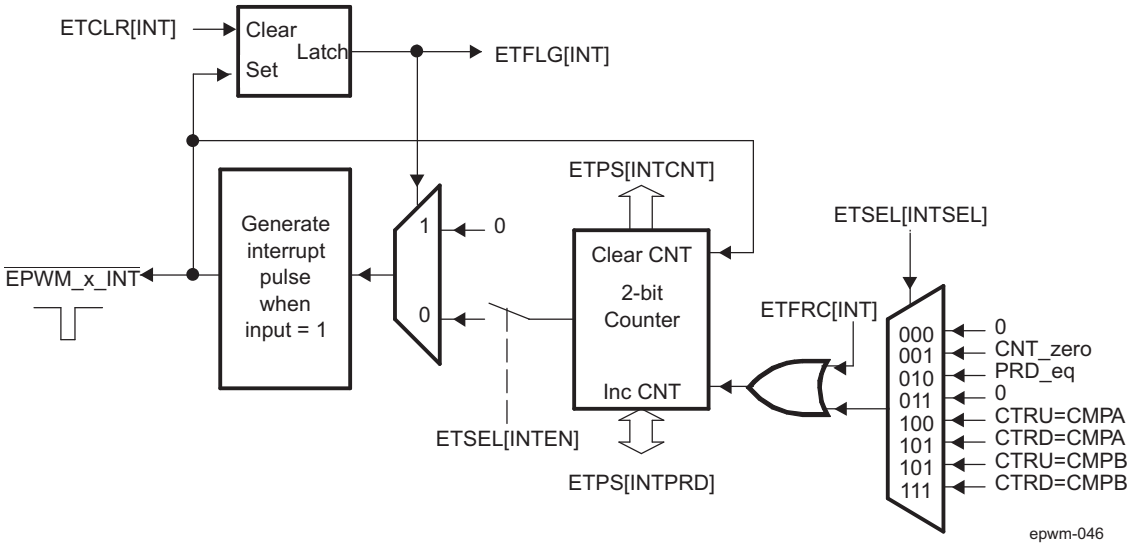


Figure 11-395 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The EPWM_ETPS[11-10] SOCACNT counter and EPWM_ETPS[9-8] SOCAPRD period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag EPWM_ETFLG[2] SOCA is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit EPWM_ETSEL[11] SOCAEN stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the EPWM_ETSEL[10-8] SOCASEL and EPWM_ETSEL[14-12] SOCBSEL bits. The possible events are the same events that can be specified for the interrupt generation logic.

Figure 11-395. ePWM Event-Trigger SOCA Pulse Generator

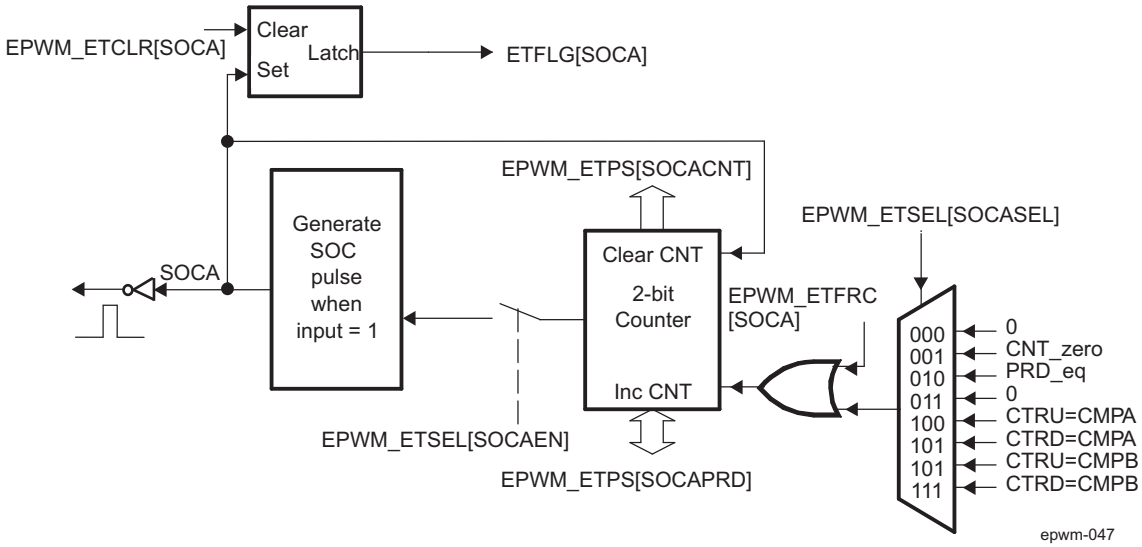

Figure 11-396 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

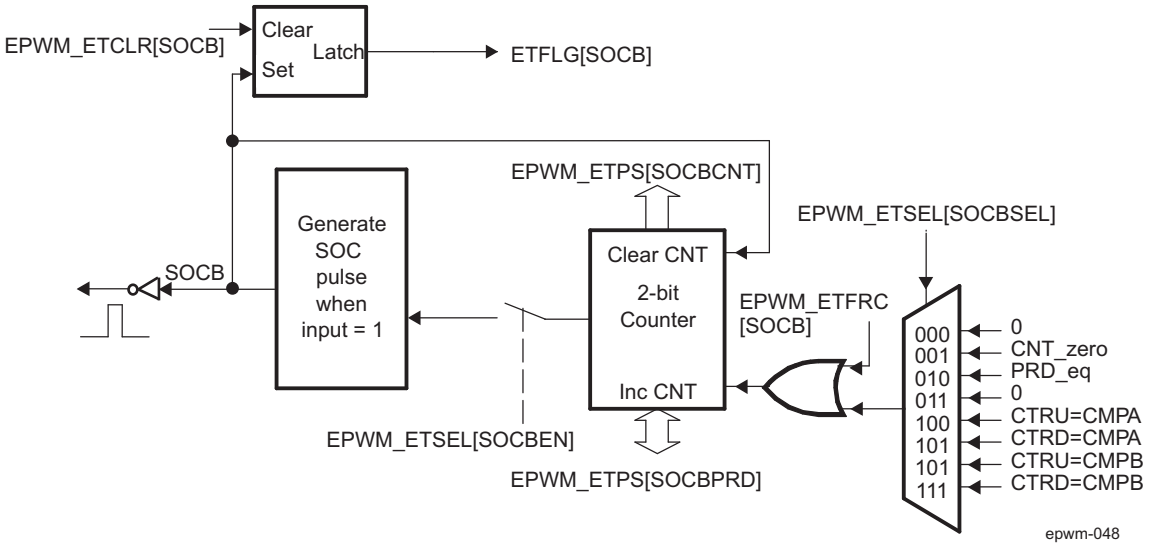
Figure 11-396. ePWM Event-Trigger SOCB Pulse Generator



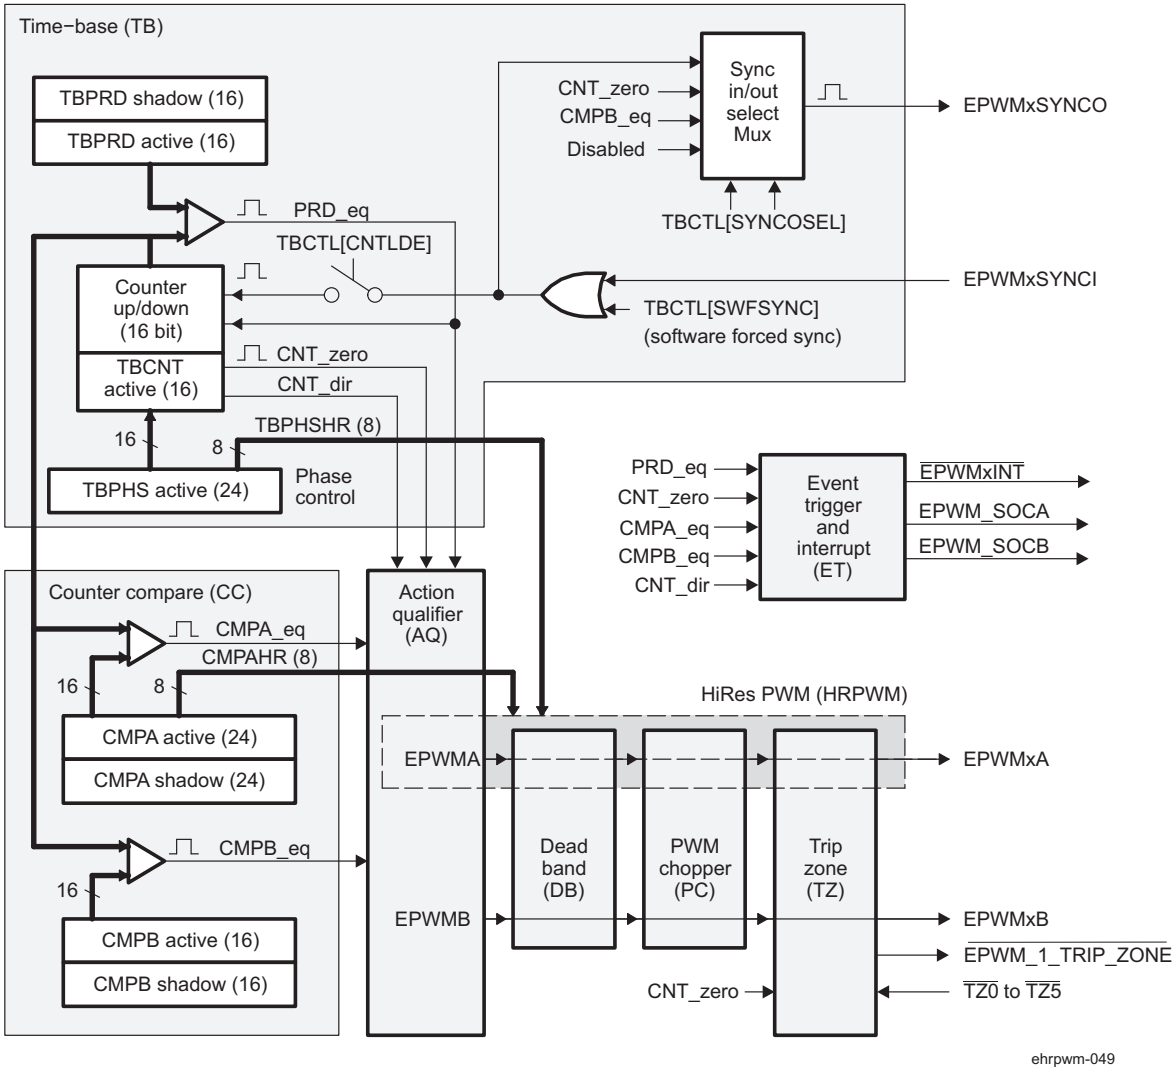
11.5.4.9 ePWM High Resolution (HRPWM) Submodule

This section describes the High-Resolution PWM (HRPWM) submodule in the PWM module.

11.5.4.9.1 Overview

Figure 11-397 shows the high-resolution PWM (HRPWM) submodule in the ePWM system. Some devices include the high-resolution PWM submodule, see Section 11.6.3 to determine which ePWM instances include this feature.

Figure 11-397. HRPWM System Interface



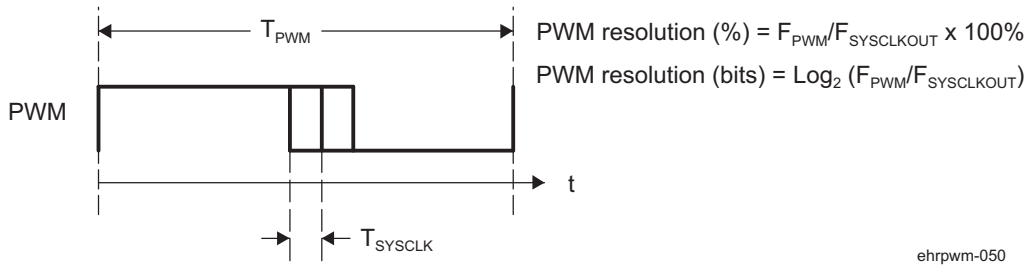
The high-resolution pulse-width modulator (HRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits.
The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. **EPWMxB output has**

conventional PWM capabilities.

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 11-398, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 11-398. Resolution Calculations for Conventionally Generated PWM



Use HRPWMI when the required PWM operating frequency does not offer sufficient resolution in PWM mode. As an example of improved performance offered by HRPWM, Table 11-825 shows resolution in bits for various PWM frequencies. Table 11-825 values assume a MEP step size of 180 ps. See the device Data Manual for typical and maximum performance specifications for the MEP.

Table 11-825. Resolution for PWM and HRPWM

	Regular Resolution (PWM)		High Resolution (HRPWM)	
PWM Frequency (kHz)	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

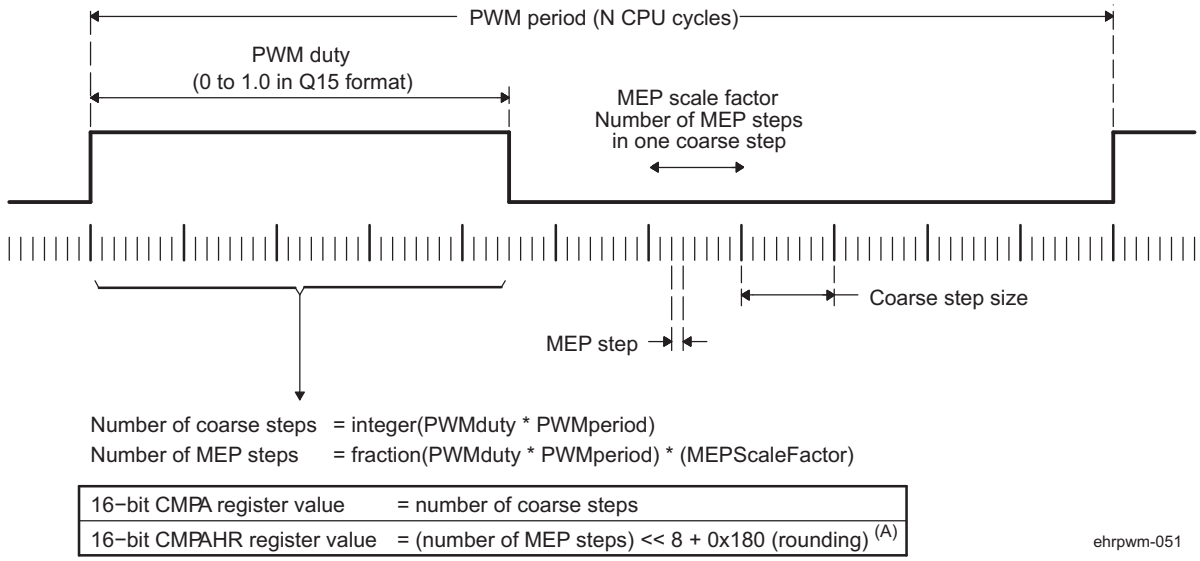
- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers.

11.5.4.9.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 11-399 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM_CMPAHR).

Figure 11-399. Operating Logic Using MEP



A For MEP range and rounding adjustment.

To generate an HRPWM waveform of a given frequency and polarity, the user needs to configure the TBM (Time-Base Module), CCM (Counter-Compare Module), and AQM (Action-Qualifier Module) registers. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

11.5.4.9.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM_TBPHS and EPWM_CMPA registers used to control PWM operation.

- HRPWM_TBPHSHR — Time-Base Phase High-Resolution Register
- HRPWM_CMPAHR — Counter-Compare A High-Resolution Register.

Table 11-826 lists the registers used to control and monitor the high-resolution PWM submodule.

Table 11-826. HRPWM Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	40h	No

11.5.4.9.4 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRPWM_HRCTL register located at offset address 40h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the HRPWM_CMPAHR register

(duty cycle control) or the HRPWM_TBPHSHR register (phase control). RE or FE control mode should be used with HRPWM_CMPAHR register. BE control mode should be used with HRPWM_TBPHSHR register.

- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the HRPWM_CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If HRPWM_TBPHSHR is used, then this option has no effect.

11.5.4.9.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM (Time-Base Module) and CCM (Counter-Compare Module) registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. Table 11-827 shows the typical range of operating frequencies supported by the HRPWM.

Table 11-827. Relationship Between MEP Steps, PWM Frequency and Resolution

System (MHz)	MEP Steps Per VBUS_CLK[1] [2] [3]	PWM Minimum (Hz)[4]	PWM Maximum (MHz)	Resolution at Maximum (Bits)[5]
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) System frequency = VBUS_CLK, that is, CPU clock. TBCLK = VBUS_CLK
(2) Table data based on a MEP time resolution of 180 ps (this is an example value)
(3) MEP steps applied = T_{VBUS_CLK}/180 ps in this example.
(4) PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.
(5) Resolution in bits is given for the maximum PWM frequency stated.

11.5.4.9.5.1 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, and so forth) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. Figure 11-400 shows that duty cycle of 40% (a compare value of 32 counts) is the closest to 40.5%. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 11-828.

Utilizing MEP allows to achieve an edge position much closer to the desired point of 324 ns. Table 11-828 shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

Figure 11-400. Required PWM Waveform for a Requested Duty = 40.5%

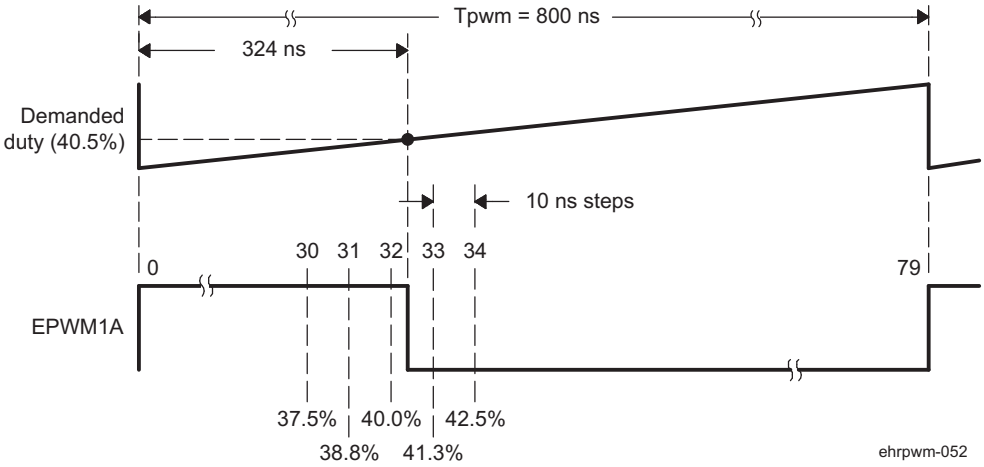


Table 11-828. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count)[1] [2] [3]	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

(1) System clock, VBUS_CLK and TBCLK = 100 MHz, 10 ns
(2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz
(3) Assumed MEP step size for the above example = 180 ps

11.5.4.9.5.2 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM_CMPA) and MEP (HRPWM_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, VBUS_CLK	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, **PWMDuty**	=	0.405 (40.5%)
PWM period in terms of coarse steps, **PWMperiod** (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), **MEP_SF**	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	180h

Step 1: Percentage Integer Duty value conversion for EPWM_CMPA register

EPWM_CMPA register value	=	int(**PWMDuty** × **PWMperiod**); int means integer part
	=	int(0.405 × 80)
	=	int(32.4)
EPWM_CMPA register value	=	32 (20h)

Step 2: Fractional value conversion for HRPWM_CMPAHR register

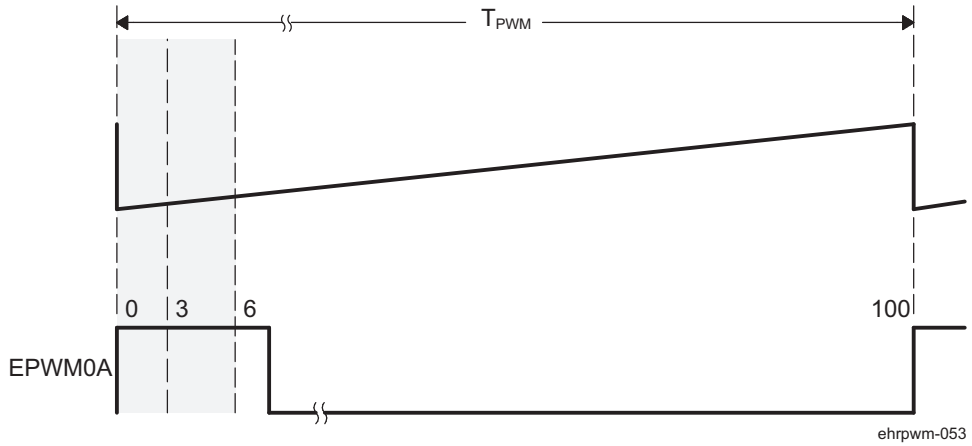
HRPWM_CMPAHR register value	=	(frac(**PWMDuty** × **PWMperiod**) × **MEP_SF**) << 8) + 180h; frac means fractional part
	=	(frac(32.4) × 55 <<8) + 180h; Shift is to move the value as CMPAHR high byte
	=	((0.4 × 55) <<8) + 180h
	=	(22 <<8) + 180h
	=	22 × 256 + 180h ; Shifting left by 8 is the same multiplying by 256.
	=	5632 + 180h
	=	1600h + 180h
HRPWM_CMPAHR value	=	1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

11.5.4.9.5.3 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 VBUS_CLK cycles after the period starts.

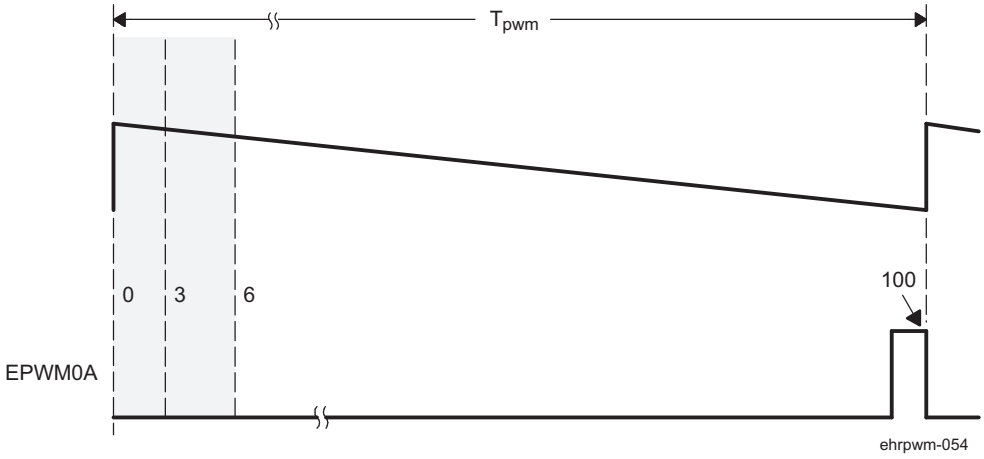
Duty cycle range limitations are illustrated in Figure 11-401. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

Figure 11-401. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz



If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 11-402. In this case low percent duty limitation is no longer an issue.

Figure 11-402. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz



11.5.4.10 ePWM / HRPWM Functional Register Groups

The Table 11-829 lists the groups of ePWM and the high-resolution PWM module registers according to their functionalities.

Table 11-829. ePWM / HRPWM Module Control and Status Registers Grouped by Submodule

Register Name	Offset	Size (×16)	Shadow	Register Description
Time-Base (TB) Submodule Registers				
EPWM_TBCTL	0h	1	No	Time-Base Control Register

Table 11-829. ePWM / HRPWM Module Control and Status Registers Grouped by Submodule (continued)

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
Counter-Compare (CC) Submodule Registers				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
Action-Qualifier (AQ) Submodule Registers				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
Dead-Band (DB) Generator Submodule Registers				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
Trip-Zone (TZ) Submodule Registers				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register (1)
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register (1)
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register (1)
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register (1)
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register (1)
Event-Trigger (ET) Submodule Registers				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
PWM-Chopper Submodule Registers				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register
High-Resolution PWM (HRPWM) Submodule Registers				
HRPWM_TBPHSHR	4h	1	No	Extension for HRPWM Phase Register
HRPWM_CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register
HRPWM_HRCTL	40h	1	No	HRPWM Control Register

(1) EALLOW protected registers.

11.5.4.11 Proper ePWM Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it is possible that interrupt flags may be set due to spurious events as the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag).
2. Disable ePWM interrupts.
3. Initialize peripheral registers.
4. Clear any spurious ePWM flags.
5. Enable ePWM interrupts.
6. Enable global interrupts.

11.5.5 ePWM Registers

Table 11-831 lists the memory-mapped registers for the ePWM. All register offset addresses not listed in Table 11-831 should be considered as reserved locations and the register contents should not be modified.

This section describes the ePWM instances registers. This section describes the ePWM instances registers.

Table 11-834. EPWM_TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0h = Stop after the next time-base counter increment or decrement 1h = Stop when counter completes a whole cycle. (a) Up-count mode: stop when the time-base counter = period (EPWM_TBCNT bitfield TBCNT = TBPRD in EPWM_TBPRD active register). (b) Down-count mode: stop when the time-base counter = 0000 (EPWM_TBCNT bitfield TBCNT = 0000h). (c) Up-down-count mode: stop when the time-base counter = 0000 (EPWM_TBCNT bitfield TBCNT = 0000h). 2h = Free run 3h = Free run
13	PHSDIR	R/W	0h	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (EPWM_TBCNT) will count after a synchronization event occurs and a new phase value is loaded from the phase (EPWM_TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0h = Count down after the synchronization event. 1h = Count up after the synchronization event.

Table 11-834. EPWM_TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12-10	CLKDIV	R/W	0h	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT / (HSPCLKDIV x CLKDIV) 0h = /1 (default on reset) 1h = /2 2h = /4 3h = /8 4h = /16 5h = /32 6h = /64 7h = /128
9-7	HSPCLKDIV	R/W	0h	High-Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT / (HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 0h = /1 1h = /2 (default on reset) 2h = /4 3h = /6 4h = /8 5h = /10 6h = /12 7h = /14
6	SWFSYNC	R/W	0h	Software Forced Synchronization Pulse. 0h = Writing a 0 has no effect and reads always return a 0. 1h = Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWMxSYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 00.
5-4	SYNCOSEL	R/W	0h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0h = EPWMxSYNC: 1h = TBCNT = 0: Time-base counter equal to zero (EPWM_TBCNT bitfield TBCNT= 0000h) 2h = TBCNT = CMPB: Time-base counter equal to counter-compare B (EPWM_TBCNT bitfield TBCNT = CMPB bitfield in EPWM_CMPB) 3h = Disable EPWMxSYNCO signal
3	PRDLD	R/W	0h	Active Period Register Load From Shadow Register Select 0h = The period register (EPWM_TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero. A write or read to the EPWM_TBPRD register accesses the shadow register. 1h = Load the EPWM_TBPRD register immediately without using a shadow register. A write or read to the EPWM_TBPRD register directly accesses the active register.
2	PHSEN	R/W	0h	Counter Register Load From Phase Register Enable 0h = Do not load the time-base counter (EPWM_TBCNT) from the time-base phase register (EPWM_TBPHS) 1h = Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit.

Table 11-834. EPWM_TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	CTRMODE	R/W	0h	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0h = Up-count mode 1h = Down-count mode 2h = Up-down-count mode 3h = Stop-freeze counter operation (default on reset)

Table 11-837. EPWM_TBSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	CTRMAX	R/W1C	0h	Time-Base Counter Max Latched Status Bit. 0h = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 1h = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.
1	SYNCI	R/W1C	0h	Input Synchronization Latched Status Bit. 0h = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 1h = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.
0	CTRDIR	R	0h	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via EPWM_TBCTL[1-0] CTRMODE. 0h = Time-Base Counter is currently counting down. 1h = Time-Base Counter is currently counting up.

Table 11-858. EPWM_CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	CMPA	R/W	0h	The value in the active EPWM_CMPA register is continuously compared to the time-base counter (register EPWM_TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the EPWM_AQCTLA and EPWM_AQCTLB registers. The actions that can be defined in the EPWM_AQCTLA and EPWM_AQCTLB registers include the following. (a) Do nothing the event is ignored. (b) Clear: Pull the EPWMxA and/or EPWMxB signal low. (c) Set: Pull the EPWMxA and/or EPWMxB signal high. (d) Toggle the EPWMxA and/or EPWMxB signal. Shadowing of this register is enabled and disabled by the EPWM_CMPCTL[4] SHDWAMODE bit. By default this register is shadowed. (a) If EPWM_CMPCTL[4] SHDWAMODE = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the EPWM_CMPCTL[1-0] LOADAMODE bit field determines which event will load the active register from the shadow register. (b) Before a write, the EPWM_CMPCTL[8] SHDWAFULL bit can be read to determine if the shadow register is currently full. (c) If EPWM_CMPCTL[4] SHDWAMODE = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (d) In either mode, the active and shadow registers share the same memory map address.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-876. EPWM_DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-6	RESERVED	R	0h	Reserved
5-4	IN_MODE	R/W	0h	Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWMxA In is the source for both falling and rising-edge delays. 0h = EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 1h = EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 2h = EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 3h = EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.
3-2	POLSEL	R/W	0h	Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that EPWM_DBCTL[1-0] OUT_MODE = 0b11 and EPWM_DBCTL[5-4] IN_MODE = 0b00. Other enhanced modes are also possible, but not regarded as typical usage modes. 0h = Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 1h = Active low complementary (ALC) mode. EPWMxA is inverted. 2h = Active high complementary (AHC). EPWMxB is inverted. 3h = Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.

Table 11-876. EPWM_DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay. 0h = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect. 1h = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by EPWM_DBCTL[5-4] IN_MODE. 2h = Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by EPWM_DBCTL[5-4] IN_MODE. 3h = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by EPWM_DBCTL[5-4] IN_MODE.

2	CBC2	R/W	0h	Trip-zone 2 (TZ2) select. Cycle-by-Cycle (CBC) trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the EPWM_TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero. 0h: Disable TZ2 as a CBC trip source for this ePWM module. 1h: Enable TZ2 as a CBC trip source for this ePWM module.
1	CBC1	R/W	0h	Trip-zone 1 (TZ1) select. Cycle-by-Cycle (CBC) trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the EPWM_TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero. 0h: Disable TZ1 as a CBC trip source for this ePWM module. 1h: Enable TZ1 as a CBC trip source for this ePWM module.
0	CBC0	R/W	0h	Trip-zone 0 (TZ0) select. Cycle-by-Cycle (CBC) trip-zone enable/disable. When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the EPWM_TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero. 0h: Disable TZ0 as a CBC trip source for this ePWM module. 1h: Enable TZ0 as a CBC trip source for this ePWM module.

Table 11-894. EPWM_TZFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event. 0h = No one-shot trip event has occurred. 1h = Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the EPWM_TZCLR register.
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0h = No cycle-by-cycle trip event has occurred. 1h = Indicates a trip event has occurred on a pin selected as a cycle-by-cycle trip source. The EPWM_TZFLG[1] CBC bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (EPWM_TBCNT bitfield TBCNT = 0000h) if the trip condition is no longer present. The condition on the pins is only cleared when the TBCNT = 0000h no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the EPWM_TZCLR register.
0	INT	R	0h	Latched Trip Interrupt Status Flag 0h = Indicates no interrupt has been generated. 1h = Indicates an EPWMxTZINT interrupt was generated because of a trip condition. No further EPWMxTZINT interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the EPWM_TZCLR register.

9-8	SOCAPRD	R/W	0h	EPWMxSOCA Period Select: These bits select how many selected event need to occur before an SOCA pulse is generated: 0h: Disable counter 1h: Generate pulse on SOCACNT = 1 (1st event) 2h: Generate pulse on SOCACNT = 2 (2nd event) 3h: Generate pulse on SOCACNT = 3 (3rd event)
7-4	RESERVED	R	0h	Reserved

Table 11-906. EPWM_ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected EPWM_ETSEL[2-0] INTSEL events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, EPWM_ETSEL[0] INT = 0 or the interrupt flag is set, EPWM_ETFLG[0] INT = 1, the counter will stop counting events when it reaches the period value EPWM_ETPS[3-2] INTCNT = EPWM_ETPS[1-0] INTPRD. 0h: No events have occurred. 1h: 1 event has occurred. 2h: 2 events have occurred. 3h: 3 events have occurred.
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected EPWM_ETSEL[2-0] INTSEL events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (EPWM_ETSEL[0] INT = 1). If the interrupt status flag is set from a previous interrupt (EPWM_ETFLG[0] INT = 1) then no interrupt will be generated until the flag is cleared via the EPWM_ETCLR[0] INT bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the EPWM_ETPS[3-2] INTCNT bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 0h: Disable the interrupt event counter. No interrupt will be generated and EPWM_ETFRC[0] INT is ignored. 1h: Generate an interrupt on the first event INTCNT = 01 (first event) 2h: Generate interrupt on EPWM_ETPS[3-2] INTCNT = 0b10 (second event) 3h: Generate interrupt on EPWM_ETPS[3-2] INTCNT = 0b11 (third event)

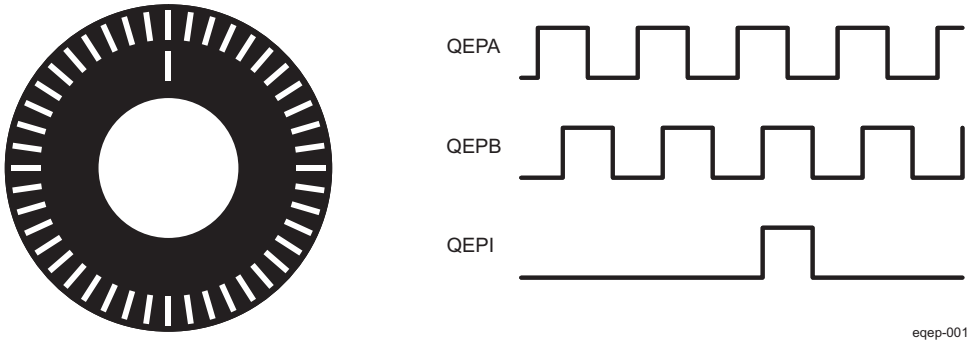
11.6 Enhanced Quadrature Encoder Pulse (eQEP) Module

This section describes the Enhanced Quadrature Encoder Pulse (eQEP) module for the device.

11.6.1 eQEP Overview

A single track of slots patterns the periphery of an incremental encoder disk, as shown in Figure 11-433. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position and zero reference.

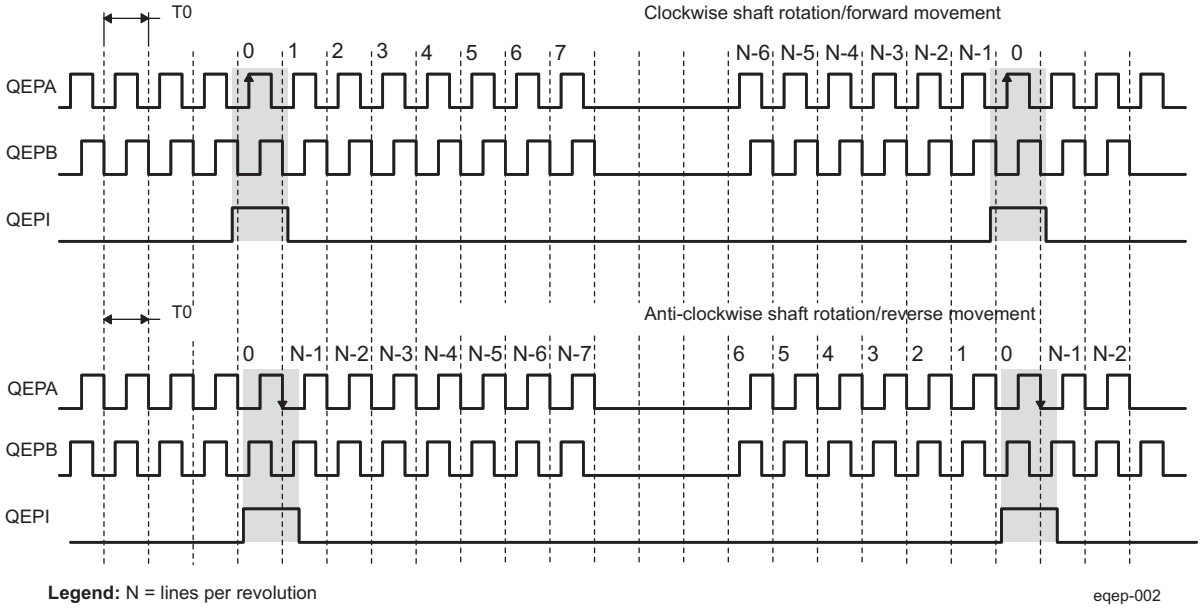
Figure 11-433. Optical Encoder Disk



To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vise versa as shown in Figure 11-434.

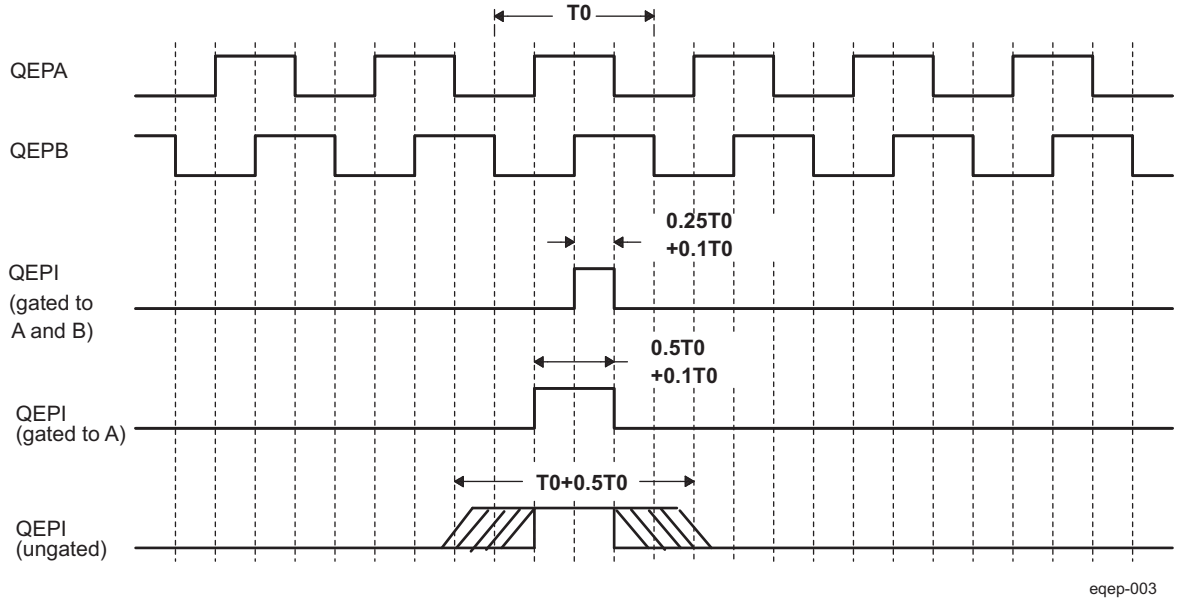
The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Figure 11-434. QEP Encoder Output Signal for Forward/Reverse Movement



Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 11-435. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 11-435. Index Pulse Example



Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside a PC mouse – the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{eqep-004} \tag{5}$$

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad \text{eqep-005} \tag{6}$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 5 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 5 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 6 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 6 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 5. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 6 at low speed and have the software switch over to Equation 5 when the motor speed rises above some specified threshold.

11.6.2 eQEP Environment

11.6.2.1 eQEP I/O Interface

Table 11-923 shows the device integrated eQEP subsystems interface signals to external devices.

Table 11-923. eQEP Subsystems I/O Signals

eQEP Modules Level Signal Name	Device Level Signal Name	I/O Type[1]	Description	Module Pin Reset Value
eQEP_0				
EQEP0_A	eQEP0_A	I	eQEP_0 Quadrature input	HiZ

eQEP_2	EQEP_2_INT	–		[30]	eQEP_2 event to the EDMA_1

11.6.3.1 Device Specific eQEP Features

The eQEP module interface have some restrictions in functionality. The eQEP restrictions are, as follows:

- **Only eQEP inputs (A/ B / INDEX and STROBE) are available to user at chip level**
- **eQEP phase error output (EQEP_ERR_PHASE_ERR) is also available**
  - The status of the phase error can be observed by software using the BOOTCFG_EQEP_STAT status register in the BOOT_CFG module.

The eQEP functional interface signals which are NOT available to user are summarized in Table 11-927.

Table 11-927. Device Limitations for the eQEP Functional Interfaces

Module Interface	Signal	Description	Comment
eQEP_n (where n= 0 to 2 for the device)	EQEP_EQEPA_O	eQEP quadrature A output	Not available at chip boundary (can not be used)
	EQEP_EQEPB_O	eQEP quadrature B output	
	EQEP_EQEPA_OEN	eQEP quadrature A output enable	
	EQEP_EQEPB_OEN	eQEP quadrature B output enable	

11.6.4 eQEP Functional Description

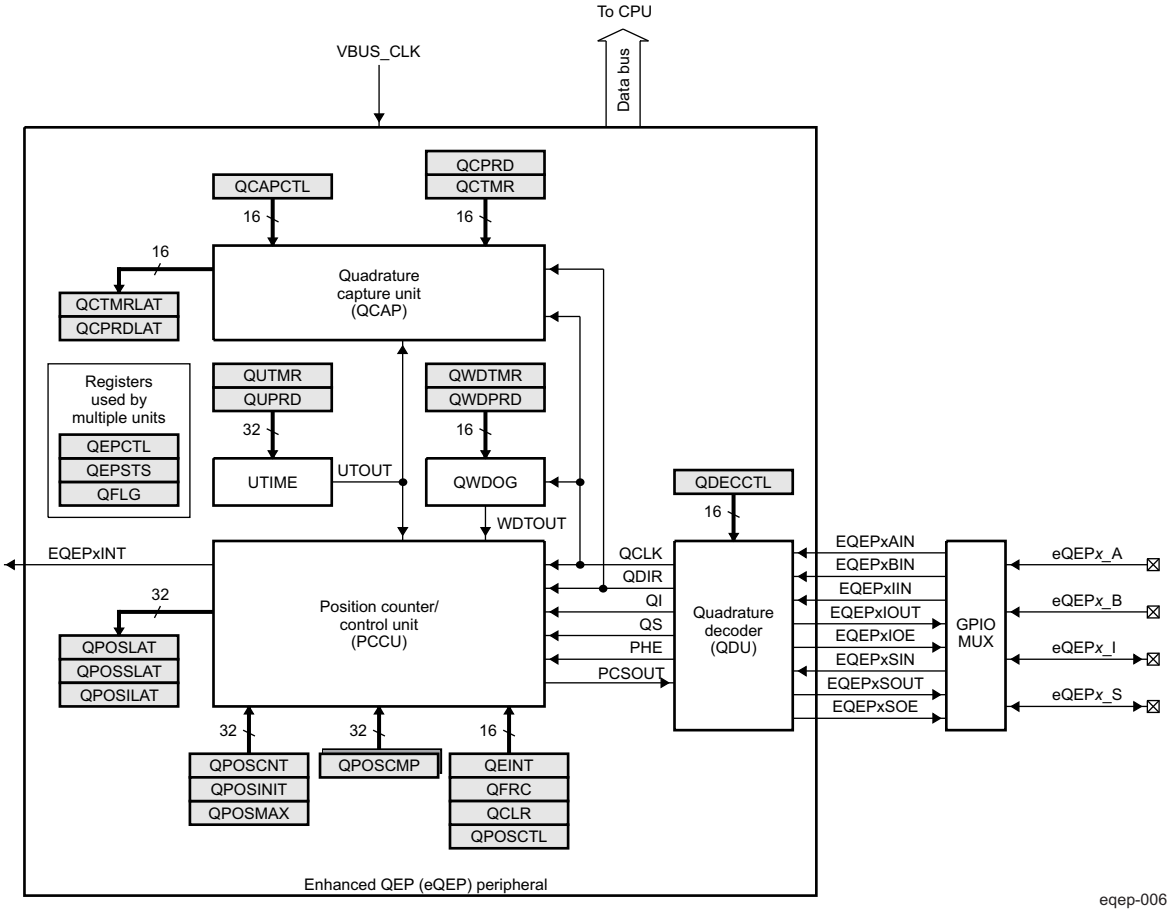
This section provides the eQEP functional description and corrsponding functional details about EQEPx inputs.

NOTE: Multiple identical eQEP modules can be contained in a system. For actual number of eQEP modules integrated in the device, refer to the Section 11.6.3, *eQEP Integration*. The letter x within a signal or module name is used to indicate a generic eQEP instance on a device. For example, output interrupt request, EQEP_0_INT belongs to eQEP0, EQEP_1_INT belongs to eQEP1, and so forth.

The eQEP peripheral contains the following major functional units (as shown in Figure 11-438):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG).

Figure 11-438. Functional Block Diagram of the eQEP Peripheral



11.6.4.1 eQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- eQEPx_A and eQEPx_B: These two pins can be used in quadrature-clock mode or direction-count

mode.

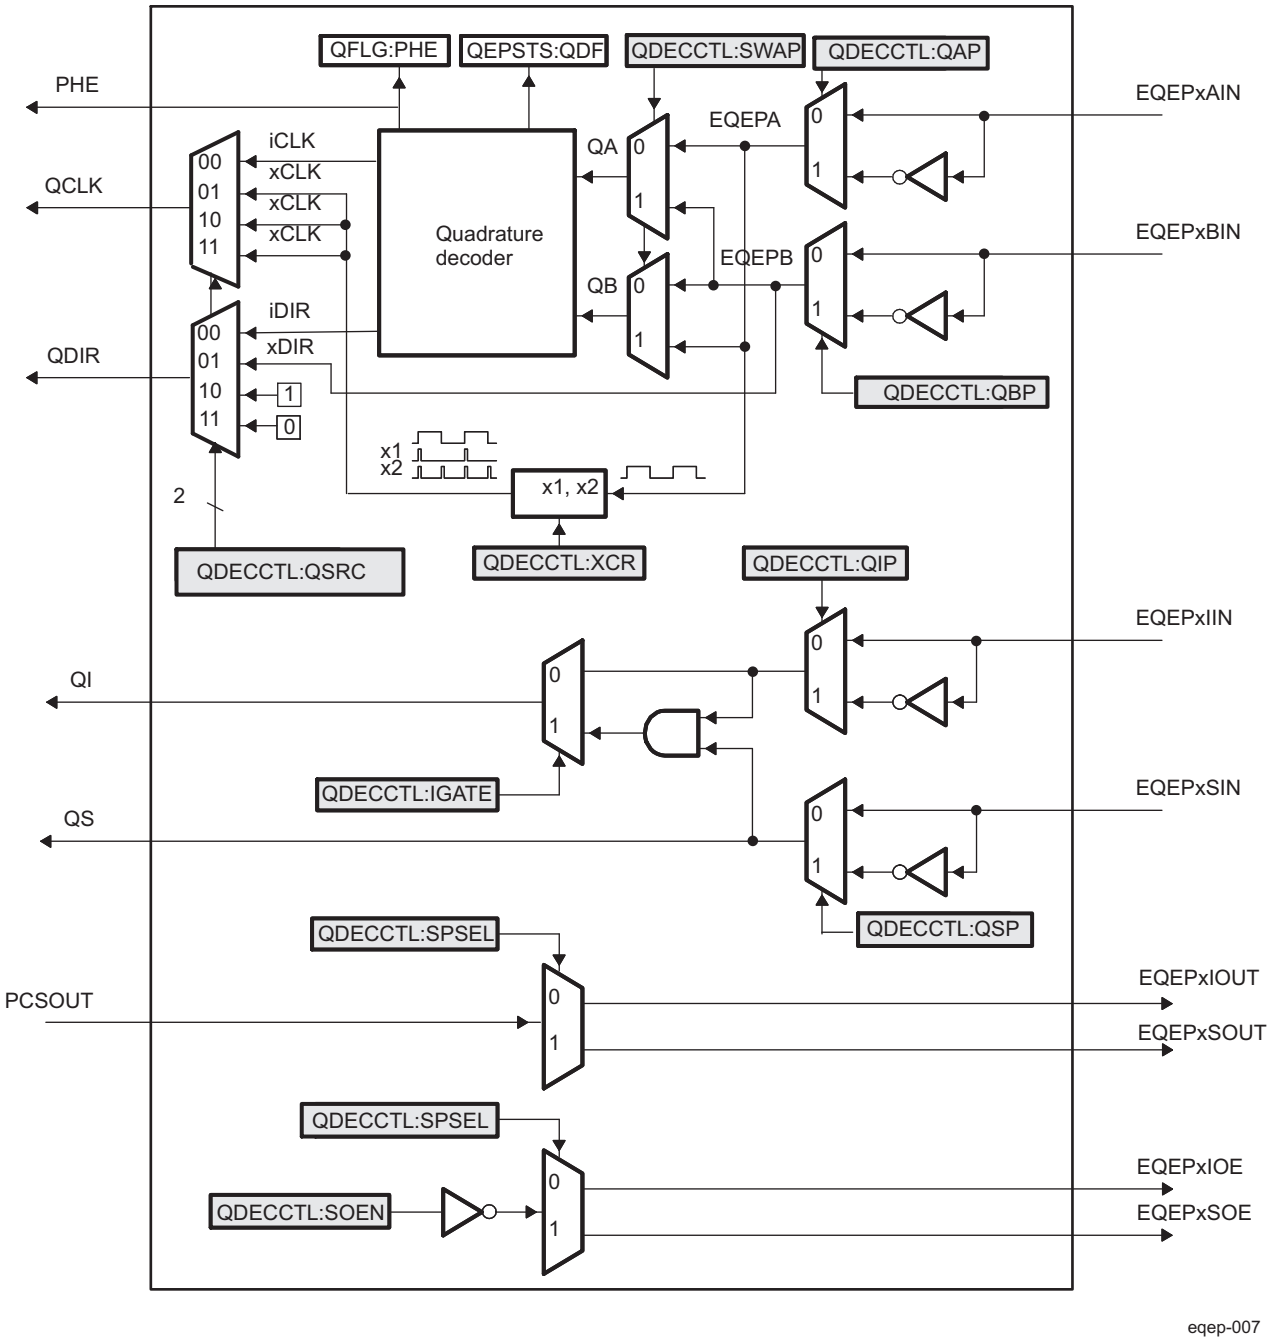
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The eQEPx_A pin provides the clock input and the eQEPx_B pin provides the direction input.

- eQEPx_I: Index or Zero Marker: The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- eQEPx_S: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

11.6.4.2 eQEP Quadrature Decoder Unit (QDU)

Figure 11-439 shows a functional block diagram of the QDU.

Figure 11-439. Functional Block Diagram of Decoder Unit



11.6.4.2.1 eQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the eQEP decoder control register (EQEP_QDECCTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode.

11.6.4.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding — The direction decoding logic of the eQEP circuit determines which one of the sequences (EQEPA, EQEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the eQEP status register (EQEP_QEPSTS). Table 11-928 and Figure 11-440 show the direction decoding logic in truth table and state machine form. Both edges of the EQEPA and EQEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 11-441 shows the direction decoding and clock generation from the eQEP input signals.

Phase Error Flag — In normal operating conditions, quadrature inputs EQEPA and EQEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the EQEP_QFLG register when edge transition is detected simultaneously on the EQEPA and EQEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 11-440 are invalid transitions that generate a phase error.

Count Multiplication — The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (EQEPA and EQEPB) as shown in Figure 11-441.

Reverse Count — In normal quadrature count operation, EQEPA input is fed to the QA input of the quadrature decoder and the EQEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the eQEP decoder control register (EQEP_QDECCTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

Table 11-928. Quadrature Decoder Truth Table

Previous Edge	Present Edge	QDIR	QPOSCNT

	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

Figure 11-440. Quadrature Decoder State Machine

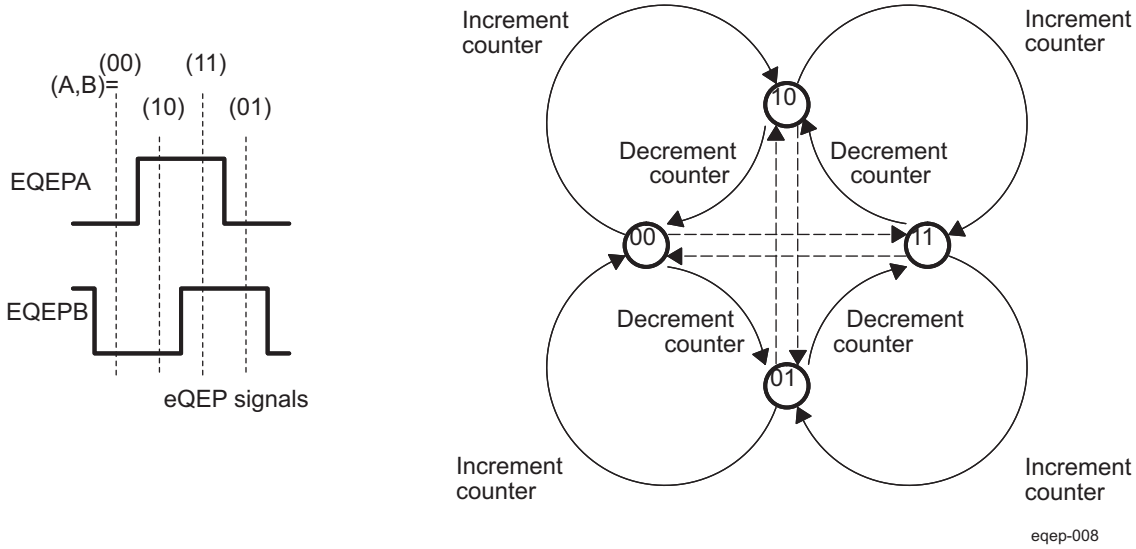

Figure 11-441. Quadrature-clock and Direction Decoding

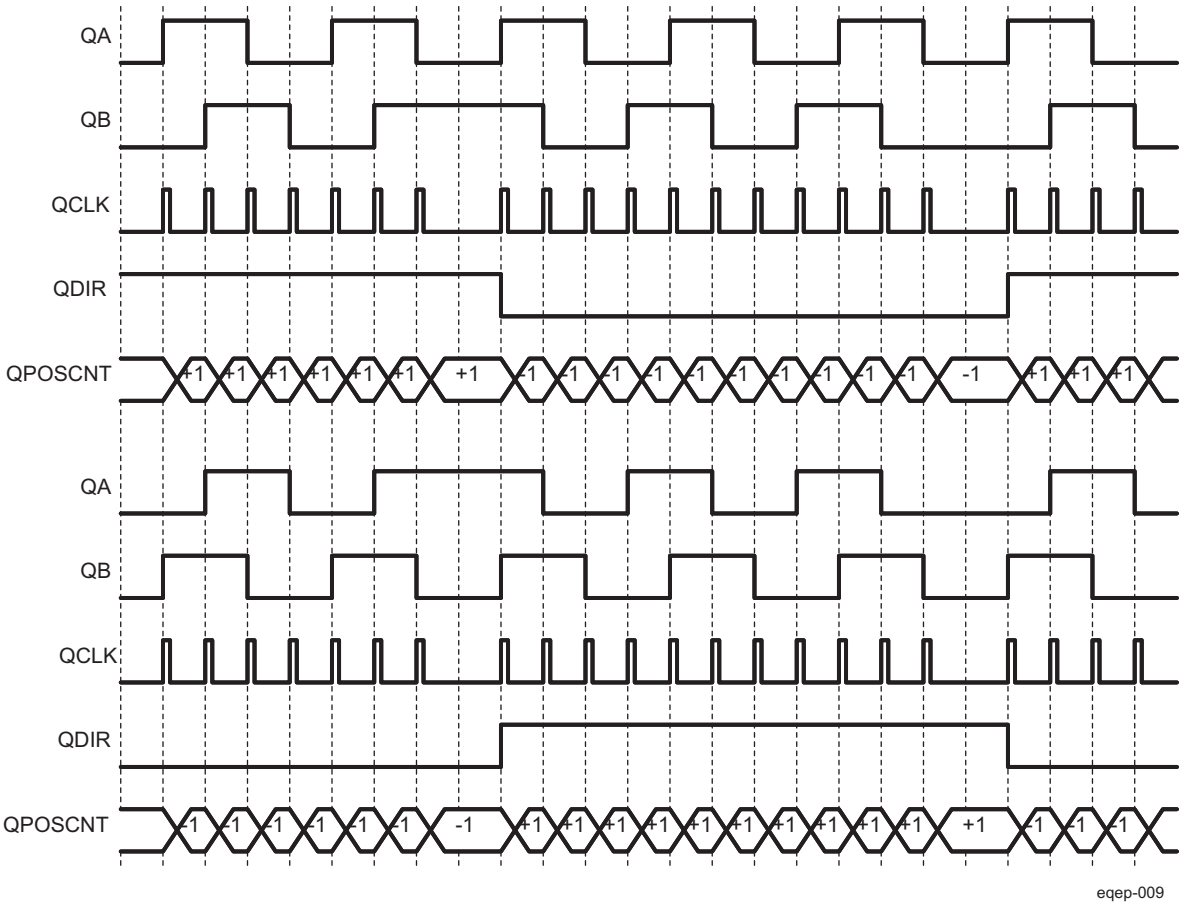


11.6.4.2.1.2 eQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. EQEPA input will provide the clock for position counter and the EQEPB input will have the direction information. The position counter is incremented on every rising edge of a EQEPA input when the direction input is high and decremented when the direction input is low.

11.6.4.2.1.3 eQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the eQEP decoder control register (EQEP_QDECCTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

11.6.4.2.1.4 eQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the eQEP decoder control register (EQEP_QDECCTL) enables clock generation to the position counter on both edges of a EQEPA input, thereby increasing the measurement resolution by 2× factor.

11.6.4.2.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using the in the eQEP decoder control register (EQEP_QDECCTL[8-5]) control bits. As an example, setting of the QIP bit in EQEP_QDECCTL inverts the index input.

11.6.4.2.3 eQEP Position-Compare Sync Output

The eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP_QPOSCNT) and the position-compare register (EQEP_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the eQEP decoder control register (EQEP_QDECCTL) enables the position-compare sync output and the SPSEL bit in EQEP_QDECCTL selects either an eQEP index pin or an eQEP strobe pin.

11.6.4.3 eQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP_QEPCTL and EQEP_QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

11.6.4.3.1 eQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement).

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX bifield value in EQEP_QPOSMAX register on underflow. Overflow occurs when the position counter counts up after QPOSMAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP_QFLG register.

11.6.4.3.1.1 eQEP Position Counter Reset on Index Event (EQEP_QEPCTL[31-12] PCRM] = 0b00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next eQEP clock.

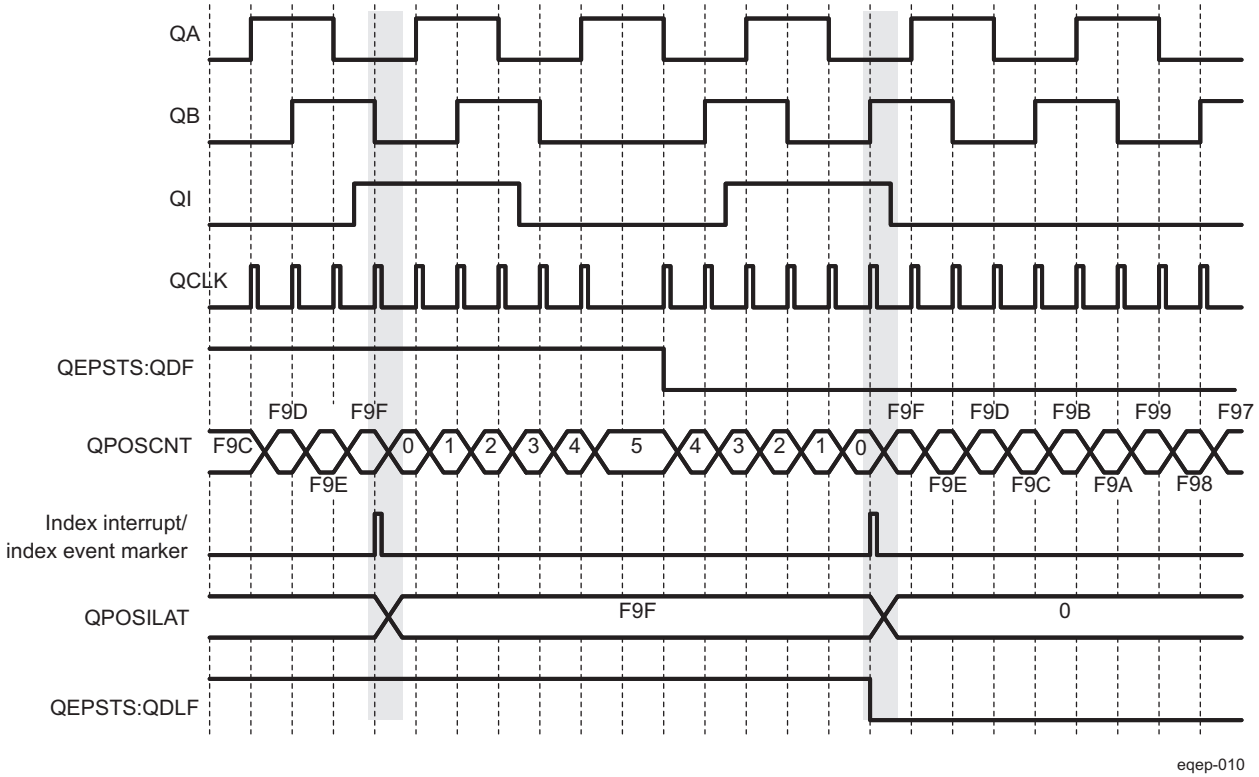
First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of EQEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of EQEPB for the forward rotation and on the rising edge of EQEPB for the reverse rotation as shown in Figure 11-442.

The position-counter value is latched to the EQEP_QPOSILAT register and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (EQEP_QEPSTS[PCEF]) and error interrupt flag (EQEP_QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (EQEP_QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (EQEP_QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration EQEP_QEPCTL[5-4] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

Figure 11-442. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)

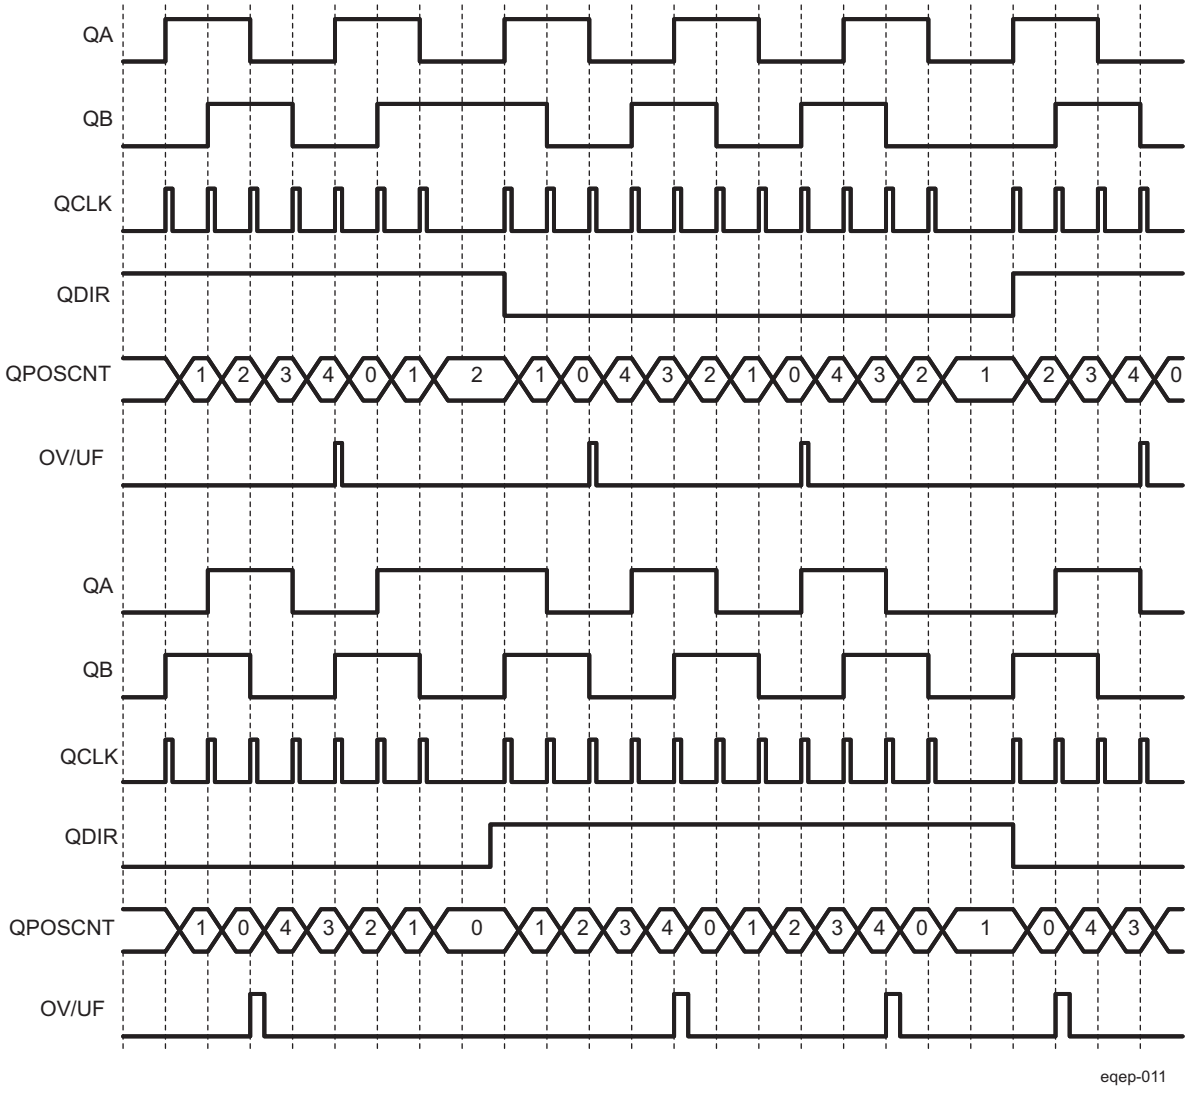


11.6.4.3.1.2 eQEP Position Counter Reset on Maximum Position (EQEP_QEPCTL[13-12] PCRM=0b01)

If the position counter is equal to QPOSMAX (in EQEP_QPOSMAX register), then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 11-443 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP_QEPCTL[5-4] IEL=0b11).

Figure 11-443. Position Counter Underflow/Overflow (QPOSMAX = 4)



11.6.4.3.1.3 Position Counter Reset on the First Index Event (EQEP_QEPCTL[13-12] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 11.6.4.3.1.2.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP_QEPCTL[5-4] IEL= 0b11).

11.6.4.3.1.4 Position Counter Reset on Unit Time out Event (EQEP_QEPCTL[13-12] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP_QPOSLAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP_QPOSMAX register, depending on the direction mode selected by EQEP_QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

11.6.4.3.2 eQEP Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP_QPOSCNT) into QPOSILAT (EQEP_QPOSILAT register) and QPOSSLAT (EQEP_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

11.6.4.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP_QEPCTL[13-12] PCRM = 0b01 and EQEP_QEPCTL[13-12] PCRM = 0b10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (EQEP_QEPCTL[5-4] IEL = 0b01)
- Latch on Falling edge (EQEP_QEPCTL[5-4] IEL = 0b10)
- Latch on Index Event Marker (EQEP_QEPCTL[5-4] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP_QFLG[10] IEL) is set when the position counter is latched to the EQEP_QPOSILAT register. The index event latch configuration bits are ignored when EQEP_QEPCTL[13-12] PCRM = 0b00.

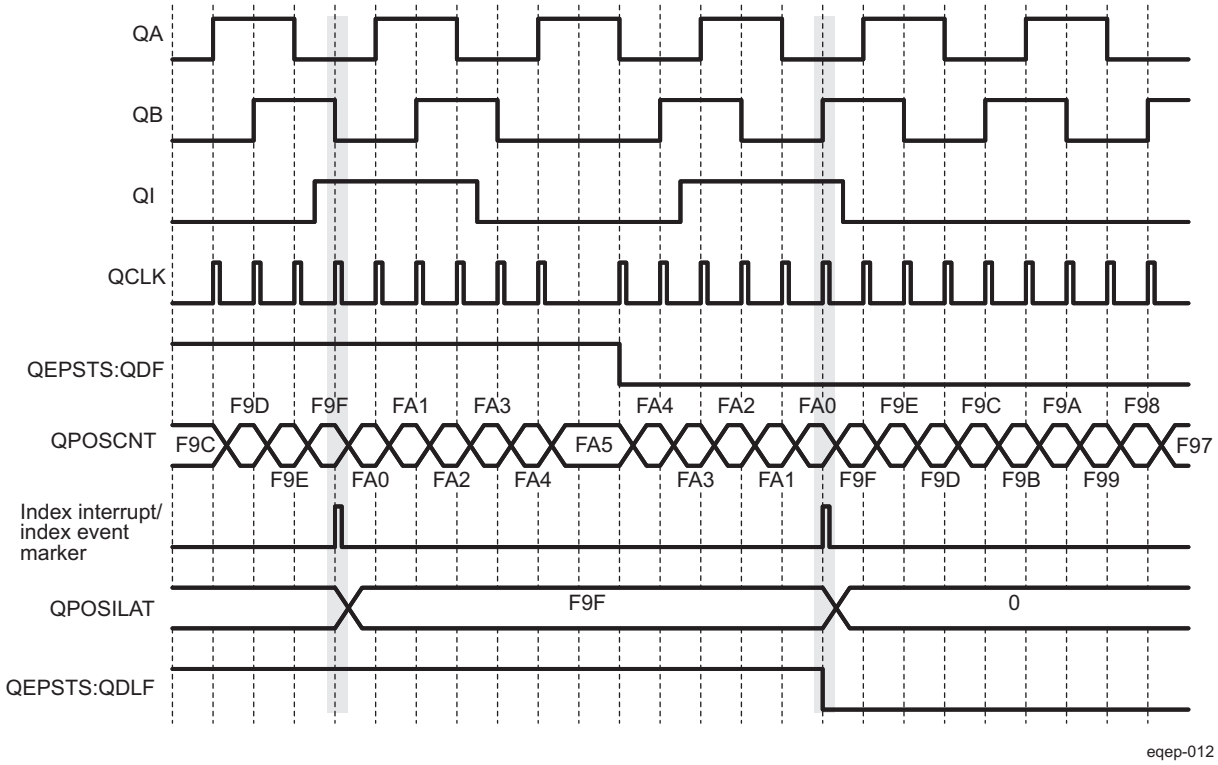
Latch on Rising Edge (EQEP_QEPCTL[5-4] IEL = 0b01) — The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (EQEP_QEPCTL[5-4] IEL = 0b10) — The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (EQEP_QEPCTL[5-4] IEL = 0b11) — The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (EQEP_QEPCTL[5-4] IEL = 0b11).

Figure 11-444 shows the position counter latch using an index event marker.

Figure 11-444. Software Index Marker for 1000-line Encoder (EQEP_QEPCTL[5-4] IEL = 0b01)



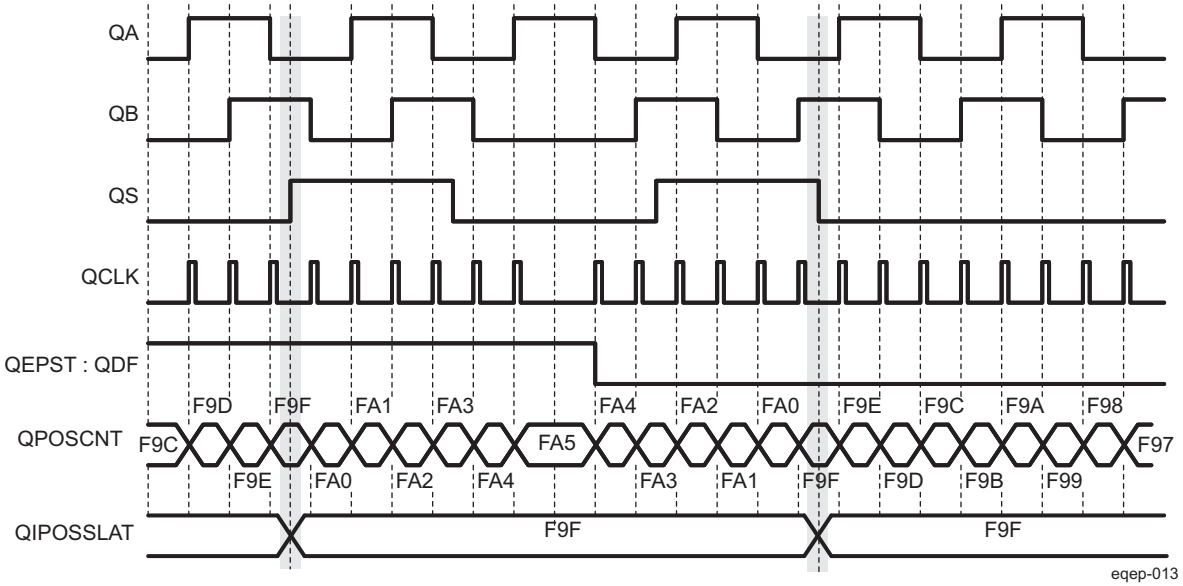
11.6.4.3.2.2 eQEP Strobe Event Latch

The position-counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input by clearing the EQEP_QEPCTL[6] SEL bit.

If the EQEP_QEPCTL[6] SEL bit is set, then the position counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in Figure 11-445.

The strobe event latch interrupt flag (EQEP_QFLG[SEL]) is set when the position counter is latched to the EQEP_QPOSSLAT register.

Figure 11-445. eQEP Strobe Event Latch (EQEP_QEPCTL[6] SEL = 0b1)



11.6.4.3.3 eQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization.

Index Event Initialization (IEI) — The eQEPx_I index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP_QEPCTL[9-8] IEI bits are 0b10, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP_QFLG[IEI]) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

Strobe Event Initialization (SEI) — If the EQEP_QEPCTL[11-10] SEI bits are 0b10, then the position counter is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input.

If the EQEP_QEPCTL[11-10] SEI bits are 0b11, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

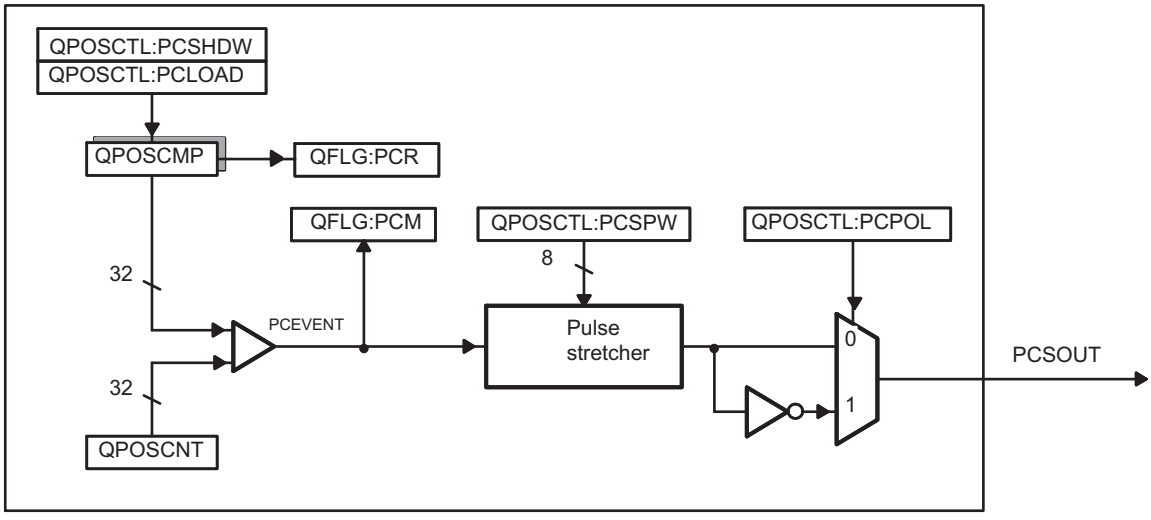
The strobe event initialization interrupt flag (EQEP_QFLG[SEI]) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

Software Initialization (SWI) — The position counter can be initialized in software by writing a '1' to the EQEP_QEPCTL[7] SWI bit, which will automatically be cleared after initialization.

11.6.4.3.4 eQEP Position-Compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 11-446 shows a diagram. The position-compare (EQEP_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP_QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 11-446. eQEP Position-compare Unit



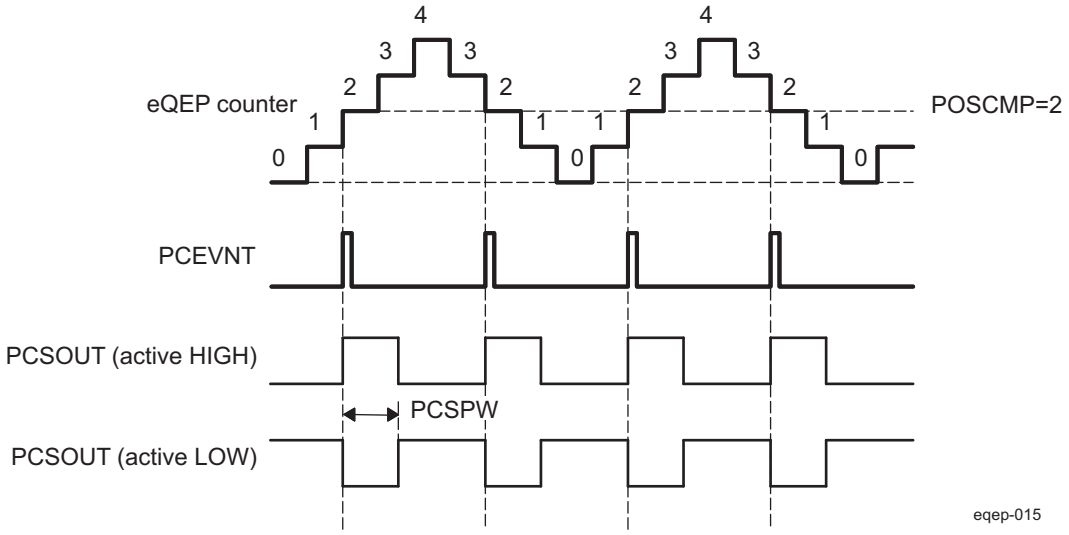
In shadow mode, SW can configure the position-compare unit (EQEP_QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP_QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event.

The position-compare match (EQEP_QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

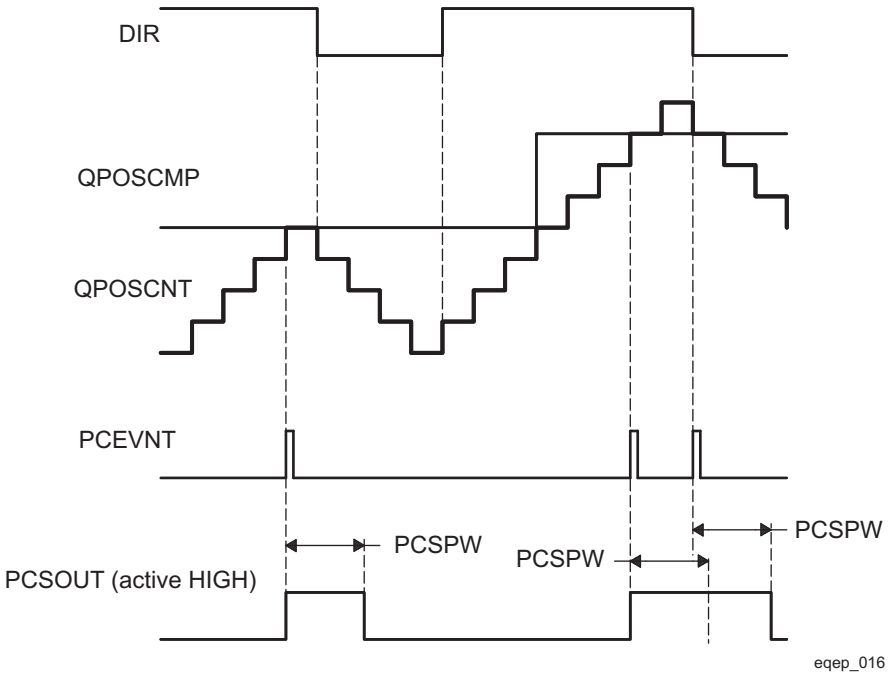
For example, if EQEP_QPOSCMP bitfield QPOSCMP = 0x2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 11-447).

Figure 11-447. eQEP Position-compare Event Generation Points



The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 11-448.

Figure 11-448. eQEP Position-compare Sync Output Pulse Stretcher



11.6.4.4 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 11-449. This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

eqep-017 (7)

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 11-450)
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR bitfield in EQEP_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP_QCAPCTL[CCPS] bits. The capture timer QCTMR value is latched into the capture period register (EQEP_QCPRD) on every unit position event and then the capture timer is reset, a flag is set in EQEP_QEPSTS[UPEVNT] to indicate that new value is latched into the EQEP_QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

NOTE: The system clock — SYSCLKOUT is the eQEP functional clock derived from the PWMSSn gateable interface and functional clock PWMSSn_GICLK, described in Section 11.6.3, *eQEP Integration*.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:
