Revision History

Changes from H Revision (May 2018) to I Revision **Page**

- Added Table Note for USB in Table Device Memory Map 215
- Updated ARMSS Endian Support Details in Section ARMSS Endian Configuration Registers and BOOTCFG_DEVSTAT Register 336
- Updated PLL Controller Base Address in Register Section of Section Clock Management 569
- Updated ARMSS Endian Support Details in Section Features, Section AXI2VBUS_MASTER Overview, and AXI2VBUS_CPU0_END Register 597
- Fixed Typo in GPIO Pin Numbers Controlled by GPIO Registers 2676
- Updated MMCHS_HCTL[2] HSPE and MMCHS_CAPA[21] HSS Bits in Section MMC/SD 3304
- Added Clarification in Section QSPI Overview 3965

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for the device, visit the Texas Instruments website at www.ti.com.

Introduction

This chapter introduces the features, subsystems, and architecture of 66AK2G1x System on Chip (SoC).

Topic **Page**

1.1 Device Overview

The 66AK2G1x SoC is a high performance, highly integrated device based on TI KeyStone II Multicore SoC architecture. It incorporates the performance optimized Arm® Cortex®-A15 and a C66x DSP core, built to meet the processing and system level integration needs of industrial communications and control, automotive and performance audio applications.

The device is targeted for a variety of applications which include, but are not limited to:

- Automotive Audio Amplifiers
- Home Audio
- Professional Audio
- Computer Navigational Control (Motion Control)
- Smart Grid (Intelligent Electric Device)
- Industrial Programmable Logic Control (PLC)
- Test and Measurement

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

The device is composed of the following main subsystems, among others:

- One Arm subsystem (ARMSS), based on a single-core Cortex-A15 processor
- One Digital Signal Processor (DSP) C66x subsystem
- Two dual-core Programmable Real-time Unit and Industrial Communication Subsystems (PRU-ICSS)
- One Display subsystem (DSS)
- One Network subsystem (NSS), consisting of Ethernet MAC (EMAC), Navigator subsystem (NAVSS), and Security Accelerator (SA)

The device provides a rich set of connectivity peripherals:

- Two USB 2.0 High Speed subsystems with integrated PHY
- One single-lane PCI Express Gen2 subsystem
- Peripherals for general connectivity, including I2C (x3), SPI (x4), UART (x3), and GPIO (x2)
- Media and storage interfaces, including one GPMC, one Quad-SPI, and MMC/SD (x2) interfaces
- Audio peripherals, including McASP (x3), one McBSP interface, and one Asynchronous Audio Sample Rate Converter (ASRC)
- Automotive interfaces, including CAN (x2), and one MediaLB® interface
- Industrial and control interfaces, including ePWM (x6), eCAP (x2), and eQEP (x3) interfaces

The device includes a dedicated power manager micro controller (PMMC), facilitating power and sleep control (PSC) management, power state transitions, and power related system configurations.

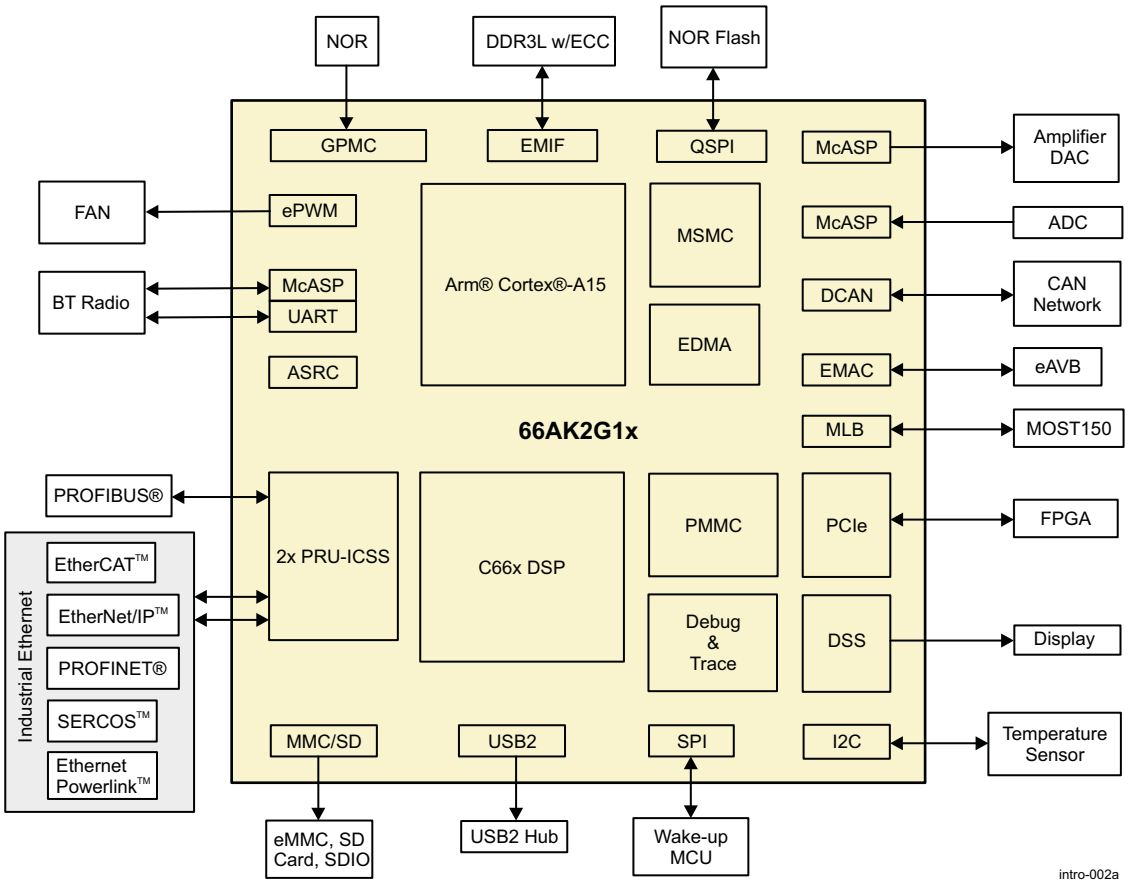
The device also integrates the following components, among others:

- Multicore Shared Memory Controller (MSMC)
- DDR External Memory Interface (EMIF)
- Message Manager (MSGMGR)
- Seven 64-bit Timer modules
- Semaphore
- Enhanced DMA controller (EDMA)
- Debug and Trace subsystem

1.2 Device Environment

Figure 1-1 is an example for a non-exhaustive connectivity diagram of the device.

Figure 1-1. Device Environment Diagram

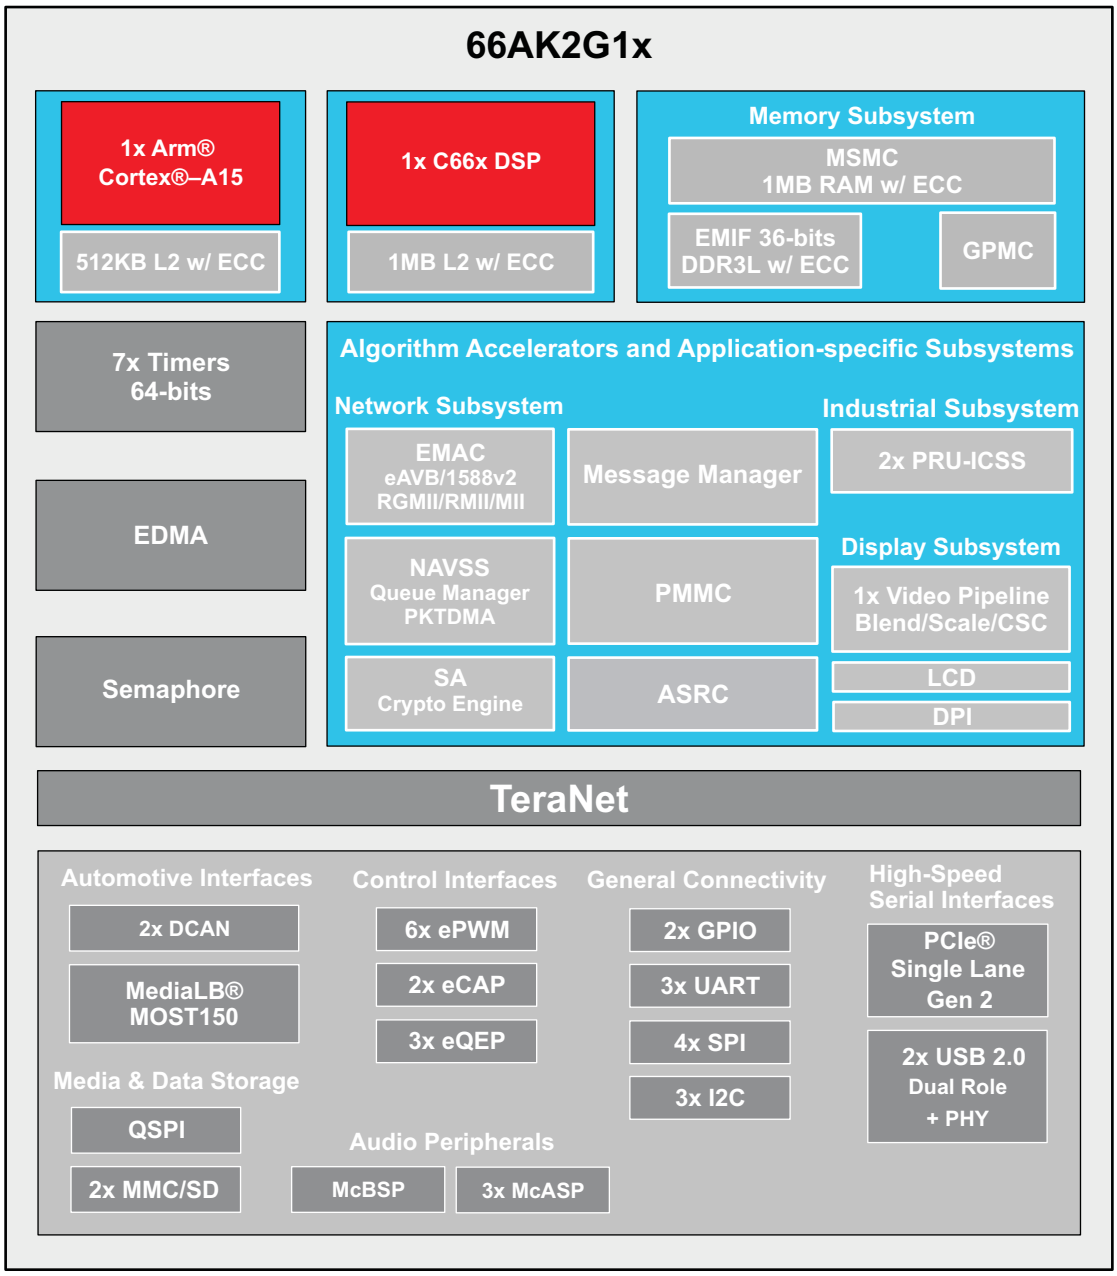


NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

1.3 Device Description

Figure 1-2 is a block diagram of the device.

Figure 1-2. Device Block Diagram



intro_001a

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

1.3.1 Arm Subsystem

The Arm Cortex-A15 subsystem provides the following main features, among others:

- Arm Cortex-A15 processor, with one central processing unit (CPU)

- Full implementation of Armv7-A architecture instruction set
- Integrated Arm® Neon™ and VFP (Vector Floating Point) unit
- 32-KB instruction and 32-KB data level 1 (L1) cache
- 512-KB level 2 (L2) cache
- Error Correction Code (ECC) protection for L1 data cache and L2 cache, parity protection for L1 instruction cache
- Support for up to four integrated general-purpose timers, in adition to one device-level watchdog timer
- Local advanced power management
- Dedicated digital phase-locked loop (ARMPLL)
- Integrated Generic Interrupt Controller (GIC)
- Debug and trace features

1.3.2 DSP Subsystem

The C66x DSP subsystem provides the following main features, among others:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- 32-KB L1D and 32-KB L1P cache or addressable SRAM
- 1024-KB local L2 cache or addressable SRAM
- Extended Memory Controller (XMC)
- Address extension unit to 36-bit address
- Memory protections for multiple segments, and for internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D, and for L2
- Integrated interrupt controller
- Support for one integrated general-purpose timer, in adition to one device-level watchdog timer
- Debug and trace features

1.3.3 Algorithm Accelerators and Application-specific Subsystems

1.3.3.1 Asynchronous Audio Sample Rate Converter (ASRC)

ASRC provides the following main features, among others:

- Hardware accelerated audio sample rate converter
- Support interpolation and decimation for asynchronous clock zone crossing for audio streams
- Capable of -140dB SNR operation
- Supports up to 16 concurrent audio channels
- Supports 4 input clock zones, and 4 output clock zones
- Up to 216 kHz sample rate input/output, sample ratios from 16:1 to 1:16
- Support direct interfacing with McASP for input or output via EDMA, without software data packing
- Two modes of operation: group mode and stream mode
- Separate DMA events for input and output for each channel and groups of channels

1.3.3.2 Display Subsystem (DSS)

DSS provides the following main features, among others:

- One video pipeline with in-loop scaling, color space conversion, and background color overlay
- Video pipeline pixel formats: BITMAP, RGB16, RGB24, RGB32, RGB48, ARGB16, ARGB32, ARGB48, YUV420, YUV422, RGB565-A8
- In-loop scaling capabilities:

  - Supports minimum of 1/4 downscaler, and up to x16 upscaler
  - Support for 5-tap (up to 1280 pixels ARGB32) or 3-tap (up to 2560 pixels ARGB32) filters
- Supported display interfaces:
  - MIPI® DPI 2.0 parallel interface
  - BT.656 4:2:2
  - BT.1120 4:2:2
  - Remote Frame Buffer Interface for MIPI DBI 2.0 support
- Display panel support features

1.3.3.3 Programmable Real-time Unit and Industrial Communication Subsystem (PRU-ICSS)

There are two PRU-ICSS in the device, each providing the following main features, among others:

- Two PRUs, each with multiplier and optional accumulator, with 16-KB program memory and 8-KB data memory
- 64-KB general purpose memory with ECC
- ECC support for all internal memories
- Two MII_RT ports configurable to connect to each PRU to support multiple industrial communication protocols
- One Industrial Ethernet Peripheral (IEP) to manage/generate Industrial Ethernet functions
- One MDIO
- One UART 16550, with a dedicated 192 MHz to support 12 Mbps PROFIBUS
- One Industrial Ethernet 64-bit timer with 9 capture and 16 compare events, alogn with slow and fast compensation
- One integrated Enhanced Capture Module (ECAP)
- Power management support

Among the interfaces supported by the PRU-ICSS are real-time industrial protocols used in master and slave mode, such as:

- EtherCAT™
- PROFINET®
- EtherNet/IP™
- PROFIBUS®
- Ethernet Powerlink™
- SERCOS™

1.3.3.4 Message Manager

Message Manager provides the following main features, among others:

- Hardware acceleration for pushing and popping messages to/from logical queues in a multicore environment
- Supports up to 512 messages, and 64 queues
- Support for (self-contained) mode with zero software initialization
- Flexible message allocation with ability to store the same message multiple times in different queues or multiple times in the same queue

1.3.3.5 Power Management Micro Controller (PMMC)

PMMC provides the following main features, among others:

- PSC management, power state transitions, and power related system configurations
- 40-KB unified memory, and 8-KB data memory for the PMMC processor, with double detection and single error correction for both memories

- Two Timer modules and one Window Watchdog Timer

1.3.3.6 Network Subsystem (NSS)

NSS consists of the following main submodules:

- Ethernet MAC subsystem (EMAC), providing the following main features, among others:
  - One-port Gigabit Ethernet: RMII/RGMII
  - 10/100/1000 Mbps full duplex support
  - 10/100 Mbps half duplex support
  - Ethernet Audio/Video Bridging (eAVB) support
  - IEEE 1588 v2 (with Annex D/E/F) Support
  - SER protection (SECDED) support
- Navigator subsystem (NAVSS), including PKTDMA controller, and Queue Manager with SER protection (SECDED) support
- Security Accelerator, providing the following encryption/decryption functions, among others:
  - Crypto function library for software acceleration (AES, 3DES, SHA1, MD5, SHA2 - 224/256)
  - Block data encryption supported via hardware cores
  - Data encryption modes supported via MCE (programmable Mode Control Engine)
  - Public Key accelerator (PKA) with Elliptic Curve Cryptography (ECC)
  - Keyed HMAC operation via hardware core
  - True Random number generator (TRNG)

1.3.4 Memory Controllers and Memory

- Multicore Shared Memory Controller (MSMC), providing the following main features, among others:
  - Common managed path to the DDR EMIF for multiple DSP cores, Arm cores, and other system masters
  - 1MB MSMC SL2 RAM (in a single bank) shared between the Arm and DSP cores, with ECC
  - 256-bit slave interfaces for DSP and Arm cores
  - Two 256-bit VBUSM slave interfaces for DMA traffic (one for MSMC SRAM, another for DDR EMIF)
  - Memory protection unit (MPU) for both MSMC SRAM and DDR memory
- DDR External Memory Interface (EMIF), providing the following main features, among others:
  - 36-bit DDR3L interface (32-bit data + 4-bit ECC)
  - DDR3L at 800 MT/s maximum speed for wirebond devices
  - DDR3L at 1066 MT/s maximum speed for flip-chip devices
  - Up to 8GB memory address range
- General Purpose Memory Controller (GPMC), providing the following main features, among others:
  - Flexible 8/16-bit asynchronous memory interface with up to 4 chip selects (NOR, Muxed-NOR, SRAM, and so forth)
  - Support for synchronous and asynchronous interface protocols with external memories or devices
  - Support for IO speeds up to 100MHz under synchronous mode, and up to 133MHz with asynchronous mode

1.3.5 Connectivity Peripherals

- One PCIe® 2.0 controller, Gen2 compliant, with single SerDes lane running at 5GBaud/2.5GBaud. Supports both root complex mode and end point mode.
- Two USB 2.0 High Speed dual-role ports with integrated PHY, each supporting:
  - USB 2.0 peripheral at speeds HS (480 Mb/s) and FS (12 Mb/s)
  - USB 2.0 host at speeds HS (480 Mb/s), FS (12 Mb/s), and LS (1.5 Mb/s)

- Three I²C interfaces, each supporting Standard mode (up to 100 KHz) and Fast mode (up to 400 KHz), with full 7-bit address field.
- Four SPI interfaces, each supporting two chip selects, and up to 50 MHz in master mode, and up to 25MHz in slave mode operation.
- Three UART interfaces, each supporting 16550 compatibility, with operation at up to 3M baud:
  - UART0 supports 8 pins with full modem control
  - UART1 and UART2 are 4-pin interfaces
- Two General Purpose IO (GPIO) modules, providing up to 212 GPIO pins with muxing.

1.3.6 Media and Storage Interfaces

- One Quad-SPI (QSPI™) module, for communication with up to four external flash devices.
- Two MMC/SD ports, both acting as HS-MMC/SD initiator controllers, supporting JEDEC JESD84 v4.5-A441 and SD3.0 physical layer with SDA3.00 standards:
  - MMC0 controller supports only 3.3 V IO modes
  - MMC1 controller supports only 1.8 V IO modes

1.3.7 Audio Peripherals

- Three Multi-Channel Audio Serial Ports (McASP), each providing support for TDM, I^2S and similar formats, DIT output, and allowing transmit/receive clock rates up to 50 MHz:
  - McASP0 with 16 serial data pins, McASP1 with 10 serial data pins, and McASP2 with 6 serial data pins
- One Multi-Channel Buffered Serial Port (McBSP), providing support for TDM, I^2S, and similar formats, and allowing transmit/receive clock rates up to 50 MHz.

1.3.8 Automotive Peripherals

- Two CAN Controller Ports (DCAN), for interface with Controller Area Network bus. Each DCAN supporting CAN version 2 part A, B, with bit rates up to 1 MBit/s.
- One Media Local Bus (MLB) module, supporting both 3-pin (up to MOST50, 1024×Fs) and 6-pin (up to MOST150, 2048×Fs) versions of MediaLB® Physical Layer Specification v4.2, with speed limited to 100 Mbps.

1.3.9 Control Interfaces

- Six enhanced High Resolution PWM modules (ePWM), each supporting dedicated 16-bit time-base with Period/Frequency control, and up to two independent PWM outputs.
- Two 32-bit enhanced Capture modules (eCAP), each configurable as either one capture input, or as one auxiliary PWM output.
- Three 32-bit enhanced Quadrature Pulse Encoder modules (eQEP), for position, speed, and frequency measurements.

1.3.10 System Level Components

- Seven 64-bit Timer modules:
  - Two dedicated 64-bit timers, one per Arm and DSP core, serving as watch dogs, or for use as general purpose timers
  - Four 64-bit timers shared for general purposes
  - One 64-bit timer dedicated to PMMC
- Semaphore module, supporting total of 64 semaphores.
- Two Enhanced DMA controllers, providing totaly:
  - Two Channel Controllers (CC)
  - Two 128-bit Transfer Controllers (TC) per CC
- Boot ROM: 128KB for DSP core, and 256KB for Arm core.

Memory Map

This chapter summarizes the memory map address regions for the device.

Topic **Page**

2.1 Memory Map Summary

Table 2-1 shows the memory map address ranges of the device.

Table 2-1. Device Memory Map

(2) The first 2GB of DDR_0_DATA. This region is alias of 08 0000 0000 - 08 7FFF FFFF. No IO coherency is supported.
(3) DDR_0_DATA (mapped to MSMC SES port). IO coherency is supported.
(4) This region is aliased to 00 2101 0000 - 00 2101 01FF.
(5) Access to 40-bit address requires XMC MPAX programming.
(6) Access to 40-bit address requires MSMC MPAX programming. MPAX from SES port need to re-map the region of 00 2101 0000 - 00 2101 01FF to this region.
(7) 8GB DDR_0_DATA data region. IO coherency is supported.
(8) 8GB DDR_0_DATA data region. Access to 40-bit address requires XMC MPAX programming.
(9) 8GB DDR_0_DATA data region. Access to 40-bit address requires MSMC MPAX programming. MPAX for SES port needs to re-map the 2GB address region 00 8000 0000 - 00 FFFF FFFF to 08 0000 0000 - 09 FFFF FFFF.

Interconnect

This chapter describes the System Interconnect and the Memory Protection Units (MPU) for the device.

Topic **Page**

3.1 System Interconnect

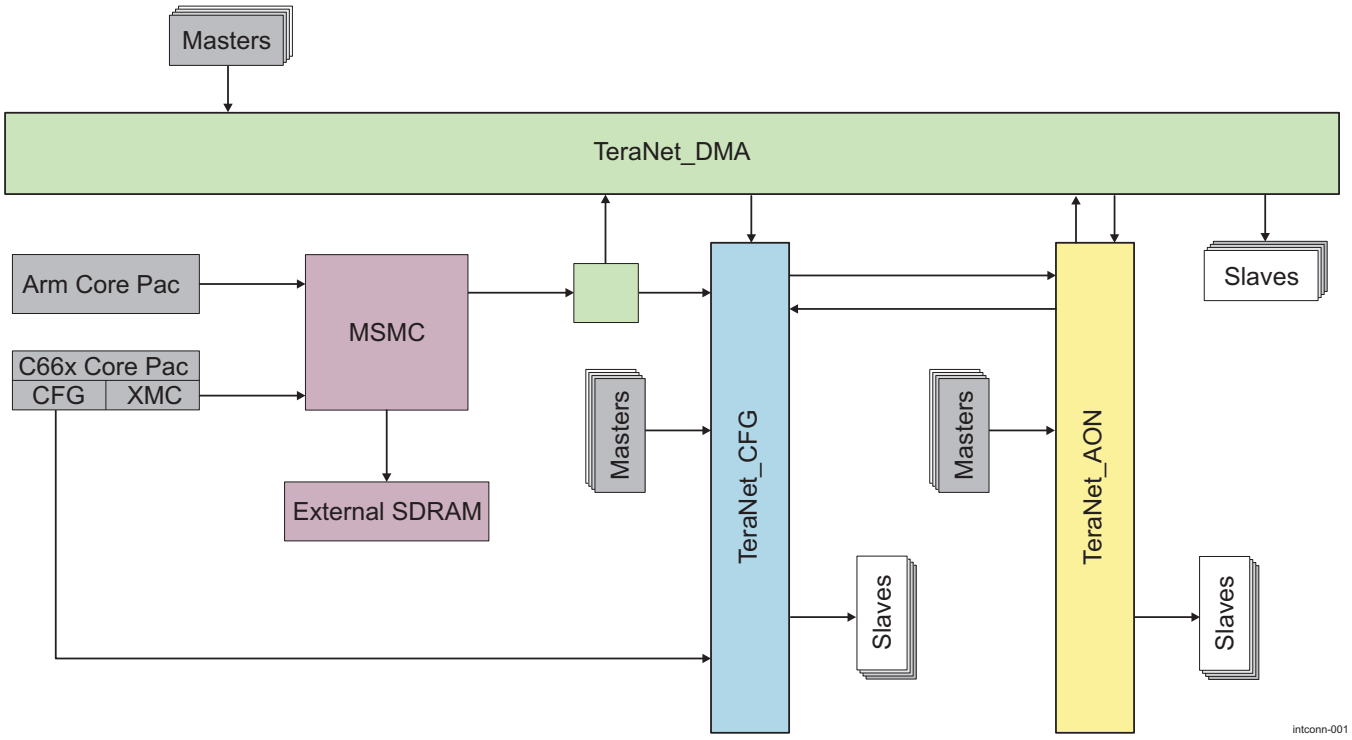
The following sections describe the device system interconnect.

3.1.1 System Interconnect Overview

All modules and subsystems in the device communicate with each other through the system interconnect. It is partitioned into three sections: main data (TeraNet_DMA), main configuration (TeraNet_CFG) and always on (TeraNet_AON) interconnect. Each of these three sections is composed by several TeraNets, which are non-blocking switch fabrics enabling fast and contention-free internal data movement. They also provide low-latency and concurrent data transfers between master and slave peripherals.

Figure 3-1 shows an overview of the device system interconnect. All modules and subsystems can be classified into two categories: masters and slaves. The masters are capable of initiating read and write transfers in the system and do not depend on the EDMA for their data transfers. The slaves on the other hand depend on the masters to perform transfers to and from them. They cannot generate read/write requests but can respond to these requests generating interrupts or DMA requests.

Figure 3-1. System Interconnect Overview



3.1.2 System Interconnect Integration

Table 3-1 and Table 3-2 summarize the integration of the system interconnect in the device.

Table 3-1. System Interconnect Integration Attributes

Module Instance	Attributes	
	Power Domain	Module Domain
TeraNet_DMA	PD4	LPSC5
TeraNet_CFG	PD4	LPSC5
TeraNet_AON	PD0	LPSC0

Table 3-2. System Interconnect Clocks and Resets

Clocks			
TeraNet Component	**Clock Signal**	**Source**	**Description**
TeraNet_M_1_256_0 TeraNet_M_1_256_1 TeraNet_M_1_256_2	CHIP_CLK1	PLL Controller	Clock to some components of TeraNet_DMA which frequency is equal to the CHIP_CLK1 clock.
TeraNet_M_3_128_0 TeraNet_M_3_128_1 TeraNet_M_3_128_2 TeraNet_M_3_128_3 TeraNet_M_3_128_4 TeraNet_M_3_32_0 TeraNet_P_3_32_1 TeraNet_P_3_32_3 TeraNet_P_3_32_5 TeraNet_P_3_32_6 TeraNet_P_3_32_7 TeraNet_P_3_32_8 TeraNet_P_3_32_9 TeraNet_P_3_32_10 TeraNet_P_3_32_11	CHIP_CLK1/3	PLL Controller	Clock to some components of TeraNet_DMA and TeraNet_CFG which frequency is equal to the CHIP_CLK1 clock divided by 3. This clock is also propagated to the MPUs.
TeraNet_P_6_32_0 TeraNet_P_6_32_1 TeraNet_P_6_32_2 TeraNet_P_6_32_3 TeraNet_P_6_32_4 TeraNet_P_6_32_5 TeraNet_P_6_32_6 TeraNet_P_6_32_7	CHIP_CLK1/6	PLL Controller	Clock to some components of TeraNet_DMA, TeraNet_CFG and TeraNet_AON which frequency is equal to the CHIP_CLK1 clock divided by 6.
Resets			
Module	**Reset Signal**	**Source**	**Description**
System Interconnect	MOD_G_RST	LPSC5	Reset to the bridges (for example, BR_MP_1, BR_OV_3, and so on) and TeraNet components.
	MOD_G_RST	LPSC0	Reset to the always on logic.

3.1.3 System Interconnect Functional Description

TeraNet_DMA includes most of the master ports and all the data slave end points. Figure 3-2 shows the connections between masters and slaves through the various sections of TeraNet_DMA.

Figure 3-2. TeraNet_DMA Master-Slave Connections

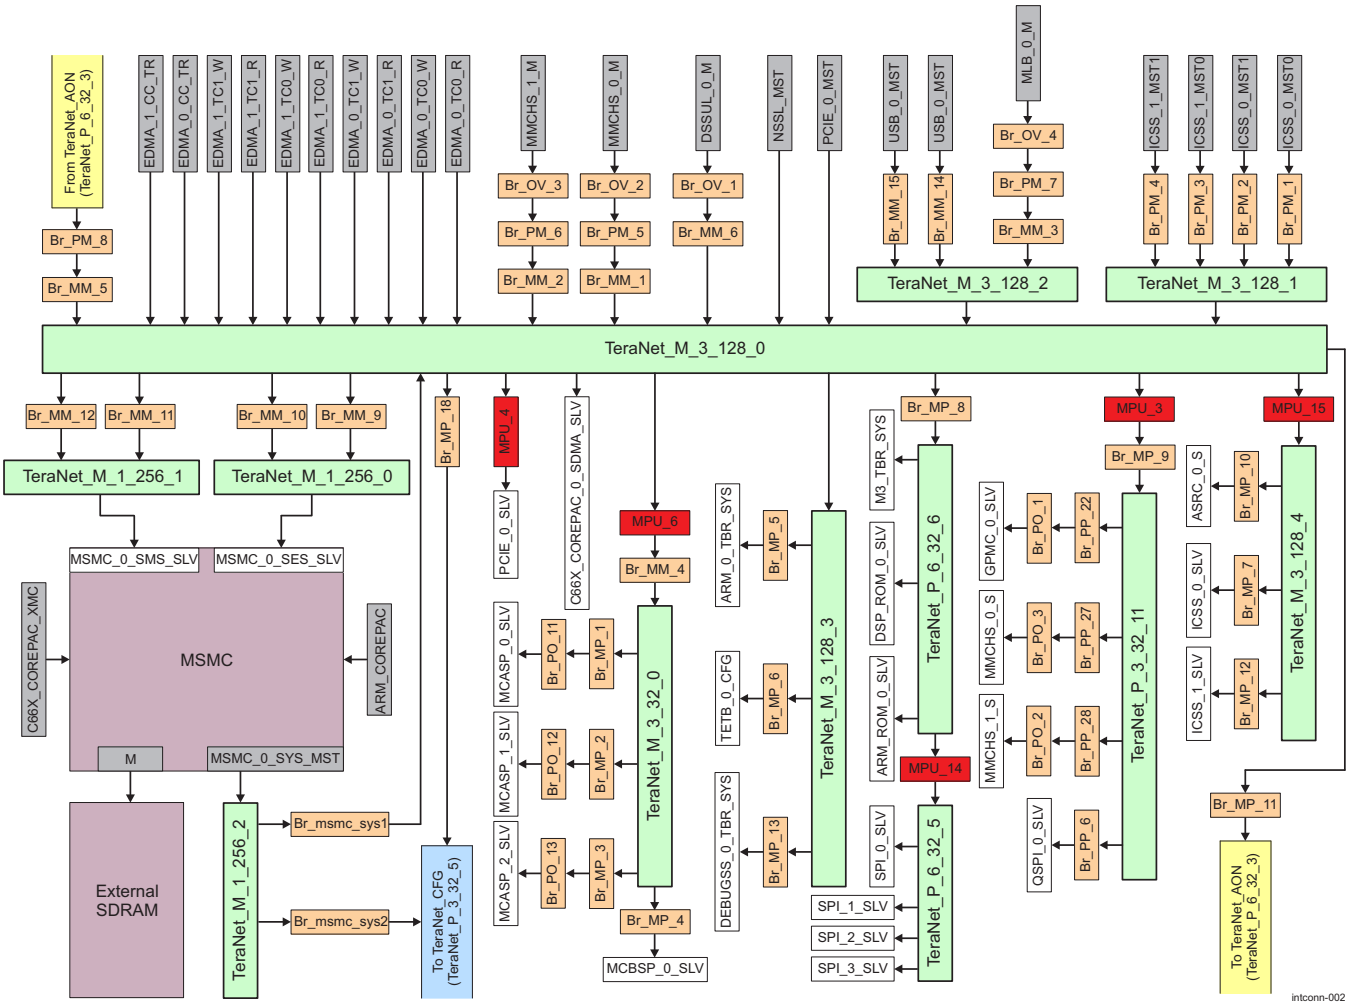


Table 3-3 lists the master and slave end point connections on TeraNet_DMA. A cell may contain one of the following:

- Y – There is a connection between this master and that slave
- N – There is no connection between this master and that slave.

Table 3-3. TeraNet_DMA Connectivity Matrix

Color Code:	Masters on TeraNet_DMA	Masters on TeraNet_CFG	Masters on TeraNet_AON

The masters on the TeraNet_DMA pass through various bridges on the way to the MSMC slave ports (SMS and SES) and other TeraNets (TeraNet_AON and TeraNet_CFG). Table 3-4 lists the connections between the TeraNet_DMA masters and various bridges. This table gives the user the flexibility to select masters (typically EDMA) that use the same or different bridges. A cell may contain one of the following:

- Y – There is a connection between this master and the bridge
- N – There is no connection between this master and the bridge.

Table 3-4. TeraNet_DMA Bridge Connectivity Matrix

TeraNet_CFG is intended to include almost all of the configuration end points. All the configuration accesses to the slave end points need to be 32-bit address aligned. 8-bit and 16-bit accesses are not supported. Figure 3-3 shows the connections between masters and slaves through the various sections of TeraNet_CFG.

It should be taken into account that some peripherals have both data bus and configuration bus interface, while others only have one type of interface. In addition, the bus interface, width and speed varies from peripheral to peripheral.

NOTE: ELM is not supported on this family of devices.

Figure 3-3. TeraNet_CFG Master-Slave Connections

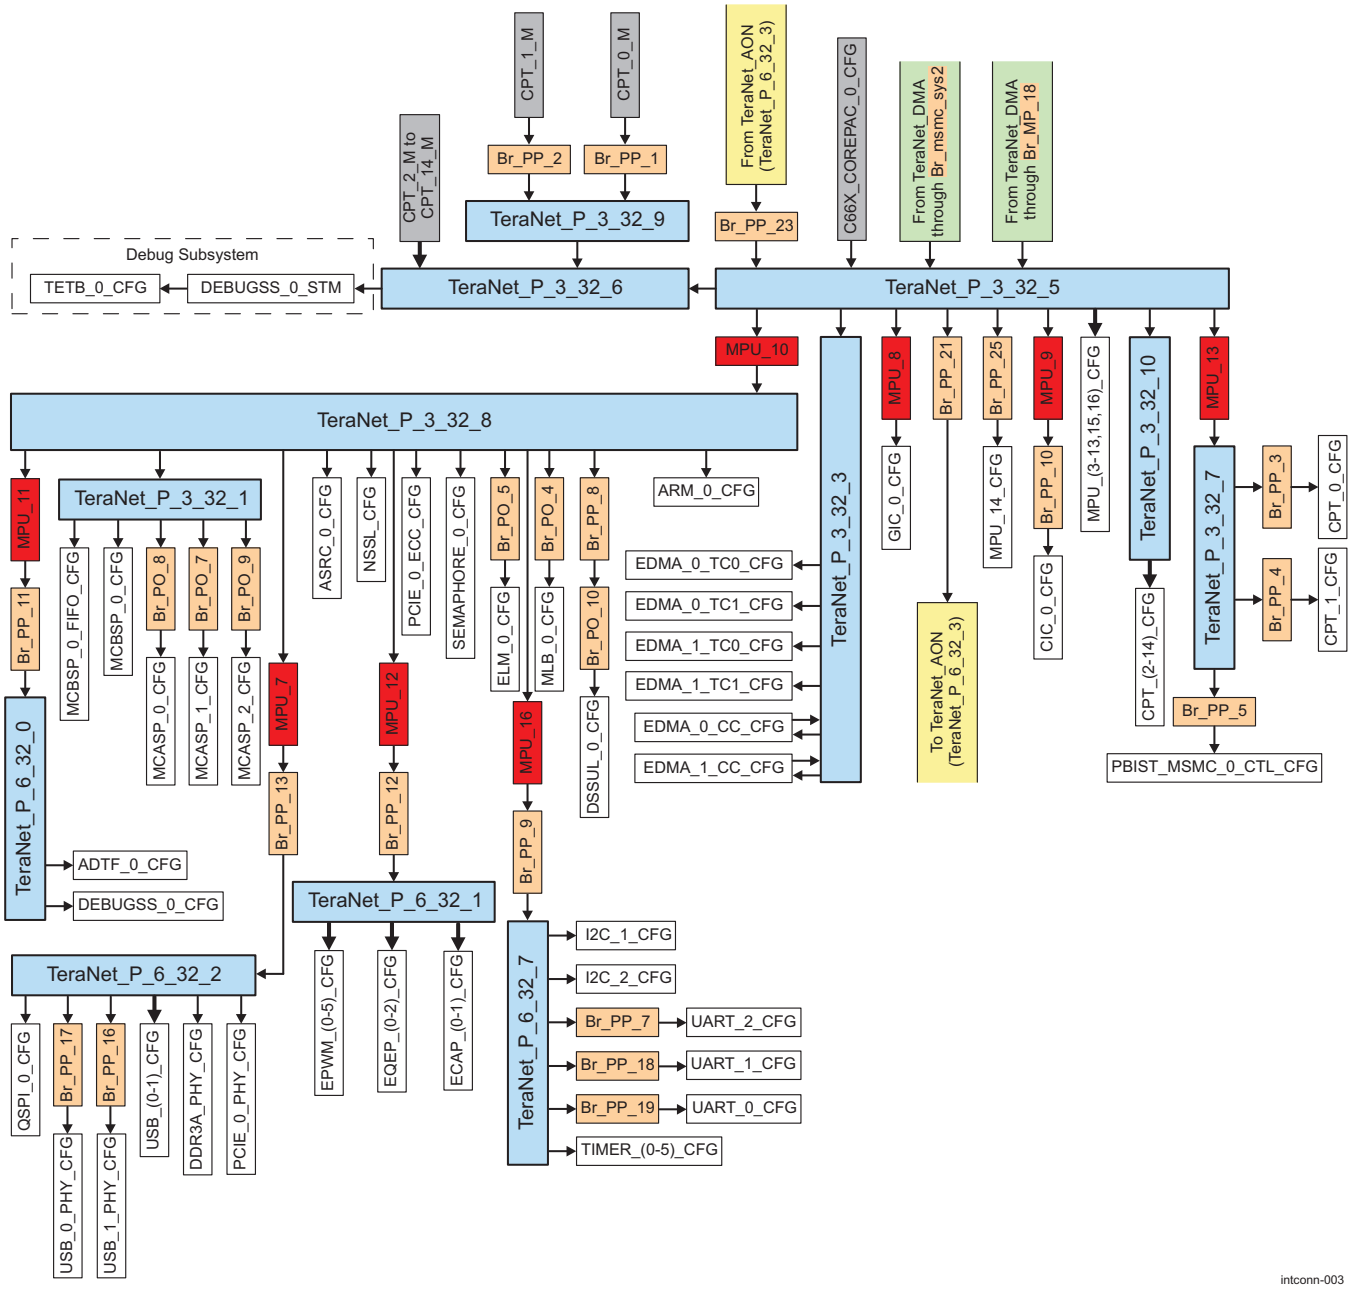

Table 3-5 and Table 3-6 list the master and slave end point connections on TeraNet_CFG. A cell may contain one of the following:

- Y – There is a connection between this master and that slave
- N – There is no connection between this master and that slave.

The MPUs (Memory Protection Units) shown on the "*Master-Slave Connections*" figures are used to prevent unauthorized access to or from a module. For more information about the device MPUs see Section 3.2, *Memory Protection Units*.

3.1.3.1 Transaction Priority for the TeraNet Masters

The transaction priority of certain masters on the TeraNet is controlled by registers which reside in the BOOT_CFG module. For more information see Section 5.1.3.1.4, *TeraNet Priority Registers*.

3.2 Memory Protection Units (MPU)

This section describes the Memory Protection Units (MPU) for the device.

3.2.1 MPU Overview

The Memory Protection Unit (MPU) protects data and configuration spaces by managing the access to these memories. It allows multiple ranges of protection with different access permissions to be defined. Each range can be made secure by limiting the access only to secure system masters. Access can also be granted or not to individual system masters based on their privilege ID or access types. The MPU can also record a detected fault or invalid access and notify the system through an interrupt.

The MPU has the following features:

- Supports multiple programmable address ranges
- Supports secure and debug access privileges
- Supports read, write, and execute access privileges
- Supports privilege ID associations with the programmable address ranges
- Generates an interrupt when there is addressing or protection violation and saves violating transfer parameters
- Supports L1/L2 cache accesses
- Supports protection of its own registers.

3.2.2 MPU Integration

This section describes the MPU modules integration in the device including information about clocks, resets, and hardware requests.

Figure 3-5 shows the integration of the MPU modules in the device.

Figure 3-5. MPU Integration

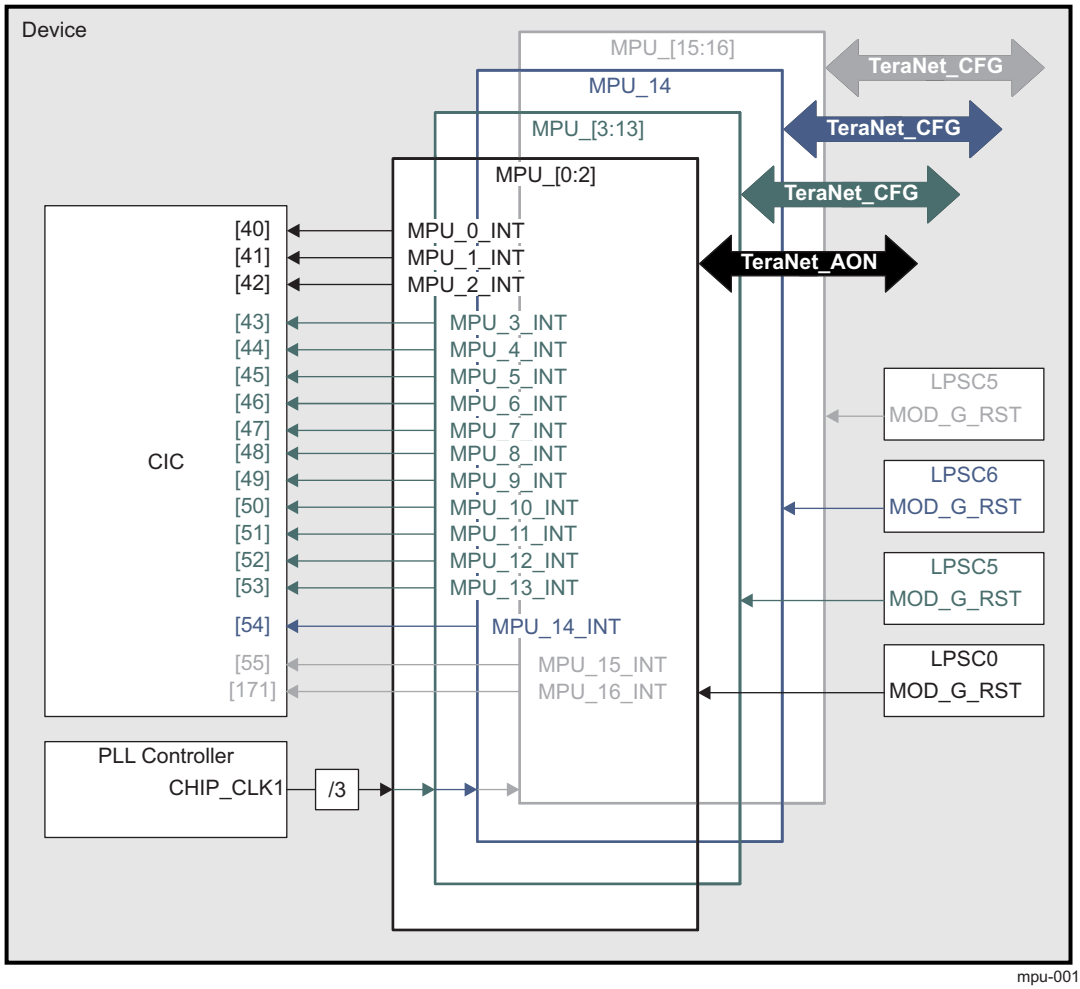

Table 3-8 through Table 3-10 summarize the integration of the MPU modules in the device.

Table 3-8. MPU Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect

MPU_15	MPU_15_INT	[55]	MPU_15 interrupt indicating addressing violation or protection violation error
MPU_16	MPU_16_INT	[171]	MPU_16 interrupt indicating addressing violation or protection violation error

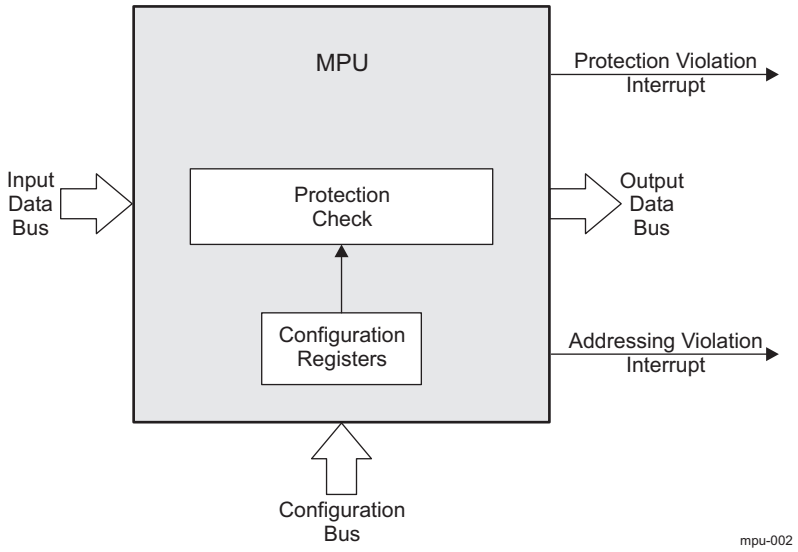
NOTE: For more information about interrupts, see Section 3.2.3.8.

3.2.3 MPU Functional Description

3.2.3.1 Functional Block Diagram

Figure 3-6 shows a block diagram of the MPU. An access to a protected memory must pass through the MPU. During an access, the MPU checks the address on the input data bus against programmable ranges. If allowed, the transfer is passed unmodified to the output data bus. If the transfer fails the protection check then the MPU does not pass the transfer to the output bus. To prevent a hang it services the transfer internally back to the input bus returning the fault status to the requestor and generates an interrupt about the fault. For read accesses the MPU returns zeros and fault status. For write accesses it receives all data and returns fault status.

Figure 3-6. MPU Block Diagram



3.2.3.2 Privilege Levels

The privilege level of a memory access determines what level of permissions the originator of the memory access might have. Two privilege levels are supported: supervisor and user.

Supervisor level is generally granted access to peripheral registers and the MPU configuration registers. User level is generally confined to the memory spaces that the OS specifically designates for its use.

Processor instruction and data accesses have a privilege level associated with them. The privilege level is inherited from the code running on the corresponding processor.

3.2.3.3 Memory Protection Ranges

The MPU divides its assigned memory into address ranges. Each MPU can support up to 16 programmable address ranges. The programmable address range allows software to program the start and end addresses.

Each programmable address range has the following set of registers:

- MPU_PROGx_MPSAR - specifies the start address of region *x*
- MPU_PROGx_MPEAR - specifies the end address of region *x*
- MPU_PROGx_MPPAR - specifies the permissions of region *x*

It is allowed to configure ranges such that they overlap each other. In this case all overlapped ranges must allow the access, otherwise the access is not allowed. The final permissions given to the access are the lowest among all types of permissions associated with these overlapped ranges.

NOTE: The amount of physical memory used by a particular design may be less than the maximum amount of memory supported by the device. In such cases, the not used memory range must be protected in order to prevent unintended (aliased) accesses to the memory in use. One of the programmable address ranges could be used to detect accesses to this not used memory range.

3.2.3.4 Permissions of Programmable Address Range

The fields of the MPU_PROGx_MPPAR register can be split into 3 groups:

- **Allowed privilege IDs** - bits MPU_PROGx_MPPAR[25-9]
- **Security** - bits MPU_PROGx_MPPAR[7-6]
- **Access types** - bits MPU_PROGx_MPPAR[5-0]

Allowed privilege IDs

With almost each master on the device there is an associated privilege ID (called also PrivID). This PrivID identifies the master for privilege purposes and accompanies all memory accesses made on behalf of that master. That is, when a master triggers a memory access command, the PrivID is carried alongside the command.

NOTE: There is no PrivID for the EDMA Controller.

Each AID bit from the MPU_PROGx_MPPAR[25-9] field specifies wheter the master accessing the given address range and having PrivID corresponding to the AID bit is checked for access permissions or not. If AID = 1 the access permissions specified via MPU_PROGx_MPPAR[7-6] and MPU_PROGx_MPPAR[5-0] bits are checked. If AID = 0 these permissions are not checked.

Security

The MPU_PROGx_MPPAR[7] NS and MPU_PROGx_MPPAR[6] EMU bits specify 3 valid protection levels for region *x* as described in Table 3-11. The term *debug access* refers to an access initiated through the emulation port of the device.

Table 3-11. Protection Levels

NS	EMU	Description
0	0	Region *x* is secure without debug: Only secure accesses are allowed. Debug accesses are not allowed. Non-secure accesses are also not allowed
0	1	Region *x* is secure with debug: Only secure and debug accesses are allowed. Non-secure accesses are not allowed
1	-	Region *x* is non-secure: All accesses (non-secure, secure and debug) are allowed.

Access types

The memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses originating from the corresponding processor or master peripheral. Execute refers to accesses associated with an instruction fetch. The memory protection model allows to control the read, write, and execute permissions independently for both privilege levels - supervisor and user. This results in 6 permission bits shown in Table 3-12.

Table 3-12. Request Type Access Controls

Bit	Description
MPU_PROGx_MPPAR[5] SR	Supervisor may read
MPU_PROGx_MPPAR[4] SW	Supervisor may write

Table 3-12. Request Type Access Controls (continued)

Bit	Description
MPU_PROGx_MPPAR[3] SX	Supervisor may execute
MPU_PROGx_MPPAR[2] UR	User may read
MPU_PROGx_MPPAR[1] UW	User may write
MPU_PROGx_MPPAR[0] UX	User may execute

For each bit, a value of 1 permits the access type, and 0 denies it. So, setting the MPU_PROGx_MPPAR[0] UX bit to 1 means that a master in user mode may execute from region *x* specified by the MPU_PROGx_MPSAR and MPU_PROGx_MPEAR registers.

The MPU allows the programmer to specify each of these 6 bits separately. Thus 64 different combinations are possible but programs might not use all of them.

3.2.3.5 Protection Check

During a memory access, the MPU checks if the address range of the input transfer overlaps one of the address ranges defined via registers MPU_PROGx_MPSAR and MPU_PROGx_MPEAR. When the address of the input transfer is within a range the transfer parameters are checked against the address range permissions specified by register MPU_PROGx_MPPAR. The MPU first checks the PrivID against the AID settings. If the corresponding AID bit is 0, then the access permissions of this PrivID are not checked and the access is allowed or not depending on the value of the MPU_CONFIG[0] ASSUME_ALLOWED bit. If the AID bit is 1, then to detect an allowed access the transfer secure and debug parameters are checked against the MPU_PROGx_MPPAR[7] NS and MPU_PROGx_MPPAR[6] EMU values as described in Table 3-11.

For non-debug accesses the read, write, and execute permissions are also checked. There is a set of permissions for supervisor mode and another for user mode. For supervisor mode accesses, the MPU_PROGx_MPPAR[5] SR, MPU_PROGx_MPPAR[4] SW, and MPU_PROGx_MPPAR[3] SX bits are checked. For user mode accesses the MPU_PROGx_MPPAR[2] UR, MPU_PROGx_MPPAR[1] UW, and MPU_PROGx_MPPAR[0] UX bits are checked.

If the address of the input transfer does not match any address range defined via registers MPU_PROGx_MPSAR and MPU_PROGx_MPEAR, then the transfer is allowed or not depending on the value of the MPU_CONFIG[0] ASSUME_ALLOWED bit. If ASSUME_ALLOWED = 0 the transfer is not allowed. If ASSUME_ALLOWED = 1 the transfer is allowed.

In case that a transfer spans multiple address ranges, all overlapped ranges must allow the access, otherwise the access is not allowed. The final permissions given to the access are the lowest among all types of permissions associated with these overlapped ranges. Therefore, if a transfer matches two ranges, one that is RW and one that is RX, then the final permission is just R.

The MPU has a special mechanism for handling DSP L1/L2 cache controller read accesses. See Section 3.2.3.6 for more details.

3.2.3.6 DSP L1/L2 Cache Controller Read Accesses

A memory read access which originates from the DSP L1/L2 cache controller is treated differently to allow memory protection to be enforced by DSP level. This is because a subsequent memory access that hits in the cache does not pass through the MPU. Instead the memory access is serviced directly by the L1/L2 memory controllers.

During a cache memory read the permission settings stored in the MPU_PROGx_MPPAR register are passed to the L1/L2 memory controllers along with the read data. The permission settings returned by the MPU are taken from the MPU_PROGx_MPPAR register that covers the address range of the original request. Only the SR, SW, SX, UR, UW, UX, NS and EMU bits are passed.

If the request address is covered by multiple address ranges, then the returned value is the logical AND of the corresponding permission settings of all MPU_PROGx_MPPAR registers associated with these multiple address ranges. If the transfer address range is not covered by an address range, then the transfer is either allowed or not based on the value of MPU_CONFIG[0] ASSUME_ALLOWED bit.

3.2.3.7 Protection of the MPU Configuration Registers

Accesses to the MPU_PROGx_MPSAR, MPU_PROGx_MPEAR and MPU_PROGx_MPPAR registers are also protected. All non-debug writes must be by a supervisor master. If the MPU_PROGx_MPPAR[7] NS bit is 0, then all writes must be by a secure master. In addition, the NS bit can be modified only by a secure master. A register write with invalid permissions results in protection fault and interrupt generation.

A debug write is only allowed if NS = 1 or the EMU = 1 regardless of the secure or privilege attributes. Neither faults are recorded nor interrupts are generated for debug accesses.

3.2.3.8 MPU Interrupt Requests

Each MPU module has one interrupt request, the MPU_x_INT (x = 0 to 16), associated with the following registers:

- MPU_IRAWSTAT - interrupt raw status register
- MPU_IENSTAT - interrupt status register
- MPU_IENSET - interrupt enable register
- MPU_IENCLR - interrupt disable register

For the interrupt behavior of each MPU module the following applies:

- The MPU module asserts its interrupt line MPU_x_INT (x = 0 to 16) only if the interrupts are enabled by setting to 1h the corresponding bits in the MPU_IENSET register. These interrupts can be disabled by setting to 1h the corresponding bits in the MPU_IENCLR register.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting to 1h the corresponding bit in the MPU_IENSTAT register which also clears the corresponding bit in the MPU_IRAWSTAT register. The status flags in the MPU_IRAWSTAT register are set even if the corresponding interrupt is disabled unlike those in the MPU_IENSTAT register, which are set only if the corresponding interrupt is enabled.
- An interrupt is also generated by the MPU, if certain bit in the MPU_IRAWSTAT register is set to 1h and the corresponding interrupt is enabled through the MPU_IENSET register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled the corresponding raw flag in the MPU_IRAWSTAT register is set to 1h when an IRQ condition occurs.
- Even if interrupts are not enabled, a status bit in the MPU_IRAWSTAT register can also be cleared by setting to 1h the corresponding bit in the MPU_IENSTAT register.

Table 3-13 lists the interrupt events which can assert the MPU_x_INT interrupt line.

Table 3-13. MPU Events

Event Flag	Event Mask	Description
MPU_IRAWSTAT[1] ADDR_ERR MPU_IENSTAT[1] ENABLED_ADDR_ERR	MPU_IENSET[1] ADDR_ERR_EN MPU_IENCLR[1] ADDR_ERR_EN_CLR	Addressing violation interrupt. Occurs when an access to a non-existent location in the MPU configuration register space is performed.
MPU_IRAWSTAT[0] PROT_ERR MPU_IENSTAT[0] ENABLED_PROT_ERR	MPU_IENSET[0] PROT_ERR_EN MPU_IENCLR[0] PROT_ERR_EN_CLR	This interrupt occurs in case of protection violation of the programmable regions or of the MPU configuration register space.

When addressing violation or protection violation occurs, the error associated details are captured in the MPU_FLTADDRR and MPU_FLTSTAT registers. MPU_FLTADDRR contains the address of the first fault access and MPU_FLTSTAT contains status attributes associated with the first fault access. To clear the current fault the MPU_FLTCLR[0] CLEAR bit must be set to 1h. If not cleared, other faults are not recorded as the MPU stores fault information for only one fault. The MPU neither records another fault nor generates another interrupt until the existing fault has been cleared. This means that all other faults are ignored. For debug accesses neither faults are recorded nor interrupts are generated.

3.2.3.9 Emulation Considerations

Memory is protected against emulation accesses by the MPU. Emulator access to memory is controlled through the MPU_PROGx_MPPAR[7] NS and MPU_PROGx_MPPAR[6] EMU bits. See Table 3-11 for more details.

The MPU also protects its registers MPU_PROGx_MPSAR, MPU_PROGx_MPEAR and MPU_PROGx_MPPAR against emulation accesses. See Section 3.2.3.7 for more details.

3.2.3.10 MPU Memory Regions

The device contains 17 MPUs. Table 3-14 lists these MPUs and also the regions protected by each MPU.

Table 3-14. Memory Regions Protected by MPUs

MPU	Regions Protected by MPU
MPU_0	MESSAGE_MANAGER_0_CFG
MPU_1	TeraNet_P_6_32_4
MPU_2	PMMC_0_SLV
MPU_3	TeraNet_P_3_32_11
MPU_4	PCIE_0_SLV
MPU_5	MPU_5 is reserved and not used
MPU_6	TeraNet_M_3_32_0
MPU_7	TeraNet_P_6_32_2
MPU_8	GIC_0_CFG
MPU_9	CIC_0_CFG
MPU_10	TeraNet_P_3_32_8
MPU_11	TeraNet_P_6_32_0
MPU_12	TeraNet_P_6_32_1
MPU_13	TeraNet_P_3_32_7
MPU_14	TeraNet_P_6_32_5
MPU_15	TeraNet_M_3_128_4
MPU_16	TeraNet_P_6_32_7

3.2.3.11 Master IDs and PrivIDs

Table 3-15 shows the unique Master ID assigned to each master on the device. Not listed values are not used and should be considered as reserved IDs.

Table 3-16 shows the PrivID assigned to each master on the device.

NOTE: Master IDs are used to determine allowed connections between masters and slaves. They are also used to determine the master performed a fault transfer.

PrivIDs are used by the MPUs and MSMC to protect a given memory range against undesirable accesses.

Master IDs are unique to each master unlike PrivIDs which are shared among different masters.

Table 3-15. Master IDs

Master ID (decimal)	Master
0	MSMC_0_SYS_MST:C66X_COREPAC_0_MDMA_MST
8	MSMC_0_SYS_MST:A15_CPU0
16	C66X_COREPAC_0_CFG

3.2.4.1 MPU_REVID Register (Offset = 0h) [reset = 4E814901h]

MPU_REVID is shown in Figure 3-7 and described in Table 3-23.

The revision ID register (MPU_REVID) contains MPU revision information.

Table 3-22. MPU_REVID Instances

Instance	Physical Address
MPU_0	0236 0000h

3.2.4.3 MPU Interrupt Registers

3.2.4.3.1 MPU_IRAWSTAT Register (Offset = 10h) [reset = 0h]

MPU_IRAWSTAT is shown in Figure 3-9 and described in Table 3-30.

Reading the interrupt raw status/set register (MPU_IRAWSTAT) returns the status of all interrupts. Software can write to MPU_IRAWSTAT to manually set an interrupt. However, an interrupt is generated only if the interrupt is enabled. Writes of 0 have no effect.

Table 3-29. MPU_IRAWSTAT Instances

Instance	Physical Address
MPU_0	0236 0010h

3.2.4.3.2 MPU_IENSTAT Register (Offset = 14h) [reset = 0h]

MPU_IENSTAT is shown in Figure 3-10 and described in Table 3-33.

Reading the interrupt enable status/clear register (MPU_IENSTAT) returns the status of only those interrupts that are enabled. Software can write to the bits of MPU_IENSTAT to clear an interrupt; the interrupt is cleared both from MPU_IENSTAT and MPU_IRAWSTAT. Writes of 0 have no effect.

3.2.4.3.4 MPU_IENCLR Register (Offset = 1Ch) [reset = 0h]

MPU_IENCLR is shown in Figure 3-12 and described in Table 3-39.

Reading the interrupt enable clear register (MPU_IENCLR) returns the interrupts that are enabled. Software can write to MPU_IENCLR to clear/disable an interrupt. Writes of 0 have no effect.

3.2.4.3.5 MPU_EOI Register (Offset = 20h) [reset = 0h]

MPU_EOI is shown in Figure 3-13 and described in Table 3-42.

The MPU_EOI register allows software to indicate when the end of interrupt service is complete. The MPU_EOI vector value is dependent on the interrupt handling.

Table 3-41. MPU_EOI Instances

Instance	Physical Address
MPU_0	0236 0020h

Table 3-42. MPU_EOI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved. Always reads as 0.
7-0	EOI_VECTOR	R/W	0h	MPU_EOI vector value. Write this with the interrupt distribution value in the device. This drives the mpu_eoi_vector output signal. MPU_EOI Value is 0 for MPU.

Table 3-43. Register Call Summary for MPU_EOI

MPU Registers • MPU Registers: [0][1][2][3]
MPU Interrupt Registers • MPU_EOI Register (Offset = 20h) [reset = 0h]: [0][1][2][3][4]

3.2.4.4 MPU Programmable Range Registers

3.2.4.4.1 MPU_PROGx_MPSAR Register (Offset = 200h + x*16) [reset = See Table 3-46]

MPU_PROGx_MPSAR (*x* = 0 to 15) is shown in Figure 3-14 and described in Table 3-45.

The programmable address start register holds the start address for the range. This register is writable by a supervisor entity only. If NS = 0 (non-secure mode) in the associated MPPA register then the register is also only writable by a secure entity.

The start address must be aligned on a page boundary. The size of the page is 1 Kbyte. The size of the page determines the width of the address field in MPSAR and MPEAR.

Table 3-44. MPU_PROGx_MPSAR Instances

Instance	Physical Address
MPU_0	0236 0200h + (x*16)

Table 3-47. Register Call Summary for MPU_PROGx_MPSAR

MPU Registers • MPU Registers: [0][1][2][3]
Memory Protection Unit Functional Description • Protection Check: [0][1] • Protection of the MPU Configuration Registers: [0] • Emulation Considerations: [0] • Permissions of Programmable Address Range: [0] • Memory Protection Ranges: [0]
MPU Programmable Range Registers • MPU_PROGx_MPSAR Register (Offset = 200h + x*16) [reset = See]: [0]

3.2.4.4.2 MPU_PROGx_MPEAR Register (Offset = 204h + x*16) [reset = See Table 3-50]

MPU_PROGx_MPEAR (*x* = 0 to 15) is shown in Figure 3-15 and described in Table 3-49.

The programmable address end register holds the end address for the range. This register is writable by a supervisor entity only. If NS = 0 (non-secure mode) in the associated MPPA register then the register is also only writable by a secure entity. The end address must be aligned on a page boundary.

3.2.4.4.3 MPU_PROGx_MPPAR Register (Offset = 208h + x*16) [reset = See Table 3-54]

MPU_PROGx_MPPAR (*x* = 0 to 15) is shown in Figure 3-16 and described in Table 3-53.

This register holds the permissions for the region. It is writable only by a non-debug supervisor entity. If NS = 0 (secure mode) then the register is also only writable by a non-debug secure entity. The NS bit is only writable by a non-debug secure entity. For debug accesses the register is writable only when NS = 1 or EMU = 1.

Initialization

This chapter describes the non-secure features of the on-chip ROM boot loader (BootROM).

Topic **Page**

4.1 Overview

ROM Boot Loader (BootROM) is software code that resides in the on-chip read only memory (ROM) to assist the customer in transferring and executing their application code. In order to accommodate various system scenarios, the BootROM supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the BootROM receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

- Initialization phase
- Boot process.

During initialization, the BootROM configures the device resources as needed to support the boot process. The resources used depend on the boot mode requirements. During the boot process the boot image is loaded into device memory and executed. The actions performed during the initialization and boot processes depend on the following factors:

- The trigger that initiated the boot operation
- The boot mode and location of the boot image (host or memory) as defined by the configuration specified on the BOOTMODE pins of the device.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in the device status register DEVSTAT. At BootROM startup, these pins are read from the DEVSTAT register to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

This chapter covers:

- The different triggers that can initiate the boot operation
- The initialization process
- The boot process based on the location of the image
- The specific boot process features for different boot modes.

If the image is in an external host, the boot process varies depending on the host knowledge of the boot device memory map.

The BootROM also provides a multi-stage boot mechanism.

4.1.1 Bootloader Modes

Table 4-1 shows the BootROM boot peripherals supported in the device.

Table 4-1. BootROM Boot Modes

Boot Peripheral	Peripheral Instances	Media/Notes
QSPI	1	QSPI flash
SPI	4	EEPROM
UART	3	External host
GPMC	1	NOR flash
I^2C	3	I^2C master boot - EEPROM I^2C slave boot - External host
Ethernet	1	BOOTP mode
PCIE	1	
MMCSD	2	Embedded MMC (eMMC) or SD card
USB	2	USB boot - device mode boot using DFU (device firmware update)

4.2 BootROM Initialization Phase

As previously mentioned, the boot process can be divided into two steps. The first step is the initialization process, which depends on the type of reset that triggers the boot. The second step is the boot mode specific process (see Section 4.3, *Boot Process, Boot Modes and Pin Usage*).

The start address of the ARMSS BootROM is 0x00000000.

4.2.1 Reset Types

In device, resets are used as the trigger for initiating the boot process and the boot process varies based on the type of the reset. There are four types of reset supported in the device architecture:

- Power-on reset (POR)
- Hard reset (warm reset initiated by either hardware or software)
- Soft reset (a subset of hard reset)
- Local reset to DSP or PMMC.

The first three types of reset are considered global resets because they affect the entire device, while the local reset affects only DSP or PMMC.

NOTE: The ARMSS may perform local reset of the DSP, but the ARMSS cannot be reset by a local reset.

For local reset, the boot process is not triggered. For further details on the reset types, see Section 5.3, *Reset Management*.

Irrespective of the global reset type, the boot process is executed by the respective boot master Core 0.

4.2.1.1 BOOTMODE Pins

External pins on the device are used at device power-up to allow customers to select the desired boot mode. There are also pins that specify some of the configuration parameters used during that boot mode. The value of these pins is latched into the device status register DEVSTAT during POR. Some boot modes also include a Minimum Boot Pin Select pin (MIN) that can be used to select predifined in ROM parameters instead of selecting them with the all BOOTMODE pins.

4.2.2 Initialization Flow

This section is divided into two sub-sections:

- Initialization Process After Power On Reset (POR)
- Initialization Process After Hard Reset or Soft Reset.

4.2.2.1 Initialization Process After Power On Reset

4.2.2.1.1 Device Initialization

POR resets the entire device. Everything on the device is reset to its default state. POR is initiated by either the PORn or RESETFULLn external pins. The PORn pin is asserted during power up of the device while the RESETFULLn pin can be asserted by a host to reset the device after it is already powered up. PORn causes all peripherals to be initialized to their default states and boot processing to be started. The state of the BOOTMODE pins are latched into the device status register (DEVSTAT) at POR. The BootROM uses the values in DEVSTAT to select how boot is performed. All initialization and boot processing is performed by ARMSS Core0.

The BootROM uses the boot configuration information from the DEVSTAT register to determine the initialization flow to perform. Initialization executed by the BootROM includes:

- The BootROM enables reset isolation in all peripherals that support it. The power state of these peripherals is not changed. Section 5.3, *Reset Management* lists the peripherals that support reset isolation.

- The BootROM enables the power and clock domains for any peripherals required during boot.
- Various PLLs may be configured depending on values specified in BOOTMODE pins. BOOTMODE pins and DEVSTAT register will contain information indicating the PLL, the input clock frequency, and when that PLL should be configured.
  - For all modes, except for SLEEP, I2C, and SPI where it is optional, the MAIN PLL is programmed so that MAIN PLL runs at the frequency indicated by the DEVICE_SPEED field in the EFUSE_BOOTROM register.
  - When the ARMSS is the boot master and MAIN PLL is locked, the ARM PLL is programmed so that the output of ARM PLL provides the frequency indicated by the ARM_SPEED field in the EFUSE_BOOTROM register.
- All interrupts are disabled except for IPC interrupts and the host interrupts that are used for an external host boot modes (PCIe)
- DSP executes an IDLE command.
- ARMSS cache is enabled
- MMU is enabled
- The BootROM uses the boot configuration information in DEVSTAT to setup and initialize a boot parameter table that is used to control the boot process. This table is stored in MSMC SRAM. Some information in the table is initialized based on the configuration parameters in DEVSTAT while the remaining information is default values based only on the boot mode. The format of the table varies depending on the boot mode. All start with a few entries that are common to all boot modes. For information about the boot parameter table see Section 4.3.3, *Boot Parameter Tables*.

4.2.2.2 Initialization Process After Hard Reset or Soft Reset

As previously mentioned, a POR reset initialized by a PORn or RESETFULLn will sample the BOOTMODE pins. The sampled information is stored internally and written to the DEVSTAT register.

After Soft/Hard resets,BootROM will carry out the same initialization process mentioned in Section 4.2.2.1, *Initialization Process After Power On Reset* followed by the boot specific process.

The only difference in this boot process compared to one triggered by the POR reset is that the BOOTMODE pins are not sampled to update the DEVSTAT register. In addition, the reset controller will not reset any peripherals that are reset-isolated in the device.

NOTE: Any update to the DEVSTAT register made by software, prior to hard/soft reset, will be lost.

If the reset is a soft reset, some of the registers and the memory are preserved in addition to the modules that are not reset by the hard reset. In addition, the reset controller will not reset any peripherals that are reset-isolated in the device.

Refer to Section 5.3, *Reset Management* for detailed descriptions of the different reset types.

4.2.3 Multi-Stage Boot

The BootROM also provides a multi-stage boot mechanism. This feature can be used when a single stage boot does not provide the desired flexibility. The typical use case for a multi-stage boot is to perform a basic boot using the boot mode and parameter settings available in DEVSTAT, let the downloaded code modify the boot parameter table to select new boot parameters or a new boot mode, and then branch to the boot re-entry point to perform a second boot.

The initial boot parameter table is built by the BootROM as described in Section 4.3, *Boot Process, Boot Modes and Pin Usage*. The boot parameter table is not modified by the BootROM when the re-entry point is used.

4.3 Boot Process, Boot Modes and Pin Usage

Because the BootROM supports many boot modes, a set of BOOTMODE pins is used to select a specific boot mode and also provide a minimal configuration for the specified boot mode.

The values on these pins are latched into the Device Status Register (DEVSTAT) as the device comes out of global reset. For more information on these BOOTMODE pins see Section 4.3.2, *BOOTMODE Pins Description*.

NOTE: The following system conditions must be met to perform device boot:

- The USB transceivers (USB2.0), internal to device, are powered upon reset.
- The SD card cage must be appropriately powered before entering the SD card boot feature on any reset.
- Devices must be appropriately powered and be up and ready (reset completed) at device startup:
  - eMMC
  - QSPI
  - NOR
  - Ethernet PHY

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

4.3.1 Boot Process Flow

The BootROM boot process flow is shown in Figure 4-1.

Figure 4-1. Boot Process

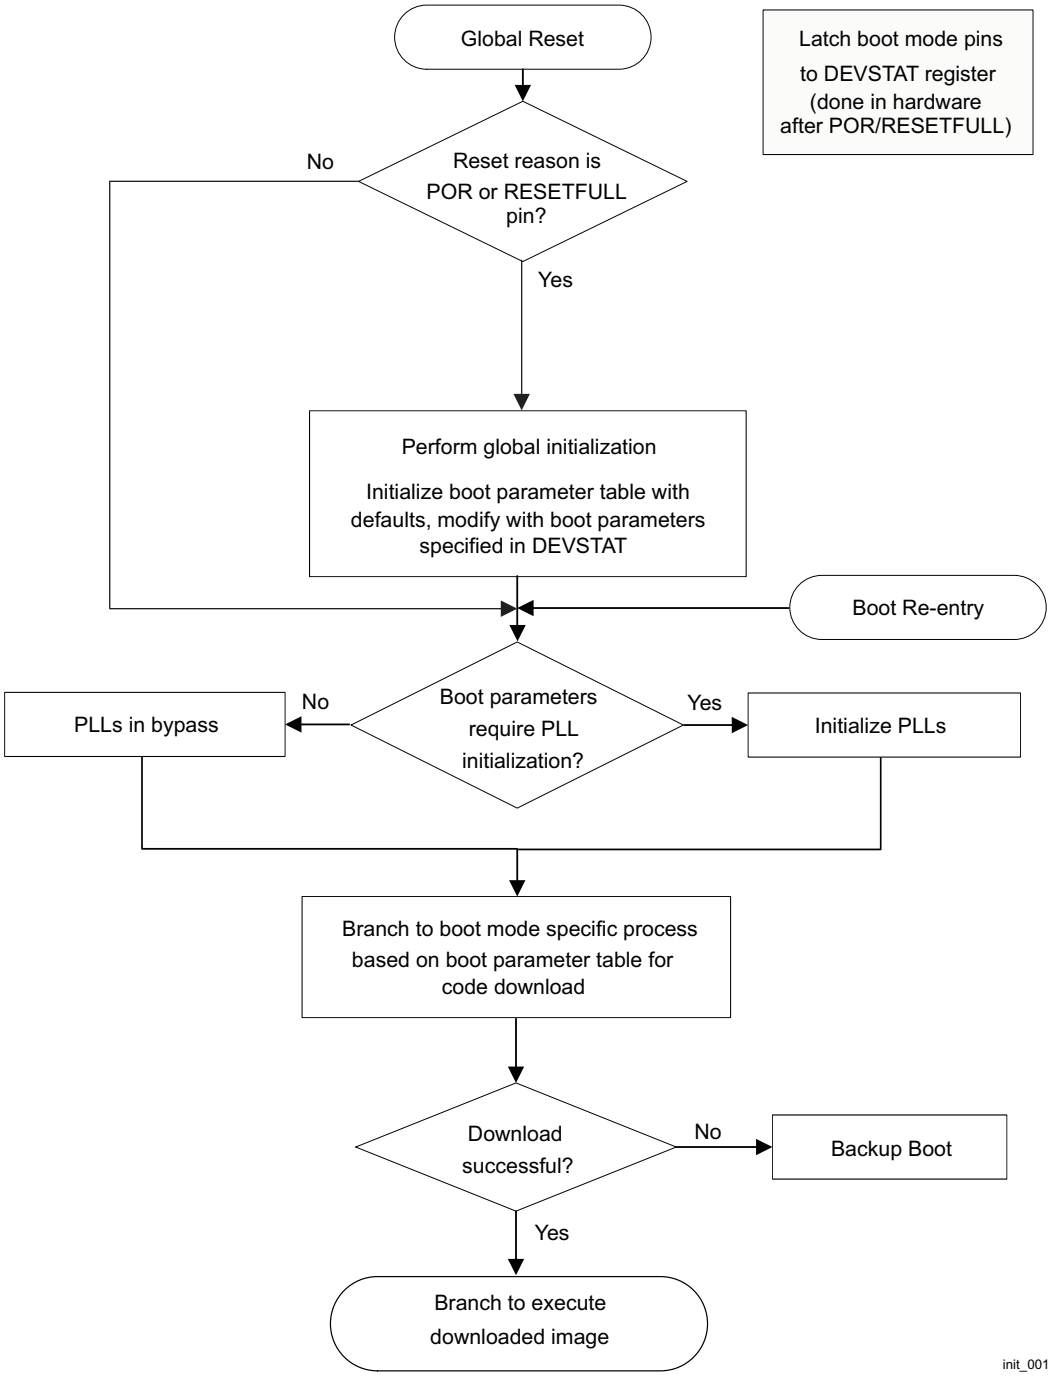

Figure 4-2 describes the external bootloader typical tasks.

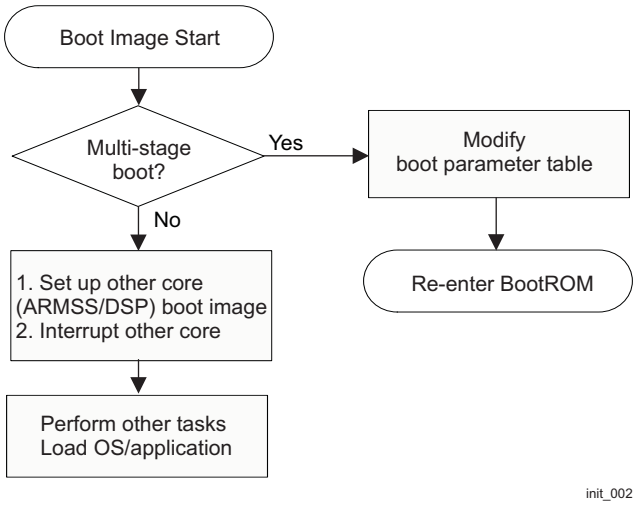
Figure 4-2. External Bootloader Tasks



4.3.2 BOOTMODE Pins Description

BOOTMODE pins provide means to select the boot mode before the device is powered up. They can be divided into the following categories:

- BOOTMODE[3:0] – Select the requested boot mode, that is, the peripheral/memory to boot from.
- BOOTMODE[4] – This is the minimum (MIN) configuration pin. MIN pin allows to not to set all [15:0] BOOTMODE pins, and thus saving DIP switches or pull-ups/pull-downs on the board. A default value, stored in ROM code, is loaded in place of certain BOOTMODE pin values. See the particular boot mode section for the MIN default values.
- BOOTMODE[15:6] – These pins provide additional boot options and are used in conjuction with the boot mode selected. See Figure 4-3 and the corresponding boot mode section.

NOTE: DEVSTAT register reflects the BOOTMODE values sampled after last cold reset.

It is important to keep in mind that BOOTMODE[15:0] **pins** map to DEVSTAT[16-1] BOOTMODE **bits** of the DEVSTAT register.

NOTE: The BootROM will try to proceed with the closest supported configuration at a detection of invalid configuration.

Figure 4-3 shows the BOOTMODE pin mapping to their functions in the different boot modes.

Figure 4-3. BOOTMODE Pin Mapping

4.3.2.3 I²C Master Boot Device Configuration

Figure 4-6 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the I²C master mode.

Figure 4-6. I²C Master Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PORT		BUS ADDR		PIDX/OFFSET			RESERVED			BOOT Master	MIN	0010			
PORT		BUS ADDR		PIDX/OFFSET			REF CLK			BOOT Master	MIN	0011			

Table 4-5. I²C Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15:14	PORT	I²C Port to use during I²C boot.	0
13:12	BUS ADDR	I²C Master bus address to use to access EEPROM. The I²C bus address will be 0x50 + this value.	0
11:9	PIDX/OFFSET	For ARMSS master the initial read is 0x2000 × this value.	0
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*. Don't care field in no-PLL mode.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 0010 = I²C without PLL • 0011 = I²C with PLL	-

4.3.2.4 SPI without PLL Boot Device Configuration

Figure 4-7 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the SPI no-PLL mode.

Figure 4-7. SPI without PLL Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PORT		CSEL	WIDTH		MODE		PIDX/OFFSET			BOOT Master	MIN	0100			

Table 4-6. SPI without PLL Mode Boot Configuration Field Descriptions

Pins	Field	Description	MIN Default Value
15:14	PORT	SPI Port [0-3] used for boot.	0
13	CSEL	Active boot chip select [0-1].	0
12:11	WIDTH	Addresses bit selection: • 0 = 16 bit SPI addresses • 1 = 24 bit SPI addresses • 2-3 = 32 bit SPI addresses	-
10:9	MODE	Mode Selection: • 0 = Data is output on the rising edge of SPICLK. Input data is latched on the falling edge. • 1 = Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK. • 2 = Data is output on the falling edge of SPICLK. Input Data is latched on the rising edge. • 3 = Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.	-
8:6	PIDX/OFFSET	For ARMSS master boot the offset value is based on the SPI address width as shown in Table 4-7.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 0100 = SPI without PLL	-

Table 4-7. SPI Initial Read Address

Address Width (bits)	Read offset
16	0x2000 × OFFSET index
24	0x80000 × OFFSET index
32	0x400000 × OFFSET index

4.3.2.5 SPI with PLL Boot Device Configuration

Figure 4-8 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the SPI with PLL mode.

Figure 4-8. SPI with PLL Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PORT		CSEL	WIDTH		MODE		REF CLK			BOOT Master	MIN	0101 0110 0111			

Table 4-8. SPI with PLL Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15:14	PORT	SPI Port [0-3] used for boot.	0
13	CSEL	Active boot chip select [0-1].	0
12:11	WIDTH	Addresses width selection: • 0 = 16-bit SPI addresses • 1 = 24-bit SPI addresses • 2-3 = 32-bit SPI addresses	-
10:9	MODE	Mode Selection: • 0 = Data is output on the rising edge of SPICLK. Input data is latched on the falling edge. • 1 = Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK. • 2 = Data is output on the falling edge of SPICLK. Input Data is latched on the rising edge. • 3 = Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK.	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 0101 = SPI with PLL, OFFSET index = 0 • 0110 = SPI with PLL, OFFSET index = 1 • 0111 = SPI with PLL, OFFSET index = 2 For ARMSS boot, the offset value is based on the SPI address width as shown in Table 4-7.	-

4.3.2.6 QSPI Boot Device Configuration

Figure 4-9 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the QSPI mode.

Figure 4-9. QSPI Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BACKUP	CSEL		ADDR WIDTH	COMMAND PIN			REF CLK			BOOT Master	MIN	1000 1001			

Table 4-9. QSPI Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15	BACKUP	• 0 = USB boot used as backup after timeout • 1 = UART boot used as backup after timeout	-
14:13	CSEL	Active boot chip select (CS0-CS3).	0
12	ADDR WIDTH	Address width selection: • 0 = 24-bit Address width • 1 = 32-bit Address width	-
11:9	COMMAND PIN	QSPI Command and Pin Configuration See Table 4-10, *QSPI Command/Pin Configuration*	0
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 1000 = QSPI 48 MHz • 1001 = QSPI 96 MHz	-

Table 4-10. QSPI Command/Pin Configuration

COMMAND PIN Pin Value	CMD Value	CMD Name	Dummy Cycles	Mode Byte	Number of Pins Driven for CMD/Mode	Number of Pins Driven for Address	Number of Pins Used for Data
0	0x0B	Fast read	8	None	1	1	1
1	0x3B	Read dual out (DOR)	8	None	1	1	2
2	0x6B	Read quad out (QOR)	8	None	1	1	4
3	0xBB	Dual I/O Read (DIOR)	8	None	1	2	2
4	0xEB	Quad I/O Read	8	None	1	4	4
5	0xBB	Dual I/O read	4	Yes (sent as 0)	1	2	2
6	0xEB	Quad I/O read	5	Yes (sent as 0)	1	4	4
7	0xEB	QPI read	6	Yes (sent as 0)	4	4	4

4.3.2.7 XIP Boot Device Configuration

For XIP boot the 256-Mbyte address space is divided into four 64-Mbyte chip select regions. A different chip select region size can be selected through a multi-stage boot.

Figure 4-10 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the XIP/NOR mode.

Figure 4-10. XIP Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADP/AD/AAD Mux		CSEL		WAIT	WIDTH	BASE	REF CLK			BOOT Master	MIN	1010			

Table 4-11. XIP Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15:14	ADP/AD/AAD	Mode selection: • 0 = ADP mode (address data parallel) • 1 = AD mode (address/data mux) • 2 = AAD mode (address/address/data mux) • 3 = ADP mode	-
13:12	CSEL	Active boot chip select (CS0-CS3).	0
11	WAIT	Enable extended wait monitor: • 0 = disable • 1 = enable	-
10	WIDTH	Bus width selection: • 0 = 16-bit bus width • 1 = 8-bit bus width	-
9	BASE	Base address boot selection: • 0 = Boot from base address for chip select • 1 = Boot from base address + 4 Mbyte for chip select	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 1010 = XIP	-

NOTE: Table 4-26 defines which GPMC_WAIT[x] input and its polarity is used during XIP boot based on the state of the CSEL and WAIT configuration inputs.

4.3.2.8 Ethernet Boot Device Configuration

Figure 4-11 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the Ethernet mode.

Figure 4-11. Ethernet Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Phy CFG	RMII CLK	S_SPD	H_DUP	External I/F		REF CLK			BOOT Master	MIN	1100			

Table 4-12. Ethernet Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15	RSVD	Reserved. Set to 0.	-
14	PHY CFG	Physical configuration: • 0 = Do not read RMII speed duplex configuration from the PHY • 1 = Read the RMII speed duplex configuration from the PHY	-
13	RMII CLK	RMII Clock configuration: • 0 = RMII ref clock configured as an output • 1 = RMII ref clock configured as an input	-
12	S_SPD	Speed configuration: • 0 = Run at highest speed (1000 or 100 Mbps) • 1 = Run at lowest speed (100 or 10 Mbps)	-
11	H_DUP	Duplex selection: • 0 = Full duplex • 1 = Half duplex	-
10:9	External I/F	External Interface selection: • 0 = RGMII with internal delay • 1 = RGMII without internal delay • 2 = RMII • 3 = G/MII	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 1100 = Ethernet	-

4.3.2.9 USB Boot Device Configuration

Figure 4-12 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the USB mode.

Figure 4-12. USB Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Phy Frequency SEL			REF_SRC		0	PORT	REF CLK			0	MIN	1101			

Table 4-13. USB Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15:13	Phy Frequency SEL	Frequency selection: • 0 = Reserved • 1 = Reserved • 2 = 12 MHz (with internal clock selects UART PLL) • 3 = 19.2 MHz (with internal clock selects UART PLL) • 4 = Reserved • 5 = 24 MHz (with internal clock selects UART PLL) • 6 = Reserved • 7 = 50 MHz (with internal clock selects NSS PLL)	-
12:11	REF_SRC	Clock selection: • 0 = Reserved • 1 = External clock connected to XO pin • 2 = Internal clock • 3 = Reserved	-
10	D_MOD	DFU support enable: • 0 = Device firmware upgrade (DFU) support enabled (device mode only)	-
9	PORT	Port enable: • 0 = Enable only port 0 • 1 = Enable only port 1	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0] • 1101 = USB	-

NOTE: When the internal reference clock is selected the choice of NSS versus UART PLL is made based on the desired reference frequency.

4.3.2.10 MMCSD Boot Device Configuration

Figure 4-13 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the MMCSD mode.

Figure 4-13. MMCSD Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BACKUP	B_ACK	BOOT	Card Type		1 bit	PORT	REF CLK			0	MIN	1110			

Table 4-14. MMCSD Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15	BACKUP	• 0 = USB boot used as backup after timeout • 1 = UART boot used as backup after timeout	-
14	B_ACK	Boot Acknowledgement: • 0 = No Boot Acknowledgement expected from MMC • 1 = Boot Acknowledgement expected, will timeout if not received	-
13	BOOT	Boot: • 0 = eMMC boot sector is not used for boot • 1 = Boot data is read from eMMC boot sector	-
12:11	Card Type	Card type selection: • 0 = Auto detect • 1 = MMC card • 2 = SD card • 3 = Auto detect	-
10	1 bit	• 0 = Use maximum available data lines • 1 = Do complete boot in 1 bit mode	-
9	PORT	Boot port: • 0 = Boot from port 0 • 1 = Boot from port 1	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 1110 = MMCSD	-

NOTE: Only MMC supports the boot sector (and not SD). Setting the BOOT bit implies the card type is MMC.

4.3.2.11 UART Boot Device Configuration

Figure 4-14 shows the BOOTMODE[15:6] pins assignment to functions when BOOTMODE[3:0] select the UART mode.

Figure 4-14. UART Boot Mode Configuration Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BACKUP		TOUT		PORT		REF CLK			BOOT Master	MIN	1111			

Table 4-15. UART Mode Boot Configuration Field Description

Pins	Field	Description	MIN Default Value
15	RSVD	Reserved. Set to 0.	-
14:13	BACKUP	Boot device after timeout: • 0 = I^2C Boot after timeout • 1 = SPI Boot after timeout • 2 = XIP Boot after timeout • 3 = Reserved	-
12:11	TOUT	Timeout configuration: • 0 = Never timeout • 1 = Timeout after 12 seconds • 2 = Timeout after 30 seconds • 3 = Timeout after 60 seconds	-
10:9	PORT	Port select: • 0 = Boot on UART 0 • 1 = Boot on UART 1 • 2 = Boot on UART 2 • 3 = Boot on UART 0	-
8:6	REF CLK	PLL reference clock. See Table 4-16, *Reference Clock Values*.	0
5	BOOT Master	Boot Master select • 0 = ARMSS is boot master	-
4	MIN	Minimum boot configuration select bit. • 0 = All fields must be independently configured • 1 = A predetermined set of values is configured	-
3:0	Boot Devices	Boot Devices[3:0]: • 1111 = UART	-

4.3.2.12 PLL Configuration

- Possible ARMSS Speeds are 200, 400, 600, 800, 1000 MHz
- Possible DSP Speeds are 400, 600, 800, 1000 MHz

The default speed to start with after cold reset is derived from EFUSE_BOOTROM register.

To select the PLL reference clock, see Table 4-16. This setting must be made according to the actual clock speed provided by system board. That is, the crystal mounted on board, or the clock supplied by an external clock generator.

Table 4-16. Reference Clock Values

REF CLK Boot Pin Value	PLL Reference Clock, MHz	Clock Source
0	19.2	System oscillator or external clock input(1)
1	24	System oscillator or external clock input
2	25	System oscillator or external clock input
3	26	System oscillator or external clock input
4-7	Reserved	Reserved

(1) See Section 5.4, *Clock Management.*

4.3.3 Boot Parameter Tables

The ROM Bootloader (BootROM) uses a set of tables to carry out the boot process. The boot parameter table is the most common format the BootROM employs to determine the boot flow. These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in Table 4-17.

The boot tables reside at a fixed location in memory which is described in Section 4.4, *Boot RAM Memory Map*.

Table 4-17. Boot Parameter Table Common Parameters

Byte Offset	Name	Default Value	Description
0	Length	-	The length of the boot parameter table, including the length field itself, in bytes.
2	Checksum	0	The 16 bits ones complement of the ones complement of the entire table. A value of 0 will disable checksum verification of the table by the boot ROM.
4	Boot Mode	See Table 4-18.	Internal values used by BootROM for different boot modes. See Table 4-18.
6	Port Num	0	Identifies the peripheral port number to boot from, if applicable. For example, ports of I2C, SPI, UART, and others.
8	PLL 0 CFG, MSW	According to PLL reference clock speed and EFUSE_BOOTROM register	MAIN PLL configuration, MSW. See Figure 4-15.
10	PLL 0 CFG, LSW		MAIN PLL configuration, LSW
12	PLL 1 CFG, MSW		ARM PLL configuration, MSW
14	PLL 1 CFG, LSW		ARM PLL configuration, LSW
16	System Frequency	From EFUSE_BOOTROM register	The frequency of the system clock in MHz
18	Core Frequency	From EFUSE_BOOTROM register	The frequency of the core clock in MHz
20	Boot Master	-	Non-zero if current core is the boot master

Table 4-18 lists the possible boot modes used in the boot parameter tables.

Table 4-18. Boot Mode Values

Boot Mode Value (decimal)	Boot Mode
30	PCIe
40	I^2C Master
41	I^2C Slave
42	I^2C Master Write (Transmit mode)
50	SPI
70	XIP
80	Reserved
90	Ethernet, BOOTP/TFTP protocol.
100	Sleep
110	UART
140	USB
150	MMCSD
160	QSPI

Figure 4-15 and Table 4-19 describe the PLL configuration fields.

Figure 4-15. PLL Configuration Fields

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTL		MULTIPLIER														PRE_DIVIDE								POST_DIVIDE							

Table 4-19. PLL Configuration Field Description

Bit	Field	Description
31-30	CTL	Initialization of PLL: • 0 = Do Not Initialize the PLL • 1 = Initialize the PLL only if it was not already enabled • 2 = Unconditionally initialize the PLL • 3 = Unconditionally disable the PLL
29-16	MULTIPLIER	The PLL multiplier to use. This is the *true multiplier value*, not the multiplier (value -1) used in the register programming of the PLL. Possible multiplier values are [0-16383].
15-8	PRE_DIVIDE	The PLL pre-divider value to use. The *true divider value.* Possible values are [0-255].
7-0	POST_DIVIDE	The PLL post divider value to use. Only values 1 and 2 are supported in this device.

4.3.3.1 Sleep Boot Parameter Table

Table 4-20 shows the boot parameter table for Sleep boot (no boot). Must be preceded with the common boot parameters described in Table 4-17.

Table 4-20. Sleep Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	0	Currently unused	NO

4.3.3.2 PCIE Boot Parameter Table

Table 4-21 shows the boot parameter table for PCIe boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-21. PCIE Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	0	bit 0 Reserved bit 1 NO_INIT • 0 = PCIe subsystem is configured by boot code • 1 = PCIe subsystem is not configured by boot code bits 15-2 Reserved	NO
24	Address WITDH	From pins	Only values 32 or 64 supported	YES in conjunction with BAR sizes
26	Link Rate	2500	Only 2500 MHz supported	NO
28	Ref Clock	From pins		YES
30	Window 1 Size	From pins, see Section 4.3.2.2, *PCIE Boot Device Configuration*	PCIE BAR 1 Size	YES
32	Window 2 Size		PCIE BAR 2 Size	YES
34	Window 3 Size		PCIE BAR 3 Size (valid only with 32-bit address)	YES
36	Window 4 Size		PCIE BAR 4 Size (valid only with 32-bit address)	YES
38	Window 5 Size		PCIE BAR 5 Size (valid only with 32-bit address)	YES
40	Vendor ID	0x104C	PCIe Vendor ID Value	NO

Table 4-21. PCIE Boot Parameter Table (continued)

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
42	Device ID	0xB00A	PCIe Device ID Value	NO
44	Class Code, Rev MSW	0x0480	Class code, class 4	NO
46	Class Code, Rev, LSW	0x0001	Revision Id	NO
48	RSVD	0	Reserved	NA
50	RSVD	1	Reserved	NA
52	RSVD	0	Reserved	NA
54	RSVD	0	Reserved	NA
56	RSVD	0	Reserved	NA
58	RSVD	0	Reserved	NA
60	Timeout	See Section 4.3.2.2, *PCIE Boot Device Configuration*	Boot timeout, seconds	NO

4.3.3.3 I^2C/I^2C Slave/I^2C Master Write Boot Parameter Table

Table 4-22 shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-22. I^2C/I^2C Slave/I^2C Master Write Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	3	bits 2-0 BOOT TYPE • 3 = GP Format Read • 4 = Slave Option receive • Others = Reserved	NO
24	Read Addr	See Section 4.3.2	The 16-bit read address (when in master boot)	NO
26	Bus Addr	See Section 4.3.2	The I^2C Bus address (when in master boot)	NO
28	Write Addr	0x11	Transmit write address (when in master transmit mode)	NO
30	Local Addr	0x10 (I^2C Slave), From pins (I^2C)	I^2C Bus address of the device I^2C port	YES (I^2C)
32	I^2C Frequency	20	I^2C Bus frequency driven by the device I^2C port	NO
34	Next Read Addr	0	Read address after completion of a CONFIG table	NO
36	Next Bus Addr	0	Bus address after completion of a CONFIG table	NO
38	Address delay	0x200	CPU cycle delay between address write and data read	NO

The Boot type field refers to how the boot code handles data read from the I^2C interface.

The following mode is supported in ARMSS master boot mode:

- GP format read – the data read from the I^2C interface is treated as GP header formatted data.

In slave receive option mode, the data read from the I^2C interface is treated as a new options field, which replaces the existing field (which must have indicated slave receive options) and the boot is restarted (with presumably boot data following).

4.3.3.4 SPI Boot Parameter Table

Table 4-23 shows the boot parameter table for SPI boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-23. SPI Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	3	bits 1-0 • 0 = Data read is formatted as a Boot Parameter Table • 1 = Data read is formatted as Boot Table Data • 2 = Data read is formatted as a BOOT CONFIG table • 3 = Data read is formatted as GP Header data bits 15-2 = Reserved	NO
24	Address Width	See Section 4.3.2	The 16-bit read address (master boot)	YES
26	NPins	8	Number of pins driven (clock, data in, data out, chip selects)	YES
28	CSEL	See Section 4.3.2	Bit field specifying chip select – with a 0 bit indicating the active select	YES
30	Mode	See Section 4.3.2	Clock Phase/Polarity setting	YES
32	C2T delay	1	SPI C2T value	NO
34	Bus Frequency (100 kHz)	5	500-kHz bus frequency by default	NO
36	Address, MSW	See Section 4.3.2	Read address, MSW	YES
38	Address, LSW		Read address, LSW	YES
40	Next CSEL	0	CSEL used after BOOT CONFIG is done	NO
42	Next read, MSW	0	Read used after BOOT CONFIG is done	NO
44	Next read, LSW	0	Read used after BOOT CONFIG is done	NO
46	SPI read command	0x03	Command used to read EEPROM	NO
48	Num Dummy bytes	0	Number of dummy bytes sent after read command	NO
50	Initial Commands	0	Not supported	NO

4.3.3.5 QSPI Boot Parameter Table

Table 4-24 shows the boot parameter table for QSPI boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-24. QSPI Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	See Description	bits 1-0 FORMAT • 0 = Data read is formatted as a Boot Parameter Table • 1 = Data read is formatted as Boot Table Data • 2 = Data read is GP header data (ARMSS default) • 3 = Reserved bits 3-2 DATA IO WIDTH • 0 = Data received in 1 IO pin (default if Addr Width boot pin is 0) • 1 = Data received in 2 IO pins • 2-3 = Data received on 4 IO pins (default if Addr Width boot pin is 1) bits 5-4 ADDRESS IO WIDTH • 0 = Address value sent on 1 IO pin (default if Addr Width boot pin is 0) • 1 = Address value sent on 2 IO pins • 2-3 = Address value sent on 4 IO pins (default if Addr Width boot pin is 1) bits 7-6 INSTRUCTION IO WIDTH • 0 = Instruction sent on 1 IO pin (default if Addr Width boot pin is 0) • 1 = Instruction sent on 2 IO pins • 2-3 = Instruction sent on 4 IO pins (default if Addr Width boot pin is 1) bit 8 MODE_EN • 0 = No mode bytes are sent after the address • 1 = One mode byte is sent after the address value (default) bits 15-9 Reserved	NO
24	Address Width	See Section 4.3.2	16, 24 or 32 bit address width	YES
26	CSEL	See Section 4.3.2	Bitfield specifying chip select – bit 0 indicating the active chip select	YES
28	Mode	See Section 4.3.2	Clock Phase/Polarity setting	YES
30	Bus Freq (100 kHz)	480	48 MHz bus frequency	NO
32	Address, MSW	0	Read address, MSW	NO
34	Address, LSW	0	Read address, LSW	NO
36	QSPI PLL CFG MSW	See Section 4.3.2	QSPI PLL Configuration. See Figure 4-15 and Table 4-19.	NO
38	QSPI PLL CFG LSW			NO
40	Module Freq, (100 kHz)	3840	384 MHz module clock	NO
42	Read Command	0x03 or 0xEB	Read command. Default based on 1 bit vs 4 bit selection	NO
44	Mode Byte value	0	Mode Byte value	NO
46	Dummy bytes	0 (1bit) or 2 (48MHz) or 8 (96MHz)	Number of dummy bytes sent after read command	NO
48	Delay, MSW	0x0808 or 0x1010(1)	Chip select delays, MSW: bits 7-0 CSDADS: Chip Select De-Assert Different Slave bits 15-8 CSDA: Chip Select De-Assert	NO

(1) The default values are chosen to be 1 QSPI bit clock. Based on a 384-MHz module clock this comes to 0x8 for 48 MHz QSPI clock or 0x10 for a 96 MHz QSPI clock.

Table 4-24. QSPI Boot Parameter Table (continued)

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
50	Delay, LSW	0x0808 or 0x1010[1]	Chip select delay, LSW: bits 7-0 CSSOT: Chip Select Start of Transfer delay bits 15-8 CSEOT: Chip Select End of Transfer delay	NO
52	CONFIG Command Array	0	Not supported	NO

4.3.3.6 XIP Boot Parameter Table

Table 4-25 shows the boot parameter table for NOR XIP boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-25. XIP Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	0	bit 0 REF_CFG • 0 = GPMC CONFIG values in parameter table are not used • 1 = GPMC CONFIG values in parameter table configures the GPMC bits 15-1 Reserved	NO
24	Type	1	GPMC type, must be 1	NO
26	Address, MSW	See Section 4.3.2	XIP memory address, MSW	YES
28	Address, LSW		XIP memory address, LSW	YES
30	Chip Select		Active chip select (0-3)	YES
32	Mem width		Memory width. Values 8 or 16 are valid.	YES
34	Wait enable		Extended wait enable 0 = disabled Other values = enabled	YES
36	Chip Select Size	64	Chip select size, MB. Only 128, 64, 32 and 16 are valid.	NO
38	GPMC Config 1 MSW	0	GPMC_CONFIG1 register, MSW	NO
40	GPMC Config 1 LSW	0	GPMC_CONFIG1 register, LSW	NO
42	GPMC Config 2 MSW	0	GPMC_CONFIG2 register, MSW	NO
44	GPMC Config 2 LSW	0	GPMC_CONFIG2 register, LSW	NO
46	GPMC Config 3 MSW	0	GPMC_CONFIG3 register, MSW	NO
48	GPMC Config 3 LSW	0	GPMC_CONFIG3 register, LSW	NO
50	GPMC Config 4 MSW	0	GPMC_CONFIG4 register, MSW	NO
52	GPMC Config 4 LSW	0	GPMC_CONFIG4 register, LSW	NO
54	GPMC Config 5 MSW	0	GPMC_CONFIG5 register, MSW	NO

Table 4-25. XIP Boot Parameter Table (continued)

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
56	GPMC Config 5 LSW	0	GPMC_CONFIG5 register, LSW	NO
58	GPMC Config 6 MSW	0	GPMC_CONFIG6 register, MSW	NO
60	GPMC Config 6 LSW	0	GPMC_CONFIG6 register, LSW	NO
62	GPMC Config 7 MSW	0	GPMC_CONFIG7 register, MSW	NO
64	GPMC Config 7 LSW	0	GPMC_CONFIG7 register, LSW	NO
66	GPMC Config MSW	0	GPMC_CONFIG register, MSW	NO
68	GPMC Config LSW	0	GPMC_CONFIG register, LSW	NO

BootROM configures the GPMC chip selects with the WAIT pins and WAIT pin polarities as shown in Table 4-26. These settings can be later overriden in the GPMC Config registers.

Table 4-26. Wait Pin Configuration

Chip Select	Wait Pin Mapping	Wait Pin Polarity
CS0	WAIT0	Active-Low
CS1	WAIT1	Active-High
CS2	WAIT0	Active-Low
CS3	WAIT1	Active-High

NOTE: The boot ROM always configures region 0. The GPMC base address and mask fields are setup to match the requested chip select.

4.3.3.7 Ethernet BOOTP/TFTP Boot Parameter Table

Table 4-27 shows the boot parameter table for Ethernet BOOTP/TFTP boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-27. BOOTP/TFTP Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	See Section 4.3.2	bit 0 NO BOOTP • 0 = BOOTP send to determine IP configuration and TFTP information • 1 = BOOTP is not sent. IP configuration and TFTP information already present. bits 4-1 Reserved bits 6-5 INIT • 0 = Fully initialize Ethernet subsystem • 1 = Initialize only currently un-initialized Ethernet subsystem components • 2 = Reserved • 3 = Do not initialize Ethernet subsystem bits 10-7 INTERFACE • 0 = Autodetect if possible • 1 = RMII • 2 = G/MII • 3 = RGMII • 4-7 = Reserved bits 15-11 Reserved	NO
24	MAC Addr, MSW	From E-FUSE	16 MSBs of the MAC address	NO
26	MAC Addr, middle		16 middle bits of the MAC address	NO
28	MAC Addr, LSW		16 LBSs of the MAC address	NO
30	Multi MAC, MSW	0xFFFF	16 MSBs of the multicast MAC address	NO
32	Multi MAC, middle	0xFFFF	16 middle bits of the multicast MAC address	NO
34	Multi MAC, LSW	0xFFFF	16 LSBs of the multicast MAC address	NO
36	BOOTP timeout, MS	4000	4-sec Initial BOOTP timeout	NO
38	TFTP ack timeout, MS	1000	1-sec TFTP timeout	NO
40	Total timeout, sec	90	90-second timeout	NO
42	BOOTP retry limit	10	Retry BOOTP 10 times	NO
44	TFTP retry limit	10	Retry TFTP 10 times	NO
46	Vendor String	“TCI c66x Bootp Boot”	BOOTP request vendor string field	NO
78	ID String	From E-FUSE	The e-fuse MAC address, not the MAC address from this table	NO
98	Lane Enable Mask	See Section 4.3.2	One bit per lane. • 0 - Lane disabled • 1 - Lane enabled	NO
100-111	Reserved	0	Reserved	NA
112	Eth ref, MSW	See Section 4.3.2	G/MII reference clock frequency, MHz. Only 12500 and 15625 are supported.	NO
114	Eth Ref, LSW			NO
116	NSS PLL, MSW		NSS PLL Configuration. Layout is same for MAIN PLL shown in Figure 4-15	NO
118	NSS PLL, LSW			NO
120	Blob Base, MSW	0x0C00	Address to receive image, MSW	NO
122	Blob Base, LSW	0x0000	Address to receive image, LSW	NO

4.3.3.8 USB Boot Parameter Table

Table 4-28 shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-28. USB Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	0	Currently unused	NA
24	USB Clk SRC	-	USB clock source 0 = external crystal, 1 = external oscillator, 2 = UART PLL, 3 = NSS PLL	YES
26	USB PLL output freq, MHz	-	PLL output frequency. 384 MHz for UART, 1000 MHz for NSS	NO
28	USB ref clock, 100 kHz	-	Value 9.6-, 10-, 12-, 19.2-, 20-, 24-, and 50-MHz are supported (×10 in this field)	YES
30	USB internal source clock divide	-	When clock source is 2 or 3, this is the additional divide factor (1 = divide by 1, 2 by 2, and so forth)	NO
32	USB PLL MSW	-	UART or NSS PLL (depending on USB Clk SRC) config, MSW	NO
34	USB PLL LSW	-	UART or NSS PLL config, LSW	NO
36	Timeout	See Section 4.3.2	Boot timeout value in ms. 0 disables timeout	NO
38	Mode		1 = DFU mode (in device (peripheral) mode) All other values are reserved	YES
40	ID Vendor	0x451	USB Vendor ID value	NO
42	ID Product	0xBB06 (from JTAGID register, PARTNUMBER field)	USB Product ID value	NO
44	BCD Device	0x0000 (from JTAGID register, VARIANT field)	Binary-coded-decimal device release version	NO
46	String OFFSET Vendor	0	Index into RAM string block containing the vendor string	NO
48	String OFFSET product	18	Index into RAM string block containing the product string	NO
50	Serial number OFFSET	27	Index into RAM string block containing the serial number string	NO

4.3.3.9 MMCSD Boot Parameter Table

Table 4-29 shows the boot parameter table for MMC or SD card boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-29. MMCSD Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	See Section 4.3.2	bit 0 1-bit • 0 = Detect and use full bus width • 1 = Boot in 1-bit mode bits 2-1 MEDIA • 0 = Auto detect • 1 = MMC • 2 = SD • 3 = Auto detect bit 3 BOOT • 0 = Do not boot from MMC boot sectors • 1 = Boot from MMC boot sectors (MEDIA must be set to 1 = MMC) bit 4 BOOT_ACK • 0 = Do not configure for boot acknowledgement • 1 = Configure for boot acknowledgement, timeout if not received bits 15-5 Reserved	YES
24	MMCSD PLL MSW	See Section 4.3.2	UART PLL setup	YES
26	MMCSD PLL LSW			YES
28	Discovery Bus Freq	400	Initial clock speed, kHz	NO
30	Module Freq	3840	Module Frequency, 100 kHz units	NO
32	File Name	“\tiboot.bin”	Boot filename for SD card in UNICODE. Each entry is 16 bits, with a 16-bit 0x0000 terminator	NO
122	Reserved	X	Reserved	NA

4.3.3.10 UART Boot Parameter Table

Table 4-30 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 4-17.

Table 4-30. UART Boot Parameter Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
22	Options	0	Currently unused	NA
24	Data Format	0	bit 0 Data Format • 0 = Data Format is BLOB. bits 15-1 Reserved	NO
26	Protocol	0	0 = XMODEM Other values are reserved	NO
28	Ping limit	See Section 4.3.2	Number of pings before failure	NO
30	Max Error	10	Error limit before failure	NO
32	Nack Timeout, sec	3	Timeout value for pings, ACKs/NACKs	NO
34	Char Timeout, msec	2	Milliseconds for inter-character timeout	NO
36	Data bits	8	Only 8 bits is supported	NO

Table 4-30. UART Boot Parameter Table (continued)

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
38	Parity	0	bits 1-0 Parity • 0 = No Parity • 1 = Odd parity • 2 = Even Parity bits 15-2 Reserved	NO
40	Num Stop bits x2	2	2× the number of stop bits used. Values 2, 3, and 4 supported	NO
42	Over sample	16	16× and 13× only supported oversample factors	NO
44	Flow control	0	bit 0 Flow Control • 0 = No Flow Control • 1 = Hardware RTS/CTS flow control bits 15-1 Reserved	NO
46	Data rate, MSW	0x0001	Baud rate, MSW. Default value = 115200	NO
48	Data rate, LSW	0x2C00	Baud rate, LSW	NO
50	Blob Base, MSW	0x0C00	For blob format, base address, MSW	NO
52	Blob Base, LSW	0x0000	Blob Base, LSW	NO
54	UART PLL, MSW	See Section 4.3.2	UART PLL configuration, MSW	YES
56	UART PLL, LSW		UART PLL configuration, LSW	YES
58	UART PLL output	3840	UART PLL output in 100-kHz units	NO

4.3.3.11 DDR_EMIF Configuration Table

The BootROM also provides an option to configure the DDR table before loading the image into the external memory. ROM function is provided for this purpose (Section 4.5, *BootROM Function Calls*). The configuration table for DDR_EMIF is shown in Table 4-31.

Table 4-31. DDR_EMIF Configuration Table

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
0	configselect msw	-	Mask for the configuration registers (below in the table) to be set. 1 = enables the register setting. Each register is represented by one bit	NO
4	configselect slsw	-	Mask for the configuration registers	NO
8	configselect lsw	-	Mask for the configuration registers	NO
12	pllprediv	-	DDR PLL pre divider value (must be the exact value, not value-1)	NO
16	pllMult	-	DDR PLL multiplier value (must be the exact value, not value-1)	NO
20	pllPostDiv	-	DDR PLL post divider value (must be the exact value, not value-1)	NO
24	sdRamConfig	-	SDRAM Config register	NO
28	sdRamConfig2	-	SDRAM Config register	NO
32	sdRamRefreshctl	-	SDRAM Refresh Control Register	NO
36	sdRamTiming1	-	SDRAM Timing 1 Register	NO
40	sdRamTiming2	-	SDRAM Timing 2 Register	NO
44	sdRamTiming3	-	SDRAM Timing 3 Register	NO
48	lpDfrNvmTiming	-	LP DDR2 NVM Timing Register	NO
52	powerMngCtl	-	Power management Control Register	NO

Table 4-31. DDR_EMIF Configuration Table (continued)

Byte Offset	Name	Default Value	Description	Configured Through BOOTMODE Pins?
56	iODFTTestLogic	-	IODFT Test Logic Global Control Register	NO
60	performcountCfg	-	Performance Counter Config Register	NO
64	performCountMstRegSel	-	Performance Counter Master Region Select Register	NO
68	readIdleCtl	-	Read IDLE counter Register	NO
72	sysVbusmIntEnSet	-	System Interrupt Enable Set Register	NO
76	sdRamOutImpdedCalcfg	-	SDRAM Output Impedance Calibration Config Register	NO
80	tempAlertCfg	-	Temperature Alert Configuration Register	NO
84	ddrPhyCtl1	-	DDR PHY Control Register 1	NO
88	ddrPhyCtl2	-	DDR PHY Control Register 1	NO
92	proClassSvceMap	-	Priority to Class of Service mapping Register	NO
96	mstId2ClsSvce1Map	-	Master ID to Class of Service Mapping 1 Register	NO
100	mstId2ClsSvce2Map	-	Master ID to Class of Service Mapping 2 Register	NO
104	eccCtl	-	ECC Control Register	NO
108	eccRange1	-	ECC Address Range1 Register	NO
112	eccRange2	-	ECC Address Range2 Register	NO
116	rdWrtExcThresh	-	Read Write Execution Threshold Register	NO
120 - 376	Chip Config	-	Chip Specific PHY configuration	NO

4.3.4 Boot Configuration Format

The BootROM uses a set of tables to carry out the boot process. The basic types of tables used by the BootROM are:

- Boot parameter table
- Boot image table

4.3.4.1 Boot Parameter Table

The boot parameter table is the most common format the BootROM employs to determine the boot flow. Boot parameter tables have a first few parameters in the table common across all the boot modes while the rest of the table format is dependant on the boot mode selected. See Section 4.3.3, *Boot Parameter Table* for the boot parameter table format for different boot modes. The BootROM copies a default boot parameter table for each boot mode into the reserved L2 section of master boot Core0 and modifies the default values based on the boot configuration selected through the BOOTMODE pins. This table forms the maps for the BootROM to execute the boot process.

4.3.4.2 Boot Image Table

The image to be loaded into the device is converted to a format recognizable by the BootROM.

4.3.4.2.1 GP Header Boot Image Format

The GP (General Purpose) header image format is blocks of data, each preceded with an 8-byte header. The 8-byte header consists of a 4-byte length and a 4-byte base address. A block of data follows each header. The data block must contain the number of bytes specified in the block length field. Each GP header image must contain at least one data block, but may contain more. Additional blocks are appended to the previous blocks. The image ends with a trailing 4-byte length field containing 0. This image format is usually used for boot modes in which the image is read from non-volatile memory. The general format of a GP header image is shown in Table 4-32.

Table 4-32. GP Header Boot Image Format

Header Image Format Parts	Subpart	Size	Description
BLOCK 0 GP HEADER	BLOCK 0 LENGTH	4 BYTES	Number of DATA bytes BLOCK 0
	BLOCK 0 BASE	4 BYTES	Address
BLOCK 0 DATA		= BLOCK 0 LENGTH	DATA
BLOCK 1 GP HEADER	BLOCK 1 LENGTH	4 BYTES	Number of DATA bytes BLOCK 1
	BLOCK 1 BASE	4 BYTES	Address
BLOCK 1 DATA		= BLOCK 1 LENGTH	DATA
...	...	...	...
BLOCK N GP HEADER	BLOCK N LENGTH	4 BYTES	Number of DATA bytes BLOCK N
	BLOCK N BASE	4 BYTES	Address
BLOCK N DATA		= BLOCK N LENGTH	DATA
TERMINATING 0		4 BYTES	Zero Length Indicator

The data in a GP header formatted image is processed as it is read from the boot source. The length field in each header tells the boot data processor how many bytes to expect in that block and the base address tells it where to store the data. Data processing continues until a terminating length of 0 is encountered. After all blocks have been read, the BootROM branches to the last base address specified in the image to begin execution of the image.

4.3.4.2.2 Blob Boot Image Format

The blob image format is simply a binary load image with the entry point being the first byte of the image. This image format is generally used for boot modes where the image is received from a host.

In boot modes in which the host does not have direct access to device memory, the image will be stored at a pre-determined address, typically the base address of MSMC SRAM. In these cases, the image must be linked to execute from that address. After the complete image has been received and stored, the BootROM branches to the image storage address for execution.

In boot modes in which the host has direct access to device memory, the host may store the image anywhere in device memory. After writing the image into device memory, the host must write the load address at the BOOT_MAGIC_ADDRESS location. When the BootROM sees a non-zero value as the BOOT_MAGIC_ADDRESS data, it branches to the address written.

4.3.4.3 Utilities Used to Generate Different Tables

4.3.4.3.1 Utilities for ARMSS Boot

Utilities used to generate different table formats for ARMSS boot are listed below:

- BYTESWAPCCS — byteswaps files in ccs format
- BYTESWAPBIN — creates a byte swapped copy of a binary file
- CATCCS — concatenates ccs format files
- CCS2BIN — converts ccs format to binary
- B2CCS — converts a hex b file into a ccs data file
- CCSADDGPHDR — adds a general-purpose header to a ccs format file
- CCSADDGPTLR — adds the 8-byte General Purpose Trailer
- CCSPAD — pad a ccs data file to a certain length. The length is in number of lines.

4.3.5 Boot Modes

4.3.5.1 Sleep Boot

The sleep boot mode does not result in any image being loaded for execution. In the ARMSS master sleep boot mode, the ARMSS simply performs ARM PLL and MAIN PLL initialization if specified by the BOOTMODE pins and then executes a polling loop of its BOOT_MAGIC_ADDRESS. This mode is typically used in debug and development environments in which code images are loaded using an emulator.

4.3.5.2 I²C Bootloader Operation

4.3.5.2.1 I²C BootROM Initialization Process

In the I²C boot mode, the BootROM configures the I²C peripheral.

I²C can operate either in master mode or in slave mode. In the master mode, the boot master drives the I²C slave device where the image is stored. In the slave mode, the data transfer is driven by an external I²C master device. The master device is usually another SoC device or a FPGA. The boot configuration options in the DEVSTAT register are used to select the master/slave mode.

The user is capable of loading the image at any block, provides the offset of the block, the speed of the I²C bus through the BOOTMODE pins values. A detailed summary of the I²C boot parameter table and the BOOTMODE pins definitions are listed in Section 4.3.3.3, *I2C/I2C Slave/I2C Master Write Boot Parameter Table*, Section 4.3.2.1, *Sleep/I2C Slave Boot Device Configuration*, and Section 4.3.2.3, *I2C Master Boot Device Configuration*.

4.3.5.2.1.1 Block Size

With ARMSS master boot the boot code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64k bytes. What this means is that if the read address is 0xFF00, the read size is 0x200 and the I²C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

4.3.5.2.2 I²C BootROM Loading Process

With ARMSS as boot master, only GP header data format is supported. The boot code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros. Also, the data is passed as a byte stream to the GP header processing function. The GP header processing function creates the information header by forming the 32-bit words for size and address of each block in big endian format. This is followed by data that is copied into place as a byte stream.

4.3.5.2.2.1 Loading a Boot Image From EEPROM

In this mode, the I²C peripheral is configured as I²C master.

When ARMSS is the boot master, the BootROM will start reading from the I²C EEPROM at the specified I²C bus address on the specified I²C port. This read will be done beginning at the specified base address offset. Data will be read in 2-Kbyte chunks. The data will be stored at the address specified in the GP header. It will continue reading GP header formatted data from the EEPROM and storing it as directed by the headers until a complete image has been read. When the complete image has been read, the BootROM will branch to the base address of the last GP data block in the image.

4.3.5.2.2.2 Master Transmit

In master transmit mode data read from an I²C EEPROM is resent out the device as a simple write. An initial 6 byte field is transmitted, 4 bytes of block header, 2 bytes of data, which is received by the slave and loaded into the slave options field.

Then every block of data read from the I2C EEPROM is retransmitted back out the I2C bus. There must be at least one slave on the bus to acknowledge the requests or the boot will fail.

4.3.5.2.2.3 Loading Image In Slave Mode

The BootROM also provides the option to set the I²C to slave mode and connect to external master device, which can then send the image to boot from. The default slave address is set to the value specified in the boot configuration in Section 4.3.3.3, *I2C/I2C Slave/I2C Master Write Boot Parameter Table*.

With ARMSS as boot master, the BootROM will initialize the I²C hardware and then start polling the specified I²C port for data. As data is read from the I²C port, it will be stored at the address specified in the GP header. The BootROM will continue polling for and reading data until a complete image has been read. Data will be read and processed in 2-Kbyte chunks. The I²C master should pad the image with zeroes to be a multiple of this size. When the complete image has been read, the BootROM will branch to the base address of the last GP data block in the image.

4.3.5.3 SPI Bootloader Operation

4.3.5.3.1 SPI BootROM Initialization Process

In the SPI boot mode, the BootROM initializes only the SPI peripheral. Similar to the I²C boot mode, in the SPI boot mode, the interrupt subsystem and the EDMA are not enabled. The BootROM also bypasses the PLL and runs the boot master at the reference clock frequency. The image is read from the NOR flash connected to the corresponding SPI port and chip-select. The the starting offset to be read can be provided by the user through the BOOTMODE pins (Section 4.3.2.4, *SPI without PLL Boot Device Configuration*). A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in Section 4.3.3.4, *SPI Boot Parameter Table*.

4.3.5.3.2 SPI BootROM Loading Process

The SPI boot loading process is similar to the loading process explained in Section 4.3.5.2.2.1, *Loading a Boot Image From EEPROM*. except that the image is read from a NOR flash. The data formats supported are also the same as in Section 4.3.5.2.2, *I2C BootROM Loading Process*. All the other loading processes that are detailed for I²C master mode work for the SPI boot mode, too.

4.3.5.4 QSPI Bootloader Operation

4.3.5.4.1 QSPI BootROM Initialization Process

In the QSPI 48-MHz and QSPI 96-MHz boot modes, the BootROM initializes the QSPI peripheral and also configures the interrupt subsystem and the EDMA, then executes the IDLE instruction. The image is read from the QSPI flash connected to the selected chip-select. The starting offset to be read can be provided by the user through the BOOTMODE pins (Section 4.3.2.6, *QSPI Boot Device Configuration*).

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in Section 4.3.3.5, *QSPI Boot Parameter Table*.

NOTE: BootROM does not support QSPI boot in XIP mode. The whole image is first read, and then, executed.

4.3.5.4.2 QSPI BootROM Loading Process

The QSPI boot loading process is similar to the loading process explained in Section 4.3.5.2.2.1, *Loading a Boot Image From EEPROM* except that the image is read from a QSPI flash. All the other loading processes that are detailed for I^2C master mode work for the QSPI 48 and QSPI 96 boot modes, too.

The quad read QSPI protocol can optionally include mode bits, as seen in Table 4-33.

Table 4-33. QSPI Protocol

IO0-IO3	<command>	<address>	<mode>	<dummy>	<data>

In most QSPI flash devices the number of dummy cycles is configurable in a non-volatile register, and the value must be selected to be larger than a minimum which is based on the operation speed. The BootROM has chosen default values to use based on the QSPI device speed, and flash devices must meet the boot settings to start in quad mode.

Some flash devices use the mode bits. The mode bits are used to allow sending multiple read command without actually sending the command byte again. The boot code does not use this protocol. However, because some devices do use the mode bytes, the boot code enables the mode bits and will send a 0 value. The reason for this is that on devices which do use mode bits the bus could wind up in a floating state if the QSPI controller floats the IO lines when the flash device is expecting the data.

If a flash device does not use mode bits, then the value in the dummy byte count register should be set to 2 + the number of dummy bytes that the BootROM sends. Essentially the boot ROM sends 2 cycles of mode bits but the flash device sees them as 2 dummy cycles. The BootROM also supports independent selection of the number of IO lines driven for command, address, and data portions of the read cycle.

4.3.5.5 PCI Express (PCIE) Bootloader Operation

4.3.5.5.1 PCIE BootROM Initialization Process

In the PCIE boot mode, the BootROM configures the BAR registers, the number of windows, and their sizes to provide memory access to the host. The different BAR configurations that are initialized are shown in Table 4-4. The BootROM also configures the SerDes from information it obtains from the boot parameter table, see Section 4.3.3.2, *PCIE Boot Parameter Table*. Furthermore, the BootROM configures the interrupt subsystem by configuring the chip-level interrupt controller. Then the BootROM executes the IDLE instruction (MSI or legacy interrupts can be used). For PCIe interrupts, refer to Section 11.14, *PCIe Subsystem*.

If the timeout value is non-zero then a TIMER module is setup with the specified timeout, and the boot will fail if the boot is not completed before the timer expires.

4.3.5.5.2 PCIE BootROM Loading Process

Once the host initiates the link with the boot device, it should load all sections of the boot image. The host is also responsible for updating the BOOT_MAGIC_ADDRESS of ARMSS Core0.

4.3.5.5.3 PCIE BootROM Hand-Over Process

In this boot mode, ARMSS Core0 is executing an IDLE until the PCIE interrupt wakes it. The interrupt can be an MSI interrupt or a legacy interrupt. Once Core0 comes out of IDLE, the BootROM reads the BOOT_MAGIC_ADDRESS and modifies the program counter to start executing the boot image.

4.3.5.6 GPMC Bootloader Operation

4.3.5.6.1 NOR Bootloader Operation

4.3.5.6.1.1 NOR BootROM Initialization Process

In this mode, the BootROM performs minimum operations. The BootROM just configures the GPMC interface based on the configuration parameters specified in the boot parameter table for the XIP boot mode, see Section 4.3.3.6, *XIP Boot Parameter Table*. The boot parameter structure definition for the XIP boot mode and the parts of this table that can be configured by the BOOTMODE pins are detailed in Section 4.3.2.7, *XIP Boot Device Configuration*.

4.3.5.6.1.2 NOR BootROM Loading Process

During this process, the BootROM just sets the program counter to the address and XIP Chip-Select that are specified in the XIP Boot Parameter Table. No return is expected. The BootROM also does not reserve any memory in L2. The image remains stored in the flash and so no image transfer occurs during this boot mode.

4.3.5.7 Ethernet Bootloader Operation

4.3.5.7.1 Ethernet BootROM Initialization Process

When the device is set to boot through the Ethernet mode, the BootROM configures PHY, NAVSS, and the EMAC. These initial configurations, as well as the interface mode (RMII, G/MII, RGMII), are determined by querying the BOOTMODE pins in the DEVSTAT register, see Section 4.3.2.8, *Ethernet Boot Device Configuration*, and the boot parameter table for the Ethernet boot, see Section 4.3.3.7, *Ethernet Boot Parameter Table*.

The queue manager is setup to route the packets to queues polled by the BootROM.

4.3.5.7.2 Ethernet BootROM Loading Process

With ARMSS as the boot master, the image must be in blob format. After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. After this connection is established, the device is able to receive image data encapsulated in Ethernet packets, see Section 4.3.5.7.2.1. Data received is stripped of its network headers and the boot data is stored in the MSMC. After transfer is complete, the BootROM will begin executing the image at the base of MSMC.

4.3.5.7.2.1 Ethernet-Ready Announcement Format

Ethernet packets are accepted only in DIX (Ethernet II) frames with IPv4 and UDP headers. Frames not matching this criteria are discarded and subsequent frames are processed.

The DIX frame contains:

- Destination MAC address = H-MAC addr (from Section 4.3.3.7, normally FF:FF:FF:FF:FF:FF)
- Source MAC address = From Section 4.3.3.7, *Ethernet Boot Parameter Table*, default comes from e-fuse
- Type = IPv4 (0x800)

The IPv4 header contains:

- Version = 4
- Header length = 0
- TOS = 0
- Len = Computed during operation
- ID = 0x001
- Flags + Fragment offset = 0

- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- DEST IP = 255.255.255.255

The UDP header contains:

- Source port = BOOTP client (68 dec)
- Destination port = BOOTP server (67 dec)
- Length = Computed during operation
- Checksum = Computed during operation

The BOOTP payload contains:

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Address Length = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0
- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address, read from e-fuse
- Server Hostname = NULL
- Filename = NULL
- Option 60, vendor ID string, from boot parameter table
- Option 61, client ID string, from boot parameter table.

TFTP is configured as dictated by the. The received data image is placed into the memory location specified by the same table. This value can be re-assigned in a multi-stage boot to allow direct loading to DDR_EMIF. A maximum data size of 0x1C_0000 bytes is supported.

4.3.5.7.3 Ethernet BootROM Hand Over Process

When boot is complete the NSS firmware is disabled, the CDMA is disabled and the queue manager is cleaned. The PHY is left enabled.

4.3.5.8 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host.The USB subsystem is driven from the NSS/IEP PLL configured to 1000 MHz.

The image read in this boot mode must be in GP header format.

The BOOTMODE pins provide a way to specify:

- PHY frequency selection
- Reference clock source
- D_MODE – The boot code implements the USB DFU protocol
- USB port number

See Section 4.3.2.9, *USB Boot Device Configuration* and Section 4.3.3.8, *USB Boot Parameter Table*.

More information about USB DFU protocol can be found at http://www.usb.org/developers/docs/devclass_docs/DFU_1.1.pdf.

After entering the enumeration phase, the BootROM will continue reading GP header formatted data from the host and storing it as directed by the headers until a complete image has been read. When the complete image has been read, the BootROM will branch to the base address of the last GP data block in the image.

4.3.5.9 MMCSD Bootloader Operation

Only single data rate with backward compatible interface timing is supported.

The BOOTMODE pins provide a way to specify:

- Card type
- Boot acknowledge
- How to complete the boot – using maximum available data lines, or in 1-bit mode
- MMCSD port number.

See Section 4.3.2.10, *MMCSD Boot Device Configuration* and Section 4.3.3.9, *MMCSD Boot Parameter Table*

If the card type is set to autodetect, then an initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)
2. Send CMD 55. If the card responds then the card type is assumed to be SD and the boot attempt fails (the device do not support SD boot). On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The BootROM will start reading from the MMCSD memory boot sector if specified by the BOOTMODE pins. The data will be stored at the address specified in the GP header. It will continue reading GP Header formatted data from the memory and storing it as directed by the headers until a complete image has been read. When the complete image has been read, the BootROM will branch to the base address of the last GP data block in the image.

4.3.5.10 UART Bootloader Operation

4.3.5.10.1 BootROM Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in Section 4.3.2.11 and Section 4.3.3.10.

Once the BootROM configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital *C* character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode.

4.3.5.10.2 UART BootROM Loading Process

The boot image to be loadedmust be in blob format. Before the ping from the device stops, load the boot table from the host using the XMODEM protocol.

4.3.5.10.3 UART BootROM Hand-Over Process

The bootloader stores data at the base of MSMC. Once the complete boot image is transferred and stored in the MSMC, the bootloader will begin execution from the base of MSMC.

4.4 Boot RAM Memory Maps

Table 4-34 shows addresses assigned for boot by the ARMSS Core0.

Table 4-34. ARMSS Boot RAM Memory Map

Start Address	Size	Description
0x0C00 0000	0xE 0000	Free (Blob base)
0x0C0E 0000	0x8000	FAT cluster buffer
0x0C0E 8000	0x7E80	Ethernet Packet Memory
0x0C0E FE80	0x80	PCIe Config Block
0x0C0E FF00	0x100	Reserved
0x0C0F 0000	0x4	ARMSS BOOT_MAGIC_ADDRESS
0x0C0F 0010	0x4	Magic Echo Address
0x0C0F 0020	0xDE0	Context
0x0C0F 0E00	0x200	DDR_EMIF Config
0x0C0F 1000	0x2C00	Boot Data
0x0C0F 3C00	0x180	ARMSS BootROM Version string
0x0C0F 3D80	0x80	Boot Status Stack
0x0C0F 3E00	0x100	Boot Stats
0x0C0F 3F00	0x100	Boot Log
0x0C0F 4000	0x100	RAM call Table
0x0C0F 4100	0x100	Boot Parameter Tables
0x0C0F 4200	0x1DE0	Boot ROM data
0x0C0F 5FE0	0x1010	Boot Trace Data
0x0C0F 6FF0	0x10	Free
0x0C0F 7000	0xC00	Supervisor Stack
0x0C0F 7C00	0x400	Undefined Mode Stack

4.5 BootROM Function Calls

Table 4-35 shows BootROM functions available when ARMSS is the boot master.

Table 4-35. Calls to ARMSS BootROM Functions

Memory Address	Function Name	Description
0x00001000	_romtMonitorFunction(void (*fcn)(), …)	This function switches to monitor mode and branches to the passed function.
0x00001004	_romtBootReentry()	BootROM re-entry function. Typically used in a two-stage boot.
0x00001008	SINT16 _romtEnableModule(UINT32 modnum)	Power up a power domain. See Section 5.2.2, *Power Sleep Controller (PSC)*.
0x0000100C	SINT16 _romtDisableModule(UINT32 modnum)	Power down a power domain. See Section 5.2.2, *Power Sleep Controller (PSC)*.
0x00001018	SINT16 _romtConfigPll(UINT32 pllNum, UINT32 prediv, UINT32 mult, UINT32 postdiv)	Configure PLL. See Section 5.4.5.3, *PLL Controller*. pllNum: 0 = MAIN PLL, 1 = NSS PLL, 2 = DDR PLL, 4 = ARM PLL, 5 = UART PLL
0x0000101C	_romtDelay(UINT32 ncycles)	A simple loop delay
0x00001020	UINT16 _romtDeviceFreqMhz()	Return device frequency specificed by device variant (e-fuse), in units of MHz
0x00001024	UINT32 _romtArmNum()	Return the ARMSS number. Must be run from the supervisor mode.
0x00001028	SINT32 _romtTetrisPsc(UINT32 core, UINT32 state)	Transition the ARMSS PSC. Must be run from the supervisor mode. 0 = STATE_ON 1 = STATE_ON_WIR 2 = STATE_OFF_DYNUP 3 = STATE_OFF
0x0000102C	_romtCacheClean()	Perform a cache clean
0x00001030	SINT16 _romtPscSetState(UINT32 modnum, UINT32 state)	Set the PSC next state of a module domain. See Section 5.2.2, *Power Sleep Controller (PSC)*.
0x00001034	_romtMainEmif4Cfg()	DDR_EMIF configuration based on ROM configuration table – Section 4.3.3.11
0x00001054	BOOL _romtPcieBlockProcessWrap(pcieBlockActivate_t * pba)	Configure the specified PCIe port as an endpoint
0x00001058	_romtCacheCleanByAddr(UINT32 addr, UINT32 sizeBytes)	Clean cache by address
0x0000105C	_romtInvalidateCache(UINT32 addr, UINT32 sizeBytes)	Invalidate cache by address

4.5.1 pcieBlockActivate_t Structure

Below is the listing of the pcieBlockActivate_t structure used in romtPcieBlockProcessWrap function.

```
typedef struct pcieConfig_s  {
    UINT32 port;
    UINT32 serdesCfgReg;
    UINT32 serdesLaneCfg[2];
    UINT32 addrWidth;              /* only 32 and 64 are valid */
    UINT32 windowSize[5];          /* Window sizes in Mb. If 64 bit address are used only 1st two
apply */
    UINT32 classCodeRevId;         /* Class code rev ID */
    UINT32 devId_VendorId;         /* Device ID (MSW), vendor ID (LSW) */
    BOOL   lockDetected;           /* Returns TRUE if a lock was detected */
    BOOL   linkUpDetected;         /* Returns TRUE if a link up was detected */
```

```
} pcieConfig_t;

#define PCIE_BLOCK_MAGIC              0xcece1110

typedef struct pcieBlock_s
{

    UINT32       pcieBlockMagic;
    UINT32       rsvd0[3];

    pcieConfig_t pcieConfig;
    UINT32       rsvd1[2];

    sbCfg_t      sbCfg;     /* First entry - multiple entries are supported */

} pcieBlock_t;

typedef struct pcieBlockActivate_s
{
    pcieBlock_t  *blockp;
    UINT32        echoInit;
    UINT32        echoFinal;
    UINT32        resultMap;

} pcieBlockActivate_t;
```

Device Configuration

Topic **Page**

5.1 Control Module (BOOT_CFG)

The following sections describe the BOOT_CFG module.

5.1.1 BOOT_CFG Overview

The BOOT_CFG is a module on the device that controls top-level device behavior in various states. It contains registers for configuration, reset modes, bootstrap signals, and IO pad multiplexing controls. In functional level, the BOOT_CFG module also supports top level scratchpad and inter-processor communication registers, as well as generating interrupts to other processor cores.

The BOOT_CFG module has registers associated with:

- Device pad configuration
- Kick protection (register write protection)
- BOOT_CFG module interrupts
- TeraNet priority
- Inter-processor communication
- Some device external signals
- Event mux control
- Reset mux control
- Timer Pin Manager
- Scratchpad
- MLB IOs Control
- Device reset status
- DSP boot address
- eCAP/ePWM/eQEP control and status
- NSS MAC address
- ARMSS endian configuration
- ARMSS and DEBUG_SS trace buffers
- PLL control
- Clock muxing, enabling and division
- Control for some device LDOs
- USB PHY control
- Modules IDs
- Device power state
- DSP NMI event generation
- Oscilator control
- DCAN RAM Initialization
- Ethernet Configuration

5.1.2 BOOT_CFG Integration

This section describes the module integration in the device including information about clocks, resets, and hardware requests.

Figure 5-1 shows the integration of the BOOT_CFG module in the device.

Figure 5-1. BOOT_CFG Integration

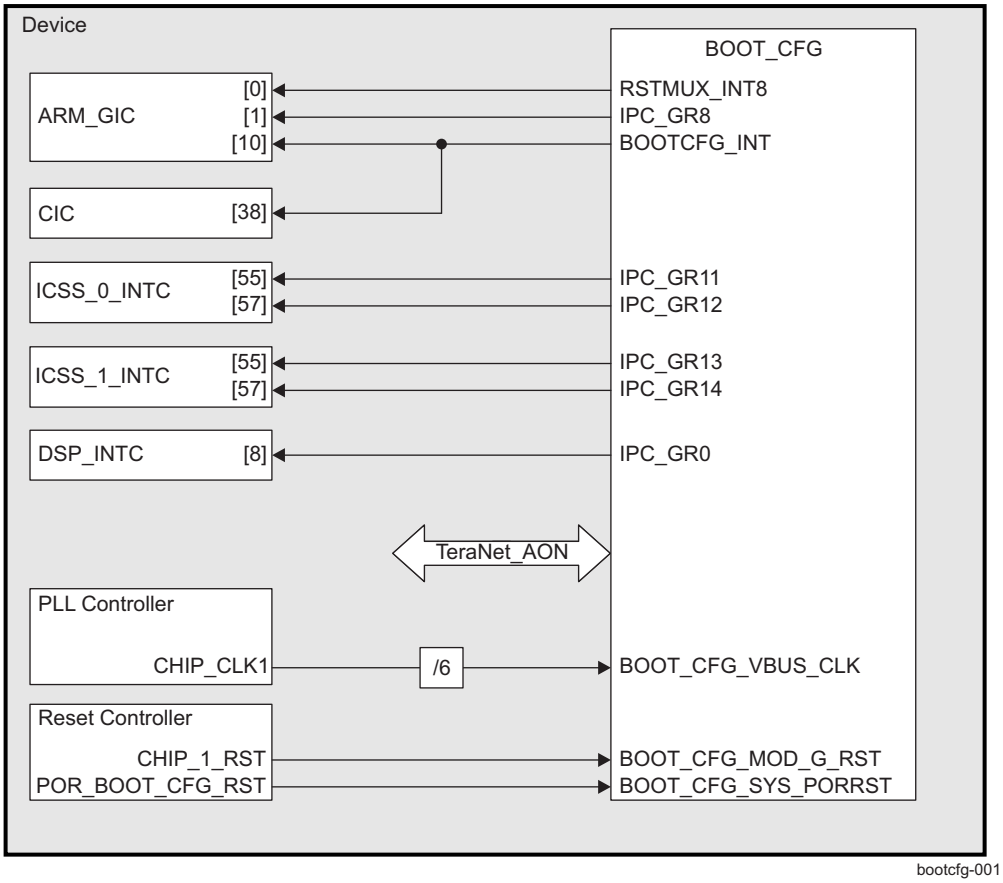

Table 5-1 through Table 5-3 summarize the integration of the BOOT_CFG module in the device.

Table 5-1. BOOT_CFG Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
BOOT_CFG	PD0	LPSC0	TeraNet_AON

Table 5-2. BOOT_CFG Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
BOOT_CFG	BOOT_CFG_VBUS_CLK	CHIP_CLK1/6	PLL Controller	Functional and interface clock for the BOOT_CFG module with frequency equal to CHIP_CLK1 divided by 6.
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
BOOT_CFG	BOOT_CFG_SYS_PORRST	POR_BOOT_CFG_RST	Reset Controller	Power On Reset
	BOOT_CFG_MOD_G_RST	CHIP_1_RST	Reset Controller	BOOT_CFG module reset

Table 5-3. BOOT_CFG Hardware Requests

Interrupt Requests							
Module Instance	**Event Name**	**Mapped To Input Event [Number]**					**Description**
		ARM GIC	**CIC**	**ICSS0 INTC**	**ICSS1 INTC**	**DSP INTC**	
BOOT_CFG	BOOTCFG_INT	[10]	[38]	-	-	-	Interrupt indicating addressing violation or protection violation error.
	IPC_GR0	-	-	-	-	[8]	Interrupt generated by writing of 1h to BOOTCFG_IPCGR0[0].
	IPC_GR8	[1]	-	-	-	-	Interrupt generated by writing of 1h to BOOTCFG_IPCGR8[0].
	IPC_GR11	-	-	[55]	-	-	Interrupt generated by writing of 1h to BOOTCFG_IPCGR11[0].
	IPC_GR12	-	-	[57]	-	-	Interrupt generated by writing of 1h to BOOTCFG_IPCGR12[0].
	IPC_GR13	-	-	-	[55]	-	Interrupt generated by writing of 1h to BOOTCFG_IPCGR13[0].
	IPC_GR14	-	-	-	[57]	-	Interrupt generated by writing of 1h to BOOTCFG_IPCGR14[0].
	RSTMUX_INT8	[0]	-	-	-	-	Interrupt generated by TIMER_5 when used as WD Timer for ARMSS.

NOTE: For more information about BOOTCFG_INT, see Section 5.1.3.1.3.

For more information about IPC_GR**x**, see Section 5.1.3.1.5.

For more information about RSTMUX_INT8, see Section 5.1.3.1.8.

5.1.3 BOOT_CFG Functional Description

5.1.3.1 Description for BOOT_CFG Register Types

The following sub-sections provide summarization and description for most of the registers which are part of the BOOT_CFG module memory space. The rest of the registers are described in the corresponding chapters where the functionality associated with particular BOOT_CFG register is covered more in detail.

5.1.3.1.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register (PADCONFIGx) is assotiated only with one pad and has bits as described in Table 5-4.

Table 5-4. Description Of The Pad Configuration Register Bits

Bits	Field Name	Description	Type
31-21	RESERVED		R
20-19	BUFFERCLASS	Buffer class selection	R/W
		For 3.3V I/Os:	
		0h and 1h: 50B — 50 ohm nominal impedance for the buffer, class B driver 100MHz in 50 ohm mode	
		2h and 3h: 40D — 40 ohm nominal impedance for the buffer, class D driver 200MHz in 40 ohm mode	
		For 1.8V I/Os:	
		0h: 50B — 50 ohm nominal impedance for the buffer, class B driver 100MHz in 50 ohm mode	
		1h: 40C — 40 ohm nominal impedance for the buffer, class C driver 150MHz in 40 ohm mode	
		2h: 40D — 40 ohm nominal impedance for the buffer, class D driver 200MHz in 40 ohm mode	
		3h: 40E — 40 ohm nominal impedance for the buffer, class E driver 250MHz in 40 ohm mode	
18	RESERVED	This bit must not be modified.	R/W
17	PULLTYPESEL	Selects pull-up or pull-down type resistor for a given pad	R/W
		0h: Pull-down is selected	
		1h: Pull-up is selected	
16	PULLUDEN	Enables pull-up or pull-down resistor for a given pad	R/W
		0h: Enables weak pull-up/down	
		1h: Disables weak pull-up/down	
15-4	RESERVED		R
3-0	MUXMODE	Selects the desired multiplexing mode for a given pad	R/W
		0h: Primary function	
		1h: Secondary function	
		2h: Tertiary function	
		3h: Quaternary function	
		4h: Quinary function	
		5h: Senary function	

Many of the device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in table "*Pin Multiplexing*" of the device Data Manual. The desired function is selected via the MUXMODE field of the associated pad configuration register.

The BUFFERCLASS field is used to select the impedance and maximum switching frequency of an I/O. That choice is mainly driven by the speed of the corresponding interface the I/O is associated with. Choosing the correct buffer class is determined by identifying the switching frequency of an interface and choosing the class that is closest to and greater than that frequency. It has to be taken into account that some of the device interfaces do not have buffer class selection bits. Only interfaces available on I/Os having pad configuration registers have the buffer class selection available. For example, USB and EMIF do not have such bits as they use PHYs instead of I/Os with pad configuration registers. Table "*Multiplexing Characteristics*" of the device Data Manual can be used to check if certain signal have or not a PADCONFIG register associated with it.

Table 5-5 shows the reset values of all pad configuration registers (BOOTCFG_PADCONFIG0 to BOOTCFG_PADCONFIG259). If a register index is not presnt in that table this means the corresponding register is not used and should be considered as Reserved. Write accesses should not be performed to these locations.

Table 5-5. BOOTCFG_PADCONFIG0 to BOOTCFG_PADCONFIG259 Reset Values

Register Index	Reset Value	Register Index	Reset Value	Register Index	Reset Value	Register Index	Reset Value	Register Index	Reset Value	Register Index	Reset Value	Register Index	Reset Value

39	00150003h	79	00140003h	119	00060003h	159	00140003h	199	00140003h	242	00050000h		

5.1.3.1.2 Kick Protection Registers

The BOOT_CFG module supports a kicker mechanism which prevents spurious writes from changing the values of any of the BOOT_CFG registers. When the kicker is locked (which is its initial state after device reset) none of the BOOT_CFG registers are writable. They can only be read. A write is required to the BOOTCFG_KICK0 and BOOTCFG_KICK1 registers with exact data values before the kicker lock mechanism is un-locked. Once released then all the BOOT_CFG registers having write permissions are writable. The read only registers are still read only. First BOOTCFG_KICK0 has to be written with 83E7 0B13h. Then BOOTCFG_KICK1 has to be written with 95A4 F1E0h. After these two steps a write access to the BOOT_CFG registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the BOOT_CFG registers.

NOTE: In order to ensure that all BOOT_CFG registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

In order to reduce the access latency some of the latency critical BOOT_CFG registers are non kick-protected. All other registers inside the BOOT_CFG module except the *Inter-processor Communication Registers* (for details, see Section 5.1.3.1.5) are kick-protected.

5.1.3.1.3 BOOT_CFG Module Interrupts

The BOOT_CFG module has one interrupt request, the BOOTCFG_INT, which is associated with the following registers:

- BOOTCFG_INTR_RAW_STAT_SET — interrupt raw status register
- BOOTCFG_INTR_ENABLED_STAT_CLR — interrupt status register
- BOOTCFG_INTR_ENABLE — interrupt enable register
- BOOTCFG_INTR_ENABLE_CLR — interrupt disable register

For the interrupt behavior of the BOOT_CFG module the following applies:

- The BOOT_CFG module asserts its interrupt line only if the interrupts are enabled by setting to 1h the corresponding bits in the BOOTCFG_INTR_ENABLE register. These interrupts can be disabled by setting to 1h the corresponding bits in the BOOTCFG_INTR_ENABLE_CLR register.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting to 1h the corresponding bit in the BOOTCFG_INTR_ENABLED_STAT_CLR register which also

clears the corresponding bit in the BOOTCFG_INTR_RAW_STAT_SET register. The status flags in the BOOTCFG_INTR_RAW_STAT_SET register are set even if the corresponding interrupt is disabled unlike those in the BOOTCFG_INTR_ENABLED_STAT_CLR register, which are set only if the corresponding interrupt is enabled.

- An interrupt is also generated by the BOOT_CFG, if certain bit in the BOOTCFG_INTR_RAW_STAT_SET register is set to 1h and the corresponding interrupt is enabled through the BOOTCFG_INTR_ENABLE register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled the corresponding raw flag in the BOOTCFG_INTR_RAW_STAT_SET register is set to 1h when an IRQ condition occurs.
- Even if interrupts are not enabled, a status bit in the BOOTCFG_INTR_RAW_STAT_SET register can also be cleared by setting to 1h the corresponding bit in the BOOTCFG_INTR_ENABLED_STAT_CLR register.

Table 5-6 lists the interrupt events which can assert the BOOTCFG_INT interrupt line.

Table 5-6. BOOT_CFG Events

Event Flag	Event Mask	Description
BOOTCFG_INTR_RAW_STAT_SET[1] ADDR_ERR BOOTCFG_INTR_ENABLED_STAT_CLR[1] ENABLED_ADDR_ERR	BOOTCFG_INTR_ENABLE[1] ADDR_ERR_EN BOOTCFG_INTR_ENABLE_CLR[1] ADDR_ERR_EN_CLR	Addressing violation interrupt. Occurs when accessing an illegal address inside the BOOT_CFG module.
BOOTCFG_INTR_RAW_STAT_SET[0] PROT_ERR BOOTCFG_INTR_ENABLED_STAT_CLR[0] ENABLED_PROT_ERR	BOOTCFG_INTR_ENABLE[0] PROT_ERR_EN BOOTCFG_INTR_ENABLE_CLR[0] PROT_ERR_EN_CLR	Protection violation interrupt. Occurs when a protected register is accessed without the required secure/privilege level permissions.

When addressing violation or protection violation occurs, the error associated details are captured in the BOOTCFG_FAULT_ADDR and BOOTCFG_FAULT_STAT registers. BOOTCFG_FAULT_ADDR contains the address of the first fault access and BOOTCFG_FAULT_STAT contains status attributes associated with the first fault access. To clear the contents of these two registers the BOOTCFG_FAULT_CLR[0] FAULT_CLR bit must be set to 1h.

5.1.3.1.4 TeraNet Priority Registers

The TeraNet priority registers are used for controlling the transaction priority of certain masters on the TeraNet. Each 3-bit field in these registers is associated only with one master. Setting this bit field to 0h means that the transaction performed by this master has highest priority over the other transactions. A value of 7h is for lowest priority. The TeraNet priority registers are:

- BOOTCFG_INITIATOR_PRIORITY0
- BOOTCFG_INITIATOR_PRIORITY1

5.1.3.1.5 Inter-processor Communication Registers

The inter-processor communication registers are used for generating interrupts to the device cores. Any master having access to the BOOT_CFG registers can generate an interrupt by writing 1h to the IPCGR**x**[0] bits. For example, writing 1h to BOOTCFG_IPCGR0[0] generates and interrupt to the DSP. These registers also provide a *Source ID* facility through the IPCGR**x**[31-4] SRC and IPCAR**x**[31-4] SRC_CLR bit fields by which up to 28 different sources of interrupts can be identified. Allocation of the source bits to source processor and meaning is entirely based on software convention. Virtually, anything can be a source for these fields as this is completely controlled by software. Writing 1h to an SRC bit sets to 1h both the SRC and corresponding SRC_CLR bit. Writing 1h to a SRC_CLR bit sets to 0h (clears) both the SRC_CLR and corresponding SRC bit.Table 5-7 summarizes the inter-processor communication (IPC) registers.

Table 5-7. Summary of the IPC Registers

IPC Register	Writing 1h to bit 0 results in:	Writing 1h to one of the bits [31-4] results in:
BOOTCFG_IPCGR0	interrupt generation to the DSP_INTC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGR8	interrupt generation to the ARM_GIC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGR11	interrupt generation to the ICSS0_INTC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGR12	interrupt generation to the ICSS0_INTC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGR13	interrupt generation to the ICSS1_INTC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGR14	interrupt generation to the ICSS1_INTC	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCGRH	interrupt generation to an external host through the HOUT device pad	setting that bit and the corresponding SRC_CLR bit to 1h
BOOTCFG_IPCAR0	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCAR8	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCAR11	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCAR12	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCAR13	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCAR14	N/A	setting that bit and the corresponding SRC bit to 0h
BOOTCFG_IPCARH	N/A	setting that bit and the corresponding SRC bit to 0h

When writing 1h to the BOOTCFG_IPCGRH[0] bit an interrupt pulse on the HOUT device pad is created. This pulse remains asserted for four BOOT_CFG_VBUS_CLK cycles followed by deassertion for four BOOT_CFG_VBUS_CLK cycles. During this period equal to eight BOOT_CFG_VBUS_CLK cycles another write to BOOTCFG_IPCGRH[0] with value of 1h cannot cause another interrupt pulse. To create another interrupt pulse on the HOUT pad, the BOOTCFG_IPCGRH[0] bit must be set to 1h after this eight BOOT_CFG_VBUS_CLK cycles window has already been elapsed.

NOTE: For latency reasons the IPC registers are non kick-protected which means that they can be written to without a need for performing unlocking procedure as described in Section 5.1.3.1.2.

5.1.3.1.6 Registers Associated With Some Device External Signals

Figure 5-2 shows the device external signals and the BOOT_CFG registers associated with these signals. Table 5-8 summarizes these registers.

Figure 5-2. External Signals and Registers Associated with Them

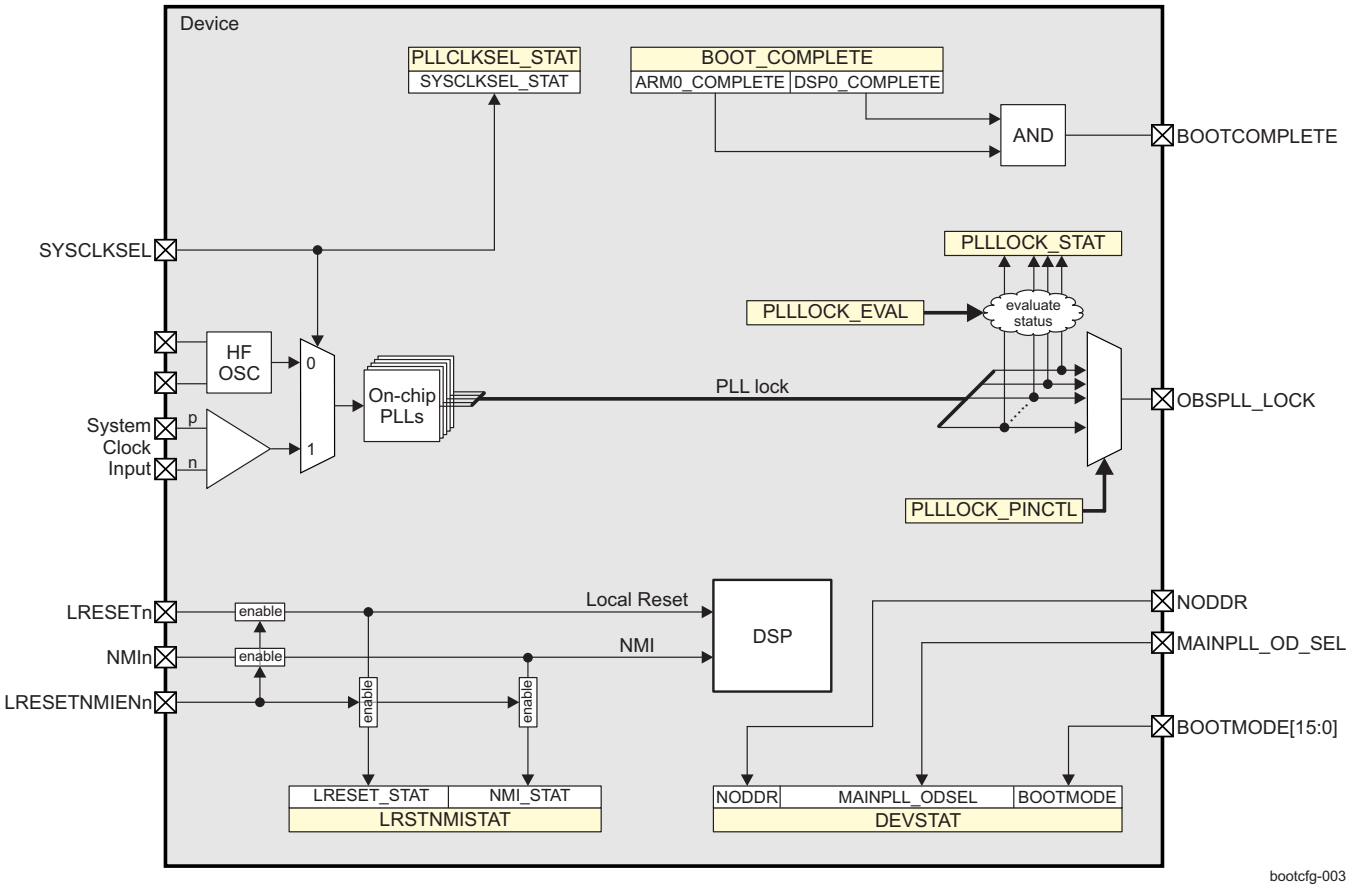

Table 5-8. Summary of the Registers Associated With the Device External Signals

BOOT_CFG Register	Associated External Device Signals	Reference
BOOTCFG_DEVSTAT	BOOTMODE[15-0], MAINPLL_OD_SEL, NODDR	see Section 5.1.3.1.6.1
BOOTCFG_BOOT_COMPLETE	BOOTCOMPLETE	see Section 5.1.3.1.6.2
BOOTCFG_LRSTNMISTAT	LRESETn, NMIn, LRESETNMIENn	see Section 5.1.3.1.6.3
BOOTCFG_LRSTNMISTAT_CLR	Used for clearing the bits in BOOTCFG_LRSTNMISTAT	
BOOTCFG_PLLLOCK_PINCTL	OBSPLL_LOCK	see Section 5.1.3.1.6.4
BOOTCFG_PLLLOCK_STAT		
BOOTCFG_PLLLOCK_EVAL		
BOOTCFG_PLLCLKSEL_STAT	SYSCLKSEL	see Section 5.1.3.1.6.5

5.1.3.1.6.1 BOOTCFG_DEVSTAT Register

The bits in the BOOTCFG_DEVSTAT register reflect the state of some device pads related to boot mode and device configuration. The boot process performed by the boot master is determined by the BOOTCFG_DEVSTAT[16-1] BOOTMODE field which reflects the values present on the BOOTMODE[15-0] pads. For more information about the booting procedure, see Section 4.3.2 in Chapter 4 *Initialization*.

The BOOTCFG_DEVSTAT[19] MAINPLL_ODSEL bit reflects the state of the MAINPLL_OD_SEL pad.

The BOOTCFG_DEVSTAT[20] NODDR bit reflects the state of the NODDR pad.

5.1.3.1.6.2 BOOTCFG_BOOT_COMPLETE Register

The BOOTCOMPLETE device pad indicates the ROM boot process completion to the external system. A value of '1' on the BOOTCOMPLETE pad is present when the ROM code sets to 1h both bits in the BOOTCFG_BOOT_COMPLETE register. One bit is associated with the DSP and the other one with the ARMSS. After device reset a value of '0' is present on the BOOTCOMPLETE pad.

5.1.3.1.6.3 LRSTNMISTAT And BOOTCFG_LRSTNMISTAT_CLR Registers

The LRESETn signal can be used by an external device to generate local reset to the DSP. The NMIn signal can be used by an external device to generate non-maskable interrupt (NMI) to the DSP. The the rising edge of the LRESETNMIENn signal is used to latch the status of the LRESETn and NMIn signals in the LRSTNMISTAT register. Writing a value of 1h to a bit in the BOOTCFG_LRSTNMISTAT_CLR register clears the corresponding bit in the LRSTNMISTAT register.

Table 5-9 shows the LRESETn and NMIn decoding based on the LRESETNMIENn values.

Table 5-9. LRESETn and NMIn Decoding

LRESETn	NMIn	LRESETNMIENn	Action
x	x	1	Neither local reset nor NMI assertion
0	x	0	Assert local reset to the DSP
1	0	0	Assert NMI to the DSP
1	1	0	Local reset and NMI de-assertion

5.1.3.1.6.4 BOOTCFG_PLLLOCK_PINCTL, BOOTCFG_PLLLOCK_STAT And BOOTCFG_PLLLOCK_EVAL Registers

The OBSPLL_LOCK pad is used to indicate when one of the device PLLs is locked. The **x**_LOCK_SEL bits in the BOOTCFG_PLLLOCK_PINCTL register select which PLL lock signal to be routed to the OBSPLL_LOCK device pad. Only one lock signal can be selected at any time. Writing 1h to a **x**_LOCK_SEL bit makes the corresponding PLL lock signal available on the OBSPLL_LOCK pad.

The BOOTCFG_PLLLOCK_STAT register has bits which show the status of each PLL lock signal. This status indicates either PLL lock or loss of PLL lock. The loss of PLL lock is captured in the **x**_LOCK_STAT bits in a sticky fashion. This means that when loss of PLL lock occurs the corresponding **x**_LOCK_STAT bit is set to 0h and it is never set again to 1h even if the corresponding PLL is locked. To reflect the current state of the corresponding PLL lock signal the associated **x**_LOCK_EVAL bit of the BOOTCFG_PLLLOCK_EVAL register must be set to 1h. In case of PLL lock the corresponding **x**_LOCK_STAT is set to 1h. If PLL is not locked a value of 0h is read. In other words, the **x**_LOCK_EVAL bit must be set 1h to update the **x**_LOCK_STAT bit with the actual value of the PLL lock signal of the corresponding on-chip PLL.

Once a PLL is programmed, it is expected that software should set to 1h the **x**_LOCK_EVAL bit to get the current status of a PLL lock signal. In anormal operation all **x**_LOCK_STAT bits show the status as '1' indicating a PLL lock.

5.1.3.1.6.5 BOOTCFG_PLLCLKSEL_STAT Register

Through the BOOTCFG_PLLCLKSEL_STAT[0] SYSCLKSEL_STAT bit the value present on the SYSCLKSEL device pad can be read. This pad is used to select the input clock for the on-chip PLLs. For more information, see Section 5.4, *Clock Management*.

5.1.3.1.7 Event Mux Control Registers

There are event multiplexers in the BOOT_CFG which collect events from the GPIO**x**. By using the BOOT_CFG event mux dedicated registers these events can be mapped to the following DMA and interrupt controllers:

- ARM_GIC
- CIC
- DSP_INTC
- PMMC_INTC
- EDMA_0
- EDMA_1

These events can also be used as a trigger source for the eCAP_**x** modules.

Table 5-10 shows all event mux associated registers and where the events can be mapped to. Each EVTSEL**x** field is associated with one event multiplexer and is an 8-bit field which can select one of 256 input events. Writing of 0h selects input event 0, writing of FFh selects input event 255 to be mapped to the output of the corresponding event multiplexer. Then this event is mapped to module listed in column "**Events Mapped to**". For exact mapping of each event mux output to each interrupt and DMA line, see Table 6-2, *AINTC Interrupt Sources*, Table 6-37, *C66x DSP Interrupt Sources*, Table 9-53, *CIC Input Events Mapping*, Table 10-7, *EDMACC_0 Synchronization Events*, and Table 10-8, *EDMACC_1 Synchronization Events*.

Figure 5-3 shows the event multiplexers. They are also referred to as GPIOMUX.

5.1.3.1.8 Reset Mux Control Registers

The BOOTCFG_RSTMUX0 and BOOTCFG_RSTMUX8 registers are used to control the two reset muxes in the device. The BOOTCFG_RSTMUX0 register controls the reset mux associated with the DSP and the BOOTCFG_RSTMUX8 register controls the reset mux associated with the ARMSS.

TIMER_0 is dedicated to DSP and TIMER_5 is dedicated to ARMSS. These timers can be used as either general purpose or watch dog (WD) timers. When used as WD timers the events they generate are routed to the two reset muxes. Depending on the BOOTCFG_RSTMUX0[3-1] OMODE0 bit field the TIMER_0 event causes one of the following:

- Local reset to the DSP
- Non-maskable interrupt (NMI) to the DSP
- NMI to the DSP followed by local reset to the DSP
- Device reset

Depending on the BOOTCFG_RSTMUX8[3-1] OMODE8 bit field the TIMER5 event causes one of the following:

- Device reset
- An interrupt to the ARM_GIC (RSTMUX_INT8)
- An interrupt to the ARM_GIC (RSTMUX_INT8) followed by a device reset

The delay between the NMI and the local reset to the DSP is configured by the BOOTCFG_RSTMUX0[7-5] DELAY0 bit field.

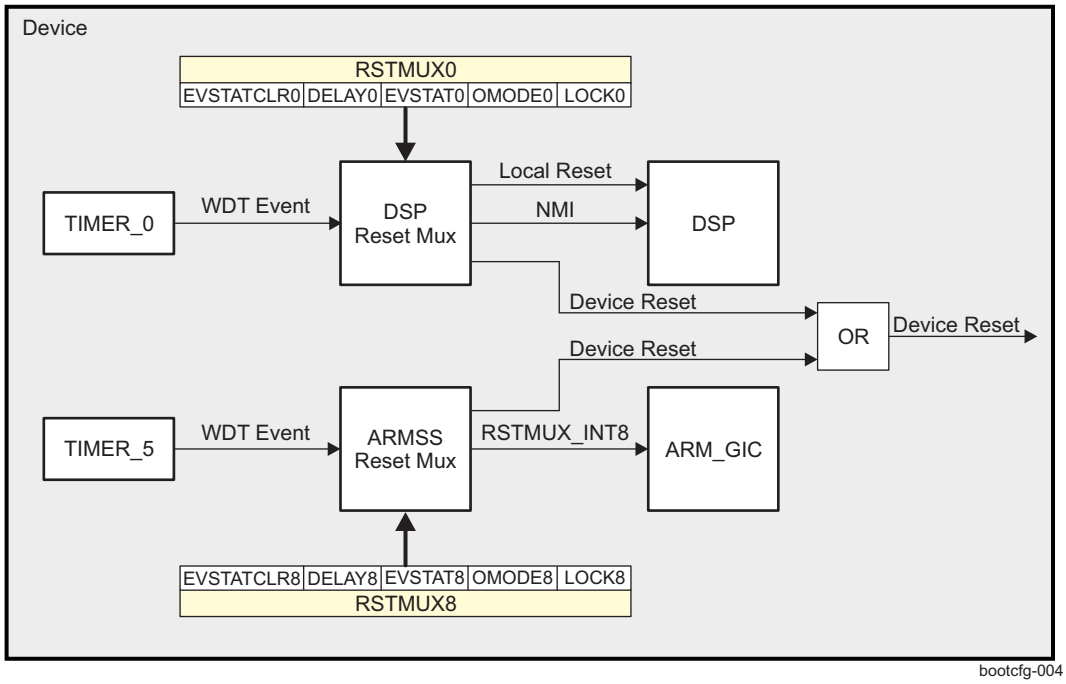
The delay between the interrupt to the ARM_GIC and the device reset is configured by the BOOTCFG_RSTMUX8[7-5] DELAY8 bit field.

When a WD timer event is received by the reset mux this is indicated in the RSTMUX**x**[4] EVSTAT**x** bits. This status is cleared by writing to 1h the EVSTATCLR**x** bit.

NOTE: To prevent any accidental modification of the RSTMUX**x** registers it is recommended to set to 1h the LOCK**x** bits after WD timers are configured.

Figure 5-4 shows the reset mux sheme.

Figure 5-4. Reset Mux Sheme



5.1.3.1.9 Timer Pin Manager Control Registers

Not all timer inputs and outputs are pinned out of the device. Through the Timer Pin Manager the inputs and outputs of the six timers (TIMER_0 through TIMER_5) can be made available on the TIMI[1:0] and TIMO[1:0] device pads.

Each timer input can be configured to be driven by one of the TIMI[1:0] pads through the corresponding bits in the BOOTCFG_TINPSEL0 and BOOTCFG_TINPSEL1 registers. Each of the TIMO[1:0] pads can be configured to be driven by any of the timer outputs through the corresponding bits in the BOOTCFG_TOUTPSEL0 register.

For more information about each timer, see Section 11.17 *Timers*.

5.1.3.1.10 Scrachpad Registers

There are several general purpose read-write registers in the BOOT_CFG memory space intended to be used as a scratchpad. Table 5-11 shows these registers.

Table 5-11. Summary of the Scratchpad Registers

Register Name	Register Name	Register Name	Register Name
BOOTCFG_SCRATCH0	BOOTCFG_SCRATCH4	BOOTCFG_SCRATCH8	BOOTCFG_SCRATCH12
BOOTCFG_SCRATCH1	BOOTCFG_SCRATCH5	BOOTCFG_SCRATCH9	BOOTCFG_SCRATCH13
BOOTCFG_SCRATCH2	BOOTCFG_SCRATCH6	BOOTCFG_SCRATCH10	BOOTCFG_SCRATCH14
BOOTCFG_SCRATCH3	BOOTCFG_SCRATCH7	BOOTCFG_SCRATCH11	BOOTCFG_SCRATCH15

5.1.3.1.11 Registers for Control of the MLB IOs

There are I/O cells specially intended for the MLB 6-pin interface. They are low-voltage differential signaling (LVDS) I/O cells with controls which reside in several registers of the BOOT_CFG module. There is also a bandgap cell intended to provide stable reference voltage to these LVDS IOs across voltage and temperature variations. Without this reference voltage these differential receivers and transmitters cannot function properly. The same bandgap cell also provides a reference voltage to the NSS LVDS buffer associated with signals CPTS_REFCLK_P and CPTS_REFCLK_N. Figure 5-5 shows the registers for controlling the MLB LVDS IOs and bandgap cell. Table 5-12 summarizes and describes these registers.

Figure 5-5. MLB I/O Cells And Their Controls

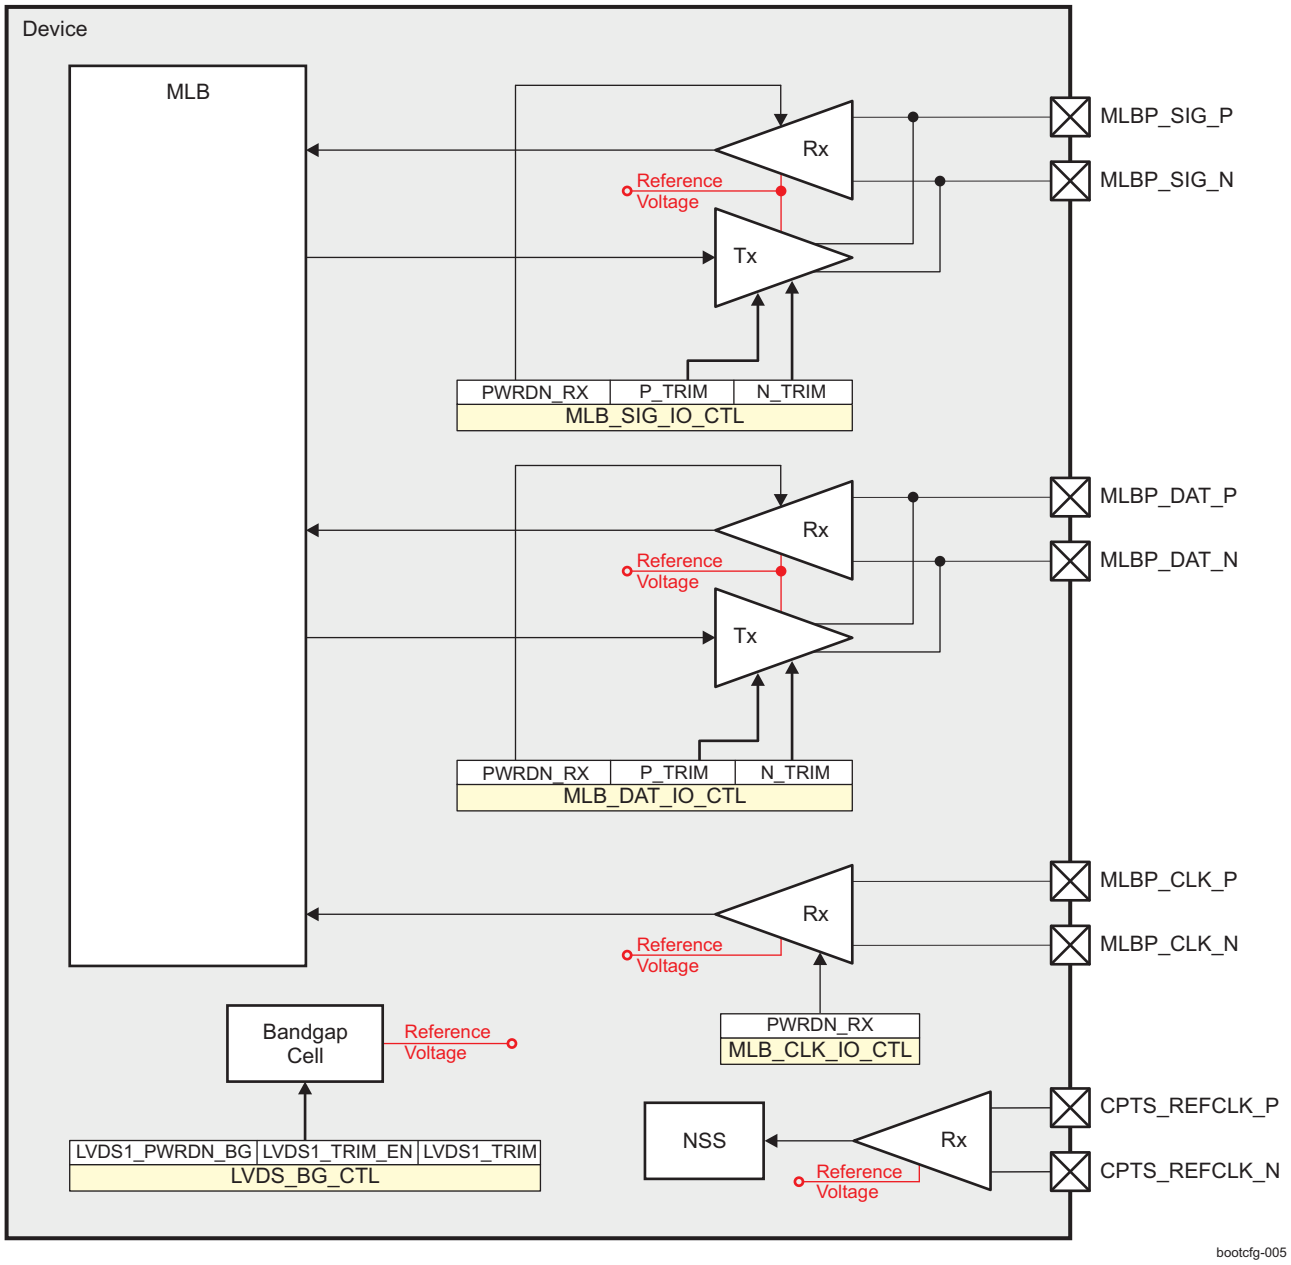


Table 5-12. Summary of the MLB IOs Control Registers

Associated Signals	Register	Bit Field	Description
MLBP_SIG_P MLBP_SIG_N	BOOTCFG_MLB_SIG_IO_CTL	N_TRIM	Trims the driver's NMOS side output impedance.
		P_TRIM	Trims the driver's PMOS side output impedance.
		PWRDN_RX	Turns ON or OFF the MLB LVDS SIG receiver.

Table 5-12. Summary of the MLB IOs Control Registers (continued)

Associated Signals	Register	Bit Field	Description
MLBP_DAT_P MLBP_DAT_N	BOOTCFG_MLB_DAT_IO_CTL	N_TRIM	Trims the driver's NMOS side output impedance.
		P_TRIM	Trims the driver's PMOS side output impedance.
		PWRDN_RX	Turns ON or OFF the MLB LVDS DAT receiver.
MLBP_CLK_P MLBP_CLK_N	BOOTCFG_MLB_CLK_IO_CTL	PWRDN_RX	Turns ON or OFF the MLB LVDS CLK receiver.
N/A	BOOTCFG_LVDS_BG_CTL	LVDS1_PWRDN_BG	Turns ON or OFF the MLB LVDS and NSS LVDS associated bandgap cell.
		LVDS1_TRIM_EN	Trim enable.
		LVDS1_TRIM	Trim value for the reference voltage generated by the bandgap cell.

NOTE: The MLB differential input/output buffers do not contain internal termination resistors, so the appropriate external termination resistors are required when using MLB in 6-pin mode.

NOTE: The BOOTCFG_LVDS_BG_CTL register has also bits for controlling another bandgap cell which provides reference voltage to the LVDS buffers associated with the following signals:

- DDR_CLK_P and DDR_CLK_N
- SYSCLK_P and SYSCLK_N

5.1.3.1.12 Device Reset Status Registers

There are two reset associated registers in the BOOT_CFG memory space. Table 5-13 shows these registers.

Table 5-13. Summary of the Device Reset Status Registers

Register Name	Bit Field	Description
BOOTCFG_RESET_STAT	GRST_STAT	Device global reset indication
	LRST_STAT0	DSP local reset indication
BOOTCFG_RESET_STAT_CLR	GRST_STAT_CLR	Writing 1h clears the BOOTCFG_RESET_STAT[31] GRST_STAT bit
	LRST_STAT_0_CLR	Writing 1h clears the BOOTCFG_RESET_STAT[0] LRST_STAT0 bit

5.1.3.1.13 DSP Boot Address Registers

There are two registers in the BOOT_CFG memory space associated with the DSP boot address. Table 5-14 shows these registers.

Table 5-14. Summary of the DSP Boot Address Associated Registers

Register Name	Description
BOOTCFG_DSP_BOOT_ADDR0	Boot address for the DSP used on secure devices
BOOTCFG_DSP_BOOT_ADDR0_NS	Boot address for the DSP used on non-secure devices

5.1.3.1.14 eCAP/ePWM/eQEP Control and Status Registers

The BOOT_CFG registers which provide control and status information for the eCAP/ePWM/eQEP modules are shown in Table 5-15.

Table 5-15. Summary of the eCAP/ePWM/eQEP Control and Status Registers

Register Name	Description	Associated Functionality Described in:
BOOTCFG_EPWM_CTL	Time base clock and other controls for the ePWM**x** module	Section 11.5.3.4 *ePWM Modules Time Base Clock Gating*, Section 11.5.3.3 *ADC start of conversion signals (EPWM_SOCA and EPWM_SOCB)* and Section 11.5.3.2 *Daisy-Chain Connectivity between ePWM Modules* in Section 11.5 *Enhanced PWM (ePWM) Module*
BOOTCFG_ECAP_CAPEVT_CTL	Selects capture event for the eCAP**x** module	Section 11.4.4.1 *eCAP Input Capture Events* in Section 11.4 *Enhanced Capture (eCAP) Module*
BOOTCFG_EQEP_STAT	Provides eQEP**x** phase error status information	Section 11.6.3.1 *Device Specific eQEP Features* in Section 11.6 *Enhanced Quadrature Encoder Pulse (eQEP) Module*

5.1.3.1.15 NSS MAC Address Registers

Each device has unique 48-bit MAC address which is stored in the BOOT_CFG registers shown in Table 5-16.

Table 5-16. Summary of the NSS MAC Address Registers

Bit Field	Description
BOOTCFG_MACID0[31-0] MACID	Contains the first, second, third and fourth octets of the NSS MAC address
BOOTCFG_MACID1[15-0] MACID	Contains the fifth and sixth octets of the NSS MAC address

5.1.3.1.16 ARMSS Endian Configuration Registers

NOTE: ARMSS supports only little-endian mode of operation. Big-endian mode is not supported on ARMSS.

The BOOT_CFG module has registers intended to provide the ARMSS with a never changing ednian view of the registers of the device peripherals in case of 32-bit accesses. Table 5-17 shows these registers and Table 5-18 lists their reset values.

Table 5-17. Summary of the ARMSS Endian Configuration Registers

Register Name	Register Name	Register Name	ARMSS Region
BOOTCFG_ARMENDIAN_CFGx_0	BOOTCFG_ARMENDIAN_CFGx_1	BOOTCFG_ARMENDIAN_CFGx_2	x (x = 0 to 7)

Table 5-18. BOOTCFG_ARMENDIAN_CFGx_0 to BOOTCFG_ARMENDIAN_CFGx_2 Reset Values

Register Name	Reset Value	Register Name	Reset Value
BOOTCFG_ARMENDIAN_CFG0_0	1C000h	BOOTCFG_ARMENDIAN_CFG4_0	23A00h
BOOTCFG_ARMENDIAN_CFG0_1	6h	BOOTCFG_ARMENDIAN_CFG4_1	5h
BOOTCFG_ARMENDIAN_CFG0_2	1h	BOOTCFG_ARMENDIAN_CFG4_2	1h
BOOTCFG_ARMENDIAN_CFG1_0	20000h	BOOTCFG_ARMENDIAN_CFG5_0	240000h

BOOTCFG_ARMENDIAN_CFG2_0	BC000h	BOOTCFG_ARMENDIAN_CFG6_0	1000000h
BOOTCFG_ARMENDIAN_CFG2_1	4h	BOOTCFG_ARMENDIAN_CFG6_1	0h
BOOTCFG_ARMENDIAN_CFG2_2	1h	BOOTCFG_ARMENDIAN_CFG6_2	1h
BOOTCFG_ARMENDIAN_CFG3_0	210000h	BOOTCFG_ARMENDIAN_CFG7_0	FFFFFF00h
BOOTCFG_ARMENDIAN_CFG3_1	8h	BOOTCFG_ARMENDIAN_CFG7_1	0h
BOOTCFG_ARMENDIAN_CFG3_2	1h	BOOTCFG_ARMENDIAN_CFG7_2	1h

5.1.3.1.17 Registers Associated with the ARMSS and DEBUG_SS Trace Buffers

There are registers in the BOOT_CFG module memory space which are intended to hold USB Transfer Request Blocks (TRBs) used in case draining of the ARMSS and Debug subsystem trace buffers is needed. Table 5-19 shows these registers. Corresponding shadow registers are also present. Table 5-20 lists the reset values of these registers.

Table 5-19. Summary of the ARMSS and DEBUG_SS Trace Buffer Associated Registers

ARMSS Trace Buffer Registers	ARMSS Trace Buffer Shadow Registers	Debug Subsystem Trace Buffer Registers	Debug Subsystem Trace Buffer Shadow Registers	TRBx Word (x = 0 to 2)
BOOTCFG_ARMTBR_TRBx_W0	BOOTCFG_ARMTBR_SHDW_TRBx_W0	BOOTCFG_DBGTBR_TRBx_W0	BOOTCFG_DBGTBR_SHDW_TRBx_W0	0
BOOTCFG_ARMTBR_TRBx_W1	BOOTCFG_ARMTBR_SHDW_TRBx_W1	BOOTCFG_DBGTBR_TRBx_W1	BOOTCFG_DBGTBR_SHDW_TRBx_W1	1
BOOTCFG_ARMTBR_TRBx_W2	BOOTCFG_ARMTBR_SHDW_TRBx_W2	BOOTCFG_DBGTBR_TRBx_W2	BOOTCFG_DBGTBR_SHDW_TRBx_W2	2
BOOTCFG_ARMTBR_TRBx_W3	BOOTCFG_ARMTBR_SHDW_TRBx_W3	BOOTCFG_DBGTBR_TRBx_W3	BOOTCFG_DBGTBR_SHDW_TRBx_W3	3

Table 5-20. Reset Values of the ARMSS and DEBUG_SS Trace Buffer Associated Registers

Register Name	Reset Value	Register Name	Reset Value
BOOTCFG_ARMTBR_TRB0_W0	20700000h	BOOTCFG_DBGTBR_TRB0_W0	20600000h

5.1.3.1.18 PLL Control Registers

The registers for controlling the device PLLs reside in the BOOT_CFG module memory space. Table 5-21 summarizes these registers. More information can be found in Section 5.4.5 *PLLs*.

Table 5-21. Summary of the PLL Control Registers

Register Name	Register Name
BOOTCFG_MAIN_PLL_CTL0	BOOTCFG_MAIN_PLL_CTL1
BOOTCFG_NSS_PLL_CTL0	BOOTCFG_NSS_PLL_CTL1
BOOTCFG_DDR3A_PLL_CTL0	BOOTCFG_DDR3A_PLL_CTL1
BOOTCFG_ARM_PLL_CTL0	BOOTCFG_ARM_PLL_CTL1
BOOTCFG_DSS_PLL_CTL0	BOOTCFG_DSS_PLL_CTL1
BOOTCFG_ICSS_PLL_CTL0	BOOTCFG_ICSS_PLL_CTL1
BOOTCFG_UART_PLL_CTL0	BOOTCFG_UART_PLL_CTL1

5.1.3.1.19 Clock Muxing, Enabling and Division Registers

There are several registers within the BOOT_CFG module address space dedicated to clock muxing, clock enabling/disabling and clock division for some device modules. Table 5-22 summarizes these registers. Related information can also be found in Section 5.4 *Clock Management*.

Table 5-22. Summary of the Clock Muxing, Enabling and Division Registers

Register Name	Register Name
BOOTCFG_DDR_CLKCTL	BOOTCFG_ICSS_CLKCTL
BOOTCFG_USB0_CLKCTL	BOOTCFG_USB1_CLKCTL
BOOTCFG_ETHERNET_CLKCTL	BOOTCFG_PCIE_CLKCTL
BOOTCFG_SERIALPORT_CLKCTL	

5.1.3.1.20 Registers for Control of Some Device LDOs

The BOOTCFG_LDO_USB_CTL and BOOTCFG_LDO_PCIE_CTL registers have bits to program the USB and PCIe LDOs.

5.1.3.1.21 USB PHY Control Registers

The registers for controlling the USB0 and USB1 PHYs are shown in Table 5-23.

Table 5-23. Summary of the USB0 and USB1 PHY Control Registers

Register Name	Register Name
BOOTCFG_USB0_PHY_CTL0	BOOTCFG_USB1_PHY_CTL0
BOOTCFG_USB0_PHY_CTL1	BOOTCFG_USB1_PHY_CTL1
BOOTCFG_USB0_PHY_CTL2	BOOTCFG_USB1_PHY_CTL2
BOOTCFG_USB0_PHY_CTL4	BOOTCFG_USB1_PHY_CTL4

5.1.3.1.22 ID Registers

The following ID registers are present in the BOOT_CFG memory space:

- BOOTCFG_REVISION
- BOOTCFG_JTAGID
- BOOTCFG_PCIEVENDORID

5.1.4 BOOT_CFG Registers

Table 5-25 lists the memory-mapped registers for the BOOT_CFG. All register offset addresses not listed in Table 5-25 should be considered as reserved locations and the register contents should not be modified.

Table 5-24. BOOT_CFG Instances

Instance	Physical Address
BOOT_CFG	0262 0000h

5.1.4.3 BOOTCFG_DEVSTAT Register (Offset = 20h) [reset = 1h]

BOOTCFG_DEVSTAT is shown in Figure 5-8 and described in Table 5-33.

Indicates device bootstrap selection upon a power-on reset by PORn or RESETFULLn. The default value of this register is determined by the bootstrap pins. Once set, these bits remain set until a power-on reset.

Table 5-32. BOOTCFG_DEVSTAT Instances

Instance	Physical Address

5.1.4.4 BOOTCFG_KICK0 Register (Offset = 38h) [reset = 0h]

BOOTCFG_KICK0 is shown in Figure 5-9 and described in Table 5-36.

The BOOT_CFG module contains a kicker mechanism to prevent spurious writes from changing any of the BOOT_CFG MMR values. When the kicker is locked (which it is initially after power-on reset), none of the BOOT_CFG MMRs are writable (they are only readable). This mechanism requires an MMR write to each of the BOOTCFG_KICK0 and BOOTCFG_KICK1 registers with exact data values before the kicker lock mechanism is unlocked. Once released, all the BOOT_CFG MMRs having write permissions are writable (the read only MMRs are still read only). The BOOTCFG_KICK0 data is 83E70B13h. The BOOTCFG_KICK1 data is 95A4F1E0h. Writing any other data value to either of these kick MMRs locks the kicker mechanism and blocks writes to BOOT_CFG MMRs. To ensure protection to all BOOT_CFG MMRs, software must always re-lock the kicker mechanism after completing the MMR writes.

5.1.4.20 BOOTCFG_BOOT_COMPLETE Register (Offset = 13Ch) [reset = 0h]

BOOTCFG_BOOT_COMPLETE is shown in Figure 5-25 and described in Table 5-84.

Register to control BOOTCOMPLETE pin status to indicate completion of the ROM booting process. The BCx bit indicates the boot complete status of the corresponding C66x or Arm cores. All BCx bits are sticky bits - that is, they can be set only once by the software after device reset and they will be cleared to 0 on all device resets. Boot ROM code is implemented such that each C66x and Arm cores sets its corresponding BCx bit immediately before branching to the predefined location in memory. When all the BCx bits are set to 1, the BOOTCOMPLETE pin status will be high indicating that device ROM booting process is complete.

5.1.4.21 BOOTCFG_RESET_STAT Register (Offset = 144h) [reset = 0h]

BOOTCFG_RESET_STAT is shown in Figure 5-26 and described in Table 5-87.

The Reset Status Register captures the status of local reset (LRx) for each of the C66x cores and also the global device reset (GR). Software can use this information to take different device initialization steps.

- In case of local reset: The LRx bits are written as 1 and the GR bit is written as 0 only when the C66x core receives a local reset without receiving a global reset.

- In case of global reset: The LRx bits are written as 0 and the GR bit is written as 1 only when a global reset is asserted.

5.1.4.22 BOOTCFG_LRSTNMISTAT Register (Offset = 148h) [reset = 0h]

BOOTCFG_LRSTNMISTAT is shown in Figure 5-27 and described in Table 5-90.

Local reset and NMI pin status register for C66x core. BOOTCFG_LRSTNMISTAT is used to latch the status of LRESETz and NMIz based on LRESETNMIENz pin. The pin status is latched on the rising edge of LRESETNMIENz. Note that LRESETz and NMIz are available only for the C66x core and not the Arm core.

5.1.4.28 BOOTCFG_IPCGR0 Register (Offset = 240h) [reset = 0h]

BOOTCFG_IPCGR0 is shown in Figure 5-33 and described in Table 5-108.

Register facilitate inter-core interrupt to C66x core 0. A write of 1 to the IPCG field of the BOOTCFG_IPCGR0 register generates an interrupt pulse to C66x core 0. The register also provides a Source ID facility identifying up to 28 different sources of interrupt. Allocation of source bits to source processor and meaning is entirely based on software convention. There can be numerous sources for the register as this is completely controlled by software. Any master that has access to BOOT_CFG module space can write to this register. Register is KICK un-locked, that means software need not go through KICK sequence in order to write to this register.

Register facilitate inter-core interrupt to ICSS1. A write of 1 to the IPCG field of the BOOTCFG_IPCGR14 register generates an interrupt pulse to ICSS1. The register also provides a Source ID facility identifying up to 28 different sources of interrupt. Allocation of source bits to source processor and meaning is entirely based on software convention. There can be numerous sources for the register as this is completely controlled by software. Any master that has access to BOOT_CFG module space can write to this register. Register is KICK un-locked, that means software need not go through KICK sequence in order to write to this register.

5.1.4.34 BOOTCFG_IPCGRH Register (Offset = 27Ch) [reset = 0h]

BOOTCFG_IPCGRH is shown in Figure 5-39 and described in Table 5-126.

Register facilitate interrupt to external host. Operation and use of the BOOTCFG_IPCGRH register is the same as for other IPCGR registers. The interrupt output pulse created by the BOOTCFG_IPCGRH register appears on device pin HOUT. The host interrupt output pulse is stretched so that it is asserted for four bootcfg clock cycles (CLK/6) followed by a deassertion of four bootcfg clock cycles. Generating the pulse results in a pulse-blocking window that is eight CLK/6-cycles long. Back-to-back writes to the BOOTCFG_IPCGRH register with the IPCGRH_REG bit (bit 0) set, generates only one pulse if the back-to-back writes to BOOTCFG_IPCGRH are less than the eight CLK/6 cycle window - the pulse blocking window. To generate back-to-back pulses, the back-to-back writes to the BOOTCFG_IPCGRH register must be written after the eight CLK/6 cycle pulse-blocking window has elapsed. Register is KICK un-locked, that means software need not go through KICK sequence in order to write to this register.

Table 5-165. BOOTCFG_MAIN_PLL_CTL0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	BWADJ	R/W	05h	8-bit LSB of a 12-bit BWADJ field that selects the values for the loop bandwidth adjustment. BWADJ[7-0] is controlled from this register and BWADJ[11-8] is controlled from BOOTCFG_MAIN_PLL_CTL1 register. BWADJ[11-0] should be programmed to a value equal to half of PLLM[12-0] value (round down if PLLM has an odd value). Example: If PLLM = 15, then BWADJ = 7
23-19	RESERVED	R		Reserved
18-12	PLLM	R/W	0h	7-bit MSB of a 13-bit PLLM field that selects the values for the multiplication factor. PLLM field is loaded with the multiply factor minus 1. The PLLM[5-0] bits of the multiplier are controlled by the PLLM register inside the PLL Controller and the PLLM[12-6] bits are controlled by this register. This field should be written just before writing to PLLM[5-0] bits of the PLLM register to have the complete 13-bit value latched when the GO operation is initiated in the PLL Controller
11-6	RESERVED	R		Reserved
5-0	PLLD	R/W	0h	A 6-bit field that selects the values for the reference divider. PLLD field is loaded with reference divider value minus 1

BOOTCFG_ARMTBR_TRBx_W2 (*where x = 0 to 2*) is shown in Figure 5-71 and described in Table 5-222.

These registers hold the software writable copy of USB xHCI Transfer Request Block (TRB) *x* for a trace buffer. Each TRB consists of 4 consecutive 32-bit words (0..3) defining the buffer address, buffer size and other control, as per xHCI definition. There are three TRBs (0..2) used for continuously draining the ARMSS trace buffer.

BOOTCFG_ARMTBR_SHDW_TRBx_W0 (*where x = 0 to 2*) is shown in Figure 5-73 and described in Table 5-228.

These are shadow registers for Transfer Request Block (TRB) *x* and shall reflect the same value as ARMTBR_TRBx_W[3:0] registers. These registers per trace buffer holds the USB readable versions of the descriptor.These registers are expected to be written by the USB module, but writes to these registers shall be ignored silently, without returning any error in the config bus. The purpose of the shadow registers are to enable USB module to use these descriptors continuously without requiring software intervention to re-initialize the Transfer Request Blocks (TRB).

Table 5-264. BOOTCFG_SPARE1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SPARE_PULSE1	WPH	0h	When this bit is set to 1, it generates a pulse for one BOOT_CFG_VBUS_CLK clock period. Read return zero.
30-7	SPARE_OUT1	R/W	0h	Reserved.
6-3	DIV_FACTOR	R/W	0h	DSS divider value. Clock is divided by DIV_FACTOR+1.
2	DIV_CLKSEL	R/W	0h	DSS divided clock select. 0 - Use DSS clock 1 - Use divided DSS clock
1	LOAD_DIV_RATIO	R/W	0h	DSS divide value load. Pulse this bit by writing 1 followed by a 0 to load the DIV_FACTOR and start the divider.
0	DIV_RSTN	R/W	0h	DSS divider reset. Clear this bit to 0 before changing the DIV_FACTOR and set to 1 after DIV_FACTOR is programmed.

BOOT_CFG Registers • BOOTCFG_PLLLOCK_PINCTL Register (Offset = 714h) [reset = 1h]: [0] • BOOT_CFG Registers: [0]

5.1.4.92 BOOTCFG_PLLLOCK_STAT Register (Offset = 718h) [reset = 0h]

BOOTCFG_PLLLOCK_STAT is shown in Figure 5-97 and described in Table 5-300.

This register holds the current status of the PLL Lock bit when BOOTCFG_PLLLOCK_EVAL bit is set and further captures loss ofLOCK in a sticky fashion. Note that the PLL being in its initial unlocked state is also a sticky state and therefore,software has to reevaluate the state using BOOTCFG_PLLLOCK_EVAL after initial PLL configuration and lock.

Bit	Field	Type	Reset	Description
31-27	RESERVED	R		Reserved
26-23	USB0_PHY_PC_TXVREFTUNE	R/W	8h	HS DC Voltage Level Adjustment. This bus adjusts the high-speed DC level voltage. 0000: -10% 0001: -8.75% 0010: -7.5% 0011: -6.25% 0100: -5% 0101: -3.75% 0110: -2.5% 0111: -1.25% 1000: Design default 1001: +1.25% 1010: +2.5% 1011: +3.75% 1100: +5% 1101: +6.25% 1110: +7.5% 1111: +8.75%
22-21	USB0_PHY_PC_TXRISETUNE	R/W	2h	HS Transmitter Rise/Fail Time Adjustment. This bus adjusts the rise/fail times of the high-speed waveform. 00: +20% 01: +15% 10: Design default 11: -10%

Table 5-315. BOOTCFG_USB0_PHY_CTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20-19	USB0_PHY_PC_TXRESTUNE	R/W	1h	USB Source impedance Adjustment. In some applications, there can be significant series resistance on the D+ and D- paths between the transceiver and cable. This bus adjusts the driver source impedance to compensate for added series resistance on the USB. Note: Any setting other than the default can result in source impedance variation across process, voltage, and temperature conditions that does not meet USB 2.0 specification limits. 00: Source impedance is increased by approximately 1.5 ohm 01: Design default 10: Source impedance is decreased by approximately 2 ohm 11: Source impedance is decreased by approximately 4 ohm
18	USB0_PHY_PC_TXPREEMPPULSETUNE	R/W	0h	HS Transmitter Pre-Emphasis Duration Control. This signal controls the duration for which the HS pre-emphasis current is sourced onto DP or DM. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580 ps and is defined as 1X pre-emphasis duration. This signal is valid only if either TXPREEMPAMPTUNE0 or TXPREEMPAMPTUNE2 is set to 1. 0 (design default): 2X, long pre-emphasis current duration 1: 1X, short pre-emphasis current duration
17-16	USB0_PHY_PC_TXPREEMPAMPTUNE	R/W	0h	HS Transmitter Pre-Emphasis Current Control. This signal controls the amount of current sourced to DP and after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600 uA and is defined as 1X pre-emphasis current. 00 (design default): HS Transmitter pre-emphasis is disabled. 01: HS Transmitter pre-emphasis circuit sources 1X pre-emphasis current. 10: HS Transmitter pre-emphasis circuit sources 2X pre-emphasis current. 11: HS Transmitter pre-emphasis circuit sources 3X pre-emphasis current. If these signals are not used, set them to 00b.
15-14	USB0_PHY_PC_TXHSXVTUNE	R/W	3h	Transmitter High-Speed Crossover Adjustment. This bus adjusts the voltage at which the DP and DM signals cross while transmitting in HS mode. 00: Reserved 01: -15mV 10: +15mV 11: Default setting
13-10	USB0_PHY_PC_TXFSLSTUNE	R/W	3h	FS/LS Source impedance Adjustment. This bus adjusts the low- and full-speed single-ended source impedance while driving high.The following adjustment values are based on nominal process, voltage, and temperature. 0000: +5% 0001: +2.5% 0011: Design default 0111: -2.5% 1111: -5% All other bit settings are reserved.

Table 5-315. BOOTCFG_USB0_PHY_CTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	USB0_PHY_PC_SQRXTUNE	R/W	3h	Squelch Threshold Adjustment. This bus adjusts the voltage level for the threshold used to detect valid high-speed data. 000: +15% 001: +10% 010: +5% 011: Design default 100: -5% 101: -10% 110: -15% 111: -20%
6-4	USB0_PHY_PC_OTGTUNE	R/W	4h	VBUS Valid Threshold Adjustment. This bus adjusts the voltage level for the VBUS valid threshold. 000: -12% 001: -9% 010: -6% 011: -3% 100: Design default 101: +3% 110: +6% 111: +9%
3	RESERVED	R		Reserved
2-0	USB0_PHY_PC_COMPDISTUNE	R/W	4h	Disconnect Threshold Adjustment. This bus adjusts the voltage level for the threshold used to detect a disconnect event at the host. 000: -6% 001: -4.5% 010: -3% 011: -1.5% 100: Design default 101: +1.5% 110: +3% 111: +4.5%

Table 5-318. BOOTCFG_USB0_PHY_CTL4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	USB0_PHY_OTG_VBUSVLDEXTSEL	R/W	1h	External VBUS Valid Select. This signal selects either the VBUSVLDEXT input or the internal Session Valid comparator to generate the OTGSESSVLD output. To avoid potential glitches in DP, VBUSVLDEXTSEL must be static prior to a power-on reset and remain static during normal operation. The OTGSESSVLD signal, in conjunction with XCVRSEL(1:0), OPMODE(1:0), TERMSEL, DPPULLDOWN, and DMPULLDOWN, control the DP pull-up resistor. If VBUSVLDEXT and the internal Session Valid comparator output are asserted, and VBUSEXTSEL changes, it is possible for OTGSESSVLD to glitch low, causing the DP resistor to be temporarily disabled. 0: The internal Session Valid comparator is used to generate OTGSESSVLD and assert the DP pull-up resistor. 1: The VBUSVLDEXT input is used to generate OTGSESSVLD and assert the DP pull-up resistor.
15	USB0_PHY_OTG_OTGDISABLE	R/W	1h	OTG Block Disable. This signal powers down the VBUS Valid comparator, but not the Session Valid comparator, ADP probe and sense comparators, nor the ID detection circuitry. To save power, if the application does not use the OTG function, this input can be set high. 0: The OTG block is powered up. 1: The OTG block is powered down.
14-0	RESERVED	R		Reserved

Bit	Field	Type	Reset	Description
31-27	RESERVED	R		Reserved
26-23	USB1_PHY_PC_TXVREFTUNE	R/W	8h	HS DC Voltage Level Adjustment. This bus adjusts the high-speed DC level voltage. 0000: -10% 0001: -8.75% 0010: -7.5% 0011: -6.25% 0100: -5% 0101: -3.75% 0110: -2.5% 0111: -1.25% 1000: Design default 1001: +1.25% 1010: +2.5% 1011: +3.75% 1100: +5% 1101: +6.25% 1110: +7.5% 1111: +8.75%
22-21	USB1_PHY_PC_TXRISETUNE	R/W	2h	HS Transmitter Rise/Fail Time Adjustment. This bus adjusts the rise/fail times of the high-speed waveform. 00: +20% 01: +15% 10: Design default 11: -10%

Table 5-327. BOOTCFG_USB1_PHY_CTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20-19	USB1_PHY_PC_TXRESTUNE	R/W	1h	USB Source impedance Adjustment. In some applications, there can be significant series resistance on the D+ and D- paths between the transceiver and cable. This bus adjusts the driver source impedance to compensate for added series resistance on the USB. Note: Any setting other than the default can result in source impedance variation across process, voltage, and temperature conditions that does not meet USB 2.0 specification limits. 00: Source impedance is increased by approximately 1.5 ohm 01: Design default 10: Source impedance is decreased by approximately 2 ohm 11: Source impedance is decreased by approximately 4 ohm
18	USB1_PHY_PC_TXPREEMPPULSETUNE	R/W	0h	HS Transmitter Pre-Emphasis Duration Control. This signal controls the duration for which the HS pre-emphasis current is sourced onto DP or DM. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580 ps and is defined as 1X pre-emphasis duration. This signal is valid only if either TXPREEMPAMPTUNE1 or TXPREEMPAMPTUNE2 is set to 1. 0 (design default): 2X, long pre-emphasis current duration 1: 1X, short pre-emphasis current duration
17-16	USB1_PHY_PC_TXPREEMPAMPTUNE	R/W	0h	HS Transmitter Pre-Emphasis Current Control. This signal controls the amount of current sourced to DP and after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600 uA and is defined as 1X pre-emphasis current. 00 (design default): HS Transmitter pre-emphasis is disabled. 01: HS Transmitter pre-emphasis circuit sources 1X pre-emphasis current. 10: HS Transmitter pre-emphasis circuit sources 2X pre-emphasis current. 11: HS Transmitter pre-emphasis circuit sources 3X pre-emphasis current. If these signals are not used, set them to 00b.
15-14	USB1_PHY_PC_TXHSXVTUNE	R/W	3h	Transmitter High-Speed Crossover Adjustment. This bus adjusts the voltage at which the DP and DM signals cross while transmitting in HS mode. 00: Reserved 01: -15mV 10: +15mV 11: Default setting
13-10	USB1_PHY_PC_TXFSLSTUNE	R/W	3h	FS/LS Source impedance Adjustment. This bus adjusts the low- and full-speed single-ended source impedance while driving high. The following adjustment values are based on nominal process, voltage, and temperature. 0000: +5% 0001: +2.5% 0011: Design default 0111: -2.5% 1111: -5% All other bit settings are reserved.

Table 5-327. BOOTCFG_USB1_PHY_CTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	USB1_PHY_PC_SQRXTUNE	R/W	3h	Squelch Threshold Adjustment. This bus adjusts the voltage level for the threshold used to detect valid high-speed data. 000: +15% 001: +10% 010: +5% 011: Design default 100: -5% 101: -10% 110: -15% 111: -20%
6-4	USB1_PHY_PC_OTGTUNE	R/W	4h	VBUS Valid Threshold Adjustment. This bus adjusts the voltage level for the VBUS valid threshold. 000: -12% 001: -9% 010: -6% 011: -3% 100: Design default 101: +3% 110: +6% 111: +9%
3	RESERVED	R		Reserved
2-0	USB1_PHY_PC_COMPDISTUNE	R/W	4h	Disconnect Threshold Adjustment. This bus adjusts the voltage level for the threshold used to detect a disconnect event at the host. 000: -6% 001: -4.5% 010: -3% 011: -1.5% 100: Design default 101: +1.5% 110: +3% 111: +4.5%

Table 5-330. BOOTCFG_USB1_PHY_CTL4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	USB1_PHY_OTG_VBUSVLDEXTSEL	R/W	1h	External VBUS Valid Select. This signal selects either the VBUSVLDEXT input or the internal Session Valid comparator to generate the OTGSESSVLD output. To avoid potential glitches in DP, VBUSVLDEXTSEL must be static prior to a power-on reset and remain static during normal operation. The OTGSESSVLD signal, in conjunction with XCVRSEL(1:0), OPMODE(1:0), TERMSEL, DPPULLDOWN, and DMPULLDOWN, control the DP pull-up resistor. If VBUSVLDEXT and the internal Session Valid comparator output are asserted, and VBUSEXTSEL changes, it is possible for OTGSESSVLD to glitch low, causing the DP resistor to be temporarily disabled. 0: The internal Session Valid comparator is used to generate OTGSESSVLD and assert the DP pull-up resistor. 1: The VBUSVLDEXT input is used to generate OTGSESSVLD and assert the DP pull-up resistor.
15	USB1_PHY_OTG_OTGDISABLE	R/W	1h	OTG Block Disable. This signal powers down the VBUS Valid comparator, but not the Session Valid comparator, ADP probe and sense comparators, nor the ID detection circuitry. To save power, if the application does not use the OTG function, this input can be set high. 0: The OTG block is powered up. 1: The OTG block is powered down.

5.2 Power Management

This chapter describes the power-management architecture implemented in the device.

5.2.1 Power Management Overview

To provide a versatile architecture that supports multiple power-management techniques, the power management framework is built with three levels of resource management: clock, power, and voltage.

These management levels are enforced by defining the managed entities or building blocks of the power management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

To minimize device power consumption, the clocks can be gated (turned off), or the power to the modules can be switched off, when they are not in use. Independent power and clock control of sections of the device allows for turning on and off specific sections of the device without affecting other sections.

5.2.2 Power Sleep Controller (PSC)

The Power Sleep Controller (PSC) includes a Global Power Sleep Controller (GPSC) and a number of Local Power Sleep Controllers (LPSC) that control overall device power by turning off unused power domains and gating off clocks to individual peripherals and modules. The PSC provides the user with an interface to control several important power and clock operations.

5.2.2.1 PSC Terminology

Term	Definition
LPSC	Local Power/Sleep Controller; one per module (domain)
GPSC	Global Power/Sleep Controller; manages the LPSCs
PSC	Power/Sleep Controller, including one GPSC and multiple LPSCs

5.2.2.2 Features

The PSC includes the following features:

- Provides software interface to:
  - Control module power on/off
  - Control module clock on/off
- Supports emulation features: power, clock, and reset.

5.2.2.3 Power Domains

The device has several power domains that can be turned on for operation or off to minimize power dissipation. The Global Power Sleep Controller (GPSC) is used to control the power gating of various power domains.

Table 5-473 shows the power domains assigned to modules in the device.

NOTE: ELM is not supported on this family of devices.

Table 5-473. Power Domains

Power Domain Number (x)	Power Domain Name	Modules	PD Default	Notes
0	ALWAYS_ON	PMMC, DCAN_[0:1], PSC, SERDES, TIMER_6, GTC, Message Manager, BOOT_CFG, I2C_0, MPU_[0:2], DFT_SS, EFUSE, PLLs, PLL controller, ICEMELTER, GPIO_[0:1]	ON	Always on. Cannot be disabled.
1	DEBUG	DEBUGSS, ETB (TETB), TBR (DBG, PMMC, ARMSS)	ON	
2	NSS	Network Coprocessor (NSS)	OFF	NSS power domain (NAVSS + EMAC) is standalone and can be used with CRYPTO power domain either enabled or disabled. However, it is not possible to use CRYPTO when the NSS power domain is OFF. During power-up sequence it is required to have the NSS power domain ON prior to turning the CRYPTO ON. Similarly during power down sequence it is required to power down CRYPTO prior to powering down the NSS domain.
3	CRYPTO	Crypto	OFF	
4	CBASS	CBASS, CPT_[2:14], MPU_[3:13, 15, 16]	ON	

Table 5-473. Power Domains (continued)

Power Domain Number (x)	Power Domain Name	Modules	PD Default	Notes
5	SYS_COMP	EDMA_0, EDMA_1, Semaphore, INTC, GIC, MPU_14, ARM_BOOTROM, TIMER_[0:5], I2C_[1:2], UART_[0:2], MCBSP, SPI[_0:3], QSPI, MMC_[0:1], GPMC, ELM, MLB, ePWM_[0:5], eQEP_[0:2], eCAP_[0:1], MCASP_[0:2]	ON	TIMER_0 and TIMER_5 are dedicated for DSP and ARMSS, respectively. When DSP or ARMSS is powered down, the corresponding TIMER is held in reset and not available for the system. Additionally, these timers are controlled by the DSP/ARMSS LPSCs.
6	Reserved	Reserved	ON	
7	MSMC	MSMC, CPT_[0:1]	ON	
8	DSP	DSP	ON	
9	ARMSS	ARMSS, A15 core	ON	
10	ASRC	ASRC	OFF	
11	ICSS	ICSS_0, ICSS_1	OFF	
12	DSS	DSS	OFF	
13	PCIE	PCIe	OFF	
14	USB	USB_0, USB_1	OFF	
15	DDR3	EMIF DDR3	ON	DDR3 EMIF controller does not support power down, but it supports clock-gating in case of No-DDR configuration.

NOTE: For details on power domain state transitions, please refer to Section 5.2.2.6, *Executing State Transitions*.

5.2.2.4 Clock Domains

Clock gating to each logic block is managed by the Local Power Sleep Controllers (LPSCs). For modules with a dedicated clock or multiple clocks, the LPSC communicates with the PLL controller to enable and disable that module's clock(s) at the source. For modules that share a clock with other modules, the LPSC controls the clock gating logic for each module.

Table 5-474 shows the clock domains in the device.

NOTE: ELM is not supported on this family of devices.

Table 5-474. Clock Domains

Module Domain Number (LPSCy)	Modules	Clock Default	Reset Isolation[1]	Notes
0	DCAN_[0:1], PSC, SERDES, TIMER_6, Message Manager, BOOT_CFG, I2C_0, MPU_[0:2], GPIO_[0:1]	ON	No	Always on power domain. Must never be clock-gated.
1	PMMC	ON	No	Always on power domain. Must never be clock-gated.
2	DEBUGSS, ETB (TETB), TBR (DBG, PMMC, ARMSS)	ON	Yes	
3	Network Coprocessor (NSS)	OFF	No	Even though NAVSS and EMAC have separate clock-stop interfaces, they are controlled by a single common LPSC (LPSC3) at the SoC level. Therefore, it is not possible to clock gate EMAC when only NAVSS is used.

(1) The reset isolation column only shows if the LPSC has reset isolation capability. The power-on default value is reset isolation disabled. The software can enable the reset isolation by writing to the respective LPSC register (MDCTLy, where y = module domain number).

Table 5-474. Clock Domains (continued)

Module Domain Number (LPSCy)	Modules	Clock Default	Reset Isolation[1]	Notes
4	Crypto	OFF	No	
5	CBASS, CPT_[2:14], MPU_[3:13, 15, 16]	ON	No	
6	EDMA_0, EDMA_1, Semaphore, INTC, GIC, MPU_14, ARM_BOOTROM, TIMER_[1:4], I2C_[1:2], UART_[0:2], MCBSP, SPI_[0:3]	ON	No	
7	QSPI	ON	No	
8	MMC_[0:1]	ON	No	
9	GPMC, ELM	ON	No	
10	Reserved	OFF	No	
11	MLB	OFF	No	
12	ePWM_[0:5]	OFF	No	
13	eQEP_[0:2]	OFF	No	
14	eCAP_[0:1]	OFF	No	
15	MCASP_[0:2]	OFF	No	
16	Reserved	ON	Yes	
17	MSMC, CPT_[0:1]	ON	No	MSMC does not support clock-gating.
18	DSP, TIMER_0	ON	No	Even though TIMER_0 and TIMER_5 are located in the SYS_COMP power domain, they are not controlled by the SYS_COMP LPSC. Instead, they are controlled by the corresponding core LPSC (that is LPSC18 for DSP timer and DPSC for A15 timer). DPSC is the Discrete PSC inside the ARMSS.
19	ARMSS, A15 core, TIMER_5 (DPSC)	ON	No	
20	ASRC	OFF	No	
21	ICSS_[0:1]	OFF	Yes	
22	Reserved	OFF	Yes	
23	DSS	OFF	No	
24	PCIe	OFF	No	
25	USB_0	OFF	No	
26	USB_1	OFF	No	
27	EMIF DDR3	ON	Yes	DDR3 EMIF controller does not support power down, but it supports clock-gating in case of No-DDR configuration.

NOTE: For details on module domain state transitions, please refer to Section 5.2.2.6, *Executing State Transitions*.

5.2.2.5 Power Domain and Module States Defined

The PSC module organizes modules into different power domains and into different modules (clock domains). Note that there is no relationship between a power domain and a module domain. These are completely separate entities and may be controlled separately.

5.2.2.5.1 Power Domain States

A power domain can be in only one of two states: ON or OFF, defined as follows:

- **ON:** Power to the power domain is on. Logic/memories are awake.
- **OFF:** Power to the power domain is off. Logic/memories are turned off.

The AlwaysOn power domain is always in the ON state when the device is powered on. The other power domains can be in either the ON or OFF state; that is, the logic/memory for a specific module can remain powered down if it is not used.

5.2.2.5.2 Module States

A module can be in one of two states: Enable or SwRstDisable. As shown in Table 5-475, these two states correspond to combinations of module reset asserted or de-asserted and module clock on or off. Note that module reset is defined to completely reset a given module, such that all hardware is put back into its default state.

Table 5-475. Module States

Module State	Module Reset	Module Clock
Enable	De-asserted	ON
SwRstDisable	Asserted	OFF

The module states are defined as follows:

- **Enable:** A module in the Enable state has its module reset de-asserted and its clock on. This is the normal run-time state for a given module.
- **SwRstDisable:** A module in the SwResetDisable state has its module reset asserted and its clock OFF.

5.2.2.5.3 Local Reset

In addition to module reset described in the previous section, the DSP core and PMMC can be reset using a special local reset. When local reset is asserted, the internal memories (L1P, L1D, and L2) for the core are still accessible. The local reset resets only the corresponding DSP core and PMMC, not the rest of the chip. Local reset is intended to be used by the watchdog timers to reset the DSP core in the event of an error. The procedures for asserting and de-asserting local reset are as follows (y denotes the module domain number):

1. Set MDCTLy[8] LRST to 0x0 to assert local reset.
2. Set MDCTLy[8] LRST to 0x1 to de-assert local reset. The DSP core immediately executes program instructions after reset is de-asserted. Note that the boot sequence does not re-occur unless there is a device-level reset. Execution of code previously in L2 begins execution.

5.2.2.6 Executing State Transitions

This section describes how to execute state transitions for power domains and modules. Examples show how to enable only power domains, only module domains, or a combination. Although the user has complete control of the sequencing, see Section 5.2.2.6.4, *Recommendations for Power Domain/Module Sequencing* for recommendations.

5.2.2.6.1 Power Domain State Transitions

This section describes the basic procedure for transitioning the state of a power domain.

NOTE: The AlwaysOn power domain is always in the ON state when the device is powered-on, and therefore it is not possible to transition this domain to the OFF state. Conversely, the other domains are in the OFF or ON state when the device is powered-on. Transitions between ON and OFF states need to follow the procedure below. See the device Data Manual and respective module TRM chapter for any other considerations especially while turning off the power domain.

The procedure for power domain state transitions follows (x denotes the power domain number, y denotes the module domain number):

1. Wait for PTSTAT[x] GOSTAT to clear to 0. Wait for any previously initiated transitions to finish before initiating a new transition.

2. Set PDCTLx[0] NEXT for an ON (1) or OFF (0) transition. NOTE: When PTCMD[x] GO is set to 1 in the next step, the PDCTLx[0] NEXT field of this power domain and the MDCTLy[4-0] NEXT field of the module in this power domain are evaluated. Therefore, the MDCTLy[4-0] NEXT field may be set for multiple modules before executing this step.
3. Set PTCMD[x] GO to 1 to initiate the state transition(s). The PSC turns on or off the logic/memory for that particular domain.
4. Wait for PTSTAT[x] GOSTAT to self-clear to 0. The domain is safely in the new state only after PTSTAT[x] GOSTAT is cleared to 0.

5.2.2.6.2 Module State Transitions

This section describes the procedure for transitioning the module state.

NOTE: The following procedure is applicable for all LPSC-controlled modules. To transition the module state, one must be aware of several system considerations. Transitions between Enable and Disable states need to follow the procedure below. See the device Data Manual and peripheral chapter for any other considerations especially while transitioning a module to Disable state. Also, before transitioning a module to Enable, if the logic/memories are not in the AlwaysOn power domain, they must be turned on before or in parallel with the transition. See Section 5.2.2.6.1, *Power Domain State Transitions*.

The procedure for module state transitions follows (x denotes the power domain number, y denotes the module domain number):

1. Wait for PTSTAT[x] GOSTAT to clear to 0x0. Wait for any previously initiated transitions to finish before initiating a new transition.
2. Set MDCTLy[4-0] NEXT to Enable (0x3) or Disable (0x0). Note that transitions in multiple MDCTLy[4-0] NEXT fields may be set in this step as long as the corresponding power domain is on.
3. Set PTCMD[x] GO to 1 to initiate the transition(s).
4. Wait for PTSTAT[x] GOSTAT to self-clear to 0. The module is safely in the new state only after PTSTAT[x] GOSTAT clears to 0.

5.2.2.6.3 Concurrent Power Domain/Module State Transitions

This section describes the basic procedure for transitioning the state of a power domain and module domain for modules that are not in the AlwaysOn domain. This may be done separately as described in the sections above, if desired.

The procedure for concurrent power domain/module state transitions follows (X denotes the power domain number, Y denotes the module domain number):

1. Wait for PTSTAT[x] GOSTAT to clear to 0. Wait for any previously initiated transitions to finish before initiating a new transition.
2. Set PDCTLx[0] NEXT for an ON (1) transition.
3. Set MDCTLy[4-0] NEXT to Enable (0x3). Note that transitions in multiple MDCTLy[4-0] NEXT fields may be set in this step as long as the corresponding power domain is on.
4. Set PTSTAT[x] GOSTAT to 1 to initiate the state transition(s). The PSC will turn on the logic/memory for that particular domain, starts the module clock, then de-asserts the module reset.
5. Wait for PTSTAT[x] GOSTAT to self-clear to 0. The module is safely in the new state only after PTSTAT[x] GOSTAT clears to 0.

5.2.2.6.4 Recommendations for Power Domain/Module Sequencing

As noted in Section 5.2.2.5, *Power Domain and Module States Defined* and Section 5.2.2.6, *Executing State Transitions*, a particular peripheral's power domain must be enabled before the module is enabled.

Unless there is a system-level reason to perform each function separately, the recommendation is to use the sequence listed in Section 5.2.2.6.3 rather than individual sequencing. Even though a single write to the appropriate GO bit starts the power domain and module transition, it is still sequenced such that the memory/logic is certain to turn on before the module is enabled. Thus, there is no ill effect in performing these together.

It is important to know that when a power domain is enabled, all logic/memories for that module are immediately turned on and moved to an active state. This means that there will be a spike in current consumption at that particular time. In other words, di/dt will be affected. To minimize the effect on di/dt of enabling power domains, it is recommended to power up modules one at a time. It is also recommended that all modules be initialized early in the application to avoid a large spike in di/dt during normal operation where the application may already be drawing a substantial amount of current from the supply.

5.2.2.7 Emulation Support in the PSC

The PSC supports commands that allow emulation tools to have some control over the state of power domains and modules.

In particular, the PSC supports the following emulation commands:

- Power on and enable features:
  - **Force Power:** Allows emulation to force the power domain into an ON state.
  - **Force Active:** Allows emulation to force the power domain into an ON state and force the module into the Enable state.
- Reset features:
  - **Assert Reset:** Allows emulation to assert the module's local reset.
  - **Wait Reset:** Allows emulation to keep local reset asserted for an extended period of time after software initiates local reset de-assert.
  - **Block Reset:** Allows emulation to block software initiated local and module resets.

Local reset applies only to the DSP core/PMMC domains; module reset applies to all other domains.

5.2.2.8 PSC Registers

5.2.2.8.1 PSC Register Memory Map

Table 5-477 shows the PSC Register memory map.

Table 5-476. PSC Instances

5.3 Reset Management

This chapter describes the reset management in the device.

5.3.1 Reset Management Overview

Resets bring the device or part of the device to a known state after events such as power-up, hardware or software requests. There are numerous reset types on this device, however, all of these resets can be categorized into the following categories.

- Global resets:
  - Power-on reset
  - Hard and Soft resets
  - Emulation reset
  - Test reset
- Local resets:
  - DSP local reset
  - PMMC CPU local reset
  - Module resets.

Local reset is a reset that is applied to any given module in a module domain or to a CPU and/or its mega-module (any tightly coupled controllers delivered with the CPU) and their associated local watchdog timers.

Table 5-499 explains further the types of reset, the reset initiator, and the effects of each reset on the device. For more information on the effects of each reset on the PLL controller and its clocks, see Section 5.4.5.3, *PLL Controller*.

Table 5-499. Reset Types

Reset Type	Initiator	Effects	Blockable?	Global Reset? (1)
Power-on reset (POR)	PORn pin RESETFULLn pin	Total reset of the device. Boot configurations are latched. ROM boot process is initiated.	No	Yes
Hard reset	RESETn pin RSCTRL Register Watchdog Timers (via RSTMUX) Emulation	Resets everything except for test/emu logic and Reset Isolated modules. Asserts both Chip Reset 0 and Chip Reset 1. More details on chip resets 0 and 1 are provided in Section 5.3.3 and Section 5.3.4. This reset is also different from POR in that the PLLCTL assumes power and clocks are stable when Device Reset is asserted. From PSC point of view, Chip Reset 0 causes PSM state machine reset, so all the power domains except the always-on and reset-isolated domains will be turned off before it gets turned on again. Boot configurations are not re-latched. ROM boot process is initiated.	Yes - only WDT No - all other reset sources	Yes
Soft reset (2)	RESETn pin RSCTRL Register Watchdog Timers (via RSTMUX)	Soft Reset will behave like Hard Reset except that PCIe registers (sticky bits only), DDR EMIF registers (DDR is reset isolated) and External Memory contents are retained. Asserts Chip Reset 1. Also, from PSC point of view, Chip Reset 1 does not cause PSM state machine reset. Boot configurations are not re-latched. ROM boot process is initiated.	Yes - only WDT No - all other reset sources	Yes
Emulation reset	On-chip Emulation logic	Equivalent to Hard reset, non-blockable.	No	Yes
Test reset	TRSTn pin (JTAG)	Resets the Test and Emulation logic. For more information about Test reset, see Chapter 12, *On-chip Debug* .	No	No

(1) Global resets are indicated with RESETSTATn output pin

(2) The Reset config register (RSCFG) of the PLLCTL must be set to select the various initiators for Soft reset

Table 5-499. Reset Types (continued)

Reset Type	Initiator	Effects	Blockable?	Global Reset? (1)
DSP local reset	LRESETn pin Watchdog Timer 0 (via RSTMUX) LPSC Registers	Register bit in LPSC controls DSP Core local reset. Used by Watchdog Timers (in the event of a timeout) to reset DSP Core. Can also be initiated by LRESETn device pin. DSP Core memory system and Slave DMA port are still running when DSP Core is in local reset. Does not initiate ROM boot process.	No	No
ARMSS local resets	Watchdog Timer 5 (via RSTMUX) PSC Registers	Resets ARMSS components such as A15 core, memory subsystem, debug logic etc. ARMSS incorporates PSC to generate resets for it's internal modules.	No	No
PMMC CPU local reset	LPSC Registers	PMMC Core will be held in Reset upon any device reset. Master CPU is responsible of loading PMMC software and releasing PMMC from reset.	No	No
Module local reset	LPSC Registers	Module reset is initiated by LPSC and only resets the module controlled by that LPSC.	No	No

NOTE: Note that PORn/RESETFULLn, RESETn and LRESETn pins must not be tied together at the board level.

5.3.2 Power-on Reset

Power-on reset (POR) is a cold reset. That means that it is assumed that the device may not have been powered and is being powered up. Therefore, all logic on the device must be reset to a default state since it was in an unknown state.

Power-on reset is used to reset the entire device, including the test and emulation logic.

Power-on reset is initiated by the following:

1. PORn pin
2. RESETFULLn pin

All output pins except certain test and status pins must not cause contention at power-up. Outputs are disabled and internal pull-up or pull-down circuitry is enabled where appropriate to hold these pins at a stable level. These two requirements must be satisfied based only on the state of the PORn pin or RESETFULLn pin. HHV logic enforces this requirement when PORn is active (low). Asynchronous logic enforces this requirement when PORn is inactive (high) and RESETFULLn is still active (low). See the device Data Manual for more details on IO state during POR /HHV. The PLL reference clocks are required before PORn/RESETFULLn de-assertion.

Reset Controller accepts this reset, and steps through the following reset sequence. See the device Data Manual for detailed reset sequencing procedure and timing diagram.

1. PORn pin needs to be pulled low (active) before powering up the device. The reset signals flow to the entire chip, resetting anything that uses reset asynchronously, and sends a tristate signal to all the I/O pads except RESETSTATn and SERDES IOs, to prevent off-chip contention (transmitters of the IO buffers are disabled during HHV). This happens asynchronously during PORn assertion, even to module-controlled IO pins. See the device Data Manual for more details on IOs during power-on reset.
2. Clocks and resets are propagated throughout the chip to reset any logic that was using reset synchronously. All logic is now reset. All system clocks are propagated at reference clock frequencies, all dividers are bypassed.
3. PORn and/or RESETFULLn must be held active (low) at least for 150µs after all supplies on the board are stable. Reference clocks of all on-chip PLLs need to be running during this time. If on-chip oscillators are used, then PORn and/or RESETFULLn low period must be extended to meet oscillator start-up time (typically around 1 ms). Also, RESETn pin need to be held inactive, that is, high. PORn and/or RESETFULLn then can be de-asserted, once these conditions are satisfied.
4. Sampled-at-reset BOOTMODE pin values are latched as soon as PORn or RESETFULLn goes high. If both PORn and RESETFULLn are active at the same time then BOOTMODE pins will be latched on

the rising edge of signal that is de-asserted last. PORn and RESETFULLn are AND-ed together before connecting to the Reset Controller.

5. The Efuse Farm is sent an active low reset signal and its clocks are enabled.
6. Efuse Farm reset is released after holding it active for the minimum time specified. Efuse Farm starts autoload process, that is, loading all Efuse registers with their values from the Efuse ROM as soon as the reset is released.
7. When the Efuse autoload is complete the Efuse signals PSC to start its initialization sequence by asserting efuse_ready.
8. Similarly, when the PSC initialization is complete it signals Reset Controller. At this point all system clocks are paused.
9. The chip internal synchronous reset is released, and after waiting 8 Main PLL reference clock cycles, all the system clocks are started again.

Generally, PORn is asserted until all power supplies are ramped up and stable plus few additional milliseconds for internal oscillator to stabilize. When a power-management IC (PMIC) is used, this wait time will be configurable in PMIC. If a discrete power-supply solution is used, it is recommended to use an external RC circuit to extend PORn for at least 5–10 ms. Small and inexpensive power supervisors like the TPS3808 with delays built-in can also be used.

5.3.3 Hard Reset (CHIP_0_RST and CHIP_1_RST Asserted)

This reset type has similar effect but assumes that the device was already powered up and has already gone through a power-on reset sequence. This type of resets is referred to commonly as warm resets, device resets, and/or hard resets.

NOTE: This type of reset will be referred to as *Hard reset* in this TRM.

Do not to be confused with hardware resets. Both Hard and Soft resets can be initiated by either hardware or software.

Hard reset does not reset any test or emulation logic. An emulator session will continue unaffected.

Resets initiated through RSTMUX (watchdog timers) are blockable by setting RSCFG register in PLLCTL.

Reset isolation is supported for

- DDR EMIF
- ICSS
- TETB
- TBR

By default, the Main PLL goes to bypass mode and clock settings are reset to default values. In order to avoid this, Reset Isolation Register (RSISO) in the Reset Controller is enabled by Boot ROM code. By doing this, the state of the PLL and/or the dividers in the PLLCTL are retained. This requirement is met in order to retain the system clocks without pausing for all the Reset Isolation modules. Secondary PLLs, namely DDR PLL, ICSS PLL, UART PLL, NSS PLL are not reset on Hard Reset since both DDR EMIF and ICSS support reset isolation feature. The corresponding registers defined in BOOT_CFG which control these PLLs are reset isolated from Hard resets.

The BOOTMODE pin latching is not performed; boot ROM execution will proceed based on values from the previous POR. The Efuse scan autoload sequence is not initiated. PORn/RESETFULLn must remain de-asserted during this time. A Hard reset takes the PSC to its default state. From PSC point of view, hard reset causes PSM state machine reset, so all the power domains except the always-on and reset isolated domains will be turned off before it gets turned on again. The minimum pulse width of RESETn active low is 12 cycles of Main PLL input clock.

Hard reset is initiated by the following:

- RESETn pin
- RSCTRL Register in the PLL Controller
- Watchdog Timers (via BOOTCFG_RSTMUX)

- Emulation

By default, all the initiators listed above are configured to generate a hard reset. Except for emulation, all of the other three initiators can be configured in the RSCFG Register in the Reset Controller to generate soft resets instead.

The Reset Controller module accepts this reset, and steps through the following reset sequence. See the device Data Manual for detailed reset sequencing procedure and timing diagram.

1. RESETn pin is pulled low or internal requestor asserts reset. The reset signals flow to the modules reset, resetting anything that uses reset asynchronously, and sends a tri-state signal to most the I/O pads, to prevent off-chip contention. IOs associated with reset isolated modules would not be tri-stated. For a list of the IOs tri-stated, see the device Data Manual.
2. Any logic that was using reset synchronously is now reset.
3. RESETn pin is released or other internal requestor de-asserts reset (driven inactive).
4. Reset is stretched for an additional 16 SLOWSYSCLK cycles.
5. The chip synchronous reset is released, and after waiting 8 Main PLL clock cycles, all the system clocks that were allowed to pause are started again.
6. When clocks restart after the previously mentioned pause, the device now is out of reset, and starts execution.

NOTE: There is a minimum pulse width requirement and no dependency on power supplies and clocks.

5.3.4 Soft Reset (CHIP_1_RST Asserted)

This reset only resets a portion of the device, a subset of the Hard reset.

NOTE: This type of resets will be referred to as *Soft reset* in this TRM.

Do not to be confused with software resets. Both Hard and Soft resets can be initiated by either hardware or software.

Soft Reset will behave like Hard Reset (see Section 5.3.3, *Hard Reset (CHIP_0_RST and CHIP_1_RST)*) except that PCIe registers (sticky bits only), DDR EMIF registers (DDR is reset isolated) and External Memory contents are retained.

By default all reset sources are configured to initiate a Hard reset. The Reset config register (RSCFG) of the Reset Controler must be set to select the required sources for the Soft reset.

Similarly to Hard reset, Soft reset can be initiated by the following:

- RESETn pin
- RSCTRL Register in the Reset Controller
- Watchdog timers via BOOTCFG_RSTMUX.

5.3.5 DSP Local Resets

The local reset to the DSP resets DSP Core without resetting any other chip components. PSC coordinates this reset from the following sources:

- By Software (through PSC Register)
- By local reset pin (LRESETn)
- DSP Watchdog (WD) timer
- ICEPICK

The DSP Core memory system is not affected by assertion of local reset and thus there is no impact on the ongoing SDMA transactions to the DSP Core.

5.3.5.1 DSP Local Reset by Software

Local reset can be issued through the PSC register bit MDCTL18[8] LRST.

5.3.5.2 DSP Local Reset by pin input (LRESETn)

Local reset is initiated by hardware, by asserting the LRESETn pin (low) and then latching it with the rising edge of LRESETNMIENn pin. The Core is held in reset until LRESETn input is latched high by the rising LRESETNMIENn input.

5.3.5.3 Local Reset by Watchdog Timers

The device incorporates one dedicated TIMER module for DSP and one for ARMSS. These TIMERs can be configured to serve as a Watchdog timer or a General-purpose timer for that core. When configured as watchdog timer, it is expected that software would periodically write the appropriate value in the specified register so that WD timer does not time out. For details, see Section 11.17, *Timers*. The timeout event from the WD timers is routed to the respective core as described in Section 5.1.3.1.8, *BOOT_CFG Reset Multiplex Block*.

When configuring TIMER_0 in Watchdog timer mode, the software must setup the BOOTCFG_RSTMUX0 bits to route the timer events with the following options:

- local DSP core reset
- DSP non-maskable interrupt (NMI)
- NMI followed by a configurable delay and then a local reset
- device reset by requesting Reset Controler.

When configuring TIMER_5 in Watchdog timer mode, the software must setup the BOOTCFG_RSTMUX8 bits to route the timer events with the following options:

- interrupt to ARMSS through GIC
- interrupt to ARMSS through GIC followed by a configurable delay and then device reset request to Reset Controller
- device reset request to Reset Controller

NOTE: TIMER_0 and TIMER_5 are always reset when their corresponding core DSP and ARMSS, respectively, is in reset.

5.3.6 ARMSS Reset

The ARMSS uses a combination of power-on-reset and module-reset to reset its components, such as the Cortex-A15 processor, memory subsystem, debug logic, and so forth. The ARMSS incorporates the PSC to generate resets for its internal modules. Details of reset generation and distribution inside the ARMSS can be found in Section 6.1, *Arm Cortex-A15 Subsystem*.

5.3.7 Reset Priority

If any of the above reset sources occur simultaneously, the PLL Controller processes only the highest priority reset request. The reset request priorities are as follows (high to low):

1. Power-on reset
2. Hard/soft reset

Note that DSP Core local reset does not go through the Reset Controller.

5.3.8 Reset Indicators

The Reset status of the Device is notified in various ways:

- Device reset output pin — RESETSTATn pin for Global resets
- RSTYPE register in PLLCTL captures Global resets

- BOOTCFG_RESET_STAT register (BOOT_CFG) captures Local resets for (each) DSP core or Global device reset
- BOOTCFG_LRSTNMISTAT register captures LRESET/NMI status that are initiated by device pins LRESETn/NMIn.
- MDSTATy PSC register for each module domain (x) shows the actual local/module reset status indicating whether the reset is ongoing or reset is complete.

5.3.8.1 RESETSTATn Pin

There is single reset output pin on this device called RESETSTATn. It provides device reset status to the external world. This pin is driven active when any of the global resets of the device is asserted. It will remain asserted while reset is being propagated throughout the chip and will be de-asserted once reset sequence is complete (when CHIP_0_RST and CHIP_1_RST are de-asserted).

5.3.8.2 RSTYPE Register

The Reset Type (RSTYPE) register inside PLL Controller identifies the last global reset to occur on the device. Software (Boot ROM, bootloaders) can use this information to take different device initialization steps, if desired. This register notes whether the latest global reset was due to power-on reset (PORn/RESETFULLn), device reset via RESETn pin, Reset Controller register (RSCTRL), WD Timers (via RSTMUX), or Emulation reset.

5.3.8.3 RESET_STAT Register

The reset status register (RESET_STAT) captures the status of Local reset (LRx) for each of the DSP cores and also the Global device reset (GRESET). Software can use this information to take different device initialization steps, if desired.

- In case of Local reset: The LRx bits are written as 1 and GR bit is written as 0 only when the DSP Core receives an LRST without receiving a GRESET.
- In case of Global reset: The LRx bits are written as 0 and GR bit is written as 1 only when a GRESET is asserted.

The BOOTCFG_RESET_STAT bits can be cleared by writing 1 to the corresponding bit in the BOOTCFG_RESET_STAT_CLR register.

5.3.9 Reset Isolation

Reset isolation means some modules or subsystems are not reset during global device resets except on PORn and RESETFULLn. PORn and RESETFULLn will reset the entire device including the reset isolated modules. The device, in hardware, supports reset isolation for the following peripherals and its subsystems:

- DDR EMIF
- TETB (DSP Core) — Whenever there is an ownership change for TETB, its registers will be reset. Therefore, the TETB ownership is tied off on the chip level as specified as below:
  - Ownership application owned
  - Treat all accesses as application-initiated
- TBR (Debug_SS, PMMC and ARMSS) — Retain registers and memory contents

Some of the above peripherals and its subsystem allow devices to be daisy-chained. Hence they all must support Reset isolation that allows packet forwarding transactions to continue when the remainder of the device is being reset.

Reset isolation register (RSISO) in Reset Controller must be set for all the reset isolated modules to retain system clocks without pausing on Non-POR resets (that is, all global resets except PORn and RESETFULLn). Also, PSC registers (MDCTLy, where y is the respective module domain) must be configured for all the Reset-isolated modules. This setting is mandatory for reset isolation to work. Therefore, Boot ROM code handles this task during start-up from POR resets.

5.3.10 ICSS Reset Isolation

The device supports warm reset isolation (Hard/Soft Resets, Watchdog Resets) on ICSS. RESETn Pin isolation is not supported.

The ICSS subsystem itself does not support reset isolation natively. Hence reset isolation must be provided by system software to delay reset signals going to ICSS so software can take necessary actions to fence ICSS from these resets. The following needs to be done in order to support reset isolation on ICSS:

- System software must block any soft resets going to ICSS and must generate a early warning event to ICSS. If it is a watchdog reset, the RESETMUX timer must be configured to provide adequate delay before a watchdog reset is issued. Refer to BOOTCFG_RSTMUX0 and BOOTCFG_RSTMUX8 registers for RESETMUX settings. Based on this early warning event, ICSS software must initiate a sequence to complete/suspend any pending events, such as interrupts, bus transactions, etc.
- ICSS pinmux controls must be maintained across these warm resets.
- All corresponding PLLs providing clocks to ICSS must not reset on warm resets. These are ICSS PLL, UART PLL and NSS PLL.

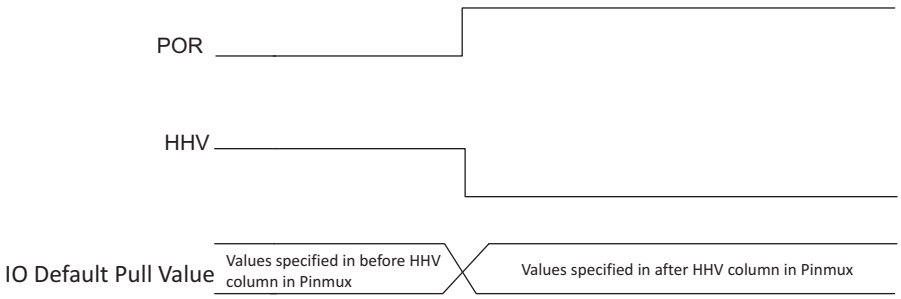
5.3.11 Device Pinmux

Pinmux configuration registers are only reset on PORn or RESETFULLn event. After reset de-assertion, the pins will default to the states defined in Section 5.1, *Control Module (BOOT_CFG)*. During boot-up, it is the responsibility of boot ROM code to configure necessary peripheral pins with correct settings to enable initial boot. Remaining pins must be configured by the secondary boot loader based on the application requirements.

5.3.12 HHV

IOs support HHV mode during power up. HHV is defined as a state when PORn signal is driven LOW. HHV allows IO cells to be tri-stated and is an IO feature. All IO cells have HHV which is asserted (driven) by HHV generated during PORn assertion (see Figure 5-162). There are default pull values during this HHV/PORn assertion specified in the device Data Manual for each pin. All HHV logic controlling the buffer high-impedance control and the associated default pull value will be asynchronous.

Figure 5-162. HHV Condition and Default Pull States on the Device IO



5.3.13 Reset Controller Integration

Pin resets (PORn, RESETFULLn and RESETn) are routed directly to the reset controller. The reset controller, then resets the appropriate device logic. To guarantee stable clocks and power rails, an external power-on reset circuit controls PORn pin of the device and releases it after each power-up. Refer to Table 5-500 for details on mapping of reset requestors to Reset Controller outputs. Here, X indicates that these signals are asserted. Note that when CHIP_0_RST is asserted, CHIP_1_RST is always asserted along with it.

Table 5-500. Mapping of Reset Requestors to Reset Controller Outputs

Requestor	Requestor Type	POR	POR_EARLY (unstretched)	CHIP_0_RST (stretched)	CHIP_0_EARLY_RST (unstretched)	CHIP_1_RST (stretched)	CHIP_1_EARLY_RST (unstretched)	FRESET
PORn	Pin	X	X	X	X	X	X	X
RESETFULLn	Pin	X	X	X	X	X	X	X
RESETn as Hard reset (default)	Pin			X	X	X	X	
RESETn as Soft reset (RSCFG[12] = 1)	Pin					X	X	
LRESETn (1)	Pin							
EMU Chip 0 reset input from Icepick	DCS			X	X	X	X	
RSCTRL as Hard reset (default)	Register			X	X	X	X	
RSCTRL as Soft reset (RSCFG[13] = 1)	Register					X	X	
WDRST (through RSTMUX) as Hard reset (default)	TIMER_0 or TIMER_5 Timeout			X	X	X	X	
WDRST (through RSTMUX) as Soft reset (RSCFG[1] = 1)	TIMER_0 or TIMER_5 Timeout					X	X	
WDRST0 (1) (through RSTMUX)	TIMER_0 Timeout							

(1) This will not request resets from the Reset Controller. They will be routed directly to the LPSC of the DSP Core to initiate a CPU reset.

Table 5-501 is high-level overview of chip-level resets going to the modules and subsystems. More details on reset mapping is shown in Table 5-502, *Reset Mapping and Description*.

Table 5-501. Mapping of Reset Controller Reset Outputs to Modules

Modules	POR	POR_EARLY	CHIP_0_RST	CHIP_0_EARLY_RST	CHIP_1_RST	CHIP_1_EARLY_RST	FRESET

5.3.14 Reset Controller Registers

The reset controller registers are part of the PLL Controller register space. For more information, see Section 5.4.5.4, *PLL Controller Registers*.

5.3.15 Reset Mapping

Details on reset mapping to module reset inputs is shown in Table 5-502.

NOTE: ELM is not supported on this family of devices.

Table 5-502. Reset Mapping and Description

Module	Module Reset Port	Description	Source	Source Port	Comments
PMMC	POR_RST	This is the power on reset. Complete debug logic is on this reset. This includes DAP interface, ITM interface, ATB Upsizer module, CTI and CM3 debug logic.	LPSC1	POR	
	MAIN_RST	This is the warm reset for PMMC. Most of the remaining PMMC logic is on this reset. All PMMC Control MMRs are sensitive to this reset.	LPSC1	MOD_G_RST	
	CPU_LOCAL_RST	This is the local reset for PMMC CPU. Host CPU ensures that UMEM is loaded with right firmware before releasing this reset.	LPSC1	LRST	
MLB	MLB_SYS_MAIN_RST	Active Low, Async asserted, Sync deasserted reset signal to MLBSS, which resets all the logic except the AHB/APB portion of the MediaLB core.	LPSC11	MOD_G_RST	
	MLB_OCP_SPB_MAIN_RST	Active Low, Async asserted, Sync deasserted reset signal to MLBSS, which resets all the logic in the APB portion of the MediaLB core and the OCP2APB bridge.	LPSC11	MOD_G_RST	
	MLB_OCP_SHB_MAIN_RST	Active Low, Async asserted, Sync deasserted reset signal to MLBSS, which resets all the logic in the AHB portion of the MediaLB IP core and the AHB2OCP bridge.	LPSC11	MOD_G_RST	
DSS	DSS_RESET	Module Asynchronous Reset	LPSC23	MOD_G_RST	
McBSP	RESET	Module Asynchronous Reset	LPSC6	MOD_G_RST	
McASP_[0:2]	MCASP_VBUSP_ASYNC_RST	Module Asynchronous Reset	LPSC15	MOD_G_RST	
ASRC	MOD_G_RST	Module Asynchronous Reset	LPSC20	MOD_G_RST	
DCAN_[0:1]	VBUSP_RST	Module Asynchronous Reset	LPSC0	MOD_G_RST	
EMIF	CHIP_RST	Typically power-up reset. This resets the registers as well as the control logic in the EMIF.	Reset Controller or BOOT_CFG	CHIP_0_RST or DDR3A_PHY_RST bit	See BOOTCFG_DDR3A_PLL_CTL1 register
	MOD_G_RST	Typically warm reset. This only resets the control logic in the EMIF. It does not reset the internal registers.		LPSC27.MOD_G_RST or CHIP_1_RST	
	CTL_RST	Active low reset for the PUB logic and DDR PHY	Reset Controller or BOOT_CFG	CHIP_0_RST or DDR3A_PHY_RST bit	See BOOTCFG_DDR3A_PLL_CTL1 register
MMC[0:1]	RESETN	Asynchronous system reset	LPSC8	MOD_G_RST	
GPMC	GPMC_RST	Module Asynchronous Reset	LPSC9	MOD_G_RST	
ELM	RST	Module Asynchronous Reset	LPSC9	MOD_G_RST	
SPI[0:3]	RESET	Module Asynchronous Reset	LPSC6	MOD_G_RST	

Table 5-502. Reset Mapping and Description (continued)

Module	Module Reset Port	Description	Source	Source Port	Comments
ICSS_0/ICSS_1	MOD_G_RST	Module Asynchronous Reset	LPSC21	MOD_G_RST

5.4 Clock Management

This chapter describes the clock architecture of the device.

NOTE: For a detailed visual representation of the distribution and management of the device clocks at the device level, see the clock interactive software (CTT) for the device.

See more about the CTT at http://www.ti.com/tool/clocktreetool

5.4.1 Overview

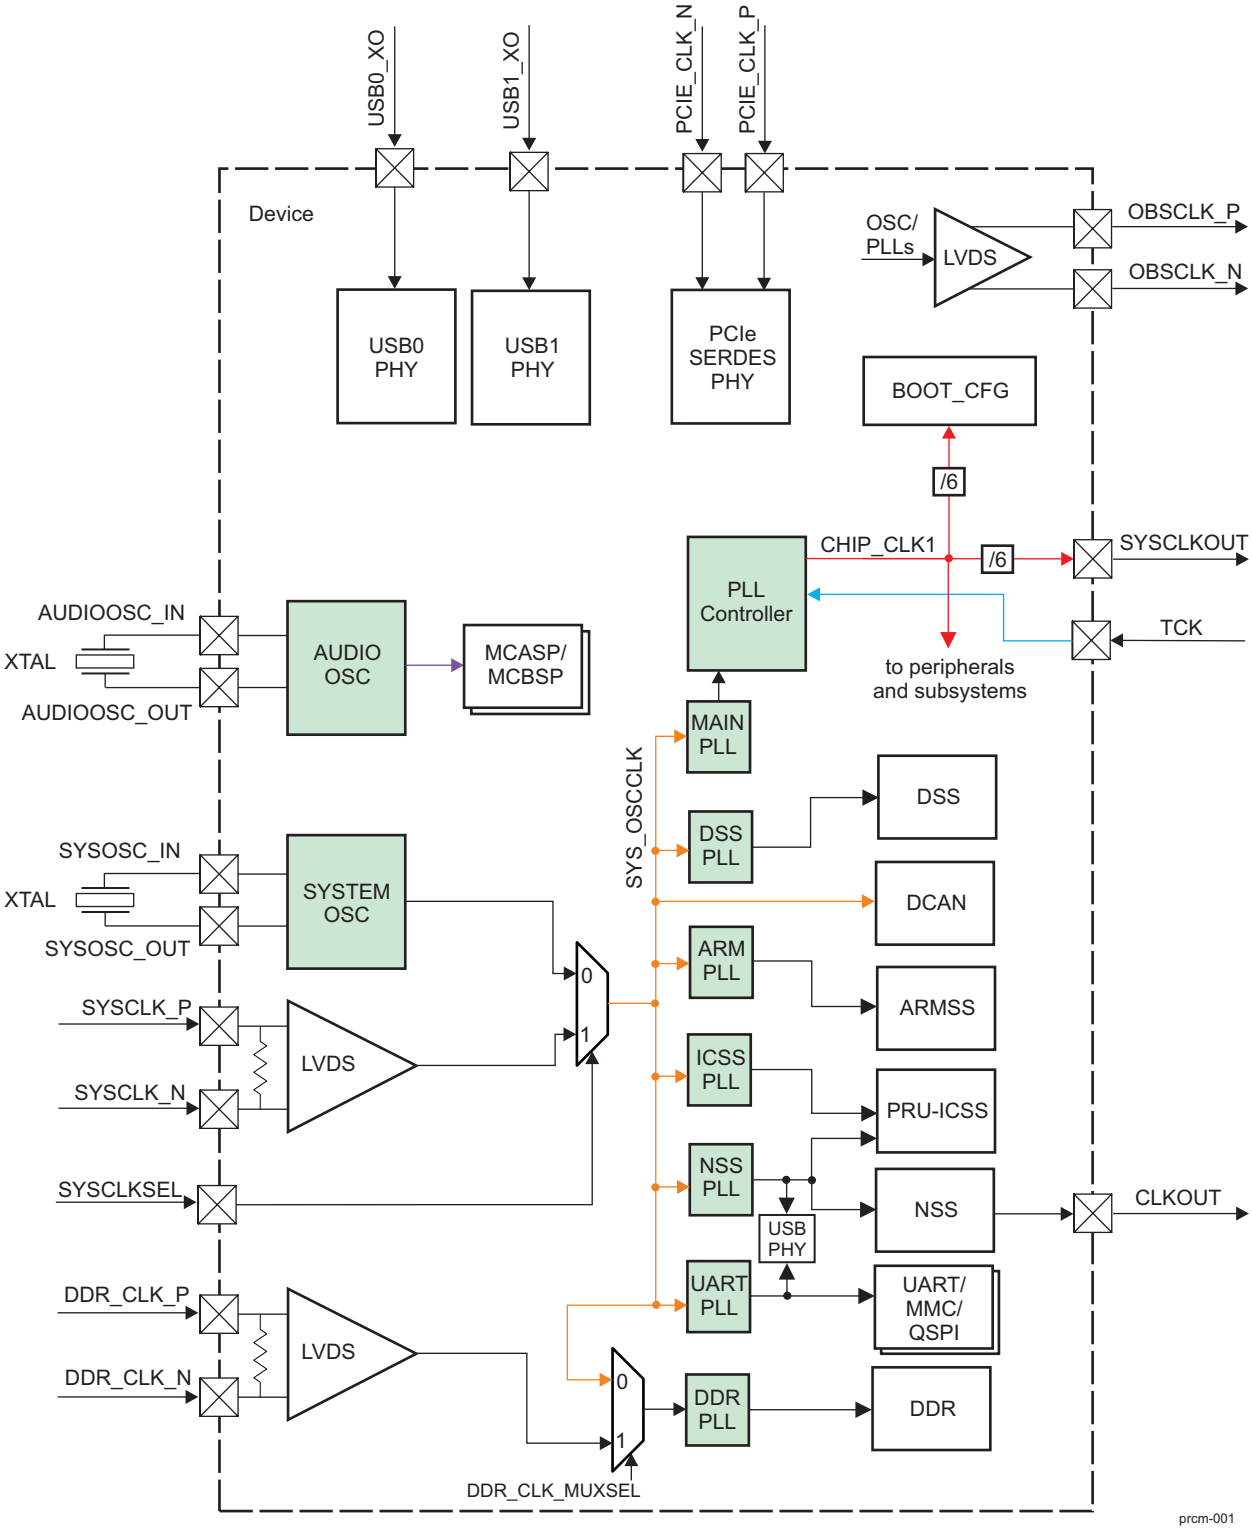
The device features multiple clock sources and clock generators (PLLs, PLL Controller, and dividers) to satisfy the various subsystems requirements. Most of the device is driven by the output from the MAIN PLL and MAIN PLL Controller except for the following modules and subsystems:

- Arm subsystem (ARMSS) has its own dedicated PLL (ARM PLL)
- DDR EMIF subsystem has its own dedicated PLL to drive EMIF and DDR PHY.
- PRU-ICSS receives clocks from several PLLs — UART PLL to generate constant 192-MHz clock, ICSS PLL to generate 225-MHz core clock and NSS/IEP PLL to generate 200-MHz ICSS core clock and 250-MHz Ethernet clocks.
- Display Subsystem (DSS) has its own dedicated PLL (DSS PLL), to generate the pixel clock
- PCIe requires separate external reference clock to drive SERDES PHYs
- USB PHYs support optional external reference clock input, additionally to UART PLL and NSS/IEP PLL
- MCASP and MCBSP modules support optional clock inputs to get required audio frequencies.

Figure 5-163 shows the device top-level block diagram including clock sources (pins and oscillators), clock outputs and PLLs.

Clock distribution is described in Table 5-557, *Module Clock Distribution*.

Figure 5-163. Top-Level Clock Diagram



5.4.2 Clock Inputs

Various external clock inputs are needed to drive the device. Summary of these input clock signals are:

- SYSOSC_IN/SYSOSC_OUT — external main crystal interface pins connected to internal oscillator which sources reference clock for all the PLLs. When internal oscillator is bypassed, reference clock input must be provided on SYSOSC_IN pin by an external clock source/generator.
- SYSCLK_P/N — optional pins to provide reference clock input to the PLLs.
- DDR_CLK_P/N — optional clock input to DDR3 PLL.
- AUDIOOSC_IN/AUDIOOSC_OUT — optional audio crystal interface pins connected to secondary internal oscillator dedicated for audio applications. See Section 5.4.4, *Audio Clocking*.
- PCIE_CLKP/N — SerDes reference clock for PCIe
- USB0_XO/USB1_XO — optional USB0/USB1 PHY reference clock input
- CPTS_REFCLKP/N — CPTS reference clock inputs

NOTE: Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapter.

The PLL reference clock (SYS_OSCCLK) can be either:

- internal high-frequency (HF) oscillator with external crystal: SYSOSC
- clock inputs provided by external clock sources

SYS_OSCCLK clock source is selected by means of SYSCLKSEL pin. The encoding of SYSCLKSEL is shown in Table 5-503.

Table 5-503. SYS_OSCCLK Clock Selection

SYSCLKSEL pin	SYS_OSCCLK Selection
0	HF OSC OUT (SYSOSC output)
1	SYSCLK_P/SYSCLK_N (LVDS clock input)

The status of SYSCLKSEL pin can be observed by software in the BOOT_CFG_PLLCLKSEL_STAT register.

Besides as a PLL reference clock, SYS_OSCCLK clock is used as the DCAN and GTC modules functional clock.

DDR PLL input reference clock is selected by another mux configured in the BOOTCFG_DDR_CLKCTL register (Table 5-504).

Table 5-504. DDR PLL Clock Selection

DDR_CLK_MUXSEL bit	DDR_CLK Selection
0 (default)	SYS_OSCCLK
1	DDR_CLK_P/DDR_CLK_N (LVDS clock input)

NOTE: SYSCLK_P/N and DDR_CLK_P/N are implemented with Low-Voltage Differential Signaling (LVDS) buffers. The system designer is responsible for using a compatible clock source/driver.

Device has the following clock oscillators built-in:

- internal high-frequency (HF) oscillator with an external crystal resonator, referred to as SYSOSC
- internal HF oscillator with an external crystal resonator, referred to as AUDIOOSC.

System oscillator clock (SYS_OSCCLK) clock frequencies supported by the device are:

- 19.2 MHz
- 24 MHz
- 25 MHz
- 26 MHz.

By default, SYSOSC is enabled and AUDIOOSC is disabled after POR. Boot Config module (BOOT_CFG) provides software means to enable/disable the two oscillators in the BOOTCFG_OSC_CTL register, as well as other oscillator settings.

NOTE: For input clock specifications, please refer to section *Clock Specifications* in the device specific Data Manual.

5.4.3 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- OBSCLK_P/OBSCLK_N
- SYSCLKOUT
- CLKOUT

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

On the differential clock output OBSCLK_P/OBSCLK_N, oscillators and PLLs clocks can be observed for tests and debug. OBSCLK output is controlled by BOOTCFG_OBSCLKCTL register in the BOOT_CFG module.

NOTE: OBSCLK_P/OBSCLK_N output cannot be used to drive external circuitry. It is for debug only.

Table 5-505. OBS_CLK Clock Selection

BOOTCFG_OBSCLKCTL[3-0] PLL_OBSCLK_SEL	OBS_CLK Selection
0x0 (default)	Reserved
0x1	MAIN PLL
0x2	DSS PLL
0x3	ARM PLL
0x4	UART PLL
0x5	ICSS PLL
0x6	DDR PLL
0x7	PLL Controller OBSCLK
0x8	NSS PLL
0x9	SYSOSC clock

SYSCLKOUT provides SYSCLK1 coming from the DPLL Controller for test and debugging. It is divided by 6 inside the device and then sent out as a LVCMOS clock signal. This signal can be used to test if the main chip clock is running or not. Output of SYSCLKOUT may be disabled or enabled by user. See BOOTCFG_DEVCFG register.

CLKOUT provides an option to output 50-MHz or 25-MHz clock. This clock can be used as a reference clock for RMII or MII/GMII Ethernet mode. Refer to Section 11.13.4, *Gigabit Ethernet MAC (EMAC) Subsystem* and BOOTCFG_ETHERNET_CLKCTL register.

There is no dedicated ball for CLKOUT function on the device. Instead, it is available as a pin muxing option. See the device Data Manual for device pin mux details and BOOTCFG_PADCONFIG for pin mux registers.

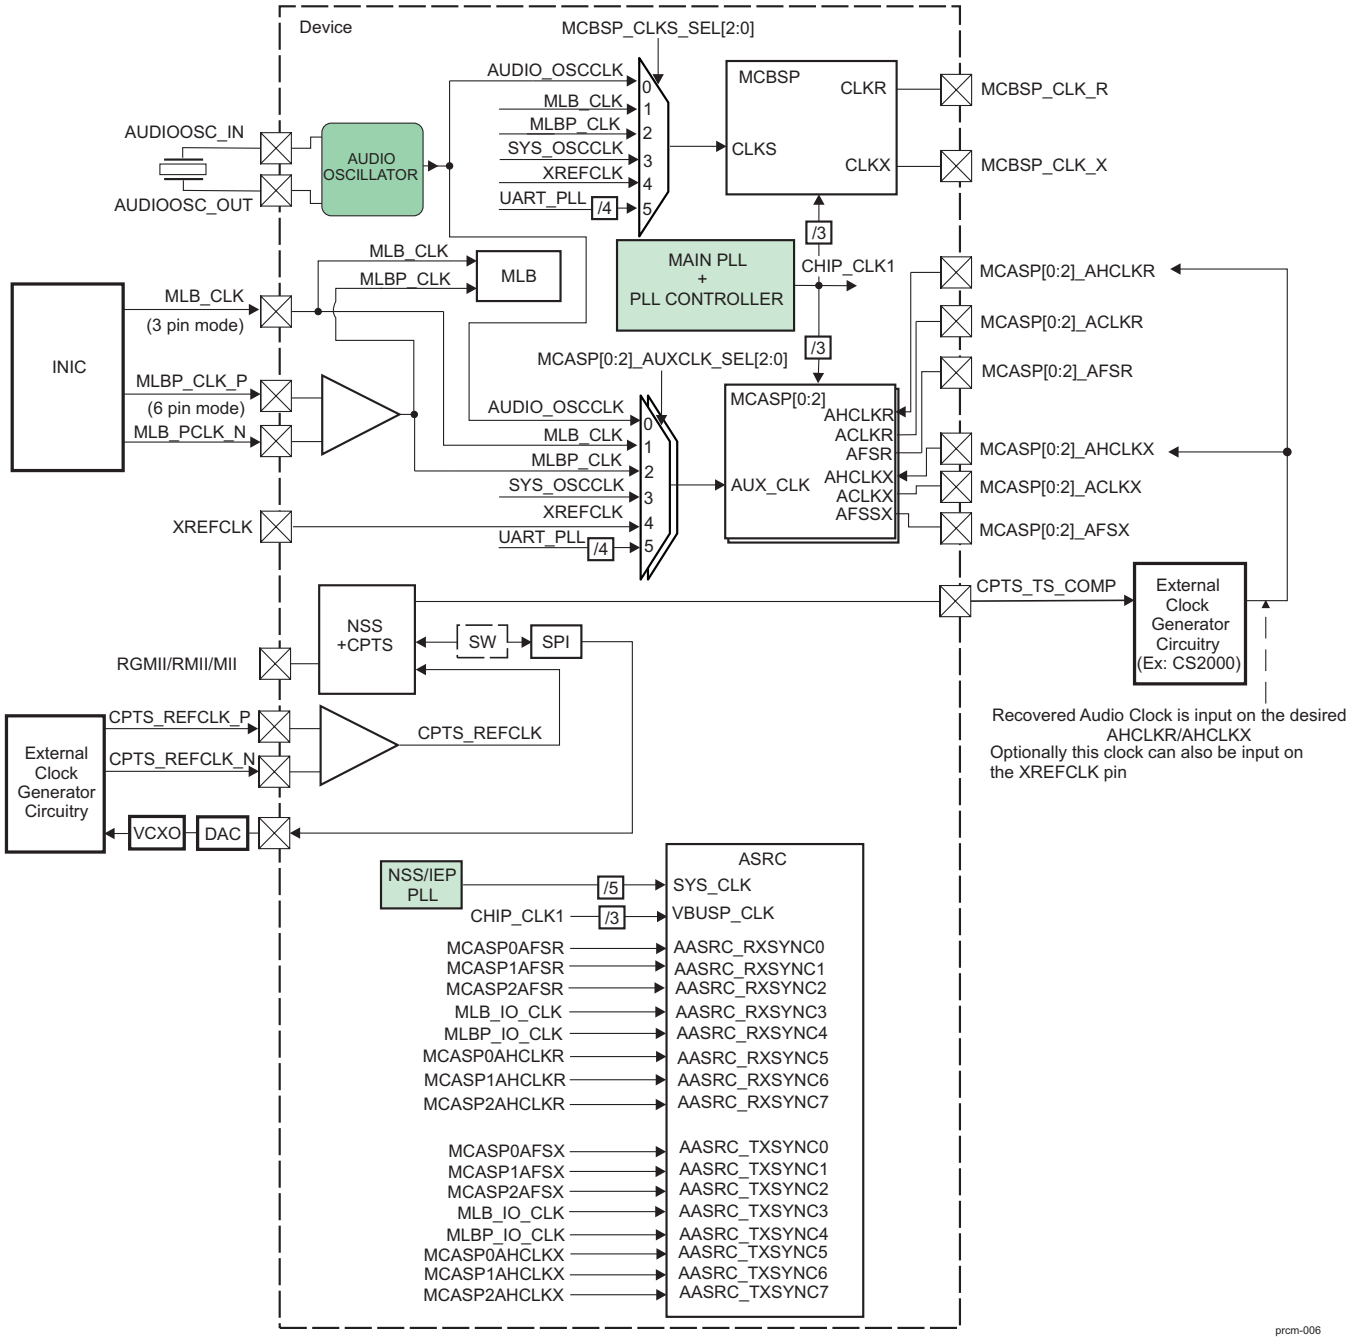
NOTE: For output clock specifications, please refer to section *Clock Specifications* in the device specific Data Manual.

5.4.4 Audio Clocking

Audio peripherals can be driven by dedicated HF audio oscillator (AUDIO_OSC). The supported frequency range for audio oscillator is 11.289 MHz to 49.152 MHz.

Figure 5-164 summarizes the audio clocking scheme of the device.

Figure 5-164. Device Audio Modules Clocking



Clock muxes on Figure 5-164 are controlled through the BOOTCFG_SERIALPORT_CLKCTL register.

NOTE: For audio peripherals description, see the respective peripheral chapter.

5.4.5 PLLs

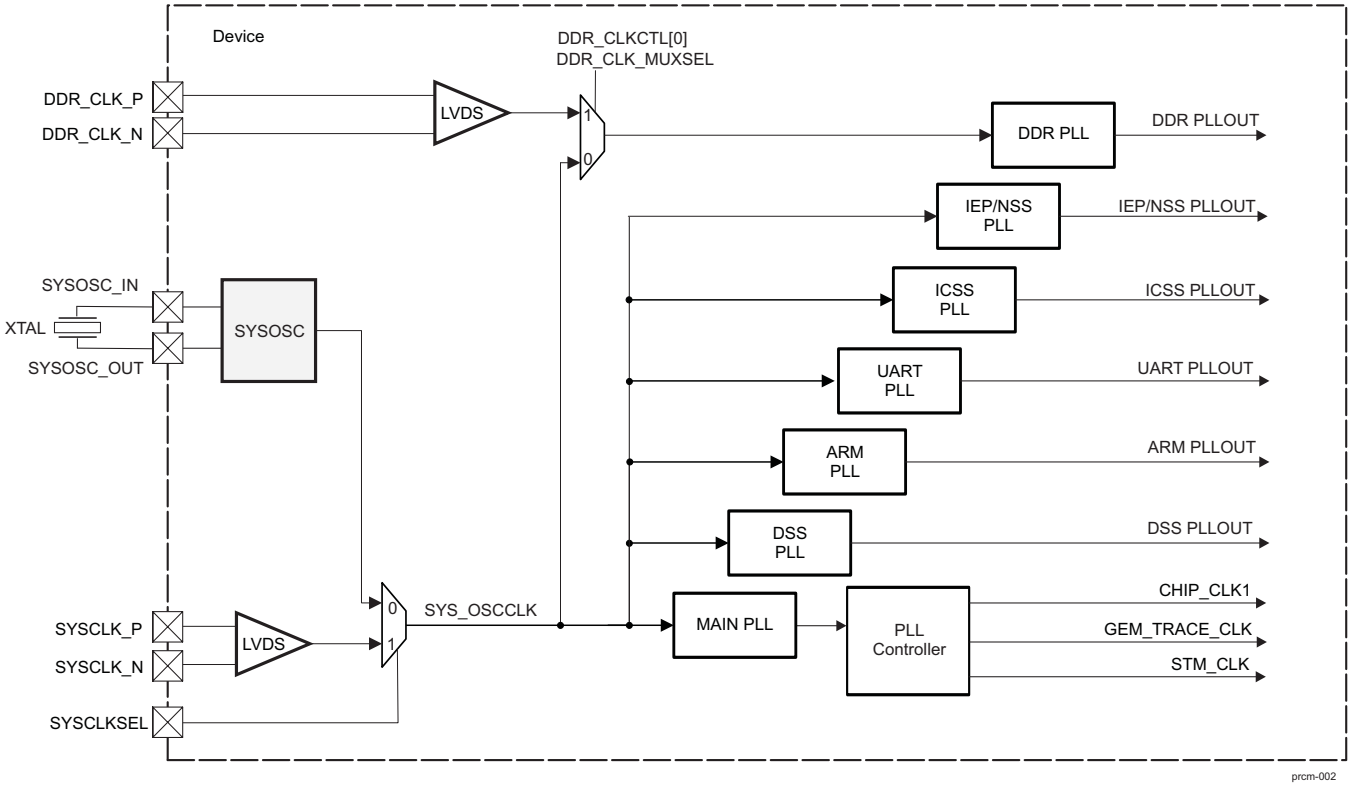
Phase-Locked Loop circuitries (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s). There are total seven PLLs in the device:

- MAIN PLL with PLL_CONTROLLER

- ARM PLL
- DSS PLL
- UART PLL
- ICSS PLL
- NSS/IEP PLL
- DDR PLL.

Overview of the device PLLs with their reference clock options is shown on Figure 5-165.

Figure 5-165. PLLs Integration



The ARM PLL, DSS PLL, UART PLL, ICSS PLL, NSS PLL, and DDR PLL are used to provide dedicated clocks to:

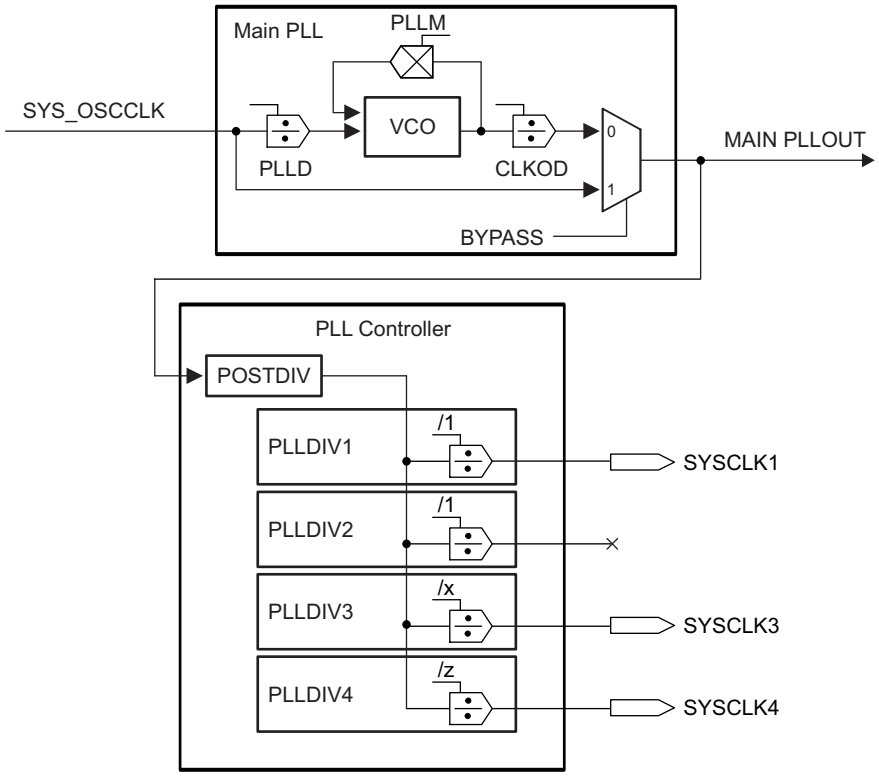
- ARM PLL: ARMSS
- DSS PLL: Display subsystem (DSS) pixel clock
- UART PLL: UARTs (including ICSS UARTs), MMC, USB PHY, QSPI
- ICSS PLL: ICSS PRU cores
- NSS/IEP PLL: NSS clocks, USB PHY, ICSS PRU cores, ICSS IEP
- DDR PLL: DDR3 EMIF and PHY

These chip level PLLs support a wide range of multiplier and divider values, which can be programmed through the chip level registers located in the BOOT_CFG and starting at BOOTCFG_NSS_PLL_CTL0 register address. The Boot ROM programs the multiplier values for MAIN PLL, ARM PLL, NSS PLL, UART PLL and DDR PLL based on the current boot mode. See Chapter 4, *Initialization* for more details on boot mode selection.

5.4.5.1 MAIN PLL and PLL Controller Overview

The MAIN PLL is controlled by the PLL Controller. The PLL Controller manages the clock ratios, alignment, and gating for the system clocks to the device. By default, the device powers up with the MAIN PLL bypassed. Figure 5-166 shows a block diagram of the MAIN PLL and the PLL Controller. For details on the operation of the PLL Controller module, see Section 5.4.5.3, *PLL Controller*.

Figure 5-166. MAIN PLL and PLL Controller



The multiplication and division ratios within the PLL and the post-division for each of the chip-level clocks are determined by a combination of this PLL and the PLL Controller. The PLLM[5-0] bits of the multiplier are controlled by the PLLM register inside the PLL Controller and the PLLM[12-6] bits are controlled by the chip-level BOOTCFG_MAIN_PLL_CTL0 register. The output divide and bypass logic of the PLL are controlled by fields in the SECCTL register in the PLL Controller. Only PLLDIV3, and PLLDIV4 are programmable on the device. See the Section 5.4.5.3.3, *PLL/PLL Controller Programming Guide* for more details on how to program the MAIN PLL and PLL controller.

NOTE: MAIN PLL Controller registers can be accessed by any master in the device.

The MAIN PLL Controller also controls reset propagation through the chip, clock alignment, and test points. The PLL Controller monitors the MAIN PLL status and provides an output signal indicating when the PLL is locked.

5.4.5.2 MAIN PLL Controller Device-Specific Information

5.4.5.2.1 Clocks Generated by PLL Controller

The MAIN PLL, used to drive the DSP CorePac, the switch fabric, and a majority of the peripheral clocks, requires a PLL Controller to manage the various clock divisions, gating, and synchronization. Output divider ratio is set in the SECCTL[22-19] OUTPUT_DIVIDE bitfield. Boot ROM sets this value during boot sequence based on MAINPLL_OD_SEL pin value. See BOOTCFG_DEVSTAT register in Section 5.1, *Control Module (BOOT_CFG)* for its description.

PLLM[5-0] input of the MAIN PLL is controlled by the PLL controller PLLM register.

The MAIN PLL Controller has four SYSCLK outputs that are listed below, along with the clock descriptions. Each SYSCLK has a corresponding divider that divides down the output clock of the PLL. Note that dividers only for SYSCLK3 and SYSCLK4 are programmable.

- **SYSCLK1:** Full-rate clock for C66x DSP CorePac. Using local dividers, SYSCLK1 is used to derive clocks required for the majority of peripherals. SYSCLK1 must be configured by software (ROM code) to be reset isolated to protect the modules that require reset isolation. That is, SYSCLK1 must maintain its frequency without pausing through non-POR resets.

  See Section 5.4.6, *Module Clock Distribution* for the complete list of peripherals fed by this clock.
- **SYSCLK2:** Unused
- **SYSCLK3:** 1/x-rate clock used to clock the C66x DSP CorePac emulation. The default rate for this clock is /3. This clock is programmable from /1 to /32, where this clock does not violate the maximum of 333 MHz. SYSCLK3 can be turned off by software.
- **SYSCLK4:** 1/z-rate clock for the system trace module only. The default rate for this clock is /5. This clock is configurable: the maximum configurable clock is 200 MHz and the minimum configuration clock is 32 MHz. SYSCLK4 can be turned off by software.

NOTE: SYSCLK names are defined as the PLL Controller outputs. Once leaving the PLL Controller, the following clock names apply at the device level:

- SYSCLK1: CHIP_CLK1, drives C66x DSP CorePac and most of the peripherals through local dividers
- SYSCLK3: GEM_TRACE_CLK, used for emulation
- SYSCLK4: STM_CLK, used for trace module.

5.4.5.2.2 MAIN PLL Controller Operating Modes

The MAIN PLL Controller has two modes of operation: bypass mode and PLL mode. The mode of operation is determined by the BYPASS bit of the PLL Secondary Control Register (SECCTL).

- In bypass mode, PLL input is fed directly out as SYSCLK1.
- In PLL mode, SYSCLK1 is generated from the PLL output using the values set in the PLLM and PLLD fields in the BOOTCFG_MAIN_PLL_CTL0 register.

External hosts must avoid access attempts to the DSP while the frequency of its internal clocks is changing. User software must implement a mechanism that causes the DSP to notify the host when the PLL configuration has completed.

5.4.5.2.3 MAIN PLL Stabilization, Lock, and Reset Times

The PLL stabilization time is the amount of time that must be allotted for the internal PLL regulators to become stable after device power-up. The device must not be taken out of reset until this stabilization time has elapsed.

The PLL reset time is the amount of wait time needed when resetting the PLL (writing PLLRST = 1), in order for the PLL to properly reset, before bringing the PLL out of reset (writing PLLRST = 0). For the MAIN PLL reset time value, see Table 5-506.

The PLL lock time is the amount of time needed from when the PLL is taken out of reset to when the PLL Controller can be switched to PLL mode. The MAIN PLL lock time is given in Table 5-506.

Table 5-506. MAIN PLL Stabilization, Lock, and Reset Times

PARAMETER	MIN	TYP	MAX	UNIT
PLL stabilization time	100			µs
PLL lock time			2000 × C[(1)]	
PLL reset time	1000			ns

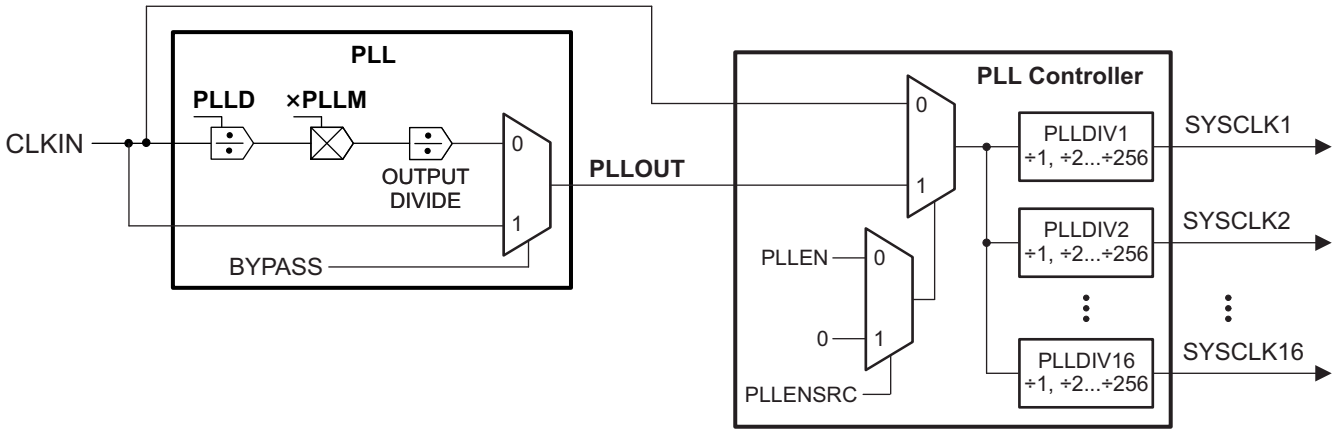
(1) C = SYSCLK1(N|P) cycle time in ns.

5.4.5.3 PLL Controller

5.4.5.3.1 PLL Controller Overview

Figure 5-167 shows the logical implementation of the PLL and the PLL Controller. The PLL Controller offers flexibility and convenience with software-configurable dividers (PLLDIV3 and PLLDIV4 in this device) to modify the input clock signal internally. The PLL Controller also contains registers (PLLM and SECCTL) that are used to drive the PLLM, OUTPUT DIVIDE, and BYPASS logic of the PLL (see Figure 5-167). The resulting clock outputs from the PLL Controller are passed to the DSP core, peripherals, and other modules inside the device.

Figure 5-167. PLL and PLL Controller Generic Block Diagram



The PLL Controller has the following input and output clocks:

- Input reference clock to the PLL Controller:
  - **PLLOUT:** Output signal from the PLL
  - **CLKIN:** Input reference clock to the PLL
- Resulting output clocks from the PLL Controller:
  - **SYSCLK1 to SYSCLK4:** System domain clocks, each output from its own divider (see Figure 5-167)

5.4.5.3.2 PLL Controller Functional Description

5.4.5.3.2.1 Dividers

The clock dividers (PLLDIV3 and PLLDIV4 in this device) are programmable in a range from ÷1 to ÷256 and may be disabled. When a clock divider is disabled, no clock is output from that clock divider. A divider outputs a clock only when it is enabled in the corresponding PLLDIVn register.

PLLD is a divider inside the PLL. BOOTCFG_MAIN_PLL_CTL0[5-0] register controls this divider.

5.4.5.3.2.2 Multiplier

The PLLM[5-0] bits of the multiplier are controlled by the PLLM register inside the PLL Controller. The PLLM[12-6] bits are controlled by the chip-level BOOTCFG_MAIN_PLL_CTL0 register. PLLM[12-6] must be written just before writing to PLLM[5-0] bits of the PLLM register to have the complete 13-bit value latched when the GO operation is initiated in the PLL controller.

5.4.5.3.2.3 PLL Control Register and Secondary Control Register

After device reset, the value of the PLL enable bit (PLLEN) in the PLL control register (PLLCTL) can be changed, but it will not have any effect on the function of the PLL Controller. To enable the PLLEN bit, the PLLENSRC bit (also in the PLLCTL register) must first be cleared to 0. Once the PLLEN bit has been enabled, it can be used to select the bypass mode or PLL mode of the PLL Controller as discussed in the next two sections. The PLLRST bit in PLLCTL is used to reset the PLL Controller.

The Secondary Control register (SECCTL) is used to drive the OUTPUT DIVIDE and BYPASS logic of the PLL.

The PLL can be operated in Bypass or PLL mode based on the status of the BYPASS, PLLENSRC, and PLLEN bits in the PLLCTL and SECCTL registers and is discussed in the next two sections.

5.4.5.3.2.4 Bypass Mode

When BYPASS = 1 (bypass enabled in the PLL Mux), that is, in bypass mode, the PLLM, PLLD, and OUTPUT DIVIDE logic of the PLL are bypassed and the input reference clock to the PLL (CLKIN) is input directly to the PLL Controller (see Figure 5-167). The PLL block is operating in Bypass Mode.

When PLLENSRC=0 and PLLEN=0 (bypass enabled in the PLL Controller mux), the entire PLL block is bypassed and the reference input from the PLL is fed as a direct input to the PLL Controller. The PLL Controller block is operating in Bypass Mode.

CAUTION

The PLL comes up in Bypass mode by default on powering up the device. Once the PLL is initialized in PLL mode, it must not be re-initialized back to Bypass mode unless the user intends to power down the device.

5.4.5.3.2.5 PLL Mode

When BYPASS = 0 (in PLL Mux), that is, in PLL mode, the PLLM, PLLD, and OUTPUT DIVIDE logic of the PLL are used (see Figure 5-167, *PLL and PLL Controller Block Diagram*). The output of the PLL (PLLOUT) is fed as an input to the PLL Controller. The PLL block is operating in PLL Mode.

When PLLENSRC=0 and PLLEN=1 (in the PLL Controller mux), the output of the PLL (PLLOUT) is fed as an input to the PLL Controller (see Figure 5-167). The PLL Controller block is operating in PLL Mode.

Further, when enabled (DnEN = 1), the system clock dividers (D1-D16) divide down by the RATIO value in PLLDIVn, the output clock of the PLL. The system clock dividers generate a 50% duty cycle output clock SYSCLKn.

5.4.5.3.3 PLL/PLL Controller Programming Guide

5.4.5.3.3.1 MAIN PLL Initialization

The MAIN PLL and PLL Controller are initialized by Boot ROM/software after reset. The PLL Controller registers must be modified only by processor or emulation. External masters, for example PCIe, must not be used to access the PLL Controller registers directly. For this purpose, a Boot ROM parameter table is provided to set the PLLs. See Chapter 4, *Initialization* for details.

The initialization of the PLL Controller must be performed as soon as possible at the beginning of the program, before initializing any peripherals. Upon device reset, the following software initialization procedures must be done to properly set up the PLL and PLL Controller.

NOTE: PLL configuration registers (BOOTCFG_MAIN_PLL_CTL0 and BOOTCFG_MAIN_PLL_CTL1) are write-protected at power-up. Software must first un-lock the BOOTCFG_KICK0 and BOOTCFG_KICK1 registers prior to writing to any chip-level registers.

5.4.5.3.3.1.1 MAIN PLL Initialization to PLL Mode

The MAIN PLL and PLL Controller must always be initialized prior to initializing the secondary PLLs. This section shows the initialization sequence if the user intends to use the PLL in PLL mode. The steps below also show when the multipliers, divider, and system clock dividers must be programmed, if required.

The following generic equation describes the MAIN PLL output when initialized to PLL mode:

PLLOUT = CLKIN × ((PLLM+1) ÷ ((OUTPUT_DIVIDE+1) × (PLLD+1)))

NOTE: For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Data Manual.

NOTE: Once the ROM boot is complete, it is highly recommended that initial software reconfigures the MAIN PLL to the desired frequency, even if it is already achieved by the ROM settings. To minimize the overall output jitter, the PLLs must be operated as close as possible to the maximum operating frequency. To maximize the VCO frequency within the PLL, the PLL must be clocked to 2× the intended frequency and the PLL Output Divider must be set to divide-by-2 as described in the below sequence.

Perform each step in sequence unless directed to jump directly to another step.

1. If executing this sequence immediately after device power-up, user must wait for the PLL to become stable. PLL stabilization time is 100 µs.
2. Check the status of BYPASS bit in SECCTL register, execute following steps if BYPASS = 1 (bypass enabled); if BYPASS = 0 then **Jump to Step 3**
   a. In MAIN_PLL_CTL1, write ENSAT = 1 (for optimal PLL operation)
   b. In PLLCTL, write PLLEN = 0 (bypass enabled in PLL Controller mux)
   c. In PLLCTL, write PLLENSRC = 0 (enable PLLEN to control PLL Controller mux)
   d. Wait 4 cycles of the reference clock CLKIN (to make sure the PLL Controller mux switches properly to the bypass)
   e. In SECCTL, write BYPASS = 1 (bypass enabled in PLL mux)
   f. In PLLCTL, write PLLPWRDN = 1 (power down the PLL)
   g. Wait for at least 5 µs based on the reference clock CLKIN (PLL power down toggling time)
   h. In PLLCTL, write PLLPWRDN = 0 (power up the PLL).
3. In PLLCTL, write PLLRST = 1 (PLL is reset)
4. PLLM is split in two different registers. Program PLLM[5-0] in PLL multiplier control register (PLLM) and PLLM[12-6] in BOOTCFG_MAIN_PLL_CTL0 register
5. BWADJ is split in two different registers. Program BWADJ[7-0] in BOOTCFG_MAIN_PLL_CTL0 and BWADJ[11-8] in BOOTCFG_MAIN_PLL_CTL1 register. BWADJ value should be set to: *BWADJ = ((PLLM+1) >> 1) - 1*.
6. Program PLLD in BOOTCFG_MAIN_PLL_CTL0 register
7. In SECCTL, write OD (Output Divide) = 1 (that is divide-by-2)
8. This step is needed only if default ratio values in PLLDIVn registers (control SYSCLKn clocks) need to be changed. Otherwise **Jump to Step 9**. Note that in this device, only SYSCLK2 and SYSCLK3 are programmable.
   a. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.
   b. Program the RATIO field in PLLDIVn to the desired new divide-down rate. If the RATIO field changed, the PLL controller will flag the change in the corresponding bit of DCHANGE.
   c. Set the respective ALNn bits in ALNCTL to align any SYSCLKs after the GO operation.
   d. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.
   e. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO

operation has completed.

9. Wait for at least 7 µs based on the reference clock CLKIN (PLL reset time)
10. In PLLCTL, write PLLRST = 0 (PLL reset is de-asserted)
11. Wait for at least *500 × CLKIN cycles × (PLLD + 1)* (PLL lock time)
12. In SECCTL, write BYPASS = 0 (enable PLL mux to switch to PLL mode)
13. In PLLCTL, write PLLEN = 1 (enable PLL Controller mux to switch to PLL mode)
14. At this point, the MAIN PLL is properly initialized.

CAUTION

Software must always perform read-modify-write to any register in the PLL and PLL Controller. This is to ensure that only the relevant bits in the register are modified and the rest of the bits including the reserved bits are not affected.

5.4.5.3.3.1.2 MAIN PLL Initialization to Bypass Mode

CAUTION

The PLL comes up in bypass mode by default on powering up the device. Once the PLL is initialized in PLL mode, it must not be re-initialized back to bypass mode unless the user intends to power down the device.

5.4.5.3.3.2 MAIN PLL Power Down

The PLL may be powered down, in which case the PLL is in bypass mode and the DSP runs from a divided-down version of the input reference clock. The DSP is able to respond to events because it is still being clocked by the bypass clock (directly from CLKIN), although at a lower frequency.

Perform the following procedure to power down the PLL:

1. In SECCTL, write BYPASS = 1 (bypass mode).
2. Wait 4 cycles of the slower of PLLOUT or CLKIN.
3. In PLLCTL, write PLLPWRDN = 1 to power down the PLL.

The above sequence assumes that the device has been powered up long enough that the PLL stabilization time has been met. If executing this sequence immediately after device power-up, user must allow time for the PLL to become stable before performing these steps. For PLL stabilization time, see Table 5-506.

5.4.5.3.3.3 MAIN PLL Wake Up

Perform the following procedure to wake up the PLL from its power-down mode.

1. In SECCTL, write BYPASS = 1 (bypass mode).
2. In PLLCTL, write PLLPWRDN = 0 to wake up the PLL.
3. Follow the PLL reset sequence in Section 5.4.5.3.3.1.1, *MAIN PLL Initialization to PLL Mode* (steps 3 to 13) to reset the PLL. Wait for the PLL to lock and to switch from bypass to PLL mode.

5.4.5.3.3.4 Secondary PLLs Initialization

Secondary PLLs (NSS/IEP PLL, DSS PLL, ARM PLL, UART PLL, ICSS PLL and DDR PLL) do not have their PLL Controllers. They are controlled through BOOT_CFG registers starting at BOOTCFG_NSS_PLL_CTL0 address.

NOTE: For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Data Manual.

Initialization steps for secondary PLLs:

1. At power-up, all secondary PLLs operate in bypass mode.
2. Then, PLLs are properly initialized by Boot ROM software depending on the selected boot mode. Once the PLLs are stabilized with correct frequency settings the PLL BYPASS Mux control is updated by Boot ROM to pass through the PLL clocks to the respective modules. See Section 5.4.5.3.3.4.1, *Secondary PLLs Initialization in PLL Mode* for PLL initialization sequence.

Modules using non-MAIN PLL clocks treat these clocks as asynchronous. For example, ICSS uses clocks from UART PLL, ICSS PLL, NSS PLL and MAIN PLL. All these clocks are asynchronous to each other. Note that PLL sequence must always be executed before powering up their module's power domains.

CAUTION

The DDR interface needs to reset every time the DDR PLL is re-programmed.

5.4.5.3.3.4.1 Secondary PLLs Initialization in PLL Mode

The MAIN PLL and PLL Controller must always be initialized prior to initializing the secondary PLLs. The sequence shown below must be followed to initialize the secondary PLLs.

NOTE: Once the ROM boot is complete, reconfiguring the PLL with the intention of optimizing and reducing output jitter may optionally be done, even if the PLL is already configured by the ROM code. To minimize the overall output jitter, the PLL VCO output must be operated close to, but not above, the maximum operating frequency of 4.2 GHz. Maximizing the VCO frequency within the PLL is done by setting the PLL Output Divider as close as possible to 15 (OUTPUT_DIVIDE+1 must be an even number only). The PLLD value must be kept at 0 or as low as possible. The target PLLOUT frequency is therefore achieved by adjusting PLLM.

PLL VCO Frequency = CLKIN / (PLLD+1) × (PLLM+1)

PLL OUT Frequency = VCO / (OUTPUT_DIVIDE+1)

NOTE: In the below sequence, only the generic names of PLL_CTL0 and PLL_CTL1 registers are used. User must add the appropriate prefix as follows:

- BOOTCFG_NSS_
- BOOTCFG_DDR3A_
- BOOTCFG_ARM_
- BOOTCFG_DSS_
- BOOTCFG_ICSS_
- BOOTCFG_UART_

Secondary PLL registers start at BOOTCFG_NSS_PLL_CTL0 address.

1. In PLL_CTL1, write ENSAT = 1 (for optimal PLL operation).
2. In PLL_CTL0, write BYPASS = 1 (set the PLL in Bypass).
3. Program PLLM and PLLD in the PLL_CTL0 register.
4. Program BWADJ[7-0] in PLL_CTL0 and BWADJ[11-8] in the PLL_CTL1 register. BWADJ[11-0] must be programmed to a value related to PLLM[12-0] value based on the equation:
   BWADJ = ((PLLM+1) >> 1) - 1
5. In PLL_CTL1, write PLLRST = 1 (PLL reset is asserted).

6. Wait for at least 5 µs based on the reference clock (PLL reset time).
7. In PLL_CTL1, write PLLRST = 0 (PLL reset is de-asserted).
8. Wait for at least *500 × REFCLK cycles × (PLLD + 1)* (PLL lock time).
9. In PLL_CTL0, write BYPASS = 0 (switch to PLL mode).
10. PLL is now initialized.

5.4.5.3.3.4.2 USB Core Clock

USB module supports various CLKCORE frequencies: 12-, 19.2-, 24-, and 50-MHz. To generate these frequencies, clock outputs from UART PLL or NSS PLL can be selected. This is done by programming USB0/1_CLKCORE_SEL bit in the BOOTCFG_USB0_CLKCTL and BOOTCFG_USB1_CLKCTL registers. There is a programmable 5-bit divider at the output of this mux to generate the correct USB CLKCORE frequency. After setting the appropriate divide value, USB0/1_CLKCORE_LOAD_DIV bit must be set to 1 in to load the divider value into the clock divider. USB Core clock dividers must be configured prior to releasing USB out of reset.

The sequence to configure USB clock core divider is the following:

1. USB_0/1 module must be held in reset
2. Wait till NSS PLL or UART PLL is out of bypass mode
3. USB0/1_CLKCORE_SEL bit must be configured to select the appropriate source (NSS PLL or UART PLL). Reset default is UART PLL clock
4. Set the USB0/1_CLKCORE_DIV field to appropriate value to get (12/19.2/24/50 MHz)
5. Program the USB0/1_CLKCORE_LOAD_DIV bit to 0
6. Program the USB0/1_CLKCORE_LOAD_DIV bit to 1
7. Release USB_0/1 from reset.

5.4.5.3.3.5 Divider n and GO Operation

The GO operation is required to change the divider ratios of the PLLDIVn registers. Section 5.4.5.3.3.5.1, *GO Operation* discusses the GO operation. Section 5.4.5.3.3.5.2, *Software Steps to Modify PLLDIVn Ratios* provides the software steps required to change the divider ratios.

5.4.5.3.3.5.1 GO Operation

The GO operation writes to the RATIO field in the PLLDIVn. Registers do not change the dividers' divide ratios immediately. The PLLDIV dividers change to the new RATIO rates only during a GO operation. This section discusses the GO operation and alignment of the SYSCLKs.

The PLL Controller clock align control register (ALNCTL) determines which SYSCLKs must be aligned. Before a GO operation, program ALNCTL so that the appropriate clocks are aligned during the GO operation.

A GO operation is initiated by setting the GOSET bit in PLLCMD to 1. During a GO operation:

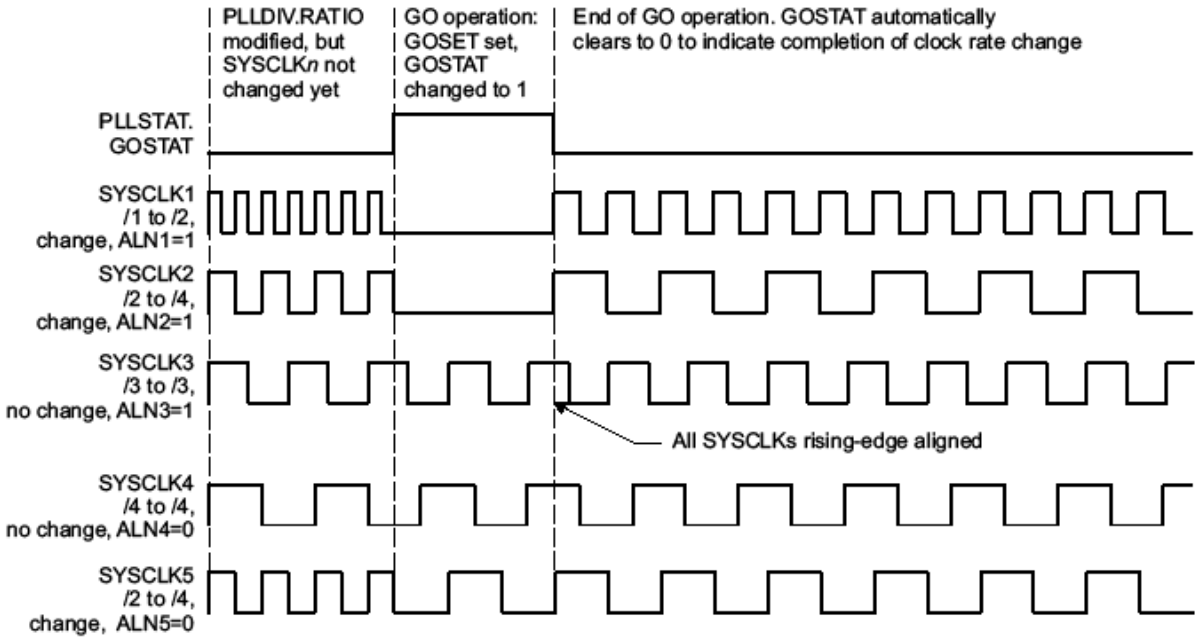
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL and SYS *n* bit in DCHANGE set to 1 is paused at the low edge. Then the PLL Controller restarts all these SYSCLKs simultaneously, aligned at the rising edge. When the SYSCLKs are restarted, SYSCLK *n* toggles at the rate programmed in the RATIO field in PLLDIVn.
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL cleared and the SYS *n* bit in DCHANGE set immediately changes to the new rate programmed in the RATIO field.
- The GOSTAT bit in PLLSTAT is set throughout the duration of a GO operation.

CAUTION

To help prevent errors, all device operation must be stopped before the GO operation.

Figure 5-168 shows an example of how the clocks are rising-edge aligned during a GO operation. Notice that because SYSCLK5 does not need to be aligned with the other clocks, it immediately switches to its new ratio during the GO operation.

Figure 5-168. Example Clock Ratio Change and Alignment with GO Operation



5.4.5.3.3.5.2 Software Steps to Modify PLLDIV Ratios

Perform the following steps to modify PLLDIV.

1. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.
2. Program the RATIO field in PLLDIVn to the desired new divide-down rate. If the RATIO field changed, the PLL Controller will flag the change in the corresponding bit of DCHANGE.
3. Set the respective ALN *n* bits in ALNCTL to align any SYSCLKs after the GO operation.
4. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.
5. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO operation has completed.

5.4.5.4 PLL Controller Registers

The PLL Controller registers are listed in Table 5-508. All other register offset addresses not listed in Table 5-508 must be considered as reserved locations and the register contents must not be modified.

Table 5-507. PLL Controller Instances

Instance	Base Address

5.4.5.4.3 PLLM Register (Offset = 110h) [reset = 0h]

The PLL multiplier control register (PLLM) is shown in Figure 5-171 and described in Table 5-516. The MSB bits PLLM[12-6] come from the chip-level register (BOOTCFG_MAIN_PLL_CTL0).

NOTE: Table 5-516 lists all the possible values for the PLL multiplier bits (PLLM). However, some of these values may not be valid for production. For a list of valid values for PLLM, see the device Data Manual.

5.4.5.4.4 PLLDIV1 Register (Offset = 118h) [reset = 0h]

The PLL Controller divider register (PLLDIV1-PLLDIV4) is shown in Figure 5-172 and described in Table 5-519. The PLLDIVn dividers generate a 50% duty cycle output clock SYSCLK1 when enabled. The PLLDIVn registers contain the default divider values on power up. Software needs to re-program a new value only if desires to change the default values. Otherwise, this register can be left unchanged.

Table 5-537. ALNCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0	Reserved. This reserved bit location is always read as 0. A value written to this field has no effect.
3	ALN4	R/W	1	SYSCLK4 alignment. • 0 = Do not align SYSCLK4 to other SYSCLKs during GO operation. If SYS 4 in DCHANGE is set, SYSCLK4 switches to the new ratio immediately after the GOSET bit in PLLCMD is set. • 1 = Align SYSCLK4 to other SYSCLKs selected in ALNCTL when the GOSET bit in PLLCMD is set and SYS 4 in DCHANGE is 1. The SYSCLK4 rate is set to the ratio programmed in the RATIO bit in PLLDIV 4.
2	ALN3	R/W	1	SYSCLK3 alignment. • 0 = Do not align SYSCLK3 to other SYSCLKs during GO operation. If SYS 3 in DCHANGE is set, SYSCLK3 switches to the new ratio immediately after the GOSET bit in PLLCMD is set. • 1 = Align SYSCLK3 to other SYSCLKs selected in ALNCTL when the GOSET bit in PLLCMD is set and SYS 3 in DCHANGE is 1. The SYSCLK3 rate is set to the ratio programmed in the RATIO bit in PLLDIV 3.
1	ALN2	R/W	1	SYSCLK2 alignment. • 0 = Do not align SYSCLK2 to other SYSCLKs during GO operation. If SYS 2 in DCHANGE is set, SYSCLK2 switches to the new ratio immediately after the GOSET bit in PLLCMD is set. • 1 = Align SYSCLK2 to other SYSCLKs selected in ALNCTL when the GOSET bit in PLLCMD is set and SYS 2 in DCHANGE is 1. The SYSCLK2 rate is set to the ratio programmed in the RATIO bit in PLLDIV 2.

Table 5-537. ALNCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	ALN1	R/W	1	SYSCLK1 alignment. • 0 = Do not align SYSCLK1 to other SYSCLKs during GO operation. If SYS 1 in DCHANGE is set, SYSCLK1 switches to the new ratio immediately after the GOSET bit in PLLCMD is set. • 1 = Align SYSCLK1 to other SYSCLKs selected in ALNCTL when the GOSET bit in PLLCMD is set and SYS 1 in DCHANGE is 1. The SYSCLK16 rate is set to the ratio programmed in the RATIO bit in PLLDIV 1.

Table 5-538. Register Call Summary for ALNCTL

PLLs
- Divider n and GO Operation: [0][1][2][3][4]
- PLL Controller Registers: [0]
- MAIN PLL Initialization: [0]
- DCHANGE Register (Offset = 144h) [reset = 0h]: [0]
- ALNCTL Register (Offset = 140h) [reset = 0h]: [0][1][2][3][4]

5.4.5.4.11 DCHANGE Register (Offset = 144h) [reset = 0h]

When a different ratio is written to the PLLDIVn registers, the PLLCTL flags the change in the DCHANGE status register. During the GO operation, the PLL Controller changes only the divide ratio of the SYSCLKs with the bit set in DCHANGE. Note that the ALNCTL register determines if that clock also needs to be aligned to other clocks. The PLLDIV divider ratio change status register is shown in Figure 5-179 and described in Table 5-540.

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0	Reserved. This reserved bit location is always read as 0. A value written to this field has no effect.
3	SYS4	R/W	0	Identifies when the SYSCLK4 divide ratio has been modified. • 0 = SYSCLK4 ratio has not been modified. When GOSET is set, SYSCLK4 will not be affected. • 1 = SYSCLK4 ratio has been modified. When GOSET is set, SYSCLK4 will change to the new ratio.
2	SYS3	R/W	0	Identifies when the SYSCLK3 divide ratio has been modified. • 0 = SYSCLK3 ratio has not been modified. When GOSET is set, SYSCLK3 will not be affected. • 1 = SYSCLK3 ratio has been modified. When GOSET is set, SYSCLK3 will change to the new ratio.
1	SYS2	R/W	0	Identifies when the SYSCLK2 divide ratio has been modified. • 0 = SYSCLK2 ratio has not been modified. When GOSET is set, SYSCLK2 will not be affected. • 1 = SYSCLK2 ratio has been modified. When GOSET is set, SYSCLK2 will change to the new ratio.
0	SYS1	R/W	0	Identifies when the SYSCLK1 divide ratio has been modified. • 0 = SYSCLK1 ratio has not been modified. When GOSET is set, SYSCLK1will not be affected. • 1 = SYSCLK 1 ratio has been modified. When GOSET is set, SYSCLK1 will change to the new ratio.

5.4.5.4.13 RSTYPE Register (Offset = E4h) [reset = 0h]

The reset type status (RSTYPE) register latches the cause of the last reset. If multiple reset sources occur simultaneously, this register latches the highest priority reset source. The Reset Type Status register is shown in Figure 5-181 and described in Table 5-546.

Table 5-545. RSTYPE Instances

5.4.5.4.14 RSCTRL Register (Offset = E8h) [reset = 3h]

This register contains a key that enables writes to the MSB of this register and the RSCFG register. The key value is 0x5A69. A valid key will be stored as 0x000C, any other key value is invalid. When the RSCTRL or the RSCFG is written, the key is invalidated. Every write must be set up with a valid key. The Software Reset Control register (RSCTRL) is shown in Figure 5-182 and described in Table 5-549.

5.4.5.4.16 RSISO Register (Offset = F0h) [reset = 0h]

This register is used to select the module clocks that must maintain their clocking without pausing through non power-on reset. Setting any of these bits effectively blocks reset to all PLLCTL registers in order to maintain current values of PLL multiplier ratios, divide ratios, and other settings. The Reset Isolation register (RSCTRL) is shown in Figure 5-184 and described in Table 5-555.

NOTE: For a list of modules that can be reset-isolated, see Section 5.3.9, *Reset Isolation* and Section 5.2.2.4, *Clock Domains*.

5.4.6 Module Clock Distribution

The clock signals from the MAIN PLL Controller are routed to various modules and peripherals on the device. Some modules and peripherals have one or more internal clock dividers. Other modules and peripherals have no internal clock dividers, but are grouped together and receive clock signals from a shared local clock divider. Internal and shared local clock dividers have fixed division ratios.

Some modules need clocks from dedicated PLLs as described below:

- ARM PLL: ARMSS
- DSS PLL: Display subsystem (DSS) pixel clock
- UART PLL: UARTs (including ICSS UARTs), MMC, USB PHY, QSPI
- ICSS PLL: ICSS PRU cores
- NSS/IEP PLL: NSS clocks, USB PHY, ICSS PRU cores, ICSS IEP
- DDR PLL: DDR3 EMIF and PHY.

Table 5-557 describes the clock distribution to device modules and subsystems.

Table 5-557. Module Clock Distribution

Module	Module Clock Port	Description	Source	Comments
PMMC	MPM_VBUS_CLK	Bus interface clock	CHIP_CLK1/6	
	MPM_FUNC_32K_CLK	32 kHz free running Clock	CHIP_CLK1/6	
	MPM_FUNC_OSC_CLK	Main Oscillator Clock	CHIP_CLK1/6	
	MPM_DAP_CLK	Debug Clock	CHIP_CLK1/6	
MLB	MLB_SYS _CLK	Min Clk = 2048Fs (Max 220 MHz)	CHIP_CLK1/3	Fs is Frame Sync Rate. This is same as Audio Sampling Rate.
	MLB_SHB_OCP_CLK	Must be less than or equal to SYS_CLK	CHIP_CLK1/3	
	MLB_SPB_OCP_CLK	Must be less than or equal to SYS_CLK	CHIP_CLK1/3	
	MLB_IO_CLK	Single IO Clock (3-pin config)	IO	Max Frequency is 49.152 MHz (1024Fs)
	MLBP_IO_CLK	Differential IO Clock (6-pin config)	IO	Max Frequency is 98.304 MHz (2048Fs)
DSS	PI_DSS_OCP_CLK	250 MHz interface clock	CHIP_CLK1/4	When CHIP_CLK1 frequency is set to 400MHz, CHIP_CLK1/4 is 100MHz. In this case only 720p display resolution can be supported.
	PI_DSS_VP_CLK	Output Pixel clock is derived from this clock. This clock needs to support various frequencies to satisfy different display resolutions. Hence a dedicated PLL is instantiated.	DSS PLL	Needs at least 150 MHz to support a resolution of 1920×1080×60fps (1080p). K2G1x supports a 4-bit divider for DSS_VP_CLK with register control in BOOT_CFG: BOOTCFG_SPARE1
	DSS_PCLK	Output on Device Pin	IO	
MCBSP	VBUS_CLK	Also known as CPU clock. This clock must be 2× the rate of IO clock. Since IO clock target is 50 MHz, vbus_clk must be at least 100 MHz.	CHIP_CLK1/3	
	CLKX	Transmit Clock (IO)	IO	
	CLKR	Receive Clock (IO)	IO	
	CLKS	External Clock Input (I)	AUDIO_OSCIN or MLB IO Clocks or SYS_OSCCLK or XREFCLK IO or UART PLL/4	Selection is made in BOOTCFG_SERIALPORT_CLKCTL register

Table 5-557. Module Clock Distribution (continued)

Module	Module Clock Port	Description	Source	Comments
MCASP	VBUS_CLK	VBUS and Functional Clock. This clock must 2× the rate of IO clock. Since the max target for IO clock rate is 75MHz. This clock must be at least 150MHz.	CHIP_CLK1/3	
	AUX_CLK	Auxillary clock input.	AUDIO_OSCIN or MLB IO Clocks or SYS_OSCCLK or XREFCLK IO or UART PLL/4	Selection is made in BOOTCFG_SERIALPORT_CLKCTL register
	ACLKX	Transmit Audio Data clock	IO	
	ACLKR	Receive Audio Data clock	IO	
	AHCLKX	Transmit Audio High Frequency Clock	IO	
	AHCLKR	Receive Audio High Frequency Clock	IO	
ASRC	SYS_CLK	System Clock (Fixed 200-MHz clock)	NSS/IEP PLL/5	
	VBUSP_CLK	VBUS clock	CHIP_CLK1/3	
	AASRC_RXSYNC0	Receive Frame Sync Channel 0	MCASP0AFSR	
	AASRC_RXSYNC1	Receive Frame Sync Channel 1	MCASP1AFSR	
	AASRC_RXSYNC1	Receive Frame Sync Channel 2	MCASP2AFSR	
	AASRC_RXSYNC3	Receive Frame Sync Channel 3	MLB_IO_CLK (3-Pin Mode)	
	AASRC_RXSYNC4	Receive Frame Sync Channel 4	MLBP_IO_CLK (6-Pin Mode)	
	AASRC_RXSYNC5	Receive Frame Sync Channel 5	MCASP0AHCLKR	
	AASRC_RXSYNC6	Receive Frame Sync Channel 6	MCASP1AHCLKR	
	AASRC_RXSYNC7	Receive Frame Sync Channel 7	MCASP2AHCLKR	
	AASRC_TXSYNC0	Transmit Frame Sync Channel 0	MCASP0AFSX	
	AASRC_TXSYNC1	Transmit Frame Sync Channel 1	MCASP1AFSX	
	AASRC_TXSYNC2	Transmit Frame Sync Channel 2	MCASP2AFSX	
	AASRC_TXSYNC3	Transmit Frame Sync Channel 3	MLB_IO_CLK (3-Pin Mode)	
	AASRC_TXSYNC4	Transmit Frame Sync Channel 4	MLBP_IO_CLK (6-Pin Mode)	
	AASRC_TXSYNC5	Transmit Frame Sync Channel 5	MCASP0AHCLKX	
	AASRC_TXSYNC6	Transmit Frame Sync Channel 6	MCASP1AHCLKX	
	AASRC_TXSYNC7	Transmit Frame Sync Channel 7	MCASP2AHCLKX	
DCAN	VBUS_CLK	VBUS clock	CHIP_CLK1/6	
	CAN_CLK	CAN functional clock used for data transmit and receive.	SYS_OSCCLK	This clock is sourced directly from System Oscillator output avoiding PLLs to achieve the lowest possible jitter.
EMIF_DDR	V_CLK	VBUSM Clock (EMIF)	CHIP_CLK1/2	
	M_CLK	Memory Clock (EMIF) = 1/2 of IO Clock ddr_clkn/p	DDR PLL CLK	
	PUB_CTL_CLK	PHY Utility Block Control Clock	DDR PLL CLK	
	PHY_CTL_CLK	PHY Control Clock	DDR PLL CLK	
	VBUSP_CLK	EMIF Config Clock (VBUSP). Must be less than or equal to pub_ctl_clk	CHIP_CLK1/6	
	DDR_CLKN/P	Complementary DDR CLK OUTPUT (PIN)	IO	
MMC	VBUS_CLK	VBUSP Master Clock	CHIP_CLK1/3	
	CLK_ADPI	Functional Clock (96 MHz)	UART PLL/4	
	CLK_ADPO/CLKFDBKI	Functional Clock Looped Back through IO Buffer	CLK_ADPI	

Table 5-557. Module Clock Distribution (continued)

Module	Module Clock Port	Description	Source	Comments
	CLK32K	32-kHz Debounce Clock	UART PLL/12000	
GPMC	GPMC_FCLK	Functional clock and VBUS clock.	CHIP_CLK1/3	
	GPMC_CLK	IO CLOCK. Max rate 133 MHz	IO	
ELM	CLK	Functional clock and VBUS clock.	CHIP_CLK1/3	
ADTF	CLK	Functional clock and VBUS clock.	CHIP_CLK1/6	
SPI	VBUSP_CLK	Functional and vbus clock	CHIP_CLK1/6	
	SPICLK	IO	IO	
PRU-ICSS_0, PRU-ICSS_1	VCLK_CLK	VBUS Clock	CHIP_CLK1/3	
	CORE0_CLK	ICSS_0 Clock	ICSS PLL or NSS/IEP PLL/5	ICSS core clock is selected based on protocols. ICSS_0 and ICSS_1 core clocks can be set independently. See BOOTCFG_ICSS_CLKCTL register.
	CORE1_CLK	ICSS_1 Clock	ICSS PLL or NSS/IEP PLL/5	
	UCLK_CLK	UART Clock (192 MHz)	UART PLL/2	UART clock rate of 192 MHz is needed to support 12 Mbps Baud rate for Profibus protocol
	IEPCLK_CLK	Ethernet Clock	NSS/IEP PLL/5	IEP Clock needs to be at a constant clock rate of 200 MHz
USB	BUS_CLK	VBUS Clock	CHIP_CLK1/6	
	PHYMMR_CLK	PHY Configuration Clock	CHIP_CLK1/24	
	SUSP_CLK	Suspend Clock	CHIP_CLK1/24	
	REF_CLK	PHY Ref clock	CHIP_CLK1/24	
	CLKCORE	Core clock	Divided version of NSS/IEP PLL or UART PLL output.	12/19.2/24/50 MHz. The clock source and speed is set in registers BOOTCFG_USB0_CLKCTL and BOOTCFG_USB1_CLKCTL
	XO	External Reference Clock Input	IO	XO clock is used to provide external reference clock input to USB. When external reference clock is not needed, internal Core clock canl be used.
Networking Subsystem (NSS)	VCLK	VBUS Clock	CHIP_CLK1/3	
	SA_UL_CLK	Core Clock for SA_UL	CHIP_CLK1/3	
	SA_UL_X1_CLK	Half Rate Clock for SA_UL	CHIP_CLK1/6	
	ESW_CLK	Core Clock for Ethernet	CHIP_CLK1/3	
	CPTS_RFTCLK	CPTS Reference Clock	CPTS_REFCLK Input	See Section 11.13.4.4.7, *Common Platform Time Sync (CPTS).*
	GMII_RFTCLK	125MHz GMII Gigabit Mode Clock	NSS/IEP PLL/8	
	GMII_MRCLK	GMII Receive Clock (Device Pin)	IO	
	GMII_MTCLK	GMII 10/100 Transmit Clock (Device Pin)	IO	
	GMII_GMTCLK	GMII Clock output (Device Pin)	IO	
	RGMII_MHZ_5_CLK	5 MHz RGMII Clock	NSS/IEP PLL/200	
	RGMII_MHZ_50_CLK	50 MHz RGMII Clock	NSS/IEP PLL/20	
	RGMII_MHZ_250_CLK	250 MHz RGMII Clock	NSS/IEP PLL/4

Topic **Page**

6.1 Arm Cortex-A15 Subsystem

This section describes the Arm® Cortex®-A15 Subsystem for the device.

6.1.1 Arm Subsystem Overview

6.1.1.1 Introduction

The Arm Subsystem (ARMSS) of the SoC integrates a single Cortex-A15 processor with additional logic for bus protocol conversion, local power management, and various debug and trace enhancements.

The Cortex-A15 processor is an Arm®v7A-compatible, multi-issue out-of-order superscalar execution engine with integrated L1 caches.

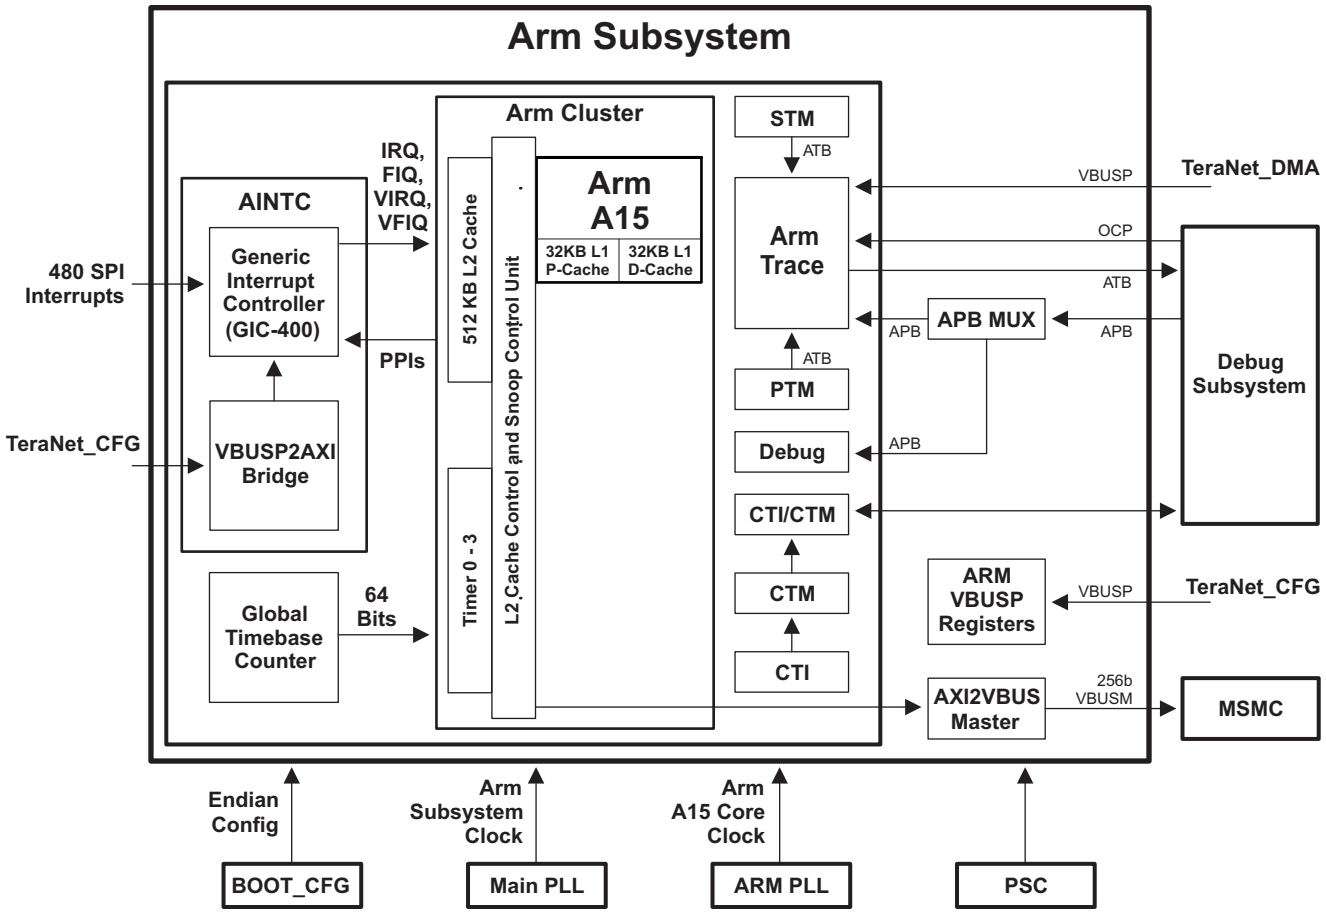
The implementation also supports advanced SIMDv2 (NEON™ technology) and VFPv4 (vector floating point) architecture extensions, security, virtualization, LPAE (large physical address extension), and multiprocessing extensions.

The Arm Subsystem includes a 512KB L2 cache and support for AMBA4 AXI and AXI coherence extension (ACE) protocols.

NOTE: The **Arm Subsystem** is also referred to as **Arm CorePac**.

Figure 6-1 shows an overview of the Arm Subsystem in the SoC.

Figure 6-1. Arm Subsystem Overview



6.1.1.2 Features

The Arm subsystem supports the following key features:

- Arm Cortex-A15 processor, full implementation of Arm®v7-A architecture instruction set
- 32KB L1 instruction (L1I) and data (L1D) caches
- 512KB L2 cache
- Super scalar, variable-length, out-of-order pipeline (12 stage in-order, 3-12 stage out-of-order)
- 128-bit instruction fetch
- 3-wide instruction decode
- 3-wide instruction dispatch
- 8-wide instruction issue
- Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB), a return stack, and an indirect predictor
- Integrated Neon and VFP (Vector Floating Point unit)
- Support for security and virtualization extensions
- Error Correction Code (ECC) protection for L1 data cache and L2 cache, parity protection for L1 instruction cache
- 32-entry fully-associative L1 Translation Look-aside Buffers (TLBs), for instruction fetch, data loads, and data stores
- 512-entry 4-way set-associative L2 TLB
- AMBA 4.0 AXI Coherency Extension (ACE) master port which is directly connected to MSMC (Multicore Shared Memory Controller) for low-latency access to shared MSMC SRAM
- Dedicated Arm clocking (ARM_PLL) for full flexibility in performance trade-offs
- Support for four integrated generic timers, in addition to 1 dedicated SoC-level watchdog timer (TIMER_5)
- Support for invasive (stop-mode) and non-invasive (tracing, performance monitoring) debug modes and cross triggering for multiprocessor debugging
- Support for processor instruction trace using Program Trace Macrocell (PTM) and data trace (printf style debug) using System Trace Macrocell (STM)
- Support for up to 480 interrupt requests via the Arm Interrupt Controller (AINTC) module
- Support for little-endian operation only

The Arm subsystem does not support the following features:

- ACP (Accelarator Coherancy Port) Slave
- Native AXI Master interface (only MSMC option is used)

6.1.2 Arm Subsystem Functional Description

6.1.2.1 ARMSS Block Diagram

Figure 6-1 shows a high-level block diagram of the Arm Subsystem along with its connectivity to other SoC subsystems and modules.

The Arm Subsystem integrates the following major blocks:

- Single-core Arm Cluster (Section 6.1.2.1.1)
- AXI2VBUS_MASTER (Section 6.1.2.1.2)
- Debug and Trace components (see *On-chip Debug* chapter)
- ARM_VBUSP registers
- AINTC
- Global Timebase Counter (GTC)
- Various interfaces for interaction with other SoC subsystems and modules

6.1.2.1.1 Arm A15 Cluster

The Arm A15 Cluster (Cortex-A15 MPCore) includes a single Cortex-A15 processor core and debug components, as well as 512KB L2 cache.

Table 6-1 shows the features supported by the Cortex-A15 processor core.

Table 6-1. Cortex-A15 Processor Core Supported Features

Features	Description
Arm version 7-A ISA	Standard Cortex-A15 processor instruction set + Thumb2, ThumbEE, JazelleX Java accelerator, and media extensions
	Backward compatible with previous Arm ISA versions
Cortex-A15 processor version	R2P2
Integer core	Main core for processing integer instructions
NEON core	Gives greatly enhanced throughput for media workloads and VFP-Lite support
Architecture Extensions	Security, virtualization and LPAE (40-bit physical address) extensions
L1 Lcache and Dcache	32KB, 2-way, 16-word line, 128-bit interface
L2 cache	512KB, 16-way, 16-word line, 128-bit interface to L1, ECC/Parity is supported shared between cores
	L2 valid bits cleared by software loop or by hardware
Cache Coherency	Support for coherent memory accesses between A15 core and other non-core master peripherals (Ex: EDMA) in the DDR3A and MSMC SRAM space.
Branch target address cache	Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB), a return stack, and an indirect predictor
Enhanced memory management unit	Mapping sizes are 4KB, 64KB, 1MB, and 16MB
Buses	128b AXI4 internal bus from Cortex-A15 converted to a 256b VBUSM to interface (through the MSMC) with MSMC SRAM, DDR EMIF, ROM, Interrupt controller and other system peripherals
Non-invasive Debug Support	Processor instruction trace using Program Trace Macrocell (Coresight™ PTM), Data trace (print-f style debug) using System Trace Macrocell (Coresight™ STM) and Performance Monitoring Unit (PMU)
Misc Debug Support	JTAG-based debug and Cross-triggering
Clocking	Dedicated ARM PLL for flexible clocking scenarios

The Arm A15 core has the following interfaces with other modules in the Arm subsystem:

- AXI (Advanced eXtensible Interface)
- APB (AMBA Advanced Peripheral Bus)
- ATB (AMBA Trace Bus)
- Cross trigger

For more information about:

- General Arm architecture, see the *Arm Architecture Reference Manual*
- Arm A15 core, see the *Arm Cortex-A15 MPCore Processor Technical Reference Manual*.

6.1.2.1.2 AXI2VBUS Master

6.1.2.1.2.1 AXI2VBUS_MASTER Overview

The AXI2VBUS_MASTER is a custom block for interfacing the A15 Cluster AXI bus to the System Interconnect through the Multicore Shared Memory Controller (MSMC). The MSMC is the global memory management unit that provides an interface between processor masters (such as DSP and ARMSS) and system memory. The AXI2VBUS_MASTER serves as a bridge between the ARMSS protocols and the MSMC, and also provides bus width and clock conversion.

The AXI2VBUS_MASTER serves the following purposes in the Arm subsystem:

- AXI-to-VBUSM protocol conversion
- Coherency extensions translation between ACE and MSMC custom protocols
- A 1:1 async boundary between the A15 Cluster and MSMC clock domains while providing 128-bit to 256-bit data width conversion, leading to no loss in overall throughput

6.1.2.1.2.2 Cache Line Size

Both MSMC and A15 core use a cache line size of 64 bytes.

6.1.2.1.3 Arm Debug Components

The Arm Subsystem integrates a number of Coresight debug components around the A15 Cluster for supporting embedded debug and trace, as well as cross-triggers. These are in addition to the PTMs inside the A15 cores and the CTM and CTI modules at the A15 core L2 level. For more details on Arm debug components, see Chapter 12, *On-chip Debug*.

6.1.2.2 ARMSS Interrupt Controller (AINTC)

The Arm interrupt controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and the secondary interrupt controller (CIC) and then generating either nIRQ or nFIQ to the Cortex-A15 processor. The type of the interrupt (nIRQ or nFIQ) and the priority of the interrupt inputs are programmable.

The AINTC has the capability to handle up to 480 requests, which can be steered/prioritized as A15 nFIQ or nIRQ interrupt requests.

The general features of the AINTC are:

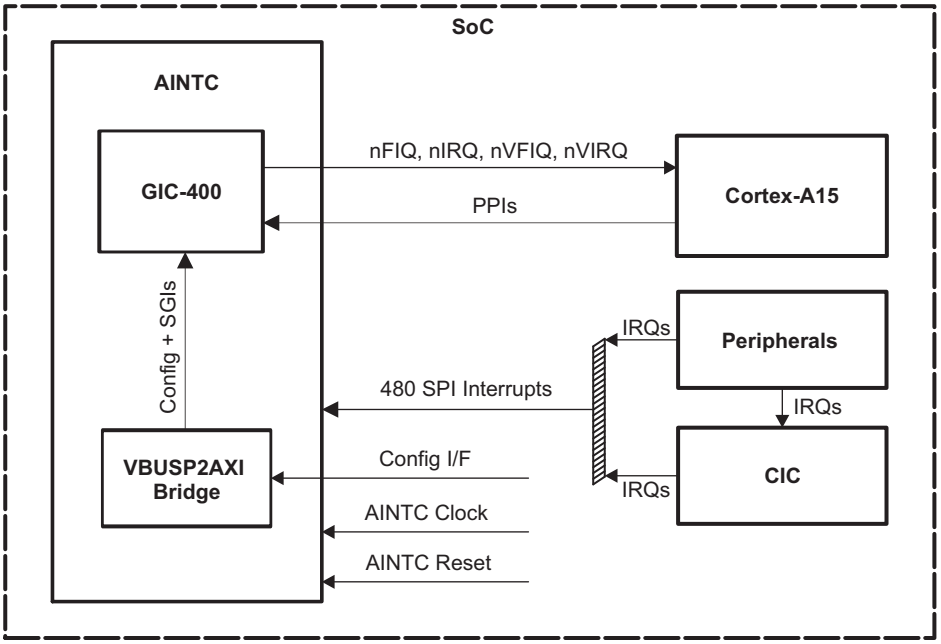
- Up to 480 shared peripheral interrupts (SPI) inputs
- Individual priority for each interrupt input
- Each interrupt can be steered to nFIQ or nIRQ
- Independent priority sorting for nFIQ and nIRQ
- Secure mask flag.

6.1.2.2.1 AINTC Block Diagram

The "core" of the AINTC is an IP block which is called Generic Interrupt Controller (GIC-400) and is provided by Arm. Additionally, the AINTC implements a VBUSP2AXI bridge to provide R/W access to its internal MMRs.

Figure 6-2 shows the block diagram of the AINTC.

Figure 6-2. AINTC Block Diagram



6.1.2.2.1.1 Generic Interrupt Controller (GIC-400)

The GIC-400 is a high-performance, area-optimized interrupt controller with an AMBA AXI interface. It detects, manages, and distributes system interrupts to the Cortex-A15 core. It also supports the separation of two groups of interrupts, typically secure and non-secure interrupts. In addition, the GIC-400 provides hardware acceleration for managing virtualized interrupts.

The GIC-400 implements the following interrupt types:

- 16 *Software Generated Interrupts* (SGIs)
- 7 *Private Peripheral Interrupts* (PPIs)
- 480 *Shared Peripheral Interrupts* (SPIs)

The GIC-400 can assert the following signals to indicate pending interrupts to the A15 CPU:

- Physical interrupts:
  - nFIQCPU[0]
  - nIRQCPU[0]
- Virtual interrupts:
  - nVFIQCPU[0]
  - nVIRQCPU[0]

The GIC-400 has a configuration register that allows software to configure each interrupt line to be level-sensitive or edge-sensitive. Because the hardware assumes all shared peripheral interrupts to be pulses, it is software responsibility to ensure the GICD_ICFGR bits are set-up correctly after reset.

NOTE: The original Arm GIC Security Extension supports both secure interrupts (Group 0) and non-secure interrupts (Group 1) but all transaction made to the GIC are treated as secure transaction in AINTC, so the user has to follow the Secure mode procedure irrespective of Arm A15 Core mode.

Detailed information about the GIC-400 is provided in the *CoreLink GIC-400 Generic Interrupt Controller Technical Reference Manual* and *Arm Generic Interrupt Controller Architecture Specification*.

6.1.2.2.1.2 VBUSP2AXI Bridge

The AINTC uses the AXI interface to provide R/W access to its internal registers. This means that it is necessary to translate VBUSP transactions into AXI transactions. This protocol conversion is handled by the VBUSP2AXI bridge instantiated inside the AINTC. The bridge handles only the protocol conversion of VBUSP into AXI transactions. It does not perform any clock rate adaptation or data width conversion.

6.1.2.2.2 AINTC Interrupt Mapping

Table 6-2 lists the interrupt sources for the AINTC/GIC-400. These interrupt sources correspond to the 480 Shared Peripheral Interrupts (SPIs) supported by the GIC-400. The association between the SPI event numbers and the corresponding GIC-400 ID numbers is also shown in this table.

NOTE: ELM is not supported on this family of devices.

Table 6-2. AINTC Interrupt Sources

SPI Event No.	GIC-400 ID	Event Name	Description
0	ID32	RSTMUX_INT8	Interrupt generated by TIMER_5 when used as WD Timer for ARMSS.
1	ID33	IPC_GR8	BOOT_CFG interprocessor communication register 8 interrupt
2	ID32	SEM_INT8	Semaphore Master 8 grant interrupt
3	ID32	SEM_ERR8	Semaphore Master 8 error interrupt
4	ID32	ARM_NPMUIRQ0	ARMSS PMU interrupt
5	ID32	ARM_NINTERRIRQ	ARMSS internal error interrupt
6	ID32	ARM_NAXIERRIRQ	ARMSS AXI error interrupt
7	ID32	ARM_NCTIIRQ0	ARMSS CTI interrupt
8	ID40	ARM_TBR_DMA	ARMSS trace buffer DMA event
9	ID41	ARM_TBR_ACQ	ARMSS trace buffer acquisition complete interrupt
10	ID42	BOOTCFG_INT	BOOT_CFG boot error interrupt
[15:11]	[ID47:ID43]	RESERVED	Reserved
16	ID48	TIMER_0_INTL	TIMER_0 low interrupt
17	ID49	TIMER_0_INTH	TIMER_0 high interrupt
18	ID50	TIMER_1_INTL	TIMER_1 low interrupt
19	ID51	TIMER_1_INTH	TIMER_1 high interrupt
20	ID52	TIMER_2_INTL	TIMER_2 low interrupt
21	ID53	TIMER_2_INTH	TIMER_2 high interrupt
22	ID54	TIMER_3_INTL	TIMER_3 low interrupt
23	ID55	TIMER_3_INTH	TIMER_3 high interrupt
24	ID56	TIMER_4_INTL	TIMER_4 low interrupt
25	ID57	TIMER_4_INTH	TIMER_4 high interrupt
26	ID58	TIMER_5_INTL	TIMER_5 low interrupt
27	ID59	TIMER_5_INTH	TIMER_5 high interrupt
28	ID60	TIMER_6_INTL	TIMER_6 low interrupt
29	ID61	TIMER_6_INTH	TIMER_6 high interrupt
[47:30]	[ID79:ID62]	RESERVED	Reserved
48	ID80	PCIE_INT0	PCIE interrupt 0
49	ID81	PCIE_INT1	PCIE interrupt 1
50	ID82	PCIE_INT2	PCIE interrupt 2
51	ID83	PCIE_INT3	PCIE interrupt 3
52	ID84	PCIE_INT4	PCIE interrupt 4
53	ID85	PCIE_INT5	PCIE interrupt 5
54	ID86	PCIE_INT6	PCIE interrupt 6

Table 6-2. AINTC Interrupt Sources (continued)

SPI Event No.	GIC-400 ID	Event Name	Description
55	ID87	PCIE_INT7	PCIE interrupt 7
56	ID87	PCIE_INT8	PCIE interrupt 8
57	ID89	PCIE_INT9	PCIE interrupt 9

6.1.2.2.3 AINTC Clock

The AINTC has a single clock domain (CHIP_CLK1/3).

6.1.2.2.4 AINTC Reset

There is a single reset coming into the AINTC module (LPSC6.MOD_G_RST). The GIC-400 is reset asynchronously whereas the VBUSPAXI bridge and other miscellaneous logic is reset synchronously.

6.1.2.3 ARMSS Timers and Watchdog Timer

The following ARMSS-dedicated timer modules are supported in the SoC:

- 4 timers integrated inside the Arm Cluster; for general-purpose use
- Additional timer integrated at SoC level – TIMER_5; its primary purpose is to serve as a Watchdog Timer but it can also be used in general-purpose mode
- Global Timebase Counter (GTC); it is used for synchronizing the ARMSS internal timers.

The four ARMSS internal timers are described in detail in the *Arm Cortex-A15 MPCore Processor Technical Reference Manual*.

The need for a SoC-level watchdog timer (TIMER_5) that is closely-coupled to the Arm processor is driven by the fact that the ARMSS internal timers are not suspendable on CPU halt. TIMER_5 operation is controlled by the DPSC module which is integrated inside the Arm Subsystem. For detailed description of TIMER_5 functionality, see Section 11.17, *Timers*.

The GTC is a simple non-configurable 64-bit counter. The only time this counter gets reset is during power-on. The initialization value of the counter during power-on-reset is all zeros. After reset, the counter keeps incrementing by 1'b1 on each rising edge of the GTC clock. Before the counter value is sent out to the timers inside the A15 core, its value is transcoded from 64-bit graycode (output from the GTC) into 64-bit binary code – **CNTVALUEB[63:0]**, required by the Arm core.

6.1.2.4 ARMSS Boot

The Arm Subsystem has a dedicated 256KB boot ROM (ARM_BOOTROM) starting at address location 0x0000_0000. It can be divided into a secure and non-secure portion in a flexible way. The A15 core always boots in *Secure Monitor* mode and always from this location. This is true irrespective of the device type (secure or non-secure). After the initialization of the *Secure Monitor* mode, the ARM_BOOTROM will execute from secure or non-secure portion based on the device type.

There is also a bootmode pin to define whether ARMSS or DSP is the boot master in the system. For more information about selecting the boot master and a detailed boot flow diagram, see Chapter 4, *Initialization*.

6.1.2.5 ARMSS Power Management, Clocking and Reset

6.1.2.5.1 ARMSS Power

The Arm Subsystem supports a hierarchical power down/power up mechanism based on the interaction between the chip-level (Global) Power Sleep Controller (GPSC) and the Discrete PSC (DPSC) which is local to the Arm Subsystem. The handshaking between the GPSC and the DPSC is built in hardware state machine, and no software intervention is needed.

In this SoC, both Arm Subsystem and A15 core reside in the same power domain (PD9) which is completely under GPSC's control only. Although the DPSC has some registers for A15 individual power state control, they are reserved and software should not modify them.

By default (after reset), the ARMSS power domain is ON.

CAUTION

The DPSC registers dedicated to A15 power management should not be used and can cause undefined behavior (for example, hang) if used.

6.1.2.5.1.1 Powering Down the ARMSS

Because the A15 core and the Arm Subsystem share the same power domain, they are powered OFF at the same time (once such request is initiated). For ARMSS power down, it is software responsibility to do the following:

1. Make sure that A15 executes WFI. The CPU is expected to reach WFI state following a series of steps in software, as follows:
    1. In software, block the cache allocation (by clearing the SCTLR.C or HSCTLR.C bit)
    2. Clean and invalidate all data from the L1 data cache
    3. Take the CPU out of coherency (by clearing the ACTLR.SMP bit which switches the CPU from SMP mode to Asymmetric mode)
    4. Save the architectural state, if required
    5. Execute an instruction barrier ISB instruction to commit all CP15 changes from previous steps
    6. Execute a data barrier DSB instruction to commit all coherency operations from previous steps
    7. Execute a WFI instruction
2. Initiate ARMSS power down request by programming the following GPSC register settings:
    1. Write '0' to the PDCTL9[0] NEXT bit
    2. Write ‘1’ to the PTCMD[9] GO9 bit

The ARMSS power domain state can be verified by reading the PDSTAT9[1-0] STATE bit field in the GPSC.

For detailed description of the A15 SCTLR, HSCTLR, and ACTLR registers, see the *Arm Cortex-A15 MPCore Processor Technical Reference Manual*.

For detailed description of the GPSC PDCTL, PDSTAT, and PTCMD registers, see Section 5.2.2, *Power Sleep Controller (PSC)*.

6.1.2.5.1.2 Powering Up the ARMSS

In order to power up the ARMSS domain, software must do the following GPSC register settings:

1. Write '1' to the PDCTL9[0] NEXT bit
2. Write ‘1’ to the PTCMD[9] GO9 bit

6.1.2.5.1.3 Interaction of Power Down/Power Up with Watchdog Timer

As noted in Section 6.1.2.3, a watchdog timer that is closely-coupled to the Arm core is instantiated at SoC level (TIMER_5).

When the A15 core is powered down, it will not be able to maintain its periodic watchdog timer counter clearing schedule, hence causing spurious watchdog timer counter expiration and global reset. To avoid this scenario, the watchdog timer clock is turned off and it is held in reset, while the A15 core is powered down. This is automatically done by the DPSC hardware (no software intervention is needed).

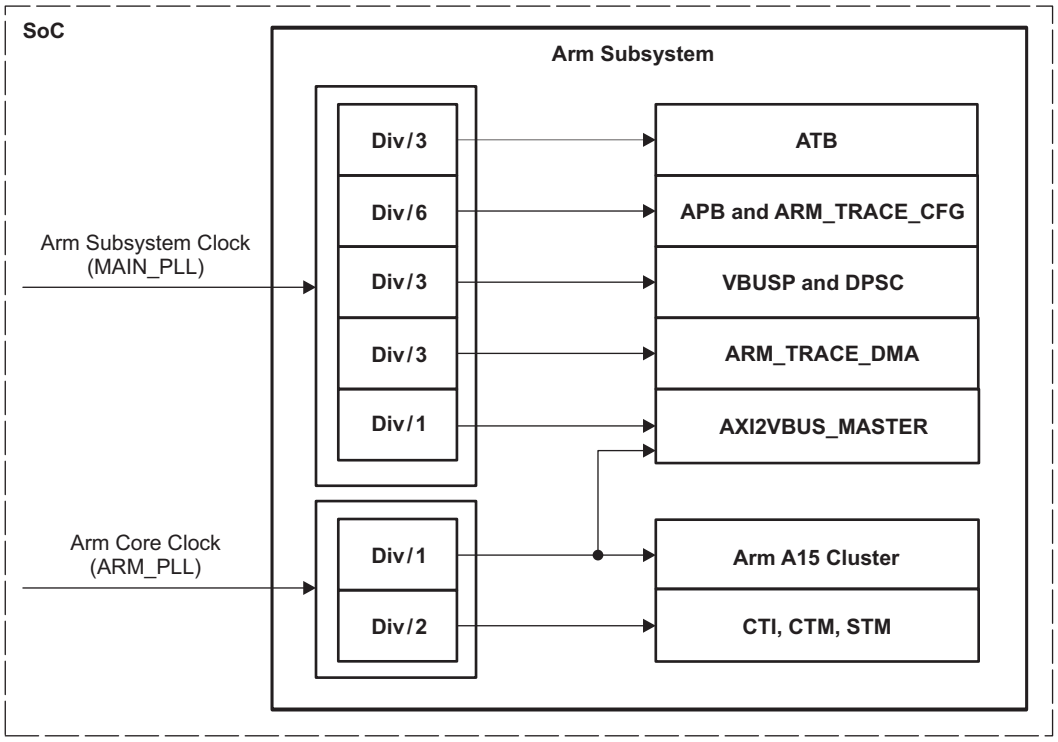
6.1.2.5.2 ARMSS Clock

The Arm subsystem has two primary functional clock inputs:

- **From SoC main PLL (MAIN_PLL).** This clock feeds the following ARMSS modules:
  - Through local DIV/1 divider: AXI2VBUS_MASTER
  - Through local DIV/3 divider: ATB, ARM_VBUSP, DPSC, and ARM_TRACE_DMA
  - Through local DIV/6 divider: APB, and ARM_TRACE_CFG
- **From dedicated ARM_PLL**. This clock feeds the following ARMSS modules:
  - Through local DIV/1 divider: A15 Cluster
  - Through local DIV/2 divider: CTI, CTM, and STM located at ARMSS level

Figure 6-3 shows the Arm Subsystem clock distribution.

Figure 6-3. Arm Subsystem Clock Distribution



For more details on MAIN_PLL and ARM_PLL, see Section 5.4, *Clock Management*.

6.1.2.5.3 ARMSS Reset

The Arm Subsystem supports a number of resets for its internal modules. The list of resets connected to the Arm Subsystem is given in Section 5.3, *Reset Management*.

The Arm Subsystem does not support the software reset feature; there is no reset hookup between the Global PSC and the Arm Subsystem. To truly support a soft reset, the Arm Subsystem must go through a full power down software sequence and hardware disconnect sequence from the interconnect. Neither of these sequences is likely to complete in the midst of a CPU hang condition (which is the reason for a soft reset in the first place). The only recovery mechanism is therefore likely to be a system-level global warm reset.

6.1.2.6 ARMSS Debug

The ARMSS debug components and features are described in Chapter 12, *On-Chip Debug*.

6.1.2.7 ARMSS Interprocessor Communication (IPC)

The Arm A15 core can communicate with other device cores (C66x DSP, PRU-ICSS PRUs) by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the BOOT_CFG memory-mapped registers (MMRs) called IPCGRx / IPCARx. For more information, see Section 5.1, *Control Module (BOOT_CFG)*.

6.1.3 Arm Subsystem Registers

This chapter does not provide register details for the Arm Cortex-A15 and other submodules except for the ARM_VBUSP registers and the AXI2VBUS_MASTER registers.

For more detailed information about the A15 core (revision r2p2) and other Arm modules (AINTC, CoreSight components, etc), visit the Arm information website: http://infocenter.arm.com/help/index.jsp.

6.1.3.1 AXI2VBUS_MASTER Registers

Table 6-4 lists the memory-mapped registers for the AXI2VBUS_MASTER. All register offset addresses not listed in Table 6-4 should be considered as reserved locations and the register contents should not be modified.

Table 6-3. AXI2VBUS_MASTER Instances

Instance	Base Address
AXI2VBUS_MASTER	0100 0000h

Table 6-4. AXI2VBUS_MASTER Registers

Offset	Acronym	Register Name	AXI2VBUS_MASTER Physical Address	Section
00h	AXI2VBUS_PID	Peripheral Identification Register	0100 0000h	Section 6.1.3.1.1
20h	AXI2VBUS_CMD_PRI	Command Priority Setup Register	0100 0020h	Section 6.1.3.1.2
30h	AXI2VBUS_CPU0_END	Endian Mode Setup Register	0100 0030h	Section 6.1.3.1.3

Table 6-5. AXI2VBUS_MASTER Registers – R/W Modes

Register Name	Readable Mode	Writable Mode
AXI2VBUS_PID	All	None
AXI2VBUS_CMD_PRI	All	Emulation, Supervisor
AXI2VBUS_CPU0_END	All	Emulation, Supervisor

6.1.3.1.1 AXI2VBUS_PID Register (Offset = 0h) [reset = 49200000h]

The Peripheral Identification Register uniquely identifies the AXI2VBUS_MASTER and the specific revision of the AXI2VBUS_MASTER. AXI2VBUS_PID is shown in Figure 6-4 and described in Table 6-7.

Table 6-6. AXI2VBUS_PID Instances

Instance	Physical Address
AXI2VBUS_MASTER	0100 0000h

Figure 6-4. AXI2VBUS_PID Register

6.1.3.1.2 AXI2VBUS_CMD_PRI Register (Offset = 20h) [reset = 7h]

This register provides the command priority information about the module. The reset value of this register is 7h, the lowest VBUSM priority. Writing to this MMR only updates future transaction of VBUSM priority signal with the written value. AXI2VBUS_CMD_PRI is shown in Figure 6-5 and described in Table 6-10.

Table 6-9. AXI2VBUS_CMD_PRI Instances

Instance	Physical Address

- AXI2VBUS_CPU0_END Register (Offset = 30h) [reset = 0h]: [0]

6.1.3.2 ARM_VBUSP Registers

Table 6-16 lists the memory-mapped registers for the ARM_VBUSP. All register offset addresses not listed in Table 6-16 should be considered as reserved locations and the register contents should not be modified.

Table 6-15. ARM_VBUSP Instances

Instance	Base Address
ARM_VBUSP	01E8 0000h

Table 6-16. ARM_VBUSP Registers

Offset	Acronym	Register Name	ARM_VBUSP Physical Address	Section
0h	ARM_PID	Peripheral Identification Register for Arm Subsystem	01E8 0000h	Section 6.1.3.2.1
4h	ARM_INTC_PID	Peripheral Identification Register for AINTC	01E8 0004h	Section 6.1.3.2.2
14h	STM_DISABLE	Disable access to STM in Arm Subsystem	01E8 0014h	Section 6.1.3.2.3
400h	PD_CPU0_PTCMD	Power domain transition command for A15 core	01E8 0400h	Section 6.1.3.2.4
404h	PD_CPU0_PDSTAT	Power domain status for A15 core	01E8 0404h	Section 6.1.3.2.5
408h	PD_CPU0_PDCTL	Power domain control for A15 core	01E8 0408h	Section 6.1.3.2.6

CAUTION

The DPSC registers dedicated to A15 power management should not be used and can cause undefined behavior (for example, hang) if used. See Section 6.1.2.5 for details.

6.1.3.2.1 ARM_PID Register (Offset = 0h) [reset = 44900900h]

ARM_PID is shown in Figure 6-7 and described in Table 6-18.

Peripheral Identification Register for Arm Subsystem.

Table 6-17. ARM_PID Instances

Instance	Physical Address

Table 6-30. PD_CPU0_PDSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	X	Reserved
18-16	DOMAIN_STATE	R	X	Shows CPU power domain ACTUAL state. • 000: Powered ON • 001: Powered ON and held-in-reset • 010: Powered OFF. Dynamic wakeup on interrupt. • 011: Powered OFF. • 100: Domain in transition NEXT state should always match current domain state unless it is in transition. The only exception is when debug prevents powering down.
15-2	RESERVED	R	0h	Reserved
1-0	NEXT_CPU	R	0h	Shows programmed CPU power domain NEXT state. • 00: Powered ON • 01: Powered ON and held-in-reset • 10: Powered OFF. Dynamic wakeup on interrupt. • 11: Powered OFF. These bits essentially reflect the NEXT state stored in the PDCTL shadow register inside the Arm CorePac. This field may not match the fields programmed into PDCTL until a GO transition command is issued

6.2 C66x DSP Subsystem

The purpose of this section is to provide an overview of the DSP subsystem (C66x CorePac) along with some integration details.

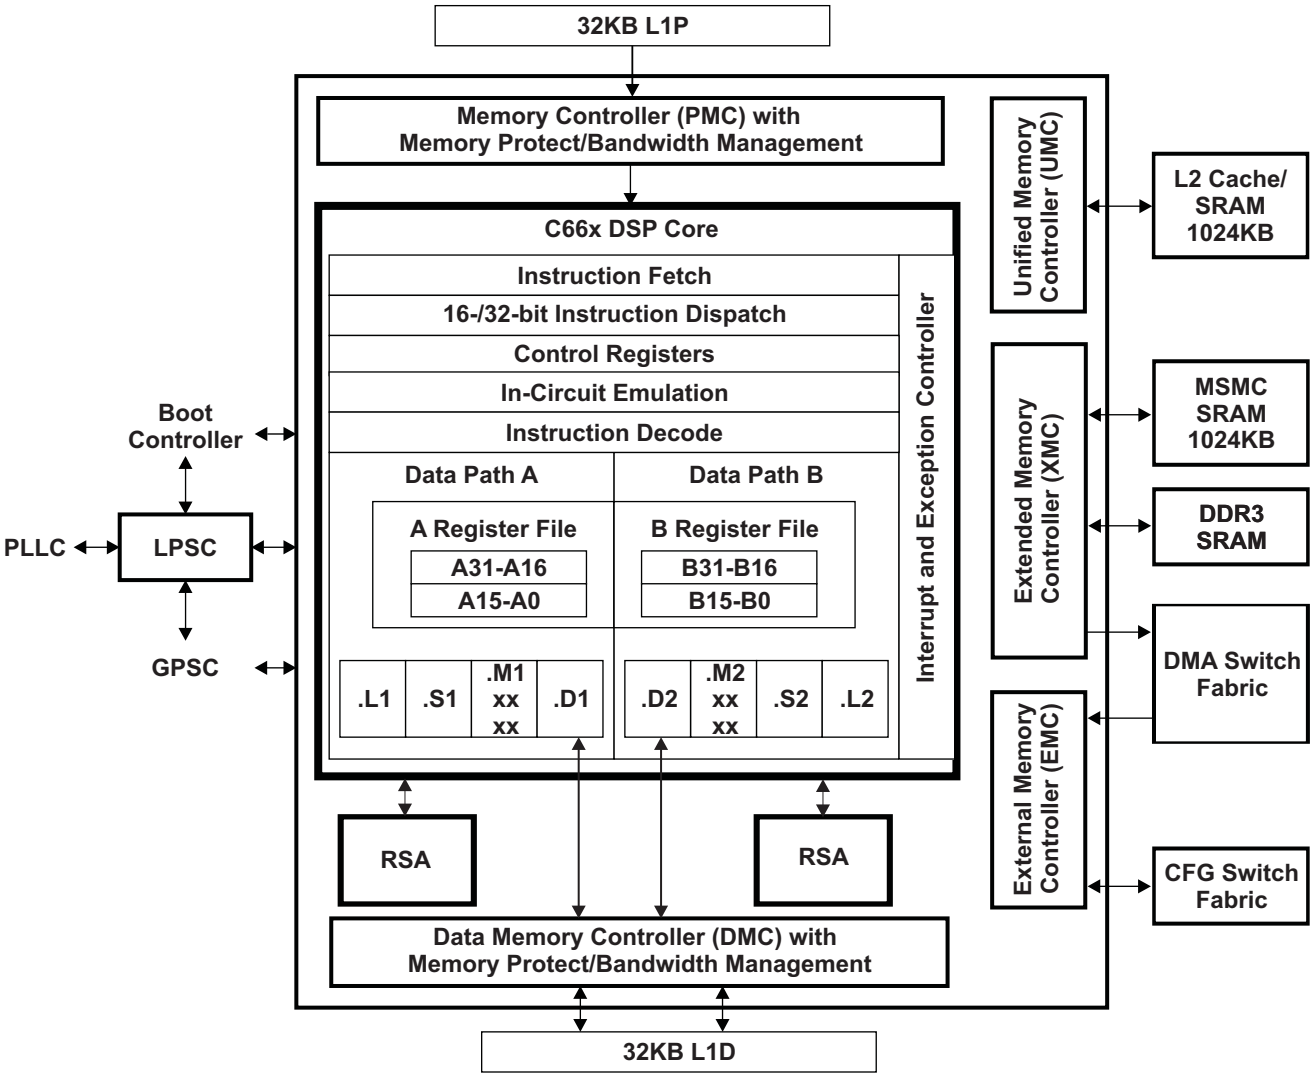
6.2.1 DSP Subsystem Overview

The DSP sybsystem (C66x CorePac) supports the following key features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program Memory Controller (PMC):
  - 32KB Level 1 Program (L1P) Cache/SRAM
- Data Memory Controller (DMC):
  - 32KB L1 Data (L1D) Cache/SRAM
- Unified Memory Controller (UMC):
  - 1024KB L2 Cache/SRAM
- External Memory Controller (EMC):
  - Internal DMA (IDMA) engine
  - One 128-bit VBUSM slave port from TeraNet_DMA
  - One 32-bit VBUSP master port to TeraNet_CFG
- XMC (Extended Memory Controller):
  - One 256-bit port to MSMC controller
- Multistream prefetch buffer
- Address extension/translation (32-bit to 36-bit)
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D
- Error Detection and Correction for all L2
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with Chip-level Interrupt Controller (CIC) for distribution of system interrupts to the C66x core. Interrupts can be routed directly to the C66x core or through the CIC module in a flexible manner
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
  - Support for halt mode, real time and monitor mode debug capabilities
  - Support for processor instruction trace and system trace (**printf**-style debug)
- Dedicated timer module (TIMER_0) for the C66x CorePac, integrated at SoC level. TIMER_0 can be used as either general-purpose timer or watchdog timer

Figure 6-13 shows an overview of the C66x CorePac.

Figure 6-13. C66x CorePac Overview



Fore more information about:

- C66x CorePac, see the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).
- C66x CPU core, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide* (SPRUGH7).
- C66x cache memory system, see the *TMS320C66x DSP Cache User Guide* (SPRUGY8).
- C66x debug/trace support, see Chapter 12, *On-Chip Debug*.

6.2.2 DSP Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Table 6-35 through Table 6-36 summarize the integration of the DSP subsystem.

Table 6-35. DSP Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
DSP	PD8	LPSC18	TeraNet

Table 6-36. DSP Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
DSP	DSP_CLK	CHIP_CLK1	PLL Controller	DSP Subsystem clock. It drives the various DSP internal resources via dividers (1/1; 1/2; 1/3; 1/4)
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
DSP	DSP_GRST	MOD_G_RST	LPSC18	Global Reset
	DSP_LRST	LRST	LPSC18	Local Reset
	DSP_POR_Z	POR	PSM8	Power on Reset
	GEM_TRSTZ			Reset from DEBUGSS

Refer to Chapter 5 for details on DSP power/clock/reset management.

6.2.2.1 DSP Interrupt Sources

Table 6-37 shows the C66x DSP interrupt sources.

Table 6-37. C66x DSP Interrupt Sources

Event No.	Event Source Name	Description
0	EVT0	C66x CorePac internal event
1	EVT1	C66x CorePac internal event
2	EVT2	C66x CorePac internal event
3	EVT3	C66x CorePac internal event
4	PRU-ICSS_0_HOST_INT0	PRU-ICSS_0 host interrupt 0
5	PRU-ICSS_1_HOST_INT0	PRU-ICSS_1 host interrupt 0
6	EDMACC_0_REGION_0_INT	EDMACC_0 region 0 DMA completion interrupt
7	EDMACC_1_REGION_0_INT	EDMACC_1 region 0 DMA completion interrupt
8	IPC_GR0	BOOT_CFG interprocessor communication register 0 interrupt
9	EMU_DTDMA	C66x CorePac internal event
10	MSMC_MPF_ERROR0	MSMC memory protection fault indicator for system master PrivID = 0 (C66x CorePac)
11	EMU_RTDXRX	C66x CorePac internal event
12	EMU_RTDXTX	C66x CorePac internal event
13	IDMA0	C66x CorePac internal event
14	IDMA1	C66x CorePac internal event
15	SEM_ERR0	Semaphore Master 0 error interrupt
16	SEM_INT0	Semaphore Master 0 grant interrupt
17	PCIE_INT4	PCIE interrupt 4

Table 6-37. C66x DSP Interrupt Sources (continued)

Event No.	Event Source Name	Description
18	RESERVED	Reserved
19	RESERVED	Reserved

6.2.3 DSP Subsystem Functional Description

For detailed DSP subsystem functional description, see the documents referenced in Section 6.2.1, *DSP Subsystem Overview*.

6.2.4 DSP Subsystem Registers

Table 6-38 lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in Table 6-38 should be considered as reserved locations and the register contents should not be modified. For base addresses of the DSP subsystem internal modules, see Chapter 2, *Memory Map*.

The C66x CorePac registers are described in detail in the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).

Table 6-38. C66x CorePac Registers

Offset	Acronym	Register Name
800000h to 80000Ch	EVTFLAG_0 to EVTFLAG_3	Event Flag Registers
800020h to 80002Ch	EVTSET_0 to EVTSET_3	Event Set Registers
800040h to 80004Ch	EVTCLR_0 to EVTCLR_3	Event Clear Registers

6.3 C66x Cache Subsystem

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* (SPRUGY8).

The device contains a 1024KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see Chapter 2, *Memory Map*).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a two-way set-associative cache, while L1P is a direct-mapped cache.

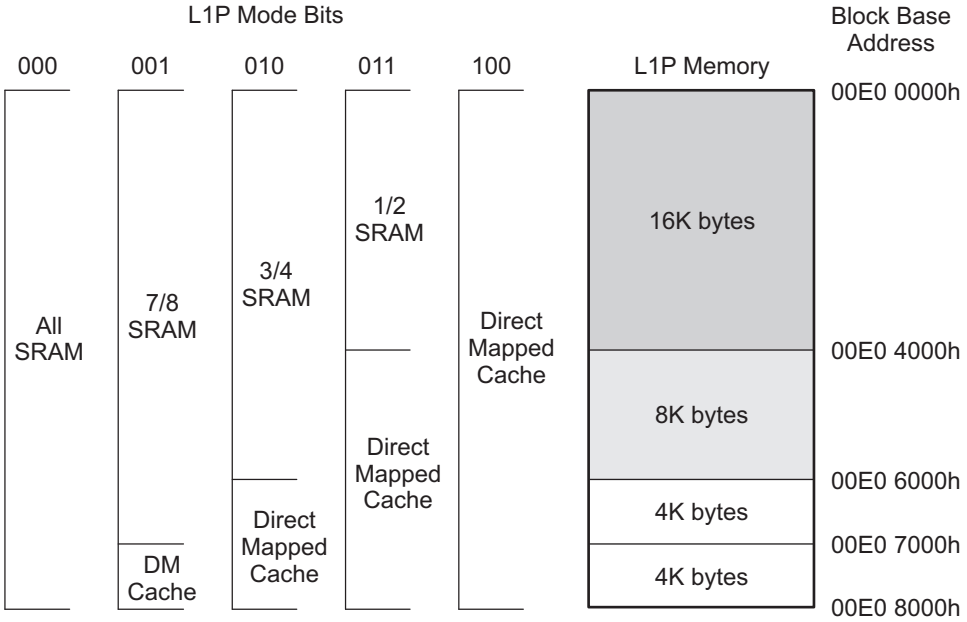
6.3.1 L1P Memory

The L1P memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states

Figure 6-14 shows the available SRAM/cache configurations for L1P.

Figure 6-14. L1P Memory Configurations



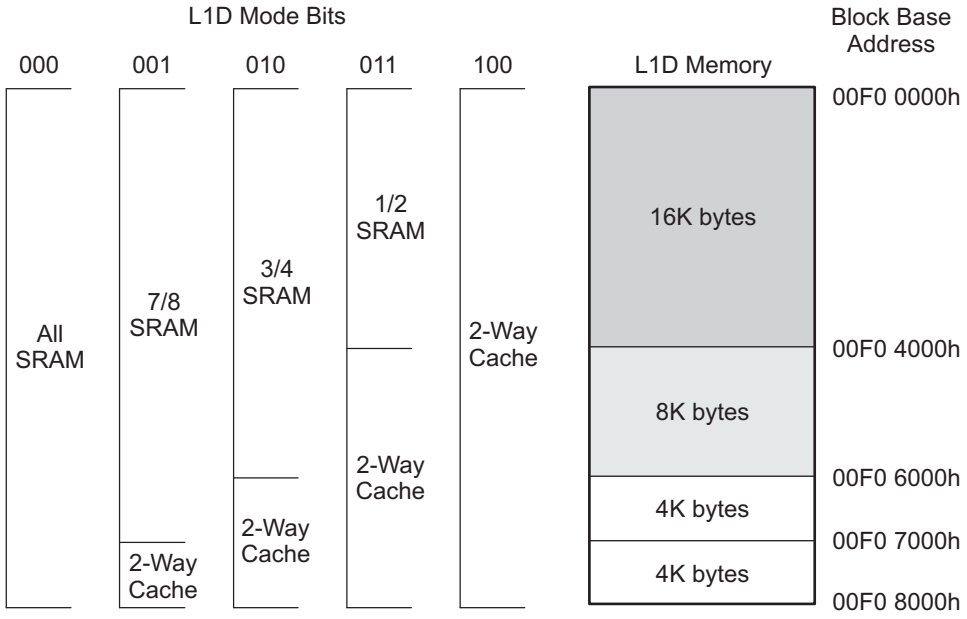
6.3.2 L1D Memory

The L1D memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states.

Figure 6-15 shows the available SRAM/cache configurations for L1D.

Figure 6-15. L1D Memory Configurations



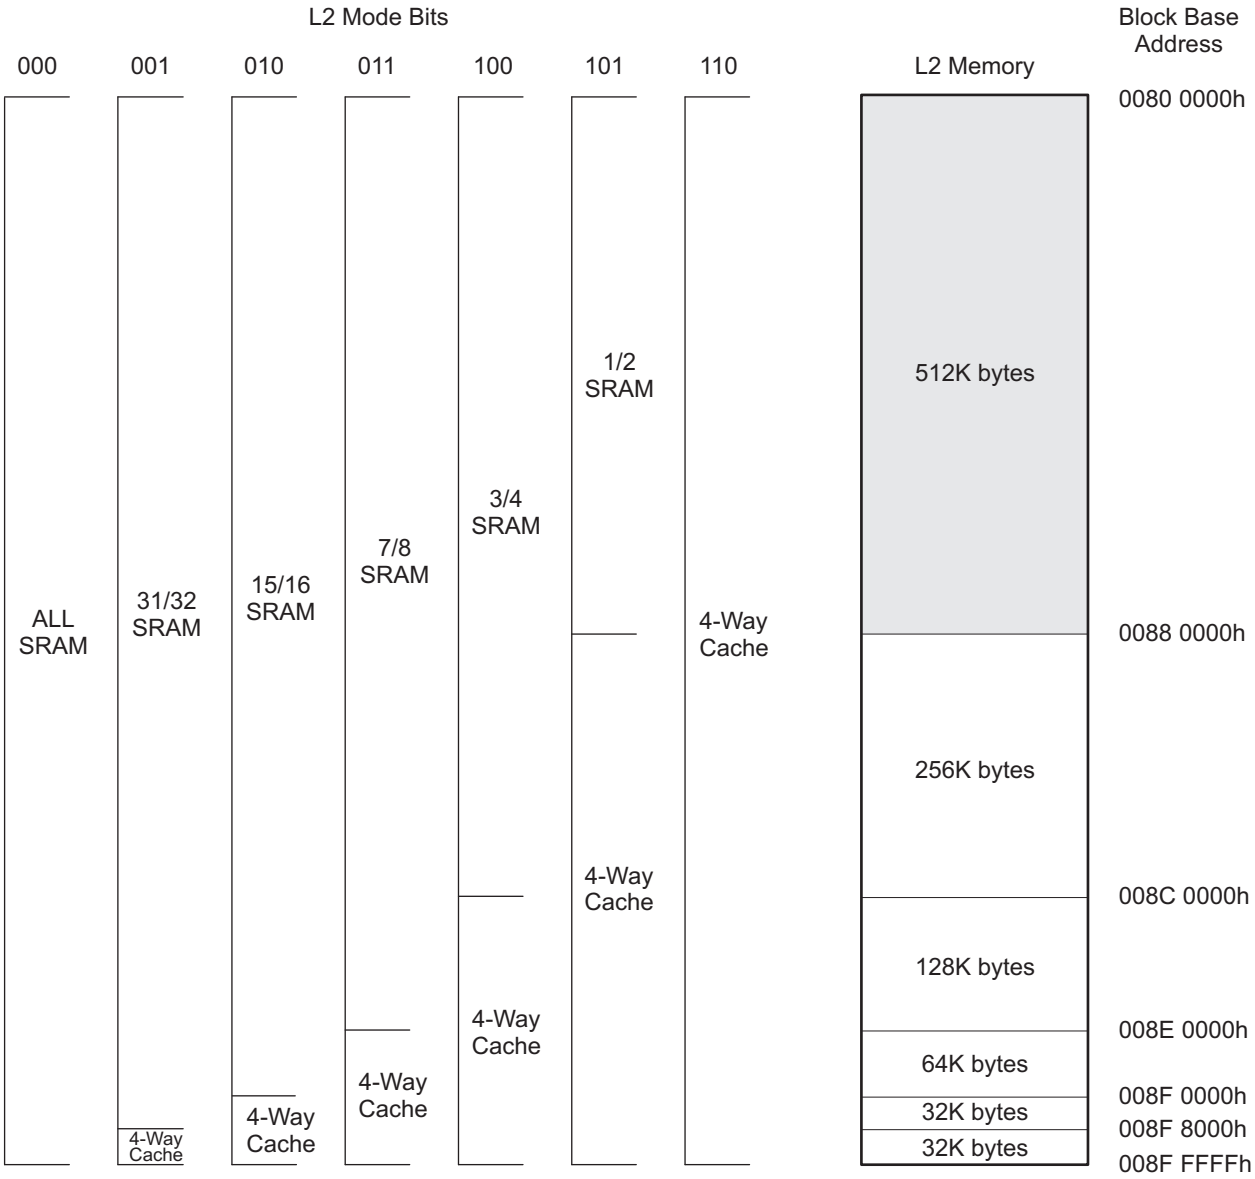
6.3.3 L2 Memory

The L2 memory configuration for this device is as follows:

- 1024KB of memory
- Local starting address is 0080 0000h.

L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac. Figure 6-16 shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

Figure 6-16. L2 Memory Configurations



6.3.4 DSP ECC configuration

The device supports ECC/parity on all DSP internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 6-39 summarizes the ECC/parity support in DSP.

Table 6-39. DSP ECC/Parity Support

DSP Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag	Parity
L1D Data RAM	ECC-SECDED (Single Error Correction, Double Error Detection)
L1D Tag	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag	ECC-SECDED

6.4 Programmable Real-Time Unit Subsystem and Industrial Communication Subsystem (PRU-ICSS)

This section describes the Programmable Real-Time Unit and Industrial Communication Subsystems (PRU-ICSS) in this device.

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

6.4.1 PRU-ICSS Overview

The Programmable Real-Time Unit Subsystem and Industrial Communication Subsystem (PRU-ICSS) consists of:

- Two 32-bit load/store RISC CPU cores — Programmable Real-Time Units (PRU0 and PRU1)
- Data RAMs per PRU core
- Instruction RAMs per PRU core
- Shared RAM
- Peripheral modules
- Interrupt controller (ICSS_INTC).

The programmable nature of the PRU cores, along with their access to pins, events and all device resources, provides flexibility in implementing fast real-time responses, specialized data handling operations, custom peripheral interfaces, and in offloading tasks from the other processor cores of the device.

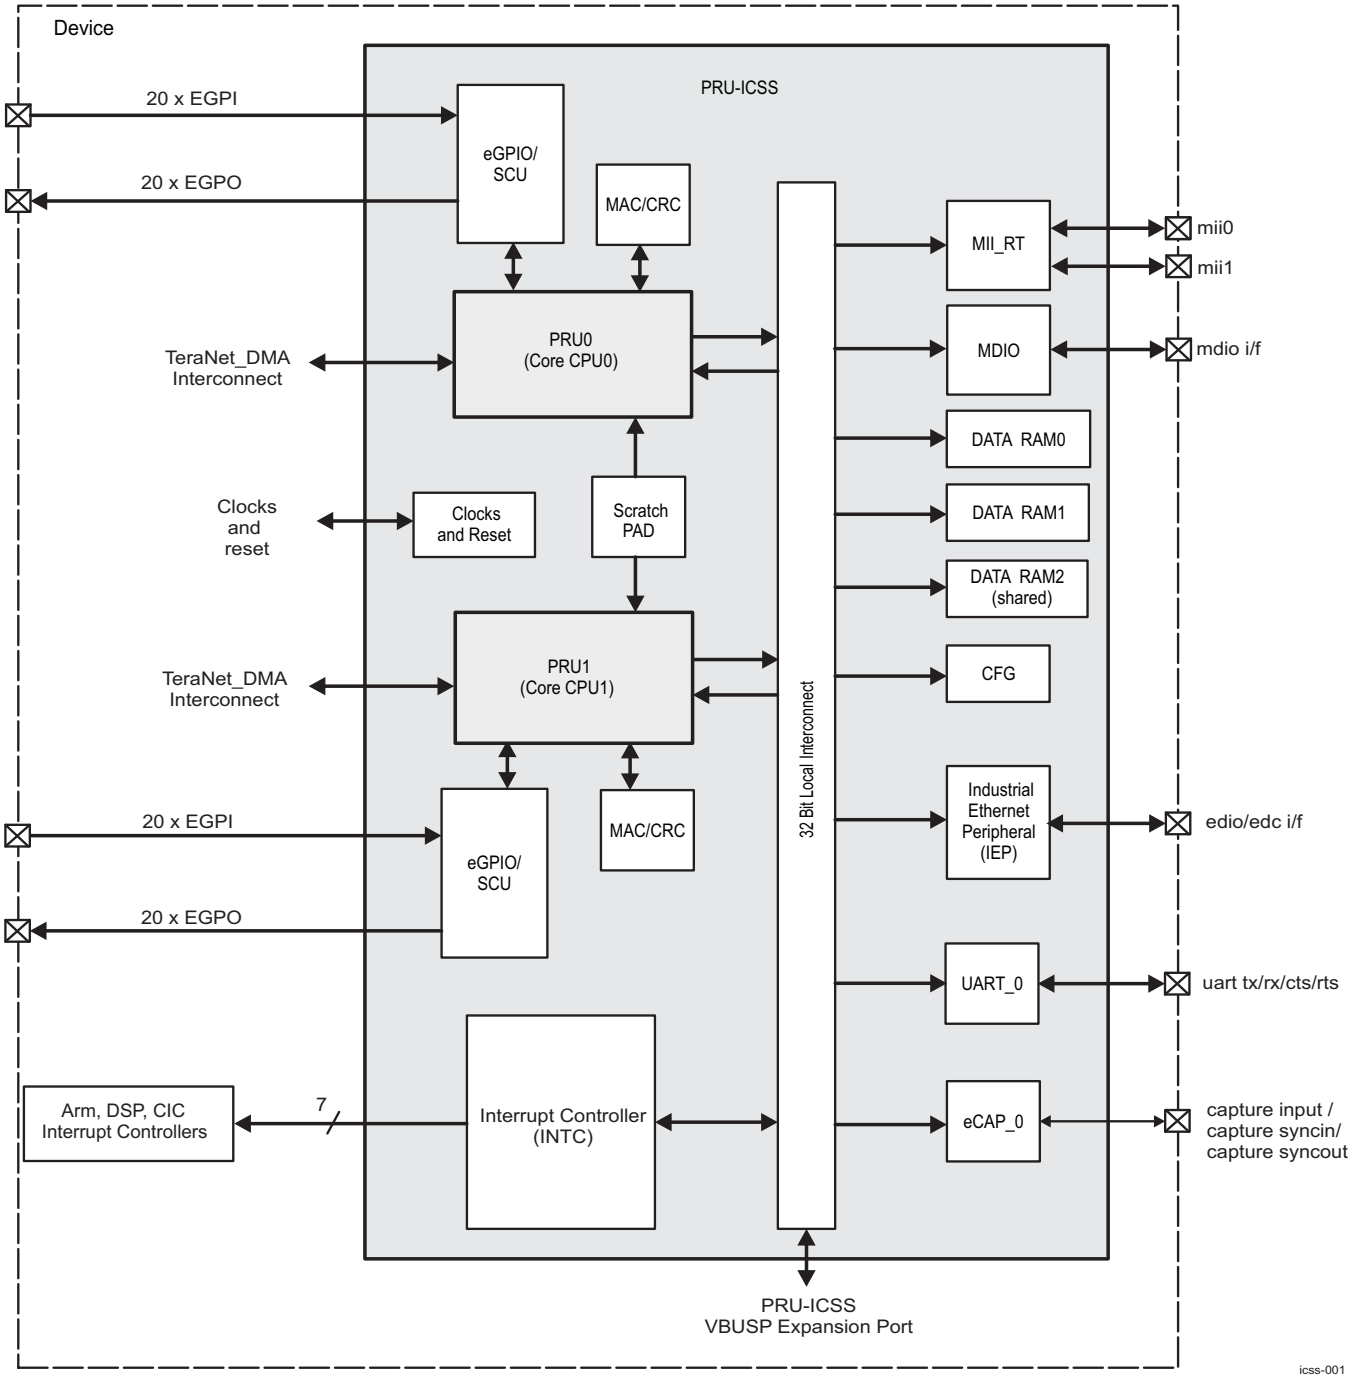
The device has integrated two identical PRU subsystems (PRU-ICSS_0 and PRU-ICSS_1).

The PRU cores within each PRU-ICSS have access to all resources on the SoC through the Interface Master port, and the external host processors can access the PRU-ICSS resources through the Interface Slave port. The 32-bit interconnect bus connects the various internal and external masters to the resources inside the PRU-ICSS. The PRU cores within the subsystems also have access to all resources on the SoC through the TeraNet DMA Interconnect. A subsystem local Interrupt Controller — ICSS_INTC handles system input events and posts events back to the device-level host CPUs.

The PRU cores are programmed with a small, deterministic instruction set. Each PRU can operate independently or in coordination with each other and can also work in coordination with the device-level host CPU. This interaction between processors is determined by the nature of the firmware loaded into the PRU's instruction memory.

Figure 6-17 shows an overview of the PRU subsystem.

Figure 6-17. PRU-ICSS Overview



6.4.1.1 PRU-ICSS Key Features

The PRU subsystem includes the following main features:

- Two PRU CPUs
  - 20 Enhanced General-Purpose Inputs (EGPI) and 20 Enhanced General-Purpose Outputs (EGPO)
  - Asynchronous capture [Serial Capture Unit (SCU)] with EnDat 2.2 protocol and Sigma-Delta demodulation support
    NOTE: There is no Sigma-Delta modulator inside the PRU. However, Sigma-Delta support is enabled through digital filtering hardware in the PRU to perform Sinc filtering.

  - Multiplier with accumulation (MAC)
  - CRC16/CRC32 HW accelerator
  - 16-KB program RAM per PRU CPU (signified IRAM0 for PRU0 and IRAM1 for PRU1) with ECC
  - 8-KB data RAM per PRU CPU (signified RAM0 for PRU0 and RAM1 for PRU1) with ECC
  - Two high-performance master (initiator) ports on the TeraNet_DMA interconnect — one per PRU
- 64-KB general purpose memory RAM (signified RAM2) with ECC, shared between PRU0 and PRU1
- One Scratch-Pad (SPAD) memory
  - 3 Banks of 30 × 32-bit registers
- Broadside direct connect between PRU cores within subsystem. Optional address translation for PRU transaction to External Host
- 16 software events generated by two PRUs
- One Ethernet MII_RT module (PRUSS_MII_RT_CFG) with two MII ports and configurable connections to PRUs
- One MDIO Port (PRUSS_MII_MDIO) to control external Ethernet PHY
- One Industrial Ethernet Peripheral (IEP) to manage/generate Industrial Ethernet functions
  - One Industrial Ethernet 64-bit timer with 9 capture and 16 compare events with slow and fast compensation
- 16550-compatible UART with a dedicated 192-MHz clock to support 12-Mbps PROFIBUS
- Enhanced Capture Module (eCAP_0)
- Interrupt Controller (ICSS_INTC)
  - Up to 64 input events supported
  - Supports up to to 10 interrupt channels
  - Generation of 10 Host interrupts: 2 Host interrupts to PRU0 and PRU1, 1 Host interrupt to PRU-ICSS_0 and PRU-ICSS_1, 7 Host interrupts exported from the ICSS for signaling the Arm interrupt controllers (pulse and level provided)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- One 32-bit VBUSP slave (target) port for memory mapped register and internal memories access
- Two (master and slave) 32-bit VBUSP ports for low-latency interface between PRU-ICSS subsystems
- Flexible power management support
- Integrated 32-bit interconnect
- All memories support ECC

PRU-ICSS unsupported features:

- Only 4 bits are supported of the 32-bit Industrial Ethernet Digital Data Input
- Only 4 bits are supported of the 32-bit Industrial Ethernet Digital Data Output
- UART Modem interface is not supported
- 12 Enhanced General-Purpose Inputs (pr<0/1>_pru0_gpi[31:20]) and 12 Enhanced General-Purpose Outputs (pr<0/1>_pru0_gpo[31:20])

6.4.2 PRU-ICSS Environment

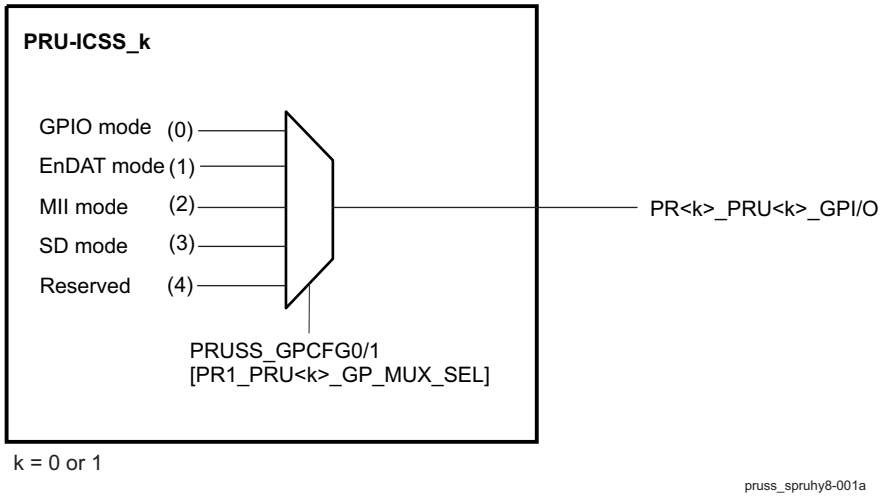
This section specifies the PRU-ICSS subsystem (top) interface signals to the device environment components.

6.4.2.1 PRU-ICSS I/O Interface

The PRU-ICSS_0 and PRU-ICSS_1 external interface signals are described in Table 6-40 and Table 6-41, respectively. The PRU-ICSS has a large number of available I/O signals. Most of these are multiplexed with other functional signals at the device level.

The PRU-ICSS_0 and PRU-ICSS_1 also support an internal wrapper multiplexing that expands the device top-level multiplexing. This wrapper multiplexing is controlled by the PRUSS_GPCFGx register (where x = 0 or 1) in the PRU-ICSS CFG register space and allows MII_RT, EnDAT, and Sigma Delta functionality to be muxed with the PRU GPI/O device signals, as shown in Figure 6-18. The PRU-ICSS wrapper multiplexing is described with the device-level signals in Table 6-40 and Table 6-41. Note that the device top-level muxing has higher priority over the internal wrapper muxing.

Figure 6-18. PRU-ICSS Internal Wrapper Multiplexing



NOTE: Additionally to PRU-ICSS wrapper multiplexing the device I/O logic maps the PRU-ICSS signals to the different device pads by programming in the BOOT_CFG Module. For more information, refer to theSection 5.1.3.1.1, *Pad Configuration Registers* in the Section 5.1, *BOOT_CFG*.

Table 6-40. PRU-ICSS_0 I/O Signals

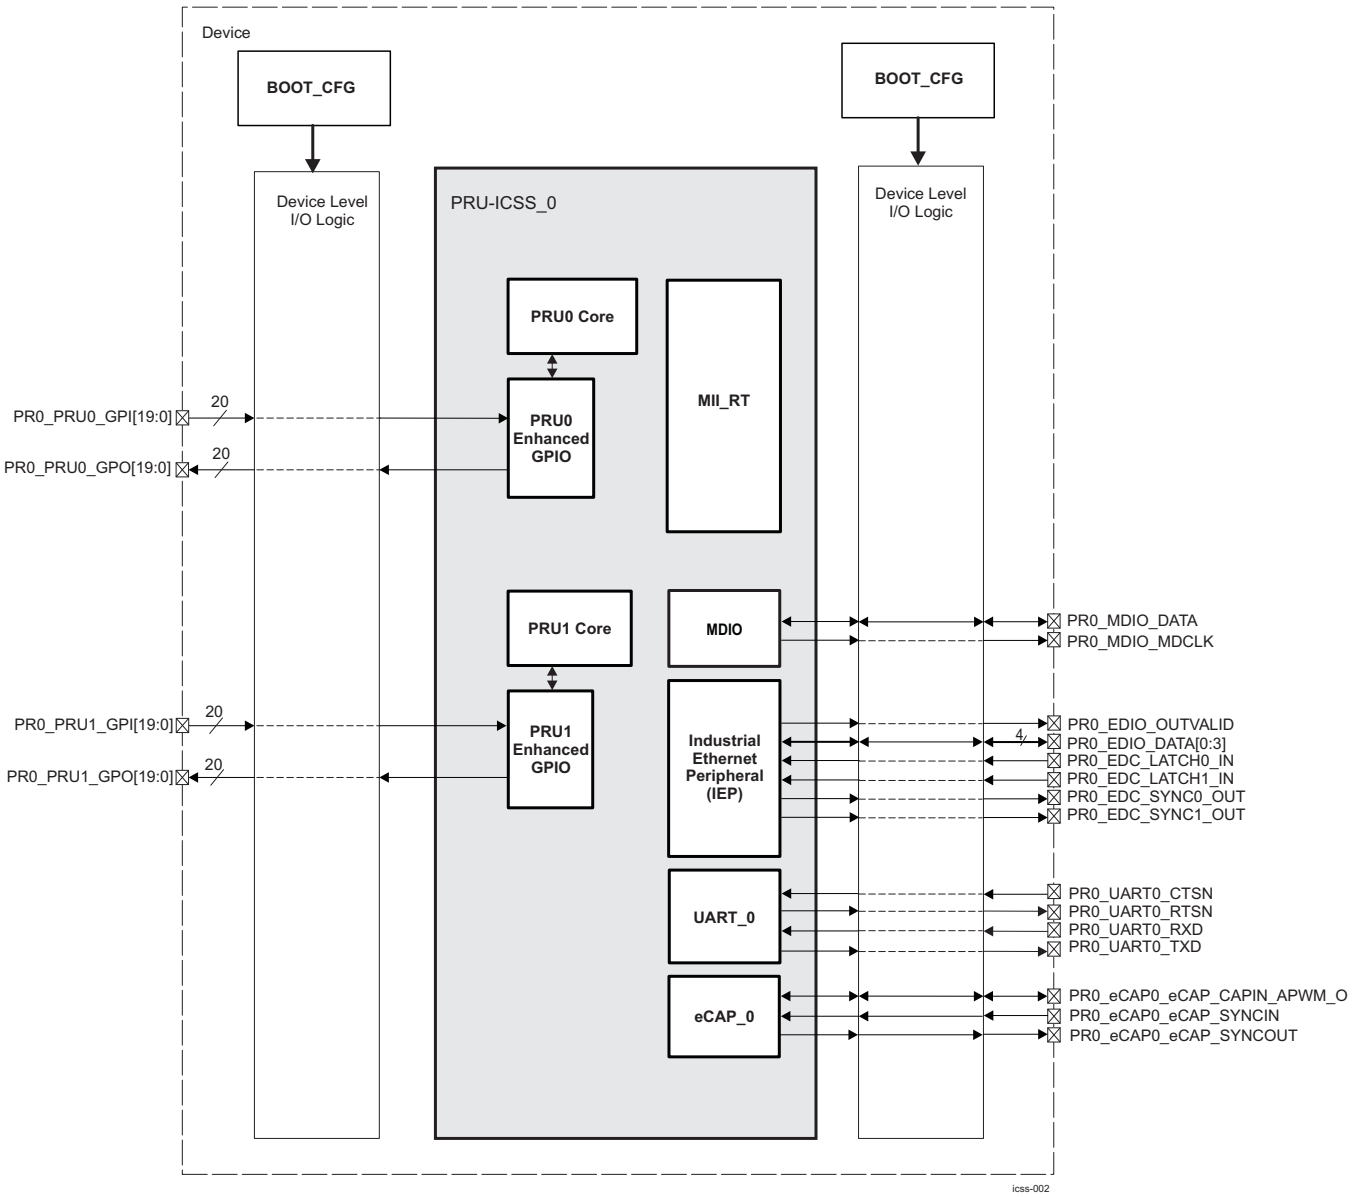
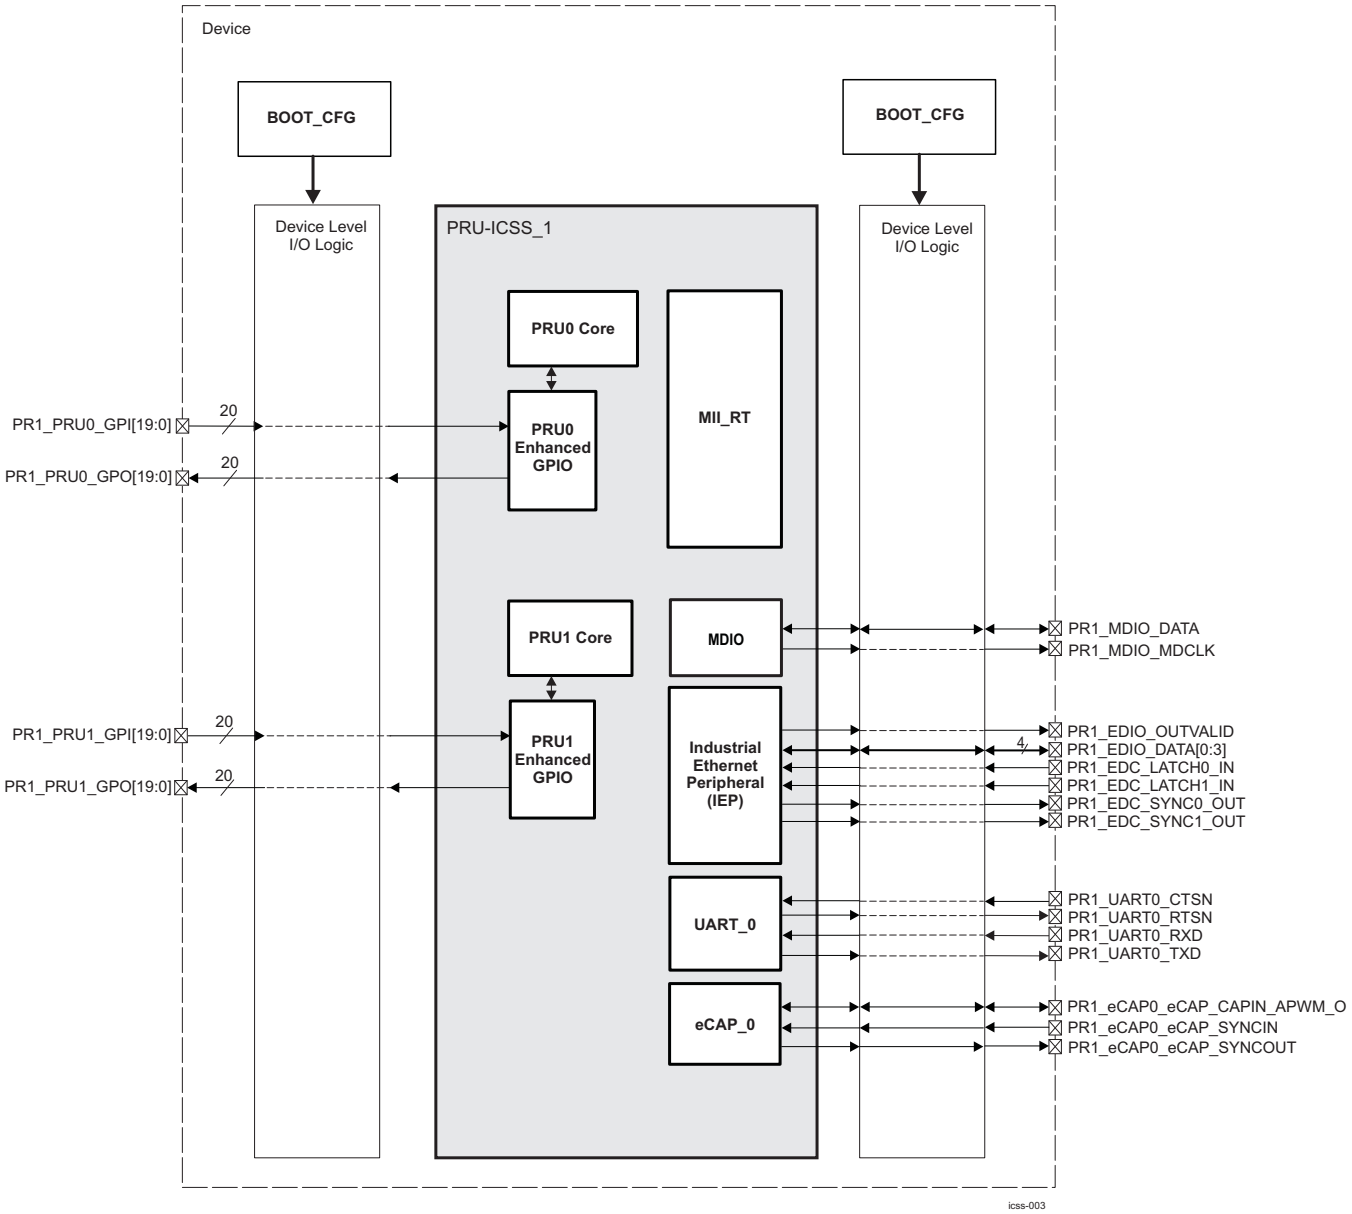
The below Figure 6-19 illustrates the PRU-ICSS_0 I/O interface signals at the device boundary.

Figure 6-19. PRU-ICSS_0 External Interface I/Os



The Figure 6-20 illustrates the PRU-ICSS_1 I/O interface signals at the device boundary.

Figure 6-20. PRU-ICSS_1 External Interface I/Os



6.4.3 PRU-ICSS Integration

The PRU-ICSS_0 and PRU-ICSS_1 subsystems integration in the device is shown in Figure 6-21 and Figure 6-22, respectively.

Figure 6-21. PRU-ICSS_0 Integration in the Device

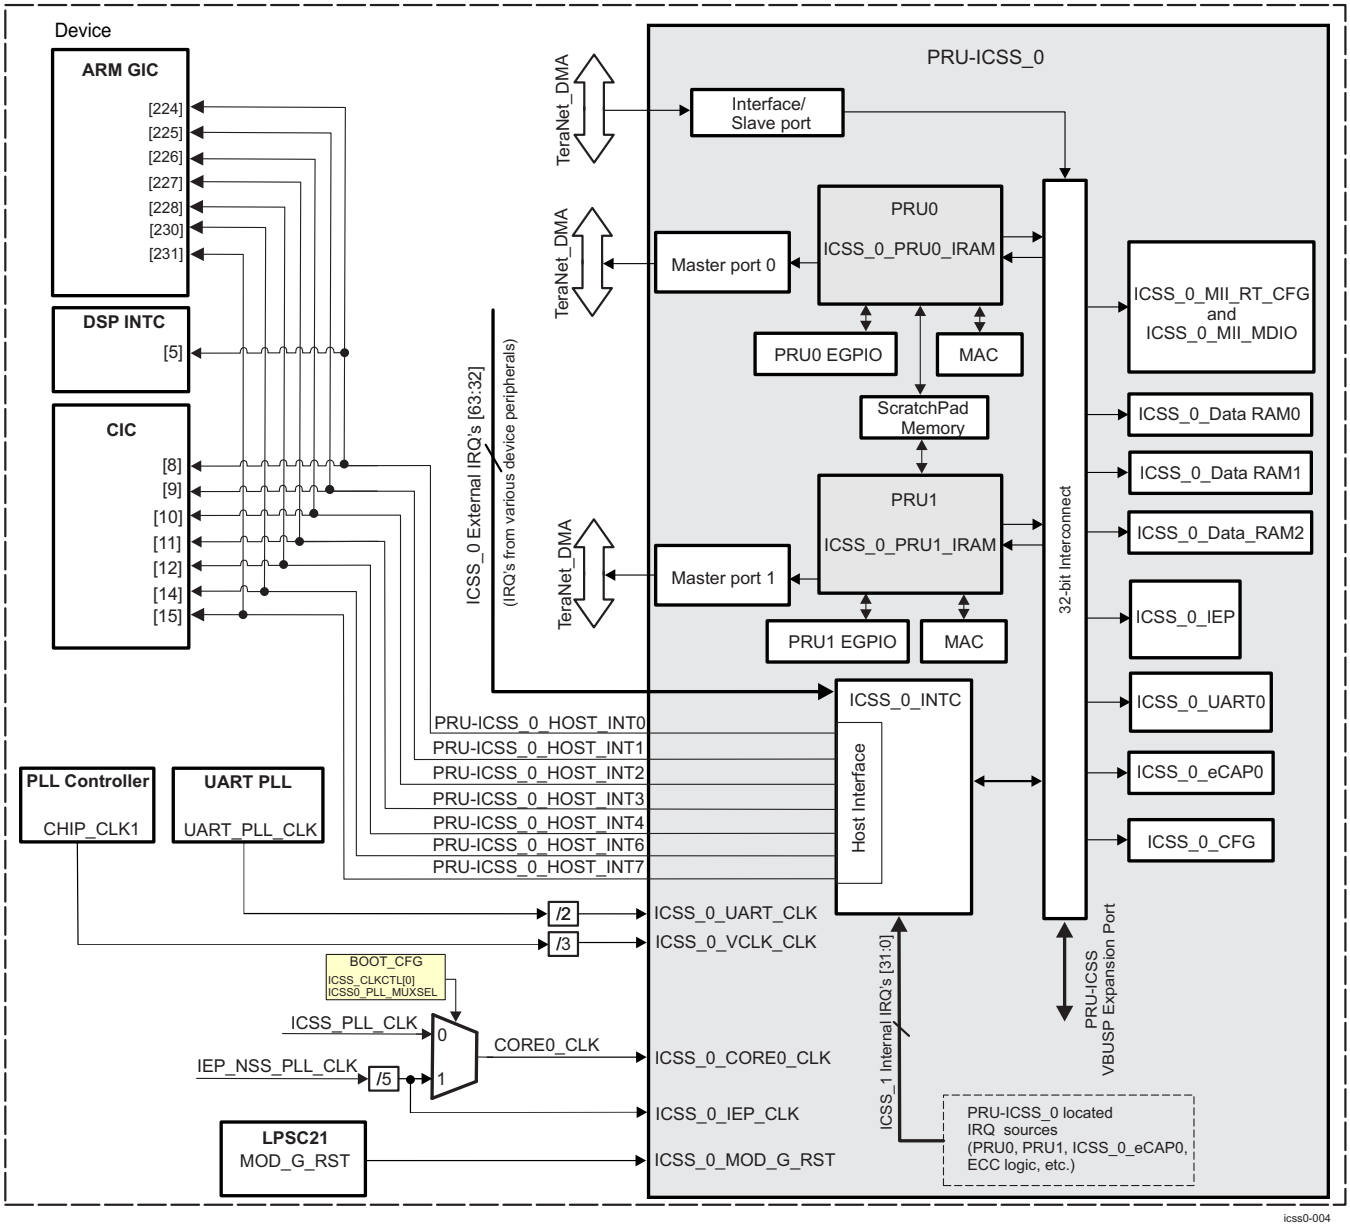


Figure 6-22. PRU-ICSS_1 Integration in the Device

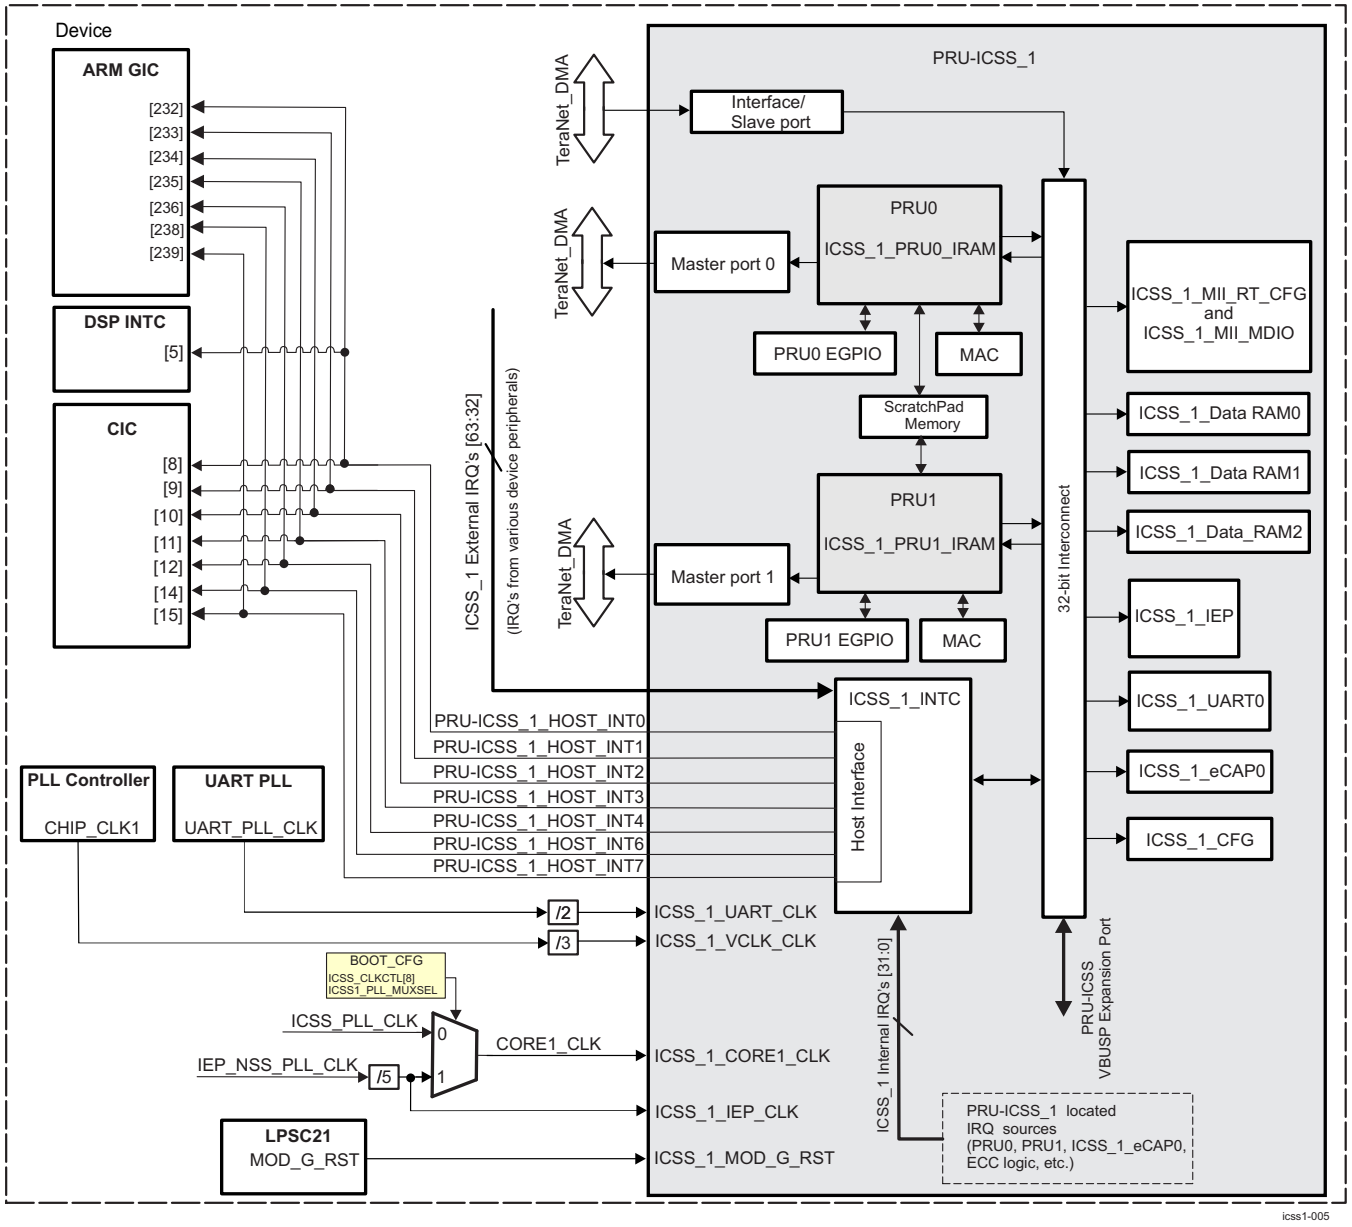

The PRU-ICSS_0 and PRU-ICSS_1 integration in the device features:

- PD11 power domain instantiation
- Two master ports (PRU0 and PRU1 core initiators) on the device TeraNet_DMA interconnect
- One slave (configuration) port on the TeraNet_DMA interconnect for device hosts (ARMSS, DSP, etc.) to access various memories and registers of PRU-ICSS
- 10 output interrupt events from local interrupt controller — ICSS_0_INTC/ ICSS_1_INTC:
  - 2 events to each PRU core (events 0 and 1)
  - 7 events mapped to the device interrupt controllers (PRU-ICSS_<0/1>_HOST_INT0 event through PRU-ICSS_<0/1>_HOST_INT4 and events PRU-ICSS_<0/1>_HOST_INT6 through PRU-ICSS_<0/1>_HOST_INT7)
  - 1 event for the other PRU-ICSS (pr<0/1>_host_intr5_intr_pend_req). For more information please see Table 6-369 and Table 6-370.
- A local software gating of clocks to several modules within PRU subsystem (local clock management

protocol), as follows:
  - PRU-ICSS_IEP
  - PRU-ICSS_eCAP0
  - PRU-ICSS_UART0
  - PRU-ICSS_INTC
  - PRU-ICSS_PRU0
  - PRU-ICSS_PRU1
- 4 input clocks obtained from device PLL Controller, IEP/ NSS PLL, UART PLL and ICSS PLL:
  - a PRU-ICSS VBUS interface clock
  - a PRU-ICSS IEP functional clock
  - a PRU-ICSS UART0 clock
  - a PRU-ICSS Core clock
- Two input PRUSS_MII_RT_CFG RX and 2 input PRUSS_MII_RT_CFG TX clocks passed as external clocks on device I/Os
- No memory/register retention is supported
- One hardware non-retention (level sensitive) reset

Table 6-42 through Table 6-44 summarize the integration of the module in the device.

Table 6-42. PRU-ICSS Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
PRU-ICSS_0	PD11	LPSC21	TeraNet_DMA
PRU-ICSS_1	PD11	LPSC21	TeraNet_DMA

6.4.4 PRU-ICSS Level Resources Functional Description

This section provides functional description of the device integrated PRU Subsystems modules.

6.4.4.1 PRU-ICSS Reset Management

The device supports warm reset isolation (Hard/Soft Reset, Watchdog Reset) on PRU-ICSS_0 and PRU-ICSS_1.

For more details on the PRU-ICSS Resets Isolation, see also the Section 5.3.10, *ICSS Reset Isolation*.

6.4.4.2 PRU-ICSS Power and Clock Management

The PRU-ICSS supports two levels of clock gating. First level gates all clocks inside the PRU-ICSS when requested by the PSC (Power Sleep Controller). The second level allows user software to enable/disable clocks in the clock gating register PRUSS_CGR to some internal modules, as follows:

- ICSS_0_IEP
- ICSS_0_eCAP0
- ICSS_0_UART0
- ICSS_0_INTC
- ICSS_0 PRU0 Core /ICSS_0_PRU0_IRAM
- ICSS_0 PRU1 Core /ICSS_0_PRU1_IRAM
- ICSS_1_IEP
- ICSS_1_eCAP0
- ICSS_1_UART0
- ICSS_1_INTC
- ICSS_1_PRU0 Core /ICSS_1_PRU0_IRAM
- ICSS_1_PRU1 Core/ICSS_1_PRU1_IRAM

The appropriate configuration registers block controls its local module set inside PRU-ICSS.

6.4.4.2.1 Module Clock Configurations at PRU-ICSS Top Level

IEP functional clock source selection: The clock source selection between ICSS_IEP_CLK (default) and ICSS_VCLK_CLK to the IEP module is done in register PRUSS_IEPCLK[0] OCP_EN in the PRUSS_CFG location. For more information on these PRU-ICSS level input clocks, refer to the Section 6.4.3.

Enhanced GPIO clock divider settings: In certain sample/shift clock settings of the PRU0 and PRU1 EGPIOs (when enabled in serial mode) two cascaded fractional dividers are done in the PRUSS_CFG top level configuration registers PRUSS_GPCFG0 and PRUSS_GPCFG1. In addition, EGPIO clock active edge selection control can be exerted via the bit PRU0_GPI_CLK_MODE for PRU0_EGPIO and PRU1_GPI_CLK_MODE for the PRU1_EGPIO.

- For the serial PRU0's EGPOs:
  - PRUSS_GPCFG0 [24-20]PRU0_GPO_DIV1
  - PRUSS_GPCFG0 [19-15]PRU0_GPO_DIV0
- For the serial PRU0's EGPIs:
  - PRUSS_GPCFG0 [12-8]PRU0_GPI_DIV1
  - PRUSS_GPCFG0 [7-3]PRU0_GPI_DIV0
- For the serial PRU1's EGPOs:
  - PRUSS_GPCFG1 [24-20]PRU1_GPO_DIV1
  - PRUSS_GPCFG1 [19-15]PRU1_GPO_DIV0
- For the serial PRU1's EGPIs:
  - PRUSS_GPCFG1 [12-8]PRU1_GPI_DIV1
  - PRUSS_GPCFG1 [7-3]PRU1_GPI_DIV0

6.4.4.3 Other PRU-ICSS Module Functional Registers at Subsystem Level

Enhanced GPIO. The other functional mode setting for PRUs EGPIOs at PRU-ICSS top registers level are:

- PRUSS_GPCFG0/PRUSS_GPCFG1 [14] PRU1_GPO_MODE — to select between direct or serial EGPO output mode of operation.
- PRUSS_GPCFG0/PRUSS_GPCFG1 [25] PRU1_GPO_SH_SEL — to select between the EGPO shadow registers 0 and 1 used for output shifting. For more details, refer to the Section 6.4.5.2.2.3.4, *Enhanced General-Purpose Module Outputs (R30)*.
- PRUSS_GPCFG0/PRUSS_GPCFG1 [1-0] PRU1_GPI_MODE — selects the EGPI input mode of operation (selects between "direct input", "parallel capture", "28-bit shift" or "MII_RT" modes).
- PRUSS_GPCFG0/PRUSS_GPCFG1 [13] PRU1_GPI_SB — **start bit event status for 28-bit EGPI input shift mode**. For more details, refer to the Section 6.4.5.2.2.3, *Enhanced General-Purpose Module Inputs (R31)*.

Enable address offset ("-0008 0000h") feature individually per PRU0 and PRU1 master ports in the PRUSS_PMAO register in case of accessing peripherals located in the PRU-ICSS space.

PRUSS_MII_RT_CFG interrupts mapping to PRU-ICSS_INTC is enabled in the PRUSS_MII_RT register.

PRUs scratchpad (SPAD) memory priority and configuration related bits are located in the PRUSS_SPP register.

6.4.4.4 PRU-ICSS Memory Maps

The PRU-ICSS comprises various distinct addressable regions that are mapped to both a local and global memory map. The local memory maps are maps with respect to the PRU point of view. The global memory maps are maps with respect to the Host point of view, but can also be accessed by the PRU-ICSS. Each PRU-ICSS can also access the memories within the other subsystem without going through an external port, thanks to PRU-ICSS VBUSP expansion port.

6.4.4.4.1 PRU-ICSS Local Memory Map

The PRU-ICSS memory map is documented in Table 6-45 (Instruction Space) and in Table 6-46 (Data Space). Note that these two memory maps are implemented inside the PRU-ICSS and are local to the components of the PRU-ICSS.

6.4.4.4.1.1 PRU-ICSS Local Instruction Memory Map

Each PRU has a dedicated 16 KB of Instruction Memory (16KB for PRU-ICSS_0, 16KB for PRU-ICSS_1) which needs to be initialized by an external to PRU-ICSS host processor before a PRU core executes any instructions.

CAUTION

The ICSS_0_PRU0/1_IRAM regions are ONLY accessible from masters, external to the PRU-ICSS (like Arm Cortex-A15, DSP, etc.) when the PRU0/PRU1 is NOT running. The access is via PRU-ICSS slave port on the device TeraNet_DMA interconnect.

Table 6-45. PRU-ICSS Local Instruction Memory Map

Start Address	PRU-ICSS_0		PRU-ICSS_1	
	PRU0	PRU1	PRU0	PRU1
0000 0000h	16 KB IRAM	16 KB IRAM	16 KB IRAM	16 KB IRAM

6.4.4.4.1.2 PRU-ICSS Local Data Memory Map

The local data memory map in Table 6-46 allows each PRU core to access the PRU-ICSS addressable regions (both its own subsystem and the other subsystem) and the external host's memory map.

The PRU accesses the other PRU-ICSS memory map through an VBUSP expansion port (External VBUSP port), starting at address 0004 0000h. The address seen by the other PRU-ICSS will be translated by hardware, subtracting 0004 0000h.

The PRU accesses the external Host memory map through the Interface Master port, starting at address 0008 0000h. By default, memory addresses between 0000 0000h–0007 FFFFh will correspond to the PRU-ICSS local address in Table 6-46. To access an address between 0000 0000h–0007 FFFFh of the external host map, the address offset of " –0008 0000h" feature is enabled through the PRUSS_PMAO[1] PMAO_PRU1 (for PRU1 core) and PRUSS_PMAO[0] PMAO_PRU0 (for PRU0 core) bits in the PRUSS_CFG subsystem level register space.

Table 6-46. PRU-ICSS Local Data Memory Map

Start Address	PRU-ICSS_0		PRU-ICSS_1

6.4.4.4.2 PRU-ICSS Global Memory Map

The global view of the PRU-ICSS internal memories and control ports is shown in Table 6-47. The offset addresses of each region are implemented inside the PRU-ICSS but the global device memory mapping places the PRU-ICSS slave port in the address range shown in the external PRU-ICSS Host top-level memory map.

The global memory map is with respect to the Host point of view (that is, device Arm Cortex-A15, DSP), but it can also be accessed by the PRU-ICSS_0/PRU-ICSS_1 itself. This is implemented via TeraNet_DMA redirecting PRU-ICSS master port traffic in the address range (0008 0000h–000B FFFFh) to the PRU-ICSS slave port when PMAO_PRU0/PMAO_PRU1 = '0b1'. Note that PRU0 and PRU1 can use either the local or global addresses to access their internal memories, but using the local addresses provides access time several cycles faster than using the global addresses. This is because when accessing via the global address the access has to be routed through the TeraNet_DMA switch fabric outside PRU-ICSS and back in through the PRU-ICSS slave port.

Example 1: PRU1 accesses its own data RAM — Data_RAM1 in the global space:

- The PRU1 CPU sets the PRUSS_PMAO[1] PMAO_PRU1 to 1 (using PRU1 local CFG address: 0002 6028h of that register) and generates destination address 0008 2000h. Thus, traffic passes through master port 1 towards PRU-ICSS_1 slave port over TeraNet_DMA to reach Data_RAM1 (location 0008 2000h - 0008 0000h = 0000 2000h in the Table 6-47).

Example 2: PRU1 accesses PRU0 data RAM — Data_RAM0 in the global space:

- The PRU1 CPU sets the PRUSS_PMAO[1] PMAO_PRU1 to 1 (using PRU1 local CFG MMR address: 0002 6028h of that register) and generates destination address 0008 0000h. Thus traffic passes through master port 1 towards PRU-ICSS1 slave port over TeraNet_DMA to reach Data_RAM0.

Example 4: PRU0 accesses a non-PRU-ICSS peripheral in the global space (address offset >= 2000 0000h):

- To access the MCASP1 config space the PRU0 keeps PRUSS_PMAO[0] PMAO_PRU0 at 0b0 and generates the MCASP1 CFG slave base address 2180 4400h. Thus traffic passes through Master port 0 and reaches MCASP1 config registers over TeraNet_DMA.

Example 5: ICSS_0_PRU1 host configures the PRU-ICSS_1 module ICSS_1_MII_RT:

- Note that in case of ICSS_0_PRU0 accessing a PRU-ICSS_1 peripheral, it must again disable the PMAO feature (writing at 0002 6028h PRUSS_PMAO[1] PMAO_PRU1 =0b0) and generate the physical address through its master port (1) adding global memory space offset of the IEP (0002 E000h from the Table 6-47) to the PRU-ICSS_1 TeraNet_DMA base address (20AC 0000h). The physical address generated from PRU-ICSS1 PRU1 therefore equals 20AE E000h).

Each of the PRU cores can access the rest of the device memory (including memory mapped peripheral and configuration registers) using the global memory space addresses.

Table 6-47. PRU-ICSS Global Memory Map

Offset Address	PRU-ICSS_0
	Target
0000 0000h	PRU-ICSS_0 Data 8 KB RAM0
0000 2000h	PRU-ICSS_0 Data 8 KB RAM1
0001 0000h	PRU-ICSS_0 Data 64 KB RAM2 (shared)
0002 0000h	PRU-ICSS_0 INTC
0002 2000h	PRU-ICSS_0 PRU0 Control
0002 2400h	PRU-ICSS_0 PRU0 Debug
0002 4000h	PRU-ICSS_0 PRU1 Control
0002 4400h	PRU-ICSS_0 PRU1 Debug
0002 6000h	PRU-ICSS_0 CFG
0002 7000h	PRU-ICSS_0 ECC_CFG
0002 8000h	PRU-ICSS_0 UART_0
0002 A000h	Reserved
0002 C000h	Reserved
0002 E000h	PRU-ICSS_0 IEP
0003 0000h	PRU-ICSS_0 eCAP_0
0003 2000h	PRU-ICSS_0 MII_RT_CFG
0003 2400h	PRU-ICSS_0 MII_MDIO
0003 4000h	PRU-ICSS_0 PRU0 16 KB IRAM
0003 8000h	PRU-ICSS_0 PRU1 16 KB IRAM
0004 0000h	External VBUSP port to PRU-ICSS_1

NOTE: The 0008_0000h-offset-subtraction feature must be enabled only in case of PRU global accesses (0008 0000h–000B FFFFh) to resources within the PRU subsystem. The PMAO feature must be disabled when accessing PRU-ICSS external locations.

6.4.4.5 PRU_ICSS_CFG Registers

Table 6-49 lists the memory-mapped registers for the PRU-ICSS subsystem. All register offset addresses not listed in Table 6-49 should be considered as reserved locations and the register contents should not be modified.

Table 6-48. PRU_ICSS_CFG Instances

Instance	Base Address
PRU_ICSS_0_CFG	20AA 6000h
PRU_ICSS_1_CFG	20AE 6000h

Table 6-72. PRUSS_SPP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	Reserved
1	XFR_SHIFT_EN	R/W	0h	Enables XIN XOUT shift functionality. When enabled, R0[4-0] (internal to PRU) defines the 32-bit offset for XIN and XOUT operations with the scratch pad. 0h: Disabled. 1h: Enabled.
0	PRU1_PAD_HP_EN	R/W	0h	Defines which PRU wins write cycle arbitration to a common scratch pad bank. The PRU which has higher priority will always perform the write cycle with no wait states. The lower PRU will get stalled wait states until higher PRU is not performing write cycles. If the lower priority PRU writes to the same byte has the higher priority PRU, then the lower priority PRU will over write the bytes. 0h: PRU0 has highest priority. 1h: PRU1 has highest priority.

PRU-ICSS Environment

6.4.5 PRU-ICSS PRU Cores

This section describes the functionality of the two Programmable Real-time Unit (PRU) processors (PRU0 and PRU1) integrated in each of the device PRU-ICSS.

6.4.5.1 PRU Cores Overview

The PRU is a processor optimized for performing embedded tasks that require manipulation of packed memory mapped data structures, handling of system events that have tight real-time constraints and interfacing with systems external to the SoC. The PRU is both very small and very efficient at handling such tasks.

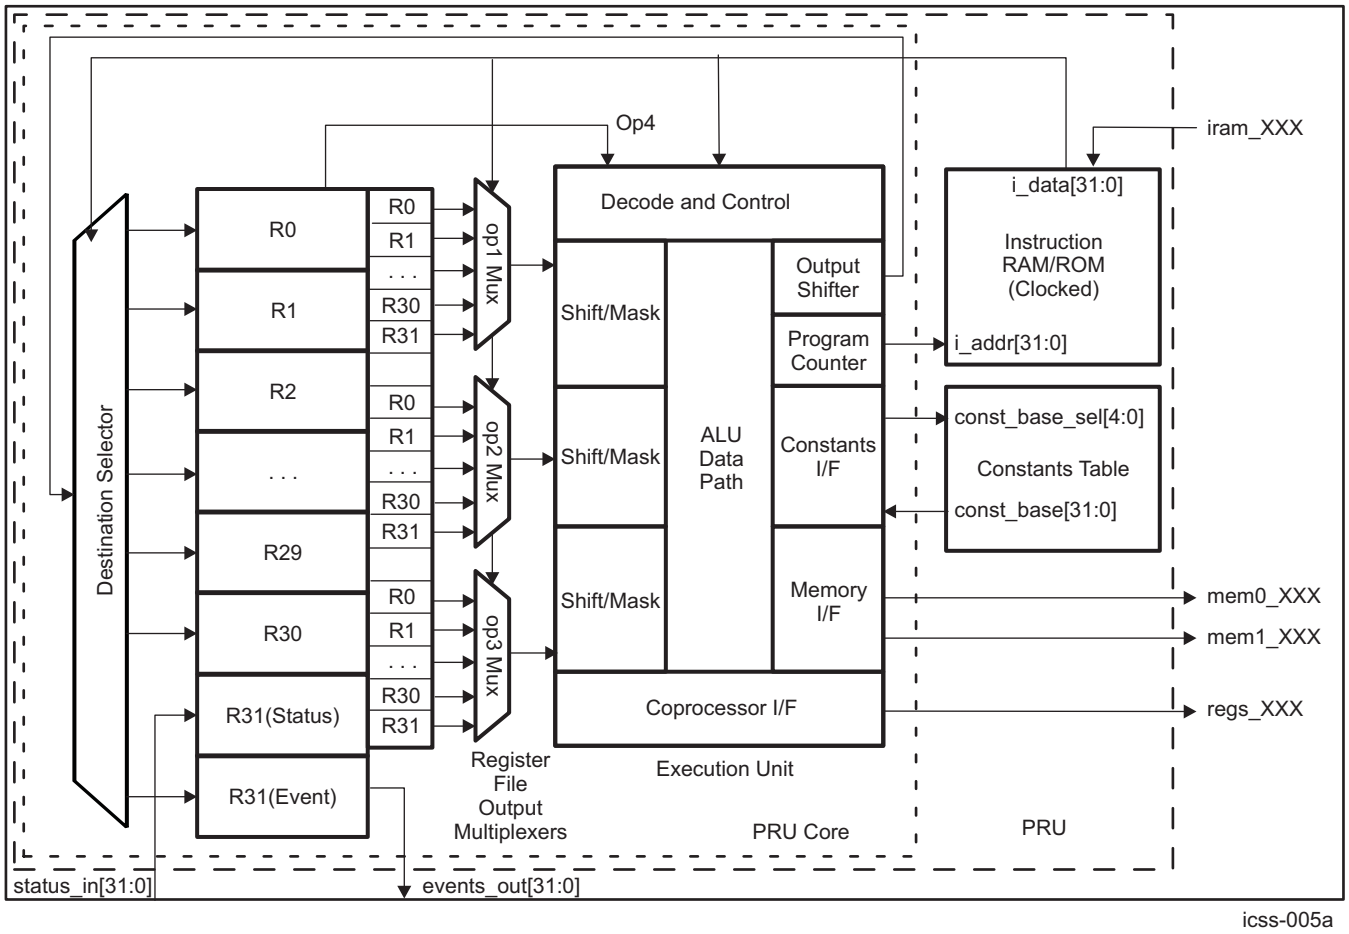
The major attributes of the PRU are in Table 6-77.

Table 6-77. PRU Features

Attribute	Value
IO Architecture	Load/Store
Data Flow Architecture	Register to Register
Core Level Bus Architecture	
Type	4-Bus Harvard (1 Instruction, 3 Data)
Instruction I/F	32-Bit
Memory I/F 0	32-Bit
Memory I/F 1	32-Bit
Execution Model	
Issue Type	Scalar
Pipelining	None (Purposefully)
Ordering	In Order
ALU Type	Unsigned Integer
Registers	
General Purpose (GP)	30 (R1 – R30)
External Status	1 (R31)
GP/Indexing	1 (R0)
Addressability in Instruction	Bit, Byte (8-bit), Half-word (16-bit), Word (32-bit), Pointer
Addressing Modes	
Load Immediate	16-bit Immediate
Load/Store – Memory	Register Base + Register Offset
	Register Base + 8-bit Immediate Offset
	Register Base with auto increment/decrement
	Constant Table Base + Register Offset
	Constant Table Base + 8-bit Immediate Offset
	Constant Table Base with auto increment/decrement
Data Path Width	32-bit
Instruction Width	32-bit
Accessibility to Internal PRU Structures	Provides 32-bit slave with three regions: • Instruction RAM • Control/Status registers • Debug access to internal registers (R0-R31) and constant table

The processor is based on a four-bus architecture which allows instructions to be fetched and executed concurrently with data transfers. In addition, an input is provided in order to allow external status information to be reflected in the internal processor status register. Figure 6-32 shows a block diagram of the processing element and the associated instruction RAM/ROM that contains the code that is to be executed.

Figure 6-32. PRU Block Diagram



6.4.5.2 PRU Cores Functional Description

This section describes the PRU cores supported functionality by describing the constant table, module interface and enhanced GPIOs.

6.4.5.2.1 PRUs Constant Table

The PRU Constants Table is a structure of hard-coded memory addresses for commonly used peripherals and memories. The constants table exists to more efficiently load/store data to these commonly accessed addresses by:

- Eliminating the PRU instruction that pre-loads a hard-coded address into the internal register file.
- Maximizing the usage of the PRU register file for embedded processing applications by moving many of the commonly used constant or deterministically calculated base addresses from the internal register file to an external table.

Table 6-78. PRU0/1 Constant Table

Entry No.	Region Pointed To	Value [31:0]
0	PRU-ICSS INTC (local)	0002_0000h
1	TIMER_1	0221_0000h
2	I2C_0	0253_0000h
3	PRU-ICSS eCAP (local)	0003_0000h
4	PRU-ICSS CFG (local)	0002_6000h
5	MMC0	2300_0000h
6	SPI0	2180_5400h
7	PRU-ICSS UART0 (local)	0002_8000h
8	MCASP_0 DMA	2180_4000h
9	NSSUL	0400_0000h
10	SEC_MGR	0250_0000h
11	UART_1	0253_1000h
12	UART_2	0253_1400h
13	CIC	0260_0000h
14	DCAN_0 CFG	0260_B200h
15	DCAN_1 CFG	0260_B400h
16	SPI1	2180_5800h
17	I2C_1	0253_0400h
18	EPWM_0	021D_0000h
19	ECAP_0	021D_1800h
20	PRU-ICSS_0, PRU-ICSS_1 IEP (Local) + 256MB	000A_E000h
21	PRU-ICSS MDIO (local)	0003_2400h
22	Semaphore	0264_0000h
23	Message Manager Queue Proxy Region5	02A5_0000h
24	PRU-ICSS PRU0/1 Data RAM (local)	0000_0n00h, n = c24_blk_index[3:0]
25	PRU-ICSS PRU1/0 Data RAM (local)	0000_2n00h, n = c25_blk_index[3:0]
26	PRU-ICSS IEP (local)	0002_En00h, n = c26_blk_index[3:0]
27	PRU-ICSS MII_RT (local)	0003_2n00h, n = c27_blk_index[3:0]
28	PRU-ICSS Shared RAM (local)	00nn_nn00h, nnnn = c28_pointer[15:0]
29	EDMA_0_CC_CFG	02nn_nn00h, nnnn = c29_pointer[15:0]
30	MSMC SRAM	0Cnn_nn00h, nnnn = c30_pointer[15:0]
31	DDR3A DATA	80nn_nn00h, nnnn = c31_pointer[15:0]

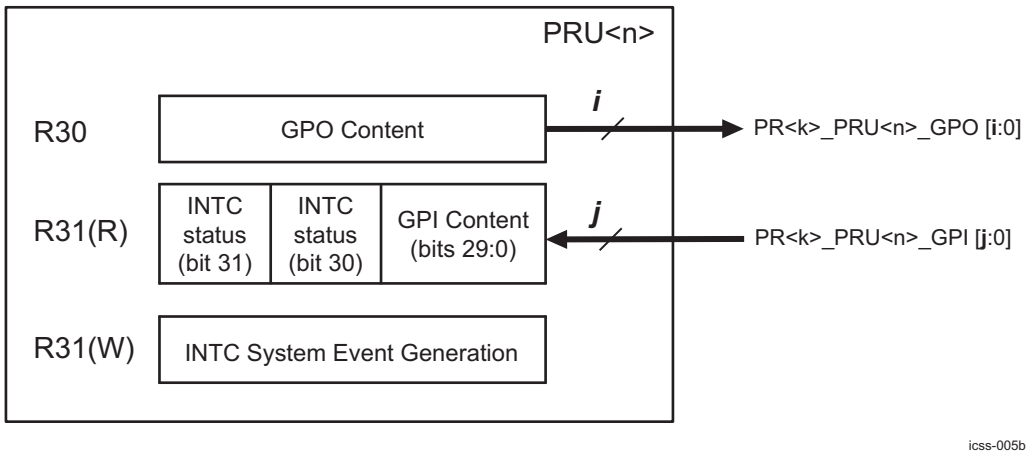
NOTE: The addresses in constants entries 24–31 are partially programmable. Their programmable bit field (for example, c24_blk_index[3:0]) is programmable through the PRU CTRL register space. As a general rule, the PRU should configure this field before using the partially programmable constant entries.

6.4.5.2.2 PRU Module Interface

The PRU module interface consists of the PRU internal registers 30 and 31 (R30 and R31). Figure 6-33 shows the PRU module interface and the functionality of R30 and R31. The register R31 serves as an interface with the dedicated PRU general purpose input (GPI) pins and ICSS_INTC. Reading R31 returns status information from the GPI pins and ICSS_INTC via the PRU Real Time Status Interface. Writing to R31 generates PRU system events via the PRU Event Interface. The register R30 serves as an interface with the dedicated PRU general purpose output (GPO) pins.

NOTE: The below sections cover different functional modes of the PRUn cores, (where n=0,1), enhanced GPIO (EGPIO) interface. The register bits which control EGPIO functionalities are part of the (PRUSS1_CFG and PRUSS2_CFG) space. For descriptions of these EGPIO register bitfield controls, refer to the Section 6.4.4.3.

Figure 6-33. PRU Module Interface



6.4.5.2.2.1 Real-Time Status Interface Mapping (R31): Interrupt Events Input

The PRU Real Time Status Interface directly feeds information into register 31 (R31) of the PRU's internal register file. The firmware on the PRU uses the status information to make decisions during execution. The status interface is comprised of signals from different modules inside of the PRU-ICSS which require some level of interaction with the PRU. More details on the Host interrupts imported into bit 30 and 31 of register R31 of both the PRUs is provided in the Section 6.4.6, *PRU-ICSS Local Interrupt Controller*.

Table 6-79. Real-Time Status Interface Mapping (R31) Field Descriptions

Bit	Field	Description
31	pru_intr_in[1]	PRU Host Interrupt 1 from local ICSS_INTC
30	pru_intr_in[0]	PRU Host Interrupt 0 from local ICSS_INTC
29:0	prun_r31_status[29:0]	Status inputs from primary input via Enhanced GPI port

6.4.5.2.2.2 Event Interface Mapping (R31): PRU System Events

This PRU Event Interface directly feeds pulsed event information out of the PRU's internal ALU. These events are exported out of the PRU-ICSS and need to be connected to the system interrupt controller at the SoC level. The event interface can be used by the firmware to create software interrupts from the PRU to the Host processor.

Figure 6-34. Event Interface Mapping (R31)

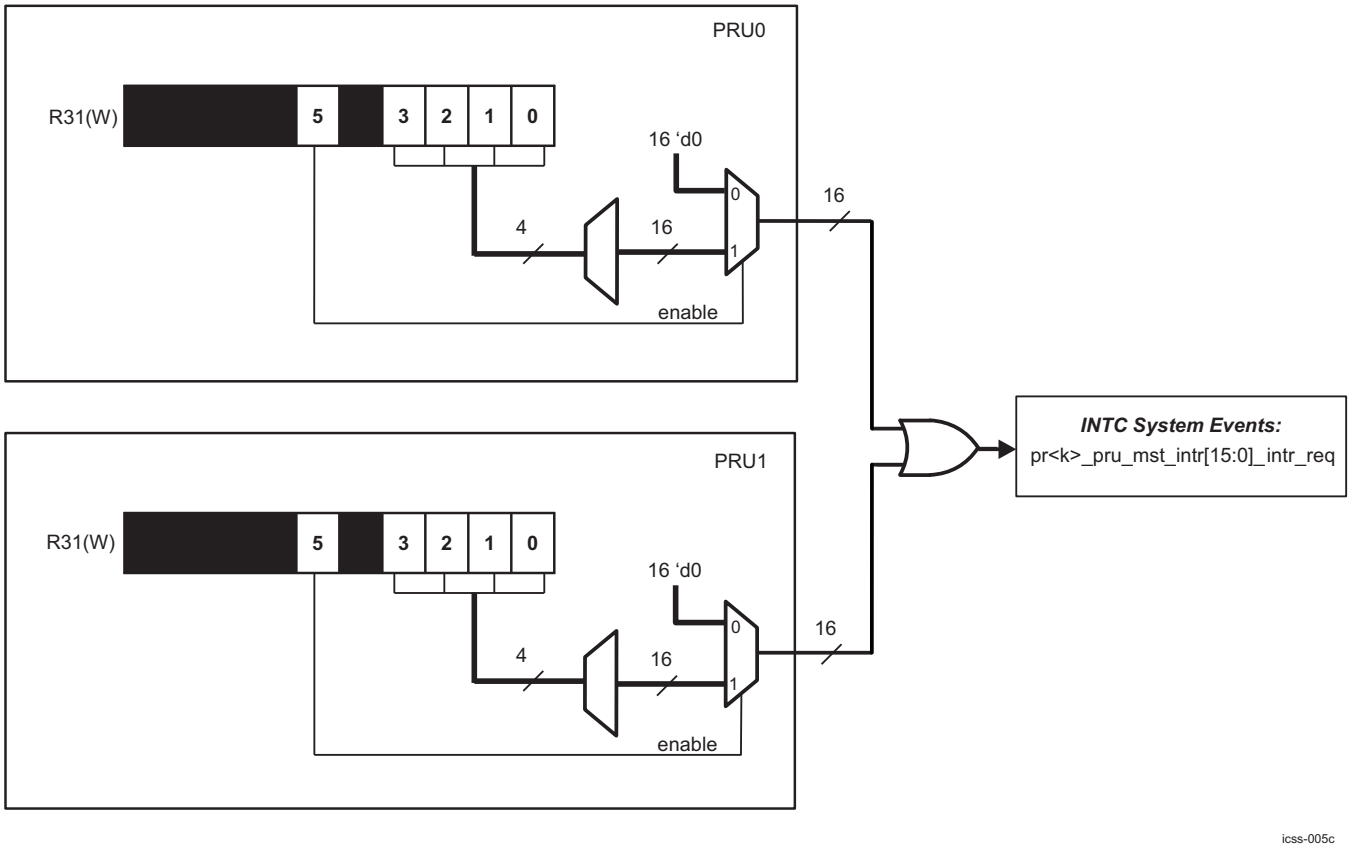


Table 6-80. Event Interface Mapping (R31) Field Descriptions

Bit	Field	Description
31:6	Reserved	
5	prun_r31_vec_valid	Valid strobe for vector output
4	Reserved	
3:0	prun_r31_vec[3:0]	Vector output

Simultaneously writing a '1' to prun_r31_vec_valid (R31 bit 5) and a channel number from 0 to 15 to prun_r31_vec[3:0] (R31 bits 3:0) creates a pulse on the output of the corresponding prk_pru_mst_intr[x]_intr_req INTC system event. For example, writing '100000' will generate a pulse on prk_pru_mst_intr[0]_intr_req, writing '100001' will generate a pulse on prk_pru_mst_intr[1]_intr_req, and so on to where writing '101111' will generate a pulse on prk_pru_mst_intr[15]_intr_req and writing '0xxxxx' will not generate any system event pulses. The output values from both PRU cores in a subsystem are ORed together.

The output channels 0-15 are connected to the ICSS_INTC system events 16-31, respectively. This allows the PRU to assert one of the system events 16-31 by writing to its own R31 register. The system event is used to either post a completion event to one of the host CPUs (Arm) or to signal the other PRU. The host to be signaled is determined by the system interrupt to interrupt channel mapping (programmable). The 16 events are named as prk_pru_mst_intr<15:0>_intr_req. See the Section 6.4.6.4, *PRU-ICSS Interrupt Requests Mapping* , in the section, *PRU-ICSS Local Interrupt Controller*, for more details.

6.4.5.2.2.3 General-Purpose Inputs (R31): Enhanced PRU GP Module

The PRU-ICSS implements an enhanced General Purpose Input/Output (GPIO) module with SCU that supports the following general-purpose input modes: direct input, 16-bit parallel capture, 28-bit serial shift in, and MII_RT. Register R31 serves as an interface with the general-purpose inputs. Table 6-81 describes the input modes in detail.

NOTE: Each PRU core can only be configured for one GPI mode at a time. Each mode uses the same R31 signals and internal register bits for different purposes. A summary is found in Table 6-82.

NOTE: The PRUSS_GPCFGn register, bitfield [29:26] PR1_PRUn_GP_MUX_SEL (where n = 0 or 1) in the PRU-ICSS CFG register space needs to be set to 0h for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and 3 channel Peripheral I/F mode.

Table 6-81. PRU R31 (GPI) Modes

Mode	Function	Configuration
Direct input	GPI[19:0] feeds directly into the PRU R31	Default state
16-bit parallel capture	DATAIN[0:15] is captured by the posedge or negedge of CLOCKIN	• Enabled by CFG_GPCFGn register • CLOCKIN edge selected by CFG_GPCFGn register
28-bit shift in	DATAIN is sampled and shifted into a 28-bit shift register. Shift Counter (Cnt_16) feature uses … • Shift Counter (Cnt_16) feature is mapped to pru<n>_r31_status[28]. • SB (Start Bit detection) feature is mapped to pru<n>_r31_status[29]	• Enabled by CFG_GPCFGn register • Cnt_16 is self clearing and is connected to the PRU INTC • Start Bit (SB) is cleared by CFG_GPCFGn register
MII_RT	mii_rt_r31_status [29:0] internally driven by the MII_RT module	Enabled by CFG_GPCFG0/1

Table 6-82. PRU GPI Signals and Configurations

Pad Names at Device Level[1]	GPI Modes		
	Direct input	Parallel Capture	28-Bit Shift in
PR<k>_PRU<n>_GPI0	GPI0	DATAIN0	DATAIN

PR<k>_PRU<n>_GPI11	GPI11	DATAIN11	
PR<k>_PRU<n>_GPI12	GPI12	DATAIN12	
PR<k>_PRU<n>_GPI13	GPI13	DATAIN13	
PR<k>_PRU<n>_GPI14	GPI14	DATAIN14	
PR<k>_PRU<n>_GPI15	GPI15	DATAIN15	

(1) These pins also being used for Sigma Delta or Peripheral I/F mode.

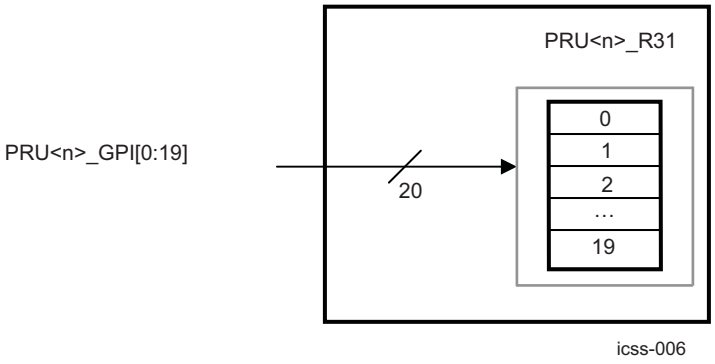
Table 6-82. PRU GPI Signals and Configurations (continued)

Pad Names at Device Level[1]	GPI Modes		
	Direct input	Parallel Capture	28-Bit Shift in
PR<k>_PRU<n>_GPI16	GPI16	CLOCKIN	
PR<k>_PRU<n>_GPI17	GPI17		
PR<k>_PRU<n>_GPI18	GPI18		
PR<k>_PRU<n>_GPI19	GPI19		

6.4.5.2.2.3.1 PRU EGPIs Direct Input

The prun_r31_status [0:19] bits of the internal PRU register file are mapped to device-level, general purpose input pins (PRUn_GPI [0:19]). In GPI Direct Input mode, PRUn_GPI [0:19] feeds directly to prun_r31_status [0:19]. Each PRU of the PRU-ICSS has a separate mapping to device input signals - PR0_PRU0_GPI[19:0] / PR1_PRU0_GPI[19:0] for the PRU-ICSS_0/ PRU-ICSS_1 PRU0 core and PR0_PRU1_GPI[19:0] / PR1_PRU1_GPI[19:0] for the PRU-ICSS_0/ PRU-ICSS_1 PRU1 core so that there are 40 total general purpose inputs to the PRU-ICSS_0/ PRU-ICSS_1 . For more details, refer also to the Section 6.4.2. See the device's system reference guide or datasheet for device specific pin mapping.

Figure 6-35. PRU R31 (EGPI) Direct Input Mode Block Diagram

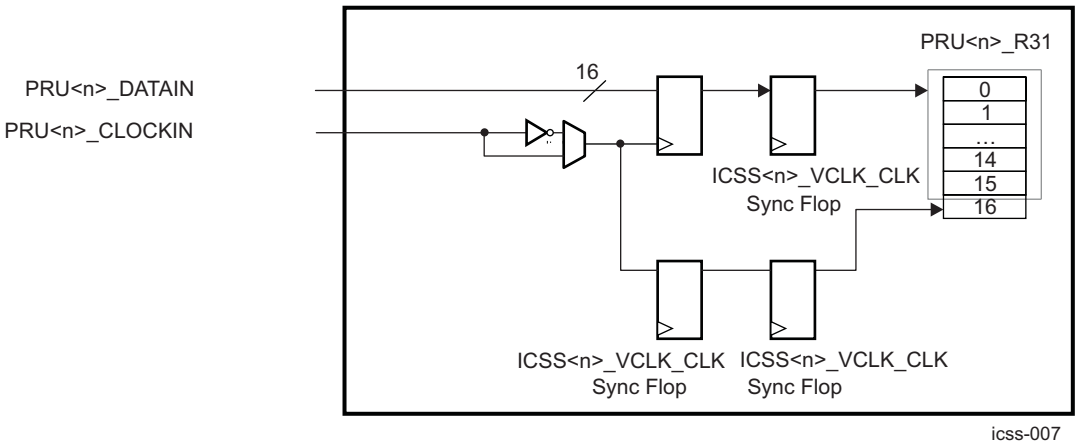


6.4.5.2.2.3.2 PRU EGPIs 16-Bit Parallel Capture

The prun_r31_status [0:15] and prun_r31_status [16] bits of the internal PRU register file mapped to device-level, general purpose input pins (PRUn_DATAIN [0:15] and PRUn_CLOCKIN, respectively). PRUn_CLOCKIN is designated for an external strobe clock, and is used to capture PRUn_DATAIN [0:15].

The PRUn_DATAIN can be captured either by the positive or the negative edge of PRUn_CLOCK, programmable through the PRU-ICSS CFG register space. If the clocking is configured through the PRU-ICSS CFG register to be positive, then it will equal PRU<n>_CLOCK; however, if the clocking is configured to be negative, then it will equal PRU<n>_CLOCK inverted.

Figure 6-36. PRU R31 (EGPI) 16-Bit Parallel Capture Mode Block Diagram



6.4.5.2.2.3.3 PRU EGPIs 28-Bit Shift In

In 28-bit shift in mode, the device-level, general-purpose input pin PRUn_DATAIN is sampled and shifted into a 28-bit shift register on an internal clock pulse. The register fills in LSB order (from bit 0 to 27) and then overflows into a bit bucket. The 28-bit register is mapped to prun_r31_status [0:27] and can be cleared in software through the PRU-ICSS CFG register space.

Note, the PRU will continually capture and shift the DATAIN input when the GPI mode has been set to 28-bit shift in.

The shift rate is controlled by the effective divisor of two cascaded dividers applied to the ICSS<n>_VCLK_CLK clock (150MHz/ 200MHz/ 225MHz). These cascaded dividers can each be configured through the PRU-ICSS CFG register space to a value of {1, 1.5, …, 16}. Table 6-83 shows sample effective clock values and the divisor values that can be used to generate these clocks.

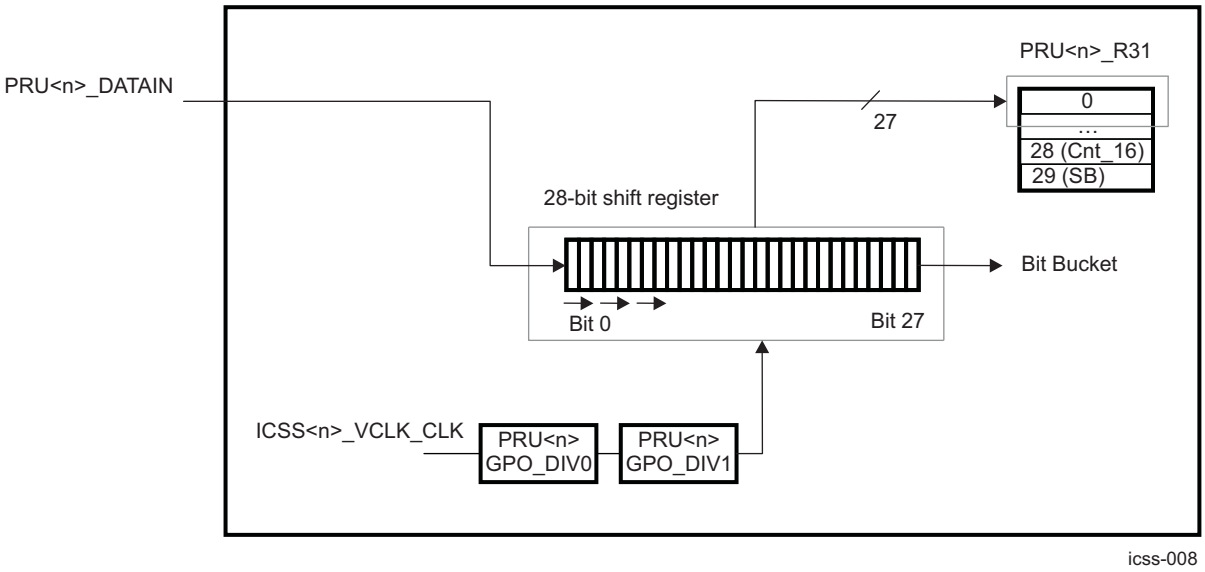
Table 6-83. PRU EGPIs Effective Clock Values

Generated clock	PRUn_GPI_DIV0	PRUn_GPI_DIV1
8-MHz	12.5 (17h)	2 (02h)
10-MHz	10 (12h)	2 (02h)
16-MHz	16 (1Eh)	1 (00h)
20-MHz	10 (12h)	1 (00h)

The 28-bit shift mode also supports the following features:

- SB (Start Bit detection) is mapped to prun_r31_status[29] and is set when the first 1 is captured on PRUn_DATAIN. The SB flag in pru<n>_r31_status[29] is cleared in software through the PRU-ICSS CFG register space.
- Cnt_16 (Shift Counter) is mapped to pru<n>_r31_status[28] and is set on every 16 shift clock samples after the Start Bit has been received. CNT_16 is self clearing and is connected to the ICSS_INTC. See the PRU-ICSS Interrupt Controller (ICSS_INTC) section for more details.

Figure 6-37. PRU R31 (EGPI) 28-Bit Shift Mode



6.4.5.2.2.3.4 General-Purpose Outputs (R30): Enhanced PRU GP Module

The PRU-ICSS implements an enhanced General Purpose Input/Output (GPIO) module that supports two general-purpose output modes: direct output and shift out.

Table 6-84 describes these modes in detail.

NOTE: Each PRU core can only be configured for one GPO mode at a time. Each mode uses the same R30 signals and internal register bits for different purposes. A summary is found in Table 6-84.

NOTE: The PRUSS_GPCFGn register, bitfield [29:26] PR1_PRUn_GP_MUX_SEL (where n = 0 or 1) in the PRU-ICSS CFG register space needs to be set to 0h for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and 3 channel Peripheral I/F mode.

Table 6-84. PRU R30 (EGPO) Output Mode

Mode	Function	Configuration
Direct output	pru<n>_r30[19:0] feeds directly to GPO[19:0]	Default state
Shift out	• pru<n>_r30[0] is shifted out on DATAOUT on every rising edge of pru<n>_r30[1] (CLOCKOUT). • LOAD_GPO_SH0 (Load Shadow Register 0) is mapped to pru<n>_r30[29]. • LOAD_GPO_SH1 (Load Shadow Register 1) is mapped to pru<n>_r30[30]. • ENABLE_SHIFT is mapped to pru<n>_r30[31].	Enabled by CFG_GPCFGn register

Table 6-85. GPO Mode Descriptions

Pad Names at Device Level (1)	GPO Modes	
	Direct output	Shift out
PR<k>_PRU<n>_GPO0	GPO0	DATAOUT

(1) These pins are also used for Sigma Delta or Peripheral I/F mode.

Table 6-85. GPO Mode Descriptions (continued)

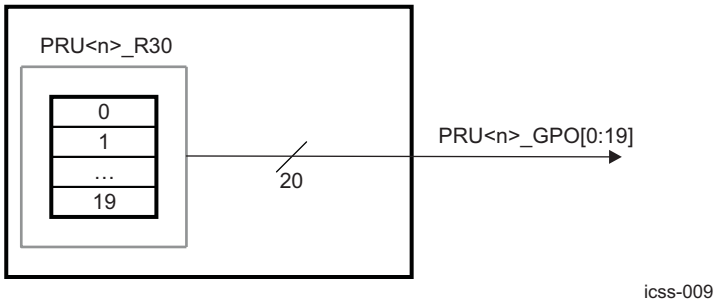
PR<k>_PRU<n>_GPO19	GPO19	

6.4.5.2.2.3.4.1 PRU EGPOs Direct Output

The prun_r30 [19:0] bits of the internal PRU register files are mapped to device-level, general-purpose output pins (PRUn_GPO[0:19]). In GPO Direct Output mode, prun_r30[0:19] feed directly to PRUn_GPO[0:19]. Each PRU of the PRU-ICSS has a separate mapping to pins, so that there are 40 total general-purpose outputs from the PRU-ICSS. See the device's system reference guide or datasheet for device-specific pin mapping.

Figure 6-38. PRU R30 (EGPO) Direct Output Mode Block Diagram



NOTE: R30 is not initialized after reset. To avoid unintended output signals, R30 should be initialized before pinmux configuration of PRU signals.

6.4.5.2.2.3.4.2 PRU EGPO Shift Out

In shift out mode, data is shifted out of prun_r30[0] (PRUn_DATAOUT) on every rising edge of prun_r30[1] (PRUn_CLOCK). The shift rate is controlled by the effective divisor of two cascaded dividers applied to the ICSS<n>_VCLK_CLK clock (150MHz/ 200MHz/ 225MHz). These cascaded dividers can each be configured through the PRU-ICSS CFG register space to a value of {1, 1.5, …, 16}. Table 6-86 shows sample effective clock values and the divisor values that can be used to generate these clocks. Note that PRUn_CLOCKOUT is a free-running clock that starts when the PRU GPO mode is set to shift out mode.

Table 6-86. Effective Clock Values

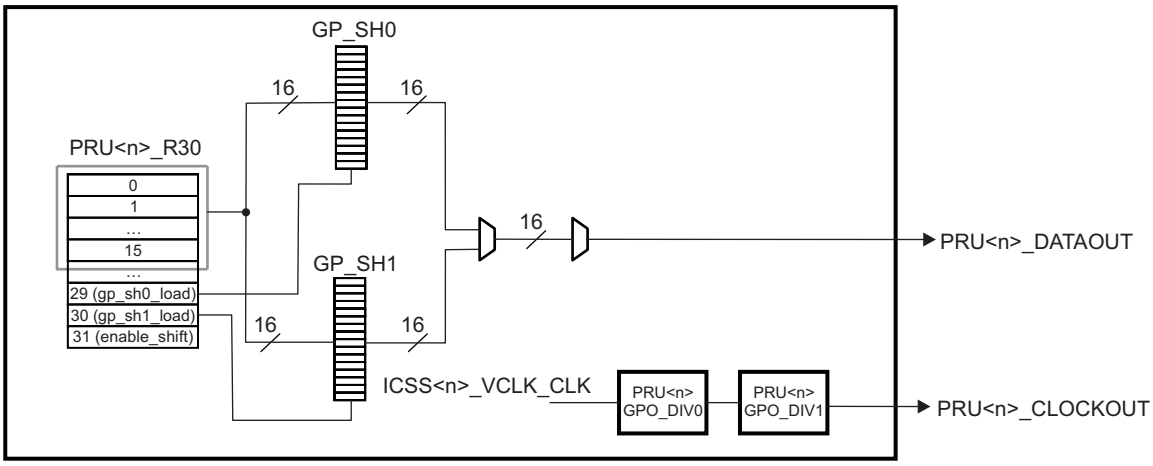
Generated Clock	PRUn_GPO_DIV0	PRUn_GPO_DIV1
8 MHz	12.5 (17h)	2 (02h)
10 MHz	10 (12h)	2 (02h)
16 MHz	16 (1Eh)	1 (00h)
20 MHz	10 (12h)	1 (00h)

Shift out mode uses two 16-bit shadow registers (gpo_sh0 and gpo_sh1) to support ping-pong buffers. Each shadow register has independent load controls programmable through prun_r30[29:30] (PRUn_LOAD_GPO_SH [0:1]). While PRUn_LOAD_GPO_SH [0/1] is set, the contents of prun_r30[0:15] are loaded into gpo_sh0/1.

NOTE: If any device-level pins mapped to prun_r30[2:15] are configured for the prun_r30 [2:15] pinmux mode, then these pins will reflect the shadow register value written to prun_r30. Any pin configured for a different pinmux setting will not reflect the shadow register value written to prun_r30.

The data shift will start from the LSB of gpo_sh0 when prun_r30[31] (PRUn_ENABLE_SHIFT) is set. Note that if no new data is loaded into gpo_shnn after shift operation, the shift operation will continue looping and shifting out the pre-loaded data. When PRUn_ENABLE_SHIFT is cleared, the shift operation will finish shifting out the current shadow register, stop, and then reset.

Figure 6-39. PRU R30 (GPO) Shift Out Mode Block Diagram



icss-010

Follow these steps to use the GPO shift out mode:

Step One: Initialization

1. Load 16-bits of data into gpo_sh0:
   (a) Set R30[29] = 1 (PRUn_LOAD_GPO_SH0)
   (b) Load data in R30[15:0]
   (c) Clear R30[29] to turn off load controller

2. Load 16-bits of data into gpo_sh1:
   (a) Set R30[30] = 1 (PRUn_LOAD_GPO_SH1)
   (b) Load data in R30[15:0]
   (c) Clear R30[30] to turn off load controller
3. Start shift operation:
   (a) Set R30[31] = 1 (PRUn_ENABLE_SHIFT)

Step 2: Shift Loop

1. Monitor when a shadow register has finished shifting out data and can be loaded with new data:
   (a) Poll PRUn_GPI_SH_SEL bit of the GPCFGn register
   (b) Load new 16-bits of data into gpo_sh0 if PRUn_GPI_SH_SEL = 1
   (c) Load new 16-bits of data into gpo_sh1 if PRUn_GPI_SH_SEL = 0
2. If more data to be shifted out, loop to Shift Loop
3. If no more data, exit loop

Step 3: Exit

1. End shift operation:
   (a) Clear R30[31] to turn off shift operation

NOTE: Until the shift operation is disabled, the shift loop will continue looping and shifting out the pre-loaded data if no new data has been loaded into gpo_shn.

6.4.5.2.2.3.5 Sigma Delta (SD) Decimation Filtering H/W

Sigma-delta Sinc filtering is achieved by the combination of PRU hardware and firmware. PRU hardware provides hardware integrators that do the accumulation part of Sinc filtering, while the differentiation part is done in firmware. The integrator serves to count the number of 1's per clock event. Each channel has three cascaded counters, which are the accumulators for the Sinc3 filter. Each counter is 24 bits, giving a maximum count of 16,777,215. Each channel has a free running rollover clock counter. This sample counter updates the count value on the effective clock event for that channel. Each channel also contains a programmable counter compare block, and the compare register has a size of 8 bits. However, the minimum value is 4 and maximum value is 202 due to the 24-bit accumulator. Once sample counter compare value is reached, the shadow register copy is updated and the shadow register copy flag is set.

Features of the integrators in PRUs SD Demodulator:

- Up to nine channels concurrent counting
- Flexible clock source configuration for each channel; option of independent clock source for each channel or one clock source for three channels
- Programmable, 8-bit sample counter compare register; used to set the OSR of Sinc filter
- Three 24-bit cascaded counters per channel for accumulation, only Sinc3 and Sinc2 modes supported
- Common channel enable (all channels are active or none are active)

6.4.5.2.2.3.5.1 Block Diagram and Signals

The Sigma Delta's I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 6-87. Note the PR<k>_PRU<n>_GP_MUX_SEL bitfield in the PRUSS_GPCFG0/1 register must be set to 3h for configure the GPI/GPO signals for SD mode.

Table 6-87. PRU GPI Signals and Configurations for Sigma Delta

Signal Names at Device Level [1]	Sigma Delta (SD) Mode (PRUSS_GPCFGn[29:26] PR1_PRUn_GP_MUX_SEL = 3h)	
PR<k>_PRU<n>_GPI0	SD0_CLK	SD demodulator clock channel 0

(1) Note these signals are shared with the GP and Peripheral I/Fs. To configure for Sigma Delta, PRUSS_GPCFG0/1[29-26] PR1_PRUn_GP_MUX_SEL (where n = 0 or 1) needs to be set to 3h for SD mode.

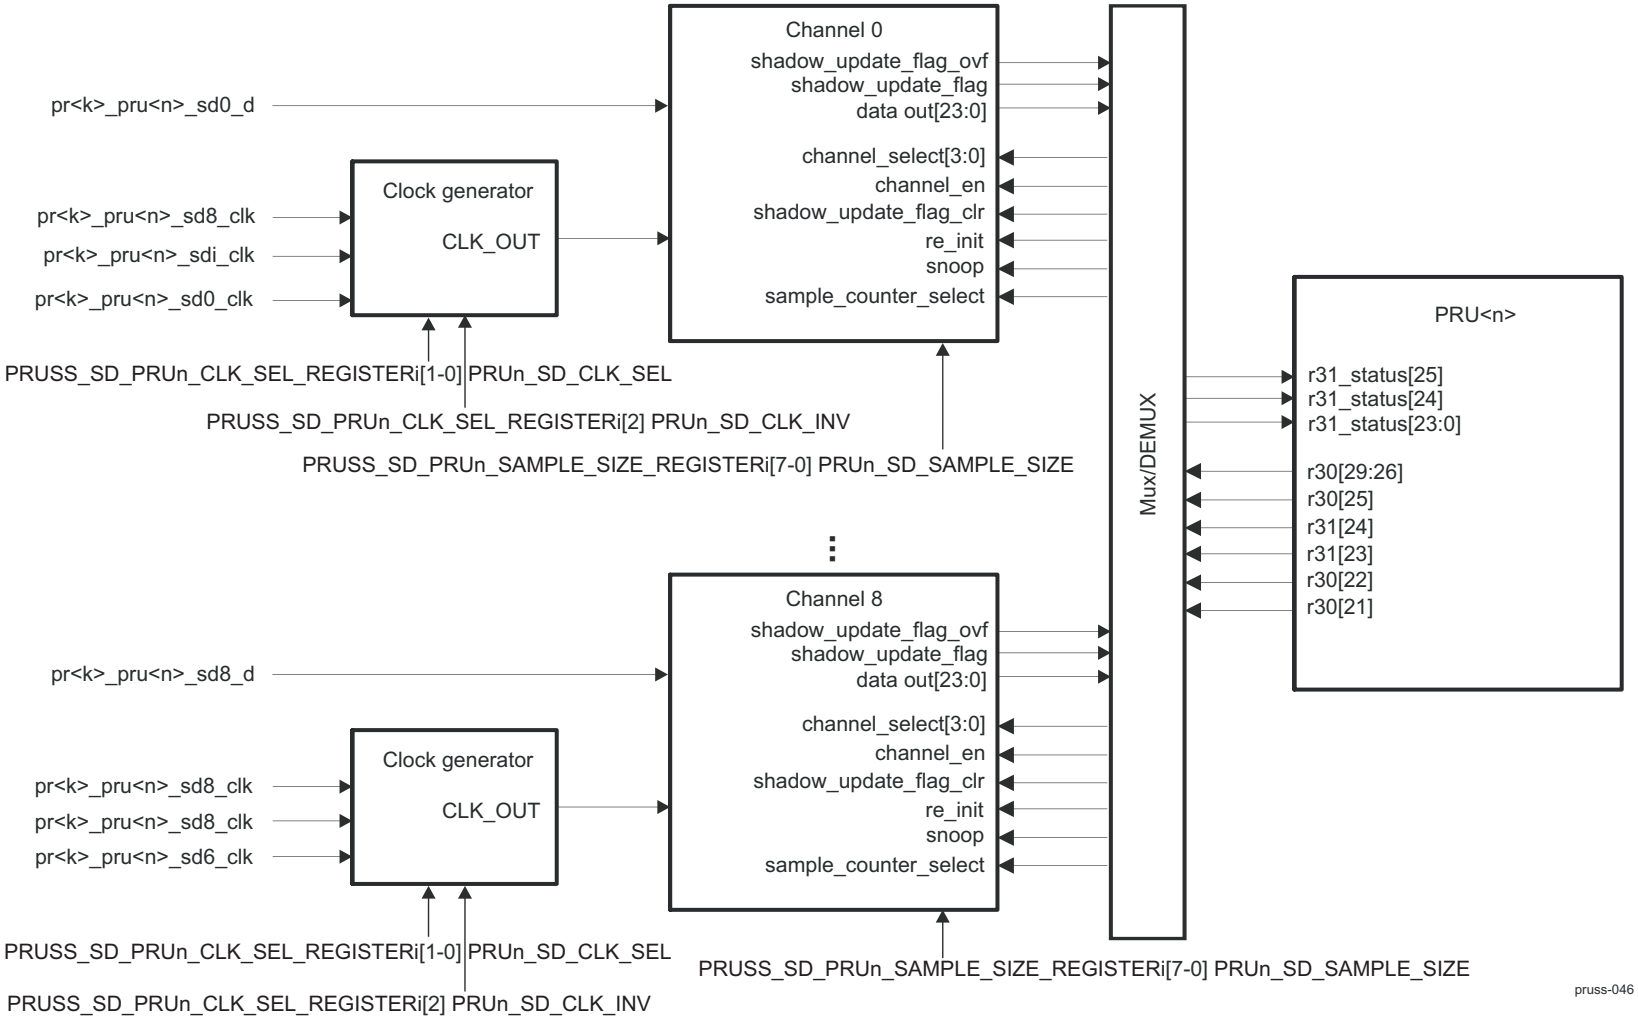
Table 6-87. PRU GPI Signals and Configurations for Sigma Delta (continued)

Signal Names at Device Level [1]	Sigma Delta (SD) Mode (PRUSS_GPCFGn[29:26] PR1_PRUn_GP_MUX_SEL = 3h)	
PR<k>_PRU<n>_GPI1	SD0_D	SD demodulator data channel 0
PR<k>_PRU<n>_GPI2	SD1_CLK	SD demodulator clock channel 1
PR<k>_PRU<n>_GPI3	SD1_D	SD demodulator data channel 1
PR<k>_PRU<n>_GPI4	SD2_CLK	SD demodulator clock channel 2
PR<k>_PRU<n>_GPI5	SD2_D	SD demodulator data channel 2
PR<k>_PRU<n>_GPI6	SD3_CLK	SD demodulator clock channel 3
PR<k>_PRU<n>_GPI7	SD3_D	SD demodulator data channel 3
PR<k>_PRU<n>_GPI8	SD4_CLK	SD demodulator clock channel 4
PR<k>_PRU<n>_GPI9	SD4_D	SD demodulator data channel 4
PR<k>_PRU<n>_GPI10	SD5_CLK	SD demodulator clock channel 5
PR<k>_PRU<n>_GPI11	SD5_D	SD demodulator data channel 5
PR<k>_PRU<n>_GPI12	SD6_CLK	SD demodulator clock channel 6
PR<k>_PRU<n>_GPI13	SD6_D	SD demodulator data channel 6
PR<k>_PRU<n>_GPI14	SD7_CLK	SD demodulator clock channel 7
PR<k>_PRU<n>_GPI15	SD7_D	SD demodulator data channel 7
PR<k>_PRU<n>_GPI16	SD8_CLK	SD demodulator clock channel 8
PR<k>_PRU<n>_GPI17	SD8_D	SD demodulator data channel 8
PR<k>_PRU<n>_GPI18		
PR<k>_PRU<n>_GPI19		

The PR<k>_PRU0_GPO1 signal (muxed with SD0_D) can be used as SD_CLKOUT when PRU-ICSS generates clock. This is a trade-off as PRU application will lose one SD channel. SD_CLKOUT needs to go through a clock generator chip if driving multiple sigma delta modulators and also be looped back into PRU-ICSS as SD_CLKIN, typically pru_gpi16.

Note to output the SD clock on PR<k>_PRU0_GPO1, this device requires that the PRU core be configured for both SD and shift out mode (PRUSS_GPCFG0/1[29-26] PR1_PRUn_GP_MUX_SEL = 3h and PRUSS_GPCFG0/1[14] PRU<n>_GPO_MODE = 1h). Be sure to configure the shift out mode's clock divisors before enabling shift out mode (PRUSS_GPCFG0/1[14] PRU<n>_GPO_MODE = 1h). Additionally, the PRU-ICSS_0 PRU0 SD clock is routed to both PR0_PRU0_GPO1 and PR0_PRU1_GPO1. Figure 6-40 shows a block diagram of the Sigma Delta implementation. Full description of the PRU R30 and R31 registers are shown in Table 6-89 and Table 6-90.

Figure 6-40. Sigma Delta Block Diagram



Note each channel can independently be configured to use one of three external clock sources. Table 6-88 shows the clock source options, selectable through PRUSS_SD_PRUn_CLK_SEL_REGISTERi[1:0] PRUn_SD_CLK_SEL (where n = 0 or 1).

Table 6-88. External Clock Sources

PRUn_SD_CLK_SEL value	Clock Source
0	pr<k>_pru<n>_sd8_clk
1	pr<k>_pru<n>_sd<m>_clk
2	pr<k>_pru<n>_sd0_clk for sd0, sd1, and sd2; pr<k>_pru<n>_sd3_clk for sd3, sd4, and sd5; pr<k>_pru<n>_sd6_clk for sd6, sd7, and sd8

6.4.5.2.2.3.5.2 PRU R30 / R31 Interface

The PRU uses the R30 and R31 registers to interface with the Sigma Delta interface. Tables Table 6-89 and Table 6-90 shows the R31 and R30 interface for the Sigma Delta mode. Note that only the parameters and data for one channel can be viewed at a time. The channel to be viewed is determined by the r30[29-26] (channel_select).

Table 6-89. Sigma Delta PRU Registers: R31

Bits	Field Name	Description
29:26	Reserved	
25	shadow_update_flag_ovf / shadow_update_flag_ovf_clr	Shadow update flag overflow, set when over sample count equals over sample size and shadow_update_flag is still set. Set this bit to clear the flag.
24	shadow_update_flag / shadow_update_flag_clr	Shadow update flag, set when over sample count equals over sample size and shadow_update_flag is still set. Set this bit to clear the flag.
23	re_init/data_out[23]	re_init (write): Set to reset all counters, flags, and shadow copy. Updates over_sample_size based on the current PRUSS_SD_PRUn_SAMPLE_SIZE_REGISTERi register (where n = 0 or 1 and i = 0 to 8) on the selected channel. data_out[23](read): most-significant bit of sample data
22:0	data_out[22:0]	Selected sample data excluding most-significant bit

Table 6-90. Sigma Delta PRU Registers: R30

Bits	Field Name	Description
31:30	Reserved	
29:26	channel_select[3:0]	Channel select 0h: Channel 0 ... 8h: Channel 8 9h: Reserved ... Fh: Reserved
25	channel_en	Global Channel enable (effects all 9 channels). 0h: All channels disabled. Counters/flags are cleared. 1h: All channels enabled.
24:23	Reserved	
22	snoop	Enable snoop (i.e. fetch data) on the selected channel. 0h: acc2/acc3 shadow copy 1h: current acc2/acc3
21	sample_counter_select	Read sample counter. 0h: Not selected 1h: Sample count selected
20:0	Reserved	

The PRU-ICSS CFG register space has additional registers for controlling the SD demodulator module:

- PRUSS_SD_PRUn_CLK_SEL_REGISTERi[4] PRUn_SD_ACC2_SEL (where n = 0 or 1, i = 0 to 8) - Selects accumulator 2 as source.
- PRUSS_SD_PRUn_CLK_SEL_REGISTERi[2] PRUn_SD_CLK_INV (where n = 0 or 1, i = 0 to 8) - Inverts clock.

- PRUSS_SD_PRUn_CLK_SEL_REGISTERi[1:0] PRUn_SD_CLK_SEL (where n = 0 or 1, i = 0 to 8) - Selects the clock source.
- PRUSS_SD_PRUn_SAMPLE_SIZE_REGISTERi[7:0] PRUn_SD_SAMPLE_SIZE (where n = 0 or 1, i = 0 to 8) - Selects number of samples to read before giving output.

6.4.5.2.2.3.5.3 Sigma Delta Description

Figure 6-41 shows a block diagram of the Sigma Delta hardware integrators and integration with the PRU R30 / R31 interface for a single channel.

Figure 6-41. Sigma Delta Hardware Integrators Block Diagram (snoop = 0)

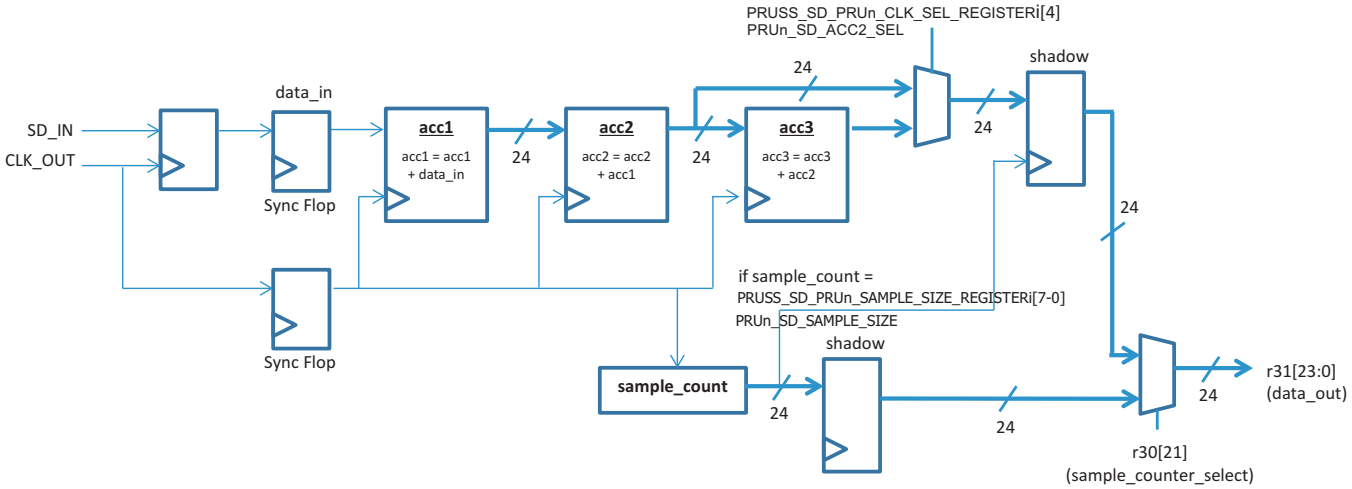


Figure 6-42. Sigma Delta Hardware Integrators Block Diagram (snoop = 1)

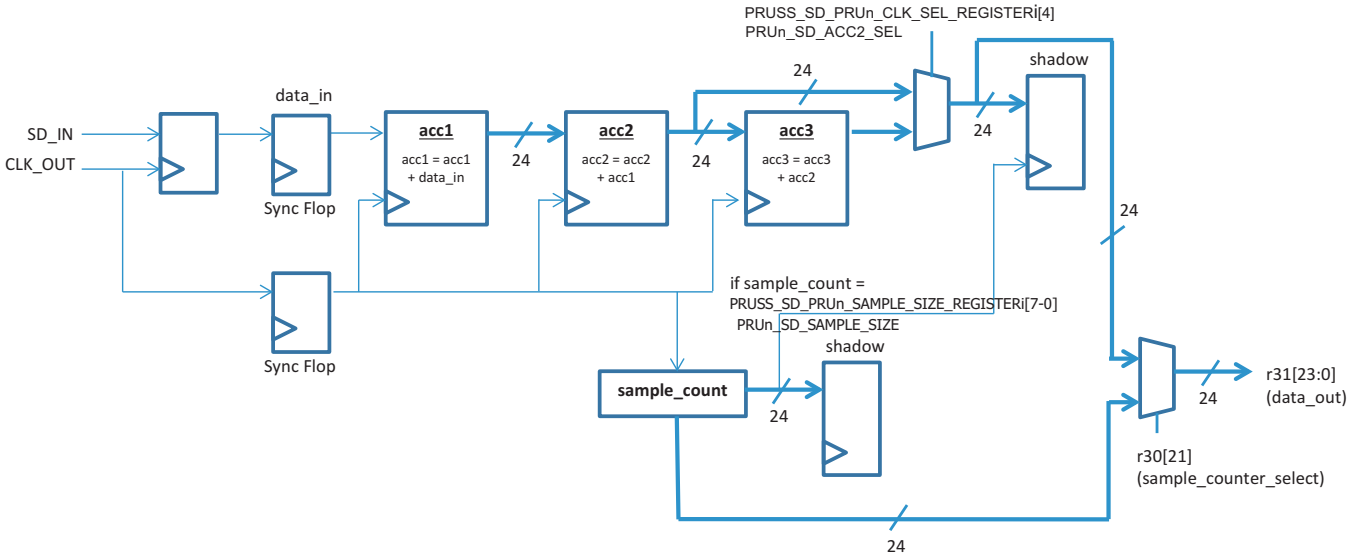

The three accumulators (acc1-acc3) for each channel are simple 24 bit adders. The input for acc1 is 1-bit, while the inputs for acc2 and acc3 are 24-bits. On each positive edge of the CLK_OUT, all three 24-bit counters (acc1-acc3) and the sample counter for each channel will get updated as follows:

```
acc1 = acc1 + data_in
acc2 = acc2 + acc1
acc3 = acc3 + acc2
sample_count = sample_count + 1
```

Each accumulator will rollover at 0xFF_FFFF. For example if acc2 = 0x10 and acc3 = 0xFF_FFFF, then acc3 will update to 0x00_0000F on the next clock event. Sample_count will rollover when it equals the defined sample size (PRUSS_SD_PRUn_SAMPLE_SIZE_REGISTERi[7-0] PRUn_SD_SAMPLE_SIZE).

Note that while the channels are not enabled, no operations are performed and all flags and counters are cleared. If a new sample size is to be loaded, the PRU firmware should assert re_init (r31[23]), and all stored count values are cleared to 0.

The Sigma Delta interface has two status flags:

- Shadow update flag (r31[24])
- Shadow update flag overflow (r31[25])

When sample_count equals the defined sample size (PRUSS_SD_PRUn_SAMPLE_SIZE_REGISTERi[7-0] PRUn_SD_SAMPLE_SIZE), then the acc2/acc3 shadow register copy will be updated, the shadow_update_flag (r31[24]) will be set, and sample_count will rollover to 0. The PRU firmware can clear this flag by writing '1' to shadow_update_flag_clr (r31[24]). If sample_count equals the defined sample size and the shadow_update_flag is still set, then shadow_update_flag_ovf (r31[25]) will be set. Similarly, the PRU firmware can clear this flag by writing '1' to shadow_update_flag_ovf_clr (r31[25]). Note that the clear operation for both flags has a higher priority than the set event.

The PRU firmware can monitor the acc2/acc3 and sample_count values through data_out[23:0] (r31[23:0]). Table 11-162 shows the configuration options for data_out[23:0].

Table 6-91. Data_out[23:0] Configuration Options

snoop (r30[22])	sample_counter_select (r30[21])	data_out (r31[23:0])
0	0	Reads acc2/acc3 shadow register copy. See Figure 6-41*Sigma Delta Hardware Integrators Block Diagram (snoop = 0).*
1	0	Reads acc2/acc3 directly. See Figure 6-42*Sigma Delta Hardware Integrators Block Diagram (snoop = 1).*
0	1	Reads sample_count shadow register copy. See Figure 6-41*Sigma Delta Hardware Integrators Block Diagram (snoop = 0).*
1	1	Reads sample_count directly. See Figure 6-42*Sigma Delta Hardware Integrators Block Diagram (snoop = 1).*

6.4.5.2.2.3.5.4 Basic Programming Example

The following programming example assumes that the PRU is configured for Sigma Delta Mode (PRUSS_GPCFG0/1[29-26] PR1_PRU<n>_GP_MUX_SEL = 3h).

1. Configure clock sources, accumulator source, and sample size:
   a. PRUSS_SD_PRUn_CLK_SEL_REGISTERi[1-0] PRUn_SD_CLK_SEL for clock source
   b. PRUSS_SD_PRUn_CLK_SEL_REGISTERi[2] PRUn_SD_CLK_INV for clock polarity
   c. PRUSS_SD_PRUn_CLK_SEL_REGISTERi[4] PRUn_SD_ACC2_SEL for accumulator source
   d. PRUSS_SD_PRUn_SAMPLE_SIZE_REGISTERi[7-0] PRUn_SD_SAMPLE_SIZE for sample size
2. Reinitialize all channels whose sample size was configured
   a. Select channel by writing to channel_select (r30[29-26])
   b. Delay at least 1 PRU cycle before executing re_int in step 2c.
   c. Reinitialize selected channel by writing to re_init (r31[23])
   d. Repeat steps 2a & 2b for all configured channels
3. Enable all channels by writing '1' to channel_en (r30[25])
4. Select channel by writing to channel_select (r30[29-26])
   a. Poll shadow_update_flag (r31[24]) to detect when acc2/acc3 shadow register copy data is ready to be ready
   b. Delay at least 1 PRU cycle before polling shadow_update_flag in Step 4c.

c. Read data_out[23:0] (r31[23:0])
d. Clear shadow_update_flag by writing '1' to r31[24]

5. Repeat step 4 for new channel

6.4.5.3 3 Channel Peripheral Interface

The 3 channel Peripheral Interface supports functionality for operations utilizing the EnDat 2.2 and BiSS protocols.

This module supports the following features:

- 3 channels with baud range from 100 kHz to 16 MHz
- ICSS_n_UART_CLK (default) or ICSS_n_VCLK_CLK master clock is an input to independent div16fr clock dividers to produce a 1X clock (ENDAT<m>_CLK) and oversampling clock
- Half-duplex (TX and RX are not supported concurrently)
- TX FIFO size of 32 bits
- RX FIFO size of 32 bits
- Configurable shift size/oversampling on RX
- Optional RX frame size auto shut off
- Programmable HW delay 1 (wire delay, controlling when the clock signal is first driven low) and delay 2 (tst delay, controlling when the clock signal is first driven high) on TX operation
- Optional programmable TX termination
- Individual TX channel start trigger (tx_channel_go) or simultaneous TX start trigger for all channels (tx_global_go)
- Flexible HW assisted clock output generation to allow free running, stop high and stop low (after last RX data), or stop high (after last TX data) operation with optional software clock override feature
- Optional SW direct snoop of data input

6.4.5.3.1 Block Diagram and Signal Configuration

The Peripheral Interface's I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 6-92. The PR<k>_PRU<n>_GP_MUX_SEL bitfield in the PRUSS_GPCFG0/1 register must be set to 1h for configure the GPI/GPO signals for Peripheral I/F mode.

Table 6-92. PRU GPI/GPO Signals and Configurations for Peripheral I/F[1]

Pad Names at Device Level[2][3]	Peripheral I/F Mode (PRUSS_GPCFG0/1[29:26] PR1_PRUn_GP_MUX_SEL = 1h)

PR<k>_PRU<n>_GPI11	ENDAT2_IN

(1) Usage of the Peripheral Interface signals are not restricted to only ENDAT interfaces.
(2) Note these signals are shared with the GP, MII and Sigma Delta modes. To configure for Peripheral I/F, PRUSS_GPCFG0/1[29:26] PR1_PRUn_GP_MUX_SEL needs to be set to 1h.
(3) Some devices may not pin out all 29 bits of R31 and all 32 bits of R30. For which pins are available on this device, see Section 6.4.2*PRU-ICSS Environment*. See the device Data Manual for device-specific pin mapping.

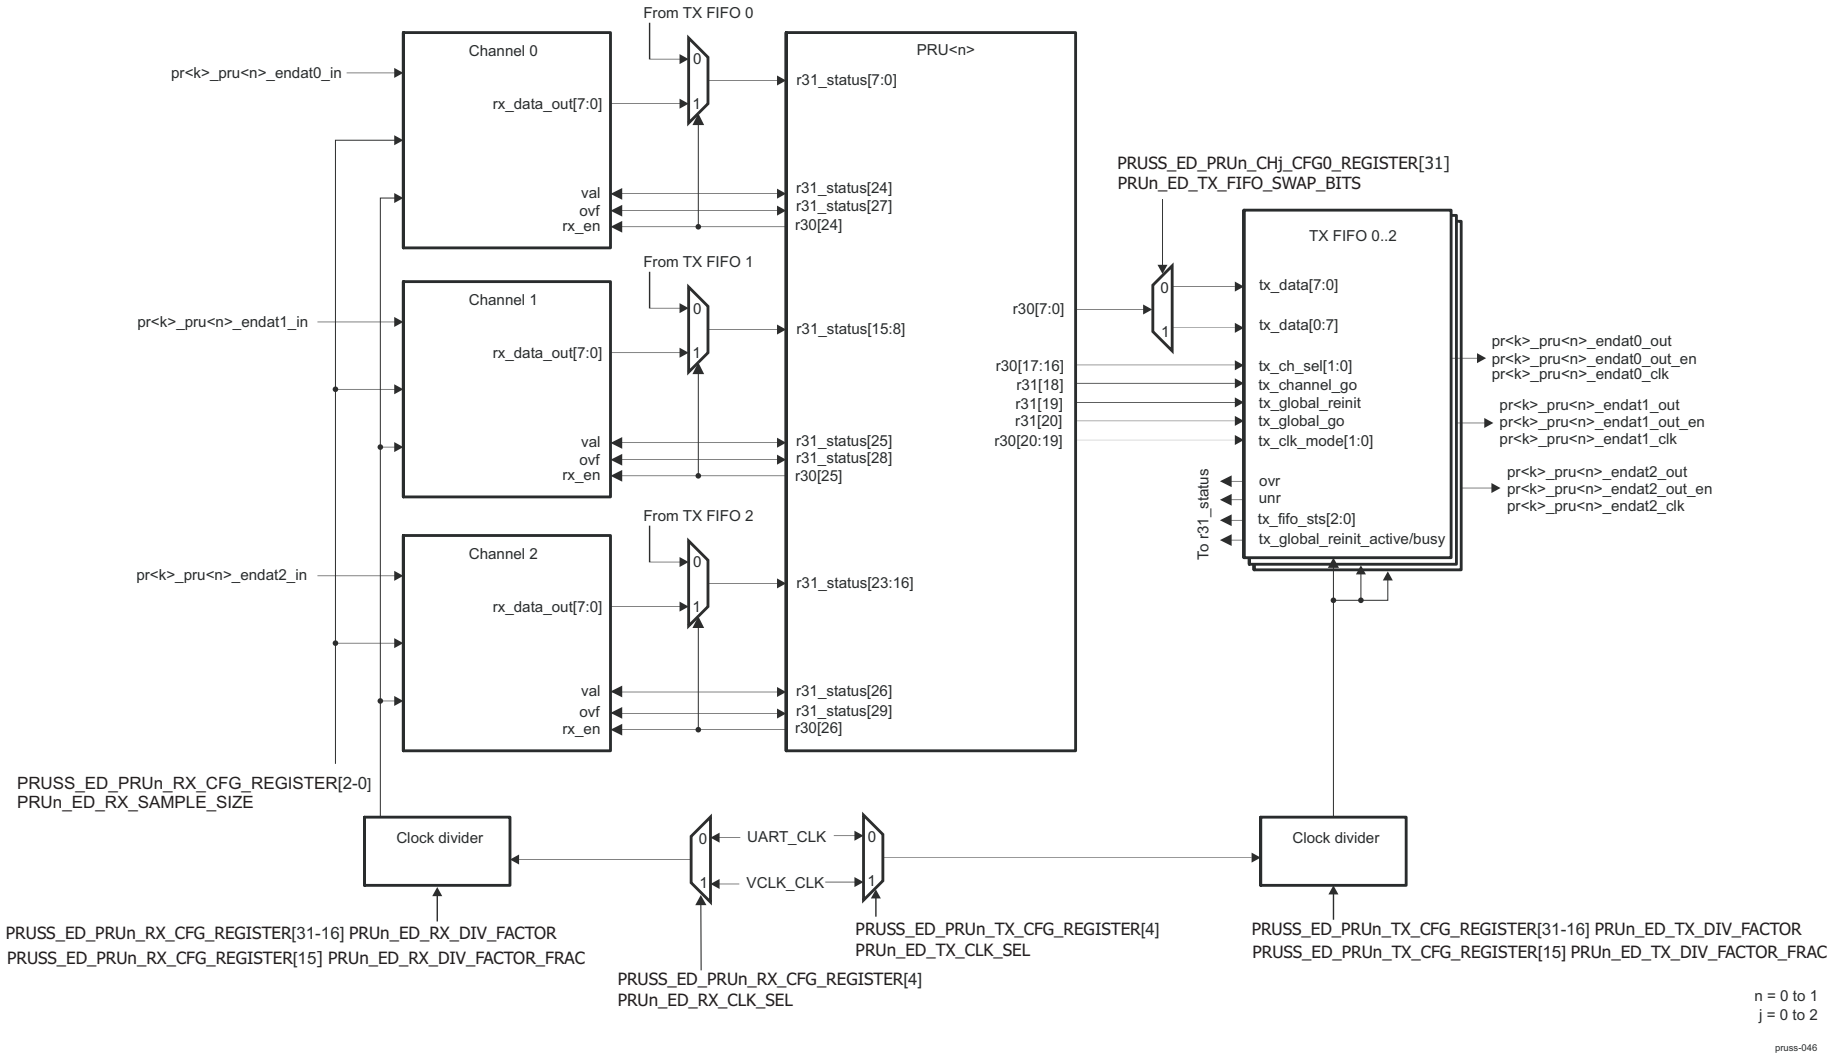
A block diagram for the Peripheral I/F is included in Figure 6-43. As shown, each channel is composed of four I/Os:

- ENDAT<m>_IN - RX input data
- ENDAT<m>_CLK - Clock (CLK_OUT) generated by the 1x (or TX) clock. The default value is 1.
- ENDAT<m>_OUT - TX output data. The default value is 0.
- ENDAT<m>_OUT_EN - TX enable output (1 = TX mode, 0 = RX mode). The default value is 0. Note this signal is auto controlled by hardware.

Figure 6-43. Peripheral I/F Block Diagram



6.4.5.3.2 PRU R30 and R31 Interface

The PRU uses the R30 and R31 registers to interface with the Peripheral I/F. Table 6-93 shows the R31 and R30 interface for the Peripheral I/F RX mode, and Table 6-94 shows the comparable interface for the TX mode.

Table 6-93. Peripheral I/F RX

Register	Bits	Field name	Description
R31	31:30	Reserved	PRU Host Interrupts 1/0 from local INTC
	29	ovf2	Overflow Flag for Channel 2. Write 1 to clear.
	28	ovf1	Overflow Flag for Channel 1. Write 1 to clear.
	27	ovf0	Overflow Flag for Channel 0. Write 1 to clear.
	26	val2	Valid Flag for Channel 2. Write 1 to clear.
	25	val1	Valid Flag for Channel 1. Write 1 to clear.
	24	val0	Valid Flag for Channel 0. Write 1 to clear.
	23:16	rx_data_out2	Oversampled Data Output for Channel 2. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	15:8	rx_data_out1	Oversampled Data Output for Channel 1. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	7:0	rx_data_out0	Oversampled Data Output for Channel 0. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
R30	31:27	Reserved	
	26	rx_en2	RX Enable for Channel 2. 0h: Channel not enabled, all counters/flags will get reset 1h: Channel is enabled
	25	rx_en1	RX Enable for Channel 1. 0h: Channel not enabled, all counters/flags will get reset 1h: Channel is enabled
	24	rx_en0	RX Enable for Channel 0. 0h: Channel not enabled, all counters/flags will get reset 1h: Channel is enabled
	23:0	Reserved	

Table 6-94. Peripheral I/F TX

Register	Bits	Field name	Description
R31	31:30	Reserved	
	29:22	Reserved	
	21	tx_global_reinit_active/ busy2	Tx_global_reinit action has some latency do to clocking. This status shows if action is completed. 1h: Active 0h: Done For non reinit case, this bit states that last bit is on tx wire. It does not mean the clock is off. 1h: Last bit is not done 0h: Last bit on tx wire Note that by using rx auto arm feature, the observation is lost at rx enable. This can be used to determine when to enable rx during non-auto arm case.
	20	tx_global_go	TX global start of all channels. Note: FIFO must not be empty. If empty, transmit will not start.
	19	tx_global_reinit	Reinit all channels into default mode. This clears all flags and state machines for all channels. Note: Sequence should be assert tx_global_reinit then de-assert rx_en. This will ensure TX and RX are in reset/default state. User must assert this after the frame has been sent and TX is not busy.
	18	tx_channel_go	TX start the channel transmit (selected by tx_ch_sel). Note: FIFO must not be empty.
	17	unr2	Under Run Flag for Channel 2. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.

Table 6-94. Peripheral I/F TX (continued)

Register	Bits	Field name	Description
	16	ovr2	Over Run Flag for Channel 2
	15:14	Reserved	
	13	tx_global_reinit_active/ busy1	Tx_global_reinit action has some latency do to clocking. This status shows if action is completed. 1h: Active 0h: Done For non reinit case, this bit states that last bit is on tx wire. It does not mean the clock is off. 1h: Last bit is not done 0h: Last bit on tx wire Note that by using rx auto arm feature, the observation is lost at rx enable. This can be used to determine when to enable rx during non-auto arm case.
	12:10	tx_fifo_sts1	TX FIFO occupancy status for Channel 1. 0 :0 Empty 1h: 1 word 2h: 2 words 3h: 3 words 4h: Full 5h-7h: Reserved
	9	unr1	Under Run Flag for Channel 1. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.
	8	ovr1	Over Run Flag for Channel 1
	7:6	Reserved	
	5	tx_global_reinit_active/ busy0	Tx_global_reinit action has some latency do to clocking. This status shows if action is completed. 1h: Active 0h: Done For non reinit case, this bit states that last bit is on tx wire. It does not mean the clock is off. 1h: Last bit is not done 0h: Last bit on tx wire Note that by using rx auto arm feature, the observation is lost at rx enable. This can be used to determine when to enable rx during non-auto arm case.
	4:2	tx_fifo_sts0	TX FIFO occupancy status for Channel 0. 0h: Empty 1h: 1 word 2h: 2 words 3h: 3 words 4h: Full 5h-7h: Reserved
	1	unr0	Under Run Flag for Channel 0. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.
	0	ovr0	Over Run Flag for Channel 0
R30	31:21	Reserved	
	20:19	clk_mode	CLK_OUT mode. 0h: Free-running/stop-low. Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop low. 1h: Free-running/stop-high (default). Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop high. Note this is the default/reset state, and a hardware reset or reinit will return clk_mode to this state. Note the initial state of the clock will be high, but the clock will not start until TX GO event. 2h: Free-run. NOTE: You must do a reinit to get out of this clock mode then you can update clk_mode to a different mode. Also if you do multiple TX GO, the 2nd go should have tst_delay and wire_delay zero since the clock is free running after the first go. 3h: Stop high after transmit. Clock will run until the last TX bit is sent and stops high.
	18	Reserved	

Table 6-94. Peripheral I/F TX (continued)

Register	Bits	Field name	Description
	17:16	tx_ch_sel	TX channel select. 0h: Channel 0 1h: Channel 1 2h: Channel 2 3h: Reserved
	15:9	Reserved	
	7:0	tx_data	TX data for FIFO. Notes: FIFO transmits MSB first and is 32-bits deep. TX_FIFO_SWAP_BITS bit in the PRU-ICSS CFG register space can be used to flip the load order of bits. The FIFO has 2 modes of operation: 1. Preload and Go. This should be done for EnDAT and frames less than 32-bits. 2. Continuous mode. This should be done for frames bigger than 32-bits. In continuous mode, software needs to keep up with the line rate and ensure that the FIFO is never empty. When the FIFO is at 2 byte level, software needs to load the next 2 bytes. If software waits till the end of the empty state, it is possible to get the TX into a bad state. The FIFO state can be recovered via re-init.

NOTE: The PRU-ICSS CFG register space has additional registers for controlling the Peripheral I/F module.

6.4.5.3.3 Clock Generation

6.4.5.3.3.1 Configuration

The Peripheral I/F module has two source clock options, ICSS_n_UART_CLK (default) and ICSS_n_VCLK_CLK. There are two independent clock dividers (div16) for the 1x and oversampling (OS) clocks, and each clock divider is configurable by two cascading dividers:

- [31-16]PRUn_ED_TX_DIV_FACTOR and [15]PRUn_ED_TX_DIV_FACTOR_FRAC for the 1x clock
- [31-16]PRUn_ED_RX_DIV_FACTOR and [15]PRUn_ED_RX_DIV_FACTOR_FRAC for the OS clock

The 1x clock is output on the ENDAT<m>_CLK signal. In TX mode, the output data is read from the TX FIFO at this 1x clock rate. The default value of this clock is high and the start and stop conditions for this clock are described in Section 6.4.5.3.3.2 *Clock Output Start Conditions* and Section 6.4.5.3.3.3 *Stop Conditions*.

In RX mode, the input data is sampled at the OS clock rate. Note the OS clock rate divided by the 1x clock rate must equal [2-0]PRUn_ED_RX_SAMPLE_SIZE.

Example clock rates and divisor values relative to the 192-MHz ICSS_n_UART_CLK source are shown in Table 6-95.

Table 6-95. Clock Rate Examples for 192-MHz PRUSSn_UART_GFCLK Clock Source

TX_DIV_FACTOR	1x Clock	RX_DIV_FACTOR	RX_DIV_FACTOR_FRAC	OS Clock	Oversample Factor
12	16 MHz	1	1.5	128 MHz	8x
16	12 MHz	2	1	96 MHz	8x
24	8 MHz	3	1	64 MHz	8x
32	6 MHz	4	1	48 MHz	8x
48	4 MHz	6	1	32 MHz	8x
96	2 MHz	12	1	16 MHz	8x
192	1 MHz	24	1	8 MHz	8x

6.4.5.3.3.2 Clock Output Start Conditions

This section describes the configurable start conditions for the ENDAT<m>_CLK. The software can completely control via PRUSS_ED_PRUn_CHj_CFG0_REGISTER when bit [29]PRUn_ED_CLK_OUT_OVR_EN = 1h. By default however, the PRU hardware will control the clocks as described in the following sections.

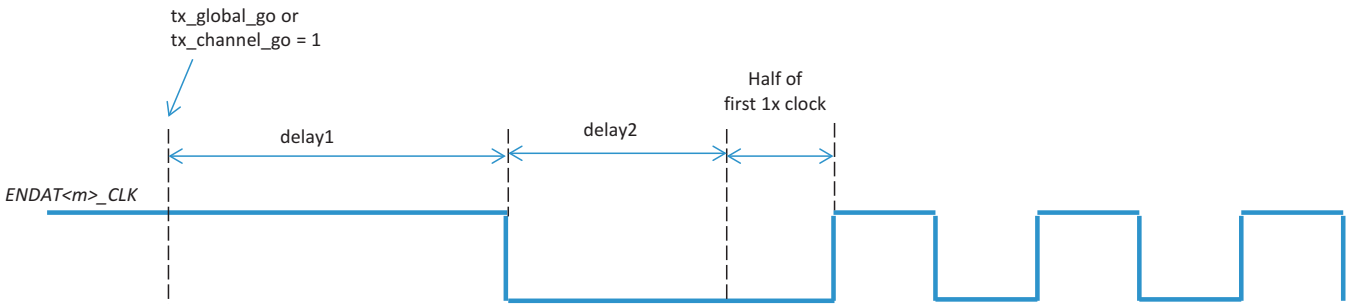
6.4.5.3.3.2.1 TX Mode (RX_EN = 0)

In TX mode, the ENDAT<m>_CLK begins after the firmware loads the TX FIFO and sets either r30[20] (tx_global_go) or r30[17:16] (tx_channel_go) to 1h. After the “go” bit is set, the delay1 (wire delay) compensation counter for each channel begins. After delay1 is complete, ENDAT<m>_CLK is driven low and then the delay2 (tst) counter begins. After the delay2 counter expires, the ENDAT<m>>_CLK starts running (first low and then high). Therefore, first rising edge of ENDAT<m>_CLK (measured from the go bit) = delay1 (tx wire delay) + delay2 (tst_counter delay) + half of the 1x clock frequency (since the clock starts low).

Figure 6-44 shows the start condition for TX mode. As shown in the figure, the default value of clock is high. The PRU-ICSS CFG register space has additional registers for controlling the TX start timing delay values:

- Delay 1: PRUSS_ED_PRUn_CHj_CFG0_REGISTER[10-0] PRUn_ED_TX_WDLY
- Delay 2: PRUSS_ED_PRUn_CHj_CFG0_REGISTER[15-0] PRUn_ED_TST_DELAY_COUNTER

Figure 6-44. TX Mode Start Condition



6.4.5.3.3.2.2 RX Mode (RX_EN = 1)

In RX mode, the ENDAT<m>_CLK will start running whenever the RX_EN is set. Note that the PRU firmware in this mode is responsible for any delay conditions.

The hardware can also auto-enable RX mode at the end of a TX transaction. The PRUSS_ED_PRUn_CHj_CFG1_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER is used to program a delay between the last TX bit sent and when the RX_EN is set.

6.4.5.3.3.3 Stop Conditions

The r30[20:19] (clk_mode[1:0]) value determines the stop condition for ENDAT<m>_CLK. There are 4 options available:

clk_mode_value	Description
0	Stop low on last RX frame
1	Stop high on last RX frame
2	Run continuously
3	Stop high on last TX bit

The last RX frame is configured by PRUSS_ED_PRUn_CHj_CFG0_REGISTER[27-16] PRUn_ED_RX_FRAME_SIZE, and the last TX bit is configured by PRUSS_ED_PRUn_CHj_CFG0_REGISTER[15-11] PRUn_ED_TX_FRAME_SIZE. Each stop condition is shown in Figure 6-45 through Figure 6-48.

Figure 6-45. ENDAT<m>_CLK Stop High on Last RX Frame

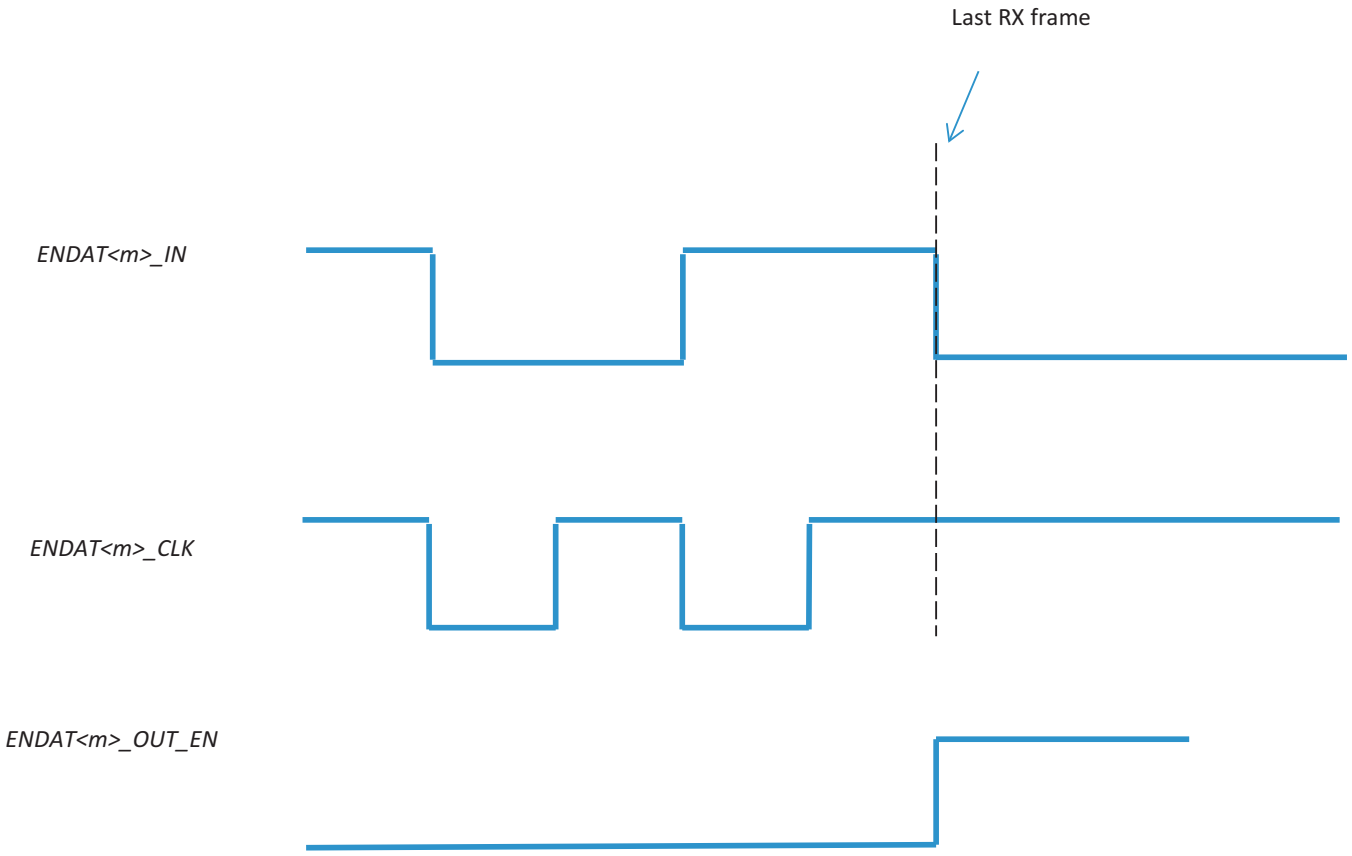


Figure 6-46. ENDAT<m>_CLK Stop Low on Last RX Frame

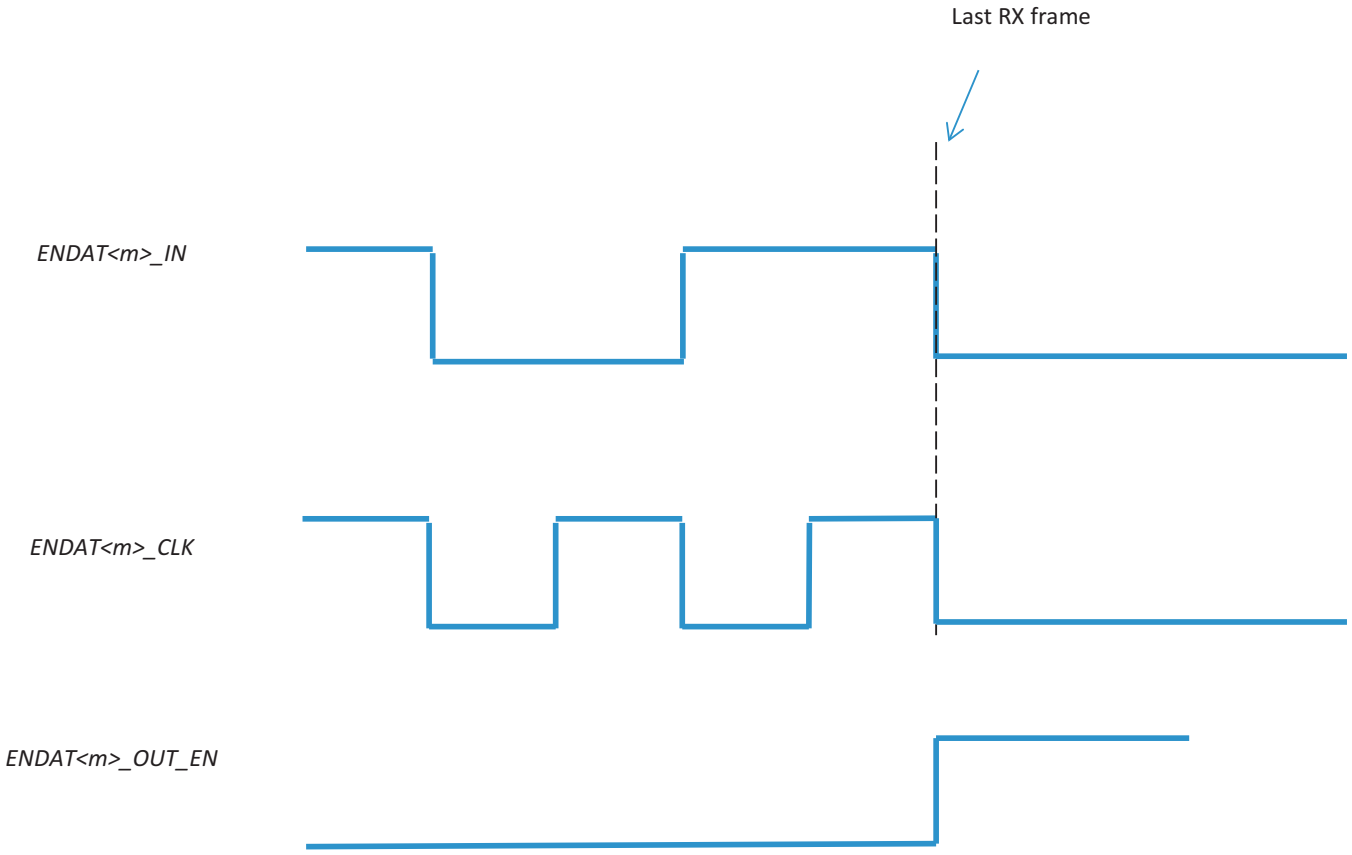

Figure 6-47. ENDAT<m>_CLK Run Continuously

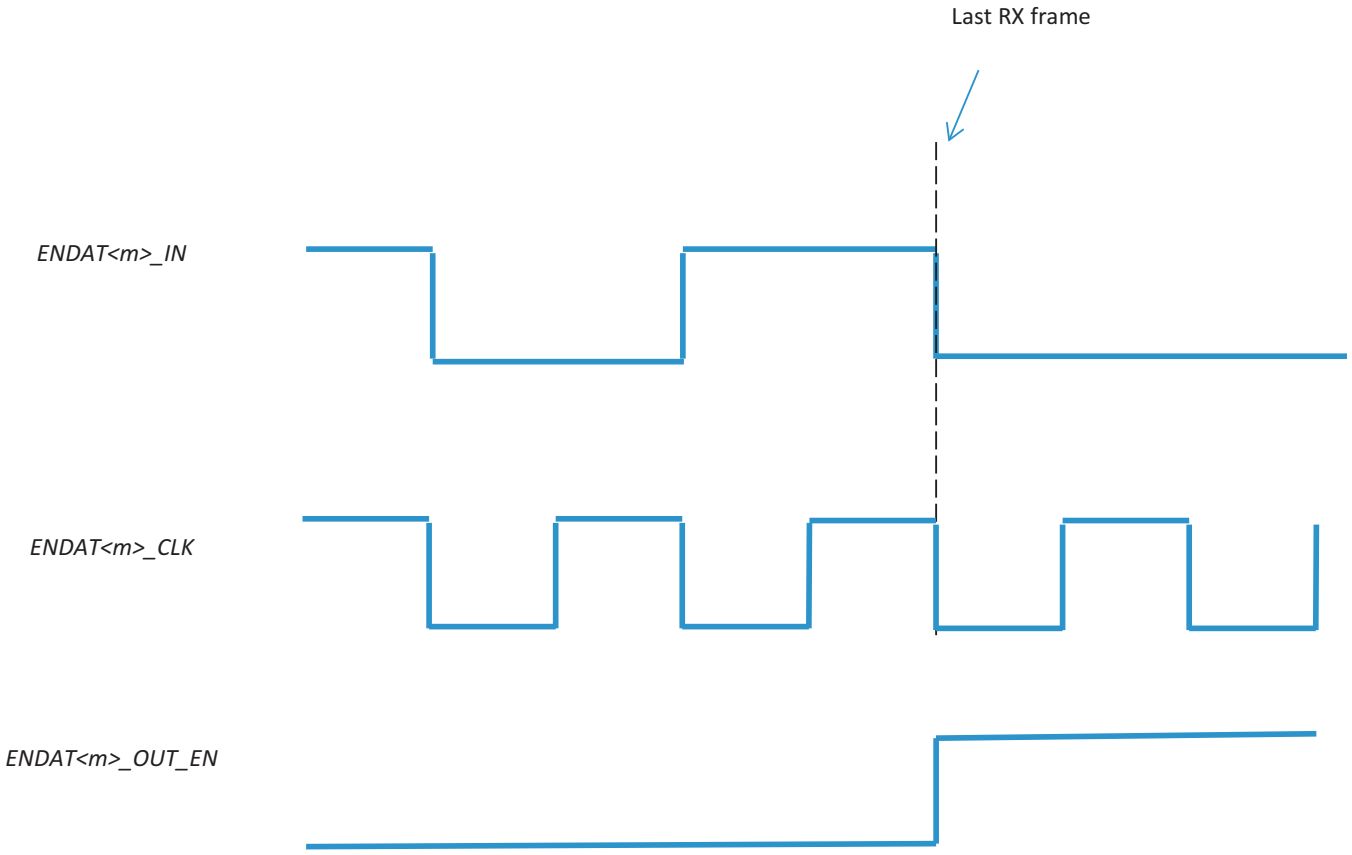

Figure 6-48. ENDAT<m>_CLK Stop High on Last TX Bit

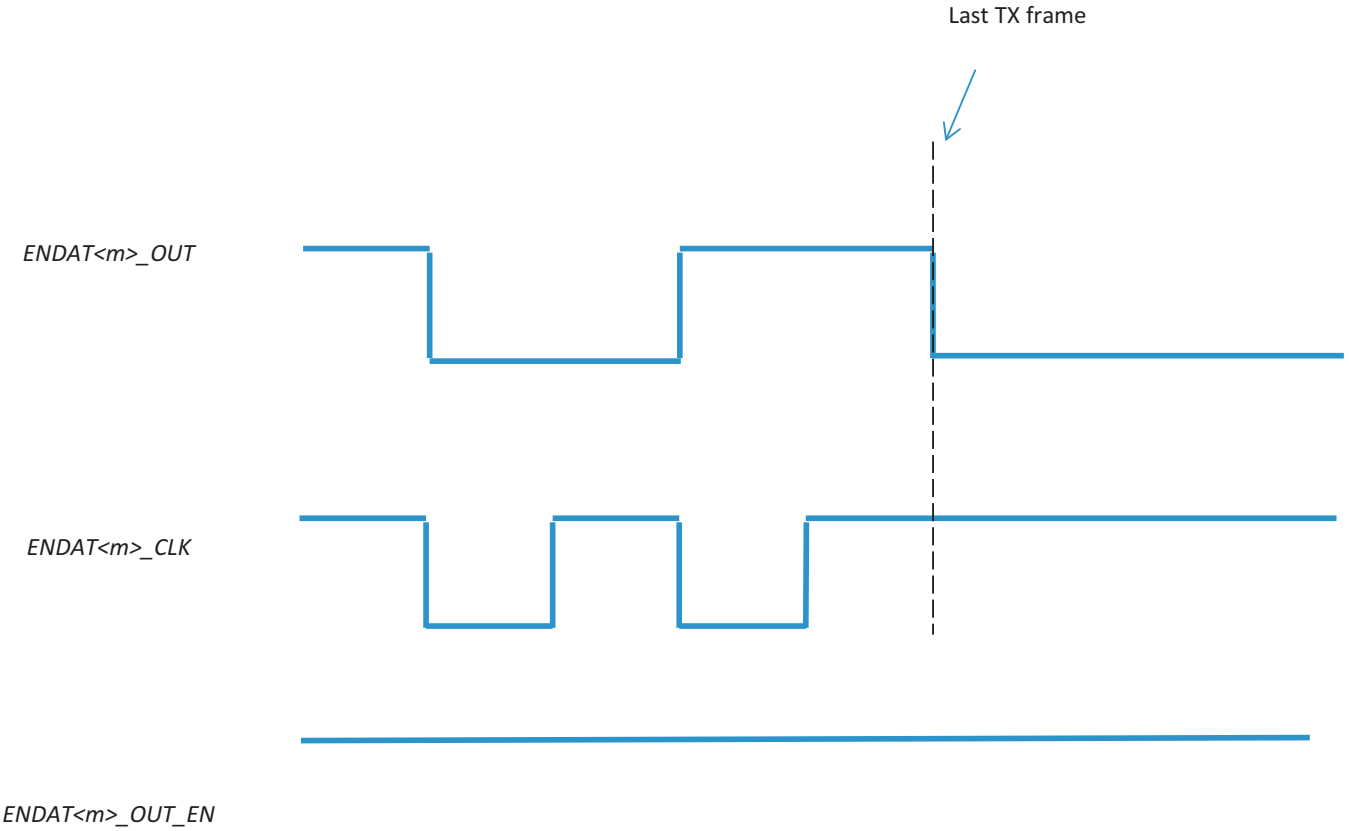


6.4.5.3.4 Basic Programming Model

The following programming models assume that the PRU is configured for 3 Peripheral Mode (PRUSS_GPCFG0/1[29-26] PR1_PRUn_GP_MUX_SEL = 1h).

6.4.5.3.4.1 Clock Generation

Follow these steps to configure Peripheral I/F clocks using the HW control of the clock:

1. Select TX and RX clock sources:
   a. PRUSS_ED_PRUn_TX_CFG_REGISTER[4] PRUn_ED_TX_CLK_SEL for the TX clock source
   b. PRUSS_ED_PRUn_RX_CFG_REGISTER[4] PRUn_ED_RX_CLK_SEL for the RX clock source
2. Configure the 1x (TX) clock frequency:
   a. Write Division Factor to PRUSS_ED_PRUn_TX_CFG_REGISTER[31-16] PRUn_ED_TX_DIV_FACTOR
   b. Write Fraction division factor to PRUSS_ED_PRUn_TX_CFG_REGISTER[15] PRUn_ED_TX_DIV_FACTOR_FRAC
3. Configure the oversampling (RX) frequency and oversample size:
   a. Write Division Factor to PRUSS_ED_PRUn_RX_CFG_REGISTER[31-16] PRUn_ED_RX_DIV_FACTOR
   b. Write Fraction division factor to PRUSS_ED_PRUn_RX_CFG_REGISTER[15] PRUn_ED_RX_DIV_FACTOR_FRAC
   c. Write RX oversample size to PRUSS_ED_PRUn_RX_CFG_REGISTER[2-0] PRUn_ED_RX_SAMPLE_SIZE
4. Select the clk_mode to configure how the ENDAT<m>_CLK signal ends after TX/RX:
   a. Write to r30[20:19] (clk_mode). Note the clk_mode setting can also be changed per transaction.

5. Configure the wire, tst, and rx_en_counter delay values:
   a. PRUSS_ED_PRUn_CHj_CFG0_REGISTER[10-0] PRUn_ED_TX_WDLY for wire delay
   b. PRUSS_ED_PRUn_CHj_CFG1_REGISTER[15-0] PRUn_ED_TST_DELAY_COUNTER for tst delay
   c. PRUSS_ED_PRUn_CHj_CFG1_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER for auto-delay between TX and RX

6.4.5.3.4.2 TX - Single Shot

Follow these steps to configure the Peripheral I/F channel(s) for a single shot transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
   1. PRUSS_ED_PRUn_CHj_CFG0_REGISTER[31] PRUn_ED_TX_FIFO_SWAP_BITS
2. Pre-load TX FIFO:
   1. Select TX channel by writing the desired channel number to R30[17:16] (tx_ch_sel)
   2. Write 1-4 bytes of data to r30[7:0] (tx_data). At each r30[7:0] write, data will be pushed into the FIFO.
   3. Repeat Steps 2a and 2b for all desired channels.
3. Configure TX frame size if less than 4 full bytes loaded into FIFO:
   1. PRUSS_ED_PRUn_CHj_CFG0_REGISTER[15-11] PRUn_ED_TX_FRAME_SIZE
4. Push TX FIFO data to ENDAT<m>_OUT (see Section 6.4.5.3.3.2 for the ENDAT<m>_CLK and ENDAT<m>_OUT start time relationship);
   1. To start TX on all channels, set r31[20] = 1 (tx_global_go).
   2. To start TX on individual channel:
      i. Select TX channel by writing the desired channel number to R30[17:16] (tx_ch_sel)
      ii. Set R31[18] = 1 (tx_channel_go)
5. If PRUSS_ED_PRUn_CHj_CFG0_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER > 0, then the channel will automatically switch into RX mode. See Section 6.4.5.3.4.4 for an example of how to program and configure RX content.
6. If PRUSS_ED_PRUn_CHj_CFG0_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or PRUSS_ED_PRUn_TX_CFG_REGISTER[7, 6, or 5] PRUn_ED_BUSY_i (where i = 0 to 2, indicates channel number) for when TX is complete

NOTE: The ENDAT<m>_CLK Peripheral I/F requires that ENDAT<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the single shot transmission in low state, then the clock needs to be reset before sending more data. The steps to reset ENDAT<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until tx_busy<m> is cleared
3. Re-configure R30[20:19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

6.4.5.3.4.3 TX - Continuous FIFO Loading

Follow these steps to configure the Peripheral I/F channel(s) for a continuous loading transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
   a. PRUSS_ED_PRUn_CHj_CFG0_REGISTER[31] PRUn_ED_TX_FIFO_SWAP_BITS
2. Pre-load TX FIFO:
   a. Select TX channel by writing the desired channel number to r30[17:16] (tx_ch_sel)
   b. Write 1-4 bytes of data to r30[7:0] (tx_data). At each r30[7:0] write, data will be pushed into the FIFO.

c. Repeat Steps 2a and 2b for all desired channels.

3. Configure TX frame size to continuously transmit the TX FIFO until empty:
   a. Set PRUSS_ED_PRUn_CHj_CFG0_REGISTER[15-11] PRUn_ED_TX_FRAME_SIZE = 0h
4. Push TX FIFO data to ENDAT<m>_OUT (see Section 6.4.5.3.3.2 for the ENDAT<m>_CLK and ENDAT<m>_OUT start time relationship):
   a. To start TX on all channels, set r31[20] = 1 (tx_global_go).
   b. To start TX on individual channel:
      i. Select TX channel by writing the desired channel number to r30[17:16] (tx_ch_sel)
      ii. Set r31[18] = 1 (tx_channel_go)
5. Monitor line rate and reload FIFO:
   a. Polling r31[xx, 12:10, 4:2] (tx_fifo_sts<m>)
   b. When FIFO level is at 2 bytes, load next 2 bytes of data (see Step 2). Do not let the FIFO get close to 0. Once the FIFO runs empty, the hardware will assume the PRU has reached end of the last transmit. Any new writes to the FIFO will NOT be sent until the software sends another tx_channel_go bit. Note there are also underrun and overrun error flags that can be monitored.
6. To end TX operation, do not send any new data to FIFO.
   a. If PRUSS_ED_PRUn_CHj_CFG1_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER > 0, then the channel will automatically switch into RX mode. See Section 6.4.5.3.4.4 for an example of how to program and configure RX content.
   b. If PRUSS_ED_PRUn_CHj_CFG1_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or PRUSS_ED_PRUn_TX_CFG_REGISTER[7, 6, or 5] PRUn_ED_BUSY_i (where i = 0 to 2, indicates channel number) for when TX is complete

NOTE: The ENDAT<m>_CLK Peripheral I/F requires that ENDAT<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the continuous loading transmission in low state, then the clock needs to be reset before sending more data. The steps to reset ENDAT<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until tx_busy<m> is cleared
3. Re-configure R30[20:19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

6.4.5.3.4.4 RX - Auto Arm or Non-Auto Arm

Follow these steps to configure the Peripheral I/F channel(s) to receive data:

1. Configure RX and frame size:
   a. PRUSS_ED_PRUn_CHj_CFG0_REGISTER[27-16] PRUn_ED_RX_FRAME_SIZE
2. To start ENDAT<m>_CLK:
   a. For the non-auto arm use case, set r30[26, 25, 24] = 1 (rx_en<m>)
   b. For the auto arm use case, rx_en<m> will be automatically enabled at the end of a TX operation when PRUSS_ED_PRUn_CHj_CFG1_REGISTER[31-16] PRUn_ED_RX_EN_COUNTER > 0
3. RX FIFO will start filling on the first start bit (ENDAT<m>_IN = 1). The data will be captured on the positive edge of the ENDAT<m>_CLK and shifted into the LSB position of the 8-bit shadow register.
4. Poll for r31[26, 25, 24] (val<m>) assertion. The valid flag will be asserted when n bits of data (determined by PRUSS_ED_PRUn_RX_CFG_REGISTER[2-0] PRUn_ED_RX_SAMPLE_SIZE) have been collected.
5. Fetch data by reading r31[23-16, 15-8, 7-0] (rx_data_out<m>). The data will remain constant for one data frame, and PRU must read data and clear valid flag within this time. Otherwise, an overflow will occur – r31[29, 28, 27] (ovf<m>) = 1 - indicating that val<m> has been continuously asserted for longer than one data frame.

6. The clock will be stopped based on the r30[20:19] (clk_mode) configured before the start of the RX operation.
7. Clear r30[26, 25, 24] (rx_en<m>) to disable RX mode. All counters and flags will be reset.

6.4.5.4 PRU Multiplier with Accumulation (MPY/MAC)

This section describes the MAC (multiplier with accumulation) module integrated to PRU0 and PRU1 cores of PRU-ICSS_0/PRU-ICSS_1.

6.4.5.4.1 PRU MACs Overview

Each of the two PRU cores (PRU0 and PRU1) has a designated unsigned multiplier with accumulation (MPY/MAC). The MAC supports two modes of operation: Multiply Only and Multiply and Accumulate.

The MAC is directly connected with the PRU internal registers R25-R29 and uses the broadside load/store PRU interface and XFR instructions to both control and mode of the MAC and import the multiplication results into the PRU.

6.4.5.4.1.1 PRU MAC Key Features

The MPY/MAC features are:

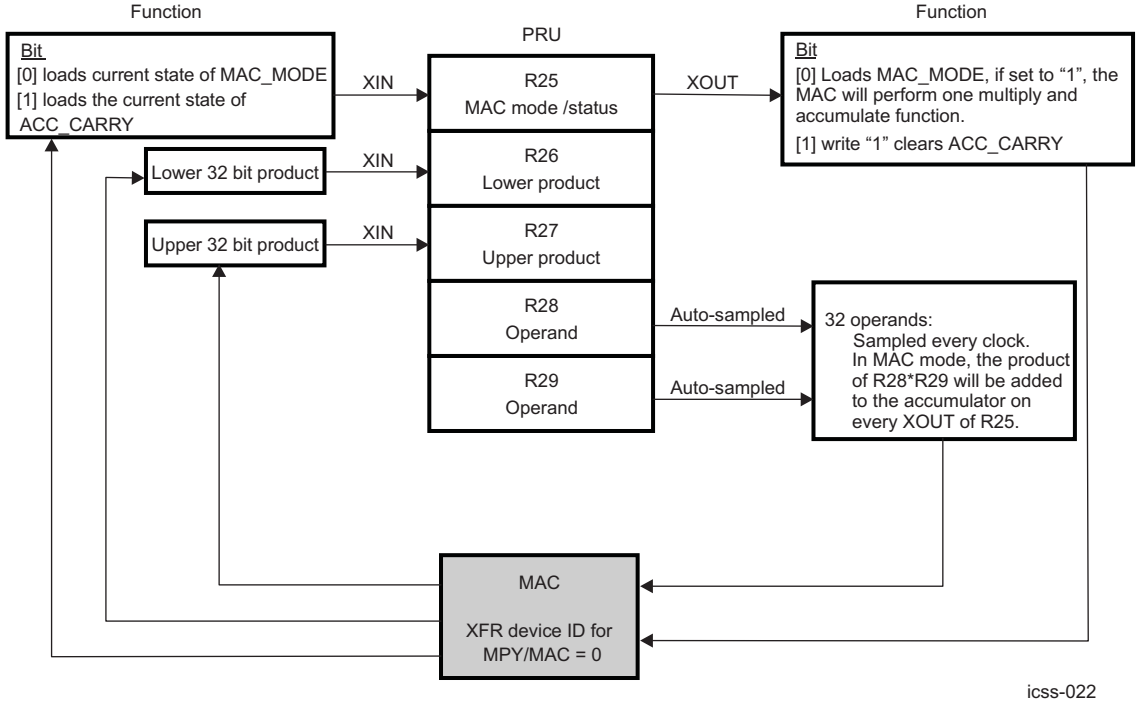
- Configurable Multiply Only and Multiply and Accumulate functionality via PRU register R25
- 32-bit operands with direct connection to PRU registers R28 and R29
- 64-bit result (with carry flag) with direct connection to PRU registers R26 and R27
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing multiplication results and initiating accumulate function

6.4.5.4.1.2 PRU MAC Operations

6.4.5.4.1.2.1 PRU versus MAC Interface

The MAC directly connects with the PRU internal registers R25-R29 through use of the PRU broadside interface and XFR instructions. Figure 6-49 shows the functionality of each register.

Figure 6-49. Integration of the PRU and MPY/MAC



The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the MAC. These instructions define the start, size, direction of the operation, and device ID. The device ID number corresponding to the MPY/MAC is shown in Table 6-96.

Table 6-96. MPY/MAC XFR ID

Device ID	Function
0	Selects MPY/MAC

The PRU register R25 is mapped to the MAC_CTRL_STATUS register (Table 6-97). The MAC's current status (MAC_MODE and ACC_CARRY states) is loaded into R25 using the XIN command on R25. The PRU sets the MAC's mode and clears the ACC_CARRY using the XOUT command on R25.

Table 6-97. MAC_CTRL_STATUS Register (R25) Field Descriptions

Bit	Field	Description
7-2	RESERVED	Reserved
1	ACC_CARRY	Write 1 to clear. 0h: 64-bit accumulator carry has not occurred 1h: 64-bit accumulator carry occurred
0	MAC_MODE	0h: Accumulation mode disabled and accumulator is cleared 1h: Accumulation mode enabled

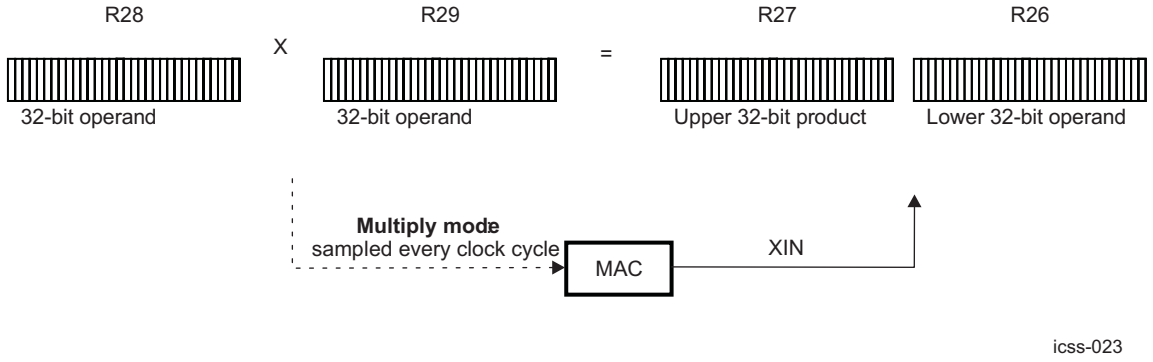
The two 32-bit operands for the multiplication are loaded into R28 and R29. These registers have a direction connection with the MAC. Therefore, XOUT is not required to load the MAC. In multiply mode, the MAC samples these registers every clock cycle. In multiply and accumulate mode, the MAC samples these registers every XOUT R25[7:0] transaction when MAC_MODE = 1.

The product from the MAC is linked to R26 (lower 32 bits) and R27 (upper 32 bits). The product is loaded into register R26 and R27 using XIN.

6.4.5.4.1.2.2 Multiply only mode(default state), MAC_MODE = 0

The Figure 6-50 summarizes the MAC operation in "Multiply-only"mode, in which the MAC multiplies the contents of R28 and R29 on every clock cycle.

Figure 6-50. MAC Multiply-only Mode- Functional Diagram



6.4.5.4.1.2.2.1 Programming PRU MAC in "Multiply-ONLY" mode

The following steps are performed by the PRU firmware for multiply-only mode:

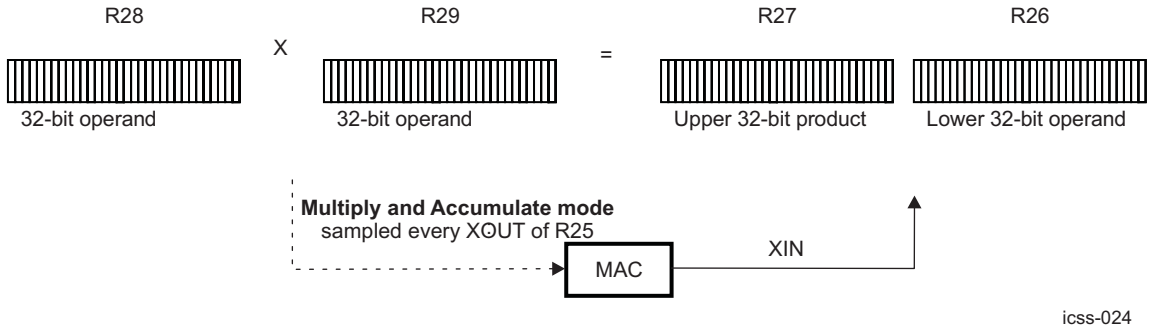
1. Enable multiply only MAC_MODE.
   (a) Clear R25[0] for multiply only mode.
   (b) Store MAC_MODE to MAC using XOUT instruction with the following parameters:
   - Device ID = 0
   - Base register = R25
   - Size = 1
2. Load operands into R28 and R29.
3. Delay at least 1 PRU cycle before executing XIN in step 4.
4. Load product into PRU using XIN instruction on R26, R27.

Repeat steps 2 and 4 for each new operand.

6.4.5.4.1.2.3 Multiply and Accumulate Mode, MAC_MODE = 1

The Figure 6-51 summarizes the MAC operation in "Multiply and Accumulate" mode. On every XOUT R25_REG[7:0] transaction, the MAC multiplies the contents of R28 and R29, adds the product to its accumulated result, and sets ACC_CARRY if an accumulation overflow occurs.

Figure 6-51. MAC Multiply and Accumulate Mode Functional Diagram



6.4.5.4.1.2.3.1 Programming PRU MAC in Multiply and Accumulate Mode

The following steps are performed by the PRU firmware for multiply and accumulate mode:

1. Enable multiply and accumulate MAC_MODE.

(a) Set R25[1:0] = 1 for accumulate mode.
(b) Store MAC_MODE to MAC using XOUT instruction with the following parameters:
- Device ID = 0
- Base register = R25
- Size = 1

2. Clear accumulator and carry flag.
(a) Set R25[1:0] = 3 to clear accumulator (R25[1]=1) and preserve accumulate mode (R25[0]=1).
(b) Store accumulator to MAC using XOUT instruction on R25.

3. Load operands into R28 and R29.

4. Multiply and accumulate, XOUT R25[1:0] = 1

Repeat step 4 for each multiply and accumulate using same operands.

Repeat step 3 and 4 for each multiply and accumulate for new operands.

5. Load the accumulated product into R26, R27, and the ACC_CARRY status into R25 using the XIN instruction.

NOTE: Steps one and two are required to set the accumulator mode and clear the accumulator and carry flag.

6.4.5.5 CRC16/32

The PRU0 and PRU1 cores of PRU-ICSS_0/PRU-ICSS_1 each have a designated CRC16/32 module.

In general, CRC adds error detection capability to communication systems. The CRC encoder appends redundant bits (or CRC bits) to the systematic data message. During reception of the data message, the received data is also encoded with the same CRC encoder. The 2 sets of CRC bits are compared together. If they match, there were no transmission errors; and if they don't match, a transmission error has been detected.

6.4.5.5.1 Features

CRC16/32 supports the following features:

- Supports CRC32:
  - $x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1$
- Supports CRC16:
  - $x^{16}+x^{15}+x^{2}+1$
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing CRC results and executing accumulate function

6.4.5.5.2 PRU and CRC16/32 Interface

The CRC16/32 module directly connects with the PRU internal registers R25-R29 through use of the PRU broadside interface and XFR instructions. shows the functionality of each register.

The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the CRC16/32 module. These instructions define the start, size, direction of the operation, and device ID. The XFR device ID number corresponding to the CRC16/32 module is 1.

Table 6-98. CRC Register to PRU Port Mapping

CRC Register	R/W	Description	PRU Mapping
CRC_CFG	W	bit [0] CRC32_ENABLE: 0: CRC16 mode is selected. Hardware will auto-set init state of CRC_SEED to 0000_0000h. Note CRC16 result value is only 16-bits 1: CRC32 mode is selected. Hardware will auto-set init state of CRC_SEED will be FFFF_FFFFh. Always write all 4 bytes.	R25_reg
CRC_DATA_8_BFLIP	R	8-bit flip of CRC_DATA. CRC_DATA_8_BFLIP has the same byte order as CRC_DATA[31:0], but each byte has all bits flipped. CRC_DATA_32_FLIP[7:0] = CRC_DATA[0:7] CRC_DATA_32_FLIP[15:8] = CRC_DATA[8:15] CRC_DATA_32_FLIP[23:16] = CRC_DATA[16:23] CRC_DATA_32_FLIP[31:24] = CRC_DATA[24:31] For CRC16, only CRC_DATA_8_BFLIP[15:0] are valid. No auto reset on CRC_DATA_8_BFLIP read.	R27_reg
CRC_SEED	W	CRC SEED value. Hardware will auto-initialize the CRC_SEED value to 0000_0000h for CRC16 and FFFF_FFFFh for CRC32. Software only needs to initialize CRC_SEED if a different default value is required. Always write 4 bytes. Note when CRC_CFG[CRC32_ENABLE] is enabled, the hardware will switch the CRC_SEED value to FFFF_FFFFh. Reading the CRC_DATA register will reset the CRC value to the CRC_SEED state.	R28_reg
CRC_DATA_32_BFLIP	R	Full 32-bit flip of CRC_DATA CRC_DATA_32_BFLIP[0] = CRC_DATA[31] … CRC_DATA_32_BFLIP[31] = CRC_DATA[0] For CRC16, only CRC_DATA_32_BFLIP[31:16] are valid. No auto reset on CRC_DATA_32_BFLIP read.	R28_reg
CRC_DATA	RW	For Write, must use a fixed width throughout the session. The CRC module supports lower 8-bit, or lower 16-bit, or full 32-bit data widths. For Read, LSB or CRC_DATA[0] is first bit on the wire. Note for CRC16, only CRC_DATA[15:0] is valid. Hardware will delay CRC_DATA read operation up to 1 clock if it occurs back to back with a CRC_DATA write.	R29_reg

6.4.5.5.3 Programming Model

The following steps are performed by the PRU firmware to use the CRC module:

Step1: Configuration (optional)

1. Configure CRC type:
   For CRC32 operation, set CRC32_ENABLE using XOUT instruction with the following parameters:
   - Device ID = 1
   - Base register = R25
   - Size = 1
2. Update CRC_SEED, if required using XOUT with the following parameters:
   - Device ID = 1
   - Base register = R28
   - Size = 1 to 4

Step 2:

1. Load new CRC data into R29
2. Push CRC data to the CRC16/32 module using XOUT with the following parameters:
   - Device ID = 1
   - Base register = R29
   - Size = 1 to 4

3. Load the accumulated CRC result into the PRU using the XIN instruction with the following parameters:
   - Device ID = 1
   - Base register = R29
   - Size = 4

Repeat Step 2, numbers 1 and 2 for each new CRC data.

NOTE: When a session starts, the PRU firmware must use the same write data width throughout the session.

6.4.5.6 PRU0 and PRU1 Scratch Pad Memory

The PRU-ICSS supports a scratch pad with three independent banks accessible by the PRU cores. The PRU cores interact with the scratch pad through broadside load/store PRU interface and XFR instructions. The scratch pad can be used as a temporary place holder for the register contents of the PRU cores. Direct connection between the PRU cores is also supported for transferring register contents directly between the cores.

This section describes the Scratch Pad Memory shared between and directly accessible by the PRU0 and PRU1 cores, as well as the XFR direct method used by the PRU cores of the PRU-ICSS_0 /PRU-ICSS_1.

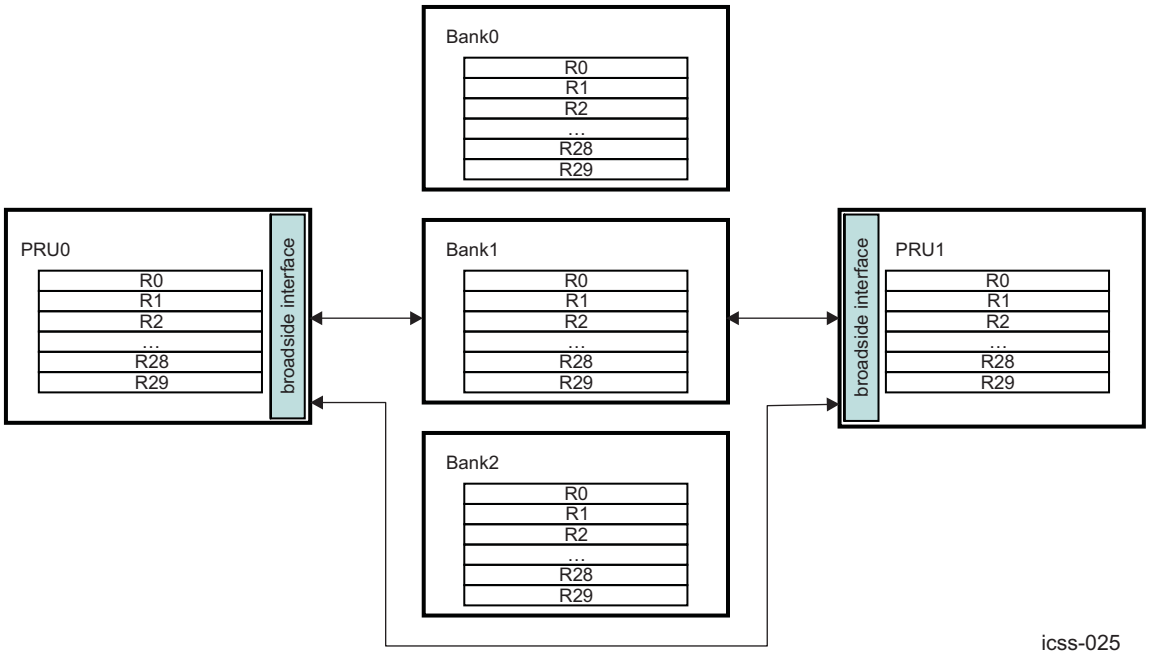
6.4.5.6.1 PRU0/1 Scratch Pad Overview

The PRU-ICSS scratch pad supports the following features:

- Three scratch pad banks of 30, 32-bit registers (R29:0)
- Flexible load/store options
  - User-defined start byte and length of the transfer
  - Length of transfer ranges from one byte of a register to the entire register content (R29 to R0)
  - Simultaneous transaction supported between PRU0 <-> Bank <n> and PRU1 <-> Bank <m>
  - Direct connection of PRU0->PRU1 or PRU1->PRU0 for all registers R29-R0
- XFR instructions operate in one clock cycle
- Optional XIN/XOUT shift functionality allows remapping of registers (R<n> -> R<m>) during load store operation

Figure 6-52 shows a simplified model of the ScratchPad integration.

Figure 6-52. ScratchPad and PRU Integration



6.4.5.6.2 PRU0 /1 Scratch Pad Operations

XFR instructions are used to load/store register contents between the PRU cores and the scratch pad banks. These instructions define the start, size, direction of the operation, and device ID. The device ID corresponds to the external source or destination (either a scratch pad bank or the other PRU core). The device ID numbers are shown in Table 6-99. Note the direct connect mode (device ID 14) can be used to synchronize the PRU cores. This mode requires the transmitting PRU core to execute XOUT and the receiving PRU core to execute XIN.

Table 6-99. Scratch Pad XFR ID

Device ID	Function/Operation
10	Selects Bank0
11	Selects Bank1
12	Selects Bank2
13	Reserved
14	Selects other PRU core (Direct connect mode)

A collision occurs when two XOUT commands simultaneously access the same asset or device ID. Table 6-100 shows the priority assigned to each operation when a collision occurs. In direct connect mode (device ID 14), any PRU transaction will be terminated if the stall is greater than 1024 cycles. This will generate the event pr<k>_xfr_timeout that is connected to INTC.

Table 6-100. Scratch Pad XFR Collision and Stall Conditions

Operation	Collision and Stall Handling
PRU<n> XOUT (->) bank[j]	If both PRU cores access the same bank simultaneously, PRU0 is given priority. PRU1 will temporarily stall until the PRU0 operation completes.
PRU<n> XOUT (->) PRU<m>	Direct connect mode requires the transmitting core (PRU<n>) to execute XOUT and the receiving core (PRU<m>) to execute XIN. If PRU<n> executes XOUT before PRU<m> executes XIN, then PRU<n> will stall until either PRU<m> executes XIN or the stall is greater than 1024 cycles.

Table 6-100. Scratch Pad XFR Collision and Stall Conditions (continued)

Operation	Collision and Stall Handling
PRU<m> XIN (<-) PRU<n>	Direct connect mode requires the transmitting core (PRU<n>) to execute XOUT and the receiving core (PRU<m>) to execute XIN. If PRU<m> executes XIN before PRU<n> executes XOUT, then PRU<m> will stall until either PRU<n> executes XOUT or the stall is greater than 1024 cycles.

6.4.5.6.2.1 Optional XIN/XOUT Shift

The optional XIN/XOUT shift functionality allows register contents to be remapped or shifted within the destination's register space. For example, the contents of PRU0 R6-R8 could be remapped to Bank1 R10-12. The XIN/XOUT shift feature is not supported for direct connect mode, only for transfers between a PRU core and scratch pad bank.

The shift feature is enabled or disabled through the PRU subsystem level register PRUSS_SPP[1] XFR_SHIFT_EN bit. When enabled, R0[4-0] (internal to the PRU) defines the number of 32-bit registers in which content is shifted in the scratch pad bank. Note that scratch pad banks do not have registers R30 or R31.

6.4.5.6.2.2 Example Scratch Pad Operations

The following PRU firmware examples demonstrate the shift functionality. Note these assume the XFR_SHIFT_EN bit of the PRUSS_SPP register of the PRU-ICSS CFG register space has been set.

XOUT Shift By 4 Registers

Store R4:R7 to R8:R11 in bank0:

- Load 4 into R0.b0
- XOUT using the following parameters:
  - Device ID = 10
  - Base register = R4
  - Size = 16

XOUT Shift By 9 Registers, With Wrap Around

Store R25:R29 to R4:R8 in bank1:

- Load 9 into R0.b0
- XOUT using the following parameters:
  - Device ID = 11
  - Base register = R25
  - Size = 20

XIN Shift By 10 Registers

Load R14:R16 from bank2 to R4:R6:

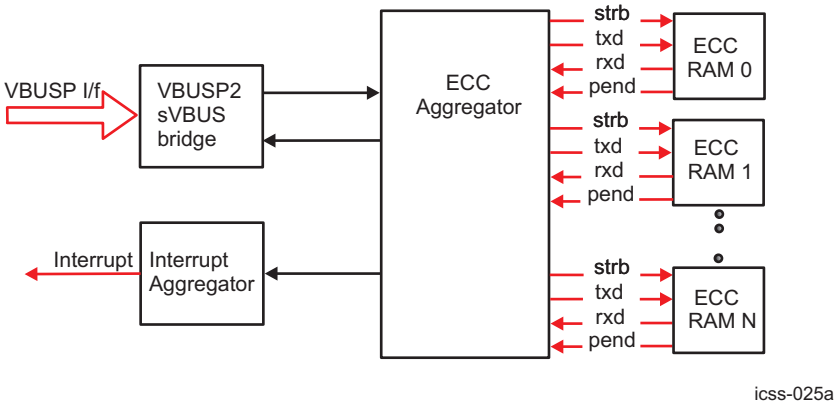
- Load 10 into R0.b0
- XIN using the following parameters:
  - Device ID = 12
  - Base register = R4
  - Size = 12

6.4.5.7 ECC Aggregator

This section describes the architecture and functional details of the ECC Aggregator module.

Figure 6-53 shows a Block Diagram of the ECC Aggregator module.

Figure 6-53. ECC Aggregator Block Diagram



6.4.5.7.1 ECC Aggregator module supported features

The ECC Aggregator module provides the following features:

- Aggregates level pending status from the ECC RAMs into a single interrupt to the host.
- Provides a mechanism to control and monitor the ECC RAMs in the ICSS subsystem via a standard 32-bit VBUSP interface.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Uses a low pin-count serial VBUSP protocol to communicate to all the ECC RAMs while bridging the standard VBUSP protocol to the serial protocol on the host interface.

6.4.5.7.2 ECC Aggregator module not supported features

The ECC Aggregator module does not support the following feature:

- Statistics such as tracking the number of single and double-bit errors. If needed these operations can be handled by software.

6.4.5.7.3 Functional operation of the ECC Aggregator module

The ECC Aggregator module is responsible for the following functions:

- Providing software access to all the ECC related registers via a standard 32-bit VBUSP interface.
- Aggregating the level pending interrupts from the ECC RAMs to the standard EOI-handshake based interrupt to the host.

6.4.5.7.3.1 ECC Aggregator Registers

The ECC Aggregator module supports all the ECC control, status and interrupt registers for all the ECC RAMs in the PRU-ICSS_0/1 subsystem. The ECC Aggregator registers are memory mapped to a 1 KB address space in the PRU-ICSS_0/1 module. There are 3 types of register accesses in the ECC Aggregator module:

- Global registers that are common to all ECC RAMs. This includes the ECC_REVISION and ECC_VECTOR registers. Every ECC RAM serviced by the Aggregator module is assigned a unique ID by the module. Writing this ID to the ECC_VECTOR register selects the ECC RAM to be controlled or read the ECC status from.
- ECC control and status registers. These are specific to each ECC RAM and selected by the bit field [10:0] RAM_ID written to the ECC_VECTOR register. The accesses to these registers are done via the serial VBUSP interface.
- Interrupt registers. These include the standard interrupt status, interrupt enable, clear and EOI registers that are part of a standard interrupt module.

6.4.5.7.3.2 Reads to ECC control and status registers

The reads to the ECC control and status registers for each ECC RAM are triggered by writing a 1h to the ECC_VECTOR[15] TRIGGER_READ register as described below:

1. Software writes the ECC ID (bits [10:0] RAM_ID), read trigger (bit [15] TRIGGER_READ), read address (bits [23:16] READ_ADDRESS) to the ECC_VECTOR register. The read address (bits [23:16] READ_ADDRESS) corresponds to any of the ECC control or status registers which require serial VBUS access to the ECC RAMs.
2. Software then polls the ECC_VECTOR[24] READ_DONE bit. If [24] READ_DONE bit is set to 1h, this indicates that the read operation has completed on the serial VBUS.
3. Software reads the data from the ECC control or status register. Read data is returned the following clock cycle.

6.4.5.7.3.3 ECC Aggregator Interrupts

The ECC Aggregator module aggregates all the level pending status from the ECC RAMs to a single EOI-handshake based interrupt to the host. Software is expected to follow the sequence described below:

1. Software enables the interrupts for the ECC RAMs by writing 1h to the [4-0]ENABLE bit in the ECC_INT_ENABLE_n register (where n = 0 to 15).
2. On receiving an interrupt, software checks the ECC_INT_STATUS_n register (where n = 0 to 15) to see which ECC RAMs caused the error. Note that this status read is not a serial VBUS operation.
3. Software writes the ECC_VECTOR[10:0] RAM_ID bit field along with the read message that includes setting bit ECC_VECTOR[15] TRIGGER_READ (to trigger the read), writing the ECC_ERROR_STATUS1 register address to the ECC_VECTOR[23:16] READ_ADDRESS bit field. Software will need to load the read message in the ECC_VECTOR register again if it needs to read the ECC_ERROR_STATUS2 register.
4. Software polls the [24] READ_DONE bit in the ECC_VECTOR register. When the READ_DONE bit is set to 1h, it does a read of the ECC_ERROR_STATUS1 and ECC_ERROR_STATUS2 registers.
5. After the interrupt has been serviced, software will clear the interrupt status by writing to bits [8] CLR_ECC_SEC, [9] CLR_ECC_DED or [10] CLR_ECC_OTHER depending on the type of ECC error in the ECC_ERROR_STATUS1 register.
6. Software has to poll the ECC_ERROR_STATUS1 register to guarantee that the status bit has been cleared. Otherwise there is no indication that the write has actually completed over the serial VBUS.
7. Software will write to the ECC_EOI register to clear the interrupt.

6.4.5.7.3.4 RAM Index Allocation

Table 6-101 shows the mapping of the RAM IDs to the ECC RAMs serviced by the aggregator.

Table 6-101. Mapping of the RAM IDs to the ECC RAMs

RAM Index	ECC RAM Prefix	Description
0	pr<k>_dram0_	Data RAM0 (8KB)
1	pr<k>_dram1_	Data RAM1 (8KB)
2	pr<k>_ram_	Shared Data RAM2 (64KB)
3	pr<k>_pru0_iram_	PRU0 Instruction Memory (16KB)
4	pr<k>_pru1_iram_	PRU1 Instruction Memory (16KB)

6.4.5.7.4 PRU-ICSS_ECC_CFG Registers

Table 6-103 lists the memory-mapped registers for the PRU-ICSS_ECC_CFG. All register offset addresses not listed in Table 6-103 should be considered as reserved locations and the register contents should not be modified.

Table 6-102. PRU-ICSS_ECC_CFG Instances

Module Name	Base Address
PRU-ICSS_0_ECC_CFG	20AA 7000h
PRU-ICSS_1_ECC_CFG	20AE 7000h

Table 6-103. PRU-ICSS_ECC_CFG Registers

Offset	Acronym	Register Name	PRU-ICSS_0_ ECC_CFG Physical Address	PRU-ICSS_1_ ECC_CFG Physical Address	Section
0h	ECC_REVISION	The Revision Register contains the ID and revision information for the ECC Aggregator module. It does not support byte access.	20AA 7000h	20AE 7000h	Section 11.13.5.1.6.1
8h	ECC_VECTOR	ECC RAM ID to select the ECC RAM to control or read status.	20AA 7008h	20AE 7008h	Section 11.13.5.1.6.2

Table 6-117. ECC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/ FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0h	Force single/double-bit error on the next RAM read.
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted.
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted.
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes.
1	ECC_CHECK	R/W	1h	Enable ECC check. ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are 0.
0	ECC_ENABLE	R/W	1h	Enable ECC generation.

Table 6-126. ECC_ERROR_STATUS1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_ROW	R	0h	Indicates the row/address where the single or double-bit error occurred.
15-11	RESERVED	R	0h	Reserved
10	CLR_ECC_OTHER	R/W1C	0h	1 indicates a successive single-bit error. Writing a 1 clears the status bit.
9	CLR_ECC_DED	R/W1C	0h	1 indicates a pending double-bit error. Writing a 1 clears the status bit.
8	CLR_ECC_SEC	R/W1C	0h	1 indicates a pending single-bit error. Writing a 1 clears the status bit.
7-3	RESERVED	R	0h	Reserved
2	ECC_OTHER	R/W1S	0h	1 indicates that successive single-bit errors have occurred while a writeback is still pending. Software can also write a 1 to set the pending status and write a ‘1’ to the corresponding clear bit to clear the status.
1	ECC_DED	R/W1S	0h	1 indicates pending double-bit error. Since the double-bit error from the ECC logic is a pulsed interrupt, this is also a status set register. The software can also write a ‘1’ to set the pending status and write a ‘1’ to the corresponding clear bit to clear the status.
0	ECC_SEC	R/W1S	0h	1 indicates pending single-bit error status. Since the single-bit error from the ECC logic is a pulsed interrupt, this is also a status set register. The software can also write a ‘1’ to set the pending status and write a ‘1’ to the corresponding clear bit to clear the status.

6.4.5.7.4.11 ECC_INT_STATUS_0 to ECC_INT_STATUS_15 Register (Offset = 40h to 7Ch) [reset = 0h]

ECC_INT_STATUS_0 to ECC_INT_STATUS_15 is shown in Figure 11-1043 and described in Table 11-2405.

These are the raw level interrupt status bits where each bit corresponds to the pending status from an ECC RAM. The bit associations with the ECC RAMs are assigned by the ECC aggregator module. There is 1 register for upto 32 ECC RAMs. The addresses increment for every additional 32-bit register required to hold the interrupt status for all the ECC RAMs (0 to N-1).

6.4.5.7.4.12 ECC_INT_ENABLE_0 to ECC_INT_ENABLE_15 Register (Offset = 80h to BCh) [reset = 0h]

ECC_INT_ENABLE_0 to ECC_INT_ENABLE_15 is shown in Figure 11-1044 and described in Table 11-2408.

These are interrupt enables associated with the interrupt from each of the ECC RAMs. Writing a 1 to a bit position in the register enables the interrupt from the associated ECC RAM. There is 1 register for upto 32 ECC RAMs. The addresses increment for every additional 32-bit register required for all ECC RAMs (0 to N-1).

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 6-146. PRU_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PCOUNTER_RST_VAL	R/W	0h	Program Counter Reset Value: This field controls the address where the PRU will start executing code from after it is taken out of reset.
15	RUNSTATE	R	0h	Run State: This bit indicates whether the PRU is currently executing an instruction or is halted. 0 = PRU is halted and host has access to the instruction RAM and debug registers regions. 1 = PRU is currently running and the host is locked out of the instruction RAM and debug registers regions. This bit is used by an external debug agent to know when the PRU has actually halted when waiting for a HALT instruction to execute, a single step to finish, or any other time when the pru_enable has been cleared.
14	BIG_ENDIAN	R	0h	
13-9	RESERVED	R	0h	Reserved
8	SINGLE_STEP	R/W	0h	Single Step Enable: This bit controls whether or not the PRU will only execute a single instruction when enabled. 0 = PRU will free run when enabled. 1 = PRU will execute a single instruction and then the pru_enable bit will be cleared. Note that this bit does not actually enable the PRU, it only sets the policy for how much code will be run after the PRU is enabled. The pru_enable bit must be explicitly asserted. It is legal to initialize both the single_step and pru_enable bits simultaneously. (Two independent writes are not required to cause the stated functionality.)
7-4	RESERVED	R	0h	Reserved
3	COUNTER_ENABLE	R/W	0h	PRU Cycle Counter Enable: Enables PRU cycle counters. 0 = Counters not enabled 1 = Counters enabled

Table 6-146. PRU_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	SLEEPING	R/W	0h	PRU Sleep Indicator: This bit indicates whether or not the PRU is currently asleep. 0 = PRU is not asleep 1 = PRU is asleep If this bit is written to a 0, the PRU will be forced to power up from sleep mode.
1	ENABLE	R/W	0h	Processor Enable: This bit controls whether or not the PRU is allowed to fetch new instructions. 0 = PRU is disabled. 1 = PRU is enabled. If this bit is de-asserted while the PRU is currently running and has completed the initial cycle of a multi-cycle instruction (LBxO,SBxO,SCAN, etc.), the current instruction will be allowed to complete before the PRU pauses execution. Otherwise, the PRU will halt immediately. Because of the unpredictability timing sensitivity of the instruction execution loop, this bit is not a reliable indication of whether or not the PRU is currently running. The pru_state bit should be consulted for an absolute indication of the run state of the core. When the PRU is halted, its internal state remains coherent therefore this bit can be reasserted without issuing a software reset and the PRU will resume processing exactly where it left off in the instruction stream.
0	SOFT_RST_N	R/W	1h	Soft Reset: When this bit is cleared, the PRU will be reset. This bit is set back to 1 on the next cycle after it has been cleared.

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 6-155. PRU_CYCLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CYCLECOUNT	R/W	0h	This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits ENABLE and COUNTENABLE set in the PRU control register). Counting halts while the PRU is disabled or counter is disabled, and resumes when re-eneabled. Counter clears the COUNTENABLE bit in the PRU control register when the count reaches FFFFFFFFh. (Count does does not wrap). The register can be read at any time. The register can be cleared when the counter or PRU is disabled. Clearing this register also clears the PRU Stall Count Register.

- PRU-ICSS_PRU_CTRL Registers: [0]
- PRU_CYCLE Register (Offset = Ch) [reset = 0h]: [0]

6.4.5.8.5 PRU_STALL Register (Offset = 10h) [reset = 0h]

PRU_STALL is shown in Figure 6-71 and described in Table 6-158.

STALL COUNT. This register counts the number of cycles for which the PRU has been enabled, but unable to fetch a new instruction. It is linked to the Cycle Count Register (0Ch) such that this register reflects the stall cycles measured over the same cycles as counted by the cycle count register. Thus the value of this register is always less than or equal to cycle count.

Table 6-157. PRU_STALL Instances

6.4.5.8.6 PRU_CTBIR0 Register (Offset = 20h) [reset = 0h]

PRU_CTBIR0 is shown in Figure 6-72 and described in Table 6-161.

CONSTANT TABLE BLOCK INDEX REGISTER 0. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching.

6.4.5.8.8 PRU_CTPPR0 Register (Offset = 28h) [reset = 0h]

PRU_CTPPR0 is shown in Figure 6-74 and described in Table 6-167.

CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 0. This register allows the PRU to set up the 256-byte page index for entries 28 and 29 in the PRU Constant Table which serve as general purpose pointers which can be configured to point to any locations inside the session router address map. This register is useful when the PRU needs to frequently access certain structures inside the session router address space whose locations are not hard coded such as tables in scratchpad memory.

Table 6-166. PRU_CTPPR0 Instances

Instance	Physical Address
PRU_ICSS_0_PRU0_CTRL	20AA 2028h

6.4.5.9.1 PRU_ICSS_DBG_GPREG0 Register (Offset = 0h) [reset = 0h]

PRU_ICSS_DBG_GPREG0 is shown in Figure 6-76 and described in Table 6-175.

Return to Summary Table.

DEBUG PRU GENERAL PURPOSE REGISTER 0. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.

Table 6-174. PRU_ICSS_DBG_GPREG0 Instances

PRU-ICSS PRU Cores

- PRU_ICSS_DBG_GPREG1 Register (Offset = 4h) [reset = 0h]: [0]
- PRU_ICSS_PRU_DEBUG Registers: [0]

6.4.5.9.3 PRU_ICSS_DBG_GPREG2 Register (Offset = 8h) [reset = 0h]

PRU_ICSS_DBG_GPREG2 is shown in Figure 6-78 and described in Table 6-181.

Return to Summary Table.

DEBUG PRU GENERAL PURPOSE REGISTER 2. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.

Table 6-180. PRU_ICSS_DBG_GPREG2 Instances

Instance	Physical Address
PRU_ICSS_0_PRU_DEBUG_0	20AA 2408h
PRU_ICSS_0_PRU_DEBUG_1	20AA 4408h
PRU_ICSS_1_PRU_DEBUG_0	20AE 2408h

6.4.5.9.16 PRU_ICSS_DBG_GPREG15 Register (Offset = 3Ch) [reset = 0h]

PRU_ICSS_DBG_GPREG15 is shown in Figure 6-91 and described in Table 6-220.

Return to Summary Table.

DEBUG PRU GENERAL PURPOSE REGISTER 15. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.

- PRU_ICSS_DBG_GPREG27 Register (Offset = 6Ch) [reset = 0h]: [0]
- PRU_ICSS_PRU_DEBUG Registers: [0]

6.4.5.9.29 PRU_ICSS_DBG_GPREG28 Register (Offset = 70h) [reset = 0h]

PRU_ICSS_DBG_GPREG28 is shown in Figure 6-104 and described in Table 6-259.

Return to Summary Table.

DEBUG PRU GENERAL PURPOSE REGISTER 28. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.

Table 6-258. PRU_ICSS_DBG_GPREG28 Instances

Instance	Physical Address

6.4.5.9.42 PRU_ICSS_DBG_CT_REG9 Register (Offset = A4h) [reset = 4A100000h]

PRU_ICSS_DBG_CT_REG9 is shown in Figure 6-117 and described in Table 6-298.

Return to Summary Table.

DEBUG PRU CONSTANTS TABLE ENTRY 9. This register allows an external agent to debug the PRU while it is disabled. Since some of the constants table entries may actually depend on system inputs / and or the internal state of the PRU, these registers are provided to allow an external agent to easily determine the state of the constants table.

Return to Summary Table.

DEBUG PRU CONSTANTS TABLE ENTRY 21. This register allows an external agent to debug the PRU while it is disabled. Since some of the constants table entries may actually depend on system inputs / and or the internal state of the PRU, these registers are provided to allow an external agent to easily determine the state of the constants table.

6.4.6 PRU-ICSS Local Interrupt Controller

This section describes functionality of the PRU-ICSS integrated Interrupt Controller - ICSS_INTC.

6.4.6.1 PRU-ICSS Interrupt Controller Overview

The PRU-ICSS interrupt controller (ICSS_INTC) maps interrupts coming from different parts of the device (mapped to PRU-ICSS_0/PRU-ICSS_1) to a reduced set of PRU-ICSS interrupt channels.

The ICSS_INTC has the following features:

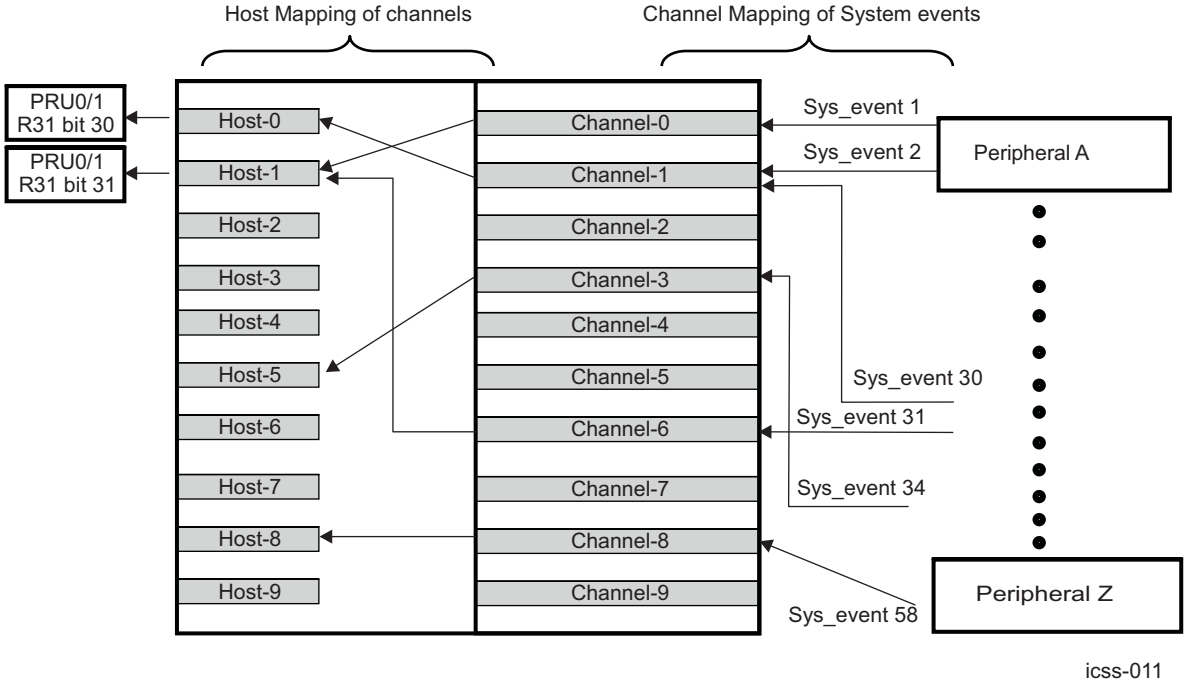
- Capturing up to 64 System Events (inputs)
- Supports up to 10 output interrupt channels.
- Generation of 10 Host Interrupts
  - 2 Host Interrupts for the PRUs.
  - 7 Host Interrupts exported from the PRU-ICSS for signaling the Arm interrupt controllers (pulse and level provided).
  - 1 Host Interrupt for the other PRU-ICSS.
- Each system event can be enabled and disabled.
- Each host event can be enabled and disabled.
- Hardware prioritization of events.

6.4.6.2 PRU-ICSS Interrupt Controller Functional Description

The PRU-ICSS incorporates an interrupt controller - ICSS_INTC that supports up to 64 system interrupts from different peripherals (including 32 interrupts from PRU-ICSS located interrupt sources). The ICSS_INTC maps these system events to 10 channels inside the ICSS_INTC (see Figure 6-140). Interrupts from these 10 channels are further mapped to 10 Host Interrupts.

- Any of the 64 system interrupts can be mapped to any of the 10 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Any of the 10 channels can be mapped to any of the 10 host interrupts. It is recommended to map channel “x” to host interrupt “x”, where x is from 0 to 9
- A channel should not be mapped to more than one host interrupt
- For channels mapping to the same host interrupt, lower number channels have higher priority.
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.
- Host Interrupt 0 is connected to bit 30 in register 31 (R31) of PRU0 and PRU1.
- Host Interrupt 1 is connected to bit 31 in register 31 (R31) for PRU0 and PRU1.
- Host Interrupts 2 through 9 exported from PRU-ICSS and mapped to interrupt controllers in the device.
- Host Interrupt 7 is exported from PRU-ICSS for signaling the other PRU-ICSS

Figure 6-140. PRU-ICSS Interrupt Controller Block Diagram



6.4.6.2.1 PRU-ICSS Interrupt Controller System Events

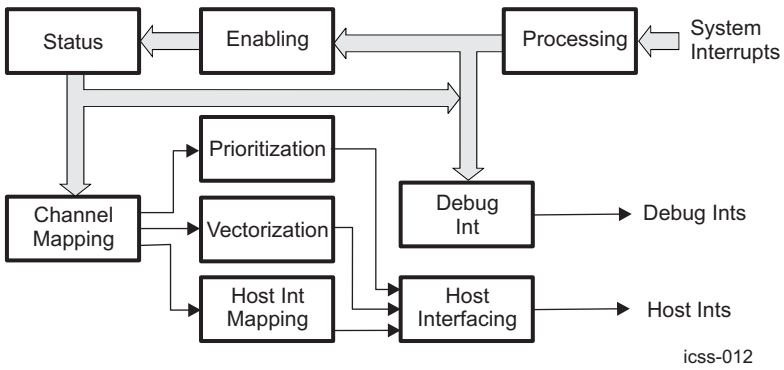
The PRU-ICSS system events - interrupt inputs. The device includes a internal mux that selects the "Standard" (default) or "MII_RT" mode system events. The mux control signal is controlled by PRUSS_MII_RT[0] MII_RT_EVENT_EN, which can be modified by software in PRU-ICSS CFG register space.

6.4.6.2.2 PRU-ICSS Interrupt Controller System Events Flow

The ICSS_INTC module controls the system event mapping to the host interrupt interface. System events are generated by the device peripherals or PRUs. The ICSS_INTC receives the system interrupts and maps them to internal channels. The channels are used to group interrupts together and to prioritize them. These channels are then mapped onto the host interrupts. Interrupts from the system side are active high in polarity. They are also pulse type of interrupts.

The ICSS_INTC encompasses many functions to process the system interrupts and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, and host interfacing. Figure 6-141 illustrates the flow of system interrupts through the functions to the host. The following subsections describe each part of the flow.

Figure 6-141. Flow of System Interrupts to Host



6.4.6.2.2.1 PRU-ICSS Interrupt Processing

This block does following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the processing block, all interrupts will be active high pulses.

6.4.6.2.2.1.1 PRU-ICSS Interrupt Enabling

The next stage of ICSS_INTC is to enable system interrupts based on programmed settings. The following sequence is to be followed to enable interrupts:

- Enable required system interrupts: System interrupts that are required to get propagated to host are to be enabled individually by writing to INDEX field in the system interrupt enable indexed set register (PRUSS_INTC_EISR). The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.
- Enable required host interrupts: By writing 1 to the appropriate bit of the INDEX field in the host interrupt enable indexed set register (PRUSS_INTC_HIEISR), enable the required host interrupts. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if that host interrupt is already enabled.
- Enable all host interrupts: By setting the ENABLE bit in the global enable register (PRUSS_INTC_GER) to 1, all host interrupts will be enabled. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.

6.4.6.2.2.2 PRU-ICSS Interrupt Status Checking

The next stage is to capture which system interrupts are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the system interrupt without regards to the enable bit for the system interrupt. Enabled status is the pending status of the system interrupts with the enable bits active. When the enable bit is inactive, the enabled status will always be inactive. The enabled status of system interrupts is captured in system interrupt status enabled/clear registers (PRUSS_INTC_SECR1 and PRUSS_INTC_SECR0).

Status of system interrupt 'N' is indicated by the N-th bit of PRUSS_INTC_SECR1 and PRUSS_INTC_SECR0. Since there are 64 system interrupts, two 32-bit registers are used to capture the enabled status of interrupts. The pending status reflects whether the system interrupt occurred since the last time the status register bit was cleared. Each bit in the status register can be individually cleared.

6.4.6.2.2.3 PRU-ICSS Interrupt Channel Mapping

The ICSS_INTC has 10 internal channels to which enabled system interrupts can be mapped. Channel 0 has highest priority and channel 9 has the lowest priority. Channels are used to group the system interrupts into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs.

When multiple system interrupts are mapped to the same channel their interrupts are ORed together so that when either is active the output is active. The channel map registers (PRUSS_INTC_CMRi, where i=0 to 15) define the channel for each system interrupt. There is one register per 4 system interrupts; therefore, there are 16 channel map registers for a system of 64 interrupts. The channel for each system interrupt can be set using these registers.

6.4.6.2.2.3.1 PRU-ICSS Host Interrupt Mapping

The hosts can be the local PRU processors (PRU0 and PRU1) as well as device processors located outside PRU-ICSS such as MPU Cortex-A15, DSP, etc. The 10 channels from the ICSS_INTC can be mapped to any of the 10 Host interrupts. The Host map registers (PRUSS_INTC_HMR0 - PRUSS_INTC_HMR2) define the channel for each system interrupt. There is one register per 4 channels; therefore, there are 3 host map registers for 10 channels. When multiple channels are mapped to the same host interrupt, then prioritization is done to select which interrupt is in the highest-priority channel and which should be sent first to the host.

6.4.6.2.2.3.2 PRU-ICSS Interrupt Prioritization

The next stage of the ICSS_INTC is prioritization. Since multiple interrupts can feed into a single channel and multiple channels can feed into a single host interrupt, it is to read the status of all system interrupts to determine the highest priority interrupt that is pending. The ICSS_INTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritizations:

- The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 9 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
- The second level of prioritization is between the active system interrupts for the prioritized channel. The system interrupt in position 0 has the highest priority and system interrupt 63 has the lowest priority. So the second level of prioritization picks the lowest position active system interrupt.

This is the final prioritized system interrupt for the host interrupt and is stored in the global prioritized index register (PRUSS_INTC_GPIR). The highest priority pending interrupt with respect to each host interrupts can be obtained using the host interrupt prioritized index registers (PRUSS_INTC_HIPIRj where j=0 to 9).

6.4.6.2.2.4 PRU-ICSS Interrupt Nesting

The ICSS_INTC can also perform a nesting function in its prioritization. Nesting is a method of disabling certain interrupts (usually lower-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

The nesting is done in one of three methods:

1. Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (PRUSS_INTC_GNLR) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
2. Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting level for the host interrupt is returned to its original value. The host interrupt nesting level registers (PRUSS_INTC_HINLRj where j=0 to 9) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.
3. Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the system interrupts, and then re-enables all the host interrupts. This now allows only the system interrupts that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out system interrupts. This method requires the most software interaction but gives the most flexibility if simple channel based nesting mechanisms are not adequate.

6.4.6.2.2.5 PRU-ICSS Interrupt Status Clearing

After servicing the interrupt (after execution of the ISR), interrupt status is to be cleared. If a system interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. It is also essential to clear all system interrupts before the PRU is halted as the PRU does not power down unless all the interrupt status are cleared. For clearing the status of an interrupt, whose interrupt number is N, write a 1 to the Nth bit position in the system interrupt status enabled/clear registers (PRUSS_INTC_SECR0 and PRUSS_INTC_SECR1). System interrupt N can also be cleared by writing the value N into the system interrupt status indexed clear register (PRUSS_INTC_SICR).

6.4.6.2.3 PRU-ICSS Interrupt Disabling

At any time, if any interrupt is not to be propagated to the host, then that interrupt should be disabled. For disabling an interrupt whose interrupt number is N, write a 1 to the Nth bit in the system interrupt enable clear registers (PRUSS_INTC_ECR0 and PRUSS_INTC_ECR1). System interrupt N can also be disabled by writing the value N in the system interrupt enable indexed clear register (PRUSS_INTC_EICR).

6.4.6.3 PRU-ICSS Interrupt Controller Basic Programming Model

Follow these steps to configure the interrupt controller.

1. Set polarity and type of system event through the System Interrupt Polarity Registers (PRUSS_INTC_SIPR1 and PRUSS_INTC_SIPR0) and the System Interrupt Type Registers (PRUSS_INTC_SITR1 and PRUSS_INTC_SITR0). Polarity of all system interrupts is always high. Type of all system interrupts is always pulse.
2. Map system event to ICSS_INTC channel through PRUSS_INTC_CMRi (i=0 to 15) channel mapping registers.
3. Map channel to host interrupt through ICSS_INTC_HMR0/1/2 registers. Recommended channel “x” to be mapped to host interrupt “x”.
4. Clear system interrupt by writing 1 to ICSS_INTC_SECR0/1 registers.
5. Enable host interrupt by writing index value to PRUSS_INTC_HIEISR register.
6. Enable interrupt nesting if desired.
7. Globally enable all interrupts through register PRUSS_INTC_GER[0] ENABLE_HINT_ANY bit.

6.4.6.4 PRU-ICSS Interrupt Requests Mapping

The PRU-ICSS_0_INTC/ PRU-ICSS_1_INTC lines 0 through 31 are mapped to events which are generated by PRU-ICSS integrated modules. Table 6-366 shows mapping of the different PRU-ICSS internally sourced IRQ events to PRU-ICSS_0_INTC/ PRU-ICSS_1_INTC interrupt lines 0 through 31.

Table 6-366. PRU-ICSS_0/ PRU-ICSS_1 Internal Interrupts

Event Number	PRU-ICSS Internal Interrupt Signal Name	Source

The IRQ input lines 32 through 63 receive interrupts which come from various device peripherals located outside PRU-ICSS_0 and PRU-ICSS_1. They are delivered on the PRU-ICSS_0_INTC/ PRU-ICSS_1_INTC inputs (32 through 63).

Note that for the PRU-ICSS_INTC input lines **32 through 55**, there is an additional multiplexing option programmable in the PRU-ICSS_CFG located register bit - PRUSS_MII_RT[0] MII_RT_EVENT_EN. By default the MII_RT_EVENT_EN is set to 0b0 which selects the IRQ sources to be the PRU-ICSS dedicated device outputs ("**Standard**" mode). By setting MII_RT_EVENT_EN to 0b1, a set of PRU-ICSS MII_RT module associated events, are mapped to the same lines.

The Table 6-367 and the Table 6-368 shows PRU-ICSS_0/PRU-ICSS_1 MII_RT events mapping on the PRU-ICSS_0_INTC / PRU-ICSS_1_INTC inputs 32 through 55 (PRU-ICSS_0) / 32 through 55 (PRU-ICSS_1) valid for the "MII_RT" mode (with PRUSS_MII_RT[0] MII_RT_EVENT_EN register bit set to "0b1").

Table 6-367. PRU-ICSS_0 MII_RT Mode Interrupts

6.4.6.5.4 PRUSS_INTC_GNLR Register (Offset = 1Ch) [reset = 100h]

PRUSS_INTC_GNLR is shown in Figure 6-145 and described in Table 6-383.

The Global Nesting Level Register allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. This register is only available when nesting is configured.

Table 6-382. PRUSS_INTC_GNLR Instances

Instance	Physical Address
PRU_ICSS_0_INTC	20AA 001Ch
PRU_ICSS_1_INTC	20AE 001Ch

6.4.6.5.5 PRUSS_INTC_SISR Register (Offset = 20h) [reset = 0h]

PRUSS_INTC_SISR is shown in Figure 6-146 and described in Table 6-386.

The System Interrupt Status Indexed Set Register allows setting the status of an interrupt. The interrupt to set is the index value written. This sets the Raw Status Register bit of the given index.

Table 6-385. PRUSS_INTC_SISR Instances

Instance	Physical Address

- PRU-ICSS Interrupt Processing: [0]

6.4.6.5.8 PRUSS_INTC_EICR Register (Offset = 2Ch) [reset = 0h]

PRUSS_INTC_EICR is shown in Figure 6-149 and described in Table 6-395.

The System Interrupt Enable Indexed Clear Register allows disabling an interrupt. The interrupt to disable is the index value written. This clears the Enable Register bit of the given index.

Table 6-394. PRUSS_INTC_EICR Instances

Instance	Physical Address

6.4.6.5.9 PRUSS_INTC_HIEISR Register (Offset = 34h) [reset = 0h]

PRUSS_INTC_HIEISR is shown in Figure 6-150 and described in Table 6-398.

The Host Interrupt Enable Indexed Set Register allows enabling a host interrupt output. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if already enabled.

Table 6-397. PRUSS_INTC_HIEISR Instances

6.4.6.5.46 PRUSS_INTC_HIPIR_7 Register (Offset = 91Ch) [reset = 80000000h]

PRUSS_INTC_HIPIR_7 is shown in Figure 6-187 and described in Table 6-509.

The Host Interrupt Prioritized Index Register_j (where j=0 to 9) shows the highest priority current pending interrupt for the host interrupt j. There is one register per host interrupt.

6.4.7 PRU-ICSS UART Module

This section describes an Universal Asynchronous Receive and Transmit (UART) module which is part of the device integrated PRU-ICSS_0 and PRU-ICSS_1 - PRU-ICSS_0_UART0 and PRU-ICSS_1_UART0, respectively.

6.4.7.1 PRU-ICSS UART Module Overview

6.4.7.1.1 Purpose of the PRU-ICSS integrated UART Peripheral

The PRU-ICSS_UART0 peripheral is based on the industry standard TL16C550 asynchronous communications element, which in turn is a functional upgrade of the TL16C450. Functionally similar to the TL16C450 on power up (single character or TL16C450 mode), the PRU-ICSS_UART0 can be placed in an alternate FIFO (TL16C550) mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

The PRU-ICSS_UART0 performs serial-to-parallel conversions on data received from a peripheral device and parallel-to-serial conversion on data received from the CPU. The CPU can read the PRU-ICSS_UART0 status at any time. The PRU-ICSS_UART0 includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

The PRU-ICSS_UART0 includes a programmable baud generator capable of dividing the PRU-ICSS_UART0 input clock by divisors from 1 to 65535 and producing a 16× reference clock or a 13× reference clock for the internal transmitter and receiver logic.

6.4.7.1.2 PRU-ICSS UART Key Features

6.4.7.1.2.1 PRU-ICSS UART Module Industry Standard Compliance Statement

The PRU-ICSS_UART0 peripheral is based on the industry standard TL16C550 asynchronous communications element, which is a functional upgrade of the TL16C450. The information in this chapter assumes that user is familiar with these standards.

6.4.7.2 PRU-ICSS UART Environment

This section describes the PRU-ICSS_UART0 module interface to the device environment

6.4.7.2.1 PRU-ICSS UART Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. For more information on the PRU-ICSS_UART0 pin multiplexing, refer to the Section 5.1.3.1.1, *Pad Configuration Registers* in the chapter, *BOOT_CFG*.

6.4.7.2.2 PRU-ICSS UART Signal Descriptions

The PRU-ICSS_UART0 utilize a minimal number of signal connections to interface with external devices. The PRU-ICSS_UART0 signal descriptions are included in Table 6-562.

Table 6-562. PRUSS_UART0 Signal Descriptions

Signal Name	Signal Type	Function
UART0_TXD	Output	Serial data transmit
UART0_RXD	Input	Serial data receive
$\overline{\text{UART0\_CTS}}$	Input	Clear-to-Send handshaking signal
$\overline{\text{UART0\_RTS}}$	Output	Request-to-Send handshaking signal

6.4.7.2.3 PRU-ICSS UART Data Format and Protocol Description

6.4.7.2.3.1 PRU-ICSS UART Transmission Protocol

The PRU-ICSS_UART0 transmitter section includes a transmitter hold register (THR), memory mapped in the register PRUSS_UART_RBR_THR_REGISTERS[7:0] DATA bitfield and a transmitter shift register (TSR), which is NOT memory mapped. When the PRU-ICSS_UART0 is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the PRU-ICSS_UART0 line control register PRUSS_UART_LINE_CONTROL_REGISTER. Based on the settings chosen in this register, the PRU-ICSS_UART0 transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

6.4.7.2.3.2 PRU-ICSS UART Reception Protocol

The PRU-ICSS_UART0 receiver section includes a receiver shift register (RSR), that is not memory mapped, and a receiver buffer register (RBR), memory mapped as the register PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA bitfield. When the PRU-ICSS_UART0 is in the FIFO mode, RBR is a 16-byte FIFO. Receiver section control is a function of the PRU-ICSS_UART0 line control register - PRUSS_UART_LINE_CONTROL_REGISTER. Based on the settings chosen in this register, the PRU-ICSS_UART0 receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

6.4.7.2.3.3 PRU-ICSS UART Data Format

The PRU-ICSS_UART0 transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

The PRU-ICSS_UART0 receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in Figure 6-205.

Figure 6-205. PRU-ICSS UART Protocol Formats

Transmit/Receive for 5-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	PARITY	STOP1

Transmit/Receive for 6-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	PARITY	STOP1

Transmit/Receive for 7-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	D6	PARITY	STOP1

Transmit/Receive for 8-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	D6	D7	PARITY	STOP1

6.4.7.2.3.3.1 Frame Formatting

Character length is specified using the PRUSS_UART_LINE_CONTROL_REGISTER[1-0] WLS bit field (see Table 11-3499).

The number of stop-bits is specified using the PRUSS_UART_LINE_CONTROL_REGISTER[2] STB bit (see Table 11-3499).

The parity bit is programmed using the PRUSS_UART_LINE_CONTROL_REGISTER[5-3] PEN, EPS, and SP bits (see Table 11-3498).

Table 6-563. Relationship Between ST, EPS, and PEN Bits in UART_LCR

ST Bit	EPS Bit	PEN Bit	Parity Option
x	x	0	Parity disabled: No PARITY bit is transmitted or checked.
0	0	1	Odd parity selected: Odd number of logic 1s.
0	1	1	Even parity selected: Even number of logic 1s.
1	0	1	Stick parity selected with PARITY bit transmitted and checked as set.
1	1	1	Stick parity selected with PARITY bit transmitted and checked as cleared.

Table 6-564. Number of STOP Bits Generated

STB Bit	WLS Bit	Word Length Selected with WLS Bits	Number of STOP Bits Generated	Baud Clock (BCLK) Cycles
0	x	Any word length	1	16
1	0h	5 bits	1.5	24
1	1h	6 bits	2	32
1	2h	7 bits	2	32
1	3h	8 bits	2	32

6.4.7.2.4 PRU-ICSS UART Clock Generation and Control

The PRU-ICSS_UART0 bit clock is derived from an input clock to the PRU-ICSS_UART0. See the device Data Manual to check the maximum data rate supported by the PRU-ICSS_UART0.

Figure 6-206 is a conceptual clock generation diagram for the PRU-ICSS_UART0. The processor clock generator receives a signal from an external clock source and produces a PRU-ICSS_UART0 input clock with a programmed frequency. The PRU-ICSS_UART0 contains a programmable baud generator that takes an input clock and divides it by a divisor in the range between 1 and (2^{16} - 1) to produce a baud clock (BCLK). The frequency of BCLK is sixteen times (16×) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times (13×) the baud rate (each received or transmitted bit lasts 13

BCLK cycles). When the PRU-ICSS_UART0 is receiving, the bit is sampled in the 8th BCLK cycle for 16× over sampling mode and on the 6th BCLK cycle for 13× over-sampling mode. The 16× or 13× reference clock is selected by configuring the mode definition register (MDR) - PRUSS_UART_MODE_DEFINITION_REGISTER [0] OSM_SEL bit. The formula to calculate the divisor is:

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 16} \quad \text{[MDR.OSM\_SEL = 0]}$$

pruss-13

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 13} \quad \text{[MDR.OSM\_SEL = 1]}$$

icss-14

Two 8-bit register fields:

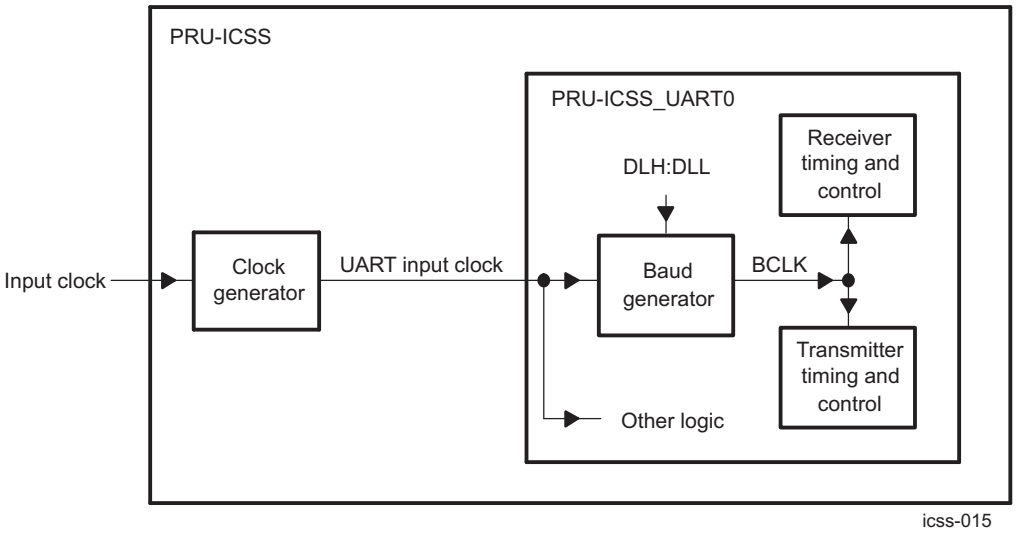
- PRUSS_UART_DIVISOR_REGISTER_MSB_[7:0] DLH
- PRUSS_UART_DIVISOR_REGISTER_LSB_[7:0] DLL,

called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see the PRU-ICSS_UART0 register descriptions in the Section 6.4.7.4, *PRU-ICSS UART Register Manual*. These divisor latches must be loaded during initialization of the PRU-ICSS_UART0 in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 6-207 summarizes the relationship between the transferred data bit, BCLK, and the PRU-ICSS_UART0 input clock. Note that the timing relationship depicted in Figure 6-207 shows that each bit lasts for 16 BCLK cycles . This is in case of 16x over-sampling mode. For 13× over-sampling mode each bit lasts for 13 BCLK cycles .

Example baud rates and divisor values relative to a 150-MHz PRU-ICSS_UART0 input clock and 16× over-sampling mode are shown in Table 6-565.

Figure 6-206. PRU-ICSS UART Clock Generation Diagram



icss-015

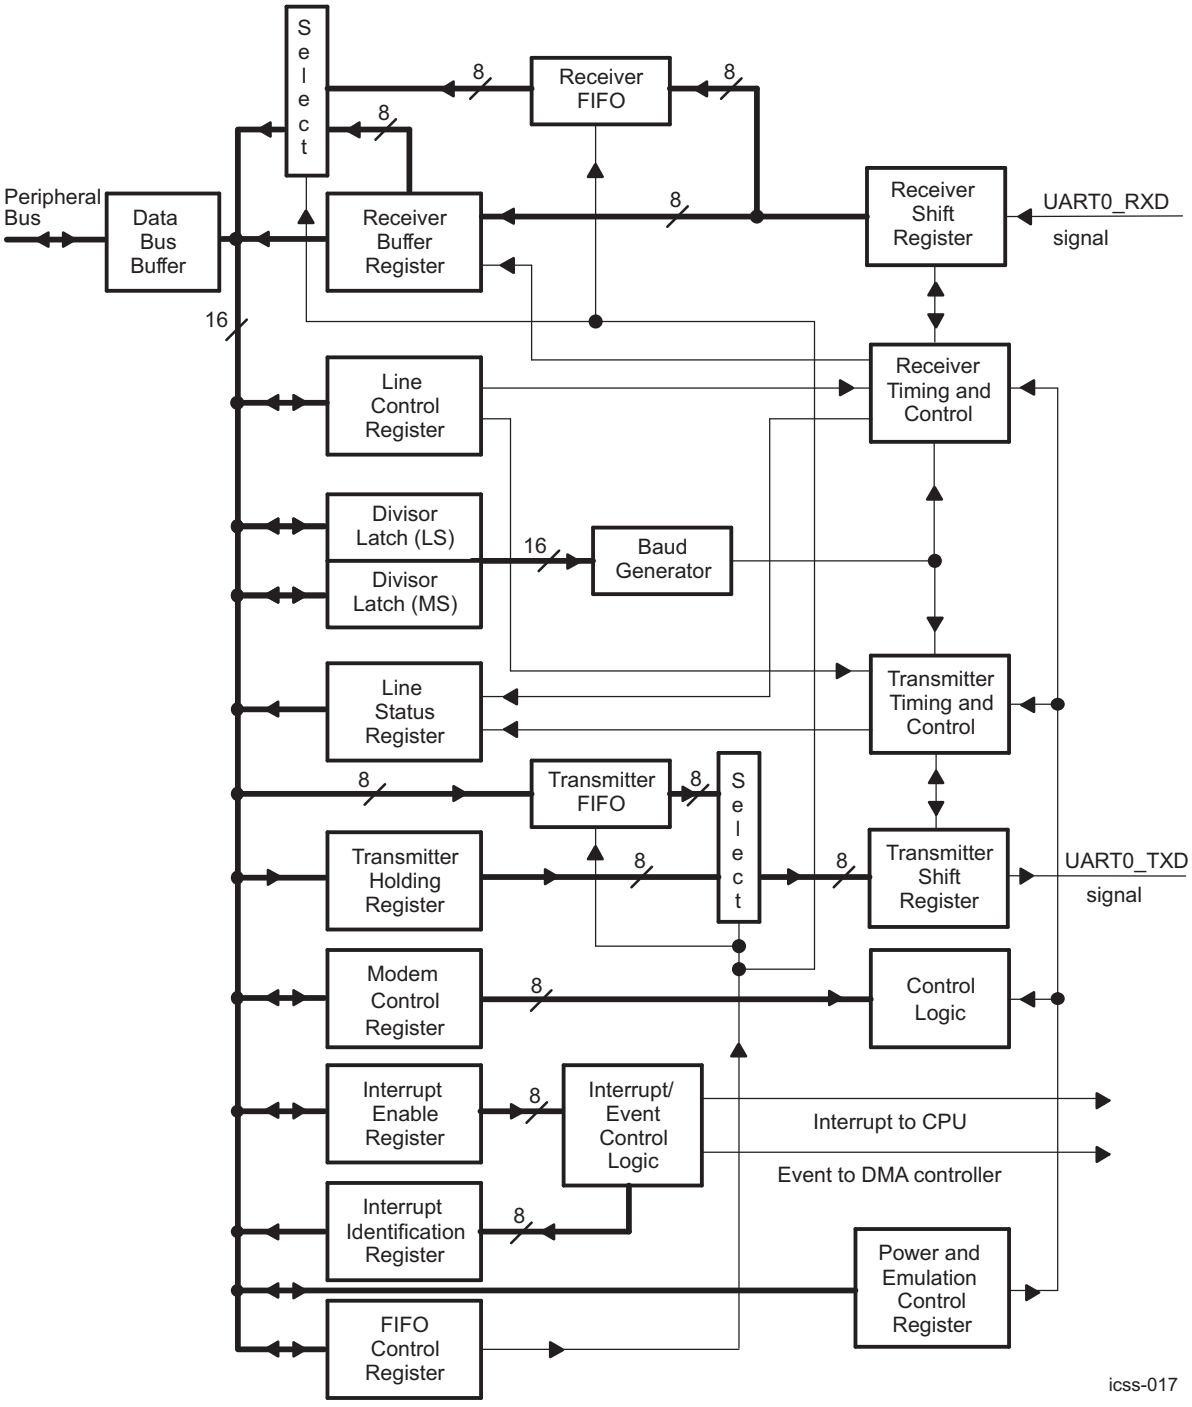
6.4.7.3 PRU-ICSS UART Module Functional Description

6.4.7.3.1 PRU-ICSS UART Functional Block Diagram

A functional block diagram of the PRU-ICSS_UART0 is shown in Figure 6-208.

Figure 6-208. PRU-ICSS UART Block Diagram



NOTE: The value *n* indicates the applicable UART where there are multiple instances. For the PRU-ICSS, there is only one instance and all UART signals should reflect this (e.g., UART0_TXD instead of UARTn_TXD).

6.4.7.3.2 PRU-ICSS UART Reset Considerations

6.4.7.3.2.1 PRU-ICSS UART Software Reset Considerations

Two bits in the power and emulation management register - PRUSS_UART_POWERMANAGEMENT_AND_EMULATION_REGISTER, control resetting the parts of the PRU-ICSS_UART0:

- The bit [14] UTRST controls resetting the transmitter only. If UTRST = 1, the transmitter is active; if UTRST = 0, the transmitter is in reset.
- The bit [13] URRST controls resetting the receiver only. If URRST = 1, the receiver is active; if URRST = 0, the receiver is in reset.

In each case, putting the receiver and/or transmitter in reset will reset the state machine of the affected portion but does not affect the PRU-ICSS_UART0 registers.

6.4.7.3.2.2 PRU-ICSS UART Hardware Reset Considerations

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the PRU-ICSS_UART0 state machine is reset and the PRU-ICSS_UART0 registers are forced to their default states. The default states of the registers are shown in .

6.4.7.3.3 PRU-ICSS UART Power Management

The PRU-ICSS_UART0 peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the PRU-ICSS_UART0 peripheral and other PRU-ICSS peripherals is controlled by the device Power Sleep Controler (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. For more details on the power management procedures using the PSC, refer to the Section 5.2, *Power Management.*

6.4.7.3.4 PRU-ICSS UART Interrupt Support

6.4.7.3.4.1 PRU-ICSS UART Interrupt Events and Requests

The PRU-ICSS_UART0 generates the interrupt requests described in Table 6-567. All requests are multiplexed through an arbiter to a single PRU-ICSS_UART0 interrupt request to the CPU, as shown in Figure 6-209. Each of the interrupt requests has an enable bit in the interrupt enable register (IER) - PRUSS_UART_INTERRUPT_ENABLE_REGISTER and is recorded in INTID bitfield of PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER.

If an interrupt occurs and the corresponding enable bit is set to 1, the interrupt request is recorded in corresponding INTID bitfield and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0, the interrupt request is blocked. The interrupt request is neither recorded in INTID, nor forwarded to the CPU.

6.4.7.3.4.2 PRU-ICSS UART Interrupt Multiplexing

The PRU-ICSS_UART0 have dedicated interrupt signals to the CPU and the interrupts are not multiplexed with any other interrupt source.

Table 6-567. PRU-ICSS UART Interrupt Requests Descriptions

PRU-ICSS_UART0 Interrupt Request	Interrupt Source	Comment
THREINT	THR-empty condition: The transmitter holding register (THR) or the transmitter FIFO is empty. All of the data has been copied from THR, (i.e. PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA) to the transmitter shift register (TSR).	If THREINT is enabled in PRUSS_UART_INTERRUPT_ENABLE_REGISTER, by setting the ETBEI bit, it is recorded in INTID bitfield. As an alternative to using THREINT, the CPU can poll the THRE bit in the line status register PRUSS_UART_LINE_STATUS_REGISTER.

Table 6-567. PRU-ICSS UART Interrupt Requests Descriptions (continued)

PRU-ICSS_UART0 Interrupt Request	Interrupt Source	Comment
RDAINT	Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.	If RDAINT is enabled in PRUSS_UART_INTERRUPT_ENABLE_REGISTER, by setting the ERBI bit, it is recorded in INTID bitfield. As an alternative to using RDAINT, the CPU can poll the DR bit in the line status register PRUSS_UART_LINE_STATUS_REGISTER. In the FIFO mode, this is not a functionally equivalent alternative because the DR bit does not respond to the FIFO trigger level. The DR bit only indicates the presence or absence of unread characters.
RTOINT	Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 6-569), and there is at least one character in the receiver FIFO during this time.	The receiver time-out interrupt prevents the PRUSS_UART0 from waiting indefinitely, in the case when the receiver FIFO level is below the trigger level and thus does not generate a receiver data-ready interrupt. If RTOINT is enabled in PRUSS_UART_INTERRUPT_ENABLE_REGISTER, by setting the ERBI bit, it is recorded in INTID bitfield. There is no status bit to reflect the occurrence of a time-out condition.
RLSINT	Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.	If RLSINT is enabled in PRUSS_UART_INTERRUPT_ENABLE_REGISTER, by setting the ELSI bit, it is recorded in INTID bitfield. As an alternative to using RLSINT, the CPU can poll the following bits in the line status register PRUSS_UART_LINE_STATUS_REGISTER: overrun error indicator (OE), parity error indicator (PE), framing error indicator (FE), and break indicator (BI).

Figure 6-209. PRU-ICSS UART Interrupt Request Enable Paths

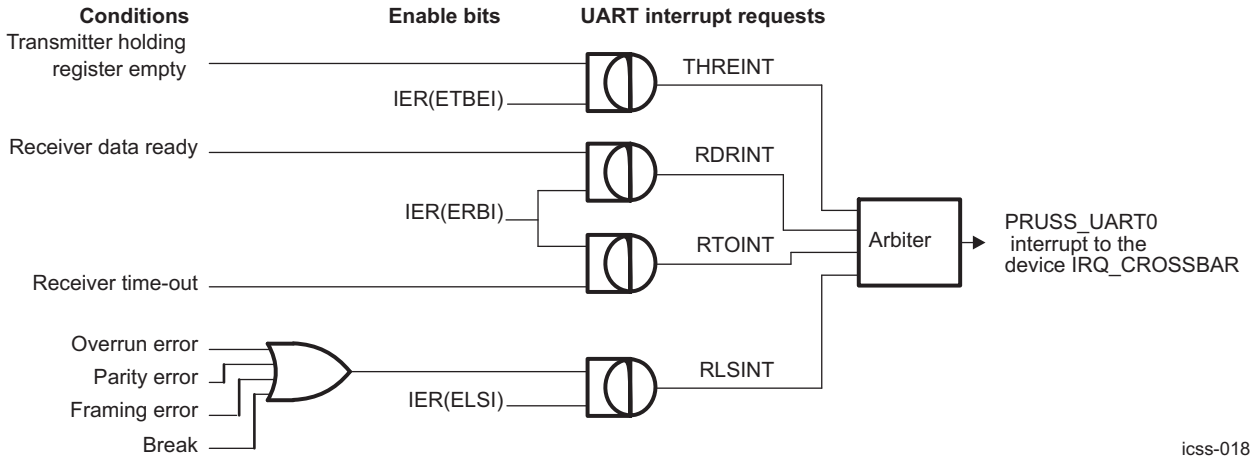


Table 6-568. Interrupt Identification and Interrupt Clearing Information

Priority Level	IIR Bits				Interrupt Type	Interrupt Source	Event That Clears Interrupt
	3	2	1	0			
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the PRUSS_UART_LINE_STATUS_REGISTER clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The receiver buffer register (RBR) is read.
						FIFO mode: Trigger level reached. If four character times (see) pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level. (1)
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times (see), and there is at least one character in the receiver FIFO during this time.	One of the following events: • A character is read from the receiver FIFO (1) • A new character arrives in the receiver FIFO • The URRST bit in the power and emulation management register (PRUSS_UART_POWERMANAGEMENT_AND_EMULATION_REGISTER) is loaded with 0.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: Transmitter holding register (THR) is empty.	A character is written to the transmitter holding register (THR) or the interrupt identification register (IIR) is read.
						FIFO mode: Transmitter FIFO is empty.	

(1) In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

6.4.7.3.5 PRU-ICSS UART DMA Event Support

In the FIFO mode, the PRU-ICSS_UART0 generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the FIFO control PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER [7:6] FIFOEN_RXFIFTL bitfield. Every time the trigger level is reached or a receiver time-out occurs, the PRU-ICSS_UART0 sends a receive event to the EDMA controller. In response, the EDMA controller reads the data from the receiver FIFO by way of the receiver buffer register PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA. Note that the receive event is not asserted if the data at the top of the receiver FIFO is erroneous even if the trigger level has been reached.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the PRU-ICSS_UART0 sends an UTXEVT signal to the EDMA controller. In response, the EDMA controller refills the transmitter FIFO by way of the transmitter holding register (THR) - PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA. The UTXEVT signal is also sent to the DMA controller when the PRU-ICSS_UART0 is taken out of reset using the UTRST bit in the power and emulation management register (PRUSS_UART_POWERMANAGEMENT_AND_EMULATION_REGISTER).

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the PRU-ICSS_UART0 generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the PRU-ICSS_UART0 event is generated. Otherwise, the DMA channel will miss the event and, unless the PRU-ICSS_UART0 generates a new event, no data transfer will occur.

6.4.7.3.6 PRU-ICSS UART Operations

6.4.7.3.6.1 PRU-ICSS UART Transmission

The PRU-ICSS_UART0 transmitter section includes a transmitter hold register (THR) mapped in the PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA bitfield and a transmitter shift register (TSR). When the PRU-ICSS_UART0 is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the PRU-ICSS_UART0 line control register PRUSS_UART_LINE_CONTROL_REGISTER. Based on the settings chosen in this register, the PRU-ICSS_UART0 transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

THR receives data from the internal data bus, and when TSR is ready, the PRU-ICSS_UART0 moves the data from THR to TSR. The PRU-ICSS_UART0 serializes the data in TSR and transmits the data on the UART0_TXD pin.

In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled in the interrupt enable register PRUSS_UART_INTERRUPT_ENABLE_REGISTER, an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER bitfield INTID is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or INTID bitfield is read.

6.4.7.3.6.2 PRU-ICSS UART Reception

The PRU-ICSS_UART0 receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR) mapped in PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA bitfield. When the PRU-ICSS_UART0 is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16× receiver clock. Receiver section control is a function of the PRU-ICSS_UART0 line control register PRUSS_UART_LINE_CONTROL_REGISTER. Based on the settings chosen in this register, the PRU-ICSS_UART0 receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

RSR receives the data bits from the UART0_RXD pin. Then RSR concatenates the data bits and moves the resulting value into RBR (or the receiver FIFO), accessible in the PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA register bitfield. The PRU-ICSS_UART0 also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled in the interrupt enable register - PRUSS_UART_INTERRUPT_ENABLE_REGISTER, an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control MSB part of the register PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER, and it is cleared when the FIFO contents drop below the trigger level.

6.4.7.3.6.3 PRU-ICSS UART FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

6.4.7.3.6.3.1 PRU-ICSS UART FIFO Interrupt Mode

When the receiver FIFO is enabled in the FIFO control register (FCR), mapped in the MSB part of the register PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER, and the receiver interrupts are enabled in the interrupt enable register PRUSS_UART_INTERRUPT_ENABLE_REGISTER, the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see Section 6.4.7.3.4.
- The data-ready (DR) bit in the line status register (LSR) - PRUSS_UART_LINE_STATUS_REGISTER, indicates the presence or absence of characters in the receiver FIFO. The DR bit is set when a character is transferred from the receiver shift register (RSR) to the empty receiver FIFO. The DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:
  - At least one character is in the FIFO,
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit, *n* data bits, 1 PARITY bit, and 1 STOP bit, where *n* depends on the word length selected with the WLS0 and WLS1 bits of the line control register PRUSS_UART_LINE_CONTROL_REGISTER. See Table 6-569.
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the URRST bit is cleared in the power and emulation management register PRUSS_UART_POWERMANAGEMENT_AND_EMULATION_REGISTER.
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER [0] IPEND_FIFOEN bit and the transmitter holding register empty (THRE) interrupt is enabled in PRUSS_UART_INTERRUPT_ENABLE_REGISTER[1] ETBEI bit, the interrupt mode is selected for the transmitter FIFO. The THRE interrupt occurs when the transmitter FIFO is empty. It is cleared when the transmitter hold register (THR) PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA bitfield is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt) or the interrupt identification register INTID bitfield is read in the PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER.

Table 6-569. Character Time for Word Lengths

Word Length (*n*)	Character Time	Four Character Times
5	Time for 8 bits	Time for 32 bits
6	Time for 9 bits	Time for 36 bits
7	Time for 10 bits	Time for 40 bits
8	Time for 11 bits	Time for 44 bits

6.4.7.3.6.3.2 PRU-ICSS UART FIFO Poll Mode

When the receiver FIFO is enabled in the FIFO control register (via setting the PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER [0] IPEND_FIFOEN to 0b1) and the receiver interrupts are disabled in the interrupt enable register (PRUSS_UART_INTERRUPT_ENABLE_REGISTER), the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled via setting the same bit (PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER [0] IPEND_FIFOEN to 0b1) and the transmitter interrupts are disabled, the transmitted FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the line status register - PRUSS_UART_LINE_STATUS_REGISTER:

- The PRUSS_UART_LINE_STATUS_REGISTER[7] RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The PRUSS_UART_LINE_STATUS_REGISTER[6] TEMT bit indicates that both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
- The PRUSS_UART_LINE_STATUS_REGISTER[5] THRE bit indicates when THR (mapped in the PRUSS_UART_RBR_THR_REGISTERS [7:0] DATA bitfield) is empty.
- The following PRUSS_UART_LINE_STATUS_REGISTER bits specify which error or errors have occurred:
  - PRUSS_UART_LINE_STATUS_REGISTER[4] BI - Break Interrupt
  - PRUSS_UART_LINE_STATUS_REGISTER[3] FE – Framing Error
  - PRUSS_UART_LINE_STATUS_REGISTER[2] PE – Parity Error
  - PRUSS_UART_LINE_STATUS_REGISTER[1] OE – Overrun Error
- The PRUSS_UART_LINE_STATUS_REGISTER[0] DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

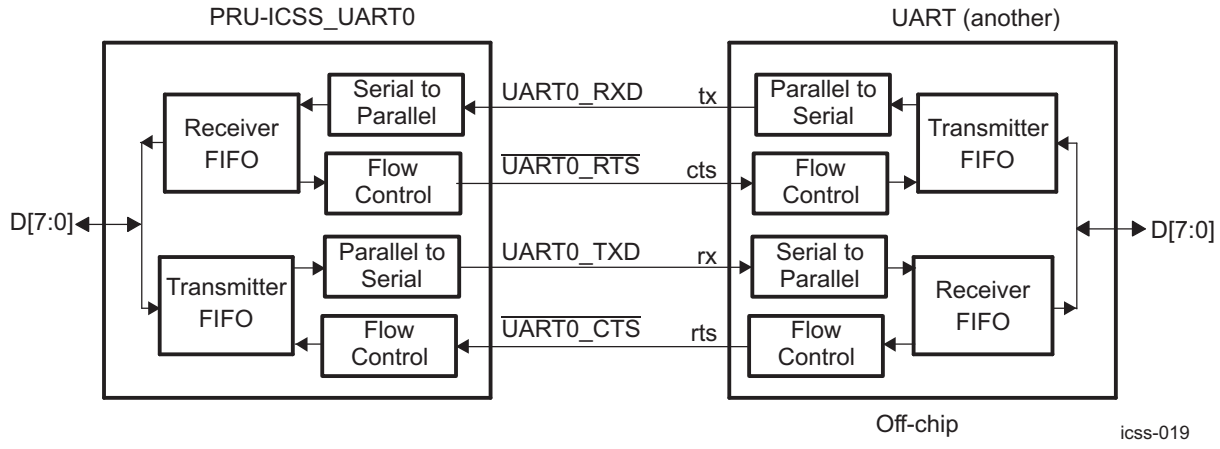
Also, in the FIFO poll mode:

- The interrupt identification register (INTID) bitfields are not affected by any events because the interrupts are disabled.
- The PRU-ICSS_UART0 does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

6.4.7.3.6.4 PRU-ICSS UART Autoflow Control

The PRU-ICSS_UART0 can employ autoflow control by connecting the $\overline{\text{UART0\_CTS}}$ and $\overline{\text{UART0\_RTS}}$ signals. The $\overline{\text{UART0\_CTS}}$ input must be active before the transmitter FIFO can transmit data. The $\overline{\text{UART0\_RTS}}$ becomes active when the receiver needs more data and notifies the sending device. When $\overline{\text{UART0\_RTS}}$ is connected to $\overline{\text{UART0\_CTS}}$, data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 6-210 with autoflow enabled, overrun errors are eliminated.

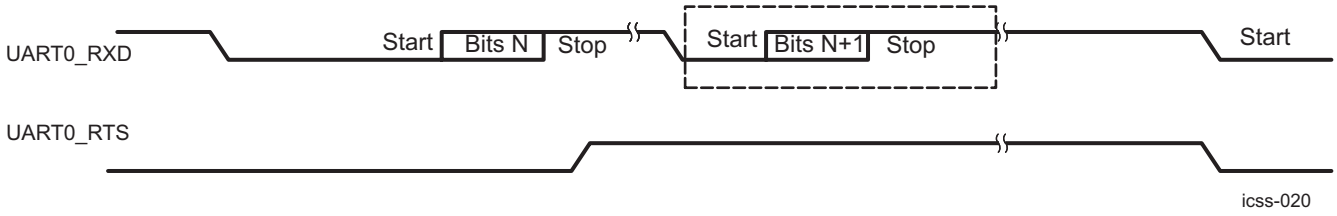
Figure 6-210. UART Interface Using Autoflow Diagram



6.4.7.3.6.4.1 PRU-ICSS UART Signal UART0_RTS Behavior

UART0_RTS data flow control originates in the receiver block (see Figure 6-208). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see Figure 6-211), UART0_RTS is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of UART0_RTS until after it has begun sending the additional byte. For trigger level 1, 4, and 8, UART0_RTS is automatically reasserted once the receiver FIFO is emptied. For trigger level 14, UART0_RTS is automatically reasserted once the receiver FIFO drops below the trigger level.

Figure 6-211. Autoflow Functional Timing Waveforms for UART0_RTS



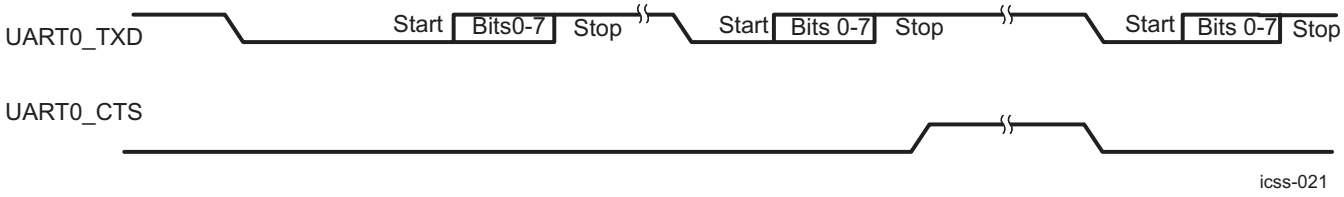
(1) N = Receiver FIFO trigger level.

(2) The two blocks in dashed lines cover the case where an additional byte is sent.

6.4.7.3.6.4.2 PRU-ICSS UART Signal UART0_CTS Behavior

The transmitter checks UART0_CTS before sending the next data byte. If UART0_CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, UART0_CTS must be released before the middle of the last STOP bit that is currently being sent (see Figure 6-212). When flow control is enabled, UART0_CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.

Figure 6-212. Autoflow Functional Timing Waveforms for UART0_CTS



(1) When UART0_CTS is active (low), the transmitter keeps sending serial data out.

(2) When UART0_CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.

(3) When UART0_CTS goes from high to low, the transmitter begins sending data again.

6.4.7.3.6.5 PRU-ICSS UART Loopback Control

The PRU-ICSS_UART0 can be placed in the diagnostic mode using the LOOP bit in the modem control register - PRUSS_UART_MODEM_CONTROL_REGISTER, which internally connects the PRU-ICSS_UART0 output back to the PRU-ICSS_UART0's input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

6.4.7.3.7 PRU-ICSS UART Initialization

The following steps are required to initialize the PRU-ICSS_UART0:

1. Perform the necessary device pin multiplexing setup (see the device Data Manual).

2. Set the desired baud rate by writing the appropriate clock divisor values to the divisor latch registers PRUSS_UART_DIVISOR_REGISTER_MSB_ [7:0] DLH and PRUSS_UART_DIVISOR_REGISTER_LSB_ [7:0] DLL.
3. If the FIFOs will be used, select the desired trigger level and enable the FIFOs by writing the appropriate values to the FIFO control register. The PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER[0] IPEND_FIFOEN bit must be set first, before the other bits in this register are configured.
4. Choose the desired protocol settings by writing the appropriate values to the line control register PRUSS_UART_LINE_CONTROL_REGISTER.
5. If autoflow control is desired, write appropriate values to the modem control register PRUSS_UART_MODEM_CONTROL_REGISTER.
6. Choose the desired response to emulation suspend events by configuring the FREE bit and enable the PRU-ICSS_UART0 by setting the UTRST and URRST bits in the power and emulation management register -PRUSS_UART_POWERMANAGEMENT_AND_EMULATION_REGISTER.

6.4.7.3.8 PRU-ICSS UART Exception Processing

6.4.7.3.8.1 PRU-ICSS UART Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

6.4.7.3.8.2 Changing Operating Mode During Busy Serial Communication of PRU-ICSS UART

Since the serial link characteristics are based on how the control registers are programmed, the PRU-ICSS_UART0 will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

6.4.7.4 PRU-ICSS_UART Registers

Table 6-571 lists the memory-mapped registers for the PRU-ICSS_UART module. All register offset addresses not listed in Table 6-571 should be considered as reserved locations and the register contents should not be modified.

Table 6-570. PRU-ICSS_UART Instances

6.4.7.4.1 PRUSS_UART_RBR_THR_REGISTERS Register (Offset = 0h) [reset = 0h]

PRUSS_UART_RBR_TBR_REGISTERS is shown in Figure 6-213 and described in Table 6-573.

Return to Summary Table.

In the non-FIFO mode, when a character is placed in Receiver buffer register and the receiver data-ready interrupt is enabled (DR = 1 in Interrupt identification register), an interrupt is generated. This interrupt is cleared when the character is read from Receiver buffer register. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register, and it is cleared when the FIFO contents drop below the trigger level.
In the non-FIFO mode, if Transmitter holding register is empty and the THR empty (THRE) interrupt is enabled (ETBEI = 1 in Interrupt enable register), an interrupt is generated. This interrupt is cleared when a character is loaded into Transmitter holding register or the Interrupt identification register is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or Interrupt identification register is read.

PRUSS_UART_INTERRUPT_ENABLE_REGISTER is shown in Figure 6-214 and described in Table 6-576.

Return to Summary Table.

The Interrupt enable register is used to individually enable or disable each type of interrupt request that can be generated by the UART. Each interrupt request that is enabled in Interrupt enable register is forwarded to the CPU.

6.4.7.4.3 PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER Register (Offset = 8h) [reset = 1h]

PRUSS_UART_INTERRUPT_IDENTIFICATION_REGISTER_FIFO_CONTROL_REGISTER is shown in Figure 6-215 and described in Table 6-579.

Return to Summary Table.

The Interrupt identification register is a read-only register at the same address as the FIFO control register, which is a write-only register. When an interrupt is generated and enabled in the Interrupt enable register, Interrupt identification register indicates that an interrupt is pending in the IPEND bit and encodes the type of interrupt in the INTID bits. Reading Interrupt identification register clears any THR empty (THRE) interrupts that are pending. The FIFOEN bit in Interrupt identification register can be checked to determine whether the UART is in the FIFO mode or the non-FIFO mode.
Use FIFO control register to enable and clear the FIFOs and to select the receiver FIFO trigger level. The FIFOEN bit in FIFO control register must be set to 1 before other FIFO control register bits are written to or the FIFO control register bits are not programmed.

Once the FIFO drops below the trigger level, the interrupt is cleared. 0h: 1 byte 1h: 4 bytes 2h: 8 bytes 3h: 14 bytes
5-4	RESERVED	R	0h	Reserved
3-1	INTID	RW	0h	**Read:** Interrupt type. See Table 11-3495. 0h: Reserved 1h: Transmitter holding register empty (priority 3) 2h: Receiver data available (priority 2) 3h: Receiver line status (priority 1, highest) 4h-5h: Reserved 6h: Character timeout indication (priority 2) 7h: Reserved
				Write: **Bit 3: DMAMODE1:** DMA MODE1 enable if FIFOs are enabled. Always write 1 to DMAMODE1. After a hardware reset, change DMAMODE1 from 0 to 1. DMAMODE1 = 1 is a requirement for proper communication between the UART and the EDMA controller. 0h: DMA MODE1 is disabled. 1h: DMA MODE1 is enabled. **Bit 2: TXCLR:** Transmitter FIFO clear. Write a 1 to TXCLR to clear the bit. 0h: No effect. 1h: Clears transmitter FIFO and resets the transmitter FIFO counter. The shift register is not cleared. **Bit 1: RXCLR:** Receiver FIFO clear. Write a 1 to RXCLR to clear the bit. 0h: No effect. 1h: Clears receiver FIFO and resets the receiver FIFO counter. The shift register is not cleared.
0	IPEND_FIFOEN	RW	1h	**Read:** Interrupt pending. When any UART interrupt is generated and is enabled in IER, IPEND is forced to 0. IPEND remains 0 until all pending interrupts are cleared or until a hardware reset occurs. If no interrupts are enabled, IPEND is never forced to 0. 0h: Interrupts pending. 1h: No interrupts pending.
				Write: Transmitter and receiver FIFOs mode enable. FIFOEN must be set before other FCR bits are written to or the FCR bits are not programmed. Clearing this bit clears the FIFO counters. 0h: Non-FIFO mode. The transmitter and receiver FIFOs are disabled, and the FIFO pointers are cleared. 1h: FIFO mode. The transmitter and receiver FIFOs are enabled.

6.4.7.4.4 PRUSS_UART_LINE_CONTROL_REGISTER Register (Offset = Ch) [reset = 0h]

PRUSS_UART_LINE_CONTROL_REGISTER is shown in Figure 6-216 and described in Table 6-582.

Return to Summary Table.

The system programmer controls the format of the asynchronous data communication exchange by using Line control register. In addition, the programmer can retrieve, inspect, and modify the content of line control register; this eliminates the need for separate storage of the line characteristics in system memory.

Table 6-581. PRUSS_UART_LINE_CONTROL_REGISTER Instances

Instance	Physical Address
PRU_ICSS_0_UART	20AA 800Ch
PRU_ICSS_1_UART	20AE 800Ch

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-582. PRUSS_UART_LINE_CONTROL_REGISTER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7	DLAB	R/W	0h	Divisor latch access bit. The divisor latch registers (DLL and DLH) can be accessed at dedicated addresses or at addresses shared by RBR, THR, and IER. Using the shared addresses requires toggling DLAB to change which registers are selected. If you use the dedicated addresses, you can keep DLAB = 0. 0h: Allows access to the receiver buffer register (RBR), the transmitter holding register (THR), and the interrupt enable register (IER) selected. At the address shared by RBR, THR, and DLL, the CPU can read from RBR and write to THR. At the address shared by IER and DLH, the CPU can read from and write to IER. 1h: Allows access to the divisor latches of the baud generator during a read or write operation (DLL and DLH). At the address shared by RBR, THR, and DLL, the CPU can read from and write to DLL. At the address shared by IER and DLH, the CPU can read from and write to DLH.
6	BC	R/W	0h	Break Control. 0h: Break condition is disabled. 1h: Break condition is transmitted to the receiving UART. A break condition is a condition where the UARTn_TXD signal is forced to the spacing (cleared) state.

Table 6-582. PRUSS_UART_LINE_CONTROL_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SP	R/W	0h	Stick parity. The SP bit works in conjunction with the EPS and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0h: Stick parity is disabled. 1h: Stick parity is enabled. • When odd parity is selected (EPS = 0), the PARITY bit is transmitted and checked as set. • When even parity is selected (EPS = 1), the PARITY bit is transmitted and checked as cleared.
4	EPS	R/W	0h	Even parity select. Selects the parity when parity is enabled (PEN = 1). The EPS bit works in conjunction with the SP and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0h: Odd parity is selected (an odd number of logic 1s is transmitted or checked in the data and PARITY bits). 1h: Even parity is selected (an even number of logic 1s is transmitted or checked in the data and PARITY bits).
3	PEN	R/W	0h	Parity enable. The PEN bit works in conjunction with the SP and EPS bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0h: No PARITY bit is transmitted or checked. 1h: Parity bit is generated in transmitted data and is checked in received data between the last data word bit and the first STOP bit.
2	STB	R/W	0h	Number of STOP bits generated. STB specifies 1, 1.5, or 2 STOP bits in each transmitted character. When STB = 1, the WLS bit determines the number of STOP bits. The receiver clocks only the first STOP bit, regardless of the number of STOP bits selected. The number of STOP bits generated is summarized in Table 11-3499. 0h: 1 STOP bit is generated. 1h: WLS bit determines the number of STOP bits: • When WLS = 0, 1.5 STOP bits are generated. • When WLS = 1h, 2h, or 3h, 2 STOP bits are generated.
1-0	WLS	R/W	0h	Word length select. Number of bits in each transmitted or received serial character. When STB = 1, the WLS bit determines the number of STOP bits. 0h: 5 bits 1h: 6 bits 2h: 7 bits 3h: 8 bits

6.4.7.4.5 PRUSS_UART_MODEM_CONTROL_REGISTER Register (Offset = 10h) [reset = 0h]

PRUSS_UART_MODEM_CONTROL_REGISTER is shown in Figure 6-217 and described in Table 6-585.

Return to Summary Table.

The Modem control register provides the ability to enable/disable the autoflow functions, and enable/disable the loopback function for diagnostic purposes.

Table 6-584. PRUSS_UART_MODEM_CONTROL_REGISTER Instances

Instance	Physical Address
PRU_ICSS_0_UART	20AA 8010h

Table 6-585. PRUSS_UART_MODEM_CONTROL_REGISTER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	AFE	R/W	0h	Autoflow control enable. Autoflow control allows the $\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ signals to provide handshaking between UARTs during data transfer. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved in this device and should be cleared to 0. 0h: Autoflow control is disabled. 1h:Autoflow control is enabled: • When RTS = 0, $\overline{\text{UARTn\_CTS}}$ is only enabled. • When RTS = 1, $\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ are enabled.

Table 6-585. PRUSS_UART_MODEM_CONTROL_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	LOOP	R/W	0h	Loop back mode enable. LOOP is used for the diagnostic testing using the loop back feature. 0h: Loop back mode is disabled. 1h: Loop back mode is enabled. When LOOP is set, the following occur: • The UARTn_TXD signal is set high. • The UARTn_RXD pin is disconnected. • The output of the transmitter shift register (TSR) is lopped back in to the receiver shift register (RSR) input.
3	OUT2	R/W	0h	OUT2 Control Bit
2	OUT1	R/W	0h	OUT1 Control Bit
1	RTS	R/W	0h	RTS control. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved in this device and should be cleared to 0. 0h: $\overline{\text{UARTn\_RTS}}$ is disabled, $\overline{\text{UARTn\_CTS}}$ is only enabled. 1h: $\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ are enabled.
0	RESERVED	R	0h	Reserved

6.4.7.4.6 PRUSS_UART_LINE_STATUS_REGISTER Register (Offset = 14h) [reset = 60h]

PRUSS_UART_LINE_STATUS_REGISTER is shown in Figure 6-218 and described in Table 6-588.

Return to Summary Table.

The Line status register provides information to the CPU concerning the status of data transfers. Line status register is intended for read operations only; do not write to this register. Bits 1 through 4 record the error conditions that produce a receiver line status interrupt.

Table 6-587. PRUSS_UART_LINE_STATUS_REGISTER Instances

Instance	Physical Address
PRU_ICSS_0_UART	20AA 8014h
PRU_ICSS_1_UART	20AE 8014h

Table 6-588. PRUSS_UART_LINE_STATUS_REGISTER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7	RXFIFOE	R	0h	Receiver FIFO error. **In non-FIFO mode:** 0h: There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver buffer register (RBR). 1h: There is a parity error, framing error, or break indicator in the receiver buffer register (RBR).
				In FIFO mode: 0h: There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver FIFO and there are no more errors in the receiver FIFO. 1h: At least one parity error, framing error, or break indicator in the receiver FIFO.

Table 6-588. PRUSS_UART_LINE_STATUS_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	TEMT	R	1h	Transmitter empty (TEMT) indicator. **In non-FIFO mode:** 0h: Either the transmitter holding register (THR) or the transmitter shift register (TSR) contains a data character. 1h: Both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
				In FIFO mode: 0h: Either the transmitter FIFO or the transmitter shift register (TSR) contains a data character. 1h: Both the transmitter FIFO and the transmitter shift register (TSR) are empty.
5	THRE	R	1h	Transmitter holding register empty (THRE) indicator. If the THRE bit is set and the corresponding interrupt enable bit is set (ETBEI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: Transmitter holding register (THR) is not empty. THR has been loaded by the CPU. 1h: Transmitter holding register (THR) is empty (ready to accept a new character). The content of THR has been transferred to the transmitter shift register (TSR).
				In FIFO mode: 0h: Transmitter FIFO is not empty. At least one character has been written to the transmitter FIFO. You can write to the transmitter FIFO if it is not full. 1h: Transmitter FIFO is empty. The last character in the FIFO has been transferred to the transmitter shift register (TSR).
4	BI	R	0h	Break indicator. The BI bit is set whenever the receive data input (UARTn_RXD) was held low for longer than a full-word transmission time. A full-word transmission time is defined as the total time to transmit the START, data, PARITY, and STOP bits. If the BI bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver buffer register (RBR). 1h: A break has been detected with the character in the receiver buffer register (RBR).
				In FIFO mode: 0h: No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver FIFO and the next character to be read from the FIFO has no break indicator. 1h: A break has been detected with the character at the top of the receiver FIFO.

Table 6-588. PRUSS_UART_LINE_STATUS_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	FE	R	0h	Framing error (FE) indicator. A framing error occurs when the received character does not have a valid STOP bit. In response to a framing error, the UART sets the FE bit and waits until the signal on the RX pin goes high. Once the RX signal goes high, the receiver is ready to detect a new START bit and receive new data. If the FE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR). 1h: A framing error has been detected with the character in the receiver buffer register (RBR).
				In FIFO mode: 0h: No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no framing error. 1h: A framing error has been detected with the character at the top of the receiver FIFO.
2	PE	R	0h	Parity error (PE) indicator. A parity error occurs when the parity of the received character does not match the parity selected with the EPS bit in the line control register (LCR). If the PE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR). 1h: A parity error has been detected with the character in the receiver buffer register (RBR).
				In FIFO mode: 0h: No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no parity error. 1h: A parity error has been detected with the character at the top of the receiver FIFO.
1	OE	R	0h	Overrun error (OE) indicator. An overrun error in the non-FIFO mode is different from an overrun error in the FIFO mode. If the OE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR). 1h: Overrun error has been detected. Before the character in the receiver buffer register (RBR) could be read, it was overwritten by the next character arriving in RBR.
				In FIFO mode: 0h: No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR). 1h: Overrun error has been detected. If data continues to fill the FIFO beyond the trigger level, an overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. An overrun error is indicated to the CPU as soon as it happens. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.

Table 6-588. PRUSS_UART_LINE_STATUS_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DR	R	0h	Data-ready (DR) indicator for the receiver. If the DR bit is set and the corresponding interrupt enable bit is set (ERBI = 1 in IER), an interrupt request is generated. **In non-FIFO mode:** 0h: Data is not ready, or the DR bit was cleared because the character was read from the receiver buffer register (RBR). 1h: Data is ready. A complete incoming character has been received and transferred into the receiver buffer register (RBR).
				In FIFO mode: 0h: Data is not ready, or the DR bit was cleared because all of the characters in the receiver FIFO have been read. 1h: Data is ready. There is at least one unread character in the receiver FIFO. If the FIFO is empty, the DR bit is set as soon as a complete incoming character has been received and transferred into the FIFO. The DR bit remains set until the FIFO is empty again.

Table 6-591. PRUSS_UART_MODEM_STATUS_REGISTER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7	CD	R	0h	Complement of the Carrier Detect input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 3 (OUT2)..
6	RI	R	0h	Complement of the Ring Indicator input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 2 (OUT1).
5	DSR	R	0h	Complement of the Data Set Ready input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 0 (DTR).
4	CTS	R	0h	Complement of the Clear To Send input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 1 (RTS).
3	DCD	R	0h	Change in DCD indicator bit. DCD indicates that the DCD input has changed state since the last time it was read by the CPU. When DCD is set and the modem status interrupt is enabled, a modem status interrupt is generated.
2	TERI	R	0h	Trailing edge of RI (TERI) indicator bit. TERI indicates that the RI input has changed from a low to a high. When TERI is set and the modem status interrupt is enabled, a modem status interrupt is generated.

Table 6-591. PRUSS_UART_MODEM_STATUS_REGISTER Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DDSR	R	0h	Change in DSR indicator bit. DDSR indicates that the DSR input has changed state since the last time it was read by the CPU. When DDSR is set and the modem status interrupt is enabled, a modem status interrupt is generated.
0	DCTS	R	0h	Change in CTS indicator bit. DCTS indicates that the CTS input has changed state since the last time it was read by the CPU. When DCTS is set (autoflow control is not enabled and the modem status interrupt is enabled), a modem status interrupt is generated. When autoflow control is enabled, no interrupt is generated.

6.4.7.4.9 PRUSS_UART_DIVISOR_REGISTER_LSB_ Register (Offset = 20h) [reset = 0h]

PRUSS_UART_DIVISOR_REGISTER_LSB_ is shown in Figure 6-221 and described in Table 6-597.

Return to Summary Table.

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. DLH holds the most-significant bits of the divisor, and DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Table 6-596. PRUSS_UART_DIVISOR_REGISTER_LSB_ Instances

Instance	Physical Address

6.4.7.4.10 PRUSS_UART_DIVISOR_REGISTER_MSB_ Register (Offset = 24h) [reset = 0h]

PRUSS_UART_DIVISOR_REGISTER_MSB_ is shown in Figure 6-222 and described in Table 6-600.

Return to Summary Table.

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. DLH holds the most-significant bits of the divisor, and DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Table 6-599. PRUSS_UART_DIVISOR_REGISTER_MSB_ Instances

Instance	Physical Address
PRU_ICSS_0_UART	20AA 8024h

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15	RESERVED	R/W	0h	Reserved. This bit must always be written with a 0.
14	UTRST	R/W	0h	UART transmitter reset. Resets and enables the transmitter. 0h: Transmitter is disabled and in reset state. 1h: Transmitter is enabled.
13	URRST	R/W	0h	UART receiver reset. Resets and enables the receiver. 0h: Receiver is disabled and in reset state. 1h: Receiver is enabled.
12-1	RESERVED	R	0h	Reserved
0	FREE	R/W	0h	Free-running enable mode bit. This bit determines the emulation mode functionality of the UART. When halted, the UART can handle register read/write requests, but does not generate any transmission/reception, interrupts or events. 0h: If a transmission is not in progress, the UART halts immediately. If a transmission is in progress, the UART halts after completion of the one-word transmission. 1h: Free-running mode is enabled; UART continues to run normally.

6.4.8 PRU-ICSS eCAP Module

6.4.8.1 PRU-ICSS eCAP Functional Description

A single instance of an **enhanced capture** event module is integrated in the device PRU-ICSS_0 subsystem - ICSS_0_eCAP0 and PRU-ICSS_1 subsystem - ICSS_1_eCAP0.

For more details on the ICSS_0_eCAP0 and ICSS_1_eCAP0I/O signals available at device level, refer to the Section 6.4.2. For ICSS_0_eCAP0 and ICSS_1_eCAP0 integration details and functionalities controlled at PRU-ICSS top level (functional clock control, etc.), refer to the Section 6.4.3 and the Section 6.4.4 .

NOTE: The ICSS_0_eCAP0 and ICSS_1_eCAP0 "SYNCIn" hardware event synchronization input and "SYNCOut" hardware synchronization output are implemented in the device PRU-ICSS_0 and PRU-ICSS_1, respectively. However, a software-forced synchronization via bit PRUSS_ECAP_ECCTL2[8] SWSYNC, can be used as an alternative, provided that PRUSS_ECAP_ECCTL2[5] SYNCI_EN bit is set to 0b1.

For full description of the ICSS_0_eCAP0 and ICSS_1_eCAP0 modules functionalities, refer to the Section 11.4, *Enhanced Capture (eCAP) Module.*

6.4.8.2 PRU-ICSS_ECAP Registers

Table 6-612 lists the memory-mapped registers for the PRU-ICSS_eCAP0 module. All register offset addresses not listed in Table 6-612 should be considered as reserved locations and the register contents should not be modified.

Table 6-611. PRU-ICSS_ECAP Instances

Table 6-635. PRUSS_ECAP_ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode 0h: Output is active high (Compare value defines high time) 1h: Output is active low (Compare value defines low time)
9	CAPAPWM	R/W	0h	CAP/APWM operating mode select 0h: ECAP module operates in capture mode. This mode forces the following configuration. (a) Inhibits TSCNT resets via CTR = PRD event. (b) Inhibits shadow loads on PRUSS_ECAP_CAP1 and PRUSS_ECAP_CAP2 registers. (c) Permits user to enable PRUSS_ECAP_CAP1-PRUSS_ECAP_CAP4 register load. (d) ECAP input/APWM output pin operates as a capture input. 1h: ECAP module operates in APWM mode. This mode forces the following configuration. (a) Resets TSCNT on CTR = PRD event (period boundary). (b) Permits shadow loading on PRUSS_ECAP_CAP1 and PRUSS_ECAP_CAP2 registers. (c) Disables loading of time-stamps into PRUSS_ECAP_CAP1 - PRUSS_ECAP_CAP4 registers. (d) ECAP input/APWM ouput pin operates as a APWM output.

Table 6-635. PRUSS_ECAP_ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SWSYNC	R/W	0h	Software-forced Counter (TSCNT) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the CTR = PRD event. Note: Selection CTR = PRD is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful. 0h: Writing a zero has no effect. Reading always returns a zero 1h: Writing a one forces a TSCNT shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 1'b00. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select 0h: Select sync-in event to be the sync-out signal (pass through) 1h: Select CTR = PRD event to be the sync-out signal 2h: Disable sync out signal 3h: Disable sync out signal
5	SYNCI_EN	R/W	0h	Counter (TSCNT) Sync-In select mode 0h: Disable sync-in option 1h: Enable counter (TSCNT) to be loaded from PRUSS_ECAP_CNTPHS register upon either a SYNCI signal or a S/W force event.
4	TSCNTSTP	R/W	0h	Time Stamp (TSCNT) Counter Stop (freeze) Control 0h: TSCNT stopped 1h: TSCNT free-running
3	REARMRESET	R/W	0h	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0h: Has no effect (reading always returns a 0) 1h: Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.
2-1	STOPVALUE	R/W	3h	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOPVALUE is compared to Mod4 counter and, when equal, the following two actions occur. (1) Mod4 counter is stopped (frozen). (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0h: Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 1h: Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 2h: Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 3h: Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
0	CONTONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) 0h: Operate in continuous mode 1h: Operate in one-shot mode

6.4.9 PRU-ICSS MII RT Module

6.4.9.1 Introduction

The Real-time Media Independent Interface (MII_RT) provides a programmable I/O interface for the PRUs to access and control up to two MII ports. The MII_RT module can also be configured to push and pull data independent of the PRU cores.

NOTE: In order to guarantee the MII_RT IO timing values published in the device data manual, the ICSS_i_VCLK_CLK (where i = 0 or 1) clock must be configured for 200MHz (default value) and PRUSS_MII_RT_TXCFG0/1 must be set to 6h (non-default value).

6.4.9.1.1 Features

The PRU-ICSS MII_RT module supports:

- Two MII ports
  - Each MII port has:
    - 32-byte RX L1 FIFO
    - 64-byte RX L2 buffer
    - 96-byte TX L1 FIFO
  - Rate decoupling on TX L1 FIFO
  - Configurable pre-amble removal on RX L1 FIFO and insertion on TX L1 FIFO
  - Configurable TX L1 FIFO trigger (10 bits with 40 ns ticks)
- MII port multiplexer per direction to support line/ring structure
  - Link detection through RX_ERR
- Cyclic redundancy check (CRC)
  - CRC32 generation on TX path
  - CRC32 checker on RX path

6.4.9.1.2 Unsupported Features

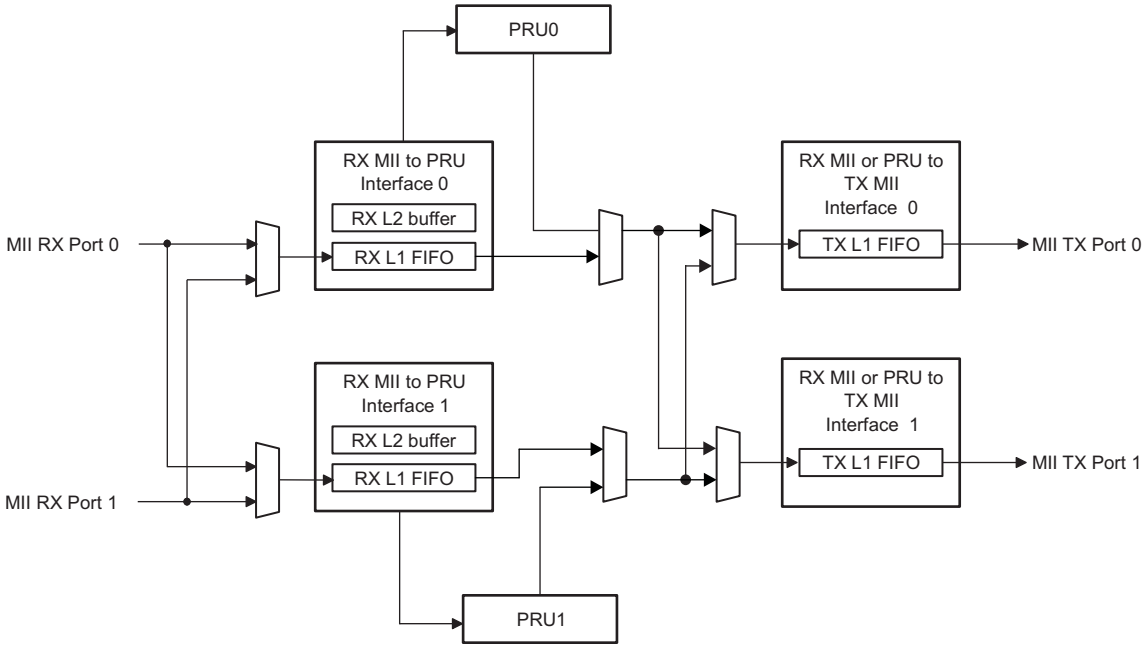
The PRU-ICSS MII_RT module does not support:

- Auto padding in TX L1 FIFO
- Dynamic TX multiplexer switching during packet handling
  - Can allow one PRU to handle both MII interfaces and a second PRU to manage the host and switch functions.

6.4.9.1.3 Block Diagram

Figure 6-239 shows the MII_RT in context of the PRU-ICSS. This diagram is a conceptual block diagram and does not necessarily reflect actual topologies.

Figure 6-239. MII_RT Block Diagram



6.4.9.2 Functional Description

6.4.9.2.1 Data Path Configuration

The MII_RT module supports three basic data path configurations. These configurations are compared in Table 6-652 and described in the following sections.

Table 6-652. Data Path Configuration Comparison

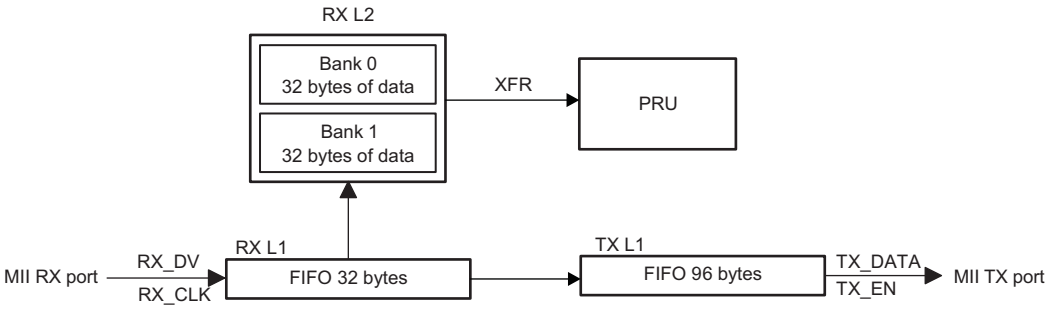
Configuration	PRU Dependency	Data Servicing	Port-to-Port Latency
Auto-forward	Snoop only	One word in flight	Low
8- or 16-bit processing with on-the-fly modifications (RX L1)	Yes	One word or byte in flight	Low
32-byte double buffer or ping-pong processing (RX L2)	Yes	Multi-words in flight	Medium (application-dependent)

6.4.9.2.1.1 Auto-forward with Optional PRU Snoop

Data is automatically forwarded from the MII RX port to the MII TX port without manipulations, as shown in Figure 6-240. This configuration does not depend on the PRU core. However, it does support an option for PRU to snoop or monitor the received data through the RX L2, shown in Figure 6-241. The PRU does not access data and status bits through R31, and it does not modify and push data.

Figure 6-240. Auto-forward

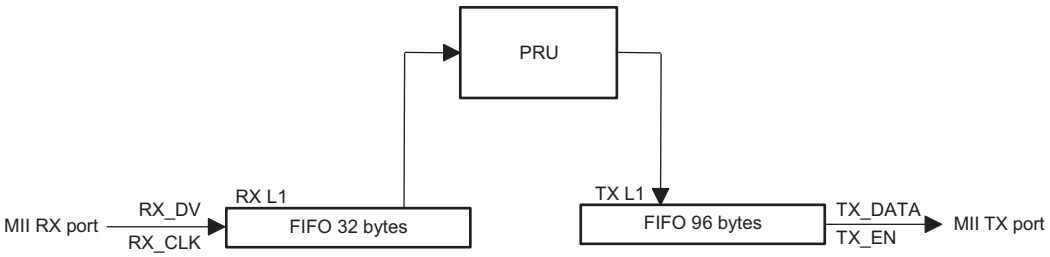
Figure 6-241. Auto-forward with PRU Snoop



6.4.9.2.1.2 8- or 16-bit Processing with On-the-Fly Modifications

This configuration services one byte or word in flight and has low latency. The PRU has the option to manipulate the received word and control popping data from the RX L1 FIFO and pushing it on the TX L1 FIFO.

Figure 6-242. 8- or 16-bit Processing with On-the-Fly Modifications

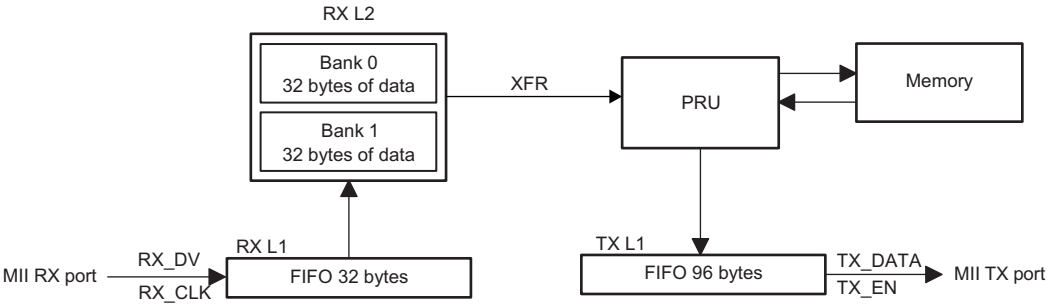


6.4.9.2.1.3 32-byte Double Buffer or Ping-Pong Processing

This configuration supports high bandwidth, high efficiency transactions. Often implementations using this mode permit relaxed servicing requirements allowing the PRU to manipulate the received data before transmitting.

Data received in this configuration is passed into the RX L2 buffer. The PRU reads multiple bytes of data from one of the RX L2 banks through the high bandwidth broadside interface and XFR instructions. The PRU can then store or manipulate data before pushing it to the TX L1 FIFO for transmission on the MII TX port.

Figure 6-243. 32-byte Double Buffer or Ping-Pong Processing



6.4.9.2.2 Definition and Terms

6.4.9.2.2.1 Data Frame Structure

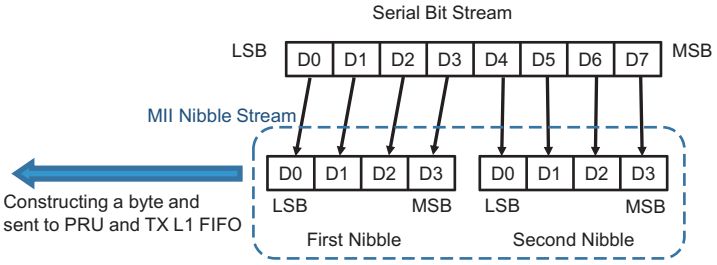
The data received and transmitted over MII conforms with the frame structure shown in Table 6-653.

Table 6-653. Frame Structure

Inter-frame	Preamble	Start of Frame Delimiter (SFD)	Data	Cyclic Redundancy Check (CRC)

The data following the SFD is formatted in a 4-bit nibble structure. Figure 6-244 illustrates the nibble order. The MSB arriving first is on the LSB side of a nibble. When receiving data, the MII_RT receive logic will wait for the next nibble to arrive before constructing a byte and delivering to the PRU.

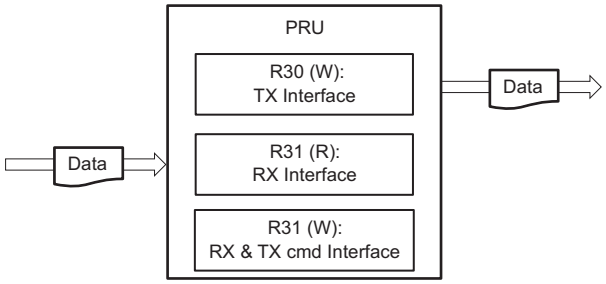
Figure 6-244. Data Nibble Structure



6.4.9.2.2.2 PRU R30 and R31

The PRU registers R30 and R31 are used to receive, transmit, and control the data for the PRU. As shown in Figure 6-245, the R31 is used to access data in the RX L1 FIFO, the R30 is used to transmit data from the PRU, and the R31 output is used the control the flow of receive and transmit. For more details about these registers, see the following sections.

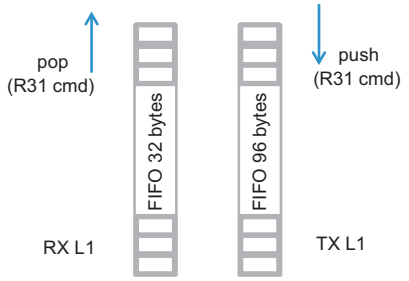
Figure 6-245. PRU R30, R31 Operations



6.4.9.2.2.3 RX and TX L1 FIFO Data Movement

To advance the next data byte seen by R31, the PRU must pop the data from the RX L1 FIFO. Likewise, the PRU can push the data from R30 to the TX L1 FIFO. These operations are illustrated in Figure 6-246.

Figure 6-246. Reading and Writing FIFO Data



6.4.9.2.2.4 CRC Computation

6.4.9.2.2.4.1 Receive CRC Computation

For the incoming data, the MII_RT calculates CRC32 and then compares against the value provided in the incoming frame. If there is a mismatch, the MII RT signals ERROR_CRC to the PRU. If a previous node or Ethernet device appended an error nibble, the CRC calculation of received packet will be wrong because the longer frame and the frame length will end at a 4-bit boundary instead of the usual 8-bit boundary. When RX_DV goes inactive on the 4-bit boundary, the interface will assert DATA_RDY and BYTE_RDY flag with the ERROR NIBBLE. The error event is also mapped into the PRU-ICSS INTC.

6.4.9.2.2.4.2 Transmit CRC Computation

For the outgoing data, the MII_RT calculates the CRC32 value and inserts it into outgoing packets. The CRC value computed on each MII transmit path is also available in memory map registers (MMRs) that can be read by the PRU and used primarily for debug and diagnostic purposes. The CRC is inserted into the outgoing packet based on the commands received through the R31 register of the PRU. The CRC will be inserted into the TX L1 FIFO, and there must be enough room to store the CRC value in the FIFO or else the FIFO will overflow. As Table 6-654 shows, the CRC programming model supports three sequences that provide more flexibility. Note “cmdR31” indicates write to the mentioned bits of the R31 command interface.

Table 6-654. TX CRC Programming Models

Option 1	Step 1: cmdR31 [TX_CRC_HIGH + TX_CRC_LOW + TX_EOF]
Option 2	Step 1: cmdR31 [TX_CRC_HIGH] Step 2: wait > 6 clocks (PRU cycles) Step 3: cmdR31 [TX_CRC_LOW + TX_EOF]
Option 3	Step 1: cmdR31 [TX_CRC_HIGH] Step 2: wait > 6 clocks (PRU cycles) Step 3: read PRUSS_MII_RT_TX_CRC0/1 Step 4: modify CRC[15:0] Step 5: cmdR31 [TX_PUSH16 + TX_EOF + TX_ERROR_NIBBLE]

6.4.9.2.3 RX MII Interface

6.4.9.2.3.1 RX MII Submodule Overview

The RX MII interface is composed of multiple submodules that process the incoming frames and pass receive data and status information into the PRU register R31. These submodules include:

- Latch received data
- Start of frame detection
- Start frame delimiter detection

- CRC calculation and error detection
- Enhanced link detection through RX error detection

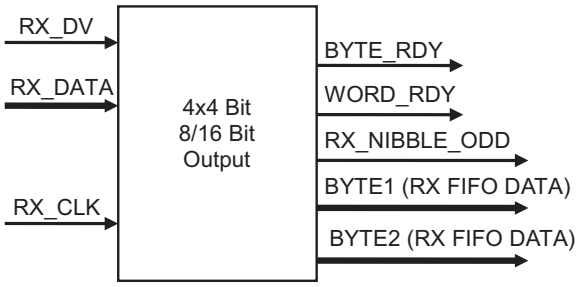
Table 6-655 includes more details about the internal signals and output of these submodules.

6.4.9.2.3.1.1 Receive Data Latch

The receive data from the MII interface is stored in the receive data FIFO which is 32 bytes. The PRU can access this data through the register R31. Depending on the configuration settings, the data can be latched on reception of one or two bytes. In each scheme, the configured number of nibbles is assembled before being copied into the PRU registers. Figure 6-247 shows the inputs and outputs of the data latch logic block.

The receiver logic in MII_RT can be programmed through the PRUSS_MII_RT_RXCFG0 and PRUSS_MII_RT_RXCFG1 registers to remove or retain the preamble + SFD from incoming frames.

Figure 6-247. RX Data Latch



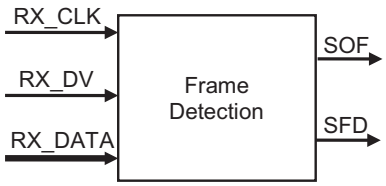
6.4.9.2.3.1.1.1 Start of Frame Detection

The start of frame detection logic tracks the frame boundaries and signals the beginning of a frame to other components of the PRU-ICSS. This logic detects two events:

- Start of Frame (SOF) event that occurs when Receive Data Valid MII signal is sampled high.
- Start of Frame Delimiter (SFD) event is seen on MII Receive Data bus.

These event triggers can be used to add timestamp to the frames. The notification for these events is available through R31 as well as through INTC which is integrated in the PRU-ICSS. Figure 6-248 shows the inputs and outputs of the start of frame detection logic block.

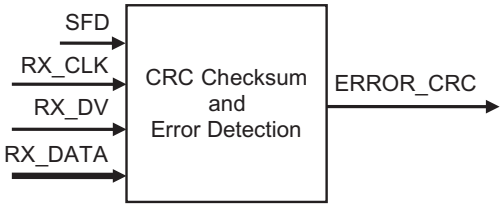
Figure 6-248. Start of Frame Detection



6.4.9.2.3.1.1.2 CRC Error Detection

For each incoming frame, the CRC is calculated by the MII_RT and compared against the CRC included in the frame. When the two values do not match, a CRC error is flagged. The ERROR_CRC indication is available in the register interface (PRU R31 Receive Interface) as well as in the FIFO interface (RX L2 Status Interface). It is also provided to the INTC which is integrated in the PRU-ICSS. Figure 6-249 shows the inputs and outputs of CRC error detection logic block.

Figure 6-249. CRC Error Detection

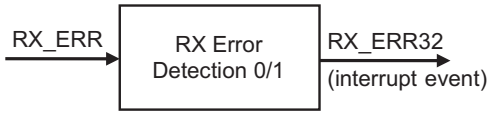


6.4.9.2.3.1.1.3 RX Error Detection and Action

The RX error detection logic tracks the receive error signaled by the physical layer and informs the PRU-ICSS INTC whenever an error is detected. Figure 6-250 shows the inputs and outputs of the RX error detection logic block. Note the following dependencies:

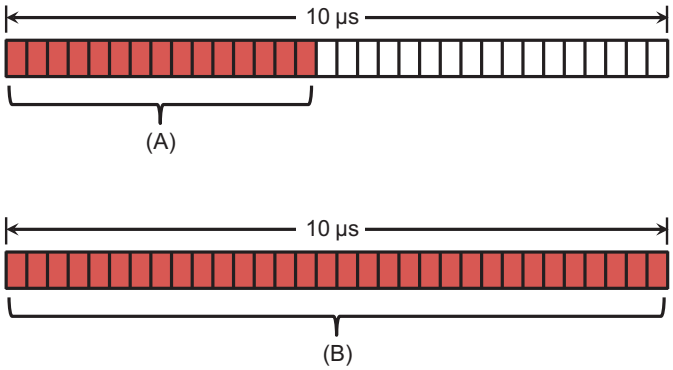
- RX_ERR signal is only sampled when RX_DV is asserted.
- All nibbles are discarded post RX_ERR event, including the nibble which had RX_ERR asserted. This state will remain until EOF occurs.
- Due to this fact, RX L1 FIFO and RX L2 FIFO will never receive any data with RX_ERR or post RX_ERR during that frame.

Figure 6-250. RX Error Detection



This submodule also keeps track of a running count of receive error events within a 10 µs error detection window, as shown in Figure 6-251. The INTC is notified when 32 or more events have occurred in a 10 µs error detection window. The error detection window is not a sliding window but a non-overlapping window with no specific initialization time with respect to incoming traffic. The timer starts its 10 µs counts immediately after de-assertion of reset to the MII_RT module.

Figure 6-251. Error Detection Window with Running Counter



A There are fewer than 32 consecutive error events in the 10 µs window. The detection module will not forward to the interrupt controller (INTC).

B There are more or equal to 32 error events in the 10 µs window. The detection module will notify the interrupt controller (INTC).

6.4.9.2.3.1.2 RX Data Path Options to PRU

There are two data path options for delivering received data to the PRU, described further in the subsequent sections:

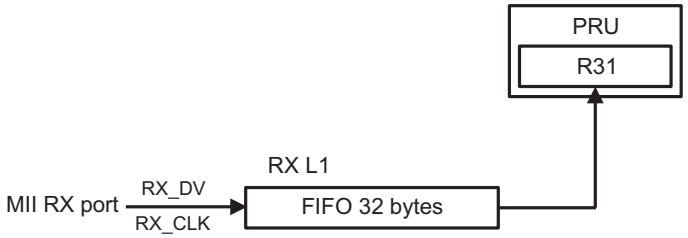
1. RX MII port → RX L1 FIFO → PRU (one word in flight)
2. RX MII port → RX L1 FIFO → RX L2 buffer → PRU (multi-word in flight)

Once the PRU has received RX data, the PRU can both manipulate received data or send data to the TX MII Interface.

6.4.9.2.3.1.2.1 RX MII Port → RX L1 FIFO → PRU

The RX L1 FIFO to PRU interface is depicted in Figure 6-252. In this mode, the data received from the MII interface is fed into the 32-byte RX L1 FIFO. The first data byte into the FIFO is automatically available in R31 of the PRU. Therefore, the PRU firmware can directly operate on this data without having to read it in a separate instruction. This allows the PRU to access receive data with low latency.

Figure 6-252. RX L1 to PRU Interface



When the new data is received, the PRU is provided with up to two bytes at a time in the R31 register, as shown in Figure 6-253. Once the PRU processes the incoming data, it instructs the MII_RT by writing to the R31 command interface bits to pop one or two bytes of data from the 32-byte RX FIFO. The pop operation causes current contents of R31 to be refreshed with new data from the incoming packet. Each time the data is popped, the status bits change to indicate so. If the pop is completed and there is no new data, the status bits immediately change to indicate no new data. Note the current R31 content, including data, will be lost after issuing the pop operation. If this information needs to be accessed later, the PRU should store the existing R31 content before popping new data.

Figure 6-253. MII RX Data to PRU R31 (R) and RX FIFO

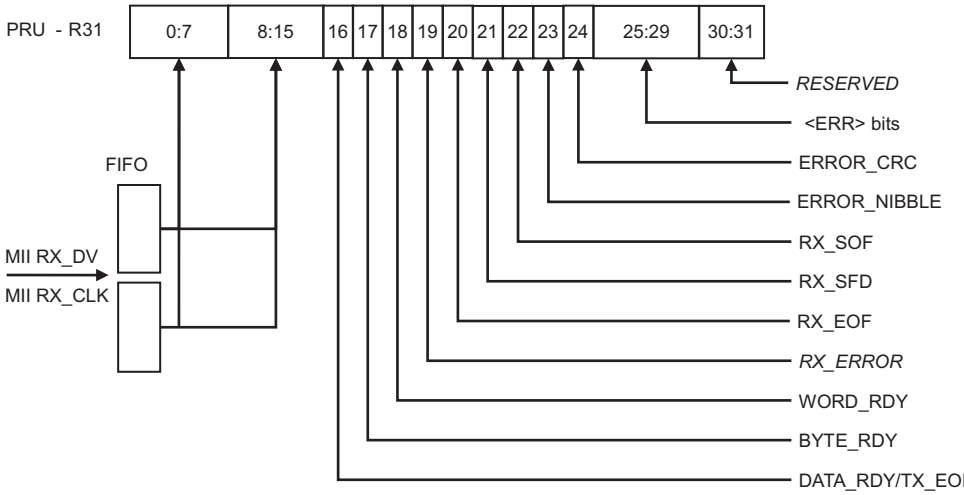


Table 6-655 describes the receive interface data and status contents provided by the R31 register. These contents are available when R31 is read. To configure this register, the PRU GPI mode should be set for MII_RT mode in the CFG register space. Note the following:

1. If the data from receive path is not read in time, it could cause an overflow event because the data is still continuously provided to the 32-byte receive FIFO. Due to the receive FIFO overflow, the data gets automatically discarded to avoid lack of space in the FIFO. At the same time, an interrupt is raised to the INTC through a system event (PRU<n>_RX_OVERFLOW). To detect an overflow condition, the PRU should poll for this system event condition and a RX RESET command through the R31 command interface is required to clear out from this condition. Note that the received Ethernet frame is corrupted and should not be used for further processing as bytes have been dropped due to the overflow condition. A FIFO reset is recommended.

2. The receive data in the R31 register is available following synchronization to the PRU clock domain. So, there is a finite delay (120 ns) when data is available from MII interface and it is accessible to the PRU.
3. The receive FIFO also has the capability to be reset through software. When reset, all contents of receive FIFO are purged and it may result in the current frame not being received as expected. When a frame is being received and the PRU resets the RX FIFO, the remaining frame is not placed into the RX FIFO. However, any new frame arriving on the receive MII port will be stored in the FIFO.

Table 6-655. PRU R31: Receive Interface Data and Status (Read Mode)

Bits	Field Name	Description
31:30	RESERVED	In case of register interface, these bits are provided to PRU by other modules in PRU-ICSS. From the MII_RT module point of view, these bits are always zero.
29	RX_MIN_FRM_CNT_ERR	RX_MIN_FRM_CNT_ERR is set to 1 when the count of total bytes of incoming frame is less than the value defined by RX_MIN_FRM_CNT. RX_MIN_FRM_CNT_ERR is cleared by RX_ERROR_CLR.
28	RX_MAX_FRM_CNT_ERR	RX_MAX_FRM_CNT_ERR is set to 1 when the count of total bytes of incoming frame is more than the value defined by RX_MAX_FRM_CNT_ERR. RX_MAX_FRM_CNT_ERR is cleared by RX_ERROR_CLR.
27	RX_EOF_ERROR	RX_EOF_ERROR is set to 1 when an RX_EOF event or RX_ERROR event occurs. RX_EOF_ERROR is cleared by RX_ EOF_CLR and/or RX_ ERROR_CLR.
26	RX_MAX_PRE_CNT_ERR	RX_MAX_PRE_CNT_ERR is set to 1 when the number of nibbles equaling 0x5 before SFD event (0xD5) is more than the value defined by PRUSS_MII_RT_RX_PCNT0/1 [RX_MAX_PCNT]. RX_MAX_PRE_CNT_ERR is cleared by RX_ERROR_CLR.
25	RX_ERR	RX_ERR is set to 1 when pr1_mii0/1_rxer is asserted while pr1_mii0/1_rxdv bit is set. RX_ERR is cleared by RX_ERROR_CLR.
24	ERROR_CRC	ERROR_CRC indicates that the frame has a CRC mismatch. This bit is valid when the RX_EOF bit is set. It should be noted that ERROR_CRC bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_CRC is cleared by RX_ERROR_CLR.
23	ERROR_NIBBLE	ERROR_NIBBLE indicates that the frame ended in odd nibble. It should be considered valid only when the RX_EOF bit and pr1_mii0/1_rxdv are set. Nibble counter is enabled post SFD event. It should be noted that ERROR_NIBBLE bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_NIBBLE is cleared by RX_ERROR_CLR.
22	RX_SOF	RX_SOF transitions from low to high when the frame data starts to arrive and pr1_mii0/1_rxdv is asserted. Note there will be a small sync delay of 0ns – 5ns. The recommended time to clear this bit via RX_SOF_CLR is at the end of frame (EOF). It should be noted that RX_SOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO.
21	RX_SFD	RX_SFD transitions from low to high when the SFD sequence (0xD5) post RX_SOF is observed on the receive MII data. The recommended time to clear this bit via RX_SFD_CLR is at the end of frame (EOF). It should be noted that RX_SFD bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO.
20	RX_EOF	RX_EOF indicates that the frame has ended and pr1_mii0/1_rxdv is de-asserted. It also validates the CRC match bit. Note there will be a small sync delay of 0ns – 5ns. It should be noted that RX_EOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. Note also if RX_L2_EOF_SCLR_DIS is set, then this flag will remain asserted when RX_L2 is enabled until RX_EOF_CLR.
19	RX_ERROR	RX_ERROR indicates one or more of the following errors occurred: • RX_MAX/MIN_FRM_CNT_ERR • RX_MAX/MIN_PRE_CNT_ERR • RX_ERR RX_ERROR is cleared by RX_ERROR_CLR.
18	WORD_RDY	WORD_RDY indicates that all four nibbles in R31 have valid data. There is a 2 clock cycle latency from the command RX_POP16 to WORD_RDY update. Therefore, firmware needs to insure it does not read WORD_RDY until 2 clock cycles after RX_POP16.
17	BYTE_RDY	BYTE_RDY indicates that the lower two nibbles in R31 have valid data. There is a 2 clock cycle latency from the command RX_POP8 to BYTE_RDY update. Therefore, PRU firmware needs to insure it does not read BYTE_RDY until 2 clock cycles after RX_POP8.

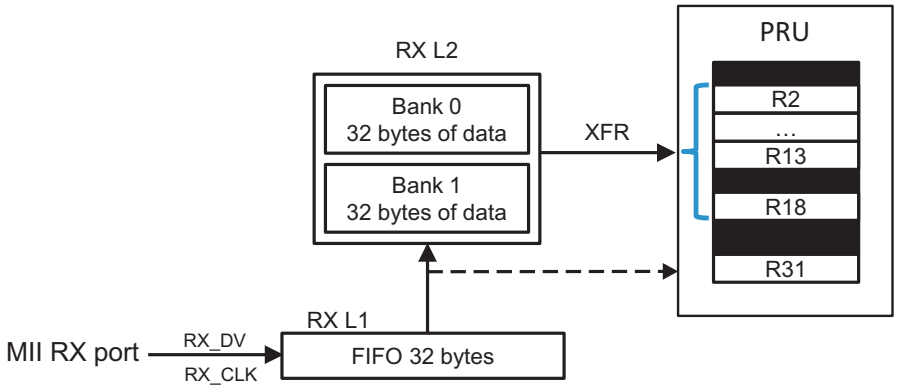
Table 6-655. PRU R31: Receive Interface Data and Status (Read Mode) (continued)

Bits	Field Name	Description
16	DATA_RDY/ TX_EOF	When RX_DATA_RDY_MODE_DIS = 0: DATA_RDY indicates there is valid data in R31 ready to be read. This bit goes to zero when the PRU does a POP8/16 and there is no new data left in the receive MII port. This bit is high if there is more receive data for PRU to read. There is a 2 clock cycle latency from the command RX_POP16/8 to WORD_RDY/BYTE_RDY update. Therefore, PRU firmware needs to insure it does not read BYTE_RDY/WORD_RDY until 2 clock cycles after RX_POP16/8. When RX_DATA_RDY_MODE_DIS = 1: TX_EOF indicates an TX EOF event (i.e. a 1 --> 0 transition on TX_EN) has occurred. This bit will clear when TX_RESET is set or when new data is first loaded. PRU firmware can wait until TX_EOF = 1, then start a new TX Frame by immediately loading new data.
15:8	BYTE1	Data Byte 1. This data is available such that it is safe to read by the PRU when the DATA_RDY/BYTE_RDY/WORD_RDY bits are asserted.
7:0	BYTE0	Data Byte 0. This data is available such that it is safe to read by the PRU when the DATA_RDY/BYTE_RDY/WORD_RDY bits are asserted.

6.4.9.2.3.1.2.2 RX MII Port → RX L1 FIFO → RX L2 Buffer → PRU

The RX L2 is an optional high performance buffer between the RX L1 FIFO and the PRU. Figure 6-254 illustrates the receive data path using RX L2 buffer. This data path is characterized by multi-word in flight transactions.

Figure 6-254. RX L2 to PRU Interface



The 64-byte RX L2 buffer is divided into two 32 byte banks, or ping/pong buffers. When the RX L2 is enabled, the incoming data from the MII RX port will transmit first to the 32 byte RX L1 FIFO. RX L1 pushes data into RX L2, starting when the first byte is ready until the final EOF marker. The RX L2 buffer does not apply any backpressure to the RX L1 FIFO. Therefore, it is the PRU firmware's responsibility to fetch the data in RX L2 before it is overwritten by the cyclic buffer. The RX L1 will remain near empty, with only one byte (nibble) stored.

Each RX L2 bank holds up to 32 bytes of data, and every four nibbles (or 16 bits) of data has a corresponding 8-bit status. The data and status information are stored in packed arrays. In each bank, R2 to R9 contains the data packed array and R10 to R13 contains the status packed array. Figure 6-255 shows the relationship of the data registers and status registers. The RX L2 status registers record status information about the received data, such as ERROR_CRC, RX_ERROR, STATUS_RDY, etc. The RX L2 status register details are described in Table 6-656. Note RX_RESET clears all Data and Status elements and resets R18.

Figure 6-255. Data and Status Register Dependency

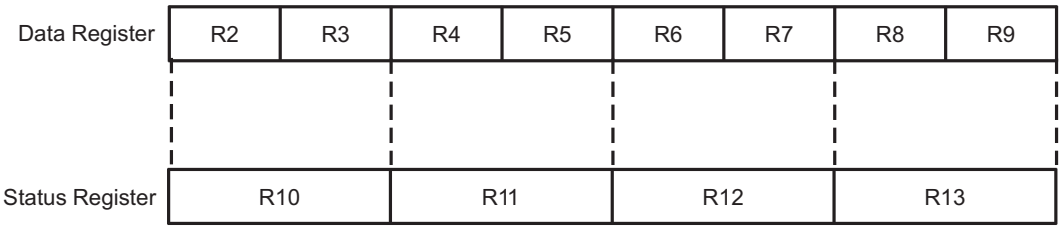


Table 6-656. RX L2 Status

Bit	Field Name	Description
7	ERROR_CRC	ERROR_CRC indicates that the frame has a CRC mismatch. This bit is valid when the RX_EOF bit is set. It should be noted that ERROR_CRC bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_CRC will only be set for one entry, self clear on next entry.
6	ERROR_NIBBLE	ERROR_NIBBLE indicates that the frame ended in odd nibble. It should be considered valid only when the RX_EOF bit and pr1_mii0/1_rxdv are set. Nibble counter is enabled post SFD event. It should be noted that ERROR_NIBBLE bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_NIBBLE will only be set for one entry, self clear on next entry.
5	RX_SOF	RX_SOF transitions from low to high when the frame data starts to arrive and pr1_mii0/1_rxdv is asserted. Note there will be a small sync delay of 0ns – 5ns. It should be noted that RX_SOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. RX_SOF will only be set for one entry, self clear on next entry.
4	RX_SFD	RX_SFD transitions from low to high when the SFD sequence (0xD5) post RX_SOF is observed on the receive MII data. It should be noted that RX_SFD bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. RX_SOF will only be set for one entry, self clear on next entry.
3	RX_EOF	RX_EOF indicates that the frame has ended and pr1_mii0/1_rxdv is de-asserted. It also validates the CRC match bit. Note there will be a small sync delay of 0ns – 5ns. It should be noted that RX_EOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. If RX_L2_EOF_SCLR_DIS = 1, then RX_EOF will remain set until RX_EOF_CLR event. Otherwise, RX_ERROR is self-clearing on next entry.
2	RX_ERROR	RX_ERROR indicates one or more of the following errors occurred: • RX_MAX/MIN_FRM_CNT_ERR • RX_MAX/MIN_PRE_CNT_ERR • RX_ERR RX_ERROR is cleared by RX_ERROR_CLR.
1	STATUS_RDY	STATUS_RDY is set when RX_EOF or write pointer advanced by 2. This is a simple method for software to determine if RX_EOF event has occurred or new data is available. If RX_EOF is not set, all status bits are static.
0	RX_ERR	RX_ERR is set to 1 when pr1_mii0/1_rxer is asserted while pr1_mii0/1_rxdv bit is set. It will get set for first pr1_mii0/1_rxer event and self clear on SOF for the next FRAME.

Bank 0 and Bank 1 are used as ping/pong buffers. RX L2 supports the reading of a write pointer in R18 that allows software to determine which bank has active write transactions, as well as the specific write address within packed data arrays.

The PRU interacts with the RX L2 buffer using the high performance XFR read instructions and broadside interface. Table 6-657 shows the device XFR ID numbers for each bank.

Table 6-657. RX L2 XFR ID

Device ID	Function	Description
20	Selects RX L2 Bank0	R2:R9 Data packed array R10:R13 Status packed array
21	Selects RX L2 Bank1	R2:R9 Data packed array R10:R13 Status packed array
20/21	Byte pointer of current write	R18[5:0] Pointer indicating location of current write in data packed array. 0 = Bank0.R2.Byte0 (default and reset value) 1 = Bank0.R2.Byte1 2 = Bank0.R2.Byte2 3 = Bank0.R2.Byte3 4 = Bank0.R3.Byte0 … 63=Bank1.R9.Byte3

XFR read transactions are passive and have no effect on any status or other states in RX L2. The firmware can also read R18 to determine which Bank has active write transactions and the location of the transaction. With this information, the firmware can read multiple times the stable preserved data. Note when RX L1 data is written to RX L2, the next status byte gets cleared at the same time the current status byte gets updated. The rest of the status buffer is persistent. When software is accessing any register of the ping/ pong buffer, software needs to issue an XFER read transaction to fetch the latest/current state of the ping/pong buffer. The PRU registers will not reflect the current snapshot of L2 unless an XFER is issued by software.

6.4.9.2.4 TX MII Interface

Data to be transmitted is loaded into the TX L1 FIFO. The transmit FIFO (TX L1) stores up to 96 bytes of transmit data. From the FIFO, the data is sent to the MII TX port of the PHY by the MII_RT transmit logic.

The transmit FIFO also has the capability to be reset through software (TX_RESET). When reset, all contents of transmit FIFO are purged and this may result in a frame not getting transmitted as expected, if the transmission is already ongoing. Any new data written in the transmit FIFO results in a new frame being composed and transmitted. An overflow event will require a TX_RESET to recover from this condition.

There are four dependencies that must be true for TX_EN to assert.

1. TX L1 FIFO not empty
2. Interpacket gap (IPG) timer expiration
3. RX_DV to TX_EN timer expiration
4. TX_EN compare timer expiration

The transmit interface also provides an underflow error signal in case there was no data loaded when TX_EN triggered. The transmit underflow signal is mapped to the INTC in PRU-ICSS. The PRU firmware must track the FIFO fill level, such as by a timer or the PRU cycle count register (PRU_ICSS_CTRL_CYCLE).The current FIFO fill level cannot be accessed by PRU firmware. The firmware can issue an R31 command via R31 bit 29 (TX_EOF) to indicate that the last byte has been written into the TX FIFO.

6.4.9.2.4.1 TX Data Path Options to TX L1 FIFO

There are two data path options for delivering data to the TX L1 FIFO and transmit port, described further in the subsequent sections:

1. PRU → TX L1 FIFO → TX MII port
2. RX L1 FIFO → TX L1 FIFO → TX MII port

6.4.9.2.4.1.1 PRU → TX L1 FIFO → TX MII Port

The PRU can be used to feed data into the TX L1 FIFO using the R30 and R31 registers, shown in Figure 6-256. The PRU has the option to write up to two or four bytes of R30 and then pushes the data into the TX L1 FIFO by writing to the R31 command interface.

Figure 6-256. PRU to TX L1 Interface

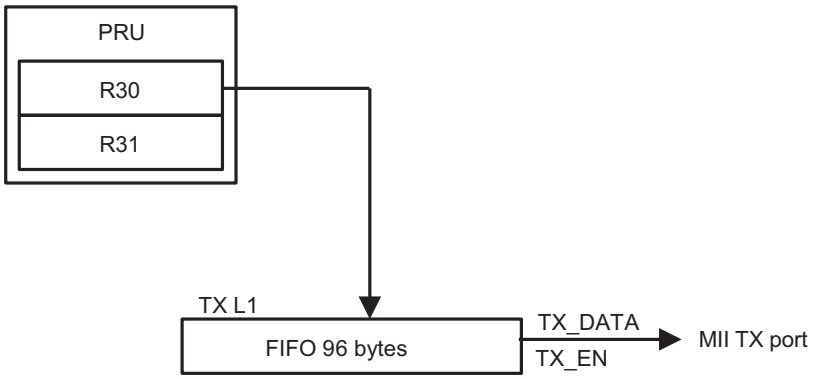

Figure 6-257 shows the R30 transmit interface. The lower 16 bits of the R30 (or FIFO transmit word) contain transmit data nibbles. When PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0, then the upper 16 bits contain mask information. Alternatively, when PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 1, then the upper 16 bits contain transmit data nibbles. The operation to be performed on the transmit interface is controlled by PRU writes to the R31 command interface. Table 6-658 describes the supported configurations for 8, 16, and 32 bit TX push operations.

Figure 6-257. PRU to TX MII Interface

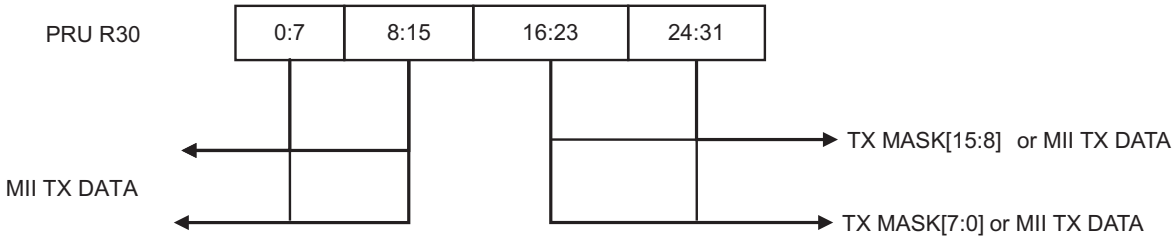

Table 6-658. TX Push

R31[25] TX_PUSH16/32	R31[24] TX_PUSH8/32	Supported R30 bits	TX_32_MODE_EN	TX_BYTE_SWAP	TX Push Action
0	1	X	0	X	8 bits of TXDATA (R30[7:0]) pushed post TX mask
1	0	X	0	X	16 bits of TXDATA (R30[15:0]) pushed post TX mask
1	1	X	0	X	Illegal
X	X	0x000000FF	1	0	8 bits of TXDATA (R30[7:0]) pushed
X	X	0x0000FFFF	1	0	16 bits of TXDATA (R30[15:0]) pushed
X	X	0xFFFFFFFF	1	X	32 bits of TXDATA (R30[31:0]) pushed
X	X	All other - reserved	1	X	Reserved

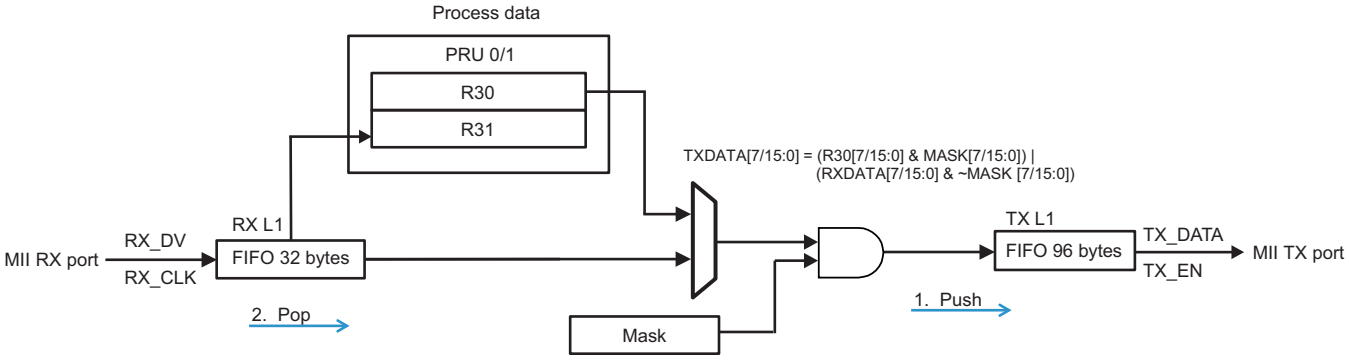
Using PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0 and the TX mask, the PRU can send a mix of R30 and RX L1 FIFO data to the TX L1 FIFO. Note the TX mask is only available when the PRU is fed one word or byte at a time by the RX L1 FIFO. It is not applicable when the RX L2 buffer is enabled. To disable TX mask, set TXMASK to 0xFFFF.

As shown in Figure 6-258, the PRU drives the MII transmit interface through its R30 register. The contents of R30 and RX data from the receive interface are taken and fed into a 96 byte transmit FIFO.

If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0, then before transmission, a mask is applied to the data portion of the R30 register. By using the mask, the PRU firmware can control whether received data from the RX L1 FIFO is sent to transmit, R30 data is sent to transmit, or a mix of the two is sent. The Boolean equation that is used by MII_RT to compose TX data is:

TXDATA[7/15:0] = (R30[7/15:0] & MASK[7/15:0]) | (RXDATA[7/15:0] & ~MASK [7/15:0])

Figure 6-258. TX Mask Mode (PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0)



6.4.9.2.4.1.2 RX L1 FIFO → TX L1 FIFO → TX MII Port

When PRUSS_MII_RT_TXCFG0/1[TX_AUTO_SEQUENCE] is set, the data frame is passed from the RX to TX FIFOs without the any interaction of the PRU. This mode of operations is shown in Figure 6-259. The RX L1 will push into TX L1 as long as it is enabled and not full.

There is no PRU dependency in this mode and no option for the PRU to perform any operation to the TX L1 FIFO. RX_RESET clears all data and status elements.

Figure 6-259. RX L1 to TX L1 Interface

6.4.9.2.5 PRU R31 Command Interface

The PRU uses writes to R31[31:16] to control the reception and transmission of packets in register mode. Table 6-659 lists the available commands. Each bit in the table is a single clock pulse output from the PRU. When more than one action is to be performed in the same instant, the PRU firmware must set those command bits in one instruction.

Table 6-659. PRU R31: Command Interface (Write Mode)

Bit	Command	Description
31	TX_CRC_ERR	TX_CRC_ERR command when set will add 0xa5 byte to the TX L1 FIFO if the current FCS is valid. This bit can only be set with the TX_EOF command and optionally with the TX_ERROR_NIBBLE command. It cannot get set with any other commands, and the PRU firmware must wait > 2 clocks from the last command. Note for proper operations auto-forward preamble must be enabled.
30	TX_RESET	TX_RESET command is used to reset the transmit FIFO and clear all its contents. This is required to recover from a TX FIFO overrun.

Table 6-659. PRU R31: Command Interface (Write Mode) (continued)

Bit	Command	Description
29	TX_EOF	TX_EOF command is used to indicate that the data loaded is considered last for the current frame
28	TX_ERROR_NIBBLE	TX_ERROR_NIBBLE command is used to insert an error nibble. This makes the frame invalid. Also, it will add 0x0 after the 32-bit CRC.
27	TX_CRC_HIGH	TX_CRC_HIGH command ends the CRC calculations and pushes CRC[31:16] to append to the outgoing frame in the TX L1 FIFO. Note PRUSS_MII_RT_TX_CRC0/1 will become valid after 6 clock cycles.
26	TX_CRC_LOW	TX_CRC_LOW command pushes CRC[15:0] to append to the outgoing frame in the TX L1 FIFO.
25	TX_PUSH16	TX_PUSH16 command pushes R30[15:0] when PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0. See Table x, TX Push for more details. Note there are no restrictions on concurrent PUSH/POP nor R30 requirements to maintain data. Back to back PUSH is supported.
24	TX_PUSH8	TX_PUSH8 command pushes R30[7:0] when PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0. See Table x, TX Push for more details. Note there are no restrictions on concurrent PUSH/POP nor R30 requirements to maintain data. Back to back PUSH is supported.
23	RX_ ERROR_CLR	RX_ERROR_CLR command is used to clear RX_ ERROR indicator bit by writing 1.
22	RX_EOF_CLR	RX_EOF_CLR command is used to clear RX_EOF status indicator bit by writing 1.
21	RX_SFD_CLR	RX_SFD_CLR command is used to clear RX_SFD indicator bit by writing 1.
20	RX_SOF_CLR	RX_SOF_CLR command is used to clear RX_SOF indicator bit by writing 1.
19	Reserved	Reserved
18	RX_RESET	RX_RESET is used to reset the receive FIFO and clear all contents. This is required to recover from a RX FIFO overrun, if software does not want to undrain. The typical use case is assertion after RX_EOF. If asserted during an active frame, the following actions will occur: 1. Terminate the current frame 2. Block/terminate all new data 3. Flush/clear all FIFO elements 4. Cause RX state machine into an idle state 5. Cause EOF event 6. Cause minimum frame error, if you abort before minimum size reached
17	RX_POP16	RX_POP16 command advances the receive traffic by two bytes. This is only required when you are using R31 to read the data. After R31[15:0] is ready to read by PRU, it will set 1 to WORD_RDY, and the next new data will be allowed to advance. RX_POP16 to WORD_RDY update has 2 clock cycles latency. Firmware needs to insure it does not read WORD_RDY/BYTE_RDY until 2 clock cycles after RX_POP16.
16	RX_POP8	RX_POP8 command advances the receive traffic by one bytes. This is only required when you are using R31 to read the data. After R31[7:0] is ready to read by PRU, it will set 1 to BYTE_RDY, and the next new data will be allowed to advance. RX_POP8 to BYTE_RDY update has 2 clock cycles latency. Firmware needs to insure it does not read WORD_RDY/BYTE_RDY until 2 clock cycles after RX_POP8.

6.4.9.2.6 Other Configuration Options

6.4.9.2.6.1 Nibble and Byte Order

The PRU core is little endian. To support big endian, the MII_RT supports optional nibble swapping on both the RX and TX side.

On the receive side, the order of the two data bytes in RX R31 and the RX L2 buffer are configurable through the RX_BYTE_SWAP bit in the PRUSS_MII_RT_RXCFG0/1 registers, as shown in Table 6-660. Note the Nibble0 is the first nibble received.

Table 6-660. RX Nibble and Byte Order

Configuration	Order
PRUSS_MII_RT_RXCFG0/1[RX_BYTE_SWAP] = 0 (default)	R31[15:8] / RXL2[15:8] = Byte1{Nibble3,Nibble2} R31[7:0] / RXL2[7:0] = Byte0{Nibble1,Nibble0}
PRUSS_MII_RT_RXCFG0/1[RX_BYTE_SWAP] = 1	R31[15:8] / RXL2[15:8] = Byte0{Nibble1,Nibble0} R31[7:0] / RXL2[7:0] = Byte1{Nibble3,Nibble2}

On the transmit side, the order of the two data bytes and mask bytes in TX R30 are configurable through the TX_BYTE_SWAP bit in the PRUSS_MII_RT_TXCFG0/1 registers, as shown in Table 6-661. Note the Nibble0 is the first nibble received.

Table 6-661. TX Nibble and Byte Order

Configuration	Order
PRUSS_MII_RT_TXCFG0/1[TX_BYTE_SWAP] = 0 (default)	If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0, R30[15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} R30[31:24] = TX_MASK[15:8] R30[23:16] = TX_MASK[7:0] If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 1, R30[31:24] = Byte3{Nibble7,Nibble6} R30[23:16] = Byte2{Nibble5,Nibble4} R30[15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0}
PRUSS_MII_RT_TXCFG0/1[TX_BYTE_SWAP] = 1	If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0, R30[15:8] = Byte0{Nibble1,Nibble0} R30[7:0] = Byte1{Nibble3,Nibble2} R30[31:24] = TX_MASK[7:0] R30[23:16] = TX_MASK[15:8] If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 1, Only 32bit push is supported. R30[31:24] = Byte0{Nibble1,Nibble0} R30[23:16] = Byte1{Nibble3,Nibble2} R30[15:8] = Byte2{Nibble5,Nibble4} R30[7:0] = Byte3{Nibble7,Nibble6}

6.4.9.2.6.2 Preamble Source

The MII_RT module has the option to preserve and forward a received preamble in the TX data stream, use a preamble provided by the PRU, or auto-generate a preamble. These configurations are highlighted in Table 6-662.

Table 6-662. Preamble Configuration Options

RX_CUT_PREAMBLE	Determines whether RX preamble is passed to the RX L1/L2 FIFO
RX_AUTO_FWD_PRE	Determines whether RX preamble is automatically passed to TX L1 FIFO

Table 6-662. Preamble Configuration Options (continued)

TX_AUTO_PREAMBLE	TX interface logic auto-generates and appends preamble to TX data stream with the first push of data into the TX L1 FIFO. Note that enabling this option does fill the TX FIFO with the preamble length, hence software has to consider this to not overrun the TX FIFO.

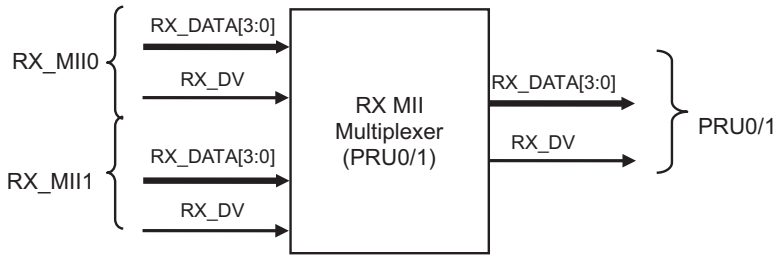
6.4.9.2.6.3 PRU and MII Port Multiplexer

The MII_RT module supports configurable PRU core to MII TXn / RXn port mapping. By default, PRU0 is mapped to TX1 and RX0 and PRU1 is mapped to TX0 and RX1. However, the system supports the flexibility to map any PRU core to any TX and RX port. Note the mapping options are destination fixed. For example, the input to PRU0 can be either RX_MII0 or RX_MII1. Similarly, the input to TX_MII0 can be either PRU0 or PRU1.

6.4.9.2.6.3.1 Receive Multiplexer

A multiplexer is provided to allow selecting either of the two MII interfaces for the receive data that is sent to PRU. Figure 6-260 shows the symbol of receive multiplexer of PRU.

Figure 6-260. MII Receive Multiplexer

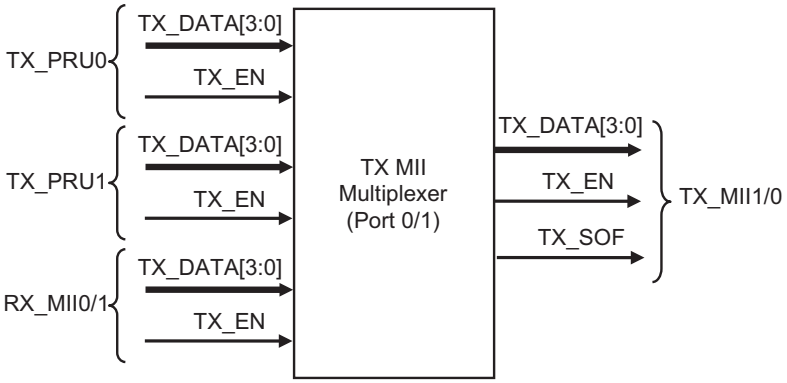


There are two receive multiplexer instances to enable selection of RX MII path for each PRU. The select lines of the RX multiplexers are driven from the PRU-ICSS programmable registers (PRUSS_MII_RT_RXCFG0/1).

6.4.9.2.6.3.2 Transmit Multiplexer

On the MII transmit ports, there is a multiplexer for each MII transmit port that enables selection of either the transmit data from the PRUs or from the RX MII interface of the other MII interface. Figure 6-261 shows the symbol of transmit multiplexer of PRU.

Figure 6-261. MII Transmit Multiplexer

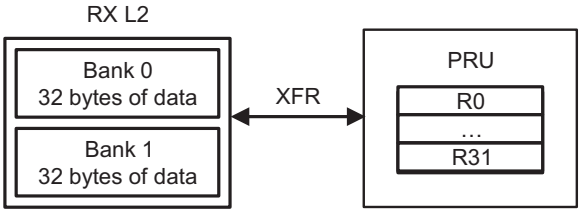


The transmit multiplexers enable the PRU-ICSS to either operate in a bypass mode where the PRU is not involved in processing MII traffic or use of one of the PRU cores for transmitting data into the MII interface. There are two instances of the TX MII multiplexer and the select lines for each TX multiplexer are provided by the PRU-ICSS. The select lines are common between register and FIFO interface. It is expected that the select lines will not change during the course of a frame so that can avoid data exchange error.

6.4.9.2.6.4 RX L2 Scratch Pad

When the RX L2 is disabled (PRUSS_MII_RT_RXCFG0/1[RX_L2_EN] = 0), the RX L2 banks can be used as a generic scratch pad. In scratch pad mode, RX L2 Bank0 and RX L2 Bank1 operate like simple write/read memory mapped registers (MMRs). All XFR size and start operations are supported. RX_RESET has no effect in this mode. This mode is shown in Figure 6-262.

Figure 6-262. Scratch Pad Mode



6.4.9.3 PRU-ICSS MII RT Registers

Table 6-664 lists the memory-mapped registers for the PRU-ICSS MII_RT module. All register offset addresses not listed in Table 6-664 should be considered as reserved locations and the register contents should not be modified.

Table 6-663. PRU-ICSS MII RT Instances

6.4.9.3.1 PRUSS_MII_RT_RXCFG0 Register (Offset = 0h) [reset = 0h]

PRUSS_MII_RT_RXCFG0 is shown in Figure 6-263 and described in Table 6-666.

MII RXCFG 0 REGISTER
This register contains the PRU0 RXCFG configuration variables (RXCFG0) for the RX path.
PRUSS_MII_RT_RXCFG0 is attached to PRU0.
PRUSS_MII_RT_RXCFG0 controls which RX port is attached to PRU0.

Table 6-665. PRUSS_MII_RT_RXCFG0 Instances

Instance	Physical Address

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30-28	TX_CLK_DELAY	R/W	0h	In order to guarantee the MII_RT IO timing values published in the device data manual, the ICSS_i_VCLK_CLK (where i = 0 or 1) clock must be configured for 200MHz and TX_CLK_DELAY must be set to 6h.
27-26	RESERVED	R	0h	Reserved

Table 6-672. PRUSS_MII_RT_TXCFG0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-16	TX_START_DELAY	R/W	40h	Defines the minimum time interval (delay) between receiving the RXDV for the current frame and the start of the transmit interface sending data to the MII interface. Delay value is in units of MII_RT clock cycles, which uses the ICSS_i_VCLK_CLK (default is 200MHz, or 5ns). Default TX_START_DELAY value is 320ns, which is optimized for minimum latency at 16 bit processing. Counter is started with RX_DV signal going active. Transmit interface stops sending data when no more data is written into transmit interface by PRU along with TX_EOF marker bit set. If the TX FIFO has data when the delay expires, then TX will start sending data. But if the TX FIFO is empty, it will not start until the TX FIFO is not empty. It is possible to overflow the TX FIFO with the max delay setting when auto-forwarding is enabled since the time delay is larger than the amount of data it needs to store. As long as TX L1 FIFO overflows, software will need to issue a TX_RESET to reset the TX FIFO. The total delay is 96-byte times (size of TX FIFO), but you need to allow delays for synchronization. Do to this fact, the maximum delay should be 80ns less when auto forwarding is enabled. Therefore, 0x3F0 is the maximum in this configuration.
15-12	RESERVED	R	0h	Reserved
11	TX_32_MODE_EN	R/W	0h	0h: Disable 32-bit Data Push mode. 1h: Enable 32-bit, 16-bit, and 8-bit Data Push mode with TX_MASK disabled. In this mode, the internal PRU R30 byte write strobes are used and not the R31 CMD TX_PUSH mode. Any update to R30 will trigger an TX PUSH. See Table 6-658.
10	RESERVED	R	0h	Reserved
9	TX_AUTO_SEQUENCE	R/W	0h	Enables transmit auto-sequence. Note the transmit data source is determined by TX_MUX_SEL setting. 0h: Disable 1h: Enable, transmit state machine based on events on receiver path that is connected to the respective transmitter. Also, the masking logic is disabled and only the MII data is used.
8	TX_MUX_SEL	R/W	1h	Selects transmit data source. The default/reset setting for TX Port 0 is 1. This setting permits MII TX Port 0 to receive data from PRU1 and the MII TX Port 1 which is connected to PRU0 by default. 0h: Data from PRU0 (default for PRUSS_MII_RT_TXCFG1) 1h: Data from PRU1 (default for PRUSS_MII_RT_TXCFG0)
7-4	RESERVED	R	0h	Reserved

Table 6-672. PRUSS_MII_RT_TXCFG0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	TX_BYTE_SWAP	R/W	0h	Defines the order of Byte0/1 placement for TX R30. This bit must be selected/updated when the port is disabled or there is no traffic. **0h: If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0,** R30[15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} R30[31:24] = TX_MASK[15:8] R30[23:16] = TX_MASK[7:0] **If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 1,** R30[31:24] = Byte3{Nibble7,Nibble6} R30[23:16] = Byte2{Nibble5,Nibble4} R30[15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} **1h: If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 0,** R30[15:8] = Byte0{Nibble1,Nibble0} R30[7:0] = Byte1{Nibble3,Nibble2} R30[31:24] = TX_MASK[7:0] R30[23:16] = TX_MASK[15:8] **If PRUSS_MII_RT_TXCFG0/1 [TX_32_MODE_EN] = 1,** (ONLY SUPPORT 32bit push) R30[31:24] = Byte0{Nibble1,Nibble0} R30[23:16] = Byte1{Nibble3,Nibble2} R30[15:8] = Byte2{Nibble5,Nibble4} R30[7:0] = Byte3{Nibble7,Nibble6 **Note Nibble0 is the first nibble received.**
2	TX_EN_MODE	R/W	0h	Enables transmit self clear on TX_EOF event. **Note that iep.cmp[3] must be set before transmission will start for TX0, and iep_cmp[4] for TX1. This is a new dependency, in addition to TX L1 FIFO not empty and TX_START_DELAY expiration, to start transmission.** 0h: Disable 1h: Enable, TX_ENABLE will be clear for a TX_EOF event by itself.
1	TX_AUTO_PREAMBLE	R/W	0h	Transmit data auto-preamble. 0h: PRU will provide full preamble 1h: TX FIFO will insert pre-amble automatically **Note: the TX FIFO does not get preloaded with the preamble until the first write occurs. This can cause the latency to be larger the min latency.**
0	TX_ENABLE	R/W	0h	Enables transmit traffic on TX PORT. If TX_EN_MODE is set, then TX_ENABLE will self clear during a TX_EOF event. Note Software can use this to pre-fill the TX FIFO and then start the TX frame during non-ECS operations. 0h: TX PORT is disabled/stopped immediately 1h: TX PORT is enabled and the frame will start once the IPG counter expired and TX Start Delay counter has expired

6.4.9.3.4 PRUSS_MII_RT_TXCFG1 Register (Offset = 14h) [reset = 00400000h]

PRUSS_MII_RT_TXCFG1 is shown in Figure 6-266 and described in Table 6-675.

MII TXCFG 1 REGISTER
This register contains the configuration variables for the transmit path on the MII interface port 1.
PRUSS_MII_RT_TXCFG1 is attached to Port TX1.
PRUSS_MII_RT_TXCFG1 controls which PRU is selected for TX1

Table 6-674. PRUSS_MII_RT_TXCFG1 Instances

Table 6-675. PRUSS_MII_RT_TXCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30-28	TX_CLK_DELAY	R/W	0h	In order to guarantee the MII_RT IO timing values published in the device data manual, the ICSS_i_VCLK_CLK (where i = 0 or 1) clock must be configured for 200MHz and TX_CLK_DELAY must be set to 6h.
27-26	RESERVED	R	0h	Reserved

Table 6-675. PRUSS_MII_RT_TXCFG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25-16	TX_START_DELAY	R/W	40h	Defines the minimum time interval (delay) between receiving the RXDV for the current frame and the start of the transmit interface sending data to the MII interface. Delay value is in units of MII_RT clock cycles, which uses the ICSS_i_VCLK_CLK, where i = 0 or 1 (default is 200MHz, or 5ns). Default TX_START_DELAY value is 320ns, which is optimized for minimum latency at 16 bit processing. Counter is started with RX_DV signal going active. Transmit interface stops sending data when no more data is written into transmit interface by PRU along with TX_EOF marker bit set. If the TX FIFO has data when the delay expires, then TX will start sending data. But if the TX FIFO is empty, it will not start until the TX FIFO is not empty. It is possible to overflow the TX FIFO with the max delay setting when auto-forwarding is enabled since the time delay is larger than the amount of data it needs to store. As long as TX L1 FIFO overflows, software will need to issue a TX_RESET to reset the TX FIFO. The total delay is 96-byte times (size of TX FIFO), but you need to allow delays for synchronization. Do to this fact, the maximum delay should be 80ns less when auto forwarding is enabled. Therefore, 0x3F0 is the maximum in this configuration.
15-12	RESERVED	R	0h	Reserved
11	TX_32_MODE_EN	R/W	0h	0h: Disable 32-bit Data Push mode. 1h: Enable 32-bit, 16-bit, and 8-bit Data Push mode with TX_MASK disabled. In this mode, the internal PRU R30 byte write strobes are used and not the R31 CMD TX_PUSH mode. Any update to R30 will trigger an TX PUSH.
10	RESERVED	R	0h	Reserved
9	TX_AUTO_SEQUENCE	R/W	0h	Enables transmit auto-sequence. Note the transmit data source is determined by TX_MUX_SEL setting. 0h: Disable 1h: Enable, transmit state machine based on events on receiver path that is connected to the respective transmitter. Also, the masking logic is disabled and only the MII data is used.
8	TX_MUX_SEL	R/W	0h	Selects transmit data source. The default/reset setting for TX Port 0 is 1. This setting permits MII TX Port 0 to receive data from PRU1 and the MII TX Port 1 which is connected to PRU0 by default. 0h: Data from PRU0 (default for PRUSS_MII_RT_TXCFG1) 1h: Data from PRU1 (default for PRUSS_MII_RT_TXCFG0)
7-4	RESERVED	R	0h	Reserved

6.4.10 PRU-ICSS MII MDIO Module

This section describes the PRU-ICSS_0 and PRU-ICSS_1 integrated **MII management interface module - MII_MDIO** module (ICSS_0_MII_MDIO / ICSS_1_MII_MDIO, respectively).

6.4.10.1 PRU-ICSS MII MDIO Overview

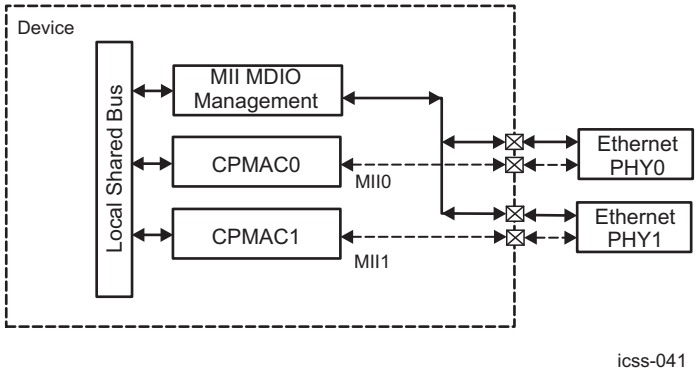
The following features are supported:

- Supports up to 32 PHY addresses.
- Two user access registers to control and monitor up to two PHYs simultaneously.
- Slave interface for configuration and control (MII RT MDIO CFG)

The PRU-ICSS MII MDIO management I/F module implements the **802.3 serial management interface** to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Figure 1 shows a device with two MACs, each connected to an Ethernet PHY, being managed by the MII interface module using a shared bus.

The Figure 6-283 gives an overview of the MII MDIO management interface.

Figure 6-283. Device PRU-ICSS MII MDIO Management Interface Overview



6.4.10.2 PRU-ICSS MII MDIO Functional Description

The MII Management interface incorporates:

- **MDIO Registers** - Host interaction with this module is facilitated through the registers in this block.
- **Control and Schedule** - The control and register logic in the MII Management Interface module contain the state machine and scheduling logic which control the wire side operation.
- **MDIO Interface** - The MDIO interface block provides the serial interface to the MDIO interface.

The MDIO logic is fully synchronous to the PRU-ICSS local shared bus clock.

6.4.10.2.1 MII MDIO Management Interface Frame Formats

The below Table 6-725 shows the read and write format of the 32-bit MII Management interface frames, respectively.

Table 6-725. MII MDIO Frame Formats

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
MDIO Read Frame Format						
FFFFFFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD
MDIO Write Frame Format						
FFFFFFFFh	01	00	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction.

Preamble
The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a "1". This sequence provides the Ethernet PHY a pattern to use to establish synchronization.

Start Delimiter
The preamble is followed by the start delimiter which is indicated by a "01" pattern. The pattern assures transitions from the default logic one state to zero and back to one.

Operation Code
The operation code for a read is "10", while the operation code for a write is a "00".

Ethernet PHY Address
The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address
The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround
An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data
The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

The Table 6-726 shows the PRU-ICSS_0 / PRU-ICSS_1 MII MDIO signals and their availability at the device boundary.

Table 6-726. PRU-ICSS MII MDIO Control and Interface Signals

MDIO Control Signals			
Pin Name	**Type**	**Available as device I/O**	**Function**
MDIO_LINKINT[1:0]	O	N.A.	Serial interface link change interrupt. Indicates a change in the state of the PHY link.
MDIO_USERINT[1:0]	O	N.A.	Serial interface user command event complete interrupt.
MDIO Interface Signals			
Pin Name	**Type**	**Available as device I/O**	**Function**
MDIO_I	I	device bidirectioanal **pr0_mdio_data** and pr1_mdio_mdclk pin in input mode	Serial data input
MDIO_O	O	device bidirectional **pr0_mdio_data** and pr1_mdio_mdclk pin in output mode	Serial data output
MDIO_OE_N	O	N.A.	Serial data output enable. Asserted "0" when data output is valid
MDCLK_O	O	device output - **pr0_mdio_mdclk** pr1_mdio_mdclk	Serial clock output
MLINK_I[1:0]	I	N.A.	Optional link status inputs from PHY. Each input is connected to a single PHY. Unused inputs are tied '0'.

6.4.10.2.2 PRU-ICSS MII MDIO Interractions

The MII Management I/F will remain idle until enabled by setting the **[30] ENABLE** bit in the PRUSS_MII_MDIO_CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the PRUSS_MII_MDIO_LINK register. The link status of two of the 32 possible PHY addresses can also be determined using the **MLINK** pin inputs. The bit **[7] LINKSEL** in the PRUSS_MII_MDIO_USERPHYSEL0/1 register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the PRUSS_MII_MDIO_LINKINTRAW register and the PRUSS_MII_MDIO_LINKINTMASKED register, if enabled by the **[6]LINKINT_ENABLE**bit in the PRUSS_MII_MDIO_USERPHYSEL0/1 register.

The PRUSS_MII_MDIO_ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the PRUSS_MII_MDIO_ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the **[15:0] DATA**, **[20:16] PHYADR**, **[25:21] REGADR**, and **[30] WRITE** fields in a PRUSS_MII_MDIO_USERACCESS0/1 register. When the host sets the **[31] GO** bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the **[31] GO** bit and set the **[1:0] USERINTRAW** bit field in the PRUSS_MII_MDIO_USERINTRAW register corresponding to the PRUSS_MII_MDIO_USERACCESS0/1 register being used. The corresponding bit in the PRUSS_MII_MDIO_USERINTMASKED register may also be set depending on the mask setting in the PRUSS_MII_MDIO_USERINTMASKSET and PRUSS_MII_MDIO_USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions which may queued by the host in different PRUSS_MII_MDIO_USERACCESS0/1 registers. The host should check the status of the **[31] GO** bit in the PRUSS_MII_MDIO_USERACCESS0/1 register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the**[29] ACK** bit in the PRUSS_MII_MDIO_USERACCESS0/1 register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to set up the autonegotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and set up the **MAC Control** register in the corresponding MAC.

6.4.10.2.3 PRU-ICSS MII MDIO Interrupts

The MII Management interface state machine will assert the **MDIO_LINKINT** signals if there is a change in the link state of the Ethernet PHY corresponding to the address in the **[4-0] PHYADR_MON** field of the PRUSS_MII_MDIO_USERPHYSEL0/1 registers and the corresponding **[6] LINKINT_ENABLE** bit is set. The **MDIO_LINKINT** event is also captured in the PRUSS_MII_MDIO_LINKINTMASKED register. **MDIO_LINKINT[0]** and **MDIO_LINKINT[1]** correspond to the PRUSS_MII_MDIO_USERPHYSEL0 and PRUSS_MII_MDIO_USERPHYSEL1 registers, respectively.

When the **[31] GO** bit in the PRUSS_MII_MDIO_USERACCESS0/1 registers transitions from ‘1’ to ‘0’, indicating the completion of a user access, and the corresponding **[1:0] USERINTMASKEDSET** field in the

PRUSS_MII_MDIO_USERINTMASKSET register is set, the **MDIO_USERINT** signal is asserted ‘1’. The **MDIO_USERINT** event is also captured in the PRUSS_MII_MDIO_USERINTMASKSET register. **MDIO_USERINT[0]** and **MDIO_USERINT[1]** correspond to the PRUSS_MII_MDIO_USERACCESS0 and PRUSS_MII_MDIO_USERACCESS1 registers, respectively.

6.4.10.3 PRU-ICSS MII MDIO Receive/Transmit Frame Host Software Interface

To facilitate transmission and reception of serial management frames, the host has to perform the following operations:

- Configure the **[20] PREAMBLE** and **[15:0] CLKDIV** fields in the PRUSS_MII_MDIO_CONTROL register.
- Enable the VBUS MII management module by setting the **[30] ENABLE** bit in the PRUSS_MII_MDIO_CONTROL register. If Byte access is being used, the **[30] ENABLE** bit should be written last.

- The PRUSS_MII_MDIO_ALIVE register can be read after a delay to determine which Ethernet PHYs responded.
- Set up the appropriate PHY addresses in the PRUSS_MII_MDIO_USERPHYSEL0/1[4-0] PHYADR_MON bits.
- Set up the appropriate **[6] LINKINT_ENABLE** bit in the PRUSS_MII_MDIO_USERPHYSEL0/1 registers.
- Set up the appropriate **[7] LINKSEL** bits in the PRUSS_MII_MDIO_USERPHYSEL0/1 registers.
- Set up the appropriate **[1:0] USERINTMASKEDSET** field in the PRUSS_MII_MDIO_USERINTMASKSET register.
- To write to an Ethernet PHY register the host should first check to ensure that the **[31] GO** bit in a PRUSS_MII_MDIO_USERACCESS0/1 register is cleared. The **[31] GO**, **[30] WRITE**, **[25:21] REGADR**, **[20:16] PHYADR** and data fields in that PRUSS_MII_MDIO_USERACCESS0/1 registers can then be updated to be appropriate value. If byte access is being used, the **[31] GO** bit should be written last. The write operation to the PHY will be scheduled and completed by the module. Completion of the write operation can be determined by examining the **[31] GO** bit in the PRUSS_MII_MDIO_USERACCESS0/1 registers. It also results in a transition on the appropriate **MDIO_INT** signal and the corresponding bit in the PRUSS_MII_MDIO_USERINTMASKED register based on the setting of the PRUSS_MII_MDIO_USERINTMASKSET register.
- To read from an Ethernet PHY register the host should first check to ensure that the **[31] GO** bit in a PRUSS_MII_MDIO_USERACCESS0/1 register is cleared. The **[31] GO**, **[25:21] REGADR**, and **[20:16] PHYADR** fields in that PRUSS_MII_MDIO_USERACCESS0/1 register can then be updated to the appropriate value. The read data value will be available in the **[15:0] DATA** field of the PRUSS_MII_MDIO_USERACCESS0/1 register after the module completes the read operation on the serial bus. The completion of the read operation can be determined by examining the **[31] GO** and **[29] ACK** bits in the PRUSS_MII_MDIO_USERACCESS0/1 register. It also results in a transition on the appropriate **MDIO_INT** signal and the corresponding bit in the PRUSS_MII_MDIO_USERINTMASKED register based on the setting of the PRUSS_MII_MDIO_USERINTMASKSET register.
- The module de-asserts the **MDIO_USERINT** signal when the host writes to the appropriate **[1:0] USERINTMASKED** bit in the PRUSS_MII_MDIO_USERINTMASKED register or the **[1:0] USERINTRAW** bit in the PRUSS_MII_MDIO_USERINTRAW register.
- The host can poll the PRUSS_MII_MDIO_LINK register periodically or use the **MDIO_LINKINT** signals to determine the state of the serial interface to a particular Ethernet PHY.
- The module de-asserts the **MDIO_LINKINT** when the host writes to the appropriate **[1:0] LINKINTRAW** bit in the PRUSS_MII_MDIO_LINKINTRAW register or the **[1:0] LINKINTMASKED** bit in the PRUSS_MII_MDIO_LINKINTMASKED register.

Table 6-727. Summary of the PRU-ICSS MII MDIO Functional Registers

Address Offset	Register Mnemonic	Register Name	Register Purpose

Table 6-734. PRUSS_MII_MDIO_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state.
30	ENABLE	R/W	0h	Enable control. Writing a 1 to this bit enables the MDIO state machine, writing a 0 disables it. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register.
29	RESERVED	R	0h	Reserved
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest useraccess channel that is available in the module and is currently set to 1. This implies that **MDIOUserAccess1** is the highest available user access channel.
23-21	RESERVED	R	0h	Reserved
20	PREAMBLE	R/W	0h	Preamble disable. Writing a 1 to this bit disables this device from sending MDIO frame preambles.
19	FAULT	RWr1Clr	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit.
18	FAULT_DETECT_ENABLE	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection.
17	INT_TEST_ENABLE	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the userint and linkint bits for test purposes.
16	RESERVED	R	0h	Reserved

Table 6-734. PRUSS_MII_MDIO_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-0	CLKDIV	R/W	FFh	Clock Divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when clkdiv is set to 0. MDCLK frequency = clk frequency/(clkdiv+1).

Table 6-737. PRUSS_MII_MDIO_ALIVE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ALIVE	RWr1Clr	0h	MDIO Alive bitfield. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.

Table 6-740. PRUSS_MII_MDIO_LINK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LINK	R	0h	MDIO Link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the **MDIOUserPhySel** registers can be determined using the **MLINK** input pins. This is determined by the **linksel** bit in the **MDIOUserPhySel** register.

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	Reserved
1-0	USERINTMASKED	RWr1Clr	0h	Masked value of MDIO user command complete interrupt for MDIOUserAccess1 through MDIOUserAccess0, respectively. When asserted 1 , a bit indicates that the previously scheduled PHY read or write command using that particular MDIOUserAccess register has completed and the corresponding userintmaskset bit is set to 1 . . Writing a 1 will clear the interrupt and writing 0 has no effect. . If the int_test bit in the MDIOControl register is set, the host may set the userintmasked bits to a 1 . This mode may be used for test purposes.

6.4.11 PRU-ICSS Industrial Ethernet Peripheral (IEP)

This section describes the Industrial Ethernet Peripheral (IEP) module which is part of the PRU-ICSS.

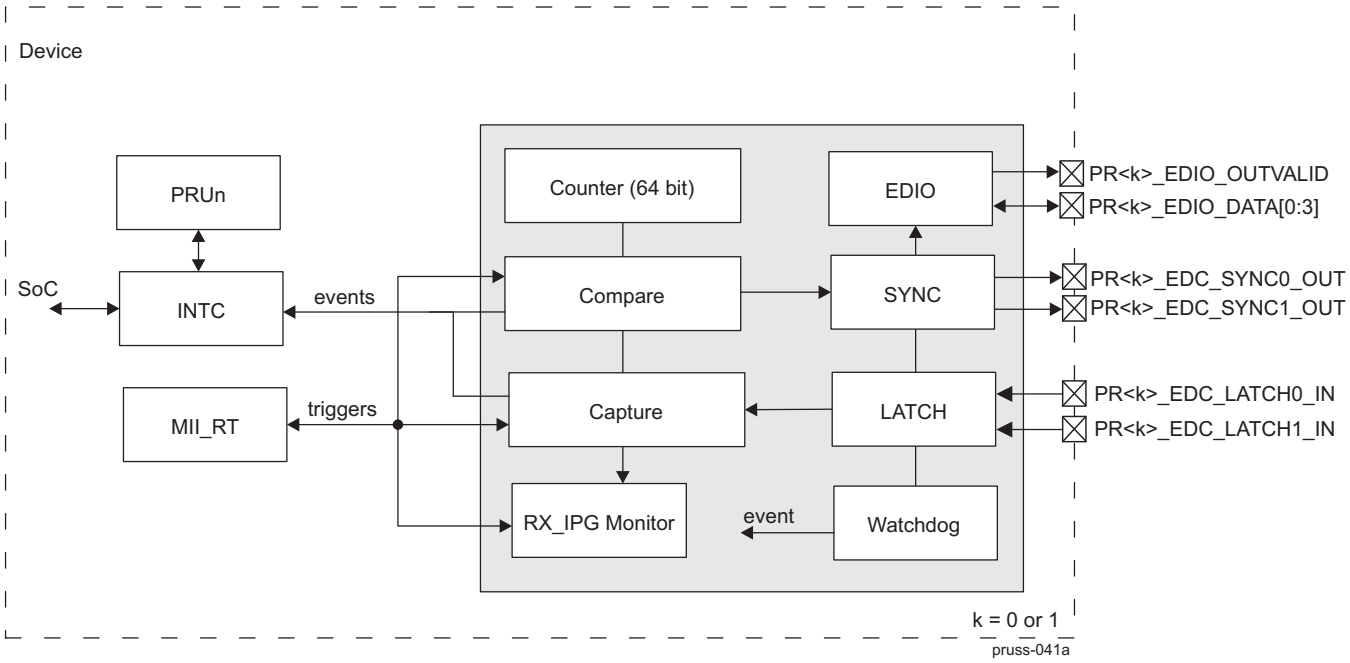
6.4.11.1 PRU-ICSS IEP Overview

The Industrial Ethernet Peripheral (IEP) performs hardware work required for Industrial Ethernet functions. The IEP module features an Industrial Ethernet Timer with 16 compare events, Industrial Ethernet Sync generator and Latch capture, Industrial Ethernet Watchdog Timer, and a digital I/O port (DIGIO).

6.4.11.2 PRU-ICSS IEP Functional Description

This section provides the functional description of the IEP components. The IEP functional block diagram is shown in Figure 6-298.

Figure 6-298. IEP Functional Block Diagram



6.4.11.2.1 PRU-ICSS IEP Clock Generation

The IEP has a selectable module input clock (ICSS_IEP_CLK, see also Section 6.4.3). The clock source is selected by the state of the PRUSS_IEPCLK[0] OCP_EN bit within the PRU-ICSS CFG register space. Two clock sources are supported for the IEP input clock:

- ICSS_IEP_CLK: The default functional clock for IEP is derived as divided version of the IEP/ NSS PLL output clock (IEP_NSS_PLL_CLK/ 5). The IEP functional clock (ICSS_IEP_CLK) runs at 200 MHz.
- ICSS_VCLK_CLK: The PRUSS_CFG interface clock (ICSS_VCLK_CLK) is derived as divided version of the device PLL Controller output clock (CHIP_CLK1/3).

Switching from ICSS_IEP_CLK to ICSS_VCLK_CLK is done by writing 1h to the PRUSS_IEPCLK[0] OCP_EN bit. This is a one time configuration step before enabling the IEP function. Switching back from ICSS_VCLK_CLK to ICSS_IEP_CLK is only supported through a hardware reset of the PRU-ICSS.

CAUTION

When software enables the clock (at PRU-ICSS level) to the IEP module clock input via setting bit PRUSS_IEPCLK[0] OCP_EN to 0b1 in the PRUSS_CFG space, there must be NO in-flight transactions to the IEP block.

CAUTION

ONLY switching from ICSS_IEP_CLK (the IEP specific functional clock source) to the ICSS_VCLK_CLK (top level interface clock) source is supported in software by device integrated PRU-ICSS. Switching back from ICSS_VCLK_CLK to ICSS_IEP_CLK is ONLY supported via assertion of a hardware reset to the PRU-ICSS.

6.4.11.2.2 PRU-ICSS Industrial Ethernet Timer

The industrial ethernet timer is a simple 64-bit timer. This timer is intended for use by industrial ethernet functions but can also be leveraged as a generic timer in other applications.

6.4.11.2.2.1 PRU-ICSS Industrial Ethernet Timer Features

The industrial ethernet timer supports the following features:

- One master 64-bit count-up counter with an overflow status bit.
  - Runs on ICSS_IEP_CLK or ICSS_VCLK_CLK clock.
  - Write 1 to clear status.
  - Supports a programmable increment value from 1 to 16 (default 5).
  - An optional compensation method allows the increment value to apply compensation increment value from 1 to 16 count up to 2^{24} ICSS_IEP_CLK/ ICSS_VCLK_CLK events with additional slow compensation mode.
- 10× 64-bit capture registers:
  - 8 capture inputs, with optional synchronous or asynchronous mode:
    - 6× rise capture, PRUSS_IEP_CAPTURE_RISE0i/PRUSS_IEP_CAPTURE_RISE1i (where i=0 to 5)
    - 2× rise capture- PRUSS_IEP_CAPTURE_RISE06/PRUSS_IEP_CAPTURE_RISE16 and PRUSS_IEP_CAPTURE_RISE07/PRUSS_IEP_CAPTURE_RISE17, each combined with a fall capture- PRUSS_IEP_CAPTURE_FALL06/PRUSS_IEP_CAPTURE_FALL16 and PRUSS_IEP_CAPTURE_FALL07/PRUSS_IEP_CAPTURE_FALL17, respectively
    - One global event (any capture event) output for interrupt
- 16× 64-bit compare registers: PRUSS_IEP_COMPARE0j/PRUSS_IEP_COMPARE1j (where j=0 to 15) and PRUSS_IEP_COMPARE_STATUS
  - 16 status bits, write 1 to clear
  - 16 individual event outputs
  - One global event output for interrupt generation triggered by any compare event
- 32 outputs, one high-level and one high-pulse for each compare hit event
- PRUSS_IEP_COMPARE_CFG[0] CMP0_RST_CNT_EN, if enabled, will reset the master counter on the next ICSS_IEP_CLK/ ICSS_VCLK_CLK cycle
- eHRPWM0_SYNCO/ eHRPWM3_SYNCO, if enabled, will reset the master counter on the next ICSS_IEP_CLK/ ICSS_VCLK_CLK cycle
- master counter reset-state is programmable

6.4.11.2.2.2 PRU-ICSS Industrial Ethernet Timer Basic Programming Sequence

Follow these basic steps to configure the IEP Timer.

Counter maintains/function:

1. Once enabled, the counter will count every PRUSS_IEP_CLK cycle, default rate of 200 MHz.
2. It is a free running counter with a sticky over flag status bit.
3. The counter over flow flag will get set when the counter switches/rollsover from 0XFFFF_FFFF to 0x0000_0000.
4. The counter will continue to count up. The software will need to read/clear the counter over flow flag and increment the MSB in software variable.

Compare function:

1. Initialize timer to known state (default values)
   - Disable counter (PRUSS_IEP_GLOBAL_CFG[0] CNT_ENABLE = 0)
   - Reset Count Register (PRUSS_IEP_LOW_COUNTER, PRUSS_IEP_HIGH_COUNTER) by writing FFFFFFFFh to clear
   - Clear overflow status register (PRUSS_IEP_STATUS[0] CNT_OVF = 1)
   - Clear compare status (PRUSS_IEP_COMPARE_STATUS) by writing FFFFFFFFh to clear
2. Set compare values PRUSS_IEP_COMPARE0j,PRUSS_IEP_COMPARE1j
3. Enable compare events (PRUSS_IEP_COMPARE_CFG[8:1] CMP_EN).
4. Set increment value (PRUSS_IEP_GLOBAL_CFG[7:4] DEFAULT_INC).
5. Set compensation value (PRUSS_IEP_COMPENSATION[23:0] COMPEN_CNT)
6. Enable counter (PRUSS_IEP_GLOBAL_CFG[0] CNT_ENABLE = 1)

Capture function:

1. Update/Enable the counter if required
2. Program the enable the desired capture event
3. Wait for global capture event
4. Read/Clear the capture status to determine which capture event occurred
5. Read the capture count

6.4.11.2.2.3 Industrial Ethernet Mapping

Some of the capture inputs and compare registers are mapped to specific industrial Ethernet functions in hardware, shown in Table 6-772. All capture inputs are mapped to industrial Ethernet functions, and these inputs are not available for any other application. The cmp1 and cmp2 compare registers also function as the start time triggers for SYNC0 and SYNC1, respectively.

Table 6-772. Industrial Ethernet Timer Mode Mapping

Capture Input	IEP Line/Function
cap0, rise only	PRU0_RX_SOF
cap1, rise only	PRU0_RX_SFD
cap2, rise only	PRU1_RX_SOF
cap3, rise only	PRU1_RX_SFD
cap4, rise only	PORT0_TX_SOF
cap5, rise only	PORT1_TX_SOF
cap6, rise and fall	latch0_in, SOC IO inputs
cap7, rise and fall	latch1_in, SOC IO inputs
cmp1	For SYNC0 trigger of start time
cmp2	For SYNC1 trigger of start time; only valid in the independent mode
cmp3	For MII TX0 start trigger, if MII register PRUSS_MII_RT_TXCFG0/1[2] TX_EN_MODE is enabled.

Table 6-772. Industrial Ethernet Timer Mode Mapping (continued)

Capture Input	IEP Line/Function
cmp4	For MII TX1 start trigger, if MII register PRUSS_MII_RT_TXCFG0/1[2] TX_EN_MODE is enabled.

6.4.11.2.3 PRU-ICSS IEP Sync0/Sync1 Signals Generation

The industrial ethernet sync block supports the generation of two synchronization signals: SYNC0 and SYNC1. SYNC0 and SYNC1 can be directly mapped to output signals (pr<k>_edc_sync0_out and pr<k>_edc_sync1_out) for external devices to use. They can also be used for internal synchronization within the PRU-ICSS. These signals are also mapped as system events and can therefore be mapped to the Arm core's Host interrupts.

6.4.11.2.3.1 PRU-ICSS IEP Sync0/Sync1 Features

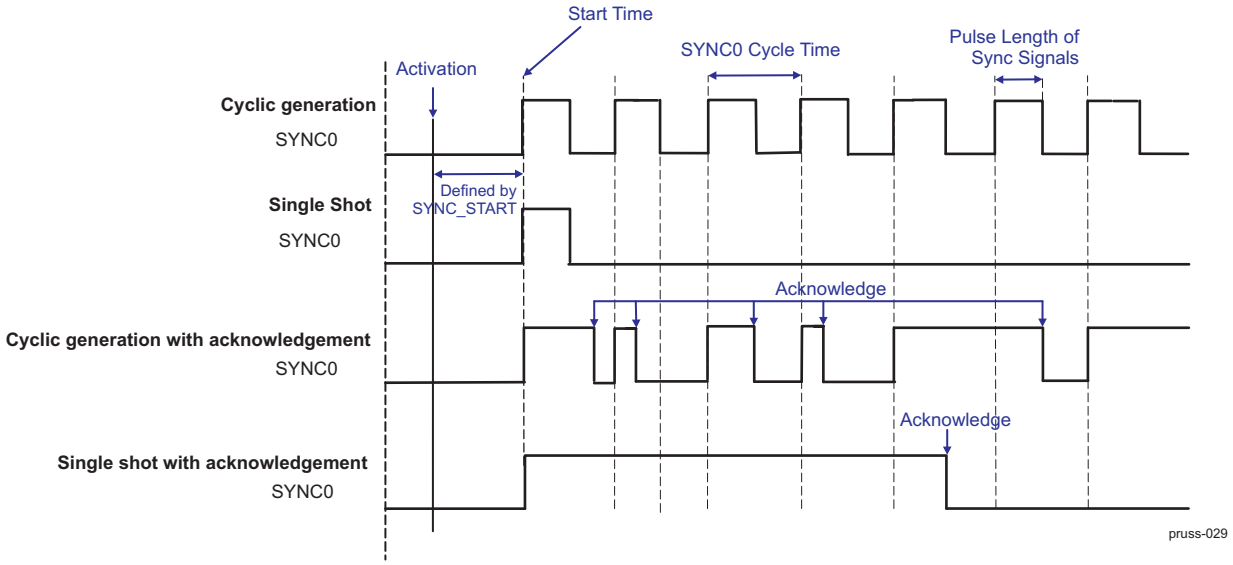
The industrial ethernet sync block supports the following features:

- Two synchronize generation signals (SYNC0, SYNC1)
  - Activation time synchronized with IEP Timer
- CMP[1] triggers SYNC0 activation time
- CMP[2] triggers SYNC1 activation time (only valid in the independent mode)
  - Pulse width defined by registers or ack mode (remain asserted until software acknowledged)
  - Cyclic or single-shot operation
  - Option to enable or disable sync generation
- Programmable number of clock cycles between the start of SYNC0 to the start of SYNC1

6.4.11.2.3.2 PRU-ICSS IEP Sync0/Sync1 Generation Modes

There are four modes of operation for the sync signals: cyclic mode, single shot mode, cyclic with acknowledge mode, and single shot with acknowledge mode. Figure 6-299 shows examples of these modes. The start time is set by the SYNC_START bit field in the PRUSS_IEP_SYNC_START register. The cycle time is configured by the SYNC0_PERIOD bit field in the PRUSS_IEP_SYNC0_PERIOD register. The pulse length is defined by SYNC_HPW bit field in the PRUSS_IEP_SYNC_PWIDTH register.

Figure 6-299. PRU-ICSS IEP SYNC0 Signal Generation Modes

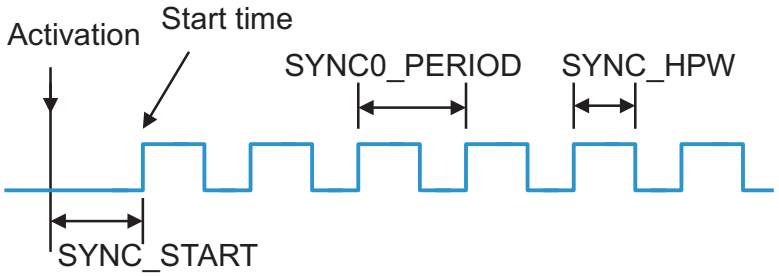


In SYNC1 dependent mode (PRUSS_IEP_SYNC_CTRL[8] SYNC1_IND_EN = 0b0), SYNC1 depends on SYNC0 and the start time of the SYNC1 can be defined by the PRUSS_IEP_SYNC1_DELAY register. Figure 6-300 shows different examples when changing the value in the PRUSS_IEP_SYNC1_DELAY register. Note if the SYNC1 delay time is 0, SYNC1 reflects SYNC0. Cyclic generation cannot be used for network time synchronized applications because only the CMP1/CMP2 hit occurs in the compensated time domain.

Figure 6-300. Examples of the Dependent Mode of SYNC1

SYNC0 : **Cyclic generation**

Field	Value
SYNC0_CYCLIC_EN	1
SYNC0_ACK_EN	0



SYNC0 : **Single shot**

6.4.11.2.4 PRU-ICSS Industrial Ethernet WatchDog

In industrial ethernet applications, the watchdog timer (WD) is used as a safety feature to monitor process data communication and to turn off the outputs of the digital input/output (DIGIO) functional block after a set time. The WD will thereby protect the system from errors or faults by timeout or expiration. The expiration is used to initiate corrective action in order to keep the system in a safe state and restore normal operation based on configuration. Therefore, if the system is stable, the watchdog timer should be regularly reset or cleared to avoid timeout or expiration.

The industrial ethernet watchdog timer supports the following features:

- One 16-bit pre-divider for generating a WD clock (default 100µs) based on ICSS_IEP_CLK input
- Two 16-bit Watchdog Timers:

  - PDI_WD for Sync Managers WD, used in conjunction with digital input/output (DIGIO)

  - PD_WD for data link layer user WD, used in conjunction with data link layer or application layer interface actions

NOTE: For more details on the PRU-ICSS Industrial Ethernet Watchdog timer, refer also to the PRU-ICSS_IEP_WD_x register descriptions covered in the .

6.4.11.2.5 PRU-ICSS Industrial Ethernet Digital IOs

The IEP digital I/O (DIGIO) block provides dedicated I/Os for industrial ethernet protocols. The digital inputs can be sampled when specific events occur or continuously as a raw input. Likewise, driving the digital outputs can be triggered by specific events or controlled by software. The timing, delay cycle clocks, data sources, and data valid of the digital input and outputs are controlled by the PRUSS_IEP_DIGIO_CTRL and PRUSS_IEP_DIGIO_EXP registers. Additionally, the IEP DIGIO block can be used as generic I/Os in other applications.

6.4.11.2.5.1 Features

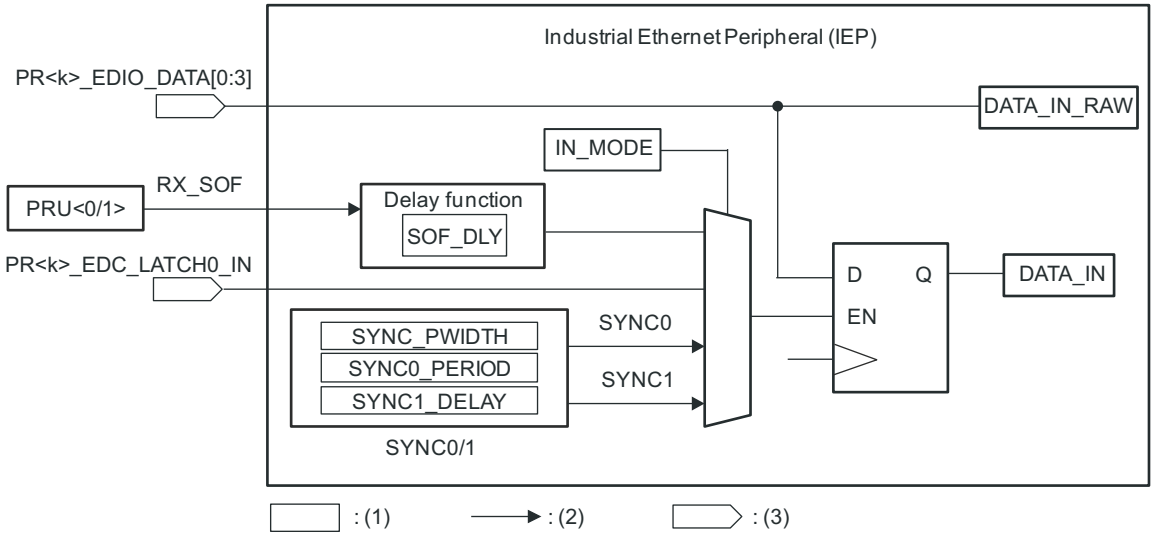
The industrial ethernet digital I/O supports the following features:

- Digital data output
  - 4 channels (PR<k>_EDIO_DATA[0:3])
  - Five event options for driving output data output:
    - End of frame event (PRU0/1_RX_EOF)
    - SYNC0 events
    - SYNC1 events
    - Watchdog trigger
    - Software enable
- Digital data out enable (optional tri-state control)
- Digital data input
  - 4 channels (PR<k>_EDIO_DATA[0:3])
  - PRUSS_IEP_DIGIO_DATA_IN_RAW supports direct sampling of PR<k>_EDIO_DATA[0:3]
  - DIGIO_DATA_IN supports four event options to trigger sampling of pr<k>_edio_data_in:
    - Start of frame event in start of frame (SOF) mode
    - pr<k>_edio_latch_in event
    - SYNC0 events
    - SYNC1 events

6.4.11.2.5.2 DIGIO Block Diagrams

Figure 6-301 shows the signals and registers for capturing the DIGIO data in. Note that IN_MODE in the PRUSS_IEP_DIGIO_CTRL register must be set to 1 for data to be latched on the external PR<k>_EDC_LATCH0_IN signal. In PRU0/1_RX_SOF mode, the delay time of capturing pr1_edio_data_in is programmable through the SOF_DLY bit of the PRUSS_IEP_DIGIO_EXP register.

Figure 6-301. IEP DIGIO Data In



(1) Register

(2) Internal signal wire

(3) External pin input/output

(1) Register

(2) External pin input/output

Figure 6-302 shows the signals and registers for driving the DIGIO data out.

The PR<k>_EDIO_DATA is immediately forced to zero when OUTVALID_MODE = 0b1, pr1_edio_oe_ext = 0b1, and PD_WD_EXP = 1, or the next update hardware post PD_WD_EXP. Delay assertion of PR<k>_EDIO_OUTVALID from PR<k>_EDIO_DATA update events are controlled by software (SW_OUTVALID).

6.4.11.2.5.3 Basic Programming Model

Follow these steps to configure and read the DIGIO Data Inpfut.

1. Read PRUSS_IEP_DIGIO_DATA_IN_RAW for raw input data

or

1. Enable sampling of PR<k>_EDIO_DATA[0:3] by setting PRUSS_IEP_DIGIO_CTRL[5:4] IN_MODE = 1h.
2. Read PRUSS_IEP_DIGIO_DATA_IN for data sampled upon PR<k>_EDC_LATCH0_IN posedge

Follow these steps to configure and write to the DIGIO Data Output.

1. Pre-configure DIGIO by setting PRUSS_IEP_DIGIO_EXP[1] OUTVALID_OVR_EN and PRUSS_IEP_DIGIO_EXP[0] SW_DATA_OUT_UPDATE
2. Write to PRUSS_IEP_DIGIO_DATA_OUT to configure output data.
3. To HiZ output, set corresponding PRUSS_IEP_DIGIO_DATA_OUT_EN bits to 1 (clear to 0 to drive value stored in PRUSS_IEP_DIGIO_DATA_OUT).

6.4.11.3 PRU-ICSS_IEP Registers

Table 6-774 lists the memory-mapped registers for the PRU-ICSS_IEP module. All register offset addresses not listed in Table 6-774 should be considered as reserved locations and the register contents should not be modified.

Table 6-773. PRU-ICSS_IEP Instances

Table 6-785. PRUSS_IEP_SLOW_COMPENSATION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SLOW_COMPEN_CNT	R/W	0h	Slow compensation counter. Write 0h: Slow compensation is disabled and counter will increment by DEFAULT_INC. Write Nh: Compensation is enabled for 1 count for every SLOW_COMPEN_CNT cycle, this is free running and continuous until software clears the MMR. For example, SLOW_COMPEN_CNT = 16, every 16 clock cycles the compensation value is used for 1 count. Note: COMPEN_CNT MUST be set to zero IF SLOW_COMPEN_CNT is not zero. Software can read the number of cycles left until the compensation event. For example, software writes SLOW_COMPEN_CNT = 100h and reads SLOW_COMPEN_CNT = 7h. This means in 6 more IEP_CLK cycles before the counter reaches 1h for the compensation event. If software writes SLOW_COMPEN_CNT = 8000h before compensation event, then the counter will reset to 8000h.

Memory Subsystem

This chapter describes the Memory Subsystem for the device.

Topic **Page**

7.1 Multicore Shared Memory Controller (MSMC)

This section describes the Multicore Shared Memory Controller (MSMC) for the device.

7.1.1 MSMC Overview

The Multicore Shared Memory Controller (MSMC) manages traffic among the device ARMSS, DSP, DMA, other master peripherals, and the EMIF controller. It also provides a shared on-chip SRAM that is accessible by the ARMSS, DSP and the master peripherals in the device.

The MSMC module has the following features:

- CPU/1 frequency of operation (that is, frequency same as that of the ARMSS/DSP)
- One 256-bit master interface for connection to external SDRAM (through EMIF controller)
- One 256-bit master interface for connection to TeraNet_DMA
- One 256-bit slave interface for the DSP
- One 256-bit slave interface for the ARMSS
- One 256-bit slave interface for accesses to the shared SRAM
- One 256-bit slave interface for accesses to the external SDRAM
- Memory protection for accesses to both the shared SRAM and external SDRAM spaces
- Address extension from 32-bit to 36-bit for larger addressing space
- Error Detection and Correction (EDC) and scrubbing support for the MSMC SRAM
- Level 2 or Level 3 shared SRAM that is accessible by the device ARMSS, DSP and the master peripherals
- Coherency between ARMSS L1/L2 cache and EDMA/system master peripherals (through SES/SMS ports) in the SRAM space and SDRAM space

7.1.2 MSMC Integration

This section describes the module integration in the device including information about clocks, resets, and hardware requests.

Figure 7-1 shows the integration of the MSMC module in the device.

Figure 7-1. MSMC Integration

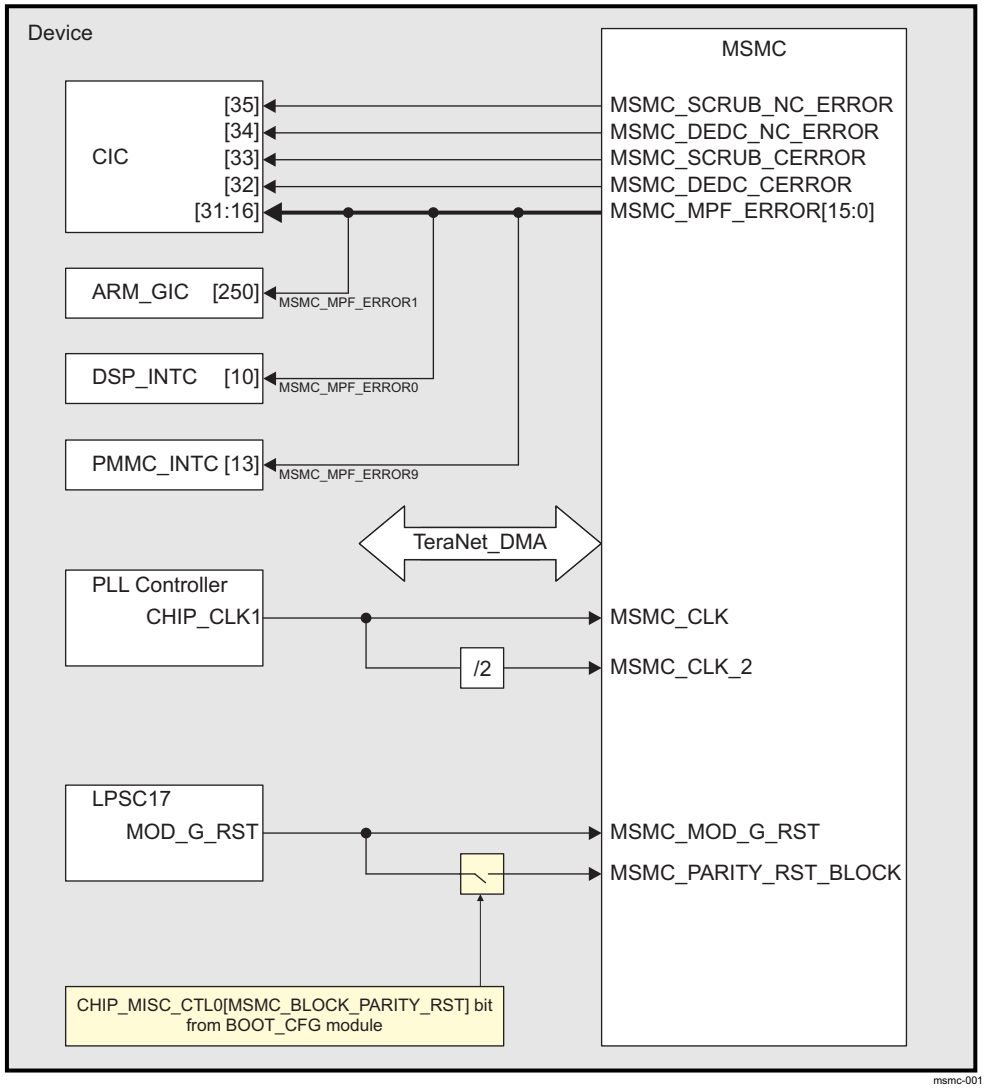

Table 7-1 through Table 7-3 summarize the integration of the MSMC module in the device.

Table 7-1. MSMC Integration Attributes

Module Instance	Attributes

	MSMC_MPF_ERROR14	-	[30]	-	-	Memory protection fault interrupt for master with PrivID = 14
	MSMC_MPF_ERROR15	-	[31]	-	-	Memory protection fault interrupt for master with PrivID = 15
	MSMC_DEDC_CERROR	-	[32]	-	-	Correctable (1-bit) soft error detected on SRAM read
	MSMC_SCRUB_CERROR	-	[33]	-	-	Correctable (1-bit) soft error detected during scrub cycle
	MSMC_DEDC_NC_ERROR	-	[34]	-	-	Non-correctable (2-bit) soft error detected on SRAM read
	MSMC_SCRUB_NC_ERROR	-	[35]	-	-	Non-correctable (2-bit) soft error detected during scrub cycle

NOTE: For more information about the MSMC interrupts, see Section 7.1.3.5.

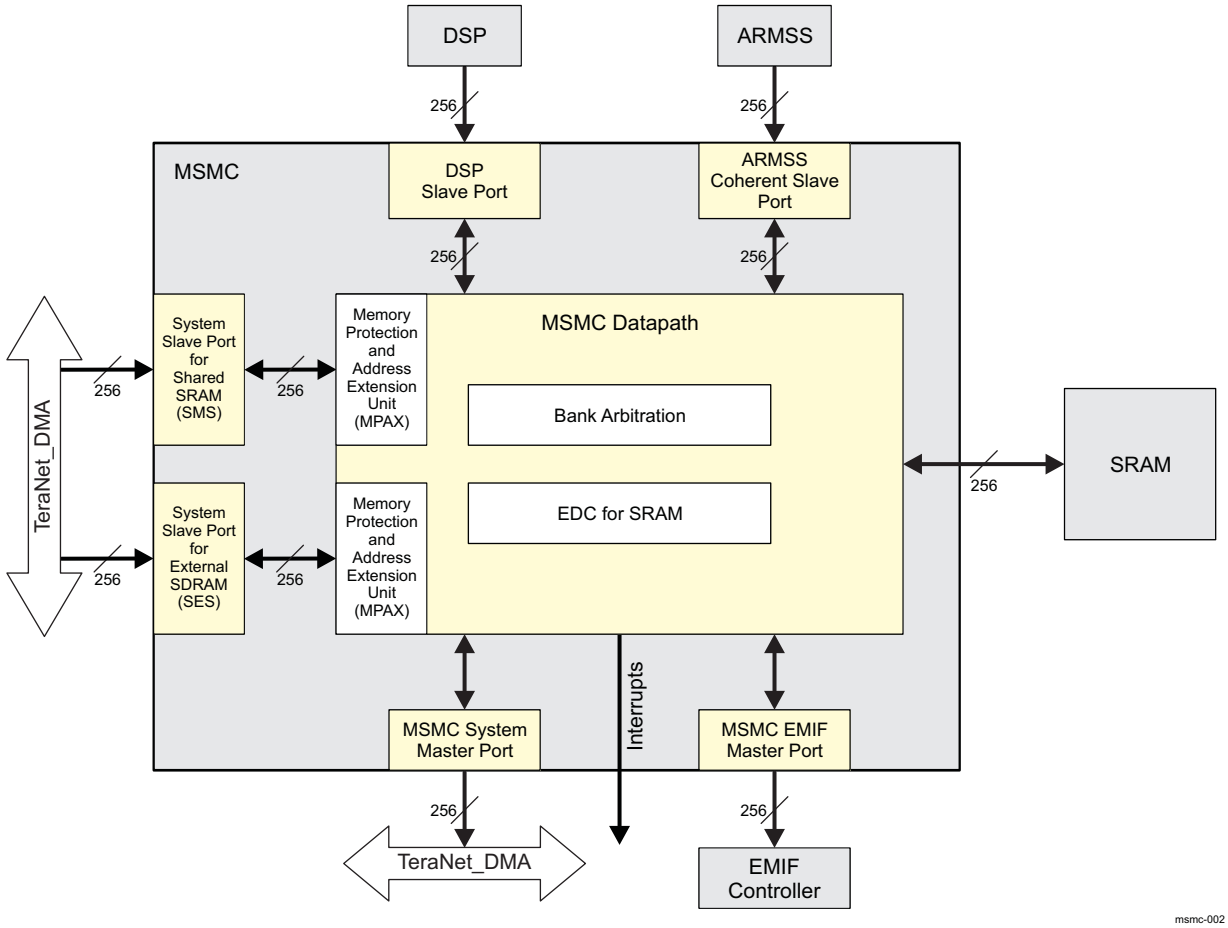
For more information about the MSMC resets, see Section 7.1.3.7.

7.1.3 MSMC Functional Description

7.1.3.1 MSMC Block Diagram

Figure 7-2 shows a high-level view of the MSMC module that includes the main interfaces, memory, and subunits.

Figure 7-2. MSMC Functional Block Diagram



The MSMC has one slave interface to connect to the DSP, one slave interface to connect to the ARMSS, two slave interfaces to connect to the system interconnect (TeraNet), one master port to connect to the EMIF controller, and one master port to connect to the system interconnect (TeraNet).

NOTE: Although the SES and SMS ports are 256 bits wide the maximum bandwidth of a master accessing MSMC through these ports is limited to 128 bits * CHIP_CLK1/3 because SES and SMS are slaves on TeraNet_M_3_128_0 as shown in Figure 3-2. TeraNet_M_3_128_0 is 128 bits wide and runs at CHIP_CLK1/3 frequency. This bandwidth limitation does not apply to ARMSS and DSP accesses as these masters have dedicated MSMC slave ports.

NOTE: The maximum bandwidth of DSP-to-MSMC-SRAM accesses is 256 bits * CHIP_CLK1 as DSP is directly connected to MSMC. The maximum bandwidth of ARMSS-to-MSMC-SRAM accesses is limited to 128 bits * CHIP_CLK1 although MSMC offers 256-bit bus width. Concurrent accesses by different masters to the MSMC SRAM are prioritized and time-sliced as there is a single SRAM bank. For SDRAM accesses the 256-bit wide EMIF interface of MSMC runs at CHIP_CLK1/2 frequency.

7.1.3.1.1 DSP and ARMSS Slave Interfaces

The MSMC has slave interfaces to connect to the ACE (AXI Coherence Extensions) port of the ARMSS and MDMA port of the DSP. The ARMSS and DSP use these interfaces to access the MSMC on-chip SRAM, the external SDRAM and the EMIF configuration registers through the MSMC EMIF Master Port or system level resources through the MSMC System Master Port.

7.1.3.1.2 System Slave Interfaces

The MSMC has two slave interfaces to handle accesses from the system masters to the MSMC SRAM and the external SDRAM.

7.1.3.1.2.1 System EMIF Access Slave Interface (SES)

The SES interface handles accesses to the external SDRAM and the configuration registers inside the EMIF module that originate from a system master different than ARMSS and DSP.

Accesses presented on this interface to any addresses outside of the address range mapped to the external memory or the EMIF configuration registers result in an addressing error returned to the requesting master.

NOTE: When MSMC SRAM is remapped to an external address space using MPAX, such accesses will not result in an addressing error as long as the accesses are within the valid external memory address range.

The address width on this interface is 32 bits. Address extension to a 36-bit address is done inside the MSMC as described in Section 7.1.3.3.

7.1.3.1.2.2 System MSMC SRAM Access Slave Interface (SMS)

The SMS interface handles accesses to MSMC SRAM that originate from a system master different than ARMSS and DSP. Accesses from system masters to the MSMC configuration registers are also expected to be presented on this interface.

Any accesses from the SMS interface that do not address the MSMC SRAM or configuration registers result in an addressing error returned to the requesting master.

7.1.3.1.3 System Master Interface

The MSMC has one master interface for the DSP and ARMSS to access system resources other than:

- MSMC SRAM
- MSMC configuration regiters
- EMIF SDRAM
- EMIF configuration regiters

Traffic from the system slave interfaces does not pass through the system master interface.

7.1.3.1.4 EMIF Master Interface

The EMIF module is connected to the MSMC through the EMIF master interface. The address width for this interface is 36 bits because it supports extended memory addressing space beyond 4 GB. The MSMC implements an address extension to 36 bits as described in Section 7.1.3.3.

7.1.3.2 MSMC Memory

7.1.3.2.1 MSMC SRAM

MSMC SRAM can serve as a Shared Level 2 or Level 3 memory

- Shared Level 2 memory — The MSMC memory is cacheable by DSP L1D and L1P caches. DSP L2 will not cache requests to the MSMC SRAM.

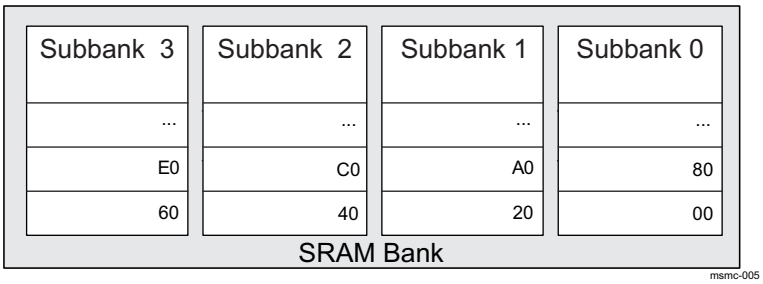
- Shared Level 3 memory — The MSMC memory is not directly cacheable at the DSP L2 but is cacheable in DSP L1D and L1P. However, if it is remapped to an external address using the address-extension capabilities in the DSP MPAX, the MSMC memory can be cached as a shared L3 memory both in the L1 and L2 caches of the DSP. To achieve this, the caching must be enabled in MAR registers (using MAR[PC] bit) for the remapped region. The MSMC memory is directly cacheable in ARMSS L2 memory by defining the MSMC SRAM region as normal cacheable memory in ARMSS MMU.

7.1.3.2.2 MSMC Memory Organisation

The memory is organized as one 128-byte wide bank that consists internally of four subbanks which hold adjacently-addressed locations. 32-byte aligned addresses within that bank are located in different subbanks. The 128-byte banking structure aligns with the DSP L2 cache line size.

Figure 7-3 shows the MSMC memory organization.

Figure 7-3. MSMC Memory Organisation



7.1.3.2.3 MSMC Bandwidth Management

The MSMC has an arbitration scheme which fairly allocates accesses of requestors with same priority level. This arbitration scheme does not have software controls. However, it is not sufficient to only ensure boundary for the wait times experienced by low priority requests. As a result requestors could starve for access when there is heavy traffic at high priority levels. To avoid indefinite starvation for low priority requests, the MSMC has a bandwidth management scheme that limits starvation times using the so called starvation bound registers. The MSMC has a starvation bound register (SBND) per requestor. The registers are programmed with a desired starvation boundary in MSMC cycles for the requestor's accesses. These registers are shown in Table 7-4.

The central arbiter for the memory bank and the EMIF master port contain a starvation counter for each of the requestors being tracked. Whenever a SCNT bitfield of a SBND register is programmed, the counter for the requestor is initialized with the same value.

Table 7-4. Starvation Counters per Requestor

Bit Field	Function
MSMC_SBNDC0[23-16] SCNTCE	Reload value (pre-scaled by 16) for the starvation counter for DSP requests at the EMIF arbiter.
MSMC_SBNDE[23-16] SCNTEE	Reload value (pre-scaled by 16) for the starvation counter for SES requests at the EMIF arbiter.
MSMC_SBNDC0[7-0] SCNTCM	Reload value for the starvation counters for DSP requests at the RAM bank arbiter.
MSMC_SBNDM[7-0] SCNTMM	Reload value for the starvation counters for SMS requests at the RAM bank arbiter.
MSMC_SBNDE[7-0] SCNTEM	Reload value for the starvation counters for SES requests at the RAM bank arbiter.

For the EMIF arbiter, if the interface to the EMIF is stalled, the SCNT countdown is suspended for that cycle.

When the SCNT reaches zero, the priority of the request is elevated to zero (the highest priority level). After the elevated priority is serviced, the starvation counter is reloaded from the SBND register for the requestor. Further accesses from the requestor are based on the original priority.

7.1.3.3 Memory Protection and Address Extension (MPAX)

Through the MPAX feature the MSMC module can support an external memory space addressable with a 36 bits even though the device addressing remains 32 bits. The DSP uses its own MPAX units to extend 32-bit addresses to 36-bit addresses before presenting them to the MSMC module. The ARMSS can optionally use the MMU with LPAE (Large Physical Address Extension) to support 40-bit physical addressing but the 4 MSBs of the physical address should be set to 0h in the ARMSS MMU.

The slave interfaces on the MSMC that receive addresses from all other masters in the system must extend the address inside the MSMC. These interfaces also provide support for memory protection for accesses from system masters to the MSMC SRAM, external SDRAM, and the EMIF configuration registers.

Both system slave interfaces (SES and SMS) have an MPAX unit which combines these functions and is also similar to the MPAX unit inside the DSP.

7.1.3.3.1 MPAX Segment Operation

The MPAX process is performed for a variable-sized segment of memory and is controlled by a register pair for each segment: MPAXH and MPAXL control registers.

- The MPAXH specifies the base address and size of the segment to match.
- The MPAXL specifies the replacement address and permissions for the segment.

Each MPAX unit provides eight control register pairs per PrivID of the system masters which allows operating on eight independent and potentially overlapping variable-size memory segments. For the PrivID values assigned to various system masters see Table 3-16 in Section 3.2, *Memory Protection Units*.

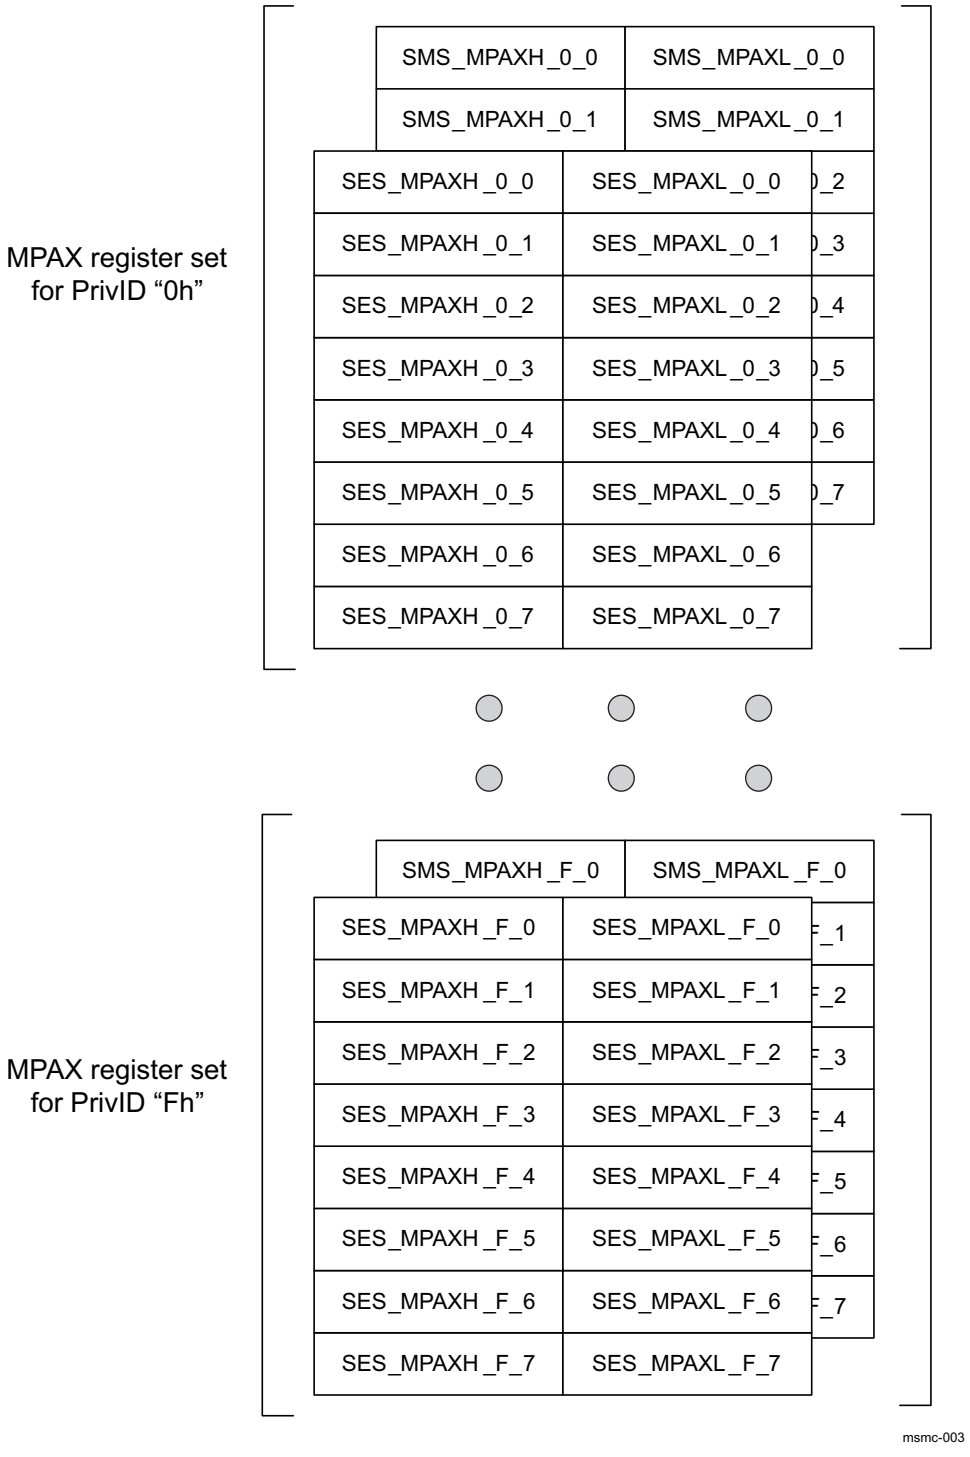
The MSMC configuration registers are not protected by the MPAX hardware. Addresses presented for any system accesses to the MSMC control registers through the SMS port are used as such.

Figure 7-4 shows how the MPAX segment registers are organized. The MPAX segment registers are described in Section 7.1.4.7.

All of the MPAX registers in the MSMC can be read by the ARMSS and DSP and also by system masters through the SMS port. Write-access control to these registers can be coordinated with the aid of semaphores external to the MSMC as well as through the locking mechanism of MSMC configuration registers.

Accesses of system masters to the segment registers are automatically protected as these registers are addressed by PrivID such that each PrivID has access to only its set of eight pairs of segment registers. Accesses to MPAX segment registers with a mismatched PrivID generates a protection error.

Figure 7-4. MPAX Segment Register Set Layout



7.1.3.3.2 MPAX Segment Register Reset Values

At reset, the MPAX segment 0 register pair has initial values that set up unrestricted access to the full MSMC SRAM address space and 2 GB of the EMIF address space. All other segments come up with the permission bits and size set to 0 (that is, no access map to those segments).

- The SMS_MPAXH_n_0 registers have reset value of 0C00 0017h and the SMS_MPAXL_n_0 registers (where n = PrivID) have reset value of 00C0 00BFh which means that segment 0 is sized to 16 MB

and matches any accesses to the address range 0CXX XXXXh.

- The SES_MPAXH_n_0 registers have reset value of 8000 001Eh and the SES_MPAXL_n_0 registers (where n = PrivID) have reset value of 8000 00BFh which means that segment 0 is sized to 2 GB and matches any accesses to the address range 8XXX XXXXh. This 2 GB space starts at the external memory base address of 8000 0000h.
- The SMS_MPAXH and SMS_MPAXL registers for segments 1 through 7 come out of reset as 0C00 0000h and 00C0 0080h respectively. The SES_MPAXH and SES_MPAXL registers for segments 1 through 7 come out of reset as 0000 0000h and 0000 0080h respectively.

These reset settings are provided for convenience of code setting-up. It is recommended that boot code sets up these registers as appropriate for the application.

7.1.3.3.3 Memory Protection

For the SES and SMS, the MPAXH register contains the Segment Base Address (BADDR) field that is matched to the incoming address on the SES port to identify the addressed segment. The BADDR and the Segment Size (SEGSZ) field describe the placement and size of the controlled segment. SEGSZ is a five-bit field that can be used to specify segment sizes ranging from 4 KB to 4 GB in powers of two, as listed in Table 7-5.

Table 7-5. MPAX Segment Size Encoding

SEGSZ	Meaning	SEGSZ	Meaning	SEGSZ	Meaning	SEGSZ	Meaning
0h	Segment disabled	8h	Reserved	10h	128KB	18h	32MB
1h	Reserved	9h	Reserved	11h	256KB	19h	64MB
2h	Reserved	Ah	Reserved	12h	512KB	1Ah	128MB
3h	Reserved	Bh	4KB	13h	1MB	1Bh	256MB
4h	Reserved	Ch	8KB	14h	2MB	1Ch	512MB
5h	Reserved	Dh	16KB	15h	4MB	1Dh	1GB
6h	Reserved	Eh	32KB	16h	8MB	1Eh	2GB
7h	Reserved	Fh	64KB	17h	16MB	1Fh	4GB

Segments are always sized to a power of two and start on a corresponding power-of-two boundary (for example, a 4 KB segment always starts on a 4 K boundary, and a 4 GB segment corresponds to the entire 32-bit address space). For the MPAX unit in the SMS port, the maximum allowed segment size is 16 MB (SEGSZ = 17h), which would cover the full MSMC storage space.

For the MPAX unit in the SES port, a sufficient number of upper bits (depending on the size specified in the SEGSZ field) of the incoming address are matched against the BADDR field of all the MPAXH registers corresponding to the access PrivID to select the MPAXH control register pair to use for memory protection and extension. For example, for 4 KB segments, all 20 bits of the BADDR field must match the upper 20 bits of the system address. For 16 MB segments, the upper eight bits of the BADDR field must match the upper eight bits of the DSP address. The remaining bits are ignored. For 4 GB segments, no BADDR bits are consulted and all addresses match.

- If an address does not match any of the programmed MPAXH registers and is not a MSMC configuration register address, the access permissions for the access are considered to be 0. This results in a protection fault.
- If an address matches multiple MPAXH registers (overlapping segment descriptors), the highest numbered MPAX register-pair is selected (that is, if the address matches BADDR in MPAXH5 and in MPAXH2, MPAXH5 is selected). Using this priority-based matching behavior, multiple MPAX entries can be programmed for overlapping segments to achieve either non-power-of-two sized segments or subsegments with different memory protection (and/or extension) parameters.

7.1.3.3.3.1 Memory Protection Fault Reporting

The MSMC memory protection fault reporting registers are listed in Table 7-6 and described in Section 7.1.4.3.

Table 7-6. MSMC Protection Fault Reporting Register List

Acronym	Register Description
MSMC_SMPFAR	Shared Memory Protection Fault Address Register
MSMC_SMPFXR	Shared Memory Protection Fault Extension Register
MSMC_SMPFR	Shared Memory Protection Fault Requestor Register
MSMC_SMPFCR	Shared Memory Protection Fault Control Register

The MPAXL register contains the permission attributes for supervisor and user accesses. If an access mismatches MPAXL with the corresponding permission attributes, a memory fault is triggered that results in the following actions:

- A memory protection fault interrupt (MSMC_MPF_ERROR**n**, where **n** = PrivID of the requestor making the offending access) is generated on the fault access, if the corresponding interrupt is enabled in the MSMC_SMIESTAT register. This is also recorded in the MSMC_SMIRSTAT register (see Section 7.1.3.5) that contains one event bit per PrivID that is set when an access from the PrivID faults and is cleared on writing 1h to the associated bit in the MSMC_SMIRC register. Only one fault is notified per PrivID. Until the interrupt status is cleared in MSMC_SMIRC, the next interrupt for that PrivID is not generated.
- The access address causing the fault is captured in the MSMC_SMPFAR register. If the fault is the result of the address not matching any of the Segment Base Address, the MSMC_SMPFXR[0] NM bit is set. The master ID and PrivID associated with the access are recorded in the MSMC_SMPFR register and a bus-protection-error status is returned to the requesting master for the fault access. For the Master ID and PrivID values assigned to various system masters see Section 3.2, *Memory Protection Units*.
- There is only one fault recorded in the MSMC_SMPFAR and MSMC_SMPFXR registers. The master is notified with a fault interrupt and receives a bus error for the access. In response, the master must clear the recorded fault by writing 1h to the MSMC_SMPFCR[0] CLR bit before further faults can be recorded.

7.1.3.3.4 Address Extension

For access to the SES interface, the 32-bit address is extended to 36 bits by replacing the appropriate number of upper bits of the address (based on segment size) with a corresponding portion of the replacement address field (RADDR) in the MPAXL register that has four more upper bits, as shown in Table 7-7.

Table 7-7. Replacement Address Used as Per-Segment Size

SEGSZ	SES / SMS RADDR bits	SEGSZ	SES RADDR bits	SMS RADDR bits	SEGSZ	SES RADDR bits	SMS RADDR bits	SEGSZ	SES RADDR bits
0h	Segment disabled	8h	Reserved	Reserved	10h	[23-5]	[19-5]	18h	[23-13]
1h	Reserved	9h	Reserved	Reserved	11h	[23-6]	[19-6]	19h	[23-14]
2h	Reserved	Ah	Reserved	Reserved	12h	[23-7]	[19-7]	1Ah	[23-15]
3h	Reserved	Bh	[23-0]	[19-0]	13h	[23-8]	[19-8]	1Bh	[23-16]
4h	Reserved	Ch	[23-1]	[19-1]	14h	[23-9]	[19-9]	1Ch	[23-17]
5h	Reserved	Dh	[23-2]	[19-2]	15h	[23-10]	[19-10]	1Dh	[23-18]
6h	Reserved	Eh	[23-3]	[19-3]	16h	[23-11]	[19-11]	1Eh	[23-19]
7h	Reserved	Fh	[23-4]	[19-4]	17h	[23-12]	[19-12]	1Fh	[23-20]

This operation is identical to that in the DSP MPAX unit. Programming the same values into the BADDR, RADDR, and SEGZ fields results in an identical address-extension operation for a system master access.

7.1.3.3.4.1 SES Aliased Access to MSMC RAM

Using address remapping in the MPAX unit at the SES port, it is possible to map some or all of the MSMC SRAM into external memory space and access it through the SES port. This provides the same ability to alias MSMC memory to external address space for system masters as is available to the DSP through its MPAX unit.

The ability to alias external addresses to the SRAM has the following constraints:

- Crossing between MSMC SRAM and external memory endpoints in the course of a transaction on SES is not supported and results in an addressing error for the endpoint first addressed in the command.
- Addressing errors get prioritized for reporting over protection errors.

7.1.3.3.4.2 SMS MPAX Address Extension

For the SMS interface, the address-extension operation is very similar except that the generated address maintains bits 31-24 to be the same as the original address (that is, the start address of the MSMC SRAM). The SMS_MPAXL contains a correspondingly smaller RADDR field. Note that this resultant address is still a 32-bit address within the address space of the MSMC SRAM and the operation is that of remapping the address segment to a different location within the MSMC SRAM.

It is possible to violate the permissions associated with a segment and checked as part of the memory-protection check by extending the address into a target segment that has more restrictive permissions. This is actually a valid configuration of the MPAX registers to carve out subsegments that overlap segments with differing permissions.

- If segment overlap is not desired or intended, it is a good practice to align the level of restriction in the segment permissions with the MPAX segment matching priority scheme, that is, configure a less restrictive segment A in a lower numbered MPAX pair than a more restrictive segment B.
- If the permissions of segment A are intended to be used for the overlap region between the two segments A and B, configure A in a higher numbered MPAX pair than the one for segment B.

7.1.3.3.4.3 Address Extension Error Reporting

If a SES address extension results in an address that is outside the range of the EMIF configuration registers of external SDRAM, the MSMC EMIF Master Port receives an addressing error from the EMIF and relays this error to the SES interface.

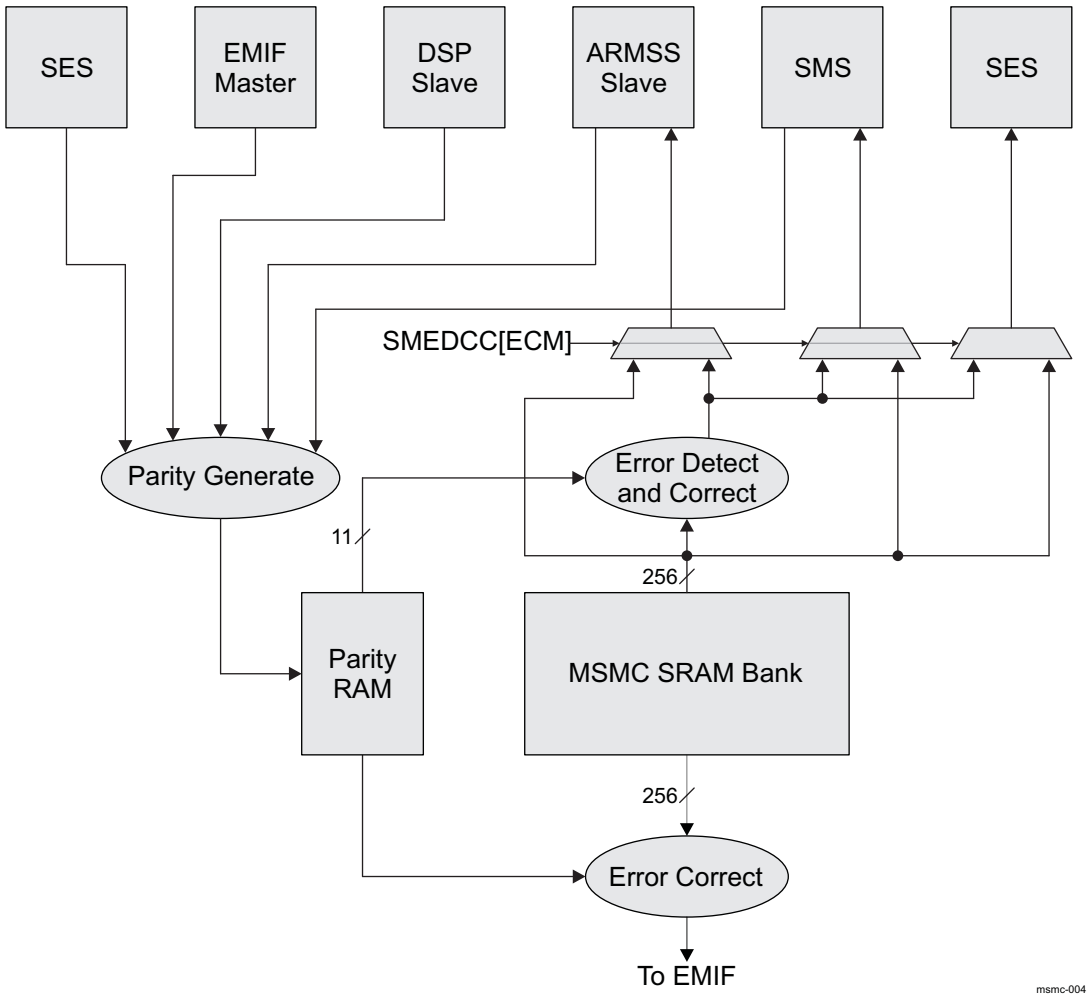
7.1.3.4 Error Detection and Correction (EDC)

The MSMC has error detection and correction hardware to protect the contents of the MSMC memory storage against corruption due to transient (soft) errors. The level of protection provided and the scheme used is one-bit error correction and two-bit error detection with parity codes calculated over a 256-bit datum.

7.1.3.4.1 Parity Generation and Checking

Figure 7-5 shows the hardware available that supports parity generation, storage, and correction. The parity code generated for each location in the MSMC SRAM bank is stored in a corresponding location in the associated parity RAM. That parity RAM location also stores its own parity code which allows detection of transient errors in the parity RAM itself.

Figure 7-5. Error Detection and Correction



7.1.3.4.2 EDC Operation

In the MSMC EDC scheme, parity is generated and tracked for each 256-bit datum which corresponds to a RAM location and a data phase for slave port access. A parity RAM entry may become invalid when data is written to the SRAM with a granularity smaller than 256 bits (for example, when the L2 cache for the DSP is off/frozen/bypassed and a write miss to the MSMC SRAM region occurs in its L1D cache). In this case, the valid bit in the corresponding parity RAM entry is reset.

The parity code for a line is recalculated when the line is transferred through any of the outgoing paths shown in Figure 7-5. The assumption on the reliability of the data being stored and transferred to/from the MSMC is that any incoming data for MSMC storage is reliable and a parity code generated from it is valid.

The EDC hardware consists of the registers listed in Table 7-8 and described in Section 7.1.4.2.

Table 7-8. MSMC EDC Registers

Register	Register Description
MSMC_SMCERRAR	MSMC SRAM correctable EDC error address register
MSMC_SMCERRXR	MSMC SRAM correctable EDC extended error register
MSMC_SMEDCC	MSMC SRAM EDC control register
MSMC_SMCEA	MSMC scrubbing error corrected address register
MSMC_SMSECC	MSMC scrubbing error corrected counter register

Table 7-8. MSMC EDC Registers (continued)

Register	Register Description
MSMC_SMNCERRAR	MSMC SRAM non-correctable EDC error address register
MSMC_SMNCERRXR	MSMC SRAM non-correctable EDC extended error register
MSMC_SMNCEA	MSMC scrubbing non-correctable address register

7.1.3.4.2.1 Error Correction Mode

Error correction adds latency for data-read accesses from slave ports. The MSMC_SMEDCC[30] ECM bit controls if error correction is enabled on all the slave port read paths. Setting the ECM bit to 0h disables error correction for slave accesses (the direct return path in Figure 7-5). Setting the ECM bit to 1h enables the error correction. Any further writes to this bit are ignored which means, once enabled, error correction stays enabled until the MSMC is reset.

7.1.3.4.2.1.1 Soft Error Correction

For data being transferred out of the MSMC storage, the EDC hardware generates the parity for the data and checks against the corresponding stored parity for errors and log information in the EDC registers. The actions and reporting are summarized in Table 7-9. More details about the interrupts can be found in Section 7.1.3.5.

Table 7-9. Soft Error Correction Actions

Read Access Port	ECM state	Soft Error Type	Interrupt Indicated in:	Data Returned
ARMSS/DSP Slave, SES, SMS	1	Correctable	MSMC_SMIRSTAT[3] CEI	Corrected
	1	Non-Correctable	MSMC_SMIRSTAT[2] NCEI	0
	1	Parity RAM	-	Uncorrected
	0	Correctable	MSMC_SMIRSTAT[3] CEI	Uncorrected
	0	Non-Correctable	MSMC_SMIRSTAT[2] NCEI	Uncorrected
	0	Parity RAM	-	Uncorrected

7.1.3.4.3 EDC Error Reporting

When an error is detected, the EDC hardware reports the error details in the EDC error reporting registers as follows:

- For a correctable (one-bit) error:
  - The lower 32 bits of the 36-bit address used in accessing the corrupted location are stored in the MSMC_SMCERRAR register and the upper 4 bits of the 36-bit address in the MSMC_SMCERRXR[3-0] SEEADDR bit field.
  - The syndrome for the corrected location is logged in the MSMC_SMCERRXR[23-16] ESYN bit field.
  - The PrivID associated with the access is saved in the MSMC_SMCERRXR[7-4] SEPID bit field. If the request came in from the SMS or the SES port, the MSMC_SMCERRXR[8] SER bit is set.
  - Generates MSMC_DEDC_CERROR interrupt if it is enabled in the MSMC_SMIESTAT register.
- For a non-correctable (two-bit) error:
  - The lower 32 bits of the 36-bit address used in accessing the corrupted location are stored in the MSMC_SMNCERRAR register and the upper 4 bits of the 36-bit address in the MSMC_SMNCERRXR[3-0] SEEADDR bit field.
  - The PrivID associated with the access is saved in the MSMC_SMNCERRXR[7-4] SEPID bit field. If the request came in from the SMS or the SES port, the MSMC_SMNCERRXR[8] SER bit is set.
  - Generates MSMC_DEDC_NC_ERROR interrupt if it is enabled in the MSMC_SMIESTAT register.
- After they are written, the error-logging registers MSMC_SMCERRAR/MSMC_SMNCERRAR and MSMC_SMCERRXR/MSMC_SMNCERRXR store the contents until further error logging is re-enabled

by clearing the associated interrupt status with a write to the MSMC_SMIRC register (see Section 7.1.3.5).

7.1.3.4.4 Background Parity Refresh (Scrubbing)

As parity is tracked at a granularity equal to the width of a subbank (32 bytes), writes that are smaller than 32 bytes can invalidate the parity information for a line. MSMC contains a background error correction hardware called Scrubbing Engine that periodically refreshes the parity bits for the memory.

The MSMC scrubbing engine is a state machine that periodically cycles through each location of each memory subbank in the MSMC, reading and correcting the data, recalculating the parity bits for the data, and storing the data and parity information. Each such “scrubbing cycle” consists of a series of read-modify-write “scrub bursts” to the memory subbanks.

7.1.3.4.4.1 Scrubbing Rate

The frequency with which each scrubbing cycle is initiated and the delay between each burst by the scrubbing engine is programmed using the MSMC_SMEDCC register:

- The MSMC_SMEDCC[7-0] REFDEL bit field is programmed to control the number of MSMC clock cycles between each scrub burst. To prevent the bursts of the scrubbing engine from posing a significant performance impact, the value in the REFDEL bit field is prescaled by 1024.
- When prescaling of the REFDEL is enabled, a value of 0h is interpreted to be the same as a value of 1h. When the prescaling is disabled, a value of 0h is interpreted as 0, that is, no delay between scrubbing bursts.
- The operation of the scrubbing engine is enabled by default after reset and parity RAM initialization but may be disabled by setting the MSMC_SMEDCC[31] SEN bit. There is no setup required to enable the scrubbing operation aside from checking for an end of the reset sequence as described in Section 7.1.3.4.5.

7.1.3.4.4.2 Scrubbing Error Logging and Statistics Collection

The MSMC scrubbing engine can log errors and collect statistics about scrubbing errors locally:

- If the scrubbing engine access detects a location where contents have been corrected, it logs the address in the MSMC_SMCEA[23-0] SECA bit field, logs the syndrome value (that identifies the erroneous bit in the data) in the MSMC_SMCEA[31-24] ESYN bit field, and increments the MSMC_SMSECC[15-0] SCEC counter bit field. It also generates MSMC_SCRUB_CERROR interrupt (if it is enabled in the MSMC_SMIESTAT register) indicating correctable (1-bit) soft error detected during scrub cycle.
- If the scrubbing engine access detects a two-bit error that is not correctable, it logs the address in the MSMC_SMNCEA[23-0] SENCA bit field and increments the MSMC_SMSECC[31-16] SNCEC counter bit field. It also generates MSMC_SCRUB_NC_ERROR interrupt (if it is enabled in the MSMC_SMIESTAT register) indicating non-correctable (2-bit) soft error detected during scrub cycle.
- Once written, the error logging registers MSMC_SMCEA and MSMC_SMNCEA store the contents till further error logging is re-enabled and these registers are cleared by clearing the associated interrupt status with a write to the MSMC_SMIRC register (see Section 7.1.3.5).
- The MSMC_SMCEA and MSMC_SMNCEA registers are both saturating counters and count all correctable and non-correctable errors, respectively, independent of the logging-enable state of the MSMC_SMCEA and MSMC_SMNCEA registers.

Periodically, the software can read the statistics collected to analyze persistent soft errors. Reading saturated counts in the error counters should indicate to the software that the error counters need to be checked more frequently to get a better indication of the error rate. If the error rate is high, scrub cycles should be initiated more frequently to decrease the probability of an un-repairable two-bit error. If the error rate is low, less frequent scrubbing may be needed to reduce power consumption and reduce interference with functional memory-access traffic.

7.1.3.4.5 Parity RAM Initialization at Reset

The MSMC EDC hardware invalidates all the parity RAM entries at reset. During this initialization cycle error correction or detection is not provided but accesses from the slaves or scrubbing engine are not stalled:

- Read accesses to the memory are serviced but no data check is done, that is, the memory locations are not protected from soft errors during this period. These initialization accesses are done with the prescaler disabled. As a result, no spurious events are generated till the parity RAM is initialized completely. At the end of the initialization the default prescaler delay of 1024 is applied.
- The MSMC_SMEDCC[26] PRR bit shows the status of this process and is 1h when the Parity RAM is ready for use in EDC and scrubbing operations. PRR is 0h after reset while the entries are being initialized. Software must check this bit before making the first read accesses to the MSMC SRAM after reset.
- Write accesses of a full 32-byte location during this period generates the corresponding parity value into the parity RAM location. When a write access arrives in the same cycle as the initialization write of the associated parity RAM location, the former takes precedence.

7.1.3.5 MSMC Interrupts

The MSMC module generates a bunch of interrupts as shown in Table 7-3.

The MSMC has a set of interrupt status and enable registers that control the generation of interrupts at the MSMC module boundary.

The MSMC interrupt operation is controlled by the registers listed in Table 7-10 and described in Section 7.1.4.6.

Table 7-10. MSMC Interrupt Control Registers

Register	Description
MSMC_SMESTAT	Interrupt status register. ANDed value of MSMC_SMIRSTAT and MSMC_SMIESTAT registers. A bit in this register is set if an interrupt condition occurs and the corresponding interrupt is enabled through the MSMC_SMIESTAT register.
MSMC_SMIRSTAT	Interrupt raw status register.
MSMC_SMIRC	Interrupt raw status clear register. Writing 0h to a bit has no effect. Writing 1h clears the coresponding bit in the MSMC_SMIRSTAT register.
MSMC_SMIESTAT	Interrupt enable register. Writing 1h to a bit enables the corresponding interrupt. Reading 0h indicates that the interrupt is disabled.
MSMC_SMIEC	Interrupt disable register. Writing 1h to a bit disables the corresponding interrupt.

The MSMC_SMIRSTAT register stores the raw interrupt status for each interrupt line. A bitfield in this register is set to 1h if the corresponding interrupt has occurred. An interrupt can be generated either when the event occurs in hardware (hardware interrupt) or when software writes to the corresponding bit in the MSMC_SMIRSTAT register (software interrupt for simulating an event). Regardless of how the interrupt is generated, it is cleared by writing 1h to the corresponding bit in the MSMC_SMIRC register.

NOTE: The memory protection fault interrupt for each PrivID is recorded in the MSMC_SMIRSTAT and the associated address and master information is logged into the MSMC_SMPFAR and MSMC_SMPFXR registers (see Section 7.1.4.3). Software must clear the MSMC_SMPFAR and MSMC_SMPFXR registers before clearing the corresponding bits for the PrivID in the MSMC_SMIRSTAT register so that the event status and associated master information are kept synchronized. This order is not enforced in hardware.

For interrupt signalling and status capture the following rules apply:

- For a given interrupt line, once an interrupt is signaled, its status is set and needs to be cleared before another occurrence can be signaled. The status for an interrupt line is set even if it is not enabled in the MSMC_SMIESTAT. Therefore, it is recommended for software to clear the interrupt status while enabling the interrupt. This can be done atomically with a double-word-store writing to the MSMC_SMIESTAT and the MSMC_SMIRC registers together.

- Because there are three sources that can modify a bit in the MSMC_SMIRSTAT, the following precedence rules apply:
  - A hardware interrupt takes precedence over a software interrupt if they arrive at the same time. This is not an intended usage mode as one would either enable a hardware interrupt to signal a real hardware event or use a software write to simulate the same event.
  - A write to set an event in the MSMC_SMIRSTAT register takes precedence over clearing an event in MSMC_SMIRC register. This situation generates an interrupt corresponding to the event that is set.

7.1.3.6 MSMC Register Access Control

The MSMC configuration registers are accessible by the DSP and all system masters that can access the MSMC through the SMS port. Updates to these registers must not be made while there are accesses through any of the system ports utilizing the registers being written to. For example, software needs to ensure that updates to a SES MPAX register are done only when there are no ongoing transfers from the same PrivID using the SES interface.

NOTE: The MSMC configuration register hardware cannot guarantee the determinism of a transfer if the configuration registers used by the transfer are being modified simultaneously. If such an update is done to the registers, the outcome of the transfer is not deterministic and undefined.

While reads to these registers from any of the masters are not restricted, it is often useful to restrict write access to the registers to prevent runaway code on one of the cores or an incorrectly-configured system master from corrupting the state of MSMC configuration. While a semaphore-based mutex access control is still expected to be used by software on the cores (and any masters that may program the registers), MSMC provides a simple lock mechanism to protect against runaway pointer writes.

MSMC register access control is managed by the lock registers listed in Table 7-11 and described in Section 7.1.4.5.

For the purpose of write-access control the MSMC registers are grouped into three categories:

- SMS MPAX registers
- SES MPAX registers
- Non-MPAX registers.

For each category, a write-lock bit (one per PrivID for the MPAX registers) controls whether writes are enabled.

Table 7-11. MSMC Configuration Write Lock Registers

Register	Description	Comment
MSMC_CFGLCK	Configuration Lock control for non-MPAX registers	Lock/unlock/status bits for non-MPAX registers with the exception of the write lock registers for all three categories
MSMC_CFGULCK	Configuration Unlock control for non-MPAX registers	
MSMC_CFGLCKSTAT	Configuration Lock Status for non-MPAX registers	
MSMC_SMS_MPAX_LCK	Configuration Lock control for SMS MPAX registers	16 lock/unlock/status bits (one bit per PrivID)
MSMC_SMS_MPAX_ULCK	Configuration Unlock control for SMS MPAX registers	
MSMC_SMS_MPAX_LCKSTAT	Configuration Lock Status for SMS MPAX registers	
MSMC_SES_MPAX_LCK	Configuration Lock control for SES MPAX registers	
MSMC_SES_MPAX_ULCK	Configuration Unlock control for SES MPAX registers	
MSMC_SES_MPAX_LCKSTAT	Configuration Lock Status for SES MPAX registers	

All the LCK and ULCK registers are modified only when the upper 16 bits of the write data match the fixed MGCID key field of these registers. Any other value used in the upper 16 bits of the write data does not modify its WLCK/WEN bits. For each category, the sequence of steps is as follows:

- To lock, write *MGCID_WLCK* into the LCK register (for example, write *2CD1_0440* to lock the SMS MPAX registers for PrivIDs 7 and 11). For non-MPAX registers, write *2CD0_0001* to the

MSMC_CFGLCK register. Until it is unlocked, all further writes to that category registers generate protection errors.

- To unlock, write *MGCID_WEN* into the ULCK register (for example, write *2CD1_0440* to unlock the SMS MPAX registers for PrivIDs 7 and 11). For non-MPAX registers, write *2CD0_0001* to the MSMC_CFGULCK register. Until it is locked, all further writes to that category of configuration registers generate protection errors.

NOTE: This provides a simple write protection mechanism that protects against unintentional modification only. It is recommended that the software uses a semaphore to ensure exclusive access when modifying the MSMC lock registers.

7.1.3.7 Reset Considerations

The MSMC module resets on all global resets. Upon reset, the following sequence apply:

- All MSMC configuration registers are reset to their initial default state.
- The parity RAM entries associated with the MSMC SRAM are invalidated as described in Section 7.1.3.4.5.
- The MSMC pipeline is reset to an idle state terminating any outstanding accesses.

In addition, the MSMC_PARITY_RST_BLOCK reset signal can be blocked or not depending on the value of the CHIP_MISC_CTL0[12] MSMC_BLOCK_PARITY_RST bit in the BOOT_CFG module. Writing a value of 1h to this bit blocks the reset.

7.1.3.8 MSMC Memory Regions

Table 7-12 shows the MSMC associated memory regions.

Table 7-12. MSMC Memory Regions

Region	Start Address	End Address	Region Size
MSMC SRAM	0C00 0000h	0C0F FFFFh	1MB
MSMC configuration registers	0BC0 0000h	0BCF FFFFh	1MB

7.1.3.9 MSMC Cache Coherence

MSMC supports hardware cache coherence between the ARMSS L1/L2 caches and EDMA/system master peripherals for shared SRAM and SDRAM spaces. This feature allows the sharing of MSMC SRAM and SDRAM data spaces by these masters on the chip, without having to use explicit software cache maintenance techniques.

MSMC does not support memory coherence for these spaces:

- EMIF Configuration Registers Space
- MSMC Configuration Registers Space
- System Master Port Peripherals/Memory
- Any memory not directly connected to MSMC.

7.1.3.9.1 Cache Coherence Operation

Coherent masters typically track more states than the traditional valid/dirty combinations to maintain coherence. MSMC uses the ACE (AXI Coherence Extensions) coherence protocol which supports the following five states (MOESI)

- Modified - Cache line is unique (no other caches currently have it) and dirty
- Owned - Cache line is shared (other caches may have it) and dirty
- Exclusive - Cache line is unique and clean
- Shared - Cache line is shared and clean

- Invalid - No allocated line.

In order to maintain coherence between cached masters, MSMC can initiate requests to coherent masters for shared regions of memory. These requests are called as snoop requests and are performed as per the ACE protocol. MSMC maintains coherence by snooping coherent caches for the latest value when an access hits a shared memory region (SES/SMS MPAXHn[7] US = 0h).

The following example demonstrates how coherence is maintained between EDMA and ARMSS, when EDMA writes to shareable memory space.

1. EDMA (master with no cache) issues a write to shareable space.
2. MSMC coherence controller issues Invalidate and Writeback snoop to the CPU.
3. CPU invalidates the line from its cache and responds with the dirty data
4. MSMC merges the EDMA write data with the victim and commits to memory.

The following example demonstrates how coherence is maintained between EDMA and ARMSS, when EDMA reads from shareable memory space.

1. EDMA issues a read to shareable space.
2. MSMC coherence controller issues a ReadOnce snoop to the CPU.
3. CPU responds with cached data.
4. MSMC returns the read data to EDMA.

Software has the ability to control which memory regions are shared among certain sets of coherent masters using ARMSS MMU and using SMS_MPAXH or SES_MPAXH register for EDMA/system master peripherals. Software should ensure that the shareability mappings between the types of masters are consistent to avoid unexpected behavior.

For example, a memory segment marked as outer shared in ARMSS MMU and marked as unshared in the respective SMS_MPAXH[7] US or SES_MPAXH[7] US bit is an inconsistent mapping and can cause unpredictable behavior.

7.1.4 MSMC Registers

Table 7-14 lists the MSMC configuration registers. All other register offset addresses not listed in Table 7-14 should be considered as reserved locations and the register contents should not be modified.

Table 7-13. MSMC Instances

7.1.4.1 MSMC_PID Register (Offset = 0h) [reset = 45000A02h]

The peripheral identification register (MSMC_PID) uniquely identifies the MSMC and the specific revision of the MSMC.

The MSMC_PID is shown in Figure 7-6 and described in Table 7-16.

Table 7-15. MSMC_PID Instances

Table 7-19. MSMC_SMEDCC Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SEN	RW	0h	Scrubbing Engine Enable • 0 = The operation of the scrubbing engine is enabled by default after reset and parity RAM initialization • 1 = The operation of the scrubbing engine is disabled
30	ECM	RW	1h	Error Correction Mode • 0 = Disables error correction • 1 = Enables error correction
29-27	RESERVED	R	0h	Reads return 0 and writes have no effect.
26	PRR	RW	0h	The PRR (Parity RAM Ready) bit shows the status of Parity RAM. • 0 = Parity RAM is not ready, this will be the state following a reset while the entries are being initialized. • 1 = Parity RAM is ready for use in EDC and scrubbing operations. Software must consult this bit before making the first read access to MSMC RAM after reset.
25-8	RESERVED	R	0h	Reads return 0 and writes have no effect.
7-0	REFDEL	RW	1h	Value = 0-FFh Controls the number of MSMC clock cycles between each scrub burst. To prevent the bursts from the scrubbing engine from posing a significant performance impact, the value in the REFDEL register is pre-scaled by 1024.

Table 7-20. Register Call Summary for MSMC_SMEDCC

7.1.4.6 MSMC Interrupt Control Registers

7.1.4.6.1 MSMC_SMESTAT Register (Offset = 80h) [reset = 0h]

The MSMC_SMESTAT register provides the status of those interrupts that are enabled; that is, a bitfield in the MSMC_SMESTAT register is set if the associated interrupt is both enabled and has occurred.

The MSMC_SMESTAT is shown in Figure 7-31 and described in Table 7-91.

7.1.4.6.2 MSMC_SMIRSTAT Register (Offset = 84h) [reset = 0h]

The MSMC_SMIRSTAT register stores the raw interrupt status for each interrupt line, a bitfield is set if the associated interrupt has occurred. An interrupt can be generated and its raw status recorded in MSMC_SMIRSTAT either when the event occurs in hardware (hardware interrupt) or when software writes to the associated bitfield in the MSMC_SMIRSTAT register (software interrupt for simulating the event).

The MSMC_SMIRSTAT is shown in Figure 7-32 and described in Table 7-94.

7.2 DDR External Memory Interface (EMIF)

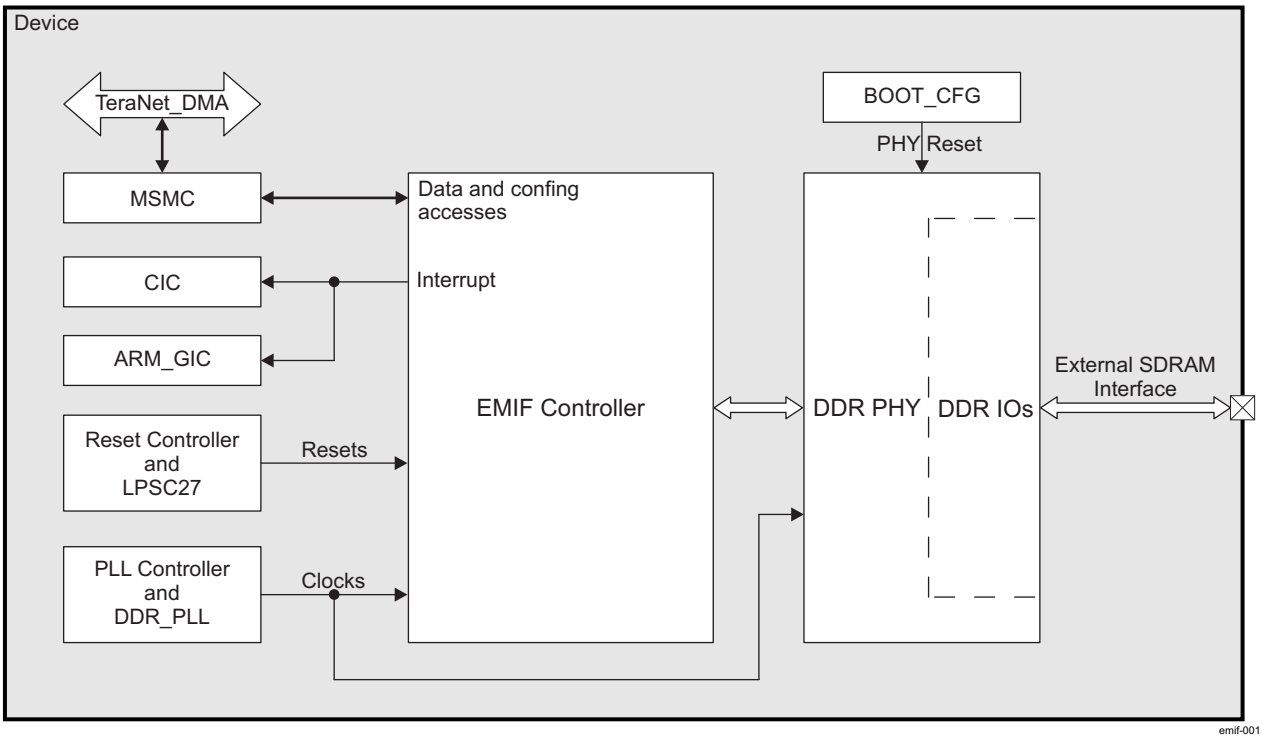
This section describes the DDR External Memory Interface (EMIF) for the device.

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

7.2.1 EMIF Overview

There is one EMIF controller in this device. It is used to provide an interface to external DDR3L SDRAM devices which can be utilized for storing program or data. Other memory types are not supported. The EMIF controller is accessed via the MSMC, and not directly through TeraNet. Figure 7-40 shows an overview of the EMIF controller and also connections to the other surrounding modules. The DDR PHY and DDR IOs are also used when performing data exchanges to and from external SDRAM.

Figure 7-40. EMIF Overview



The EMIF controller supports:

- Devices compliant to JEDEC JESD79-3F and JESD79-3-1 (DDR3L addendum) standards
- 16-bit and 32-bit SDRAM data bus width without ECC:
  - 16-bit: 2x8-bit SDRAMs
  - 16-bit: 1x16-bit SDRAM
  - 32-bit: 4x8-bit SDRAMs
  - 32-bit: 2x16-bit SDRAMs
- 32-bit SDRAM data bus width with 4-bit ECC:
  - 36-bit: 5x8-bit SDRAMs (32 bits for data and 4 bits for ECC, not used bits should be tied-off)
  - 36-bit: 3x16-bit SDRAMs (32 bits for data and 4 bits for ECC, not used bits should be tied-off)
- CAS latencies of 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 and 16
- CAS write latencies of 5, 6, 7, 8, 9, 10, 11, and 12
- 1, 2, 4, and 8 internal banks
- Burst length of 8
- Sequential burst type
- 8GB address space available over two chip selects
- 33-bit system address for address space of 8GB
- Page sizes with 256, 512, 1024, and 2048 words
- Self-refresh mode
- Power-down mode
- Output impedance calibration
- On-Die Termination (ODT)
- Prioritized refresh scheduling
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Only little endian mode
- ECC on SDRAM data bus:
  - 8-bit ECC per 64-bit data quanta without additional cycle latency
  - 1-bit correction and 2-bit detection
  - Statistics for 1-bit ECC and 2-bit ECC errors
  - Programmable address ranges to define ECC protected region
  - ECC calculated and stored on all writes to ECC protected address region
  - ECC verified on all reads to ECC protected address region
  - Two ECC modes supported:
    - Read-Modify-Write (RMW) ECC enabled to support sub quanta accesses to the ECC space.
    - RMW ECC disabled
- Class of service
- UDIMM address mirroring.

The EMIF controller does not support:

- Any memory types except DDR3L
- RDIMMs
- ECC for 16-bit mode
- Single ended DQS
- Mixed 8-bit and 16-bit SDRAM configurations
- 4-bit SDRAMs.

7.2.2 EMIF Environment

This section describes the external connections of the EMIF.

Figure 7-41 shows an example configuration of the EMIF for connection to 2x16-bit DDR3L memories per chip select without ECC.

Figure 7-42 shows an example configuration of the EMIF for connection to 3x16-bit DDR3L memories per chip select with ECC. In this case two 16-bit memories are used for data and one 16-bit (only 4 bits) memory is used for ECC.

For simplification the DDR PHY and DDR IOs are not shown. Only the IO signals for connection to external SDRAM are shown.

Figure 7-41. Example EMIF Configuration without ECC

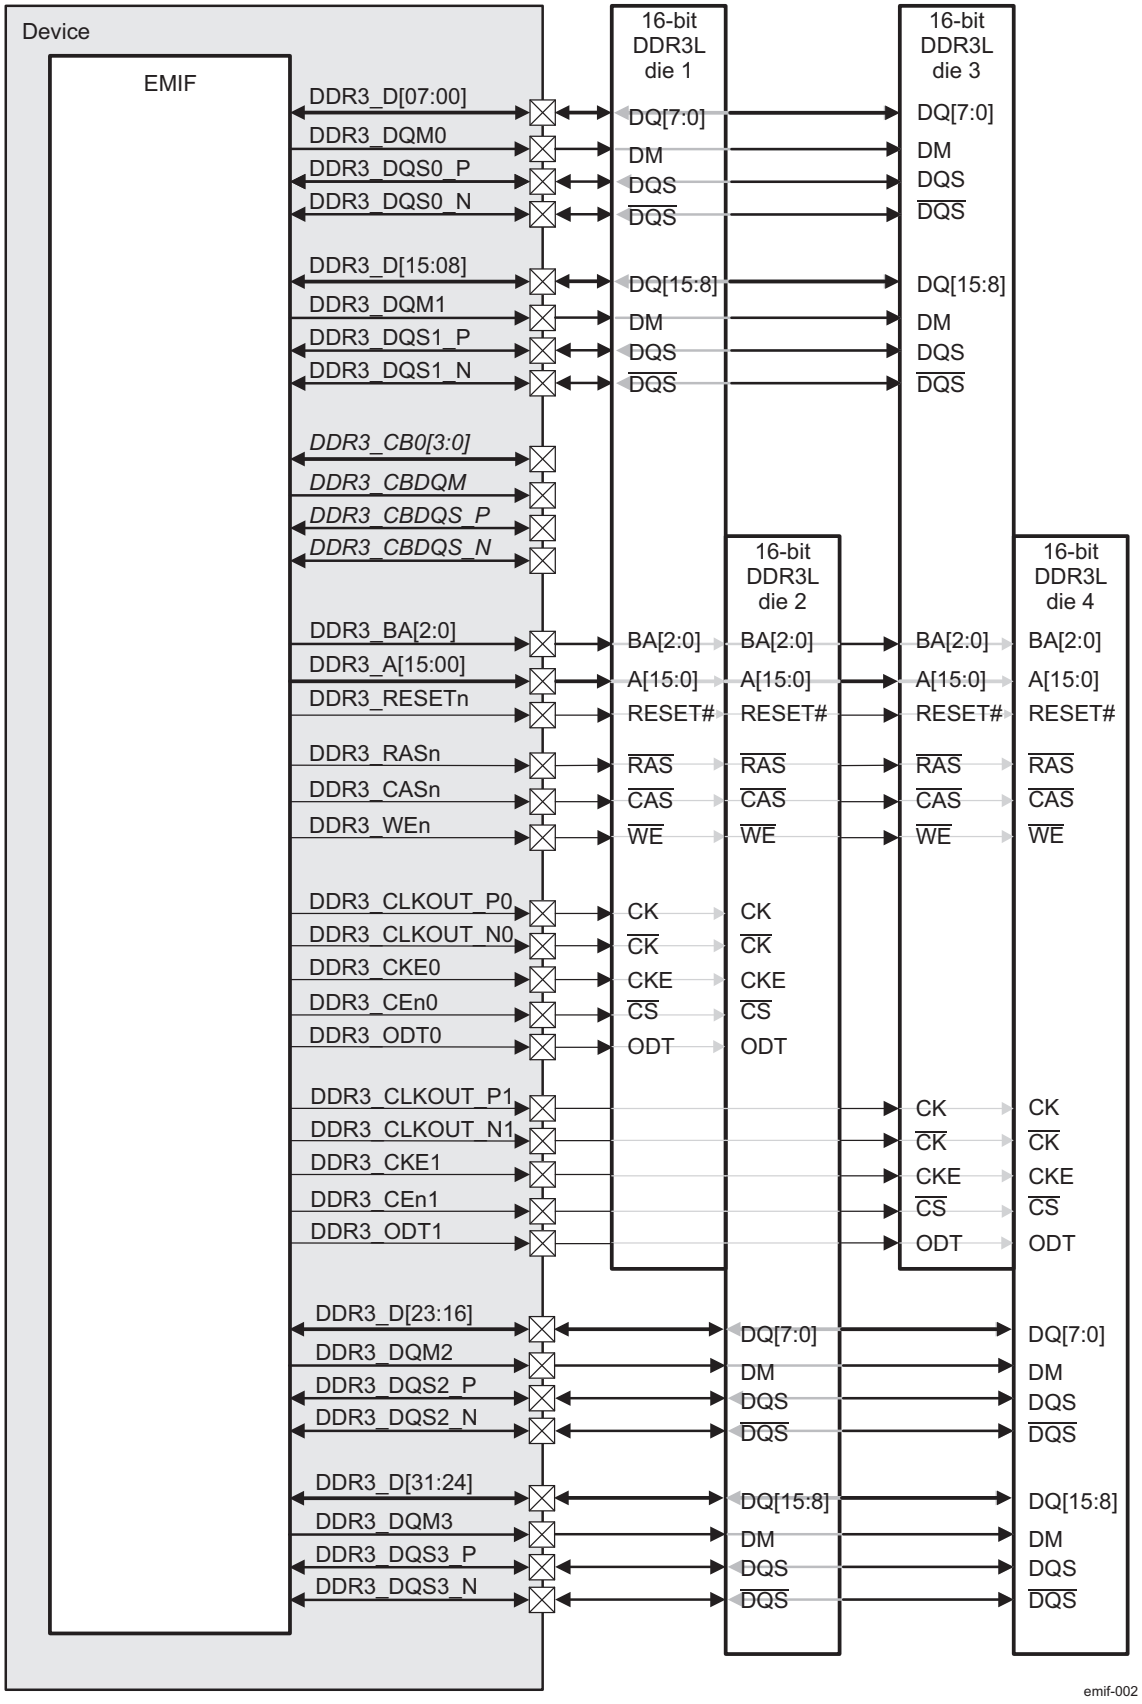


Figure 7-42. Example EMIF Configuration with ECC

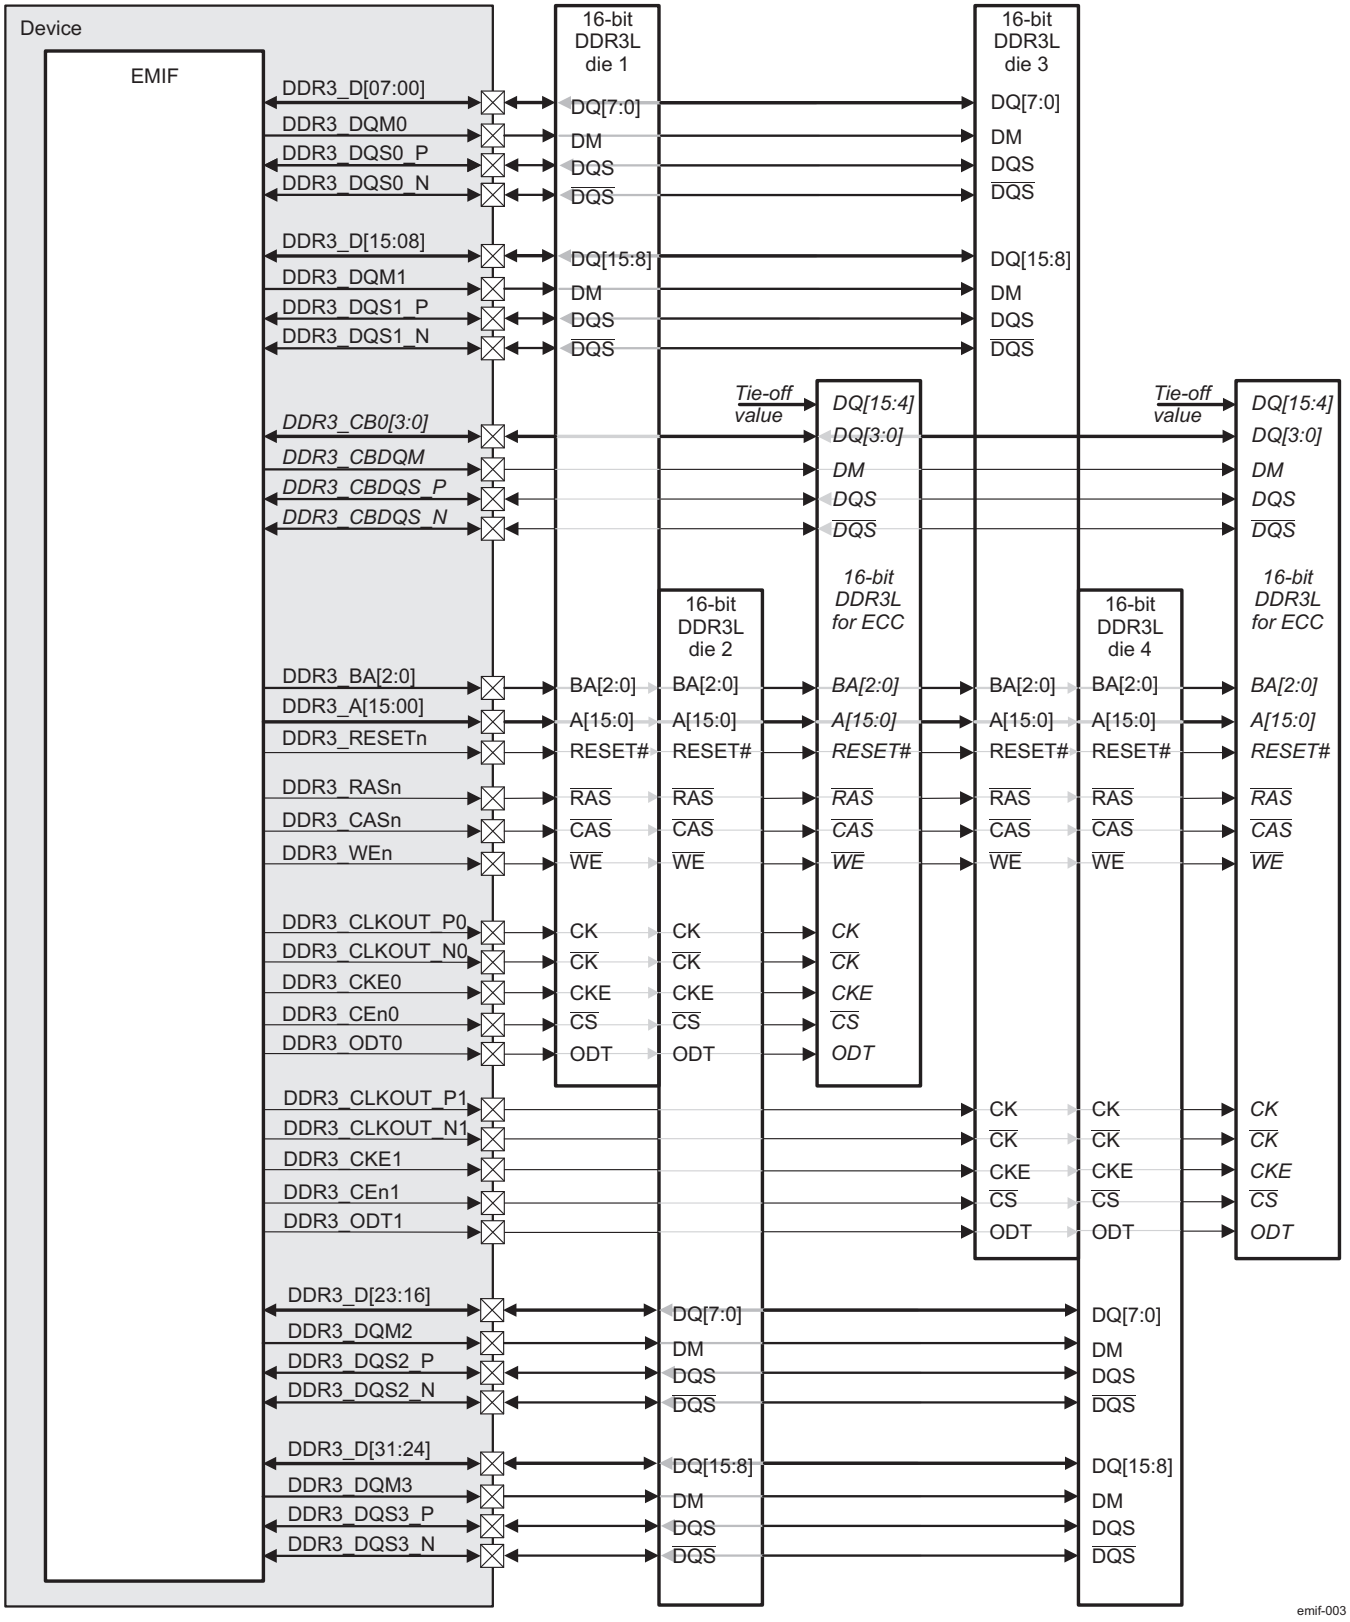

Table 7-117 describes the EMIF associated IO signals used for connection to DDR3L memories.

Table 7-117. EMIF IO signals

Signal Name	Direction	Description
Data Signals		
DDR3_D[31:00]	IOZ	Data bus
DDR3_DQM[3:0]	OZ	Data mask
DDR3_DQS[3:0]_P	IOZ	Data strobe
DDR3_DQS[3:0]_N	IOZ	Data strobe invert
DDR3_CB0[3:0]	*IOZ*	*Data bus used for ECC*
DDR3_CBDQM	*OZ*	*Data mask used for ECC*
DDR3_CBDQS_P	*IOZ*	*Data strobe used for ECC*
DDR3_CBDQS_N	*IOZ*	*Data strobe invert used for ECC*
Command and Control Signals		
DDR3_CEn0	OZ	Chip enable 0
DDR3_CEn1	OZ	Chip enable 1
DDR3_BA[2:0]	OZ	Bank address
DDR3_A[15:00]	OZ	Address bus
DDR3_CASn	OZ	Column address strobe
DDR3_RASn	OZ	Row address strobe
DDR3_WEn	OZ	Write enable

DDR3_CKE1	OZ	Clock enable 1
DDR3_CLKOUT_P0	OZ	Differential clock pair 0 used to drive the external SDRAM
DDR3_CLKOUT_N0	OZ	
DDR3_CLKOUT_P1	OZ	Differential clock pair 1 used to drive the external SDRAM
DDR3_CLKOUT_N1	OZ	
DDR3_ODT0	OZ	On Die Termination Output 0 used to set termination on the SDRAM
DDR3_ODT1	OZ	On Die Termination Output 1 used to set termination on the SDRAM
DDR3_RESETn	OZ	DDR3 reset signal

7.2.3 EMIF Integration

This section describes the EMIF integration in the device and includes information about clocks, resets, and hardware requests. Figure 7-43 shows the EMIF integration.

Figure 7-43. EMIF Integration

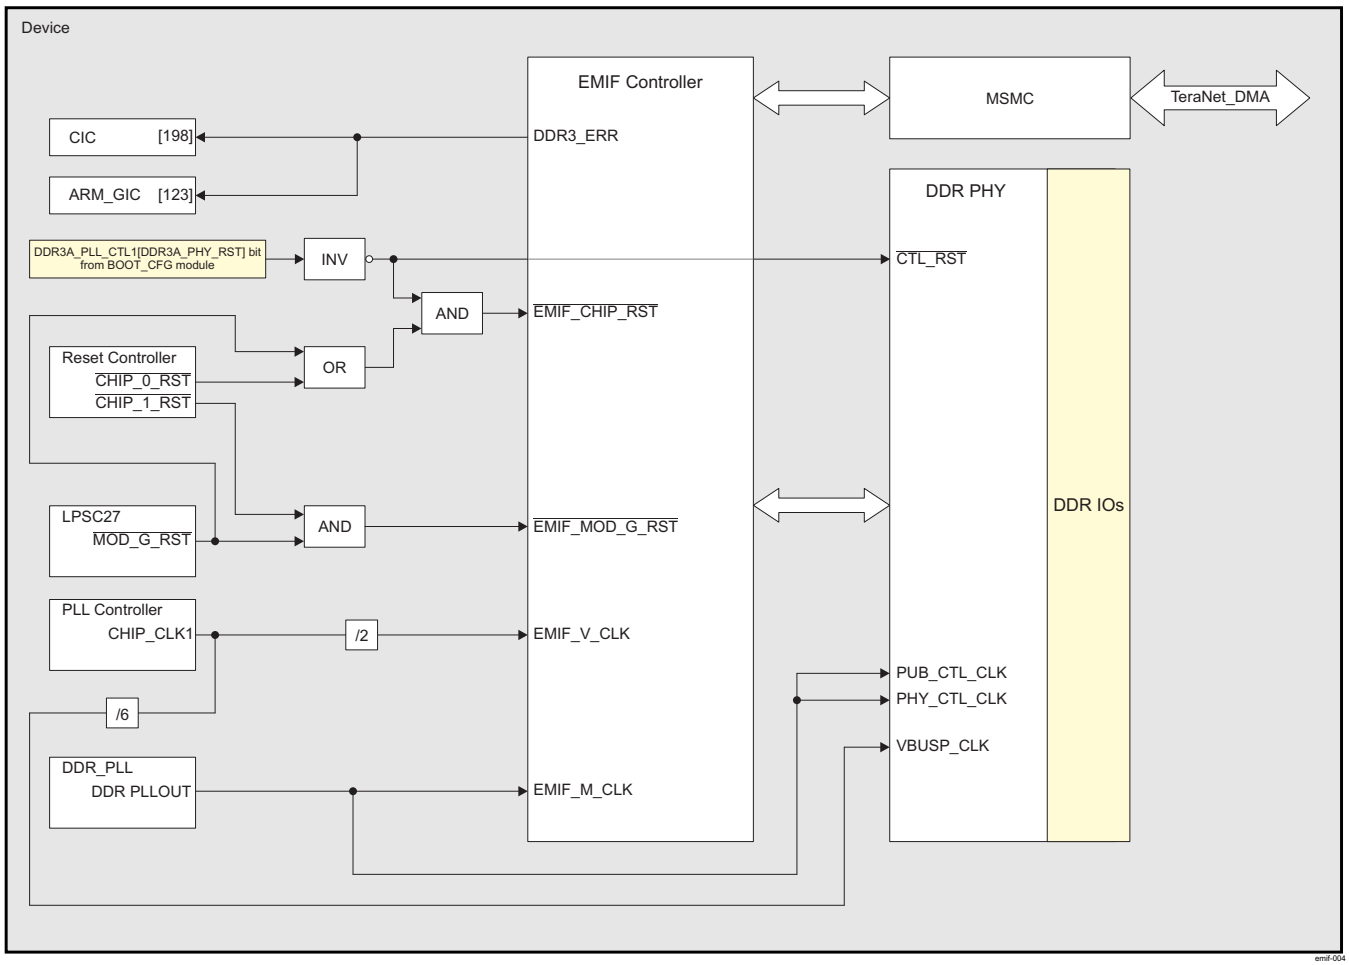

Table 7-118 through Table 7-120 summarize the integration of the EMIF module in the device.

Table 7-118. EMIF Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
EMIF	PD15	LPSC27	Accessed via MSMC, and not directly through TeraNet_DMA

Table 7-119. EMIF Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 7-119. EMIF Clocks and Resets (continued)

EMIF	EMIF_V_CLK	CHIP_CLK1/2	PLL Controller	Interface clock for EMIF. It is used for driving the interface logic for connection to the MSMC.
	EMIF_M_CLK	DDR PLLOUT	DDR_PLL	Functional and interface clock for EMIF. This clock runs at half the DDR3L clock rate and drives the EMIF state machine and configuration registers.
DDR PHY	PUB_CTL_CLK	DDR PLLOUT	DDR_PLL	Clocks for the DDR PHY with frequency and phase same as EMIF_M_CLK
	PHY_CTL_CLK	DDR PLLOUT	DDR_PLL	
	VBUSP_CLK	CHIP_CLK1/6	PLL Controller	Interface clock for the DDR PHY. This clock drives the PHY configuration registers.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF	EMIF_CHIP_RST	MOD_G_RST	LPSC27	Resets the EMIF state machine, FIFOs and all EMIF configuration registers. The EMIF_CHIP_RST can be activated when: • Both LPSC27.MOD_G_RST and CHIP_0_RST are activated. • The DDR3A_PLL_CTL1[31] DDR3A_PHY_RST bit is set to 1h Access to the EMIF configuration registers cannot be performed while the EMIF_CHIP_RST is asserted (active).
		CHIP_0_RST	Reset Controller	
		DDR3A_PLL_CTL1[31] DDR3A_PHY_RST	BOOT_CFG	
	EMIF_MOD_G_RST	MOD_G_RST	LPSC27	Resets the EMIF state machine, FIFOs and only the interrupt registers. The EMIF_MOD_G_RST can be activated when: • LPSC27.MOD_G_RST is activated. • CHIP_1_RST is activated. Access to the EMIF configuration registers cannot be performed while the EMIF_MOD_G_RST is asserted (active).
		CHIP_1_RST	Reset Controller	
DDR PHY	CTL_RST	DDR3A_PLL_CTL1[31] DDR3A_PHY_RST	BOOT_CFG	Reset to the DDR PHY. The DDR PHY is reset when the DDR3A_PLL_CTL1[31] DDR3A_PHY_RST bit is set to 1h.

Table 7-120. EMIF Hardware Requests

Interrupt Requests				
Module Instance	**Event Name**	**Mapped To Input Event [Number]**		**Description**
		ARM GIC	**CIC**	
EMIF	DDR3_ERR	[123]	[198]	EMIF error interrupt

NOTE: For more information about interrupts, see Section 7.2.4.10.

7.2.4 EMIF Functional Description

7.2.4.1 Block Diagram

To move data efficiently from on-chip resources to an external SDRAM device, the EMIF controller makes use of:

- One command FIFO
- One write data FIFO
- One write status FIFO
- One read command FIFO
- SDRAM read data FIFO
- Register read data FIFO
- Command scheduler
- Data scheduler.

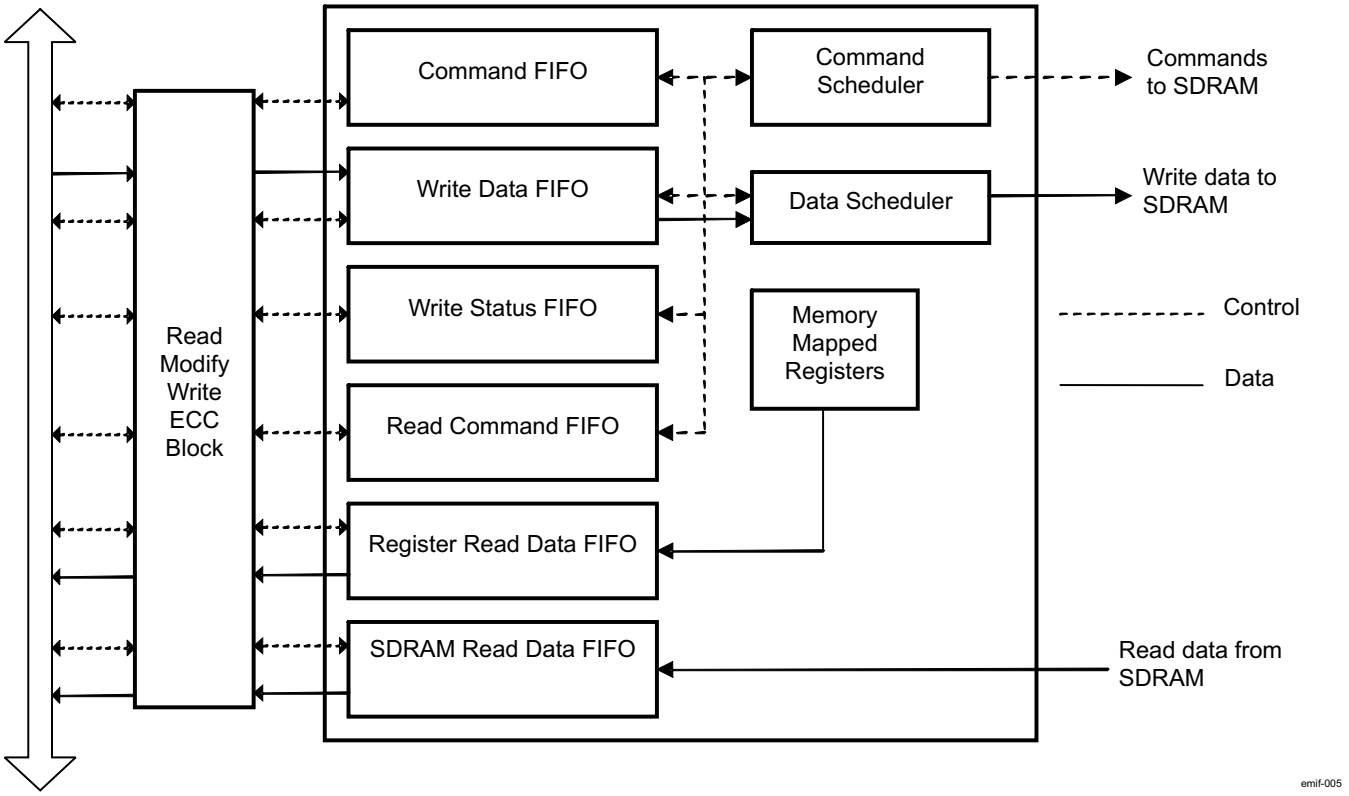
Table 7-121 describes the purpose of each FIFO.

Figure 7-44 shows a block diagram of the EMIF controller FIFOs. Commands, write data, and read data arrive at the EMIF controller parallel to each other. The same bus is used to write and read data to and from external SDRAM as well as EMIF configuration registers.

Table 7-121. EMIF controller FIFOs Description

FIFO	Description	Depth
Command	Stores all commands coming from on-chip requestors	16
Write Data	Stores write data coming from on-chip requestors to memory	20 (512-bit wide)
Write Status	Stores the write status information for each write transaction	7
Read Command	Stores all read transactions that have to be issued to on-chip requestors	28
SDRAM Read Data	Stores read data coming from SDRAM memory to on-chip requestors	28 (256-bit wide)
Register Read Data	Stores read data coming from EMIF configuration registers to on-chip requestors	2 (256-bit wide)

Figure 7-44. Block Diagram of EMIF FIFOs



7.2.4.1.1 Reordering of Commands in the Command FIFO

The EMIF controller performs command reordering and scheduling to achieve efficient transfers with maximum throughput. The goal is to maximize the usage of the data, address, and command buses while hiding the overhead of opening and closing SDRAM rows. Command reordering takes place within the command FIFO.

The EMIF controller examines all the commands stored in the command FIFO to schedule commands to the external memory. For each master, EMIF reorders the commands based on the following rules:

- The EMIF controller pushes a read command before an older write command from the same master if the read is to different address block (2048 bytes) and the read priority is equal to or greater than the write priority.
- The EMIF controller blocks a read command regardless of the master or priority if that read command is to the same address block (2048 bytes) as an older write command.

Thus, one pending read, write or both might exist for each master. Among all pending reads, the EMIF controller selects all reads that have their corresponding SDRAM banks already open. Among all pending writes, the EMIF controller selects all writes that have their corresponding SDRAM banks already open.

As a result of this command reordering several pending reads and writes may exist that have their corresponding banks open. The highest priority read is selected from the pending reads, and the highest priority write from the pending writes. If two or more commands have highest priority, the oldest command is selected. As a result, EMIF might have a final read and a final write command. It chooses either the read or the write command depending on the values programmed in the EMIF_RWTHRESH[12-8] WR_THRSH and EMIF_RWTHRESH[4-0] RD_THRSH fields. EMIF executes read commands until the read threshold is reached and then switches to write commands. EMIF executes write commands until the write threshold is reached and then it switches again to read commands.

The EMIF controller supports interleaving of commands for maximum efficiency. This means that the controller partially executes one command and switches to another higher priority command before finishing the first command.

Apart from reads and writes the EMIF controller also opens and closes SDRAM banks and maintains the refresh counts for an SDRAM. The priority of the SDRAM commands with respect to refresh levels is as follows:

1. (Highest priority) SDRAM refresh request due to Refresh Must level of refresh urgency reached.
2. Read request without a higher priority write (from the reordering algorithm already described).
3. Write request.
4. SDRAM Activate commands.
5. SDRAM Deactivate commands.
6. SDRAM Power-Down request.
7. SDRAM refresh request due to Refresh May or Release level of refresh urgency reached.
8. (Lowest priority) SDRAM self-refresh request.

7.2.4.1.2 Command Starvation

While performing the scheduling algorithm described in Section 7.2.4.1.1 the EMIF controller is subject to the following:

- A continuous stream of high priority commands can block lower priority commands.
- A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

To avoid continuous blocking effect that can be caused by a continuous stream of high priority commands which thus block lower priority commands, the EMIF momentarily raises the priority of the oldest command over all other commands when the time for the oldest command configured through the EMIF_VBUSM_CONFIG[7-0] PR_OLD_COUNT bit field expires. In addition, the order of command accesses can also be adjusted by grouping commands in two categories or “classes” and assigning different latency expiration counters to each category. For more information see Section 7.2.4.1.4, *Class of Service of Commands in the Command FIFO*.

In addition, the highest priority condition is the rising edge of EMIF_CHIP_RST or EMIF_MOD_G_RST. If this occurs, the EMIF controller stops whatever it is currently doing and goes to idle state. In this case commands and data stored in the FIFOs are lost.

7.2.4.1.3 Possible Race Condition

A race condition may exist when certain masters write data to the EMIF controller. For example, if master A passes a software message via a buffer in the SDRAM and does not wait for indication that the write it complete, when master B attempts to read the software message it may read old data and therefore receive an incorrect message. In order to confirm that a write from master A has completed before a read from master B is performed, master A must wait for the write to complete before indicating to master B that the data is ready to be read. For example, an EDMA transfer controller should wait for the transfer completion event to occur before signaling a CPU to read the message from the SDRAM.

If master A does not wait for indication that a write is complete, it must perform the following:

1. Perform the required write.
2. Perform a dummy write to the EMIF_MIDR register.
3. Perform a dummy read from the EMIF_MIDR register.
4. Indicate to master B that the data is ready to be read after completion of the read in step 3. The completion of the read in step 3 ensures that the previous write has been done.

7.2.4.1.4 Class of Service of Commands in the Command FIFO

The commands in the Command FIFO can be mapped to two categories called also *classes of service*: 1 and 2. The mapping of commands to a particular class of service can be done based on priority or master ID. The mapping based on priority can be done by setting the appropriate values in the EMIF_PRI_COS_MAP register. The mapping based on master ID can be done by setting the appropriate values of master ID and masks in the EMIF_MSTID_COS_1_MAP and EMIF_MSTID_COS_2_MAP registers.

There are three master ID and mask values that can be set for each class of service. In conjunction with the masks each class of service can have a maximum of 144 master IDs mapped to it. For example, a master ID value of FFh along with a mask value of 3h maps all master IDs from F8h to FFh to that particular class of service. By default all commands are mapped to class of service 2.

Each class of service has an associated latency counter. The value of this counter can be set in the EMIF_VBUSM_CONFIG[23-16] COS_COUNT_1 and EMIF_VBUSM_CONFIG[15-8] COS_COUNT_2 fields. When the latency counter for a command expires, that is, reaches the value programmed for the class of service that the command belongs to, that command is executed next. If there is more than one command that has expired latency counters, the command with the highest priority is executed first. One exception to this rule is if the EMIF_VBUSM_CONFIG[7-0] PR_OLD_COUNT value expires for the oldest command in the queue. That command is executed first irrespective of priority or class of service. This is done to prevent the continuous blocking effect described in Section 7.2.4.1.2, *Command Starvation*.

7.2.4.2 Power Management

7.2.4.2.1 SDRAM Power-Down Mode

The EMIF controller supports SDRAM power-down mode. Automatic SDRAM power-down is enabled by setting the EMIF_PMCTL[10-8] LP_MODE field to 4h. The memory is put into power-down after the EMIF controller is idle for EMIF_PMCTL[15-12] PD_TIM number of DDR3CLKOUT cycles. In power-down mode, the EMIF controller does not stop the clocks to the memory. The controller maintains DDR3CKE low to maintain the power-down state. When the SDRAM is in power-down mode the EMIF controller services accesses to its configuration registers as usual.

If the SDRAM is in power-down mode and one of the following occurs, the EMIF brings the SDRAM out of power-down mode:

- The EMIF_PMCTL[10-8] LP_MODE field is set to value different than 4h.
- SDRAM access is requested.
- Refresh-must level is reached.

To exit power-down mode the EMIF does the following:

1. Drives DDR3CKE high after EMIF_SDTIM3[3-0] T_CKE + 1 cycles have elapsed since the power-down command has been issued.
2. Waits for EMIF_SDTIM3[30-28] T_XP + 1 cycles.
3. Enters its idle state and can issue any commands.

7.2.4.2.2 SDRAM Self-Refresh Mode

The EMIF controller supports self-refresh mode for low power. The controller maintains DDRCKE low to maintain the self-refresh state. In self-refresh the memory maintains valid data while consuming minimal amount of power.

Self-refresh mode is enabled by setting the EMIF_PMCTL[10-8] LP_MODE field to 2h. The EMIF controller automatically puts the SDRAM into self-refresh after the controller is idle for EMIF_PMCTL[7-4] SR_TIM number of DDR3CLKOUT cycles.

In self-refresh mode, the EMIF controller automatically stops the SDRAM clock (DDR3CLKOUT). The EMIF drives DDR3CKE low to maintain self-refresh mode. When the SDRAM is in self-refresh mode the EMIF controller services accesses to its configuration registers as usual.

If the SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings the SDRAM out of selfrefresh mode:

- The EMIF_PMCTL[10-8] LP_MODE field is set to value different than 2h
- SDRAM access is requested
- The EMIF_PMCTL[7-4] SR_TIM field is cleared

To exit self-refresh the EMIF does the following:

1. Enables the SDRAM clock
2. Drives DDR3CKE high

3. Waits EMIF_SDTIM3[27-18] T_XSNR + 1 cycles
4. Starts a refresh cycle in the next cycle
5. Issues a ZQCL command, if the EMIF_ZQ_CONFIG[28] ZQ_SFEXITEN bit is set to 1
6. Enters its idle state and can issue any other command except write or read command. A write or a read command is issued only after EMIF_SDTIM3[17-8] T_XSRD + 1 cycles have elapsed since DDR3CKE has been driven high.

In a situation where memory accesses and a self-refresh command are sent to the EMIF controller, the controller always prioritizes the memory access. Thus, if a reset is triggered when memory accesses and a self-refresh command are queued in the controller, it is likely that self-refresh will not be entered.

The user must ensure that all memory accesses have been completed and verify that self-refresh is set by reading the EMIF_STATUS[27] SELF_REF bit before initiating a reset.

NOTE: The EMIF controller completes all pending memory accesses and refreshes before it puts SDRAM into self-refresh. If a request for a memory access is received, the EMIF controller services the memory access request then returns to the self-refresh state upon completion.

7.2.4.2.2.1 SDRAM Extended Temperature Range

The normal operating temperature range for DDR3 SDRAMs is typically 0 to 85°C. When operating in self-refresh mode within the extended temperature range (85°C to 95°C), the memory device must be refreshed at 2× the normal refresh rate. For this purpose either the auto self-refresh (bit DDR_PHY_MR2[6] ASR) or self-refresh temperature (bit DDR_PHY_MR2[7] SRT) feature should be used. Under normal operating conditions, both ASR and SRT should be disabled (equal to 0). If ASR is enabled, the internal refresh rate of the SDRAM automatically switches to 2× the refresh rate when the operating case temperature Tc is greater than 85°C in case of self-refresh mode. If SRT is enabled, the internal refresh rate of the SDRAM is forced to 2× the refresh rate regardless of the operating case temperature Tc. Both ASR and SRT cannot be enabled at the same time. One must be disabled if the other is enabled.

NOTE: ASR and SRT are used only in self-refresh mode (EMIF_PMCTL[10-8] LP_MODE = 2h). When operating in extended temperature range with LP_MODE = 0h (not in self-refresh), it is up to the user to program the manual refresh rate to 2× the normal refresh rate for proper operation.

If it is guaranteed that Tc will exceed 85°C, it is recommended to set the SRT bit to 1 to force the refresh rate to 2× regardless of the operating temperature.

7.2.4.3 SDRAM Refresh Scheduling

The EMIF controller uses two counters to schedule refresh (REF) commands:

- 13-bit decrementing refresh interval counter
- 4-bit refresh backlog counter.

The interval counter is loaded at reset with the value of the EMIF_SDRFC[15-0] REFRESH_RATE field. The interval counter decrements by one each cycle until it reaches zero. At this point it reloads from value EMIF_SDRFC[15-0] REFRESH_RATE and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF_SDRFC[15-0] REFRESH_RATE field is updated.

The refresh backlog counter records the number of the outstanding REF commands which the EMIF controller currently has. The backlog counter increments by one (unless it has reached its maximum value of 15) each time the 13-bit interval counter reloads. The backlog counter decrements by one (unless it is already at zero) each time the EMIF controller issues a REF command.

For the range of values the backlog counter can take there are three levels of urgency with which the EMIF controller should perform refresh cycle in which it issues REF commands:

- *Refresh-may* level: reached whenever the backlog count is greater than 0. This indicates there is a refresh backlog, so if the EMIF controller is not busy and none of the SDRAM banks are open, it

should perform a refresh cycle.

- *Refresh-release* level: reached whenever the backlog count is greater than 4. This indicates the refresh backlog is getting higher, so if the EMIF controller is not busy it should perform a refresh cycle even if there is an open SDRAM bank.
- *Refresh-must* level: reached whenever the backlog count is greater than 7. This indicates the refresh backlog is getting excessive and the EMIF controller must perform a refresh cycle before servicing any new memory access requests.

The EMIF controller starts servicing new memory accesses after refresh-release level is cleared. If any of the commands in the Command FIFO have class-of-service latency counters that are expired, the EMIF controller does not wait for refresh-release level to be cleared. It only performs one refresh command and exits the refresh state.

The two counters do not operate when the SDRAM is in self-refresh mode. They start tracking the missed refreshes (the outstanding REF commands) only after the EMIF_SDRFC[31] INITREF_DIS bit is set to 0h.

The time between two REF commands is set through the EMIF_SDTIM4[13-4] T_RFC bit field.

7.2.4.4 Leveling

The EMIF controller supports leveling to compensate for the command and DQS skew as a result of the fly-by topology. Leveling compensates the skew for both reads and writes. The controller does not require the user to program initial leveling values to establish the starting point of the search window before triggering hardware leveling. The logic inside the DDR PHY is able to automatically search for and determine the optimal starting point when leveling and training sequence is triggered by writing to the DDR_PHY_PIR register.

7.2.4.5 Access Cycles

By default EMIF keeps its SDRAM chip select signals high (CSs are active-low). To direct a command to only one of the SDRAMs, EMIF asserts the chip select to that SDRAM for the duration of the command. If the EMIF_SDCFG[3] EBANK bit is set to 0, DDR3CE1z is always driven high except for Refresh, Power-Down and Self-Refresh commands.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may be needed to service a single burst request to the port via which EMIF is connected to the system. Table 7-122 through Table 7-124 show a few examples how EMIF accesses the SDRAM for a linear incrementing transaction type. T0, T1, and so on are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Table 7-122. 64-Byte Linear Read Starting at Address 0h

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11
R0				R8							
				D0-1	D2-3	D4-5	D6-7	D8-9	D10-11	D12-13	D14-15

Table 7-123. 64-Byte Linear Read Starting at Address 10h

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R4		R8				R16							
				D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	Unused	Unused

Table 7-124. 64-Byte Linear Read Starting at Address 18h

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding tables by issuing successive read commands if there are reads to open banks pending in the command FIFO.

7.2.4.6 Turnaround Time

Table 7-125 shows the turnaround time that the EMIF controller introduces on the data bus for various back-to-back accesses. Note that the EMIF controller takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turn around time on the data bus.

Table 7-125. Turnaround Time

Previous Access	Next Access	Turnaround Time in SDRAM clock cycles (DDR3CLKOUT)
SDRAM Write	SDRAM Write to same chip select	0
SDRAM Write	SDRAM Write to different chip select	EMIF_SDTIM4[31-28] T_CSTA + 1
SDRAM Read	SDRAM Read to same chip select	0
SDRAM Read	SDRAM Read to different chip select	EMIF_SDTIM4[31-28] T_CSTA + 1
SDRAM Write	SDRAM Read	EMIF_SDTIM1[3-0] T_WTR + 1 + CL
SDRAM Read	SDRAM Write	EMIF_SDTIM1[3-0] T_RTW + 1

7.2.4.7 SDRAM Address Mapping

The EMIF controller views the external SDRAM as one continuous block of memory across the two chip selects. If smaller devices are used, the memory is seen to roll over. The EMIF controller receives SDRAM access requests along with 33-bit logical address from the rest of the system. The controller uses this logical address to generate a row (page), column, bank address, and chip selects for the DDR3L SDRAM. The number of bank and column address bits used is determined by the EMIF_SDCFG[6-5] IBANK and EMIF_SDCFG[1-0] PAGESIZE fields as shown in Table 7-126. The chip select lines used are determined by the EMIF_SDCFG[3] EBANK field.

Table 7-126. Bank Configuration Register Fields for Address Mapping

Bit Field in register EMIF_SDCFG	Bit Value	Bit Description
[6-5] IBANK		Defines the number of internal banks on external DDR3 memory
	0h	1 bank
	1h	2 banks
	2h	4 banks
	3h	8 banks
[3] EBANK		External chip select setup. Defines whether SDRAM accesses use 1 or 2 chip select lines
	0h	Use only chip enable 0 for all SDRAM accesses
	1h	Use chip enables 0 and 1 for SDRAM accesses
[1-0] PAGESIZE		Defines the page size of each page of the external DDR3 memory
	0h	256 words (requires 8 column address bits)
	1h	512 words (requires 9 column address bits)
	2h	1024 words (requires 10 column address bits)
	3h	2048 words (requires 11 column address bits)

NOTE: The EMIF_SDCFG[6-5] IBANK field should always be set to 3h since the DDR3 memory devices offer only 8-bank support unlike DDR2 with the option of 4-bank or 8-bank memories.

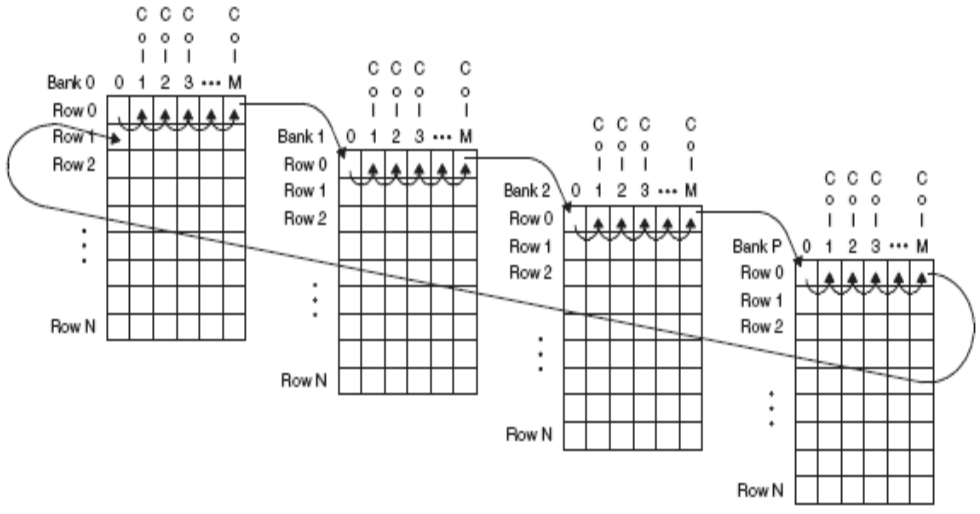
Table 7-127 shows the logical address-to-SDRAM address mapping. The effect of the address-mapping scheme is that as the source address increments across the SDRAM pages, EMIF moves to the same page in the next bank on the current chip select. This movement across the banks continues until the same page is accessed in all banks. Then EMIF moves to the next page in the first bank if the EMIF_SDCFG[3] EBANK bit is set to 0h. This process is illustrated on Figure 7-45. If EBANK is set to 1h the EMIF proceeds to the same page on the next chip select. Then it continues until the same page is accessed in all banks before accessing the next page on the first chip select.The EMIF uses this movement across chip selects and internal banks while remaining on the same page to maximize the number of the open SDRAM banks within the overall SDRAM space. Thus, the EMIF controller can keep a maximum of 16 banks (8 internal banks across two chip selects) open at a time and can interleave among all of them.

Table 7-127. Logical Address-to-SDRAM Address Mapping

Logical Address [32:N](1)							
Row Address		Chip Select		Bank Address		Column Address	
		EBANK	ncs(2)	IBANK	nbb(2)	PAGESIZE	ncb(2)
16 bits		0	0 bits	0	0 bits	0	8 bits
		1	1 bit	1	1 bit	1	9 bits
				2	2 bits	2	10 bits
				3	3 bits	3	11 bits
Logical address mapping for row address		Logical address mapping for chip select		Logical address mapping for bank address		Logical address mapping for column address	
MSB	LSB	MSB	LSB	MSB	LSB	MSB	LSB
M3 + 15	M3 + 1	M3 = M2 + ncs - 1	M2 + 1	M2 = M1 + nbb - 1	M1 + 1	M1 = N + ncb - 1	N

(1) N = 1 for 16-bit SDRAMs, N = 2 for 32-bit SDRAMs.
(2) nrb = number of row bits; ncs = number of chip select bits; nbb = number of bank address bits.

Figure 7-45. DDR3L SDRAM Column, Row, and Bank Access When EBANK = 0



A M is number of columns (as determined by PAGESIZE) minus 1, P is number of banks (as determined by IBANK) minus 1, and N is number of rows (as determined by both PAGESIZE and IBANK) minus 1.

7.2.4.8 DDR3L Output Impedance Calibration

The EMIF controller supports automatic output impedance (ZQ) calibration for DDR3L memories. The ZQ calibration can be enabled per chip select by setting the EMIF_ZQ_CONFIG[31] ZQ_CS1EN and EMIF_ZQ_CONFIG[30] ZQ_CS0EN bits. The EMIF supports the following types of ZQ calibration commands:

- ZQCS: ZQ calibration short command
- ZQCL: ZQ calibration long command.

The EMIF controller issues ZQCS command each time the EMIF_ZQ_CONFIG[15-0] ZQ_REFINTERVAL bit field expires. In other words, the ZQ_REFINTERVAL defines the interval between two ZQCS commands. When ZQCS command is issued, the EMIF waits and blocks any other command for EMIF_SDTIM4[23-16] ZQ_ZQCS + 1 number of DDR3CLKOUT clock cycles.

If the EMIF_ZQ_CONFIG[28] ZQ_SFEXITEN bit field is set to 1h, the EMIF issues ZQCL command every time it exits self-refresh mode. When ZQCL command is issued, the EMIF waits and blocks any other command for (EMIF_ZQ_CONFIG[18-16] ZQ_ZQCL_MULT + 1) × (EMIF_SDTIM4[23-16] ZQ_ZQCS + 1) number of DDR3CLKOUT clock cycles.

The ZQ calibration must be performed simultaneously over both chip selects. To enable ZQ calibration to be performed simultaneously over both chip selects the EMIF_ZQ_CONFIG[29] ZQ_DUALCALEN bit must be set to 1h. If ZQ_DUALCALEN is set to 0h, the EMIF performs ZQ calibration serially per chip select. ZQ_DUALCALEN = 0h is not supported and must not be used.

7.2.4.9 Error Correction And Detection

For data integrity, the EMIF controller supports ECC on the data written to or read from the ECC protected address ranges in memory. The ECC algorithm is a single-error-correct-double-error-detect (SECDED) algorithm and uses the (72,64) Hamming code. 8-bit ECC is calculated over 64-bit data quanta. ECC is enabled by setting to 1h both the EMIF_ECCCTL[31] ECC_EN and DDR_PHY_DX8GCR[0] DXEN bits. ECC is disabled by setting these two bits to 0h. The address ranges can be programmed in the EMIF_ECCADDR1 and EMIF_ECCADDR2 registers. Both registers have identical bits and functionality. This provides flexibility allowing two non-overlapping memory regions to be ECC protected. The system must ensure that any burst access with start address in the ECC protected region must not cross over to the unprotected region and vice-versa.

NOTE: The ECC is stored inside the SDRAM during writes. After enabling ECC and before performing any functional reads or writes, the SDRAM space configured as ECC should be first written with known data that is 64-bit aligned and with byte count multiple of 64-bit. This is to ensure the correct ECC values are stored in the ECC SDRAM before functional use.

NOTE: For both reads and writes the 64-bit data quanta is broken into two 32-bit words with 8-bit ECC calculated and stored over both 32-bit words.

The EMIF controller also has an additional read-modify-write (RMW) feature to support sub quanta accesses to the ECC protected memory. This feature can be enabled by setting to 1h the EMIF_ECCCTL[28] RMW_EN bit. If the RMW ECC feature is disabled (EMIF_ECCCTL[28] RMW_EN = 0h) and write access with byte count not multiple of 64-bit quanta or with non-64-bit-aligned address is performed within the address range protected by the ECC, the result is write ECC error interrupt. In this case the EMIF controller writes to the SDRAM but the ECC value written is corrupted. When RMW is enabled the controller performs a RMW operation if a write results in a sub-64-bit access. The details how EMIF performs RMW operations are described in Section 7.2.4.9.1.1.

NOTE: If ECC is used the RMW_EN bit must always be set to 1h to enable the RMW feature.

The ECC is read and verified during reads if the EMIF_ECCCTL[29] ECC_VERIFY_EN bit is set to 1h. ECC verification is disabled during reads if ECC_VERIFY_EN is set to 0h.

If there is 1-bit error, the EMIF controller corrects the data and sends it on the read interface. For 2-bit errors EMIF generates read ECC error interrupt. In both cases the data in the SDRAM is corrupted. It is software responsibility to correct that data.

NOTE: The user should note that the algorithm used by the ECC logic cannot detect more than 2-bit errors per 64-bit quanta. For these errors the output of the algorithm is unknown. It may erroneously detect as 1-bit, 2-bit or no error. More than 2-bit errors are expected to be very rare in a well designed system.

NOTE: To disable ECC, set to 0h both the EMIF_ECCCTL[31] ECC_EN and DDR_PHY_DX8GCR[0] DXEN bits before triggering the leveling sequence in the DDR_PHY_PIR register. By default DXEN is 1h, so the ECC byte lane is enabled from perspective of the PHY.

7.2.4.9.1 ECC Enhancements

7.2.4.9.1.1 Read-Modify-Write

NOTE: If ECC is used the EMIF_ECCCTL[28] RMW_EN bit must always be set to 1h to enable the RMW feature.

As shown in Figure 7-44, the Read-Modify-Write (RMW) module is placed before internal FIFO logic of the controller. The RMW module splits all SDRAM writes into a burst size of 64-bytes and converts any sub-quanta write into a RMW of aligned burst size (64 bytes). A quanta is defined as 8 bytes. Read bursts are not fragmented.

The RMW module has been designed such that normal aligned ECC block read or write bursts are unaffected. That is, they pass through without adding delay as well as maintaining all memory coherence. If RMW module detects write data that does not form a complete quanta, a read for that burst (64 bytes) is then issued by the controller. This return data burst is then merged with the sub-quanta write data and the modified 64-byte burst is then written to the SDRAM.

The controller maintains coherence across all outstanding commands in the command FIFO whether or not they are affected by the RMW module and also follows the normal command arbitration described in Section 7.2.4.1.1. The RMW process for sub-quanta writes means the execution of the write command will be delayed compared to if the command was not sub-quanta and was 64-bit aligned.

7.2.4.9.1.2 Logging 1-bit ECC Error Address

For 1-bit ECC error the controller logs the start address of the SDRAM burst in an internal 2-level deep address FIFO. The EMIF_ONE_BIT_ECC_ERR_ADDR_LOG register displays the address on top of the internal FIFO. Software must write 1h to the EMIF_ONE_BIT_ECC_ERR_ADDR_LOG register to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. It must be noted that no address comparison is performed, that is, if a single address has ECC errors back-to-back, that address is logged twice.

7.2.4.9.1.3 Counting the Number of 1-bit ECC Errors

The number of 1-bit ECC errors can be counted using the EMIF_ONE_BIT_ECC_ERR_CNT register. The controller also supports programming a threshold and a window in the EMIF_ONE_BIT_ECC_ERR_THRSH register. The window is programmed in number of refresh periods. When the programmed window value is 0, that is, window is disabled and the internal error count exceeds the programmed threshold, the controller generates a 1-bit ECC error interrupt. When servicing the interrupt software has to set the EMIF_ONE_BIT_ECC_ERR_CNT register with a value less than the

threshold otherwise the interrupt will not be triggered again. When the programmed window value is non-zero, that is, window is enabled, the controller generates a 1-bit ECC error interrupt only if the internal error count exceeds the programmed threshold in that window. The EMIF_ONE_BIT_ECC_ERR_CNT register is reset every time the window expires. Software can use this to measure the degree of 1-bit ECC errors occurring in the system.

7.2.4.9.1.4 Diagnosing the Data Bus Bit on Which 1-bit ECC Errors Occur

For diagnosis, the controller has the EMIF_ONE_BIT_ECC_ERR_DIST_1 register that represent whether an error has occurred in a given bit location on the data. This is useful to detect whether the errors are random or systemic. The EMIF_ONE_BIT_ECC_ERR_DIST_1 register overlays all 1-bit ECC errors until software clears the register. Therefore, multiple bits could be set as a result of multiple 1-bit ECC errors occurring over multiple read accesses.

For 2-bit ECC errors the controller generate a 2-bit ECC error interrupt. It must be noted that the controller detects but does not correct 2-bit ECC errors. The controller generates a 2-bit ECC error interrupt and sends the resultant data from the ECC correction logic. The read data received from the memory may have further been corrupted by the ECC correction logic since it will have attempted to correct the read data but failed due to uncorrectable error.

7.2.4.9.1.5 Logging 2-bit ECC Error Address

For all uncorrectable ECC errors the controller logs the start address of the SDRAM burst in the EMIF_TWO_BIT_ECC_ERR_ADDR_LOG register. This register shows the address of the first uncorrectable error. After software clears the register, it will be loaded with the address for the next uncorrectable error.

7.2.4.10 Interrupt Requests

The EMIF controller generates one interrupt request, the DDR3_ERR, associated with the following registers:

- EMIF_IRQSTATUS_RAW_SYS — interrupt raw status register
- EMIF_IRQSTATUS_SYS — interrupt status register
- EMIF_IRQENABLE_SET_SYS — interrupt enable register
- EMIF_IRQENABLE_CLR_SYS — interrupt disable register

For the interrupt behavior of the EMIF controller the following applies:

- EMIF asserts its interrupt line DDR3_ERR only if the interrupts are enabled by setting to 1h the corresponding bits in the EMIF_IRQENABLE_SET_SYS register. These interrupts can be disabled by setting to 1h the corresponding bits in the EMIF_IRQENABLE_CLR_SYS register.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting to 1h the corresponding bit in the EMIF_IRQSTATUS_SYS register which also clears the corresponding bit in the EMIF_IRQSTATUS_RAW_SYS register. The status flags in the EMIF_IRQSTATUS_RAW_SYS register are set even if the corresponding interrupt is disabled unlike those in the EMIF_IRQSTATUS_SYS register, which are set only if the corresponding interrupt is enabled.
- An interrupt is also generated by the EMIF, if certain bit in the EMIF_IRQSTATUS_RAW_SYS register is set to 1h and the corresponding interrupt is enabled through the EMIF_IRQENABLE_SET_SYS register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled the corresponding raw flag in the EMIF_IRQSTATUS_RAW_SYS register is set to 1h when an interrupt condition occurs.
- Even if interrupts are not enabled, a status bit in the EMIF_IRQSTATUS_RAW_SYS register can also be cleared by setting to 1h the corresponding bit in the EMIF_IRQSTATUS_SYS register.

Table 7-128 lists the interrupt events which can assert the DDR3_ERR interrupt line.

Table 7-128. EMIF Events

Event Flag	Event Mask	Description
EMIF_IRQSTATUS_RAW_SYS[5] 1B_ECC_ERR_SYS EMIF_IRQSTATUS_SYS[5] 1B_ECC_ERR_SYS	EMIF_IRQENABLE_SET_SYS[5] 1B_ECC_ERR_SYS EMIF_IRQENABLE_CLR_SYS[5] 1B_ECC_ERR_SYS	1-bit ECC error interrupt. See Section 7.2.4.9.1.3 for more information.
EMIF_IRQSTATUS_RAW_SYS[4] 2B_ECC_ERR_SYS EMIF_IRQSTATUS_SYS[4] 2B_ECC_ERR_SYS	EMIF_IRQENABLE_SET_SYS[4] 2B_ECC_ERR_SYS EMIF_IRQENABLE_CLR_SYS[4] 2B_ECC_ERR_SYS	2-bit ECC error interrupt. See Section 7.2.4.9.1.5 for more information.
EMIF_IRQSTATUS_RAW_SYS[3] WR_ECC_ERR_SYS EMIF_IRQSTATUS_SYS[3] WR_ECC_ERR_SYS	EMIF_IRQENABLE_SET_SYS[3] WR_ECC_ERR_SYS EMIF_IRQENABLE_CLR_SYS[3] WR_ECC_ERR_SYS	Interrupt for memory access made to a non-quanta aligned location or done with byte count not multiple of the ECC quanta.
EMIF_IRQSTATUS_RAW_SYS[0] ERR_SYS EMIF_IRQSTATUS_SYS[0] ERR_SYS	EMIF_IRQENABLE_SET_SYS[0] EN_ERR_SYS EMIF_IRQENABLE_CLR_SYS[0] EN_ERR_SYS	Interrupt for command or address error.

7.2.4.11 Performance Monitoring

The EMIF_PERF_CNT_1 and EMIF_PERF_CNT_2 registers are used to monitor or calculate the EMIF Controller bandwidth and efficiency. These counters are able to count events such as accesses made to EMIF, Activate (ACT) commands sent to SDRAM, read and write accesses made to EMIF, and other events. Each counter counts independent of the other. In addition to the ability of events counting, the counters are also able to filter the events from a particular master or address space. The events counting and filter enabling are configured using the EMIF_PERF_CNT_CFG register. The actual value of the filter is configured through the EMIF_PERF_CNT_SEL register. Each counter can be configured independently.

Table 7-129 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter is applied to an event if the following bits are set to 1h for that event:

- For Performance Counter 1: EMIF_PERF_CNT_CFG[15] CNTR1_MSTID_EN and EMIF_PERF_CNT_CFG[14] CNTR1_REGION_EN
- For Performance Counter 2: EMIF_PERF_CNT_CFG[31] CNTR2_MSTID_EN and EMIF_PERF_CNT_CFG[30] CNTR2_REGION_EN

The CNTR*n*_CFG (*n* = 1 or 2) fields in the EMIF_PERF_CNT_CFG register are used to select the event to count.

Table 7-129. Performance Counter Filter Configuration

CNTR*n*_CFG[(1)]	CNTR*n*_REGION_EN	CNTR*n*_MSTID_EN	Event Selected for Counting
0h	0h	0h or 1h	Count the accesses made to EMIF
1h	0h	0h or 1h	Count the Activate (ACT) commands sent to SDRAM
2h	0h or 1h	0h or 1h	Count the read accesses made to EMIF
3h	0h or 1h	0h or 1h	Count the write accesses made to EMIF
4h	0h	0h	Count the number of EMIF_M_CLK clock cycles during which the Command FIFO is full
5h	0h	0h	Count the number of EMIF_M_CLK clock cycles during which the Write Data FIFO is full
6h	0h	0h	Count the number of EMIF_M_CLK clock cycles during which the Read Data FIFO is full
7h	0h	0h	Count the number of EMIF_M_CLK clock cycles during which the Write Status FIFO is full
8h	0h or 1h	0h or 1h	Count the number of priority elevations
9h	0h	0h	Count the number of EMIF_M_CLK clock cycles that a command was pending

(1) *n* = 1 or 2

Table 7-129. Performance Counter Filter Configuration (continued)

CNTR*n*_CFG[(1)]	CNTR*n*_REGION_EN	CNTR*n*_MSTID_EN	Event Selected for Counting
Ah	0h	0h	Count the number of EMIF_M_CLK cycles for which the SDRAM data bus was transferring data.
Bh	0h	0h	Count the number of SDRAM read bursts resulting from RMW and wRMW accesses
Ch	0h	0h	Count the number of SDRAM write bursts resulting from wRMW accesses
Dh-Fh	0h	0h	Reserved for future use.

NOTE: The EMIF performance counters cannot distinguish between single access and burst access. In both cases they are incremented by 1. If the actual SDRAM bandwidth of an initiator has to be measured the EMIF performance counters may not be sufficient.

7.2.4.11.1 Performance Counters General Examples

- **General Example for Counting Total Accesses made to EMIF**
  If the EMIF_PERF_CNT_2 register is used to count total accesses made to EMIF regardless of the address space or master the following steps should be performed:
  - To enable counting of all accesses to the SDRAM, the EMIF_PERF_CNT_CFG[19-16] CNTR2_CFG bit field must be set to 0h.
  - To disable filtering, both the EMIF_PERF_CNT_CFG[31] CNTR2_MSTID_EN and EMIF_PERF_CNT_CFG[30] CNTR2_REGION_EN bits must be set to 0h.

    With this configuration EMIF_PERF_CNT_2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.
- **General Example for Counting All Read Accesses made to EMIF**
  If the EMIF_PERF_CNT_1 register is used to count all read accesses made to EMIF from master with Master ID equal to 41 (that is, EDMA_0_TC0_R) to the SDRAM space the following steps should be performed:
  - To enable counting reads, the EMIF_PERF_CNT_CFG[3-0] CNTR1_CFG bit field must be set to 2h.
  - The EMIF_PERF_CNT_SEL[15-8] MSTID1 bit field must be set to 29h
  - The EMIF_PERF_CNT_SEL[3-0] REGION_SEL1 bit field must be set to 0h for SDRAM space.
  - To enable filtering, both the EMIF_PERF_CNT_CFG[15] CNTR1_MSTID_EN and the EMIF_PERF_CNT_CFG[14] CNTR1_REGION_EN bits must be set to 1h.

    With this configuration EMIF_PERF_CNT_1 counts every read made to the EMIF from master with ID 41 to the SDRAM space. This does not include accesses from other masters or to other address spaces (for example, EMIF configuration registers) and does not include commands other than reads.

7.2.4.12 Emulation Considerations

The EMIF controller remains fully functional during emulation halts to allow emulation access to external memory.

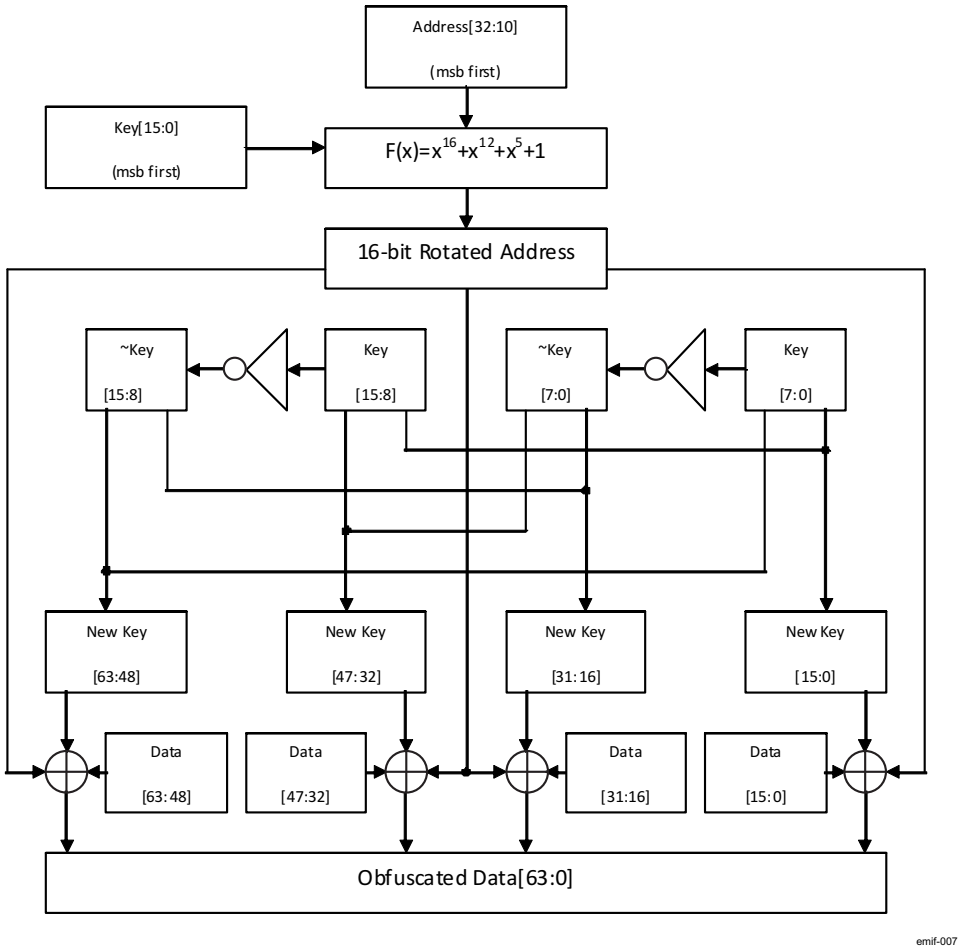
7.2.4.13 Data Bus Obfuscation

For security, the EMIF controller supports obfuscation for data written to the SDRAM. Data written to the EMIF configuration registers is not obfuscated.

NOTE: Obfuscation is available only on secure TI devices. Contact a TI sales office for additional information.

Figure 7-46 shows the obfuscation scheme.

Figure 7-46. Data Bus Obfuscation



Obfuscation is enabled by setting to 1 the OBFUSCATION_ENABLE bit inside the Security Manager. This causes the obfuscation key to be latched inside the controller. The 16-bit key should be programmed by software inside the Security Manager.

NOTE: Since the key is latched when obfuscation is enabled, the key should not be modified further.

The key is further modified to create a 64-bit new key. Data going out from the controller during writes is obfuscated and data coming back during reads is de-obfuscated. As seen from Figure 7-46, the obfuscation logic makes use of the upper address bits to ensure that obfuscation is different for different regions of memory.

Further, the data is also XORed with four copies of the 16-bit rotated address and the new key to ensure that obfuscation is also unique for each 1KB page of memory.

Enabling obfuscation does not increase the latency on command execution.

7.2.5 EMIF Registers

Table 7-131 lists the EMIF configuration registers and also the DDR_PHY configuration registers. All other register offset addresses not listed in Table 7-131 should be considered as reserved locations and the register contents should not be modified.

Table 7-130. EMIF and DDR_PHY Instances

Table 7-136. EMIF_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BE	R	0h	Indicates whether the EMIF is in big or little-endian mode. **NOTE: Only little-endian mode is supported on this device.**
30-29	RESERVED	R	0h	This field is tied off to 1h.
28	OBF_STAT	R	0h	Obfuscation Status. • 0 = Obfuscation disabled. • 1 = Obfuscation enabled.
27	SELF_REF	R	0h	Self refresh mode status. • 0 = SDRAM is not in self refresh mode. • 1 = SDRAM is in self refresh mode.
26	PWRDN	R	0h	Power down status. • 0 = SDRAM is not in power down mode. • 1 = SDRAM is in power down mode.
25-3	RESERVED	R	0h	Reserved. A value written to this field has no effect
2	IFRDY	R	0h	EMIF controller interface logic ready bit. The interface logic controls the signals used to communicate with DDR3 SDRAM devices. This bit displays the status of the interface logic. • 0 = Interface logic is not ready; either powered down, not ready, or not locked. • 1 = Interface logic is powered up, locked and ready for operation.
1-0	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

EMIF Registers • EMIF Registers: [0]

7.2.5.3 EMIF_SDCFG Register (Offset = 8h) [reset = 200h]

The SDRAM Configuration Register (EMIF_SDCFG) contains field that program the EMIF controller to meet the specifications of the DDR3 memory. These fields configure the EMIF controller to match the data bus width, CAS latency, number of internal banks, and page size of the external DDR3 memory.

Table 7-138. EMIF_SDCFG Instances

Instance	Physical Address

Table 7-139. EMIF_SDCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	SDRAM_TYPE	RW	0h	SDRAM type selection. Set to 3 for DDR3. All other values reserved.
28	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
27-25	DDR_TERM	RW	0h	Defines termination resistor value. • 0 = Disables termination • 1 = RZQ/4 • 2 = RZQ/2 • 3 = RZQ/6 • 4 = RZQ/12 • 5 = RZQ/8
24	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
23-22	DYN_ODT	RW	0h	Dynamic On-Die Termination • 0 = Turn off dynamic ODT. • 1 = RZQ/4 • 2 = RZQ/2 All other values reserved.
21-17	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

Table 7-139. EMIF_SDCFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16-14	CWL	RW	0h	CAS Write Latency. Lower value gives better performance. • 0 = CAS write latency of 5 • 1 = CAS write latency of 6 • 2 = CAS write latency of 7 • 3 = CAS write latency of 8 • 4 = CAS write latency of 9 • 5 = CAS write latency of 10 • 6 = CAS write latency of 11 • 7 = CAS write latency of 12
13-12	NM	RW	0h	DDR3 data bus width. • 1 = 32-bit bus width. • 2 = 16-bit bus width. All other values reserved.
11-8	CL	RW	2h	CAS Latency. The value of this field defines the CAS latency, to be used when accessing connected SDRAM devices. • 2 = CAS latency of 5. • 4 = CAS latency of 6. • 6 = CAS latency of 7. • 8 = CAS latency of 8. • 10 = CAS latency of 9. • 12 = CAS latency of 10. • 14 = CAS latency of 11. • 1 = CAS latency of 12. • 3 = CAS latency of 13. • 5 = CAS latency of 14. • 7 = CAS latency of 15. • 9 = CAS latency of 16. All other values are reserved.
7	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
6- 5	IBANK	RW	0h	Internal SDRAM bank setup bits. Defines number of banks inside connected SDRAM devices. Values 4-7 are reserved for this field. A word is equal to the bus width of the individual SDRAM devices used (example, 1 byte for x8 and 2bytes for x16 devices) • 0 = 1 bank SDRAM devices. • 1 = 2 bank SDRAM devices. • 2 = 4 bank SDRAM devices. • 3 = 8 bank SDRAM devices.
4	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
3	EBANK	RW	0h	External chip select setup. Defines whether SDRAM accesses use 1 or 2 chip select lines as follows: • 0 = Use DDR3_CEn0 for all SDRAM accesses. • 1 = Use DDR3_CEn0 and DDR3_CEn1 for SDRAM accesses.
2	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1-0	PAGESIZE	RW	0h	Page size bits. Defines internal page size of the external DDR3 memory. Values 4-7 are reserved for this field. A word is equal to the bus width of the individual SDRAM devices used (example, 1 byte for x8 and 2 bytes for x16 devices) • 0 = 256-word page requiring 8 column address bits. • 1 = 512-word page requiring 9 column address bits. • 2 = 1024-word page requiring 10 column address bits. • 3 = 2048-word page requiring 11 column address bits.

7.2.5.4 EMIF_SDRFC Register (Offset = 10h) [reset = 80000000h]

The SDRAM Refresh Control Register (EMIF_SDRFC) is used to configure the EMIF controller to:

- Enter and Exit the self-refresh state.
- Meet the refresh requirements of the attached SDRAM device by programming a rate at which the EMIF controller issues autorefresh commands.

The EMIF_SDRFC register is described in the following figure and table.

Table 7-141. EMIF_SDRFC Instances

Instance	Physical Address

7.2.5.5 EMIF_SDTIM1 Register (Offset = 18h) [reset = 3FFFFFFFh]

SDRAM Timing 1 register (EMIF_SDTIM1) configures the EMIF controller to meet many of the AC timing specifications of the DDR3 memory. Note that DDR3_CLKOUT is equal to the period of the DDR3_CLKOUT signal. See the DDR3 memory data sheet for information on appropriate values to program each field. The EMIF_SDTIM1 register is described in the following figure and table.

Table 7-144. EMIF_SDTIM1 Instances

Table 7-145. EMIF_SDTIM1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect
29-25	T_WR	RW	1Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from the last write transfer to a precharge command, minus 1. The value of this parameter can be derived from the t_{WR} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_WR = (t_{WR}/t_{CK}) - 1$
24-18	T_RAS	RW	7Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from an activate command to precharge command, minus 1. The value of this parameter can be derived from the minimum value of the t_{RAS} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_RAS = (t_{RAS}/t_{CK}) - 1$
17-10	T_RC	RW	FFh	These bits specify the minimum number of DDR3_CLKOUT cycles from an activate command to an activate command, minus 1. The value of this parameter can be derived from the t_{RC}AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_RC = (t_{RC}/t_{CK}) - 1$
9-4	T_RRD	RW	3Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from an activate to an activate in a different bank, minus 1. The value of this parameter can be derived from the t_{FAW} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_RRD = (t_{FAW}/(4*t_{CK})) - 1$

Table 7-145. EMIF_SDTIM1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	T_WTR	RW	Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from the last write to a read command, minus 1. The value of this parameter can be derived from the t_{WTR} AC timing parameter in the DDR3 memory data sheet. Convert the t_{WTR} value from the memory data sheet into ns before using the formula below. Calculate using the formula: $T\_WTR = (t_{WTR}/t_{CK}) - 1$

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Value = 0 Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
12-10	T_RTW	RW	7h	Minimum number of DDR3_CLKOUT cycles between read and write date phases, minus 1. This is not an SDRAM timing parameter. The value depends on the board topology supported. For single rank: reg_t_RTW= (((2*dqs_delay_for_cs0)+tDQSCK+ wr_leveling_tolerance)/clock_period)-1 For dual rank: reg_t_RTW= ((dqs_delay_for_cs0+dqs_delay_for_cs1+ absolute(command_delay_for_cs0- command_delay_for_cs1)+tDQSCK+ wr_leveling_tolerance)/clock_period)-1
9-5	T_RP	RW	1Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from a precharge command to a refresh or activate command, minus 1. The value of this parameter can be derived from the t_{RP} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_RP = (t_{RP}/t_{CK}) - 1$
4-0	T_RCD	RW	1Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from an activate command to a read or write command, minus 1. The value of this parameter can be derived from the t_{RCD} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_RCD = (t_{RCD}/t_{CK}) - 1$

Bit	Field	Type	Reset	Description
31-28	T_XP	RW	Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from Power down exit to any command other than a read command, minus 1. The value of this parameter can be derived from the t_{XP} AC timing parameter in the DDR3 memory data sheet. Convert the t_{XP} data sheet parameter value into ns before using the formula below. Calculate using the formula: $T\_XP = (t_{XP}/t_{CK}) - 1$
27-18	T_XSNR	RW	3FFh	These bits specify the minimum number of DDR3_CLKOUT cycles from a self-refresh exit to a command that does not require a locked DLL, minus 1. The value of this parameter can be derived from the t_{XS} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_XSNR = (t_{XS}/t_{CK}) - 1$
17-8	T_XSRD	RW	3FFh	These bits specify the minimum number of DDR3_CLKOUT cycles from a self-refresh exit to a command that requires a locked DLL, minus 1. The value of this parameter can be derived from the t_{XSDLL} AC timing parameter in the DDR3 memory data sheet. This parameter typically appears in the data sheet in terms of t_{CK} clock cycles. Calculate using the formula: $T\_XSRD = t_{XSDLL} - 1$
7-4	T_RTP	RW	Fh	These bits specify the minimum number of DDR3_CLKOUT cycles from the last read to precharge command, minus 1. The value of this parameter can be derived from the t_{RTP} AC timing parameter in the DDR3 memory data sheet. Convert the t_{XP} data sheet parameter value into ns before using formula below. Calculate using the formula: $T\_RTP = (t_{RTP}/t_{CK}) - 1$

Table 7-151. EMIF_SDTIM3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	T_CKE	RW	Fh	These bits specify the minimum number of DDR3_CLKOUT cycles between transitions on the DDR3_CKE pin, minus 1. The value of this parameter can be derived from the t_{CKE} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: $T\_CKE = (t_{CKE}/t_{CK}) - 1$

Table 7-154. EMIF_SDTIM4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	T_CSTA	RW	Fh	Minimum DDR3_CLKOUT cycles between write-to-write or read-to-read data phases to different chip selects, minus 1.
27-24	T_CKESR	RW	Fh	Value = 0 Minimum DDR3_CLKOUT cycles for which DDR3 should remain in self-refresh. This parameter typically appears as number of t_{CK} clock cycles. T_CKESR = (t_{CKESR}/t_{CK}) – 1
23-16	ZQ_ZQCS	RW	FFh	These bits specify the minimum number of DDR3_CLKOUT cycles for a ZQCS command, minus 1. The value of this parameter can be derived from the t_{ZQCS} AC timing parameter in the DDR3 memory data sheet. This parameter typically appears as number of t_{CK} clock cycles. Calculate using the formula : ZQ_ZQCS = t_{ZQCS} – 1
15-14	RESERVED	R	0h	Value = 0 Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13-4	T_RFC	RW	3FFh	These bits specify the minimum number of DDR3_CLKOUT cycles from a refresh or load mode command to a refresh or activate command, minus 1. The value of this parameter can be derived from the t_{RFC} AC timing parameter in the DDR3 memory data sheet. Calculate using the formula: T_RFC = (t_{RFC}/t_{CK}) – 1
3-0	T_RAS_MAX	RW	Fh	This field must always be programmed to Fh.

Set this value to 1 to issue a ZQCL command upon self-refresh exit.
27-19	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
18-16	ZQ_ZQCL_MULT	RW	0h	Number of ZQCS intervals that make up a ZQCL interval, minus one. ZQCS interval is defined by the EMIF_SDTIM4[23-16] ZQ_ZQCS field. The value of this parameter can be derived using the formula: T_ZQ_ZQCL_MULT = (t_{ZQoper}/t_{ZQCS} – 1)

Table 7-193. EMIF_ZQ_CONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-0	ZQ_REFINTERVAL	RW	0h	Number of refresh periods between ZQCS commands, minus one. This field supports between one refresh period to 256 ms between ZQCS calibration commands. Refresh period is defined by the EMIF_SDRFC[15-0] REFRESH_RATE field. ZQ_REFINTERVAL = number of refresh periods between ZQCS commands. The interval is calculated as = 0.5% / [(Tsens x Tdriftrate) + (Vsens x Vdriftrate)]. Tsens = max (dRTTdT, dRONdTM) from the memory device data sheet. Vsens = max(dRTTdV, dRONdVM) from the memory device data sheet Tdriftrate = drift rate in ^{o} C/second. This is the temperature drift rate that the SDRAM is subject to in the application. Vdriftrate = drift rate in mV/second. This is the voltage drift rate that the SDRAM is subject to in the application. Example: If Tsens= 1.5%/ ^{o} C, Vsens = 0.15%/mV, Tdriftrate = 1.2 ^{o} C/second and Vdriftrate = 10mV/second, Interval = 0.5/[(1.5 x 1.2) + (0.15 x 10)] = 152ms. Since refresh interval = 7.8µs, ZQ_REFINTERVAL = 152ms/7.8µs = 4C1Fh

Table 7-226. EMIF_ONE_BIT_ECC_ERR_ADDR_LOG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	1B_ECC_ERR_ADDR	RW	0h	1-bit ECC error address. Most significant bits of the starting address of the first two SDRAM bursts that had the 1-bit ECC error. This field displays the first address logged in the 2 deep address logging FIFO. Writing a 1h will pop one element of the FIFO. Writing a 2h will pop both the elements of the FIFO. Writing any other value has no effect..

Table 7-227. Register Call Summary for EMIF_ONE_BIT_ECC_ERR_ADDR_LOG

EMIF Functional Description • Logging 1-bit ECC Error Address: [0][1]

- EMIF Registers: [0]

7.2.5.35 DDR_PHY_PIR Register (Offset = 4h) [reset = 0h]

The PHY Initialization register is used to configure and control initialization of the DDR PHY. This includes the triggering of certain initialization routines, as well as reset of the PHY and/or the PLLs used in the PHY. Any DDR_PHY_PIR register bit used to trigger an initialization routine (bits 0 to 15) is self clearing and is set to 0 once the initialization is done. Any configuration register write that sets the DDR_PHY_PIR[INIT] register bit triggers initialization as selected by the other DDR_PHY_PIR register bits. The completion status of this initialization can be checked by polling the PHY General Status Register 0.

Table 7-235. DDR_PHY_PIR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	INITBYP	RW	0h	Initialization Bypass: Bypasses or stops, if set, all initialization routines currently running, including PHY initialization, DRAM initialization, and PHY training. Initialization may be triggered manually using INIT and the other relevant bits of the DDR_PHY_PIR register. This bit is self-clearing.
30	ZCALBYP	RW	0h	Impedance Calibration Bypass: Bypasses or stops, if set, impedance calibration of all ZQ control blocks that automatically triggers after reset. Impedance calibration may be triggered manually using INIT and ZCAL bits of the DDR_PHY_PIR register. This bit is self-clearing.
29	DCALBYP	RW	0h	Digital Delay Line (DDL) Calibration Bypass: Bypasses or stops, if set, DDL calibration that automatically triggers after reset. DDL calibration may be triggered manually using INIT and DCAL bits of the DDR_PHY_PIR register. This bit is self-clearing.
28	LOCKBYP	RW	0h	PLL Lock Bypass: Bypasses or stops, if set, the waiting of PLLs to lock. PLL lock wait is automatically triggered after reset. PLL lock wait may be triggered manually using INIT and PLLLOCK bits of the DDR_PHY_PIR register. This bit is self-clearing.

Table 7-235. DDR_PHY_PIR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	CLRSR	RW	0h	Clear Status Registers: A write of '1' to this bit will clear (reset to '0') all status registers, including PGSR and DXnGSR. The clear status register bit is self-clearing. Note, this bit does not clear the PGSR.IDONE bit. If the IDONE bit is set it remains at 1'b1 to indicate the PUB has competed its task. This bit is primarily for debug purposes and is typically not needed during normal functional operation. It can be used when PGSR.IDONE=1, to manually clear the PGSR status bits, although starting a new init process will automatically clear the PGSR status bits. Or it can be used to manually clear the DXnGSR status bits, although starting a new data training process will automatically clear the DXnGSR status bits.
26-19	RESERVED	R	0h	Returns zeros on reads.
18	CTLDINIT	RW	0h	Controller DRAM Initialization: Indicates if set that DRAM initialization will be performed by the controller. Otherwise if not set it indicates that DRAM initialization will be performed using the built-in initialization sequence or using software through the configuration port.
17	PLLBYP	RW	0h	PLL Bypass: A setting of 1 on this bit will put all PHY PLLs in bypass mode.
16	ICPC	RW	0h	Initialization Complete Pin Configuration: Specifies how the DFI initialization complete output pin (dfi_init_complete) should be used to indicate the status of initialization. Valid value are: • 0 = Asserted after PHY initialization (DLL locking and impedance calibration) is complete. • 1 = Asserted after PHY initialization is complete and the triggered the PUB initialization (DRAM initialization, data training, or initialization trigger with no selected initialization) is complete.
15	WREYE	RW	0h	Write Data Eye Training: Executes a PUB training routine to maximize the write data eye.
14	RDEYE	RW	0h	Read Data Eye Training: Executes a PUB training routine to maximize the read data eye.
13	WRDSKW	RW	0h	Write Data Bit Deskew: Executes a PUB training routine to deskew the DQ bits during write
12	RDDSKW	RW	0h	Read Data Bit Deskew: Executes a PUB training routine to deskew the DQ bits during read
11	WLADJ	RW	0h	Write Leveling Adjust (DDR3 Only): Executes a PUB training routine that readjusts the write latency used during write in case the write leveling routine changed the expected latency.
10	QSGATE	RW	0h	Read DQS Gate Training: Executes a PUB training routine to determine the optimum position of the read data DQS strobe for maximum system timing margins
9	WL	RW	0h	Write Leveling (DDR3 Only): Executes a PUB write leveling routine.
8	DRAMINIT	RW	0h	DRAM Initialization: Executes the DRAM initialization sequence
7	DRAMRST	RW	0h	DRAM Reset: Issues a reset to the DRAM (by driving the DRAM reset pin low) and wait 200us. This can be triggered in isolation or with the full DRAM initialization (DRAMINIT). For the later case, the reset is issued and 200us is waited before starting the full initialization sequence.
6	PHYRST	RW	0h	PHY Reset: Resets the AC and DATX8 modules by asserting the AC/DATX8 reset pin.
5	DCAL	RW	0h	Digital Delay Line (DDL) Calibration: Performs PHY delay line calibration.
4	PLLINIT	RW	0h	PLL Initialization: Executes the PLL initialization sequence which includes correct driving of PLL power-down, reset and gear shift pins, and then waiting for the PHY PLLs to lock.

Table 7-235. DDR_PHY_PIR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	RESERVED	R	0h	Returns zeros on reads
1	ZCAL	RW	0h	Impedance Calibration: Performs PHY impedance calibration. When set the impedance calibration will be performed in parallel with PHY initialization (PLL initialization + DDL calibration + PHY reset).
0	INIT	RW	0h	Initialization Trigger: A write of '1' to this bit triggers the DDR system initialization, including PHY initialization, DRAM initialization, and PHY training. The exact initialization steps to be executed are specified in bits 1 to 15 of this register. A bit setting of 1 means the step will be executed as part of the initialization sequence, while a setting of '0' means the step will be bypassed. The initialization trigger bit is self-clearing.

Table 7-238. DDR_PHY_PGCR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	CKEN	RW	2Ah	CK Enable: Controls whether the CK going to the SDRAM is enabled (toggling) or disabled (static value) and whether the CK is inverted. Two bits for each of the up to three CK pairs. Valid values for the two bits are: • 00 = CK disabled (Driven to constant 0) • 01 = CK toggling with inverted polarity • 10 = CK toggling with normal polarity (This should be the default setting) • 11 = CK disabled (Driven to constant 1) TI recommends that this field be always programmed to 101010b.
25-19	RESERVED	R	0h	Returns zeros on reads.

Table 7-238. DDR_PHY_PGCR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18-14	DTOSEL	RW	0h	Digital Test Output Select: Selects the PHY digital test output that should be driven onto PHY digital test output (phy_dto) pin: Valid values are: • 00000 = DATX8 0 PLL digital test output • 00001 = DATX8 1 PLL digital test output • 00010 = DATX8 2 PLL digital test output • 00011 = DATX8 3 PLL digital test output • 00100 = DATX8 4 PLL digital test output • 00101 = DATX8 5 PLL digital test output • 00110 = DATX8 6 PLL digital test output • 00111 = DATX8 7 PLL digital test output • 01000 = DATX8 8 PLL digital test output • 01001 = AC PLL digital test output • 01010 – 01111 = Reserved • 10000 = DATX8 0 delay line digital test output • 10001 = DATX8 1 delay line digital test output • 10010 = DATX8 2 delay line digital test output • 10011 = DATX8 3 delay line digital test output • 10100 = DATX8 4 delay line digital test output • 10101 = DATX8 5 delay line digital test output • 10110 = DATX8 6 delay line digital test output • 10111 = DATX8 7 delay line digital test output • 11000 = DATX8 8 delay line digital test output • 11001 = AC delay line digital test output • 11010 – 11111 = Reserved
13-12	OSCWDL	RW	3h	Oscillator Mode Write-Leveling Delay Line Select: Selects which of the two write leveling LCDLs is active. The delay select value of the inactive LCDL is set to zero while the delay select value of the active LCDL can be varied by the input write leveling delay select pin. Valid values are: • 00 = No WL LCDL is active • 01 = DDR WL LCDL is active • 10 = SDR WL LCDL is active • 11 = Both LCDLs are active
11-9	OSCDIV	RW	7h	Oscillator Mode Division: Specifies the factor by which the delay line oscillator mode output is divided down before it is output on the delay line digital test output pin dl_dto. Valid values are: • 000 = Divide by 1 • 001 = Divide by 256 • 010 = Divide by 512 • 011 = Divide by 1024 • 100 = Divide by 2048 • 101 = Divide by 4096 • 110 = Divide by 8192 • 111 = Divide by 65536
8	OSCEN	RW	0h	Oscillator Enable: Enables, if set, the delay line oscillation.
7	DLTST	RW	0h	Delay Line Test Start: A write of '1' to this bit will trigger delay line oscillator mode period measurement. This bit is not self clearing and needs to be reset to '0' before the measurement can be re-triggered.
6	DLTMODE	RW	0h	Delay Line Test Mode: Selects, if set, the delay line oscillator test mode.
5	RDBVT	RW	1h	Read Data BDL VT Compensation: Enables, if set the VT drift compensation of the read data bit delay lines
4	WDBVT	RW	1h	Write Data BDL VT Compensation: Enables, if set the VT drift compensation of the write data bit delay lines.

Table 7-238. DDR_PHY_PGCR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RGLVT	RW	1h	Read DQS Gating LCDL Delay VT Compensation: Enables, if set the VT drift compensation of the read DQS gating LCDL
2	RDLVT	RW	1h	Read DQS LCDL Delay VT Compensation: Enables, if set the VT drift compensation of the read DQS LCDL.
1	WDLVT	RW	1h	Write DQ LCDL Delay VT Compensation: Enables, if set the VT drift compensation of the write DQ LCDL.
0	WLLVT	RW	1h	Write Leveling LCDL Delay VT Compensation: Enables, if set, the VT drift compensation of the write leveling LCDL

Table 7-241. DDR_PHY_PGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	LBMODE	RW	0h	Loopback Mode: Indicates, if set, that the PHY/PUB is in loopback mode
30-29	LBGDQS	RW	0h	Loopback DQS Gating: Selects the DQS gating mode that should be used when the PHY is in loopback mode, including BIST loopback mode. Valid values are: • 00 = DQS gate is always on • 01 = DQS gate training will be triggered on the PUB • 10 = DQS gate is set manually using software • 11 = Reserved
28	LBDQSS	RW	0h	Loopback DQS Shift: Selects how the read DQS is shifted during loopback to ensure that the read DQS is centered into the read data eye. Valid values are: • 0 = PUB sets the read DQS LCDL to 0; DQS is already shifted 90 degrees by write path • 1 = The read DQS shift is set manually through software
27	IOLB	RW	0h	I/O Loop-Back Select: Selects where inside the I/O the loop-back of signals happens. Valid values are: • 0 = Loopback is after output buffer; output enable must be asserted • 1 = Loopback is before output buffer; output enable is don't care
26	INHVT	RW	0h	VT Calculation Inhibit: Inhibits calculation of the next VT compensated delay line values. A value of 1 will inhibit the VT calculation. This bit should be set to 1 during writes to the delay line registers. This bit should NOT be set to 1 until after PHY initialization completes

Table 7-241. DDR_PHY_PGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	PHYHRST	RW	1h	PHY High-Speed Reset: A write of '0' to this bit resets the AC and DATX8 macros without resetting PUB RTL logic. This bit is not self-clearing and a '1' must be written to de-assert the reset
24-23	ZCKSEL	RW	2h	Impedance Clock Divider Select: Selects the divide ratio for the clock used by the impedance control logic relative to the clock used by the memory controller and SDRAM. Valid values are: • 00 = Divide by 2 • 01 = Divide by 8 • 10 = Divide by 32 • 11 = Divide by 64 TI recommends that this field be always programmed to 01b.
22-15	DLDLMT	RW	1h	Delay Line VT Drift Limit: Specifies the minimum change in the delay line VT drift in one direction which should result in the assertion of the delay line VT drift status signal (vt_drift). The limit is specified in terms of delay select values. A value of 0 disables the assertion of delay line VT drift status signal.
14-13	FDEPTH	RW	2h	Filter Depth: Specifies the number of measurements over which all AC and DATX8 initial period measurements, that happen after reset or when calibration is manually triggered, are averaged. Valid values are: • 00 = 2 • 01 = 4 • 10 = 8 • 11 = 16
12-11	LPFDEPTH	RW	0h	Low-Pass Filter Depth: Specifies the number of measurements over which MDL period measurements are filtered. This determines the time constant of the low pass filter. Valid values are: • 00 = 2 • 01 = 4 • 10 = 8 • 11 = 16
10	LPFEN	RW	1h	Low-Pass Filter Enable: Enables, if set, the low pass filtering of MDL period measurements.
9	MDLEN	RW	0h	Master Delay Line Enable: Enables, if set, the AC master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or on when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high.
8-7	IODDRM	RW	0h	This field should be programmed to 1h if using DDR3 and 2h if using DDR3L. • 1 = DDR3 • 2 = DDR3L
6	WLSELT	RW	1h	Write Leveling Select Type: Selects the encoding type for the write leveling select signal depending on the desired setup/hold margins for the internal pipelines. Valid values are: • 0 = Setup margin of 90 degrees and hold margin of 90 degrees • 1 = Setup margin of 135 degrees and hold margin of 45 degrees
5-3	RESERVED	R	4h	Return zeros on reads.
2	WLSTEP	RW	0h	Write Leveling Step: Specifies the number of delay step-size increments during each step of write leveling. Valid values are: • 0 = 32 step sizes • 1 = 1 step size

Table 7-241. DDR_PHY_PGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	WLMODE	RW	0h	Write Leveling (Software) Mode: Indicates if set that the PHY is in software write leveling mode in which software executes single steps of DQS pulsing by writing '1' to DDR_PHY_PIR.WL. The write leveling DQ status from the DRAM is captured in DXnGSR0.WLDQ
0	PDDISDX	RW	1h	Power Down Disabled Byte: Indicates if set that the PLL and I/Os of a disabled byte should be powered down

Table 7-244. DDR_PHY_PGCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	DYNACPDD	RW	0h	Dynamic AC Power Down Driver: Powers down, when set, the output driver on I/O for the address and bank address lines
30-28	RESERVED	R	0h	These bits should be always programmed to 0.
27-20	DTPMXTMR	RW	Fh	Data Training PUB Mode Timer Exit: Specifies the number of controller clocks to wait when entering and exiting pub mode data training. The default value ensures controller refreshes do not cause memory model errors when entering and exiting data training. The value should be increased if controller initiated SDRAM ZQ short or long operation may occur just before or just after the execution of data training.
19	FXDLAT	RW	0h	Fixed Latency: Specified whether all reads should be returned to the controller with a fixed read latency. Enabling fixed read latency increases the read latency. Valid values are: • 0 = Disable fixed read latency • 1 = Enable fixed read latency Fixed read latency is calculated as (12 + (maximum DXnGTR.RxDGSL)/2) half data rate clock cycles.
18	NOBUB	RW	0h	No Bubbles: Specified whether reads should be returned to the controller with no bubbles. Enabling no-bubble reads increases the read latency. Valid values are: • 0 = Bubbles are allowed during reads • 1 = Bubbles are not allowed during reads

Table 7-244. DDR_PHY_PGCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17-0	TREFPRD	RW	12480h	Refresh Period: Indicates the period in clock cycles after which the PUB has to issue a refresh command to the SDRAM. This is derived from the maximum refresh interval from the data sheet, tRFC(max) or REFI, divided by the clock cycle time. A further 400 clocks must be subtracted from the derived number to account for command flow and missed slots of refreshes in the internal PUB blocks. The default corresponds to DDR3 9*7.8us at 1066MHz (DDR3-2133) when a burst of 9 refreshes are issued at every refresh interval. TI recommends tREFPRD be programmed to 5*tREFI.

Table 7-247. DDR_PHY_PGSR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	APLOCK	R	0h	AC PLL Lock: Indicates, if set, that AC PLL has locked. This is a direct status of the AC PLL lock pin
30-28	RESERVED	R	0h	Returns zeros on reads.
27	WEERR	R	0h	Write Eye Training Error: Indicates if set that there is an error in write eye training.
26	REERR	R	0h	Read Eye Training Error: Indicates if set that there is an error in read eye training
25	WDERR	R	0h	Write Bit Deskew Error: Indicates if set that there is an error in write bit deskew
24	RDERR	R	0h	Read Bit Deskew Error: Indicates if set that there is an error in read bit deskew
23	WLAERR	R	0h	Write Leveling Adjustment Error: Indicates if set that there is an error in write leveling adjustment
22	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training.
21	WLERR	R	0h	Write Leveling Error: Indicates if set that there is an error in write leveling.
20	ZCERR	R	0h	Impedance Calibration Error: Indicates if set that there is an error in impedance calibration.
19-12	RESERVED	R	0h	Returns zeros on reads.
11	WEDONE	R	0h	Write Eye Training Done: Indicates if set that write eye training has completed
10	REDONE	R	0h	Read Eye Training Done: Indicates if set that read eye training has completed
9	WDDONE	R	0h	Write Bit Deskew Done: Indicates if set that write bit deskew has completed.

Table 7-247. DDR_PHY_PGSR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	RDDONE	R	0h	Read Bit Deskew Done: Indicates if set that read bit deskew has completed
7	WLADONE	R	0h	Write Leveling Adjustment Done: Indicates if set that write leveling adjustment has completed
6	QSGDONE	R	0h	DQS Gate Training Done: Indicates if set that DQS gate training has completed.
5	WLDONE	R	0h	Write Leveling Done: Indicates if set that write leveling has completed.
4	DIDONE	R	0h	DRAM Initialization Done: Indicates if set that DRAM initialization has completed
3	ZCDONE	R	0h	Impedance Calibration Done: Indicates if set that impedance calibration has completed
2	DCDONE	R	0h	Digital Delay Line (DDL) Calibration Done: Indicates if set that DDL calibration has completed
1	PLDONE	R	0h	PLL Lock Done: Indicates if set that PLL locking has completed.
0	IDONE	R	0h	Initialization Done: Indicates if set that the DDR system initialization has completed. This bit is set after all the selected initialization routines in DDR_PHY_PIR register have completed.

7.2.5.42 DDR_PHY_PTR0 Register (Offset = 1Ch) [reset = 42C21582h]

PHY Timing Registers are used to program different timing parameters used by the PHY logic. All the default values shown in these tables are in decimal format and correspond to the DDR3-2133N speed grade. This corresponds to DRAM bit rate of 2133Mbps, DRAM clock frequency of 1066MHz, controller clock frequency of 533MHz, and configuration clock frequency of 533MHz. Configure these parameters assuming controller and configuration clocks of 533MHz. The clocks in which the timing numbers are measured are specified in the description of each parameter.

Table 7-256. DDR_PHY_PTR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-21	TPLLPD	RW	216h	PLL Power-Down Time: Number of VBUSP_CLK cycles that the PLL must remain in power-down mode, that is, number of clock cycles from when PLL power-down pin is asserted to when PLL power-down pin is de-asserted. This must correspond to a value that is equal to or more than 1us. Default value corresponds to 1us.
20-6	TPLLGS	RW	856h	PLL Gear Shift Time: Number of VBUSP_CLK cycles from when the PLL reset pin is de-asserted to when the PLL gear shift pin is de-asserted. This must correspond to a value that is equal to or more than 4us. Default value corresponds to 4us.
5-0	TPHYRST	RW	2h	PHY Reset Time: Number of VBUSP_CLK cycles that the PHY reset must remain asserted after PHY calibration is done before the reset to the PHY is de-asserted. This is used to extend the reset to the PHY so that the reset is asserted for some clock cycles after the clocks are stable. TI recommends setting this to 15.

23	DYNDXPDR	RW	0h	Data Power Down Receiver: Dynamically powers down, when set, the input receiver on I/O for the DQ pins of the active DATX8 macros. Applies only when DXPDR and DXnGCR.DXPDR are not set to 1.
22	DYNDXPDD	RW	0h	Dynamic Data Power Down Driver: Dynamically powers down, when set, the output driver on I/O for the DQ pins of the active DATX8 macros. Applies only when DXPDD and DXnGCR.DXPDD are not set to 1.
21	UDQIOM	RW	0h	Unused DQ I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for unused DQ pins.
20	UDQPDR	RW	1h	Unused DQ Power Down Receiver: Powers down, when set, the input receiver on the I/O for unused DQ pins.
19	UDQPDD	RW	1h	Unused DQ Power Down Driver: Powers down, when set, the output driver on the I/O for unused DQ pins.
18	UDQODT	RW	0h	Unused DQ On-Die Termination: Enables, when set, the on-die termination on the I/O for unused DQ pins.
17-15	MSBUDQ	RW	0h	Most Significant Byte Unused DQs: Specifies the number of DQ bits that are not used in the most significant byte. The used (valid) bits for this byte are [8-MSBDQ- 1:0]. To disable the whole byte, use the DXnGCR.DXEN register.

Table 7-274. DDR_PHY_DXCCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14-13	DXSR	RW	0h	Data Slew Rate: Selects slew rate of the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. 00 = very fast (use as default for DDR3 and DDR3L) 01 = fast 10 = medium 11 = slow
12-9	DQSNRES	RW	Ch	DQS# Resistor: Selects the on-die pull-up/pull-down resistor for DQS# pins. Same encoding as DQSRES.
8-5	DQSRES	RW	4h	DQS Resistor: Selects the on-die pull-down/pull-up resistor for DQS pins. DQSRES[3] selects pull-down (when set to 0) or pull-up (when set to 1). DQSRES[2:0] selects the resistor value as follows: 000 = Open: On-die resistor disconnected (use external resistor) 001 = 688 ohms 010 = 611 ohms 011 = 550 ohms 100 = 500 ohms 101 = 458 ohms 110 = 393 ohms 111 = 344 ohms
4	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the PDR configuration bit of the individual DATX8.
3	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ,DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the PDD configuration bit of the individual DATX8.
2	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, all DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or on when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the MDLEN bit in the individual DATX8
1	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the IOM configuration bit of the individual DATX8.
0	DXODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the ODT configuration bit of the individual DATX8

Table 7-277. DDR_PHY_DCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reads return zeros.
29	UDIMM	RW	0h	Un-buffered DIMM Address Mirroring: Indicates if set that there is address mirroring on the second rank of an un-buffered DIMM (the rank connected to CS1). DDR_PHY_DCR[NOSRA] must be set if address mirroring is enabled.
28	RESERVED	R	0h	Reads return zeros.
27	NOSRA	RW	0h	No Simultaneous Rank Access: Specifies if set that simultaneous rank access on the same clock cycle is not allowed. This means that multiple chip select signals will not be asserted at the same time. This bit must be set if address mirroring is enabled in DDR_PHY_DCR[UDIMM]. NOSRA should be set to 0 if address mirroring is enabled (for example, DDR_PHY_DCR[UDIMM]=1).
26-18	RESERVED	R	0h	Reads return zeros.
17-10	BYTEMASK	RW	1h	Byte Mask: Mask applied to all beats of read data on all bytes lanes during read DQS gate training. This allows training to be conducted based on selected bit(s) from the byte lanes. Valid values for each bit are: • 0 = Disable compare for that bit • 1 = Enable compare for that bit Note that this mask in DDR3 MPR operation mode as well and must be in keeping with the PDQ field setting. TI recommends that this field be always programmed to 0000 0001b.
9-8	RESERVED	R	0h	Reads return zeros.

Table 7-277. DDR_PHY_DCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	MPRDQ	RW	0h	Multi-Purpose Register (MPR) DQ (DDR3 Only): Specifies the value that is driven on non-primary DQ pins during MPR reads. Valid values are: • 0 = Primary DQ drives out the data from MPR (0-1-0-1); non-primary DQs drive '0' • 1 = Primary DQ and non-primary DQs all drive the same data from MPR (0-1-0-1) TI recommends that this bit be always programmed to 0.
6-4	PDQ	RW	0h	Primary DQ (DDR3 Only): Specifies the DQ pin in a byte that is designated as a primary pin for Multi-Purpose Register (MPR) reads. Valid values are 0 to 7 for DQ[0] to DQ[7], respectively. TI recommends that this field be always programmed to 000b.
3	DDR8BNK	RW	1h	DDR 8-Bank: Indicates if set that the SDRAM used has 8 banks.
2-0	DDRMD	RW	3h	DDR Mode: Set to 3h for DDR3 mode.

Table 7-280. DDR_PHY_DTPR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	TRC	RW	32h	Activate to activate command delay (same bank). Valid values are 2 to 63
25-22	TRRD	RW	7h	Activate to activate command delay (different banks). Valid values are 1 to 15.
21-16	TRAS	RW	24h	Activate to precharge command delay. Valid values are 2 to 63
15-12	TRCD	RW	Eh	Activate to read or write delay. Minimum time from when an activate command is issued to when a read or write to the activated row can be issued. Valid values are 2 to 15.
11-8	TRP	RW	Eh	Precharge command period: The minimum time between a precharge command and any other command. Valid values are 2 to 15.
7-4	TWTR	RW	8h	Internal write to read command delay. Valid values are 1 to 15.
3-0	TRTP	RW	8h	Internal read to precharge command delay. Valid values are 2 to 15.

Table 7-283. DDR_PHY_DTPR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29-26	TWLO	RW	8h	Write leveling output delay: Number of clock cycles from when write leveling DQS is driven high by the PHY to when the results from the SDRAM on DQ is sampled by the PHY. This must include the SDRAM tWLO timing parameter plus the round trip delay from the DUT to SDRAM back to the DUT. TI recommends that this field always be programmed to 12 decimal.
25-20	TWLMRD	RW	28h	Minimum delay from when write leveling mode is programmed to the first DQS/DQS# rising edge
19-11	TRFC	RW	176h	Refresh-to-Refresh: Indicates the minimum time, in clock cycles, between two refresh commands or between a refresh and an active command. This is derived from the minimum refresh interval from the data sheet, tRFC(min), divided by the clock cycle time.
10-5	TFAW	RW	26h	4-bank activate period. No more than 4-bank activate commands may be issued in a given tFAW period. Valid values are 2 to 63.
4-2	TMOD	RW	4h	Load mode update delay. The minimum time between a load mode register command and a non-load mode register command. Valid values are: • 000 = 12 • 001 = 13 • 010 = 14 • 011 = 15 • 100 = 16 • 101 = 17 • 110 – 111 = Reserved

Table 7-283. DDR_PHY_DTPR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	TMRD	RW	2h	Load mode cycle time: The minimum time between a load mode register command and any other command. For DDR3 this is the minimum time between two load mode register commands. the value used for tMRD is 4 plus the value programmed in these bits, that is, tMRD ranges from 4 to 7.

Table 7-284. Register Call Summary for DDR_PHY_DTPR1

Table 7-286. DDR_PHY_DTPR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TCCD	RW	0h	Read to read and write to write command delay. Valid values are: • 0 = 4 DRAM clock cycles • 1 = 5 DRAM clock cycles
30	TRTW	RW	0h	Read to Write command delay. This parameter is only used when the PHY issues commands during initialization and leveling. During normal operation, the controller issues commands to the SDRAM and uses the timing parameters programmed in the controller. TI recommends that this bit be always set to 1 to provide additional margin during PHY initiated initialization/leveling.
29	TRTODT	RW	0h	Read to ODT delay. This parameter is only used when the PHY issues commands during initialization and leveling. During normal operation, the controller issues commands to the SDRAM and uses the timing parameters programmed in the controller. TI recommends that this bit be always set to 0.
28-19	TDLLK	RW	200h	DLL locking time. Valid values are 2 to 1023.
18-15	TCKE	RW	6h	CKE minimum pulse width. Also specifies the minimum time that the SDRAM must remain in power down or self refresh mode. This parameter must be set to the value of tCKESR which is usually bigger than the value of tCKE. Valid values are 2 to 15.
14-10	TXP	RW	1Ah	Power down exit delay. The minimum time between a power down exit command and any other command. This parameter must be set to the maximum of the various minimum power down exit delay parameters specified in the SDRAM data sheet, that is, max(tXP, tXPDLL). Valid values are 2 to 31.

Table 7-286. DDR_PHY_DTPR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-0	TXS	RW	200h	Self refresh exit delay. The minimum time between a self refresh exit command and any other command. This parameter must be set to the maximum of the various minimum self refresh exit delay parameters specified in the SDRAM data sheet, that is, (tXS, tXSDLL) for DDR3. Valid values are 2 to 1023.

Table 7-289. DDR_PHY_MR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Returns zeros on reads. Bits [15-13] are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’.
12	PD	RW	0h	Power-Down Control: Controls the exit time for power-down modes. This must always be set to 1.
11-9	WR	RW	5h	Write Recovery: This is the value of the write recovery in clock cycles. It is calculated by dividing the data sheet write recovery time, tWR (ns) by the data sheet clock cycle time, tCK (ns) and rounding up a non-integer value to the next integer. Valid values are: • 001 = 5 • 010 = 6 • 011 = 7 • 100 = 8 • 101 = 10 • 110 = 12 • 111 = 14 • 000 = 16 All other settings are reserved and should not be used.
8	DR	RW	0h	DLL Reset: Writing a ‘1’ to this bit will reset the SDRAM DLL. This bit is self-clearing, that is, it returns back to ‘0’ after the DLL reset has been issued.
7	TM	RW	0h	Operating Mode: Always set to 0 for normal operating mode.

Table 7-289. DDR_PHY_MR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6-4	CL_UP	RW	5h	**NOTE: bit [2] of this register is also part of the CL field.** CAS Latency: The delay, in clock cycles, between SDRAM read command to data available. Valid values are: • 0010 = 5 • 0100 = 6 • 0110 = 7 • 1000 = 8 • 1010 = 9 • 1100 = 10 • 1110 = 11 • 0001 = 12 • 0011 = 13 • 0101 = 14 All other settings are reserved and should not be used.
3	BT	RW	0h	Burst type: Set to 0 for sequential burst (interleaved burst is not supported)
2	CL_LOW	RW	0h	This is the least significant bit of the CL field. For description, see bits [6-4].
1-0	BL	RW	3h	Burst Length: Determines the maximum number of column locations that can be accessed during a given read or write command. Set to 0 for a fixed burst length of 8 (other burst lengths are not supported)

Table 7-292. DDR_PHY_MR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Returns zeros on reads. Bits [15-13] are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’.
12	QOFF	RW	0h	Output Enable/Disable: Program to ‘0’ for all outputs to function as normal.
11	TDQS	RW	0h	Termination Data Strobe: This must always be set to 0.
10	RESERVED	R	0h	Reserved. This is a JEDEC reserved bit for DDR3 and is recommended by JEDEC to be programmed to ‘0’.
9	RTT_UP	RW	0h	On Die Termination: Selects the effective resistance for SDRAM on die termination. Valid values are: • 000 = ODT disabled • 001 = RZQ/4 • 010 = RZQ/2 • 011 = RZQ/6 • 100 = RZQ/12 • 101 = RZQ/8 All other settings are reserved and should not be used **NOTE: This bit is used together with bit [6] and bit [2] of this register.**
8	RESERVED	R	0h	Reserved. This is a JEDEC reserved bit for DDR3 and is recommended by JEDEC to be programmed to ‘0’.
7	LEVEL	RW	0h	Write Leveling Enable: Enables write-leveling when set.

Table 7-292. DDR_PHY_MR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	RTT_MID	RW	0h	On Die Termination: Selects the effective resistance for SDRAM on die termination. Valid values are: • 000 = ODT disabled • 001 = RZQ/4 • 010 = RZQ/2 • 011 = RZQ/6 • 100 = RZQ/12 • 101 = RZQ/8 All other settings are reserved and should not be used **NOTE: This bit is used together with bit [9] and bit [2] of this register.**
5	DIC_UP	RW	0h	Output Driver Impedance Control: Controls the output drive strength. Valid values are: • 00 = Reserved for RZQ/6 • 01 = RZQ7 • 10 = Reserved • 11 = Reserved **NOTE: This bit is used together with bit [1] of this register.**
4-3	AL	RW	0h	Posted CAS Additive Latency: the controller does not support this feature. This must always be set to 0.
2	RTT_LOW	RW	0h	On Die Termination: Selects the effective resistance for SDRAM on die termination. Valid values are: • 000 = ODT disabled • 001 = RZQ/4 • 010 = RZQ/2 • 011 = RZQ/6 • 100 = RZQ/12 • 101 = RZQ/8 All other settings are reserved and should not be used **NOTE: This bit is used together with bit [9] and bit [6] of this register.**
1	DIC_LOW	RW	0h	Output Driver Impedance Control: Controls the output drive strength. Valid values are: • 00 = Reserved for RZQ/6 • 01 = RZQ7 • 10 = Reserved • 11 = Reserved **NOTE: This bit is used together with bit [5] of this register.**
0	DE	RW	0h	DLL Enable/Disable: Enable (0) or disable (1) the DLL. DLL must be enabled for normal operation.

Table 7-295. DDR_PHY_MR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	Returns zeros on reads. Bits [15-11] are JEDEC reserved bits and are recommended by JEDEC to be programmed to '0'.
10-9	RTTWR	RW	0h	Dynamic ODT: Selects RTT for dynamic ODT. Valid values are: • 00 = Dynamic ODT off • 01 = RZQ/4 • 10 = RZQ/2 • 11 = Reserved
8	RESERVED	R	0h	These are JEDEC reserved bits and are recommended by JEDEC to be programmed to '0'.
7	SRT	RW	0h	Self-Refresh Temperature Range: Selects either normal ('0') or extended ('1') operating temperature range during self-refresh.
6	ASR	RW	0h	Auto Self-Refresh: When enabled ('1'), SDRAM automatically provides self-refresh power management functions for all supported operating temperature values. Otherwise the SRT bit must be programmed to indicate the temperature range.
5-3	CWL	RW	0h	CAS Write Latency: The delay, in clock cycles, between when the SDRAM registers a write command to when write data is available. Valid values are: • 000 = 5 (tCK > 2.5ns) • 001 = 6 (2.5ns > tCK > 1.875ns) • 010 = 7 (1.875ns > tCK> 1.5ns) • 011 = 8 (1.5ns > tCK > 1.25ns) • 100 = 9 (1.25ns > tCK > 1.07ns) • 101 = 10 (1.07ns > tCK > 0.935ns) • 110 = 11 (0.935ns > tCK > 0.833ns) • 111 = 12 (0.833ns > tCK > 0.75ns) All other settings are reserved and should not be used

Table 7-295. DDR_PHY_MR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	PASR	RW	0h	Partial Array Self Refresh: Specifies that data located in areas of the array beyond the specified location will be lost if self refresh is entered. • 000 = Full Array • 001 = Half Array (BA[2:0] = 000, 001, 010 & 011) • 010 = Quarter Array (BA[2:0] = 000, 001) • 011 = 1/8 Array (BA[2:0] = 000) • 100 = 3/4 Array (BA[2:0] = 010, 011, 100, 101, 110 & 111) • 101 = Half Array (BA[2:0] = 100, 101, 110 & 111) • 110 = Quarter Array (BA[2:0] = 110 & 111) • 111 = 1/8 Array (BA[2:0] 111)

7.2.5.57 DDR_PHY_ODTCR Register (Offset = 64h) [reset = 84210000h]

This register configures how ODT should be controlled on the different ranks when writing or reading a particular rank. This provides full flexibility on how the overall termination of the SDRAM system is set depending on how many ranks are used and whether the DIMM slots are occupied or not.

For example, assume the system is a 2-rank configuration and during Read commands the user wishes to always enable the ODT on the SDRAM which is not providing the Read data. In this case, the user would write “0010” to RDODT0 and “0001” to RDODT1.

Table 7-301. DDR_PHY_ODTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	WRODT3	RW	8h	Write ODT: Specifies whether ODT should be enabled (‘1’) or disabled (‘0’) on each of the up to four ranks when a write command is sent to rank n. WRODT0, WRODT1, WRODT2, and WRODT3 specify ODT settings when a write is to rank 0, rank 1, rank 2, and rank 3, respectively. The four bits of each field each represent a rank, the LSB being rank 0 and the MSB being rank 3. Default is to enable ODT only on rank being written to
27-24	WRODT2	RW	4h	See description for WRODT3.
23-20	WRODT1	RW	2h	See description for WRODT3.
19-16	WRODT0	RW	1h	See description for WRODT3.
15-12	RDODT3	RW	0h	Read ODT: Specifies whether ODT should be enabled (‘1’) or disabled (‘0’) on each of the up to four ranks when a read command is sent to rank n. RDODT0, RDODT1, RDODT2, and RDODT3 specify ODT settings when a read is to rank 0, rank 1, rank 2, and rank 3, respectively. The four bits of each field each represent a rank, the LSB being rank 0 and the MSB being rank 3. Default is to disable ODT during reads.
11-8	RDODT2	RW	0h	See description for RDODT3.
7-4	RDODT1	RW	0h	See description for RDODT3.
3-0	RDODT0	RW	0h	See description for RDODT3.

Table 7-304. DDR_PHY_DTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RFSHDT	RW	9h	Refresh During Training: A non-zero value specifies that a burst of refreshes equal to the number specified in this field should be sent to the SDRAM after training each rank except the last rank
27-24	RANKEN	RW	Fh	Rank Enable: Specifies the ranks that are enabled for data-training. Bit 0 controls rank 0, bit 1 controls rank 1, bit 2 controls rank 2, and bit 3 controls rank 3. Setting the bit to '1' enables the rank, and setting it to '0' disables the rank.
23	RESERVED	R	0h	
22	DTEXD	RW	0h	Data Training Extended Write DQS: Enables, if set, an extended write DQS whereby two additional pulses of DQS are added as post-amble to a burst of writes. Generally this should only be enabled when running read bit deskew with the intention of performing read eye deskew prior to running write leveling adjustment
21	DTDSTP	RW	0h	Data Training Debug Step: A write of 1 to this bit steps the data training algorithm through a single step. This bit is self-clearing
20	DTDEN	RW	0h	Data Training Debug Enable: Enables, if set, the data training debug mode
19-16	DTDBS	RW	0h	Data Training Debug Byte Select: Selects the byte during data training debug mod
15-14	RESERVED	R	0h	Returns zeros on reads.
13	DTBDC	RW	1h	Data Training Bit Deskew Centering: Enables, if set, eye centering capability during write and read bit deskew training.
12	DTWBDDM	RW	1h	Data Training Write Bit Deskew Data Mask. If set it enables write bit deskew of the data mask
11-8	DTWDQM	RW	5h	Training WDQ Margin: Defines how close to 0 or how close to 2*(wdq calibration_value) the WDQ lcdl can be moved during training. Basically defines how much timing margin.

Table 7-304. DDR_PHY_DTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	DTCMPD	RW	1h	Data Training Compare Data: Specifies, if set, that DQS gate training should also check if the returning read data is correct. Otherwise data-training only checks if the correct number of DQS edges were returned.
6	DTMPR	RW	0h	Data Training Using MPR (DDR3 Only): Specifies, if set, that DQS gate training should use the SDRAM Multi-Purpose Register (MPR) register. Otherwise data training is performed by first writing to some locations in the SDRAM and then reading them back.
5-4	DTRANK	RW	0h	Data Training Rank: Selects the SDRAM rank to be used during data bit deskew and eye centering
3-0	DTRPTN	RW	7h	Data Training Repeat Number: Repeat number used to confirm stability of DDR write or read

Table 7-307. DDR_PHY_ZQ0CR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ZQPD	RW	0h	ZQ Power Down: Powers down, if set, the impedance control block.
30	ZCALEN	RW	1h	Impedance Calibration Enable: Enables if set the impedance calibration of the ZQn control block when impedance calibration is triggered using either the ZCAL bit of DDR_PHY_PIR register or the DFI update interface.
29	ZCALBYP	RW	0h	Impedance Calibration Bypass: Bypasses, if set, impedance calibration of the ZQn control block when impedance calibration is already in progress. Impedance calibration can be disabled prior to trigger by using the ZCALEN bit.
28	ZDEN	RW	0h	Impedance Over-ride Enable: When this bit is set, it allows users to directly drive the impedance control using the data programmed in the ZDATA field. Otherwise, the control is generated automatically by the impedance control logic
27-0	ZDATA	RW	014Ah	Impedance Over-Ride Data: Data used to directly drive the impedance control. ZDATA field mapping is as follows: • ZDATA[27:21] is used to select the pull-up on-die termination impedance • ZDATA[20:14] is used to select the pull-down on-die termination impedance • ZDATA[13:7] is used to select the pull-up output impedance • ZDATA[6:0] is used to select the pull-down output impedance

Table 7-331. DDR_PHY_ZQ2CR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ZQPD	RW	0h	ZQ Power Down: Powers down, if set, the impedance control block.
30	ZCALEN	RW	1h	Impedance Calibration Enable: Enables if set the impedance calibration of the ZQn control block when impedance calibration is triggered using either the ZCAL bit of DDR_PHY_PIR register or the DFI update interface.
29	ZCALBYP	RW	0h	Impedance Calibration Bypass: Bypasses, if set, impedance calibration of the ZQn control block when impedance calibration is already in progress. Impedance calibration can be disabled prior to trigger by using the ZCALEN bit.
28	ZDEN	RW	0h	Impedance Over-ride Enable: When this bit is set, it allows users to directly drive the impedance control using the data programmed in the ZDATA field. Otherwise, the control is generated automatically by the impedance control logic
27-0	ZDATA	RW	014Ah	Impedance Over-Ride Data: Data used to directly drive the impedance control. ZDATA field mapping is as follows: • ZDATA[27:21] is used to select the pull-up on-die termination impedance • ZDATA[20:14] is used to select the pull-down on-die termination impedance • ZDATA[13:7] is used to select the pull-up output impedance • ZDATA[6:0] is used to select the pull-down output impedance

Table 7-343. DDR_PHY_DX0GCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CALBYP	RW	0h	Calibration Bypass: Prevents, if set, period measurement calibration from automatically triggering after PHY initialization.
30	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, the DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the common DATX8 MDL enable bit.
29-26	WLRNKEN	RW	Fh	Write Level Rank Enable: Specifies the ranks that should be write leveled for this byte. Write leveling responses from ranks that are not enabled for write leveling for a particular byte are ignored and write leveling is flagged as done for these ranks. WLRKEN[0] enables rank 0, [1] enables rank 1, [2] enables rank 2, and [3] enables rank 3.
25-20	RESERVED	R	0h	Reads return zeros
19	PLLBYP	RW	0h	PLL Bypass: Puts the byte PLL in bypass mode by driving the PLL bypass pin. This bit is not self-clearing and a '0' must be written to de-assert the bypass. This bit is ORed with the global BYP configuration bit in DDR_PHY_PLLCR
18	GSHIFT	RW	0h	Gear Shift: Enables, if set, rapid locking mode on the byte PLL
17	PLLPD	RW	0h	PLL Power Down: Puts the byte PLL in power down mode by driving the PLL power down pin. This bit is not self-clearing and a '0' must be written to de-assert the power-down. This bit is ORed with the global PLLPD configuration bit in DDR_PHY_PLLCR
16	PLLRST	RW	0h	PLL Rest: Resets the byte PLL by driving the PLL reset pin. This bit is not selfclearing and a '0' must be written to de-assert the reset. This bit is ORed with the global PLLRST configuration bit in DDR_PHY_PLLCR

Table 7-343. DDR_PHY_DX0GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	DXOEO	RW	0h	Data Byte Output Enable Override: Specifies whether the output I/O output enable for the byte lane should be set to a fixed value. Valid values are: • 00 = No override. Output enable is controlled by DFI transactions • 01 = Ouput enable is asserted (I/O is forced to output mode). • 10 = Output enable is de-asserted (I/O is forced to input mode) • 11 = Reserved
13	RTTOAL	RW	0h	RTT On Additive Latency: Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles. Valid values are: • 0 = ODT control is set to DQSODT/DQODT almost two cycles before read data preamble • 1 = ODT control is set to DQSODT/DQODT almost one cycle before read data preamble
12-11	RTTOH	RW	1h	RTT Output Hold: Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble
10	DQRTT	RW	1h	DQ Dynamic RTT Control: Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.
9	DQSRTT	RW	1h	DQS Dynamic RTT Control: Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field
8-7	DSEN	RW	1h	Write DQS Enable: Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tri-stated. Valid settings are: • 00 = DQS disabled (Driven to constant 0) • 01 = DQS toggling with normal polarity (This should be the default setting) • 10 = DQS toggling with inverted polarity • 11 = DQS disabled (Driven to constant 1)
6	DQSRPD	RW	0h	DQSR Power Down: Powers down, if set, the PDQSR cell.
5	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
4	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
3	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte.
2	DQODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
1	DQSODT	RW	0h	DQS On-Die Termination: Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte

Table 7-343. DDR_PHY_DX0GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DXEN	RW	1h	Data Byte Enable: Enables if set the data byte. Setting this bit to '0' disables the byte, that is, the byte is not used in PHY initialization or training and is ignored during SDRAM read/write operations. Note: Software-initiated PHY initialization and leveling is only required after ECC has been enabled in the PHY by writing to DDR_PHY_DX8GCR.DXEN. Once ECC is enabled in the PHY and the PHY is initialized and leveled, the ECC enable bit in the controller (ECCCTL.ECC_EN) can be enabled or disabled without re-triggering PHY initialization and leveling.

EMIF Registers
- EMIF Registers: [0]

7.2.5.72 DDR_PHY_DX0GSR0 Register (Offset = 1C4h) [reset = 0h]

DDR_PHY_DX0GSR0 and DDR_PHY_DX0GSR2 are general status registers for the DATX8. They indicate among other things whether write leveling or period measurement calibration is done. Note that WDQCAL, RDQSCAL, RDQSNCAL, GDQSCAL, and WLCAL are calibration measurement-done flags that should be used for debug purposes if the global calibration done flag (DDR_PHY_PGSR0[CAL]) is not asserted. These flags will typically assert for a minimum of two VBUSP_CLK cycles and then de-assert when all measurement done flags are asserted.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reads return zeros.
28	WLDQ	R	0h	Write Leveling DQ Status: Captures the write leveling DQ status from the DRAM during software write leveling
27-24	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training. One bit for each of the up to 4 ranks
23-16	GDQSPRD	R	0h	Read DQS gating Period: Returns the DDR clock period measured by the read DQS gating LCDL during calibration. This value is PVT compensated
15	DPLOCK	R	0h	DATX8 PLL Lock: Indicates, if set, that the DATX8 PLL has locked.
14-7	WLPRD	R	0h	Write Leveling Period: Returns the DDR clock period measured by the write leveling LCDL during calibration. The measured period is used to generate the control of the write leveling pipeline which is a function of the write-leveling delay and the clock period. This value is PVT compensated
6	WLERR	R	0h	Write Leveling Error: Indicates, if set, that there is a write leveling error in the DATX8.
5	WLDONE	R	0h	Write Leveling Done: Indicates, if set, that the DATX8 has completed write leveling.
4	WLCAL	R	0h	Write Leveling Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write leveling slave delay line
3	GDQSCAL	R	0h	Read DQS gating Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS gating LCDL.

Table 7-346. DDR_PHY_DX0GSR0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	RDQSNCAL	R	0h	Read DQS# Calibration (Type B/B1 PHY Only): Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS# LCDL
1	RDQSCAL	R	0h	Read DQS Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS LCDL.
0	WDQCAL	R	0h	Write DQ Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write DQ LCDL.

- DDR_PHY_DX0GSR2 Register (Offset = 1F4h) [reset = 0h]: [0]
- EMIF Registers: [0]

7.2.5.74 DDR_PHY_DX0LCDLR0 Register (Offset = 1E0h) [reset = 0h]

The DATX8 local calibrated delay line registers 0-2 are used to select the delay value on the LCDLs used in the DATX8 macros. A single LCDL field in the LCDLR register connects to a corresponding LCDL. The following tables describe the bits of the DATX8 LCDLR registers. The write data delay (WDQD) and the read DQS delay (RDQSD) are automatically derived from the measured period during calibration. WDQD and RDQSD correspond to a 90 degrees phase shift for DQ during writes and DQS during reads, respectively. The 90 degrees phase shift is used to centre DQS into the write and read data eyes. A 90 degrees phase shift is equivalent to half the DDR clock period. After calibration WDQD and RDQSD fields will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period). The write leveling delay (RnWLD) and read DQS gating delay DQSGD are derived from the write leveling and DQS training algorithms. These are normally run automatically by the PHY control block or they can be executed in software by the user. After calibration RnWLD field will contain a value that corresponds to the DDR clock period (or half of the SDRAM clock period), while RnDQSGD field will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period).

After the initial setting, all LCDL register fields are automatically updated by the VT compensation logic to track drifts due to voltage and temperature. The user can however override these values by writing to the respective fields of the register and/or optionally disabling the automatic drift compensation.

Table 7-367. DDR_PHY_DX1GCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CALBYP	RW	0h	Calibration Bypass: Prevents, if set, period measurement calibration from automatically triggering after PHY initialization.
30	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, the DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the common DATX8 MDL enable bit.
29-26	WLRNKEN	RW	Fh	Write Level Rank Enable: Specifies the ranks that should be write leveled for this byte. Write leveling responses from ranks that are not enabled for write leveling for a particular byte are ignored and write leveling is flagged as done for these ranks. WLRKEN[0] enables rank 0, [1] enables rank 1, [2] enables rank 2, and [3] enables rank 3.
25-20	RESERVED	R	0h	Reads return zeros
19	PLLBYP	RW	0h	PLL Bypass: Puts the byte PLL in bypass mode by driving the PLL bypass pin. This bit is not self-clearing and a '0' must be written to de-assert the bypass. This bit is ORed with the global BYP configuration bit in DDR_PHY_PLLCR
18	GSHIFT	RW	0h	Gear Shift: Enables, if set, rapid locking mode on the byte PLL
17	PLLPD	RW	0h	PLL Power Down: Puts the byte PLL in power down mode by driving the PLL power down pin. This bit is not self-clearing and a '0' must be written to de-assert the power-down. This bit is ORed with the global PLLPD configuration bit in DDR_PHY_PLLCR
16	PLLRST	RW	0h	PLL Rest: Resets the byte PLL by driving the PLL reset pin. This bit is not selfclearing and a '0' must be written to de-assert the reset. This bit is ORed with the global PLLRST configuration bit in DDR_PHY_PLLCR

Table 7-367. DDR_PHY_DX1GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	DXOEO	RW	0h	Data Byte Output Enable Override: Specifies whether the output I/O output enable for the byte lane should be set to a fixed value. Valid values are: • 00 = No override. Output enable is controlled by DFI transactions • 01 = Ouput enable is asserted (I/O is forced to output mode). • 10 = Output enable is de-asserted (I/O is forced to input mode) • 11 = Reserved
13	RTTOAL	RW	0h	RTT On Additive Latency: Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles. Valid values are: • 0 = ODT control is set to DQSODT/DQODT almost two cycles before read data preamble • 1 = ODT control is set to DQSODT/DQODT almost one cycle before read data preamble
12-11	RTTOH	RW	1h	RTT Output Hold: Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble
10	DQRTT	RW	1h	DQ Dynamic RTT Control: Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.
9	DQSRTT	RW	1h	DQS Dynamic RTT Control: Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field
8-7	DSEN	RW	1h	Write DQS Enable: Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tri-stated. Valid settings are: • 00 = DQS disabled (Driven to constant 0) • 01 = DQS toggling with normal polarity (This should be the default setting) • 10 = DQS toggling with inverted polarity • 11 = DQS disabled (Driven to constant 1)
6	DQSRPD	RW	0h	DQSR Power Down: Powers down, if set, the PDQSR cell.
5	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
4	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
3	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte.
2	DQODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
1	DQSODT	RW	0h	DQS On-Die Termination: Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte

Table 7-367. DDR_PHY_DX1GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DXEN	RW	1h	Data Byte Enable: Enables if set the data byte. Setting this bit to '0' disables the byte, that is, the byte is not used in PHY initialization or training and is ignored during SDRAM read/write operations. Note: Software-initiated PHY initialization and leveling is only required after ECC has been enabled in the PHY by writing to DDR_PHY_DX8GCR.DXEN. Once ECC is enabled in the PHY and the PHY is initialized and leveled, the ECC enable bit in the controller (ECCCTL.ECC_EN) can be enabled or disabled without re-triggering PHY initialization and leveling.

EMIF Registers
- EMIF Registers: [0]

7.2.5.80 DDR_PHY_DX1GSR0 Register (Offset = 204h) [reset = 0h]

DDR_PHY_DX1GSR0 and DDR_PHY_DX1GSR2 are general status registers for the DATX8. They indicate among other things whether write leveling or period measurement calibration is done. Note that WDQCAL, RDQSCAL, RDQSNCAL, GDQSCAL, and WLCAL are calibration measurement-done flags that should be used for debug purposes if the global calibration done flag (DDR_PHY_PGSR0[CAL]) is not asserted. These flags will typically assert for a minimum of two VBUSP_CLK cycles and then de-assert when all measurement done flags are asserted.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reads return zeros.
28	WLDQ	R	0h	Write Leveling DQ Status: Captures the write leveling DQ status from the DRAM during software write leveling
27-24	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training. One bit for each of the up to 4 ranks
23-16	GDQSPRD	R	0h	Read DQS gating Period: Returns the DDR clock period measured by the read DQS gating LCDL during calibration. This value is PVT compensated
15	DPLOCK	R	0h	DATX8 PLL Lock: Indicates, if set, that the DATX8 PLL has locked.
14-7	WLPRD	R	0h	Write Leveling Period: Returns the DDR clock period measured by the write leveling LCDL during calibration. The measured period is used to generate the control of the write leveling pipeline which is a function of the write-leveling delay and the clock period. This value is PVT compensated
6	WLERR	R	0h	Write Leveling Error: Indicates, if set, that there is a write leveling error in the DATX8.
5	WLDONE	R	0h	Write Leveling Done: Indicates, if set, that the DATX8 has completed write leveling.
4	WLCAL	R	0h	Write Leveling Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write leveling slave delay line
3	GDQSCAL	R	0h	Read DQS gating Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS gating LCDL.

7.2.5.82 DDR_PHY_DX1LCDLR0 Register (Offset = 220h) [reset = 0h]

The DATX8 local calibrated delay line registers 0-2 are used to select the delay value on the LCDLs used in the DATX8 macros. A single LCDL field in the LCDLR register connects to a corresponding LCDL. The following tables describe the bits of the DATX8 LCDLR registers. The write data delay (WDQD) and the read DQS delay (RDQSD) are automatically derived from the measured period during calibration. WDQD and RDQSD correspond to a 90 degrees phase shift for DQ during writes and DQS during reads, respectively. The 90 degrees phase shift is used to centre DQS into the write and read data eyes. A 90 degrees phase shift is equivalent to half the DDR clock period. After calibration WDQD and RDQSD fields will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period). The write leveling delay (RnWLD) and read DQS gating delay DQSGD are derived from the write leveling and DQS training algorithms. These are normally run automatically by the PHY control block or they can be executed in software by the user. After calibration RnWLD field will contain a value that corresponds to the DDR clock period (or half of the SDRAM clock period), while RnDQSGD field will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period).

After the initial setting, all LCDL register fields are automatically updated by the VT compensation logic to track drifts due to voltage and temperature. The user can however override these values by writing to the respective fields of the register and/or optionally disabling the automatic drift compensation.

Table 7-391. DDR_PHY_DX2GCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CALBYP	RW	0h	Calibration Bypass: Prevents, if set, period measurement calibration from automatically triggering after PHY initialization.
30	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, the DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the common DATX8 MDL enable bit.
29-26	WLRNKEN	RW	Fh	Write Level Rank Enable: Specifies the ranks that should be write leveled for this byte. Write leveling responses from ranks that are not enabled for write leveling for a particular byte are ignored and write leveling is flagged as done for these ranks. WLRKEN[0] enables rank 0, [1] enables rank 1, [2] enables rank 2, and [3] enables rank 3.
25-20	RESERVED	R	0h	Reads return zeros
19	PLLBYP	RW	0h	PLL Bypass: Puts the byte PLL in bypass mode by driving the PLL bypass pin. This bit is not self-clearing and a '0' must be written to de-assert the bypass. This bit is ORed with the global BYP configuration bit in DDR_PHY_PLLCR
18	GSHIFT	RW	0h	Gear Shift: Enables, if set, rapid locking mode on the byte PLL
17	PLLPD	RW	0h	PLL Power Down: Puts the byte PLL in power down mode by driving the PLL power down pin. This bit is not self-clearing and a '0' must be written to de-assert the power-down. This bit is ORed with the global PLLPD configuration bit in DDR_PHY_PLLCR
16	PLLRST	RW	0h	PLL Rest: Resets the byte PLL by driving the PLL reset pin. This bit is not selfclearing and a '0' must be written to de-assert the reset. This bit is ORed with the global PLLRST configuration bit in DDR_PHY_PLLCR

Table 7-391. DDR_PHY_DX2GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	DXOEO	RW	0h	Data Byte Output Enable Override: Specifies whether the output I/O output enable for the byte lane should be set to a fixed value. Valid values are: • 00 = No override. Output enable is controlled by DFI transactions • 01 = Ouput enable is asserted (I/O is forced to output mode). • 10 = Output enable is de-asserted (I/O is forced to input mode) • 11 = Reserved
13	RTTOAL	RW	0h	RTT On Additive Latency: Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles. Valid values are: • 0 = ODT control is set to DQSODT/DQODT almost two cycles before read data preamble • 1 = ODT control is set to DQSODT/DQODT almost one cycle before read data preamble
12-11	RTTOH	RW	1h	RTT Output Hold: Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble
10	DQRTT	RW	1h	DQ Dynamic RTT Control: Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.
9	DQSRTT	RW	1h	DQS Dynamic RTT Control: Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field
8-7	DSEN	RW	1h	Write DQS Enable: Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tri-stated. Valid settings are: • 00 = DQS disabled (Driven to constant 0) • 01 = DQS toggling with normal polarity (This should be the default setting) • 10 = DQS toggling with inverted polarity • 11 = DQS disabled (Driven to constant 1)
6	DQSRPD	RW	0h	DQSR Power Down: Powers down, if set, the PDQSR cell.
5	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
4	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
3	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte.
2	DQODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
1	DQSODT	RW	0h	DQS On-Die Termination: Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte

Table 7-391. DDR_PHY_DX2GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DXEN	RW	1h	Data Byte Enable: Enables if set the data byte. Setting this bit to '0' disables the byte, that is, the byte is not used in PHY initialization or training and is ignored during SDRAM read/write operations. Note: Software-initiated PHY initialization and leveling is only required after ECC has been enabled in the PHY by writing to DDR_PHY_DX8GCR.DXEN. Once ECC is enabled in the PHY and the PHY is initialized and leveled, the ECC enable bit in the controller (ECCCTL.ECC_EN) can be enabled or disabled without re-triggering PHY initialization and leveling.

EMIF Registers
- EMIF Registers: [0]

7.2.5.88 DDR_PHY_DX2GSR0 Register (Offset = 244h) [reset = 0h]

DDR_PHY_DX2GSR0 and DDR_PHY_DX2GSR2 are general status registers for the DATX8. They indicate among other things whether write leveling or period measurement calibration is done. Note that WDQCAL, RDQSCAL, RDQSNCAL, GDQSCAL, and WLCAL are calibration measurement-done flags that should be used for debug purposes if the global calibration done flag (DDR_PHY_PGSR0[CAL]) is not asserted. These flags will typically assert for a minimum of two VBUSP_CLK cycles and then de-assert when all measurement done flags are asserted.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reads return zeros.
28	WLDQ	R	0h	Write Leveling DQ Status: Captures the write leveling DQ status from the DRAM during software write leveling
27-24	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training. One bit for each of the up to 4 ranks
23-16	GDQSPRD	R	0h	Read DQS gating Period: Returns the DDR clock period measured by the read DQS gating LCDL during calibration. This value is PVT compensated
15	DPLOCK	R	0h	DATX8 PLL Lock: Indicates, if set, that the DATX8 PLL has locked.
14-7	WLPRD	R	0h	Write Leveling Period: Returns the DDR clock period measured by the write leveling LCDL during calibration. The measured period is used to generate the control of the write leveling pipeline which is a function of the write-leveling delay and the clock period. This value is PVT compensated
6	WLERR	R	0h	Write Leveling Error: Indicates, if set, that there is a write leveling error in the DATX8.
5	WLDONE	R	0h	Write Leveling Done: Indicates, if set, that the DATX8 has completed write leveling.
4	WLCAL	R	0h	Write Leveling Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write leveling slave delay line
3	GDQSCAL	R	0h	Read DQS gating Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS gating LCDL.

- EMIF Registers: [0]

7.2.5.90 DDR_PHY_DX2LCDLR0 Register (Offset = 260h) [reset = 0h]

The DATX8 local calibrated delay line registers 0-2 are used to select the delay value on the LCDLs used in the DATX8 macros. A single LCDL field in the LCDLR register connects to a corresponding LCDL. The following tables describe the bits of the DATX8 LCDLR registers. The write data delay (WDQD) and the read DQS delay (RDQSD) are automatically derived from the measured period during calibration. WDQD and RDQSD correspond to a 90 degrees phase shift for DQ during writes and DQS during reads, respectively. The 90 degrees phase shift is used to centre DQS into the write and read data eyes. A 90 degrees phase shift is equivalent to half the DDR clock period. After calibration WDQD and RDQSD fields will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period). The write leveling delay (RnWLD) and read DQS gating delay DQSGD are derived from the write leveling and DQS training algorithms. These are normally run automatically by the PHY control block or they can be executed in software by the user. After calibration RnWLD field will contain a value that corresponds to the DDR clock period (or half of the SDRAM clock period), while RnDQSGD field will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period).

After the initial setting, all LCDL register fields are automatically updated by the VT compensation logic to track drifts due to voltage and temperature. The user can however override these values by writing to the respective fields of the register and/or optionally disabling the automatic drift compensation.

13-12	R0WLSL	RW	1h	See description for R3WLSL.
11-9	R3DGSL	RW	0h	Rank n DQS Gating System Latency: This is used to increase the number of clock cycles needed to expect valid DDR read data by up to seven extra clock cycles. This is used to compensate for board delays and other system delays. Power-up default is 000 (that is, no extra clock cycles required). The SL fields are initially set by the PHY during automatic DQS data training but these values can be overwritten by a direct write to this register. Every three bits of this register control the latency of each of the (up to) four ranks. R0DGSL controls the latency of rank 0, R1DGSL controls rank 1, and so on. Valid values are 0 to 7.
8-6	R2DGSL	RW	0h	See description for R3DGSL.
5-3	R1DGSL	RW	0h	See description for R3DGSL.
2-0	R0DGSL	RW	0h	See description for R3DGSL.

Table 7-415. DDR_PHY_DX3GCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CALBYP	RW	0h	Calibration Bypass: Prevents, if set, period measurement calibration from automatically triggering after PHY initialization.
30	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, the DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the common DATX8 MDL enable bit.
29-26	WLRNKEN	RW	Fh	Write Level Rank Enable: Specifies the ranks that should be write leveled for this byte. Write leveling responses from ranks that are not enabled for write leveling for a particular byte are ignored and write leveling is flagged as done for these ranks. WLRKEN[0] enables rank 0, [1] enables rank 1, [2] enables rank 2, and [3] enables rank 3.
25-20	RESERVED	R	0h	Reads return zeros
19	PLLBYP	RW	0h	PLL Bypass: Puts the byte PLL in bypass mode by driving the PLL bypass pin. This bit is not self-clearing and a '0' must be written to de-assert the bypass. This bit is ORed with the global BYP configuration bit in DDR_PHY_PLLCR
18	GSHIFT	RW	0h	Gear Shift: Enables, if set, rapid locking mode on the byte PLL
17	PLLPD	RW	0h	PLL Power Down: Puts the byte PLL in power down mode by driving the PLL power down pin. This bit is not self-clearing and a '0' must be written to de-assert the power-down. This bit is ORed with the global PLLPD configuration bit in DDR_PHY_PLLCR
16	PLLRST	RW	0h	PLL Rest: Resets the byte PLL by driving the PLL reset pin. This bit is not selfclearing and a '0' must be written to de-assert the reset. This bit is ORed with the global PLLRST configuration bit in DDR_PHY_PLLCR

Table 7-415. DDR_PHY_DX3GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	DXOEO	RW	0h	Data Byte Output Enable Override: Specifies whether the output I/O output enable for the byte lane should be set to a fixed value. Valid values are: • 00 = No override. Output enable is controlled by DFI transactions • 01 = Ouput enable is asserted (I/O is forced to output mode). • 10 = Output enable is de-asserted (I/O is forced to input mode) • 11 = Reserved
13	RTTOAL	RW	0h	RTT On Additive Latency: Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles. Valid values are: • 0 = ODT control is set to DQSODT/DQODT almost two cycles before read data preamble • 1 = ODT control is set to DQSODT/DQODT almost one cycle before read data preamble
12-11	RTTOH	RW	1h	RTT Output Hold: Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble
10	DQRTT	RW	1h	DQ Dynamic RTT Control: Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.
9	DQSRTT	RW	1h	DQS Dynamic RTT Control: Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field
8-7	DSEN	RW	1h	Write DQS Enable: Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tri-stated. Valid settings are: • 00 = DQS disabled (Driven to constant 0) • 01 = DQS toggling with normal polarity (This should be the default setting) • 10 = DQS toggling with inverted polarity • 11 = DQS disabled (Driven to constant 1)
6	DQSRPD	RW	0h	DQSR Power Down: Powers down, if set, the PDQSR cell.
5	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
4	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
3	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte.
2	DQODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
1	DQSODT	RW	0h	DQS On-Die Termination: Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte

Table 7-415. DDR_PHY_DX3GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DXEN	RW	1h	Data Byte Enable: Enables if set the data byte. Setting this bit to '0' disables the byte, that is, the byte is not used in PHY initialization or training and is ignored during SDRAM read/write operations. Note: Software-initiated PHY initialization and leveling is only required after ECC has been enabled in the PHY by writing to DDR_PHY_DX8GCR.DXEN. Once ECC is enabled in the PHY and the PHY is initialized and leveled, the ECC enable bit in the controller (ECCCTL.ECC_EN) can be enabled or disabled without re-triggering PHY initialization and leveling.

- EMIF Registers: [0]

7.2.5.96 DDR_PHY_DX3GSR0 Register (Offset = 284h) [reset = 0h]

DDR_PHY_DX3GSR0 and DDR_PHY_DX3GSR2 are general status registers for the DATX8. They indicate among other things whether write leveling or period measurement calibration is done. Note that WDQCAL, RDQSCAL, RDQSNCAL, GDQSCAL, and WLCAL are calibration measurement-done flags that should be used for debug purposes if the global calibration done flag (DDR_PHY_PGSR0[CAL]) is not asserted. These flags will typically assert for a minimum of two VBUSP_CLK cycles and then de-assert when all measurement done flags are asserted.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reads return zeros.
28	WLDQ	R	0h	Write Leveling DQ Status: Captures the write leveling DQ status from the DRAM during software write leveling
27-24	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training. One bit for each of the up to 4 ranks
23-16	GDQSPRD	R	0h	Read DQS gating Period: Returns the DDR clock period measured by the read DQS gating LCDL during calibration. This value is PVT compensated
15	DPLOCK	R	0h	DATX8 PLL Lock: Indicates, if set, that the DATX8 PLL has locked.
14-7	WLPRD	R	0h	Write Leveling Period: Returns the DDR clock period measured by the write leveling LCDL during calibration. The measured period is used to generate the control of the write leveling pipeline which is a function of the write-leveling delay and the clock period. This value is PVT compensated
6	WLERR	R	0h	Write Leveling Error: Indicates, if set, that there is a write leveling error in the DATX8.
5	WLDONE	R	0h	Write Leveling Done: Indicates, if set, that the DATX8 has completed write leveling.
4	WLCAL	R	0h	Write Leveling Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write leveling slave delay line
3	GDQSCAL	R	0h	Read DQS gating Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS gating LCDL.

- EMIF Registers: [0]

7.2.5.98 DDR_PHY_DX3LCDLR0 Register (Offset = 2A0h) [reset = 0h]

The DATX8 local calibrated delay line registers 0-2 are used to select the delay value on the LCDLs used in the DATX8 macros. A single LCDL field in the LCDLR register connects to a corresponding LCDL. The following tables describe the bits of the DATX8 LCDLR registers. The write data delay (WDQD) and the read DQS delay (RDQSD) are automatically derived from the measured period during calibration. WDQD and RDQSD correspond to a 90 degrees phase shift for DQ during writes and DQS during reads, respectively. The 90 degrees phase shift is used to centre DQS into the write and read data eyes. A 90 degrees phase shift is equivalent to half the DDR clock period. After calibration WDQD and RDQSD fields will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period). The write leveling delay (RnWLD) and read DQS gating delay DQSGD are derived from the write leveling and DQS training algorithms. These are normally run automatically by the PHY control block or they can be executed in software by the user. After calibration RnWLD field will contain a value that corresponds to the DDR clock period (or half of the SDRAM clock period), while RnDQSGD field will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period).

After the initial setting, all LCDL register fields are automatically updated by the VT compensation logic to track drifts due to voltage and temperature. The user can however override these values by writing to the respective fields of the register and/or optionally disabling the automatic drift compensation.

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	Reads return zeros
19-18	R3WLSL	RW	1h	Rank n Write Leveling System Latency: This is used to adjust the write latency after write leveling. Power-up default is 01 (that is, no extra clock cycles required). The SL fields are initially set by the PUB during automatic write leveling but these values can be overwritten by a direct write to this register. Every two bits of this register control the latency of each of the (up to) four ranks. R0WLSL controls the latency of rank 0, R1WLSL controls rank 1, and so on. Valid values: • 00 = Write latency = WL - 1 • 01 = Write latency = WL • 10 = Write latency = WL + 1 • 11 = Reserved
17-16	R2WLSL	RW	1h	See description for R3WLSL.
15-14	R1WLSL	RW	1h	See description for R3WLSL.
13-12	R0WLSL	RW	1h	See description for R3WLSL.
11-9	R3DGSL	RW	0h	Rank n DQS Gating System Latency: This is used to increase the number of clock cycles needed to expect valid DDR read data by up to seven extra clock cycles. This is used to compensate for board delays and other system delays. Power-up default is 000 (that is, no extra clock cycles required). The SL fields are initially set by the PHY during automatic DQS data training but these values can be overwritten by a direct write to this register. Every three bits of this register control the latency of each of the (up to) four ranks. R0DGSL controls the latency of rank 0, R1DGSL controls rank 1, and so on. Valid values are 0 to 7.
8-6	R2DGSL	RW	0h	See description for R3DGSL.
5-3	R1DGSL	RW	0h	See description for R3DGSL.
2-0	R0DGSL	RW	0h	See description for R3DGSL.

Table 7-439. DDR_PHY_DX8GCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CALBYP	RW	0h	Calibration Bypass: Prevents, if set, period measurement calibration from automatically triggering after PHY initialization.
30	MDLEN	RW	1h	Master Delay Line Enable: Enables, if set, the DATX8 master delay line calibration to perform subsequent period measurements following the initial period measurements that are performed after reset or when calibration is manually triggered. These additional measurements are accumulated and filtered as long as this bit remains high. This bit is ANDed with the common DATX8 MDL enable bit.
29-26	WLRNKEN	RW	Fh	Write Level Rank Enable: Specifies the ranks that should be write leveled for this byte. Write leveling responses from ranks that are not enabled for write leveling for a particular byte are ignored and write leveling is flagged as done for these ranks. WLRKEN[0] enables rank 0, [1] enables rank 1, [2] enables rank 2, and [3] enables rank 3.
25-20	RESERVED	R	0h	Reads return zeros
19	PLLBYP	RW	0h	PLL Bypass: Puts the byte PLL in bypass mode by driving the PLL bypass pin. This bit is not self-clearing and a '0' must be written to de-assert the bypass. This bit is ORed with the global BYP configuration bit in DDR_PHY_PLLCR
18	GSHIFT	RW	0h	Gear Shift: Enables, if set, rapid locking mode on the byte PLL
17	PLLPD	RW	0h	PLL Power Down: Puts the byte PLL in power down mode by driving the PLL power down pin. This bit is not self-clearing and a '0' must be written to de-assert the power-down. This bit is ORed with the global PLLPD configuration bit in DDR_PHY_PLLCR
16	PLLRST	RW	0h	PLL Rest: Resets the byte PLL by driving the PLL reset pin. This bit is not selfclearing and a '0' must be written to de-assert the reset. This bit is ORed with the global PLLRST configuration bit in DDR_PHY_PLLCR

Table 7-439. DDR_PHY_DX8GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	DXOEO	RW	0h	Data Byte Output Enable Override: Specifies whether the output I/O output enable for the byte lane should be set to a fixed value. Valid values are: • 00 = No override. Output enable is controlled by DFI transactions • 01 = Ouput enable is asserted (I/O is forced to output mode). • 10 = Output enable is de-asserted (I/O is forced to input mode) • 11 = Reserved
13	RTTOAL	RW	0h	RTT On Additive Latency: Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles. Valid values are: • 0 = ODT control is set to DQSODT/DQODT almost two cycles before read data preamble • 1 = ODT control is set to DQSODT/DQODT almost one cycle before read data preamble
12-11	RTTOH	RW	1h	RTT Output Hold: Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble
10	DQRTT	RW	1h	DQ Dynamic RTT Control: Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.
9	DQSRTT	RW	1h	DQS Dynamic RTT Control: Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field
8-7	DSEN	RW	1h	Write DQS Enable: Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tri-stated. Valid settings are: • 00 = DQS disabled (Driven to constant 0) • 01 = DQS toggling with normal polarity (This should be the default setting) • 10 = DQS toggling with inverted polarity • 11 = DQS disabled (Driven to constant 1)
6	DQSRPD	RW	0h	DQSR Power Down: Powers down, if set, the PDQSR cell.
5	DXPDR	RW	0h	Data Power Down Receiver: Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
4	DXPDD	RW	0h	Data Power Down Driver: Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte.
3	DXIOM	RW	0h	Data I/O Mode: Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte.
2	DQODT	RW	0h	Data On-Die Termination: Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
1	DQSODT	RW	0h	DQS On-Die Termination: Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte

Table 7-439. DDR_PHY_DX8GCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DXEN	RW	1h	Data Byte Enable: Enables if set the data byte. Setting this bit to '0' disables the byte, that is, the byte is not used in PHY initialization or training and is ignored during SDRAM read/write operations. Note: Software-initiated PHY initialization and leveling is only required after ECC has been enabled in the PHY by writing to DDR_PHY_DX8GCR.DXEN. Once ECC is enabled in the PHY and the PHY is initialized and leveled, the ECC enable bit in the controller (ECCCTL.ECC_EN) can be enabled or disabled without re-triggering PHY initialization and leveling.

Table 7-440. Register Call Summary for DDR_PHY_DX8GCR

EMIF Functional Description • Error Correction And Detection: [0][1]
EMIF Registers • DDR_PHY_DX2GCR Register (Offset = 240h) [reset = 7C000E81h]: [0] • DDR_PHY_DX0GCR Register (Offset = 1C0h) [reset = 7C000E81h]: [0] • DDR_PHY_DX3GCR Register (Offset = 280h) [reset = 7C000E81h]: [0] • DDR_PHY_DX1GCR Register (Offset = 200h) [reset = 7C000E81h]: [0] • EMIF Registers: [0] • DDR_PHY_DX8GCR Register (Offset = 3C0h) [reset = 7C000E81h]: [0]

7.2.5.104 DDR_PHY_DX8GSR0 Register (Offset = 3C4h) [reset = 0h]

DDR_PHY_DX8GSR0 and DDR_PHY_DX8GSR2 are general status registers for the DATX8. They indicate among other things whether write leveling or period measurement calibration is done. Note that WDQCAL, RDQSCAL, RDQSNCAL, GDQSCAL, and WLCAL are calibration measurement-done flags that should be used for debug purposes if the global calibration done flag (DDR_PHY_PGSR0[CAL]) is not asserted. These flags will typically assert for a minimum of two VBUSP_CLK cycles and then de-assert when all measurement done flags are asserted.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reads return zeros.
28	WLDQ	R	0h	Write Leveling DQ Status: Captures the write leveling DQ status from the DRAM during software write leveling
27-24	QSGERR	R	0h	DQS Gate Training Error: Indicates if set that there is an error in DQS gate training. One bit for each of the up to 4 ranks
23-16	GDQSPRD	R	0h	Read DQS gating Period: Returns the DDR clock period measured by the read DQS gating LCDL during calibration. This value is PVT compensated
15	DPLOCK	R	0h	DATX8 PLL Lock: Indicates, if set, that the DATX8 PLL has locked.
14-7	WLPRD	R	0h	Write Leveling Period: Returns the DDR clock period measured by the write leveling LCDL during calibration. The measured period is used to generate the control of the write leveling pipeline which is a function of the write-leveling delay and the clock period. This value is PVT compensated
6	WLERR	R	0h	Write Leveling Error: Indicates, if set, that there is a write leveling error in the DATX8.
5	WLDONE	R	0h	Write Leveling Done: Indicates, if set, that the DATX8 has completed write leveling.
4	WLCAL	R	0h	Write Leveling Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the write leveling slave delay line
3	GDQSCAL	R	0h	Read DQS gating Calibration: Indicates, if set, that the DATX8 has finished doing period measurement calibration for the read DQS gating LCDL.

- EMIF Registers: [0]

7.2.5.106 DDR_PHY_DX8LCDLR0 Register (Offset = 3E0h) [reset = 0h]

The DATX8 local calibrated delay line registers 0-2 are used to select the delay value on the LCDLs used in the DATX8 macros. A single LCDL field in the LCDLR register connects to a corresponding LCDL. The following tables describe the bits of the DATX8 LCDLR registers. The write data delay (WDQD) and the read DQS delay (RDQSD) are automatically derived from the measured period during calibration. WDQD and RDQSD correspond to a 90 degrees phase shift for DQ during writes and DQS during reads, respectively. The 90 degrees phase shift is used to centre DQS into the write and read data eyes. A 90 degrees phase shift is equivalent to half the DDR clock period. After calibration WDQD and RDQSD fields will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period). The write leveling delay (RnWLD) and read DQS gating delay DQSGD are derived from the write leveling and DQS training algorithms. These are normally run automatically by the PHY control block or they can be executed in software by the user. After calibration RnWLD field will contain a value that corresponds to the DDR clock period (or half of the SDRAM clock period), while RnDQSGD field will contain a value that corresponds to half the DDR clock period (or a quarter of the SDRAM clock period).

After the initial setting, all LCDL register fields are automatically updated by the VT compensation logic to track drifts due to voltage and temperature. The user can however override these values by writing to the respective fields of the register and/or optionally disabling the automatic drift compensation.

7.3 General-Purpose Memory Controller (GPMC)

This section describes the General-Purpose Memory Controller (GPMC) for the device.

NOTE: Due to device limitation, NAND functionality of the GPMC is not supported and the NAND functionality described in Section 7.3, *General-Purpose Memory Controller (GPMC)* is not applicable.

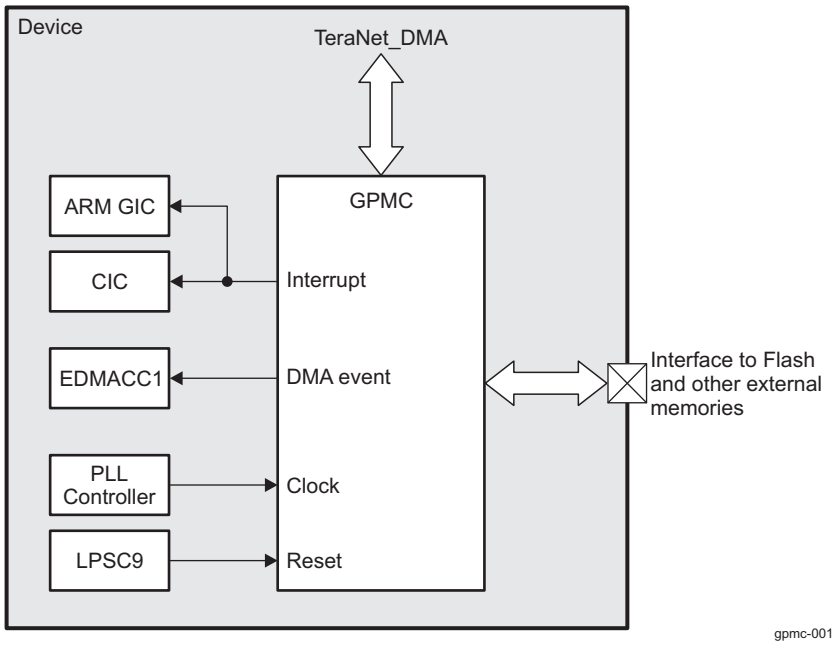
7.3.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Figure 7-157 shows the GPMC module overview.

Figure 7-157. GPMC Overview



The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1 GB
- Supports on-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity

of one GPMC_FCLK clock cycle.

- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit TeraNet slave interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

NOTE: Page mode is available only in non-multiplexed mode.

7.3.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options and gives four possible interfaces.

7.3.2.1 GPMC Modes

This section shows four GPMC external connection options:

- Figure 7-158 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed but this protocol uses fewer address pins) external memory device.
- Figure 7-159 shows a connection between the GPMC and a 16-bit synchronous non-multiplexed external memory device.
- Figure 7-160 shows a connection between the GPMC and an 8-bit synchronous non-multiplexed external memory device.
- Figure 7-161 shows a connection between the GPMC and an 8-bit NAND device.

7.3.2.2 GPMC Signals

Table 7-462 lists the GPMC subsystem input/output (I/O) pins.

Table 7-462. GPMC I/O Description

Pin Name	Device Signal	IOZ[1]	Description
A[27:0]	GPMC_A[27:0]	OZ	28-bit output address bus.
A[16:1]/D[15:0]	GPMC_AD[15:0]	IOZ	Multiplexed address/data.
nCS[3:0]	GPMC_CSn[3:0]	OZ	Chip-selects (active low).
CLK	GPMC_CLK	IOZ	Clock generated for the external memory or device
nADV/ALE	GPMC_ADVn_ALE	OZ	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	GPMC_OEn_REn	OZ	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	GPMC_WEn	OZ	Write enable (active low)
nBE0/CLE	GPMC_BEn0_CLE	OZ	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	GPMC_BEn1	OZ	Upper-byte enable (active low).
WAIT[1:0]	GPMC_WAIT[1:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-selects.
nWP	GPMC_WPn	OZ	Write protect (active low).
DIR	GPMC_DIR	OZ	This signal can be used to control an external buffer direction. It also controls the signal direction of D[15:0]. Low during transmit (for write access: data OUT from GPMC to memory). High during receive (for read access: data IN from memory to GPMC).

(1) I = Input; O = Output; Z = High Impedance

Table 7-463 shows the use of address and data GPMC pins based on the type of external device.

NOTE: Due to device limitation, NAND functionality of the GPMC is not supported and the NAND functionality described in Section 7.3, *General-Purpose Memory Controller (GPMC)* is not applicable.

GPMC_AD[4]	A5/D4	D4	D4	D4	D4
GPMC_AD[3]	A4/D3	D3	D3	D3	D3
GPMC_AD[2]	A3/D2	D2	D2	D2	D2
GPMC_AD[1]	A2/D1	D1	D1	D1	D1
GPMC_AD[0]	A1/D0	D0	D0	D0	D0

(1) Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0h.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (where i = 0 to 3).
- Asynchronous page mode is not supported for multiplexed address and data devices.

7.3.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Table 7-466 shows the GPMC integration.

Figure 7-162. GPMC Integration

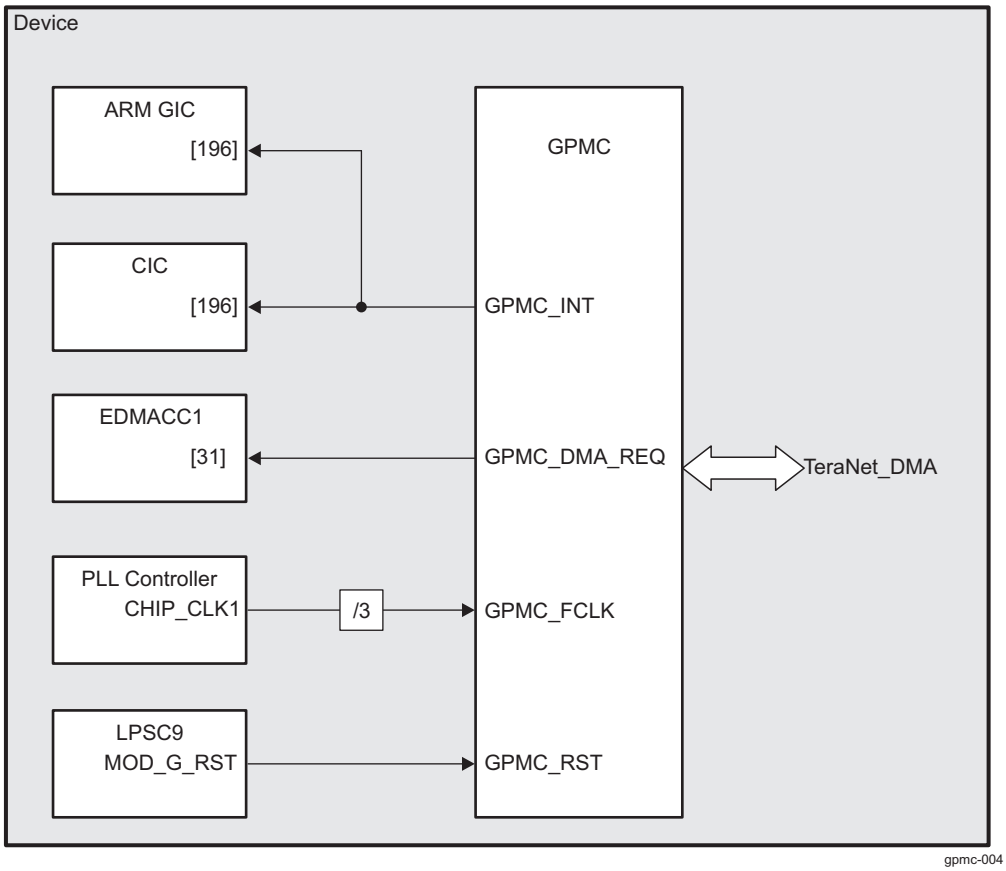

Table 7-464 through Table 7-466 summarize the integration of the GPMC module in the device.

Table 7-464. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect

		EDMACC1		
GPMC	GPMC_DMA_REQ	[31]		DMA event

NOTE: For interrupt description, see Section 7.3.4.5, *GPMC Interrupt Requests*.

7.3.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

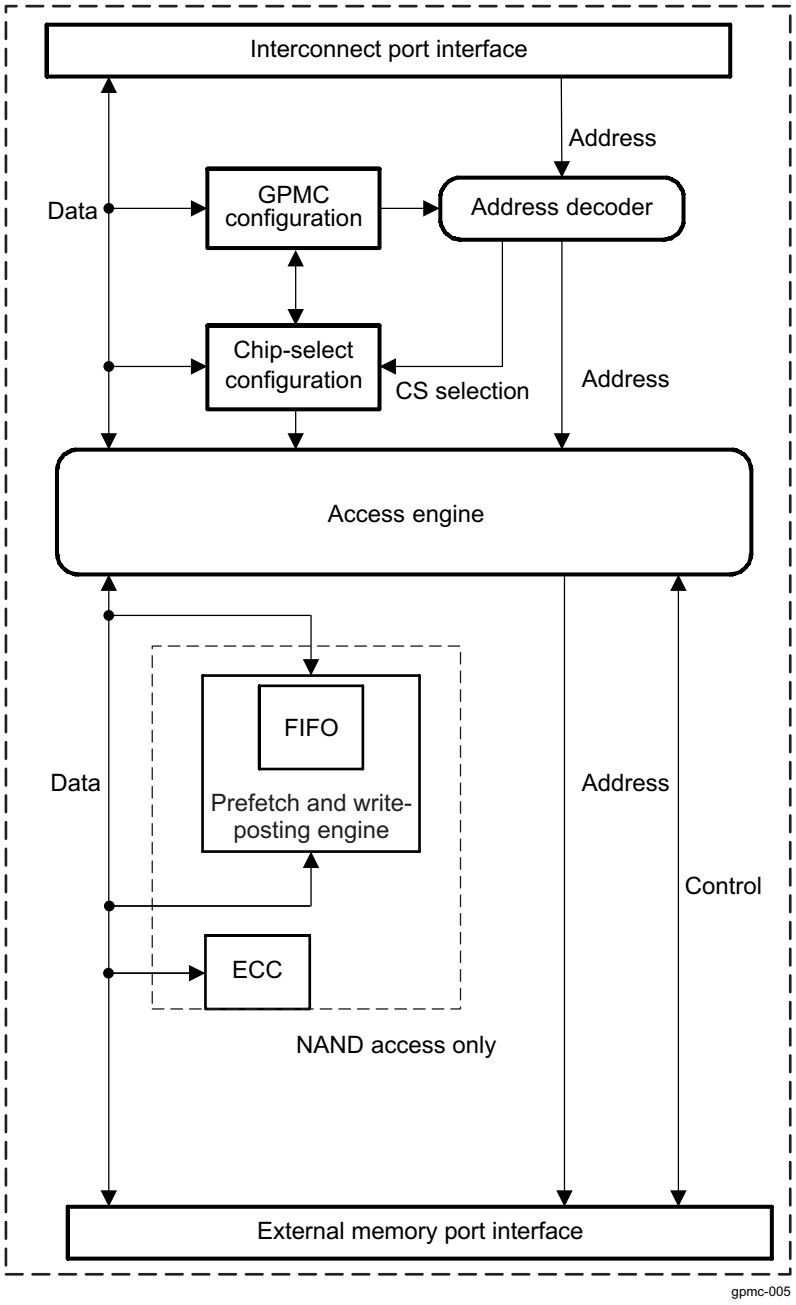
- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

7.3.4.1 GPMC Block Diagram

Figure 7-163 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 7-163. GPMC Block Diagram



The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

7.3.4.2 GPMC Clock Configuration

Table 7-467 describes the GPMC clocks.

Table 7-467. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices

(1) I = Input; O = Output

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 7-465. The GPMC_CLK is configured using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in Table 7-468.

Table 7-468. GPMC_CLK Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

7.3.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

7.3.4.4 GPMC Power Management

Table 7-469 describes the local power-management features available for the GPMC module.

Table 7-469. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle and smart-idle modes are available.

7.3.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see Table 7-466).

Table 7-470 lists the event flags, and their mask, that can cause module interrupts.

Table 7-470. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.

Table 7-470. GPMC Interrupt Events (continued)

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

7.3.4.6 Interconnect Port Interface

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

7.3.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with a limited address range of 2KB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: GPMC_AD[15:8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: GPMC_A[27:16].
- 8-bit-wide NAND devices do not use GPMC I/O: GPMC_A[27:16] and GPMC I/O: GPMC_AD[15:8].

7.3.4.7.1 GPMC I/O Configuration Setting

NOTE: In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 3.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

7.3.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

7.3.4.8.1 Chip-Select Base Address and Region Size

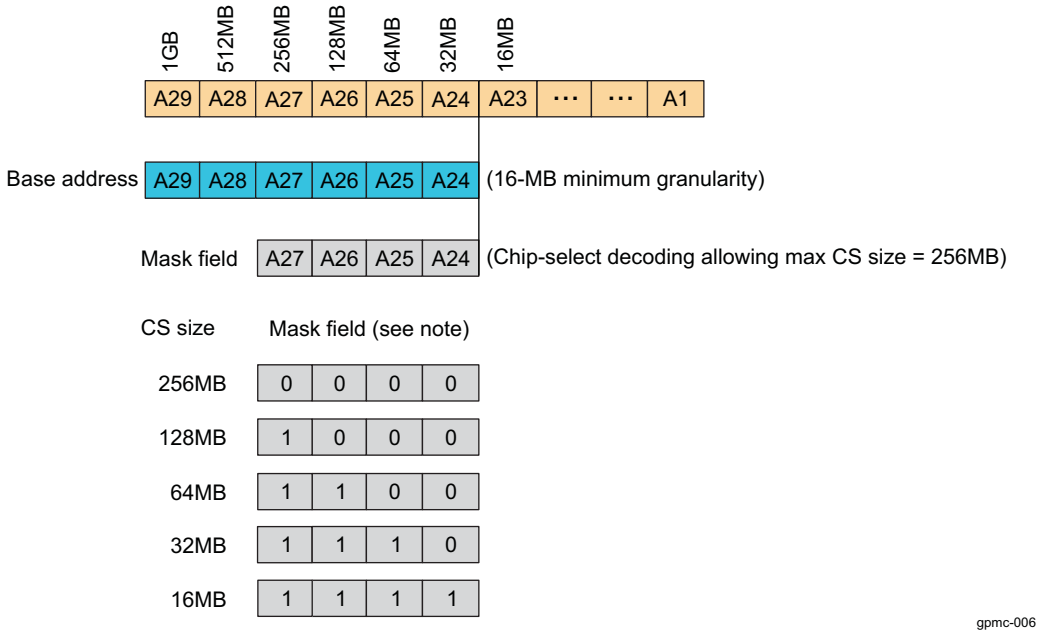
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MB contiguous address space. For more information, see Chapter 2, *Memory Mapping*.

The GPMC 512-MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16 MB to 256 MB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 7-164 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

Figure 7-164. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device Data Manual.

7.3.4.8.2 Access Protocol

7.3.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see Section 7.3.4.12, *NAND Device Basic Programming Model*, and Section 7.3.4.12.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

7.3.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE bit field (where i = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

7.3.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (where i = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 7.3.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 7.3.4.12, *NAND Device Basic Programming Model*.

7.3.4.8.3 External Signals

7.3.4.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external GPMC_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input wait pins: GPMC_WAIT1, and GPMC_WAIT0. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit field (where i = 0 to 3) selects which input GPMC_WAIT pin is used for the device attached to the corresponding chip-select.
- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

7.3.4.8.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

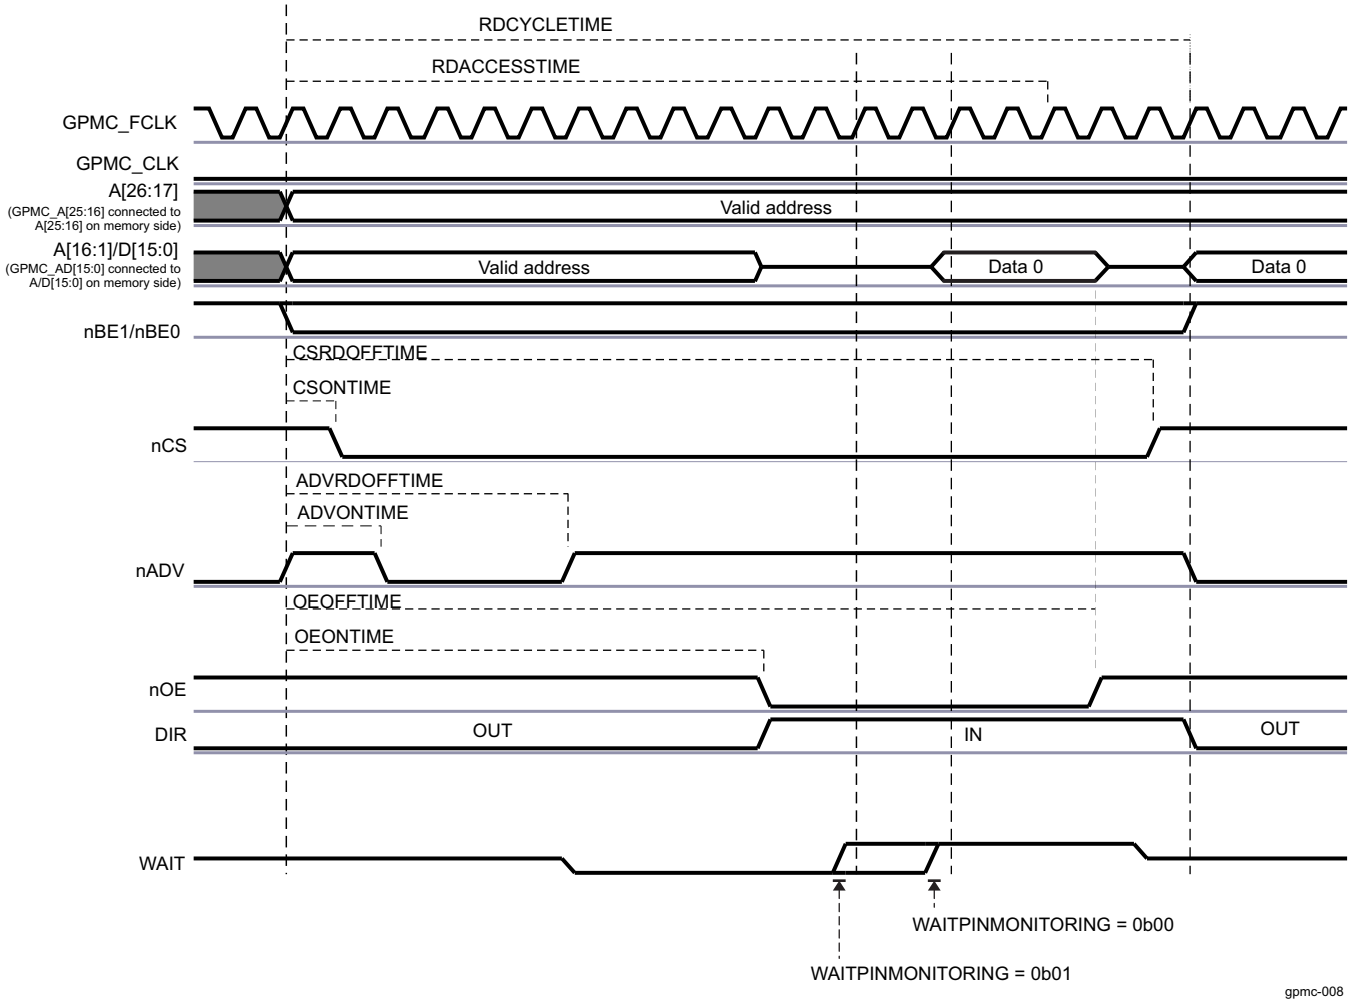
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 7-165 shows wait behavior during an asynchronous single read access.

Figure 7-165. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

7.3.4.8.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 1h), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

7.3.4.8.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

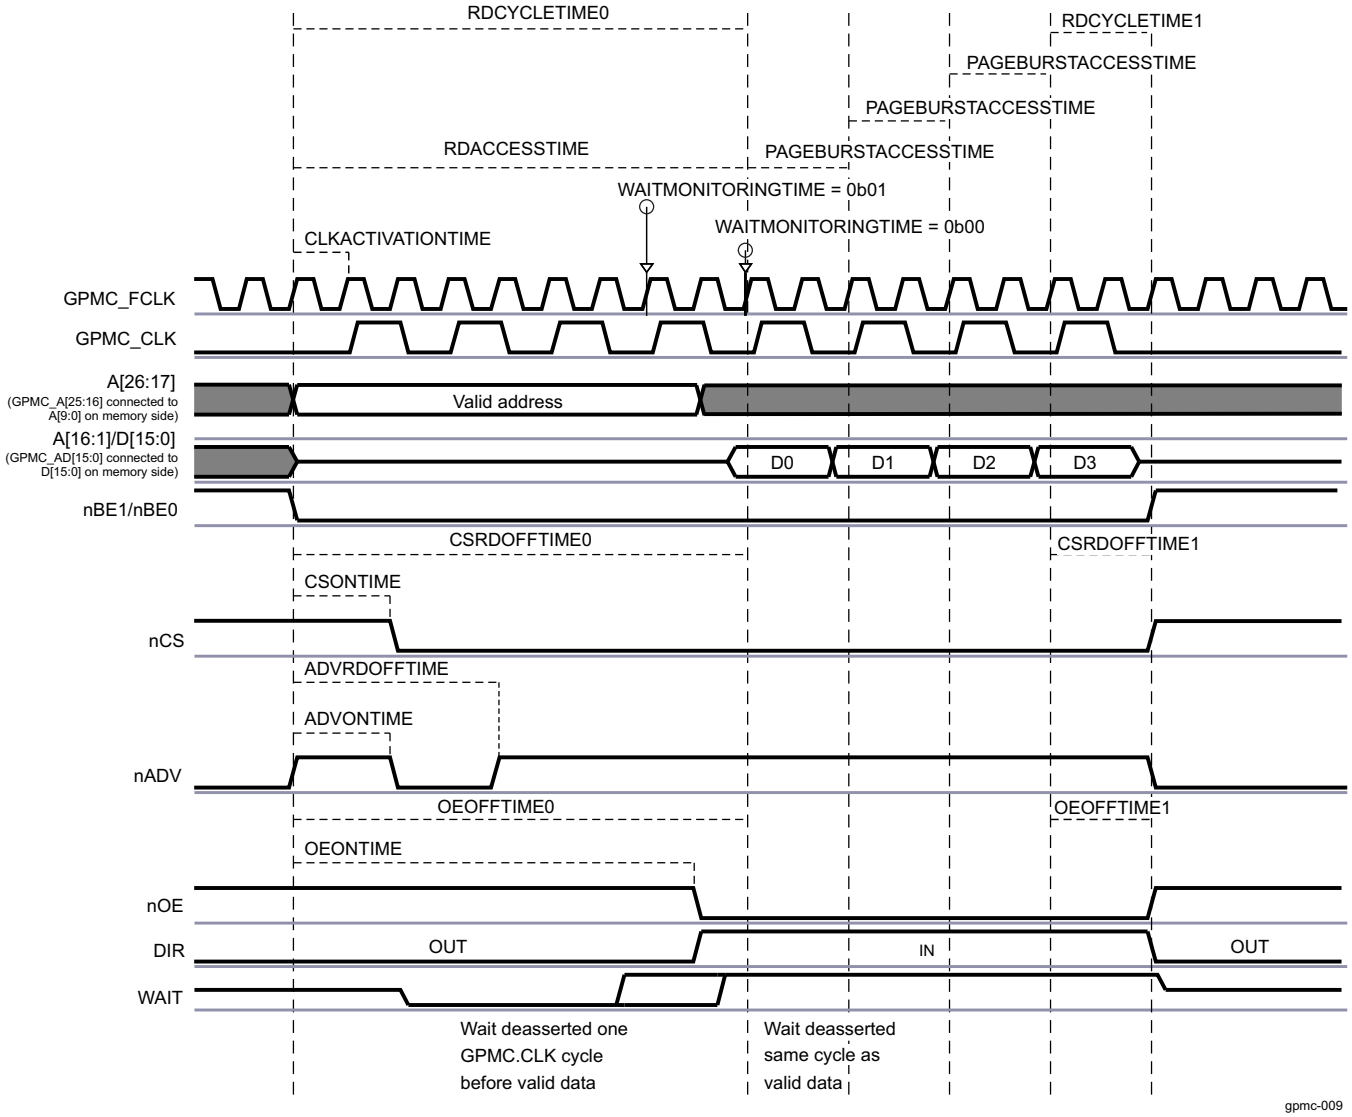
- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 7-166 shows wait behavior during a synchronous read burst access.

Figure 7-166. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

7.3.4.8.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with WAIT pin monitoring enabled (the WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: WAIT monitoring is supported for all configurations except GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0h (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is equal to 0h or 1h, respectively).

7.3.4.8.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see Section 7.3.4.12.2, *NAND Device-Ready Pin*.

7.3.4.8.3.1.6 Idle Cycle Control Between Successive Accesses

7.3.4.8.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see Figure 7-167 through Figure 7-169).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

Figure 7-167. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

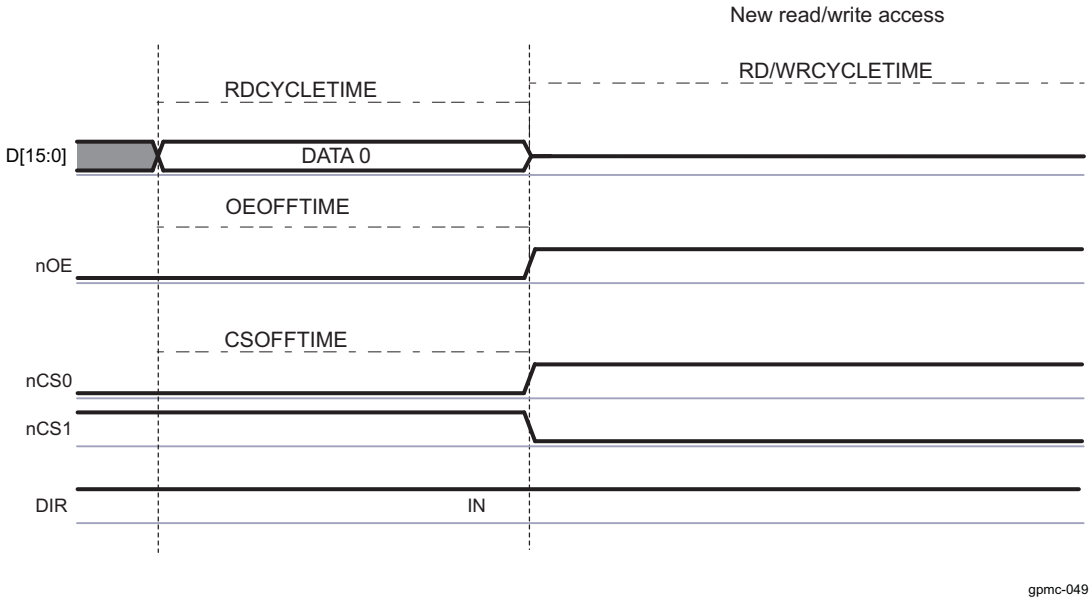


Figure 7-168. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround

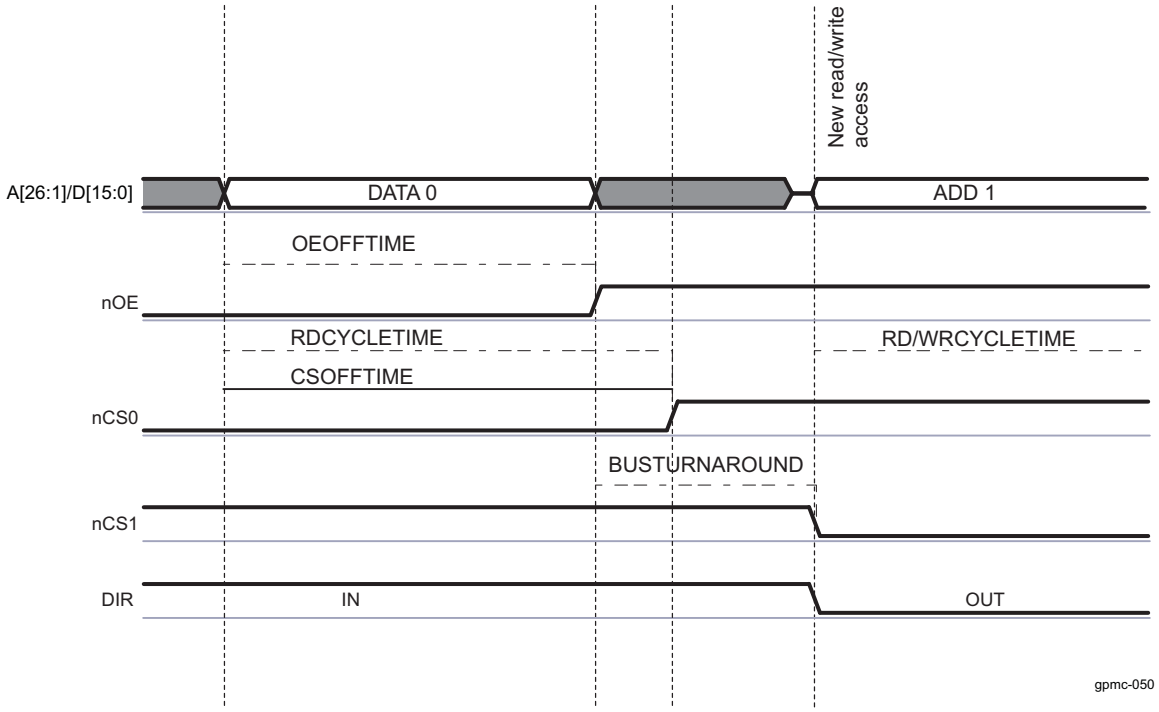

Figure 7-169. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround

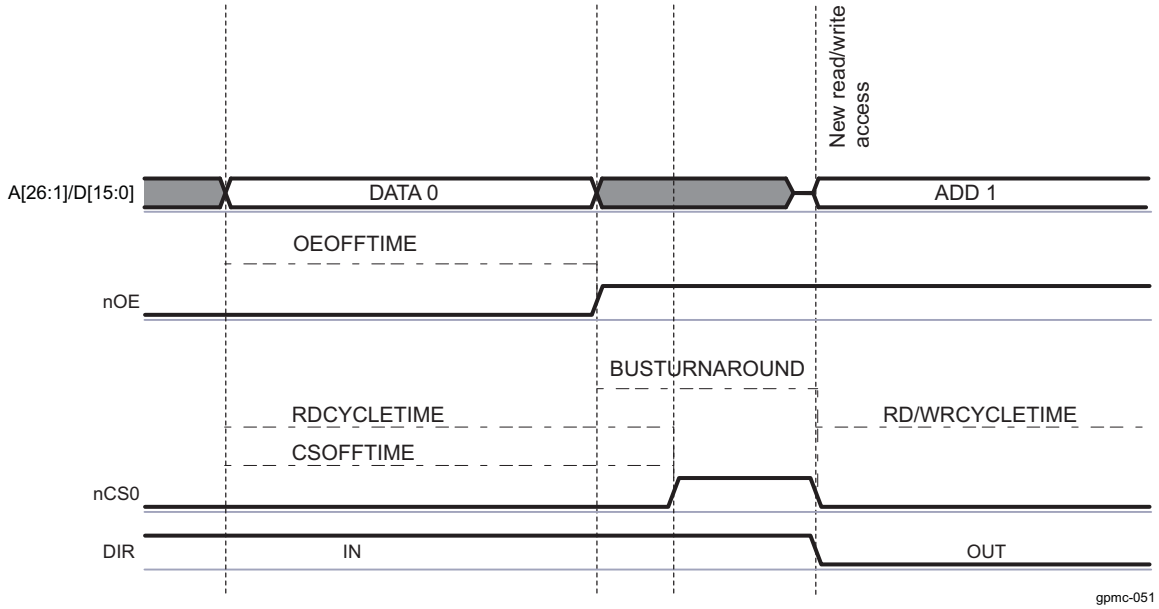


7.3.4.8.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 3) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

7.3.4.8.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 7.3.4.8.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 7-471 describes the configuration required for idle cycle insertion.

Table 7-471. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

7.3.4.8.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select i, where i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

7.3.4.8.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15:0]. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see Section 7.3.4.9.10). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

7.3.4.8.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

GPMC_RST is the reset signal for the GPMC module. It is connected and controlled by LPSC9. That reset signal initializes the internal state-machine and the internal configuration registers.

7.3.4.8.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The nWP output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit which is common for all chip selects.

7.3.4.8.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

7.3.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-

cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

7.3.4.9 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLK and GPMC_FCLK see Section 7.3.4.9.6, *GPMC_CLK*.

NOTE: In the following sections, the start access time refers to the time at which the access begins.

7.3.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME bit fields (where i = 0 to 3) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

7.3.4.9.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

7.3.4.9.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 7.3.4.12, *NAND Access Description*.

7.3.4.9.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME /

OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

7.3.4.9.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

7.3.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device Data Manual.

- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

7.3.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

7.3.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

7.3.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 7.3.4.8.3.1, *WAIT Pin Monitoring Control*.

7.3.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC_WAIT pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 7.3.4.8.3.1, *WAIT Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 7.3.4.8.3.1, *WAIT Pin Monitoring Control*.

7.3.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

7.3.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 7.3.4.8.3.1, *WAIT Pin Monitoring Control*.

7.3.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 7.3.4.8.3.1, *WAIT Pin Monitoring Control*.

7.3.4.9.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

7.3.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

7.3.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

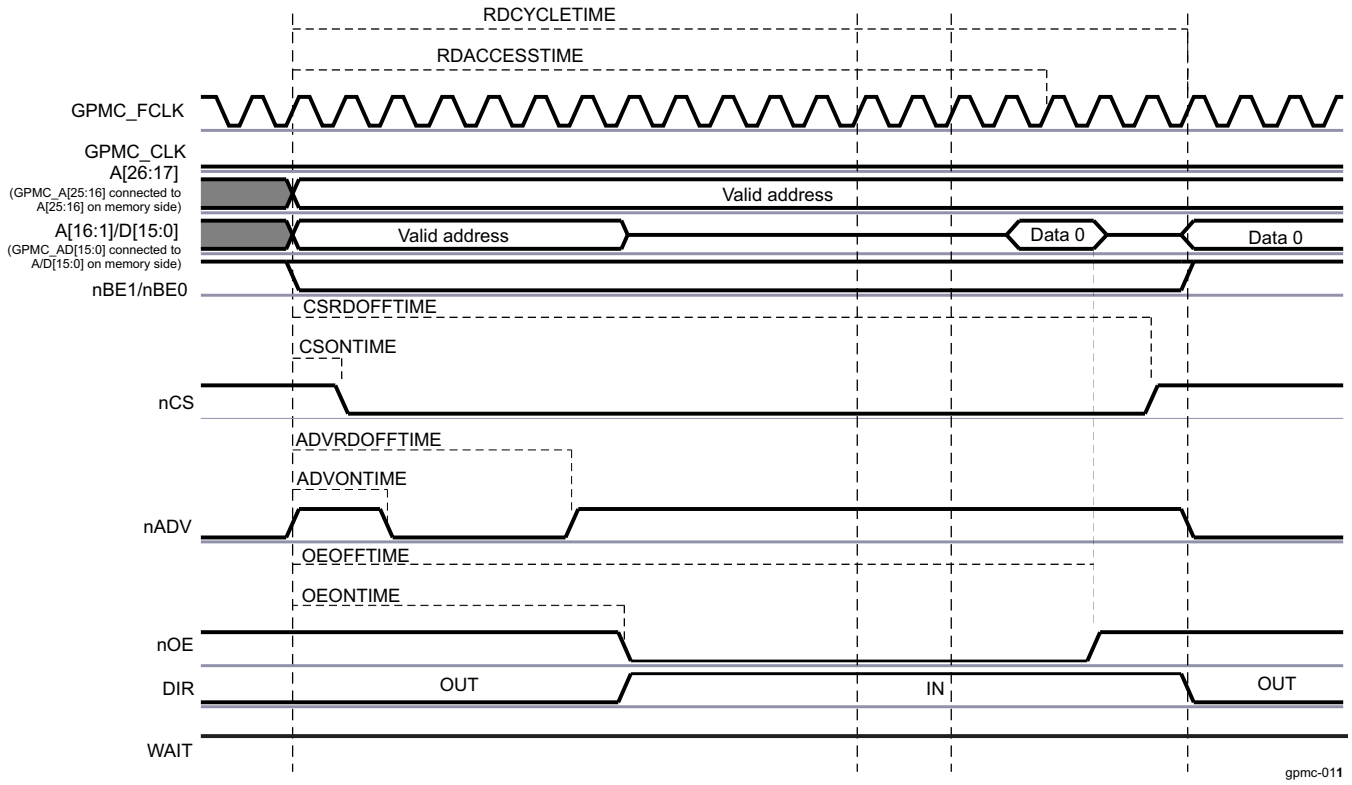
In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

7.3.4.10.1.1 Access on Address/Data Multiplexed Devices

7.3.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 7-170 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 7-170. Asynchronous Single Read on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 7.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 7-502 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 7.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[27:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

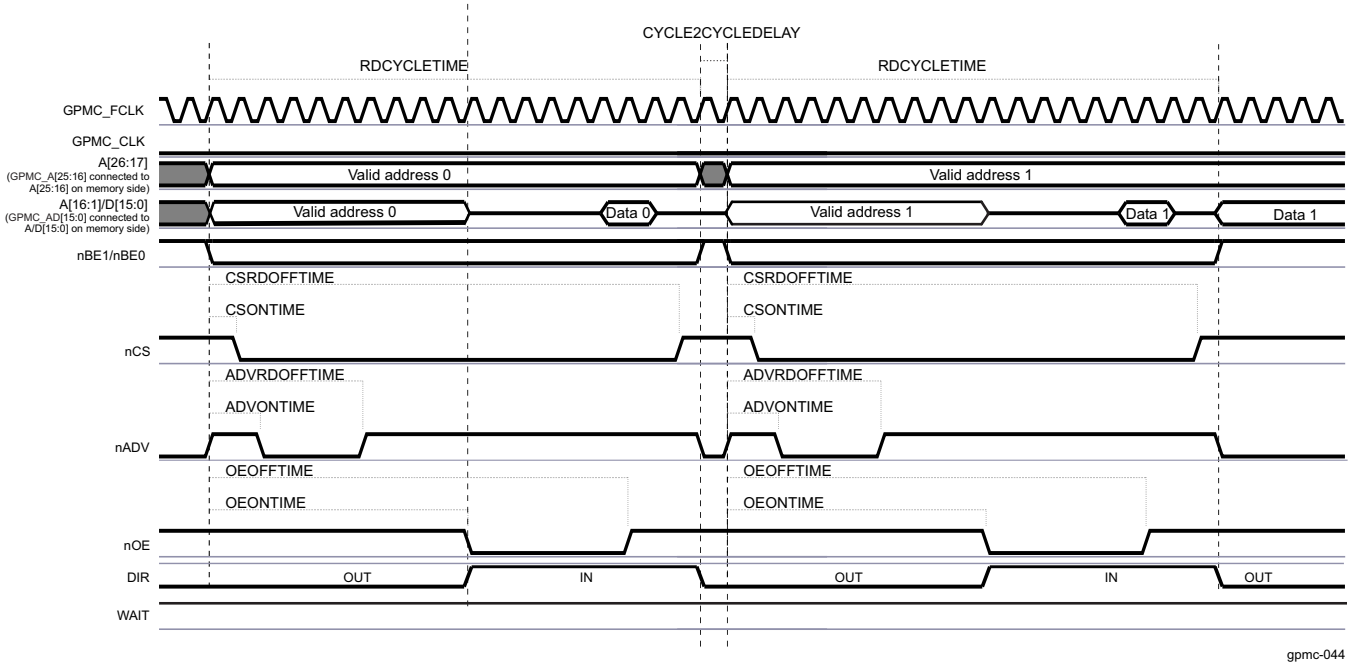
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 7.3.4.10.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

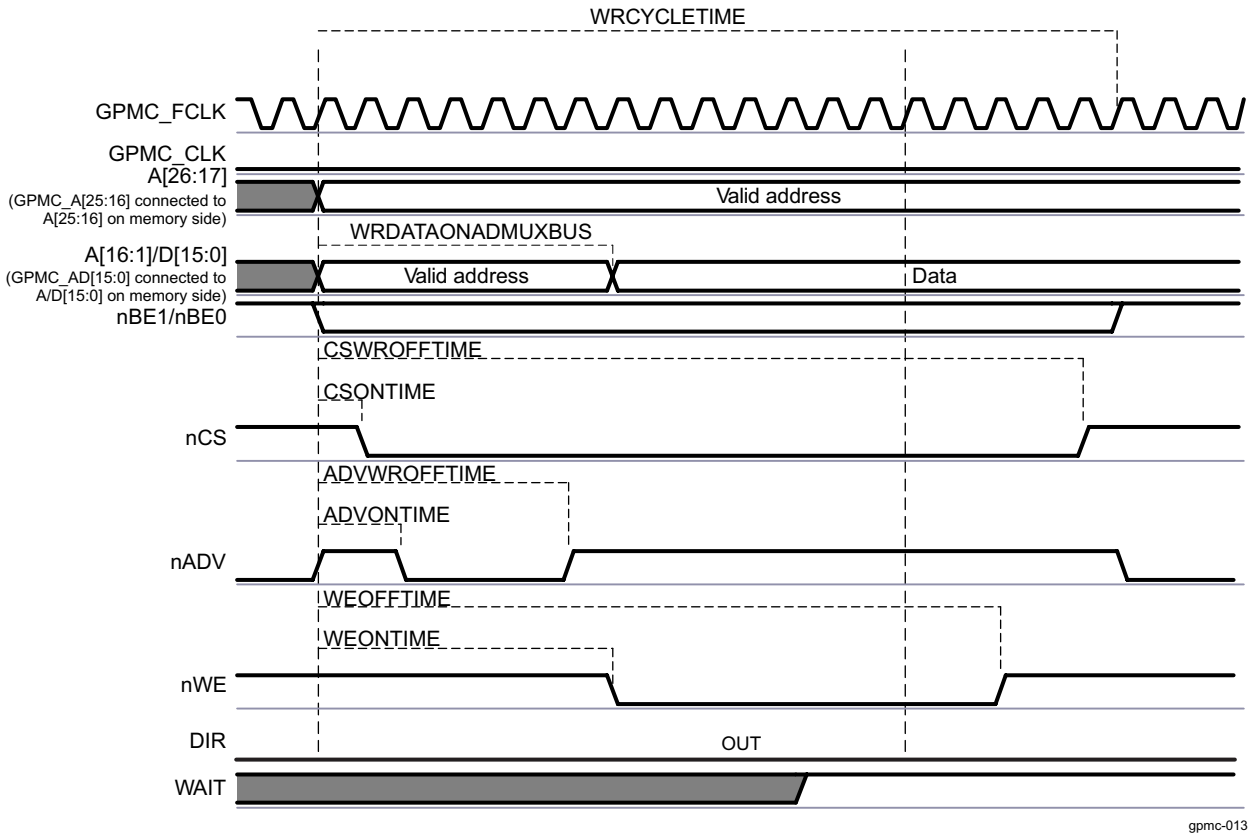
Figure 7-171. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)



7.3.4.10.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 7-172 shows an asynchronous single-write operation on an address/data-multiplexed device.

Figure 7-172. Asynchronous Single-Write on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 7.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 7-502 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 7.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 7.3.4.9.10, *Bus Keeping Support*.

7.3.4.10.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (1h) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0h), the GPMC processes single asynchronous accesses.

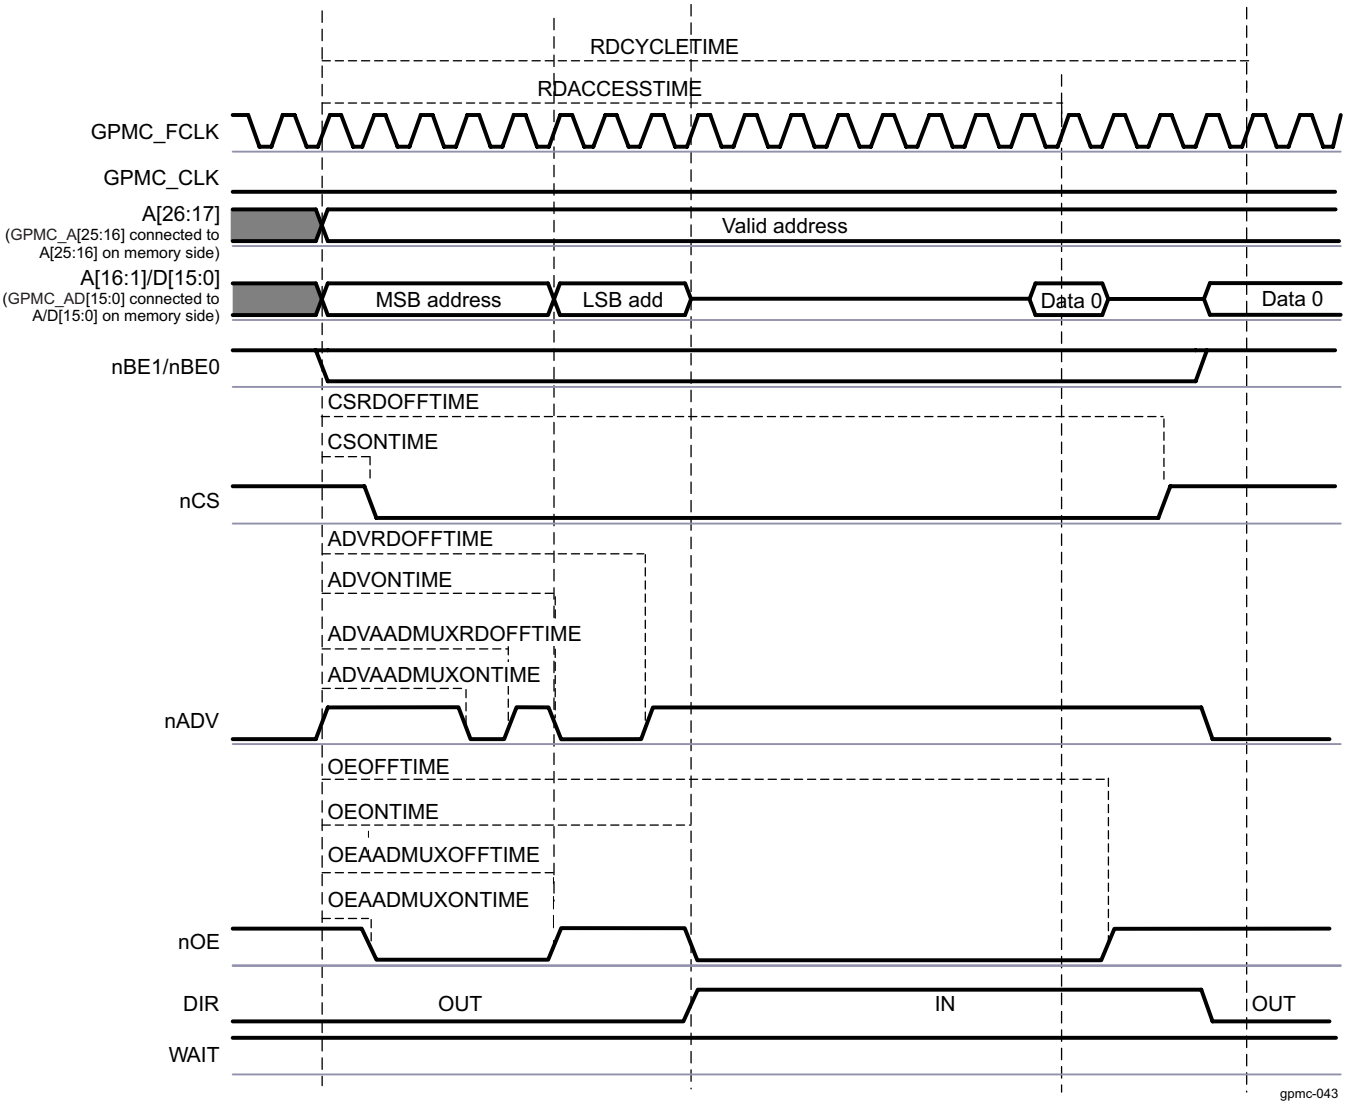
For accesses on non-multiplexed devices, see Section 7.3.4.10.3, *Asynchronous and Synchronous Accesses in non-multiplexed Mode*.

7.3.4.10.1.2 Access on Address/Address/Data-Multiplexed Devices

7.3.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 7-173 shows an asynchronous single-read operation on an AAD-multiplexed device.

Figure 7-173. Asynchronous Single Read on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 7.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 7-502 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

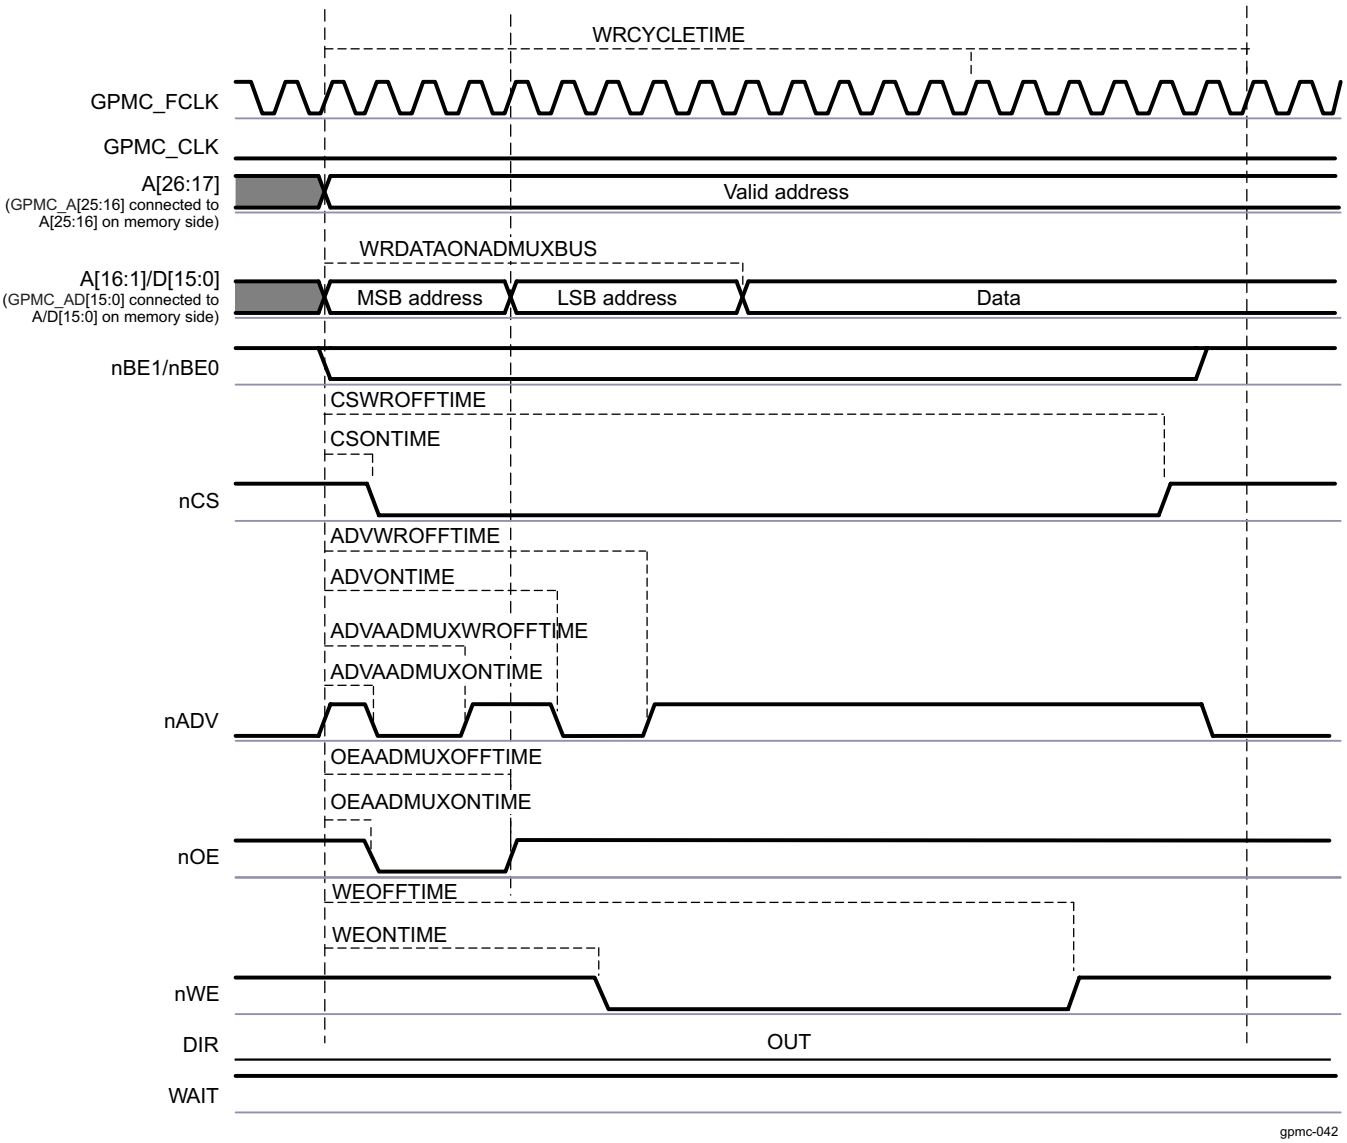
- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.

  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

7.3.4.10.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 7-174 shows an asynchronous single-write operation on an AAD-multiplexed device.

Figure 7-174. Asynchronous Single Write on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 7.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 7-502 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 7-493.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

7.3.4.10.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (1h) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0h), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 7.3.4.10.3, *Asynchronous and Synchronous Accessed in non-multiplexed Mode*.

7.3.4.10.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see Section 7.3.4.10.3, *Asynchronous and Synchronous Accessed in non-multiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

7.3.4.10.2.1 Synchronous Single Read

Figure 7-175 and Figure 7-176 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 7-175. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

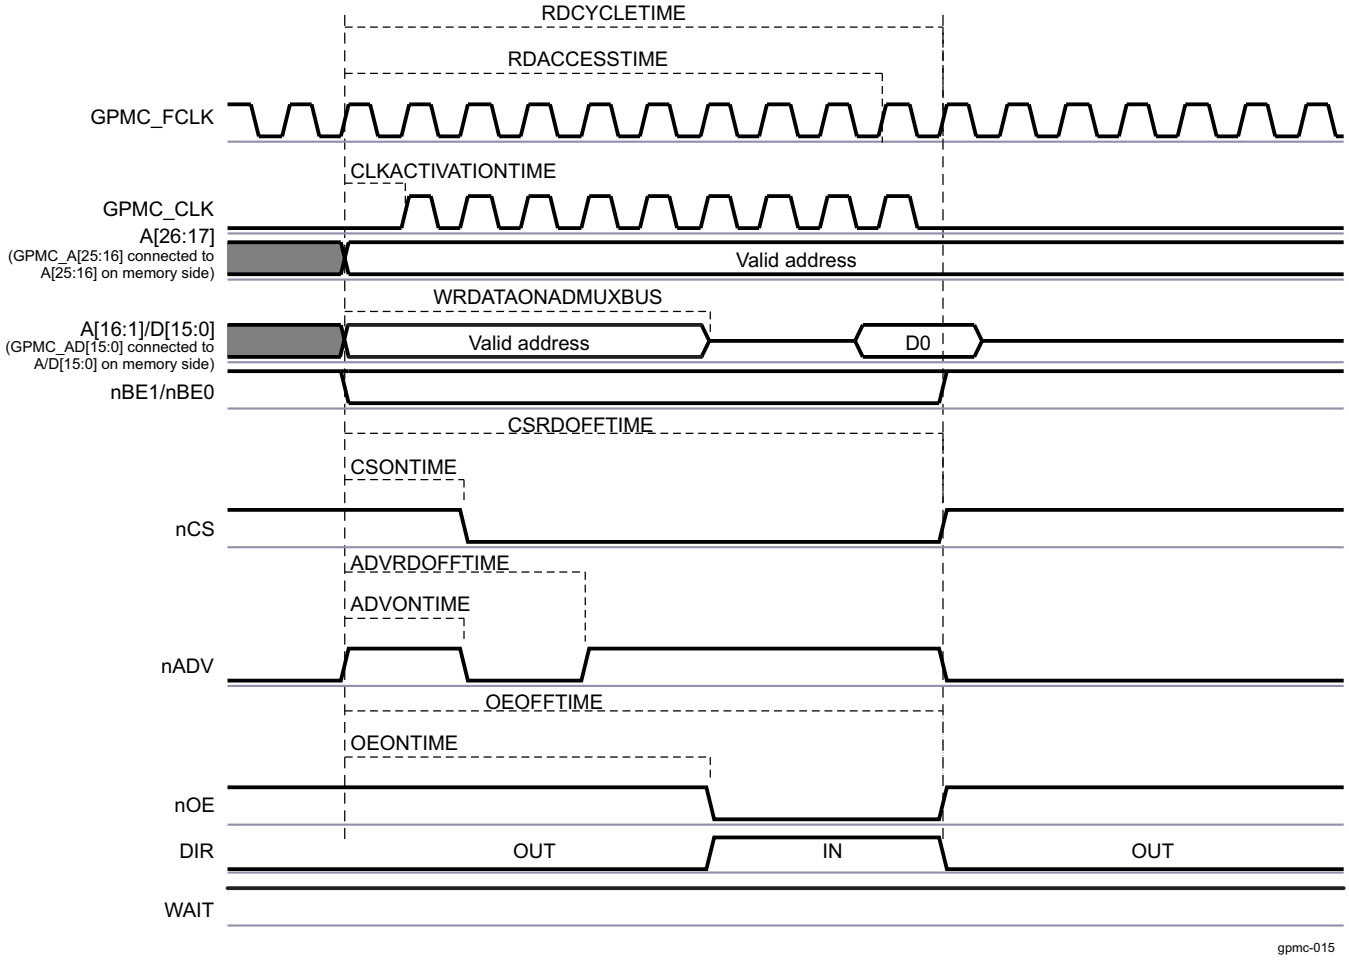


Figure 7-176. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

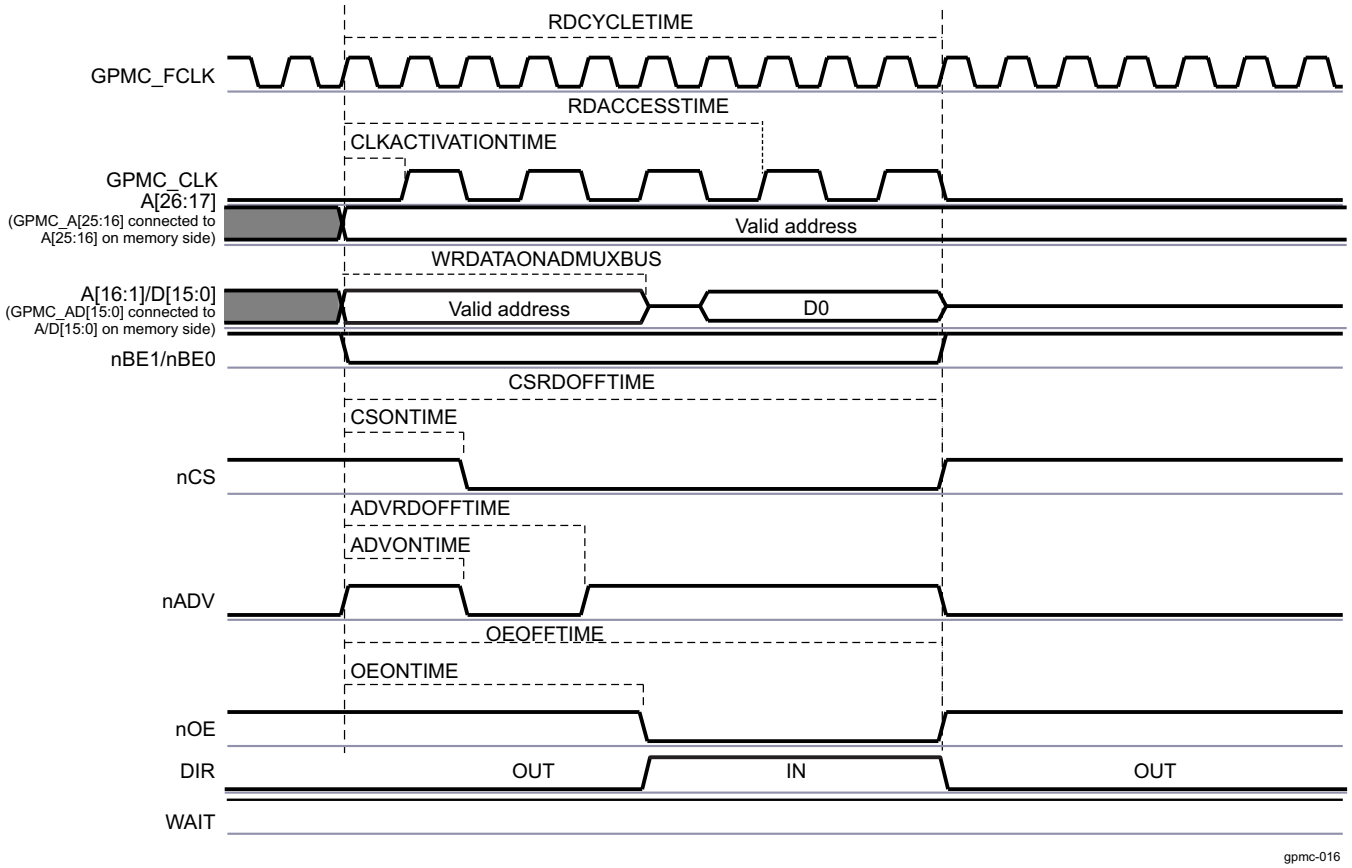

For formulas to calculate timing parameters, see Section 7.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 7-502 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 7.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 7.3.4.9.10, *Bus Keeping Support*.

7.3.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 7-177 and Figure 7-178 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 7-177. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

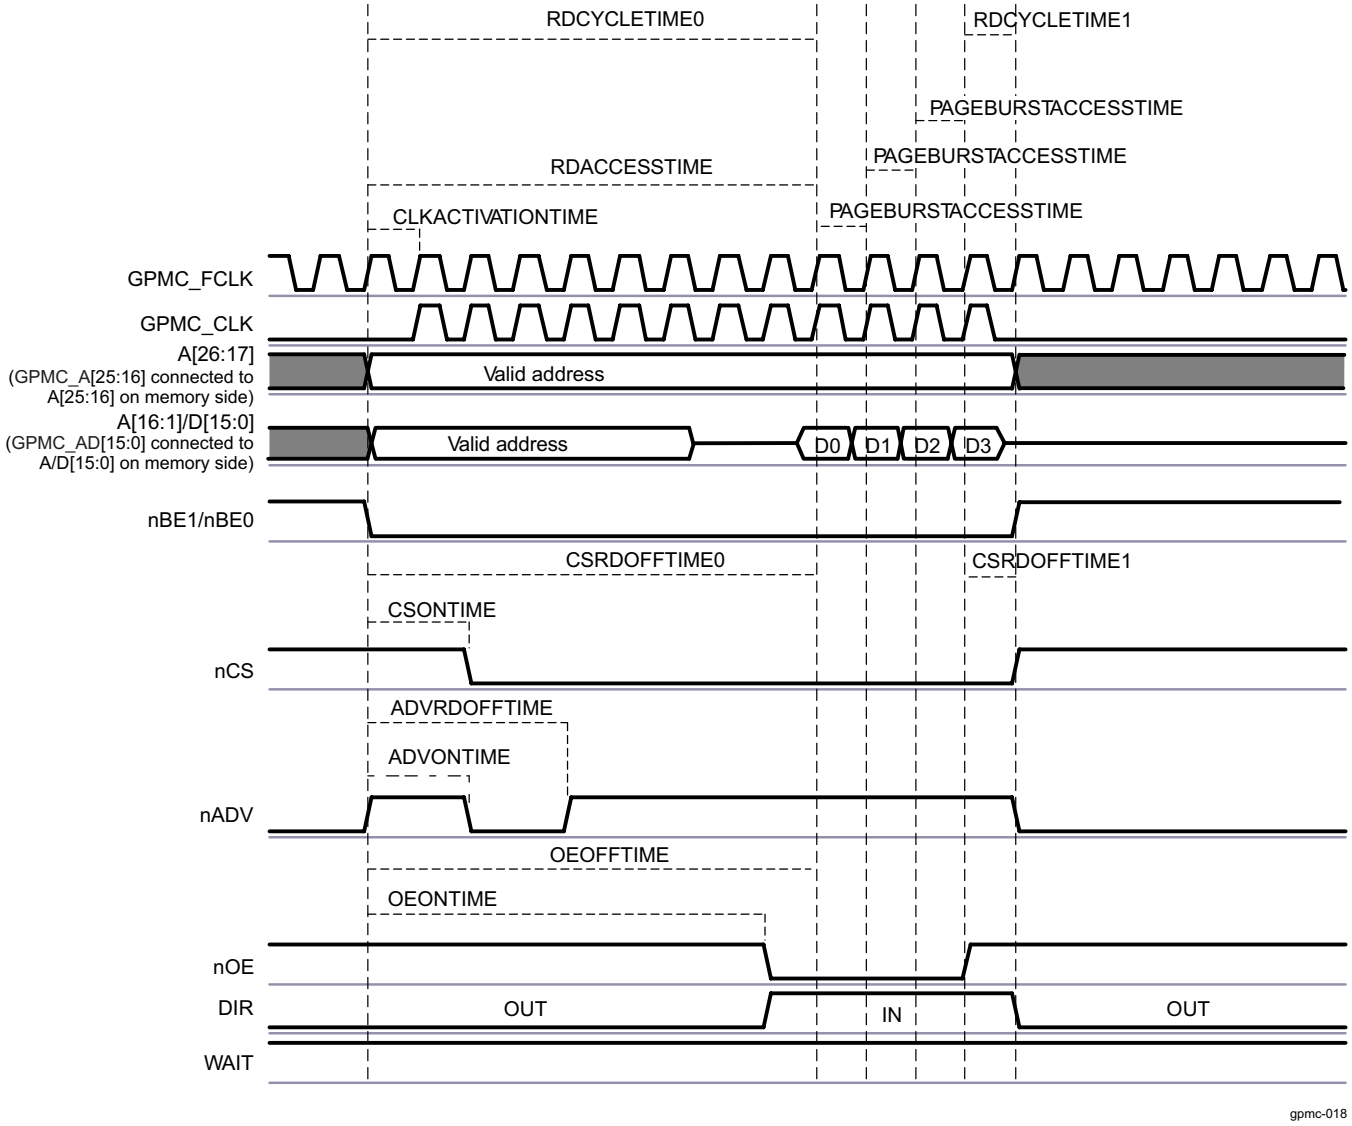

Figure 7-178. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

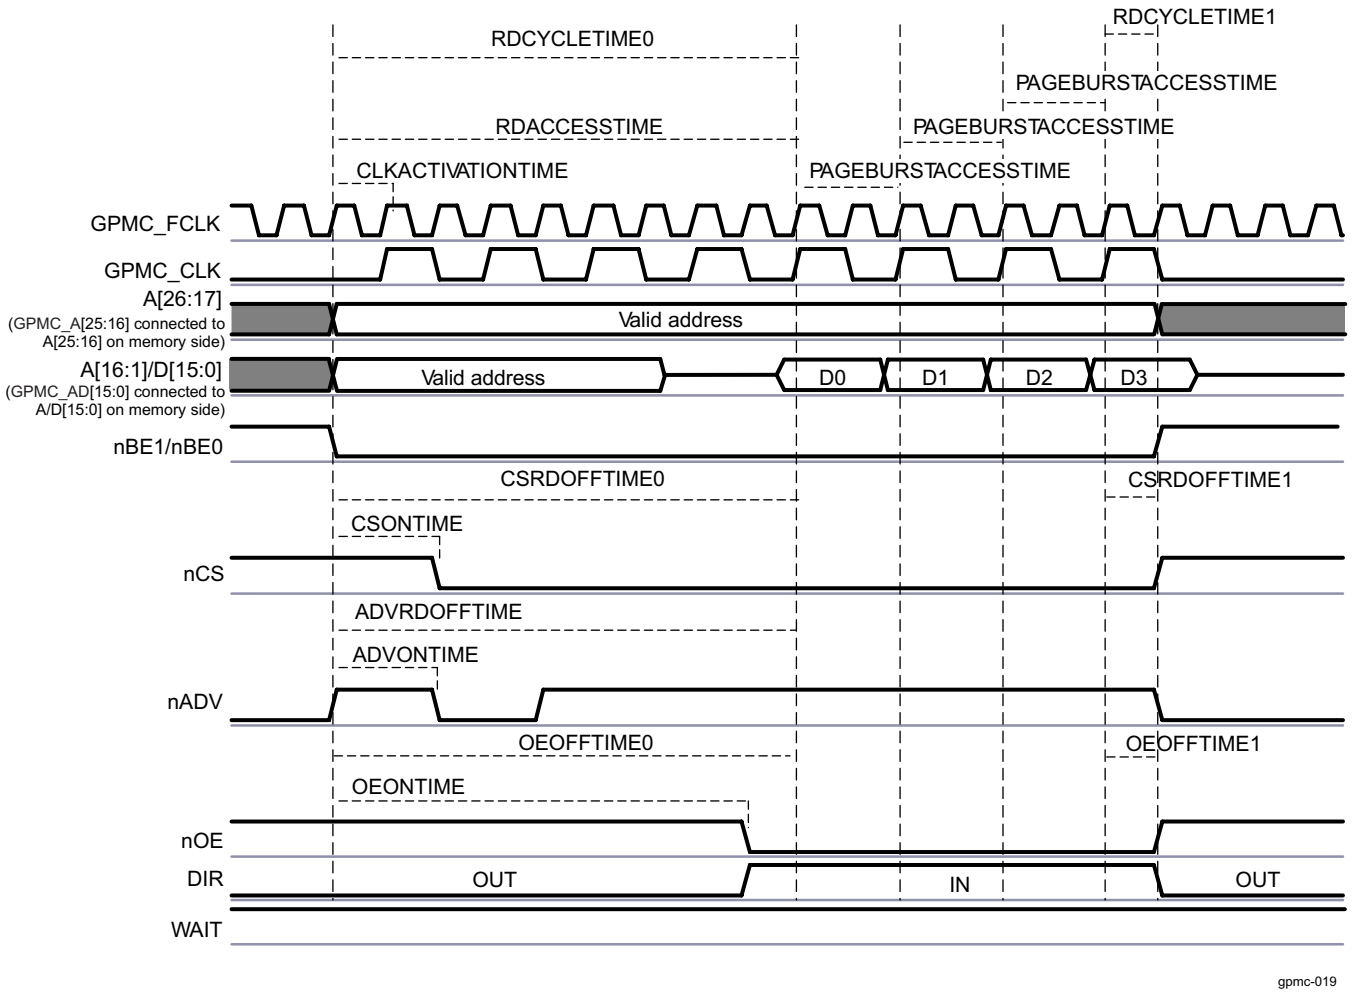


When the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 7-488.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 7-178, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

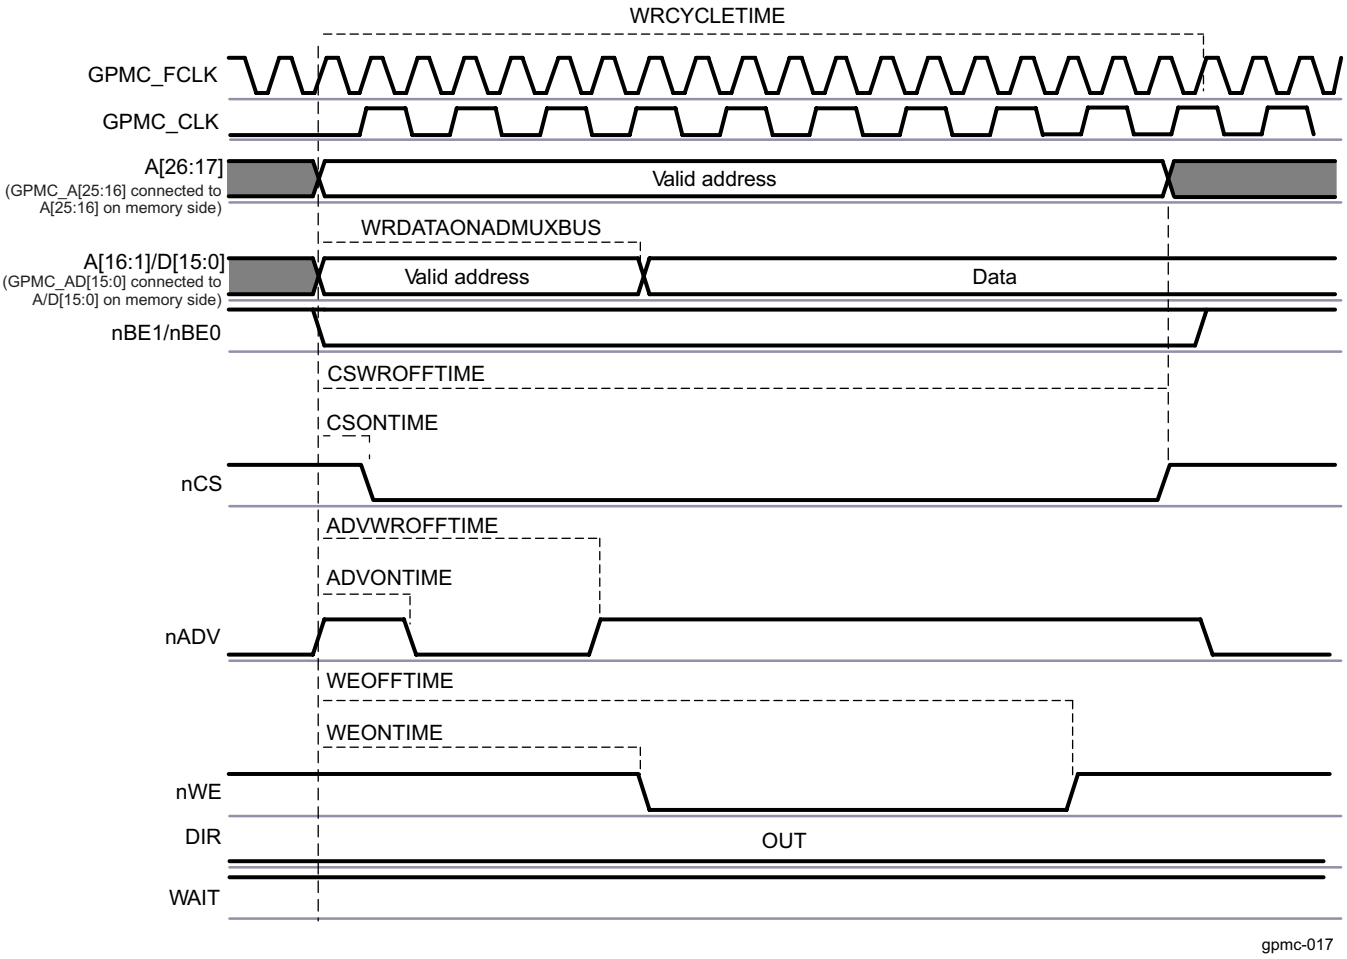
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 7.3.4.9.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

7.3.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 7-179. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

7.3.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 7-180 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 7-180. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

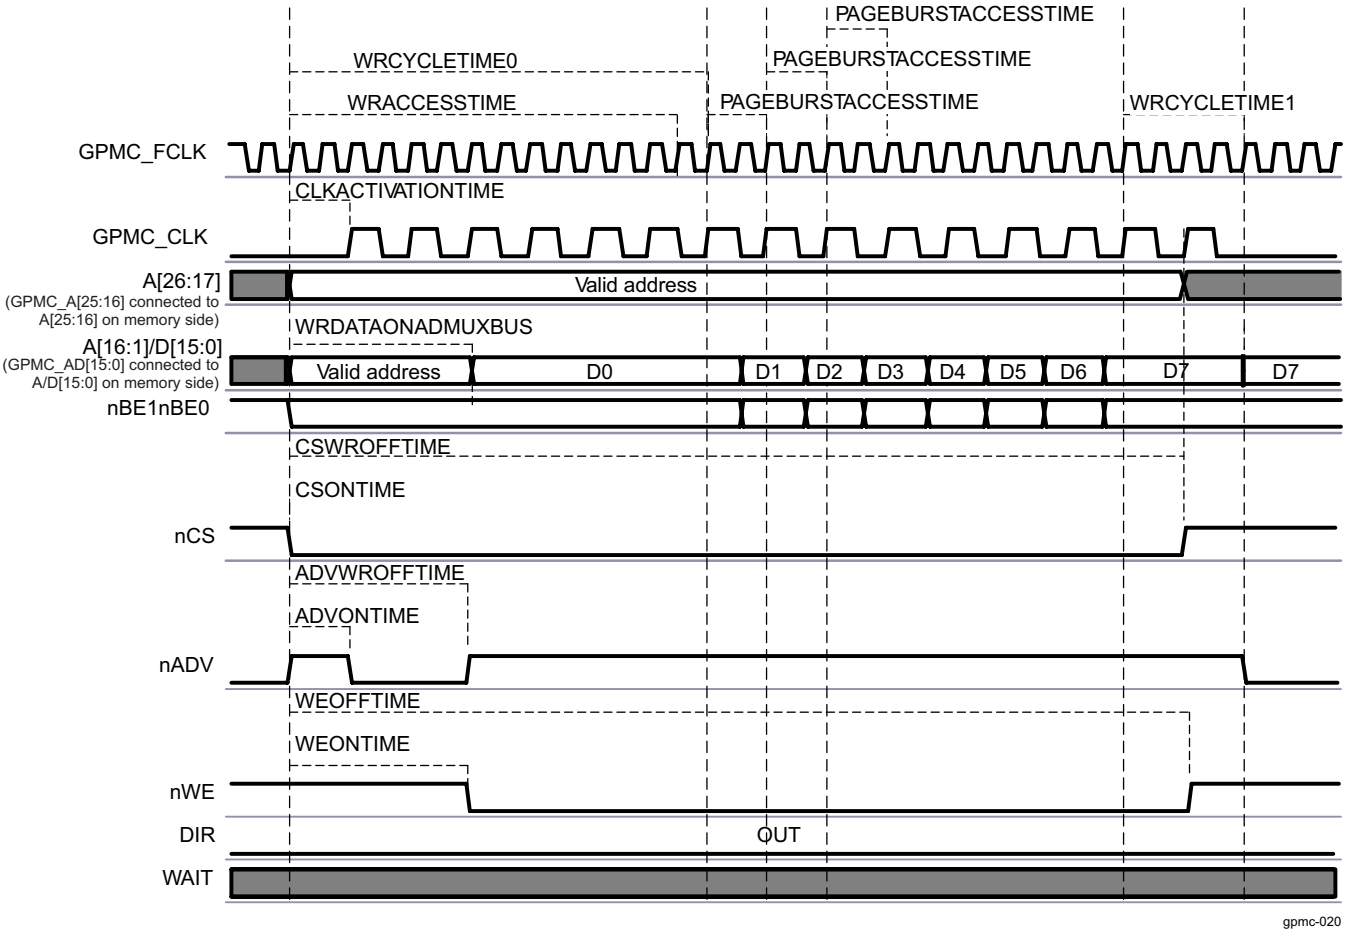


Figure 7-181 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

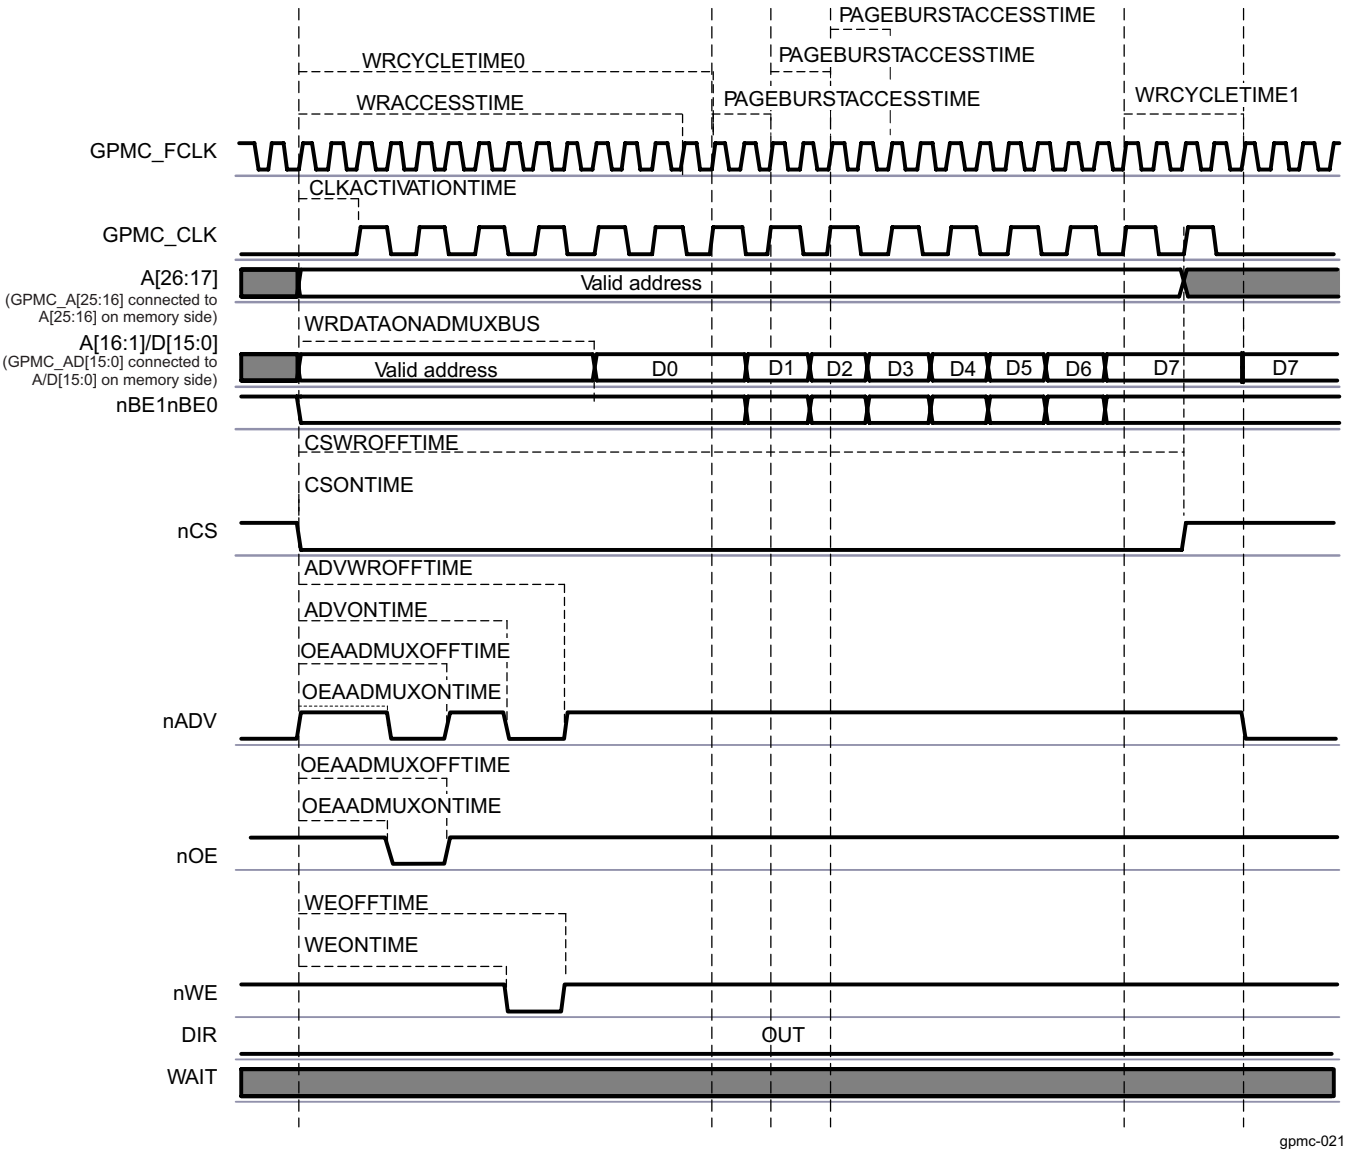
Figure 7-181. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 7.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 7-180, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 7.3.4.9.10, *Bus Keeping Support*.

7.3.4.10.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

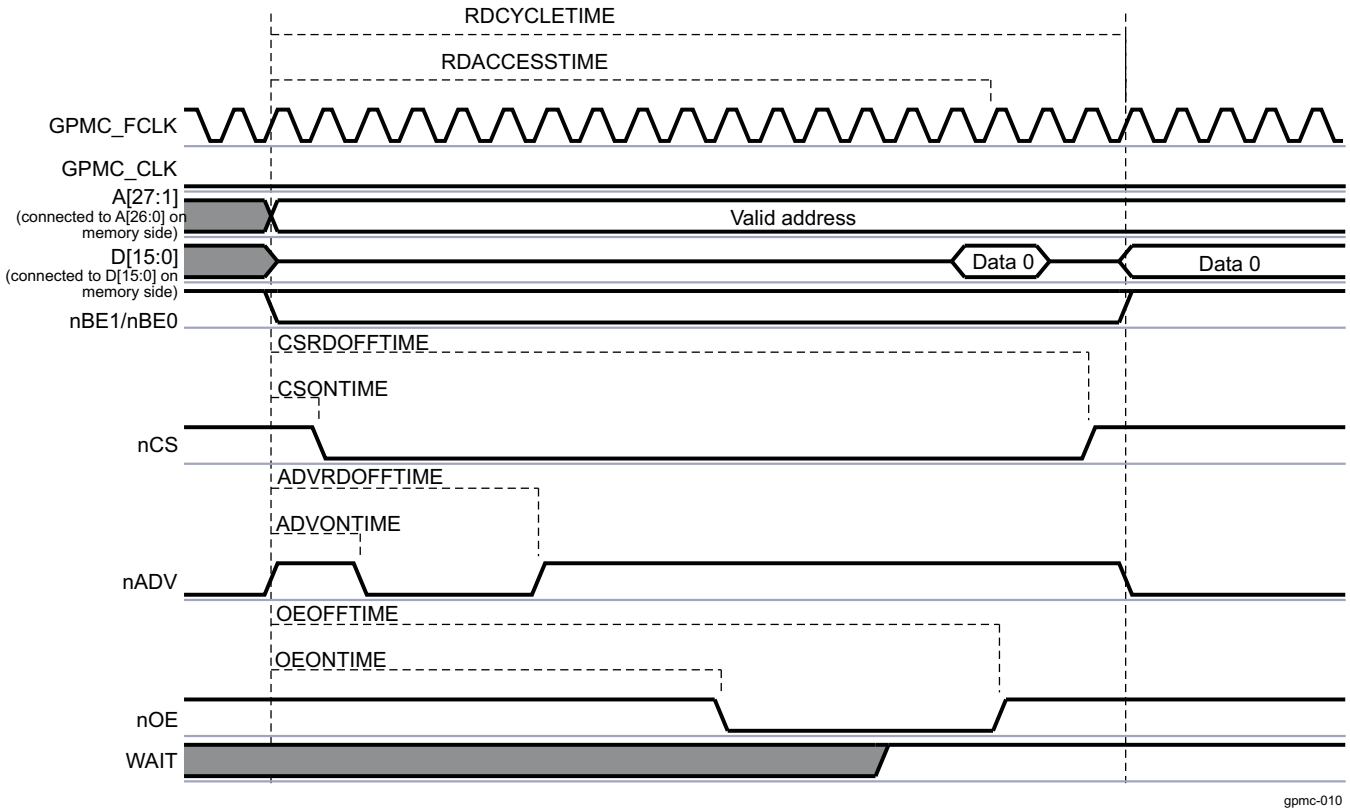
- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device

- Synchronous operations on a non-multiplexed device

7.3.4.10.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

Figure 7-182 shows an asynchronous single-read operation on a non-multiplexed device.

Figure 7-182. Asynchronous Single Read on an Address/Data-non-multiplexed Device



The 27-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

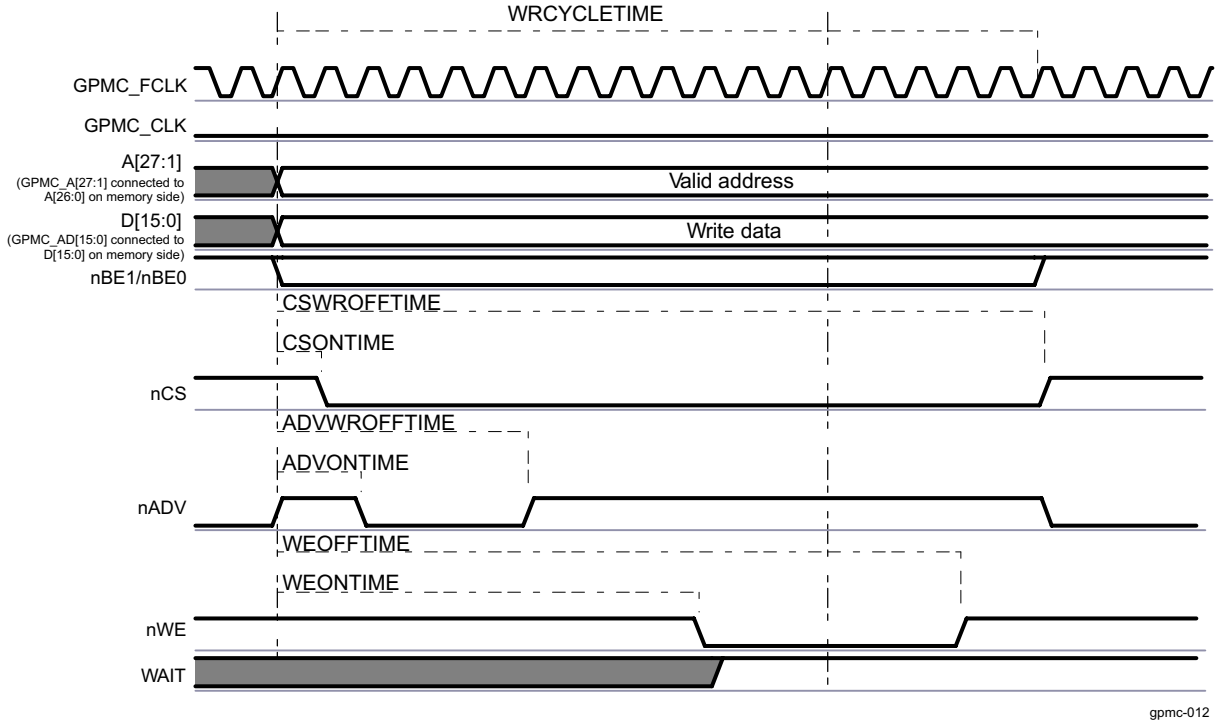
Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 7-493).

7.3.4.10.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

Figure 7-183 shows an asynchronous single-write operation on a non-multiplexed device.

Figure 7-183. Asynchronous Single Write on an Address/Data-non-multiplexed Device

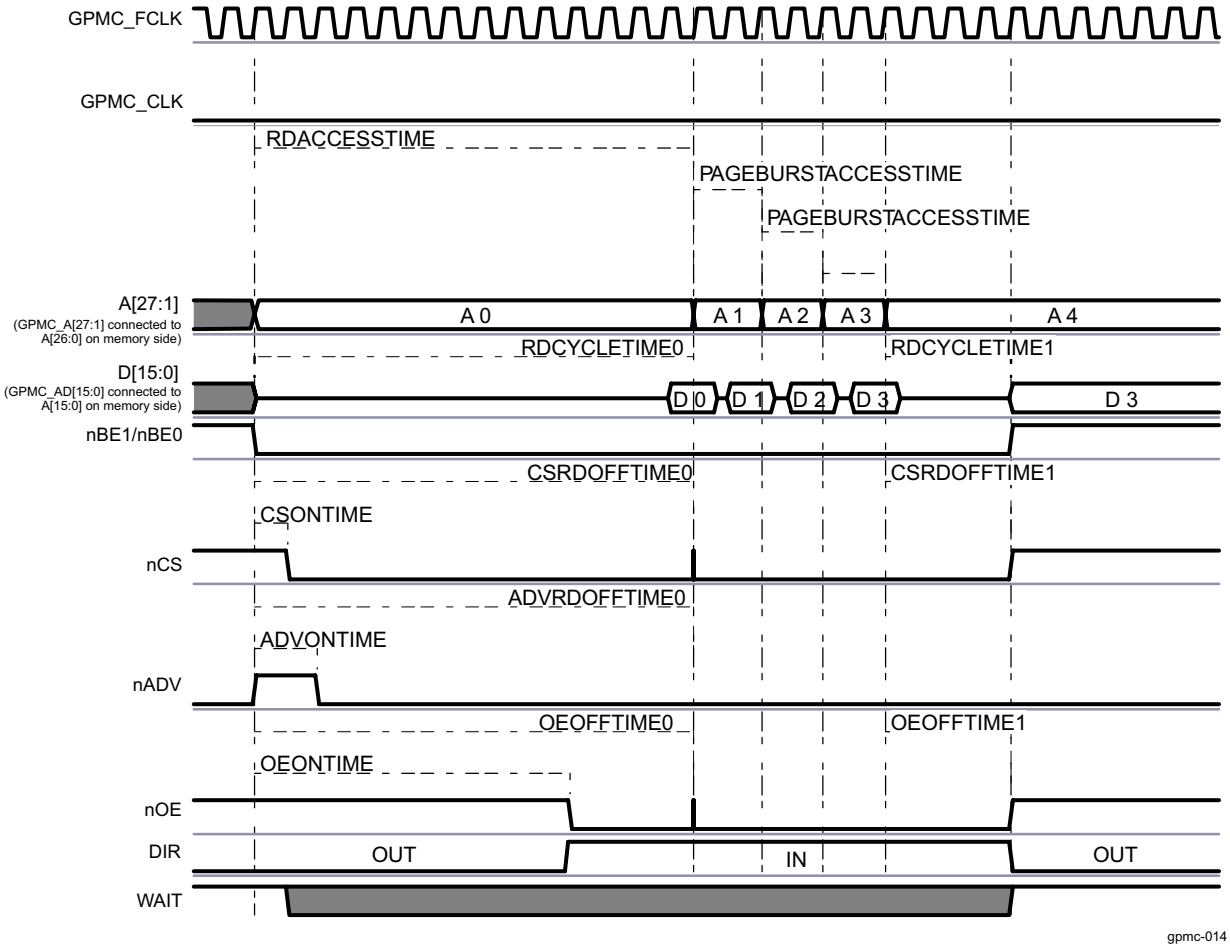


The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 7-493).

7.3.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

Figure 7-184 shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

Figure 7-184. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 7-493).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (where i = 0 to 3). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field.
- In Figure 7-184, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

7.3.4.10.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 7.3.5.3, *GPMC Configuration in NOR Mode*.

7.3.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

7.3.4.10.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), WAIT pin monitoring must be enabled to dynamically control data access completion within the burst.

NOTE: When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

7.3.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11-10] DEVICETYPE bit field (where i = 0 to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

7.3.4.12 NAND Access Description

NOTE: Due to device limitation, NAND functionality of the GPMC is not supported and the NAND functionality described in Section 7.3, *General-Purpose Memory Controller (GPMC)* is not applicable.

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

7.3.4.12.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

7.3.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 7-472. Failure to comply with these settings corrupts the NAND interface protocol.

Table 7-472. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine

(1) i = 0 to 3

Table 7-472. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
