- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (EQEP_QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP_QEPSTS[CDEF]).

Capture Timer (EQEP_QCTMR register) and Capture period register (EQEP_QCPRD) can be configured to latch on following events.

- CPU read of EQEP_QPOSCNT register
- Unit time-out event

If the EQEP_QEPCTL[2] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP_QCTMRLAT and EQEP_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP_QPOSCNT.

If the EQEP_QEPCTL[2] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP_QPOSLAT, EQEP_QCTMRLAT and EQEP_QCPRDLAT registers, respectively, on unit time out.

Figure 11-451 shows the capture unit operation along with the position counter.

NOTE: The EQEP_QCAPCTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLKOUT/4 to SYSCLKOUT/8, where SYSCLKOUT is equivalent to EQEP_x_VBUS_CLK). The capture unit must be disabled before changing the prescaler.

Figure 11-449. eQEP Edge Capture Unit

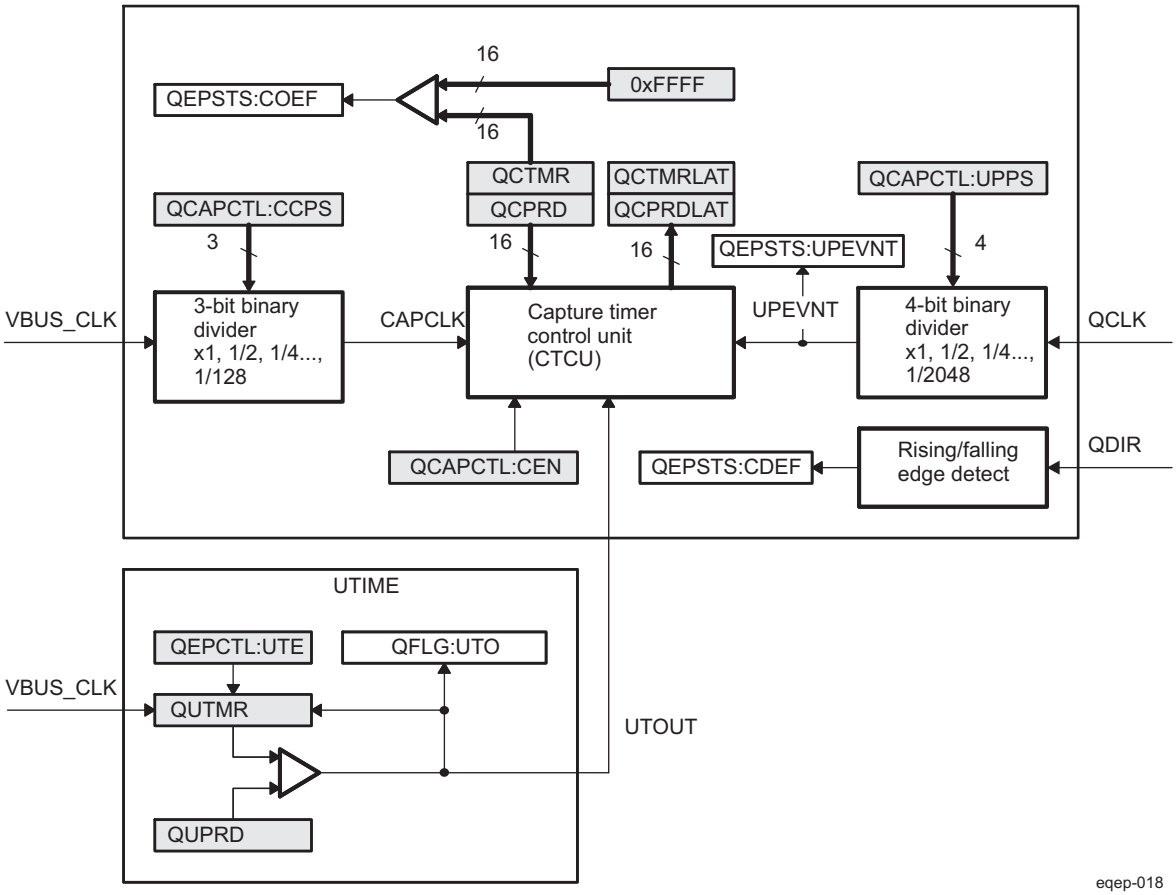

Figure 11-450. Unit Position Event for Low Speed Measurement (EQEP_QCAPCTL[UPPS] = 0010)

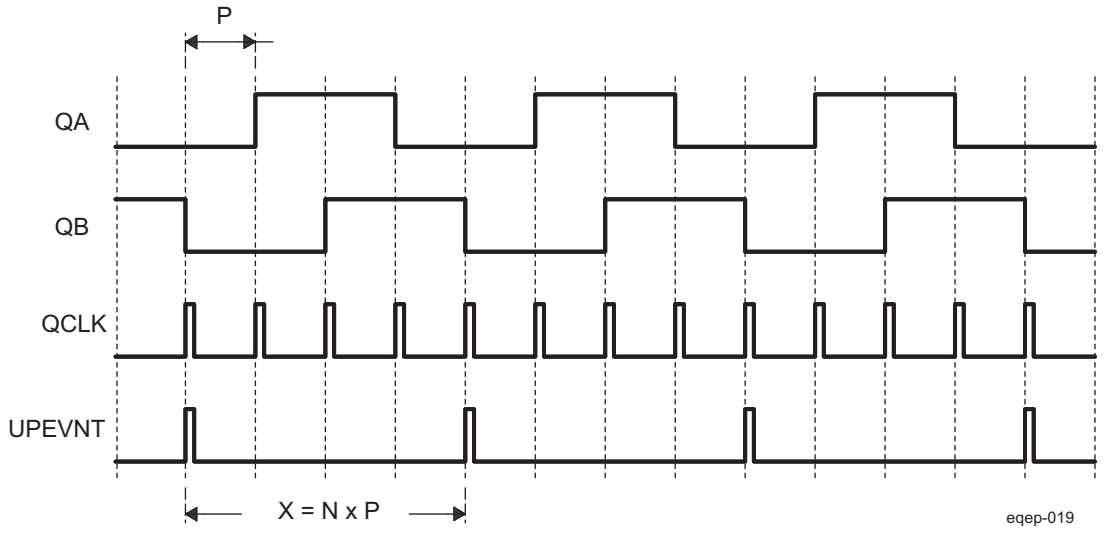
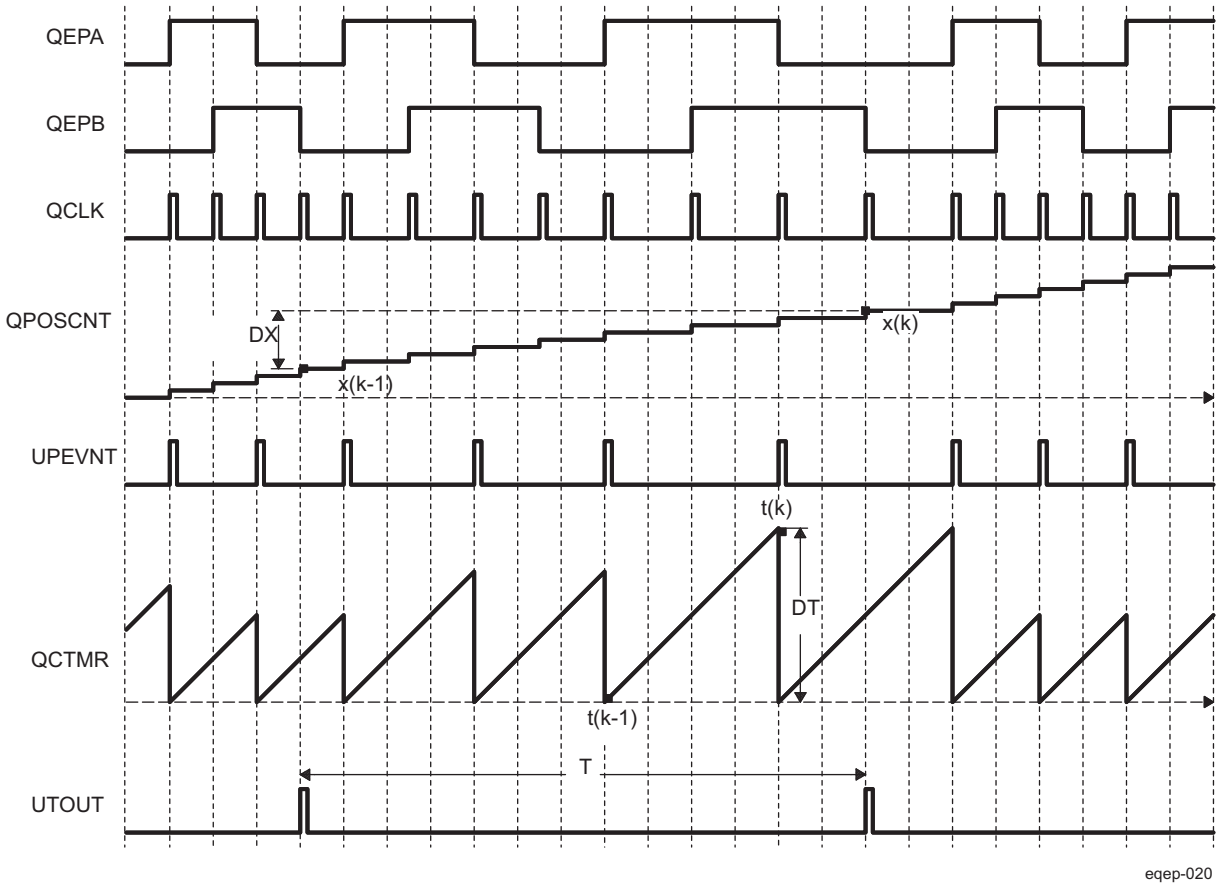


N - Number of quadrature periods selected using EQEP_QCAPCTL[UPPS] bits

Figure 11-451. eQEP Edge Capture Unit - Timing Details



Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{or}$$

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

eqep_021 (8)

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

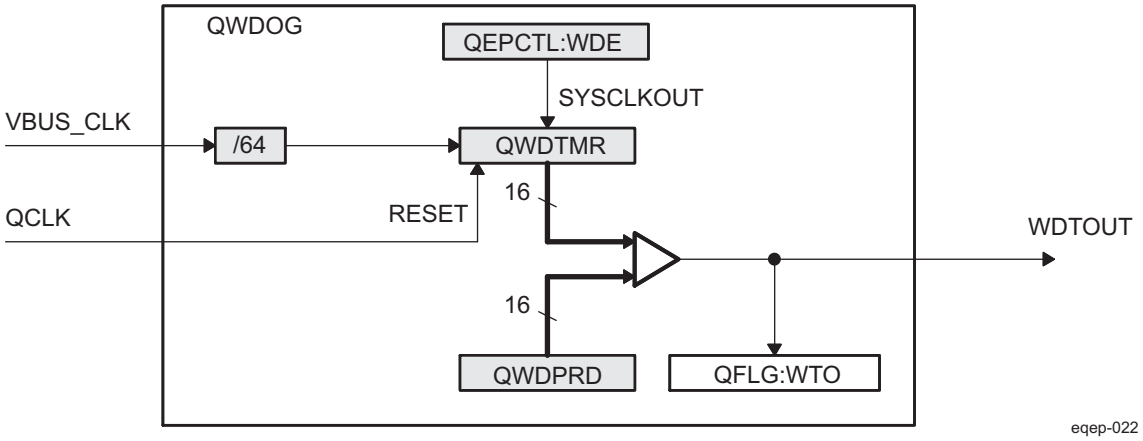
Unit time (T) and unit period (X) are configured using the EQEP_QUPRD and EQEP_QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the EQEP_QPOSLAT and EQEP_QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(k - 1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

11.6.4.5 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrate clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP_QFLG[WTO]). The time-out value is programmable through the watchdog period register (EQEP_QWDPRD).

Figure 11-452. eQEP Watchdog Timer

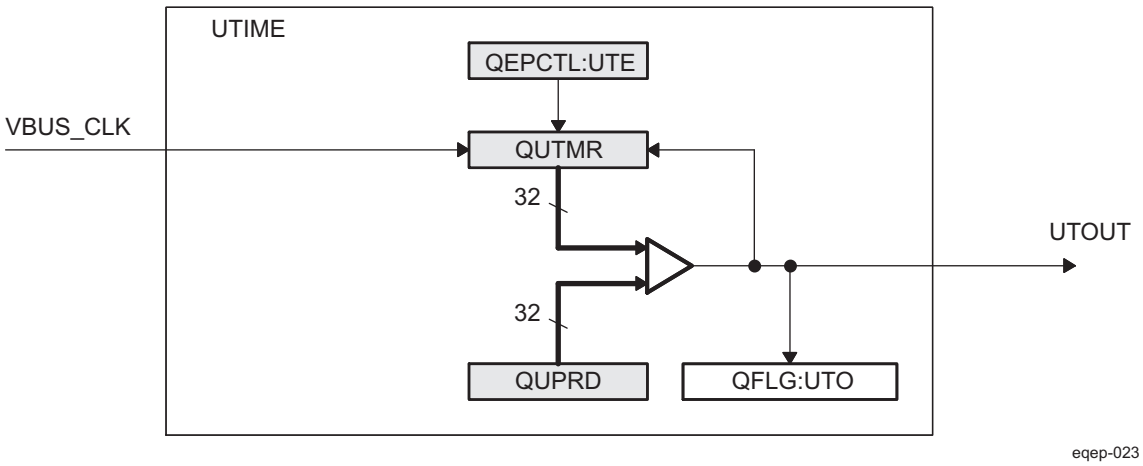


11.6.4.6 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (EQEP_QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (EQEP_QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section Section 11.6.4.4.

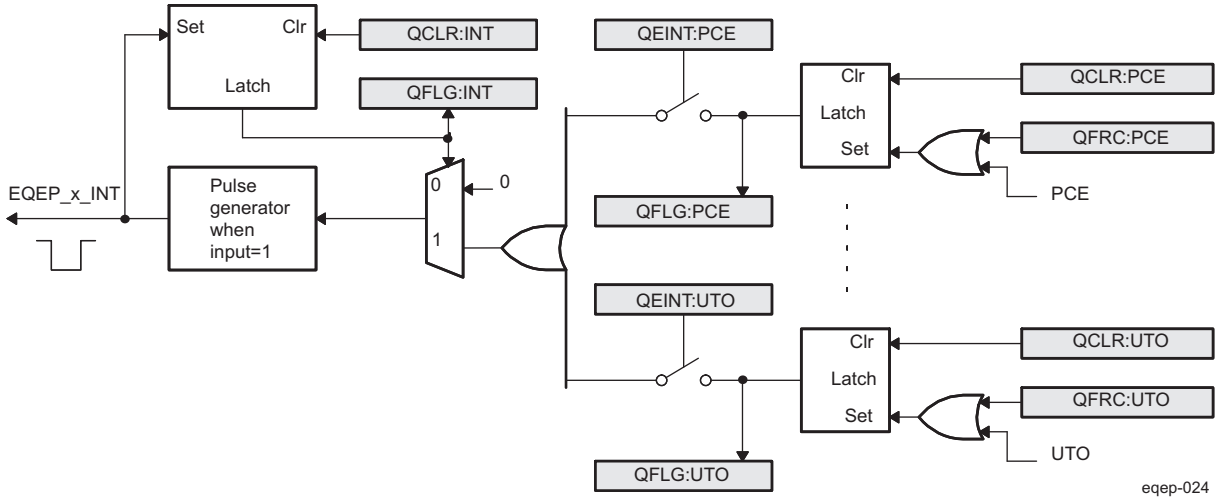
Figure 11-453. eQEP Unit Time Base



11.6.4.7 eQEP Interrupt Structure

Figure 11-454 shows how the interrupt mechanism works in the EQEP module.

Figure 11-454. EQEP Interrupt Generation



Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (EQEP_QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (EQEP_QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (EQEP_QCLR), before any other interrupt pulses are generated. SW can force an interrupt event by way of the interrupt force register (EQEP_QFRC), which is useful for test purposes.

11.6.4.8 Summary of eQEP Functional Registers

Table 11-929 lists the registers with their memory locations, sizes, and reset values.

Table 11-929. eQEP Control and Status Functional Registers

Table 11-969. EQEP_QEPCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Control Bits. In the values 0 through 3 listed below, x is different for the four following behaviors. EQEP_QPOSCNT behavior, x refers to the Position counter. QWDTMR behavior, x refers to the Watchdog counter. QUTMR behavior, x refers to the Unit timer. QCTMR behavior, x refers to the Capture timer. 0h = x stops immediately. For QPOSCNT behavior, the stop is on emulation suspend. 1h = x continues to count until the rollover. 2h = x is unaffected by emulation suspend. 3h = x is unaffected by emulation suspend.
13-12	PCRM	R/W	0h	Position counter reset mode 0h = Position counter reset on an index event 1h = Position counter reset on the maximum position 2h = Position counter reset on the first index event 3h = Position counter reset on a unit time event
11-10	SEI	R/W	0h	Strobe event initialization of position counter 0h = Does nothing (action disabled) 1h = Does nothing (action disabled) 2h = Initializes the position counter on rising edge of the QEPS signal 3h = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe. Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe
9-8	IEI	R/W	0h	Index event initialization of position counter 0h = Do nothing (action disabled) 1h = Do nothing (action disabled) 2h = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)
7	SWI	R/W	0h	Software initialization of position counter 0h = Do nothing (action disabled) 1h = Initialize position counter, this bit is cleared automatically

Table 11-969. EQEP_QEPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	SEL	R/W	0h	Strobe event latch of position counter 0h = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the EQEP_QDECCTL register. 1h = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe. Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe.
5-4	IEL	R/W	0h	Index event latch of position counter (software index marker) 0h = Reserved 1h = Latches position counter on rising edge of the index signal 2h = Latches position counter on falling edge of the index signal 3h = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the EQEP_QPOSILAT register and the direction flag is latched in the EQEP_QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	PHEN	R/W	0h	Quadrature position counter enable/software reset 0h = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. 1h = eQEP position counter is enabled
2	QCLM	R/W	0h	eQEP capture latch mode 0h = Latch on position counter read by CPU. Capture timer and capture period values are latched into EQEP_QCTMRLAT and EQEP_QCPRDLAT registers when CPU reads the EQEP_QPOSCNT register. 1h = Latch on unit time out. Position counter, capture timer and capture period values are latched into EQEP_QPOSLAT, EQEP_QCTMRLAT and EQEP_QCPRDLAT registers on unit time out.
1	UTE	R/W	0h	eQEP unit timer enable 0h = Disable eQEP unit timer 1h = Enable unit timer
0	WDE	R/W	0h	eQEP watchdog enable 0h = Disable the eQEP watchdog timer 1h = Enable the eQEP watchdog timer

11.7 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Interface (GPIO) for the device.

11.7.1 GPIO Overview

The general-purpose input/output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

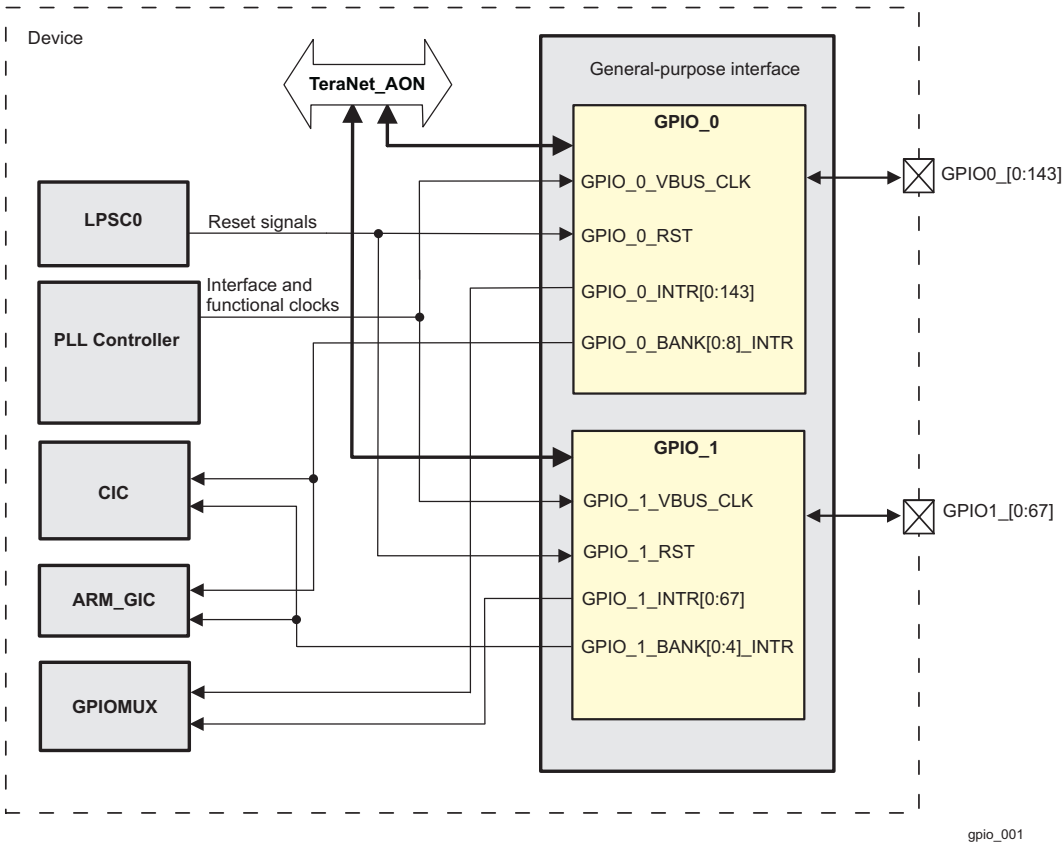
In addition, the GPIO peripheral can produce CPU interrupts and EDMA synchronization events in different interrupt/event generation modes.

The device has two instances of GPIO144 modules (GPIO_0 and GPIO_1). The GPIO pins are grouped into banks (16 pins per bank), which means that each GPIO module provides up to 144 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 288 (2 instances × (9 banks x 16 pins)) pins. Since GPIO1_[143:68] are reserved in this Device, general-purpose interface supports up to 212 pins.

All GPIO pins are muxed with other device pins. For details on specific muxing and for the availability of the register bits, see the device Data Manual. GPINTj (where j = bit index, j = [0:31]) are all available as synchronization events to the EDMA and as interrupt sources to the CPU.

Figure 11-480 is an overview of the general-purpose interface.

Figure 11-480. GPIO Overview



Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:

  - Can enable interrupts for each bank of 16 GPIO signals
  - Interrupts can be triggered by rising and/or falling edge (or neither edge = disabled), specified for each interrupt capable GPIO signal
- Set/clear functionality:
  - Software writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple software processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
  - Output register in addition to set/clear so that if preferred by software, some GPIO output signals can be toggled by direct write to the output register(s).
  - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status and open-drain I/O cell, allows wired logic be implemented.

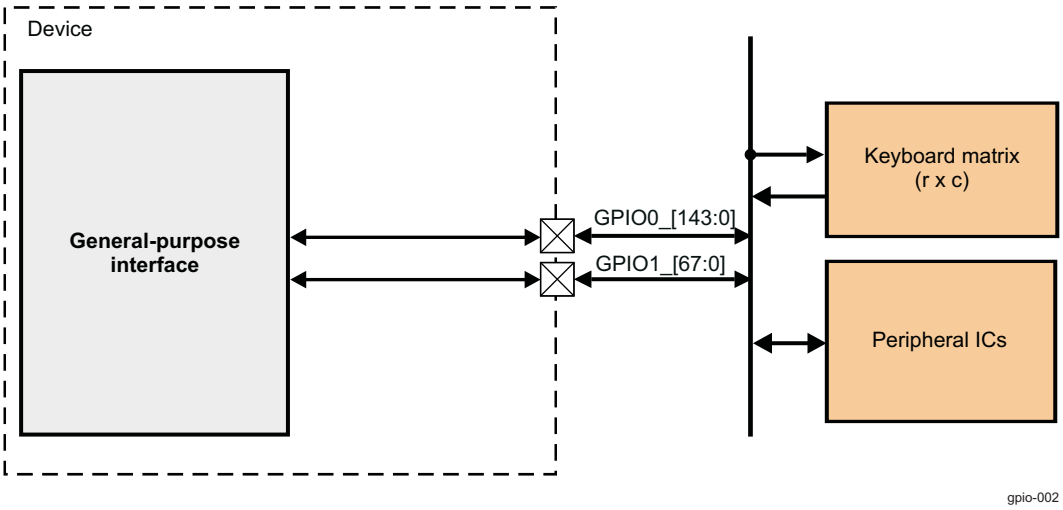
11.7.2 GPIO Environment

The general-purpose interface combines two GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

Figure 11-481 shows a typical application using the general-purpose interface.

Figure 11-481. GPIO Typical Application



11.7.2.1 General-Purpose Interface Signals

Table 11-1007 describes the module signals.

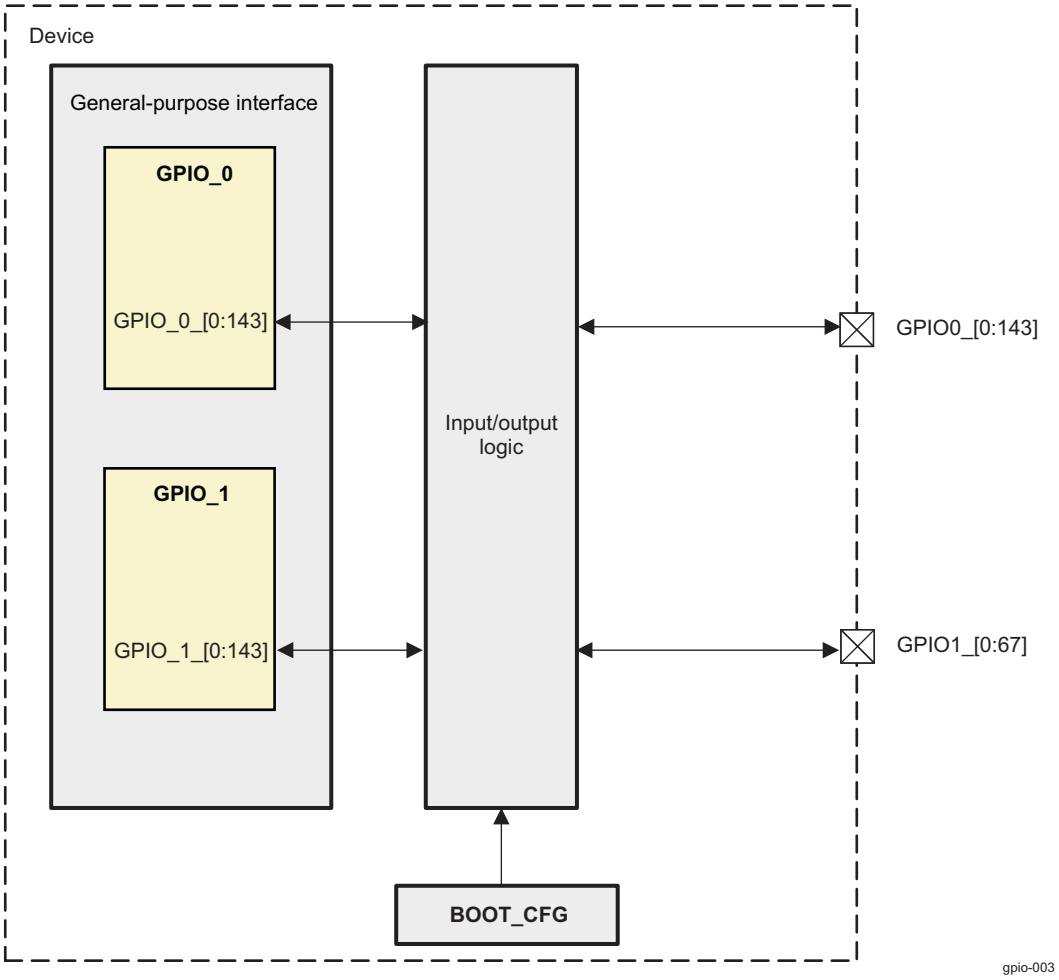
Table 11-1007. GPIO Description

Signal	I/O[1]	Description	Reset Value[2]
GPIO0_[0:143]	I/O	GPIO	HiZ
GPIO1_[0:67]	I/O	GPIO	HiZ

(1) I = Input; O = Output; I/O = Bidirectional
(2) HiZ = High Impedance

Figure 11-482 shows the signal connections of GPIO_0 and GPIO_1.

Figure 11-482. GPIO_0 and GPIO_1 Signal Connections



NOTE: For more information about GPIO signal multiplexing, see Section 5.1.3.1.1, *Pad Configuration Registers* in Section 5.1, *BOOT_CFG*.

11.7.3 GPIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-483 shows this module integration.

Figure 11-483. GPIO Integration

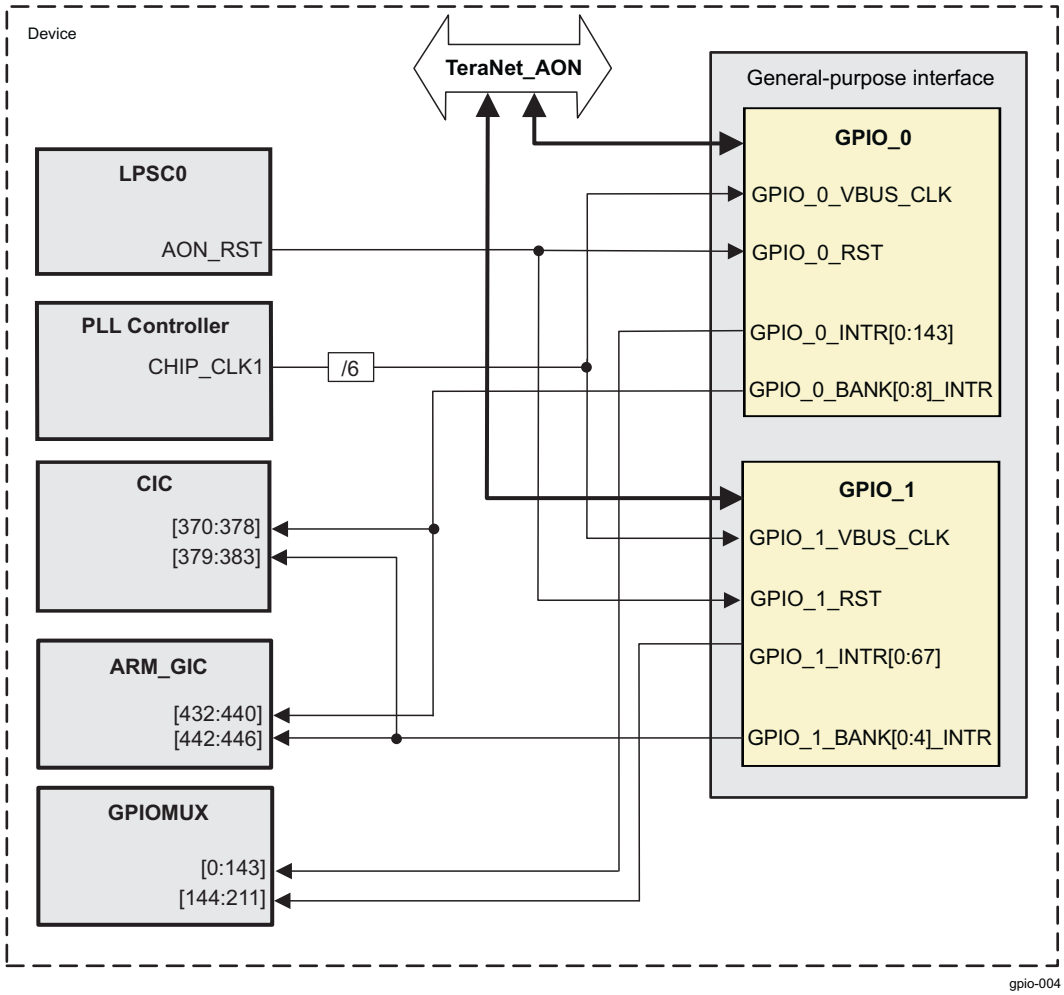


Table 11-1008 through Table 11-1010 summarize the integration of the module in the device.

Table 11-1008. GPIO Integration Attributes

Module Instance	Attributes

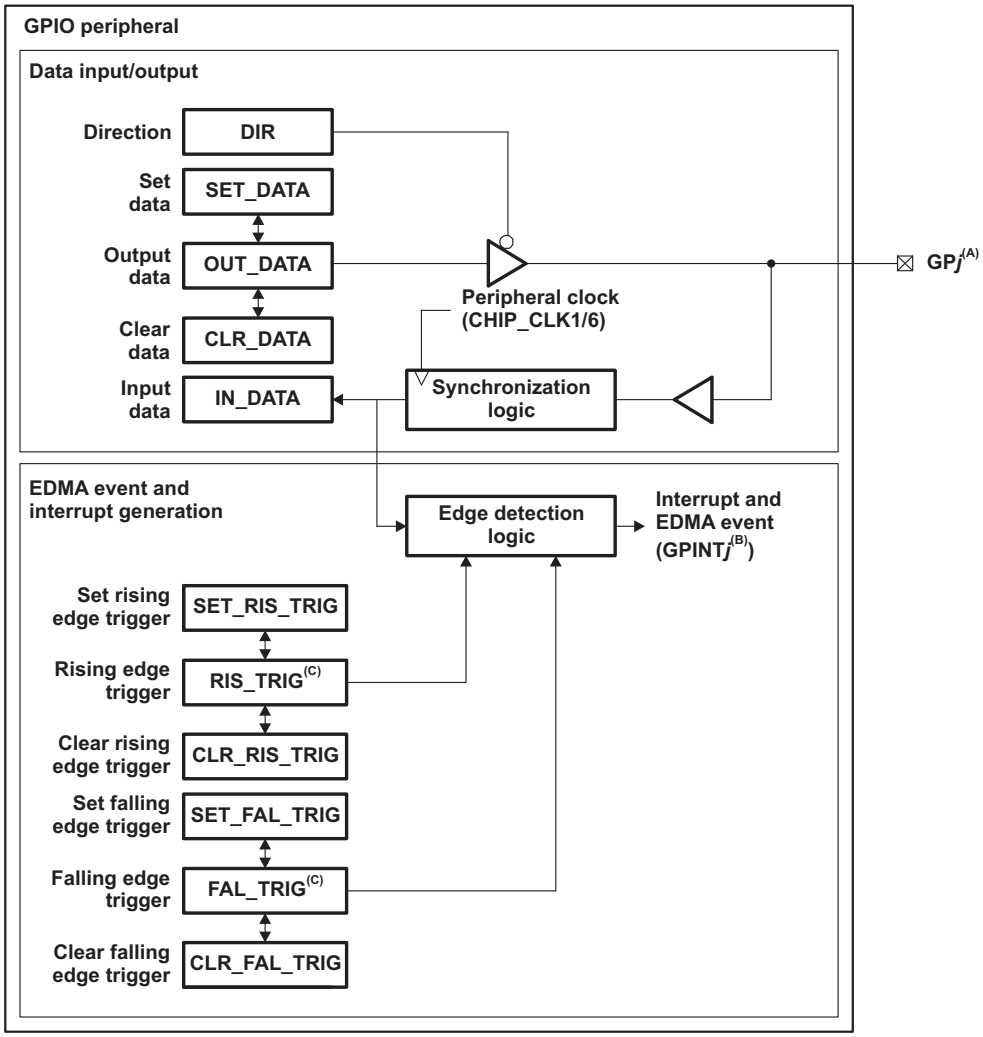
(1) For GPIOMUX output event mapping to the device interrupt/DMA controllers, see the corresponding interrupt/DMA mapping tables.
For GPIO input event mapping, see Table 11-1012.
For GPIOMUX description, see Section 5.1.3.1.7, *Event Mux Control Registers*.

11.7.4 GPIO Functional Description

11.7.4.1 GPIO Block Diagram

Figure 11-484 shows the general-purpose interface block diagram.

Figure 11-484. GPIO Block Diagram



A Some of the GPj pins are muxed with other device signals. For details, see the device Data Manual.

B All GPINTj can be used as CPU interrupts and synchronization events to the EDMA.

C The RIS_TRIG and FAL_TRIG registers are internal to the GPIO module and are not visible to the CPU.

11.7.4.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO_SET_DATA01 register

- Read in GPIO_OUT_DATA01 register, change the eighth bit to 1, and write the new value back to GPIO_OUT_DATA01

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO_CLR_DATA01 register
- Read in GPIO_OUT_DATA01 register, change the eighth bit to 0, and write the new value back to GPIO_OUT_DATA01

Note that writing a 0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN_DATA) will return the pin state. Reading the SET_DATA register or the CLR_DATA data register will return the value in OUT_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

11.7.4.3 Interrupt and Event Generation

Each GPIO pin (GPj) can be configured to generate a CPU interrupt (GPINTj) and a synchronization event to the EDMA (GPINTj). Configuration is on per-bank basis. Each bit of the BANK_INTR_EN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt and EDMA event can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt and EDMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts and EDMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt and EDMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPINT pin is configured as input, transitions on the pin trigger interrupts. When the GPINT pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPINT signal are available at module boundary. Each group of 16 GPINT signals also has their masked interrupt outputs ORed together to generate per bank interrupt, available at module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

11.7.4.3.1 Interrupt Enable (per Bank)

GPIO_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

11.7.4.3.2 Trigger Configuration (per Bit)

Two internal registers, RIS_TRIG and FAL_TRIG, specify which edge of the GPj signal generates an interrupt and EDMA event. Each bit in these two registers corresponds to a GPj pin. Table 11-1011 describes the CPU interrupt and EDMA event generation of GPj pin based on the bit settings of the RIS_TRIG and FAL_TRIG registers.

Table 11-1011. GPIO Interrupt and EDMA Event Configuration Options

RIS_TRIG Bit n	FAL_TRIG Bit n	CPU Interrupt and EDMA Event Generation
0	0	GPINTj interrupt and EDMA event is disabled
0	1	GPINTj interrupt and EDMA event is triggered on falling edge of GPj signal
1	0	GPINTj interrupt and EDMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and EDMA event is triggered on both rising and falling edge of GPj signal

RIS_TRIG and FAL_TRIG are not directly accessible or visible to the CPU. These registers are accessed indirectly through four registers: SET_RIS_TRIG, CLR_RIS_TRIG, SET_FAL_TRIG, and CLR_FAL_TRIG. Writing 1 to a bit on the SET_RIS_TRIG register sets the corresponding bit on the RIS_TRIG register. Writing 1 to a bit of CLR_RIS_TRIG register clears the corresponding bit on the RIS_TRIG register. Writing to SET_FAL_TRIG and CLR_FAL_TRIG works the same way on the FAL_TRIG register.

Reading the SET_RIS_TRIG or CLR_RIS_TRIG register returns the value of RIS_TRIG register. Reading from SET_FAL_TRIG and CLR_FAL_TRIG register returns the value of FAL_TRIG register.

To use the GPIO pins as sources for CPU interrupts and EDMA events, bit 0 in the bank interrupt enable register (GPIO_BINTEN) must be set to 1.

11.7.4.3.3 Interrupt Status and Clear (per Bit)

INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

NOTE: GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

11.7.4.4 GPIO Interrupt Connectivity

Because this device muxes all GPIO signals with other functional signals, the availability of any particular GPIO and hence the usability of its associated interrupt will change based on the use case. The large number of possible GPIO interrupt sources makes it impractical to route all interrupt events to each processor. Since most applications don't typically require a large number of GPIO interrupts, the interrupt uncertainty is resolved by mapping all GPIO interrupts to a series of event muxes (GPIOMUX). These muxes allow any one of the available GPIO interrupts (per pin) to be selected and passed on as an event to the various processor interrupt controllers and DMA controllers. Event selection is controlled through associated BOOT_CFG module registers EVENT_MUXCTL0/11. Table 11-1012 summarizes the GPIOMUX input event mapping.

There is a use case to use some of the GPIO pins as interrupt sources for the DSP core (connected either directly or through CPINTC) and Arm core (connected via GIC). Also, some of the GPIO pins can be used as wake-up sources for the PMMC, so they are directly connected to the PMMC interrupt inputs.

One of the GPIO pins has a potential use case as an Arm reset input and should therefore be routed as highest priority interrupt in the GIC and mapped to nFIQ in software.

Table 11-1012. GPIOMUX Input Event Mapping

Input Event	Event Name	Description
0	GPIO_0_INTR0	GPIO0 pin 0 interrupt
1	GPIO_0_INTR1	GPIO0 pin 1 interrupt

Refer to Section 5.1, *Control Module (BOOT_CFG)*, for more details on the GPIO interrupt muxes and connectivity.

11.7.4.5 Emulation Halt Operation

The GPIO peripheral is not affected by emulation halts.

11.7.5 GPIO Programming Guide

11.7.5.1 GPIO Low-Level Programming Models

11.7.5.1.1 Global Initialization

11.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see Section 11.7.2, *GPIO Environment*, and Section 11.7.3, *GPIO Integration*.

Table 11-1013. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
LPSC0	Module reset must be enabled. For more information about the module configuration, see Section 5.2, *Power Management*.
PLL Controller	Interface and functional clocks must be enabled. For more information about the module configuration, see Section 5.4.5.3, *PLL Controller*.
ARM_GIC	ARM_GIC configuration must be done to enable the interrupts from the general-purpose interface module. See Section 6.1, *Arm Cortex-A15 Subsystem*.
CIC	CIC configuration must be done to enable the interrupts from the general-purpose interface module. See Chapter 9, *Interupts*.
GPIOMUX	GPIOMUX configuration must be done to enable the interrupts from the general-purpose interface module. See Section 5.1.3.1.7, *Event Mux Control Registers*.

11.7.5.1.1.2 GPIO Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

Table 11-1014. GPIO Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure GPIO channels as input or output of the corresponding bank	DIR	-h
Interrupt requests configuration		
Configure detection events	SET_RIS_TRIG and/or SET_FAL_TRIG	-h
Clear interrupt status	INTSTAT	FFFFh
Enable interrupts for desired banks [0:8]	GPIO_BINTEN[8:0]	-h

11.7.5.1.2 GPIO Operational Modes Configuration

11.7.5.1.2.1 GPIO Read Input Register

Table 11-1015. GPIO Read Input Register

Step	Register/Bit Field/Programming Model	Value
Read interrupt status of the corresponding bank	INTSTAT	-h
Read input register value	IN_DATA	-h
Clear interrupt status	INTSTAT	FFFF FFFFh

11.7.5.1.2.2 GPIO Set Bit Function

Table 11-1016. GPIO Set Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 1h to set desired bit(s) in SET_DATA register.	SET_DATA	-h

11.7.5.1.2.3 GPIO Clear Bit Function

Table 11-1017. GPIO Clear Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 1h to clear desired bit(s) in CLR_DATA register.	CLR_DATA	-h

11.7.6 GPIO Registers

11.7.6.1 GPIO Instance Summary

Table 11-1018 summarizes the general-purpose interface instance.

Table 11-1019 provides the register summary and associated offset addresses for the GPIO internal registers.

Table 11-1018. GPIO Instances

Instance	Base Address
GPIO_0	0260 3000h
GPIO_1	0260 A000h

Table 11-1019. GPIO Registers

Offset	Acronym	Register Name	GPIO_0 Physical Address	GPIO_1 Physical Address	Section
0h	GPIO_PID	Peripheral Identification Register	0260 3000h	0260 A000h	Section 11.7.6.2
8h	GPIO_BINTEN	Interrupt Per-Bank Enable Register	0260 3008h	0260 A008h	Section 11.7.6.3

11.7.6.4 GPIO_DIR01 Register (Offset = 10h) [reset = FFFF FFFFh]

The GPIO direction 0 and 1 register (GPIO_DIR01, GPIO[0:31] pins) determines if a given Bank0/1 GPIO pin is an input or an output. By default, all the GPIO pins are configured as input pins.

When GPIO pins are configured as output pins, the GPIO output buffer drives the GPIO pin. If it is necessary to place the GPIO output buffer in a high-impedance state, the GPIO pin must be configured as an input pin (DIRj = 1). At reset, GPIO pins default to input mode.

Figure 11-487 shows the Direction 0 and 1 register and Table 11-1027 describes the fields.

Table 11-1026. GPIO_DIR01 Instances

- GPIO Instance Summary: [0]

11.7.6.13 GPIO_INTSTAT01 Register (Offset = 34h) [reset = 0h]

The GPIO_INTSTAT01 (GPIO[0:31] pins) register provides interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding Bank0/1 bit position(s).

The interrupt status and clear feature is for the per bank interrupt connection scheme. Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note that the GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

Also note, for the per-bank interrupt connection, ISR software should make sure that no triggering events escape detection.

Figure 11-496 shows the Interrupt Status 0 and 1 Register and Table 11-1054 describes the fields.

11.7.6.14 GPIO_DIR23 Register (Offset = 38h) [reset = FFFF FFFFh]

The GPIO direction 2 and 3 register (GPIO_DIR23, GPIO[32:63] pins) determines if a given Bank2/3 GPIO pin is an input or an output. By default, all the GPIO pins are configured as input pins.

When GPIO pins are configured as output pins, the GPIO output buffer drives the GPIO pin. If it is necessary to place the GPIO output buffer in a high-impedance state, the GPIO pin must be configured as an input pin (DIRj = 0). At reset, GPIO pins default to input mode.

Figure 11-497 shows the Direction 2 and 3 register and Table 11-1057 describes the fields.

11.7.6.23 GPIO_INTSTAT23 Register (Offset = 5Ch) [reset = 0h]

The GPIO_INTSTAT23 (GPIO[32:63] pins) register provides interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding Bank2/3 bit position(s).

The interrupt status and clear feature is for the per bank interrupt connection scheme. Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note that the GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

Also note, for the per-bank interrupt connection, ISR software should make sure that no triggering events escape detection.

Figure 11-506 shows the Interrupt Status Register 2 and 3 and Table 11-1084 describes the fields.

11.7.6.33 GPIO_INTSTAT45 Register (Offset = 84h) [reset = 0h]

The GPIO_INTSTAT45 (GPIO[64:95] pins) register provides interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding Bank4/5 bit position(s).

The interrupt status and clear feature is for the per bank interrupt connection scheme. Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note that the GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

Also note, for the per-bank interrupt connection, ISR software should make sure that no triggering events escape detection.

Figure 11-516 shows the Interrupt Status Register 4 and 5 and Table 11-1114 describes the fields.

11.7.6.34 GPIO_DIR67 Register (Offset = 88h) [reset = FFFF FFFFh]

The GPIO direction 6 and 7register (GPIO_DIR67, GPIO[96:127] pins) determines if a given Bank6/7 GPIO pin is an input or an output. By default, all the GPIO pins are configured as input pins.

When GPIO pins are configured as output pins, the GPIO output buffer drives the GPIO pin. If it is necessary to place the GPIO output buffer in a high-impedance state, the GPIO pin must be configured as an input pin (DIRj = 0). At reset, GPIO pins default to input mode.

Figure 11-517 shows the Direction 6 and 7 register and Table 11-1117 describes the fields.

11.7.6.41 GPIO_SET_FAL_TRIG67 Register (Offset = A4h) [reset = 0h]

The GPIO falling trigger 6 and 7 register (FAL_TRIG67, GPIO[96:127] pins) configures the edge detection logic to trigger Bank6/7 GPIO interrupts and EDMA events on the falling edge of GPIO signals. Setting a bit to 1 in FAL_TRIG67 causes the corresponding GPIO interrupt and EDMA event (GPINTj) to be generated on the falling edge of GPIOj. FAL_TRIG67 is not directly accessible by the CPU; it must be configured using the GPIO set falling trigger 6 and 7 and clear falling trigger 6 and 7 registers.

Writing a 1 to a bit of GPIO_SET_FAL_TRIG67 sets the corresponding bit in FAL_TRIG67. Writing a 0 has no effect. Reading GPIO_SET_FAL_TRIG67 returns the value in FAL_TRIG67.

Figure 11-524 shows the Set Falling Edge Interrupt 6 and 7 register and Table 11-1138 describes the fields.

11.7.6.43 GPIO_INTSTAT67 Register (Offset = ACh) [reset = 0h]

The GPIO_INTSTAT67 (GPIO[96:127] pins) register provides interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding Bank6/7 bit position(s).

The interrupt status and clear feature is for the per bank interrupt connection scheme. Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note that the GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

Also note, for the per-bank interrupt connection, ISR software should make sure that no triggering events escape detection.

Figure 11-526 shows the Interrupt Status Register 6 and 7 and Table 11-1144 describes the fields.

11.7.6.44 GPIO_DIR8 Register (Offset = B0h) [reset = FFFFh]

The GPIO direction 8 register (GPIO_DIR8, GPIO[128:143] pins) determines if a given Bank8 GPIO pin is an input or an output. By default, all the GPIO pins are configured as input pins.

When GPIO pins are configured as output pins, the GPIO output buffer drives the GPIO pin. If it is necessary to place the GPIO output buffer in a high-impedance state, the GPIO pin must be configured as an input pin (DIRj = 0). At reset, GPIO pins default to input mode.

Figure 11-527 shows the Direction 8 register and Table 11-1147 describes the fields.

11.8 Inter-IC Module (I2C)

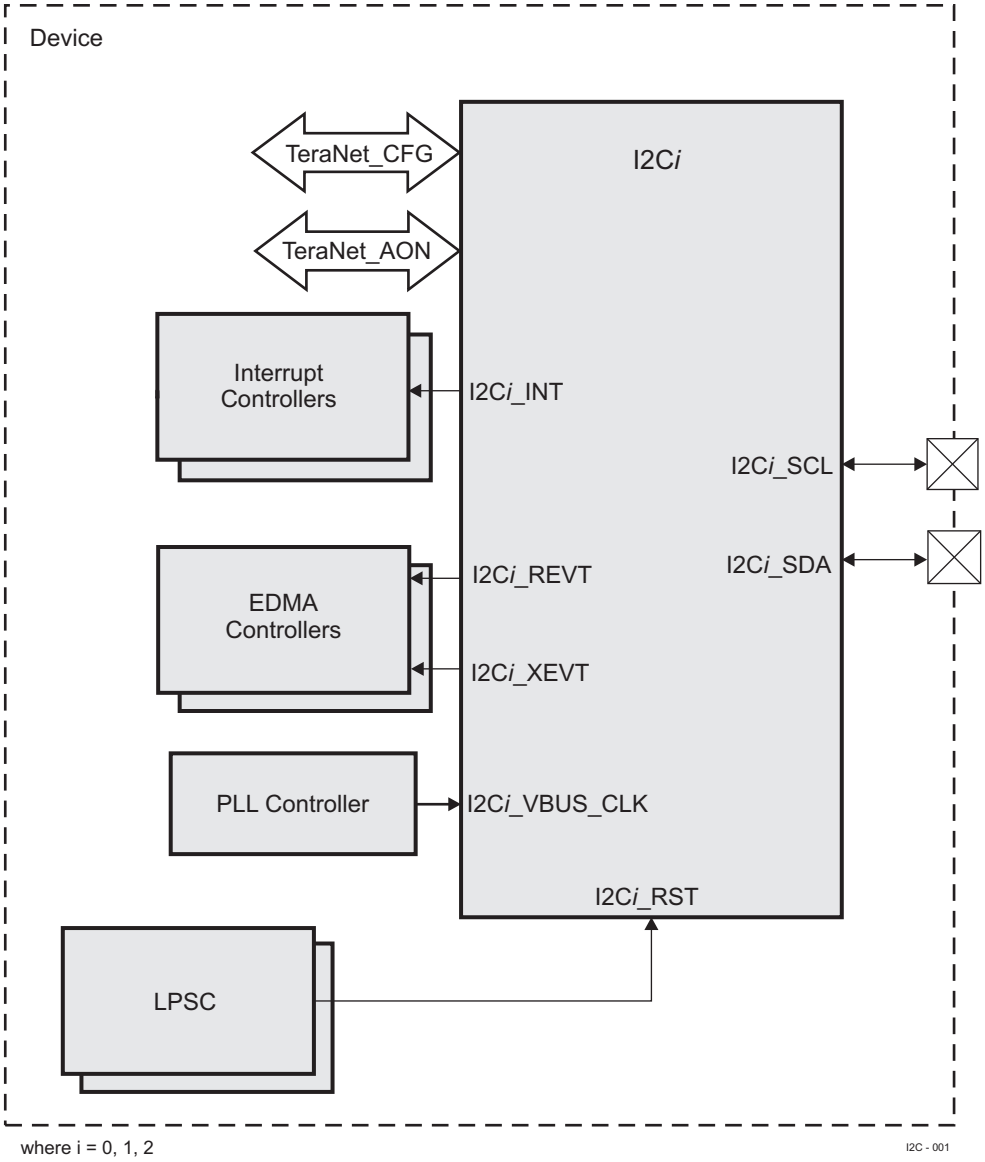
This section describes the inter-integrated circuit (I2C) module in the device.

11.8.1 I2C Overview

The multi-master inter-integrated circuit (I2C) peripheral provides an interface between the device and any I^2C-bus-compatible device that is connected via the I^2C serial bus. External components attached to the I^2C bus can serially transmit/receive up to 8-bit data to/from the device through the two-wire I^2C interface.

Figure 11-537 shows an overview of the I2C modules in the device.

Figure 11-537. I2C Modules Overview



11.8.1.1 Features

Each I2C module has the following features:

- Compliance with the Philips Semiconductors I^2C-bus specification (version 2.1):
  - Supports standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
  - Support for byte format transfer
  - 7-bit addressing mode
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers mode
  - Support for multiple slave-transmitters and master-receivers mode
  - Combined master transmit/receive and receive/transmit mode
- 2 to 7 bit format transfer
- Free data format mode
- One read DMA event and one write DMA event that can be used by the DMA
- Seven interrupts that can be used by the CPU
- Module enable/disable capability

I2C module unsupported features:

- GPIO mode
- High-speed (HS) mode
- 10-bit device addressing mode

11.8.1.2 Industry Standard(s) Compliance Statement

The I2C module is compliant with the Philips Semiconductors Inter-IC bus (I^2C-bus) specification version 2.1.

11.8.2 I2C Environment

This section describes the I²C application fields from an environment point of view (external connections).

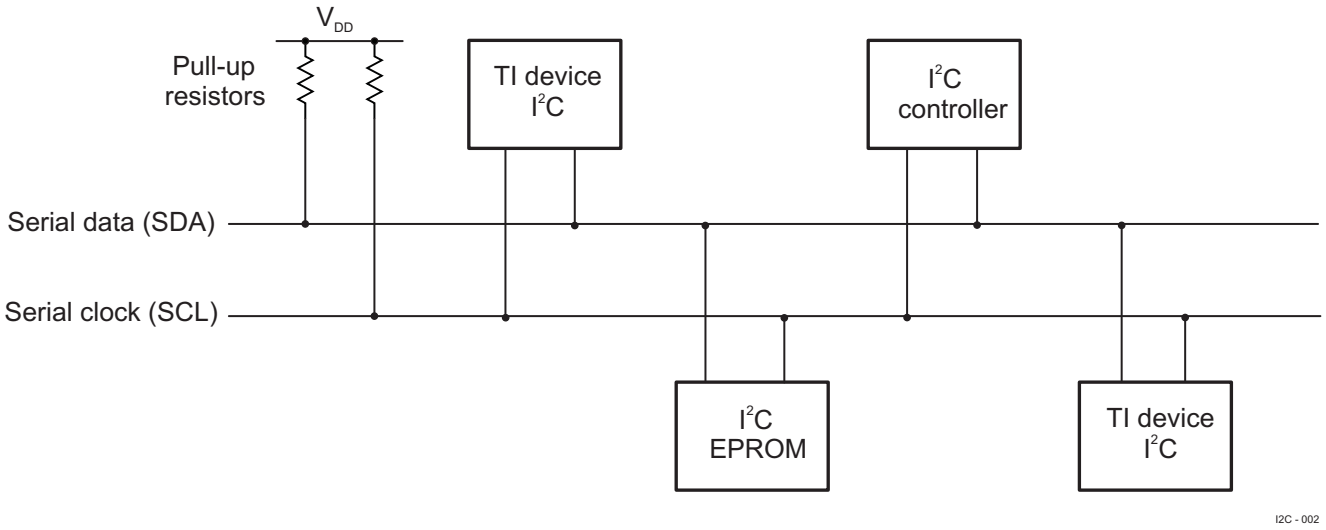
11.8.2.1 I2C Typical Application

The I²C bus is a multi-master bus. The I2C module supports the multi-master mode that allows more than one device capable of controlling the bus to be connected to it. Each I2C device is recognized by a unique address and can operate as either transmitter or receiver depending on the function of the device. In addition to being a transmitter or receiver, devices connected to the I²C bus also can be considered as master or slave when performing data transfers.

Note that a master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave.

Figure 11-538 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

Figure 11-538. Multiple I2C Modules Connected



11.8.2.2 I2C Signal Descriptions

Data is communicated to devices interfacing with the I²C via the serial data line (SDA) and the serial clock line (SCL). These two pins carry information between the device and other devices connected to the I²C-bus. Both SDA and SCL are bi-directional pins. Each one must be connected to a positive supply voltage via a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

Table 11-1176 lists the pins associated with the I²C interface.

Table 11-1176. I2C Input/Output Signals

Interface Name	Device Level Signal	I/O[(1)]	Description
I2C_0	I2C0_SCL	I/O	I²C serial clock line. Open-drain output buffer. Requires external pull-up resistor (Rp).
	I2C0_SDA	I/O	I²C serial data line. Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_1	I2C1_SCL	I/O	I²C serial clock line. Open-drain output buffer. Requires external pull-up resistor (Rp).
	I2C1_SDA	I/O	I²C serial data line. Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_2	I2C2_SCL	I/O	I²C serial clock line. Open-drain output buffer. Requires external pull-up resistor (Rp).
	I2C2_SDA	I/O	I²C serial data line. Open-drain output buffer. Requires external pull-up resistor (Rp).

(1) I = Input; O = Output; I/O = Bidirectional

For additional timing and electrical specifications for these pins, see the device Data Manual.

NOTE: One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I^2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated power supply level. For details, see the device Data Manual.

11.8.3 I2C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-539 shows the integration of the three I2C modules in the device.

Figure 11-539. I2C Integration

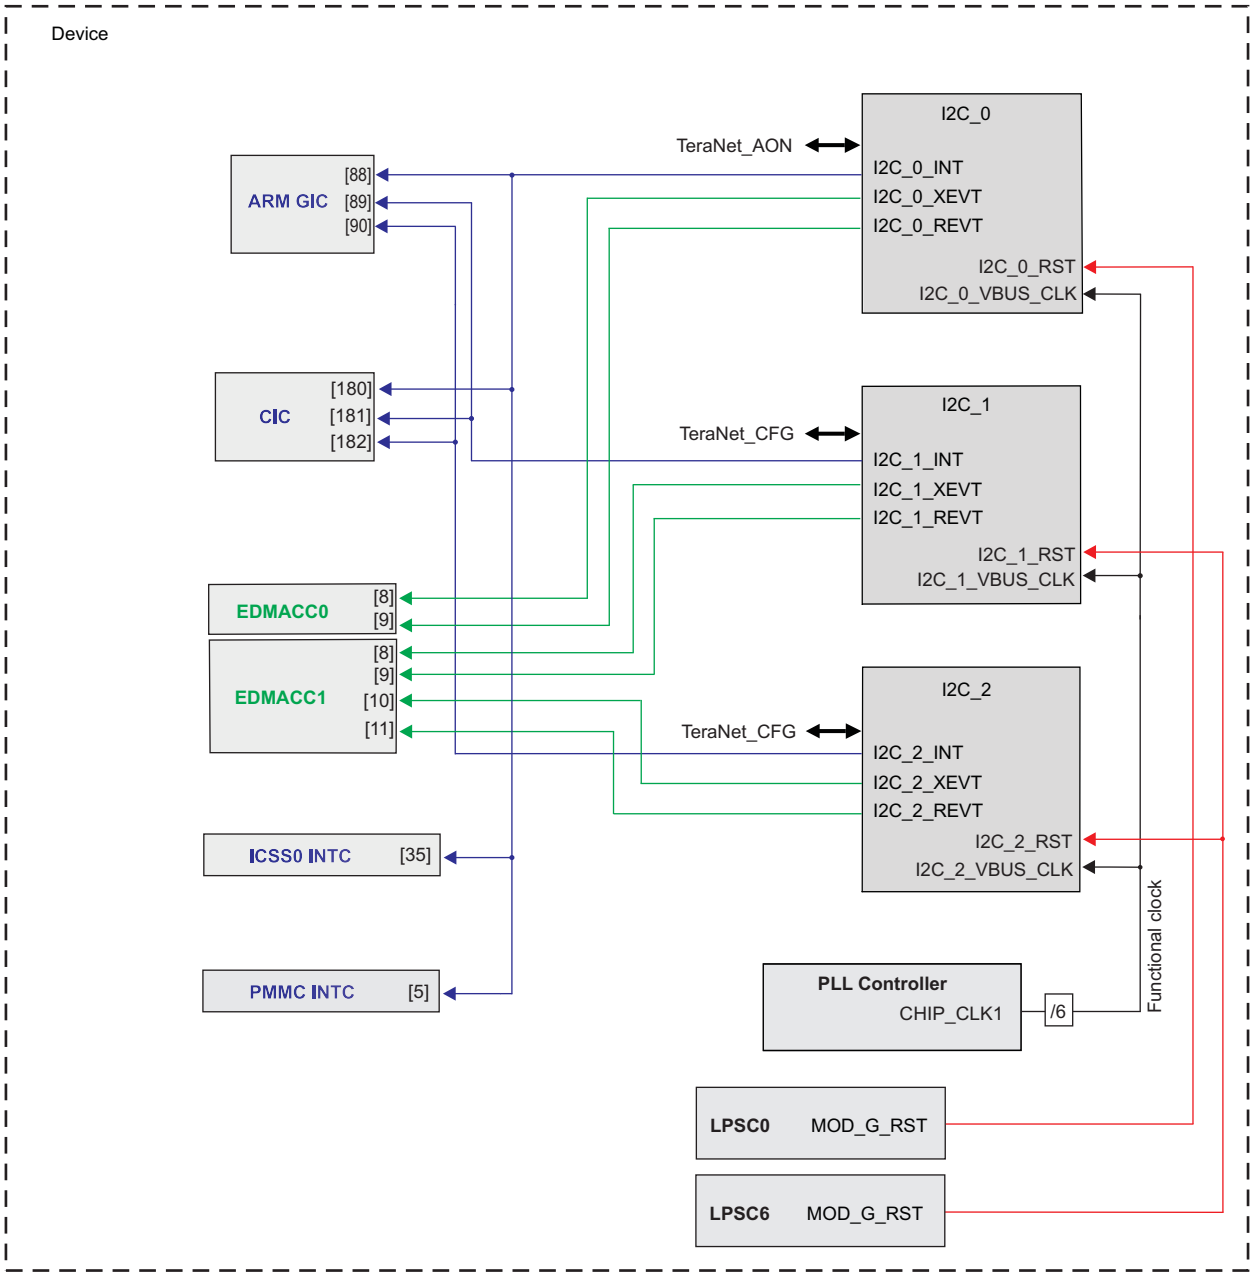


Table 11-1177 through Table 11-1179 summarize the integration of the module in the device.

Table 11-1177. I2C Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
I2C_0	PD0	LPSC0	TeraNet_AON
I2C_1	PD5	LPSC6	TeraNet_CFG
I2C_2	PD5	LPSC6	TeraNet_CFG

Table 11-1178. I2C Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**

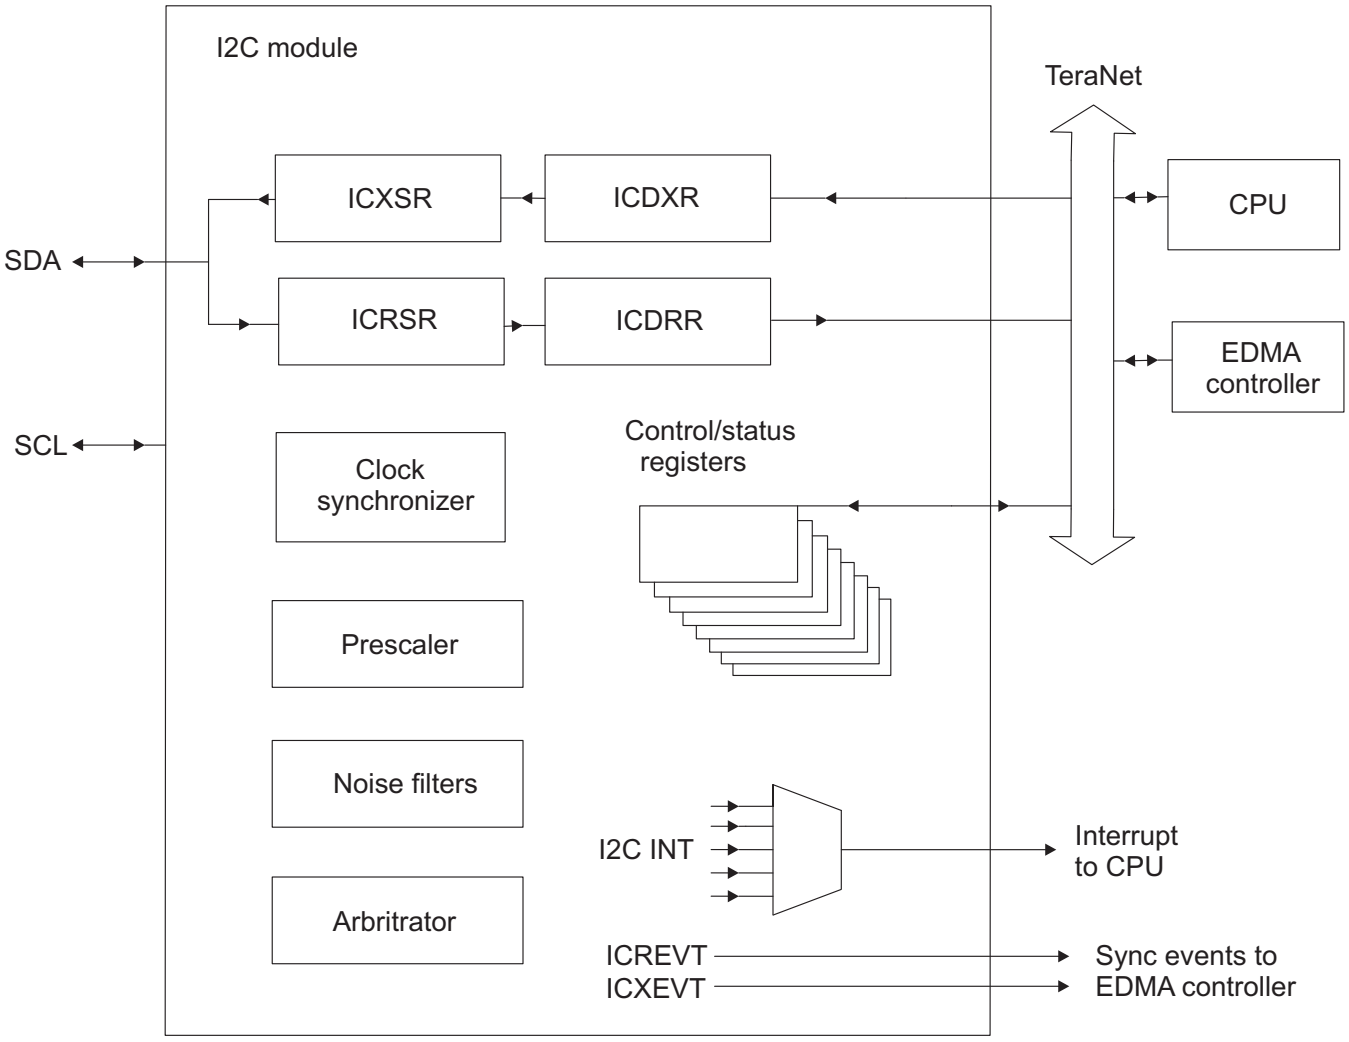
11.8.4 I2C Functional Description

NOTE: In this section, a single instance of I^2C is described for simplification as all three general-purpose I2C modules are functionally identical.

11.8.4.1 I2C Block Diagram

Figure 11-540 shows the I2C module block diagram.

Figure 11-540. I2C Block Diagram



The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU or the EDMA controller
- Control and status registers
- A peripheral data bus interface to enable the CPU and the EDMA controller to access the I2C module registers
- A clock synchronizer to synchronize the I^2C input clock (from the clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module

- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- EDMA event generation logic, so that activity in the EDMA controller can be synchronized to data reception and data transmission in the I2C module

Figure 11-540 shows the four registers used for transmission and reception. The CPU or the EDMA controller writes data for transmission to I2C_ICDXR and reads received data from I2C_ICDRR. When the I2C module is configured as a transmitter, data written to I2C_ICDXR is copied to ICXSR and shifted out on the SDA pin one bit a time. When the I2C module is configured as a receiver, received data is shifted into ICRSR and then copied to I2C_ICDRR.

11.8.4.2 I2C Clock Generation

The I2C module is recommended to operate with a module clock in a range of 7 to 12 MHz. This clock is generated via the I^2C prescaler block. The I^2C prescaler register I2C_ICPSC is used to divide-down the input clock to obtain a clock within the specified range for the I2C module.

As shown in Figure 11-541, the PLL Controller produces an I^2C input clock with a programmed frequency. The clock is then divided twice more inside the I2C module to produce to the module clock and the master clock.

The module clock determines the frequency at which the I2C module operates. Figure 11-541 shows how this clock is generated. A programmable prescaler in the I2C module divides down the I^2C input clock to produce the module clock. To specify the divide-down value, initialize the IPSC field of the I^2C prescaler register I2C_ICPSC. The resulting frequency is:

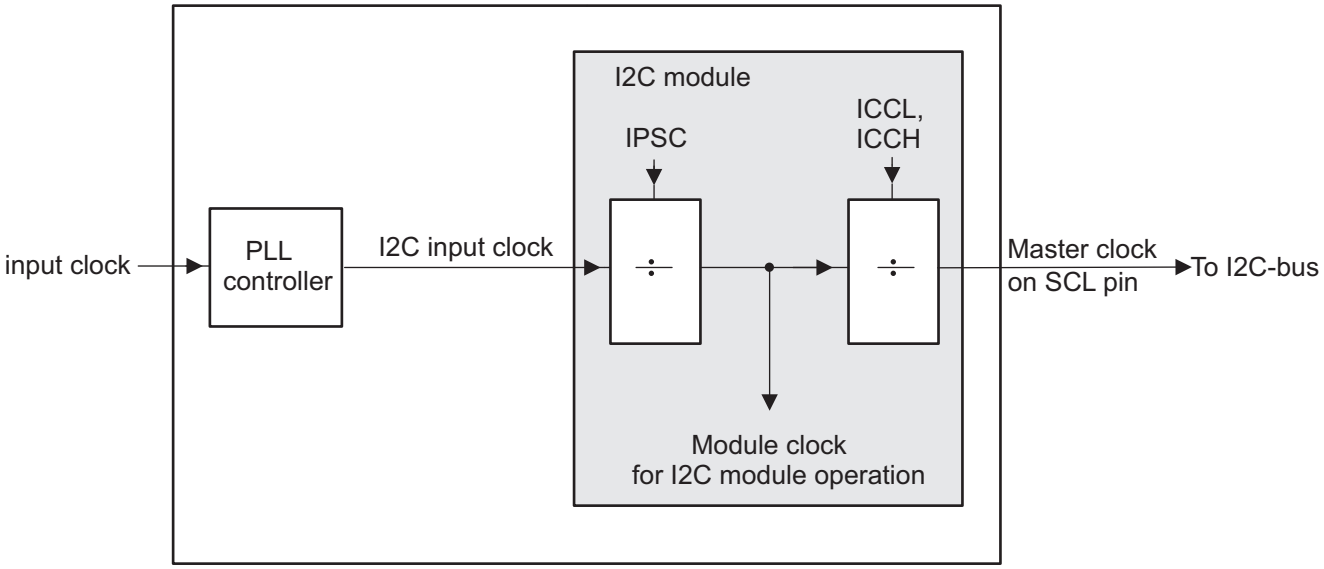
$$\text{module clock frequency} = \frac{I^2C \text{ input clock frequency}}{(\text{IPSC}+1)}$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2C_ICMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I^2C-bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 11-541, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2C_ICCLKL to divide-down the low portion of the module clock signal and uses the ICCH value of I2C_ICCLKH to divide-down the high portion of the module clock signal. The resulting frequency is:

$$\text{master clock frequency} = \frac{\text{module clock frequency}}{(\text{ICCL}+6)+(\text{ICCH}+6)}$$

Figure 11-541. Clocking Diagram for the I2C Module



11.8.4.3 I2C Reset

The I2C module has two reset sources:

- Hardware reset: it causes all I2C module registers to be reset to their default values.
- Software reset: it can be applied by writing 0 to the I²C reset (IRS) bit in the I²C mode register I2C_ICMDR. This bit has exactly the same action on the module logic as the hardware reset (all registers are reset to their default values).

In both cases, the I2C module remains disabled until the IRS bit is changed to 1. Upon reset the SDA and SCL pins are in the high-impedance (HiZ) state.

NOTE: The IRS bit must be cleared to 0 during I2C module configuration/reconfiguration. Forcing IRS to 0 can be used to save power and to clear error conditions.

NOTE: If the IRS bit is cleared to 0 during a transfer, this can cause the I²C bus to hang. For more information, see Section 11.8.4.8, *I²C Bus Hang Caused by Reset*.

11.8.4.4 I2C Interrupt Support

The I2C module is capable of interrupting a device CPU and sends a single interrupt signal to the CPU. The CPU can determine which I²C events caused the interrupt by reading the I²C interrupt vector register I2C_ICIVR. I2C_ICIVR contains a binary-coded interrupt vector type to indicate which interrupt has occurred. Reading I2C_ICIVR clears the interrupt flag; if other interrupts are pending, a new interrupt is generated. If there is more than one pending interrupt flag, reading I2C_ICIVR clears the highest-priority interrupt flag.

The I2C module can generate the interrupts described in Table 11-1180. Each interrupt has a flag bit in the I²C interrupt status register I2C_ICSTR and a mask bit in the interrupt mask register I2C_ICIMR. When one of the specified events occurs, its flag bit is set. If the corresponding mask bit is 0, the interrupt request is blocked; if the mask bit is 1, the request is forwarded to the CPU as an I²C interrupt.

Table 11-1180. Descriptions of the I2C Interrupt Events

I²C Interrupt	Initiating Event
Arbitration-lost interrupt (AL)	Generated when the I²C arbitration procedure is lost or illegal START/STOP conditions occur.
No-acknowledge interrupt (NACK)	Generated when the master I²C does not receive any acknowledge from the receiver.
Registers-ready-for-access (ARDY)	Generated by the I²C when the previously programmed address, data and command have been interrupt performed and the status bits have been updated. This interrupt is used to let the controlling processor know that the I²C registers are ready to be accessed.
Receive interrupt/status (ICRINT and ICRRDY)	Generated when the received data in the receive-shift register ICRSR has been copied into the I2C_ICDRR. The ICRRDY bit can also be polled by the CPU to read the received data in the I2C_ICDRR.
Transmit interrupt/status (ICXINT and ICXRDY)	Generated when the transmitted data has been copied from I2C_ICDXR to the transmit-shift register ICXSR and shifted out on the SDA pin. This bit can also polled by the CPU to write the next transmitted data into the I2C_ICDXR.
Stop-Condition-Detection interrupt (SCD)	Generated when a STOP condition has been detected.
Address-as-Slave interrupt (AAS)	Generated when the I²C has recognized its own slave address or an address of all (8) zeros.

11.8.4.5 I2C DMA Events

The I2C module generates two DMA events which can be used by a EDMA controller to handle transmit and receive data. Activity in EDMA channels can be synchronized to these events:

- Receive/Read event ICREVT: When receive data has been copied from the receive shift register ICRSR to the data receive register I2C_ICDRR, the I2C module sends an REVT signal to the EDMA controller. In response, the EDMA controller can read the data from I2C_ICDRR.
- Transmit/Write event ICXEVT: When transmit data has been copied from the data transmit register I2C_ICDXR to the transmit shift register ICXSR, the I2C module sends an XEVT signal to the EDMA controller. In response, the EDMA controller can write the next transmit data value to I2C_ICDXR.

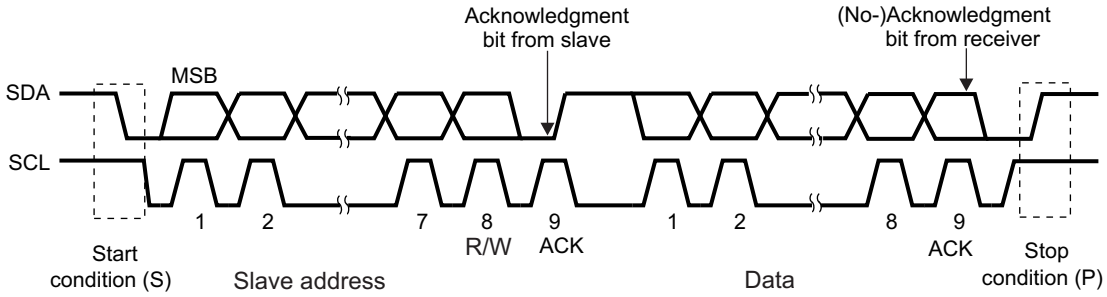
11.8.4.6 I2C Operation

11.8.4.6.1 I2C Serial Data Format

The I2C module supports a data word size of 1 bit to 8 bits depending on the bit count (BC) bits of I2C_ICMDR.

Figure 11-542 shows an example of a data transfer on the I²C-bus for an 8-bit data word (BC = 000 in I2C_ICMDR). Each bit put on the SDA line corresponds to one pulse on the SCL line and the data is always transferred with the most-significant bit (MSB) first. The number of data words that can be transmitted or received is unrestricted; however, the transmitters and receivers must agree on the number of data bits in a word being transferred.

Figure 11-542. I²C Data Transfer



The I2C module supports the following data formats:

- 7-bit addressing mode
- Free data format mode

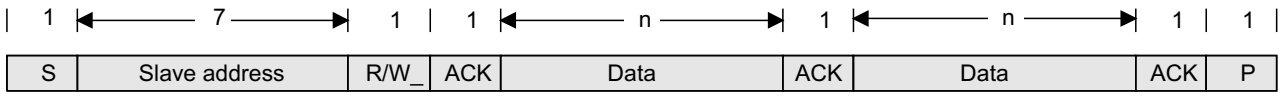
11.8.4.6.1.1 7-Bit Addressing Format

In the 7-bit addressing format Figure 11-543, the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/$\overline{W}$ bit. The R/$\overline{W}$ bit determines the direction of the data:

- R/$\overline{W}$ = 0: The master writes (transmits) data to the addressed slave.
- R/$\overline{W}$ = 1: The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after the R/$\overline{W}$ bit. If the ACK bit is inserted by the slave, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit), n is a number from 1 to 8 determined by the bit count (BC) bits of I2C_ICMDR. After the data bits have been transferred, the receiver inserts an ACK bit. To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2C_ICMDR.

Figure 11-543. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2C_ICMDR)



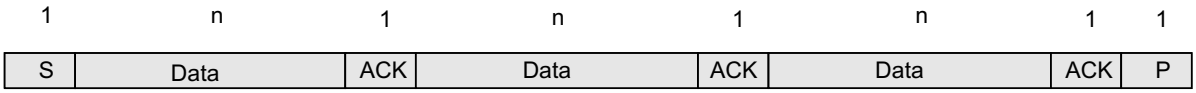
n = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICMDR.

11.8.4.6.1.2 Free Data Format

In the free data format Figure 11-544, the first bits after a START condition (S) are a data word. An ACK bit is inserted after each data word, which can be from 1 to 8 bits, depending on the bit count (BC) bits of I2C_ICMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

To select the free data format, write 1 to the free data format (FDF) bit of I2C_ICMDR.

Figure 11-544. I2C Module Free Data Format (FDF = 1 in I2C_ICMDR)

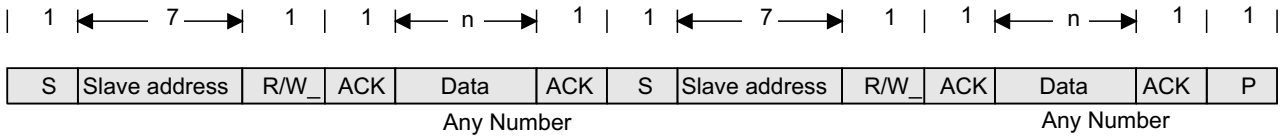


n = The number of data bits (from 1 to 8) specified by the bit count (BC) field of ICMDR.

11.8.4.6.1.3 Using a Repeated START Condition

The repeated START condition can be used with the 7-bit addressing and free data format. The 7-bit addressing format using a repeated START condition (S) is shown in Figure 11-545. At the end of each data word, the master can drive another START condition. Using this capability, a master can transmit/receive any number of data words before driving a STOP condition. The length of a data word can be from 1 to 8 bits and is selected with the bit count (BC) bits of I2C_ICMDR.

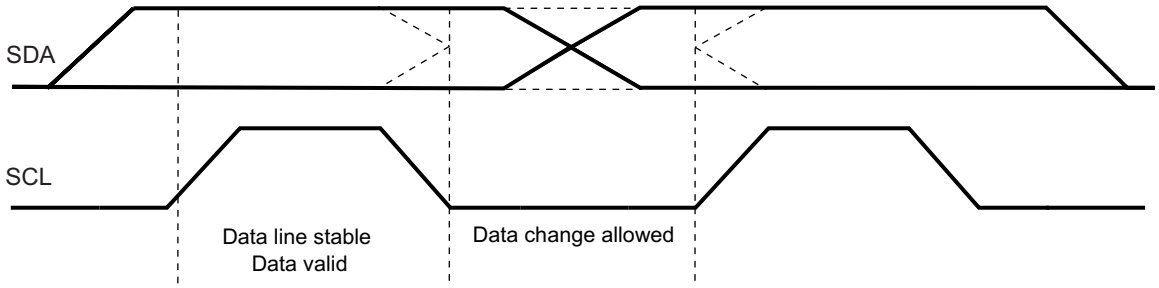
Figure 11-545. I2C Module 7-Bit Addressing Format With Repeated START Condition



11.8.4.6.2 I2C Data Validity

The data on the SDA line must be stable during the high period of the clock (see Figure 11-546). The high and low states of the data line can only change when the clock signal on the SCL line is low.

Figure 11-546. Bit Transfer on the I²C-Bus

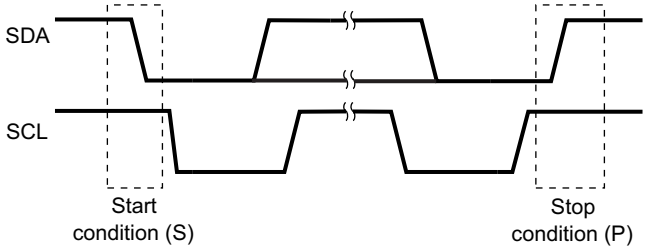


11.8.4.6.3 I2C START and STOP Conditions

The I2C module generates START and STOP conditions when it is configured as a master on the I²C-bus. As shown in Figure 11-547:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

Figure 11-547. I²C START and STOP Condition Events



After a START condition and before a subsequent STOP condition, the I²C-bus is considered busy, and the bus busy (BB) bit of I2C_ICSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode (MST) bit and the START condition (STT) bit in I2C_ICMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition (STP) bit must be set to 1. When BB is set to 1 and STT is set to 1, a repeated START condition is generated. For a description of the MST, STT, and STP bits, see Section 11.8.6.9.

11.8.4.6.4 I2C Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. For the names and descriptions of the modes, see Table 11-1181.

If the I2C module is a master, it begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. In order to receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, it begins as a slave-receiver and, typically, sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

Table 11-1181. Operating Modes of the I2C Module

Operating Mode	Description
Slave-receiver mode	The I2C module is a slave and receives data from a master. All slave modules begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the CPU is required (RSFULL = 1 in I2C_ICSTR) after data has been received.
Slave-transmitter mode	The I2C module is a slave and transmits data to a master. This mode can only be entered from the slave-receiver mode; the I2C module must first receive a command from the master. When any of the 7-bit/free data addressing format is being used, the I2C module enters its slave-transmitter mode if the slave address is the same as its own address (in I2C_ICOAR) and the master has transmitted R/$\overline{W}$ = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the CPU is required (XSMT = 0 in I2C_ICSTR) after data has been transmitted.
Master-receiver mode	The I2C module is a master and receives data from a slave. This mode can only be entered from the master-transmitter mode; the I2C module must first transmit a command to the slave. When any of the 7-bit/free data addressing formats is being used, the I2C module enters its master-receiver mode after transmitting the slave address and R/$\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the CPU is required (RSFULL = 1 in I2C_ICSTR) after data has been received.
Master-transmitter mode	The I2C module is a master and transmits control information and data to a slave. All master modules begin in this mode. In this mode, data assembled in any of the 7-bit/free data addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the CPU is required (XSMT = 0 in I2C_ICSTR) after data has been transmitted.

11.8.4.6.5 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 11-1182 summarizes the various ways the I2C module sends a NACK bit.

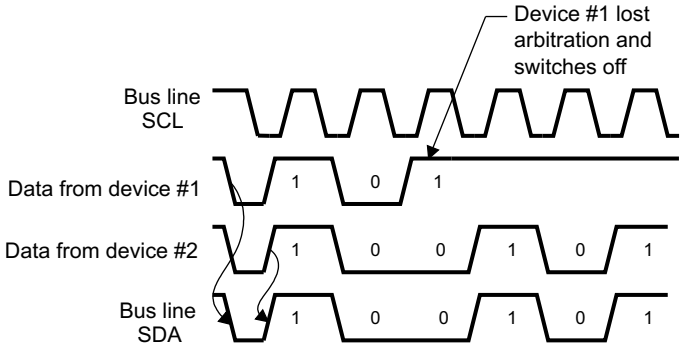
Table 11-1182. Generating a NACK Bit

	Description	
I2C module Condition	**Basic**	**Optional**
Slave-receiver mode	1. Disable data transfers (STT = 0 in I2C_ICSTR). 2. Allow an overrun condition (RSFULL = 1 in I2C_ICSTR). 3. Reset the module (IRS = 0 in I2C_ICMDR).	Before the rising edge of the last data bit intended to be received, set the NACKMOD bit of I2C_ICMDR.
Master-receiver mode AND Repeat mode (RM = 1 in I2C_ICMDR)	1. Generate a STOP condition (STOP = 1 in I2C_ICMDR). 2. Reset the module (IRS = 0 in I2C_ICMDR).	Before the rising edge of the last data bit intended to be received, set the NACKMOD bit of I2C_ICMDR.
Master-receiver mode AND Nonrepeat mode (RM = 0 in I2C_ICMDR)	1. If STP = 1 in I2C_ICMDR, allow the internal data counter to count down to 0 and force a STOP condition. 2. If STP = 0, make STP = 1 to generate a STOP condition. 3. Reset the module (IRS = 0 in I2C_ICMDR).	Before the rising edge of the last data bit intended to be received, set the NACKMOD bit of I2C_ICMDR.

11.8.4.6.6 I2C Bus Arbitration

If two or more master-transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 11-548 illustrates the arbitration procedure between two devices.

Figure 11-548. Arbitration Procedure Between Two Master-Transmitters



The first master-transmitter, which drives SDA high, is overruled by another master-transmitter that drives SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

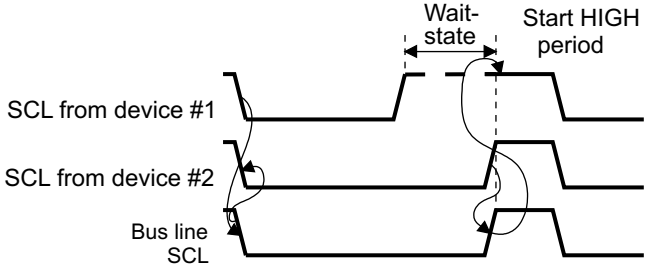
- A repeated START condition and a data bit
- A repeated START condition and a STOP condition
- A STOP condition and a data bit

11.8.4.6.7 I2C Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 11-549 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL (device #1) overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for SCL to be released, before starting their high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received data word or to prepare a data word to be transmitted.

Figure 11-549. Synchronization of Two I²C Clock Generators During Arbitration



11.8.4.7 I2C Emulation Considerations

The response of the I^2C events to emulation suspend events (such as halts and breakpoints) is controlled by the FREE bit in the I^2C mode register I2C_ICMDR. The I2C module either stops exchanging data (FREE = 0) or continues to run (FREE = 1) when an emulation suspend event occurs. How the I^2C module terminates data transactions is affected by whether the I^2C module is acting as a master or a slave. For a description of the FREE bit see Section 11.8.6.9.

11.8.4.8 I2C Bus Hang Caused by Reset

It is generally known that the I^2C bus can hang if an I^2C master is removed from the bus in the middle of a data read. This can occur because the I^2C protocol does not mandate a minimum clock rate. Therefore, if a master is reset in the middle of a read while a slave is driving the data line low, the slave will continue driving the data line low while it waits for the next clock edge. This prevents bus masters from initiating transfers. If this condition is detected, the following three steps will clear the bus hang condition:

- An I^2C master must generate up to 9 clock cycles.
- After each clock cycle, the data pin must be observed to determine whether it has gone high while the clock is high.
- As soon as the data pin is observed high, the master can initiate a start condition.

Section 11.8.7 contains more information on this topic.

11.8.5 I2C Programming Guide

11.8.5.1 Configure the I2C Module Before Enabling the Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the Functional clock (see Table 11-1178).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C*i*.I2C_ICPSC[7-0] IPSC bit field. This value depends on the frequency of the functional clock (I2C*i*_FCLK).
3. Program the I²C*i*.I2C_ICCLKL[15-0] ICLL and I²C*i*.I2C_ICCLKH[15-0] ICCH bit fields to obtain a bit rate of 100 kbps, 400 kbps.

- Configure the Own Address of the I²C controller by storing it in the I2C*i*.I2C_ICOAR [6-0] OADDR bit field.
- Take the I²C controller out of reset by setting the I2C*i*.I2C_ICMDR [5] IRS bit to 1.

11.8.5.2 Initialize the I2C Controller

Configure the I2C*i*.I2C_ICMDR.

1. For master or slave mode, set the I2C*i*.I2C_ICMDR[10] MST bit (0: slave; 1: master).
2. For transmitter or receiver mode, set the I2C*i*.I2C_ICMDR[9] TRX bit (0: receiver; 1: transmitter).
3. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C*i*.I2C_ICIMR register to 1 (the I2C*i*.I2C_ICIMR [4] ICXRDY bit for the transmit interrupt, the I2C*i*.I2C_ICIMR [3] ICRDRDY bit for the receive interrupt).
4. If using DMA to receive and transmit data, set the corresponding bit in the I2C*i*.I2C_ICDRR register to 1 (the I2C*i*.I2C_ICDRR [7] D bit for the receive DMA channel, the I2C*i*.I2C_ICDRR [7] D bit for the transmit DMA channel).

11.8.5.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2C*i*.I2C_ICSAR [9-0] SADDR bit field and the number of data bytes (I2C data payload) associated with the transfer by programming the I2C*i*.I2C_ICCNT [15-0] ICDC bit field.

11.8.5.4 Initiate a Transfer

Poll the I2C*i*.I2C_ICSTR [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C*i*.I2C_ICMDR [13] STT and I2C*i*.I2C_ICMDR [11] STP bits. To initiate a transfer, the I2C*i*.I2C_ICMDR [13] STT bit must be set to 1, and it is not mandatory to set the I2C*i*.I2C_ICMDR [11] STP bit to 1.

11.8.6 I2C Registers

Table 11-1184 lists the memory-mapped registers for the I²C. All register offset addresses not listed in Table 11-1184 should be considered as reserved locations and the register contents should not be modified.

Table 11-1183. I²C Instances

11.8.6.1 I2C_ICOAR Register (Offset = 0h) [reset = 0h]

The I^2C own address register I2C_ICOAR is used to specify its own slave address, which distinguishes it from other slaves connected to the I^2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2C_ICMDR), only bits 6-0 are used; bits 9-7 are ignored. The I2C_ICOAR register is shown in Figure 11-550 and described in Table 11-1186

Table 11-1185. I2C_ICOAR Instances

Instance	Physical Address
I2C_0	0253 0000h
I2C_1	0253 0400h
I2C_2	0253 0800h

Table 11-1186. I2C_ICOAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	These reserved bit location are always read as zeroes. A value written to this field has no effect.
9-0	OADDR	R/W	0h	Value = 0-3FFh Own slave address. Provides the slave address of the I^2C. In 7-bit addressing mode (XA = 0 in I2C_ICMDR): bits 6-0 provide the 7-bit slave address of the I^2C. Bits 9-7 are ignored. In 10-bit addressing mode (XA = 1 in I2C_ICMDR): bits 9-0 provide the 10-bit slave address of the I^2C.(1)

(1) 10-bit addressing mode is not supported feature on this device.

Table 11-1192. I2C_ICSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	These reserved bit location are always read as zeroes. A value written to this field has no effect.
14	SDIR	R/W1toCl	0h	Slave direction bit. In digital-loopback mode (DLB), the SDIR bit is cleared to 0. • 0 = I²C is acting as a master-transmitter/receiver or a slave-receiver. SDIR is cleared by one of the following events: – A STOP or a START condition. – SDIR is manually cleared. To clear this bit, write a 1 to it. • 1 = I²C is acting as a slave-transmitter.
13	NACKSNT	R/W1toCl	0h	No-acknowledgment sent bit. NACKSNT bit is used when the I²C is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Section 11.8.6.9). • 0 = NACK is not sent. NACKSNT is cleared by one of the following events: – It is manually cleared. To clear this bit, write a 1 to it. – The I²C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = NACK is sent. A no-acknowledge bit was sent during the acknowledge cycle on the I²C-bus.

Table 11-1192. I2C_ICSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	BB	R/W1toCl	0h	Bus busy bit. BB bit indicates whether the I²C-bus is busy or is free for another data transfer. In the master mode, BB is controlled by the software. • 0 = Bus is free. BB is cleared by one of the following events: – The I²C receives or transmits a STOP bit (bus free). – BB is manually cleared. To clear this bit, write a 1 to it. – The I²C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = Bus is busy. When the STT bit in I2C_ICMDR is set to 1, a restart condition is generated. BB is set by one of the following events: – The I²C has received or transmitted a START bit on the bus. – SCL is in a low state and the IRS bit in I2C_ICMDR is 0.
11	RSFULL	R	0h	Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when the receive shift register ICRSR is full with new data but the previous data has not been read from the data receive register I2C_ICDRR. The new data will not be copied to I2C_ICDRR until the previous data is read. As new bits arrive from the SDA pin, they overwrite the bits in ICRSR. • 0 = No overrun is detected. RSFULL is cleared by one of the following events: – I2C_ICDRR is read. – The I²C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = Overrun is detected.
10	XSMT	R/W	1h	Underflow occurs when the transmit shift register ICXSR is empty but the data transmit register I2C_ICDXR has not been loaded since the last I2C_ICDXR-to-ICXSR transfer. The next I2C_ICDXR-to-ICXSR transfer will not occur until new data is in I2C_ICDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin. • 0 = Underflow is detected. • 1 = No underflow is detected. XSMT is set by one of the following events: – Data is written to I2C_ICDXR. – The I²C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset).
9	AAS	R	0h	Addressed-as-slave bit. • 0 = The AAS bit has been cleared by a repeated START condition or by a STOP condition. • 1 = AAS is set by one of the following events: – I²C has recognized its own slave address or an address of all zeros (general call). – The first data word has been received in the free data format (FDF = 1 in I2C_ICMDR).
8	AD0	R	0h	Address 0 bit. • 0 = AD0 has been cleared by a START or STOP condition. • 1 = An address of all zeros (general call) is detected.
7-6	RESERVED	R	0h	These reserved bit location are always read as zeroes. A value written to this field has no effect.

Table 11-1192. I2C_ICSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SCD	R/W1toCl	0h	Stop condition detected bit. SCD indicates when a STOP condition has been detected on the I ^{2}C bus. The STOP condition could be generated by the I^{2}C or by another I^{2}C device connected to the bus. • 0 = No STOP condition has been detected. SCD is cleared by one of the following events: – By reading the INCODE bits in ICICR as 110b. – SCD is manually cleared. To clear this bit, write a 1 to it. • 1 = A STOP condition has been detected.
4	ICXRDY	R/W1toCl	0h	Transmit-data-ready interrupt flag bit. ICXRDY indicates that the data transmit register I2C_ICDXR is ready to accept new data because the previous data has been copied from I2C_ICDXR to the transmit shift register ICXSR. The CPU can poll ICXRDY or use the XRDY interrupt request. • 0 = I2C_ICDXR is not ready. ICXRDY is cleared by one of the following events: – Data is written to I2C_ICDXR. – ICXRDY is manually cleared. To clear this bit, write a 1 to it. • 1 I= CDXR is ready. Data has been copied from I2C_ICDXR to ICXSR. ICXRDY is forced to 1 when the I^{2}C is reset.
3	ICRDRDY	R/W1toCl	0h	Receive-data-ready interrupt flag bit. ICRDRDY indicates that the data receive register I2C_ICDRR is ready to be read because data has been copied from the receive shift register ICRSR to I2C_ICDRR. The CPU can poll ICRDRDY or use the RRDY interrupt request. • 0 = I2C_ICDRR is not ready. ICRDRDY is cleared by one of the following events: – I2C_ICDRR is read. – ICRDRDY is manually cleared. To clear this bit, write a 1 to it. – The I^{2}C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = I2C_ICDRR is ready. Data has been copied from ICRSR to I2C_ICDRR.
2	ARDY	R/W1toCl	0h	Register-access-ready interrupt flag bit (only applicable when the I^{2}C is in the master mode). ARDY indicates that the I^{2}C registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request. • 0 = The registers are not ready to be accessed. ARDY is cleared by one of the following events: – The I^{2}C starts using the current register contents. – ARDY is manually cleared. To clear this bit, write a 1 to it. – The I^{2}C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = The registers are ready to be accessed. • In the nonrepeat mode (RM = 0 in I2C_ICMDR): If STP = 0 in I2C_ICMDR, ARDY is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I^{2}C generates a STOP condition when the counter reaches 0). • In the repeat mode (RM = 1): ARDY is set at the end of each data word transmitted from I2C_ICDXR.

Table 11-1192. I2C_ICSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	NACK	R/W1toCl	0h	No-acknowledgment interrupt flag bit. NACK applies when the I^2C is a transmitter (master or slave). NACK indicates whether the I^2C has detected an acknowledge bit (ACK) or a no-acknowledge bit (NACK) from the receiver. The CPU can poll NACK or use the NACK interrupt request. • 0 = ACK received/NACK is not received. NACK is cleared by one of the following events: – An acknowledge bit (ACK) has been sent by the receiver. – NACK is manually cleared. To clear this bit, write a 1 to it. – The CPU reads the interrupt source register ICISR when the register contains the code for a NACK interrupt. – The I^2C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1= NACK bit is received. The hardware detects that a no-acknowledge (NACK) bit has been received. Note: While the I^2C performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.
0	AL	R/W1toCl	0h	Arbitration-lost interrupt flag bit (only applicable when the I^2C is a master-transmitter). AL primarily indicates when the I^2C has lost an arbitration contest with another master-transmitter. The CPU can poll AL or use the AL interrupt request. • 0 = Arbitration is not lost. AL is cleared by one of the following events: • AL is manually cleared. To clear this bit, write a 1 to it. • The CPU reads the interrupt source register ICISR when the register contains the code for an AL interrupt. • The I^2C is reset (either when 0 is written to the IRS bit of I2C_ICMDR or when the device is reset). • 1 = Arbitration is lost. AL is set by one of the following events: • The I^2C senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously. • The I^2C attempts to start a transfer while the BB (bus busy) bit is set to 1. When AL is set to 1, the MST and STP bits of I2C_ICMDR are cleared, and the I^2C becomes a slave-receiver.

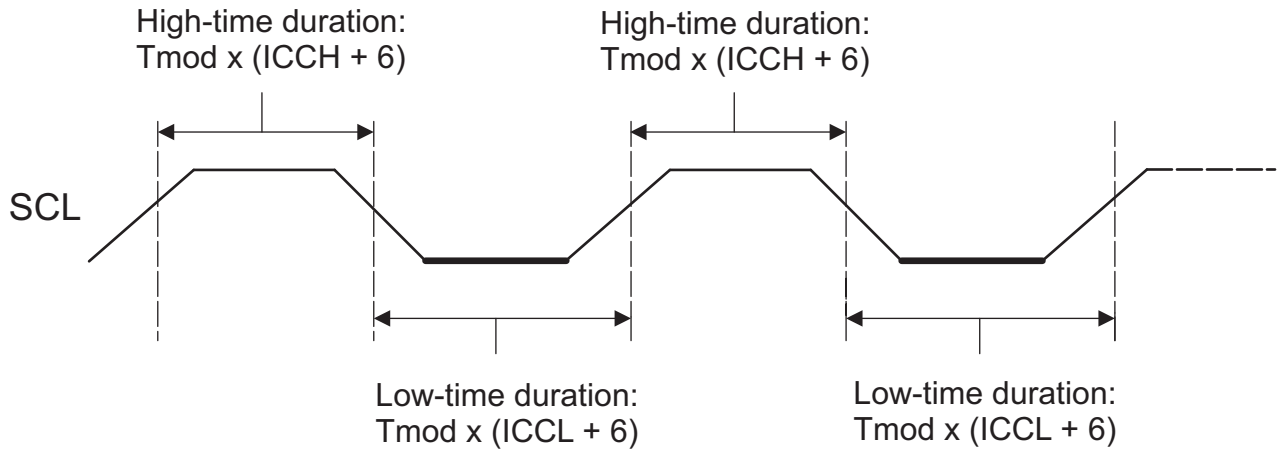
11.8.6.4 I²C Clock Divider Registers (I2C_ICCLKL and I2C_ICCLKH)

When the I²C is a master, the module clock is divided down for use as the master clock on the SCL pin. As shown in Figure 11-553, the shape of the master clock depends on two divide-down values, ICCL and ICCH.The frequency of the master clock can be calculated as:

$$\text{master clock frequency} = \frac{\text{module clock frequency}}{(\text{ICCL}+6)+(\text{ICCH}+6)}$$

Figure 11-553. Roles of the Clock Divide-Down Values (ICCL and ICCH)



Tmod = module clock period = 1/ module clock frequency

11.8.6.4.1 I2C_ICCLKL Register (Offset = Ch) [reset = 0h]

The I²C clock low-time divider register I2C_ICCLKL is shown in Figure 11-554 and described in Table 11-1195. For each master clock cycle, ICCL determines the amount of time the signal is low. I2C_ICCLKL must be configured while the I²C is still in reset (IRS = 0 in I2C_ICMDR).

Table 11-1194. I2C_ICCLKL Instances

I2C Functional Description • I2C Clock Generation: [0]

11.8.6.5 I2C_ICCNT Register (Offset = 14h) [reset = 0h]

The I^2C data count register I2C_ICCNT is used to indicate how many data words to transfer when the I^2C is configured as a master-transmitter (MST = 1 and TRX = 1 in I2C_ICMDR) and the repeat mode is off (RM = 0 in I2C_ICMDR). In the repeat mode (RM = 1), I2C_ICCNT is not used. The I2C_ICCNT register is shown in Figure 11-556 and described in Table 11-1201.

The value written to I2C_ICCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each data word transferred (I2C_ICCNT remains unchanged). If a STOP condition is requested (STP = 1 in I2C_ICMDR), the I^2C terminates the transfer with a STOP condition when the countdown is complete (that is, when the last data word has been transferred).

Table 11-1200. I2C_ICCNT Instances

Instance	Physical Address

Table 11-1201. I2C_ICCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Value = 0 These reserved bit location are always read as zeroes. A value written to this field has no effect.
15-0	ICDC	R/W	0h	Value = 0-FFFFh Data count value. When RM = 0 in I2C_ICMDR, ICDC indicates the number of data words to transfer in the nonrepeat mode. When RM = 1 in I2C_ICMDR, the value in I2C_ICCNT is a don't care. If STP = 1 in I2C_ICMDR, a STOP condition is generated when the internal data counter counts down to 0. • 0 = The start value loaded to the internal data counter is 65536. • 1h-FFFFh = The start value loaded to internal data counter is 1-65535.

11.8.6.6 I2C_ICDRR Register (Offset = 18h) [reset = 0h]

The I²C data receive register I2C_ICDRR is used by the DSP to read the receive data. The I2C_ICDRR can receive a data value of up to 8 bits; data values with fewer than 8 bits are right-aligned in the D bits and the remaining D bits are undefined. The number of data bits is selected by the bit count bits (BC) of I2C_ICMDR. The I²C receive shift register ICRSR shifts in the received data from the SDA pin. Once data is complete, the I²C copies the contents of ICRSR into I2C_ICDRR. The CPU and the EDMA controller cannot access ICRSR. The I2C_ICDRR register is shown in Figure 11-557 and described in Table 11-1204.

11.8.6.7 I2C_ICSAR Register (Offset = 1Ch) [reset = 0h]

The I^2C slave address register I2C_ICSAR contains a 7-bit slave address. When the I^2C is not using the free data format (FDF = 0 in I2C_ICMDR), it uses this address to initiate data transfers with a slave or slaves. When the address is non-zero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2C_ICMDR), only bits 6-0 of I2C_ICSAR are used; bits 9-7 are ignored. The I2C_ICSAR register is shown in Figure 11-558 and described in Table 11-1207.

Table 11-1206. I2C_ICSAR Instances

Instance	Physical Address

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Value = 0 These reserved bit location are always read as zeroes. A value written to this field has no effect.
9-0	SADDR	R/W	3FFh	Value = 0-3FFh Slave address. Provides the slave address of the I^2C. In 7-bit addressing mode (XA = 0 in I2C_ICMDR): bits 6-0 provide the 7-bit slave address that the I^2C transmits when it is in the master-transmitter mode. Bits 9-7 are ignored. In 10-bit addressing mode (XA = 1 in I2C_ICMDR): Bits 9-0 provide the 10-bit slave address that the I^2C transmits when it is in the master-transmitter mode.(1)

(1) 10-bit addressing mode is not supported feature on this device.

I2C Registers • I2C_ICSAR Register (Offset = 1Ch) [reset = 0h]: [0][1][2] • I2C Registers: [0] • I2C_ICMDR Register (Offset = 24h) [reset = 0h]: [0][1][2]

11.8.6.8 I2C_ICDXR Register (Offset = 20h) [reset = 0h]

The CPU writes transmit data to the I²C data transmit register I2C_ICDXR. The I2C_ICDXR can accept a data value of up to 8 bits. When writing a data value with fewer than 8 bits, the CPU must make sure that the value is right-aligned in the D bits. The number of data bits is selected by the bit count bits (BC) of I2C_ICMDR. Once data is written to I2C_ICDXR, the I²C copies the contents of I2C_ICDXR into the I²C transmit shift register ICXSR. The ICXSR shifts out the transmit data from the SDA pin. The CPU and the EDMA controller cannot access ICXSR. The I2C_ICDXR register is shown in Figure 11-559 and described in Table 11-1210.

Table 11-1213. I2C_ICMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	These reserved bit location are always read as zeroes. A value written to this field has no effect.
15	NACKMOD	R/W	0h	No-acknowledge (NACK) mode bit (only applicable when the I²C is a receiver). • 0 = In slave-receiver mode: The I²C sends an acknowledge (ACK) bit to the transmitter during the each acknowledge cycle on the bus. The I²C only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit. In master-receiver mode: The I²C sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. When the counter reaches 0, the I²C sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit. • 1 = In either slave-receiver or master-receiver mode: The I²C sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared. To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.

Table 11-1213. I2C_ICMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	FREE	R/W	0h	This emulation mode bit is used to determine the state of the I²C when a breakpoint is encountered in the high-level language debugger. • 0 = When I²C is master: If SCL is low when the breakpoint occurs, the I²C stops immediately and keeps driving SCL low, whether the I²C is the transmitter or the receiver. If SCL is high, the I²C waits until SCL becomes low and then stops. When I²C is slave: A breakpoint forces the I²C to stop when the current transmission/reception is complete. • 1 = The I²C runs free; that is, it continues to operate when a breakpoint occurs.
13	STT	R/W	0h	START condition bit (only applicable when the I²C is a master). The RM, STT, and STP bits determine when the I²C starts and stops data transmissions (see Table 11-1214). Note that the STT and STP bits can be used to terminate the repeat mode. • 0 = In master mode, STT is automatically cleared after the START condition has been generated. In slave mode, if STT is 0, the I²C does not monitor the bus for commands from a master. As a result, the I²C performs no data transfers. • 1 = In master mode, setting STT to 1 causes the I²C to generate a START condition on the I²C-bus. In slave mode, if STT is 1, the I²C monitors the bus and transmits/receives data in response to commands from a master.
12	RESERVED	R	0h	These reserved bit location are always read as zeroes. A value written to this field has no effect.
11	STP	R/W	0h	STOP condition bit (only applicable when the I²C is a master). The RM, STT, and STP bits determine when the I²C starts and stops data transmissions (see Table 11-1214). Note that the STT and STP bits can be used to terminate the repeat mode. • 0 = STP is automatically cleared after the STOP condition has been generated. • 1 = STP has been set by the DSP to generate a STOP condition when the internal data counter of the I²C counts down to 0.
10	MST	R/W	0h	Master mode bit. MST determines whether the I²C is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I²C master generates a STOP condition (see Table 11-1215). • 0 = Slave mode. The I²C is a slave and receives the serial clock from the master. • 1 = Master mode. The I²C is a master and generates the serial clock on the SCL pin.
9	TRX	R/W	0h	Transmitter mode bit. When relevant, TRX selects whether the I²C is in the transmitter mode or the receiver mode. Table 11-1215 summarizes when TRX is used and when it is a don't care. • 0 = Receiver mode. The I²C is a receiver and receives data on the SDA pin. • 1 = Transmitter mode. The I²C is a transmitter and transmits data on the SDA pin.
8	XA	R/W	0h	Expanded address enable bit. • 0 = 7-bit addressing mode (normal address mode). The I²C transmits 7-bit slave addresses (from bits 6-0 of I2C_ICSAR), and its own slave address has 7 bits (bits 6-0 of I2C_ICOAR). • 1 = 10-bit addressing mode (expanded address mode). The I²C transmits 10-bit slave addresses (from bits 9-0 of I2C_ICSAR), and its own slave address has 10 bits (bits 9-0 of I2C_ICOAR).(1)

(1) 10-bit addressing mode is not supported feature on this device.

Table 11-1213. I2C_ICMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	RM	R/W	0h	Repeat mode bit (only applicable when the I^2C is a master-transmitter). The RM, STT, and STP bits determine when the I^2C starts and stops data transmissions (see Table 11-1214). If the I^2C is configured in slave mode, the RM bit is don't care. • 0 = Nonrepeat mode. The value in the data count register I2C_ICCNT determines how many data words are received/transmitted by the I^2C. • 1 = Repeat mode. Data words are continuously received/transmitted by the I^2C until the STP bit is manually set to 1, regardless of the value in I2C_ICCNT.
6	DLB	R/W	0h	Digital loopback mode bit (only applicable when the I^2C is a master-transmitter). This bit disables or enables the digital loopback mode of the I^2C. The effects of this bit are shown in Figure 11-561. Note that DLB mode in the free data format mode (DLB = 1 and FDF = 1) is not supported. • 0 = Digital loopback mode is disabled. • 1 = Digital loopback mode is enabled. In this mode, the MST bit must be set to 1 and data transmitted out of I2C_ICDXR is received in I2C_ICDRR after n DSP cycles by an internal path, where: n = ((I^2C input clock frequency/module clock frequency) × 8) The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2C_ICOAR.
5	IRS	R/W	0h	I^2C reset bit. Note that if IRS is reset during a transfer, it can cause the I^2C bus to hang. For more information, see Section 11.8.4.8. • 0 = The I^2C is in reset/disabled. When this bit is cleared to 0, all status bits (in I2C_ICSTR) are set to their default values. SDA and SCL are in a high-impedance state. • 1 = The I^2C is enabled.
4	STB	R/W	0h	START byte mode bit (only applicable when the I^2C is a master). As described in version 2.1 of the Philips I^2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I^2C is a slave, the I^2C ignores a START byte from a master, regardless of the value of the STB bit. • 0 = The I^2C is not in the START byte mode. • 1 = The I^2C is in the START byte mode. When you set the START condition bit (STT), the I^2C begins the transfer with more than just a START condition. Specifically, it generates: 1. A START condition 2. A START byte (0000 0001b) 3. A dummy acknowledge clock pulse 4. A repeated START condition The I^2C sends the slave address that is in I2C_ICSAR.
3	FDF	R/W	0h	Free data format mode bit. Note that DLB mode in the free data format mode (DLB = 1 and FDF = 1) is not supported (see Table 11-1215). • 0 = Free data format mode is disabled. Transfers use the 7-bit addressing format selected by the XA bit. • 1 = Free data format mode is enabled.

Table 11-1213. I2C_ICMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data word that is to be received or transmitted by the I^2C. The number of bits selected with BC must match the data size of the other device. Note that when BC = 0, a data word has 8 bits. If the bit count is less than 8, receive data is right aligned in the D bits of I2C_ICDRR and the remaining D bits are undefined. Also, transmit data written to I2C_ICDXR must be right aligned. • 0 = 8 bits per data word • 1h = 1 bit per data word • 2h = 2 bits per data word • 3h = 3 bits per data word • 4h = 4 bits per data word • 5h = 5 bits per data word • 6h = 6 bits per data word • 7h = 7 bits per data word

Table 11-1214. Master-Transmitter/Receiver Bus Activity Defined by RM, STT, and STP Bits

I2C_ICMDR Bit				
RM	STT	STP	Bus Activity (1)	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D	START condition, slave address, n data words (n = value in I2C_ICCNT)
0	1	1	S-A-D..(n)..D-P	START condition, slave address, n data words, STOP condition (n = value in I2C_ICCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D..	Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) A = Address; D = Data word; P = STOP condition; S = START condition

Table 11-1215. How the MST and FDF Bits Affect the Role of TRX Bit

I2C_ICMDR Bit			
MST	FDF	I^2C State	Function of TRX Bit
0	0	In slave mode but not free data format mode	TRX is a don't care. Depending on the command from the master, the I^2C responds as a receiver or a transmitter.
0	1	In slave mode and free data format mode	The free data format mode requires that the transmitter and receiver be fixed. TRX identifies the role of the I^2C: • TRX = 0: The I^2C is a receiver. • TRX = 1: The I^2C is a transmitter.
1	0	In master mode but not free data format mode	TRX identifies the role of the I^2C: • TRX = 0: The I^2C is a receiver. • TRX = 1: The I^2C is a transmitter.
1	1	In master mode and free data format mode	The free data format mode requires that the transmitter and receiver be fixed. TRX identifies the role of the I^2C: • TRX = 0: The I^2C is a receiver. • TRX = 1: The I^2C is a transmitter.

11.8.6.10 I2C_ICIVR Register (Offset = 28h) [reset = 0h]

The I²C interrupt vector register I2C_ICIVR is used by the CPU to determine which event generated the I²C interrupt. Reading I2C_ICIVR clears the interrupt flag; if other interrupts are pending, a new interrupt is generated. If there are more than one interrupt flag, reading I2C_ICIVR clears the highest priority interrupt flag. Note that you must read (clear) I2C_ICIVR before doing another start; otherwise, I2C_ICIVR could contain an incorrect (old interrupt flags) value. The I2C_ICIVR register is shown in Figure 11-562 and described in Table 11-1218.

Table 11-1217. I2C_ICIVR Instances

11.8.6.12 I2C_ICPSC Register (Offset = 30h) [reset = 0h]

The I²C prescaler register I2C_ICPSC is used for dividing down the I²C input clock to obtain the desired module clock for the operation of the I²C. The I2C_ICPSC register is shown in Figure 11-564 and described in Table 11-1224.

The IPSC bits must be initialized while the I²C is in reset (IRS = 0 in I2C_ICMDR). The prescaled frequency takes effect only when the IRS bit is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

11.8.7 I2C Appendix: I2C Lockup Issue

SoCs can use a memory device connected with an I^2C interface as a source for boot code. A reset of the SoC while it is reading from the memory device can cause the I^2C interface to enter a state which will prevent the SoC from accessing the attached memory device. Once the I^2C interface enters this state it will not recover, even if additional SoC resets are issued. This condition will prevent the SoC from booting until the power is removed from the system or from the I^2C device. This failure mode is possible as part of the normal behavior of the I^2C interface as described in the I^2C specification. To prevent a system from entering this unrecoverable state, a hardware workaround is needed to force the I^2C interface into a usable condition. This appendix describes the problem and a hardware workaround that can be used to fix the issue.

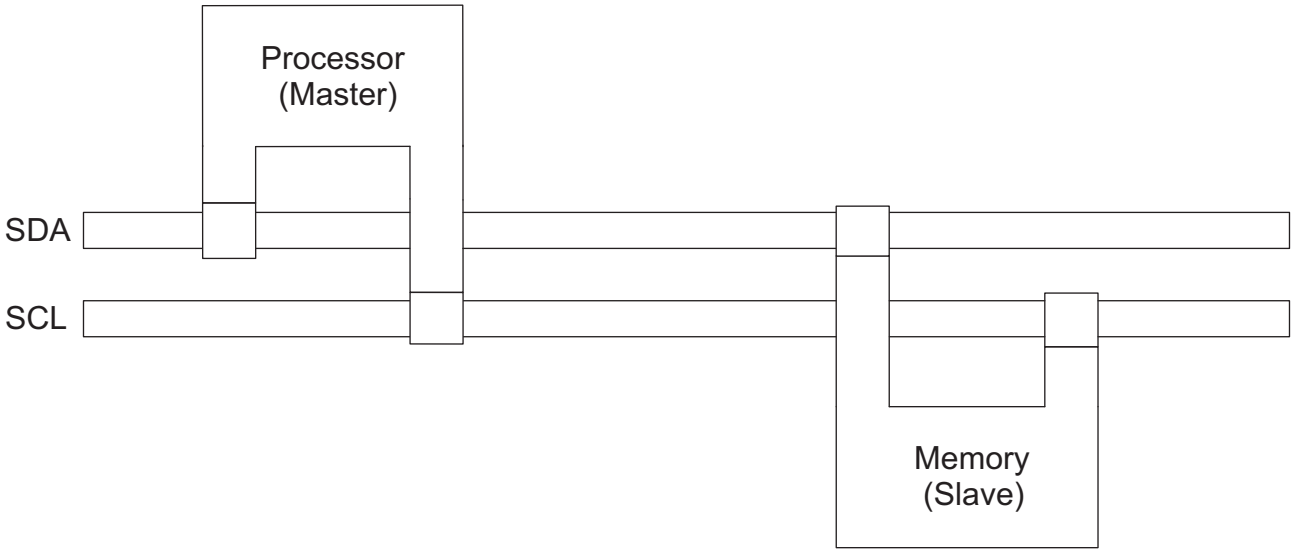
The I^2C interface consists of two bidirectional lines, SDA and SCL, which are pulled to a positive supply voltage with external resistors. The output stages for these signals are open-drain or open-collector, allowing multiple devices to share the same I^2C interfaces. These devices can be either a master-type device or a slave-type device.

Master devices initiate data transfers and generate the clock signals to permit transfers. Once a master device has initiated a transfer and gained control of the bus through the arbitration process it continues to control the bus until the end of an access. Under certain conditions if a reset to the controlling master device occurs during a transfer, the bus can remain in a locked state which does not allow the transfer to be completed and does not allow any other master device to gain control. This condition, inherent to the I^2C specification, must be considered when designing a system dependent on I^2C accesses.

This appendix presents a brief overview of the I^2C bus and describes the condition that can halt accesses. The scenario of a single I^2C master device connected to a slave device is described as well as a strategy to recover from the locked condition. This is followed by a discussion of the additional complications found in a multi-master environment.

In the simplest environment, a single master device will be connected to one or more slave devices. The example, shown in Figure 11-567 is a processor attached to a memory device using the I^2C interface.

Figure 11-567. Example I^2C Interface

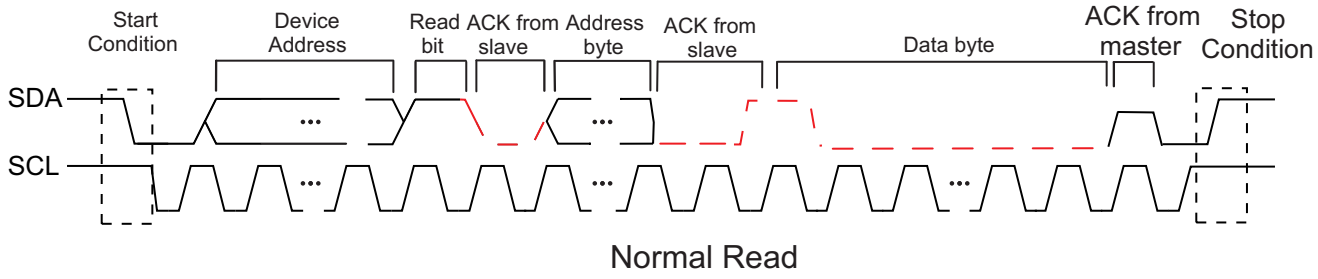


To initiate a transfer the master device will generate a start condition. The start condition is defined as a high-to-low transition on the SDA line while SCL is high. Once the master has initiated a transfer with a start condition, the bus is considered busy until the master generates a stop condition. The stop condition is defined as a low-to-high transition of the SDA line while the SCL is high. Once the transfer is initiated by the start condition, the SDA line must remain stable while SCL is high. SDA will only transition when SCL is low until the master releases the bus with a stop condition.

The start condition is followed by a series of byte transfers consisting of eight bits followed by a single acknowledge bit. The first byte contains the slave device address and a read/write bit. Once the slave device has received the correct address and the read/write bit, it will drive the SDA signal low as an acknowledgement that it has received the information correctly. The bytes that follow the device address vary in function from device to device. In the case of a sequential write to a slave memory device, the device address will be followed by a word address byte and a series of data bytes. Again, each byte transmitted from the master is acknowledged by the slave by driving the ninth bit low. When the master is done transmitting data it will send the stop condition releasing the bus.

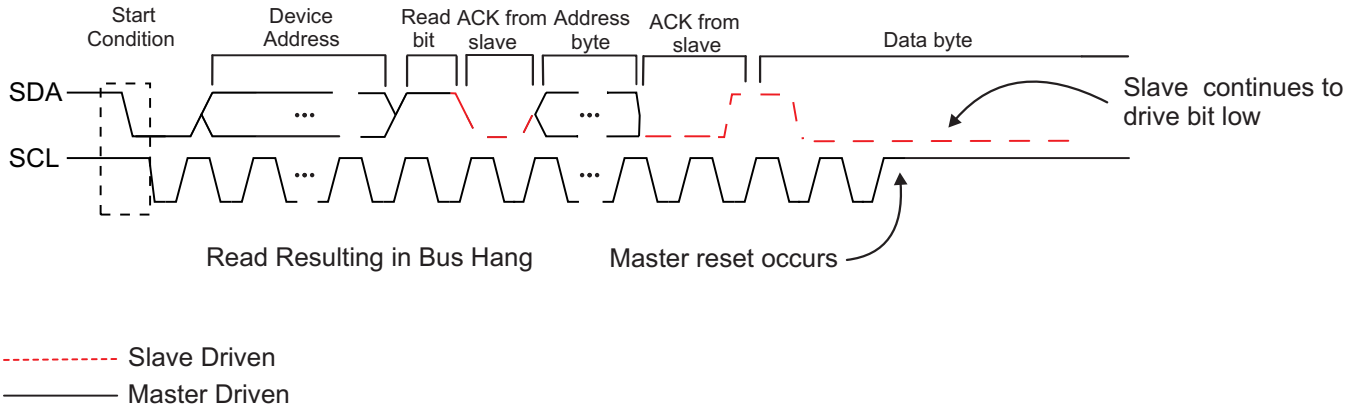
During a write cycle the slave will only drive the SDA low during the acknowledge (ACK). During a read cycle the slave will drive the data byte one bit at a time in response to the read command. There is a period of time during which the slave device will drive eight consecutive bits based on the clock provided by the master. When the master drives the clock low, it will drive the next bit onto the SDA line. When the master stops driving SCL, the pull-up resistor will return it to a high state signaling the slave device to hold the SDA signal level. Once all eight bits are clocked onto the SDA, the master can end the access by generating a stop condition freeing the bus. Figure 11-568 shows a normal read cycle. The period when the slave is driving SDA is indicated by the red lines.

Figure 11-568. Normal Read Cycle



If a reset to the master device occurs during the data transfer of a read cycle, there is the possibility of the bus entering in a state that will prevent any master from regaining control. Consider the situation shown in Figure 11-569.

Figure 11-569. Bus-Hang Read Cycle

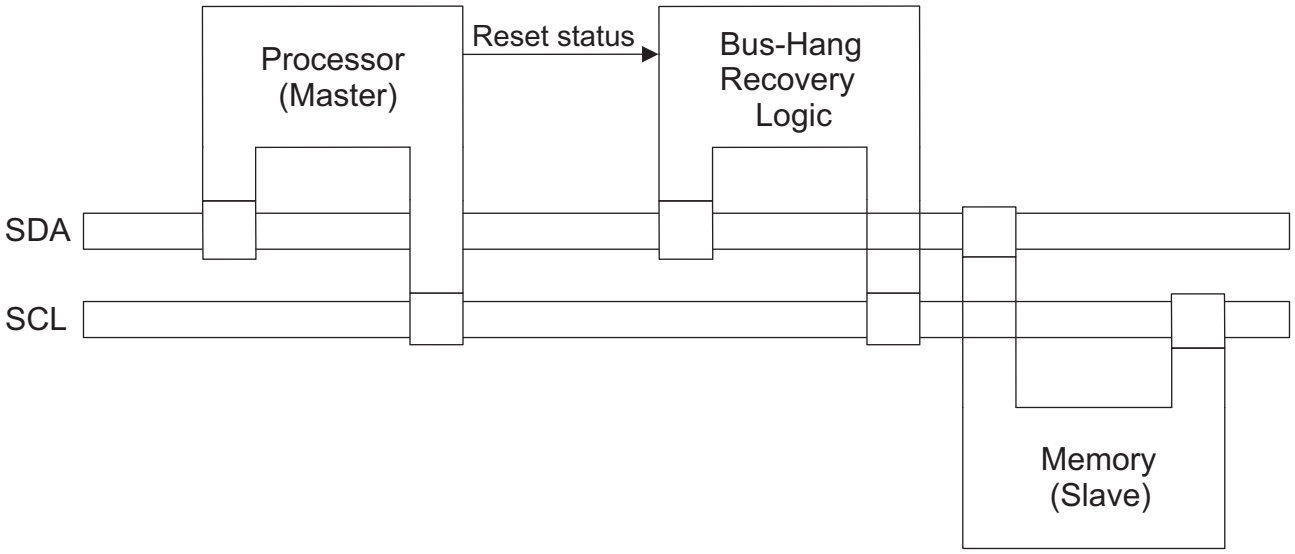


The master initiates a read in the normal fashion but a reset occurs while the SCL is high and the slave is driving the SDA low. The slave device will continue to drive SDA low waiting for the master to provide the next clock however the master has been reset and is no longer attempting to complete the read cycle. In addition, if the master attempts to access the bus after its reset has been released it will fail to arbitrate for control.

Arbitration for the I²C bus is performed on the SDA line. The master will attempt to generate a start condition beginning with both the SDA and the SCL lines high. Remember that the SDA and SCL lines are open-collector so the slave device will continue to hold the SDA line in a low state. When the master detects that the SDA line is not high, it will assume that some other device is in control of the bus and discontinue its attempt to start an access. This state will continue indefinitely blocking all attempts to access devices on the I²C interface.

This state is especially debilitating if the I²C slave is a memory device used as a boot memory. If the bus hang occurs during a reset, the processor acting as an I²C master will not be able to read its boot code and will fail to initialize. The processor cannot recover from this condition, even if additional resets are applied. To resolve this condition, additional hardware attached to the I²C bus is required (see Figure 11-570).

Figure 11-570. I²C Master Bus Hang



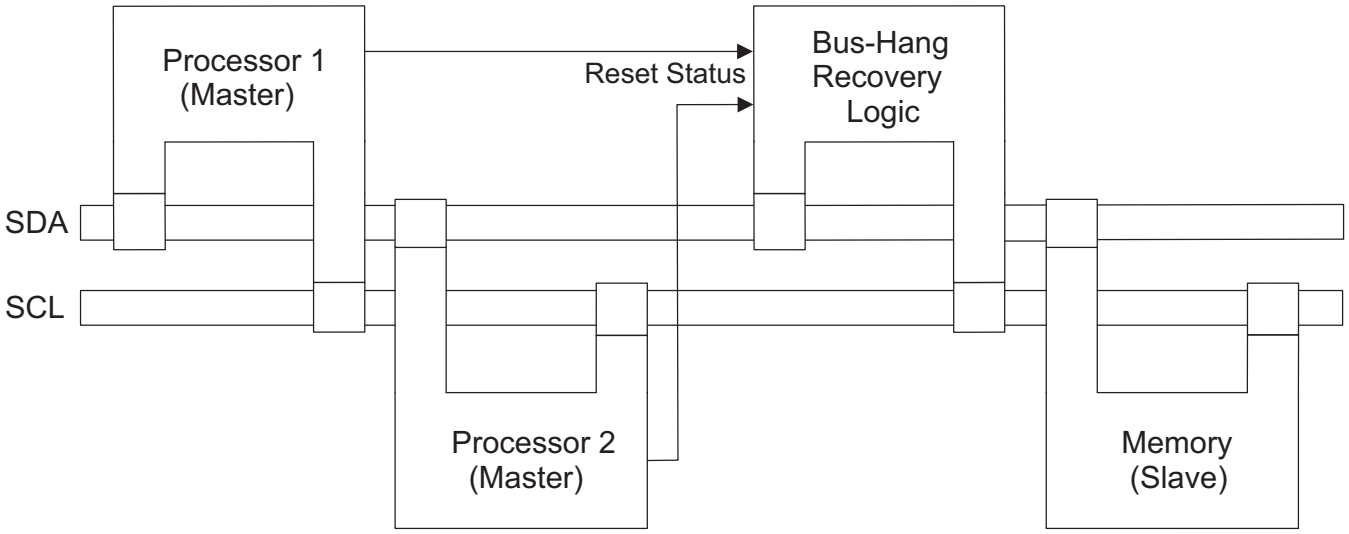
The bus-hang recovery logic needs to have knowledge of the reset status of the processor either through a RESETSTAT or a GPIO signal as well as the ability to monitor and drive the SDA and SCL signals. This logic may be a state machine in a programmable logic device or a software-driven solution in a microcontroller or processor using GPIO pins, but it must meet the open-collector driver requirements for the SDA and SCL signals to ensure the proper operation of the I²C.

Once the logic senses that the processor has entered reset, it should sample the SDA signal to determine if it is stuck in a low state. In a single master environment, the SDA should be pulled high as soon as the reset is applied to the master. If the logic senses that the SDA is low during a reset state, it can take action to free the bus. The logic should toggle SCL nine times ending in a high state.

These clock pulses must meet all the specification timing requirements for the high and low states. This will clock any remaining data bits from the slave memory device. Once these bits have been transmitted on the SDA, the slave device should release SDA and allow it to return to a high state. The recovery logic should sample SDA to ensure it has been released. The I²C bus should now be ready to respond to any requests for data by the processor.

The I²C interface with multiple master devices requires more complex logic to clear a bus-hang condition. In addition to determining that a master has been reset, the logic must also determine that a second master is not making a valid access to the bus (see Figure 11-571).

Figure 11-571. Multiple Master Bus Hang



In this environment, a reset to one of the processors during a read can cause the same bus-hang condition described above but detection of that condition is more complicated. When a single master is present on the bus, it is clear that there should not be any activity while that master is in reset. In this case, it is sufficient to sample the SDA signal while the RESET to the master is active, as described above. If multiple master devices are connected to the I^2C, a second master can access a working I^2C interface while the first master is in reset. This would create the condition where SDA is low while the first processor is in reset. In this environment, the logic must monitor the reset status from both master devices to determine if either is in reset.

Once a reset has been detected, the logic should monitor the SDA signal and no further action is needed. If the SDA signal is low and the SCL is toggling, another master is accessing the slave device and the interface is not hung. Again, no further action is needed. If the SDA signal is low and the SCL signal is high for too long the bus-hang condition is present and the logic must take action to recover.

The period of time that defines a failure can vary, depending on the slave devices on the bus and the speed of the I^2C interface. Slave devices can only add wait time to accesses by holding the SCL low so the average time that the SCL is high and the SDA is low should depend on the frequency that the masters are using to drive the interface. Once the slowest frequency is determined, the longest value for SCL high during an access should be multiplied by four to determine the period of time that defines a bus-hang condition. The logic should sample the SDA and SCL many times during the expected clock period to detect a stall condition.

If a bus-hang condition is present, the logic should send nine clock pulses onto SCL complete the in-process read from the slave memory. The slave should release SDA and allow it to be pulled high. In multi-master environments, a stop sequence should be generated after the nine clock pulses to release the bus for arbitration. This should clear the bus-hang condition and allow the I^2C master devices to access the memory.

11.9 Multi-Channel Audio Serial Port (McASP)

This section describes the Multi-channel Audio Serial Port (McASP) module.

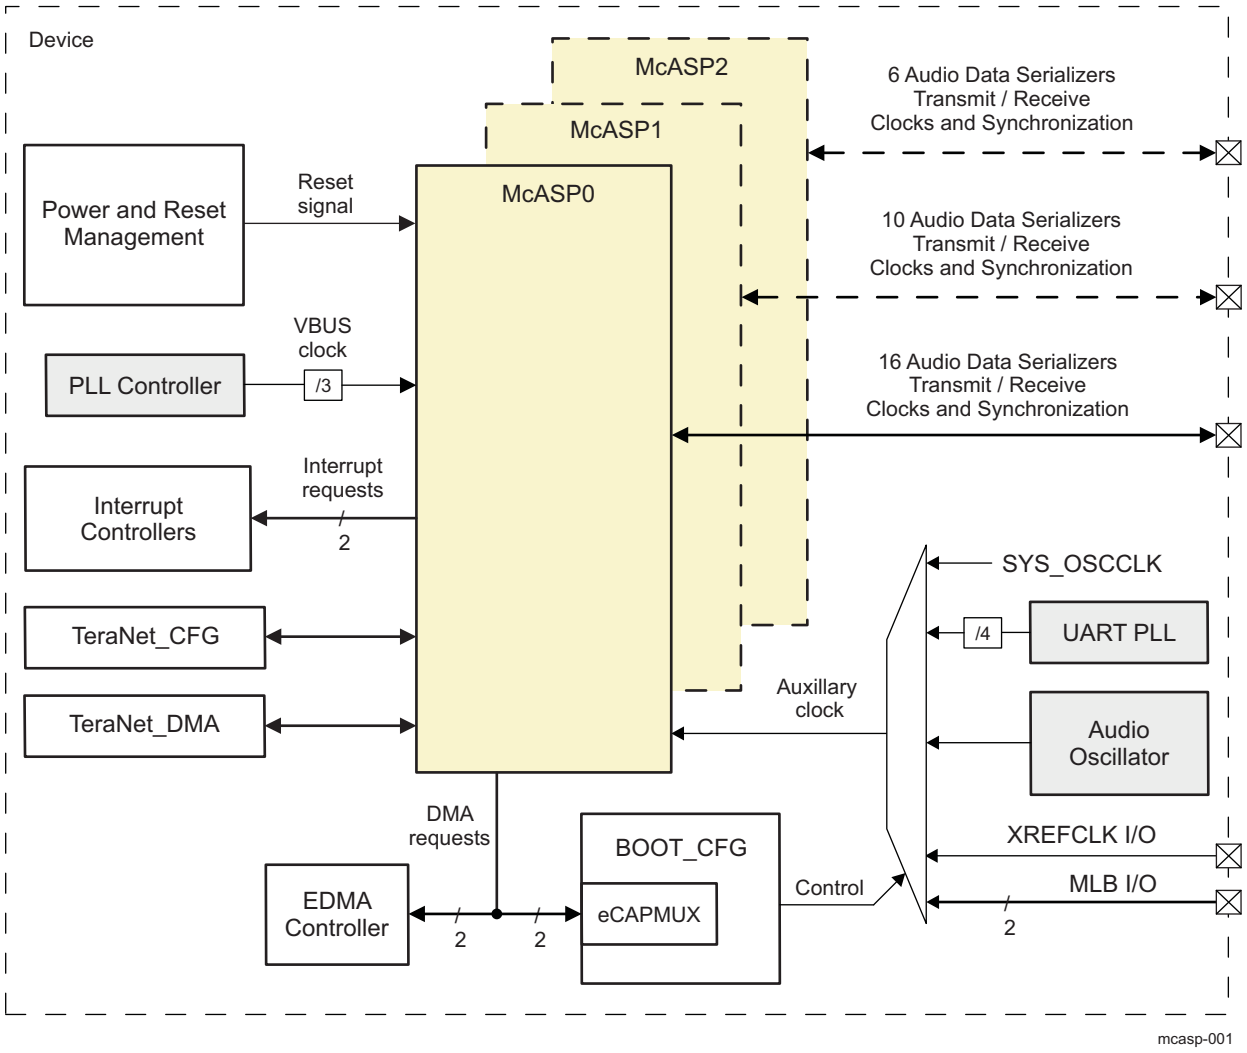
11.9.1 McASP Overview

The Multi-channel Audio Serial Port (McASP) module functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP supports transmission and reception of time-division multiplexed (TDM) and Inter-IC Sound (I^2S) protocols. In addition, it supports intercomponent digital audio interface transmission (DIT).

The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes up to 16 serializers that can be individually enabled to either transmit or receive.

Figure 11-572 shows the McASP modules in the device.

Figure 11-572. McASP Modules Overview



The device integrates three McASP modules (McASP0, McASP1, and McASP2) with:

- McASP0 supporting 16 serializers with independent TX/RX clock zones
- McASP1 supporting 10 serializers with independent TX/RX clock zones
- McASP2 supporting 6 serializers with independent TX/RX clock zones

Each McASP module includes the following main features:

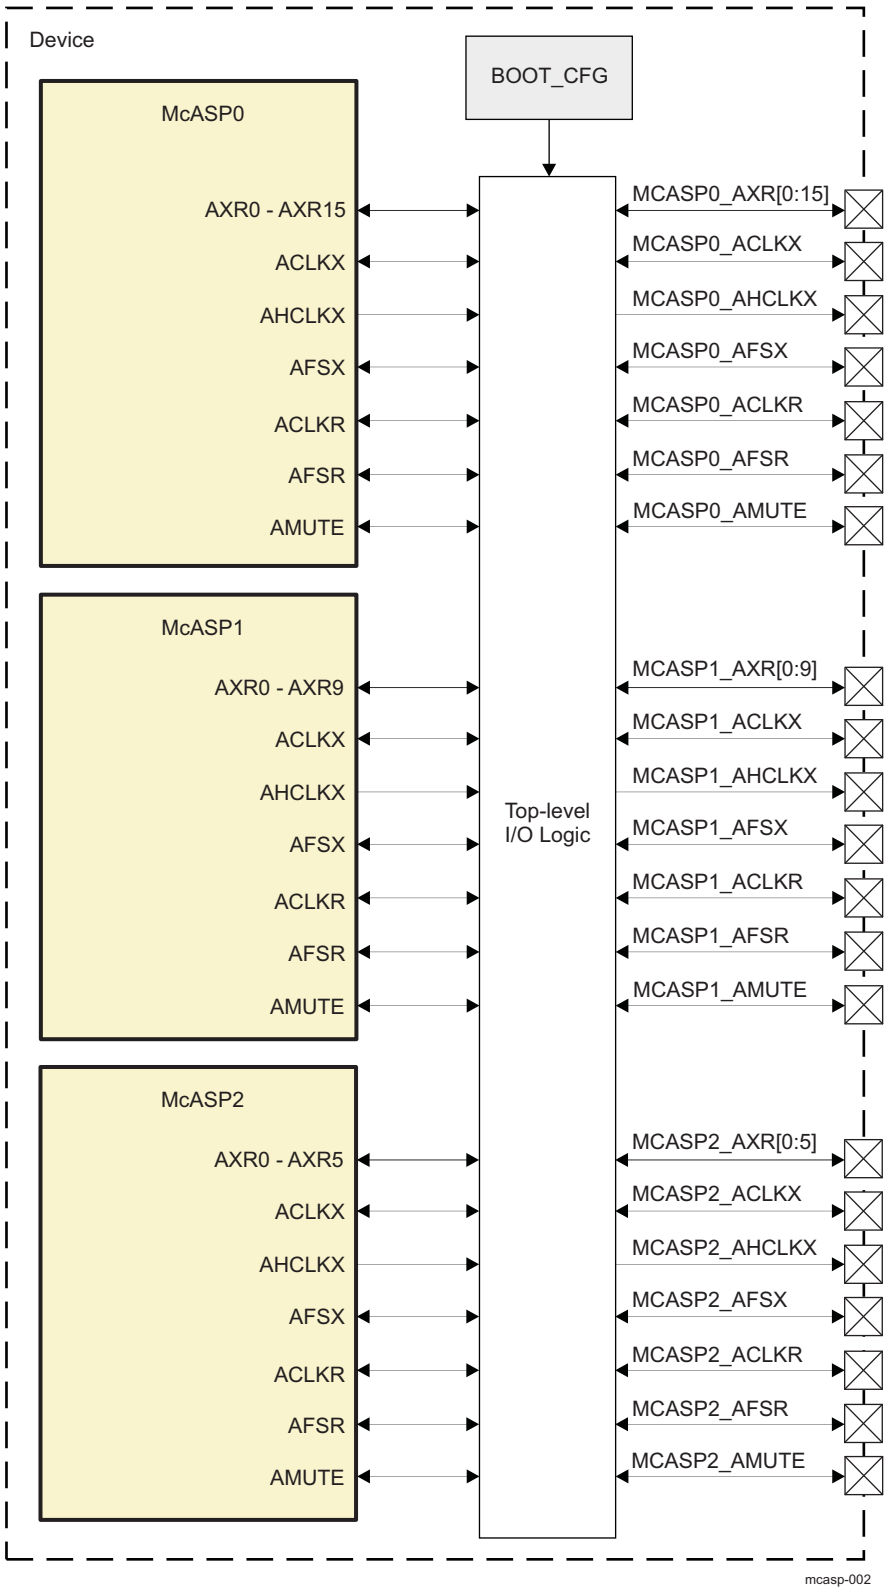
- Up to 16 individually assignable serializers, each with its own data pins (AXR)
- A single 32-bit buffer per serializer for transmit and receive operations
- 2x interconnect slave interface ports:
  - A configuration (CFG) port
  - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Configurable functional clocks:
  - May be generated internally (master mode)
  - May be supplied by an external device (slave mode)
  - May be divided down internally
- Independent transmit and receive modules, each providing:
  - Programmable clock and frame sync generator
  - TDM streams from 2 to 32, and 384 time slots
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
  - Data formatter for bit manipulation
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Support for wide variety of I^2S and similar bit-stream formats
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM
- 384-slot TDM with external digital audio interface receiver (DIR) device
  - For DIR reception, an external DIR receiver integrated circuit should be used with I^2S output format and connected to the McASP receive section
- Support for 2x DMA requests (1 per direction) per each McASP module:
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
- One transmit interrupt request common for all serializers per McASP module
- One receive interrupt request common for all serializers per McASP module
- Extensive error checking and recovery:
  - Transmit underruns and receiver overruns due to the system not meeting real-time requirements
  - Early or late frame sync in TDM mode
  - DMA error due to incorrect programming
- McASP Audio FIFO (AFIFO):
  - Provides additional data buffering
  - Provides added tolerance to variations in host/DMA controller response times
  - May be used as a DMA event pacer
  - Independent Read FIFO and Write FIFO
  - 256 bytes of RAM for each FIFO (read and write), where
    - 256 bytes = four 32-bit words per serializer in the case of 16 data pins
    - 256 bytes = 64 32-bit words in the case of one data pin
  - Option to bypass Write FIFO and/or Read FIFO independently

NOTE: Because each serializer is assigned to a single McASP data pin (AXR), the user may configure each serializer for either transmit or receive mode, but not both directions at the same time. Each serializer has its own direction control.

11.9.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections). This section also lists the possible interfaces and describes the protocol and data format used in each case. Figure 11-573 shows the McASP modules in their environment in the device.

Figure 11-573. McASP Modules Environment



11.9.2.1 McASP Signals

Table 11-1232 describes the McASP module pins, their corresponding signal names at device level and specifies their links to functions.

AMUTE	MCASP2_AMUTE	I/O	Audio mute	HiZ

NOTE: A serializer AXRn data pin (where n = 0 up to 15) is shared between the transmit and receive logic of this serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control registers MCASP_SRCTL0 through MCASP_SRCTL15.

11.9.2.2 McASP Protocols and Data Formats

11.9.2.2.1 Protocols Supported

The McASP modules supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I^2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - S/PDIF, IEC60958-1, AES-3 formats
- Receive section supports:
  - Wide variety of I^2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I^2S protocol (one time slot for each DIR subframe)

The transmit and receive sections of each module may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

NOTE: In I²S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I²S mode, due to the need to generate Biphase Mark Encoded Data).

NOTE: The McASP does NOT natively support DIR-mode reception (that is receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I²S-output converter implemented by an external device (that is external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

11.9.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 11-574 shows two of the three basic components: the clock signal (ACLKX / ACLKR) and the data signals AXRn. Figure 11-574 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

  A word is a group of bits that make up the data being transferred between the McASP and the external device. Figure 11-574 shows an 8-bit word.

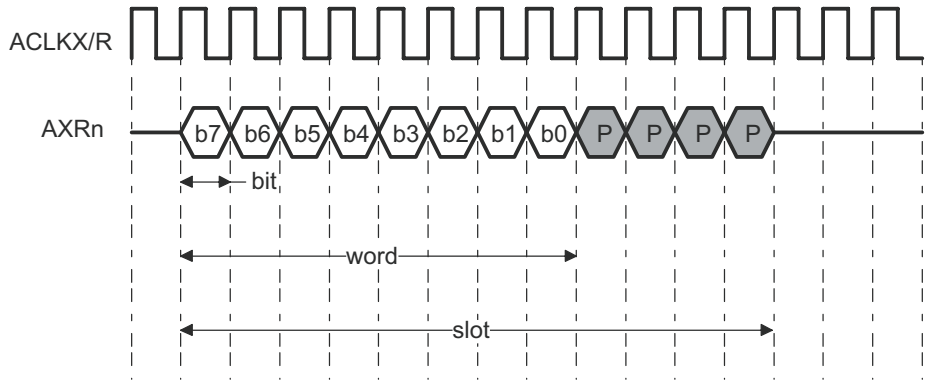
- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 11-574, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

  When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can

be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, that is left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 11-575 shows these options.

Figure 11-574. McASP Definition of Bit, Word, and Slot



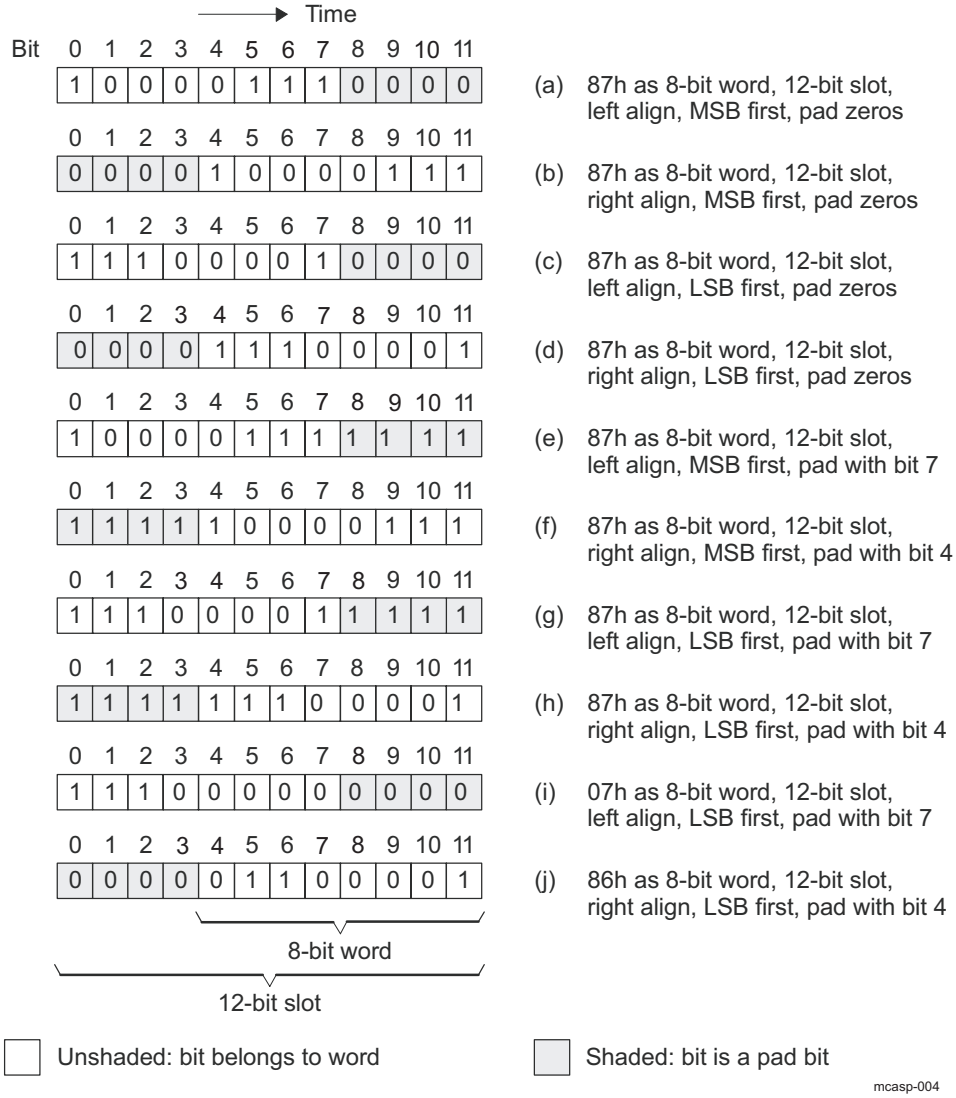
(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

Figure 11-575. McASP Bit Order and Word Alignment Within a Slot Examples



- Frame

  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 11-576 shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver – AFSR signal. Figure 11-576 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I^2S format) and a frame-sync (FS) duration of a slot length.

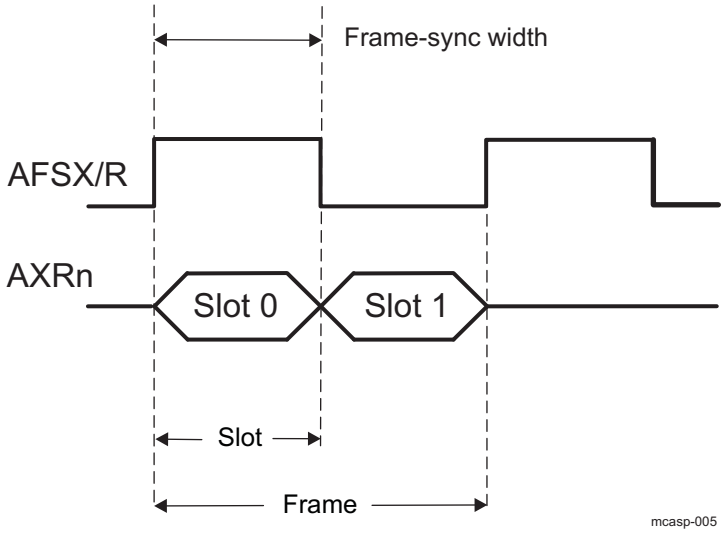
  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 11.9.2.2.3, *TDM Format* and Section 11.9.2.2.5, *S/PDIF-Coding Format*.

NOTE: All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

– AHCLKX, ACLKX and AFSX for the transmitting section

– ACLKR and AFSR for the receiving section

Figure 11-576. McASP Definition of Frame and Frame-Sync Width



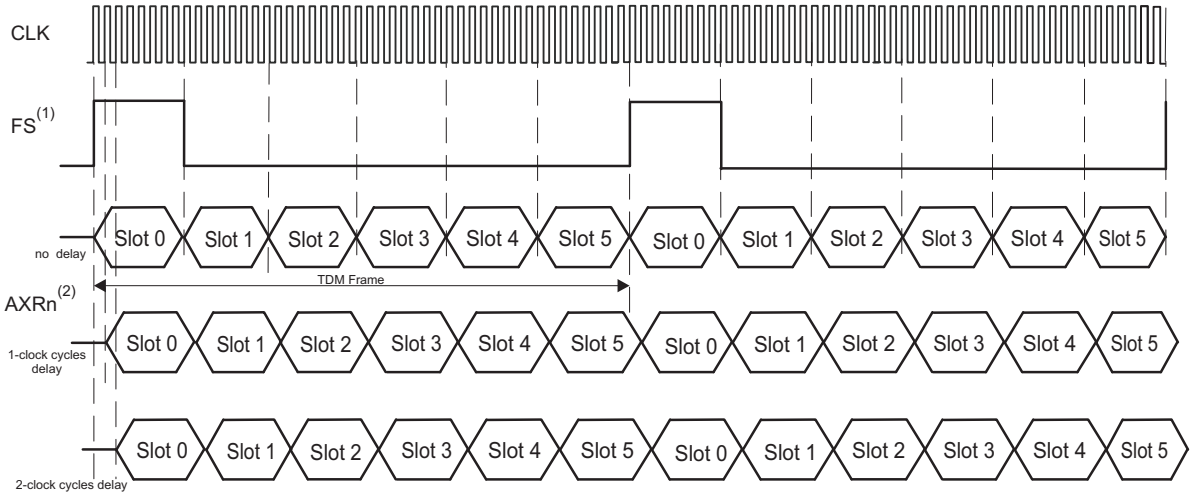
The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See Section 11.9.2.2.3, *TDM Format*, for details on the TDM protocol.
- I^2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I^2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I^2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

11.9.2.2.3 TDM Format

The TDM format is used to transfer data between the SoC and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin, AXRn, is illustrated on Figure 11-577.

Figure 11-577. McASP TDM Format - 6 Channel Example



(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported

(2) - Slot 0 of AXRn stream shown offsetted with 0-, 1- and 2-cycle delay from the frame sync respectively

mcasp-006

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 11.9.2.2.2, *Definition of Terms*), the latter being also refered to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-,1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does NOT determine the boundaries of a slot, **there is a requirement for a connected transmitter and receiver to agree on the number of transfered bits per slot.**

In a typical audio system involving McASP module, a single TDM data frame is transfered during each sample period Ts of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

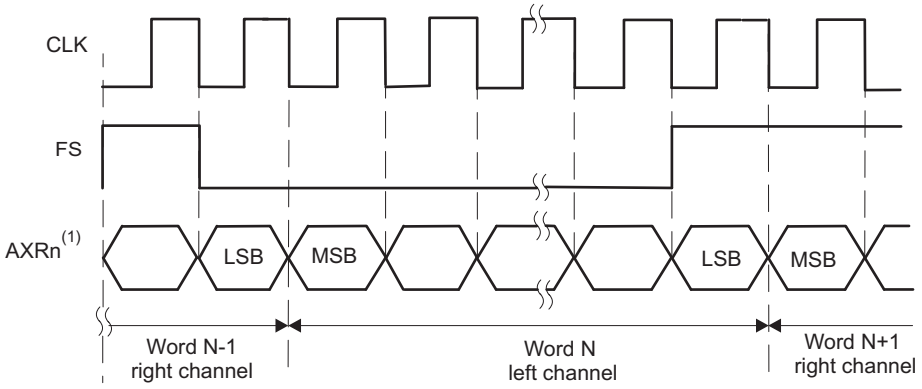
11.9.2.2.4 I²S Format

The Inter-IC Sound (I^2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I^2S format when configured for two slots per frame, with a 1-bit data delay, and falling edge of frame sync indicating start of frame.

The TDM transfer mode of the McASP supports the I^2S format when frame is configured to have 2 slots. I^2S format is specifically designed to transfer a stereo channel pair (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "audio channels". The frame width duration in the I^2S format equals size of a slot. The frame signal is also referred to as "word select" in the I^2S format.

The I^2S protocol is illustrated on Figure 11-578.

Figure 11-578. McASP I²S Format Overview



(1) - The example shows I²S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-007

11.9.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the DIT-transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

NOTE: The DIR-reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

11.9.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter n, the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 11-579 and Table 11-1233 show how data is encoded to the BMC format.

As shown in Figure 11-579, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 11.9.2.2.5.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

Figure 11-579. McASP Biphase-Mark Code

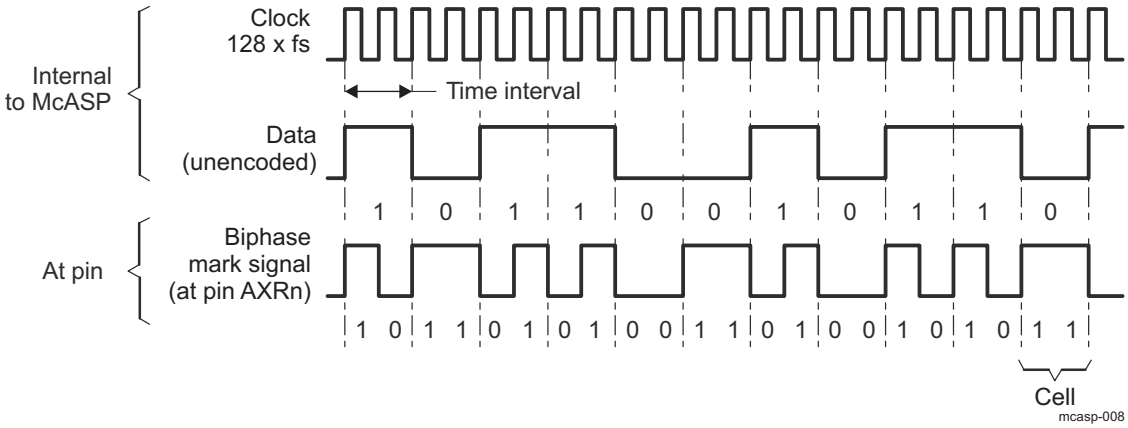


Table 11-1233. McASP Biphase-Mark Encoder

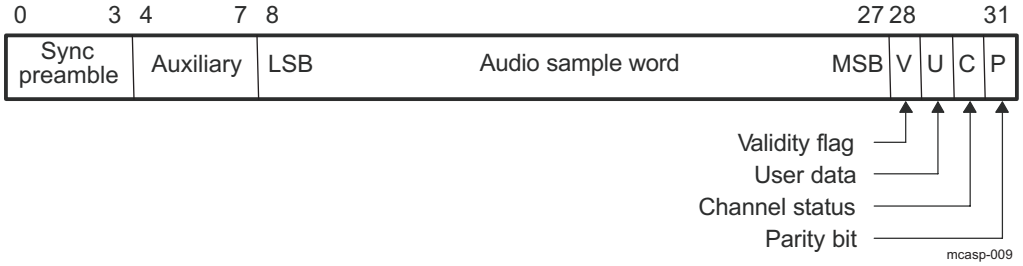
Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

11.9.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 11-580 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row, see Table 11-1234.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 11-1234, the preambles (time intervals 0–3) are also defined with even parity.

Figure 11-580. McASP S/PDIF Subframe Format



As listed in Table 11-1234, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 11-1234. McASP Preamble Codes

Preamble Code[1]	Previous Logical State	Logical States on pin AXRn[2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

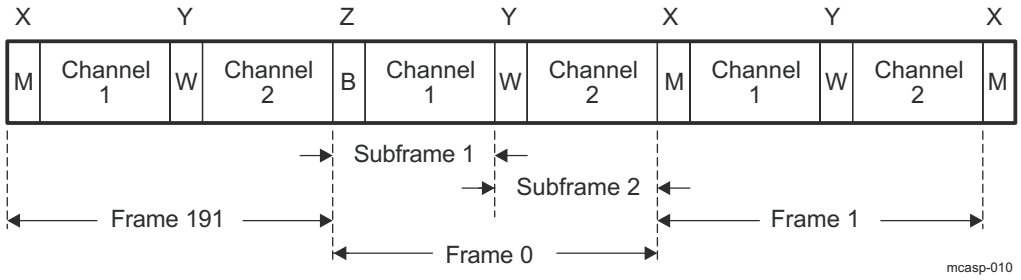
11.9.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 11-581). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 11-581. McASP S/PDIF Frame Format



11.9.3 McASP Integration

This section describes McASP modules integration in the device, including information about clocks, resets, and hardware requests.

A McASP module includes the following features:

- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

Figure 11-582 shows McASP integration.

Figure 11-582. McASP Integration

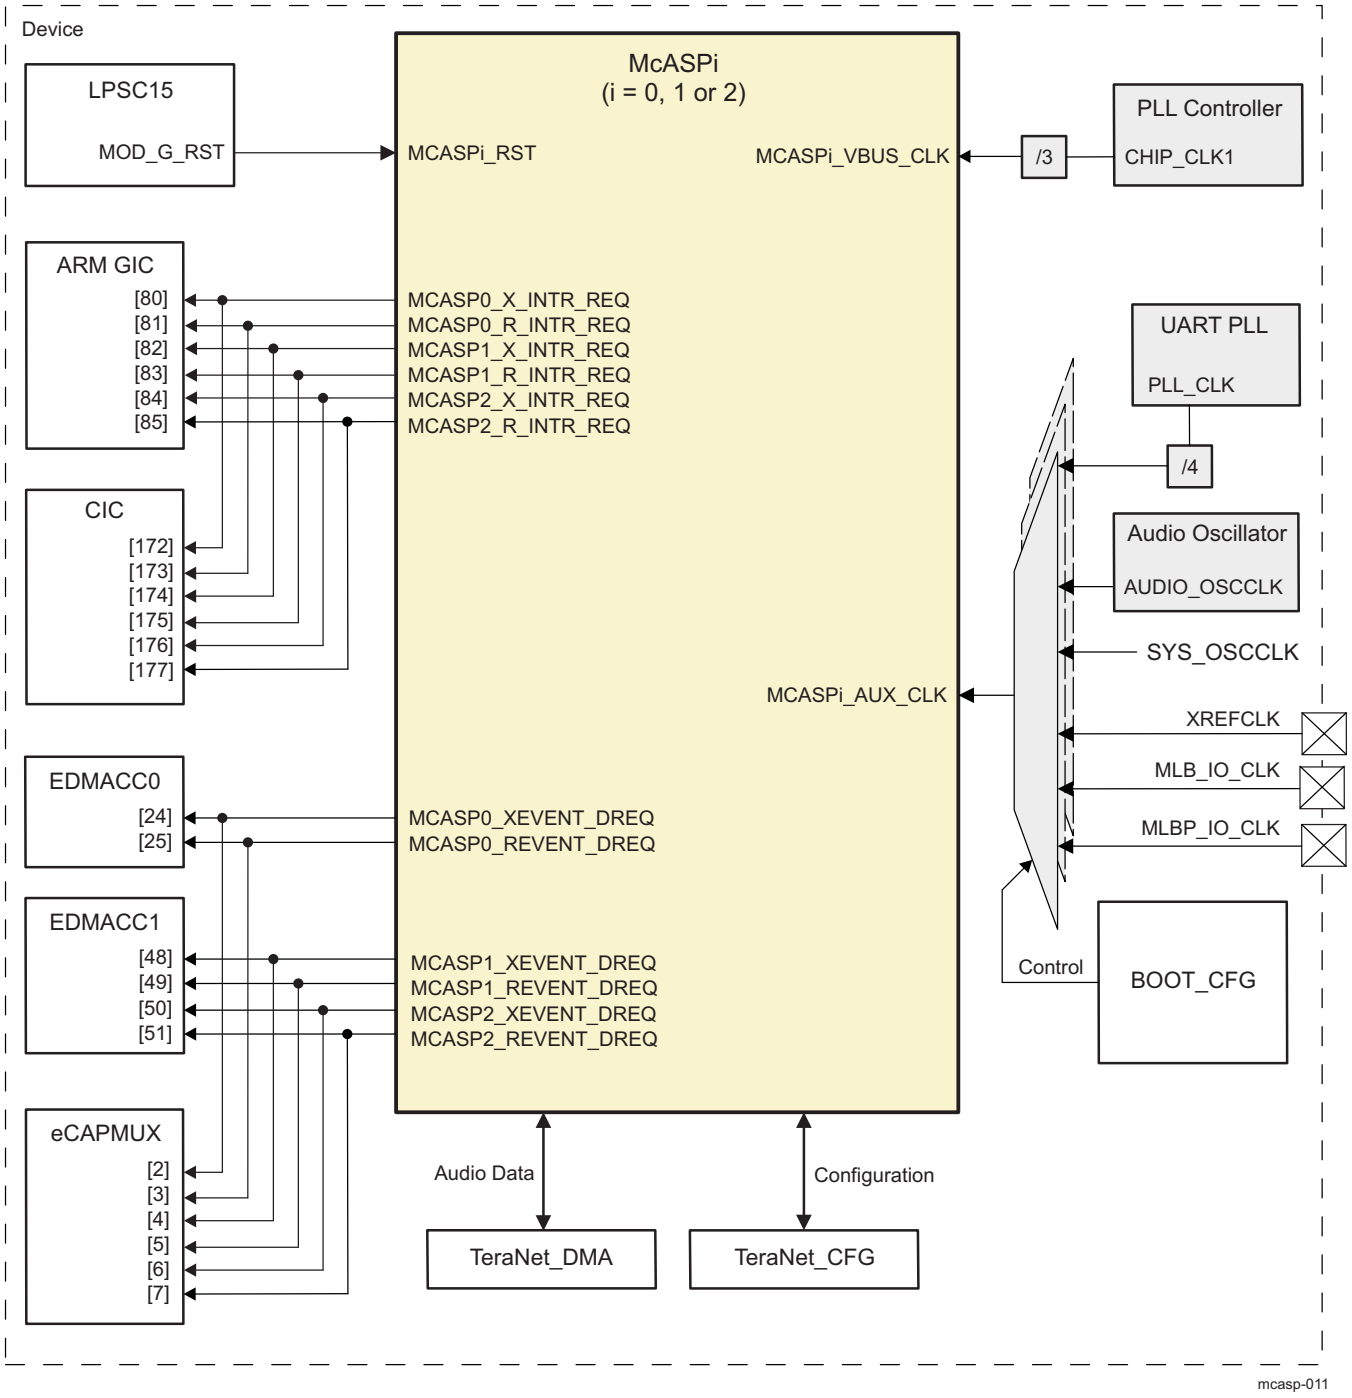


Table 11-1235 through Table 11-1237 summarize the integration of the McASP modules in the device.

Table 11-1235. McASP Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
McASP0 McASP1 McASP2	PD5	LPSC15	TeraNet_DMA (for data traffic) TeraNet_CFG (for configuration and data traffic)

Table 11-1236. McASP Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Destination Signal Description**
McASPi i = 0, 1 or 2	MCASPi_VBUS_CLK	CHIP_CLK1 / 3	PLL Controller	VBUS and functional clock. This clock must be 2x the rate of IO clock. For this SoC, this clock must be at least 150MHz.
	MCASPi_AUX_CLK	PLL_CLK / 5	UART PLL	Auxillary clock AUXCLK. Output of multiplexer (one per McASP module), see Figure 11-582, *McASP Integration*. Multiplexers control is provided via MCASPi_AUXCLK_SEL bit-fields of BOOTCFG_SERIALPORT_CLKCTL register. Audio clocks are derived from this clock.
		AUDIO_OSCCLK	Audio Oscillator

NOTE: For a description of the interrupt sources, see Section 11.9.4.12, *McASP Events and Interrupt Requests*.

For a description of the DMA sources, see Section 11.9.4.13, *McASP DMA Requests*.

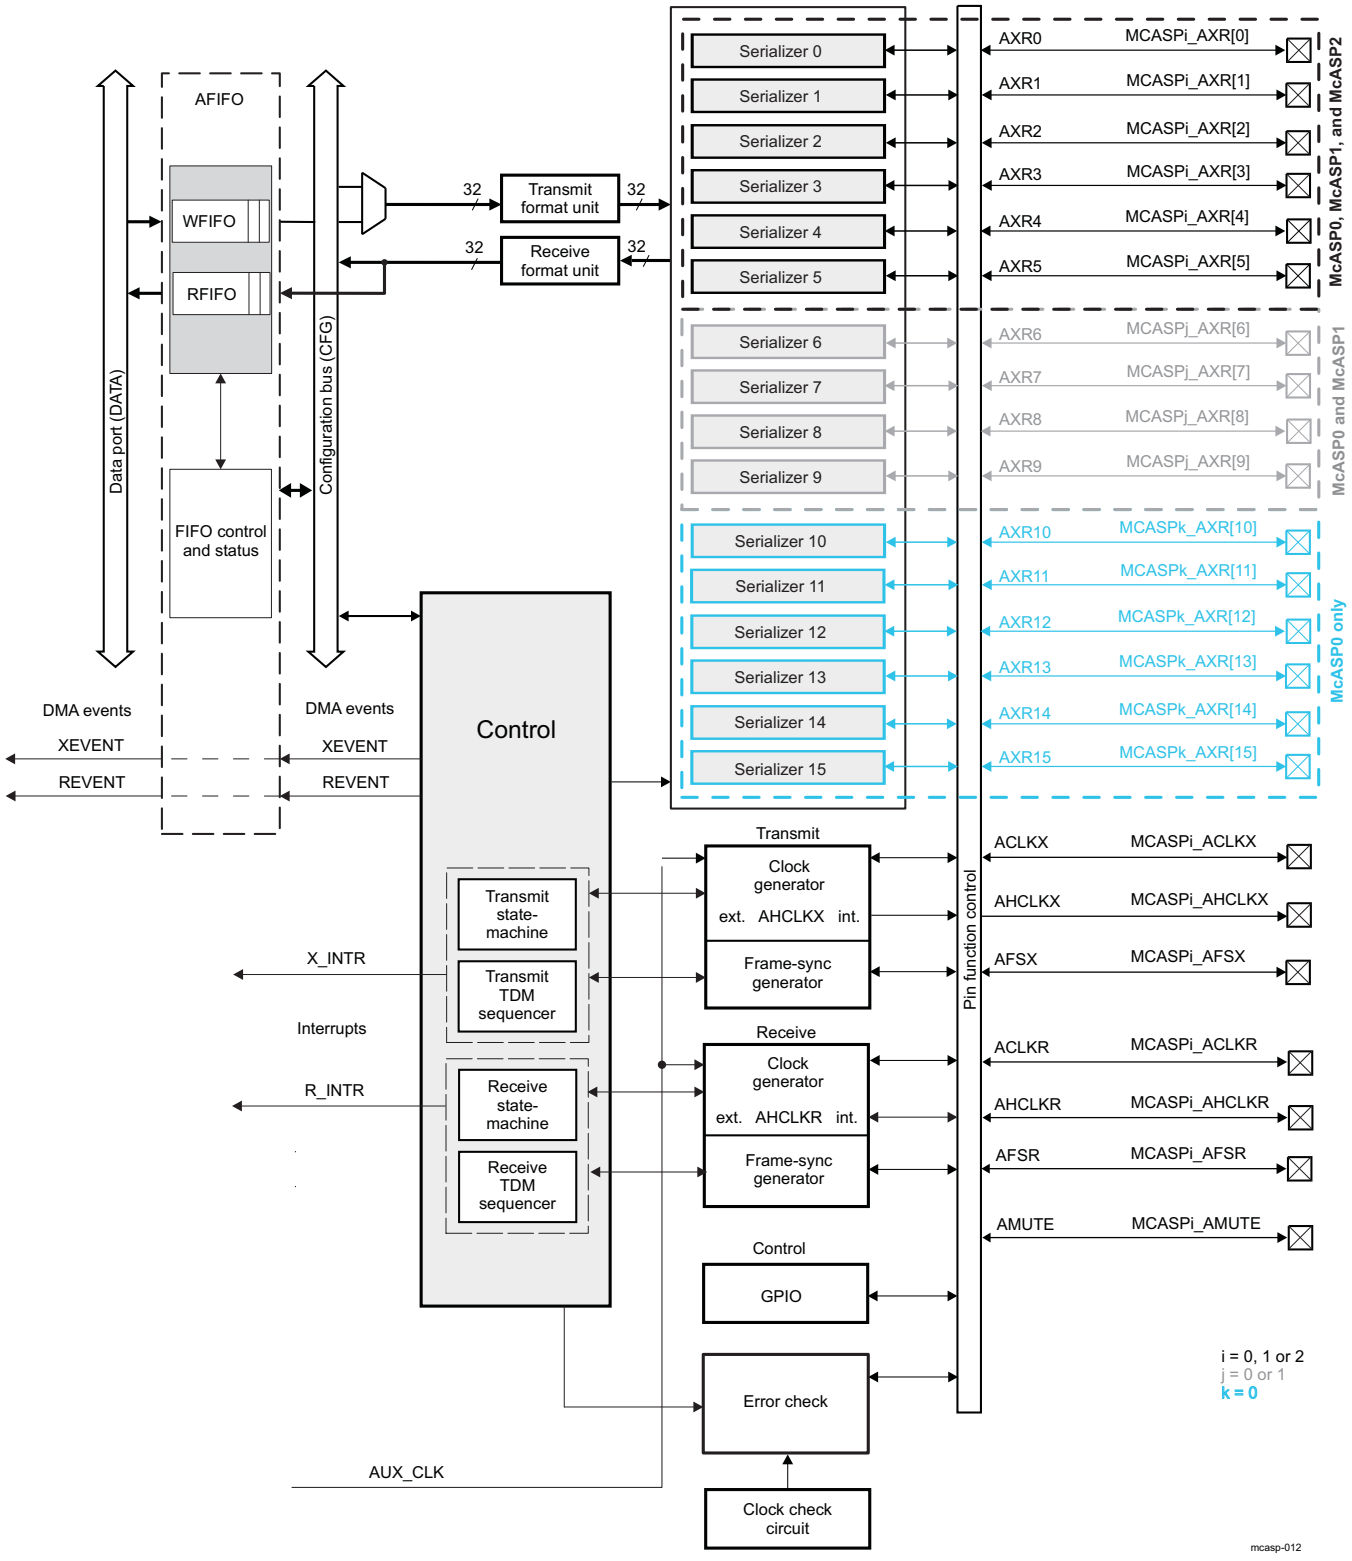
11.9.4 McASP Functional Description

All three McASP modules are functionally indentical, therefore in the text below a single instance of McASP is described. Differences for each McASP module will be highlighted in the text.

11.9.4.1 McASP Block Diagram

Figure 11-583 shows the major blocks of the McASP module. McASP0 has 16 serializers, McASP1 has 10 serializers, and McASP2 has 6 serializers. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

Figure 11-583. McASP Module Block Diagram



NOTE: The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

11.9.4.2 McASP Clocks and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx parts of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx and Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the Tx part) and ACLKR (for the Rx part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the Tx part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

11.9.4.2.1 Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4-0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in Section 11.9.4.2, *McASP Clocks and Frame-Sync Configurations*), the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11-0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see Figure 11-584). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in Figure 11-584, that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

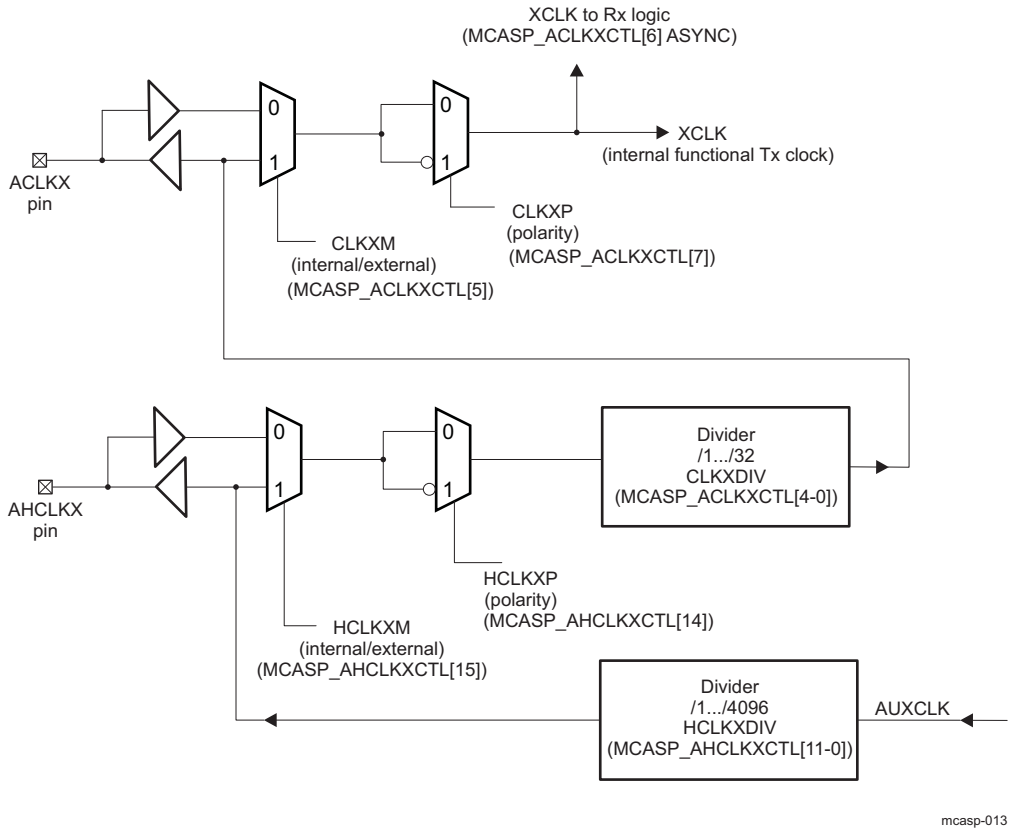
NOTE: The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

NOTE: In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 11-584 is the block diagram of the transmit clock generator.

Figure 11-584. McASP Transmit Clock Generator Block Diagram



NOTE: For more details on McASP integration, see Section 11.9.2, *McASP Environment*, and Section 11.9.3, *McASP Integration*.

11.9.4.2.2 Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4-0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in Section 11.9.4.2, *McASP Clocks and Frame-Sync Configurations*), then the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11-0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

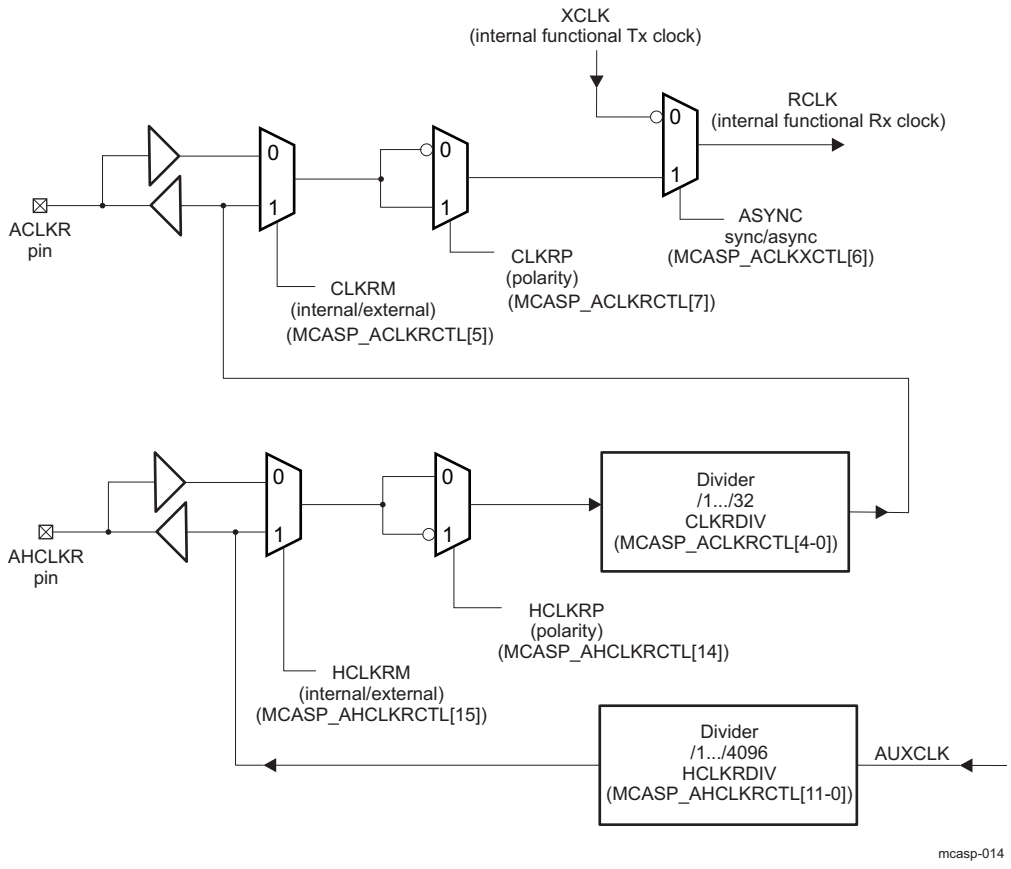
NOTE: The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see Figure 11-584 and Figure 11-585) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to Section 11.9.4.2.4.

Figure 11-585 is the block diagram of the receive clock generator.

Figure 11-585. McASP Receive Clock Generator Block Diagram

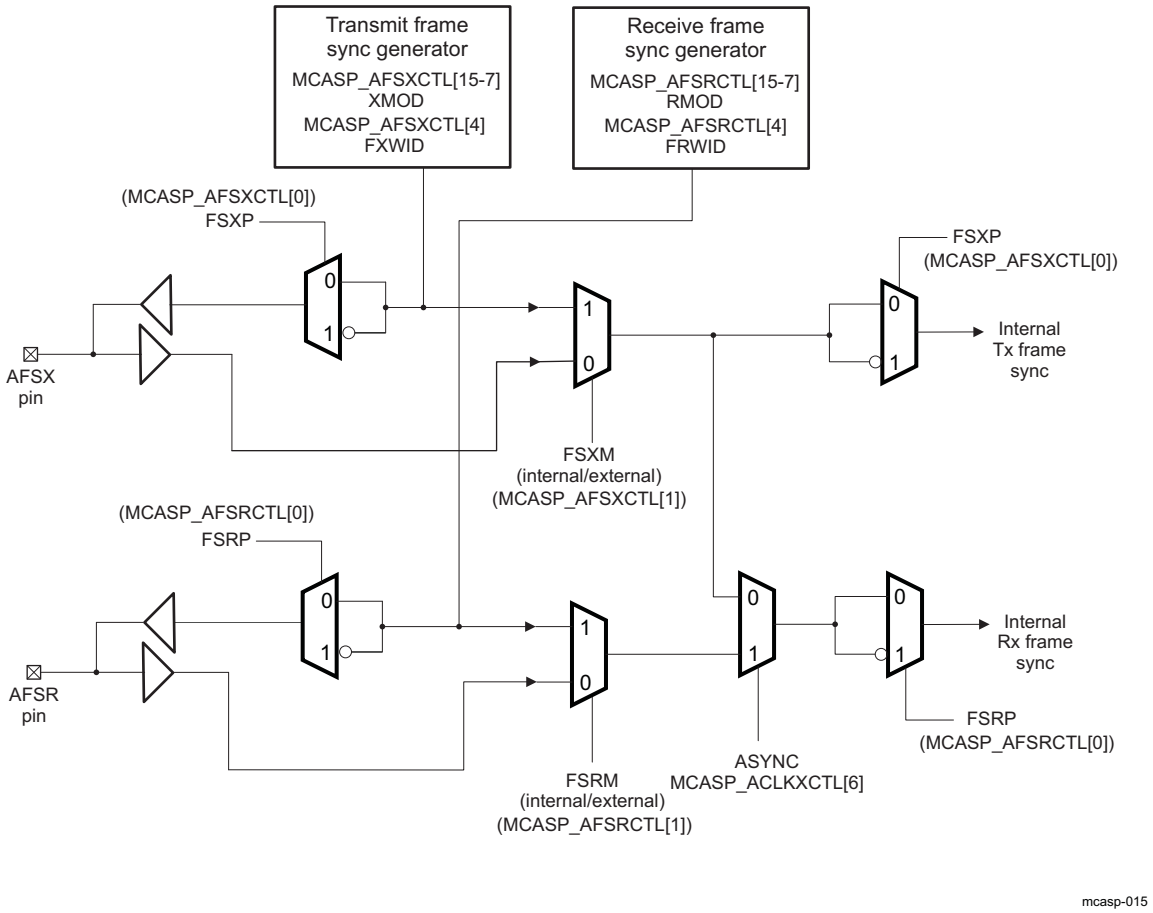


NOTE: For more details on McASP integration, see Section 11.9.2, *McASP Environment*, and Section 11.9.3, *McASP Integration*.

11.9.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in Figure 11-586. I/O buffers are not part of the McASP module, and they are not shown in the figure.

Figure 11-586. McASP Frame Sync Generator Block Diagram



NOTE: For more details on McASP integration, see Section 11.9.2, *McASP Environment*, and Section 11.9.3, *McASP Integration*.

For the transmit logic, the following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_AFSXCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_AFSXCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_AFSXCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_AFSXCTL[15-7] XMOD, as follows:
  - For DIT mode (384 slots) - MCASP_AFSXCTL[15-7] XMOD = 0x180
  - For I^2S mode (2 TDM slots) - MCASP_AFSXCTL[15-7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_AFSXCTL[15-7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_XFMT[17-16] XDATDLY

For the receive logic, the following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_AFSRCTL[1] FSRM

- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_AFSRCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_AFSRCTL[4] FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_AFSRCTL[15-7] RMOD, as follows:
  - For I^2S mode (2 TDM slots) - MCASP_AFSRCTL[15-7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_AFSRCTL[15-7] RMOD set in range 0x3–0x20
  - For the special 384-slot TDM mode - MCASP_AFSRCTL[15-7] RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RFMT[17-16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to Section 11.9.4.2.4, *McASP Synchronous and Asynchronous Transmit and Receive Operations*.

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

NOTE: Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in Section 11.9.4.2.4, *McASP Synchronous and Asynchronous Transmit and Receive Operations*.

11.9.4.2.4 McASP Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown in Figure 11-585, with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_DITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

NOTE: Synchronous transmit and receive operations are allowed only in the McASP TDM (I^2S) mode (that is when MCASP_DITCTL[0] DITEN=0b0).

11.9.4.3 McASP Serializers

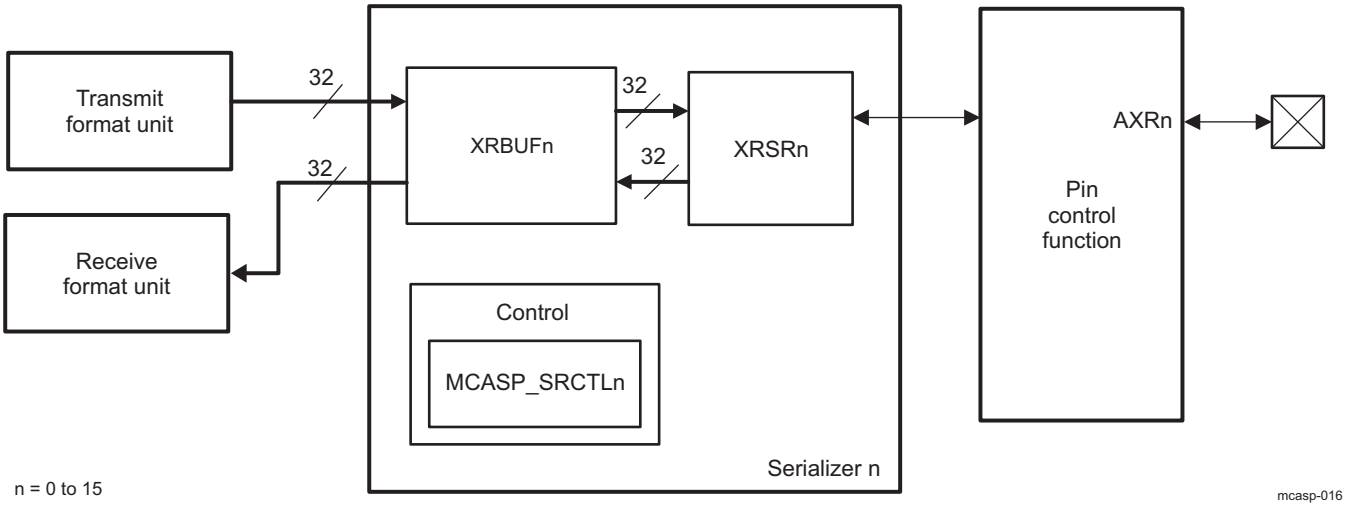
The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n (n = 0 to 15) consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register MCASP_XBUF0 through MCASP_XBUF15) or for receiving (read accessible in register MCASP_RBUF0 through MCASP_RBUF15) data. In addition, each serializer has a dedicated control register (MCASP_SRCTL0 through MCASP_SRCTL15) and a serial bidirectional data pin - AXRn. The register MCASP_SRCTL0 through MCASP_SRCTL15 allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in MCASP_SRCTL0 through MCASP_SRCTL15, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in MCASP_SRCTL0 through MCASP_SRCTL15, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal), if configured to transmit, or clocked from the receive section clock (ACLKR signal), if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 11-587 is the serializer block diagram.

Figure 11-587. McASP Individual Serializer and Connections



Transmission on the n-th serializer (where n = 0 to 15 for McASP0, and n = 0 to 9 for McASP1, and n = 0 to 5 for McASP2) is performed as follows: the CPU services the McASP by writing data into the register MCASP_XBUF0 through MCASP_XBUF15, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer (where n = 0 to 15 for McASP0, and n = 0 to 9 for McASP1, and n = 0 to 5 for McASP2) is performed as follows: the data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn, and can be accessed in the MCASP_RBUF0 through MCASP_RBUF15 register, which is an alias of the serializer data buffer - XRBUFn for receive function. When CPU reads data from this register, the McASP passes the data through the receive format unit, hence it returns formatted data to the CPU.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_SRCTL0 through MCASP_SRCTL15[1-0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_SRCTL0 through MCASP_SRCTL15[3-2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or HiZ).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_SRCTL0 through MCASP_SRCTL15[1-0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_SRCTL0 through MCASP_SRCTL15[1-0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, and so forth). For more information, see Section 11.9.2.2.5, *S/PDIF Coding Format*.

11.9.4.4 McASP Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the CPU (such as a Q31 representation) and the required format for the external serial device (for example I^2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I^2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

NOTE: The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RFMT/MCASP_XFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order – reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

The RDATDLY/XDATDLY bits in the MCASP_RFMT/MCASP_XFMT registers, respectively, also determine the data format. For example, the difference between I^2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I^2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RFMT/MCASP_XFMT registers means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal CPU (ARMSS or DSP) data representation.

11.9.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 11-588 shows the transmit formatting unit.

The McASP transmitter supports serial formats of:

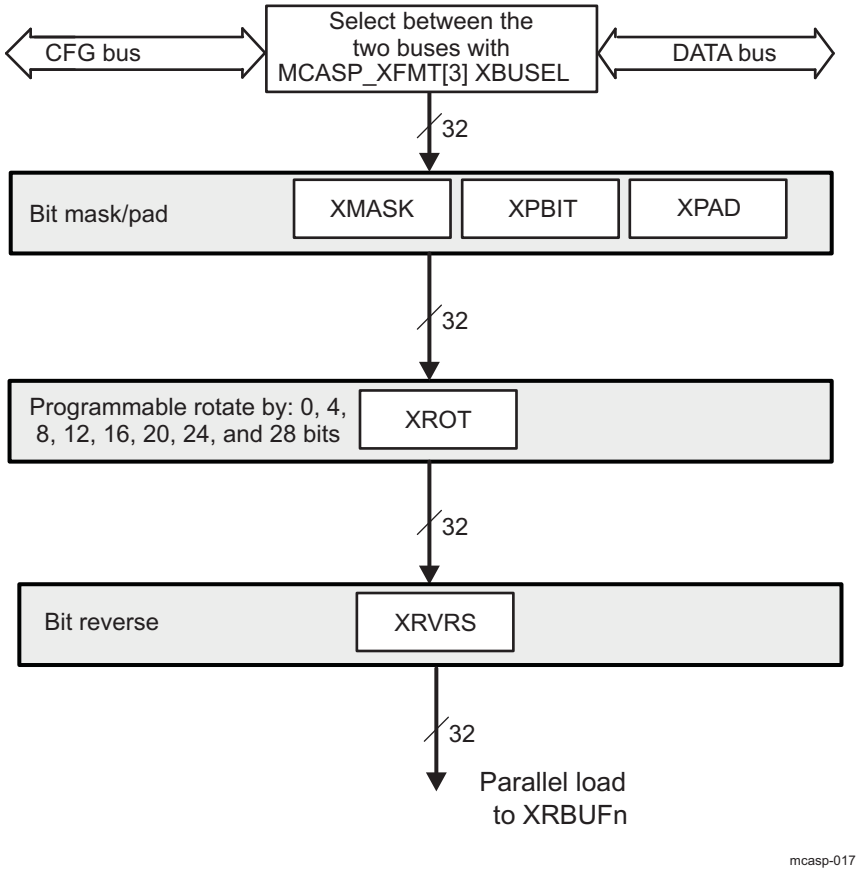
- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size <= Slot size
- Alignment: when more bits/slot than bits/words, then:

  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register – MCASP_XFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

Figure 11-588. McASP Transmit Format Unit



As shown in Figure 11-588, the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_XFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to Section 11.9.4.10.1.3, *Transfers Through the DATA Port*, and Section 11.9.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_XMASK[31-0] MCASP_XMASK contents. The masked data is then right-rotated to MCASP_XFMT[2-0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

11.9.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I²S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream. **Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.**

Table 11-1238 shows the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The Table 11-1238 assumes that all slot size (SLOT in Table 11-1238) and word size (WORD in Table 11-1238) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the ARMSS or DSP (typically Q31 or integer).

Table 11-1238. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_XFMT bits	
			XROT[1]	XRVRS
MSB first[2]	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first[2]	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I²S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

11.9.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_XFMT[17-16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_XFMT[2-0] XROT =
  - 0x2 (rotate right by 8 bits) – for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) – for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) – for a 16-bit output audio data
- MCASP_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_XMASK[32] MCASP_XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_XFMT[2-0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_XMASK[32] MCASP_XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 11-1239 should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 11-1239. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	MCASP_XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by CPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the Table 11-1239, the user must set MCASP_XMASK = 0xFFFFF000, and to select a right-rotation to 12 positions (XROT = 0x3).

- After applying 0-s (XPAD = 0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is : 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word – 0x yyyyE4B4 is generated by CPU on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set MCASP_XMASK = 0x0000FFFF, and to select right-rotation to 0 positions (XROT = 0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

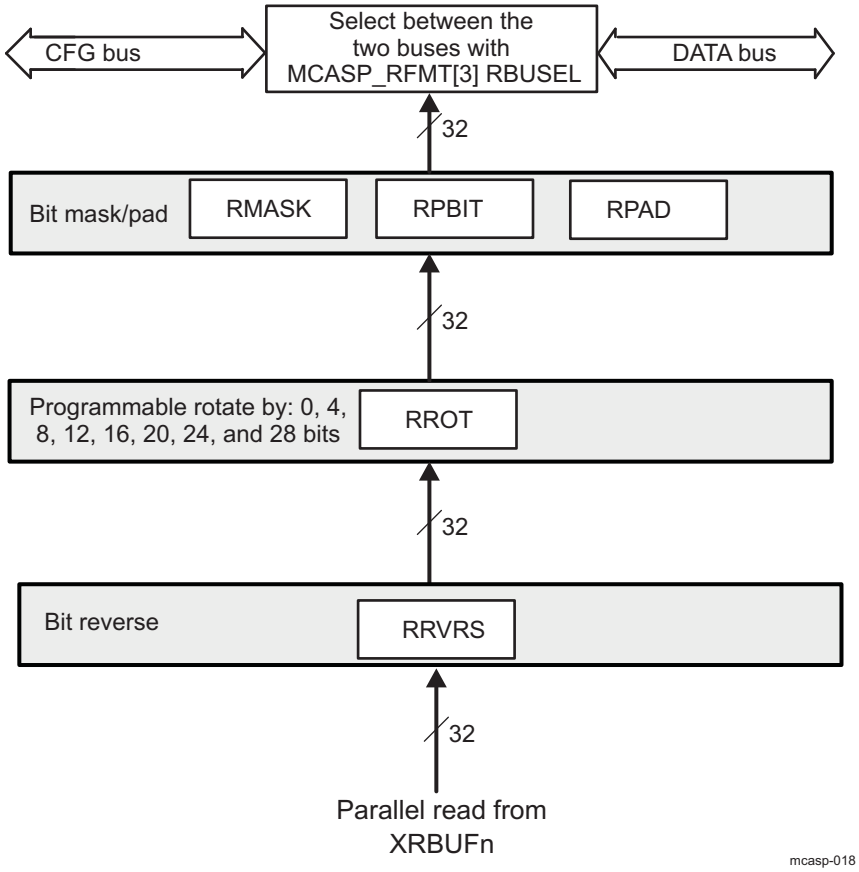
11.9.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 11-589 shows the receive format unit (RFU).

Figure 11-589. McASP Receive Format Unit



The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size <= Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register – MCASP_RFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on Figure 11-589, the data processed in the RFU can be output to CPUs (device ARMSS/DSP) through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to Section 11.9.4.10.1.3, *Transfers Through the DATA Port*, and Section 11.9.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

11.9.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream. **Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.**

Table 11-1240 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 11-1240. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RFMT bits	
			RROT[1]	RRVRS
MSB first[2]	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first[2]	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To receive in I^2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

Table 11-1240 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 11-589), and the data is aligned in the same representation as it is read from the receiver by the DSP (typically Q31 or integer).

11.9.4.5 McASP State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_XFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_XSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RSTAT).

11.9.4.6 McASP TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RTDM/MCASP_XTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins – AXRn in a predetermined state – logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_SRCTL0 through MCASP_SRCTL15[3-2] DISMOD. Refer also to Section 11.9.4.9.2.1, *TDM Time Slots Generation and Processing*, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_XBUF0 through MCASP_XBUF15 (where n = 0 to 15) register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_XTDM register and reports the current transmit slot to the MCASP_XSLOT[9-0] XSLOTCNT bit field.

11.9.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

11.9.4.8 McASP Power Management

Table 11-1241 describes power-management features available to the McASP.

Table 11-1241. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device level, the user software is strongly recommended to choose **No Idle** mode, setting MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE to 0x1. Before disabling McASP at device level, user software is strongly recommended to choose a **Smart-Idle** mode, setting MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE to 0x2.

11.9.4.9 McASP Transfer Modes

11.9.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

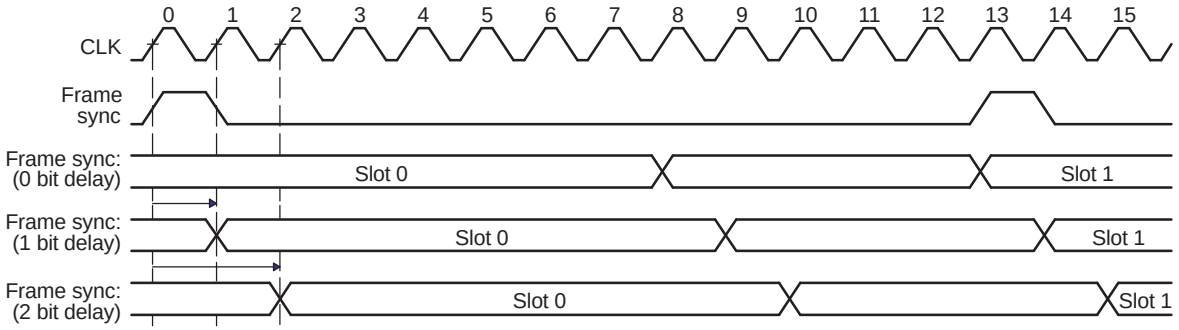
When operating in burst frame sync mode (see Figure 11-590), as specified for transmit (MCASP_AFSXCTL[15-7] XMOD = 0) and receive (MCASP_AFSRCTL[15-7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_AFSRCTL[4] FRWID = 0, MCASP_AFSXCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUFn (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUFn (for every serializer set to operate as a receiver) has been read.

Figure 11-590. McASP Burst Frame Sync Mode



The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_AMUTE: Not applicable. Leave at default.
- MCASP_DLBCTL: If loopback mode is desired, configure this register according to Section 11.9.4.14, *McASP Loopback Modes*, otherwise leave this register at default.
- MCASP_DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP_RMASK/MCASP_XMASK: Mask desired bits according to Section 11.9.4.4, *Format Units*.
- MCASP_RFMT/MCASP_XFMT: Program all fields according to data format desired. See Section 11.9.4.4, *Format Units*.
- MCASP_RFMT/MCASP_XFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. See Section 11.9.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired, see Section 11.9.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_RTDM/MCASP_XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP_RINTCTL/MCASP_XINTCTL: Program all fields according to interrupts desired.
- MCASP_RCLKCHK/MCASP_XCLKCHK: Not applicable. Leave at default.
- MCASP_SRCTL0 through MCASP_SRCTL15: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- MCASP_DITCSRA0 through MCASP_DITCSRA5, MCASP_DITCSRB0 through MCASP_DITCSRB5, MCASP_DITUDRA0 through MCASP_DITUDRA5, MCASP_DITUDRB0 through MCASP_DITUDRB5: Not applicable. Leave at default.

11.9.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 11.9.2.2.3, *TDM Format*.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX – transmit bit clock
- AFSX – transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the section Section 11.9.4.2.1, *Transmit Clock*, and Section 11.9.4.2.3, *Frame-Sync Generator* .

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR – receive bit clock
- AFSR – receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to the Section 11.9.4.2.2, *Receive Clock*, and Section 11.9.4.2.3, *Frame-Sync Generator* .

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence described in the , *Operational Modes Configuration*.
- MCASP_AMUTE: Leave this register at default state.
- MCASP_DLBCTL: If loopback mode is desired, configure this register according to Section 11.9.4.14, *McASP Loopback Modes*, otherwise leave this register at default.
- MCASP_DITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RMASK/MCASP_XMASK: Mask desired bits according to Section 11.9.4.4, *Format Units*.
- MCASP_RFMT/MCASP_XFMT: Program all fields according to data format desired, see Section 11.9.4.4, *Format Units*.
- MCASP_AFSRCTL/MCASP_AFSXCTL: Set RMOD/XMOD bits to (0x2–0x20) for Rx/Tx (2–32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. For more inforamtion, refer to Section 11.9.4.2.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to Section 11.9.4.2.
- MCASP_RTDM/MCASP_XTDM: Program all fields according to the time slot characteristics desired.
- MCASP_XINTCTL : Program all fields according to transmit interrupts desired.
- MCASP_RCLKCHK/MCASP_XCLKCHK: Program all fields according to clock checking desired.
- MCASP_SRCTL0 through MCASP_SRCTL15: Program all fields according to serializer operation desired.

NOTE: The MCASP_DITCSRA0 through MCASP_DITCSRA5, MCASP_DITCSRB0 through MCASP_DITCSRB5, MCASP_DITUDRA0 through MCASP_DITUDRA5, MCASP_DITUDRB0 through MCASP_DITUDRB5 settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

11.9.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring MCASP_XTDM and/or MCASP_RTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_XTDM or MCASP_RTDM to determine if the McASP transmits/receives in that time slot.

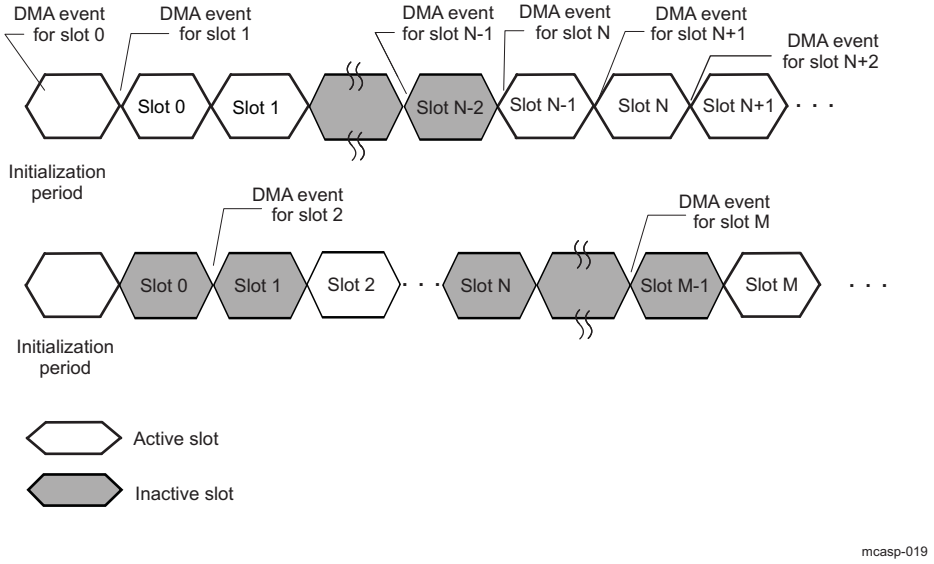
NOTE: If a MCASP_XTDM/MCASP_RTDM bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_SRCTL0 through MCASP_SRCTL15[3-2] DISMOD.

Figure 11-591 shows when the transmit DMA event – XEVENT is generated. See Section 11.9.4.10.1, *Data Ready Status and Event/Interrupt Generation*, for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 11-591. McASP Transmit DMA Event (XEVENT) Generation in TDM Time Slots



11.9.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RTDM) should be programmed to all 1s during reception of a DIR block. **Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).** To receive data in DIR mode, the following pins are typically needed:

- ACLKR – receive bit clock
- AFSR – receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive

- For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in MCASP_AFSRCTL to 384 (0x180) to receive 384 time slots

11.9.4.9.3 McASP DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. **The DIT mode applies only to a serializer configured as transmitter, NOT receiver.** For a description of the S/PDIF format, see Section 11.9.2.2.5, *S/PDIF Coding Format*.

11.9.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

NOTE: The transmit TDM time slot register (MCASP_XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see Section 11.9.4.4.1.2, *DIT Mode Transmission Data Alignment Settings*.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

11.9.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_AFSXCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin – AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Leave this register at default state.

- MCASP_DITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP_XMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- MCASP_XFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in Section 11.9.4.4.1.2, *DIT Mode Transmission Data Alignment Settings* .
- MCASP_AFSXCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_XTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_XINTCTL: Program all fields according to the interrupts desired.
- MCASP_XCLKCHK: Program all fields according to the clock checking desired.
- MCASP_SRCTL0 through MCASP_SRCTL15: Set SRMOD = 1 (transmitter) for the DIT pins.
- MCASP_DITCSRA0 through MCASP_DITCSRA5 and MCASP_DITCSRB0 through MCASP_DITCSRB5: Program the channel status bits as desired.
- MCASP_DITUDRA0 through MCASP_DITUDRA5 and MCASP_DITUDRB0 through MCASP_DITUDRB5: Program the user data bits as desired.

NOTE: In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I^2S) mode, due to the need to generate Biphase Mark Encoded Data, see Section 11.9.2.2.5.1, *Biphase-Mark Code*).

11.9.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRA0 through MCASP_DITCSRA5 and MCASP_DITCSRB0 through MCASP_DITCSRB5) and user data registers (MCASP_DITUDRA0 through MCASP_DITUDRA5 and MCASP_DITUDRB0 through MCASP_DITUDRB5) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 11.9.2.2.5.2, *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 11-581. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 11-1242.

Table 11-1242. McASP Channel Status and User Data for Each DIT Block

Frame	Subframe	Preamble	Channel Status Defined in:	User Data Defined in:

11.9.4.10 McASP Data Transmission and Reception

The CPU services the McASP by writing data to the MCASP_XBUF0 through MCASP_XBUF15 registers for transmit operations, and by reading data from the MCASP_RBUF0 through MCASP_RBUF15 registers for receive operations. The McASP sets status flags and notifies the CPU whenever data is ready to be serviced. Section 11.9.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in details.

The McASP transmit/receive XRBUFn buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus – CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

Section 11.9.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 11.9.4.10.1.4, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

The CPU and DMA usages are discussed in Section 11.9.4.10.1.5, *Using the device CPUs for McASP Servicing*, and Section 11.9.4.10.1.6, *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently, using burst transfers. The physical addresses to access these registers are listed in Table 11-1248.

11.9.4.10.1 Data Ready Status and Event/Interrupt Generation

11.9.4.10.1.1 Transmit Data Ready

The transmit data ready flag – XDATA in the MCASP_XSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer – XRBUFn to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer – XRBUFn is emptied and ready to accept new data from the host (ARMSS/DSP or DMAs). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_SRCTL0 through MCASP_SRCTL15[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_XBUF0 through MCASP_XBUF15 is written to by the host, the MCASP_SRCTL0 through MCASP_SRCTL15[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA = 0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_XBUF0 through MCASP_XBUF15 register has to be currently written. Once all requested MCASP_XBUF0 through MCASP_XBUF15 are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_XSTAT[5] XDATA bit is written to 0b1, or once MCASP_XBUF0 through MCASP_XBUF15 registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_XEVENT_DREQ line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_XBUF0 through MCASP_XBUF15 empty status. An interrupt – MCASPi_X_INTR_REQ can be also generated if the XDATA interrupt is enabled in the MCASP_XINTCTL register (for details, see Section 11.9.4.12.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_XSTAT be read between DMA events. This means that, even if MCASP_XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

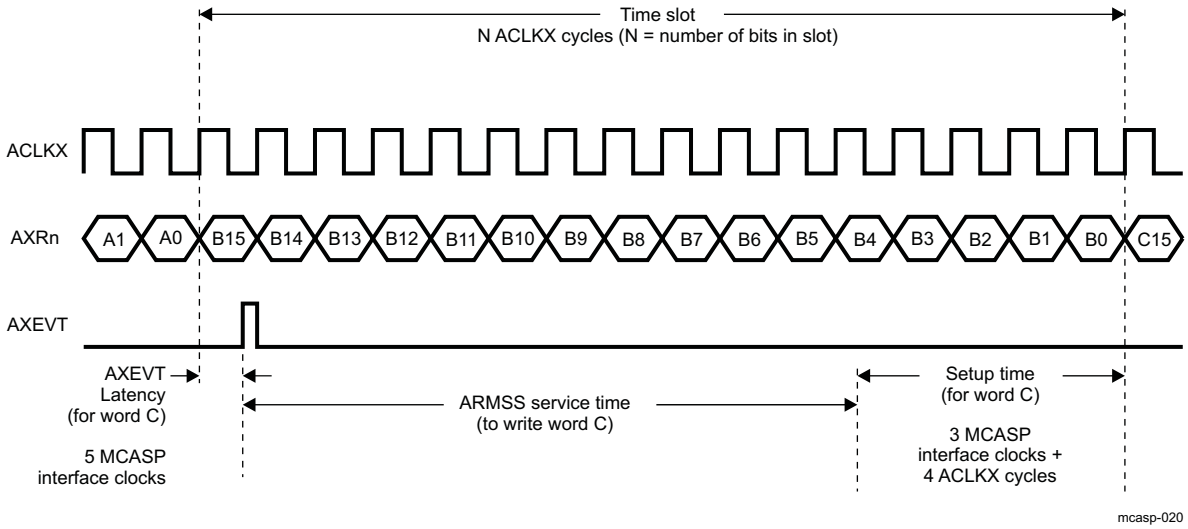
Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 11-592 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the DSP/ARMSS can begin servicing the McASP by writing word C into the MCASP_XBUF0 through MCASP_XBUF15 (service time). The CPU must write word C into the MCASP_XBUF0 through MCASP_XBUF15 within the setup time required by the McASP (setup time).

The maximum service time (see Figure 11-592) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

Figure 11-592. McASP CPU Service Time Upon Transmit DMA Event (AXEVT)



11.9.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag – RDATA in the MCASP_RSTAT register reflects the data ready status of XRBUFn buffers for all of the **active slot receiving serializers**. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer – RXBUFn already contains received data (that means that a buffer is full) and is ready to transfer it to the host (ARMSS/DSP). The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_SRCTL0 through MCASP_SRCTL15 [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RBUF0 through MCASP_RBUF15 is read from the host, the MCASP_SRCTL0 through MCASP_SRCTL15 [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RBUF0 through MCASP_RBUF15 register has to be currently read. Once all requested MCASP_RBUF0 through MCASP_RBUF15 are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

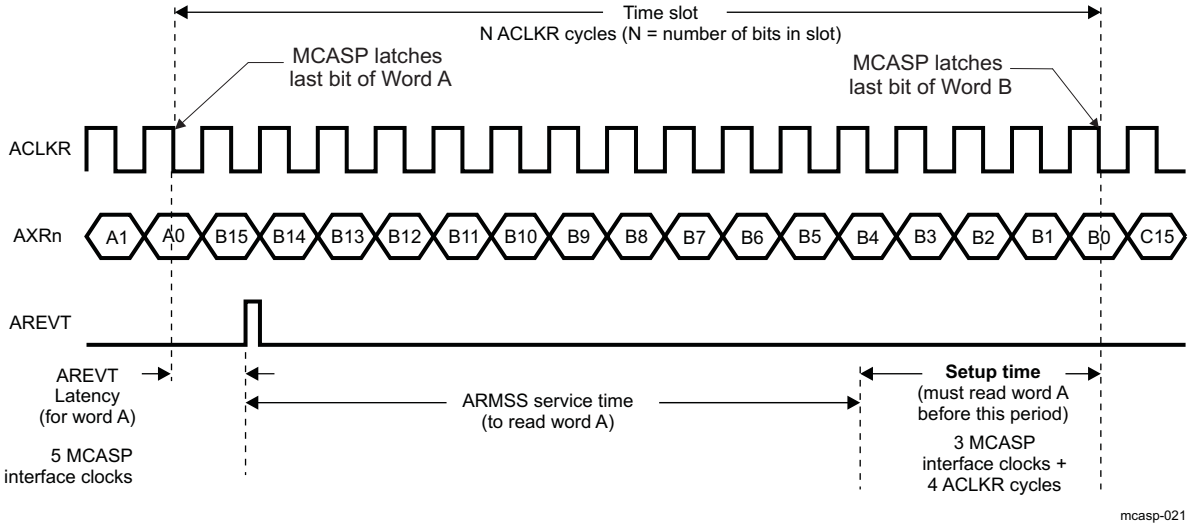
The global RDATA flag can be cleared when the MCASP_RSTAT[5] RDATA bit is written to 0b1, or once MCASP_RBUF0 through MCASP_RBUF15 registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_REVENT_DREQ line (if enabled in the MCASP_REVTCTL register) to notify the DMA of the MCASP_RBUF0 through MCASP_RBUF15 full status. An interrupt – MCASPi_R_INTR_REQ can be also generated if the RDATA interrupt is enabled in the MCASP_RINTCTL register (for details, see Section 11.9.4.12.1, *Receive Data Ready Interrupt*).

Figure 11-593 shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the DSP/ARMSS can begin servicing the McASP by reading Word A from the MCASP_RBUF0 through MCASP_RBUF15 (service time). The DSP/ARMSS must read Word A from the MCASP_RBUF0 through MCASP_RBUF15 register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see Figure 11-593) can be calculated as:
Service Time = Time Slot - AREVT Latency - Setup Time

Figure 11-593. McASP CPU Service Time Upon Receive Event (AREVT)



11.9.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_XFMT/MCASP_RFMT register, respectively. Failure to do so may result in software malfunction.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the McASP data port (DATA). ARMSS and DSP hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address on main interconect. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconect DATA port location. The ARMSS/DSP write or read access corresponding Tx/Rx buffer through Interconect DATA port location, as specified in the Table 11-1248. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in Section 11.9.4.11.

For accesses through the DATA port, the DMAs/ARMSS or DSP service all the serializers through accessing only a single address. In addition, **the same physical DATA port address is used regardless of a read or write access is performed** by device ARMSS/DSP, see Table 11-1248. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

NOTE: DATA port allows the DMAs/ARMSS or DSP to automatically access only the data buffers. There is no way for DMAs/ARMSS or DSP to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, **the host must always write to the same transmit buffer DATA port address** (which is same than the receive buffer DATA port adress) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMAs/ARMSS or DSP destination address to match the DATA port location of TXBUF buffer (See Table 11-1248).

In addition, the DMAs/ARMSS or DSP must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, the DMAs/ARMSS or DSP should write to the same transmit buffer DATA port address twice – first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

NOTE: For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, **the DMA/ARMSS or DSP must always read from the same receive buffer DATA port address** (which is same than the transmit buffer DATA port adress) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/ARMSS or DSP source address to match the DATA port location of RXBUF buffer (see Table 11-1248).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the ARMSS or DSP should read from the same receive buffer DATA port address three times to obtain data for serializers 0,1 and 3 in this exact order, upon each receive data ready event.

NOTE: To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to Table 11-1248), respectively.

See Table 11-1248, *McASP DMA Space Registers*, for more details about XRBUFn buffer physical address corresponding to the McASP DATA port.

NOTE: When transmitting through the DATA port, the DMAs/ARMSS or DSP must write data (at the same address) to each serializer configured as **active** (active slot selected in MCASP_XTDM) and **transmit** (Tx enabled in MCASP_SRCTL0 through MCASP_SRCTL15) within each time slot. Failure to do so results in a buffer underrun condition (see Section 11.9.4.15.1, *Buffer Underrun Error - Transmitter*). Similarly, when DMA/ARMSS or DSP receives, data must be read from each serializer configured as **active** (active slot selected in MCASP_RTDM) and **receive** (Rx enabled in MCASP_SRCTL0 through MCASP_SRCTL15) within each time slot. Failure to do results in a buffer overrun condition (see Section 11.9.4.15.2, *Buffer Overrun Error - Receiver*).

11.9.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_XFMT/MCASP_RFMT registers, respectively. Failure to do so may result in software malfunction.

In this method, the DMAs/ARMSS or DSP accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased – MCASP_XBUF0 through MCASP_XBUF15 in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_XBUF2 register. Similarly, the XRBUFn buffer of the n-th serializer configured as a receiver is aliased – MCASP_RBUF0 through MCASP_RBUF15 in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RBUF3 register.

Accessing the XRBUF through the DATA port (see Section 11.9.4.10.1.3) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index , while accessing through the peripheral configuration port – CFG, the DMA, ARMSS or DSP must provide the exact MCASP_XBUF0 through MCASP_XBUF15 or MCASP_RBUF0 through MCASP_RBUF15 address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_XBUF0 through MCASP_XBUF15 and MCASP_RBUF0 through MCASP_RBUF15 addresses corresponding to McASP CFG port, see Table 11-1246, *McASP Configuration Space Registers*.

11.9.4.10.1.5 Using the device CPUs for McASP Servicing

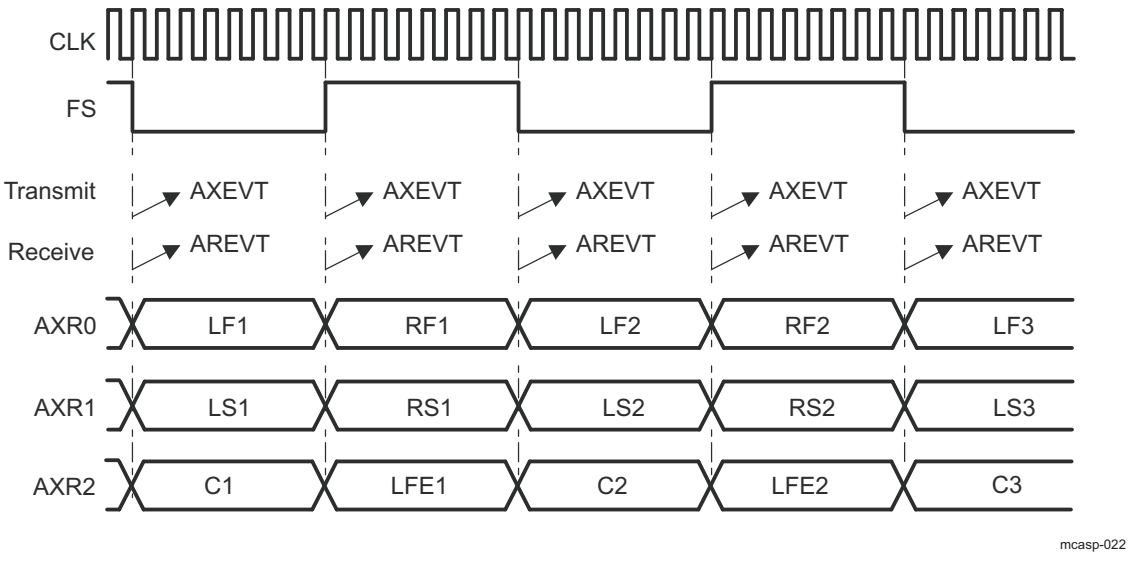
The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_X_INTR_REQ and MCASPi_R_INTR_REQ interrupts). Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_XSTAT register and RDATA bit in the MCASP_RSTAT register can be performed by device CPUs, respectively. As discussed in Section 11.9.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 11.9.4.10.1.4, *Transfers Through the Configuration Bus (CFG)* , the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_XINTCTL/MCASP_RINTCTL registers, to generate interrupts MCASPi_X_INTR_REQ /MCASPi_R_INTR_REQ to the device CPUs upon data ready

11.9.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to DMA system (see Figure 11-583). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in Section 11.9.4.11, *McASP Audio FIFO (AFIFO)*. The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in Section 11.9.4.11, *McASP Audio FIFO (AFIFO)*, the requests (transmit or receive) are forwarded to the DMA system via MCASPi_XEVENT_DREQ and MCASPi_REVENT_DREQ outputs. If the AFIFO is disabled (default state) it is transperrant for the McASP module and all request are directly sent to the DMA system.

Figure 11-594. McASP DMA Transmit and Receive Event in an Audio Example – One Event



In transmit mode, the DMA event – AXEVT (MCASPi_XEVENT_DREQ output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUFn transmit buffers. In receive mode, the DMA event AREVT (MCASPi_REVENT_DREQ output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUFn receive buffers.

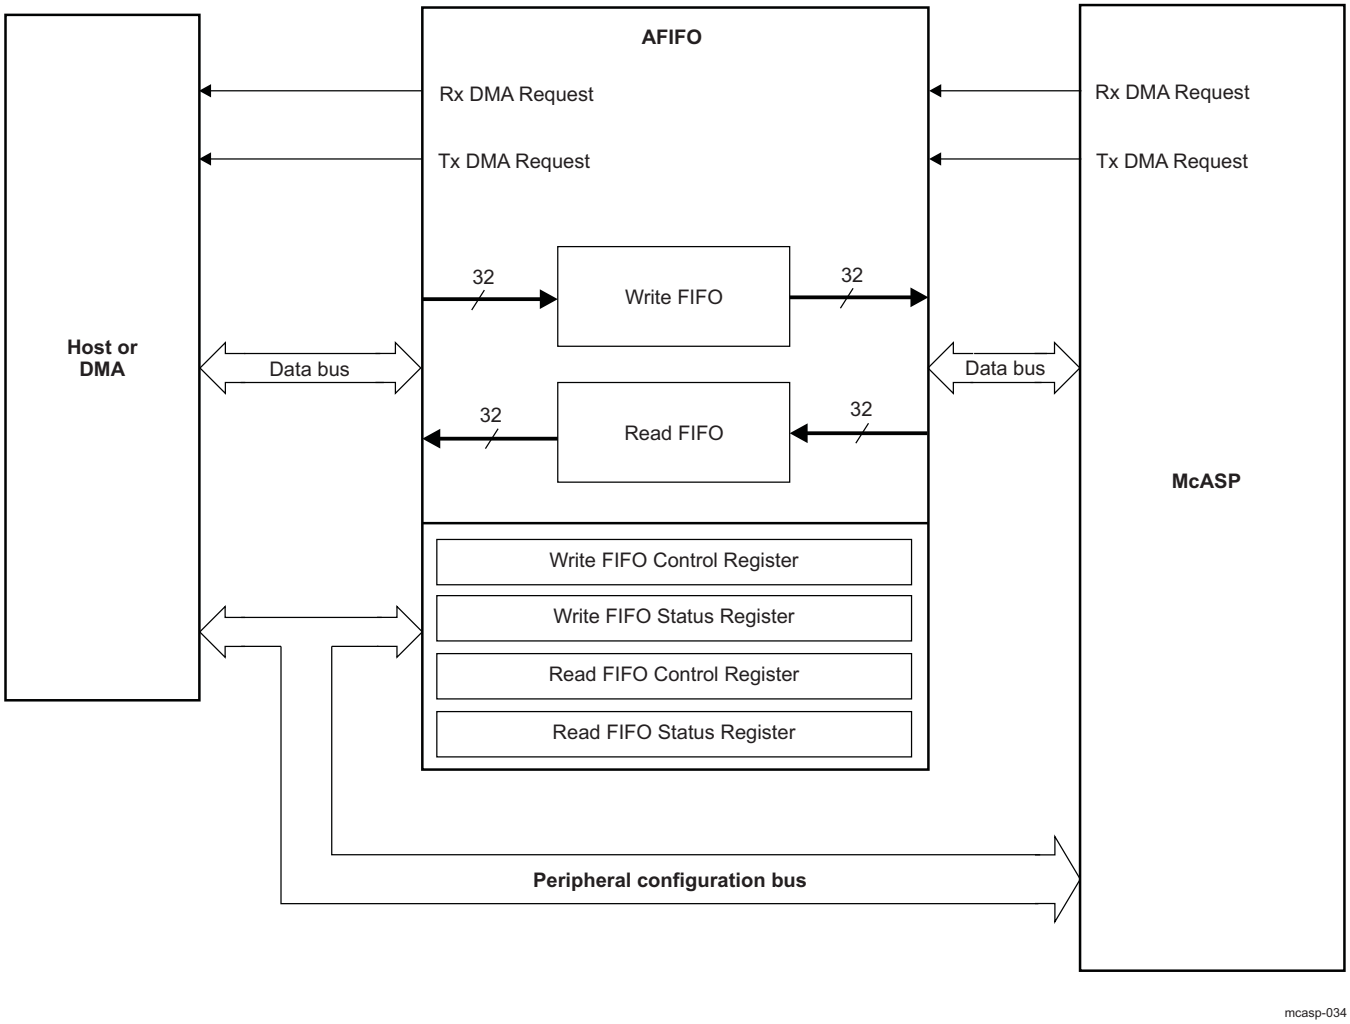
Figure 11-594 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals – AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 11-594, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

11.9.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 11-595 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the MCASP_WFIFOCTL and MCASP_RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

Figure 11-595. McASP Audio FIFO (AFIFO) Block Diagram



11.9.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for MCASP_WFIFOCTL[7-0] WNUMDMA.) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

11.9.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If

there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, MCASP_WFIFOCTL[15-8] WNUMEVT should be set to a non-zero integer multiple of the value in MCASP_WFIFOCTL[7-0] WNUMDMA. If transmit DMA event pacing is not desired, then the value in MCASP_WFIFOCTL[15-8] WNUMEVT should be set equal to the value in MCASP_WFIFOCTL[7-0] WNUMDMA.

11.9.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for MCASP_RFIFOCTL[7-0] RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

11.9.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, MCASP_RFIFOCTL[15-8] RNUMEVT should be set to a non-zero integer multiple of the value in MCASP_RFIFOCTL[7-0] RNUMDMA. If receive DMA event pacing is not desired, then the value in MCASP_RFIFOCTL[15-8] RNUMEVT should be set equal to the value in MCASP_RFIFOCTL[7-0] RNUMDMA.

11.9.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

11.9.4.12 McASP Events and Interrupt Requests

Table 11-1243 lists all the transmit event flags. Table 11-1244 lists all the receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectively.

Table 11-1243. McASP TX Events[(1)]

Event Mask	Event Flag	Map to [(2)]	Description
MCASP_XINTCTL[0] XUNDRN	MCASP_XSTAT[0] XUNDRN	MCASPi_X_INTR_REQ	Transmit buffer underrun
MCASP_XINTCTL[1] XSYNCERR	MCASP_XSTAT[1] XSYNCERR	MCASPi_X_INTR_REQ	Unexpected transmit frame sync
MCASP_XINTCTL[2] XCKFAIL	MCASP_XSTAT[2] XCKFAIL	MCASPi_X_INTR_REQ	Transmit clock failure
MCASP_XINTCTL[3] XDMAERR	MCASP_XSTAT[7] XDMAERR	MCASPi_X_INTR_REQ	DATA port transmit error
MCASP_XINTCTL[4] XLAST	MCASP_XSTAT[4] XLAST	MCASPi_X_INTR_REQ	Transmit last slot interrupt
MCASP_XINTCTL[5] XDATA	MCASP_XSTAT[5] XDATA	MCASPi_X_INTR_REQ	Transmit data-ready interrupt

(1) Global events for all transmitting serializers in a single McASPi module.
(2) Every McASPi module (where i = 0, 1, 2) generates separate IRQ event.

Table 11-1243. McASP TX Events[1] (continued)

Event Mask	Event Flag	Map to [2]	Description
MCASP_XINTCTL[7] XSTAFRM	MCASP_XSTAT[6] XSTAFRM	MCASPi_X_INTR_REQ	Transmit start of frame interrupt
NA	MCASP_XSTAT[8] XERR	NA	OR-event of all Tx-error events: (XDMAERR | XCKFAIL | XUNDRN | XSYNCERR). It is cleared ONLY when all error flags are cleared
NA	MCASP_XSTAT[3] XTDMSLOT	NA	Qualifies the current TDM slot as an odd or an even slot.

Table 11-1244. McASP RX Events[1]

Event Mask	Event Flag	Map to[2]	Description
MCASP_RINTCTL[0] ROVRN	MCASP_RSTAT[0] ROVRN	MCASPi_R_INTR_REQ	Receive buffer overrun
MCASP_RINTCTL[1] RSYNCERR	MCASP_RSTAT[1] RSYNCERR	MCASPi_R_INTR_REQ	Unexpected receive frame sync
MCASP_RINTCTL[2] RCKFAIL	MCASP_RSTAT[2] RCKFAIL	MCASPi_R_INTR_REQ	Receive clock failure
MCASP_RINTCTL[3] RDMAERR	MCASP_RSTAT[7] RDMAERR	MCASPi_R_INTR_REQ	DATA port receive error
MCASP_RINTCTL[4] RLAST	MCASP_RSTAT[4] RLAST	MCASPi_R_INTR_REQ	Receive last slot
MCASP_RINTCTL[5] RDATA	MCASP_RSTAT[5] RDATA	MCASPi_R_INTR_REQ	Receive data-ready
MCASP_RINTCTL[7] RSTAFRM	MCASP_RSTAT[6] RSTAFRM	MCASPi_R_INTR_REQ	Receive start of frame
NA	MCASP_RSTAT[8] RERR	NA	OR-event of all Rx-error events: (RDMAERR | RCKFAIL | ROVRN | RSYNCERR). RERR event is cleared once all error flags are cleared.
NA	MCASP_RSTAT[3] RTDMSLOT	NA	Qualifies the current TDM slot as an odd or an even slot.

(1) Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

(2) Every McASPi module (where i = 0, 1, 2) generates separate IRQ event.

Software has to read the MCASP_XSTAT/MCASP_RSTAT register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_SRCTL0 through MCASP_SRCTL15 registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_X_INTR_REQ, i = 0, 1, 2) is asserted (active high) when one of the MCASP_XSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_XINTCTL bit. Similarly, a Rx interrupt line (MCASPi_R_INTR_REQ, i = 0, 1, 2) is asserted (active high) when one of MCASP_RSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_RINTCTL bit. See also Section 11.9.4.12.5, *Multiple Interrupts*, and Section 11.9.4.10.1, *Data Ready Status and Event/Interrupt Generation*.

11.9.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_XSTAT register and XDATA is enabled in MCASP_XINTCTL. Section 11.9.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_XSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

11.9.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the MCASP_RSTAT register and RDATA is enabled in MCASP_RINTCTL. Section 11.9.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when RDATA flag is set in the MCASP_RSTAT register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

11.9.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_XSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_XINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RSTAT):

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_RINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

11.9.4.12.4 Audio Mute (MCASP_AMUTE) Function

The McASP includes an automatic audio mute function that asserts in hardware the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (MCASP_AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set.

When one or more of the errors is detected and enabled, the AMUTE pin is driven to an active state that is selected by MUTEN bit in MCASP_AMUTE register. The active polarity of the MCASP_AMUTE pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE pin remains driven active until software clears all the error interrupt flags that are enabled to mute

11.9.4.12.5 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** A flag in MCASP_XSTAT is set and the interrupt is enabled in MCASP_XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_XSTAT/MCASP_RSTAT and the interrupt enabled in MCASP_XINTCTL/MCASP_RINTCTL generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_XSTAT/MCASP_RSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

11.9.4.13 McASP DMA Requests

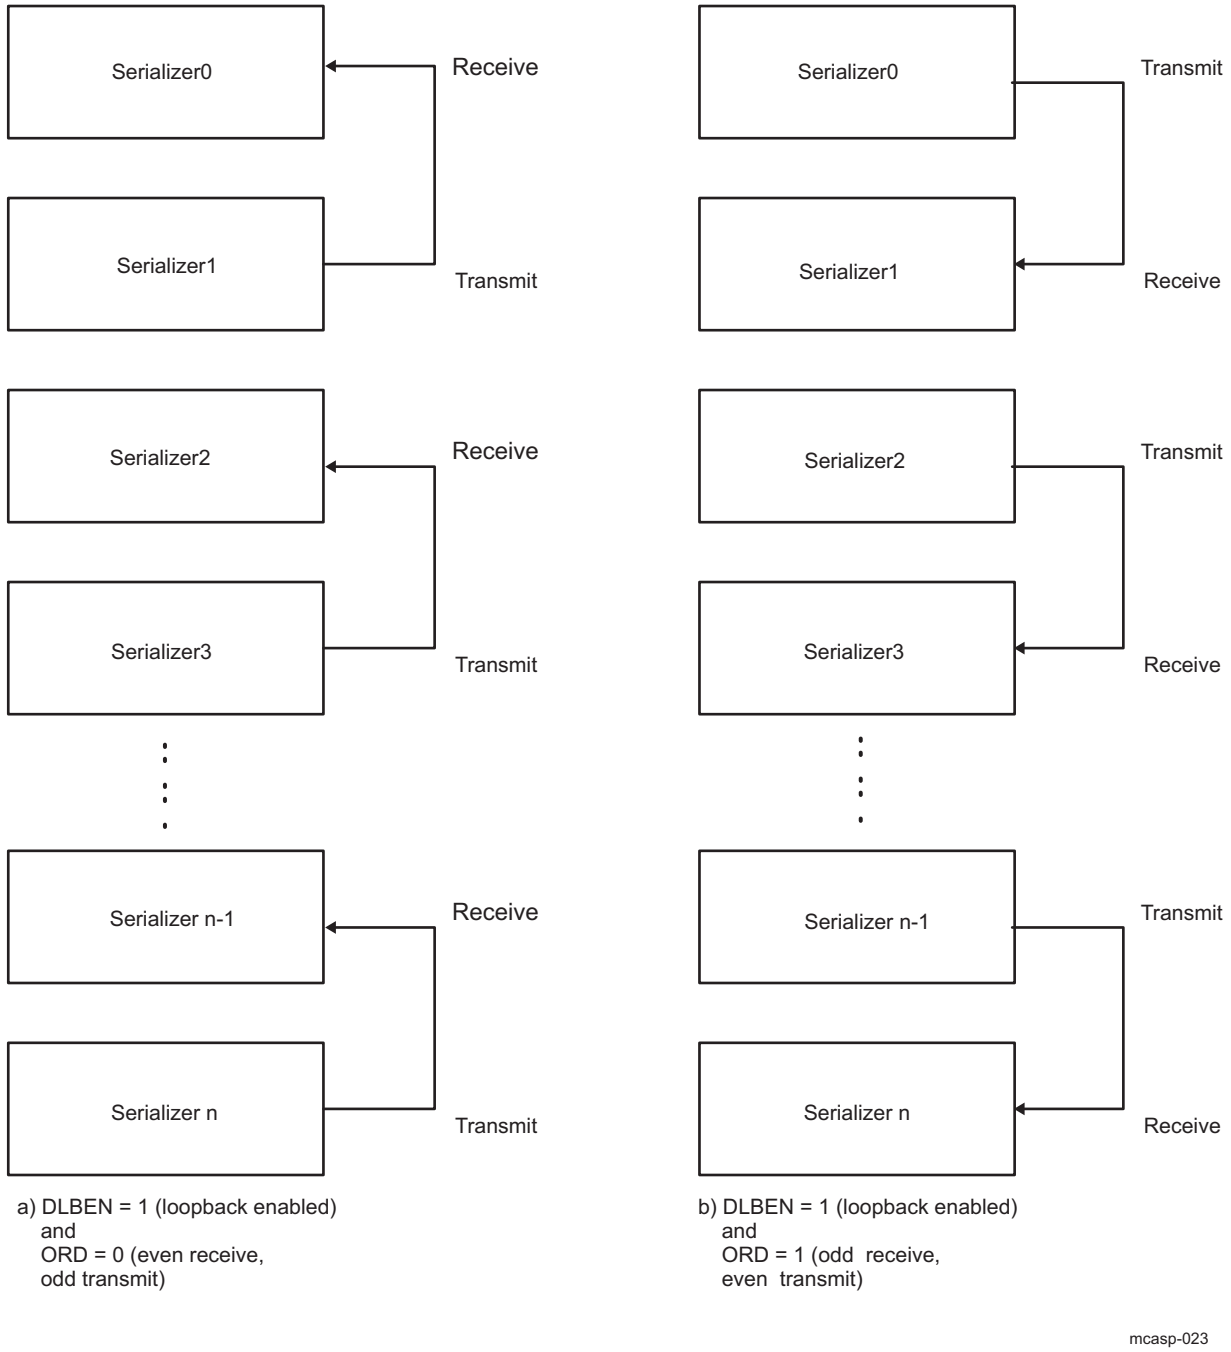
The McASP can generate one DMA request to transmit (MCASPi_XEVENT_DREQ) or receive (MCASPi_REVENT_DREQ) data. A DMA request to transmit data is generated if the XDATDMA bit in the MCASP_XEVTCTL register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the MCASP_REVTCTL register is cleared.

11.9.4.14 McASP Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

Figure 11-596shows the basic logical connection of the serializers in loopback mode.

Figure 11-596. McASP Serializers Operation in Loopback Mode



Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register – MCASP_DLBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_DLBCTL) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected (MCASP_DLBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (that is to function as McASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_DLBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (that is reaching device I/O buffers).

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_DLBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

11.9.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The MCASP_DLBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The MCASP_DLBCTL[4] IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The MCASP_DLBCTL[3-2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_DLBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The MCASP_ACLKXCTL[6] ASYNC bit must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields MCASP_AFSRCTL[15-7] RMOD and MCASP_AFSXCTL[15-7] XMOD must be set within range (0x2–0x20) to indicate TDM mode.

NOTE: Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR-reception.

11.9.4.15 McASP Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

11.9.4.15.1 Buffer Underrun Error-Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP_XBUF0 through MCASP_XBUF15) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_XSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

11.9.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RBUF0 through MCASP_RBUF15 register has not yet been read since the last time the transfer occured. When this occurs, the receiver state machine sets the overrun flag – ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

11.9.4.15.3 DATA Port Error-Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_XSTAT register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The MCASP_XSTAT[7] XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

11.9.4.15.4 DATA Port Error-Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RSTAT register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The MCASP_RSTAT[7] RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

11.9.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The

next frame sync, which occurs after the current frame is completed, will be resynchronized.

2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

NOTE: Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

11.9.4.15.6 Clock Failure Detection

11.9.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_XCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_XSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   1. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_XINTCTL)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
   1. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_RINTCTL)

11.9.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 11-597) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_XCLKCHK) every 32 high-rate serial clock cycles.

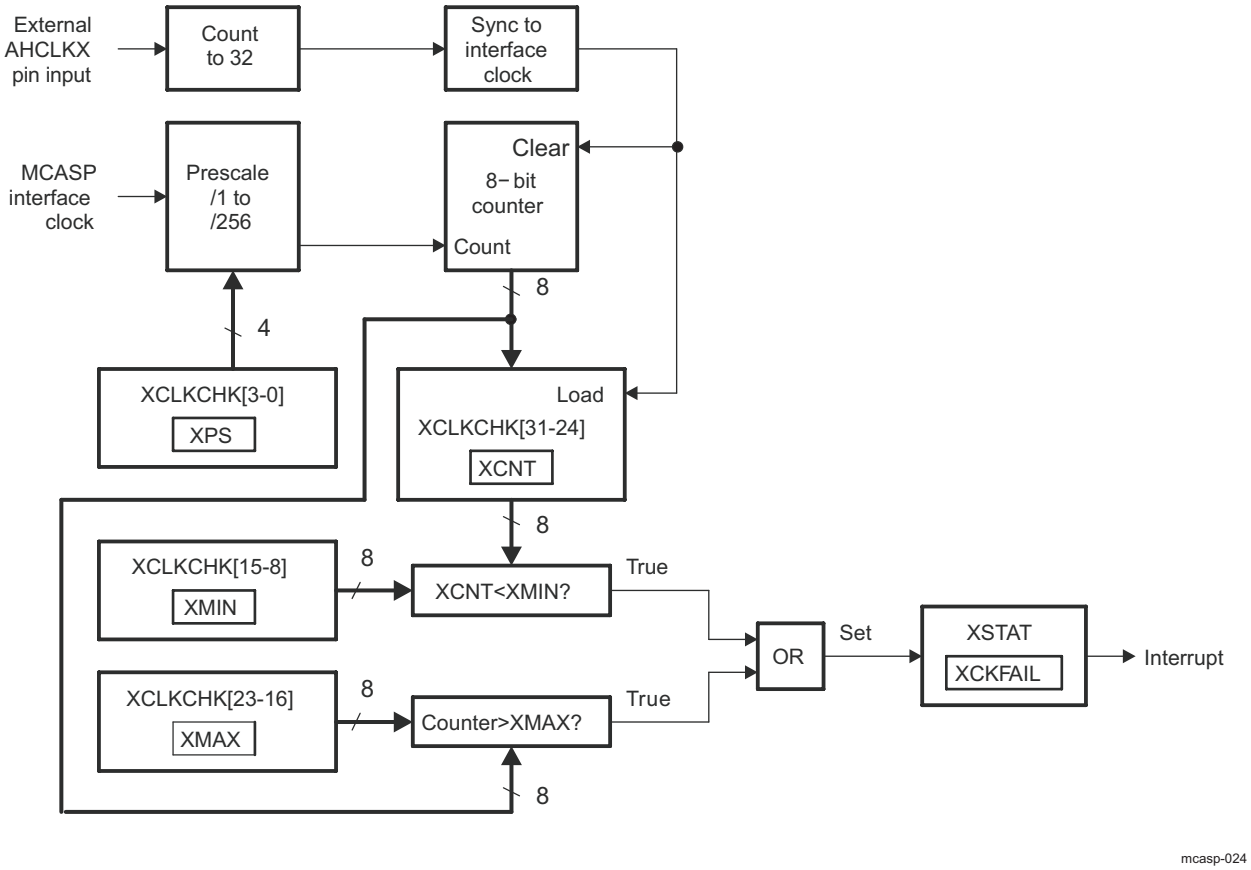
The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_XSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_XSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_XINTCTL is set.

Figure 11-597. McASP Transmit Clock Failure Detection Circuit Block Diagram



11.9.4.15.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see Figure 11-598) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

N/A[1]	MCASP_RBUF	Rx Buffer Data	2180 4000h	2180 4400h	2180 4800h	Section 11.9.5.114

(1) N/A denotes an example for DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when ARMSS / DSP performs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

NOTE: For MCASP_XBUF and MCASP_RBUF buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_XFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

NOTE: The McASP DATA port is exclusively assigned for DMAs / device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

11.9.5.1 MCASP_REV Register (Offset = 0h) [reset = 44300A02h]

MCASP_REV is shown in Figure 11-599 and described in Table 11-1250.

The revision identification register (MCASP_REV) contains identification data for the peripheral.

11.9.5.4 MCASP_PDIR Register (Offset = 14h) [reset = 0h]

MCASP_PDIR is shown in Figure 11-602 and described in Table 11-1259.

The pin direction register (MCASP_PDIR) specifies the direction of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. Regardless of the pin function register (MCASP_PFUNC) setting, each MCASP_PDIR bit must be set to 1 for the specified pin to be enabled as an output and each MCASP_PDIR bit must be cleared to 0 for the specified pin to be an input. For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the MCASP_PFUNC bit must be cleared to 0 (McASP function) and the MCASP_PDIR bit must be set to 1 (an output). When AXRn is configured to transmit, the MCASP_PFUNC bit must be cleared to 0 (McASP function) and the MCASP_PDIR bit must be set to 1 (an output). Similarly, when AXRn is configured to receive, the MCASP_PFUNC bit must be cleared to 0 (McASP function) and the MCASP_PDIR bit must be cleared to 0 (an input). CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

11.9.5.5 MCASP_PDOUT Register (Offset = 18h) [reset = 0h]

MCASP_PDOUT is shown in Figure 11-603 and described in Table 11-1262.

The pin data output register (MCASP_PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output). When reading data, returns the corresponding bit value in MCASP_PDOUT[n], does not return input from I/O pin; when writing data, writes to the corresponding MCASP_PDOUT[n] bit. MCASP_PDOUT has these aliases or alternate addresses: PDSET When written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged. MCASP_PDCLR When written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged. There is only one set of data out bits, MCASP_PDOUT[31-0]. The other registers, PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

McASP Registers • McASP Registers: [0] • MCASP_PDCLR Register (Offset = 20h) [reset = 0h]: [0][1][2][3][4][5][6][7][8][9][10][11][12][13][14][15][16][17] • MCASP_PDOUT Register (Offset = 18h) [reset = 0h]: [0][1][2][3][4][5][6][7][8][9][10][11] • MCASP_PDSET Register (Offset = 1Ch) [reset = 0h]: [0][1]

11.9.5.6 MCASP_PDIN Register (Offset = 1Ch) [reset = 0h]

MCASP_PDIN is shown in Figure 11-604 and described in Table 11-1265.

The pin data input register (MCASP_PDIN) holds the I/O pin state of each of the McASP pins. MCASP_PDIN allows the actual value of the pin to be read, regardless of the state of MCASP_PFUNC and MCASP_PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

11.9.5.7 MCASP_PDSET Register (Offset = 1Ch) [reset = 0h]

MCASP_PDSET is shown in Figure 11-605 and described in Table 11-1265.

The pin data set register (MCASP_PDSET) is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDSET bit sets the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic high on the pin. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

McASP Registers • McASP Registers: [0] • MCASP_PDSET Register (Offset = 1Ch) [reset = 0h]: [0][1][2]

11.9.5.8 MCASP_PDCLR Register (Offset = 20h) [reset = 0h]

MCASP_PDCLR is shown in Figure 11-606 and described in Table 11-1271.

The pin data clear register (MCASP_PDCLR) is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDCLR bit clears the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic low on the pin. MCASP_PDCLR is useful for a multitasking system because it allows clearing to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

25	AMUTE	R/W	0h	Allows the corresponding AMUTE bit in MCASP_PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port. 0h (R/W) = No effect. 1h (R/W) = MCASP_PDOUT[25] bit is cleared to 0.
24-4	RESERVED	R	0h	Reserved
3-0	AXR	R/W	0h	Allows the corresponding AXR[n] bit in MCASP_PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port. 0h (R/W) = No effect. 1h (R/W) = MCASP_PDOUT[n] bit is cleared to 0.

Table 11-1272. Register Call Summary for MCASP_PDCLR

McASP Functional Description • Burst Transfer Mode: [0] • Time-Division Multiplexed (TDM) Transfer Mode: [0]
McASP Registers • McASP Registers: [0] • MCASP_PDCLR Register (Offset = 20h) [reset = 0h]: [0][1][2][3] • MCASP_PDOUT Register (Offset = 18h) [reset = 0h]: [0][1][2]

11.9.5.9 MCASP_GBLCTL Register (Offset = 44h) [reset = 0h]

MCASP_GBLCTL is shown in Figure 11-607 and described in Table 11-1274.

The global control register (MCASP_GBLCTL) provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before MCASP_GBLCTL is programmed, SW must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, SW should select the internal serial clock source in MCASP_AHCLKXCTL, MCASP_AHCLKRCTL, MCASP_ACLKXCTL, and MCASP_ACLKRCTL before MCASP_GBLCTL is programmed. Also, after programming any bits in MCASP_GBLCTL SW should not proceed until a read back from MCASP_GBLCTL is performed and it is verified that the bits are latched in MCASP_GBLCTL.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-1274. MCASP_GBLCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12	XFRST	R/W	0h	Transmit frame sync generator reset enable bit. 0h (R/W) = Transmit frame sync generator is reset. 1h (R/W) = Transmit frame sync generator is active. When released from reset, the transmit frame sync generator begins counting serial clocks and generating frame sync as programmed.
11	XSMRST	R/W	0h	Transmit state machine reset enable bit. 0h (R/W) = Transmit state machine is held in reset. AXRn pin state: If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1; then the serializer drives the AXRn pin to the state specified for inactive time slot (as determined by DISMOD bits in SRCTL). 1h (R/W) = Transmit state machine is released from reset. When released from reset, the transmit state machine immediately transfers data from XRBUF[n] to XRSR[n]. The transmit state machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XRBUF[n] have not been preloaded with data before reset is released. The transmit state machine also immediately begins detecting frame sync and is ready to transmit. Transmit TDM time slot begins at slot 0 after reset is released.

Table 11-1274. MCASP_GBLCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	XSRCLR	R/W	0h	Transmit serializer clear enable bit. By clearing then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and MCASP_XBUF is not loaded with new data before the start of the next active time slot, an underrun will occur. 0h (R/W) = Transmit serializers are cleared. 1h (R/W) = Transmit serializers are active. When the transmit serializers are first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate MCASP_XBUF is ready to be written.
9	XHCLKRST	R/W	0h	Transmit high-frequency clock divider reset enable bit. 0h (R/W) = Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1h (R/W) = Transmit high-frequency clock divider is running.
8	XCLKRST	R/W	0h	Transmit clock divider reset enable bit. 0h (R/W) = Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1h (R/W) = Transmit clock divider is running.
7-5	RESERVED	R	0h	Reserved
4	RFRST	R/W	0h	Receive frame sync generator reset enable bit. 0h (R/W) = Receive frame sync generator is reset. 1h (R/W) = Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.
3	RSMRST	R/W	0h	Receive state machine reset enable bit. 0h (R/W) = Receive state machine is held in reset. 1h (R/W) = Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.
2	RSRCLR	R/W	0h	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0h (R/W) = Receive serializers are cleared. 1h (R/W) = Receive serializers are active.
1	RHCLKRST	R/W	0h	Receive high-frequency clock divider reset enable bit. 0h (R/W) = Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1h (R/W) = Receive high-frequency clock divider is running.
0	RCLKRST	R/W	0h	Receive high-frequency clock divider reset enable bit. 0h (R/W) = Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1h (R/W) = Receive clock divider is running.

Table 11-1277. MCASP_AMUTE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12	XDMAERR	R/W	0h	If transmit DMA error (XDMAERR), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of transmit DMA error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of transmit DMA error, MCASP_AMUTE is active and is driven according to MUTEN bit.
11	RDMAERR	R/W	0h	If receive DMA error (RDMAERR), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of receive DMA error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of receive DMA error, MCASP_AMUTE is active and is driven according to MUTEN bit.
10	XCKFAIL	R/W	0h	If transmit clock failure (XCKFAIL), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of transmit clock failure is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of transmit clock failure, MCASP_AMUTE is active and is driven according to MUTEN bit

Table 11-1277. MCASP_AMUTE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	RCKFAIL	R/W	0h	If receive clock failure (RCKFAIL), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of receive clock failure is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of receive clock failure, MCASP_AMUTE is active and is driven according to MUTEN bit.
8	XSYNCERR	R/W	0h	If unexpected transmit frame sync error (XSYNCERR), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of unexpected transmit frame sync error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of unexpected transmit frame sync error, MCASP_AMUTE is active and is driven according to MUTEN bit.
7	RSYNCERR	R/W	0h	If unexpected receive frame sync error (RSYNCERR), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of unexpected receive frame sync error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of unexpected receive frame sync error, MCASP_AMUTE is active and is driven according to MUTEN bit.
6	XUNDRN	R/W	0h	If transmit underrun error (XUNDRN), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of transmit underrun error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of transmit underrun error, MCASP_AMUTE is active and is driven according to MUTEN bit.
5	ROVRN	R/W	0h	If receiver overrun error (ROVRN), drive MCASP_AMUTE active enable bit. 0h (R/W) = Drive is disabled. Detection of receiver overrun error is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). Upon detection of receiver overrun error, MCASP_AMUTE is active and is driven according to MUTEN bit.
4	INSTAT	R	0h	Determines drive on AXRn pin when MCASP_PFUNC[n] and MCASP_PDIR[n] bits are set to 1. 0h (R/W) = AMUTEIN pin is inactive. 1h (R/W) = AMUTEIN pin is active. Audio mute in error is detected.
3	INEN	R/W	0h	Drive MCASP_AMUTE active when AMUTEIN error is active (INSTAT = 1). 0h (R/W) = Drive is disabled. AMUTEIN is ignored by MCASP_AMUTE. 1h (R/W) = Drive is enabled (active). INSTAT = 1 drives MCASP_AMUTE active.
2	INPOL	R/W	0h	Audio mute in (AMUTEIN) polarity select bit. 0h (R/W) = Polarity is active high. A high on AMUTEIN sets INSTAT to 1. 1h (R/W) = Polarity is active low. A low on AM UTEIN sets INSTAT to 1.
1-0	MUTEN	R/W	0h	MCASP_AMUTE pin enable bit (unless overridden by GPIO registers). 0h (R/W) = MCASP_AMUTE pin is disabled, pin goes to tri-state condition. 1h (R/W) = MCASP_AMUTE pin is driven high if error is detected. 2h (R/W) = MCASP_AMUTE pin is driven low if error is detected. 3h (R/W) = Reserved

11.9.5.11 MCASP_DLBCTL Register (Offset = 4Ch) [reset = 0h]

MCASP_DLBCTL is shown in Figure 11-609 and described in Table 11-1280.

The digital loopback control register (MCASP_DLBCTL) controls the internal loopback settings of the McASP in TDM mode.

Table 11-1279. MCASP_DLBCTL Instances

Table 11-1280. MCASP_DLBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-2	MODE	R/W	0h	Loopback generator mode bits. Applies only when loopback mode is enabled (DLBEN = 1). 0h (R/W) = Default and reserved on loopback mode (DLBEN = 1). When in non-loopback mode (DLBEN = 0), MODE should be left at default (00). When in loopback mode (DLBEN = 1), MODE = 00 is reserved and is not applicable. 1h (R/W) = Transmit clock and frame sync generators used by both transmit and receive sections. When in loopback mode (DLBEN = 1), MODE must be 01. 2h (R/W) = Reserved. 3h (R/W) = Reserved.
1	ORD	R/W	0h	Loopback order bit when loopback mode is enabled (DLBEN = 1). 0h (R/W) = Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly. 1h (R/W) = Even serializers N transmit to odd serializers N + 1 that receive. The corresponding serializers must be programmed properly.
0	DLBEN	R/W	0h	Loopback mode enable bit. 0h (R/W) = Loopback mode is disabled. 1h (R/W) = Loopback mode is enabled.

11.9.5.12 MCASP_DITCTL Register (Offset = 50h) [reset = 0h]

MCASP_DITCTL is shown in Figure 11-610 and described in Table 11-1283.

The DIT mode control register (MCASP_DITCTL) controls DIT operations of the McASP.

Table 11-1282. MCASP_DITCTL Instances

Table 11-1283. MCASP_DITCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3	VB	R/W	0h	Valid bit for odd time slots (DIT right subframe). 0h (R/W) = V bit is 0 during odd DIT subframes. 1h (R/W) = V bit is 1 during odd DIT subframes.
2	VA	R/W	0h	Valid bit for even time slots (DIT left subframe). 0h (R/W) = V bit is 0 during even DIT subframes. 1h (R/W) = V bit is 1 during even DIT subframes.
1	RESERVED	R	0h	Reserved
0	DITEN	R/W	0h	DIT mode enable bit. DITEN should only be changed while the XSMRST bit in MCASP_GBLCTL is in reset (and for startup, XSRCLR also in reset). However, it is not necessary to reset the XCLKRST or XHCLKRST bits in MCASP_GBLCTL to change DITEN. 0h (R/W) = DIT mode is disabled. Transmitter operates in TDM or burst mode. 1h (R/W) = DIT mode is enabled. Transmitter operates in DIT encoded mode.

11.9.5.13 MCASP_RGBLCTL Register (Offset = 60h) [reset = 0h]

MCASP_RGBLCTL is shown in Figure 11-611 and described in Table 11-1286.

Alias of the global control register (MCASP_GBLCTL). Writing to the receiver global control register (MCASP_RGBLCTL) affects only the receive bits of MCASP_GBLCTL (bits 4-0). Reads from MCASP_RGBLCTL return the value of MCASP_GBLCTL. MCASP_RGBLCTL allows the receiver to be reset independently from the transmitter.

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17-16	RDATDLY	R/W	0h	Receive bit delay. 0h (R/W) = 0-bit delay. The first receive data bit, AXRn, occurs in same ACLKR cycle as the receive frame sync (AFSR). 1h (R/W) = 1-bit delay. The first receive data bit, AXRn, occurs one ACLKR cycle after the receive frame sync (AFSR). 2h (R/W) = 2-bit delay. The first receive data bit, AXRn, occurs two ACLKR cycles after the receive frame sync (AFSR). 3h (R/W) = Reserved.
15	RRVRS	R/W	0h	Receive serial bitstream order. 0h (R/W) = Bitstream is LSB first. No bit reversal is performed in receive format bit reverse unit. 1h (R/W) = Bitstream is MSB first. Bit reversal is performed in receive format bit reverse unit.
14-13	RPAD	R/W	0h	Pad value for extra bits in slot not belonging to the word. This field only applies to bits when MCASP_RMASK[n] = 0. 0h (R/W) = Pad extra bits with 0. 1h (R/W) = Pad extra bits with 1. 2h (R/W) = Pad extra bits with one of the bits from the word as specified by RPBIT bits. 3h (R/W) = Reserved.
12-8	RPBIT	R/W	0h	RPBIT value determines which bit (as read by the CPU or DMA from MCASP_RBUF[n]) is used to pad the extra bits. This field only applies when RPAD = 2h. 0h (R/W) = Pad with bit 0 value. 1h (R/W) = Pad with bit 1 to bit 31 value from 1h to 1Fh.

Table 11-1292. MCASP_RFMT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-4	RSSZ	R/W	0h	Receive slot size. 0h (R/W) = Reseved. 1h (R/W) = Reserved. 2h (R/W) = Reserved. 3h (R/W) = Slot size is 8 bits. 4h (R/W) = Reserved 5h (R/W) = Slot size is 12 bits. 6h (R/W) = Reserved 7h (R/W) = Slot size is 16 bits. 8h (R/W) = Reserved 9h (R/W) = Slot size is 20 bits. Ah (R/W) = Reserved Bh (R/W) = Slot size is 24 bits Ch (R/W) = Reserved Dh (R/W) = Slot size is 28 bits. Eh (R/W) = Reserved Fh (R/W) = Slot size is 32 bits.
3	RBUSEL	R/W	0h	Selects whether reads from serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port. 0h (R/W) = Reads from XRBUF[n] originate on data port. Reads from XRBUF[n] on configuration bus are ignored. 1h (R/W) = Reads from XRBUF[n] originate on configuration bus. Reads from XRBUF[n] on data port are ignored.
2-0	RROT	R/W	0h	Right-rotation value for receive rotate right format unit. 0h (R/W) = Rotate right by 0 (no rotation). 1h (R/W) = Rotate right by 4 bit positions. 2h (R/W) = Rotate right by 8 bit positions. 3h (R/W) = Rotate right by 12 bit positions. 4h (R/W) = Rotate right by 16 bit positions. 5h (R/W) = Rotate right by 20 bit positions. 6h (R/W) = Rotate right by 24 bit positions. 7h (R/W) = Rotate right by 28 bit positions.

Table 11-1302. Register Call Summary for MCASP_AHCLKRCTL

McASP Functional Description • Receive Clock: [0][1][2][3] • Burst Transfer Mode: [0] • Time-Division Multiplexed (TDM) Transfer Mode: [0]
McASP Registers • McASP Registers: [0] • MCASP_AHCLKRCTL Register (Offset = 74h) [reset = 0h]: [0][1] • MCASP_GBLCTL Register (Offset = 44h) [reset = 0h]: [0]

11.9.5.19 MCASP_RTDM Register (Offset = 78h) [reset = 0h]

MCASP_RTDM is shown in Figure 11-617 and described in Table 11-1304.

The receive TDM time slot register (MCASP_RTDM) specifies which TDM time slot the receiver is active.

Table 11-1303. MCASP_RTDM Instances

Instance	Physical Address

Bit	Field	Type	Reset	Description
31-0	RTDMS	R/W	0h	Receiver mode during TDM time slot n. 0h (R/W) = Receive TDM time slot n is inactive. The receive serializer does not shift in data during this slot. 1h (R/W) = Receive TDM time slot n is active. The receive serializer shifts in data during this slot.

Table 11-1305. Register Call Summary for MCASP_RTDM

McASP Functional Description • TDM Time Slots Generation and Processing: [0][1][2] • Transfers Through the Data Port (DATA): [0] • McASP TDM Sequencers: [0] • Burst Transfer Mode: [0] • Time-Division Multiplexed (TDM) Transfer Mode: [0] • Special 384-Slot TDM Mode for Connection to External DIR: [0]
McASP Registers • McASP Registers: [0] • MCASP_RTDM Register (Offset = 78h) [reset = 0h]: [0][1]

11.9.5.20 MCASP_RINTCTL Register (Offset = 7Ch) [reset = 0h]

MCASP_RINTCTL is shown in Figure 11-618 and described in Table 11-1307.

The receiver interrupt control register (MCASP_RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. See the MCASP_RSTAT register for a description of the interrupt conditions.

Table 11-1306. MCASP_RINTCTL Instances

11.9.5.21 MCASP_RSTAT Register (Offset = 80h) [reset = 0h]

MCASP_RSTAT is shown in Figure 11-619 and described in Table 11-1310.

The receiver status register (MCASP_RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated.

LEGEND: R = Read Only; R/W = Read/Write; R/W1C = Read/Write 1 to Clear Bit; *-n* = value after reset

Table 11-1310. MCASP_RSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8	RERR	R/W	0h	RERR bit always returns a logic-OR of: ROVRN OR RSYNCERR OR RCKFAIL OR RDMAERR. Allows a single bit to be checked to determine if a receiver error interrupt has occurred. 0h (R/W) = No errors have occurred. 1h (R/W) = An error has occurred.
7	RDMAERR	R/W1C	0h	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the data port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = Receive DMA error did not occur. 1h (R/W) = Receive DMA error did occur.
6	RSTAFRM	R/W1C	0h	Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = No new receive frame sync (AFSR) is detected. 1h (R/W) = A new receive frame sync (AFSR) is detected.

Table 11-1310. MCASP_RSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	RDATA	R/W1C	0h	Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = No new data in MCASP_RBUF. 1h (R/W) = Data is transferred from XRSR to MCASP_RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).
4	RLAST	R/W1C	0h	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = Current slot is not the last slot in a frame. 1h (R/W) = Current slot is the last slot in a frame. RDATA is also set.
3	RTDMSLOT	R	0h	Returns the LSB of MCASP_RSLOT. Allows a single read of MCASP_RSTAT to determine whether the current TDM time slot is even or odd. 0h (R/W) = Current TDM time slot is odd. 1h (R/W) = Current TDM time slot is even.
2	RCKFAIL	R/W1C	0h	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = Receive clock failure did not occur. 1h (R/W) = Receive clock failure did occur.
1	RSYNCERR	R/W1C	0h	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = Unexpected receive frame sync did not occur. 1h (R/W) = Unexpected receive frame sync did occur.
0	ROVRN	R/W1C	0h	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to MCASP_RBUF, but the former data in MCASP_RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in MCASP_RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h (R/W) = Receiver overrun did not occur. 1h (R/W) = Receiver overrun did occur.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-1316. MCASP_RCLKCHK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RCNT	R	0h	Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.
23-16	RMAX	R/W	0h	Receive clock maximum boundary. This 8 bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in MCASP_RSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	RMIN	R/W	0h	Receive clock minimum boundary. This 8 bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in MCASP_RSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	RESERVED	R	0h	Reserved
3-0	RPS	R/W	0h	Receive clock check prescaler value. 0h (R/W) = McASP system clock divided by 1. 1h (R/W) = McASP system clock divided by 2. 2h (R/W) = McASP system clock divided by 4. 3h (R/W) = McASP system clock divided by 8. 4h (R/W) = McASP system clock divided by 16. 5h (R/W) = McASP system clock divided by 32. 6h (R/W) = McASP system clock divided by 64. 7h (R/W) = McASP system clock divided by 128. 8h (R/W) = McASP system clock divided by 256. 9h (R/W) = Reserved from 9h to Fh.

11.9.5.24 MCASP_REVTCTL Register (Offset = 8Ch) [reset = 0h]

MCASP_REVTCTL is shown in Figure 11-622 and described in Table 11-1319.

The receiver DMA event control register (MCASP_REVTCTL) contains a disable bit for the receiver DMA event. Note for device-specific registers: Accessing MCASP_REVTCTL not implemented on a specific device may cause improper operation.

11.9.5.25 MCASP_XGBLCTL Register (Offset = A0h) [reset = 0h]

MCASP_XGBLCTL is shown in Figure 11-623 and described in Table 11-1322.

Alias of the global control register (MCASP_GBLCTL). Writing to the transmitter global control register (MCASP_XGBLCTL) affects only the transmit bits of MCASP_GBLCTL (bits 12-8). Reads from MCASP_XGBLCTL return the value of MCASP_GBLCTL. MCASP_XGBLCTL allows the transmitter to be reset independently from the receiver. See the MCASP_GBLCTL register for a detailed description of MCASP_GBLCTL.

11.9.5.27 MCASP_XFMT Register (Offset = A8h) [reset = 0h]

MCASP_XFMT is shown in Figure 11-625 and described in Table 11-1328.

The transmit bit stream format register (MCASP_XFMT) configures the transmit data format.

Table 11-1327. MCASP_XFMT Instances

Table 11-1328. MCASP_XFMT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17-16	XDATDLY	R/W	0h	Transmit sync bit delay. 0h (R/W) = 0-bit delay. The first transmit data bit, AXRn, occurs in same ACLKX cycle as the transmit frame sync (AFSX). 1h (R/W) = 1-bit delay. The first transmit data bit, AXRn, occurs one ACLKX cycle after the transmit frame sync (AFSX). 2h (R/W) = 2-bit delay. The first transmit data bit, AXRn, occurs two ACLKX cycles after the transmit frame sync (AFSX). 3h (R/W) = Reserved.
15	XRVRS	R/W	0h	Transmit serial bitstream order. 0h (R/W) = Bitstream is LSB first. No bit reversal is performed in transmit format bit reverse unit. 1h (R/W) = Bitstream is MSB first. Bit reversal is performed in transmit format bit reverse unit.
14-13	XPAD	R/W	0h	Pad value for extra bits in slot not belonging to word defined by MCASP_XMASK. This field only applies to bits when MCASP_XMASK[n] = 0. 0h (R/W) = Pad extra bits with 0. 1h (R/W) = Pad extra bits with 1. 2h (R/W) = Pad extra bits with one of the bits from the word as specified by XPBIT bits. 3h (R/W) = Reserved.

Table 11-1328. MCASP_XFMT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12-8	XPBIT	R/W	0h	XPBIT value determines which bit (as written by the CPU or DMA to MCASP_XBUF[n]) is used to pad the extra bits before shifting. This field only applies when XPAD = 2h. 0h (R/W) = Pad with bit 0 value. 1h (R/W) = Pad with bit 1 to bit 31 value from 1h to 1Fh.
7-4	XSSZ	R/W	0h	Transmit slot size. 0h (R/W) = Reserved. 1h (R/W) = Reserved. 2h (R/W) = Reserved. 3h (R/W) = Slot size is 8 bits. 4h (R/W) = Reserved. 5h (R/W) = Slot size is 12 bits. 6h (R/W) = Reserved. 7h (R/W) = Slot size is 16 bits. 8h (R/W) = Reserved. 9h (R/W) = Slot size is 20 bits. Ah (R/W) = Reserved. Bh (R/W) = Slot size is 24 bits. Ch (R/W) = Reserved. Dh (R/W) = Slot size is 28 bits. Eh (R/W) = Reserved. Fh (R/W) = Slot size is 32 bits.
3	XBUSEL	R/W	0h	Selects whether writes to serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port. 0h (R/W) = Writes to XRBUF[n] originate from the data port. Writes to XRBUF[n] from the configuration bus are ignored with no effect to the McASP. 1h (R/W) = Writes to XRBUF[n] originate from the configuration bus. Writes to XRBUF[n] from the data port are ignored with no effect to the McASP.
2-0	XROT	R/W	0h	Right-rotation value for transmit rotate right format unit. 0h (R/W) = Rotate right by 0 (no rotation). 1h (R/W) = Rotate right by 4 bit positions. 2h (R/W) = Rotate right by 8 bit positions. 3h (R/W) = Rotate right by 12 bit positions. 4h (R/W) = Rotate right by 16 bit positions. 5h (R/W) = Rotate right by 20 bit positions. 6h (R/W) = Rotate right by 24 bit positions. 7h (R/W) = Rotate right by 28 bit positions.

11.9.5.31 MCASP_XTDM Register (Offset = B8h) [reset = 0h]

MCASP_XTDM is shown in Figure 11-629 and described in Table 11-1340.

The transmit TDM time slot register (MCASP_XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). MCASP_XTDM operates modulo 32, that is, XTDMS specifies the TDM activity for time slots 0, 32, 64, 96, 128, and so on.

11.9.5.32 MCASP_XINTCTL Register (Offset = BCh) [reset = 0h]

MCASP_XINTCTL is shown in Figure 11-630 and described in Table 11-1343.

The transmitter interrupt control register (MCASP_XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. See the MCASP_XSTAT register for a description of the interrupt conditions.

- MCASP_XINTCTL Register (Offset = BCh) [reset = 0h]: [0][1]

11.9.5.33 MCASP_XSTAT Register (Offset = C0h) [reset = 0h]

MCASP_XSTAT is shown in Figure 11-631 and described in Table 11-1346.

The transmitter status register (MCASP_XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated.

LEGEND: R = Read Only; R/W = Read/Write; R/W1C = Read/Write 1 to Clear Bit; *-n* = value after reset

Table 11-1346. MCASP_XSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8	XERR	R/W	0h	XERR bit always returns a logic-OR of: XUNDRN OR XSYNCERR OR XCKFAIL OR XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0h (R/W) = No errors have occurred. 1h (R/W) = An error has occurred.
7	XDMAERR	R/W1C	0h	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the data port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = Transmit DMA error did not occur. 1h (R/W) = Transmit DMA error did occur.
6	XSTAFRM	R/W1C	0h	Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = No new transmit frame sync (AFSX) is detected. 1h (R/W) = A new transmit frame sync (AFSX) is detected.

Table 11-1346. MCASP_XSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	XDATA	R/W1C	0h	Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = MCASP_XBUF is written and is full. 1h (R/W) = Data is copied from MCASP_XBUF to XRSR. MCASP_XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).
4	XLAST	R/W1C	0h	Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = Current slot is not the last slot in a frame. 1h (R/W) = Current slot is the last slot in a frame. XDATA is also set.
3	XTDMSLOT	R	0h	Returns the LSB of MCASP_XSLOT. Allows a single read of MCASP_XSTAT to determine whether the current TDM time slot is even or odd. 0h (R/W) = Current TDM time slot is odd. 1h (R/W) = Current TDM time slot is even.
2	XCKFAIL	R/W1C	0h	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = Transmit clock failure did not occur. 1h (R/W) = Transmit clock failure did occur.
1	XSYNCERR	R/W1C	0h	Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = Unexpected transmit frame sync did not occur. 1h (R/W) = Unexpected transmit frame sync did occur.
0	XUNDRN	R/W1C	0h	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from MCASP_XBUF to XRSR, but MCASP_XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in MCASP_XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h (R/W) = Transmitter underrun did not occur. 1h (R/W) = Transmitter underrun did occur. For details on McASP action upon underrun conditions, see Buffer Underrun Error - Transmitter.

11.9.5.34 MCASP_XSLOT Register (Offset = C4h) [reset = 0h]

MCASP_XSLOT is shown in Figure 11-632 and described in Table 11-1349.

The current transmit TDM time slot register (MCASP_XSLOT) indicates the current time slot for the transmit data frame.

Table 11-1349. MCASP_XSLOT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved
9-0	XSLOTCNT	R	0h	Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for >32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-1352. MCASP_XCLKCHK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	XCNT	R	0h	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.
23-16	XMAX	R/W	0h	Transmit clock maximum boundary. This 8 bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in MCASP_XSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	XMIN	R/W	0h	Transmit clock minimum boundary. This 8 bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in MCASP_XSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	RESERVED	R	0h	Reserved
3-0	XPS	R/W	0h	Transmit clock check prescaler value. Fh = Reserved from 9h to Fh. 0h (R/W) = McASP system clock divided by 1. 1h (R/W) = McASP system clock divided by 2. 2h (R/W) = McASP system clock divided by 4. 3h (R/W) = McASP system clock divided by 8. 4h (R/W) = McASP system clock divided by 16. 5h (R/W) = McASP system clock divided by 32. 6h (R/W) = McASP system clock divided by 64. 7h (R/W) = McASP system clock divided by 128. 8h (R/W) = McASP system clock divided by 256. 9h (R/W) = Reserved from 9h to Fh.

11.9.5.37 MCASP_DITCSRA0 Register (Offset = 100h) [reset = 0h]

MCASP_DITCSRA0 is shown in Figure 11-635 and described in Table 11-1358.

The DIT left channel status registers (MCASP_DITCSRA0) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is SW responsibility to update the register file in time, if a different set of data need to be sent.

11.9.5.46 MCASP_DITCSRB3 Register (Offset = 124h) [reset = 0h]

MCASP_DITCSRB3 is shown in Figure 11-644 and described in Table 11-1385.

The DIT right channel status registers (MCASP_DITCSRB0) provide the status of each right channel (odd TDM time slot). Each of the six 32-bit registers can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is SW responsibility to update the register file in time, if a different set of data need to be sent.

McASP Functional Description • DIT Channel Status and User Data Register Files: [0][1][2]
McASP Registers • MCASP_DITUDRB4 Register (Offset = 158h) [reset = 0h]: [0] • McASP Registers: [0]

11.9.5.60 MCASP_DITUDRB5 Register (Offset = 15Ch) [reset = 0h]

MCASP_DITUDRB5 is shown in Figure 11-658 and described in Table 11-1427.

The DIT right channel user data registers (MCASP_DITUDRB0) provides the user data of each right channel (odd TDM time slot). Each of the six 32-bit registers can store 192 bits of user data for a complete block of transmission. The DIT reuses the same data for the next block. It is SW responsibility to update the register in time, if a different set of data need to be sent.

Table 11-1448. MCASP_SRCTL6 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	RRDY	R	0h	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to MCASP_RBUF. 0h (R/W) = Receive buffer (MCASP_RBUF) is empty. 1h (R/W) = Receive buffer (MCASP_RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.
4	XRDY	R	0h	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in MCASP_GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). 0h (R/W) = Transmit buffer (MCASP_XBUF) contains data. 1h (R/W) = Transmit buffer (MCASP_XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.

4	XRDY	R	0h	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in MCASP_GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). 0h (R/W) = Transmit buffer (MCASP_XBUF) contains data. 1h (R/W) = Transmit buffer (MCASP_XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.

Table 11-1469. MCASP_SRCTL13 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	DISMOD	R/W	0h	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (MCASP_PFUNC = 0). 0h (R/W) = Drive on pin is 3-state. 1h (R/W) = Reserved. 2h (R/W) = Drive on pin is logic low. 3h (R/W) = Drive on pin is logic high.
1-0	SRMOD	R/W	0h	Serializer mode bit. 0h (R/W) = Serializer is inactive. 1h (R/W) = Serializer is transmitter. 2h (R/W) = Serializer is receiver. 3h (R/W) = Reserved.

11.9.5.75 MCASP_SRCTL14 Register (Offset = 1B8h) [reset = 0h]

MCASP_SRCTL14 is shown in Figure 11-673 and described in Table 11-1472.

Each serializer on the McASP has a serializer control register (MCASP_SRCTL0). There are up to 16 serializers per McASP. Note for device-specific registers: Accessing SRCTL0n not implemented on a specific device may cause improper device operation.

- MCASP_XBUF9 Register (Offset = 224h) [reset = 0h]: [0]

11.9.5.87 MCASP_XBUF10 Register (Offset = 228h) [reset = 0h]

MCASP_XBUF10 is shown in Figure 11-685 and described in Table 11-1508.

The transmit buffers for the serializers (MCASP_XBUF0) hold data from the transmit format unit. For transmit operations, the MCASP_XBUF0 is an alias of the XRBUF in the serializer. Accessing MCASP_XBUF0 registers not implemented on a specific device may cause improper device operation.

11.9.5.103 MCASP_RBUF10 Register (Offset = 2A8h) [reset = 0h]

MCASP_RBUF10 is shown in Figure 11-701 and described in Table 11-1556.

The receive buffers for the serializers (MCASP_RBUF0) hold data from the serializer before the data goes to the receive format unit. For receive operations, the MCASP_RBUF0 is an alias of the XRBUF0 in the serializer. Accessing MCASP_XBUF registers not implemented on a specific device may cause improper device operation.

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	Reserved
16	WENA	R/W	0h	Write FIFO enable bit. 0h (R/W) = Write FIFO is disabled. The WLVL bit in the Write FIFO status register (MCASP_WFIFOSTS) is reset to 0 and pointers are initialized, that is, the Write FIFO is flushed. 1h (R/W) = Write FIFO is enabled. If Write FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	WNUMEVT	R/W	0h	Write word count per DMA event (32 bit). When the Write FIFO has space for at least WNUMEVT words of data, then an AXEVT (transmit DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as transmitters. This value must be set prior to enabling the Write FIFO. 40h = 3 to 64 words from 3h to 40h. FFh = Reserved from 41h to FFh. 0h (R/W) = 0 words 1h (R/W) = 1 word 2h (R/W) = 2 words 3h (R/W) = 3 to 64 words from 3h to 40h. 41h (R/W) = Reserved from 41h to FFh.

Table 11-1574. MCASP_WFIFOCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	WNUMDMA	R/W	0h	Write word count per transfer (32 bit words). Upon a transmit DMA event from the McASP, WNUMDMA words are transferred from the Write FIFO to the McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the Write FIFO. FFh = Reserved from 11h to FFh. 0h (R/W) = 0 words 1h (R/W) = 1 word 2h (R/W) = 2 words 3h (R/W) = 3-16 words from 3h to 10h. 11h (R/W) = Reserved from 11h to FFh.

11.9.5.113 MCASP_XBUF Register (Offset = 0h) [reset = 0h]

MCASP_XBUF is shown in Figure 11-711 and described in Table 11-1586.

Through the DATA port, the Host can service all serializers through a single address and the MCASP automatically cycles through the appropriate serializers. For transmit operations through the DATA port, the Host should write to the same DATA port address to service all of the active transmit serializers upon each transmit data ready event. To enable accesses from the Host to the MCASP XRBUFn registers through the DATA port, one must clear the XBUSEL bits to 0 in the respective MCASP_XFMT registers.

11.9.5.114 MCASP_RBUF Register (Offset = 0h) [reset = 0h]

MCASP_RBUF is shown in Figure 11-712 and described in Table 11-1589.

Through the DATA port , the Host can service all serializers through a single address and the MCASP automatically cycles through the appropriate serializers. For receive operations through the DATA port, the Host should read from the same MCASP_RBUF DATA port address to service all of the active receive serializers upon each receive data ready event. To enable accesses from the Host to the MCASP XRBUFn registers through the DATA port, one must clear the RBUSEL bits to 0 in the respective MCASP_RFMT registers.

11.10 Multi-channel Buffered Serial Port (McBSP)

This section describes the Multi-channel Buffered Serial Port (McBSP) module in the device.

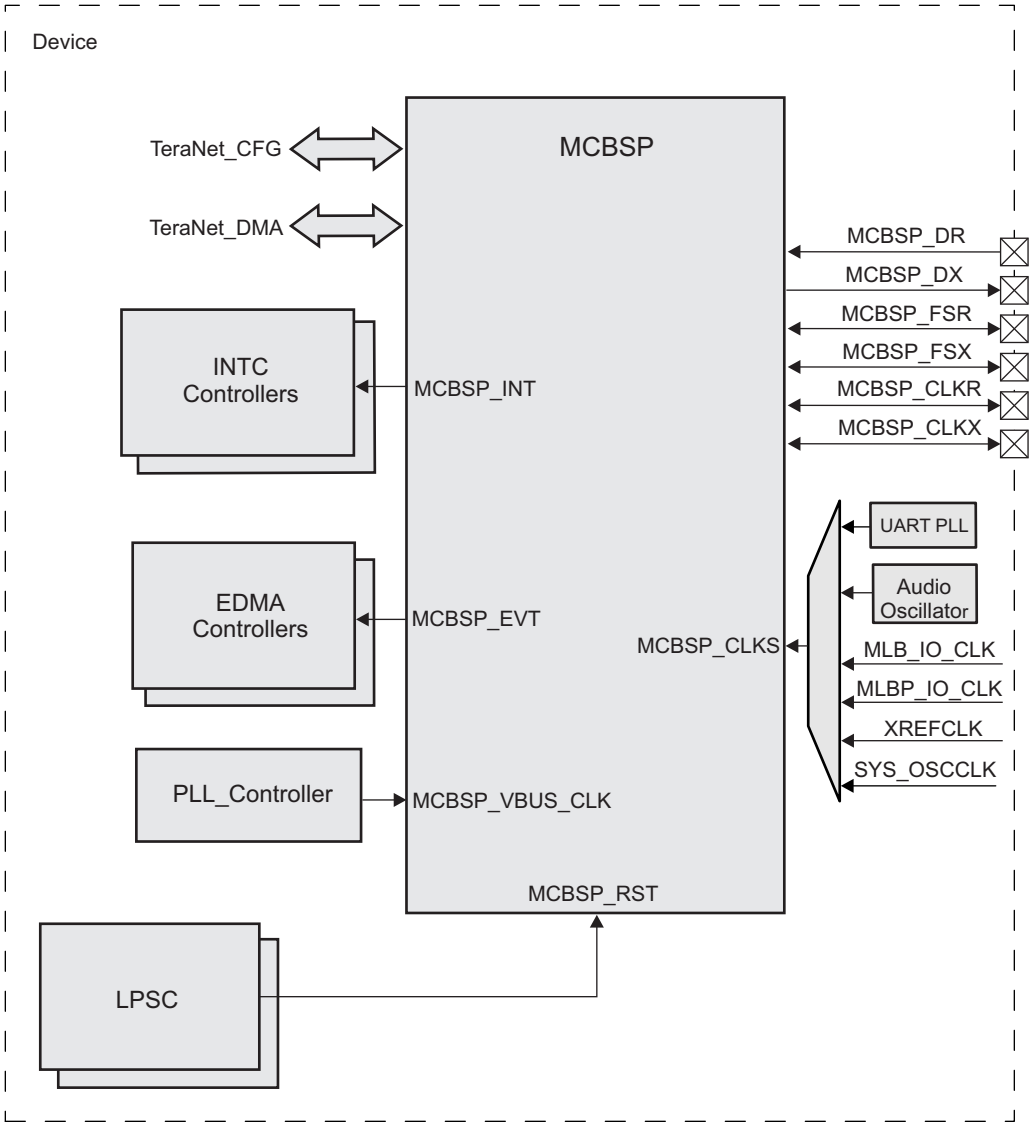
11.10.1 McBSP Overview

This section describes the Multi-channel Buffered Serial Port (McBSP) module in the device.

The Multi-channel Buffered Serial Port (McBSP) provides a full-duplex serial communication interface between the device and other devices in a system. The primary use for the McBSP is for audio interface purposes. The main audio modes that are supported are the AC97 and I^2S modes. In addition to the primary audio modes, the McBSP can be programmed to support other serial formats but is not intended to be used as a high-speed interface. The device communicates to the McBSP using 32-bit-wide control registers accessible via the internal peripheral bus.

Figure 11-713 shows an overview of the McBSP module in the device.

Figure 11-713. McBSP Module Overview



11.10.1.1 Features

The McBSP provides the following functions:

- Full-duplex communication
- Double-buffered data registers, which allow a continuous data stream
- Independent framing and clocking for receive and transmit
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected analog-to-digital (A/D) and digital-to-analog (D/A) devices
- External shift clock or an internal, programmable frequency shift clock for data transfer

In addition, the McBSP has the following capabilities:

- Direct interface to:
  - T1/E1 framers
  - MVIP switching compatible and ST-BUS compliant devices including:
    - MVIP framers
    - H.100 framers
    - SCSA framers
  - IOM-2 compliant devices
  - AC97 compliant devices (the necessary multiphase frame synchronization capability is provided)
  - I^2S compliant devices
- Multi-channel transmit and receive of up to 128 channels
- A wide selection of data sizes, including 8, 12, 16, 20, 24, and 32 bits
- μ-Law and A-Law companding
- 8-bit data transfers with the option of LSB or MSB first
- Programmable polarity for both frame synchronization and data clocks
- Highly programmable internal clock and frame generation
- Additional McBSP Buffer FIFO (BFIFO):
  - Provides additional data buffering
  - Provides added tolerance to variations in host/DMA controller response times
  - May be used as a DMA event pacer
  - Independent Read FIFO and Write FIFO
  - 256 bytes of RAM for each FIFO (read and write)
  - Option to bypass Write FIFO and/or Read FIFO, independently

McBSP module unsupported features:

- The McBSP on this device does not support the SPI protocol.
- 512 Channel Mode
- Individual enable/disable channel control
- Timeslot buffering
- Super frame synchronization
- ABIS Mode

11.10.1.2 Industry Standard Compliance Statement

The McBSP supports the following industry standard interfaces:

AC97 — The AC97 standard specifies a 5-wire digital serial link between an audio codec device and its digital controller.

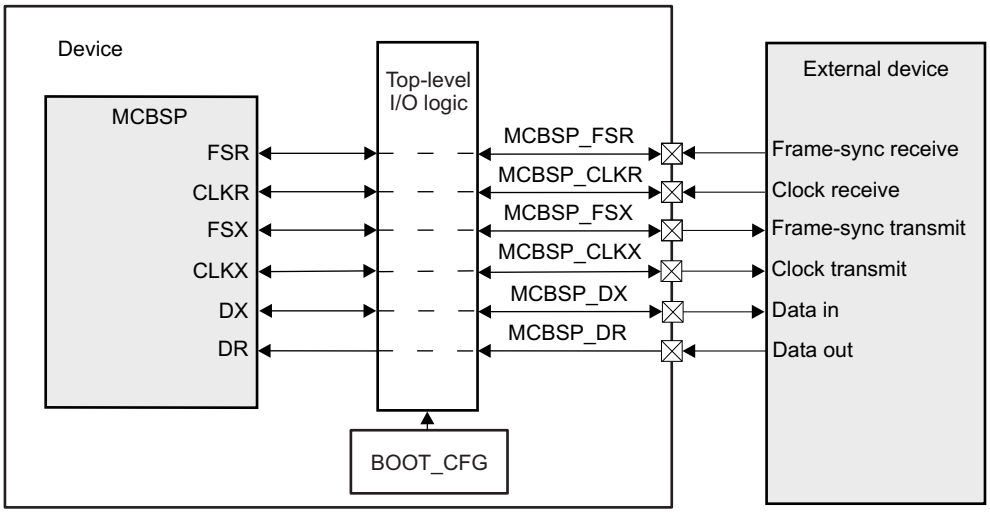
Inter-IC Sound — I^2S is a protocol specifically designed to transfer a stereo channel (left and right) over a single data pin. The I^2S bus is an industry standard interface for streaming stereo audio between devices, typically between a CPU/DSP and a DAC/ADC.

11.10.2 McBSP Environment

This section describes the McBSP application fields from an environment point of view (external connections).

Figure 11-714 shows the connection between the McBSP module and an external device.

Figure 11-714. McBSP Module Environment



11.10.2.1 Signal Descriptions

The McBSP consists of a data path and a control path that connect to external devices. Separate pins for transmission and reception communicate data to these external devices. The data is communicated from devices via the Data Transmit (DX) pin for transmit and the Data Receive (DR) pin for receive. Control information in the form of clocking and frame synchronization is communicated via CLKS, CLKX, CLKR, FSX and FSR.

Table 11-1591 lists the pins associated with the McBSP interface.

Table 11-1591. McBSP Input/Output Signals

Module Pin Name	Device Level Signal	I/O/Z[1]	Description
CLKR	MCBSP_CLKR	I/O/Z	Receive serial clock. Supplies or receives a reference clock for the receiver.
CLKX	MCBSP_CLKX	I/O/Z	Transmit serial clock. Supplies or receives a reference clock for the transmitter.
DR	MCBSP_DR	I	Received serial data
DX	MCBSP_DX	O/Z	Transmitted serial data
FSR	MCBSP_FSR	I/O/Z	Receive frame synchronization. Control signal to synchronize the start of received data.
FSX	MCBSP_FSX	I/O/Z	Transmit frame synchronization. Control signal to synchronize the start of transmitted data.

(1) I = Input; O = Output; I/O = Bidirectional;

11.10.2.2 Pad Multiplexing

Extensive pad multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pad multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. See the device Data Manual to determine how pad multiplexing affects the McBSP.

11.10.3 McBSP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-715 shows the integration of the McBSP module in the device.

Figure 11-715. McBSP Integration

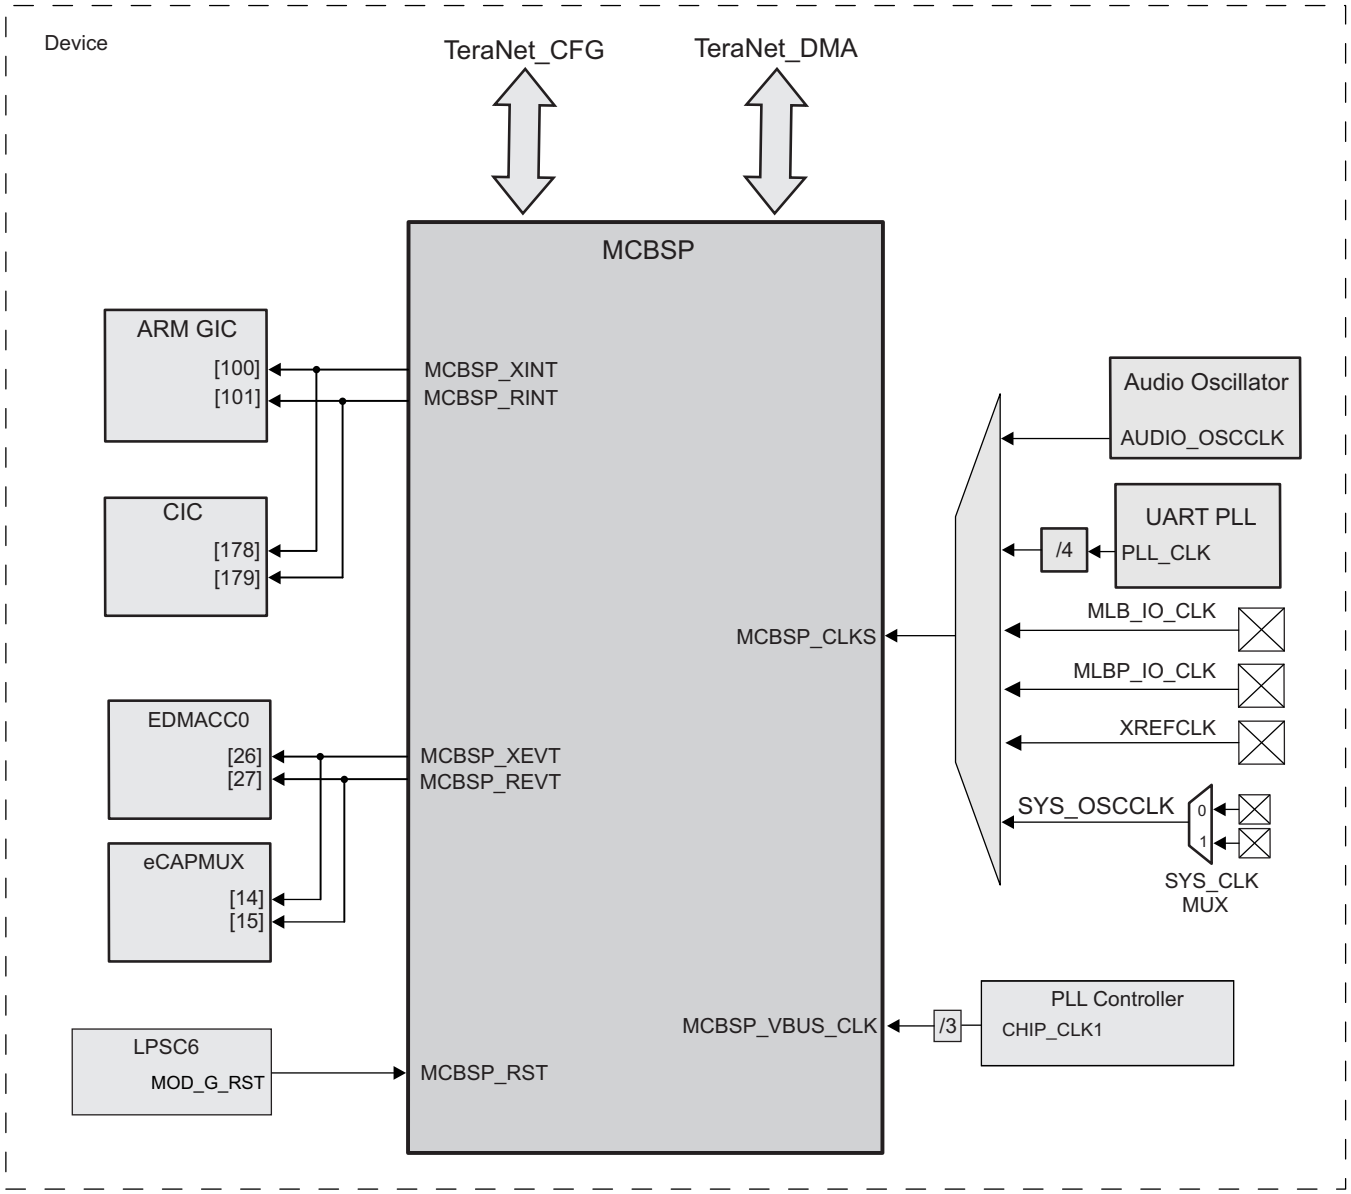


Table 11-1592 through Table 11-1594 summarize the integration of the module in the device.

Table 11-1592. McBSP Integration Attributes

Module Instance	Attributes

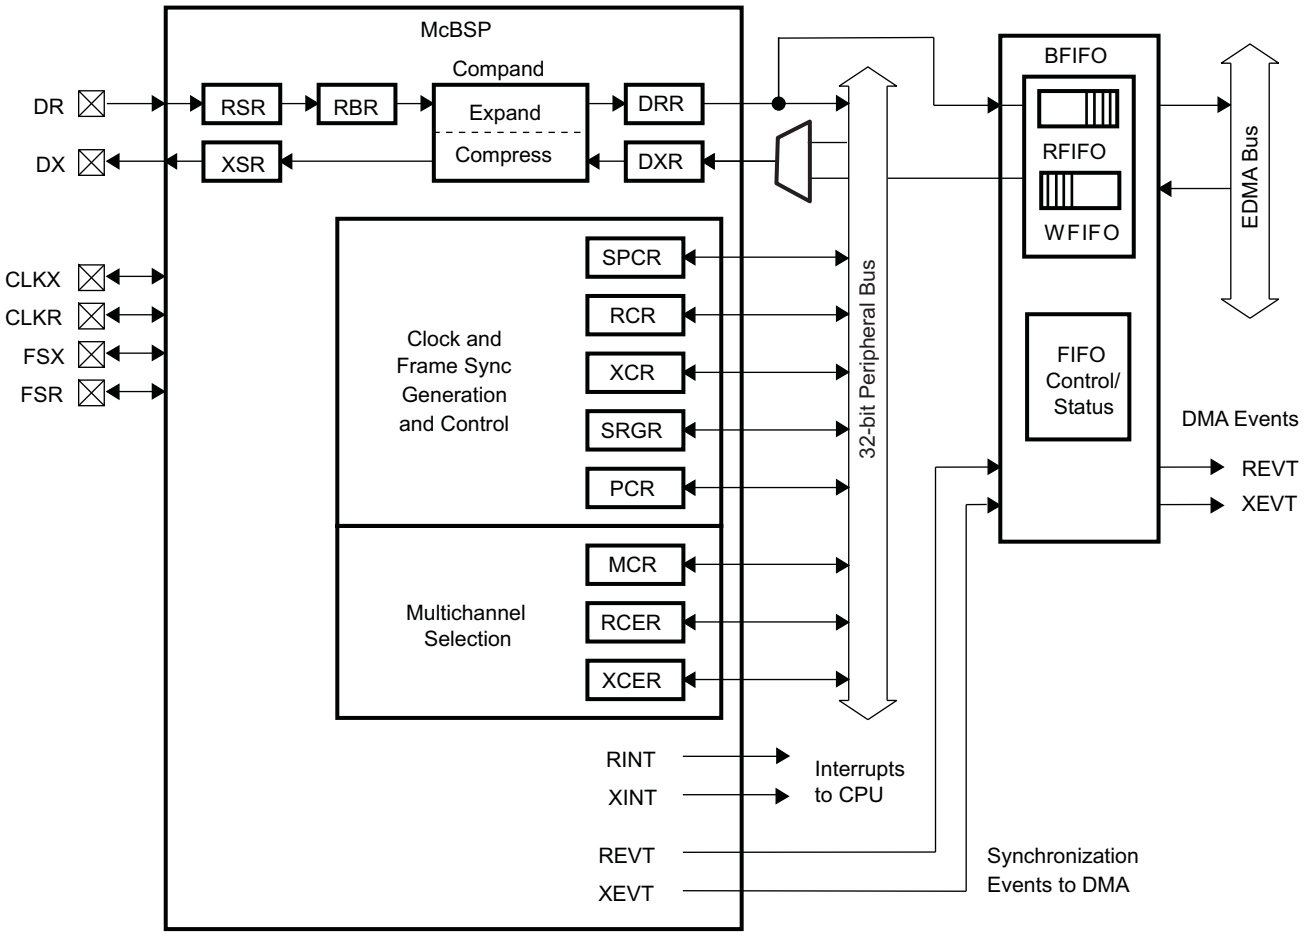
11.10.4 McBSP Functional Description

This section describes the functional description of the McBSP module.

11.10.4.1 McBSP Functional Block Diagram

Figure 11-716 shows the functional block diagram of the McBSP module.

Figure 11-716. McBSP Block Diagram

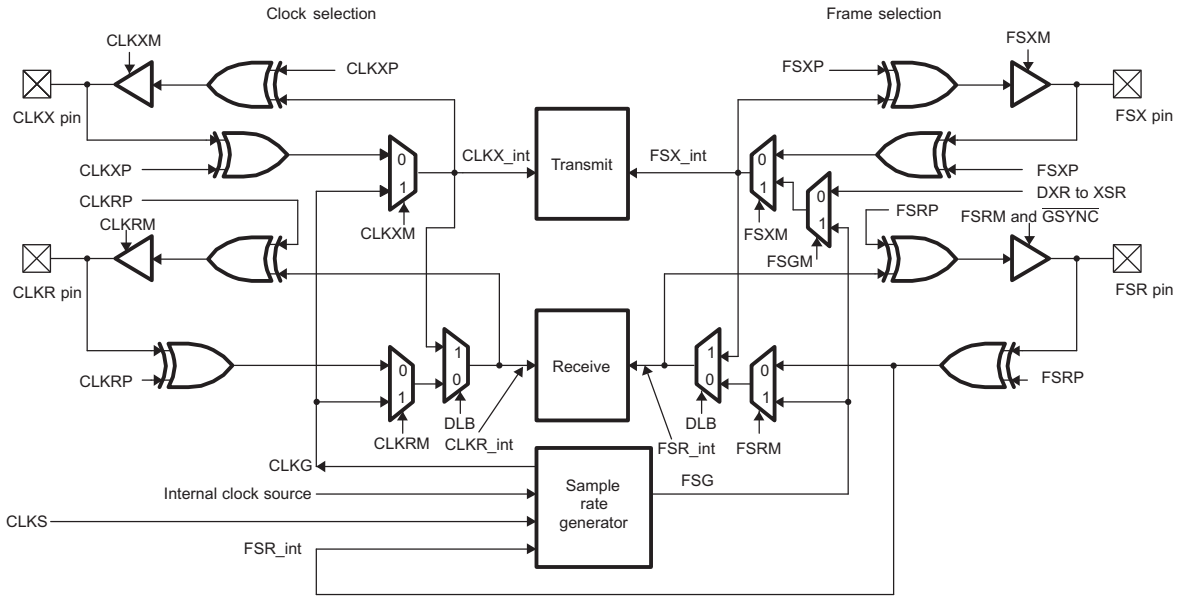


11.10.4.2 Clock, Frames, and Data

The McBSP can use an internal or external clock source. Either clock source can be divided-down inside the McBSP to generate the actual interface bit clock frequency.

The McBSP has several ways of selecting clocking and framing for both the receiver and transmitter. Clocking and framing can be sent to both portions by the sample rate generator. Each portion can select external clocking and/or framing independently. Figure 11-717 is a block diagram of the clock and frame selection circuitry.

Figure 11-717. Clock and Frame Generation



11.10.4.2.1 Frame and Clock Operation

Receive and transmit frame sync pulses (FSR/X), and clocks (CLKR/X), can either be generated internally by the sample rate generator (see Section 11.10.4.2.2) or be driven by an external source. The source of frame sync and clock is selected by programming the mode bits, FS(R/X)M and CLK(R/X)M respectively, in the pin control register (MCBSP_PCR). FSR is also affected by the GSYNC bit in the sample rate generator register (MCBSP_SRGR), see Section 11.10.4.2.4.2 for details.

When FSR and FSX are inputs (FSXM = FSRM = 0), the McBSP detects them on the internal falling edge of clock, CLKR_int and CLKX_int, respectively (see Figure 11-717). The receive data arriving at the DR pin is also sampled on the falling edge of CLKR_int. These internal clock signals are either derived from an external source via the CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X)_int. Similarly, data on DX is output on the rising edge of CLKX_int.

The FSRP, FSXP, CLKRP, and CLKXP bits in MCBSP_PCR configure the polarities of FSR, FSX, CLKR, and CLKX. All frame sync signals (FSR_int and FSX_int) internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to the McBSP) and FSRP = FSXP = 1, the external active (low) frame sync signals are inverted before being sent to the receiver signal (FSR_int) and transmitter signal (FSX_int). Similarly, if internal synchronization is selected (FSR/FSX are outputs and GSYNC = 0), the internal active (high) sync signals are inverted if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin. Figure 11-717 shows this inversion using XOR gates.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of CLKX_int (see Figure 11-718). If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge-triggered input clock on CLKX is inverted to a rising-edge-triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge-triggered) clock, CLKX_int, is inverted before being sent out on the CLKX pin.

Similarly, the receiver can reliably sample data that is clocked (by the transmitter) with a rising-edge clock. The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of CLKR_int (see Figure 11-719). Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge-triggered clock is inverted to a rising edge before being sent out on the CLKR pin.

In a system where the same clock (internal or external) is used to clock the receiver and transmitter, CLKRP = CLKXP. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold times of data around this edge. Figure 11-719 shows how data clocked by an external serial device using a rising-edge clock can be sampled by the McBSP receiver with the falling edge of the same clock.

Figure 11-718. Transmit Data Clocking

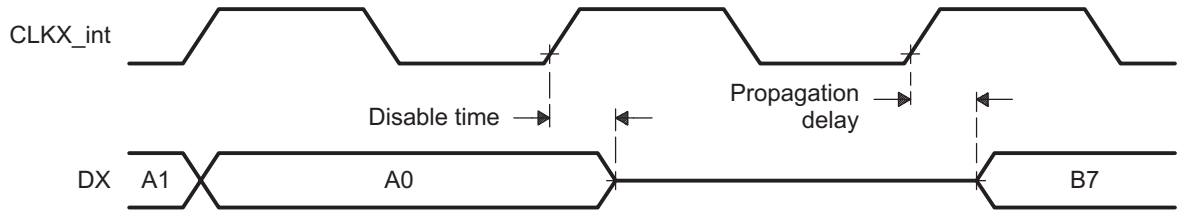


Figure 11-719. Receive Data Clocking

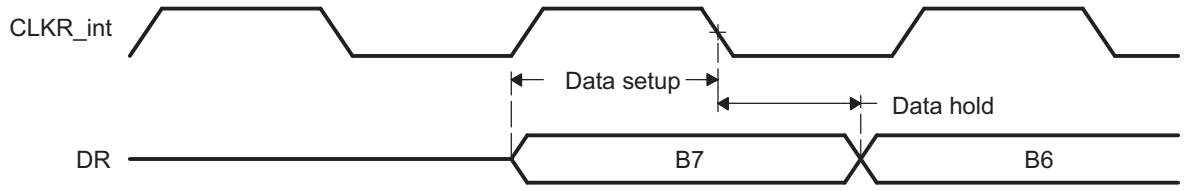


11.10.4.2.2 Sample Rate Generator Clocking and Framing

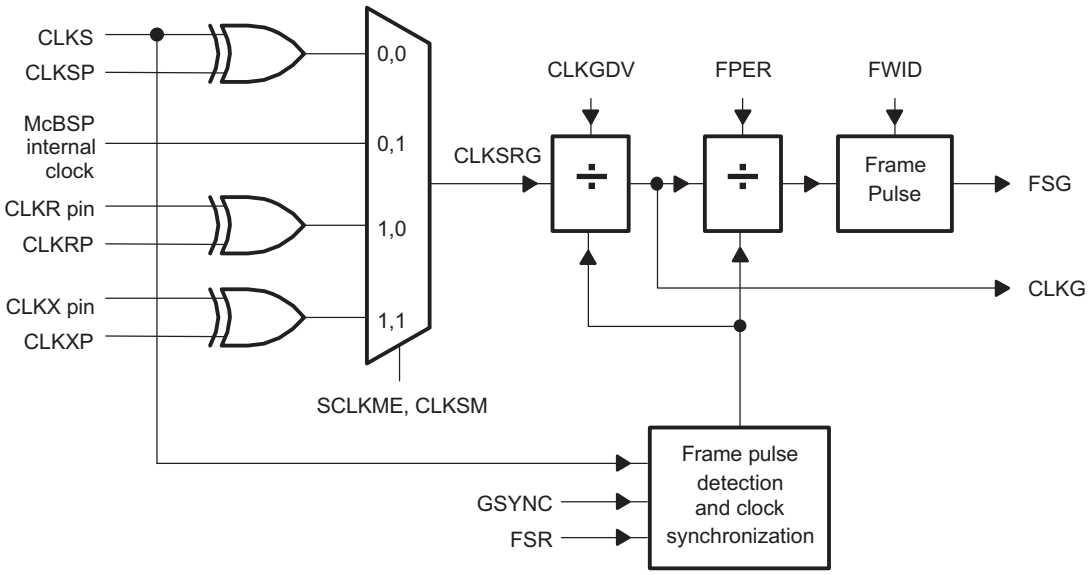
The sample rate generator is composed of a 3-stage clock divider that provides a programmable data clock (CLKG) and framing signal (FSG), as shown in Figure 11-720. CLKG and FSG are McBSP internal signals that can be programmed to drive receive and/or transmit clocking, CLK(R/X), and framing, FS(R/X). The sample rate generator can be programmed to be driven by an internal clock source or an internal clock derived from an external clock source.

The sample rate generator is not used when CLKX, FSX, CLKR, and FSR are driven by an external source. Therefore, the GRST bit in the serial port control register (MCBSP_SPCR) does not need to be enabled (GRST = 1) for this setup. The three stages of the sample rate generator circuit compute:

- Clock divide-down (CLKGDV): The number of input clocks per data bit clock
- Frame period (FPER): The frame period in data bit clocks
- Frame width (FWID): The width of an active frame pulse in data bit clocks

In addition, a frame pulse detection and clock synchronization module allows synchronization of the clock divide-down with an incoming frame pulse. The operation of the sample rate generator during device reset is described in Section 11.10.4.3.1.

Figure 11-720. Sample Rate Generator Block Diagram



11.10.4.2.3 Data Clock Generation

When the receive/transmit clock mode is set to 1 (CLK(R/X)M = 1 in the pin control register (MCBSP_PCR)), the data clocks (CLK(R/X)) are driven by the internal sample rate generator output clock, CLKG. A variety of data bit clocks can be select for the receiver and transmitter including:

- The input clock to the sample rate generator, which can be either the internal clock source or a dedicated external clock source via the CLKX, CLKR pins or CLKS. See Section 11.10.4.2.3.1 for details on the source of the McBSP internal clock.
- The input clock source (internal clock source or external clock CLKX/CLKR/CLKS) to the sample rate generator can be divided-down by a programmable value (CLKGDV bit in the sample rate generator register (MCBSP_SRGR)) to drive CLKG.

Regardless of the source to the sample rate generator, the rising edge of CLKSRG (see Figure 11-720) generates CLKG and FSG.

11.10.4.2.3.1 Input Clock Source Mode: CLKSM and SCLKME

The sample rate generator input clock signal can be driven from one of four sources selectable with the SCLKME bit in the pin control register (MCBSP_PCR) and the CLKSM bit in the sample rate generator register (MCBSP_SRGR), see Table 11-1595.

Table 11-1595. Choosing an Input Clock for the Sample Rate Generator with the SCLKME and CLKSM Bits

SCLKME Bit in MCBSP_PCR	CLKSM Bit in MCBSP_SRGR	Input Clock for Sample Rate Generator
0	0	Signal on CLKS
0	1	McBSP internal input clock
1	0	Signal on CLKR pin
1	1	Signal on CLKX pin

11.10.4.2.3.2 Sample Rate Generator Data Bit Clock Rate: CLKGDV

The first divider stage generates the serial data bit clock from the input clock. This divider stage uses a counter that is preloaded by the CLKGDV bit in the sample rate generator register (MCBSP_SRGR) and that contains the divide ratio value. The output of this stage is the data bit clock that is output on the sample rate generator output, CLKG, and that serves as the input for the second and third divider stages.

CLKG has a frequency equal to 1/(CLKGDV + 1) of the sample rate generator input clock. Thus, the sample rate generator input clock frequency is divided by a value between 1 to 256. The CLKGDV value chosen must result in a clock that meets the timing requirements/limitations specified in the device Data Manual.

When CLKGDV is an odd value or equal to 0, the CLKG duty cycle is 50%. Note that an odd CLKGDV value means an even divide down of the source clock and an even CLKGDV value means an odd divide down of the source clock. When CLKGDV is an even value (2p), the high state duration is p + 1 cycles and the low state duration is p cycles. This is illustrated in Example 11-2, Example 11-3, and Example 11-4.

In the following examples:

S_{IN} = sample generator input clock period

f_{IN} = sample generator input clock frequency

S_G = CLKG period

f_G = CLKG frequency

The following equation is given above:

$f_G = f_{IN} / dd(CLKGDV + 1))$; therefore, $S_G = (CLKGDV + 1) \times S_{IN}$.

Example 11-2. CLKGDV = 0

CLKGDV = 0

$S_G = (CLKGDV + 1) \times S_{IN} = (0 + 1) \times S_{IN} = S_{IN}$

Pulse width high = $S_{IN} \times (CLKGDV + 1) / 2 = S_{IN} \times (0 + 1) / 2 = 0.5 \times S_{IN}$

Pulse width low = $S_{IN} \times (CLKGDV + 1) / 2 = S_{IN} \times (0 + 1) / 2 = 0.5 \times S_{IN}$

Example 11-3. CLKGDV = 1

CLKGDV = 1

$S_G = (CLKGDV + 1) \times S_{IN} = (1 + 1) \times S_{IN} = 2 \times S_{IN}$

Pulse width high = $S_{IN} \times (CLKGDV + 1) / 2 = S_{IN} \times (1 + 1) / 2 = S_{IN}$

Pulse width low = $S_{IN} \times (CLKGDV + 1) / 2 = S_{IN} \times (1 + 1) / 2 = S_{IN}$

Example 11-4. CLKGDV = 2

CLKGDV = 2

$S_G = (CLKGDV + 1) \times S_{IN} = (2 + 1) \times S_{IN} = 3 \times S_{IN}$

Pulse width high = $S_{IN} \times (CLKGDV / 2 + 1) / 2 = S_{IN} \times (2 / 2 + 1) / 2 = 2 \times S_{IN}$

Pulse width low = $S_{IN} \times CLKGDV / 2 = S_{IN} \times 2 / 2 = 1 \times S_{IN}$

11.10.4.2.3.3 Bit Clock Polarity: CLKSP

CLKS is selected to drive the sample rate generator clock divider by selecting CLKSM = 0 in the sample rate generator register (MCBSP_SRGR) and SCLKME = 0 in the pin control register (MCBSP_PCR). In this case, the CLKSP bit in MCBSP_SRGR selects the edge of CLKS on which sample rate generator data bit clock (CLKG) and frame sync signal (FSG) are generated. Since the rising edge of CLKSRG generates CLKG and FSG, the rising edge of CLKS when CLKSP = 0 or the falling edge of CLKS when CLKSP = 1 causes the transition on CLKG and FSG.

11.10.4.2.3.4 Bit Clock and Frame Synchronization

CLKS is selected to drive the sample rate generator (CLKSM = 0 in MCBSP_SRGR and SCLKME = 0 in MCBSP_PCR), the GSYNC bit in MCBSP_SRGR can be used to configure the timing of CLKG relative to CLKS. GSYNC = 1 ensures that the McBSP and the external device to which it is communicating are dividing down the CLKS with the same phase relationship. If GSYNC = 0, this feature is disabled and CLKG runs freely and is not resynchronized. If GSYNC = 1, an inactive-to-active transition on FSR triggers a resynchronization of CLKG and the generation of FSG. CLKG always begins at a high state after synchronization. Also, FSR is always detected at the same edge of CLKS that generates CLKG, regardless of the length of the FSR pulse. Although an external FSR is provided, FSG can still drive internal receive frame synchronization when GSYNC = 1. When GSYNC = 1, FPER does not matter, because the frame period is determined by the arrival of the external frame sync pulse.

Figure 11-721 and Figure 11-722 show this operation with various polarities of CLKS and FSR. These figures assume that FWID is 0, for a FSG = 1 CLKG wide.

These figures show what happens to CLKG when it is initially in sync and GSYNC = 1, as well as when it is not in sync with the frame synchronization and GSYNC = 1.

Figure 11-721. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1

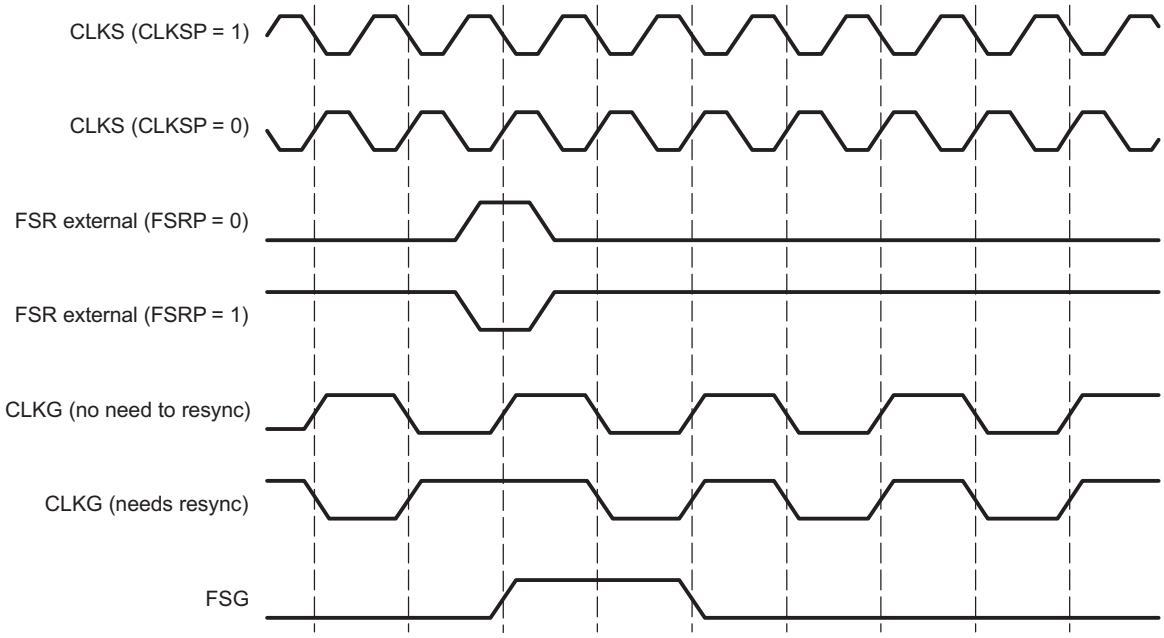


Figure 11-722. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3

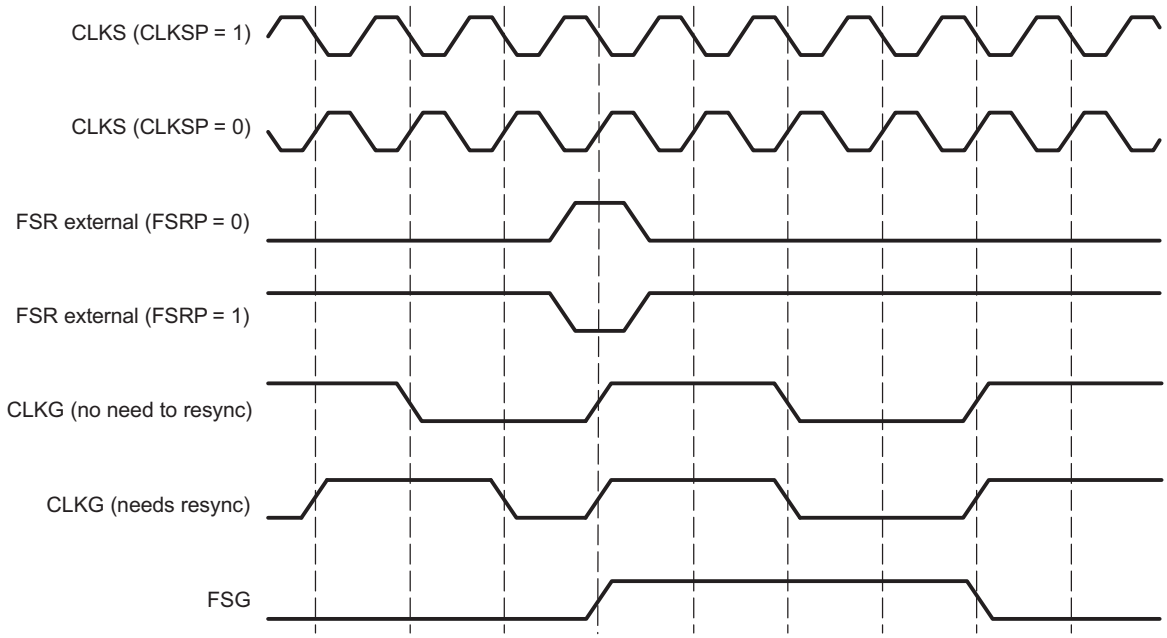


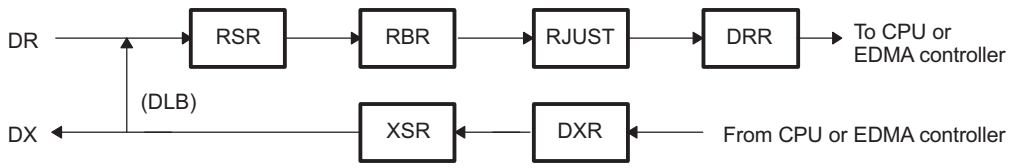
When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that the following conditions are met:

- FSX is programmed to be driven by the sample rate generator frame sync, FSG (FSGM = 1 in MCBSP_SRGR and FSXM = 1 in MCBSP_PCR).
- The sample-rate generator clock should drive the transmit and receive bit clock (CLK(R/X)M = 1 in MCBSP_SPCR). Therefore, the CLK(R/X) pin should not be driven by any other source.

11.10.4.2.3.5 Digital Loopback Mode: DLB

The DLB mode cannot be used when the McBSP is in clock stop mode (CLKSTP = 2h or 3h in the serial port control register (MCBSP_SPCR)). Setting DLB = 1 in MCBSP_SPCR enables digital loopback mode. In DLB mode, DR, FSR, and CLKR are internally connected through multiplexers to DX, FSX, and CLKX, respectively, as shown in Figure 11-717 and Figure 11-756. DLB mode allows testing of serial port code without using the external interface of the McBSP. CLKX and FSX must be enabled as outputs (CLKXM = FSXM = 1) in DLB mode.

Figure 11-723. Digital Loopback Mode



11.10.4.2.3.6 Receive Clock Selection: DLB, CLKRM

Table 11-1596 shows how the digital loopback bit (DLB) in the serial port control register (MCBSP_SPCR) and the CLKRM bit in the pin control register (MCBSP_PCR) select the receiver clock. In digital loopback mode (DLB = 1), the transmitter clock drives the receiver. CLKRM determines whether the CLKR pin is an input or an output.

Table 11-1596. Receive Clock Selection

DLB Bit in MCBSP_SPCR	CLKRM Bit in MCBSP_PCR	Source of Receive Clock	CLKR Function
0	0	CLKR acts as an input driven by the external clock and inverted as determined by CLKRP before being used.	Input.
0	1	The sample rate generator clock (CLKG) drives CLKR.	Output. CLKG inverted as determined by CLKRP before being driven out on CLKR.
1	0	CLKX_int drives the receive clock CLKR_int as selected and is inverted.	High impedance.
1	1	CLKX_int drives CLKR_int as selected and is inverted.	Output. CLKR (same as CLKX) is inverted as determined by CLKRP before being driven out.

11.10.4.2.3.7 Transmit Clock Selection: CLKXM

Table 11-1597 shows how the CLKXM bit in the pin control register (MCBSP_PCR) selects the transmit clock and whether the CLKX pin is an input or output.

Table 11-1597. Transmit Clock Selection

CLKXM Bit in MCBSP_PCR	Source of Transmit Clock	CLKX Function
0	The external clock drives the CLKX input pin. CLKX is inverted as determined by CLKXP before being used.	Input.
1	The sample rate generator clock (CLKG) drives the transmit clock.	Output.CLKG is inverted as determined by CLKXP before being driven out on CLKX.

11.10.4.2.3.8 Stopping Clocks

Two methods can be used to stop serial clocks between data transfers:

- The SPI CLKSTP mode where clocks are stopped between single-element transfers. This mode is not supported on this device.
- The clocks are inputs to the McBSP (CLKXM or CLKRM = 0 in the pin control register (MCBSP_PCR)) and the McBSP operates in non-SPI mode (the clocks can be stopped between data transfers). If the external device stops the serial clock between data transfers, the McBSP interprets it as a slowed-down serial clock. Ensure that there are no glitches on the CLK(R/X) lines as the McBSP may interpret them as clock-edge transitions. Restarting the serial clock is equivalent to a normal clock transition after a slow CLK(R/X) cycle. Note that just as in normal operations, transmit under flow (XEMPTY) may occur if the MCBSP_DXR is not properly serviced at least three CLKX cycles before the next frame sync. Therefore, if the serial clock is stopped before MCBSP_DXR is properly serviced, the external device needs to restart the clock at least three CLKX cycles before the next frame sync to allow the MCBSP_DXR write to be properly synchronized. See Figure 11-744 for a graphical explanation on when MCBSP_DXR needs to be written to avoid underflow.

11.10.4.2.4 Frame Sync Generation

Data frame synchronization is independently programmable for the receiver and the transmitter for all data delay values. When the FRST bit in the serial port control register (MCBSP_SPCR) is set to 1 the frame generation logic is activated to generate frame sync signals, provided that FSGM = 1 in the sample rate generator register (MCBSP_SRGR). The frame sync programming options are:

- A frame pulse with a programmable period between sync pulses and a programmable active width specified in MCBSP_SRGR.
- The transmitter can trigger its own frame sync signal that is generated by a DXR-to-XSR copy. This causes a frame sync to occur on every DXR-to-XSR copy. The data delays can be programmed as required. However, maximum packet frequency cannot be achieved in this method for data delays of 1 and 2.

- Both the receiver and transmitter can independently select an external frame synchronization on the FSR and FSX pins, respectively.

11.10.4.2.4.1 Frame Period (FPER) and Frame Width (FWID)

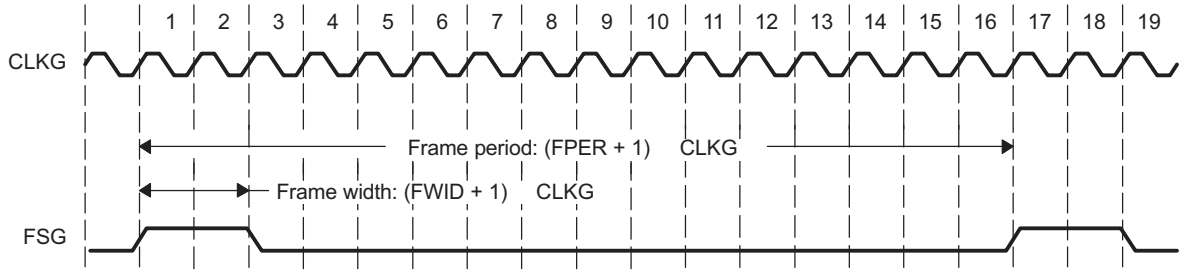
The FPER bits in the sample rate generator register (MCBSP_SRGR) are a 12-bit down-counter that can count down the generated data clocks from 4095 to 0. FPER controls the period of active frame sync pulses. The FWID bits in MCBSP_SRGR are an 8-bit down-counter. FWID controls the active width of the frame sync pulse.

When the sample rate generator comes out of reset, FSG is in an inactive (low) state. After this, when FRST = 1 in MCBSP_SPCR and FSGM = 1 in MCBSP_SRGR, frame sync signals are generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0 when FSG goes low. Thus, the value of FWID + 1 determines an active frame pulse width ranging from 1 to 256 data bit clocks.

At the same time, the frame period value (FPER + 1) is also counting down, and when this value reaches 0, FSG goes high again indicating a new frame is beginning. Thus, the value of FPER + 1 determines a frame length from 1 to 4096 data bits. When GSYNC = 1 in MCBSP_SRGR, the value of FPER does not matter. Figure 11-724 shows a frame of 16 CLKG periods (FPER = 15 or 0000 1111b).

It is recommended that FWID be programmed to a value less than (R/X)WDLEN1/2.

Figure 11-724. Programmable Frame Period and Width



11.10.4.2.4.2 Receive Frame Synchronization Selection: DLB and FSRM

Table 11-1598 shows how to select various sources to provide the receive frame synchronization signal. Note that in digital loopback mode (DLB = 1 in the serial port control register (MCBSP_SPCR)), the transmit frame sync signal is used as the receive frame sync signal and that DR is internally connected to DX.

NOTE: FSR_int and FSX_int are shown in Figure 11-717.

Table 11-1598. Receive Frame Synchronization Selection

DLB Bit in MCBSP_SPCR	FSRM Bit in MCBSP_PCR	GSYNC Bit in MCBSP_SRGR	Source of Receive Frame Synchronization	FSR Pin Function
0	0	X	External frame sync signal drives the FSR input pin, whose signal is then inverted as determined by FSRP before being used as FSR_int.	Input.
0	1	0	Sample rate generator frame sync signal (FSG) drives FSR_int, FRST = 1.	Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin.
0	1	1	Sample rate generator frame sync signal (FSG) drives FSR_int, FRST = 1.	Input. The external frame sync input on FSR is used to synchronize CLKG and generate FSG.
1	0	0	FSX_int drives FSR_int. FSX is selected as shown in Table 11-1599.	High impedance.

Table 11-1598. Receive Frame Synchronization Selection (continued)

DLB Bit in MCBSP_SPCR	FSRM Bit in MCBSP_PCR	GSYNC Bit in MCBSP_SRGR	Source of Receive Frame Synchronization	FSR Pin Function
1	X	1	FSX_int drives FSR_int and is selected as shown in Table 11-1599.	Input. External FSR is not used for frame synchronization but is used to synchronize CLKG and generate FSG since GSYNC = 1.
1	1	0	FSX_int drives FSR_int and is selected as shown in Table 11-1599.	Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out.

11.10.4.2.4.3 Transmit Frame Synchronization Selection: FSXM and FSGM

Table 11-1599 shows how to select the source of the transmit frame synchronization signal. The three choices are:

- External frame sync input
- The sample rate generator frame sync signal (FSG)
- A signal that indicates a DXR-to-XSR copy has been made

NOTE: FSR_int and FSX_int are shown in Figure 11-717.

Table 11-1599. Transmit Frame Synchronization Selection

FSXM Bit in MCBSP_PCR	FSGM Bit in MCBSP_SRGR	Source of Transmit Frame Synchronization	FSX Pin Function
0	X	External frame sync input on the FSX pin. This is inverted by FSXP before being used as FSX_int.	Input
1	1	Sample rate generator frame sync signal (FSG) drives FSX_int. FRST = 1.	Output. FSG is inverted by FSXP before being driven out on FSX.
1	0	A DXR-to-XSR copy activates transmit frame sync signal.	Output. 1-bit-clock-wide signal inverted as determined by FSXP before being driven out on FSX.

11.10.4.2.4.4 Frame Detection

To facilitate detection of frame synchronization, the receive and transmit CPU interrupts (RINT and XINT) can be programmed to detect frame synchronization by setting the RINTM and XINTM bits in the serial port control register (MCBSP_SPCR) to 10b. The associated portion (receiver/transmitter) of the McBSP must be out of reset.

11.10.4.2.5 Data and Frames

All data transfers require a valid frame synchronization.

11.10.4.2.5.1 Frame Synchronization Phases

Frame synchronization indicates the beginning of a transfer on the McBSP. The data stream following frame synchronization can have up to two phases: phase 1 and phase 2. The number of phases can be selected by the phase bit, (R/X)PHASE, in MCBSP_RCR and MCBSP_XCR. The number of elements per frame and bits per element can be independently selected for each phase via (R/X)FRLEN1/2 and (R/X)WDLEN1/2, respectively.

Figure 11-725 shows a frame in which the first phase consists of two elements of 12 bits, each followed by a second phase of three elements of 8 bits each. The entire bit stream in the frame is contiguous, no gaps exist either between elements or phases. Table 11-1600 shows the fields in the receive/transmit control registers (MCBSP_RCR/MCBSP_XCR) that control the frame length and element length for each phase for both the receiver and the transmitter. The maximum number of elements per frame is 128 for a single-phase frame and 256 elements in a dual-phase frame. The number of bits per element can be 8, 12, 16, 20, 24, or 32.

NOTE: For a dual-phase frame with internally generated frame synchronization, the maximum number of elements per phase depends on the word length. This is because the frame period, FPER, is only 12-bits wide and, therefore, provides 4096 bits per frame. Hence, the maximum number of 256 elements per dual-phase frame applies only when the WDLEN is 16 bits. However, any combination of element numbers and element size (defined by the FRLEN and WDLEN bits, respectively) is valid as long as their product is less than or equal to 4096 bits. This limitation does not apply for dual-phase with external frame sync.

Figure 11-725. Dual-Phase Frame Example

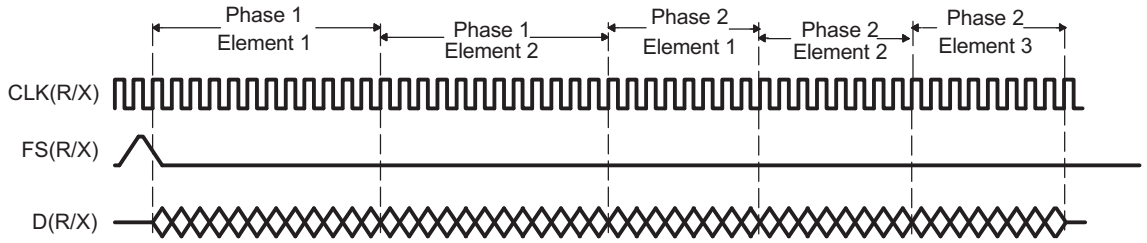


Table 11-1600. MCBSP_RCR/MCBSP_XCR Fields Controlling Elements per Frame and Bits per Element

Serial Port	Frame Phase	MCBSP_RCR/MCBSP_XCR Field Control	
		Elements per Frame	Bits per Element
Receive	1	RFRLEN1	RWDLEN1
Receive	2	RFRLEN2	RWDLEN2
Transmit	1	XFRLEN1	XWDLEN1
Transmit	2	XFRLEN2	XWDLEN2

11.10.4.2.5.2 Frame Length: RFRLEN1/2 and XFRLEN1/2

Frame length specifies the maximum number of serial elements or logical time slots or channels that are available for transfer per frame synchronization signal. In multi-channel selection mode, the frame length value is independent of, and possibly different from, the actual number of channels that the device is programmed to receive or transmit per frame via the MCBSP_MCR, RCEREn, and XCEREn registers. See Section 11.10.4.7 for details on multi-channel selection mode operation.

The 7-bit (R/X)FRLEN1/2 bits in (R/X)CR support up to 128 elements per phase in a frame, as shown in Table 11-1601. (R/X)PHASE = 0 selects a single-phase data frame, and (R/X)PHASE = 1 selects a dual-phase frame for the data stream. For a single-phase frame, the value of (R/X)FRLEN2 does not matter. Program the frame length fields with (w minus 1), where w represents the number of elements per frame. For Figure 11-725, (R/X)FRLEN1 = 1 or 000 0001b and (R/X)FRLEN2 = 2 or 000 0010b.

Table 11-1601. Receive/Transmit Frame Length Configuration

(R/X)PHASE	(R/X)FRLEN1	(R/X)FRLEN2	Frame Length
0	0 ≤ n ≤ 127	x	Single-phase frame; (n + 1) elements per frame
1	0 ≤ n ≤ 127	0 ≤ m ≤ 127	Dual-phase frame; (n + 1) plus (m + 1) elements per frame

11.10.4.2.5.3 Element Length: RWDLEN1/2 and XWDLEN1/2

The (R/X)WDLEN1/2 fields in the receive/transmit control register (MCBSP_RCR and MCBSP_XCR) determine the element length in bits per element for the receiver and the transmitter for each phase of the frame, as indicated in Table 11-1600. Table 11-1602 shows how the value of these fields selects particular element lengths in bits. For the example in Figure 11-725, (R/X)WDLEN1 = 001b and (R/X)WDLEN2 = 000b. If (R/X)PHASE = 0, indicating a single-phase frame, then (R/X)WDLEN2 is not used by the McBSP and its value does not matter.

Table 11-1602. Receive/Transmit Element Length Configuration

(R/X)WDLEN1/2	Element Length (Bits)
000	8
001	12
010	16
011	20
100	24
101	32
110	Reserved
111	Reserved

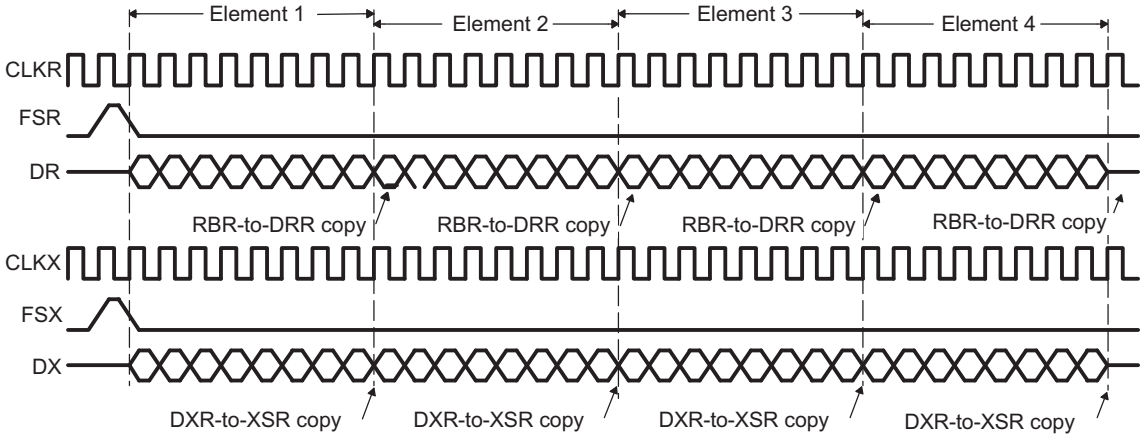
11.10.4.2.5.4 Data Packing Using Frame Length and Element Length

The frame length and element length can be manipulated to effectively pack data. For example, consider a situation in which four 8-bit elements are transferred in a single-phase frame, as shown in Figure 11-726. In this case:

- (R/X)PHASE = 0, indicating a single-phase frame
- (R/X)FRLEN1 = 000 0011b, indicating a 4-element frame
- (R/X)WDLEN1 = 000b, indicating 8-bit elements

In Figure 11-726 four 8-bit data elements are transferred to and from the McBSP by the CPU or the EDMA controller. Four reads of MCBSP_DRR and four writes of MCBSP_DXR are necessary for each frame.

Figure 11-726. Single-Phase Frame of Four 8-Bit Elements

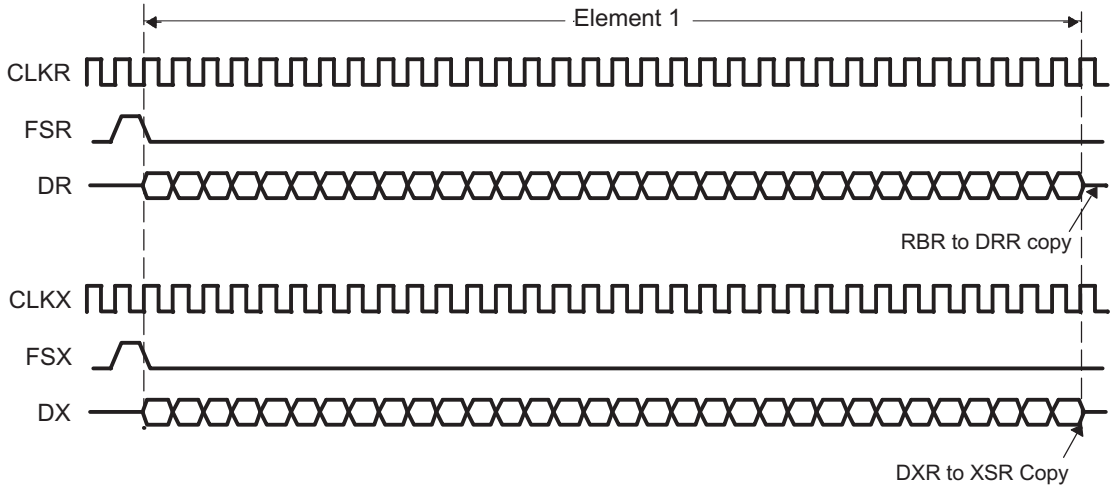


The example in Figure 11-726 can also be viewed as a data stream of a single-phase frame of one 32-bit data element, as shown in Figure 11-727. In this case:

- (R/X)PHASE = 0, indicating a single phase frame
- (R/X)FRLEN1 = 0, indicating a 1-element frame
- (R/X)WDLEN1 = 101b, indicating 32-bit elements

In Figure 11-727, one 32-bit data element is transferred to and from the McBSP by the CPU or the EDMA controller. Thus, one read of MCBSP_DRR and one write of MCBSP_DXR is necessary for each frame. As a result, the number of transfers is one-fourth that of the previous example (Figure 11-726). This manipulation reduces the percentage of bus time required for serial port data movement.

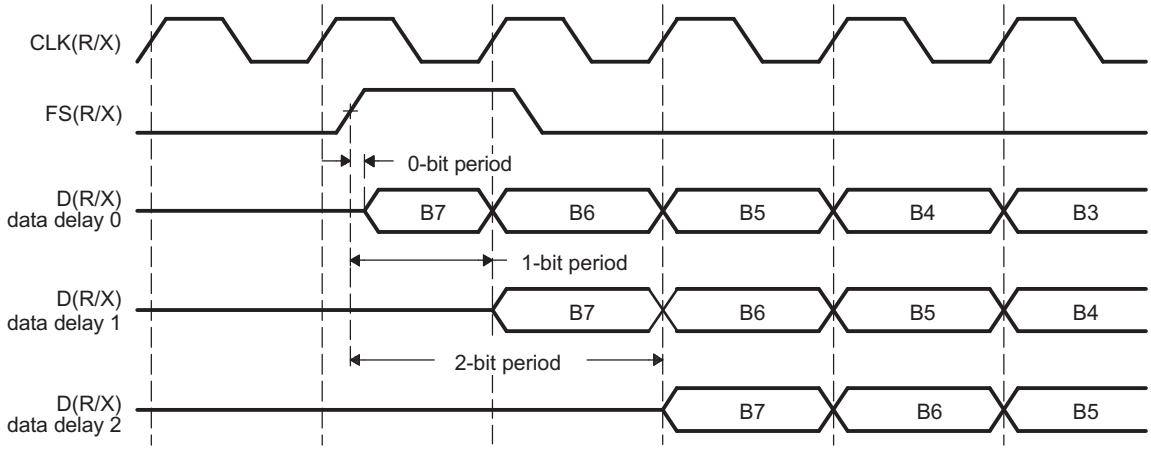
Figure 11-727. Single-Phase Frame of One 32-Bit Element



11.10.4.2.5.5 Data Delay: RDATDLY and XDATDLY

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay. RDATDLY (in MCBSP_RCR) and XDATDLY (in MCBSP_XCR) specify the data delay for reception and transmission, respectively. The range of programmable data delay is zero to two bit clocks ((R/X)DATDLY = 00b to10b), as shown in Figure 11-728. Typically, a 1-bit delay is selected because data often follows a 1-cycle active frame sync pulse.

Figure 11-728. Data Delay



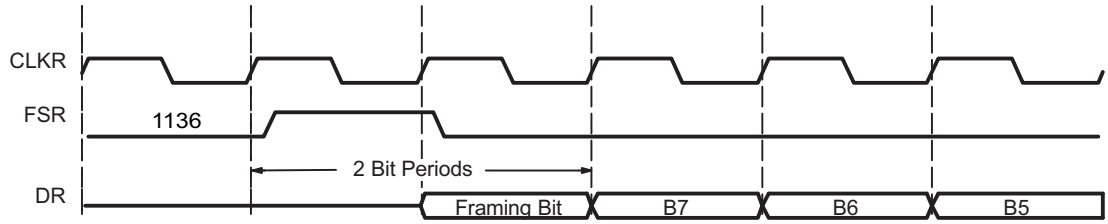
Normally, a frame sync pulse is detected or sampled with respect to an edge of serial clock CLK(R/X). Thus, on a subsequent cycle (depending on data delay value), data can be received or transmitted. However, in the case of a 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle. For reception, this problem is solved by receive data being sampled on the first falling edge of CLKR when an active (high) FSR is detected.

However, data transmission must begin on the rising edge of CLKX that generated the frame synchronization. Therefore, the first data bit is assumed to be in the XSR and DX. The transmitter then asynchronously detects the frame synchronization, FSX goes active, and it immediately starts driving the first bit to be transmitted on the DX pin.

Another common operation uses a data delay of 2. This configuration allows the serial port to interface to different types of T1 framing devices in which the data stream is preceded by a framing bit. During the reception of such a stream with a data delay of two bits, the framing bit appears after a 1-bit delay and data appears after a 2-bit delay).

The serial port essentially discards the framing bit from the data stream, as shown in Figure 11-729. In transmission, by delaying the first transfer bit, the serial port essentially inserts a blank period (high-impedance period) in place of the framing bit. Here, it is expected that the framing device inserts its own framing bit or that the framing bit is generated by another device. Alternatively, the desired value may be achieved by pull up or pull down DX.

Figure 11-729. 2-Bit Data Delay Used to Discard Framing Bit



11.10.4.2.5.6 Receive Data Justification and Sign Extension: RJUST

The RJUST bit in the serial port control register (MCBSP_SPCR) selects whether data in RBR is right-or left-justified (with respect to the MSB) in the MCBSP_DRR. If right justification is selected, RJUST further selects whether the data is sign-extended or zero-filled. Table 11-1603 and Table 11-1604 summarize the effect that various values of RJUST have on example receive data.

Table 11-1603. Effect of RJUST Bit Values With 12-Bit Example Data ABCh

RJUST Bit in MCBSP_SPCR	Justification	Extension	Value in MCBSP_DRR
00	Right	Zero-fill MSBs	0000 0ABCh
01	Right	Sign-extend MSBs	FFFF FABCh
10	Left	Zero-fill LSBs	ABC0 0000h
11	Reserved	Reserved	Reserved

Table 11-1604. Effect of RJUST Bit Values With 20-Bit Example Data ABCDEh

RJUST Bit in MCBSP_SPCR	Justification	Extension	Value in MCBSP_DRR
00	Right	Zero-fill MSBs	000A BCDEh
01	Right	Sign-extend MSBs	FFFA BCDEh
10	Left	Zero-fill LSBs	ABCD E000h
11	Reserved	Reserved	Reserved

11.10.4.2.5.7 32-Bit Reversal: RWDREVRS, XWDREVRS

Normally all transfers are sent and received with the MSB first. However, the receive/transmit bit ordering of a 32-bit element (LSB first) using the 32-bit reversal feature of the McBSP can be reversed by setting all of the following:

- (R/X)WDREVRS = 1 in the receive/transmit control register (MCBSP_RCR/MCBSP_XCR).
- (R/X)COMPAND = 01b in MCBSP_RCR/MCBSP_XCR.
- (R/X)WDLEN(1/2) = 101b in MCBSP_RCR/MCBSP_XCR to indicate 32-bit elements.

When the register fields are set as above, the bit ordering of the 32-bit element is reversed before being received by or sent from the serial port. If the (R/W)WDREVRS and (R/X)COMPAND fields are set as above, but the element size is not set to 32-bit, operation is undefined.

11.10.4.3 McBSP Resets

11.10.4.3.1 Resetting the Serial Port: RRST, XRST, GRST, and RESET

Device reset or McBSP reset: When the McBSP is reset by device reset or McBSP reset, the state machine is reset to its initial state. All counters and status bits are reset. This includes the receive status bits RFULL, RRDY, and RSYNCERR, and the transmit status bits XEMPTY, XRDY, and XSYNCERR in the serial port control register (MCBSP_SPCR).

The serial port can be reset in the following two ways:

- Device reset (RESET pin is low) places the receiver, the transmitter, and the sample rate generator in reset. When the device reset is removed (RESET = 1), FRST = GRST = RRST = XRST = 0 in MCBSP_SPCR, keeping the entire serial port in the reset state.
- The serial port transmitter and receiver can be independently reset by the XRST and RRST bits in MCBSP_SPCR. The sample rate generator is reset by the GRST bit in MCBSP_SPCR.

Table 11-1605 shows the state of the McBSP pins when the serial port is reset by these methods.

Table 11-1605. Reset State of McBSP Pins

Pin	Direction	Device Reset (RESET = 0)	McBSP Reset
DR	I	Input	**Receiver Reset (RRST = 0 and GRST = 1)**
			Input
CLKR	I/O/Z	Input	Known state if input; CLKR if output
FSR	I/O/Z	Input	Known state if input; FSRP (inactive state) if output
DX	O/Z	High impedance	**Transmitter Reset (XRST = 0 and GRST = 1)**
			High impedance
CLKX	I/O/Z	Input	Known state if input; CLKX if output
FSX	I/O/Z	Input	Known state if input; FSXP (inactive state) if output

11.10.4.3.1.1 Software Reset Considerations

McBSP reset: When the receiver and transmitter reset bits, RRST and XRST in MCBSP_SPCR, are written with 0, the respective portions of the McBSP are reset and activity in the corresponding section stops. All input-only pins, such as DR, and all other pins that are configured as inputs are in a known state. FS(R/X) is driven to its inactive state (same as its polarity bit, FS(R/X)P) if it is an output. If CLK(R/X) are programmed as outputs, they are driven by CLKG, provided that GRST = 1. The DX pin is in the high-impedance state when the transmitter is reset.

During normal operation, the sample rate generator can be reset by writing a 0 to GRST. The sample rate generator should only be reset when not being used by the transmitter or the receiver. In this case, the internal sample rate generator clock CLKG, and its frame sync signal (FSG) is driven inactive (low). When the sample rate generator is not in the reset state (GRST = 1), FSR and FSX are in an inactive state when RRST = 0 and XRST = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the McBSP is in reset, the other portion can continue operation when FRST = 1 and frame sync is driven by FSG.

Sample-rate generator reset: The sample rate generator is reset when the device is reset or when its reset bit, GRST in MCBSP_SPCR, is written with 0.

Emulator software reset: In the event of an emulator software reset initiated from the DSP, the McBSP register values are reset to their default values.

11.10.4.3.1.2 Hardware Reset Considerations

When the McBSP is reset due to device reset, the entire serial port (including the transmitter, receiver, and the sample rate generator) is reset. All input-only pins and 3-state pins should be in a known state. The output-only pin, DX, is in the high-impedance state. When the device is pulled out of reset, the serial port remains in the reset condition (RRST = XRST = FRST = GRST = 0 in MCBSP_SPCR).

11.10.4.4 Interrupt Support

The McBSP can send both receive and transmit interrupts to the device interrupt controller. For more details, see the Interrupt Controller (INTC) section.

11.10.4.4.1 Interrupt Events and Requests

The RRDY and XRDY bits in the serial port control register (MCBSP_SPCR) indicate the ready state of the McBSP receiver and transmitter, respectively. Writes and reads from the serial port can be synchronized by any of the following methods:

- Polling RRDY and XRDY bits in MCBSP_SPCR
- Using the events sent to the EDMA controller (REVT and XEVT)
- Using the interrupts to the CPU (RINT and XINT) that the events generate

Reading MCBSP_DRR and writing to MCBSP_DXR affects RRDY and XRDY, respectively.

11.10.4.4.1.1 Interrupt Events: RINT and XINT

The receive interrupt (RINT) and transmit interrupt (XINT) signals inform the DSP of changes to the serial port status. Three options exist for configuring these interrupts. These options are set by the receive/transmit interrupt mode bits (RINTM and XINTM) in MCBSP_SPCR. The possible values of the mode, and the configurations they represent, are:

- (R/X)INTM = 00b: Interrupt on every serial element by tracking the (R/X)RDY bits in MCBSP_SPCR.
- (R/X)INTM = 01b: Interrupt at the end of a subframe (16 elements or less) within a frame. See Section 11.10.4.7.9 for more details.
- (R/X)INTM = 10b: Interrupt on detection of frame synchronization pulses. The associated portion (receiver/transmitter) of the McBSP must be out of reset.
- (R/X)INTM = 11b: Interrupt on frame synchronization error. Note that if any of the other interrupt modes are selected, (R/X)SYNCERR may be read when servicing the interrupts to detect this condition. See Section 11.10.4.6.5.2 and Section 11.10.4.6.5.5 for more details on synchronization error.

11.10.4.4.1.2 Receive Ready Status: RINT and RRDY

RRDY = 1 indicates that the RBR contents have been copied to MCBSP_DRR and that the data can now be read by either the CPU or the EDMA controller. Once that data has been read by either the CPU, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into MCBSP_DRR. RRDY directly drives the McBSP receive interrupt (RINT) to the CPU if RINTM = 00b (default value) in MCBSP_SPCR.

11.10.4.4.1.3 Transmit Ready Status: XINT and XRDY

XRDY = 1 indicates that the MCBSP_DXR contents have been copied to XSR and that MCBSP_DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1), XRDY also transitions from 0 to 1 indicating that MCBSP_DXR is ready for new data. Once new data is loaded by the CPU, the XRDY bit is cleared to 0. However, once this data is copied from MCBSP_DXR to XSR, the XRDY bit transitions again from 0 to 1. The CPU can write to MCBSP_DXR although XSR has not yet been shifted out on DX. XRDY directly drives the McBSP transmit interrupt (XINT) to the CPU if XINTM = 00b (default value) in MCBSP_SPCR.

NOTE: If the polling method is used to service the transmitter, the CPU should wait for one McBSP bit clock (CLKX) before polling again to write the next element in MCBSP_DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to overwrites.

11.10.4.5 EDMA Event Support

There are two types of events supported: transmit and receive.

11.10.4.5.1 Receive Ready Status: REVT and RRDY

RRDY = 1 in the serial port control register (MCBSP_SPCR) indicates that the RBR contents have been copied to MCBSP_DRR and that the data can now be read by the EDMA controller. Once that data has been read by the EDMA controller, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0 in MCBSP_SPCR), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into MCBSP_DRR. RRDY directly drives the McBSP receive event to the EDMA controller (via REVT).

11.10.4.5.2 Transmit Ready Status: XEVT and XRDY

XRDY = 1 in the serial port control register (MCBSP_SPCR) indicates that the MCBSP_DXR contents have been copied to XSR and that MCBSP_DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1 in MCBSP_SPCR), XRDY also transitions from 0 to 1 indicating that MCBSP_DXR is ready for new data. Once new data is loaded by the EDMA controller, the XRDY bit is cleared to 0.

However, once this data is copied from MCBSP_DXR to XSR, the XRDY bit transitions again from 0 to 1. The EDMA controller can write to MCBSP_DXR although XSR has not yet been shifted out on DX. XRDY directly drives the transmit synchronization event to the EDMA controller (via XEVT).

NOTE: If the polling method is used to service the transmitter, the CPU should wait for one McBSP bit clock (CLKX) before polling again to write the next element in MCBSP_DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to overwrites.

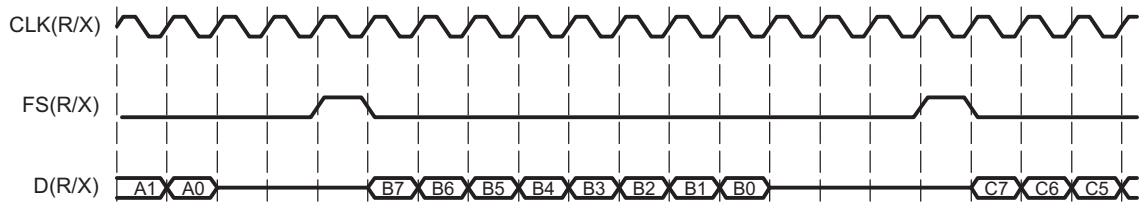
11.10.4.6 McBSP Standard Operation

During a serial transfer, there are typically periods of serial port inactivity between packets or transfers. The receive and transmit frame synchronization pulse occurs for every serial transfer. When the McBSP is not in the reset state and has been configured for the desired operation, a serial transfer can be initiated by programming (R/X)PHASE = 0 for a single-phase frame with the required number of elements programmed in (R/X)FRLEN1. The number of elements can range from 1 to 128 ((R/X)FRLEN1 = 00h to 7Fh). The required serial element length is set in the (R/X)WDLEN1 field in the (R/X)CR. If a dual-phase frame is required for the transfer, RPHASE = 1 and each (R/X)FRLEN1/2 can be set to any value between 0h and 7Fh.

Figure 11-730 shows a single-phase data frame of one 8-bit element. Since the transfer is configured for a 1-bit data delay, the data on the DX and DR pins are available one bit clock after FS(R/X) goes active. This figure, as well as all others in this section, use the following assumptions:

- (R/X)PHASE = 0, specifying a single-phase frame
- (R/X)FRLEN1 = 0b, specifying one element per frame
- (R/X)WDLEN1 = 000b, specifying eight bits per element
- (R/X)FRLEN2 = (R/X)WDLEN2 = Value is ignored
- CLK(R/X)P = 0, specifying that the receive data is clocked on the falling edge and that transmit data is clocked on the rising edge
- FS(R/X)P = 0, specifying that active (high) frame sync signals are used
- (R/X)DATDLY = 01b, specifying a 1-bit data delay

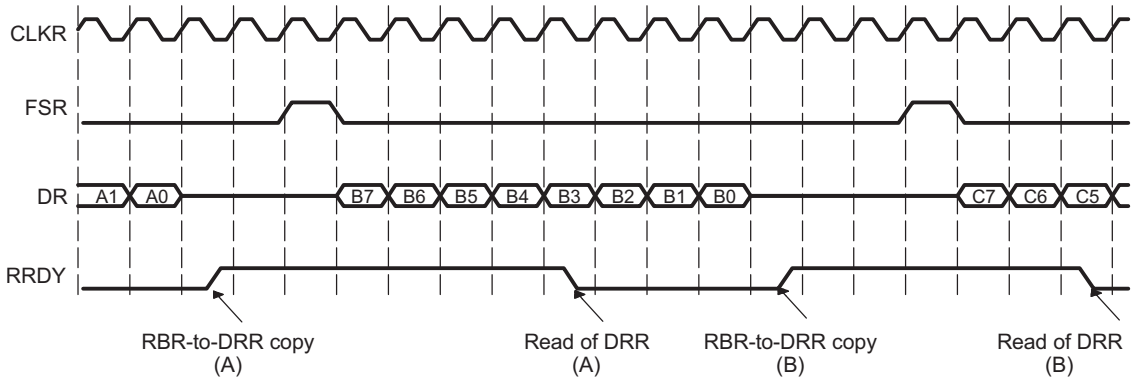
Figure 11-730. McBSP Standard Operation



11.10.4.6.1 Receive Operation

Figure 11-731 shows serial reception. Once the receive frame synchronization signal (FSR) transitions to its active state, it is detected on the first falling edge of the receivers CLKR. The data on the DR pin is then shifted into the receive shift register (RSR) after the appropriate data delay as set by the RDATDLY bit in the receive control register (MCBSP_RCR). The contents of RSR is copied to RBR at the end of every element on the rising edge of the clock, provided RBR is not full with the previous data. Then, an RBR-to-DRR copy activates the RRDY status bit in the serial port control register (MCBSP_SPCR) to 1 on the following falling edge of CLKR. This indicates that the receive data register (MCBSP_DRR) is ready with the data to be read by the CPU or the EDMA controller. RRDY is deactivated when the MCBSP_DRR is read by the CPU or the EDMA controller. See also Section 11.10.4.4.1.2 and Section 11.10.4.5.1.

Figure 11-731. Receive Operation

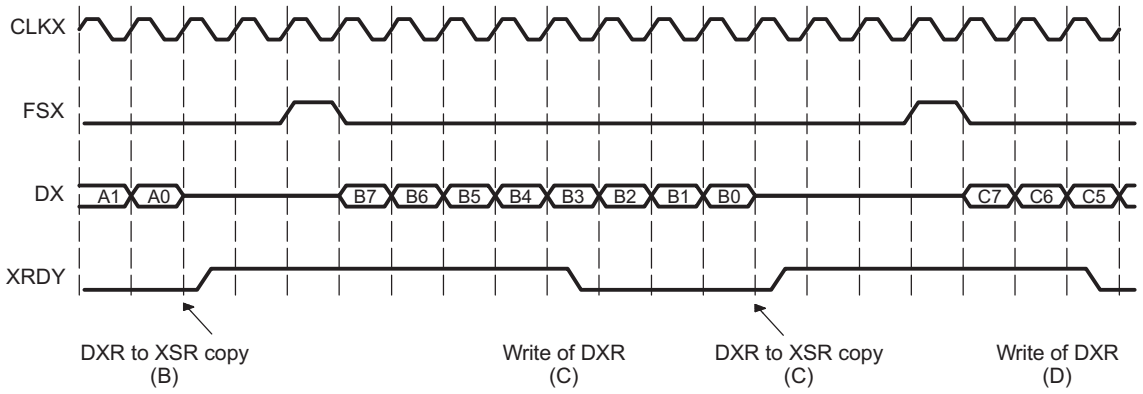


11.10.4.6.2 Transmit Operation

Once transmit frame synchronization occurs, the value in the transmit shift register (XSR) is shifted out and driven on the DX pin after the appropriate data delay as set by the XDATDLY bit in the transmit control register (MCBSP_XCR). The XRDY bit in the serial port control register (MCBSP_SPCR) is activated after every DXR-to-XSR copy on the following falling edge of CLKX, indicating that the data transmit register (MCBSP_DXR) can be written with the next data to be transmitted. XRDY is deactivated when the MCBSP_DXR is written by the CPU or the EDMA controller.

Figure 11-732 illustrates serial transmission. See Section 11.10.4.6.5.4 for information on transmit operation when the transmitter is pulled out of reset (XRST = 1). See also Section 11.10.4.4.1.3 and Section 11.10.4.5.2.

Figure 11-732. Transmit Operation



11.10.4.6.3 Maximum Frame Frequency

The frame frequency is determined by the following equation, which calculates the period between frame synchronization signals:

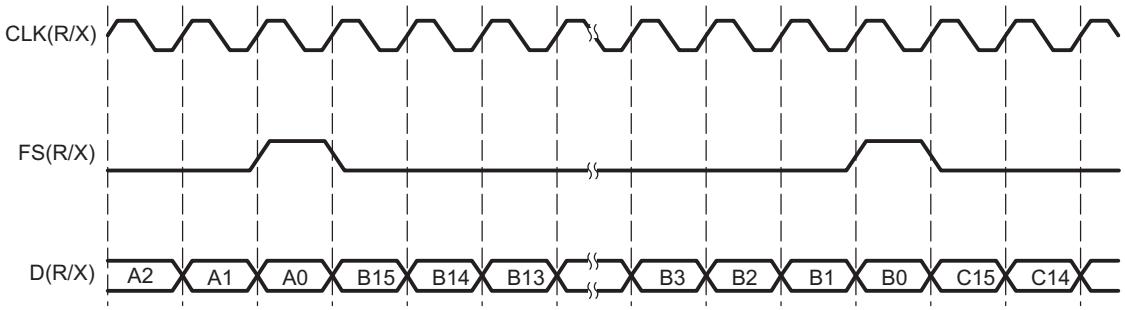
$$\text{Frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bit clocks between frame sync signals}}$$

The frame frequency may be increased by decreasing the time between frame synchronization signals in bit clocks (which is limited only by the number of bits per frame). As the frame transmit frequency is increased, the inactivity period between the data frames for adjacent transfers decreases to 0. The minimum time between frame synchronization pulses is the number of bits transferred per frame. This time also defines the maximum frame frequency, which is calculated by the following equation:

$$\text{Maximum frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bits per frame}}$$

Figure 11-733 shows the McBSP operating at maximum frame frequency. The data bits in consecutive frames are transmitted continuously with no inactivity between bits. If there is a 1-bit data delay, as shown, the frame synchronization pulse overlaps the last bit transmitted in the previous frame.

Figure 11-733. Maximum Frame Frequency for Transmit and Receive



NOTE: For (R/X)DATDLY = 0, the first bit of data transmitted is asynchronous to CLKX, as shown in Figure 11-728.

Maximum frame frequency may not be possible when the word length is 8-bits, depending on the clock divide value CLKGDV. The CPU or EDMA may not be able to service serial port requests that occur as frequently as every 8-bit clocks. This situation can be resolved by allowing additional space between words or choosing a slower bit clock (larger CLKGDV value).

11.10.4.6.4 Frame Synchronization Ignore

The McBSP can be configured to ignore transmit and receive frame synchronization pulses. The (R/X)FIG bit in (R/X)CR can be cleared to 0 to recognize frame sync pulses, or it can be set to 1 to ignore frame sync pulses. In this way,(R/X)FIG can be used either to pack data, if operating at maximum frame frequency, or to ignore unexpected frame sync pulses.

11.10.4.6.4.1 Frame Sync Ignore and Unexpected Frame Sync Pulses

RFIG and XFIG are used to ignore unexpected internal or external frame sync pulses. Any frame sync pulse is considered unexpected if it occurs one or more bit clocks earlier than the programmed data delay from the end of the previous frame specified by ((R/X)DATDLY). Setting the frame ignore bits to 1 causes the serial port to ignore these unexpected frame sync signals.

In reception, if not ignored (RFIG = 0), an unexpected FSR pulse discards the contents of RSR in favor of the incoming data. Therefore, if RFIG = 0, an unexpected frame synchronization pulse aborts the current data transfer, sets RSYNCERR in MCBSP_SPCR to 1, and begins the reception of a new data element. When RFIG = 1, the unexpected frame sync pulses are ignored.

In transmission, if not ignored (XFIG = 0), an unexpected FSX pulse aborts the ongoing transmission, sets the XSYNCERR bit in MCBSP_SPCR to 1, and reinitiates transmission of the current element that was aborted. When XFIG = 1, unexpected frame sync signals are ignored.

Figure 11-734 shows that element B is interrupted by an unexpected frame sync pulse when (R/X)FIG = 0. The reception of B is aborted (B is lost), and a new data element (C) is received after the appropriate data delay. This condition causes a receive synchronization error and thus sets the RSYNCERR bit. However, for transmission, the transmission of B is aborted and the same data (B) is retransmitted after the appropriate data delay. This condition is a transmit synchronization error and thus sets the XSYNCERR bit. Synchronization errors are discussed in Section 11.10.4.6.5.2 and Section 11.10.4.6.5.5.

Figure 11-734. Unexpected Frame Synchronization With (R/X)FIG = 0

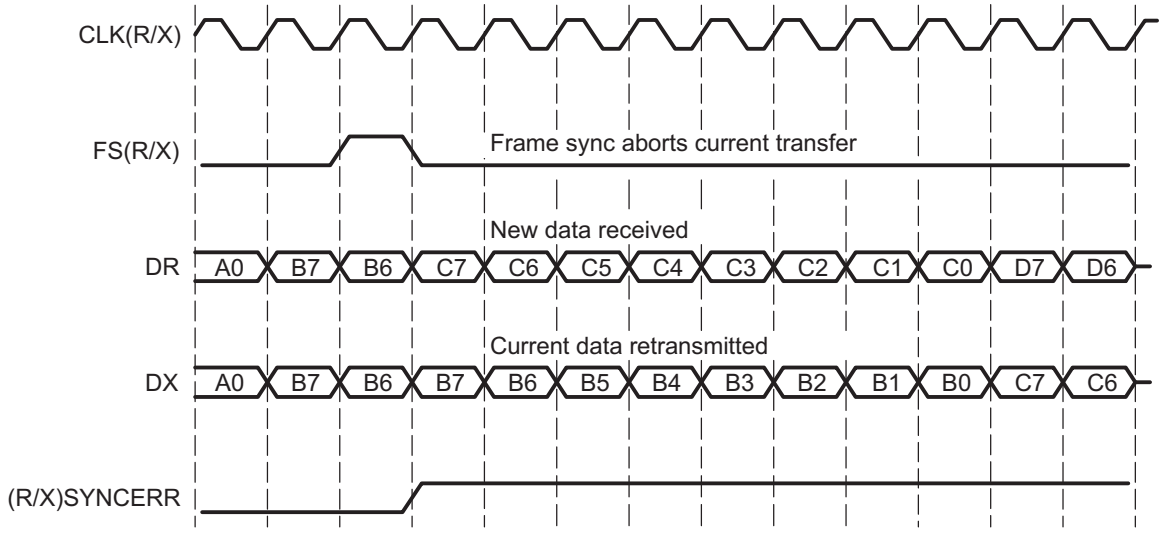


Figure 11-735 shows McBSP operation when unexpected internal or external frame synchronization signals are ignored by setting (R/X)FIG = 1. Here, the transfer of element B is not affected by an unexpected frame synchronization.

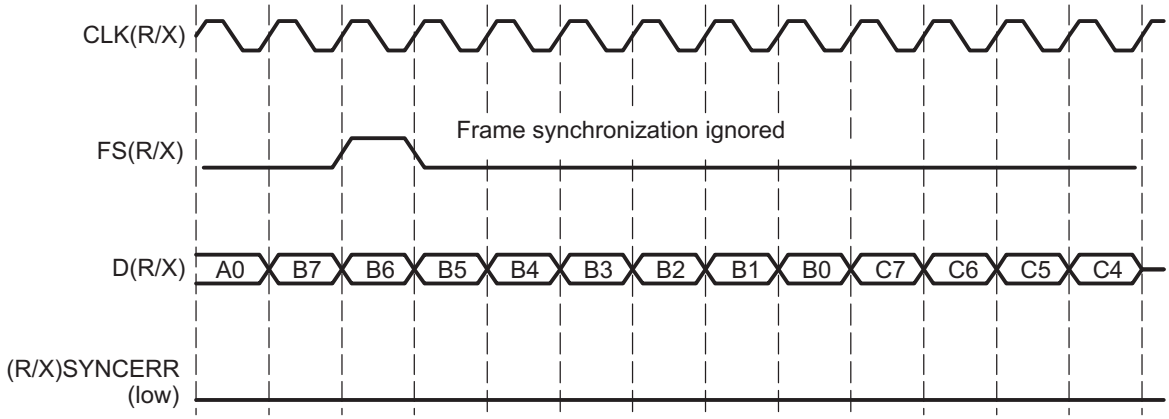
Figure 11-735. Unexpected Frame Synchronization With (R/X)FIG = 1



11.10.4.6.4.2 Data Packing using Frame Sync Ignore Bits

Section 11.10.4.2.5.4 describes one method of changing the element length and frame length to simulate 32-bit serial element transfers, thus requiring much less bus bandwidth than four 8-bit transfers require. This example works when there are multiple elements per frame.

Now consider the case of the McBSP operating at maximum packet frequency, as shown in Figure 11-736. Here, each frame has only a single 8-bit element. This stream takes one read transfer and one write transfer for each 8-bit element. Figure 11-737 shows the McBSP configured to treat this stream as a continuous stream of 32-bit elements.

In this example, (R/X)FIG is set to 1 to ignore unexpected subsequent frames. Only one read transfer and one write transfer is needed every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth of the bandwidth needed to transfer four 8-bit blocks.

Figure 11-736. Maximum Frame Frequency Operation With 8-Bit Data

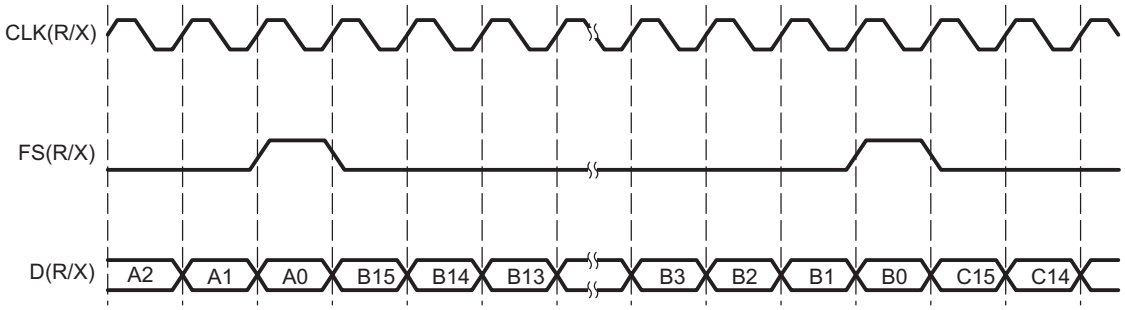


Figure 11-737. Data Packing at Maximum Frame Frequency With (R/X)FIG = 1

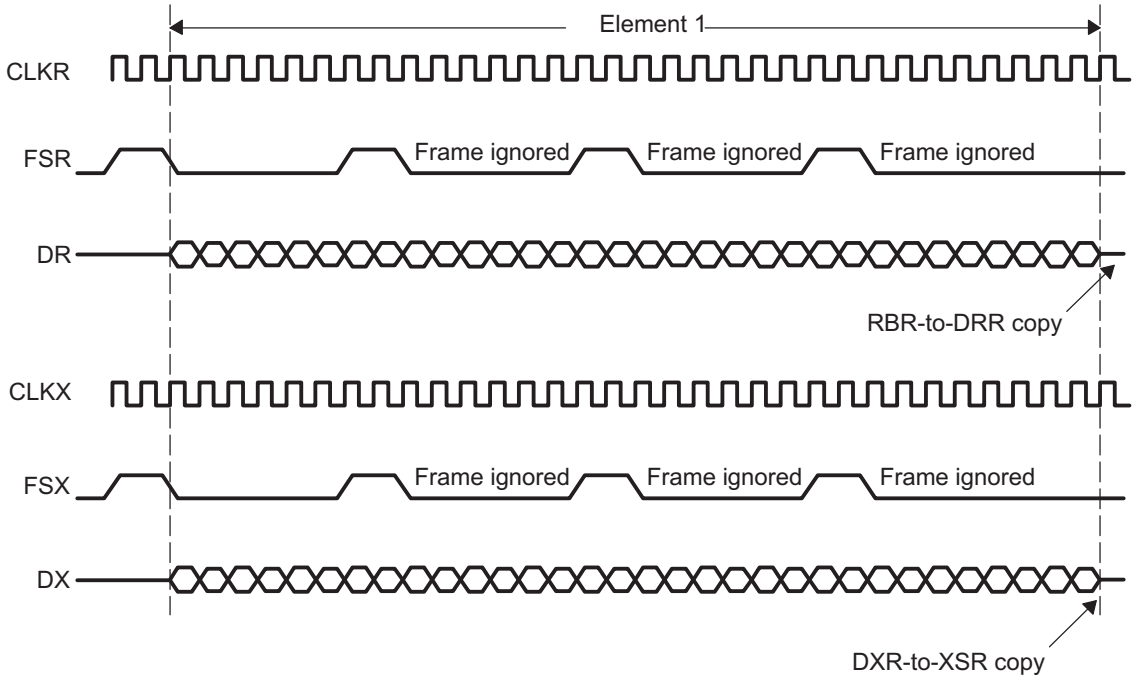

11.10.4.6.5 Serial Port Exception Conditions

There are five serial port events that can constitute a system error:

- Receive overrun (RFULL = 1 in MCBSP_SPCR)
- Unexpected receive frame synchronization (RSYNCERR = 1 in MCBSP_SPCR)
- Transmit data overwrite
- Transmit empty (XEMPTY = 0 in MCBSP_SPCR)
- Unexpected transmit frame synchronization (XSYNCERR = 1 in MCBSP_SPCR)

11.10.4.6.5.1 Receive Overrun: RFULL

RFULL = 1 in the serial port control register (MCBSP_SPCR) indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when the following conditions are met:

- MCBSP_DRR has not been read since the last RBR-to-DRR transfer.
- RBR is full and an RBR-to-DRR copy has not occurred.
- RSR is full and an RSR-to-RBR transfer has not occurred.

The data arriving on DR is continuously shifted into RSR (Figure 11-738). Once a complete element is shifted into RSR, an RSR-to-RBR transfer can occur only if an RBR-to-DRR copy is complete. Therefore, if MCBSP_DRR has not been read by the CPU or the EDMA controller since the last RBR-to-DRR transfer (RRDY = 1), an RBR-to-DRR copy does not take place until RRDY = 0. This prevents an RSR-to-RBR copy.

New data arriving on the DR pin is shifted into RSR, and the previous contents of RSR are lost. After the receiver starts running from reset, a minimum of three elements must be received before RFULL can be set, because there was no last RBR-to-DRR transfer before the first element.

This data loss can be avoided if MCBSP_DRR is read no later than two and a half CLKR cycles before the end of the third element (data C) in RSR, as shown in Figure 11-739.

Either of the following events clears the RFULL bit to 0 and allows subsequent transfers to be read properly:

- Reading MCBSP_DRR

- Resetting the receiver (RRST = 0) or the device

Another frame synchronization is required to restart the receiver.

Figure 11-738 shows the receive overrun condition. Because element A is not read before the reception of element B is complete, B is not transferred to MCBSP_DRR yet. Another element, C, arrives and fills RSR. MCBSP_DRR is finally read, but not earlier than two and one half cycles before the end of element C. New data D overwrites the previous element C in RSR. If RFULL is still set after the MCBSP_DRR is read, the next element can overwrite D if MCBSP_DRR is not read in time.

Figure 11-739 shows the case in which RFULL is set but the overrun condition is averted by reading the contents of MCBSP_DRR at least two and a half cycles before the next element, C, is completely shifted into RSR. This ensures that a RBR-to-DRR copy of data B occurs before the next element is transferred from RSR to RBR.

Figure 11-738. Serial Port Receive Overrun

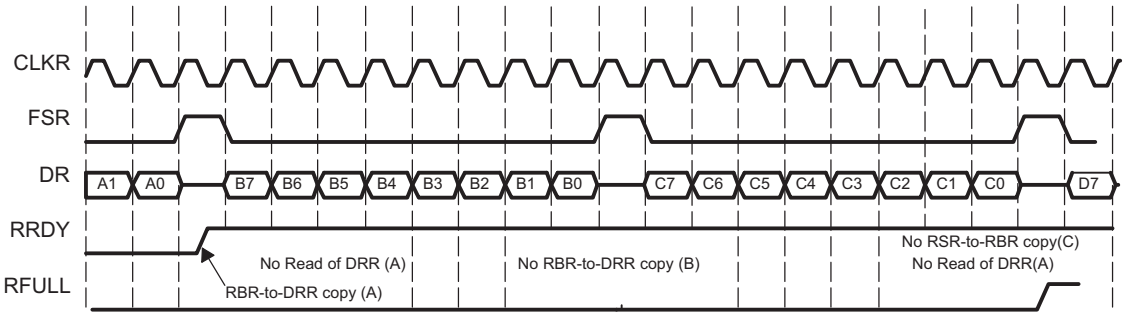

Figure 11-739. Serial Port Receive Overrun Avoided

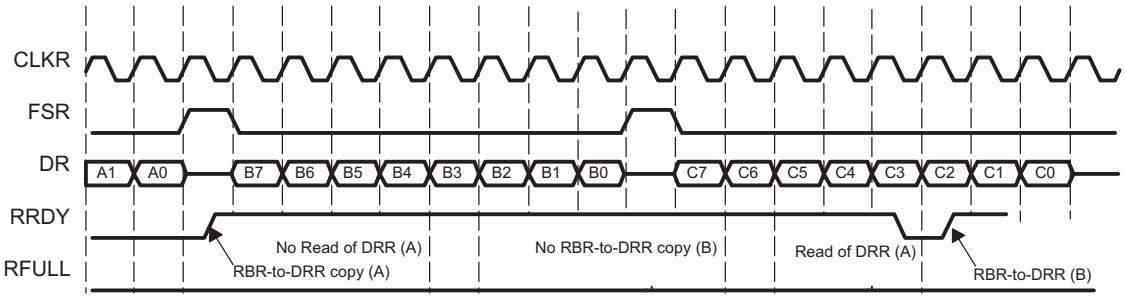

11.10.4.6.5.2 Unexpected Receive Frame Synchronization: RSYNCERR

Figure 11-740 shows the decision tree that the receiver uses to handle all incoming frame synchronization pulses. The diagram assumes that the receiver has been activated (RRST = 1). Unexpected frame sync pulses can originate from an external source or from the internal sample rate generator. An unexpected frame sync pulse is defined as a sync pulse which occurs RDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSR pulses with RFIG = 1. This case is discussed in Section 11.10.4.6.4.1 and shown in Figure 11-735. Here, receive frame sync pulses are ignored and the reception continues.
- Case 2: Normal serial port reception. There are three reasons for a receive not to be in progress:
  - This FSR is the first after RRST = 1.
  - This FSR is the first after MCBSP_DRR has been read clearing an RFULL condition.
  - The serial port is in the inter-packet intervals. The programmed data delay (RDATDLY) for reception may start during these inter-packet intervals for the first bit of the next element to be received. Thus, at maximum frame frequency, frame synchronization can still be received RDATDLY bit clocks before the first bit of the associated element.
  - For this case, reception continues normally, because these are not unexpected frame sync pulses.
- Case 3: Unexpected receive frame synchronization with RFIG = 0 (unexpected frame not ignored). This case was shown in Figure 11-734 for maximum packet frequency. Figure 11-741 shows this case during normal operation of the serial port with time intervals between packets. Unexpected frame sync pulses are detected when they occur the value in RDATDLY bit clocks before the last bit of the previous element is received on DR. In both cases, RSYNCERR in MCBSP_SPCR is set. RSYNCERR can be cleared only by receiver reset or by writing a 0 to this bit in MCBSP_SPCR. If RINTM = 11b in MCBSP_SPCR, RSYNCERR drives the receive interrupt (RINT) to the CPU.

NOTE: Note that the RSYNCERR bit in MCBSP_SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

Figure 11-740. Decision Tree Response to Receive Frame Synchronization Pulse

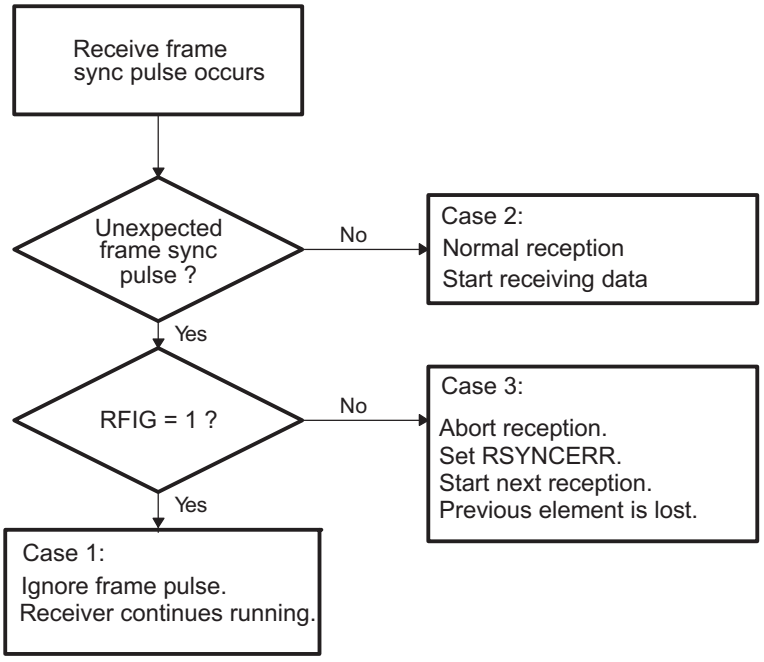

Figure 11-741. Unexpected Receive Frame Synchronization Pulse

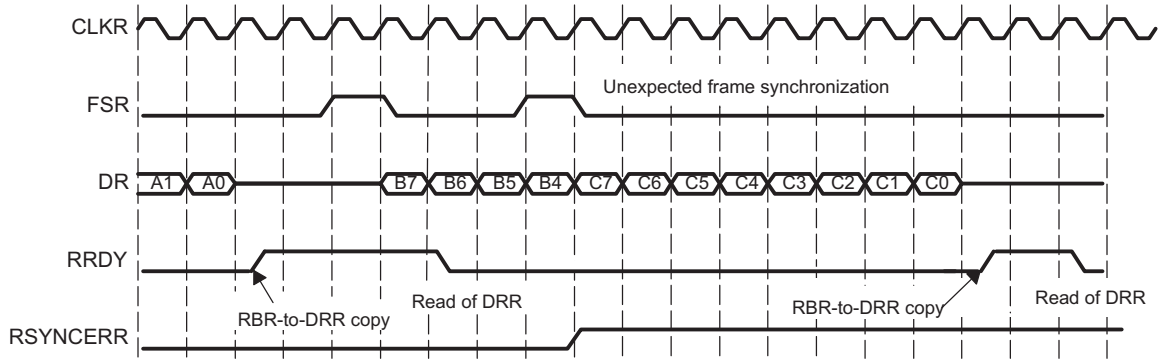
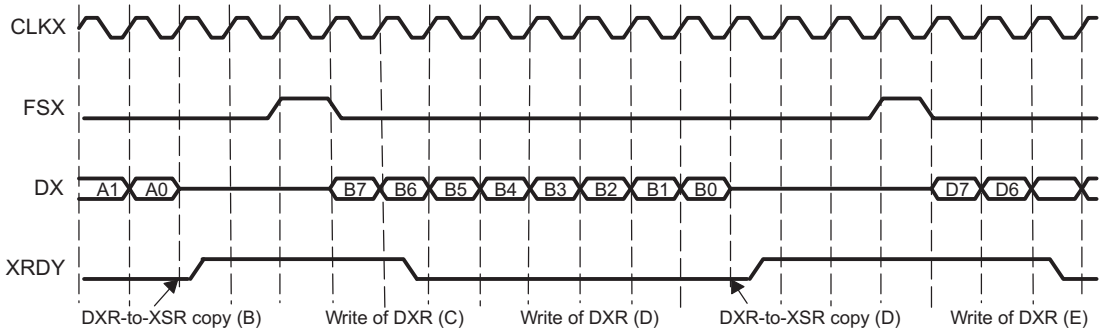


11.10.4.6.5.3 Transmit With Data Overwrite

Figure 11-742 shows what happens if the data in MCBSP_DXR is overwritten before it is transmitted. For example, load the MCBSP_DXR with data C. A subsequent write to the MCBSP_DXR overwrites C with D before C is copied to the XSR. Thus, C is never transmitted on DX. The CPU can avoid overwriting data by polling XRDY before writing to MCBSP_DXR or by waiting for a programmed XINT to be triggered by XRDY (XINTM = 00b). The EDMA controller can avoid overwriting by synchronizing data writes with XEVT. See also Section 11.10.4.4.1.3.

Figure 11-742. Transmit with Data Overwrite



11.10.4.6.5.4 Transmit Empty: XEMPTY

XEMPTY indicates whether the transmitter has experienced underflow. Either of the following conditions causes XEMPTY to become active (XEMPTY = 0):

- During transmission, MCBSP_DXR has not been loaded since the last DXR-to-XSR copy, and all bits of the data element in XSR have been shifted out on DX.
- The transmitter is reset (XRST = 0 or the device is reset), and then restarted.

During an underflow condition, the transmitter continues to transmit the old data in MCBSP_DXR for every new frame sync signal FSX (generated by an external device, or by the internal sample rate generator) until a new element is loaded into MCBSP_DXR by the CPU or the EDMA controller. XEMPTY is deactivated
(XEMPTY = 1) when this new element in MCBSP_DXR is transferred to XSR. In the case when the FSX is generated by a DXR-to-XSR copy (FSXM = 1 in MCBSP_PCR and FSGM = 0 in MCBSP_SRGR), the McBSP does not generate any new frame sync until new data is written to the MCBSP_DXR and a DXR-to-XSR copy occurs.

When the transmitter is taken out of reset (XRST = 1), it is in a transmit ready (XRDY = 1) and transmit empty (XEMPTY = 0) condition. If MCBSP_DXR is loaded by the CPU or the EDMA controller before FSX goes active, a valid DXR-to-XSR transfer occurs. This allows for the first element of the first frame to be valid even before the transmit frame sync pulse is generated or detected. Alternatively, if a transmit frame sync is detected before MCBSP_DXR is loaded, 0s are output on DX.

Figure 11-743 shows a transmit underflow condition. After B is transmitted, B is retransmitted on DX if the MCBSP_DXR is failed to reload before the subsequent frame synchronization. Figure 11-744 shows the case of writing to MCBSP_DXR just before a transmit underflow condition that would otherwise occur. After B is transmitted, C is written to MCBSP_DXR before the next transmit frame sync pulse occurs.

Figure 11-743. Transmit Empty

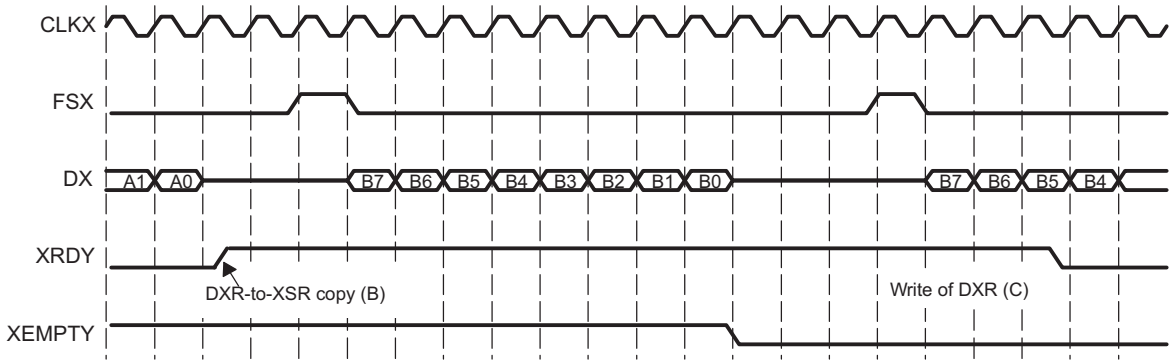


Figure 11-744. Transmit Empty Avoided

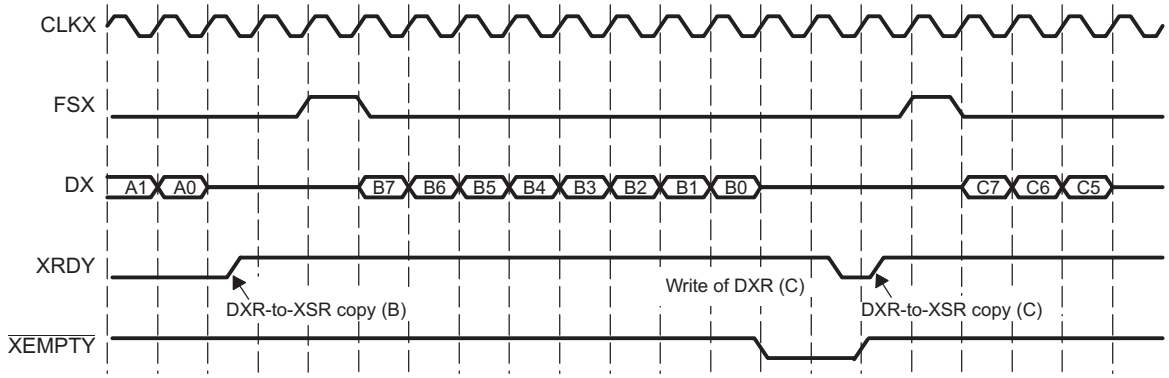

11.10.4.6.5.5 Unexpected Transmit Frame Synchronization: XSYNCERR

A transmit frame sync error (XSYNCERR) may occur the first time the transmitter is enabled (XRST = 1) after a device reset. To avoid this, after enabling the transmitter for the first time, the following procedure must be followed:

1. Wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
2. Disable the transmitter (XRST = 0). This clears any XSYNCERR.
3. Re-enable the transmitter (XRST = 1).

See also Section 11.10.5.1 for details on initialization procedure.

Figure 11-745 shows the decision tree that the transmitter uses to handle all incoming frame synchronization signals. The diagram assumes that the transmitter has been started (XRST = 1). An unexpected transmit frame sync pulse is defined as a sync pulse that occurs XDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSX pulses with XFIG = 1. This case is discussed in Section 11.10.4.6.4.1 and shown in Figure 11-735. In this case, unexpected FSX pulses are ignored and the transmission continues.
- Case 2: FSX pulses with normal serial port transmission. This case is discussed in Section 11.10.4.6.2. There are two possible reasons for a transmit not to be in progress:
  - This FSX pulse is the first one to occur after XRST = 1.
  - The serial port is in the interpacket intervals. The programmed data delay (XDATDLY) may start during these interpacket intervals before the first bit of the next element is transmitted. Therefore, if operating at maximum packet frequency, frame synchronization can still be received XDATDLY bit clocks before the first bit of the associated element.
- Case 3: Unexpected transmit frame synchronization with XFIG = 0. The case was shown in Figure 11-734 for frame synchronization with XFIG = 0 at maximum packet frequency. Figure 11-746 shows the case for normal operation of the serial port with interpacket intervals. In both cases, XSYNCERR in MCBSP_SPCR is set. XSYNCERR can be cleared only by transmitter reset or by writing a 0 to this bit in MCBSP_SPCR.
  If XINTM = 11b in MCBSP_SPCR, XSYNCERR drives the receive interrupt (XINT) to the CPU.

NOTE: The XSYNCERR bit in MCBSP_SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

Figure 11-745. Decision Tree Response to Transmit Frame Synchronization Pulse

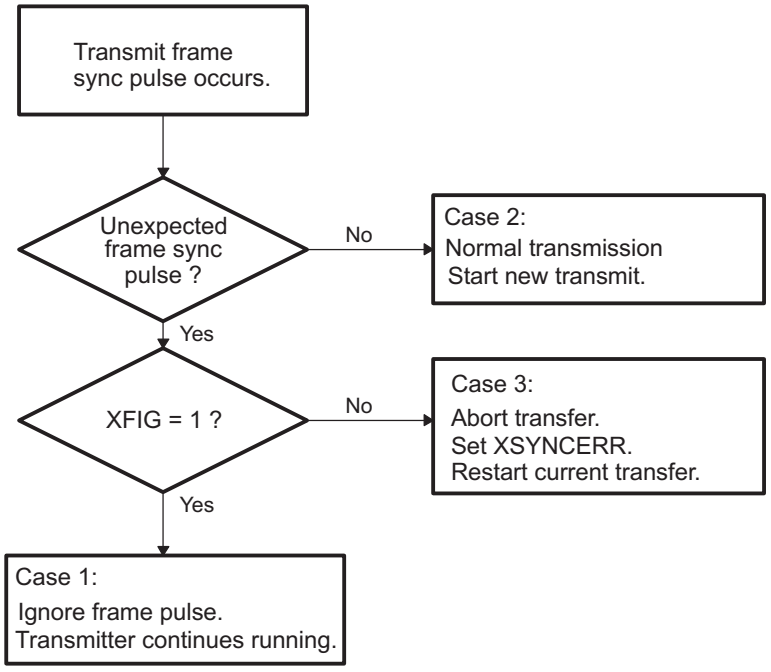

Figure 11-746. Unexpected Transmit Frame Synchronization Pulse

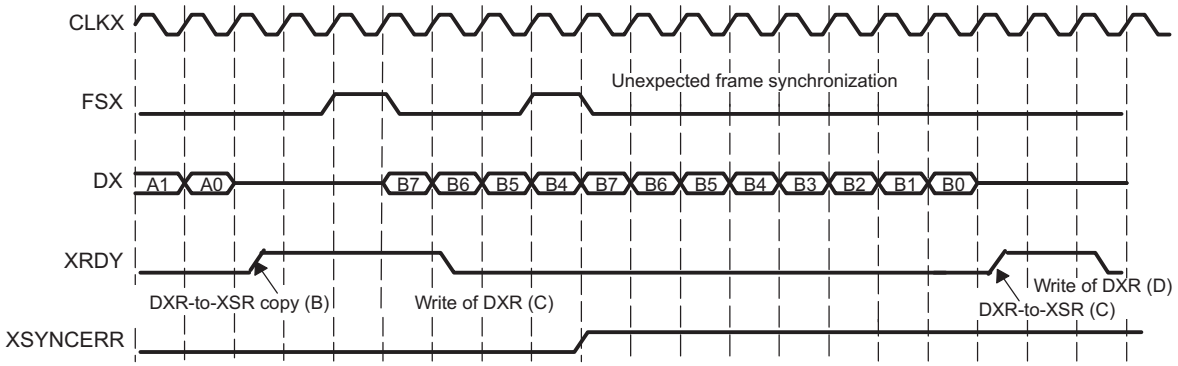


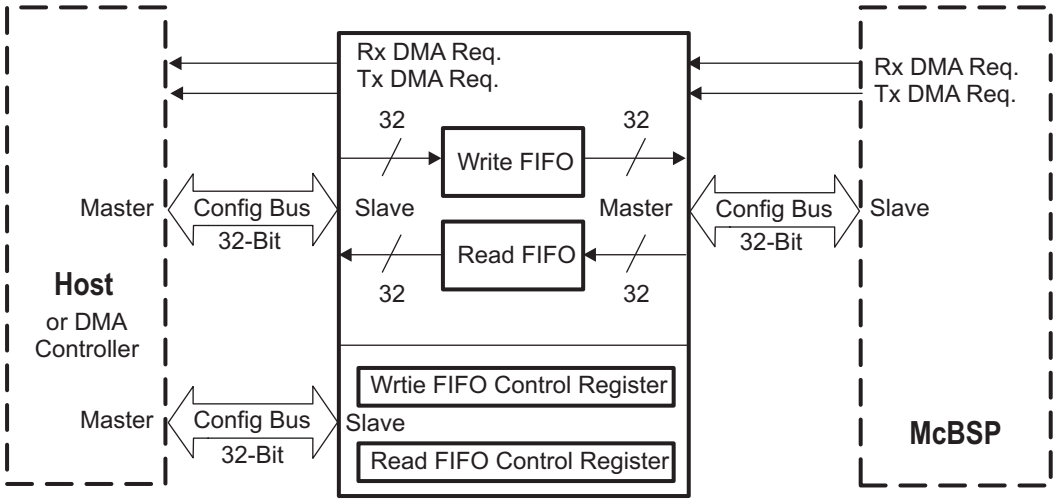
11.10.4.6.6 McBSP Buffer FIFO (BFIFO)

The McBSP Buffer FIFO (BFIFO) provides additional data buffering for the McBSP. The time it takes the host CPU or EDMA controller to respond to DMA requests from the McBSP may vary; the additional buffering provided by the BFIFO allows greater tolerance to such variations.

The BFIFO contains two FIFOs: one Read FIFO (RFIFO) and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 11-747 for a high-level block diagram of the BFIFO.

The BFIFO can be enabled/disabled and configured using the Write FIFO control register (MCBSP_WFIFOCTL) and the Read FIFO control register (MCBSP_RFIFOCTL). Note that if the Read or Write FIFO is to be enabled, it must be enabled before initializing the receive/transmit section of the McBSP (see Section 11.10.5.1 for details).

Figure 11-747. McBSP Buffer FIFO (BFIFO) Block Diagram



NOTE: The McBSP Buffer FIFO (BFIFO) has a different memory-map than the McBSP memory-mapped registers (MMRs); therefore, the BFIFO is accessible by way of a different Configuration Bus.

11.10.4.6.6.1 BFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass directly from the McBSP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McBSP generates transmit DMA requests as needed; the BFIFO is invisible to the McBSP.

When the Write FIFO is enabled, transmit DMA requests from the McBSP are sent to the BFIFO, which then generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled during a transmit DMA request from the McBSP, the WFIFO writes *WNUMDMA* 32-bit words to the McBSP, if and when there are at least two *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied; at this point, it writes *WNUMDMA* words to the McBSP.

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO accepts host writes until full. Beyond this point, excess data is discarded.

Note that when the WFIFO is first enabled, it immediately issues a transmit DMA request to the host. This is because it begins in an empty state and is therefore ready to accept data.

11.10.4.6.6.1.1 Transmit DMA Event Pacer

The BFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and waits for a response. As soon as *WNUMEVT* words have been written to the WFIFO, the WFIFO checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO attempts to stay filled.

If transmit DMA event pacing is desired, the WNUMEVT bits in MCBSP_WFIFOCTL should be set to a non-zero integer multiple of the value in the WNUMDMA bits. If transmit DMA event pacing is not desired, the value in the WNUMEVT bits should be set equal to the value in the WNUMDMA bits.

11.10.4.6.6.2 BFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass directly from McBSP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McBSP generates receive DMA requests as needed; the BFIFO is invisible to the McBSP.

When the Read FIFO is enabled, receive DMA requests from the McBSP are sent to the BFIFO, which then generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McBSP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McBSP, if and when the RFIFO has space for *RNUMDMA* words. If the RFIFO does not have space, the RFIFO waits until this condition has been satisfied; at this point, it reads *RNUMDMA* words from the McBSP.

If the host CPU reads the Read FIFO independent of a receive DMA request and the RFIFO currently contains no *RNUMEVT* words, those words will be read correctly, emptying the RFIFO.

11.10.4.6.6.2.1 Receive DMA Event Pacer

The BFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. As soon as *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO attempts to stay empty.

If receive DMA event pacing is desired, the RNUMEVT bits in MCBSP_RFIFOCTL should be set to a non-zero integer multiple of the value in RNUMDMA bits. If receive DMA event pacing is not desired, then the value in the RNUMEVT bits should be set equal to the value in the RNUMDMA bits.

11.10.4.6.6.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

11.10.4.7 Multi-channel Selection Modes

This section defines the functions and related information concerning the multi-channel selection modes.

11.10.4.7.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. Each McBSP supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that each contain 16 contiguous channels:

- Block 0: Channels 0 through 15
- Block 1: Channels 16 through 31
- Block 2: Channels 32 through 47
- Block 3: Channels 48 through 63
- Block 4: Channels 64 through 79
- Block 5: Channels 80 through 95
- Block 6: Channels 96 through 111
- Block 7: Channels 112 through 127

The blocks are assigned to partitions according to the selected partition mode. In the 2-partition mode, one even-numbered block (0, 2, 4, or 6) is assigned to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode, blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, it is possible to use 2 receive partitions (A and B) and 8 transmit partitions (A through H).

11.10.4.7.2 Multi-channel Selection

When McBSP uses a time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, use a multi-channel selection mode to prevent data flow in some of the channels. The McBSP has one receive multi-channel selection mode and three transmit multi-channel selection modes.

Each channel partition has a dedicated channel enable register. If the appropriate multi-channel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

11.10.4.7.3 Configuring a Frame for Multi-channel Selection

Before enabling a multi-channel selection mode, make sure that the data frame is properly configured:

- Select a single-phase frame (RPHASE/XPHASE = 0). Each frame represents a TDM data stream.
- Set a frame length (RFRLEN1/XFRLEN1) that includes the highest-numbered channel that is to be used. For example, to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If XFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

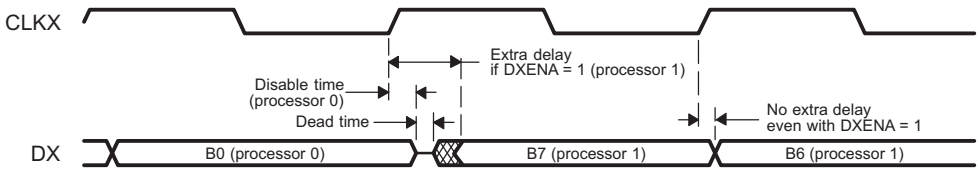
NOTE: The frame-sync pulse can be generated internally by the sample rate generator or it can be supplied externally by another source. In a multi-channel mode configuration with external frame-sync generation, the McBSP transmitter will ignore the first frame-sync pulse after it is taken out of reset. The transmitter will transmit only on the second frame-sync pulse. The receiver will shift in data on the first frame-sync pulse, regardless of whether it is generated internally or externally.

11.10.4.7.4 DX Enabler: DXENA

The DXENA bit in the serial port control register (MCBSP_SPCR) controls the high-impedance enable on the DX pin. When DXENA = 1, the McBSP enables extra delay for the DX pin turn-on time. This feature is useful for McBSP multi-channel operations, such as in a time-division multiplexed (TDM) system. The McBSP supports up to 128 channels in a multi-channel operation. These channels can be driven by different devices in a TDM data communication line, such as the T1/E1 line.

In any multi-channel operation where multiple devices transmit over the same DX line, to avoid bus contention two devices should not transmit data simultaneously. Enough dead time should exist between the transmission of the first data bit of the current device and the transmission of the last data bit of the previous device. In other words, the last data bit of the previous device needs to be disabled to a high-impedance state before the next device begins transmitting data to the same data line, as shown in Section 11.10.4.7.5.

Figure 11-748. DX Timing for Multi-channel Operation



When two McBSPs are used to transmit data over the same TDM line, bus contention occurs if DXENA = 0. The first McBSP turns off the transmission of the last data bit (changes DX from valid to a high-impedance state) after a disable time specified in the device Data Manual. As shown in Section 11.10.4.7.5, this disable time is measured from the CLKX active clock edge.

The next McBSP turns on its DX pin (changes from a high-impedance state to valid) after a delay time. Again, this delay time is measured from the CLKX active clock edge. Bus contention occurs because the dead time between the two devices is not enough. In this case an alternative software or hardware methods need to be applied to ensure proper multi-channel operation.

If DXENA = 1 is set in the second McBSP, the second McBSP turns on its DX pin after some extra delay time. This ensures that the previous McBSP on the same DX line is disabled before the second McBSP starts driving out data. The DX enabler controls only the high-impedance enable on the DX pin, not the data itself. Data is shifted out to the DX pin at the same time as in the case when DXENA = 0. The only difference is that with DXENA = 1, the DX pin is masked to a high-impedance state for some extra CPU cycles before the data is seen on the TDM data line. Therefore, only the first bit of data is delayed.

11.10.4.7.5 Using Two Partitions

For multi-channel selection operation in the receiver and/or the transmitter, two partitions or eight partitions can be used. In the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A.

11.10.4.7.5.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B (see Table 11-1606), which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B (see Table 11-1607). To change which blocks of channels are assigned to the partitions, see Section 11.10.4.7.5.2.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bit in the multi-channel control register (MCBSP_MCR). In the receive multi-channel selection mode, the channels in this partition are controlled by the enhanced receive channel enable register partition A/B (MCBSP_RCERE0).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bit in MCBSP_MCR. In the receive multi-channel selection mode, the channels in this partition are controlled by the enhanced receive channel enable register partition A/B (MCBSP_RCERE0).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bit in the multi-channel control register (MCBSP_MCR). In one of the transmit multi-channel selection modes, the channels in this partition are controlled by the enhanced transmit channel enable register partition A/B (MCBSP_XCERE0).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bit in MCBSP_MCR. In one of the transmit multi-channel selection modes, the channels in this partition are controlled by the enhanced transmit channel enable register partition A/B (MCBSP_XCERE0).

Table 11-1606. Receive Channel Assignment and Control When Two Receive Partitions are Used

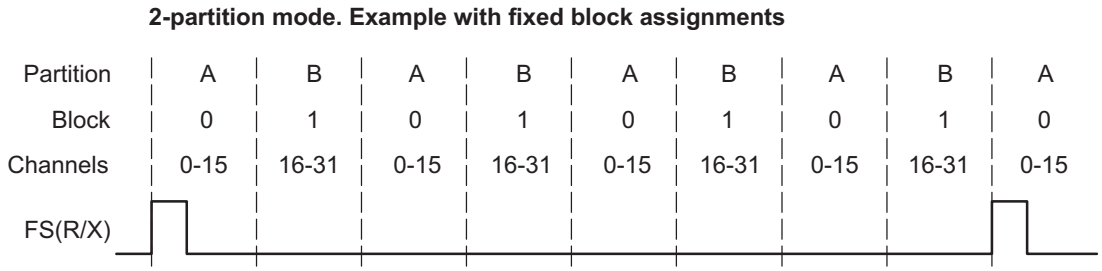
Receive Partition	Assigned Block of Receive Channels	RPABLK Bit in MCBSP_MCR	RPBBLK Bit in MCBSP_MCR	MCBSP_RCERE0 Bits
A	Block 0: channels 0 through 15	0	–	RCE0-RCE15
A	Block 2: channels 32 through 47	1h	–	RCE0-RCE15
A	Block 4: channels 64 through 79	2h	–	RCE0-RCE15
A	Block 6: channels 96 through 111	3h	–	RCE0-RCE15
B	Block 1: channels 16 through 31	–	0	RCE16-RCE31
B	Block 3: channels 48 through 63	–	1h	RCE16-RCE31
B	Block 5: channels 80 through 95	–	2h	RCE16-RCE31
B	Block 7: channels 112 through 127	–	3h	RCE16-RCE31

Table 11-1607. Transmit Channel Assignment and Control When Two Transmit Partitions are Used

Transmit Partition	Assigned Block of Transmit Channels	XPABLK Bit in MCBSP_MCR	XPBBLK Bit in MCBSP_MCR	MCBSP_XCERE0 Bits
A	Block 0: channels 0 through 15	0	–	XCE0-XCE15
A	Block 2: channels 32 through 47	1h	–	XCE0-XCE15
A	Block 4: channels 64 through 79	2h	–	XCE0-XCE15
A	Block 6: channels 96 through 111	3h	–	XCE0-XCE15
B	Block 1: channels 16 through 31	–	0	XCE16-XCE31
B	Block 3: channels 48 through 63	–	1h	XCE16-XCE31
B	Block 5: channels 80 through 95	–	2h	XCE16-XCE31
B	Block 7: channels 112 through 127	–	3h	XCE16-XCE31

Figure 11-749 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0-15 have been assigned to partition A, and channels 16-31 have been assigned to partition B. In response to a frame-sync pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 11-749. Alternating Between the Channels of Partition A and the Channels of Partition B



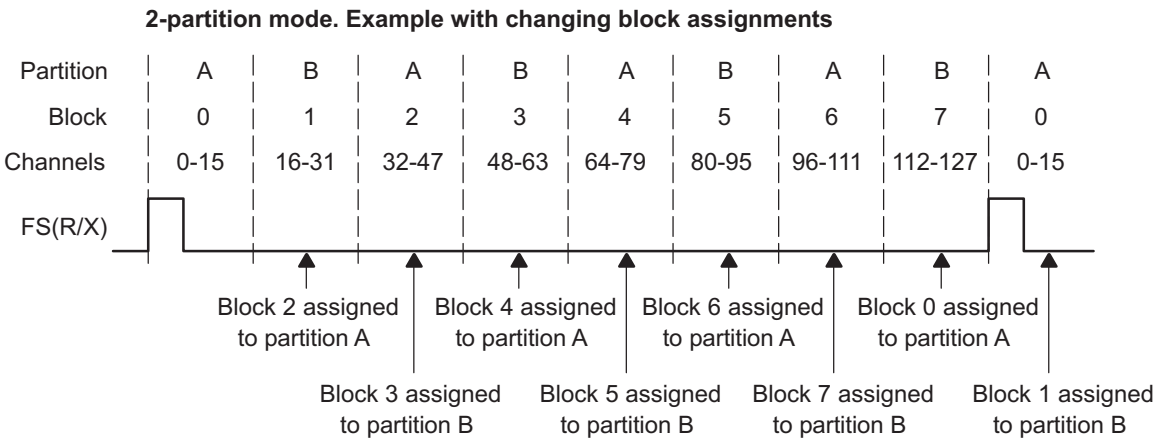
11.10.4.7.5.2 Reassigning Blocks During Reception/Transmission

To use more than 32 channels, change which channel blocks are assigned to partitions A and B during the course of a data transfer. However, these changes must be carefully timed. While a partition is being transferred, the associated block assignment bits cannot be modified, and its associated channel enable register cannot be modified. For example, if block 3 is being transferred and block 3 is assigned to partition A, (R/X)PABLK cannot be modified to assign different channels to partition A, and (R/X)CERE0 cannot be modified to change the channel configuration for partition A. Several features of the McBSP help to time the reassignment:

- The block of channels currently involved in reception/transmission (the current block) is reflected in the RCBLK/XCBLK bits. The program can poll these bits to determine which partition is active. When a partition is not active, it is safe to change its block assignment and channel configuration.
- At the end of every block (at the boundary of two partitions), an interrupt can be sent to the CPU. In response to the interrupt, the CPU can then check the RCBLK/XCBLK bits and update the inactive partition.

Figure 11-750 shows an example of reassigning channels throughout a data transfer. In response to a frame-sync pulse, the McBSP alternates between partitions A and B. Whenever partition B is active, the CPU changes the block assignment for partition A. Whenever partition A is active, the CPU changes the block assignment for partition B.

Figure 11-750. Reassigning Channel Blocks Throughout a McBSP Data Transfer



11.10.4.7.6 Using Eight Partitions

For multi-channel selection operation in the receiver and/or the transmitter, eight partitions or two partitions can be used. To choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP partitions are activated in the following order: A, B, C, D, E, F, G, H. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A. In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 11-1608 and Table 11-1609. These assignments cannot be changed. Table 11-1608 and Table 11-1609 also show the registers used to control the channels in the partitions.

Table 11-1608. Receive Channel Assignment and Control When Eight Receive Partitions are Used

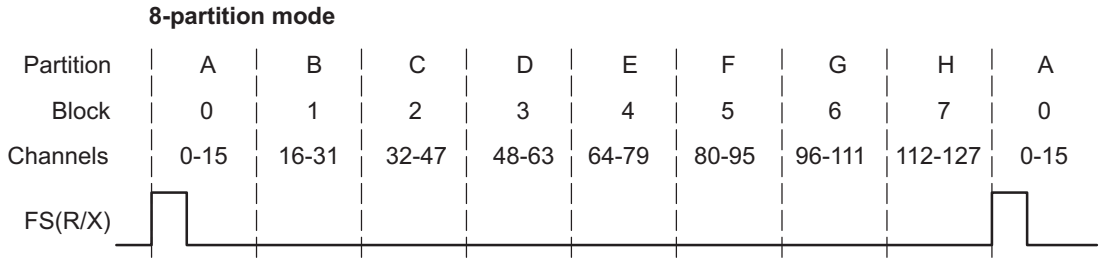
Receive Partition	Assigned Block of Receive Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	MCBSP_RCERE0
B	Block 1: channels 16 through 31	MCBSP_RCERE0
C	Block 2: channels 32 through 47	MCBSP_RCERE1
D	Block 3: channels 48 through 63	MCBSP_RCERE1
E	Block 4: channels 64 through 79	MCBSP_RCERE2
F	Block 5: channels 80 through 95	MCBSP_RCERE2
G	Block 6: channels 96 through 111	MCBSP_RCERE3
H	Block 7: channels 112 through 127	MCBSP_RCERE3

Table 11-1609. Transmit Channel Assignment and Control When Eight Transmit Partitions are Used

Transmit Partition	Assigned Block of Transmit Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	MCBSP_XCERE0
B	Block 1: channels 16 through 31	MCBSP_XCERE0
C	Block 2: channels 32 through 47	MCBSP_XCERE1
D	Block 3: channels 48 through 63	MCBSP_XCERE1
E	Block 4: channels 64 through 79	MCBSP_XCERE2
F	Block 5: channels 80 through 95	MCBSP_XCERE2
G	Block 6: channels 96 through 111	MCBSP_XCERE3
H	Block 7: channels 112 through 127	MCBSP_XCERE3

Figure 11-751 shows an example of the McBSP using the 8-partition mode. In response to a frame-sync pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 11-751. McBSP Data Transfer in the 8-Partition Mode



11.10.4.7.7 Receive Multi-channel Selection Mode

The RMCM bit in the multi-channel control register (MCBSP_MCR) determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multi-channel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate enhanced receive channel enable register (RCEREn). The way channels are assigned to the RCEREn depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit in MCBSP_MCR.
- If a receive channel is disabled, any bits received in that channel are passed only as far as the receive buffer register (RBR). The receiver does not copy the content of the RBR to the MCBSP_DRR, and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated, and if the receiver interrupt mode depends on RRDY (RINTM = 0), no interrupt is generated.

As an example of how the McBSP behaves in the receive multi-channel selection mode, enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

1. Accepts bits shifted in from the DR pin in channel 0.
2. Ignores bits received in channels 1-14.
3. Accepts bits shifted in from the DR pin in channel 15.
4. Ignores bits received in channels 16-38.
5. Accepts bits shifted in from the DR pin in channel 39.

11.10.4.7.7.1 RCEREn Registers Used in Receive Multi-channel Selection Mode

For multi-channel selection operation, the assignment of channels to the enhanced receive channel enable register (RCERE *n*) depends on whether 32 or 128 channels are individually selectable, as defined by the RMCME bit in the multi-channel control register (MCR). For each of these two cases, shows which block of channels is assigned to each RCERE *n* used. For each RCERE *n*, shows which channel is assigned to each of the bits.

Table 11-1610. Use of the Receive Channel Enable Registers

	Block Assignments		Channel Assignments	
Number of selectable channels	**RCERE n**	**Block assigned[(1)]**	**Bit in RCERE n**	**Channel assigned[(1)]**
32 (RMCME = 0)	RCERE0	Channels *n* to (*n* + 15) The block of channels (0, 2, 4, or 6) is selected with the RPABLK bit in MCR	RCE0 RCE1 ... RCE15	Channel *n* Channel (*n* + 1) ... Channel (*n* + 15)
		Channels m to (*m* + 15) The block of channels (1, 3, 5, or 7) is selected with the RPBBLK bit in MCR	RCE16 RCE17 ... RCE31	Channel *m* Channel (*m* + 1) ... Channel (*m* + 15)

(1) *n* is any even-numbered block 0, 2, 4, or 6. *m* is any odd-numbered block 1, 3, 5, or 7.

Table 11-1610. Use of the Receive Channel Enable Registers (continued)

	Block Assignments		Channel Assignments	
Number of selectable channels	**RCERE n**	**Block assigned[1]**	**Bit in RCERE n**	**Channel assigned[1]**
128 (RMCME = 1)	RCERE0	Block 0	RCE0 ... RCE15	Channel 0 ... Channel 15
		Block 1	RCE16 ... RCE31	Channel 16 ... Channel 31
	RCERE1	Block 2	RCE0 ... RCE15	Channel 32 ... Channel 47
		Block 3	RCE16 ... RCE31	Channel 48 ... Channel 63
	RCERE2	Block 4	RCE0 ... RCE15	Channel 64 ... Channel 79
		Block 5	RCE16 ... RCE31	Channel 80 ... Channel 95
	RCERE3	Block 6	RCE0 ... RCE15	Channel 96 ... Channel 111
		Block 7	RCE16 ... RCE31	Channel 112 ... Channel 127

11.10.4.7.8 Transmit Multi-channel Selection Mode

The XMCM bit in the multi-channel control register (MCBSP_MCR) determines whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP has three transmit multi-channel selection modes (XMCM = 1, XMCM = 2h, and XMCM = 3h), which are described in Table 11-1611.

Table 11-1611. Selecting a Transmit Multi-channel Selection Mode With the XMCM Bits

XMCM Bit in MCBSP_MCR	Transmit Multi-channel Selection Mode
0	No transmit multi-channel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
1h	All channels are disabled unless they are selected in the appropriate enhanced transmit channel enable register (XCERE *n*). If enabled, a channel in this mode is also unmasked.
	The XMCME bit in MCBSP_MCR determines whether 32 channels or 128 channels are selectable in XCERE *n*.
2h	All channels are enabled, but they are masked unless they are selected in the appropriate enhanced transmit channel enable register (XCERE *n*).
	The XMCME bit in MCBSP_MCR determines whether 32 channels or 128 channels are selectable in XCERE *n*.
3h	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate enhanced receive channel enable register (RCERE *n*). Once enabled, they are masked unless they are also selected in the appropriate enhanced transmit channel enable register (XCERE *n*).

Table 11-1611. Selecting a Transmit Multi-channel Selection Mode With the XMCM Bits (continued)

XMCM Bit in MCBSP_MCR	Transmit Multi-channel Selection Mode
	The XMCME bit in MCBSP_MCR determines whether 32 channels or 128 channels are selectable in RCERE *n* and XCERE *n*.

As an example of how the McBSP behaves in a transmit multi-channel selection mode, suppose that XMCM = 1 (all channels disabled unless individually enabled) and only channels 0,15, and 39 have been enabled. Suppose also that the frame length is 40. The McBSP:

1. Shifts data to the DX pin in channel 0.
2. Places the DX pin in the high-impedance state in channels 1–14.
3. Shifts data to the DX pin in channel 15.
4. Places the DX pin in the high-impedance state in channels 16–38.
5. Shifts data to the DX pin in channel 39.

11.10.4.7.8.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The following definitions explain the channel control options:

Enabled channel — A channel that can begin transmission by passing data from the data transmit register (DXR) to the transmit shift register (XSR).

Masked channel — A channel that cannot complete transmission. The DX pin is held in the high-impedance state; data cannot be shifted out on the DX pin.

In systems where symmetric transmit and receive provides software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.

Disabled channel — A channel that is not enabled. A disabled channel is also masked.

Because no DXR-to-XSR copy occurs, the XRDY bit in MCBSP_SPCR is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 0 in MCBSP_SPCR), no interrupt is generated.

The XEMPTY bit in MCBSP_SPCR is not affected.

Unmasked channel — A channel that is not masked. Data in the XSR is shifted out on the DX pin.

11.10.4.7.8.2 Activity on McBSP Pins for Different Values of XMCM

Figure 11-752 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- In transmit control register (MCBSP_XCR):
  - XPHASE = 0: Single-phase frame (required for multi-channel selection modes)
  - XFRLEN1 = 3h: 4 words per frame
  - XWDLEN1 = 0: 8 bits per word
- In multi-channel control register (MCBSP_MCR):
  - XMCME = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 3h, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In Figure 11-752, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

11.10.4.7.8.3 XCEREn Registers Used in Transmit Multi-channel Selection Mode

For multi-channel selection operation, the assignment of channels to the enhanced transmit channel enable register (XCERE *n*) depends on whether 32 or 128 channels are individually selectable, as defined by the XMCME bit in the multi-channel control register (MCR). For each of these two cases, Table 11-1612 shows which block of channels is assigned to each XCERE *n* used. For each XCERE *n*, Table 11-1612 shows which channel is assigned to each of the bits.

When XMCM = 3h (symmetric transmission and reception), the transmitter uses the enhanced receive channel enable register (RCERE *n*) to enable channels and uses XCERE *n* to unmask channels for transmission.

Table 11-1612. Use of the Transmit Channel Enable Registers

Number of selectable channels	Block Assignments		Channel Assignments	
	XCERE n	Block assigned[1]	Bit in XCERE n	Channel assigned[1]
32 (XMCME = 0)	XCERE *0*	Channels *n* to (*n* + 15)	XCE0	Channel *n*
		When XMCM = 1h or 2h, the block of channels (0, 2, 4, or 6) is selected with the XPABLK bit in MCR.	XCE1	Channel (*n* + 1)
		When XMCM = 3h, the block of channels (0, 2, 4, or 6) is selected with the RPABLK bit in MCR.	...	...
			XCE15	Channel (*n* + 15)
		Channels *m* to (*m* + 15)	XCE16	Channel *m*
		When XMCM = 1h or 2h, the block of channels (1, 3, 5, or 7) is selected with the XPBBLK bit in MCR.	XCE17	Channel (*m* + 1)
		When XMCM = 3h, the block of channels (1, 3, 5, or 7) is selected with the RPBBLK bit in MCR.	...	...
			XCE31	Channel (m + 15)

(1) *n* is any even-numbered block 0, 2, 4, or 6. *m* is any odd-numbered block 1, 3, 5, or 7.

Table 11-1612. Use of the Transmit Channel Enable Registers (continued)

Number of selectable channels	Block Assignments		Channel Assignments	
	XCERE n	Block assigned[1]	Bit in XCERE n	Channel assigned[1]
128 (XMCME = 1)	XCERE0	Block 0	XCE0 ... XCE15	Channel 0 ... Channel 15
		Block 1	XCE16 ... XCE31	Channel 16 ... Channel 31
	XCERE1	Block 2	XCE0 ... XCE15	Channel 32 ... Channel 47
		Block 3	XCE16 ... XCE31	Channel 48 ... Channel 63
	XCERE2	Block 4	XCE0 ... XCE15	Channel 64 ... Channel 79
		Block 5	XCE16 ... XCE31	Channel 80 ... Channel 95
	XCERE3	Block 6	XCE0 ... XCE15	Channel 96 ... Channel 111
		Block 7	XCE16 ... XCE31	Channel 112 ... Channel 127

11.10.4.7.9 Using Interrupts Between Block Transfers

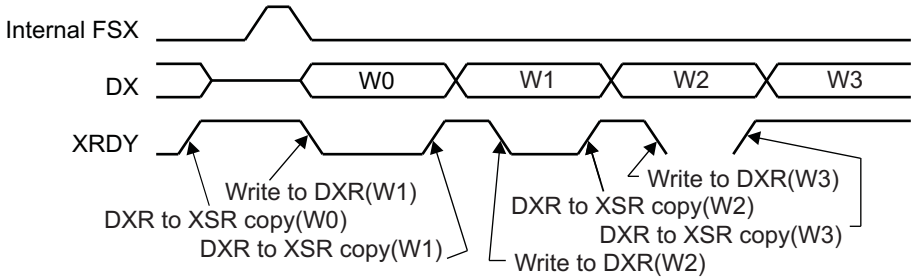
When a multi-channel selection mode is used, an interrupt request can be sent to the CPU at the end of every 16-channel block (at the boundary between partitions and at the end of the frame). In the receive multi-channel selection mode, a receive interrupt (RINT) request is generated at the end of each block transfer if the RINTM bit in the serial port control register (MCBSP_SPCR) is set to 1. In any of the transmit multi-channel selection modes, a transmit interrupt (XINT) request is generated at the end of each block transfer if the XINTM bit in MCBSP_SPCR is set to 1. When RINTM/XINTM = 1, no interrupt is generated unless a multi-channel selection mode is on.

These interrupt pulses are active high and last for two McBSP internal input clock cycles.

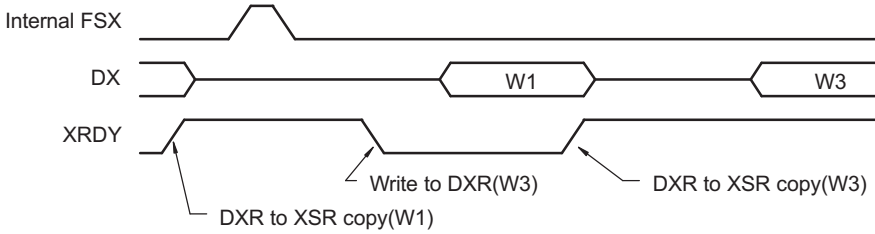
This type of interrupt is especially helpful if the two-partition mode is used and want to know when to assign a different block of channels to partition A or B.

Figure 11-752. Activity on McBSP Pins for the Possible Values of XMCM

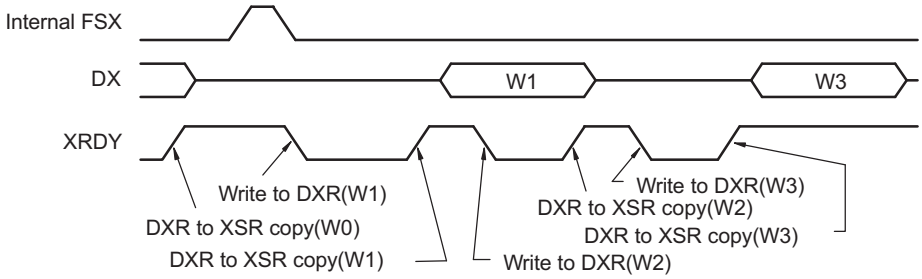
(a) XMCM = 0: All channels enabled and unmasked



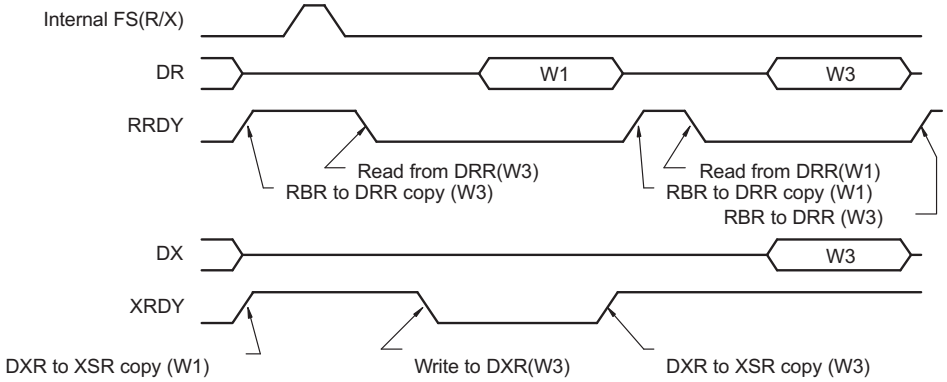
(b) XMCM = 1h, XPABLK = 0, XCERE0 = 0000 000Ah: Only channels 1 and 3 enabled and unmasked



(c) XMCM = 2h, XPABLK = 0, XCERE0 = 0000 000Ah: All channels enabled, only 1 and 3 unmasked



(d) XMCM = 3h, RPABLK = 0, XPABLK = x, RCERE0 = 0000 0008h, XCERE0 = 0000 000Ah: Receive channels: 1 and 3 enabled; transmit channels: 1 and 3 enabled, but only 3 unmasked



11.10.4.8 μ-Law/A-Law Companding Hardware Operation

Companding (compressing and expanding) hardware allows compression and expansion of data in either μ-law or A-law format. The specification for μ-law and A-law log PCM is part of the CCITT G.711 recommendation. The companding standard employed in the United States and Japan is μ-law and allows 14 bits of dynamic range. The European companding standard is A-law and allows 13 bits of dynamic range. Any values outside these ranges are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or the EDMA controller must be at least 16 bits wide.

The μ-law and A-law formats encode data into 8-bit code elements. Companded data is always 8 bits wide, so the appropriate (R/X)WDLEN1/2 must be cleared to 0, indicating an 8-bit serial data stream. If companding is enabled and either phase of the frame does not have an 8-bit element length, companding continues as if the element length is eight bits.

When companding is used, transmit data is encoded according to the specified companding law, and receive data is decoded to 2s-complement format. Companding is enabled and the desired format is selected by appropriately setting (R/X)COMPAND in the (R/X)CR. Compression occurs during the process of copying data from MCBSP_DXR to XSR and expansion occurs from RBR to MCBSP_DRR, as shown in Figure 11-753.

For transmit data to be compressed, it should be 16-bit, left-justified data, such as LAW16, as shown in Figure 11-754. The value can be either 13 or 14 bits wide, depending on the companding law. This 16-bit data is aligned in MCBSP_DXR, as shown in Figure 11-755.

For reception, the 8-bit compressed data in RBR is expanded to a left-justified 16-bit data, LAW16. This can be further justified to 32-bit data by programming the RJUST bits in the serial port control register (MCBSP_SPCR), as shown in Table 11-1613.

Figure 11-753. Companding Flow

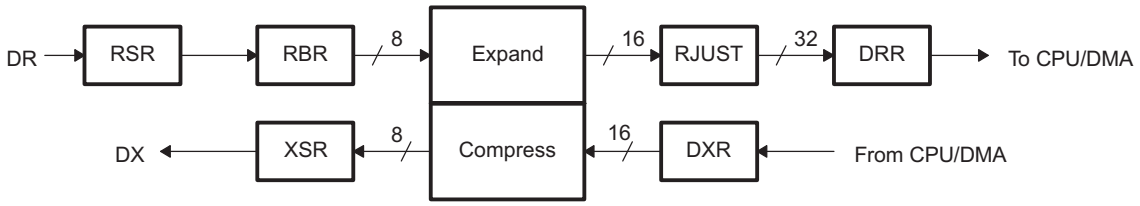


Figure 11-754. Companding Flow

LAW16	15	2	1	0
μ-Law	Value		0	0

LAW16	15	3	2	1	0
A-Law	Value		0	0	0

10	LAW16		0	
11	Reserved			

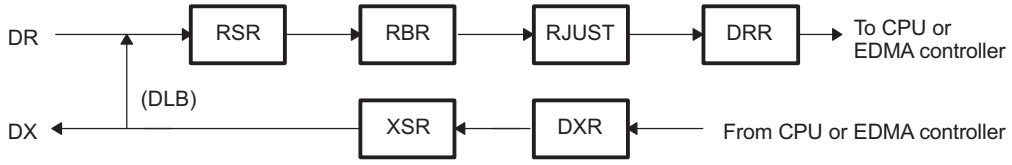
11.10.4.8.1 Companding Internal Data

If the McBSP is unused, the companding hardware can compand internal data. This hardware can be used to:

- Convert linear data to the appropriate μ-law or A-law format.
- Convert μ-law or A-law data to the linear format.
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 11-756 shows the method by which the McBSP can compand internal data. The data path is indicated by the (DLB) arrow. The McBSP is enabled in digital loopback (DLB) mode with companding appropriately enabled by the RCOMPAND and XCOMPAND bits. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or the EDMA controller to these conversions, respectively. The time for this companding depends on the serial bit rate selected.

Figure 11-756. Companding of Internal Data



11.10.4.8.2 Bit Ordering

Normally, all transfers on the McBSP are sent and received with the MSB first. However, certain 8-bit data protocols (that do not use companded data) require the LSB to be transferred first. By setting the (R/X)COMPAND = 01b in (R/X)CR, the bit ordering of 8-bit elements is reversed (LSB first) before being sent to the serial port. Like the companding feature, this feature is enabled only if the appropriate (R/X)WDLEN1/2 bit is cleared to 0, indicating that 8-bit elements are to be serially transferred. A 32-bit reversal feature is also available, as shown in Section 11.10.4.2.5.7.

11.10.4.9 Power Management

The McBSP can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device.

In order for the McBSP to be placed in power-down mode by the PSC, ensure that the XRDY and RRDY flags in the serial port control register (MCBSP_SPCR) are cleared by performing the following steps:

11.10.4.9.1 Clearing the Serial Port Control Register (MCBSP_SPCR)

1. Place the McBSP in reset by clearing the XRST, RRST, FRST, and GRST bits to 0 in MCBSP_SPCR.
   If EDMA is being used to service the transmitter and/or the receiver, disable the associated EDMA channels.
2. Switch the McBSP clocks and frames to internal clock source:
   a. Set the CLKSM and FSGM bits to 1 in the sample rate generator register (MCBSP_SRGR).
   b. Set the CLKXM, CLKRM, FSXM, and FSRM bits to 1 in the pin control register (MCBSP_PCR).
   c. Clear the SCLKME bit to 0 in MCBSP_PCR.
3. Bring the McBSP out of reset by setting the XRST, RRST, and GRST bits to 1 in MCBSP_SPCR.
4. Wait for two CLKSRG cycles for proper internal synchronization.
5. Write a dummy data value to the data transmit register (MCBSP_DXR) in order to clear the first XRDY flag.
6. Wait for at least one McBSP bit clock, since once the first dummy data value is internally copied from MCBSP_DXR to XSR, the XRDY flag transitions again from 0 to 1.
7. Write a second dummy data value to MCBSP_DXR in order to clear the second XRDY flag.
8. Check the RRDY flag in MCBSP_SPCR and if set to 1, read the data receive register (MCBSP_DRR) and discard the data to clear the RRDY flag.
9. If required, place the McBSP in power-down mode by issuing the proper PSC commands.

NOTE: After waking up the McBSP from a power-down mode using the proper PSC commands, remember to reconfigure the MCBSP_SPCR, MCBSP_SRGR, and MCBSP_PCR registers to the clock and frame combination that they were in before entering the power-down sequence and discard the two dummy data values that were used to clear the XRDY flags. If EDMA is used, re-enable the corresponding EDMA channels.

11.10.4.10 Emulation Considerations

The FREE and SOFT bits are special emulation bits in the serial port control register (MCBSP_SPCR) that determine the state of the McBSP when an emulation suspend event occurs in the emulator. An emulation suspend event corresponds to any type of emulator access to the DSP, such as a hardware or software breakpoint, a probe point, or a printf instruction.

Table 11-1614 shows the effects of the FREE and SOFT bits on the response of the McBSP to emulation suspend events.

Table 11-1614. McBSP Emulation Modes Selectable With the FREE and SOFT Bits of MCBSP_SPCR

FREE Bit in MCBSP_SPCR	SOFT Bit in MCBSP_SPCR	McBSP Emulation Mode
0	0	Immediate stop mode (reset condition). The transmitter and receiver stop immediately in response to an emulation suspend event.
0	1	Soft stop mode. When an emulation suspend event occurs, the transmitter stops after completion of the current word. The receiver is not affected.
1	0 or 1	Free run mode. The transmitter and receiver continue to run when an emulation suspend event occurs.

11.10.5 McBSP Programming Guide

This section describes the programming model of a typical McBSP module.

11.10.5.1 McBSP Initialization Procedure

The McBSP initialization procedure varies depending on the specific system setup. Section 11.10.5.1.1 provides a general initialization sequence.

The transmitter and the receiver of the McBSP can operate independently from each other. Therefore, they can be placed in or taken out of reset individually by modifying only the desired bit in the registers without disrupting the other portion. The steps in the following sections discuss the initialization procedure for taking both the transmitter and the receiver out of reset. To initialize only one portion, configure only the portion desired.

The McBSP internal sample rate generator and internal frame sync generator are shared between the transmitter and the receiver. Table 11-1615 and Table 11-1616 describe their usage based upon the clock and frame sync configurations of the receiver and transmitter, respectively.

Table 11-1615. Receiver Clock and Frame Configurations

CLKR Source	FSR Source	Comment on Configuration
Internal	Internal	The McBSP internal sample rate generator and internal frame sync generator are used by the receiver.
External	Internal	The McBSP internal sample rate generator and internal frame sync generator are used by the receiver.
Internal	External	The McBSP internal sample rate generator is used but the internal frame sync generator is not used by the receiver.
External	External	The McBSP internal sample rate generator and internal frame sync generator are not used by the receiver.

Table 11-1616. Transmitter Clock and Frame Configurations

CLKX Source	FSX Source	Comment on Configuration
Internal	Internal	The McBSP internal sample rate generator is used by the transmitter. The transmitter can generate frame sync FSX in one of two ways. First, it can generate FSX by using the internal frame sync generator (FSGM = 1). Alternatively, it can generate FSX upon each DXR-to-XSR copy (FSGM = 0). In this case, the internal frame sync generator can be kept in reset (FRST = 0) if it is not used by the receiver. The general initialization sequence can be followed in Section 11.10.5.1.1.
External	Internal	The McBSP internal sample rate generator and internal frame sync generator are not used by the transmitter. This configuration is only valid with FSGM = 0 where the McBSP transmitter generates FSX upon each DXR-to-XSR copy. The general initialization sequence can be followed in Section 11.10.5.1.1.
Internal	External	The McBSP internal sample rate generator is used by the transmitter but the internal frame sync generator is not.
External	External	The McBSP internal sample rate generator and internal frame sync generator are not used by the transmitter.

11.10.5.1.1 General Initialization Procedure

This section provides the general initialization procedure.

11.10.5.1.1.1 General Initialization

1. With the McBSP still in reset and the Power and Sleep Controller (PSC) in the default state:
   a. Program the PSC registers to put the McBSP in the enable state if required.
   b. Perform the necessary device pad multiplexing setup (see the device Data Manual).
2. Ensure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0 in MCBSP_SPCR). The respective portion of the McBSP must be in reset (XRST = 0 and/or RRST = 0 in MCBSP_SPCR).
3. Program the control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0). Also ensure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0).
4. Wait for internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in MCBSP_SRGR and the SCLKME bit in MCBSP_PCR.
5. Skip this step if the bit clock is provided by the external device. This step applies only if the McBSP is the bit clock master and the internal sample rate generator is used.
   a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit cycles for synchronization. CLKG is the output of the sample rate generator.
   b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to 1/(CLKGDV + 1) of the sample rate generator source clock CLKSRG.
6. Skip this step if the transmitter is not used. If the transmitter is used, a transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
   a. Set the XRST bit to 1 to enable the transmitter.
   b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
   c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
   a. If the EDMA is used to service the McBSP, setup data acquisition as desired and start the EDMA in this step, before the McBSP is taken out of reset.
   b. If CPU interrupt is used to service the McBSP, enable the transmit and/or receive interrupt as required.
   c. If CPU polling is used to service the McBSP, no action is required in this step.
8. Set the XRST bit and/or the RRST bit to 1 to enable the corresponding section of the McBSP. The McBSP is now ready to transmit and/or receive.
   a. If the EDMA is used to service the McBSP, it services the McBSP automatically upon receiving the XEVT and/or REVT.
   b. If CPU interrupt is used to service the McBSP, the interrupt service routine is automatically entered upon receiving the XINT and/or RINT.
   c. If CPU polling is used to service the McBSP, it can do so now by polling the XRDY and/or RRDY bit.

9. If the internal frame sync generator is used (FSGM = 1), proceed to the additional steps to turn on the internal frame sync generator. Initialization is complete if any one of the following is true:
   a. The external device generates frame sync FSX and/or FSR. The McBSP is now ready to transmit and/or receive upon receiving external frame sync.
   b. The McBSP generates transmit frame sync FSX upon each DXR-to-XSR copy. The internal frame sync generator is not used (FSGM = 0).

   The following additional steps to turn on the internal frame sync generator apply only if FSGM = 1:
10. Skip this step if the transmitter is not used. If the transmitter is used, ensure that MCBSP_DXR is serviced before the start of the internal frame sync generator. That can be done by checking XEMPTY = 1 (XSR is not empty) in MCBSP_SPCR.
11. Set the FRST bit to 1 to start the internal frame sync generator. The internal frame sync signal FSG is generated on a CLKG active edge after 7 to 8 CLKG clocks have elapsed.

11.10.5.1.2 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset (XRST = 1), it waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or EDMA controller may not have a chance to service the data transmit register (MCBSP_DXR). In this case, the transmitter shifts out the default data in the transmit shift register (XSR) instead of the desired value, which has not yet arrived in MCBSP_DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word may appear in the second channel instead of the first).

To ensure proper operation when the external device is the frame master, MCBSP_DXR must be already serviced with the first word when a frame sync occurs. To do so, keep the transmitter in reset until the first frame sync is detected. Software is set up such that it will only take the transmitter out of reset (XRST = 1) promptly after detecting the first frame sync. This assures that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the DSP to service MCBSP_DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, MCBSP_DXR is already serviced with the first word.

11.10.5.1.2.1 How to Detect First Frame Sync

Although the McBSP is capable of generating an interrupt to the CPU upon the detection of frame synchronization (XINTM = 2h and/or RINTM = 2h in the serial port control register (MCBSP_SPCR)), the McBSP requires the associated portion (receiver/transmitter) of the McBSP to be out of reset in order for the interrupt to be generated. Therefore, instead of directly using the McBSP interrupt to detect the first frame sync, use the GPIO peripheral. This can be achieved by connecting the frame sync signal to a GPIO pin. Software can either poll the GPIO pin to detect the first frame sync or program the GPIO peripheral to generate an interrupt to the CPU upon detecting the first frame sync edge.

The following are some recommended GPIO pin(s) on the device that can be used to detect the first McBSP external frame sync:

- **GPIO pin located near the McBSP pins**. Connect the external frame sync to both the McBSP FSX/FSR pin(s) and the dedicated GPIO pin.
- **GPIO pin multiplexed with the McBSP FSX signal**. Note that on the device, the GPIO pins (of the GPIO peripheral) are multiplexed with the McBSP pins. Software can program the device's pad multiplexing register (PADCONFIG) to default these pins to the GPIO function, and only switch them to the McBSP function upon detecting the first frame sync. This method is only recommended if the external device is both the frame sync and clock master; that is, the external device drives both the FSX and CLKX signals. This method is not recommended if the McBSP is the clock master (driving CLKX and/or CLKR), as the “on-the-fly” pin multiplexed switching can cause a glitch on the CLKX/CLKR pin.

11.10.5.1.2.2 Initialization Procedure When External Device is Frame Sync Master

The initialization procedure assumes the following:

- Using a GPIO pin multiplexed with the McBSP FSX signal. If a dedicated GPIO pin is used instead, skip step 1 and step 8b.
- Software polls the GPIO pin to detect the first frame sync. If the GPIO interrupt is used instead to detect the first frame sync, step 8 can be performed within an interrupt service routine (ISR).

11.10.5.1.2.2.1 Initialization When External Device is Frame Sync Master

1. The GPIO and McBSP signals are multiplexed together on the device. Start by programming the pad multiplexing register (PADCONFIG) to select the GPIO function on the GPIO/McBSP multliplexed pins. Program the GPIO peripheral so that these pins function as GPIO inputs.
2. Ensure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0 in MCBSP_SPCR). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRST = 0 in MCBSP_SPCR).
3. Program the sample rate generator register (MCBSP_SRGR) and other control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0 in MCBSP_SPCR). Also ensure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0 in MCBSP_SPCR).
4. Wait for proper McBSP internal synchronization:
   a. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. Skip step 5.
   b. If the McBSP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in MCBSP_SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit clock master and the internal sample rate generator is used.
   a. Start the sample rate generator by setting the GRST bit in MCBSP_SPCR to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
   b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to 1/(CLKGDV + 1) of the sample rate generator source clock CLKSRG.
6. A transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
   a. Set the XRST bit in MCBSP_SPCR to 1 to enable the transmitter.
   b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
   c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
   a. If the EDMA controller is used to service the McBSP, setup data acquisition as desired and start the EDMA controller in this step, before the McBSP is taken out of reset.
   b. If the CPU interrupt is used to service the McBSP, no action is required in this step.
   c. If CPU polling is used to service the McBSP, no action is required in this step.
8. Poll the GPIO pin (through reading the appropriate registers in the GPIO peripheral) to detect the first transmit frame sync from the external device. Upon detection of the first frame sync, perform the following in this order:
   a. Set the XRST bit and/or the RRST bit to 1 to enable the respective portion of the McBSP. The McBSP is now ready to transmit and/or receive.
   b. Program PADCONFIG to switch the GPIO/McBSP multiplexed pins to the McBSP function.
9. Service the McBSP:
   a. If CPU polling is used to service the McBSP in normal operations, it can do so upon exit from the

ISR.

b. If the CPU interrupt is used to service the McBSP in normal operations, upon XRDY interrupt service routine is entered. The ISR should be setup to verify that XRDY = 1 and service the McBSP accordingly.

c. If the EDMA controller is used to service the McBSP in normal operations, it services the McBSP automatically upon receiving the XEVT and/or REVT.

10. Upon detection of the second frame sync, MCBSP_DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the DSP.

11.10.5.2 Reset and Initialization Procedure for the SRG

To reset and initialize the SRG:

1. Place the MCBSP SRG in reset.
2. Program the registers that affect the SRG.
3. Enable the SRG (take it out of reset).
4. If necessary, and/or the transmitter.
5. If necessary, remove the receiver and/or transmitter from reset.

11.10.5.3 Receiver Configuration

To configure the MCBSP receiver, perform the following steps:

Step 1. Place the MCBSP receiver in reset.

Step 2. Program the MCBSP registers for the desired receiver operation.

Step 3. Take the receiver out of reset.

11.10.5.3.1 Place the Receiver in Reset (Step 1)

Table 11-1617. Receiver Reset

Step	Register/Bit Field/Programming Model
Place the receiver in reset.	MCBSP_SPCR[0] RRST

11.10.5.3.2 Programming the MCBSP Registers for the Desired Receiver Configuration (Step 2)

This section describes the steps to be performed when software configures the MCBSP receiver.

Global Configuration

Table 11-1618 describes the steps to perform the global configuration.

Table 11-1618. Global Configuration

Step	Register/Bit Field/Programming Model
Enable/disable DLB mode(1).	MCBSP_SPCR[15] DLB
Enable/disable the receive multi-channel selection Mode(1).	MCBSP_MCR[0] RMCM

(1) Software decision

NOTE: In DLB mode the SRG and frame-sync generator must be enabled to generate the CLKX and FSX signals.

Data Configuration

Table 11-1619 describes the steps to perform the data configuration.

Table 11-1619. Data Configuration

Step	Register/Bit Field/Programming Model
Select single/dual-phase frame (1).	MCBSP_RCR[31] RPHASE
Set the receive word length(s) for phase 1(1).	MCBSP_RCR[7-5] RWDLEN1
Set the receive word length(s) for phase 2(1).	MCBSP_XCR[23-21] XWDLEN2
Set the receive frame length*.	MCBSP_RCR[14-8] RFRLEN1 MCBSP_RCR[30-24] RFRLEN2
Set the receive sign-extension and justification mode(1).	MCBSP_SPCR[14-13] RJUST
Enable the serial receiver port.	MCBSP_SPCR[0] RRST

(1) Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

Frame-Sync Configuration

Table 11-1620 describes the steps to perform the frame-sync configuration.

Table 11-1620. Frame-Sync Configuration

Step	Register/Bit Field/Programming Model
Set the receive frame-sync mode(1).	MCBSP_PCR[10] FSRM
Select SRG synchronization(1).	MCBSP_SRGR[31] GSYNC
Set the receive frame-sync polarity (1).	MCBSP_PCR[2] FSRP
Set the SRG frame-sync period(1).	MCBSP_SRGR[27-16] FPER
Set the SRG frame-sync pulse width(1).	MCBSP_SRGR[15-8] FWID

11.10.6.1 MCBSP_DRR Register (Offset = 0h) [reset = 0h]

The data receive register (MCBSP_DRR) contains the value to be written to the data bus. The MCBSP_DRR is shown in Figure 11-757 and described in Table 11-1632.

Both the CPUs and the EDMA can access MCBSP_DRR in all the memory-mapped locations. An access to any EDMA bus location is equivalent to an access to MCBSP_DRR of the corresponding McBSP.

11.10.6.2 MCBSP_DXR Register (Offset = 4h) [reset = 0h]

The data transmit register (MCBSP_DXR) contains the value to be loaded into the data transmit shift register (XSR). The MCBSP_DXR is shown in Figure 11-758 and described in Table 11-1635.

MCBSP_DXR is accessible via the peripheral bus and via the EDMA bus. Both the CPUs and the EDMA can access MCBSP_DXR in all the memory-mapped locations.

11.10.6.3 MCBSP_SPCR Register (Offset = 8h) [reset = 0h]

The serial port is configured via the serial port control register (MCBSP_SPCR) and the pin control register (MCBSP_PCR). The MCBSP_SPCR contains McBSP status control bits. The MCBSP_SPCR is shown in Figure 11-759 and described in Table 11-1638.

Table 11-1638. MCBSP_SPCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
25	FREE	R/W	0h	Free-running enable mode bit. This bit is used in conjunction with SOFT bit to determine state of serial port clock during emulation halt. • 0 = Free-running mode is disabled. During emulation halt, SOFT bit determines operation of McBSP. • 1 = Free-running mode is enabled. During emulation halt, serial clocks continue to run.
24	SOFT	R/W	0h	Soft bit enable mode bit. This bit is used in conjunction with FREE bit to determine state of serial port clock during emulation halt. This bit has no effect if FREE = 1. • 0 = Soft mode is disabled. Serial port clock stops immediately during emulation halt, thus aborting any transmissions. • 1 = Soft mode is enabled. During emulation halt, serial port clock stops after completion of current transmission.
23	FRST	R/W	0h	Frame-sync generator reset bit. • 0 = Frame-synchronization logic is reset. Frame-sync signal (FSG) is not generated by the sample-rate generator. • 1 = Frame-sync signal (FSG) is generated after (FPER + 1) number of CLKG clocks; that is, all frame counters are loaded with their programmed values.
22	GRST	R/W	0h	Sample-rate generator reset bit. • 0 = Sample-rate generator is reset. • 1 = Sample-rate generator is taken out of reset. CLKG is driven as per programmed value in sample-rate generator register (MCBSP_SRGR).

Table 11-1638. MCBSP_SPCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21-20	XINTM	R/W	0h	Transmit interrupt (XINT) mode bit. • 0 = XINT is driven by XRDY (end-of-word). • 1h = Reserved • 2h = XINT is generated by a new frame synchronization. • 3h = XINT is generated by XSYNCERR.
19	XSYNCERR	R/W	0h	Transmit synchronization error bit. Writing a 1 to XSYNCERR sets the error condition when the transmitter is enabled (XRST = 1). Thus, it is used mainly for testing purposes or if this operation is desired. • 0 = No synchronization error is detected. • 1 = Synchronization error is detected.
18	XEMPTY	R	0h	Transmit shift register empty bit. • 0 = XSR is empty. • 1 = XSR is not empty.
17	XRDY	R	0h	Transmitter ready bit. • 0 = Transmitter is not ready. • 1 = Transmitter is ready for new data in MCBSP_DXR.
16	XRST	R/W	0h	Transmitter reset bit resets or enables the transmitter. • 0 = Serial port transmitter is disabled and in reset state. • 1 = Serial port transmitter is enabled.
15	DLB	R/W	0h	Digital loop back mode enable bit. • 0 = Digital loop back mode is disabled. • 1 = Digital loop back mode is enabled.
14-13	RJUST	R/W	0h	Receive sign-extension and justification mode bit. • 0 = Right-justify and zero-fill MSBs in MCBSP_DRR. • 1h = Right-justify and sign-extend MSBs in MCBSP_DRR. • 2h = Left-justify and zero-fill LSBs in MCBSP_DRR. • 3h = Reserved
12-11	CLKSTP	R	0h	Clock stop mode bit. • 0 = Clock stop mode is disabled. Normal clocking for non-SPI mode. • 1h-3h = Reserved
10-8	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
7	DXENA	R/W	0h	DX enabler bit. See Section 11.10.4.7.4 for details on the DX enabler bit. • 0 = DX enabler is off. • 1 = DX enabler is on.
6	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
5-4	RINTM	R/W	0h	Receive interrupt (RINT) mode bit. • 0 = RINT is driven by RRDY (end-of-word). • 1h = Reserved • 2h = RINT is generated by a new frame synchronization. • 3h = RINT is generated by RSYNCERR.
3	RSYNCERR	R/W	0h	Receive synchronization error bit. Writing a 1 to RSYNCERR sets the error condition when the receiver is enabled (RRST = 1). Thus, it is used mainly for testing purposes or if this operation is desired. • 0 = No synchronization error is detected. • 1 = Synchronization error is detected.
2	RFULL	R	0h	Receive shift register full bit. • 0 = RBR is not in overrun condition. • 1 = MCBSP_DRR is not read, RBR is full, and RSR is also full with new word.

Table 11-1638. MCBSP_SPCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	RRDY	R	0h	Receiver ready bit. • 0 = Receiver is not ready. • 1 = Receiver is ready with data to be read from MCBSP_DRR.
0	RRST	R/W	0h	Receiver reset bit resets or enables the receiver. • 0 = The serial port receiver is disabled and in reset state. • 1 = The serial port receiver is enabled.

Table 11-1647. MCBSP_SRGR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	GSYNC	R/W	0h	Sample-rate generator clock synchronization bit is only used when CLKS drives the sample-rate generator clock (CLKSM = 0). • 0 = The sample-rate generator clock (CLKG) is free running. • 1 = The sample-rate generator clock (CLKG) is running; however, CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period (FPER) is a don't care because the period is dictated by the external frame-sync pulse.
30	CLKSP	R/W	0h	CLKS polarity clock edge select bit is only used when CLKS drives the sample-rate generator clock (CLKSM = 0). • 0 = Rising edge of CLKS generates CLKG and FSG. • 1 = Falling edge of CLKS generates CLKG and FSG.
29	CLKSM	R/W	1h	Sample rate generator input clock mode bit. The sample rate generator can accept an input clock signal and divide it down according to CLKGDV to produce an output clock signal, CLKG. The frequency of CLKG is: *CLKG frequency = Input clock frequency/(CLKGDV + 1)* CLKSM is used in conjunction with the SCLKME bit in the pin control register (MCBSP_PCR) to determine the source for the input clock. A DSP reset selects the McBSP internal input clock as the input clock and forces the CLKG frequency to 1/2 the McBSP internal input clock frequency. • 0 = The input clock for the sample rate generator is taken from the CLKS or from the CLKR pin, depending on the value of the SCLKME bit in MCBSP_PCR • 1 = The input clock for the sample rate generator is taken from the McBSP internal input clock or from the CLKX pin, depending on the value of the SCLKME bit in MCBSP_PCR For more information about choosing an Input Clock for Sample Rate Generator with SCLKME bit see Table 11-1595.

Table 11-1647. MCBSP_SRGR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	FSGM	R/W	0h	Sample-rate generator transmit frame-synchronization mode bit is only used when FSXM = 1 in MCBSP_PCR. • 0 = Transmit frame-sync signal (FSX) is generated on every DXR-to-XSR copy. When FSGM = 0, FWID bit and FPER bit are ignored. • 1 = Transmit frame-sync signal (FSX) is driven by the sample-rate generator frame-sync signal (FSG).
27-16	FPER	R/W	0h	0-FFFh = Frame period value plus 1 specifies when the next frame-sync signal becomes active. Range is 1 to 4096 sample-rate generator clock (CLKG) periods.
15-8	FWID	R/W	0h	0-FFh = Frame width value plus 1 specifies the width of the frame-sync pulse (FSG) during its active period.
7-0	CLKGDV	R/W	1h	0-FFh = Sample-rate generator clock (CLKG) divider value is used as the divide-down number to generate the required sample-rate generator clock frequency.

11.10.6.7 MCBSP_MCR Register (Offset = 18h) [reset = 0h]

The multichannel control register (MCBSP_MCR) has control and status bits for multichannel selection operation in the receiver (with an R prefix) and the same type of bits for the transmitter (with an X prefix). The MCBSP_MCR is shown in Figure 11-763 and described in Table 11-1650. This I/O-mapped register enables you to:

- Enable all channels or only selected channels for reception (RMCM).
- Choose which channels are enabled/disabled and masked/unmasked for transmission (XMCM).
- Specify whether two partitions (32 channels at a time) or eight partitions (128 channels at a time) can be used (RMCME for reception, XMCME for transmission).
- Assign blocks of 16 channels to partitions A and B when the 2-partition mode is selected (RPABLK and RPBBLK for reception, XPABLK and XPBBLK for transmission).
- Determine which block of 16 channels is currently involved in a data transfer (RCBLK for reception, XCBLK for transmission).

Table 11-1650. MCBSP_MCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved.
25	XMCME	R/W	0h	Transmit multichannel partition mode bit. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). XMCME determines whether only 32 channels or all 128 channels are to be individually selectable. 0 = 2-partition mode. Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit. **If XMCM = 1 or 2h:** assign 16 channels to partition A with the XPABLK bit and assign 16 channels to partition B with the XPBBLK bit. **If XMCM = 3h:** (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bit and assign 16 channels to receive partition B with the RPBBLK bit. 1 = 8-partition mode. All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bit. You control the channels with the appropriate enhanced transmit channel enable register (XCEREn): MCBSP_XCERE0: Channels 0 through 31 MCBSP_XCERE1: Channels 32 through 63 MCBSP_XCERE2: Channels 64 through 95 MCBSP_XCERE3: Channels 96 through 127
24-23	XPBBLK	R/W	0h	Transmit partition B block bit. XPBBLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. The 128 transmit channels of the McBSP are divided equally among 8 blocks (0 through 7). When XPBBLK is applicable, use the XPBBLK bit to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B; use the XPABLK bit to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A. If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the transmitter is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The XCBLK bit is regularly updated to indicate which block is active. When XMCM = 3h (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK). • 0 = Block 1: channels 16 through 31 • 1h = Block 3: channels 48 through 63 • 2h = Block 5: channels 80 through 95 • 3h = Block 7: channels 112 through 127
22-21	XPABLK	R/W	0h	Transmit partition A block bit. XPABLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. See the XPBBLK bit description for more information about assigning blocks to partitions A and B. • 0 = Block 0: channels 0 through 15 • 1h = Block 2: channels 32 through 47 • 2h = Block 4: channels 64 through 79 • 3h = Block 6: channels 96 through 111

Table 11-1650. MCBSP_MCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20-18	XCBLK	R	0h	Transmit current block indicator. XCBLK indicates which block of 16 channels is involved in the current McBSP transmission. • 0 = Block 0: channels 0 through 15 • 1h = Block 1: channels 16 through 31 • 2h = Block 2: channels 32 through 47 • 3h = Block 3: channels 48 through 63 • 4h = Block 4: channels 64 through 79 • 5h = Block 5: channels 80 through 95 • 6h = Block 6: channels 96 through 111 • 7h = Block 7: channels 112 through 127
17-16	XMCM	R/W	0h	Transmit multichannel selection mode bit. XMCM determines whether all channels or only selected channels are enabled and unmasked for transmission. • 0 = Transmit multichannel selection is off. All channels are enabled and unmasked. No channels can be disabled or masked. • 1h = All channels are disabled unless they are selected in the appropriate enhanced transmit channel enable register (XCERE *n*). If enabled, a channel in this mode is also unmasked. The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERE *n*. • 2h = All channels are enabled, but they are masked unless they are selected in the appropriate enhanced transmit channel enable register (XCERE *n*). The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERE *n*. • 3h = This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate enhanced receive channel enable register (RCERE *n*). Once enabled, they are masked unless they are also selected in the appropriate enhanced transmit channel enable register (XCERE *n*). The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERE *n* and XCERE *n*.
15-10	RESERVED	R	0h	Reserved.
9	RMCME	R/W	0h	Receive multichannel partition mode bit. RMCME is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). RMCME determines whether only 32 channels or all 128 channels are to be individually selectable. 0 = 2-partition mode. Only partitions A and B are used. You can control up to 32 channels in the receive multichannel selection mode (RMCM = 1). Assign 16 channels to partition A with the RPABLK bit and assign 16 channels to partition B with the RPBBLK bit. You control the channels with the enhanced receive channel enable register partition A/B (MCBSP_RCERE0). 1 = You can control up to 128 channels in the receive multichannel selection mode. You control the channels with the appropriate enhanced receive channel enable register (RCEREn): MCBSP_RCERE0: Channels 0 through 31 MCBSP_RCERE1: Channels 32 through 63 MCBSP_RCERE2: Channels 64 through 95 MCBSP_RCERE3: Channels 96 through 127

Table 11-1650. MCBSP_MCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8-7	RPBBLK	R/W	0h	Receive partition B block bit. RPBBLK is only applicable if channels can be individually disabled/enabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver. The 128 receive channels of the McBSP are divided equally among 8 blocks (0 through 7). When RPBBLK is applicable, use the RPBBLK bit to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B; use the RPABLK bit to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A. If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the receiver is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The RCBLK bit is regularly updated to indicate which block is active. When XMCM = 3h (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK). • 0 = Block 1: channels 16 through 31 • 1h = Block 3: channels 48 through 63 • 2h = Block 5: channels 80 through 95 • 3h = Block 7: channels 112 through 127
6-5	RPABLK	R/W	0h	Receive partition A block bit. RPABLK is only applicable if channels can be individually disabled/enabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver. See the RPBBLK bit description for more information about assigning blocks to partitions A and B. • 0 = Block 0: channels 0 through 15 • 1h = Block 2: channels 32 through 47 • 2h = Block 4: channels 64 through 79 • 3h = Block 6: channels 96 through 111
4-2	RCBLK	R	0h	Receive current block indicator. RCBLK indicates which block of 16 channels is involved in the current McBSP reception. • 0 = Block 0: channels 0 through 15 • 1h = Block 1: channels 16 through 31 • 2h = Block 2: channels 32 through 47 • 3h = Block 3: channels 48 through 63 • 4h = Block 4: channels 64 through 79 • 5h = Block 5: channels 80 through 95 • 6h = Block 6: channels 96 through 111 • 7h = Block 7: channels 112 through 127
1	RESERVED	R	0h	Reserved.
0	RMCM	R/W	0h	Receive multichannel selection mode bit. RMCM determines whether all channels or only selected channels are enabled for reception. • 0 = All 128 channels are enabled. • 1 = Multichannel selection mode. Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate enhanced receive channel enable register (RCERE *n*). The way channels are assigned to RCERE *n* depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit.

11.10.6.8 MCBSP_RCERE0 Register (Offset = 1Ch) [reset = 0h]

The enhanced receive channel enable register MCBSP_RCERE0 is shown in Figure 11-764 and described in Table 11-1653. The RCERE*n* are used to enable any of 128 elements for receive. MCBSP_RCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_RCERE0-MCBSP_RCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The receive multichannel partition mode (RMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). The RMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When RMCME = 0:** Only partitions A and B are used. MCBSP_RCERE0 is used to enable any of the 32 elements for a receive. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B. The 16 channels in partition A are assigned with the RPABLK bit in MCBSP_MCR and the 16 channels in partition B are assigned with the RPBBLK bit in MCBSP_MCR.
- **When RMCME = 1:** All partitions are used. MCBSP_RCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a receive. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.7.1 shows the 128 channels in a multichannel data stream and their corresponding enable bits in RCEREn.

11.10.6.9 MCBSP_RCERE1 Register (Offset = 28h) [reset = 0h]

The enhanced receive channel enable register MCBSP_RCERE1 is shown in Figure 11-765 and described in Table 11-1656. The RCERE*n* are used to enable any of 128 elements for receive. MCBSP_RCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_RCERE0-MCBSP_RCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The receive multichannel partition mode (RMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). The RMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When RMCME = 0:** Only partitions A and B are used. MCBSP_RCERE0 is used to enable any of the 32 elements for a receive. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B. The 16 channels in partition A are assigned with the RPABLK bit in MCBSP_MCR and the 16 channels in partition B are assigned with the RPBBLK bit in MCBSP_MCR.
- **When RMCME = 1:** All partitions are used. MCBSP_RCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a receive. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.7.1 shows the 128 channels in a multichannel data stream and their corresponding enable bits in RCEREn.

0	RCE0	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE0. • 1 = Enable the channel that is mapped to RCERE0.

Table 11-1657. Register Call Summary for MCBSP_RCERE1

McBSP Functional Description • Using Eight Partitions: [0][1]
McBSP Registers • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0] • McBSP Registers: [0] • MCBSP_RCERE1 Register (Offset = 28h) [reset = 0h]: [0]

11.10.6.10 MCBSP_RCERE2 Register (Offset = 30h) [reset = 0h]

The enhanced receive channel enable register MCBSP_RCERE2 is shown in Figure 11-766 and described in Table 11-1659. The RCERE*n* are used to enable any of 128 elements for receive. MCBSP_RCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_RCERE0-MCBSP_RCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The receive multichannel partition mode (RMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). The RMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When RMCME = 0:** Only partitions A and B are used. MCBSP_RCERE0 is used to enable any of the 32 elements for a receive. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B. The 16 channels in partition A are assigned with the RPABLK bit in MCBSP_MCR and the 16 channels in partition B are assigned with the RPBBLK bit in MCBSP_MCR.
- **When RMCME = 1:** All partitions are used. MCBSP_RCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a receive. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.7.1 shows the 128 channels in a multichannel data stream and their corresponding enable bits in RCEREn.

Table 11-1660. Register Call Summary for MCBSP_RCERE2

McBSP Functional Description • Using Eight Partitions: [0][1]
McBSP Registers • MCBSP_RCERE2 Register (Offset = 30h) [reset = 0h]: [0] • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0] • McBSP Registers: [0]

11.10.6.11 MCBSP_RCERE3 Register (Offset = 38h) [reset = 0h]

The enhanced receive channel enable register MCBSP_RCERE3 is shown in Figure 11-767 and described in Table 11-1662. The RCERE*n* are used to enable any of 128 elements for receive. MCBSP_RCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_RCERE0-MCBSP_RCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The receive multichannel partition mode (RMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled for reception (RMCM = 1). The RMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When RMCME = 0:** Only partitions A and B are used. MCBSP_RCERE0 is used to enable any of the 32 elements for a receive. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B. The 16 channels in partition A are assigned with the RPABLK bit in MCBSP_MCR and the 16 channels in partition B are assigned with the RPBBLK bit in MCBSP_MCR.
- **When RMCME = 1:** All partitions are used. MCBSP_RCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a receive. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The RCE0-RCE15 bits enable elements within the 16-channel elements in partition A and the RCE16-RCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.7.1 shows the 128 channels in a multichannel data stream and their corresponding enable bits in RCEREn.

Bit	Field	Type	Reset	Description
4	RCE4	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE4. • 1 = Enable the channel that is mapped to RCERE4.
3	RCE3	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE3. • 1 = Enable the channel that is mapped to RCERE3.
2	RCE2	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE2. • 1 = Enable the channel that is mapped to RCERE2.
1	RCE1	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE1. • 1 = Enable the channel that is mapped to RCERE1.
0	RCE0	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1 in MCBSP_MCR). • 0 = Disable the channel that is mapped to RCERE0. • 1 = Enable the channel that is mapped to RCERE0.

Table 11-1663. Register Call Summary for MCBSP_RCERE3

McBSP Functional Description • Using Eight Partitions: [0][1]
McBSP Registers • MCBSP_RCERE3 Register (Offset = 38h) [reset = 0h]: [0][1] • McBSP Registers: [0] • MCBSP_RCERE0 Register (Offset = 1Ch) [reset = 0h]: [0] • MCBSP_RCERE2 Register (Offset = 30h) [reset = 0h]: [0] • MCBSP_RCERE1 Register (Offset = 28h) [reset = 0h]: [0] • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0]

11.10.6.12 MCBSP_XCERE0 Register (Offset = 20h) [reset = 0h]

The enhanced transmit channel enable register MCBSP_XCERE0 is shown in Figure 11-768 and described in Table 11-1665. The XCERE*n* are used to enable any of 128 elements for transmit. MCBSP_XCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_XCERE0-MCBSP_XCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The transmit multichannel partition mode (XMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). The XMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When XMCME = 0:** Only partitions A and B are used. MCBSP_XCERE0 is used to enable any of the 32 elements for a transmit. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit in MCBSP_MCR.
- **When XMCME = 1:** All partitions are used. MCBSP_XCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a transmit. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.8.3 shows the 128 channels in a multichannel data stream and their corresponding enable bits in XCEREn.

Bit	Field	Type	Reset	Description
19	XCE19	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE19. – 1 = Enable and unmask the channel that is mapped to XCE19. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE19. – 1 = Unmask the channel that is mapped to XCE19. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE19. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE19. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
18	XCE18	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE18. – 1 = Enable and unmask the channel that is mapped to XCE18. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE18. – 1 = Unmask the channel that is mapped to XCE18. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE18. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE18. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
17	XCE17	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE17. – 1 = Enable and unmask the channel that is mapped to XCE17. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE17. – 1 = Unmask the channel that is mapped to XCE17. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE17. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE17. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	XCE16	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE16. – 1 = Enable and unmask the channel that is mapped to XCE16. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE16. – 1 = Unmask the channel that is mapped to XCE16. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE16. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE16. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
15	XCE15	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE15. – 1 = Enable and unmask the channel that is mapped to XCE15. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE15. – 1 = Unmask the channel that is mapped to XCE15. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE15. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE15. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
14	XCE14	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE14. – 1 = Enable and unmask the channel that is mapped to XCE14. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE14. – 1 = Unmask the channel that is mapped to XCE14. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE14. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE14. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	XCE13	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE13. – 1 = Enable and unmask the channel that is mapped to XCE13. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE13. – 1 = Unmask the channel that is mapped to XCE13. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE13. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE13. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
12	XCE12	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE12. – 1 = Enable and unmask the channel that is mapped to XCE12. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE12. – 1 = Unmask the channel that is mapped to XCE12. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE12. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE12. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
11	XCE11	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE11. – 1 = Enable and unmask the channel that is mapped to XCE11. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE11. – 1 = Unmask the channel that is mapped to XCE11. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE11. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE11. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	XCE10	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE10. – 1 = Enable and unmask the channel that is mapped to XCE10. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE10. – 1 = Unmask the channel that is mapped to XCE10. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE10. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE10. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
9	XCE9	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE9. – 1 = Enable and unmask the channel that is mapped to XCE9. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE9. – 1 = Unmask the channel that is mapped to XCE9. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE9. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE9. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
8	XCE8	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE8. – 1 = Enable and unmask the channel that is mapped to XCE8. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE8. – 1 = Unmask the channel that is mapped to XCE8. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE8. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE8. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	XCE7	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE7. – 1 = Enable and unmask the channel that is mapped to XCE7. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE7. – 1 = Unmask the channel that is mapped to XCE7. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE7. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE7. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
6	XCE6	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE6. – 1 = Enable and unmask the channel that is mapped to XCE6. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE6. – 1 = Unmask the channel that is mapped to XCE6. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE6. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE6. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
5	XCE5	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE5. – 1 = Enable and unmask the channel that is mapped to XCE5. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE5. – 1 = Unmask the channel that is mapped to XCE5. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE5. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE5. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	XCE4	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE4. – 1 = Enable and unmask the channel that is mapped to XCE4. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. – 1 = Unmask the channel that is mapped to XCE4. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE4. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
3	XCE3	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE3. – 1 = Enable and unmask the channel that is mapped to XCE3. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. – 1 = Unmask the channel that is mapped to XCE3. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE3. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
2	XCE2	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE2. – 1 = Enable and unmask the channel that is mapped to XCE2. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. – 1 = Unmask the channel that is mapped to XCE2. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE2. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1665. MCBSP_XCERE0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	XCE1	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE1. – 1 = Enable and unmask the channel that is mapped to XCE1. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. – 1 = Unmask the channel that is mapped to XCE1. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE1. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
0	XCE0	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE0. – 1 = Enable and unmask the channel that is mapped to XCE0. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. – 1 = Unmask the channel that is mapped to XCE0. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE0. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1666. Register Call Summary for MCBSP_XCERE0

McBSP Functional Description • Using Eight Partitions: [0][1] • Assigning Blocks to Partitions A and B: [0][1][2]
McBSP Registers • MCBSP_XCERE0 Register (Offset = 20h) [reset = 0h]: [0][1][2][3][4] • MCBSP_XCERE1 Register (Offset = 2Ch) [reset = 0h]: [0][1][2][3] • MCBSP_XCERE2 Register (Offset = 34h) [reset = 0h]: [0][1][2][3] • MCBSP_XCERE3 Register (Offset = 3Ch) [reset = 0h]: [0][1][2][3] • McBSP Registers: [0] • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0]

11.10.6.13 MCBSP_XCERE1 Register (Offset = 2Ch) [reset = 0h]

The enhanced transmit channel enable register MCBSP_XCERE1 is shown in Figure 11-769 and described in Table 11-1668. The XCERE*n* are used to enable any of 128 elements for transmit. MCBSP_XCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_XCERE0-MCBSP_XCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The transmit multichannel partition mode (XMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). The XMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When XMCME = 0:** Only partitions A and B are used. MCBSP_XCERE0 is used to enable any of the 32 elements for a transmit. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit in MCBSP_MCR.
- **When XMCME = 1:** All partitions are used. MCBSP_XCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a transmit. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.8.3 shows the 128 channels in a multichannel data stream and their corresponding enable bits in XCEREn.

Table 11-1668. MCBSP_XCERE1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	XCE31	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE31. – 1 = Enable and unmask the channel that is mapped to XCE31. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE31. – 1 = Unmask the channel that is mapped to XCE31. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE31. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE31. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
30	XCE30	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE30. – 1 = Enable and unmask the channel that is mapped to XCE30. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE30. – 1 = Unmask the channel that is mapped to XCE30. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE30. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE30. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
29	XCE29	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE29. – 1 = Enable and unmask the channel that is mapped to XCE29. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE29. – 1 = Unmask the channel that is mapped to XCE29. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE29. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE29. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1668. MCBSP_XCERE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	XCE28	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE28. – 1 = Enable and unmask the channel that is mapped to XCE28. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE28. – 1 = Unmask the channel that is mapped to XCE28. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE28. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE28. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
27	XCE27	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE27. – 1 = Enable and unmask the channel that is mapped to XCE27. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE27. – 1 = Unmask the channel that is mapped to XCE27. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE27. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE27. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
26	XCE26	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE26. – 1 = Enable and unmask the channel that is mapped to XCE26. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE26. – 1 = Unmask the channel that is mapped to XCE26. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE26. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE26. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1668. MCBSP_XCERE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	XCE25	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE25. – 1 = Enable and unmask the channel that is mapped to XCE25. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE25. – 1 = Unmask the channel that is mapped to XCE25. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE25. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE25. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
24	XCE24	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE24. – 1 = Enable and unmask the channel that is mapped to XCE24. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE24. – 1 = Unmask the channel that is mapped to XCE24. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE24. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE24. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
23	XCE23	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE23. – 1 = Enable and unmask the channel that is mapped to XCE23. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE23. – 1 = Unmask the channel that is mapped to XCE23. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE23. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE23. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1668. MCBSP_XCERE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	XCE22	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE22. – 1 = Enable and unmask the channel that is mapped to XCE22. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE22. – 1 = Unmask the channel that is mapped to XCE22. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE22. Bit	Field	Type	Reset	Description
4	XCE4	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE4. – 1 = Enable and unmask the channel that is mapped to XCE4. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. – 1 = Unmask the channel that is mapped to XCE4. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE4. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
3	XCE3	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE3. – 1 = Enable and unmask the channel that is mapped to XCE3. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. – 1 = Unmask the channel that is mapped to XCE3. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE3. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
2	XCE2	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE2. – 1 = Enable and unmask the channel that is mapped to XCE2. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. – 1 = Unmask the channel that is mapped to XCE2. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE2. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1668. MCBSP_XCERE1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	XCE1	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE1. – 1 = Enable and unmask the channel that is mapped to XCE1. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. – 1 = Unmask the channel that is mapped to XCE1. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE1. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
0	XCE0	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE0. – 1 = Enable and unmask the channel that is mapped to XCE0. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. – 1 = Unmask the channel that is mapped to XCE0. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE0. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1669. Register Call Summary for MCBSP_XCERE1

McBSP Functional Description • Using Eight Partitions: [0][1]
McBSP Registers • MCBSP_XCERE1 Register (Offset = 2Ch) [reset = 0h]: [0] • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0] • McBSP Registers: [0]

11.10.6.14 MCBSP_XCERE2 Register (Offset = 34h) [reset = 0h]

The enhanced transmit channel enable register MCBSP_XCERE2 is shown in Figure 11-770 and described in Table 11-1671. The XCERE*n* are used to enable any of 128 elements for transmit. MCBSP_XCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_XCERE0-MCBSP_XCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The transmit multichannel partition mode (XMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). The XMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When XMCME = 0:** Only partitions A and B are used. MCBSP_XCERE0 is used to enable any of the 32 elements for a transmit. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit in MCBSP_MCR.
- **When XMCME = 1:** All partitions are used. MCBSP_XCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a transmit. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.8.3 shows the 128 channels in a multichannel data stream and their corresponding enable bits in XCEREn.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	XCE31	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE31. – 1 = Enable and unmask the channel that is mapped to XCE31. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE31. – 1 = Unmask the channel that is mapped to XCE31. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE31. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE31. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
30	XCE30	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE30. – 1 = Enable and unmask the channel that is mapped to XCE30. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE30. – 1 = Unmask the channel that is mapped to XCE30. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE30. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE30. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
29	XCE29	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE29. – 1 = Enable and unmask the channel that is mapped to XCE29. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE29. – 1 = Unmask the channel that is mapped to XCE29. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE29. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE29. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	XCE28	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE28. – 1 = Enable and unmask the channel that is mapped to XCE28. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE28. – 1 = Unmask the channel that is mapped to XCE28. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE28. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE28. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
27	XCE27	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE27. – 1 = Enable and unmask the channel that is mapped to XCE27. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE27. – 1 = Unmask the channel that is mapped to XCE27. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE27. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE27. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
26	XCE26	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE26. – 1 = Enable and unmask the channel that is mapped to XCE26. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE26. – 1 = Unmask the channel that is mapped to XCE26. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE26. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE26. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	XCE25	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE25. – 1 = Enable and unmask the channel that is mapped to XCE25. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE25. – 1 = Unmask the channel that is mapped to XCE25. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE25. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE25. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
24	XCE24	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE24. – 1 = Enable and unmask the channel that is mapped to XCE24. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE24. – 1 = Unmask the channel that is mapped to XCE24. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE24. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE24. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
23	XCE23	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE23. – 1 = Enable and unmask the channel that is mapped to XCE23. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE23. – 1 = Unmask the channel that is mapped to XCE23. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE23. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE23. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	XCE22	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE22. – 1 = Enable and unmask the channel that is mapped to XCE22. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE22. – 1 = Unmask the channel that is mapped to XCE22. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE22. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE22. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
21	XCE21	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE21. – 1 = Enable and unmask the channel that is mapped to XCE21. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE21. – 1 = Unmask the channel that is mapped to XCE21. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE21. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE21. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
20	XCE20	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE20. – 1 = Enable and unmask the channel that is mapped to XCE20. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE20. – 1 = Unmask the channel that is mapped to XCE20. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE20. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE20. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	XCE19	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE19. – 1 = Enable and unmask the channel that is mapped to XCE19. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE19. – 1 = Unmask the channel that is mapped to XCE19. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE19. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE19. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
18	XCE18	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE18. – 1 = Enable and unmask the channel that is mapped to XCE18. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE18. – 1 = Unmask the channel that is mapped to XCE18. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE18. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE18. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
17	XCE17	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE17. – 1 = Enable and unmask the channel that is mapped to XCE17. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE17. – 1 = Unmask the channel that is mapped to XCE17. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE17. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE17. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

4	XCE4	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE4. – 1 = Enable and unmask the channel that is mapped to XCE4. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. – 1 = Unmask the channel that is mapped to XCE4. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE4. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
3	XCE3	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE3. – 1 = Enable and unmask the channel that is mapped to XCE3. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. – 1 = Unmask the channel that is mapped to XCE3. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE3. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
2	XCE2	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE2. – 1 = Enable and unmask the channel that is mapped to XCE2. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. – 1 = Unmask the channel that is mapped to XCE2. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE2. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1671. MCBSP_XCERE2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	XCE1	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE1. – 1 = Enable and unmask the channel that is mapped to XCE1. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. – 1 = Unmask the channel that is mapped to XCE1. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE1. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
0	XCE0	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE0. – 1 = Enable and unmask the channel that is mapped to XCE0. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. – 1 = Unmask the channel that is mapped to XCE0. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE0. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

McBSP Functional Description • Using Eight Partitions: [0][1]
McBSP Registers • MCBSP_XCERE2 Register (Offset = 34h) [reset = 0h]: [0] • MCBSP_MCR Register (Offset = 18h) [reset = 0h]: [0] • McBSP Registers: [0]

11.10.6.15 MCBSP_XCERE3 Register (Offset = 3Ch) [reset = 0h]

The enhanced transmit channel enable register MCBSP_XCERE3 is shown in Figure 11-771 and described in Table 11-1674. The XCERE*n* are used to enable any of 128 elements for transmit. MCBSP_XCERE0 is the only register used in normal mode (up to 32 channels can be selected in partitions A and B, RMCME = XMCME = 0 in MCBSP_MCR). MCBSP_XCERE0-MCBSP_XCERE3 are used when in enhanced mode (up to 128 channels can be selected in all partitions, RMCME = XMCME = 1 in MCBSP_MCR).

The transmit multichannel partition mode (XMCME) bit in the multichannel control register (MCBSP_MCR) is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). The XMCME bit determines whether only 32 channels or all 128 channels are to be individually selectable:

- **When XMCME = 0:** Only partitions A and B are used. MCBSP_XCERE0 is used to enable any of the 32 elements for a transmit. Of the 32 elements, 16 channels belong to a subframe in partition A and 16 channels belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bit in MCBSP_MCR.
- **When XMCME = 1:** All partitions are used. MCBSP_XCERE0 is used to enable any of the 32 elements in channels 0 through 31 for a transmit. Of the 32 elements, channels 0 to 15 belong to a subframe in partition A and channels 16 to 31 belong to a subframe in partition B. The XCE0-XCE15 bits enable elements within the 16-channel elements in partition A and the XCE16-XCE31 bits enable elements within the 16-channel elements in partition B.

Section 11.10.4.7.8.3 shows the 128 channels in a multichannel data stream and their corresponding enable bits in XCEREn.

Bit	Field	Type	Reset	Description
10	XCE10	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE10. – 1 = Enable and unmask the channel that is mapped to XCE10. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE10. – 1 = Unmask the channel that is mapped to XCE10. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE10. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE10. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
9	XCE9	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE9. – 1 = Enable and unmask the channel that is mapped to XCE9. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE9. – 1 = Unmask the channel that is mapped to XCE9. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE9. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE9. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
8	XCE8	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE8. – 1 = Enable and unmask the channel that is mapped to XCE8. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE8. – 1 = Unmask the channel that is mapped to XCE8. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE8. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE8. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1674. MCBSP_XCERE3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	XCE7	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE7. – 1 = Enable and unmask the channel that is mapped to XCE7. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE7. – 1 = Unmask the channel that is mapped to XCE7. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE7. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE7. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
6	XCE6	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE6. – 1 = Enable and unmask the channel that is mapped to XCE6. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE6. – 1 = Unmask the channel that is mapped to XCE6. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE6. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE6. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
5	XCE5	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE5. – 1 = Enable and unmask the channel that is mapped to XCE5. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE5. – 1 = Unmask the channel that is mapped to XCE5. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE5. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE5. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1674. MCBSP_XCERE3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	XCE4	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE4. – 1 = Enable and unmask the channel that is mapped to XCE4. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. – 1 = Unmask the channel that is mapped to XCE4. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE4. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE4. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
3	XCE3	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE3. – 1 = Enable and unmask the channel that is mapped to XCE3. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. – 1 = Unmask the channel that is mapped to XCE3. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE3. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE3. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
2	XCE2	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE2. – 1 = Enable and unmask the channel that is mapped to XCE2. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. – 1 = Unmask the channel that is mapped to XCE2. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE2. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE2. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1674. MCBSP_XCERE3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	XCE1	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE1. – 1 = Enable and unmask the channel that is mapped to XCE1. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. – 1 = Unmask the channel that is mapped to XCE1. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE1. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE1. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.
0	XCE0	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel mode is selected with the XMCM bit in MCBSP_MCR • **When XMCM = 1h (all channels disabled unless selected):** – 0 = Disable and mask the channel that is mapped to XCE0. – 1 = Enable and unmask the channel that is mapped to XCE0. • **When XMCM = 2h (all channels enabled but masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. – 1 = Unmask the channel that is mapped to XCE0. • **When XMCM = 3h (all channels masked unless selected):** – 0 = Mask the channel that is mapped to XCE0. Even if this channel is enabled by the corresponding enhanced receive channel enable bit, this channel's data cannot appear on the DX pin. – 1 = Unmask the channel that is mapped to XCE0. Even if this channel is also enabled by the corresponding enhanced receive channel enable bit, full transmission can occur.

Table 11-1677. MCBSP_PCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. If writing to bit [12] and bit [13] in this field, always write the default value of 0 to ensure proper McBSP operation.
11	FSXM	R/W	0h	Transmit frame-synchronization mode bit. • 0 = Frame-synchronization signal is derived from an external source. • 1 = Frame-synchronization signal is determined by FSGM bit in MCBSP_SRGR.
10	FSRM	R/W	0h	Receive frame-synchronization mode bit. • 0 = Frame-synchronization signal is derived from an external source. FSR is an input pin. • 1 = Frame-synchronization signal is generated internally by the sample-rate generator. FSR is an output pin.
9	CLKXM	R/W	0h	Transmit clock mode bit. When CLKSTP bit in MCBSP_SPCR is cleared to 0: • 0 = CLKX is an input pin and is driven by an external clock. • 1 = CLKX is an output pin and is driven by the internal sample-rate generator.
8	CLKRM	R/W	0h	Receive clock mode bit. • **Digital loop back mode is disabled (DLB = 0 in MCBSP_SPCR):** – 0 = CLKR is an input pin and is driven by an external clock. – 1 = CLKR is an output pin and is driven by the internal sample-rate generator. • **Digital loop back mode is enabled (DLB = 1 in MCBSP_SPCR):** – 0 = Receive clock (not the CLKR pin) is driven by transmit clock (CLKX) that is based on CLKXM bit. CLKR pin is in high-impedance state. – 1 = CLKR is an output pin and is driven by the transmit clock. The transmit clock is based on CLKXM bit.

Table 11-1677. MCBSP_PCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	SCLKME	R/W	0h	Sample rate generator input clock mode bit. The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is: *CLKG frequency = Input clock frequency/(CLKGDV + 1)* SCLKME is used in conjunction with the CLKSM bit in the sample rate generator register (MCBSP_SRGR) to select the input clock. A DSP reset selects the McBSP internal input clock as the input clock and forces the CLKG frequency to 1/2 the McBSP internal input clock frequency. 0 = The input clock for the sample rate generator is taken from the CLKS or from the McBSP internal input clock, depending on the value of the CLKSM bit in MCBSP_SRGR 1 = The input clock for the sample rate generator is taken from the CLKR pin or from the CLKX pin, depending on the value of the CLKSM bit in MCBSP_SRGR For more information about choosing an Input Clock for Sample Rate Generator with CLKSM bit see Table 11-1595.
6-4	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. If writing to bit [6] in this field, always write the default value of 0 to ensure proper McBSP operation.
3	FSXP	R/W	0h	Transmit frame-synchronization polarity bit. • 0 = Transmit frame-synchronization pulse is active high. • 1 = Transmit frame-synchronization pulse is active low.
2	FSRP	R/W	0h	Receive frame-synchronization polarity bit. • 0 = Receive frame-synchronization pulse is active high. • 1 = Receive frame-synchronization pulse is active low.
1	CLKXP	R/W	0h	Transmit clock polarity bit. • 0 = Transmit data driven on rising edge of CLKX. • 1 = Transmit data driven on falling edge of CLKX.
0	CLKRP	R/W	0h	Receive clock polarity bit. • 0 = Receive data sampled on falling edge of CLKR. • 1 = Receive data sampled on rising edge of CLKR.

11.11 Media Local Bus (MLB)

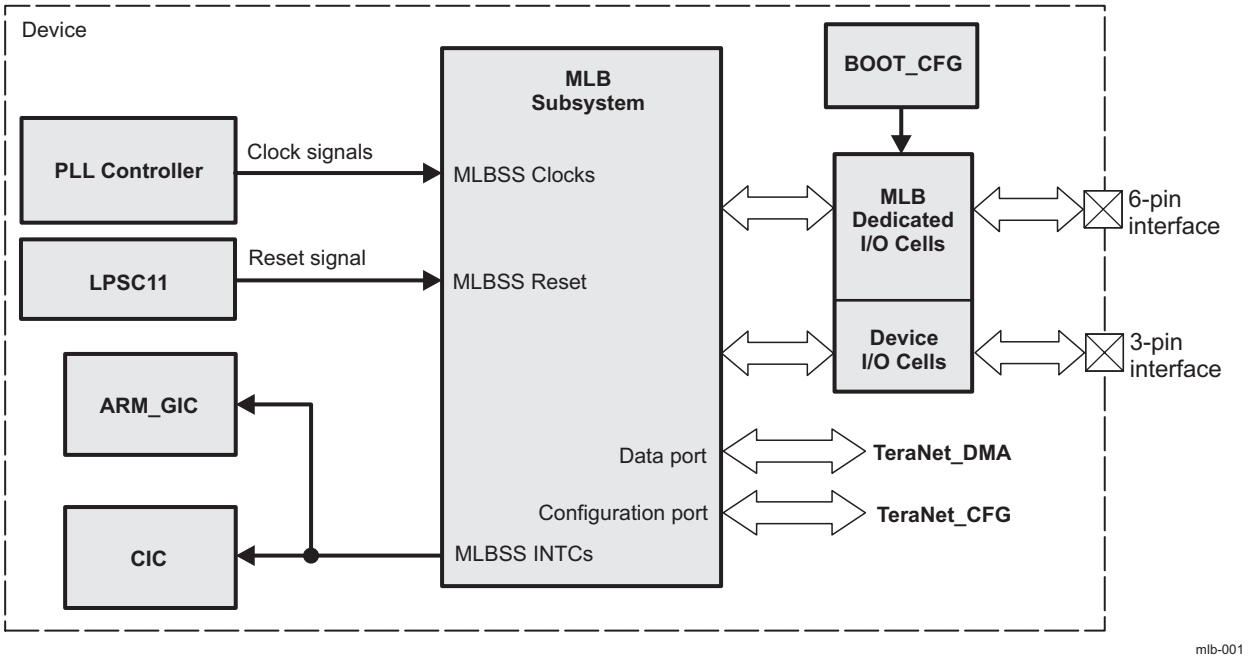
This chapter describes the function, operation, and configuration of the Media Local Bus (MLB) subsystem in the device.

11.11.1 MLB Overview

The Media Local Bus subsystem (MLBSS) is based on a module designed by SMSC. This module provides a MediaLB/MediaLB+ controller and an interface to other MediaLB/MediaLB+ devices. The MediaLB/MediaLB+ interface allows also connection to a MOST (Media Oriented Systems Transport) network controller.

Figure 11-778 shows the MLBSS overview.

Figure 11-778. MLB Overview



11.11.1.1 MLB Features

The MLBSS supports the following features:

- 3-pin MediaLB 3.3V LVCMOS I/Os compliant to MediaLB Physical Layer and Link Layer Specification v4.2
- 6-pin MediaLB+ low-voltage differential signaling (LVDS) I/Os (3 differential pairs) compliant to MediaLB Physical Layer and Link Layer Specification v4.2
- MediaLB core functionality compliant to MediaLB Physical Layer and Link Layer Specification v4.2
- Supports 256/512/1024Fs in 3-pin mode and 2048Fs in 6-pin mode
- Supports all types of transfer (synchronous stream data, asynchronous packet data, control message data, and isochronous data) over 64 logical channels
- Supports single 32-bit TeraNet_CFG slave interface for configuration
- Supports single 32-bit TeraNet_DMA master interface with burst capability for DMA transfers into system memory. The maximum burst size is 32 Bytes
- Has 16 KB buffer for all types of transfers in the subsystem
- Dedicated BOOT_CFG bits for controlling the MLBSS priority on the system interconnect

The MLBSS does not support:

- 5-pin mode

- Digital Transmission Content Protection (DTCP) cipher accelerators

11.11.2 MLB Environment

Figure 11-779 shows the MLBSS associated signals available on device pads.

Figure 11-779. MLB Subsystem Environment

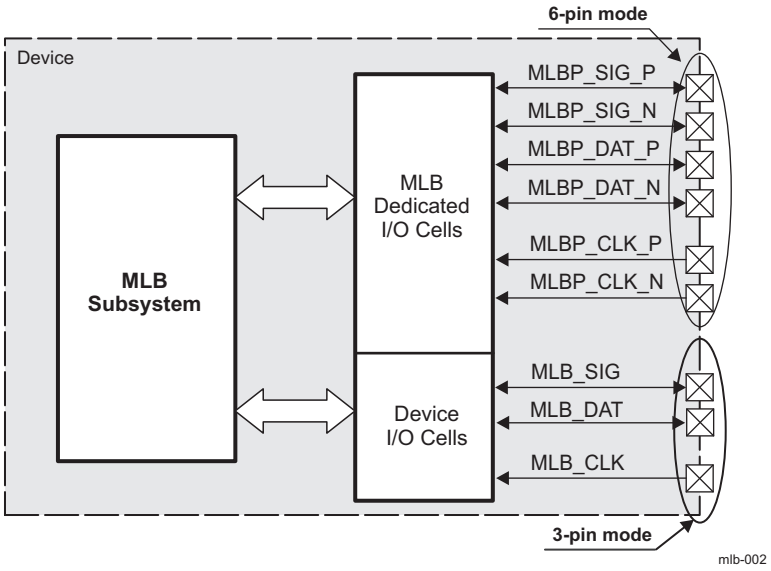


Table 11-1694 describes the MLBSS I/O signals used in both 3-pin and 6-pin modes.

Table 11-1694. MLB Subsystem I/O Description

Signal/Pad Name	I/O[1]	Description
	6-pin mode	
MLBP_SIG_P	I/O	Differential pair signal line
MLBP_SIG_N	I/O	
MLBP_DAT_P	I/O	Differential pair data line
MLBP_DAT_N	I/O	
MLBP_CLK_P	I	Differential pair clock line
MLBP_CLK_N	I	
	3-pin mode	
MLB_SIG	I/O	Single ended signal line
MLB_DAT	I/O	Single ended data line
MLB_CLK	I	Single ended clock line

(1) I = Input; O = Output; I/O = Bidirectional

11.11.2.1 MLB I/O Cell Controls

NOTE: There are two I/O cells specially intended for MLB when 6-pin mode is selected. For more information about MLB I/O cell controls see Section 5.1.3.1.11, *Registers for Control of the MLB IOs*, in Section 5.1, *Control Module (BOOT_CFG)*.

11.11.3 MLB Integration

Figure 11-780 shows the integration of the MLB subsystem in the device.

Figure 11-780. MLB Subsystem Integration

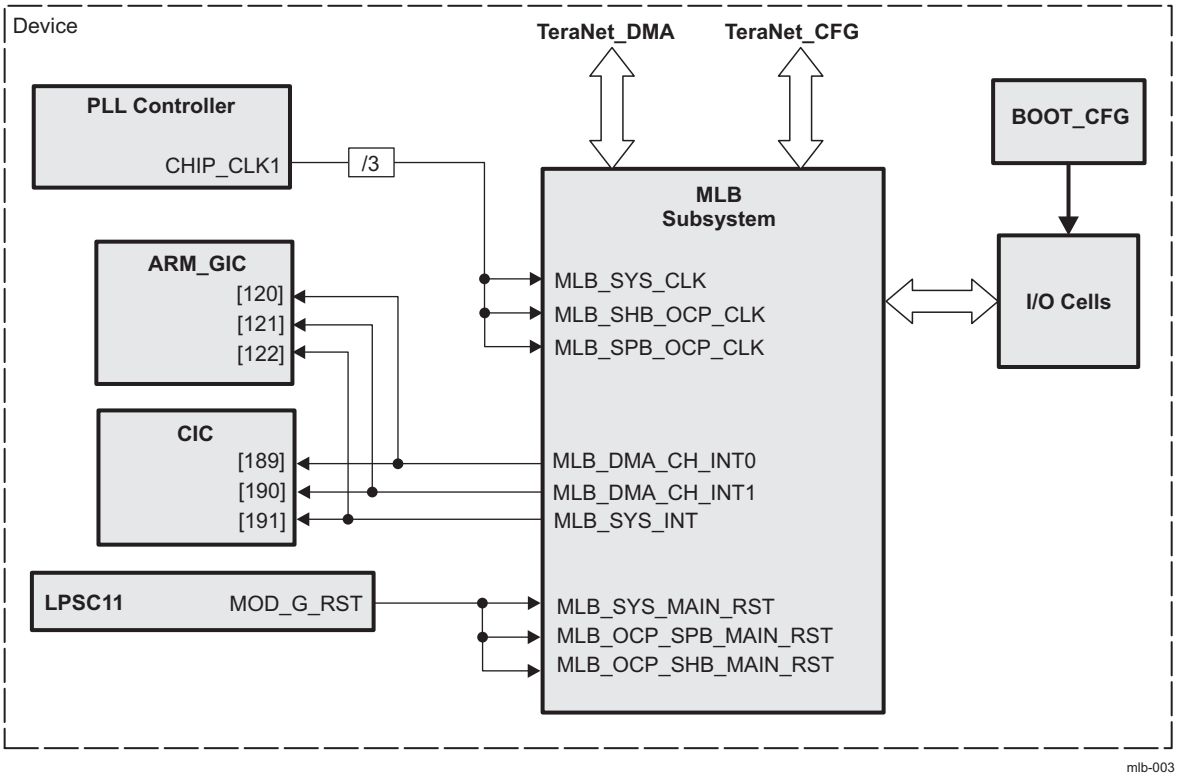

Table 11-1695 through Table 11-1697 summarize the integration of the MLB subsystem in the device.

Table 11-1695. MLB Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect

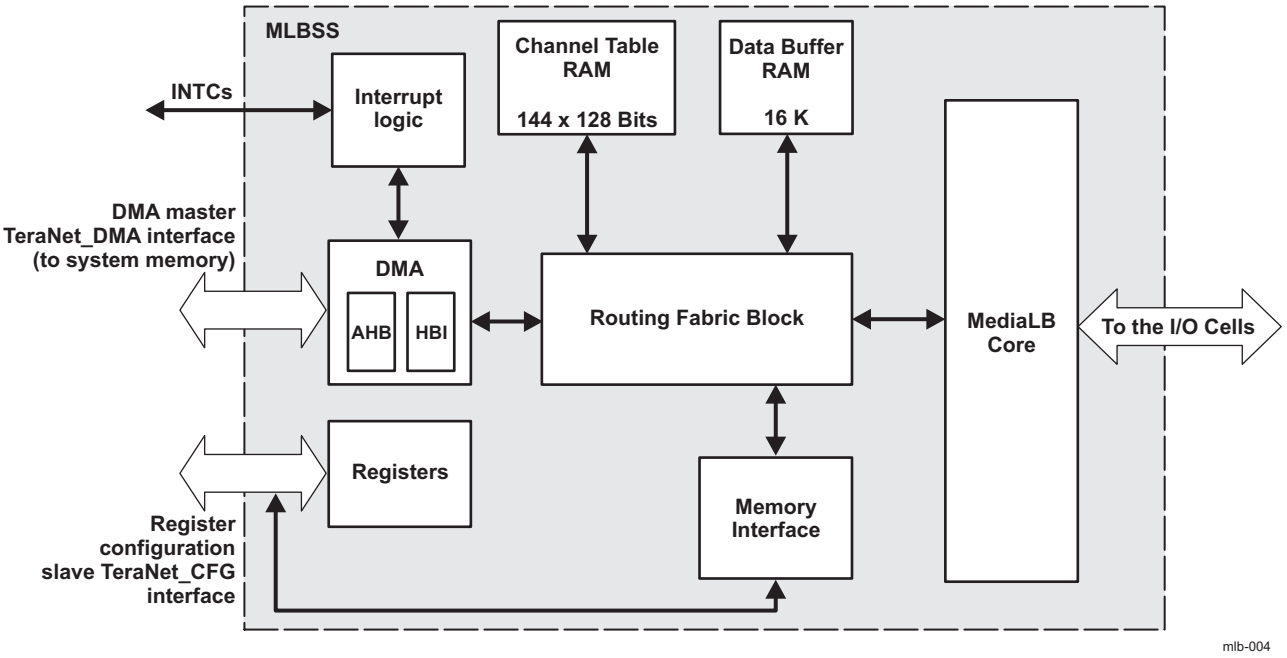
11.11.4 MLB Functional Description

11.11.4.1 Block Diagram

Figure 11-781 shows the MLBSS block diagram. It includes the following functional blocks:

- MediaLB core – Implements the physical and link layer requirements of either a 3-pin or the 6-pin interface. Serial-to-parallel/parallel-to-serial are also implemented along with MediaLB frame synchronization.
- Routing fabric block – Manages the flow of data between the MediaLB core and the DMA block, implementing bus arbiter and muxing logic to the channel table RAM and the data buffer RAM.
- Channel table RAM (CTR) – Used for storing channel descriptors for managing accesses to dynamic buffers in the data buffer RAM.
- Data buffer RAM (DBR) – Provides dynamic circular buffering between the transmit and receive devices.
- Memory interface – Implements a bridge between the configuration TeraNet_CFG slave interface and the channel table RAM or data buffer RAM interfaces.
- DMA – Implements a bus bridge between the DMA master and the routing fabric block.
- Registers – Used for configuration.
- Interrupt logic.

Figure 11-781. MLBSS Structural Overview



AHB - Advanced High-performance Bus

HBI - Host Bus Interface

11.11.4.1.1 MediaLB Core Block

Although the MediaLB block supports both a MediaLB 3-pin and 6-pin interface, only one of these interfaces is active at any given time. The selection is done through the MLB_MLBC0[5] MLBPEN bit. Table 11-1694 describes the signals associated with 3-pin and 6-pin modes. Both MediaLB interfaces provide real-time access to all network data types including streaming, packet, control, and isochronous data.

The MediaLB 3-pin interface supports the MediaLB protocol for single-ended 3-pin mode with a maximum data rate of 1024Fs.

The MediaLB 6-pin interface supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data rate of 2048Fs.

There is a set of physical channels implemented for exchanging data over the MediaLB 3-pin or 6-pin interface. These physical channels (called quadlets) are 4-byte wide and can also be grouped together to form logical channels. These logical channels are referenced using channel addresses, and define a uni-directional path between a specific MediaLB device transmitting data and another specific MediaLB device receiving data. In other words, the logical channel is a group of multiple quadlets, which selects a unique pair of MediaLB devices with a unique channel address. The logical channels, configured by the system software can be of any combination of channel types (synchronous, asynchronous, control, or isochronous) and direction (transmit/receive).

The MediaLB channel addresses are mapped to the logical channels as shown in Table 11-1698.

Table 11-1698. MediaLB Channel Address to Logical Channel Mapping

MediaLB Channel Address	Logical Channel Number
02h	1
04h	2
06h	3
…	…
007Ch	62
007Eh	63
01FEh	0 (1)

(1) The logical channel 0 is the system channel and is reserved.

Thus, 64 logical channels can be supported and one of them is the system channel which is reserved.

NOTE: The MediaLB channel address should always be an even number.

11.11.4.1.2 Routing Fabric Block

The routing fabric block manages the flow of data between the MediaLB core and the DMA block. Bus multiplexers and a bus arbiter are implemented in the routing fabric block for accessing the channel table RAM and data buffer RAM. Each DMA controller in the routing fabric uses channel descriptors to manage access to dynamic buffers in the data buffer RAM. These channel descriptors are stored in the channel table RAM.

11.11.4.1.3 Data Buffer RAM

The data buffer RAM is 8-bit × 16k entries deep and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the channel descriptor table, which is located in the channel table RAM.

The DMA controllers in the routing fabric are responsible for ensuring that the circular buffers do not overflow or underflow. Each channel type (that is, synchronous, isochronous, asynchronous and control) has full and empty detection.

11.11.4.1.4 Channel Table RAM

The channel table RAM is 128-bit × 144-entry (max). It allows system software to dynamically configure channel routing and allocate data buffers in the data buffer RAM.

The channel table RAM is logically divided into three subtables:

- Channel descriptor table
- DMA descriptor table
- Channel allocation table

The details of the channel descriptor table and channel allocation table are described in Table 11-1699.

The details of the DMA descriptor table are described in Table 11-1709.

Table 11-1699. Channel Table RAM Address Mapping

Label	Address	Bits 127-96	Bits 95-64	Bits 63-32	Bits 31-0
Channel Descriptor Table (CDT):					
Channel descriptor table	00h	CDT0[127-0], CL = 0			
	01h	CDT1[127-0], CL = 1			
	02h	CDT2[127-0], CL = 2			
	…	…			
	3Dh	CDT61[127-0], CL = 61			
	3Eh	CDT62[127-0], CL = 62			
	3Fh	CDT63[127-0], CL = 63			
DMA Descriptor Table (DDT):					
DMA descriptor table	40h	DDT0[127-0], CAT64			
	41h	DDT1[127-0], CAT65			
	42h	DDT2[127-0], CAT66			
	…	…			
	7Dh	DDT61[127-0], CAT125			
	7Eh	DDT62[127-0], CAT126			
	7Fh	DDT63[127-0], CAT127			
Channel Allocation Table (CAT):					
Channel allocation table for MediaLB	80h	CAT7	CAT6	CAT5	CAT4	CAT3	CAT2	CAT1	CAT0
	...	...	...	...	...	...	...	...	...
	87h	CAT63	CAT62	CAT61	CAT60	CAT59	CAT58	CAT57	CAT56
Channel allocation table for DMA	88h	CAT71	CAT70	CAT69	CAT68	CAT67	CAT66	CAT65	CAT64
	...	...	...	...	...	...	...	...	...
	8Fh	CAT127	CAT126	CAT125	CAT124	CAT123	CAT122	CAT121	CAT120

NOTE: A fixed relationship between DMA descriptor table entries and DMA channel allocation table entries exists. When using DMA channel 0 (CAT64) software should program DDT0. When using DMA channel 1 (CAT65) software should program DDT1, in case of CAT66 DDT2 should be programmed and so on. In case of CAT127 software should program DDT63.

The following base addresses are valid:

- Channel descriptor table has base address 00h
- DMA descriptor table has base address 40h
- Channel allocation table for MediaLB has base address 80h
- Channel allocation table for DMA has base address 88h

11.11.4.1.4.1 Channel Allocation Table

The channel allocation table comprises 16 entries of the channel table RAM. Each entry is 16-bit. The first entry starts at address 80h and the sixteenth entry at address 8Fh. Each 16-bit channel allocation table entry represents a logical connection to or from a transmit/receive device (that is, MediaLB or DMA channel). All entries are indexed according to a fixed physical address assigned to every Rx/Tx channel. This is shown in Table 11-1700. The value stored in a channel allocation table entry includes a 6-bit connection label (CL[5-0]), which provides a pointer to the channel descriptor table. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the Rx and Tx channels.

Table 11-1700. Channel Allocation Table Entry Map

Peripheral	Number of Tx Channels Allowed	Number of Rx Channels Allowed	Channel Allocation Table Start Index	Channel Allocation Table End Index	Entries
MediaLB	0 to 64	64 - (Number of Tx channels)	0	63	64
DMA	0 to 64	64 - (Number of Tx channels)	64	127	64

The format of a full channel allocation table entry is shown in Table 11-1701. All reserved bits should be written to zero.

Table 11-1701. Format Of Channel Allocation Table Entry

Channel Type	15	14	13	12	11	10 8	7 6	5 0
Isochronous	Reserved	FCE	Reserved	RNW	CE	CT[2-0] = 3	Reserved	CL[5-0]
Asynchronous	Reserved		MT	RNW	CE	CT[2-0] = 2	Reserved	CL[5-0]
Control	Reserved		MT	RNW	CE	CT[2-0] = 1	Reserved	CL[5-0]
Synchronous	Reserved	MFE	MT	RNW	CE	CT[2-0] = 0	Reserved	CL[5-0]

The field descriptions of a channel allocation table entry are shown in Table 11-1702.

Table 11-1702. Field Descriptions Of Channel Allocation Table Entry

Field	Description
CL[5-0]	Connection Label (offset into channel descriptor table)
CT[2-0]	Channel type
	111 = Reserved
	110 = Reserved
	101 = Reserved
	100 = Reserved
	011 = Isochronous
	010 = Asynchronous
	001 = Control
	000 = Synchronous
CE	Channel enable
	0 = Disabled
	1= Enabled
RNW	Read, not Write (1)
	1 = Read
	0 = Write
MT	Mute Bit (2)
	1= Enabled
	0 = Disabled
FCE	Flow control enable (3)
	1 = Enabled
	0 = Disabled

(1) For a Tx channel (from the host to the MediaLB interface):
- DMA channel allocation table entry: RNW = 0 (write)
- MediaLB channel allocation table entry: RNW = 1 (read)

For a Rx channel (data from MediaLB to host):
- DMA channel allocation table entry: RNW = 1 (read)
- MediaLB channel allocation table entry: RNW = 0 (write)

(2) When set for synchronous channels, the MT bit forces Rx channels to write zeros into the channel data buffer, and Tx channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.

(3) The FCE bit is used by MediaLB isochronous Rx channels only.

Table 11-1702. Field Descriptions Of Channel Allocation Table Entry (continued)

Field	Description
MFE	Multi-frame per sub-buffer enable [4]
	1 = Enabled
	0 = Disabled
Reserved	Reserved. Software writes zeros to all reserved bits when the entry is initialized. The reserved bits are read-only after initialization.

[4] The MFE bit is used by MediaLB synchronous channels only.

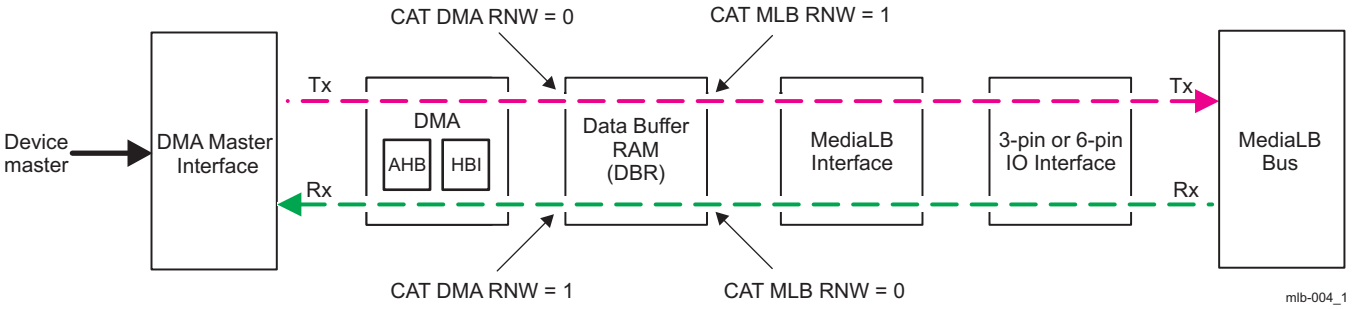
11.11.4.1.4.1.1 Channel Setup

Data direction in the MLBSS is in reference to the DBR; therefore, the data direction of DMA entries corresponding to the same channel is reversed for the CAT DMA and the CAT MLB.

- For a Tx channel (from Device master to the MediaLB interface):
  - CAT DMA entry: RNW = 0 (write)
  - CAT MLB entry: RNW = 1 (read)
- Conversely, for a Rx channel (data from MediaLB to Device master):
  - CAT DMA entry: RNW = 1 (read)
  - CAT MLB entry: RNW = 0 (write)

Figure 11-782 illustrates the directional relationship in the MLBSS.

Figure 11-782. MLBSS DBR Directional Relationship



11.11.4.1.4.2 Channel Descriptor Table

The channel descriptor table comprises 64 channel table RAM entries. Each entry is 128-bit. The first entry starts at address 00h and the 64th entry at address 3Fh. Each 128-bit entry of the channel descriptor table is referenced by a connection label and contains information about data buffer in the data buffer RAM (that is, buffer size, or address pointers). The format of each channel descriptor table entry depends on the channel type (synchronous, isochronous, asynchronous, or control).

Software must write all reserved channel descriptor bits to ’0’ when the entry is initialized.

Synchronous Channel Descriptor Table

The MLBSS provides two modes of operation (standard and multi-frame per sub-buffer) to provide flexibility for implementing synchronous channels.

Channels set up for standard mode require less buffer space. For channels configured for standard mode, the host controller must transfer one full frame of streaming data in/out of the data buffer of each streaming channel.

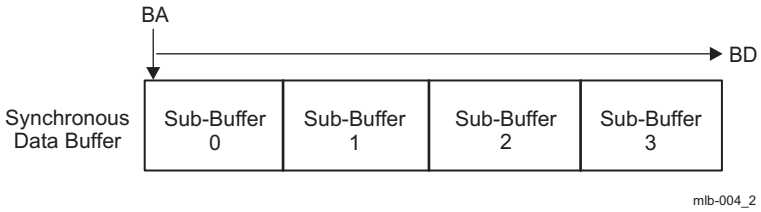
Channels set up for multiple-frames per sub-buffer mode require more buffer space. For channels configured for multiple-frames per sub-buffer mode, the host controller must transfer N full frames of streaming data in/out of the data buffer of each streaming channel.

To set up a channel in multi-frame per sub-buffer mode:

- Program the MLB_MLBC0[17-15] FCNT bit field to select the number of frames per sub-buffer
- Program the channel allocation table to enable multi-frame sub-buffering (MFE = 1) for each particular channel
- Set the buffer depth (BD[11-0]) in the channel descriptor table
- Repeat for additional synchronous channels

A sample synchronous data buffer is shown in Figure 11-783. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by MLB_MLBC0[17-15] FCNT bit field.

Figure 11-783. Synchronous Data Buffer Structure



The format of a synchronous channel descriptor table entry is shown in Table 11-1703. All reserved bits should be written to zero.

Table 11-1703. Format Of Synchronous Channel Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	WSBC[1-0]		Reserved													
16	RSBC[1-0]		Reserved													
32	Reserved															
48	Reserved															
64	WSTS[3-0]				WPTR[11-0]											
80	RSTS[3-0]				RPTR[11-0]											
96	Reserved				BD[11-0]											
112	Reserved		BA[13-0]													

The field descriptions of a synchronous channel descriptor table entry are shown in Table 11-1704.

Table 11-1704. Field Descriptions Of Synchronous Channel Descriptor Table Entry

Field	Description	Details	Accessibility (1)
BA	Buffer base address	BA can start at any byte in the 16k data buffer RAM	r, w
BD	Buffer depth	1. BD = size of buffer in bytes - 1 2. Buffer end address = BA + BD 3. BD = 4 × m × bpf - 1, where: m = frames per sub-buffer (for MFE = 0, m = 1) bpf = bytes per frame	r, w
RPTR	Read pointer	1. Software initializes to zero, hardware updates 2. Counts the read address offset within a buffer 3. DMA read address = BA + RPTR	r, w, u
WPTR	Write pointer	1. Software initializes to zero, hardware updates 2. Counts the write address offset within a buffer 3. DMA write address = BA + WPTR	r, w, u

(1)

- r - software readable
- w - software writable
- u - updated periodically by hardware

Table 11-1704. Field Descriptions Of Synchronous Channel Descriptor Table Entry (continued)

Field	Description	Details	Accessibility [1]
RSBC	Read sub-buffer counter	1. Software initializes to zero, hardware updates 2. Counts the read sub-buffer offset 3. DMA uses for pointer management	r, w, u
WSBC	Write sub-buffer counter	1. Software initializes to zero, hardware updates 2. Counts the write sub-buffer offset 3. DMA uses for pointer management	r, w, u
RSTS	Read status	1. Software initializes to zero, hardware updates 2. RSTS states: (Only for DMA associated with MLB) xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle	r, w, u
WSTS	Write status	1. Software initializes to zero, hardware updates 2. WSTS states: (Only for DMA associated with MLB) xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle 1xxx = command protocol error	r, w, u
Reserved	Reserved	Software writes a zero to all Reserved bits when the entry is initialized. The Reserved bits are Read-only after initialization.	r, w, u

Isochronous Channel Descriptor Table

The format of an isochronous channel descriptor table entry is shown in Table 11-1705. All reserved bits should be written to zero.

Table 11-1705. Format Of Isochronous Channel Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	Reserved															
16	Reserved															
32	Reserved							BS[8-0]								
48	Reserved															
64	WSTS[2-0]			WPTR[12-0]												
80	RSTS[2-0]			RPTR[12-0]												
96	Reserved			BD[12-0]												
112	BF	Reserved	BA[13-0]													

The field descriptions of an isochronous channel descriptor table entry are shown in Table 11-1706.

Table 11-1706. Field Descriptions Of Isochronous Channel Descriptor Table Entry

Field	Description	Details	Accessibility [1]
BA	Buffer Base Address	BA can start at any byte in the 16k data buffer RAM	r, w

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware

Table 11-1706. Field Descriptions Of Isochronous Channel Descriptor Table Entry (continued)

Field	Description	Details	Accessibility [1]
BD	Buffer Depth	1. BD = size of buffer in bytes - 1 2. Buffer end address = BA + BD 3. Isochronous buffers must be large enough to hold at least 3 blocks (packets) of data 4. Buffer depth must be a integer multiple of blocks	r, w
BF	Buffer Full	1. Software initializes to zero, hardware updates 2. DMA write hardware sets BF when the buffer is full 3. DMA read hardware clears BF when the buffer is empty 4. BF is valid only when the buffer is full or empty, otherwise ignore	r, w, u
BS	Block Size	1. BS defines when to begin the DMA to the data buffer 2. BS = buffer block size in bytes - 1 3. For Rx channels, the DMA writes start when the number of empty bytes (SPACE) in the data buffer >= the block size 4. For Tx channels, the DMA reads start when the number of valid bytes (VALID) in the data buffer >= the block size	r, w, u
RPTR	Read Pointer	1. Software initializes to zero, hardware updates 2. Counts the read address offset within a buffer 3. DMA read address = BA + RPTR	r, w, u
WPTR	Write Pointer	1. Software initializes to zero, hardware updates 2. Counts the write address offset within a buffer 3. DMA write address = BA + WPTR	r, w, u
RSTS	Read status	1. Software initializes to zero, hardware updates 2. RSTS Status states (Only for DMA associated with MLB) xx1 = active xx0 = idle	r, w, u
WSTS	Write status	1. Software initializes to zero, hardware updates 2. WSTS states: (Only for DMA associated with MLB) xx1 = active xx= idle x1x = command protocol error 1xx = buffer overflow (FCE = 0 only)	r, w, u
Reserved	Reserved	Software writes a zero to all reserved bits when the entry is initialized. The reserved bits are read-only after initialization.	r, w, u

Asynchronous and Control Channel Description Table

The format of an asynchronous and control channel descriptor table entry is shown in Table 11-1707. All reserved bits should be written to zero.

Table 11-1707. Format Of Asynchronous and Control Channel Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

112	Reserved		BA[13-0]													

The field descriptions of an asynchronous and control channel descriptor table entry are shown in Table 11-1708.

Table 11-1708. Field Descriptions Of Asynchronous And Control Channel Descriptor Table Entry

Field	Description	Details	Accessibility (1)
BA	Buffer Base Address	BA can start at any byte in the 16k data buffer RAM	r, w
BD	Buffer Depth	1. BD = size of buffer in bytes - 1 2. Buffer end address = BA + BD 3. BD >= max packet length - 1	r, w
RPC	Read Packet Count	1. Software initializes to zero, hardware updates 2. Used in conjunction with WPC, RPTR and WPTR to determine if the buffer is empty or full	r, w, u
WPC	Write Packet Count	1. Software initializes to zero, hardware updates 2. Used in conjunction with RPC, RPTR and WPTR to determine if the buffer is empty or full	r, w, u
RPTR	Read Pointer	1. Software initializes to zero, hardware updates 2. Counts the read address offset within a buffer 3. DMA read address = BA + RPTR	r, w, u
WPTR	Write Pointer	1. Software initializes to zero, hardware updates 2. Counts the write address offset within a buffer 3. DMA write address = BA + WPTR	r, w, u
RSTS	Read status	1. Software initializes to zero, hardware updates 2. Status states:(2) x0x00 = idle xx1xx = ReceiverProtocolError response received from Rx device 1xxxx = ReceiverBreak response received from Rx device	r, w, u
WSTS	Write status	1. Software initializes to zero, hardware updates 2. Status states:(2) x0x00 = idle xx1xx = command protocol error detected 1xxxx = AsyncBreak/ControlBreak command received from Tx device	r, w, u
Reserved	Reserved	Software writes a zero to all reserved bits when the entry is initialized. The Reserved bits are read-only after initialization.	r, w, u

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware

(2) Only valid for DMA pointers associated with the MediaLB core. Not valid for DMA block related pointers.

11.11.4.1.5 DMA Block

The DMA block manages data exchange between the local channel data buffers which reside in the MLBSS and a memory buffer residing in the system memory. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for DMA descriptor table entries. 64 DMA descriptor table entries are directly mapped to the 64 DMA physical channels.

Each logical channel is assigned a separate 128-bit descriptor, defining data buffers in the system memory which are used by the DMA interface for this logical channel. The descriptors are stored at fixed addresses in the channel table RAM.

The description of the DMA descriptor table fields is shown in Table 11-1709.

Table 11-1709. Field Descriptions Of DMA Descriptor Table

Field	Numbers of bits	Description	Accessibilty (1)
CE	1	Channel enable: 0 = Disabled 1 = Enabled	r, w, u
LE	1	Endianess Enable: 0 = Big endian 1 = Little Endian	r, w
PG	1	Page pointer. Software initializes to zero, hardware writes thereafter. 0 = Ping buffer 1 = Pong buffer	r, w, u
RDY1	1	Buffer ready bit for ping buffer page: 0 = Not ready 1 = Ready	r, w
RDY2	1	Buffer ready bit for pong buffer page: 0 = Not ready 1 = Ready	r, w
DNE1	1	Buffer done bit for ping buffer page: 0 = Not done 1 = Done	r, u, c0
DNE2	1	Buffer done bit for pong buffer page: 0 = Not done 1 = Done	r, u, c0
ERR1	1	DMA error response detected for ping buffer page: 0 = No error 1 = Error	r, u, c0
ERR2	1	DMA error response detected for pong buffer page: 0 = No error 1 = Error	r, u, c0
PS1	1	Packet start bit for ping buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r, w, u (both Tx and Rx)

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware
- c0 - software writes '0' to clear

Table 11-1709. Field Descriptions Of DMA Descriptor Table (continued)

Field	Numbers of bits	Description	Accessibilty [1]
PS2	1	Packet start bit for pong buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r, w, u (both Tx and Rx)
MEP1	1	Most ethernet packet (MEP) indicator for ping buffer page: 0 = No MEP 1 = MEP MEP1 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels	r, w, u (both Tx and Rx)
MEP2	1	Most ethernet packet (MEP) indicator for pong buffer page: 0 = No MEP 1 = MEP MEP2 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels	r, w, u (both Tx and Rx)
BD1[2]	11 to 13	Buffer depth for ping buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r, w
BD2[2]	11 to 13	Buffer depth for pong buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r, w
BA1	32	Buffer base address for ping buffer page	r, w
BA2	32	Buffer base address for pong buffer page	r, w
Reserved	varies	Software writes a zero to all Reserved bits when the entry is initialized. The Reserved bits are Read-only after initialization.	r, w, u

(2) The buffer depth (BD1 and BD2) for synchronous channels must consider if multi-frame per sub-buffer mode (the MFE bit in the Channel Allocation Table) is enabled.

Data exchange across the DMA interface can be configured as little endian (LE = 1h) or big endian (LE = 0h). Figure 11-784 provides an overview of the endian options, chosen by the LE bit.

Figure 11-784. DMA Descriptor Table Endian Options

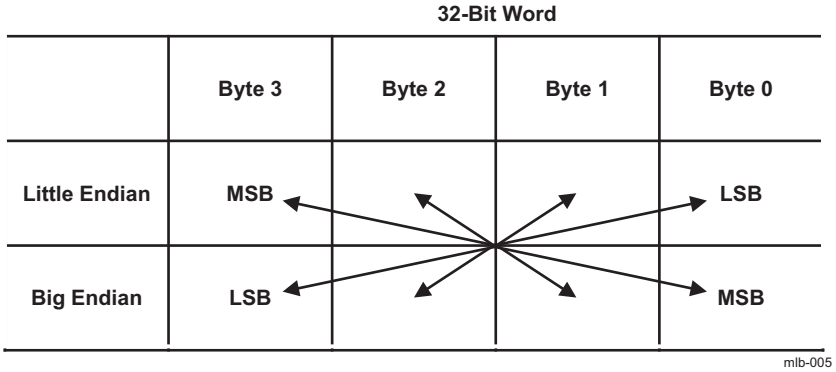

Figure 11-785 shows an example of ping-pong system memory structure. This system memory structure is similar for all channel types and shows the relationship between the BA1, BA2, BD1, BD2 and PG descriptor fields.

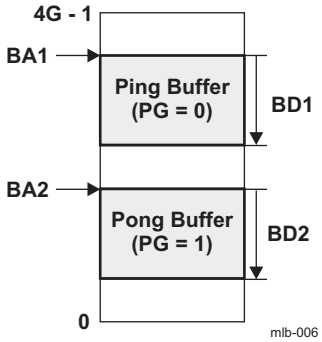
Figure 11-785. Ping-Pong System Memory Structure



Each DMA descriptor table entry (also referred to as a channel descriptor) holds a 32-bit BAn (n = 1 and 2) field which defines the start of each ping or pong buffer within system memory. The BDi (i = 1 and 2) field is used to indicate the size for the respective ping or pong page. The maximum size is 2k-entries for asynchronous and control channels, and 8k-entries for isochronous and synchronous channels.

11.11.4.1.5.1 Synchronous Channel Descriptor

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDi) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (that is, BDi = n × m × bpf - 1).

Table 11-1710 shows the format for a synchronous DMA descriptor table entry. For more details about the field descriptions see Table 11-1709. Each synchronous channel buffer can be up to 8k-bytes deep.

NOTE: In synchronous transmit mode software should take care that the pong DDT is configured before ping DMA completion and ping DDT is configured before pong DMA completion. For more information about ping and pong DMA configuration see Table 11-1722 and Table 11-1723, respectively.

Table 11-1710. Format Of Synchronous DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved

64	BA1[15-0]															
80	BA1[31-16]															
96	BA2[15-0]															
112	BA2[31-16]															

11.11.4.1.5.2 Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDi) must be defined in terms of an integer number (n) and block size (BS) (that is, BDi = n × (BS + 1) - 1).

Table 11-1711 shows the format for an isochronous DMA descriptor table entry. For more details about the field descriptions see Table 11-1709. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 11-1711. Format Of Isochronous DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved

112	BA2[31-16]															

11.11.4.1.5.3 Asynchronous and Control Channel Descriptors

Every asynchronous and control designates the first two bytes of each packet as the packet length. Each packet must be no more than 2048 bytes (packet length ≤ 2048).

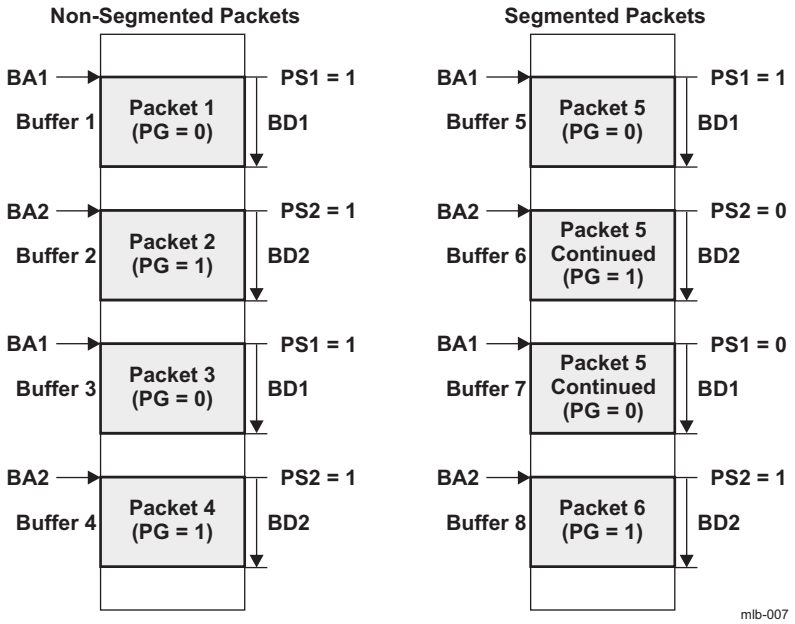
Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt. When hardware finishes the buffer processing, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two-packet modes are supported by hardware for programming the DMA. These are single-packet mode and multiple-packet mode.

11.11.4.1.5.3.1 Single-Packet Mode

The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (that is, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (that is ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers. Figure 11-786 shows the memory space usage for both non-segmented and segmented asynchronous or control packets along with the packet start bit (PSn).

Figure 11-786. Single-Packet Mode Memory Space



While using single-packet mode, buffer done (DNEn) is set in hardware when a packet is done or the buffer is full.

Table 11-1712 shows the format for single-packet mode asynchronous and control DMA descriptor table entries. For more details about the field descriptions see Table 11-1709.

Table 11-1712. Format Of Single-Packet Asynchronous and Control DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY 1	DNE1	ERR 1	PS1	MEP1	BD1[10-0]										
48	RDY 2	DNE2	ERR 2	PS2	MEP2	BD2[10-0]										
64	BA1[15-0]															
80	BA1[31-16]															
96	BA2[15-0]															
112	BA2[31-16]															

11.11.4.1.5.3.2 Multiple-Packet Mode

The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in Figure 11-787. The multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For Tx packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For Tx packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for Tx packet channels in multiple-packet mode.

For Rx packet channels in multiple-packet mode, PSn has no meaning and should be ignored. Software is responsible for keeping track of where each packet starts and ends within the multiple-packet buffer via the packet PML. The buffer done bit (DNEn) is set in hardware for Rx channels when a buffer is full (see Buffer 1 in Figure 11-787) or if a packet ends exactly 1-byte before the end of the buffer (see Buffer 2 in Figure 11-787). Multiple-packet mode also supports segmented Rx packets spanning two or more buffers (see Buffers 3 – 6 in Figure 11-787).

Figure 11-787. Multi-Packet Mode System Memory

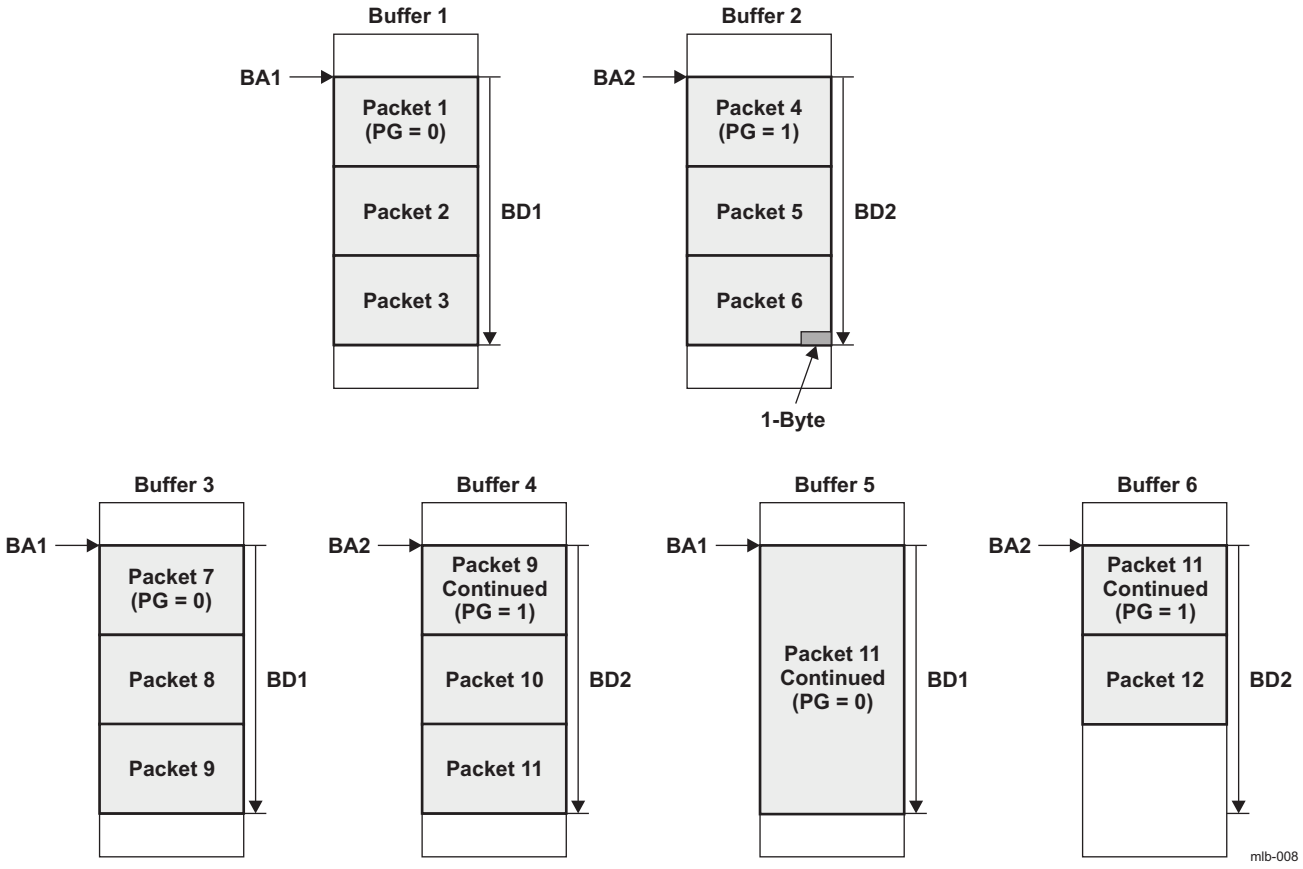


Table 11-1713. Format Of Multiple-Packet Asynchronous And Control DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved

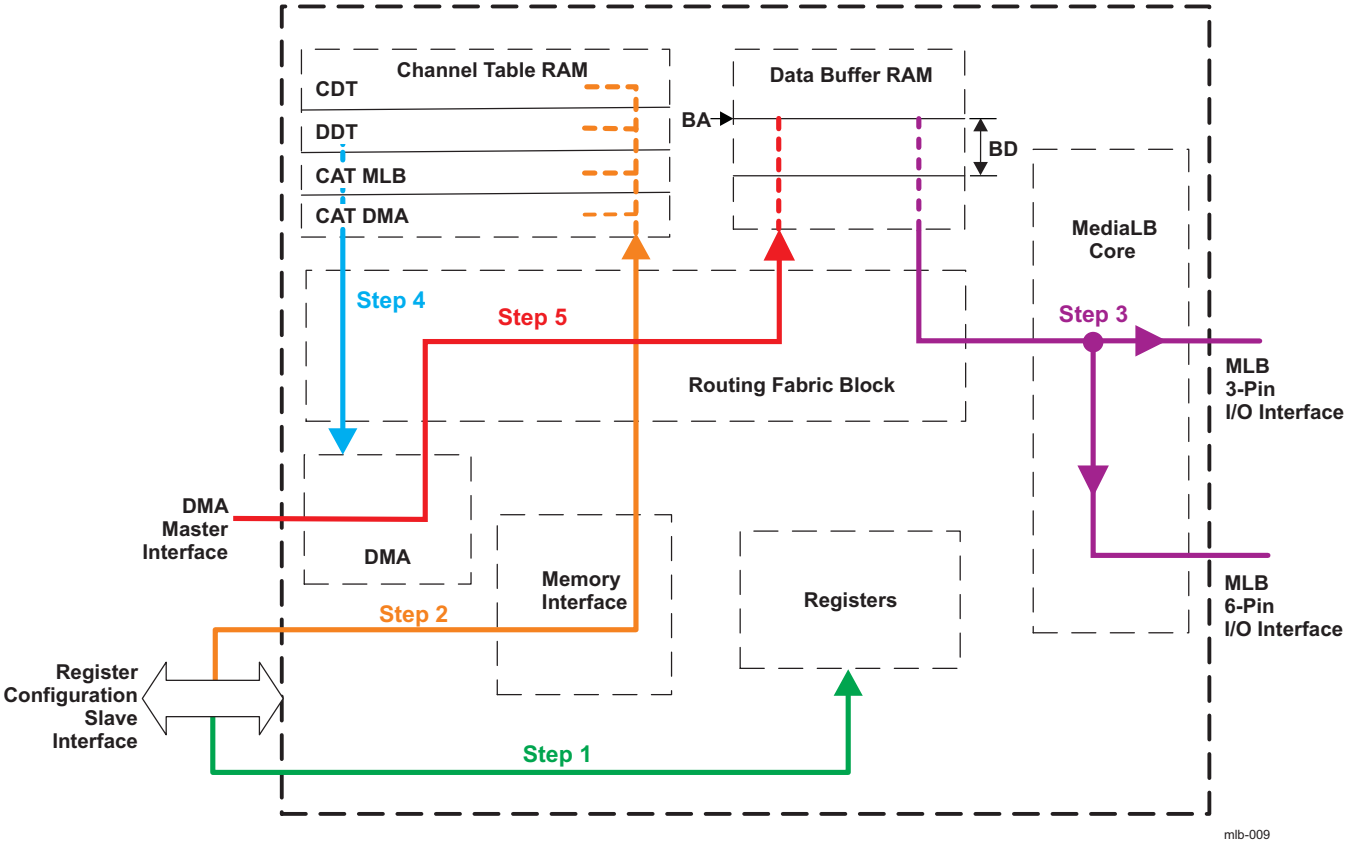
48	RDY2	DNE2	ERR2	PS2 (1)	BD2[11-0]											
64	BA1[15-0]															
80	BA1[31-16]															
96	BA2[15-0]															
112	BA2[31-16]															

(1) PS1 and PS2 have no meaning and should be ignored in Rx mode.

11.11.4.2 Software and Data Flow for MLBSS

Figure 11-788 shows an overview of the MLBSS software and data flow when transmitting.

Figure 11-788. MLBSS Software and Data Tx Flow Overview

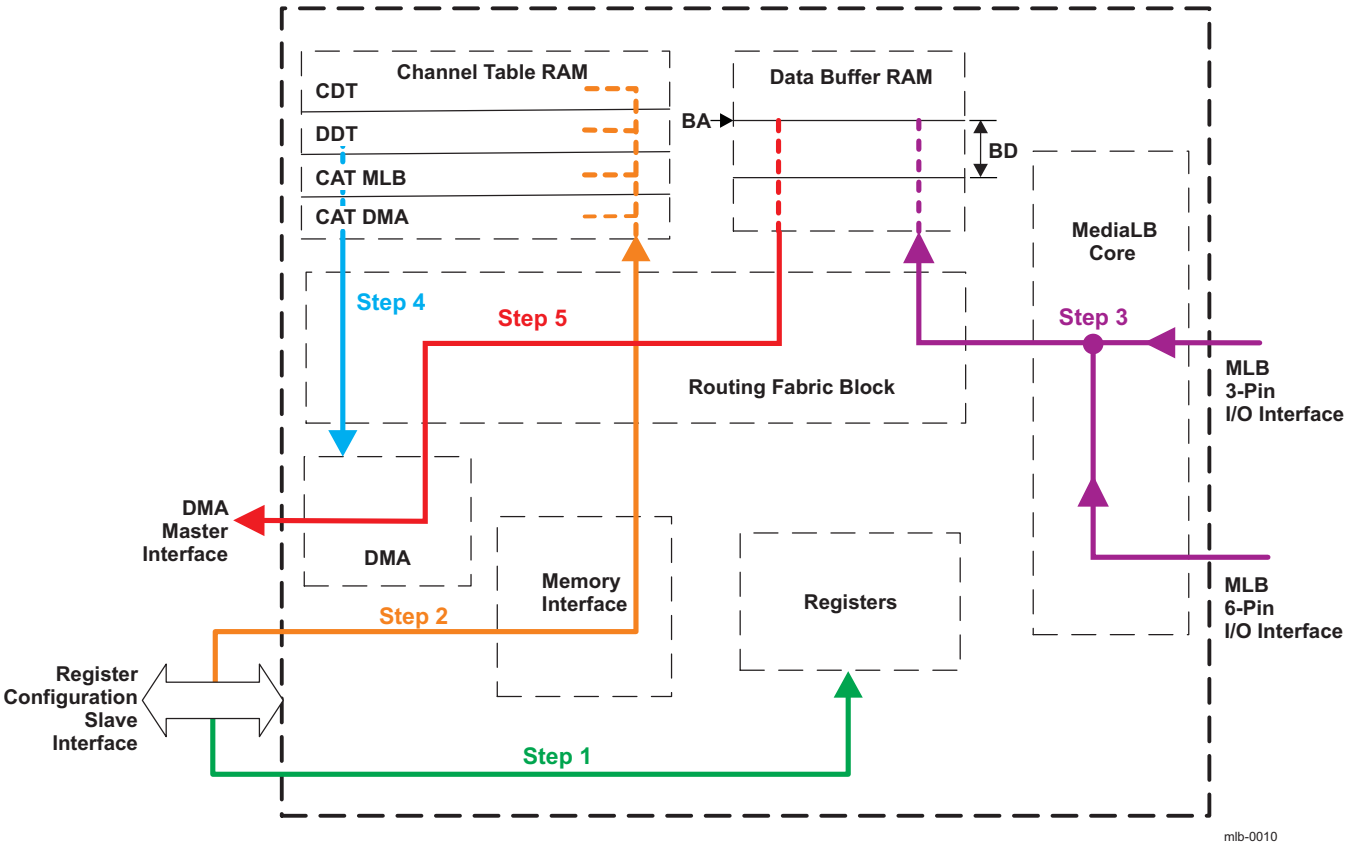


The MLBSS data Tx flow is defined in the following way:

1. Hardware is configured (see Table 11-1716).
2. Channel table RAM is cleared and configured (see Table 11-1717).
3. Data Tx begins through MediaLB 3-pin or 6-pin interface after MLBSS is synchronized to the incoming MLB framesync.
4. DMA reads from channel table RAM.
5. Data Tx is done through the DMA master interface.

Figure 11-789 shows an overview of the MLBSS software and data flow when receiving.

Figure 11-789. MLBSS Software and Data Rx Flow Overview



The MLBSS data Rx flow is defined in the following way:

1. Hardware is configured (see Table 11-1716).
2. Channel table RAM is cleared and configured (see Table 11-1717).
3. Data Rx begins through MediaLB 3-pin or 6-pin interface after MLBSS is synchronized to the incoming MLB framesync.
4. DMA reads from channel table RAM.
5. Data Rx is done through the DMA master interface.

Steps 1 and 2 from Figure 11-788 and Figure 11-789 are done by software. For more information see Section 11.11.5.1.2.1, *Channel Initialization*.

Steps 3-5 from Figure 11-788 and Figure 11-789 are handled by MLBSS internal hardware.

The top-level software tasks that the application must perform, can be placed in two categories:

- Channel initialization
- Channel servicing

For more information about channel initialization, see Section 11.11.5.1.2.1, *Channel Initialization*.

For more information about channel servicing, see Section 11.11.5.2.1, *Channel Servicing*.

11.11.4.2.1 Data Flow For Receive Channels

The data flow for receive channels is as follows:

1. After MLBSS is configured (see Section 11.11.5.1.2.1) and MediaLB has synchronized to the incoming MediaLB framesync (MLB_MLBC0[7] MLBLK = 1h), serial data is received either through the MLBP_DAT_P and MLBP_DAT_N pads or through the MLB_DAT pad, depending on the pin mode (6-pin or 3-pin) selected.

2. The MLBSS logic writes incoming data to the appropriate buffer in the data buffer RAM. The data buffer RAM address to which data is written is the BA field of the channel descriptor table entry. The channel descriptor table entry is specified by the CL field of the MediaLB channel allocation table entry for the channel. The MediaLB channel allocation table entry equals (1/2)*ChannelAddr.
3. The DMA access for a particular DMA channel (DMA channel allocation table entry) is started when there is sufficient data for the DMA channel in the data buffer RAM to write into system memory and the system memory buffer (ping or pong depending on the PG bit in DMA descriptor table entry) is marked as ready. Note that presence of a frame for synchronous/isochronous traffic (multiple frames in multi frame mode) or a packet for control/asynchronous traffic (multiple packets in multi packet mode) is deemed sufficient data to mark a DMA channel as ready.
4. The DMA hardware reads from the data buffer RAM memory address specified by the BA field of the channel descriptor table entry and writes to the system memory address specified in the DMA descriptor table. The CL field in the DMA channel allocation table entry is used to determine the appropriate channel descriptor table entry. Note that CL field of DMA channel allocation table and MLB channel allocation table entries must be the same, thus providing the common data buffer RAM address for MLB core to write into DMA and the DMA to read from the MLB core. Further, each DMA channel allocation table entry corresponds to a DMA descriptor table entry as per the following mapping:
   - Address of DMA descriptor table entry = 40h + Index of DMA channel allocation table entry.

11.11.4.2.2 Data Flow for Transmit Channels

The data flow for transmit channels is as follows:

1. The DMA access for a particular DMA channel (DMA channel allocation table entry) is started when data buffer RAM has sufficient buffer space and the system memory buffer (ping or pong depending on the PG bit in DMA descriptor table entry) is marked as ready for a particular DMA channel allocation table entry. Each DMA channel allocation table entry corresponds to a DMA descriptor table entry as per the following mapping:
   - Address of DMA descriptor table entry = 40h + Index of DMA channel allocation table entry.
2. The DMA reads from the system memory address specified in the DMA descriptor table and writes to the data buffer RAM memory address specified by the BA field of the channel descriptor table entry. The CL field in the DMA channel allocation table entry is used to determine the appropriate channel descriptor table entry. Note that CL field of DMA channel allocation table and MLB channel allocation table entries must be the same, thus providing the common data buffer RAM address for DMA to write into MLB core and the MLB core to read from the DMA.
3. Once the MLBSS is synchronized to the incoming MediaLB framesync (MLB_MLBC0[7] MLBLK = 1h) and a MediaLB channel address is received, the MediaLB core refers to the specific MediaLB channel allocation table entry and reads data from the data buffer RAM buffer. The data buffer RAM address from which data is read is the BA field of the channel descriptor table entry. The channel descriptor table entry is specified by the CL field of the MLB channel allocation table entry for the channel. The MediaLB channel allocation table entry equals (1/2)*ChannelAddr.
4. This data is serialized and transmitted through the MediaLB 3-pin or 6-pin interface.

11.11.4.3 MLB Priority On The System Interconnect

There is a register used for controlling the priority of the MLB subsystem on the system interconnect. This is done through the INITIATOR_PRIORITY0[6-4] MLB_PRI bit field which reside in the BOOT_CFG module. Setting this bit field to 0h means that the MLB traffic has highest priority over the other initiator traffics. A value of 7h is for lowest priority.

11.11.5 MLB Programming Guide

This section describes the programming sequences for the configuration and use of the MLBSS.

11.11.5.1 Global Initialization

11.11.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MLB subsystem. For more information, see Section 11.11.3, *MLB Integration*, and Section 11.11.2, *MLB Environment*. Table 11-1714 shows the global initialization of MLBSS surrounding modules.

Table 11-1714. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PLL Controller	PLL Controller configuration must be done to enable the MLBSS clocks. See Section 5.4.5.3, *PLL Controller*.
ARM_GIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling ARM_GIC interrupts, see Section 6.1, *Arm Cortex-A15 Subsystem*.
CIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling CIC interrupts, see Chapter 9, *Interrupts*.
LPSC11	Module reset must be enabled. For more information about the module configuration, see Section 5.2, *Power Management*.
BOOT_CFG	The pad muxing must be configured in the BOOT_CFG. The MLBSS I/Os must be configured also in the BOOT_CFG. See Section 5.1.3.1.1, *Pad Configuration Registers* in Section 5.1, *Control Module (BOOT_CFG)*. See also section Multiplexing characteristics in the device Data Manual.

11.11.5.1.2 MLBSS Global Initialization

11.11.5.1.2.1 Channel Initialization

A channel initialization must be performed in order to ensure proper operation. Table 11-1715 shows the sequence.

Table 11-1715. Channel Initialization Steps

Step	Crossreference
Configuring the hardware	Table 11-1716
Programming the routing fabric block	Table 11-1717
Programming the DMA block	Table 11-1721
Synchronizing and unmuting the synchronous channel	Table 11-1724

Configuring The Hardware

To configure the MediaLB interface, the steps shown in Table 11-1716 should be followed.

Table 11-1716. Configuring The Hardware

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Clear channel table RAM, to ensure that no stray interrupts are generated	-	0h
Clear the interrupt status bits for logical channels 0 to 63	MLB_ACSR0 and MLB_ACSR1	FFFF FFFFh
Mask all interrupts for DMA channels (from 0 to 63)	MLB_ACMR0 and MLB_ACMR1	0000 0000h

Table 11-1716. Configuring The Hardware (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Select 3-pin or 6-pin MediaLB operation	MLB_MLBC0[5] MLBPEN	0h for 3-pin 1h for 6-pin
Select MediaLB clock speed	MLB_MLBC0[4-2] MLBCLK	-h
Enable the MediaLB	MLB_MLBC0[0] MLBEN	1h
Activate (unmask) all channels	MLB_HCMR0 and MLB_HCMR1	FFFF FFFFh
Enable the HBI block	MLB_HCTL[15] EN	1h
Set the DMA channel mask bits according to all active DMA channels	MLB_HCMR0 and MLB_HCMR1	-h
Select DMA Mode 1 to be used	MLB_ACTL[2] DMA_MODE	1h
Select software to clear the interrupts	MLB_ACTL[0] SCE	1h
Enable MLB interrupts, if required	MLB_MIEN	-h

Programming The Routing Fabric Block

The channel allocation table and channel descriptor table reside in the channel table RAM and are programmed indirectly through the memory interface block. The steps to be followed are shown in Table 11-1717.

Table 11-1717. Programming The Routing Fabric Block

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Initialize all bits of the channel allocation table	-	0h
2. Select a connection label	CL	N = 0h to 3Fh
3. Program the channel descriptor table for channel N	Use the memory interface registers to do a write to the channel descriptor table. See Table 11-1718.	Mask to be used: FFFF FFFFh
4. Program the channel allocation table for inbound data buffer RAM access	Write to the data buffer RAM. See Table 11-1719.	-
5. Program the channel allocation table for outbound data buffer RAM access	Read from the data buffer RAM. See Table 11-1720.	-
6. Repeat steps 2-5 to initialize all logical channels	-	-

Table 11-1718. Subsequence - Program The Channel Descriptor Table

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Set the 14-bit base address	BA	-h
2. Set the 12-bit or 13-bit buffer depth	BD (set this according to the BA so that it doesn't overflow the buffer)	BD = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) = 4 × frames per sub-buffer (m) × bytes per frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) >= max packet length (1024 for a MOST Data Packet (MDP))
ENDIF		

Table 11-1718. Subsequence - Program The Channel Descriptor Table (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
IF: Control channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) >= max packet length (64)
ENDIF		
3. For isochronous channels, configure the block size	BS	BS = block size in bytes - 1
4. Write to all other bits of the channel descriptor table		0h

Table 11-1719. Subsequence - Write To The Data Buffer RAM

Step	Register/ Bit Field/ Programming Model/ Comments	Value
For Tx channels the DMA block does the inbound data buffer RAM access	A Tx channel is from MLBSS to external host	-
For Rx channels MediaLB does the inbound data buffer RAM access	An Rx channel is from external host to MLBSS	-
Set the channel direction	RNW	0h
Set the channel type	CT[2-0]	0h: synchronous 1h: control 2h: asynchronous 3h: isochronous
Set the connection label	CL[5-0]	CL[5-0] = N
IF: CT[2-0] = 0h (synchronous)		
Set the mute bit.	MT (the mute bit is set to avoid any flow of the garbage data that will be there in the data buffer prior to any transfer)	1h
ENDIF		
Set the channel enable bit	CE	1h
Clear all other bits of the channel allocation table	-	0h

Table 11-1720. Subsequence - Read From The Data Buffer RAM

Step	Register/ Bit Field/ Programming Model/ Comments	Value
For Tx channels MediaLB does the outbound data buffer RAM access	A Tx channel is from MLBSS to external host	-
For Rx channels the DMA block does the outbound data buffer RAM access	An Rx channel is from external host to MLBSS	-
Set the channel direction	RNW	1h
Set the channel type	CT[2-0]	0h: synchronous 1h: control 2h: asynchronous 3h: isochronous
Set the connection label	CL[5-0]	CL[5-0] = N
IF: CT[2-0] = 000 (synchronous),		
Set the mute bit.	MT	1h
ENDIF		
Set the channel enable bit	CE	1h
Clear all other bits of the channel allocation table	-	0h

Programming The DMA Block

The DMA descriptor table resides in the channel table RAM and is programmed through TeraNet_CFG slave interface using the registers of the memory interface block. The steps to be followed are shown in Table 11-1721.

Table 11-1721. Programming The DMA Block

Step [1]	Register/ Bit Field/ Programming Model/ Comments	Value
1. Initialize all bits of the DMA descriptor table	-	0h
2. Select a connection label	CL (Note that the CL number chosen in this step should be equal to the CL number chosen in step 2 of Table 11-1717)	N = 0h to 3Fh
3. Program the DMA block ping page for channel N [2]	See Table 11-1722	-
4. Program the DMA block pong page for channel N	See Table 11-1723	-
5. Select big or little endian	LE	-h
6. Select the active page	PG (Program this bit only once in the beginning of the configuration. It shouldn't be touched by the software after that. The hardware updates this bit as the transactions happen)	-h
7. Set the channel enable bit for all active logical channels	CE	1h
8. Repeat steps 2-7 for all active logical channels	-	-

(1) **Tip:** In order to program the MLB and DMA channel allocation table entries with respect to corresponding MLB and DMA channel address, the following steps are recommended:
- Given the MLB channel address is X (1-63), the MLB channel allocation table entry to be programmed should be X/2.
- Given the DMA channel address is X (0-63), the DMA channel allocation table entry to be programmed is X.

(2) For programming the 128-bit DMA descriptor table entry,
- IF: The DMA descriptor table is initialized with zeros and the PG bit is intended to be set to 0h, the following mask should only be used: MLB_MDWE0 = 000C 0000h
- ELSE: The following steps should be performed:
  - The mask to be used: = 000E 0000h.
  - Program the DMA descriptor table and the PG bit.
  - Change the MLB_MDWE0 mask value to 000C 0000h after the first configuration has been done to prevent any further writes by host to the PG bit during ongoing MLB transactions.
  - Write the FFFF FFFFh mask to the MLB_MDWE1, MLB_MDWE2 and MLB_MDWE3 registers

Table 11-1722. Subsequence - Program The DMA Block Ping Page

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Set the 32-bit base address	BA1	-h
Set the 11-bit buffer depth	BD1	BD1 = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 11-bit buffer depth	BD1	(BD1+ 1) = n × frames per sub-buffer (m) × bytes-per-frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 11-bit buffer depth	BD1	(BD1 + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous and control Rx channels		
Set the 11-bit buffer depth	BD1	5 <= (BD1 + 1) <= 4096 [1]
ENDIF		

(1) 4096 is the max packet length.

Table 11-1722. Subsequence - Program The DMA Block Ping Page (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
IF: Asynchronous and control Tx channels		
Set the 11-bit buffer depth	BD1	5 <= (BD1 + 1) <= 4096 (1)
Set the packet start bit if the page contains the start of the packet	PS1	1h
ENDIF		
Clear the page done bit	DNE1	0h
Clear the error bit	ERR1	0h
Set the page ready bit	RDY1	1h

Table 11-1723. Subsequence - Program The DMA Block Pong Page

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Set the 32-bit base address	BA2	-h
Set the 11-bit buffer depth	BD2	BD2 = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 11-bit buffer depth	BD2	(BD2+ 1) = n × frames per sub-buffer (m) × bytes-per-frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 11-bit buffer depth	BD2	(BD2 + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous and control Rx channels		
Set the 11-bit buffer depth	BD2	5 <= (BD2 + 1) <= 4096 (1)
ENDIF		
IF: Asynchronous and control Tx channels		
Set the 11-bit buffer depth	BD2	5 <= (BD2 + 1) <= 4096 (1)
Set the packet start bit if the page contains the start of the packet	PS2	1h
ENDIF		
Clear the page done bit	DNE2	0h
Clear the error bit	ERR2	0h
Set the page ready	RDY2	1h

(1) 4096 is the max packet length.

Synchronizing And Unmuting The Synchronous Channel

The steps to be followed are shown in Table 11-1724

Table 11-1724. Synchronizing And Unmuting The Synchronous Channel

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Check that MediaLB clock is running	MLB_MLBC1[7] CLKMERR	0h
IF: The MediaLB clock is not toggling at the pads	MLB_MLBC1[7] CLKMERR	1h
Clear the register bit	MLB_MLBC1[7] CLKMERR	
Wait one MLB_SPB_OCP_CLK or MLB I/O clock cycle		

Table 11-1724. Synchronizing And Unmuting The Synchronous Channel (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Check that MediaLB clock is running	MLB_MLBC1[7] CLKMERR	0h
ENDIF		
Poll for MediaLB lock	MLB_MLBC0[7] MLBLK	1h
Wait four frames	-	-
Unmute the synchronous channel/channels	MT	0h

11.11.5.2 MLBSS Operational Modes Configuration

11.11.5.2.1 Channel Servicing

After initialization, each channel requires periodic servicing. Table 11-1725 shows the steps which can be performed concurrently and in any order.

Table 11-1725. Channel Servicing Steps

Step	Crossreference
Servicing the DMA Interrupts	Table 11-1726
Servicing MLB Interrupts	Table 11-1728
Polling for MediaLB System Commands	Table 11-1729

Servicing the DMA Interrupts

The steps to be followed are shown in Table 11-1726

Table 11-1726. Servicing the DMA Interrupts

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Enable (unmask) the interrupts from all active DMA channels	MLB_ACMR0 and MLB_ACMR1	1h for each bit associated with an active DMA channel
2. Select the status clear method	MLB_ACTL[0] SCE	-h
3. Select one (MLB_DMA_CH_INT0 only) or two (MLB_DMA_CH_INT0 and MLB_DMA_CH_INT1) interrupt signals	MLB_ACTL[1] SMX	-h
4. Wait for an interrupt from MLB_DMA_CH_INT0 and/or MLB_DMA_CH_INT1 line	-	-
5. Determine which channel or channels are causing an interrupt	Read the MLB_ACSR0 and MLB_ACSR1 registers	-h
6. IF: MLB_ACTL[0] SCE = 1h (software clears the interrupts)		
Write the results of step 5 back to the MLB_ACSR0 and MLB_ACSR1 registers to clear the interrupt	MLB_ACSR0 and MLB_ACSR1	MLB_ACSR0 and MLB_ACSR1
ENDIF		
7. Select a logical channel (N = 0-63) with an interrupt to service	-	-
8. Read the DMA descriptor table entry for channel N	See Table 11-1727	-
9. Reprogram the expired or broken DMA page/pages via steps 3 and 4 of Table 11-1721	-	-
10. Repeat steps 6-9 for all channels with pending interrupts	-	-

Table 11-1726. Servicing the DMA Interrupts (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
11. Repeat steps 4-10 while there are active channels	-	-

NOTE: The MLB_ACSR0, MLB_ACSR1, MLB_ACMR0 and MLB_ACMR1 register bits correspond to the DMA channel address for a particular logical channel. This should not be confused with the MLB channel address.

Channels that receive a DMA error response are disabled (CE = 0) by hardware.

Table 11-1727. Subsequence - Reading The DMA Descriptor Table Entry

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Determine the active page (ping or pong)	Use the PG bit	-h
Determine which page/pages are done	Use the DNE1 and DNE2 bits	1h
Determine which channels encountered a DMA error	Use the ERR1 and ERR2 bits	1h
Determine which asynchronous and control Rx channel pages contain a packet start	Use the PS1 and PS2 bits	1h

Servicing MLB Interrupts

To service the MLB interrupts, the steps desctibed in Table 11-1728 should be followed.

Table 11-1728. Servicing MLB Interrupts

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Clear the appropriate MediaLB channel status bits	MLB_MS0 and MLB_MS1 registers	0h
Enable protocol error interrupts for all active MediaLB channels	MLB_MIEN[28] CTX_PE MLB_MIEN[25] CRX_PE MLB_MIEN[21] ATX_PE MLB_MIEN[18] ARX_PE MLB_MIEN[16] SYNC_PE MLB_MIEN[0] ISOC_PE	1h 1h 1h 1h 1h 1h
Wait for an interrupt on the MLB_SYS_INT line		
Determine which channel/channels are causing the interrupt	Read the MLB_MS0 and MLB_MS1 registers	1h
Determine the interrupt type	Read the RSTS and WSTS bits of the appropriate channel descriptor tables	-h
IF: Synchronous channels		
Clear WSTS errors to resume channel operation	WSTS[3]	0h
ENDIF		
IF: Isochronous channels		
Clear WSTS errors to resume channel operation	WSTS[2-1]	0h
ENDIF		
IF: Asynchronous and control channels		

Table 11-1728. Servicing MLB Interrupts (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Clear RSTS and WSTS errors to resume channel operation	RSTS[4], WSTS[4], RSTS[2] and WSTS[2]	0h
ENDIF		

Polling For MediaLB System Commands

The MediaLB core supports the MediaLB system commands (MlbScan, MlbReset, MOST_Unlock). The MLB_MSS register is used to detect a system command received from the MediaLB controller. The MLB automatically sends the appropriate system response to the MediaLB Controller. Software should follow the procedure shown in Table 11-1729.

Table 11-1729. Polling For MediaLB System Commands

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Poll periodically for a system command received from the MediaLB controller	MLB_MSS	-h
Clear the appropriate bits in MLB_MSS register after the application finishes the servicing	MLB_MSS	0h
IF: Software system command is detected	MLB_MSS[4] SWSYSCMD	1h
Read the MLB_MSD register to receive the system data sent from MediaLB Controller	MLB_MSD	-h
ENDIF		

11.11.5.2.2 Channel Table RAM Access

The memory interface block allows a direct software access to the channel table RAM. Any write to the MLB_MADR register triggers a single read or write cycle. Reading from the MLB_MADR register does not initiate a read or write access.

Table 11-1730 shows a direct write to the channel table RAM.

Table 11-1730. Direct Channel Table RAM Writes

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Load the 128-bit data entry	MLB_MDAT0, MLB_MDAT1, MLB_MDAT2 and MLB_MDAT3 registers	-h
Enable writing data	MLB_MDWE0, MLB_MDWE1, MLB_MDWE2 and MLB_MDWE3 registers	1h
Write the 8-bit channel table RAM target address	MLB_MADR[7-0] ADDR_7_0	-h
Initiate a write cycle	MLB_MADR[31] WNR	1h
Determine when the transfer is complete	Poll the MLB_MCTL[0] XCMP	1h

Table 11-1731 shows a direct read from the channel table RAM.

Table 11-1731. Direct Channel Table RAM Reads

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Write the 8-bit channel table RAM target address	MLB_MADR[7-0] ADDR_7_0	-h

Table 11-1731. Direct Channel Table RAM Reads (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Initiate a read cycle	MLB_MADR[31] WNR	0h
Determine when the transfer is complete	Poll the MLB_MCTL[0] XCMP	1h
Read the 128-bit data entry	MLB_MDAT0, MLB_MDAT1, MLB_MDAT2 and MLB_MDAT3 registers	-h

11.11.6 MLB Registers

Table 11-1733 lists the memory-mapped registers for the MLB. All register offset addresses not listed in Table 11-1733 should be considered as reserved locations and the register contents should not be modified.

This section describes the MLB instances registers.

Table 11-1732. MLB Instances

Bit	Field	Type	Reset	Description
31-30	RESERVED	R/W	0h	Reserved
29	CTX_BREAK	R/W	0h	Control Tx break enable. When set, a ReceiverBreak response received from the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
28	CTX_PE	R/W	0h	Control Tx protocol error enable. When set, a ProtocolError generated by the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
27	CTX_DONE	R/W	0h	Control Tx packet done enable. When set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
26	CRX_BREAK	R/W	0h	Control Rx break enable. When set, a ControlBreak command received from the transmitter on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
25	CRX_PE	R/W	0h	Control Rx protocol error enable. When set, a ProtocolError detected on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
24	CRX_DONE	R/W	0h	Control Rx packet done enable. When set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
23	RESERVED	R/W	0h	Reserved
22	ATX_BREAK	R/W	0h	Asynchronous Tx break enable. When set, a ReceiverBreak response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 11-1750. MLB_MIEN Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
21	ATX_PE	R/W	0h	Asynchronous Tx protocol error enable. When set, a ProtocolError generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
20	ATX_DONE	R/W	0h	Asynchronous Tx packet done enable. When set, a packet transmitted with no errors on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
19	ARX_BREAK	R/W	0h	Asynchronous Rx break enable. When set, a AsyncBreak command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
18	ARX_PE	R/W	0h	Asynchronous Rx protocol error enable. When set, a ProtocolError detected on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
17	ARX_DONE	R/W	0h	Asynchronous Rx done enable. When set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
16	SYNC_PE	R/W	0h	Synchronous protocol error enable. When set, a ProtocolError detected on a synchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
15-2	RESERVED	R/W	0h	Reserved
1	ISOC_BUFO	R/W	0h	Isochronous Rx buffer overflow enable. When set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
0	ISOC_PE	R/W	0h	Isochronous Rx protocol error enable. When set, a ProtocolError detected on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

11.12 MMC/SD

11.12.1 MMC/SD Overview

The Multimedia Card (MMC), Secure Digital (SD), and Secure Digital I/O (SDIO) high speed controller (MMC/SD) provides an interface between local host (LH) such as microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory card, or SDIO card and handles MMC/SD/SDIO transactions with minimal LH intervention.

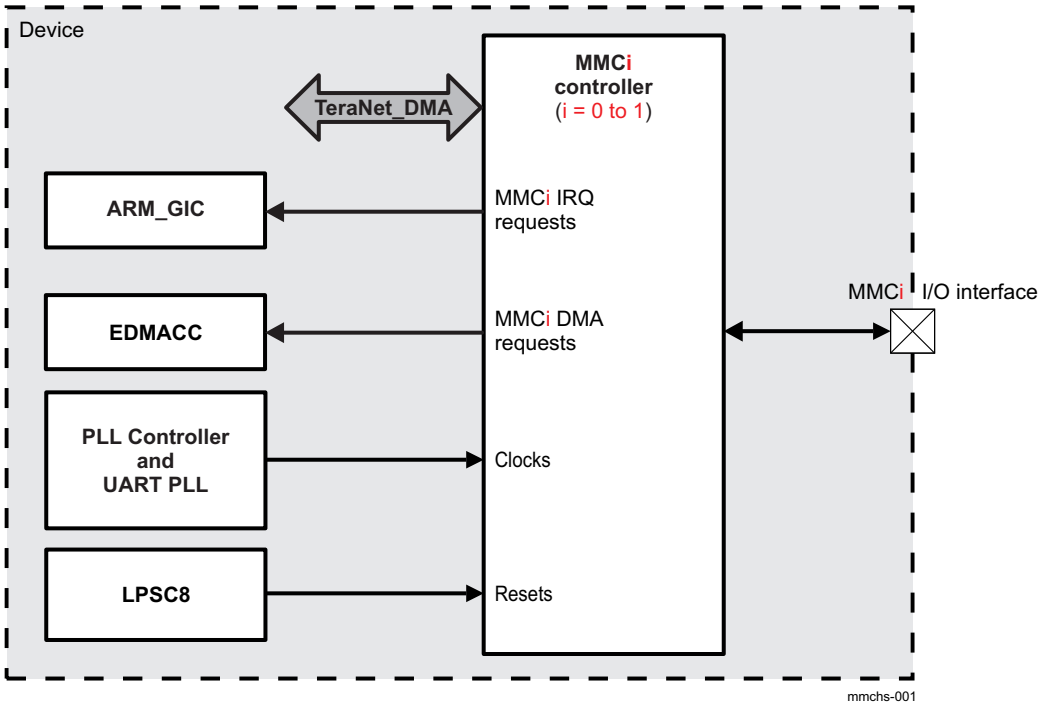
The MMC/SD host controller deals with MMC/SD protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The application interface can send every MMC/SD command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of the end of operation.

The application interface can read card responses or card flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD host controller also supports either two DMA slave channels or DMA master access (in this case, slave DMA channels are deactivated) depending on its integration generic parameter setting MMCHS_HL_HWINFO[0] MADMA_EN bit and MMCHS_CON[20] DMA_MNS bit.

There are two MMC/SD host controllers inside the device. Each controller has 8-bit wide data bus. The MMC/SDi controller is also referred to as MMCi. Figure 11-819 gives an overview of the MMCi (i = 0 to 1) controller.

Figure 11-819. MMCi Overview (i = 0 to 1)



11.12.1.1 MMC Features

This section describes the features supplied by the MMC host controllers.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the JC64 MMC/eMMC standard specification, v4.5.
- Full compliance with SD command/response sets as defined in the SD Physical Layer specification v3.01.
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00.
- Full compliance with SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00.

Main features of the MMC host controllers:

- Flexible architecture allowing support for new command structure
- 32-bit wide access bus to maximize bus throughput
- Designed for low power (Local Power Management)
- Programmable clock generation
- Card insertion/removal detection and write protect detection
- The slave interface supports:
  - 32-bit wide data bus
  - Streaming burst supported only with burst length up to 7
  - WNP supported
- The master interface supports:
  - 32-bit wide data bus
  - Burst supported
- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Support JC 64 v4.4.1 boot mode operations
- Support SDA 3.00 Part A2 programming model
- Support SDA 3.00 Part A2 DMA feature (ADMA2)
- Supported data transfer rates:
  - MMC0 supports the following data transfer rates (eMMC/SD):
    - SDR12 (3.3 V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (3.3 V IOs): up to 24 MBps (48 MHz clock)
    - HS mode (3.3 V IOs): up to 24 MBps (48 MHz clock)
    - DS mode (3.3 V IOs): up to 12 MBps (24 MHz clock)
    - Default SD mode 1-bit data transfer up to 24 Mbps (3 MBps)
  - MMC1 supports the following data transfer rates (eMMC):
    - SDR12 (1.8 V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (1.8 V IOs): up to 24 MBps (48 MHz clock)
    - DDR50 (1.8 V IOs): up to 48 MBps (48 MHz clock)
    - 1.8 V legacy modes with 1/4/8-bit single data rate at up to 26 MHz bus clock
- MMC0 Supports 3.3-V IO modes only
- MMC1 Supports 1.8-V IO modes only

The differences between the MMC host controller and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v3.00 are:

- The clock divider in the MMC host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v3.0. The MMC host controller supports odd and even clock ratio.
- The MMC host controller supports configurable busy time-out.
- ADMA2 64-bit mode is not supported.
- There is no external LED control.

The following features are not supported:

- Byte or half-word accesses. Only word accesses to the slave port are supported.
- MMC Out-of-band interrupt.
- Dual voltage I/O (MMC0 supports 3.3 V only. MMC1 supports 1.8 V only).
- No built-in hardware support for error correction codes (ECC).
- SPI transfers are not supported.
- Module doesn't support card insertion/removal sensing with pull up resistor on MMCi_DAT[3] data bus line as specified in the SD physical layer specification.

11.12.2 MMC/SD Environment

Each MMC host controller can support the following combination of external devices:

- One or more low/high speed MMC sharing the same bus, with respect to load and timings defined by standards on MMC bus depending on bus frequency.
- One single SD memory card or SDIO card.

NOTE: When a bus is shared between two devices and one device is inserted or removed while data transfer is occurring to the other device, it may create some protocol errors that the software will need to resolve.

11.12.2.1 MMC/SD Functional Modes

11.12.2.1.1 MMC Connected to a MMC/SD/SDIO Card or eMMC Device

Figure 11-820 shows the MMCi host controller (where i = 0 to 1) connected to a MMC/SD/SDIO card or eMMC device and its related external connections.

Figure 11-820. MMCi Host Controller Connected to a MMC/SD/SDIO Card or eMMC Device (where i = 0 to 1)

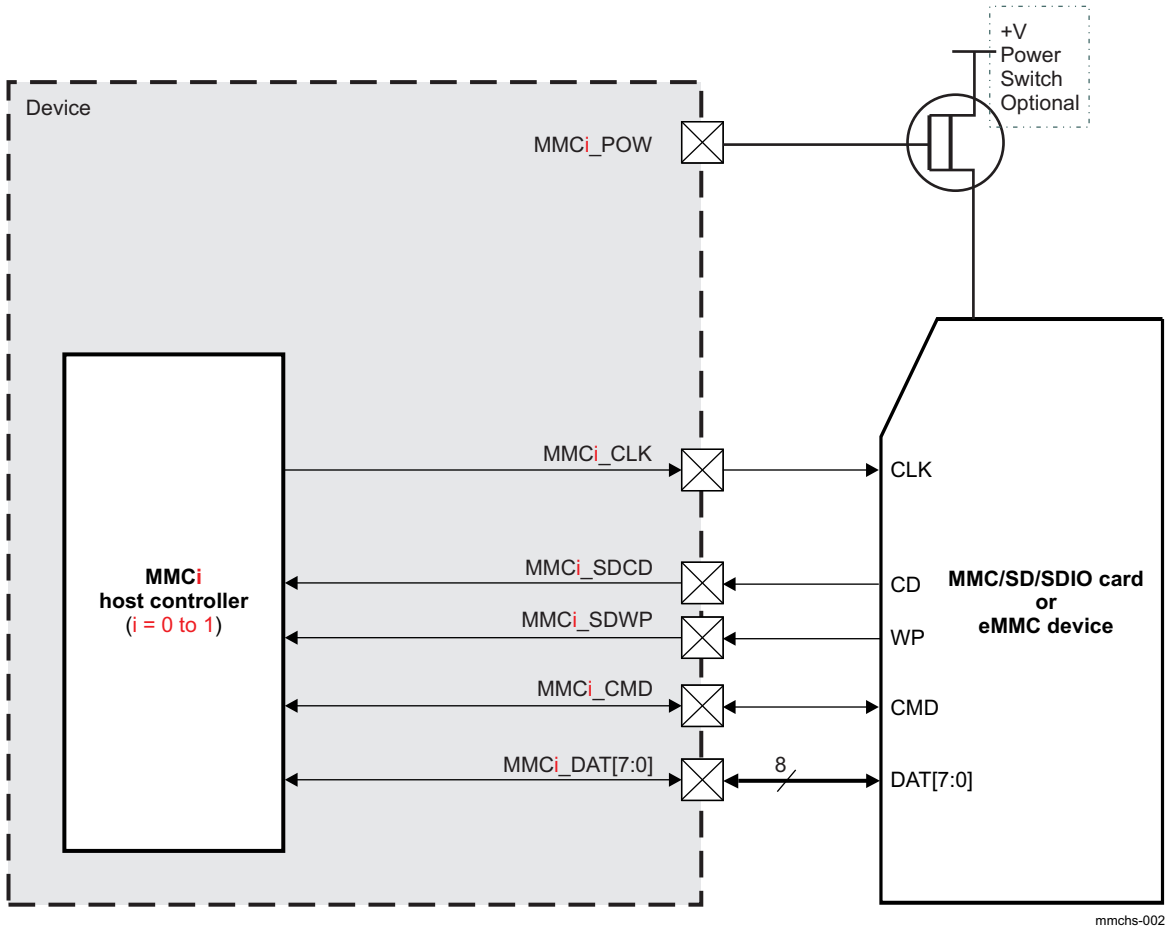


Table 11-1821 describes the MMCi host controller I/Os (where i = 0 to 1).

Table 11-1821. Description of MMCi host controller I/Os (where i = 0 to 1)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC0	MMC0_CLK	I/O	External clock for MMC/SD/SDIO card	0
	MMC0_CMD	I/O	Command line	HiZ[3]
	MMC0_DAT[7:0]	I/O	Data signals	HiZ[3]
	MMC0_SDCD	I	Card insertion/removal detection signal	HiZ
	MMC0_SDWP	I	Write protect detection signal	HiZ
	MMC0_POW	O	Card on/off power supply control	0

(1) I = Input; O = Output; I/O = Bidirectional
(2) HiZ = High Impedance
(3) Initialized as input upon reset

Table 11-1821. Description of MMCi host controller I/Os (where i = 0 to 1) (continued)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC1	MMC1_CLK	I/O	External clock for eMMC device	0
	MMC1_CMD	I/O	Command line	HiZ[3]
	MMC1_DAT[7:0]	I/O	Data signals	HiZ[3]
	MMC1_SDCD[4]	I	Card insertion/removal detection signal	HiZ
	MMC1_SDWP	I	Write protect detection signal	HiZ
	MMC1_POW[5]	O	Card on/off power supply control	0

(4) The MMC1_SDCD terminal must be pulled to a valid logic low state when booting from an on-board eMMC device connected to MMC1.

(5) The MMC1_POW signal is supported but not used because MMC1 host controller is intended for on-board eMMC devices which are always powered on.

11.12.2.2 Protocol and Data Format

The bus protocol between the MMCi host controller and the card is message-based. Each message is represented by one of the following parts:

- Command: A command starts an operation. The command is transferred serially from the MMC host controller to the card on the CMD line.
- Response: A response is an answer to a command. The response is sent from the card to the MMC host controller. It is transferred serially on the CMD line.
- Data: Data are transferred from the MMC host controller to the card or from a card to the MMC host controller using the data lines.
- Busy: The DAT[0] signal is maintained low by the card as far as it is programming the data received.
- CRC status: The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

11.12.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1*).

Figure 11-821 and Figure 11-822 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the CMD line.

NOTE: Stream commands are supported only by MMCs.

Figure 11-821. Sequential Read Operation (MMCs Only)

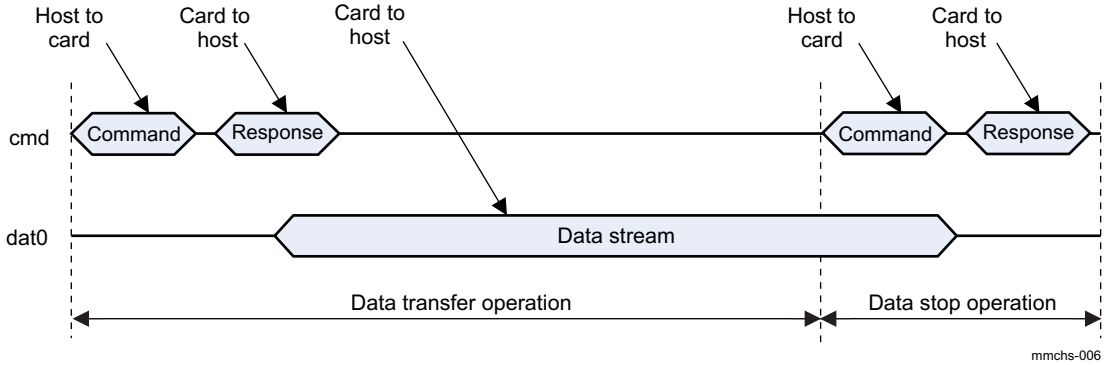

Figure 11-822. Sequential Write Operation (MMCs Only)

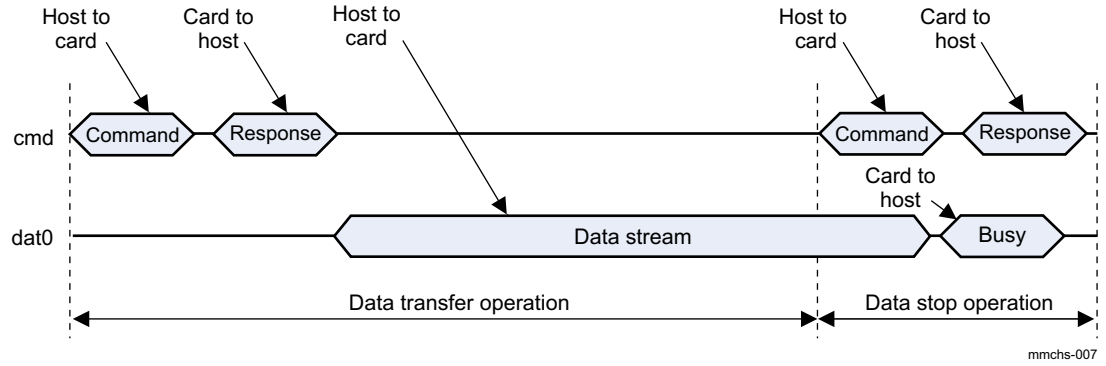

Figure 11-823 and Figure 11-824 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the CMD line. These operations are available for all kinds of cards.

Figure 11-823. Multiple Block Read Operation

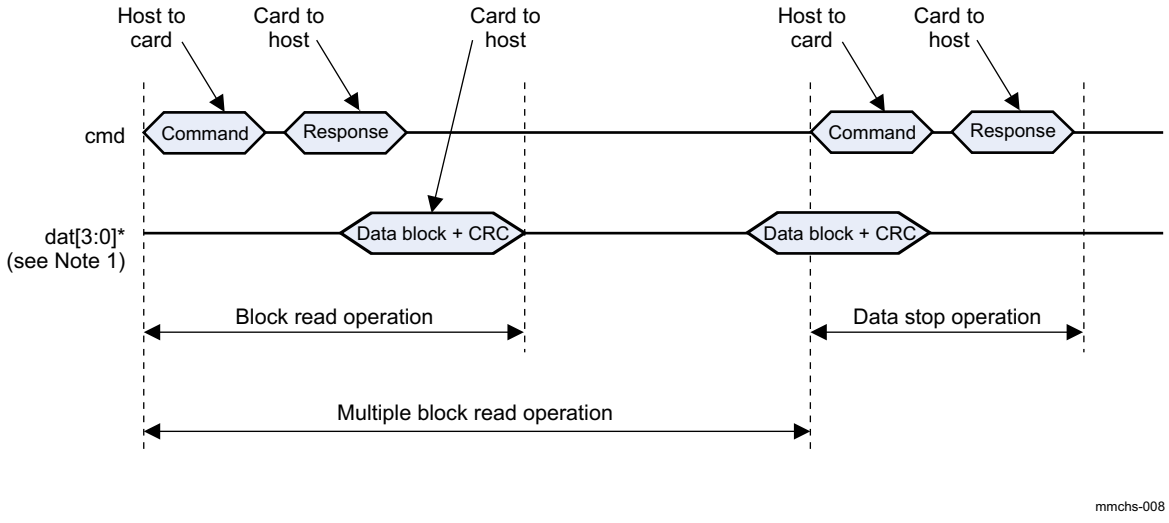

Figure 11-824. Multiple Block Write Operation With Card Busy Signal

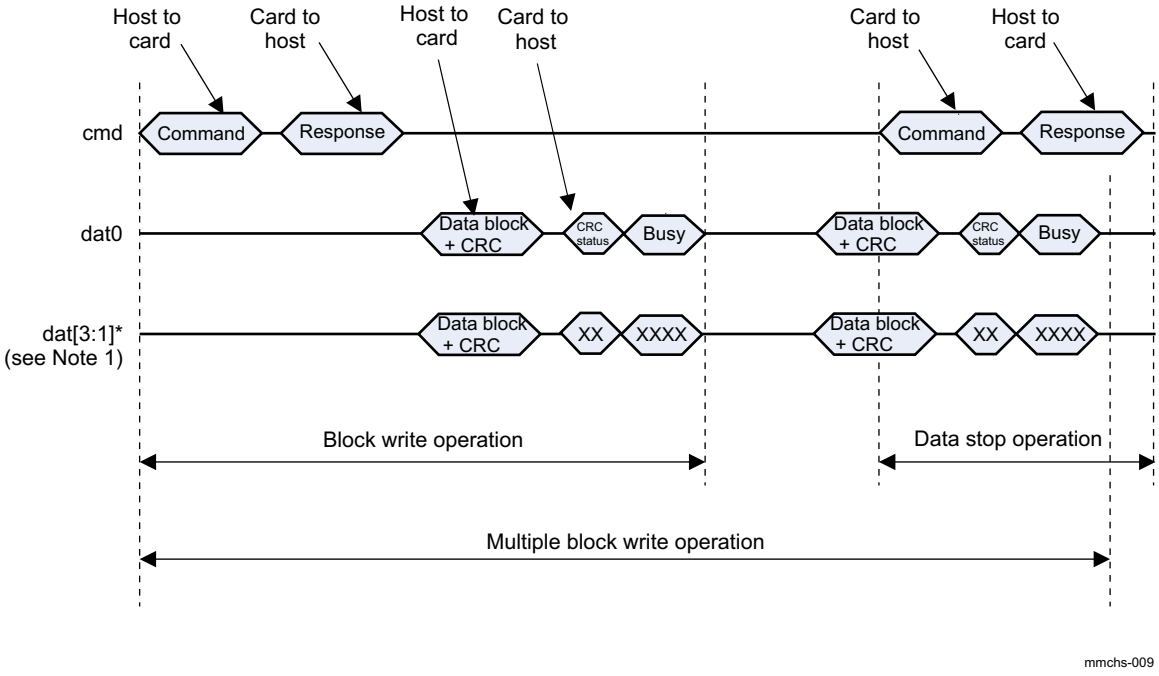


NOTE:

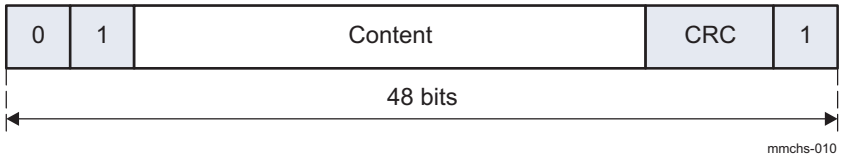
- The card busy signal is not always generated by the card; refer to Figure 11-823 and Figure 11-824, that show a particular case.
- Software must perform a software reset (set the MMCi.MMCHS_SYSCTL[26] SRD bit to 1h) after a data time-out to ensure that MMCi_CLK is stopped.
- For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMCs supports this feature).

11.12.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 11-825).

Figure 11-825. Command Token Format



Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see Figure 11-826 and Figure 11-827). Depending on the type of commands sent to the card, the MMCi.MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 11-1822). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 11-826. Response Token Format (R1, R3, R4, R5, R6, R7)

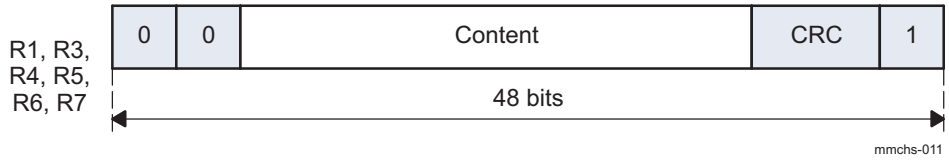


Figure 11-827. Response Token Format (R2)

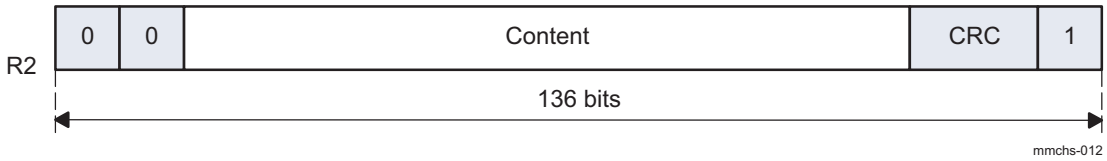

Table 11-1822. Relationship Between Configuration and Name of Response Type

Response Type MMCi.MMCHS_CMD[17-16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 11-828 through Figure 11-830).

Figure 11-828. Data Token Format for 1-Bit Transfers

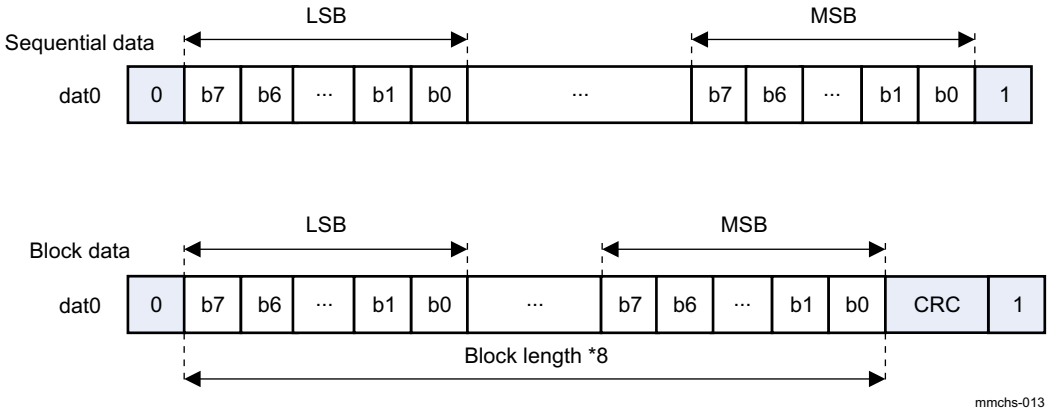

Figure 11-829. Data Token Format for 4-Bit Transfers

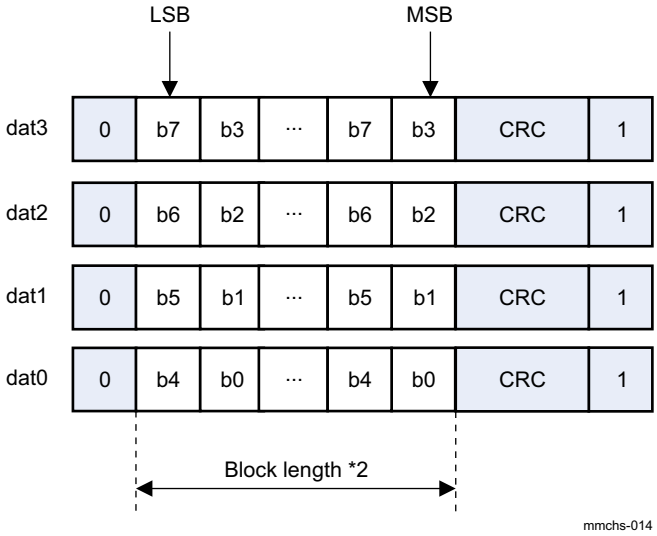

Figure 11-830. Data Token Format for 8-Bit Transfers

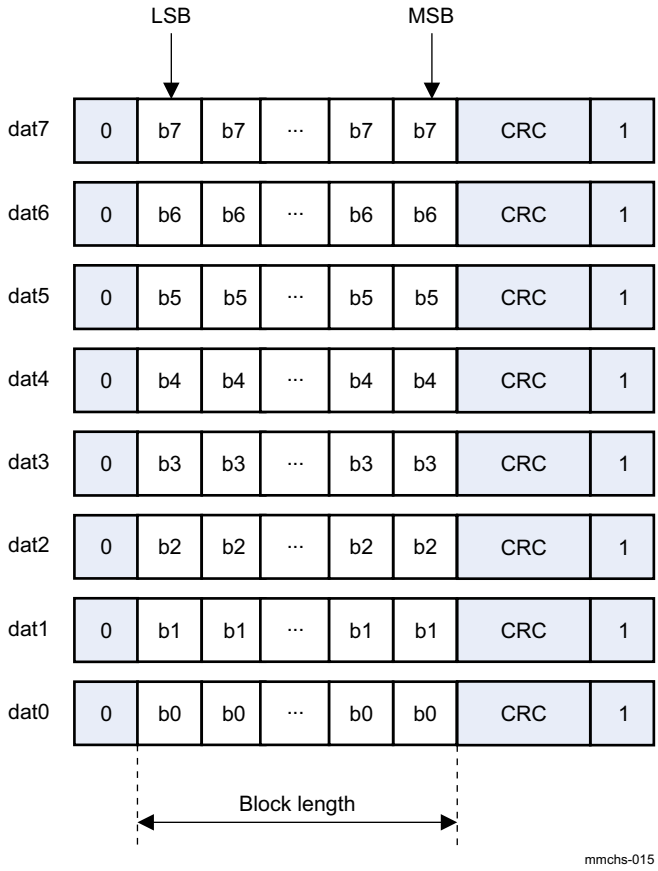

11.12.3 MMC/SD Integration

This section describes the module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-831 shows the MMC module integration.

Figure 11-831. MMC Integration

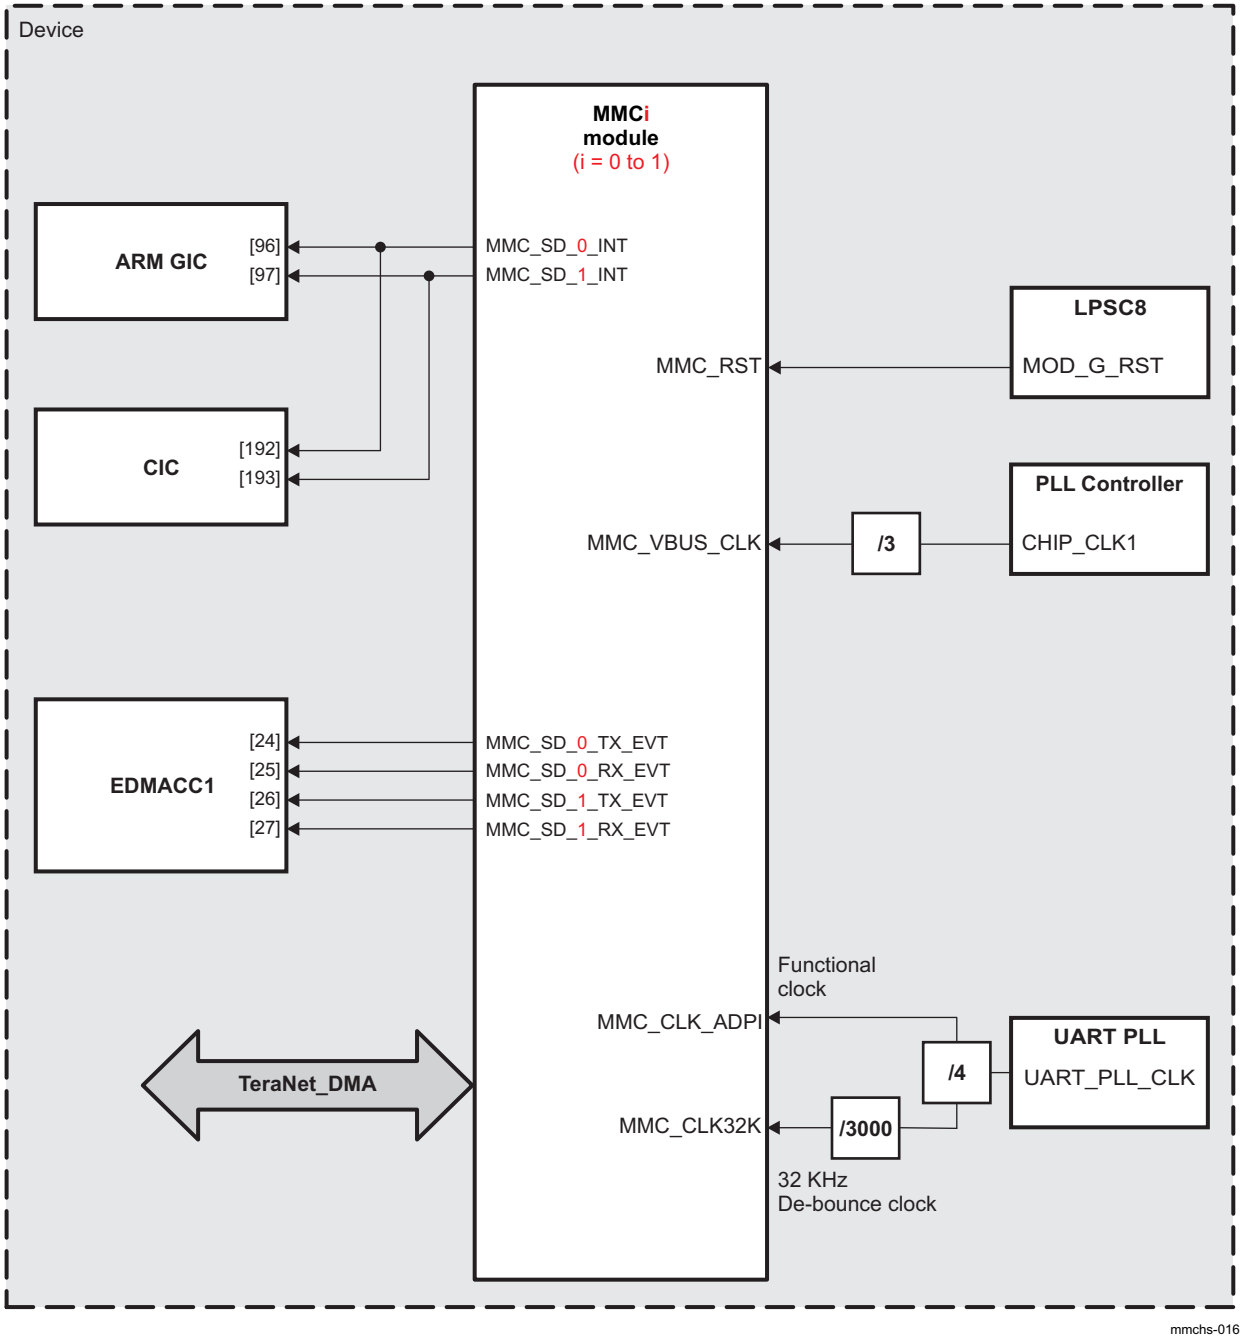

Table 11-1823 through Table 11-1825 summarize the integration of the module in the device.

Table 11-1823. MMC Integration Attributes

Module Instance	Attributes

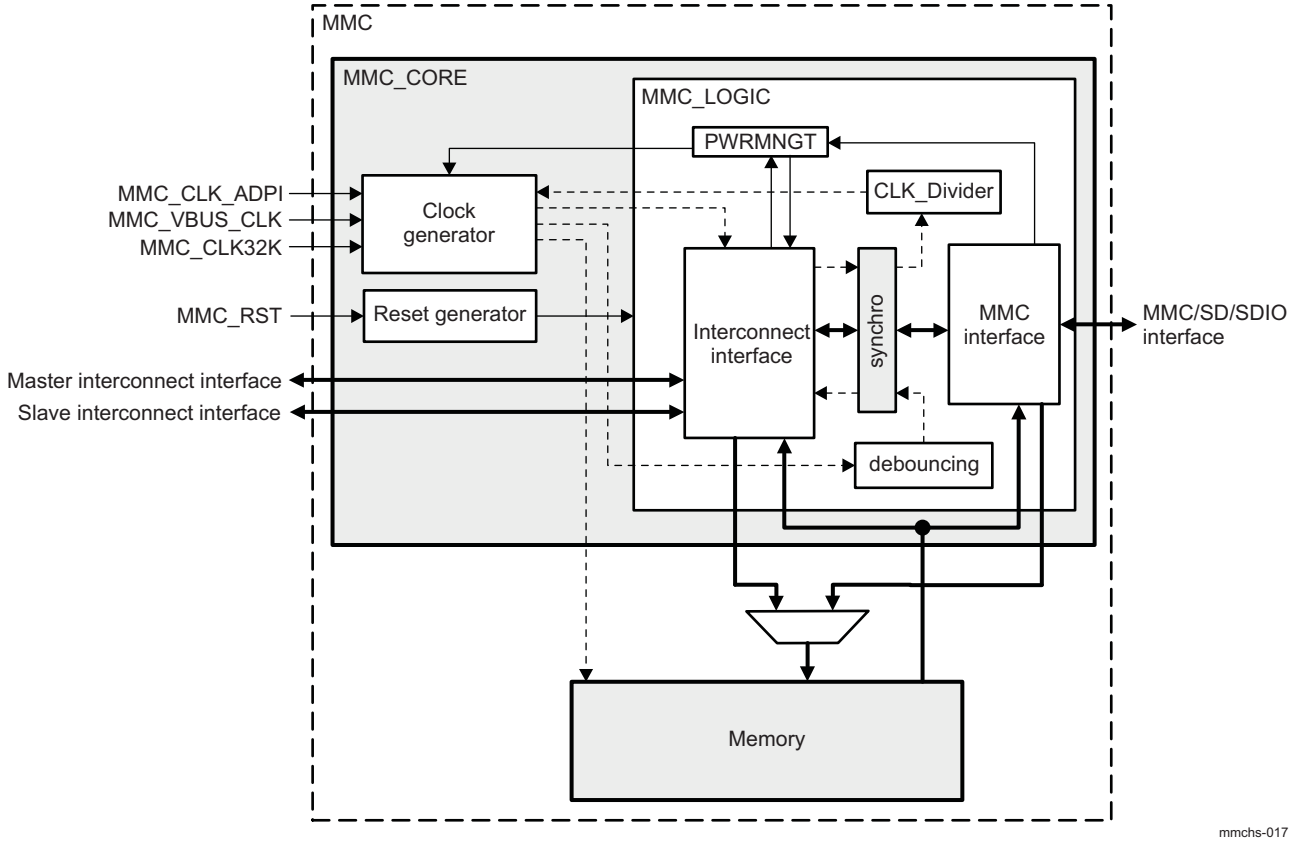
- For a description of the DMA source, see Section 11.12.4.5, *DMA Modes*.

11.12.4 MMC/SD Functional Description

11.12.4.1 Block Diagram

Figure 11-832 is a block diagram of the MMC host controller.

Figure 11-832. MMC Diagram



11.12.4.2 Resets

11.12.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 11-1824 for more information about reset signals).

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (MMC_CLK_ADPI) and interface clock (MMC_VBUS_CLK) must be provided to the module to allow the MMCi.MMCHS_SYSSTATUS[0] RESETDONE status bit to be set.

The debounce clock (MMC_CLK32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

11.12.4.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same effect on the module logic as the hardware signal (MMC_RST), with the following exceptions:

- Debounce logic.
- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description).

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD.
- MMCi.MMCHS_SYSCTL[25] SRC.

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

11.12.4.3 Power Management

The MMC host controller can save power by autogating of interface and functional clocks.

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the slave interface interconnect.
- A transaction on the MMC interface starts.

Local Power Management

describes the power management features available for the MMCi controllers.

Table 11-1826. Local Power Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMC_VBUS_CLK clock upon the interface activity, or gating the MMC_CLK_ADPI clock upon the internal activity.
Clock activity	MMCHS_SYSCONFIG[8-9] CLOCKACTIVITY	For configuration details, see Table 11-1827.

Table 11-1827. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State
	MMC_VBUS_CLK	MMC_CLK_ADPI	
00	OFF	OFF	None
10	OFF	ON	None
01	ON	OFF	None
11	ON	ON	All

11.12.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable or disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMC_SD_i_INT on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1h (the MMCi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the MMCi host controller does not transmit an interrupt request.

NOTE: If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMCi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 11-1828 lists the event flags, and their mask, that can cause module interrupts.

Table 11-1828. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMC_SD_i_INT	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE = 0).
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMC_SD_i_INT	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT[26] TE	MMCHS_IE[26] TE_ENABLE	MMC_SD_i_INT	Tuning Error. This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure. The Tuning Error is with higher priority than the other error interrupts generated during data transfer.

Table 11-1828. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMC_SD_i_INT	ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMC_SD_i_INT	Auto CMD12 error and Auto CMD23 error. This bit is set automatically when one of the bits MMCHS_AC12[4-0] changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMC_SD_i_INT	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMC_SD_i_INT	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMC_SD_i_INT	Data time-out error. This bit is set automatically according to the following conditions: • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMC_SD_i_INT	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMC_SD_i_INT	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMC_SD_i_INT	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMC_SD_i_INT	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMC_SD_i_INT	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[31-16]) are set, this bit is set to 1.

Table 11-1828. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMC_SD_i_INT	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 1h or 2h and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMC_SD_i_INT	Card interrupt. This bit is used only for SD and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous . In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[7] CREM	MMCHS_IE[7] CREM_ENABLE	MMC_SD_i_INT	Card removal. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.
MMCHS_STAT[6] CINS	MMCHS_IE[6] CINS_ENABLE	MMC_SD_i_INT	Card insertion. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 0 to 1.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMC_SD_i_INT	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10-0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMC_SD_i_INT	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10-0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMC_SD_i_INT	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMC_SD_i_INT	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.

Table 11-1828. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMC_SD_i_INT	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). • In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). • In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMC_SD_i_INT	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

NOTE: To send an interrupt request to the MMC_SD_i_INT line, the mask/unmask bit must be set in the MMCi.MMCHS_IE and MMCi.MMCHS_ISE registers.

The MMCi host controller supports interrupt-driven operation and polling.

11.12.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the MMCi.MMCHS_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0h), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS_STAT register (bits 31 through 16) are cleared.

11.12.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning clearing of the CIRQ and ERRI bits.

11.12.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If MMCHS_CAPA[29] AIS is set to 0, writing to MMCHS_AC12[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If MMCHS_AC12[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

11.12.4.5 DMA Modes

Two DMA management modes can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode:

  DMA master mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the master interface interconnect, which supports burst accesses to maximize throughput.

  NOTE: This mode is supported only by modules connected to the master interface interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit. Refer to this register for a more detailed description.

  This mode is available for modules MMC0 and MMC1.

- DMA slave mode:

  DMA slave mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMC_SD_i_TX_EVT and MMC_SD_i_RX_EVT).

  NOTE: This mode is the only mode supported by modules that are not connected to the master interface interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit. Refer to this register for a more detailed description.

  This mode is available for modules MMC0 and MMC1.

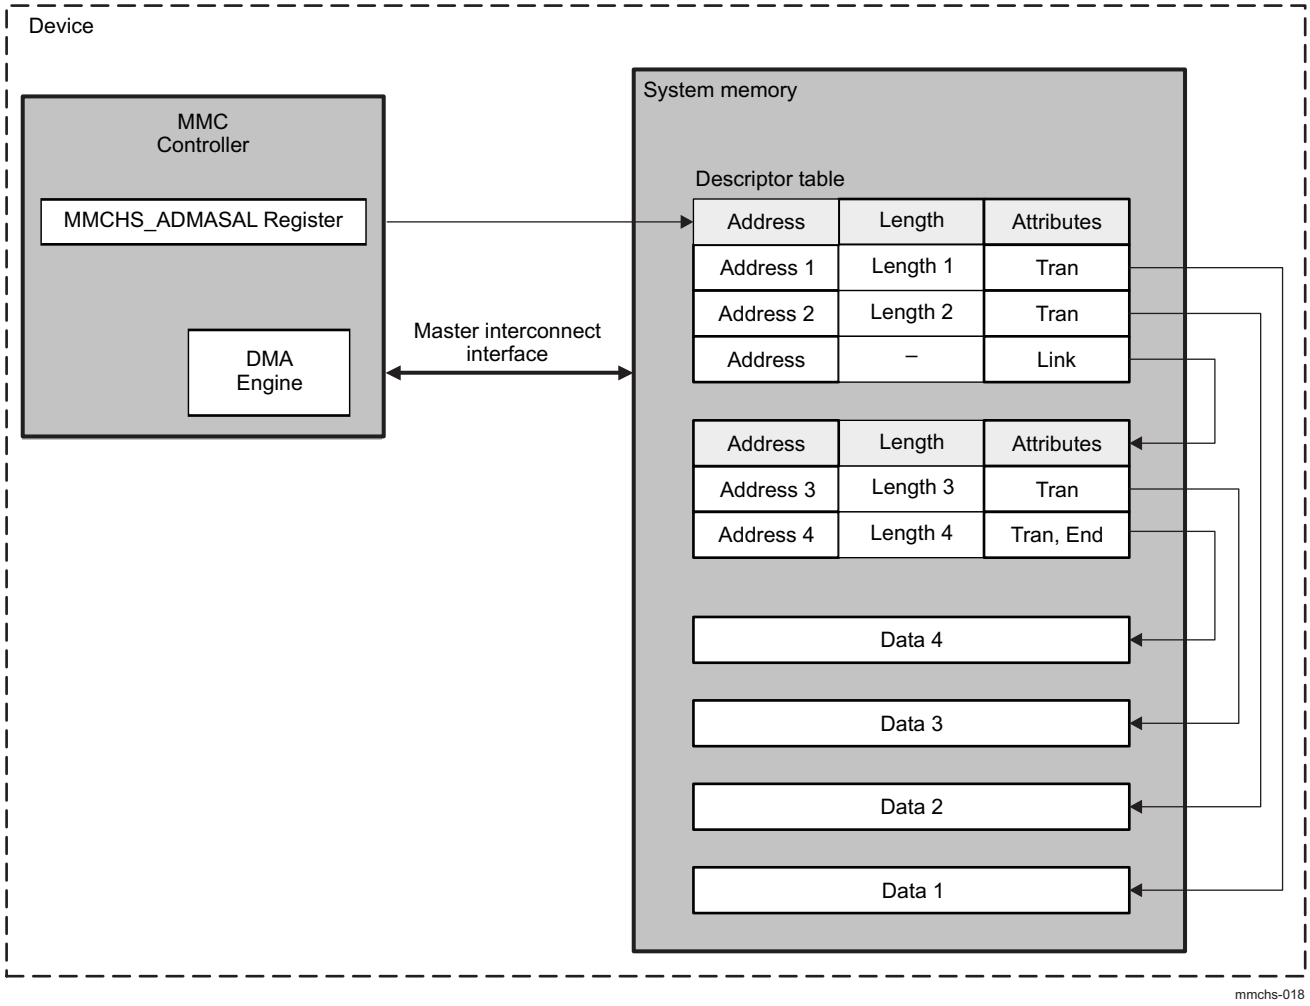
11.12.4.5.1 Master DMA Operations

The MMCi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the MMCHS_ADMASAL register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

NOTE: This mode is supported only by modules connected to the master interface interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit. Refer to this register for a more detailed description.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in Figure 11-833. In this case the MMCHS_ADMASAL register is used as the program address pointer.

Figure 11-833. ADMA Block Diagram Overview



11.12.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the master interface interconnect, and requires two 32-bit accesses to memory.

Table 11-1829 shows the structure of a descriptor line.

Table 11-1829. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit address		16-bit length		0h		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 11-1830 describes the available actions of a descriptor line.

Table 11-1830. Available Actions of a Descriptor Line

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 11-1831 describes the additional parameters of a descriptor line.

Table 11-1831. Additional Parameters of a Descriptor Line

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

11.12.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

11.12.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KB.
- Total length = $Length_1$ + $Length_2$+ $Length_3$ + ... + $Length_n$ must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the MMCHS_BLK[31-16] NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (MMCHS_CMD[1] BCE bit) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

NOTE: The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (MMCHS_PSTATE[9] RTA), write transfer active (MMCHS_PSTATE[8] WTA), and DAT line active (MMCHS_PSTATE[2] DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

11.12.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap request (the MMCHS_HCTL[16] SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the MMCHS_STAT[2] BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

11.12.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1-0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If the ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If the ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

11.12.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each MMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

NOTE: Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 11.12.4.5.1.1, *Descriptor Table Description*) and an FSM, as shown in Figure 11-834.

Figure 11-834. ADMA Finite State-Machine

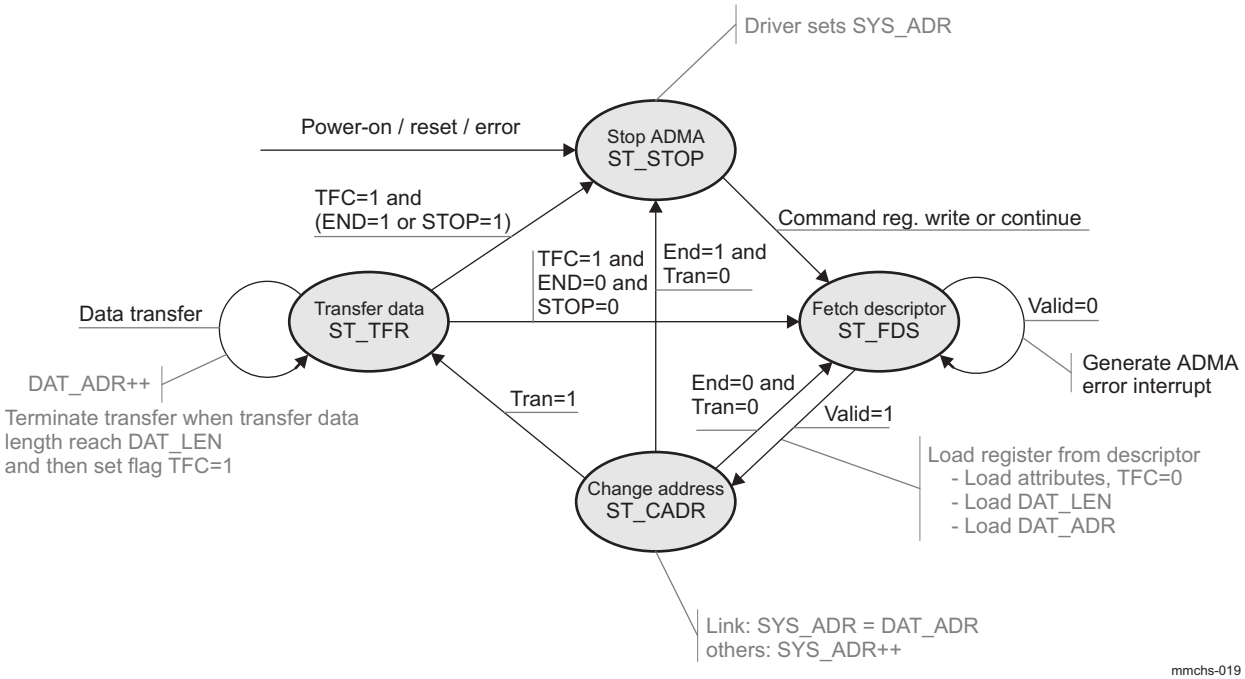


Table 11-1832 describes each state of the ADMA FSM.

Table 11-1832. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If End = 0, go to ST_FDS state. **NOTE**: ADMA2 does not stop at this state if some errors occur.
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: • If data transfer continues (End = 0), go to ST_FDS state. • If data transfer completes, go to ST_STOP state.
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: • After power-on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 11-1833 gives the description of each symbol used in the ADMA FSM (see Figure 11-834).

Table 11-1833. ADMA FSM Symbol Definition

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

11.12.4.5.2 Slave DMA Operations

The MMCi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (more than 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

NOTE: This mode is implied by modules that are not connected to the master interface interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 11.12.4.5.1, *Master DMA Operations*.

The DMA request is issued if the following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the MMCi host controller to write an entire block (BLEN writes).

11.12.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMC_SD_i_RX_EVT is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10-0] BLEN bit field.

MMC_SD_i_RX_EVT is deasserted to its inactive level when the a certain device DMA module reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA reads is Integer (BLEN/4) + 1.

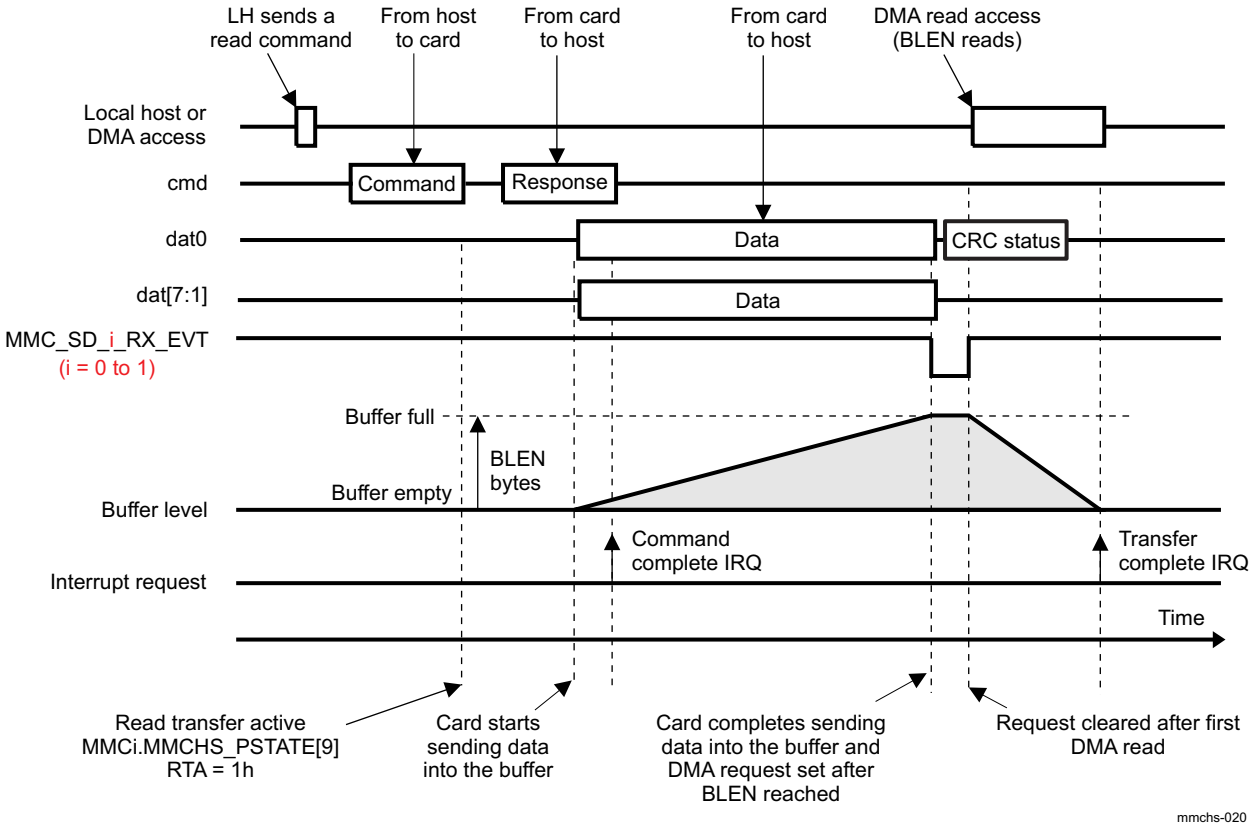
The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the MMCi_CLK clock signal (provided to the card) is momentarily stopped until a certain device DMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 11-835 shows DMA receive mode.

Figure 11-835. DMA Receive Mode



11.12.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMC_SD_i_TX_EVT is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10-0] BLEN bit field.

MMC_SD_i_TX_EVT is deasserted to its inactive level when a certain device DMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

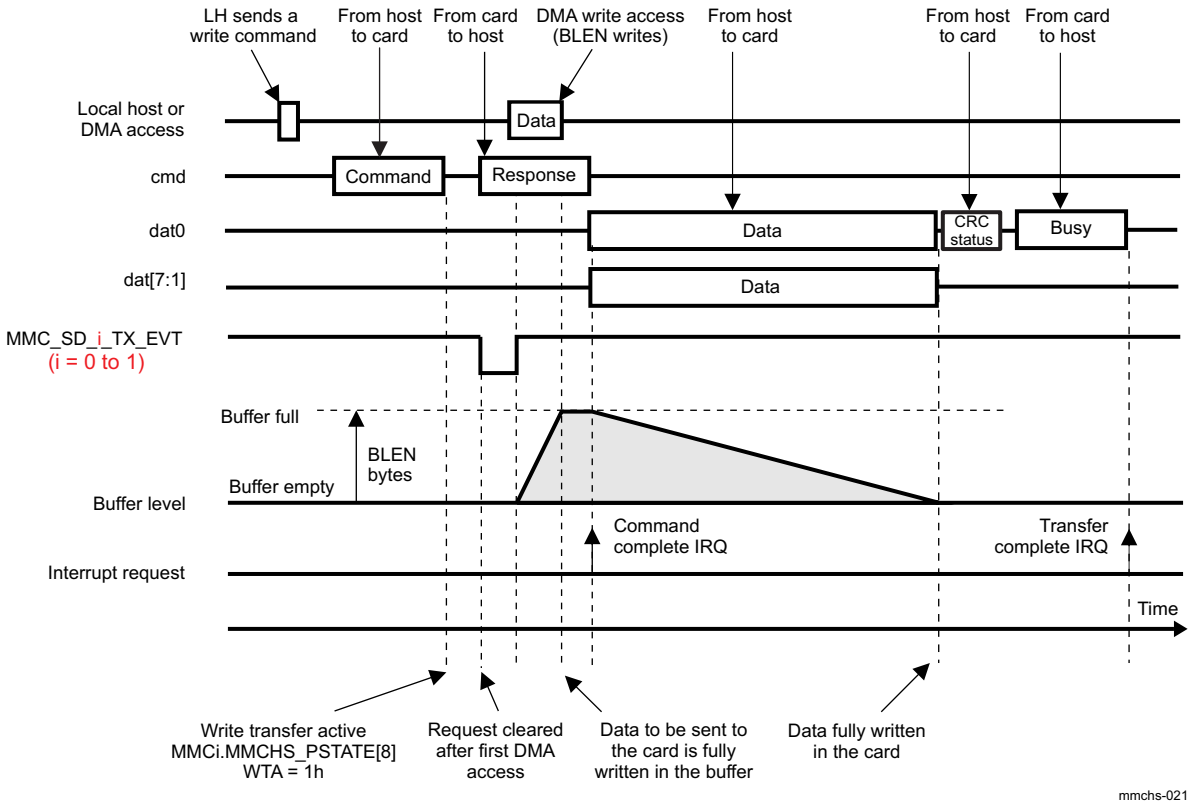
New DMA requests are internally masked if the DMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA reads is Integer (BLEN/4) + 1) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 11-836 shows DMA transmit mode.

Figure 11-836. DMA Transmit Mode



11.12.4.6 Mode Selection

The MMC host controller can be used in two modes: MMC and SD/SDIO (see Section 11.12.2, *MMC/SD Environment*). It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

11.12.4.7 Buffer Management

11.12.4.7.1 Data Buffer

The MMCi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[11-0] BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17-16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The MMCi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 200h (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 11-837 and Figure 11-838 show the buffer management for a write and a read, respectively.

Figure 11-837. Buffer Management for a Write

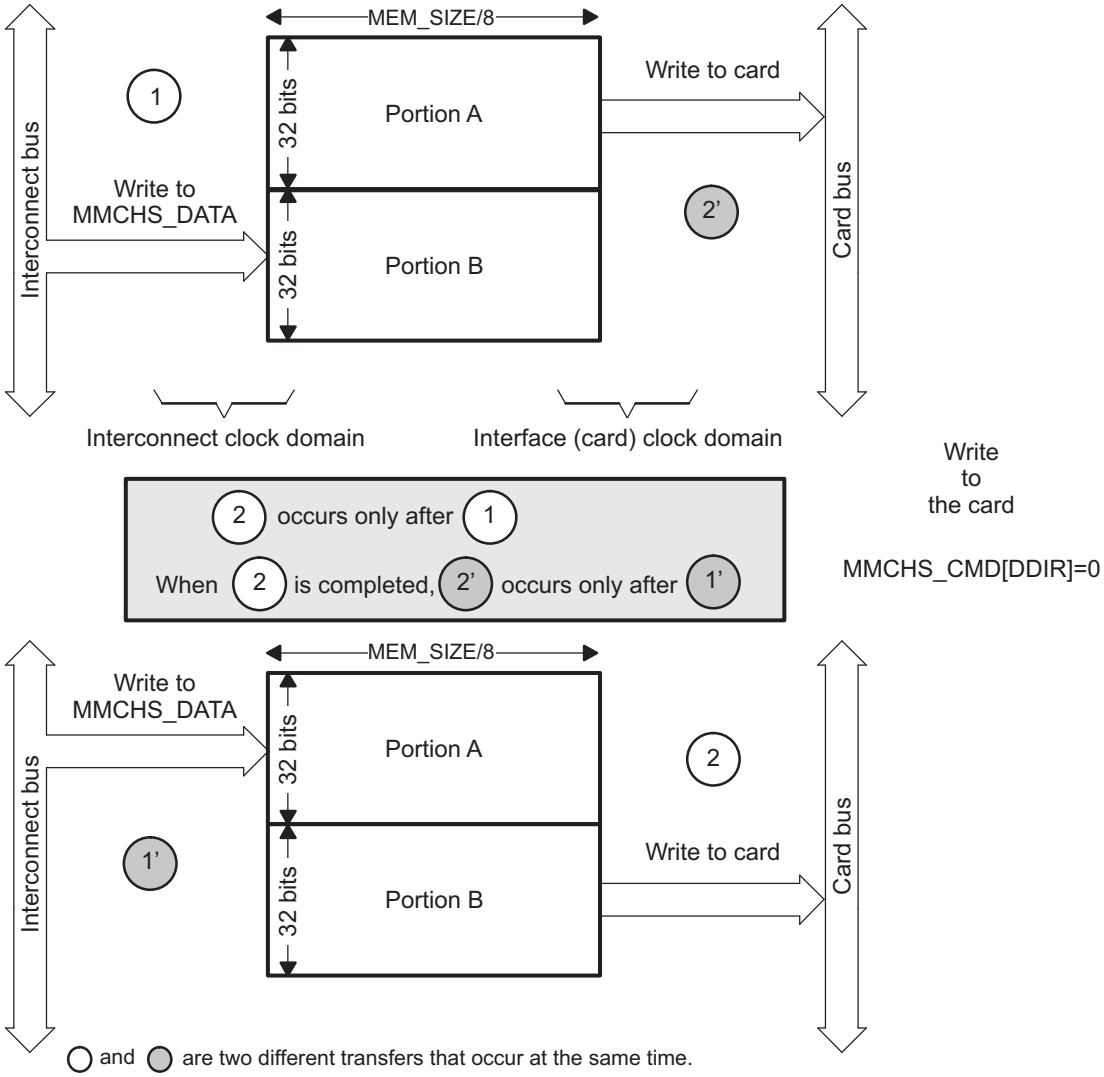


Figure 11-838. Buffer Management for a Read

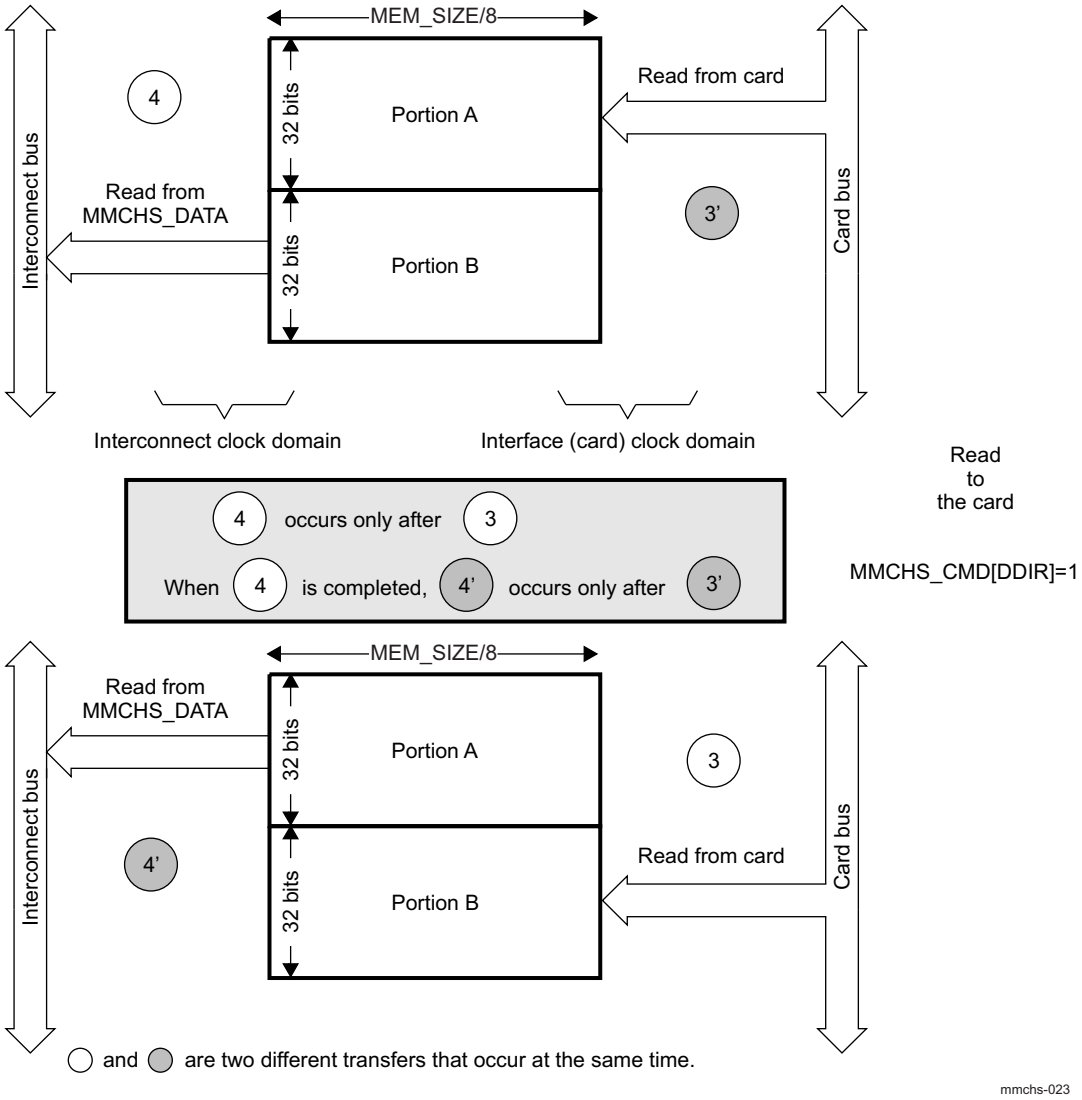


- When the size of the data block to transfer is larger than MEM_SIZE/2, only one data transfer at a time can occur from one data bus to the other data bus. The MMCi host controller uses the entire data buffer as a single portion.

  In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

11.12.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 11-1834).

NOTE: Double-buffering is always the buffer management for large memory depth.

Table 11-1834. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5-2] MEM_SIZE in bytes)	512	1024
Maximum block length supported	512	1024

Table 11-1834. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5-2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

NOTE: For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[4] DDIR bit is 1).

11.12.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

11.12.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

11.12.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*; or *the SD Card Specification, Part A2, SD Host Controller Standard Specification*.

11.12.4.8.2 Different Types of Responses

Different types of responses are specific to the eMMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*; *SD Memory Card Specifications*; *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*.

Table 11-1835 describes how the eMMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 11-1835. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8](1)	MMCHS_RSP10[31-0]
R1b (Auto CMD12 response), R1(Auto CMD23 response)	RESP[39:8](1)	MMCHS_RSP76[31-0]
R2	RESP[127:0](1)	MMCHS_RSP76[31-0] MMCHS_RSP54[31-0] MMCHS_RSP32[31-0] MMCHS_RSP10[31-0]

(1) RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31-0] register because the host controller may execute multiple block data transfers on the DATA line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

While executing Auto CMD23 the response of CMD23 is saved in the MMCHS_RSP76[31-0] register and the response of multiple-block read and write command is saved in the MMCHS_RSP10 register. The response error of CMD23 is indicated in the MMCHS_AC12 register, bits [7-0].

11.12.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMCi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see Table 11-1836 and the register description.

Table 11-1836. CC and TC Values Upon Error Detected

Error Hold in MMCi.MMCHS_STAT		CC	TC	Comments
29	BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

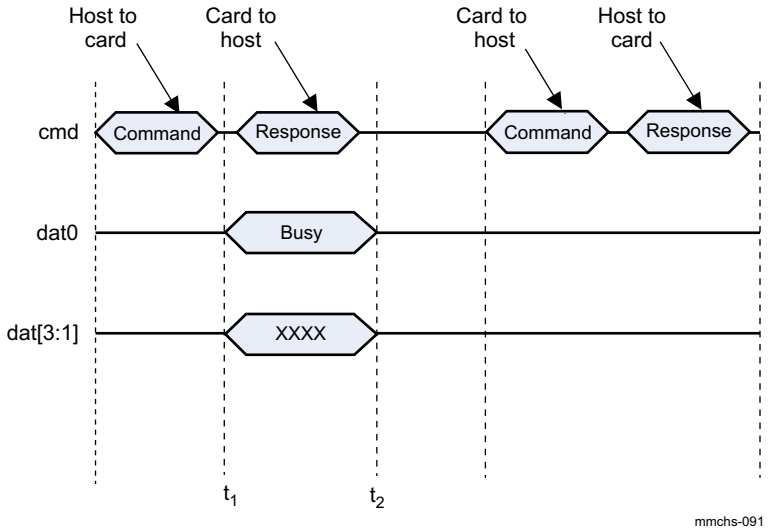
A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

11.12.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 11-839 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

Figure 11-839. Busy Time-Out for R1b, R5b Response Type



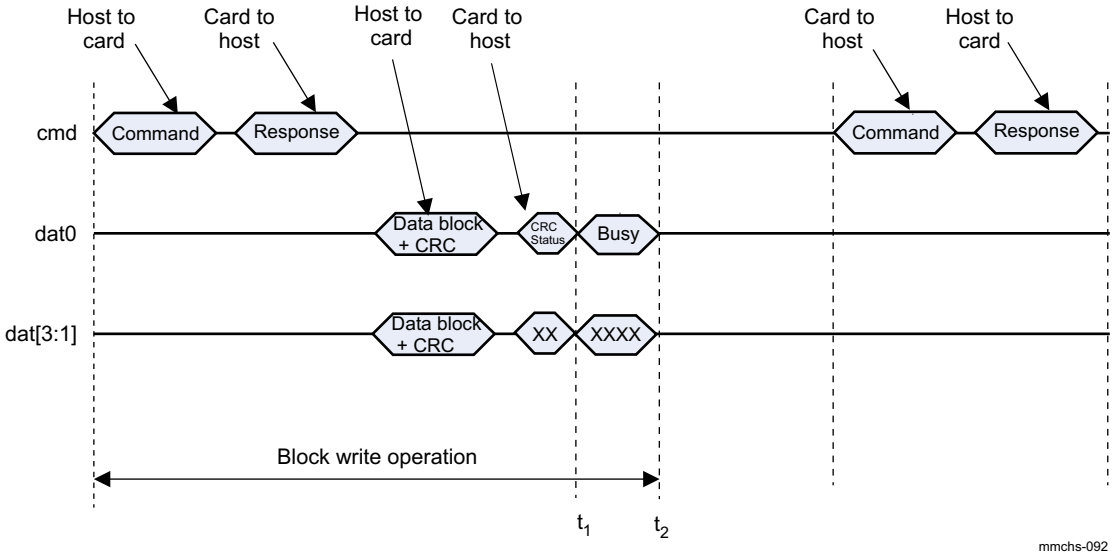
t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

11.12.4.9.2 Busy Time-Out After Write CRC Status

Figure 11-840 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

Figure 11-840. Busy Time-Out After Write CRC Status



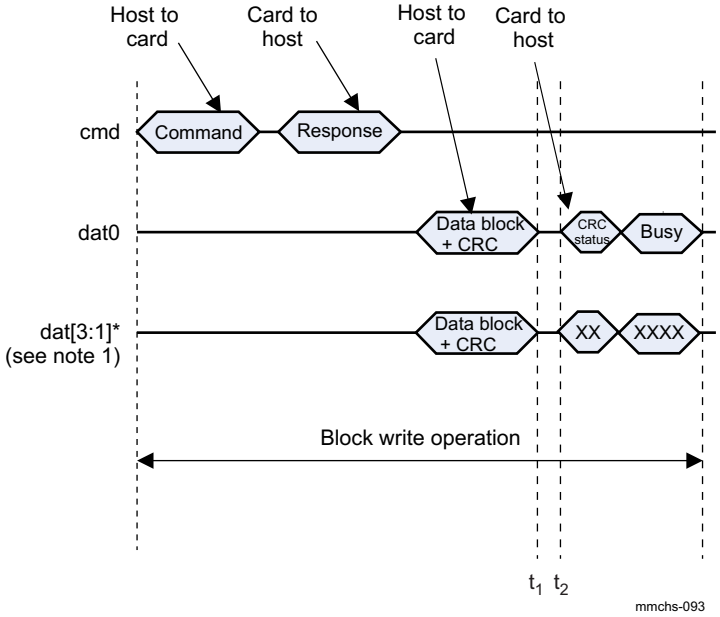
t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

11.12.4.9.3 Write CRC Status Time-Out

Figure 11-841 shows the DTO event condition asserted when there is a write CRC status time-out.

Figure 11-841. Write CRC Status Time-Out



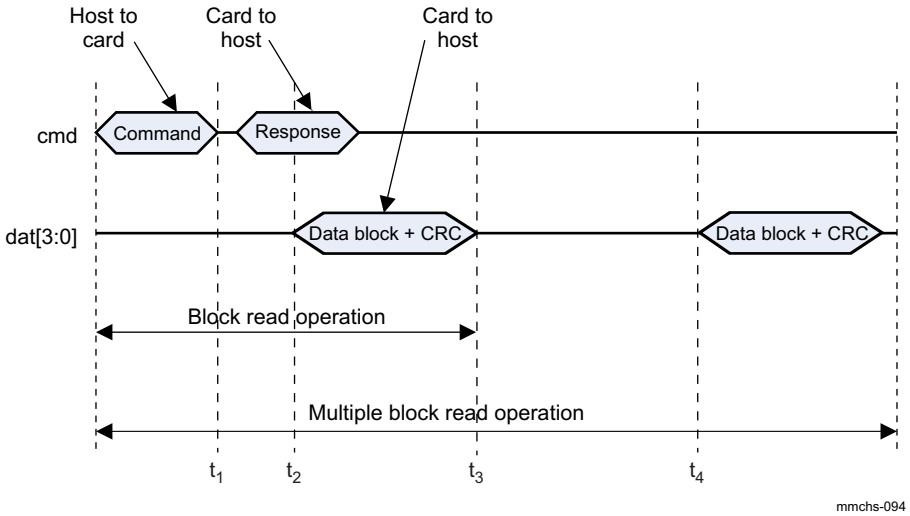
t_1 – Data time-out counter is loaded and starts after data block + CRC.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

11.12.4.9.4 Read Data Time-Out

Figure 11-842 shows the DTO event condition asserted when there is a read data time-out.

Figure 11-842. Read Data Time-Out



t_1 – Data time-out counter is loaded and starts after command transmission.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

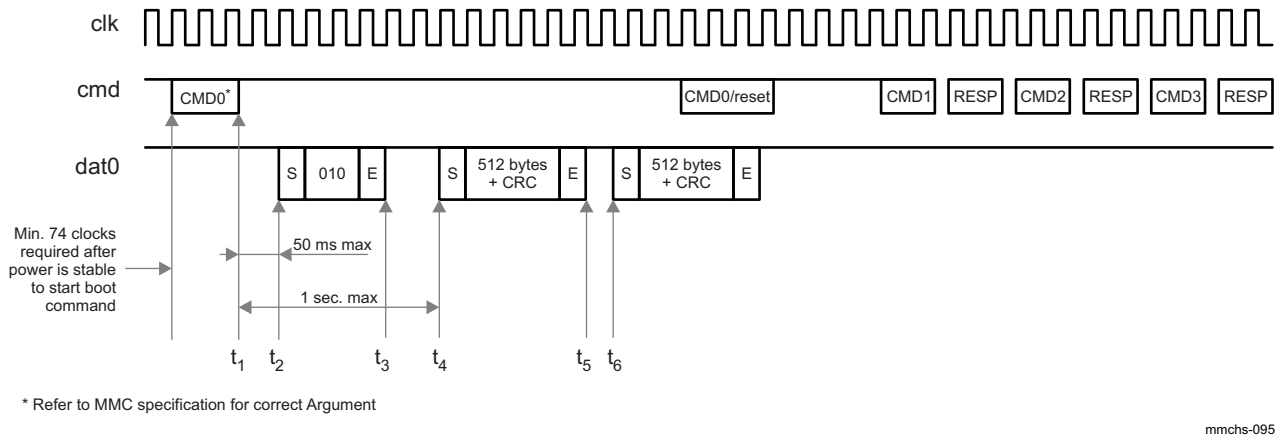
t_3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

11.12.4.9.5 Boot Acknowledge Time-Out

Figure 11-843 shows the DTO event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

Figure 11-843. Boot Acknowledge Time-Out When Using CMD0



t_1 – Data time-out counter is loaded and starts after CMD0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

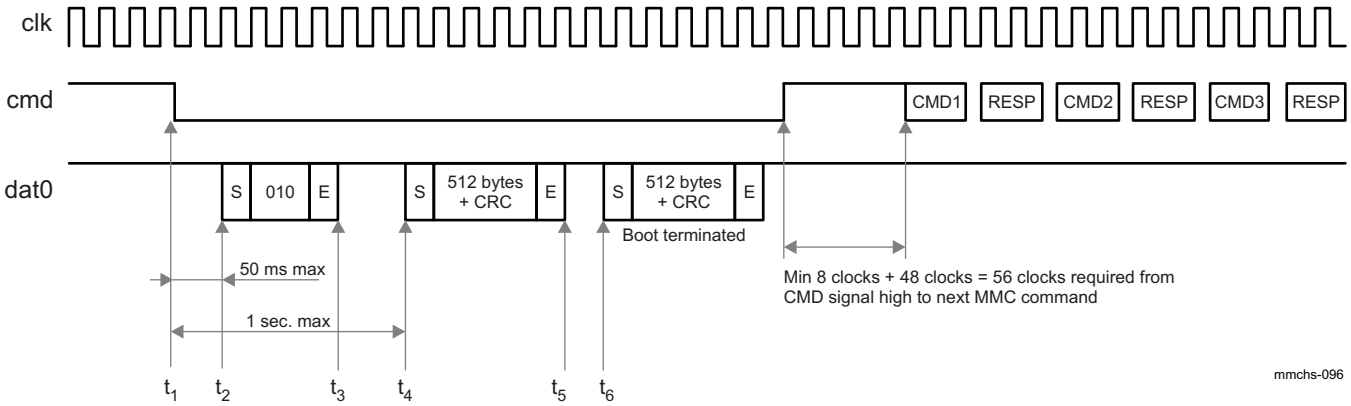
t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

Figure 11-844 shows the DTO event condition asserted when there is a boot acknowledge time-out when the CMD line is tied to 0.

Figure 11-844. Boot Acknowledge Time-Out When CMD Line Tied to 0



t_1 – Data time-out counter is loaded and starts after the CMD line is tied to 0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

11.12.4.10 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)
- Continuous stream transfers (transfer has an infinite length)

NOTE: Because the MMCi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The MMCi controller includes three features that make a transfer stop more convenient and easier to manage:

- Auto CMD12/Auto CMD23 (for eMMC and SD only):

  Auto CMD12/Auto CMD23 feature is enabled by setting the MMCi.MMCHS_CMD[3-2] ACEN bit field to 1h or to 2h respectively (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12/Auto CMD23 feature is enabled, the MMCi controller automatically issues a CMD12/CMD23 command when the expected number of blocks is exchanged.
- Stop at block gap:

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 1h. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- ADMA mode:

  For ADMA-capable modules (MMC0 and MMC1) (for more information, see Section 11.12.4.5, *DMA Modes*), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

NOTE: For eMMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

Table 11-1837 shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 11-1837. MMCi Controller Transfer Stop Command Summary

		Write Transfer	Read Transfer
		SD/MMC	SD/MMC
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12/CMD23. Wait TC.	Send CMD12/CMD23. Wait TC.
	Stop at the end of the transfer (finite transfer only)	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.

NOTE: The MMCi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

11.12.4.11 Output Signals Generation

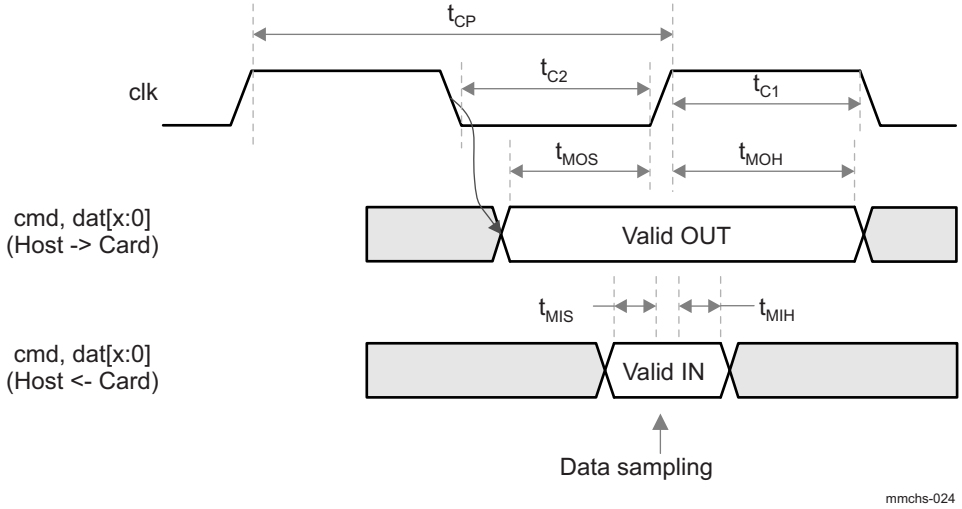
The MMC output signals can be driven on clock falling edge only (see MMCHS_HCTL[2] HSPE bit).

11.12.4.11.1 Generation on Falling Edge of MMC Clock

The controller defaults to this mode to maximize hold timings. In this case, the MMCHS_HCTL[2] HSPE bit is set to 0.

Figure 11-845 shows the output signals of the module when generating from the falling edge of the MMC clock.

Figure 11-845. Output Driven on Falling Edge



11.12.4.12 Card Boot Mode Management

Boot operation mode lets the MMCi host controller read boot data from the connected slave (MMC device) by keeping the CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

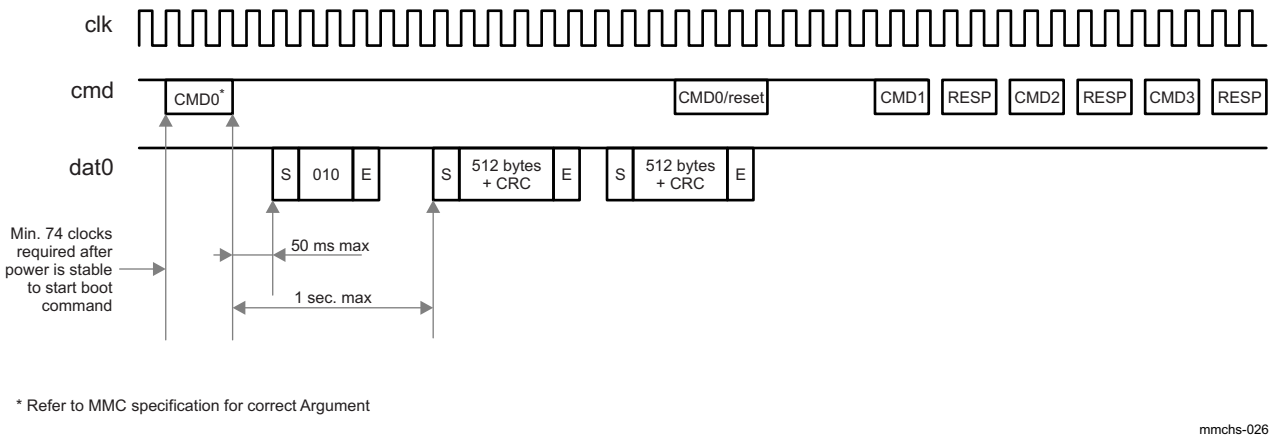
Power-on boot defines a way for the boot code to be accessed by the MMCi host controller without an upper-level software driver, thus speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

11.12.4.12.1 Boot Mode Using CMD0

Figure 11-846 shows the timing diagram of a boot sequence using CMD0.

Figure 11-846. Boot Mode Using the CMD0 Timing Diagram



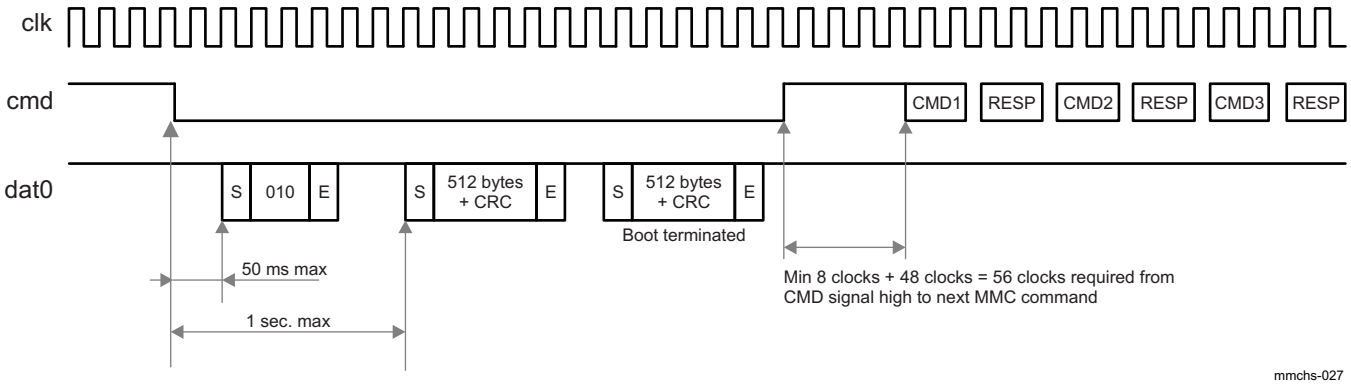
NOTE: Refer to MMC specification for correct Argument.

For more information about how to configure the MMC host controller, see Section 11.12.5.1.2.2.1, *Boot Using the CMD0*.

11.12.4.12.2 Boot Mode With CMD Line Tied to 0

Figure 11-847 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 11-847. Boot Mode With CMD Line Tied to 0 Timing Diagram



For more information about how to configure the MMC host controller, see Section 11.12.5.1.2.2.2, *Boot With CMD Line Tied to 0*.

11.12.4.13 MMC CE-ATA Command Completion Disable Management

The MMCi host controller supports CE-ATA features, in particular the detection of the command completion token. When a command that requires a CCS (the MMCHS_CON[12] CEATA bit is set to 1 and the MMCHS_CMD[3-2] ACEN bit field is set to 1h) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- Set the MMCHS_CON[12] CEATA bit to 1.
- Set the MMCHS_CON[2] HR bit to 1.
- Clear the MMCHS_ARG register.
- Write into the MMCHS_CMD register with the value 0000 0000h.

When a command completion disable token was emitted (that is, the MMCHS_STAT[0] CC bit is received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when CCSD is emitted during the last data block transfer, and the sequence on the command line is sent close to the CCS token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:

  An interrupt CIRQ is generated when CCS is detected, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

11.12.4.14 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register (MMCHS_FE) is used to control the error status and error interrupt status for Auto CMD12 and Auto CMD23.

The system test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the MMCHS_CON[4] MODE bit = 1) for boundary connectivity verification.

The MMCHS_HCTL[7] CDSS and MMCHS_HCTL[6] CDTL bits enable manual control of MMCHS_PSTATE[16] CINS and interrupt generating indicated in MMCHS_STAT[7] CREM and MMCHS_STAT[6] CINS.

11.12.4.15 MMC Hardware Status Features

Table 11-1838 describes the MMC hardware status features.

Table 11-1838. MMC Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 11.12.4.4, *Interrupt Requests.*	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23-20] DLEV	Indicates the level of the data lines
Write protect switch pin level	Status	MMCHS_PSTATE[19] WP	Indicates whether the SD card is write protected or not.
Card detect pin level	Status	MMCHS_PSTATE[18] CDPL	Indicates the level of the MMCi_SDCD signal/pad
Card State Stable	Status	MMCHS_PSTATE[17] CSS	Used for testing. Indicates MMCi_SDCD stable state
Card inserted	Status	MMCHS_PSTATE[16] CINS	Indicates whether the SD card is inserted
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Re - Tuning Request	Status	MMCHS_PSTATE[3] RTR	Indicates whether the sampling clock needs re - tuning or not.
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active

Table 11-1838. MMC Hardware Status Features (continued)

Feature	Type	Register/Bit Field	Description
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

Table 11-1839 describes the MMC preset value features.

Table 11-1839. MMC Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 and SDR50 speed modes(1)
Preset value register	Status	MMCHS_PVSDR104DDR50	Preset Values for SDR104 and DDR50 speed modes(2)

(1) SDR50 mode is not supported.
(2) SDR104 mode is not supported.

11.12.5 MMC/SD Programming Guide

11.12.5.1 Low-Level Programming Models

11.12.5.1.1 Global Initialization

11.12.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MMCi module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC modules. For more information, see Section 11.12.3, *MMC/SD Integration*, and Section 11.12.2, *MMC/SD Environment*. Table 11-1840 shows the global initialization of surrounding modules.

Table 11-1840. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
Clock Management	Module interface and functional clocks must be enabled. See Section 5.4, *Clock Management*.
BOOT_CFG	Module-specific pad muxing and configuration must be set in the BOOT_CFG. See Section 5.1, *Control Module (BOOT_CFG)*.
Interrupt Controller	Device INTCs must be configured to enable the interrupt request generation. See Chapter 9, *Interrupts*.

11.12.5.1.1.2 MMC Host Controller Initialization Flow

Table 11-1841 shows the general boot process.

Table 11-1841. MMC Controller Meta Initialization Steps

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 11.12.5.1.1.2.1, *Enable Interface and Functional Clock for MMC controller*.	
Software reset of the controller.		See Section 11.12.5.1.1.2.2, *MMC Soft Reset Flow*.	
Set module hardware capabilities.		See Section 11.12.5.1.1.2.3, *Set MMC Default Capabilities*.	

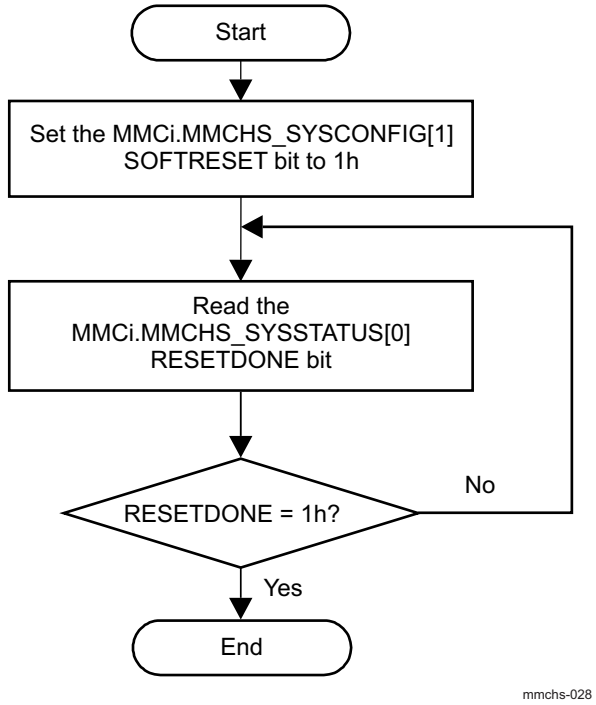
11.12.5.1.1.2.1 Enable Interface and Functional Clock for MMC Controller

Before any MMC register access, the MMC interface and functional clock in the Clock Management registers must be enabled. See Section 5.4, *Clock Management*.

11.12.5.1.1.2.2 MMC Soft Reset Flow

Figure 11-848 shows the soft reset process of the MMC controller.

Figure 11-848. MMC Controller Software Reset Flow



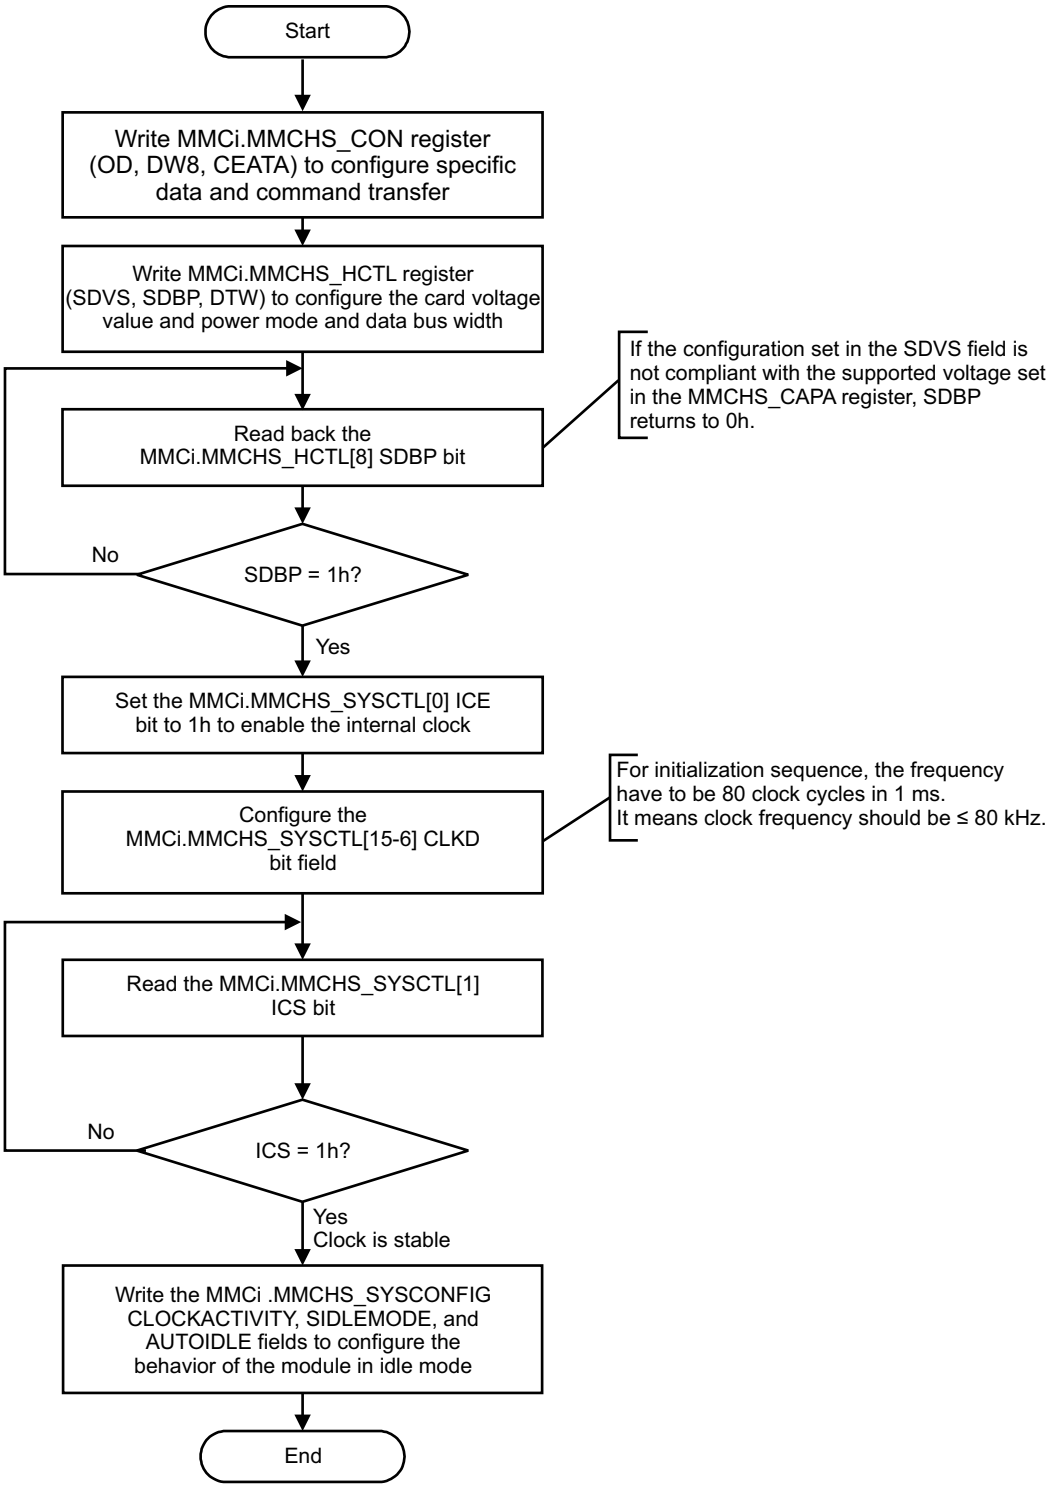
11.12.5.1.1.2.3 Set MMC Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS_CAPA[26-24] and MMCi.MMCHS_CUR_CAPA[23-0] bit fields before the MMC host driver is started.

11.12.5.1.1.2.4 MMC Host and Bus Configuration

Figure 11-849 shows the MMC bus configuration process.

Figure 11-849. MMC Controller Bus Configuration



11.12.5.1.2 Operational Modes Configuration

11.12.5.1.2.1 Basic Operations for MMC Host Controller

The MMC host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

11.12.5.1.2.1.1 Card Detection, Identification, and Selection

Figure 11-850 and Figure 11-851 show the card detection, identification and selection process.

Figure 11-850. MMC Controller Card Identification and Selection – Part 1

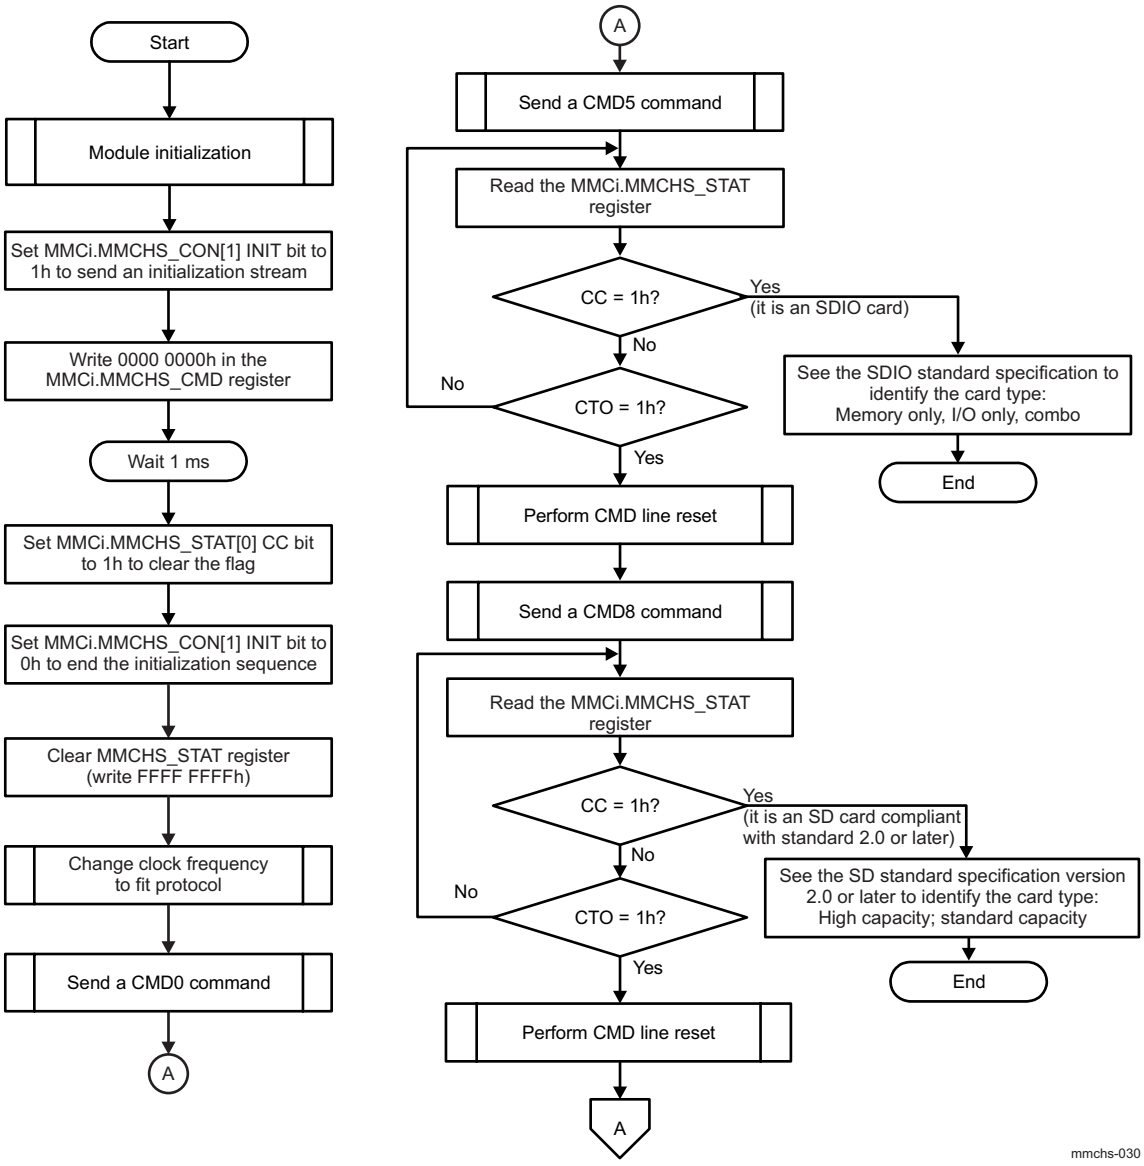


Figure 11-851. MMC Controller Card Identification and Selection – Part 2

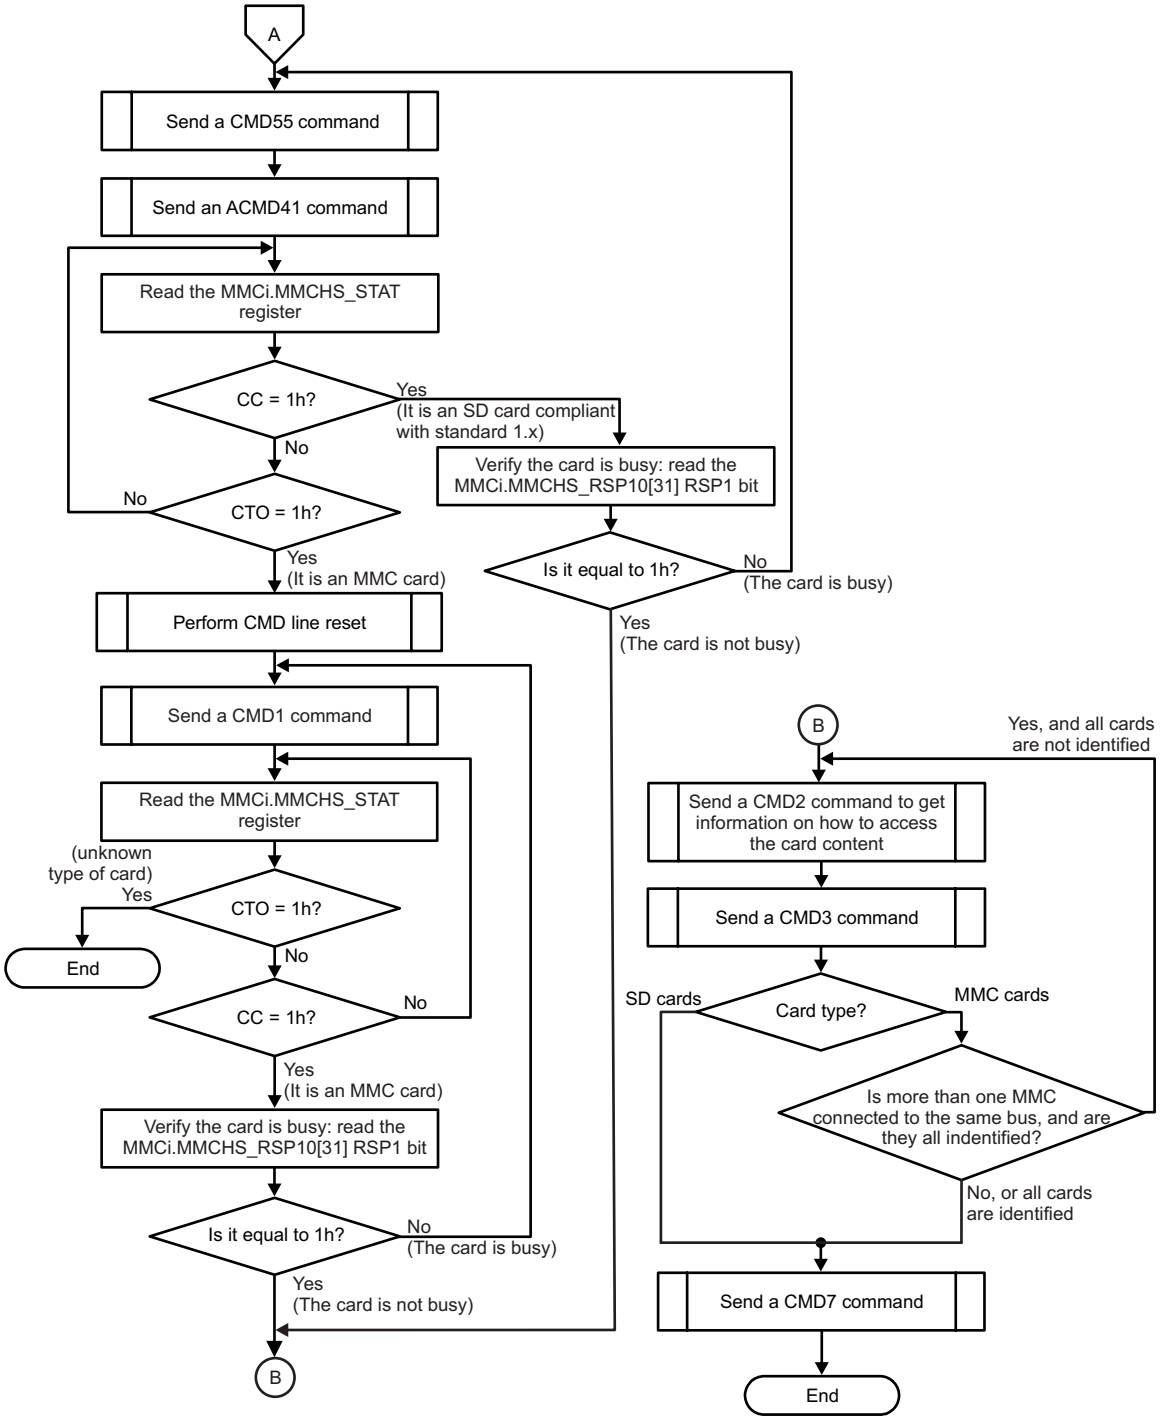

Table 11-1842 lists the subprocess call summary.

Table 11-1842. Subprocess Call Summary for Main Sequence – Card Identification and Selection

Subprocess Name	Cross-Reference

11.12.5.1.2.1.5 Read/Write Transfer Flow in CE-ATA Mode

Figure 11-855 shows the read and write CE-ATA protocol when in polling mode.

Figure 11-855. MMC Controller Read/Write in CE-ATA Mode

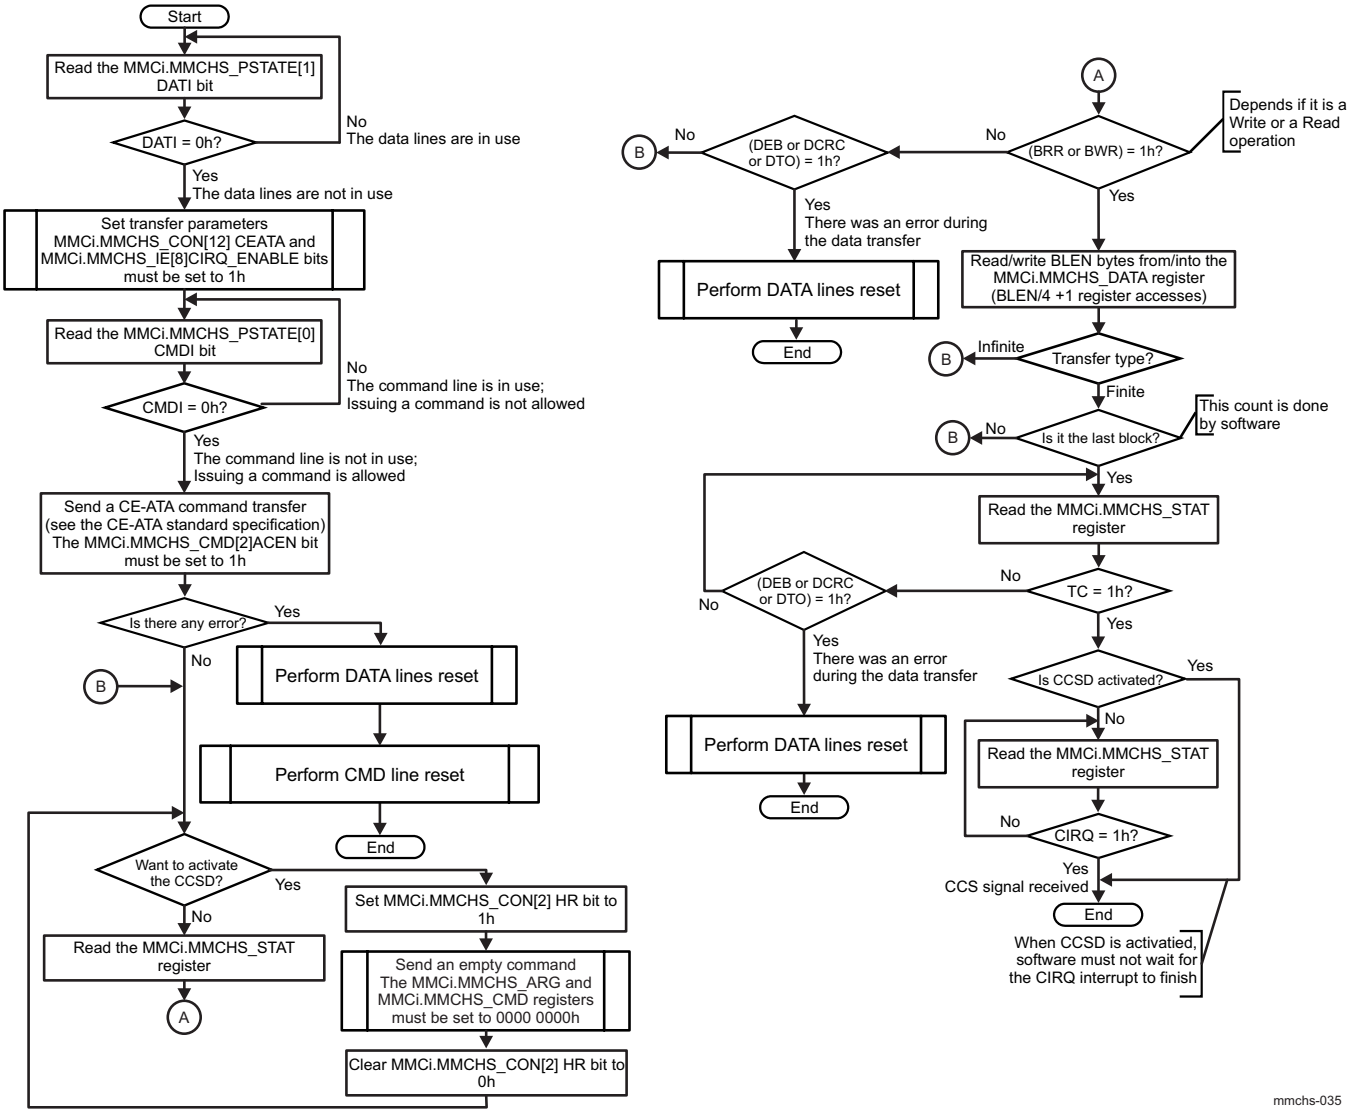

Table 11-1848. Subprocess Call Summary for Main Sequence – Read/Write in CE-ATA Mode

Subprocess Name	Cross-Reference
Perform CMD line reset.	See Section 11.12.5.1.2.1.1.1, *CMD Line Reset Procedure*.
Perform DATA lines reset.	See Section 11.12.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

11.12.5.1.2.1.6 Suspend-Resume Flow

The suspend-and-resume feature is supported only by SDIO cards.

11.12.5.1.2.1.6.1 Suspend Flow

Figure 11-856 shows the suspend flow for SDIO cards.

Figure 11-856. MMC Controller Suspend Flow

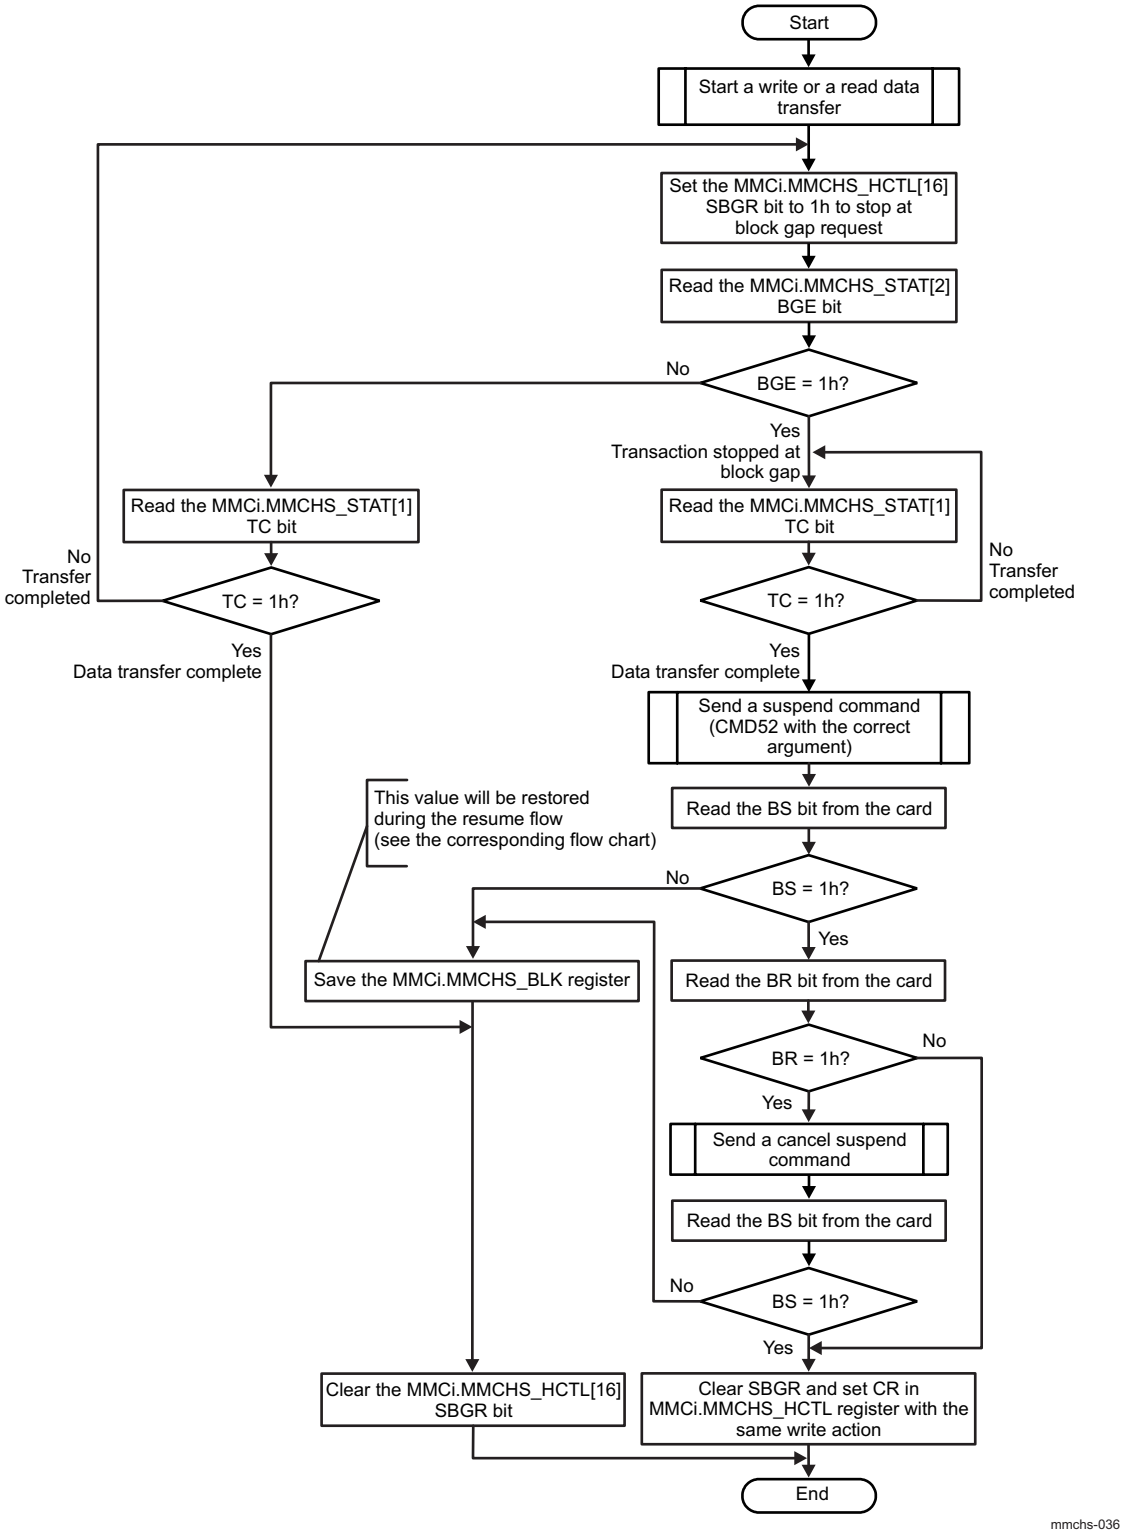

Table 11-1849. Subprocess Call Summary for Main Sequence – Suspend Flow

Table 11-1853. Subprocess Call Summary for Main Sequence – Bus Width Configuration Flow

Subprocess Name	Cross-Reference
Initialize module and card.	See Section 11.12.5.1.1.2, *MMC Host Controller Initialization Flow*. See Section 11.12.5.1.2.1.1, *Card Detection, Identification, and Selection*.
Send a SEND_CSD command (CMD9).	See Section 11.12.5.1.2.1.7.1, *Command Transfer Flow*.
Send SWITCH command (CMD6).	See Section 11.12.5.1.2.1.7.1, *Command Transfer Flow*.

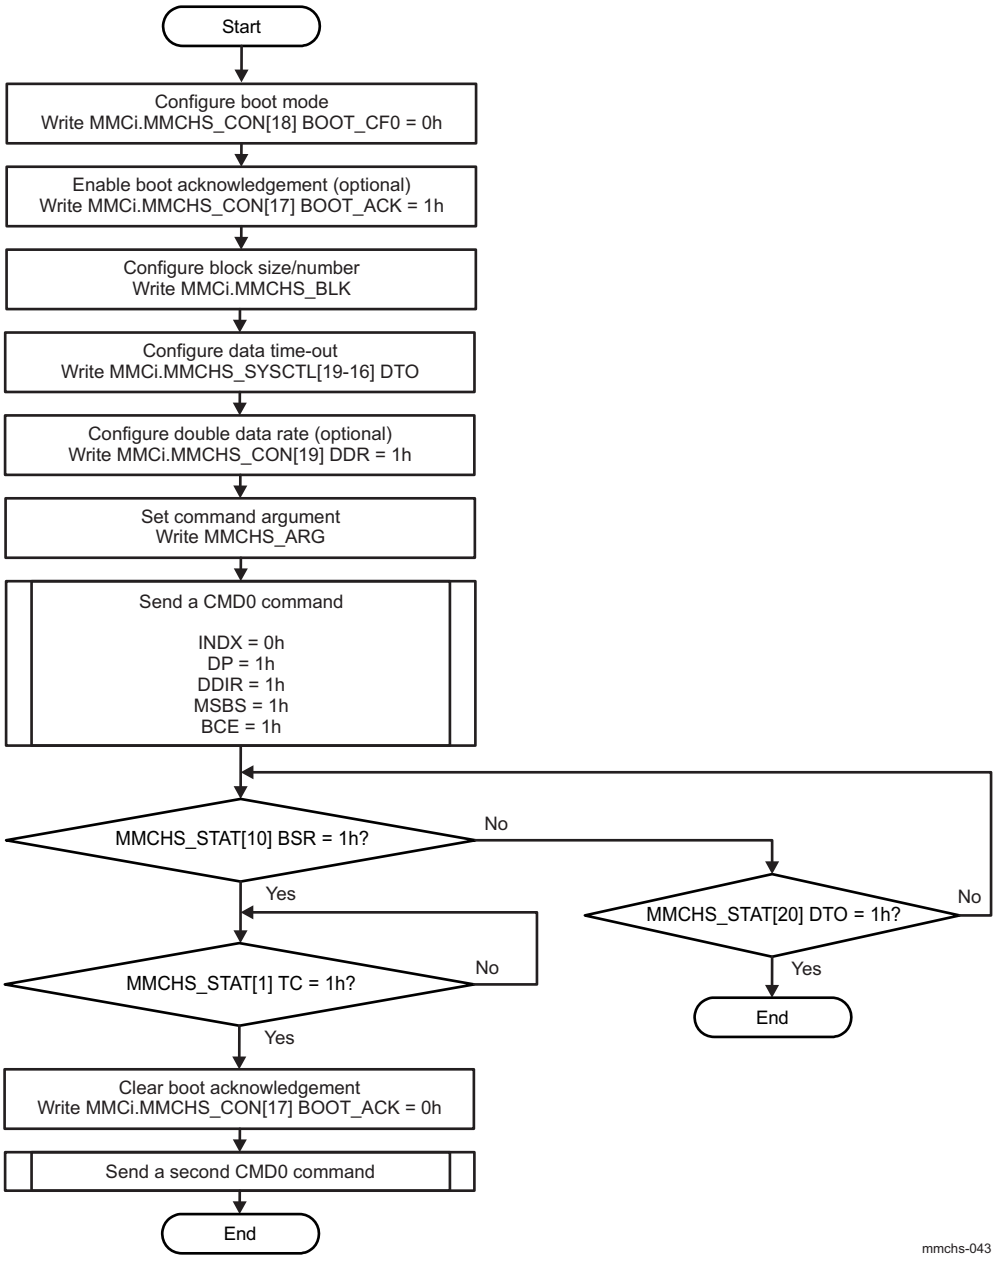
11.12.5.1.2.2 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

11.12.5.1.2.2.1 Boot Using CMD0

Figure 11-862 shows the necessary steps to configure the controller boot mode using CMD0.

Figure 11-862. MMC Controller Boot Using CMD0



To abort a boot sequence, the system must issue a CMD0 with the MMCHS_CMD[23-22] CMD_TYPE bit field set to 3h (the MMCHS_CON[17] BOOT_ACK bit previously cleared to 0h) during the transfer to abort the transfer and enable the card to exit from boot state.

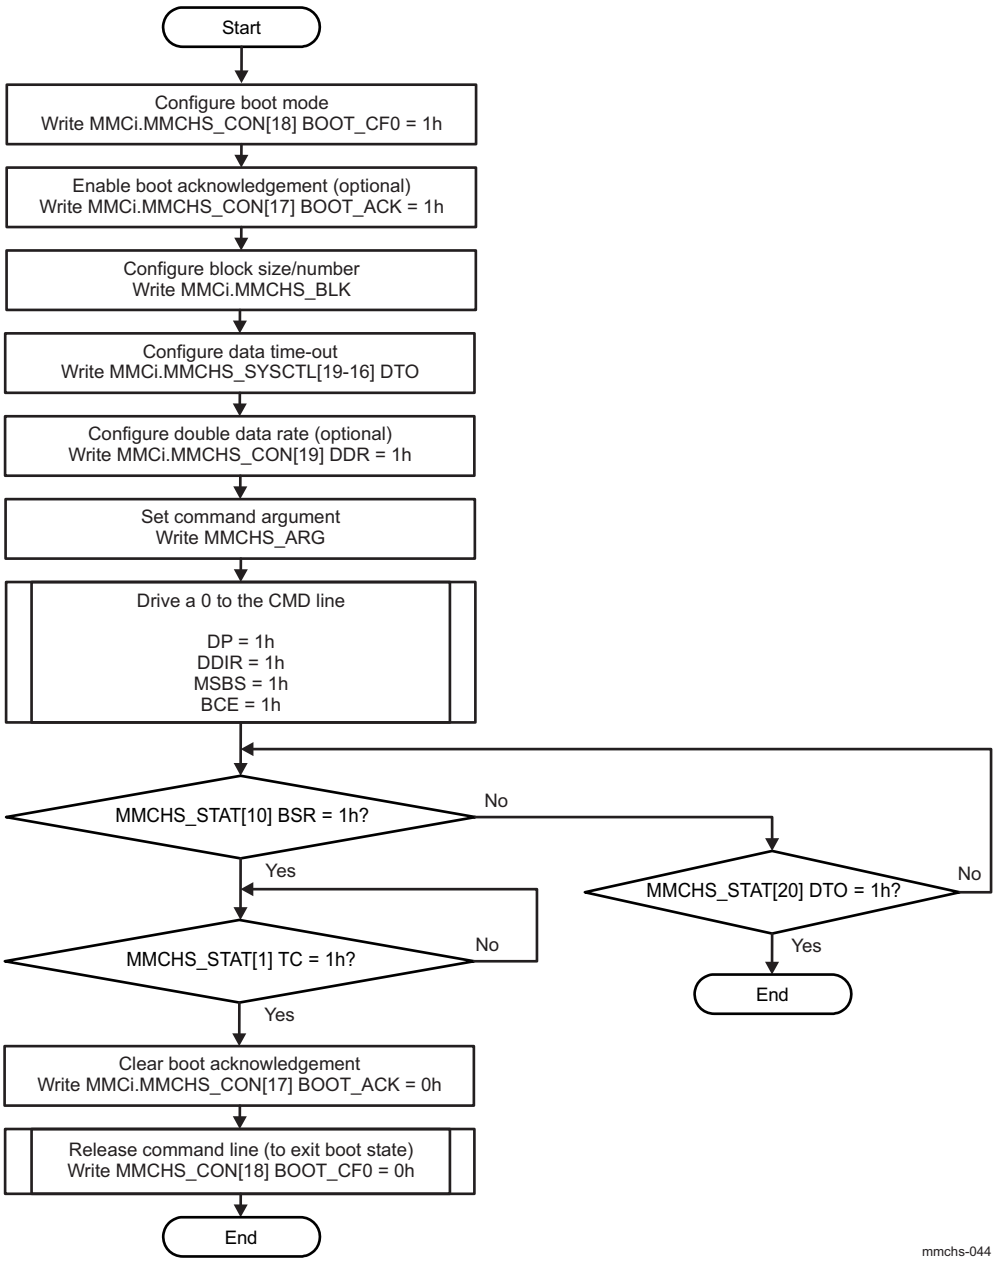
Table 11-1854. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 11.12.5.1.2.1.7.1, *Command Transfer Flow*.

11.12.5.1.2.2.2 Boot With CMD Line Tied to 0

Figure 11-863 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

Figure 11-863. MMC Controller Boot With CMD Line Tied to 0



To abort the boot sequence, the system must clear the MMCHS_CON[18] BOOT_CF0 bit to 0h during the transfer to abort the transfer and enable the card to exit from boot state.

Table 11-1855. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 11.12.5.1.2.1.7.1, *Command Transfer Flow*.

11.12.6 MMC/SD Registers

Table 11-1857 lists the memory-mapped registers for the MMC. All register offset addresses not listed in Table 11-1857 should be considered as reserved locations and the register contents should not be modified.

Table 11-1856. MMC Instances

Instance	Base Address
MMCSD_0	2300 0000h
MMCSD_1	2310 0000h

Table 11-1857. MMC Registers

Table 11-1862. MMCHS_HL_HWINFO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	-h	Reserved
6	RETMODE	R	-h	Retention Mode generic parameter This bit field indicates whether the retention mode is supported using the pin PIRFFRET. 0h (R) = Retention mode disabled. 1h (R) = Retention mode enabled. **Note:** Retention mode is not supported. Read returns 0.
5-2	MEM_SIZE	R	-h	Memory size for FIFO buffer 1h (R) = Memory of 512 bytes, max block length is 512 bytes. 2h (R) = Memory of 1024 bytes, max block length is 1024 bytes. 4h (R) = Memory of 2048 bytes, max block length is 2048 bytes. 8h (R) = Memory of 4096 bytes, max block length is 2048 bytes.
1	MERGE_MEM	R	-h	Memory merged for FIFO buffer This bit field defines the configuration of FIFO buffer architecture. If the bit is set STA and DFT shall support clock multiplexing and balancing. 0h (R) = 2 memories instantiated, one per data transfer direction. 1h (R) = A single memory is used with multiplexed addresses, data and clocks.
0	MADMA_EN	R	-h	Master DMA enabled generic parameter This bit defines the configuration of the controller to know if it supports the master DMA management called ADMA. 0h (R) = No Master DMA (ADMA) management supported. 1h (R) = Controller supports ADMA. **Note:** Read returns 1.

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5-4	STANDBYMODE	R/W	2h	Configuration of the local initiator state management mode By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0h (R/W) = Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 1h (R/W) = No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 2h (R/W) = Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. MMC module shall not generate (initiator-related) wakeup events. 3h (R/W) = Smart-Standby wakeup-capable mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. MMC module may generate (master-related) wakeup events when in standby state. Mode is only relevant if the appropriate MMC module "mwakeup" output is implemented. **Note:** Wakeup feature is not supported.

Table 11-1865. MMCHS_HL_SYSCONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the MMC module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the MMC module's internal requirements. MMC module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the MMC module's internal requirements. MMC module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate MMC module "swakeup" output(s) is (are) implemented. **Note:** Wakeup feature is not supported.
1	FREEEMU	R/W	0h	Sensitivity to emulation (debug) suspend input signal Functionality NOT implemented in MMC. 0h (R/W) = MMC module is sensitive to emulation suspend. 1h (R/W) = MMC module is not sensitive to emulation suspend.
0	SOFTRESET	R/W	0h	Software reset (Optional) 0h (W) = No action. 1h (W) = Initiate software reset . 0h (R) = Reset done, no pending action. 1h (R) = Reset (software or other) ongoing.

Table 11-1868. MMCHS_SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	Reserved
13-12	STANDBYMODE	R/W	2h	Master interface Power Management, standby/wait control The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a '0'. 0h (R/W) = Force-standby. Mstandby is forced unconditionnaly. 1h (R/W) = No-standby. Mstandby is never asserted. 2h (R/W) = Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. MMC module shall not generate (initiator-related) wakeup events.
11-10	RESERVED	R	0h	Reserved
9-8	CLOCKACTIVITY	R/W	0h	Clocks activity Bit8: Interface clock. Bit9: Functional clock. 0h (R/W) = Interface and Functional clock may be switched off. 1h (R/W) = Interface clock is maintained. Functional clock may be switched-off. 2h (R/W) = Functional clock is maintained. Interface clock may be switched-off. 3h (R/W) = Interface and Functional clocks are maintained.
7-5	RESERVED	R	0h	Reserved

Table 11-1868. MMCHS_SYSCONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-3	SIDLEMODE	R/W	2h	Power management 0h (R/W) = If an IDLE request is detected, the MMC acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 1h (R/W) = If an IDLE request is detected, the request is ignored and the module keeps on behaving normally. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the MMC module's internal requirements. MMC module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the MMC module's internal requirements. MMC module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate MMC module "swakeup" output(s) is (are) implemented. **Note:** Wakeup feature is not supported. Smart-idle wakeup-capable mode is not supported.
2	ENAWAKEUP	R/W	1h	Wakeup feature control 0h (R/W) = Wakeup capability is disabled. 1h (R/W) = Wakeup capability is enabled. **Note:** Wakeup feature is not supported.
1	SOFTRESET	R/W	0h	Software reset The bit is automatically reset by the hardware. During reset, it always returns 0. 0h (W) = No effect. 1h (W) = Trigger a module reset. 0h (R) = Normal mode. 1h (R) = The module is reset.
0	AUTOIDLE	R/W	1h	Internal Clock gating strategy 0h (R/W) = Clocks are free-running. 1h (R/W) = Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity.

11.12.6.6 MMCHS_CSRE Register (Offset = 124h) [reset = 0h]

MMCHS_CSRE is shown in Figure 11-869 and described in Table 11-1874.

Card Status Response Error
This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO.
When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP10[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP10).
Note: No automatic card error detection for auto CMD12 is implemented; the host system has to check auto CMD12 response register (MMCHS_RSP76) for possible card errors.

11.12.6.7 MMCHS_SYSTEST Register (Offset = 128h) [reset = 0h]

MMCHS_SYSTEST is shown in Figure 11-870 and described in Table 11-1877.

System Test Register
This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.
Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLEN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.

11.12.6.8 MMCHS_CON Register (Offset = 12Ch) [reset = 600h]

MMCHS_CON is shown in Figure 11-871 and described in Table 11-1880.

Configuration Register
This register is used:
- to select the functional mode or the SYSTEST mode for any card.
- to send an initialization sequence to any card.
- to enable the detection on DAT[1] of a card interrupt for SDIO cards only.
and also to configure:
- specific data and command transfers for MMC cards only.
- the parameters related to the card detect and write protect input signals.

Table 11-1880. MMCHS_CON Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved
21	SDMA_LNE	R/W	0h	Slave DMA Level/Edge Request The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0h (R/W) = Slave DMA edge sensitive, Early DMA de-assertion. 1h (R/W) = Slave DMA level sensitive, Late DMA de-assertion.
20	DMA_MNS	R/W	0h	DMA Master or Slave selection When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is asserted to '1'. 0h (R/W) = The controller is slave on data transfers with system. 1h (R/W) = The controller is master on data exchange with system, controller must be configured as using DMA.

Table 11-1880. MMCHS_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	DDR	R/W	0h	Dual Data Rate mode When this bit field is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting. 0h (R/W) = Standard mode: data are transmitted on a single edge depending on MMCHS_HCTL[HSPE]. 1h (R/W) = Data Bytes and CRC are transmitted on both edge.
18	BOOT_CF0	R/W	0h	Boot status supported This bit field is set when the CMD line need to be forced to '0' for a boot sequence. CMD line is driven to '0' after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction. 0h (W) = CMD line is released when it was previously forced to '0' by a boot sequence. 1h (W) = CMD line forced to '0' is enabled and will be active after writing into MMCHS_CMD. 0h (R) = CMD line not forced. 1h (R) = CMD line forced to '0' is enabled.
17	BOOT_ACK	R/W	0h	Boot acknowledge received When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0h (R/W) = No acknowledge to be received. 1h (R/W) = A boot status will be received on DAT0 line after issuing a command.
16	CLKEXTFREE	R/W	0h	External clock free running This bit field is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set. 0h (R/W) = External card clock is cut off outside active transaction period. 1h (R/W) = External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.
15	PADEN	R/W	0h	Control Power for MMC Lines This bit field is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit. 0h (R/W) = ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 1h (R/W) = ADPIDLE module pin is forced to active state. **Note:** This feature is not supported.

Table 11-1880. MMCHS_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	OBIE	R/W	0h	Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMC OBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0h (R/W) = Out-of-Band interrupt detection disabled. 1h (R/W) = Out-of-Band interrupt detection enabled. **Note:** Out-Of-Band Interrupt feature is not supported.
13	OBIP	R/W	0h	Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0h (R/W) = Active high level. 1h (R/W) = Active low level. **Note:** Out-Of-Band Interrupt feature is not supported.
12	CEATA	R/W	0h	CE-ATA control mode MMC cards compliant with CE-ATA: By default, this bit is set to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0h (R/W) = Standard MMC/SD/SDIO mode. 1h (R/W) = CE-ATA mode next commands are considered as CE-ATA commands.
11	CTPL	R/W	0h	Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0h (R/W) = Disable all the input buffers outside of a transaction. 1h (R/W) = Disable all the input buffers except the buffer of DAT[1] outside of a transaction.
10-9	DVAL	R/W	3h	Debounce filter value All cards: This bit field is used to define a debounce period to filter the card detect input signal (MMCi_SDCD). The usage of the card detect input signal (MMCi_SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = 33 us debounce period. 1h (R/W) = 231 us debounce period. 2h (R/W) = 1 ms debounce period. 3h (R/W) = 8,4 ms debounce period.

Table 11-1880. MMCHS_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	WPP	R/W	0h	Write protect polarity For SD and SDIO cards only: This bit selects the active level of the write protect input signal (MMCi_SDWP). The usage of the write protect input signal (MMCi_SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = Active high level. 1h (R/W) = Active low level.
7	CDP	R/W	0h	Card detect polarity All cards: This bit selects the active level of the card detect input signal (MMCi_SDCD). The usage of the card detect input signal (MMCi_SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = Active low level. 1h (R/W) = Active high level.
6	MIT	R/W	0h	MMC interrupt command Only for MMC cards: This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0h (R/W) = Command timeout enabled. 1h (R/W) = Command timeout disabled.
5	DW8	R/W	0h	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6). 0h (R/W) = 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards). 1h (R/W) = 8-bit Data width (DAT[7:0] used, MMC cards).
4	MODE	R/W	0h	Mode select All cards: This bit select between Functional mode and SYSTEST mode. 0h (R/W) = Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register. 1h (R/W) = SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.

Table 11-1880. MMCHS_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	STR	R/W	0h	Stream command Only for MMC cards: This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0h (R/W) = Block oriented data transfer. 1h (R/W) = Stream oriented data transfer.
2	HR	R/W	0h	Broadcast host response Only for MMC cards: This bit field is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCHS_CON[CEATA] is set to 1 and MMCHS_ARG set to 0000 0000h when writing 0000 0000h into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token that is, CMD line held to '0' during 47 cycles followed by a 1. 0h (R/W) = The host does not generate a 48-bit response instead of a command. 1h (R/W) = The host generates a 48-bit response instead of a command or a command completion signal disable token.
1	INIT	R/W	0h	Send initialization stream All cards: When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms (see section 9.3, "Power-Up", in the MMC card specification, or section 6.4 in the SD card specification). **Note:** in this mode, there is no command sent to the card and no response is expected. 0h (R/W) = The host does not send an initialization sequence. 1h (R/W) = The host sends an initialization sequence.
0	OD	R/W	0h	Card open drain mode Only for MMC cards: This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[HR]). 0h (R/W) = No Open Drain. 1h (R/W) = Open Drain or Broadcast host response.

11.12.6.9 MMCHS_PWCNT Register (Offset = 130h) [reset = 0h]

MMCHS_PWCNT is shown in Figure 11-872 and described in Table 11-1883.

Power Counter Register
This register is used to program a MMC counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage.

Table 11-1882. MMCHS_PWCNT Instances

MMC/SD Functional Description

11.12.6.10 MMCHS_DLL Register (Offset = 134h) [reset = 80000000h]

MMCHS_DLL is shown in Figure 11-873 and described in Table 11-1886.

DLL control and status register
This register is used for tuning procedure required for SDR104 speed mode.
It gives visibility and control on the DLL.

Note: DLL feature and SDR104/HS200 Mode are not supported.

Table 11-1885. MMCHS_DLL Instances

Table 11-1889. MMCHS_SDMASA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SDMA_ARG2	R/W	0h	SDMA System Address / Argument 2 This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23. (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

Table 11-1892. MMCHS_BLK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NBLK	R/W	0h	Blocks count for current transfer This bit field is enabled when Block count Enable (MMCHS_CMD[BCE]) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. **Note:** The host controller decrements the block count after each block transfer and stops when the count reaches zero. This bit field can be accessed only if no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this bit field. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0h (R/W) = Stop count. 1h (R/W) = 1 block. 2h (R/W) = 2 blocks. FFFFh (R/W) = 65535 blocks.
15-12	RESERVED	R	0h	Reserved

Table 11-1892. MMCHS_BLK Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-0	BLEN	R/W	0h	Transfer Block Size This bit field specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCHS_STAT[TC] set to 1) will not return the true byte number of data length while the stop occurs but the value written in this bit field before transfer is launched. 0h (R/W) = No data transfer. 1h (R/W) = 1 byte block length. 2h (R/W) = 2 bytes block length. 3h (R/W) = 3 bytes block length. 1FFh (R/W) = 511 bytes block length. 200h (R/W) = 512 bytes block length. 7FFh (R/W) = 2047 bytes block length. 800h (R/W) = 2048 bytes block length.

11.12.6.14 MMCHS_CMD Register (Offset = 20Ch) [reset = 0h]

MMCHS_CMD is shown in Figure 11-877 and described in Table 11-1898.

Command and Transfer Mode Register
MMCHS_CMD[31-16] = the command register
MMCHS_CMD[15-0] = the transfer mode.
This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCHS_CMD[15-0] registers during data transfer has no effect.
This register shall be used for any card.
Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer.

Table 11-1898. MMCHS_CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
				35h (R/W) = CMD53 or ACMD53. 36h (R/W) = CMD54 or ACMD54. 37h (R/W) = CMD55 or ACMD55. 38h (R/W) = CMD56 or ACMD56. 39h (R/W) = CMD57 or ACMD57. 3Ah (R/W) = CMD58 or ACMD58. 3Bh (R/W) = CMD59 or ACMD59. 3Ch (R/W) = CMD60 or ACMD60. 3Dh (R/W) = CMD61 or ACMD61. 3Eh (R/W) = CMD62 or ACMD62. 3Fh (R/W) = CMD63 or ACMD63.
23-22	CMD_TYPE	R/W	0h	Command type This bit field specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 0h (R/W) = Others Commands. 1h (R/W) = CMD52 for writing "Bus Suspend" in CCCR. 2h (R/W) = CMD52 for writing "Function Select" in CCCR. 3h (R/W) = Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR.
21	DP	R/W	0h	Data present select This bit field indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command with no data transfer but using busy signal on DAT[0]. - command using only CMD line. - Resume command. 0h (R/W) = Command with no data transfer. 1h (R/W) = Command with data transfer.
20	CICE	R/W	0h	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to1). **Note:** The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0h (R/W) = Index check disable. 1h (R/W) = Index check enable.
19	CCCE	R/W	0h	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). **Note:** The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0h (R/W) = CRC7 check disable. 1h (R/W) = CRC7 check enable.
18	RESERVED	R	0h	Reserved

Table 11-1898. MMCHS_CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17-16	RSP_TYPE	R/W	0h	Response type This bits defines the response type of the command. 0h (R/W) = No response. 1h (R/W) = Response Length 136 bits. 2h (R/W) = Response Length 48 bits. 3h (R/W) = Response Length 48 bits with busy after response.
15-6	RESERVED	R	0h	Reserved
5	MSBS	R/W	0h	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0h (R/W) = Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK]. 1h (R/W) = Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.
4	DDIR	R/W	0h	Data transfer Direction SelectThis bit defines either data transfer will be a read or a write 0h (R/W) = Data Write (host to card). 1h (R/W) = Data Read (card to host).
3-2	ACEN	R/W	0h	Auto CMD Enable - SD card only This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation. 1. Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 2. Auto CMD23 Enable When this bit field is set to 10b, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. The Host Controller Version 3.00 and later shall support this function. The following conditions are required to use the Auto CMD23. – Auto CMD23 Supported (Host Controller Version is 3.00 or later). – A memory card that supports CMD23 (SCR[33]=1). – If DMA is used, it shall be ADMA. – Only when CMD18 or CMD25 is issued. (**Note:** the Host Controller does not check command index). Auto CMD23 can be used with or without ADMA. By writing the Command register, the Host Controller issues a CMD23 first and then issues a command specified by the Command Index in Command register. If response errors of CMD23 are detected, the second command is not issued. A CMD23 error is indicated in the Auto CMD Error Status register (MMCHS_AC12). 32-bit block count value for CMD23 is set to SDMA System Address / Argument 2 register (MMCHS_SDMASA). 0h (R/W) = Auto Command Disabled. 1h (R/W) = Auto CMD12 enable or CCS detection enabled. 2h (R/W) = Auto CMD23 Enable. 3h (R/W) = Reserved.

Table 11-1898. MMCHS_CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	BCE	R/W	0h	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0h (R/W) = Block count disabled for infinite transfer. 1h (R/W) = Block count enabled for multiple block transfer with known number of blocks.
0	DE	R/W	0h	DMA EnableThis bit is used to enable DMA mode for host data access 0h (R/W) = DMA mode disable. 1h (R/W) = DMA mode enable.

11.12.6.19 MMCHS_DATA Register (Offset = 220h) [reset = 0h]

MMCHS_DATA is shown in Figure 11-882 and described in Table 11-1913.

Data Register
This register is the 32-bit entry point of the buffer for read or write data transfers.
The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.
Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7-0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.
Example 1: Byte or 16-bit access
Mbyteen[3-0]=0001 (1-byte) => Mbyteen[3-0]=0010 (1-byte) => Mbyteen[3-0]=1100 (2-bytes) OK
Mbyteen[3-0]=0001 (1-byte) => Mbyteen[3-0]=0010 (1-byte) => Mbyteen[3-0]=0100 (1-byte) OK
Mbyteen[3-0]=0001 (1-byte) => Mbyteen[3-0]=0010 (1-byte) => Mbyteen[3-0]=1000 (1-byte) Bad.

Table 11-1916. MMCHS_PSTATE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved
24	CLEV	R	-h	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this bit field after reset depends on the CMD line level at that time. 0h (R) = The CMD line level is 0. 1h (R) = The CMD line level is 1.
23-20	DLEV	R	-h	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.

Table 11-1916. MMCHS_PSTATE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	WP	R	-h	Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (MMCi_SDWP) level. The value of this bit field after reset depends on the protect input pin (MMCi_SDWP) level at that time. 0h (R) = If MMCHS_CON[WPP] is set to 0 (default), the card is write protected, otherwise the card is not protected. 1h (R) = If MMCHS_CON[WPP] is set to 0 (default), the card is not write protected, otherwise the card is protected.
18	CDPL	R	-h	Card detect pin level This bit reflects the inverse value of the card detect input pin (MMCi_SDCD), debouncing is not performed on this bit and bit is valid only when Card State Stable MMCHS_PSTATE[CSS]) is set to 1. Use of this bit is limited to testing since it must be debounced y software. The value of this bit field after reset depends on the card detect input pin (MMCi_SDCD) level at that time. 0h (R) = The value of the card detect input pin (MMCi_SDCD) is 1. 1h (R) = The value of the card detect input pin (MMCi_SDCD) is 0.
17	CSS	R	0h	Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[CDPL]). Debouncing is performed on the card detect input pin (MMCi_SDCD) to detect card stability. 0h (R) = Reset or Debouncing. 1h (R) = No card or card inserted. **Note:** This bit is not affected by a software reset.
16	CINS	R	0h	Card inserted This bit is the debounced value of the card detect input pin (MMCi_SDCD). An inactive to active transition of the card detect input pin (MMCi_SDCD) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (MMCi_SDCD) will generate a card removal interrupt (MMCHS_STAT[REM]). 0h (R) = If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 0, the card has been inserted. 1h (R) = If MMCHS_CON[CDP] is set to 1, the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 0, no card is detected. The card may have been removed from the card slot. **Note:** This bit is not affected by a software reset.
15-12	RESERVED	R	0h	Reserved

Table 11-1916. MMCHS_PSTATE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	BRE	R	0h	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). 0h (R) = Read BLEN bytes disable. 1h (R) = Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE	R	0h	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. 0h (R) = There is no room left in the buffer to write BLEN bytes of data. 1h (R) = There is enough space in the buffer to write BLEN bytes of data.
9	RTA	R	0h	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. 0h (R) = No valid data on the DAT lines. 1h (R) = read data transfer on going.
8	WTA	R	0h	Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. 0h (R) = No valid data on the DAT lines. 1h (R) = Write data transfer on going.
7-4	RESERVED	R	0h	Reserved
3	RTR	R	0h	Re-Tuning Request Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting MMCHS_AC12[22] ET. This bit isn't set to 1 if MMCHS_AC12[23] SCLK_SEL is set to 0 (using fixed sampling clock). Refer to MMCHS_CAPA2[15-14] RTM for more detail. 0h (R) = Fixed or well tuned sampling clock. 1h (R) = Sampling clock needs re-tuning.

Table 11-1916. MMCHS_PSTATE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	DLA	R	0h	DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. 0h (R) = DAT Line inactive. 1h (R) = DAT Line active.
1	DATI	R	0h	Command inhibit (DAT) This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]). 0h (R) = Issuing of command using the DAT lines is allowed. 1h (R) = Issuing of command using DAT lines is not allowed.
0	CMDI	R	0h	Command inhibit (CMD) This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC] or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this bit field is not automatically cleared. 0h (R) = Issuing of command using CMD line is allowed. 1h (R) = Issuing of command using CMD line is not allowed.

Table 11-1919. MMCHS_HCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	Reserved
27	OBWE	R/W	0h	Wakeup event enable for 'Out-of-Band' Interrupt This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). The write to this bit field is ignored when MMCHS_CON[OBIE] is not set. 0h (R/W) = Disable wakeup on 'Out-of-Band' Interrupt. 1h (R/W) = Enable wakeup on 'Out-of-Band' Interrupt. **Note:** Out-Of-Band Interrupt feature is not supported. **Note:** Wakeup feature is not supported.
26	REM	R/W	0h	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0h (R/W) = Disable wakeup on card removal. 1h (R/W) = Enable wakeup on card removal. **Note:** Wakeup feature is not supported.

Table 11-1919. MMCHS_HCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	INS	R/W	0h	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0h (R/W) = Disable wakeup on card insertion. 1h (R/W) = Enable wakeup on card insertion. **Note:** Wakeup feature is not supported.
24	IWE	R/W	0h	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0h (R/W) = Disable wakeup on card interrupt. 1h (R/W) = Enable wakeup on card interrupt. **Note:** Wakeup feature is not supported.
23-20	RESERVED	R	0h	Reserved
19	IBG	R/W	0h	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0h (R/W) = Disable interrupt detection at the block gap in 4-bit mode. 1h (R/W) = Enable interrupt detection at the block gap in 4-bit mode.
18	RWC	R/W	0h	Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0h (R/W) = Disable Read Wait Control. Suspend/Resume cannot be supported. 1h (R/W) = Enable Read Wait Control.
17	CR	R/W	0h	Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted that is DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]). The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit. 0h (R/W) = No affect. 1h (R/W) = transfer restart.
16	SBGR	R/W	0h	Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0h (R/W) = Transfer mode. 1h (R/W) = Stop at block gap.

Table 11-1919. MMCHS_HCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11-9	SDVS	R/W	0h	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer. 5h (R/W) = 1.8 V (Typical). 6h (R/W) = 3.0 V (Typical). 7h (R/W) = 3.3 V (Typical).
8	SDBP	R/W	0h	SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]). 0h (R/W) = Power off. 1h (R/W) = Power on.
7	CDSS	R/W	0h	Card Detect Signal Selection This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupts caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0h (R/W) = MMCi_SDCD is selected (for normal use). 1h (R/W) = MMCHS_HCTL[6] CDTL is selected (for test purpose).
6	CDTL	R/W	0h	Card Detect Test Level This bit is enabled while MMCHS_HCTL[7] CDSS is set to 1 and it indicates whether the card is inserted or not. 0h (R/W) = No Card. 1h (R/W) = Card Inserted.
5	RESERVED	R	0h	Reserved
4-3	DMAS	R/W	0h	DMA Select Mode One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register MMCHS_CAPA. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This bit field is only meaningful when MADMA_EN is set to 1. When MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0h (R/W) = Reserved. 1h (R/W) = Reserved. 2h (R/W) = 32-bit Address ADMA2 is selected. 3h (R/W) = Reserved.
2	HSPE	R/W	0h	High Speed Enable: Before setting this bit, the Host Driver shall check the MMCHS_CAPA[21] HSS. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[19] DDR. 0h (R/W) = The Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. 1h (R/W) = The Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. **Note:** Do not set this bit to 0x1 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.

Table 11-1919. MMCHS_HCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	DTW	R/W	0h	Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This bit field has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[DW8] set to1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0h (R/W) = 1-bit Data width (DAT[0] used). 1h (R/W) = 4-bit Data width (DAT[3:0] used).
0	LED	R	0h	Reserved bit LED control feature is not supported. This bit is initialized to zero, and writes to it are ignored.

11.12.6.22 MMCHS_SYSCTL Register (Offset = 22Ch) [reset = 0h]

MMCHS_SYSCTL is shown in Figure 11-885 and described in Table 11-1922.

SD System Control Register
This register defines the system controls to set software resets, clock frequency management and data timeout.
MMCHS_SYSCTL[31-24] = Software resets
MMCHS_SYSCTL[23-16] = Timeout control
MMCHS_SYSCTL[15-0] = Clock control.

Table 11-1921. MMCHS_SYSCTL Instances

Instance	Physical Address

Table 11-1922. MMCHS_SYSCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R	0h	Reserved
26	SRD	R/W	0h	Software reset for DAT line This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see Section 11.12.5.1.2.1.2.1, *DATA Lines Reset Procedure*. DAT finite state machine in both clock domain are also reset. Here below are the registers cleared by MMCHS_SYSCTL[SRD]: - MMCHS_DATA - MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0h (R/W) = Reset completed. 1h (R/W) = Software reset for DAT line.

Table 11-1922. MMCHS_SYSCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	SRC	R/W	0h	Software reset for CMD line For more information about SRC bit manipulation, see Section 11.12.5.1.2.1.1.1, *CMD Line Reset Procedure*. This bit is set to 1 for reset and released to 0 when completed. CMD finite state machine in both clock domain are also reset. Here below the registers cleared by MMCHS_SYSCTL[SRC]: - MMCHS_PSTATE: CMDI - MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0h (R/W) = Reset completed. 1h (R/W) = Software reset for CMD line.
24	SRA	R/W	0h	Software reset for all This bit is set to 1 for reset and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit andcapabilities registers (MMCHS_CAPA and MMCHS_CUR_CAPA). 0h (R/W) = Reset completed. 1h (R/W) = Software reset for all the design.
23-20	RESERVED	R	0h	Reserved
19-16	DTO	R/W	0h	Data timeout counter value and busy timeout This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bitfield based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[TCF]). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STAT[DTO]). The MMCHS_SYSCTL[DTO] register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0h (R/W) = TCF x 2^13. 1h (R/W) = TCF x 2^14. Eh (R/W) = TCF x 2^27. Fh (R/W) = Reserved.
15-6	CLKD	R/W	0h	Clock frequency select These bits define the ratio between MMC_CLK_ADPI and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0h (R/W) = MMC_CLK_ADPI bypass. 1h (R/W) = MMC_CLK_ADPI bypass. 2h (R/W) = MMC_CLK_ADPI / 2. 3h (R/W) = MMC_CLK_ADPI / 3. 3FFh (R/W) = MMC_CLK_ADPI / 1023.

Table 11-1922. MMCHS_SYSCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	CGS	R	0h	Clock Generator Select - For SD cards Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in MMCHS_SYSCTL[15-6] CLKD. If the Programmable Clock Mode is supported (non-zero value is set to MMCHS_CAPA2[23-16] CM), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read. This bit depends on the setting of MMCHS_AC12[31] PV_ENABLE. If PV_ENABLE = 0, this bit is set by Host Driver. If PV_ENABLE = 1, this bit is automatically set to a value specified in one of Preset Value registers, see, Table 11-1839.
4-3	RESERVED	R	0h	Reserved
2	CEN	R/W	0h	Clock enable This bit controls if the clock is provided to the card or not. 0h (R/W) = The clock is not provided to the card. Clock frequency can be changed. 1h (R/W) = The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value). The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[ICS]).
1	ICS	R	0h	Internal clock stable (status) This bit indicates either the internal clock is stable or not. 0h (R) = The internal clock is not stable. 1h (R) = The internal clock is stable after enabling the clock (MMCHS_SYSCTL[ICE]) or after changing the clock ratio (MMCHS_SYSCTL[CLKD]).
0	ICE	R/W	0h	Internal clock enable This bit field controls the internal clock activity. In very low power state, the internal clock is stopped. **Note:** The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this bit field. 0h (R/W) = The internal clock is stopped (very low power state). 1h (R/W) = The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value).

11.12.6.23 MMCHS_STAT Register (Offset = 230h) [reset = 0h]

MMCHS_STAT is shown in Figure 11-886 and described in Table 11-1925.

Interrupt Status Register
The interrupt status regroups all the status of the module internal events that can generate an interrupt.
MMCHS_STAT[31-16] = Error Interrupt Status
MMCHS_STAT[15-0] = Normal Interrupt Status.

Table 11-1924. MMCHS_STAT Instances

Instance	Physical Address

Table 11-1925. MMCHS_STAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved
29	BADA	R/W	0h	Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[BRE] =0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[BWE] =0). 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Interrupt. 1h (R) = Bad Access.

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	CERR	R/W	0h	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE in set. There is no card error detection for auto CMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Error. 1h (R) = Card error.
27	RESERVED	R	0h	Reserved
26	TE	R/W	0h	Tuning Error This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure (Occurrence of an error during tuning procedure is indicated by Sampling Select). By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning. To reset tuning circuit, Sampling Clock shall be set to 0 before executing tuning procedure. The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning Error, the Host Driver should discard data transferred by a current read/write command and retry data transfer after the Host Controller retrieved from tuning circuit error. The bit is set if the lock is lost (but not during the tuning process) or if the lock counter expires without the lock being asserted. If the latter happens, the SW can decide to ignore the interrupt and wait some more for the lock to be set. 0h (R/W) = No Error. 1h (R/W) = Error.
25	ADMAE	R/W	0h	ADMA Error This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Interrupt. 1h (R) = ADMA error.
24	ACE	R/W	0h	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register (MMCHS_AC12) has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Error. 1h (R) = Auto CMD error.
23	RESERVED	R	0h	Reserved

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	DEB	R/W	0h	Data End Bit error This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Error. 1h (R) = Data end bit error.
21	DCRC	R/W	0h	Data CRC Error This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Error. 1h (R) = Data CRC error.
20	DTO	R/W	0h	Data timeout error This bit is set automatically according to the following conditions: - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No error. 1h (R) = Time out.
19	CIE	R/W	0h	Command index error This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[CICE] register. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No error. 1h (R) = Command index error.
18	CEB	R/W	0h	Command end bit error This bit is set automatically when detecting a 0 at the end bit position of a command response. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No error. 1h (R) = Command end bit error.
17	CCRC	R/W	0h	Command CRC Error This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[CCCE] register. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Error. 1h (R) = Command CRC error.

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	CTO	R/W	0h	Command Timeout Error This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No error. 1h (R) = Time Out.
15	ERRI	R	0h	Error Interrupt If any of the bits in the Error Interrupt Status register (MMCHS_STAT[31-16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. 0h (R) = No Interrupt. 1h (R) = Error interrupt event(s) occurred.
14-11	RESERVED	R	0h	Reserved
10	BSR	R/W	0h	Boot status received interrupt This bit is set automatically when MMCHS_CON[BOOT] is set 1h or 2h and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Interrupt. 1h (R) = Boot status received interrupt.
9	OBI	R/W	0h	Out-Of-Band interrupt This bit is set automatically when MMCHS_CON[OBIE] is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[OBIP]. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Out-Of-Band interrupt. 1h (R) = Interrupt Out-Of-Band occurs. **Note:** Out-Of-Band Interrupt feature is not supported.

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	CIRQ	R	0h	Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMCHS_IE[CIRQ] to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[CIRQ] is set to 1. Writes to this bit are ignored. 0h (R) = No card interrupt. 1h (R) = Generate card interrupt. **Note:** Wakeup feature is not supported.
7	CREM	R/W	0h	Card removal This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = Card state stable or Debouncing. 1h (R) = Card removed. **Note:** Wakeup feature is not supported.
6	CINS	R/W	0h	Card insertion This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = Card state stable or debouncing. 1h (R) = Card inserted. **Note:** Wakeup feature is not supported.
5	BRR	R/W	0h	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[BLEN] is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. **Note:** If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = Not Ready to read buffer. 1h (R) = Ready to read buffer.

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	BWR	R/W	0h	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[BLEN]. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. **Note:** If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = Not Ready to write buffer. 1h (R) = Ready to write buffer.
3	DMA	R/W	0h	DMA interrupt This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = Dma interrupt detected. 1h (R) = No dma interrupt.
2	BGE	R/W	0h	Block gap event When a stop at block gap is requested (MMCHS_HCTL[SBGR]), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[DLA]) between data blocks generates a Block gap event interrupt. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No block gap event. 1h (R) = Transaction stopped at block gap.
1	TC	R/W	0h	Transfer completed This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[SBGR]). In Read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[RTA]). In write mode: This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[DLA]). 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No transfer complete. 1h (R) = Data transfer complete.

Table 11-1925. MMCHS_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	CC	R/W	0h	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[CMDI]) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[CTO]) has higher priority than command complete (MMCHS_STAT[CC]). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. 0h (W) = Status bit unchanged. 1h (W) = Status is cleared. 0h (R) = No Command complete. 1h (R) = Command complete.

11.12.6.24 MMCHS_IE Register (Offset = 234h) [reset = 0h]

MMCHS_IE is shown in Figure 11-887 and described in Table 11-1928.

Interrupt Status Enable Register
This register allows to enable/disable the module to set status bits, on an event-by-event basis.
MMCHS_IE[31-16] = Error Interrupt Status Enable
MMCHS_IE[15-0] = Normal Interrupt Status Enable.

Table 11-1927. MMCHS_IE Instances

11.12.6.26 MMCHS_AC12 Register (Offset = 23Ch) [reset = 0h]

MMCHS_AC12 is shown in Figure 11-889 and described in Table 11-1934.

Host Control 2 Register and Auto CMD Error Status Register
This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The Host driver can determine what kind of Auto CMD12 / CMD23 errors occur by this register. Auto CMD23 errors are indicated only in bits[4-1]. Bits[7-0] are valid only when the MMCHS_CMD[3-2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24]ACE) is set.

Table 11-1934. MMCHS_AC12 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PV_ENABLE	R/W	0h	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 11-1839. If this bit is set to 0, MMCHS_SYSCTL[15-6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21-20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15-6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21-20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 11-1839. 0h (R/W) = SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 1h (R/W) = Automatic Selection by Preset Value are Enabled.

Table 11-1934. MMCHS_AC12 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
30	AI_ENABLE	R/W	0h	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0h (R/W) = Disabled. 1h (R/W) = Enabled.
29-24	RESERVED	R	0h	Reserved
23	SCLK_SEL	R/W	0h	Sampling Clock Select Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when MMCHS_AC12[22] ET is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting MMCHS_AC12[22] ET. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block. 0h (R/W) = Fixed clock is used to sample data. 1h (R/W) = Tuned clock is used to sample data.
22	ET	R/W	0h	Execute Tuning This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to MMCHS_AC12[23] SCLK_SEL. Tuning procedure is aborted by writing 0. This is Read-Write with automatic clear register. 0h (R/W) = Not Tuned or Tuning Completed. 1h (R/W) = Execute Tuning.
21-20	DS_SEL	R/W	0h	Driver Strength Select Host Controller output driver in 1.8 V signaling is selected by this bit. In 3.3 V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register. This bit depends on setting of Preset Value Enable MMCHS_AC12[31] PV_ENABLE bit. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 11-1839. 0h (R/W) = Driver Type B is selected (Default). 1h (R/W) = Driver Type A is selected. 2h (R/W) = Driver Type C is selected. 3h (R/W) = Driver Type D is selected. **Note:** This feature is not supported.

Table 11-1934. MMCHS_AC12 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	V1V8_SIGEN	R/W	0h	1.8 V Signaling Enable This bit controls voltage regulator for I/O cell. 3.3 V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3 V to 1.8 V. 1.8 V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8 V signaling fails. Clearing this bit from 1 to 0 starts changing signal voltage from 1.8 V to 3.3 V. 3.3 V regulator output shall be stable within 5ms. Host Driver can set this bit to 1 when Host Controller supports 1.8 V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x). 0h (R/W) = 3.3 V Signaling. 1h (R/W) = 1.8 V Signaling. **Note:** This feature is not supported (MMCSD_0 supports 3.3 V only. MMCSD_1 supports 1.8 V only).
18-16	UHSMS	R/W	0h	UHS Mode Select This field is used to select one of UHS-I modes and effective when 1.8 V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15-6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21-20] DS_SEL according to Preset Value registers, see, Table 11-1839. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again. When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. 0h (R/W) = SDR12. 1h (R/W) = SDR25. 2h (R/W) = SDR50. 3h (R/W) = SDR104. 4h (R/W) = DDR50. 5h (R/W) = Reserved. 6h (R/W) = Reserved. 7h (R/W) = Reserved. **Note:** This feature is not supported.
15-8	RESERVED	R	0h	Reserved
7	CNI	R	0h	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this bit field. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. 0h (R) = No error. 1h (R) = Command not issued.
6-5	RESERVED	R	0h	Reserved
4	ACIE	R	0h	Auto CMD Index Error - For Auto CMD12 and Auto CMD23 This bit is set if the Command Index error occurs in response to a command. 0h (R) = No error. 1h (R) = Error.

Table 11-1934. MMCHS_AC12 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	ACEB	R	0h	Auto CMD End Bit Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting that the end bit of command response is 0. 0h (R) = No error. 1h (R) = End bit Error Generated.
2	ACCE	R	0h	Auto CMD CRC Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting a CRC error in the command response. 0h (R) = No error. 1h (R) = CRC Error Generated.
1	ACTO	R	0h	Auto CMD Timeout Error - For Auto CMD12 and Auto CMD23 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to1, the other error status bits (D04-D02) are meaningless. 0h (R) = No error. 1h (R) = Auto CMD Time Out.
0	ACNE	R	0h	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. 0h (R) = Auto CMD12 Executed. 1h (R) = Auto CMD12 Not Executed.

Table 11-1937. MMCHS_CAPA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved
29	AIS	R	1h	Asynchronous Interrupt Support Refer to SDIO Specification Version 3.00 about asynchronous interrupt. 0h (R) = Asynchronous Interrupt Not Supported. 1h (R) = Asynchronous Interrupt Supported.
28	BIT64	R	0h	64 Bit System Bus Support Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. 0h (R) = 32 bit System bus address. 1h (R) = 64 bit System bus address.
27	RESERVED	R	0h	Reserved
26	VS18	R/W	0h	Voltage support 1.8 V Initialization of this bit field (via a write access to this bit field) depends on the system capabilities. The host driver shall not modify this bit field after the initilaization. This bit field is only reinitialized by a hard reset (via MMC_RST signal). 0h (W) = 1.8 V Not supported. 1h (W) = 1.8 V Supported. 0h (R) = 1.8 V Not Supported. 1h (R) = 1.8 V Supported.

Table 11-1937. MMCHS_CAPA Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	VS30	R/W	0h	Voltage support 3.0 V Initialization of this bit field (via a write access to this bit field) depends on the system capabilities. The host driver shall not modify this bit field after the initilaization. This bit field is only reinitialized by a hard reset (via MMC_RST signal). 0h (W) = 3.0 V Not supported. 1h (W) = 3.0 V Supported. 0h (R) = 3.0 V Not Supported. 1h (R) = 3.0 V Supported.
24	VS33	R/W	0h	Voltage support 3.3 V Initialization of this bit field (via a write access to this bit field) depends on the system capabilities. The host driver shall not modify this bit field after the initilaization. This bit field is only reinitialized by a hard reset (via MMC_RST signal). 0h (W) = 3.3 V Not supported. 1h (W) = 3.3 V Supported. 0h (R) = 3.3 V Not Supported. 1h (R) = 3.3 V Supported.
23	SRS	R	1h	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. 0h (R) = The Host controller does not Suspend/Resume functionality. 1h (R) = The Host controller supports Suspend/Resume functionality.
22	DS	R	1h	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. 0h (R) = DMA Not Supported. 1h (R) = DMA Supported.
21	HSS	R	1h	High speed support This bit indicates that the host controller supports high speed operations and can supply an up-to maximum card frequency. 0h (R) = High Speed Not Supported. 1h (R) = High Speed Supported. **Note:** High Speed modes are supported, but MMCHS_HCTL[2] HSPE bit must always be set to 0x0 because device was timing closed with MMCHS_HCTL[2] HSPE bit set to 0x0 for all supported modes of operation.
20	RESERVED	R	0h	Reserved
19	AD2S	R	0h	ADMA2 Support This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN. 0h (R) = ADMA2 not Supported. 1h (R) = ADMA2 Supported.
18	RESERVED	R	0h	Reserved

Table 11-1937. MMCHS_CAPA Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17-16	MBL	R	1h	Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512 bytes and 1024 bytes block transfers. 0h (R) = 512 bytes. 1h (R) = 1024 bytes. 2h (R) = 2048 bytes.
15-8	BCF	R	0h	Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1 MHz. The supported clock range is 10 MHz to 255 MHz. FFh : 255 MHz ..... : ..... 02h : 2 MHz 01h : 1 MHz 00h : Get information via another method If the real frequency is 16.5 MHz, the lager value shall be set 0001 0001b (17 MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15-6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method. 0h (R) = The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this bit filed. Get the information via another method.
7	TCU	R	1h	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]). 0h (R) = KHz. 1h (R) = MHz.
6	RESERVED	R	0h	Reserved
5-0	TCF	R	0h	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). 0h (R) = The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this bit field.

11.12.6.28 MMCHS_CAPA2 Register (Offset = 244h) [reset = F77h]

MMCHS_CAPA2 is shown in Figure 11-891 and described in Table 11-1940.

Capabilities 2 Register
This register provides the Host Driver with information specific to the Host Controller implementation. The Host Controller may implement these values as fixed or loaded from flash memory during power on initialization. Refer to Software Reset For All in the Software Reset register for loading from flash memory and completion timing control.

Setting 00h means that Host Controller does not support programmable clock generator. 00h : Clock Multiplier is Not Supported 01h : Clock Multiplier M = 2 02h : Clock Multiplier M = 3 ..... : ..... FFh : Clock Multiplier M = 256.

Table 11-1940. MMCHS_CAPA2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	RTM	R	0h	Re-Tuning Modes This field selects re-tuning method and limits the maximum data length. Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length. There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers. (1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MB. (2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. (3) Re-Tuning Mode 3 The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. Re-Tuning Timer Control Example for Re-Tuning Mode 1 The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this bit field. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared. Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3 The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode. 0h (R) = Timer - Max data length 4 MB. 1h (R) = Timer and Re-Tuning Request - Max data length 4 MB. 2h (R) = Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request. 3h (R) = Reserved.

Table 11-1940. MMCHS_CAPA2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	TSDR50	R	0h	Use Tuning for SDR50 If this bit is set to 1, this Host Controller requires tuning to operate SDR50. (Tuning is always required to operate SDR104). 0h (R) = SDR50 does not require tuning. 1h (R) = SDR50 requires tuning. **Note:** SDR50 mode is not supported.
12	RESERVED	R	0h	Reserved

11.12.6.29 MMCHS_CUR_CAPA Register (Offset = 248h) [reset = 0h]

MMCHS_CUR_CAPA is shown in Figure 11-892 and described in Table 11-1943.

Maximum Current Capabilities Register
This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (MMCHS_CAPA).
Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization.
This register is only reinitialized by a hard reset (via MMC_RST signal).

11.12.6.30 MMCHS_FE Register (Offset = 250h) [reset = 0h]

MMCHS_FE is shown in Figure 11-893 and described in Table 11-1946.

Force Event Register for Auto CMD Error Status and Error Interrupt status
The Force Event Register is not a physically implemented register. Rather, it is an address at which the Auto CMD Error Status Register (MMCHS_AC12) can be written.
Writing 1: set each bit of the Auto CMD Error Status Register
Writing 0: no effect
Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.
Writing 1: set each bit of the Error Interrupt Status Register
Writing 0: no effect
Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

11.12.6.31 MMCHS_ADMAES Register (Offset = 254h) [reset = 0h]

MMCHS_ADMAES is shown in Figure 11-894 and described in Table 11-1949.

ADMA Error Status Register
When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:
ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
ST_CADR: This sate is never set because do not generate ADMA error in this state.
ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address
In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

11.13 Networking Subsystem (NSS)

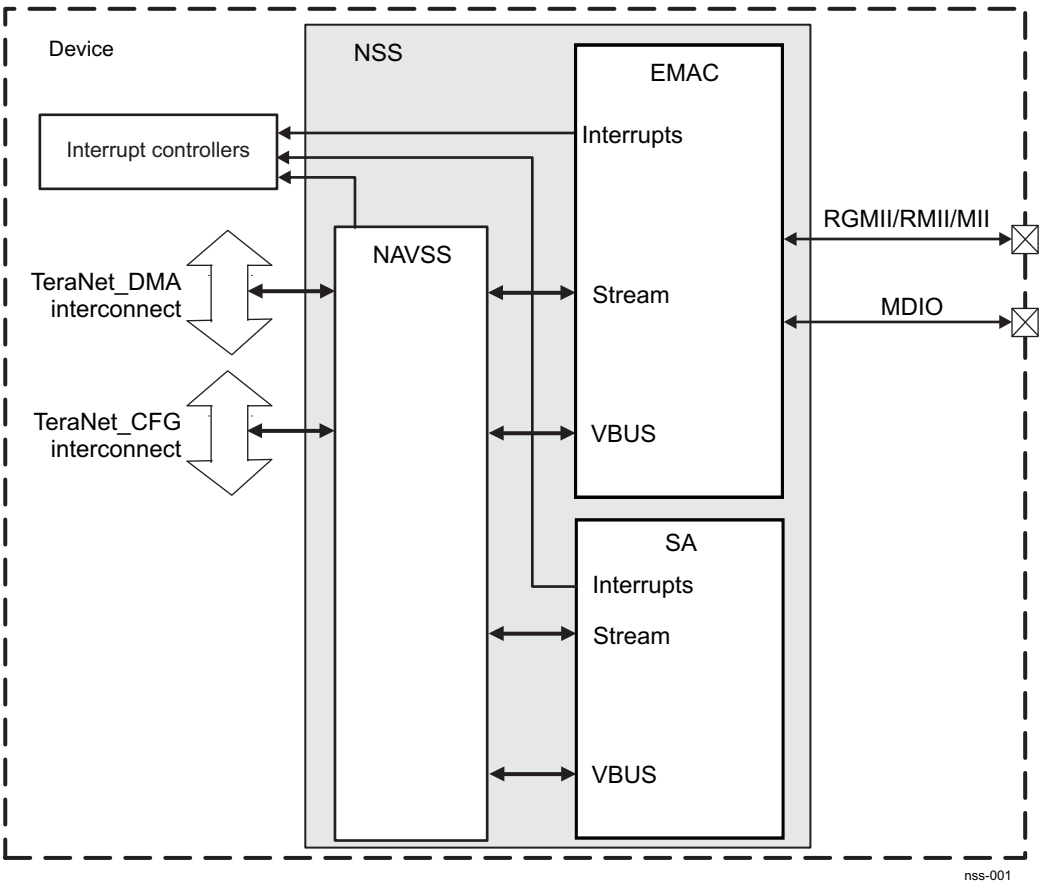
This chapter describes the features and functions of the Networking Subsystem (NSS) in the device.

11.13.1 NSS Overview

Networking Subsystem (NSS) consists of DMA/Queue Management components – Navigator Subsystem (NAVSS), an Ethernet MAC (EMAC) Subsystem, and a packet Security Accelerator (SA).

Figure 11-901 shows the NSS overview.

Figure 11-901. NSS Overview



NAVSS – The Navigator Subsystem consists of a CPPI DMA, CPPI Queue Manager (QM), and miscellanous infrastructure. The NAVSS also contains an embedded Streaming Switch, which connects the CDMA with the I/O Peripheral streaming ports (EMAC and SA).

EMAC – The two-port (one Ethernet and one host) Gigabit Ethernet Subsystem functions as an Ethernet MAC. Packets can be transmitted on one of 8 priorities by being queued through the CDMA. Received packets are queued to the CDMA and steered to specific queues via the RX FLOW field.

SA – The Security Accelerator (SA) is an encryption/decryption accelerator. Packets for encryption/decryption can be queued to it via the CDMA threads. Ask your TI representative for SA specification with programming details.

NOTE: Networking Subsystem is a notional subsystem. Besides full-feature mode, NSS modules can be used also in NAVSS-only, EMAC + NAVSS, and SA + NAVSS modes, if required.

11.13.1.1 NSS Features

The NSS, presented by its general sub-components, supports the following features:

- NAVSS
  - High Performance CPPI DMA Controller, 32 Receive Flows, 4 Loopback threads for infrastructure mode
  - CPPI Queue Manager (QM) features:
    - Single QM
    - Supports up to 128 queues – 21 QPEND signals for TX use, remaining 107 QPEND signals are for host use
    - 2048 buffers supported in Internal Linking RAM
    - Two Queue Proxies provided for host interaction (one per DSP and ARMSS)
      - Queue Proxy 0 assigned to DSP
      - Queue Proxy 1 assigned to ARMSS
  - Support for SER protection (SECDED)
- EMAC Subsystem
  - One Gigabit Ethernet port: MII/RMII/RGMII interfaces
    - Supports 10/100/1000 Mbps full duplex
    - Supports 10/100 Mbps half duplex
  - One Host Port 0 CPPI Streaming Packet Interface (PSI)
  - Support Ethernet Audio/Video Bridging (eAVB) (P802.1Qav/D6.0)
  - Maximum frame size 2016 bytes (2020 bytes with VLAN)
  - Eight priority level QOS support (802.1p)
  - IEEE 1588 (2008 annex D, annex E, and annex F) to facilitate Audio/Video bridge 802.1AS Precision Time Protocol
    - Timestamp module capable of time stamping external timesync events like Pulse Per Second and also generating Pulse Per Second outputs
    - CPTS module that supports time stamping for IEEE1588 with support for 8 hardware push events and generation of compare output pulses
  - DSCP Priority Mapping (IPv4 and IPv6)
  - Energy Efficient Ethernet Support (802.3az)
  - Maximum frame size 2016 bytes (2020 with VLAN)
  - Address Lookup Engine (ALE)
  - Castagnoli or Ethernet CRC selectable for Ethernet ingress/egress (Host Port0 CRC is Ethernet only)
  - MDIO module for PHY management
  - EtherStats and 802.3Stats RMON statistics gathering
  - Support for SER protection (SECDED)
- Security Accelerator (SA)
  - Support IPSec and SRTP protocol stack
  - Support various encryption modes and algorithms such as:
    - ECB, CBC, CFB, OFB, F8, CTR, CBC-MAC, CCM, GCM, GMAC and AES-CMAC
    - AES, DES, 3DES, SHA-1, SHA-2 (224, 256-bit operation) and MD5
  - Support for True random number generator (TRNG) and Public Key Accelerator (PKA)
  - Support for SER protection (SECDED)

The NSS does not support the following features:

- No external queue RAM supported

- Priority Based Flow Control is not supported.
- No Castignoli CRC to Host CPPI port.

11.13.1.2 NSS Modes of Operation

The NSS can operate in five modes:

1. Full Disable – In this mode, all modules are in clock stop state
2. Infrastructure Mode – In this mode, the SA and EMAC are in clock stop state, and the NAVSS is enabled. In this mode, the CDMA and QM can be used for infrastructure DMA purposes
3. Security-only Mode – In this mode, the NAVSS and SA are enabled, and EMAC is in clock stop state. In this mode, the SA can be used for encryption/decryption, and NAVSS can be used for infrastructure purposes
4. Ethernet-only Mode – In this mode, the NAVSS and EMAC are enabled, and SA is in clock stop state. In this mode, the EMAC may be used to send and receive packets, and CDMA can be used for infrastructure purposes
5. Full Enable – In this mode, all sub-modules are enabled. All functions are available.

NOTE: NSS power domain (NAVSS + EMAC) is standalone and can be used with CRYPTO power domain either enabled or disabled. However, it is not possible to use CRYPTO PD when the NSS PD is OFF. During power-up sequence it is required to have the NSS power domain ON prior to turning the CRYPTO domain ON. Similarly, during power down sequence, it is required to power down CRYPTO domain prior to powering down the NSS domain.

11.13.1.3 NSS Memory Map

Table 11-1969 covers the main NSS components with their addresses and links to register descriptions.

Table 11-1969. NSS Top Level Memory Map

0040 0000h	0440 0000h		SA	ARMSS/DSP	See SA spec.

NOTE: The NSS contains 2K (2048) internal linking RAM entries. The internal linking RAM control in the QM actually only supports 2K-1 entires. In order to use the entire 2K entries, the following procedure must be used:

1. Program linking RAM0 size to 0
2. Program the linking RAM1 address to the internal linking RAM address (0402 0000h)

11.13.1.4 Thread Map

Streaming Switch connects the CDMA with the I/O Peripheral streaming ports (EMAC, SA). The mapping of threads in the streaming switch is contained in Table 11-1970.

Table 11-1970. NAVSS Thread Map

	Slave	CDMA	SA	EMAC
	Slave Threads	15	1	8
Master	**Master Threads**			
CDMA	21	0–3/0–3	4/0	5–12/0–7
SA	2	0–1/4–5		
EMAC	1	0/6		

11.13.1.5 CDMA Receive Flow Mapping

There is not a one-to-one mapping of receive threads and receive flows on the CDMA. Though it is possible to use the default receive flow for a thread (default flow number equals thread number), it is recommended that all flows be explicitly defined, and that all packets received from the streaming domain use a specified flow, not a default flow. This section contains an example for how to assign receive flows. Though it is recommended to use explicit receive flows in each packet, this example does allow for the use of default flows on everything but the Ethernet MAC. The CPSW uses a single thread, but requires a contiguous block of 16 receive flows (8 for priority based classification and 8 for other classifiers), the base of which is specified in CPSW_P0_FLOW_ID_OFFSET register in the CPSW. The mapping of threads is shown in Table 11-1970 *NAVSS Thread Map*. Table 11-1971 shows an example of a receive flow map.

Table 11-1971. CDMA Receive Flow Mapping Example

Source	CDMA Receive Thread(s)	CDMA Receive Flow(s)
CDMA (Infrastructure Channels)	0–3	0–3
SA	4–5	4–5
EMAC	6	15–30
Spare flows		6, 31

11.13.1.6 Network Subsystem High-Level Initialization

High-level initialization of NSS must follow the below sequence.

1. Turn on the NSS power domain
2. Ungate the clocks for all modules used
3. Configure the queue manager
4. Configure the CDMA
   a. Configure the linking RAM
   b. Initialize descriptors
   c. Configure receive flows
   d. Enable transmit channels
   e. Enable receive channels
5. Initialize the Ethernet subsystem
6. Configure the SA.

11.13.1.7 Error Packets Forwarded Through CDMA

The CDMA streaming transmit interface does not have PKT_ERROR bits. Because of this, if a packet is received with error bits set and configured to be forwarded directly to another block without host intervention, that packet may be treated as if it is a good packet. For example, if a packet is received from the Ethernet MAC with error bits set, goes to the CDMA, then is transmited to the SA without host intervention, the SA may treat that packet as a good packet. In order to avoid this, a host process must intervene before transmitting to the SA (or other block) to make sure it wasn't an error packet, or the data flow must be tolerant of processing error packets and be able to check them at some other point.

11.13.2 Navigator Subsystem (NAVSS)

11.13.2.1 Overview

NAVSS specifies the data structures used by Texas Instruments standard communications modules to facilitate direct memory access (DMA) and to provide a consistent application programming interface (API) to the host software in multi-core devices. The data structures and the API used to manipulate them will be jointly referred to as NAVSS.

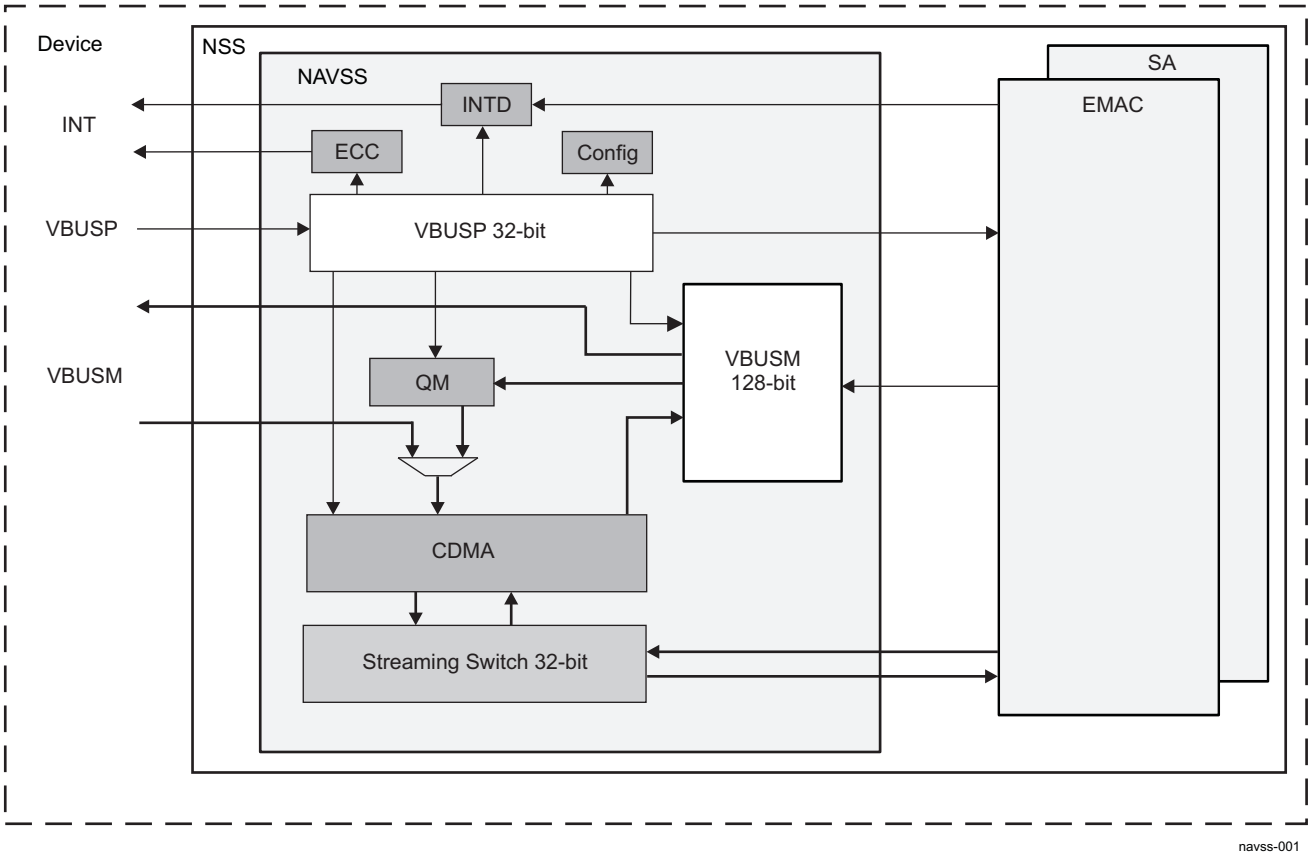
Frequent tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the host software and communication module interface. In networking systems, packet transmission and reception are critical tasks. Texas Instruments has developed the NAVSS standard, which is aimed at maximizing the efficiency of interaction between the host software and communications modules.

The design goals for NAVSS are as follows:

- Minimize host interaction
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections/buffer sizes/queue sizes/protocols supported
- Minimize protocol specific features
- Minimize complexity

Navigator subsystem hardware components are shows on Figure 11-902. Slave peripherals, Ethernet MAC and Security accelerator, are shown for illustrative purposes.

Figure 11-902. Navigator Subsystem Hardware Block Diagram



11.13.2.1.1 Queue Manager

The queue manager (QM) is a hardware module that is responsible for accelerating management of the packet queues. Packets are added to a packet queue by writing the 32-bit descriptor address to a particular memory mapped location in the queue manager module. Packets are de-queued by reading the same location for that particular queue. NAVSS queue manager modules are capable of queuing only descriptors that have been allocated from the descriptor regions of the associated queue manager.

11.13.2.1.2 Packet DMA (CDMA)

The Packet DMA is a CPPI DMA in which data destination is determined by a destination and free descriptor queue index, not an absolute memory address. In receive mode, the CDMA fetches a free descriptor, traverses the descriptor to find the buffer, CDMA transfers the payload into the buffer, and puts the descriptor into the destination queue. In transmit mode, the CDMA pops the descriptor from the TX queue, traverses the descriptor, reads the payload from the buffer, and DMA transfers the payload to the transmit port.

11.13.2.1.3 Navigator Cloud

A Navigator Cloud is a set of CDMAs and descriptors. Neither CDMAs nor descriptors address the physical Queue Manager(s) directly, but instead use a *queue_manager:queue_number* (qmgr:qnum) notation and registers to create a logical mapping into the physical Queue Manager(s). All CDMAs with the same logical mapping are said to be part of the same Navigator Cloud. A descriptor can be sent to any CDMA in the same cloud, but may or may not transfer correctly through CDMAs in different clouds. A non-compatible logical qmgr:qnum mapping will cause descriptors to arrive in unexpected queues, potentially causing a memory leak.

It is possible to send a descriptor from one cloud to another, but each qmgr:qnum reference must point to the same physical queue for the CDMAs in both clouds. Another way to say this is by example: Let CDMA 1 and 2 have the same base addresses programmed for logical QM0 and QM1 in their respective QMn Base Address registers, but their QM2 and QM3 base addresses are different (so by definition they represent different clouds). Any descriptor traveling between them must reference only QM0 and/or QM1 in every descriptor and RX Flow qmgr:qnum fields. This is especially true if the RX (output) queue for the first CDMA is the same physical queue as the TX (input) queue for the second CDMA.

11.13.2.1.4 Virtualization

Physical memory addresses can be virtualized by using the MPAX units inside the MSMC controller and DSP. It is important to understand how Navigator uses virtualized addresses in a system where both physical and virtual addresses may be used by various components, or when different mappings may address the same physical memory. Here is the summary:

- The Queue Manager does not understand memory translations. It simply converts QM pushed addresses to linking RAM indexes based on the programming of QMSS Memory Regions (see Section 11.13.5.2.4.2, *QM Descriptor Regions*). Virtual addresses can be used, but they must be programmed into the QMSS Memory Regions and used for every push and descriptor reference. Using a physical address when virtual addresses have been programmed into QMSS will result in erroneous behavior.
- The CDMA also does not understand memory translations. It simply makes VBUS transactions using popped descriptor addresses and the memory references inside descriptors. A virtual address used by the CDMA will be translated by MPAX to a physical address. Because the CDMA uses popped addresses, addresses embedded in descriptors, and Rx Flow configurations (containing qmgr:qnum mappings), these must all present a unified view of memory or the result of transfers will be unexpected.

11.13.2.1.5 ARMSS-DSP Shared Use

Most of the time, an ARMSS's memory virtualization will be different than that of the DSPs. Both ARMSSs and DSPs should define their own Navigator Cloud(s). This is an easy and efficient way to keep resources separated. However, Most ARMSS-DSP applications require transferring data between them. There are at least two ways to do this: 1) either use a CDMA to transfer data from one cloud to another, or 2) create a common shared area to be used by both. The common shared area is the preferred approach, because CDMA loading may be reduced, and because configuring two clouds to communicate can sometimes be difficult.

In the common shared area approach, one or more Navigator Clouds are defined specifically for ARMSS-DSP data transfers. This means that memory virtualization is the same (ARMSS, DSP and QMSS use the same address regions whether virtual or physical), they use common descriptor memory regions, and all descriptor references point to memory and queues containing descriptors from one of the common descriptor memory regions.

In this approach, either the ARMSS or DSP writes data to the common shared area and the recipient is notified. This is done without the CDMA because no data transfer is necessary, and notification is accomplished using the QM by itself. Notification occurs with either a queue pend queue and an interrupt on the recipient core, or the recipient core polling on the receive queue.

11.13.2.1.6 NAVSS Definition of Terms

Host— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts. In a typical system, the Host can be a DSP, ARMSS, or other.

Port— A port is the communications module (peripheral hardware) that contains the control logic for Direct Memory Access for a single transmit/receive interface or set of interfaces. Each port may have multiple communication channels that transfer data using homogenous or heterogeneous protocols. A port is usually subdivided into transmit and receive pairs which are independent of each other.

Channel— A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.

Data Buffer— A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.

Buffer Descriptor— A buffer descriptor is a single data structure that contains information about one or more data buffers.

Packet Descriptor— A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).

Free Descriptor/Buffer Queue— A free descriptor/buffer queue is a hardware managed list of available descriptors with prelinked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Queue Manager.

Free Descriptor Queue— A free descriptor queue is a hardware managed list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Queue Manager

Packet Queue— A packet queue is a hardware managed list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes.

Queue Manager— The queue manager is a hardware module that is responsible for accelerating management of the packet queues. Packets are added to a packet queue by writing the 32-bit descriptor address to a particular memory mapped location in the Queue Manager module. Packets are de-queued by reading the same location for that particular queue.

Memory— Memory is an area of data storage managed by the host. This area is visible to the port as a 32-bit addressable area.

Device Driver— A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without knowing every bit field location or initialization sequence.. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

SOP— Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

MOP— Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

EOP— End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

11.13.2.2 NAVSS Integration

Table 11-1972 through Table 11-2017 summarize the integration of the NAVSS in the device.

Table 11-1972. NAVSS Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
NAVSS	PD2 (NSS)	LPSC3	TeraNet_DMA TeraNet_CFG

Table 11-1973. NAVSS Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
NAVSS	VCLK	CHIP_CLK1/3	PLL Controller	VBUS interface and functional clock
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
NAVSS	NAVSS_MOD_G_RST	MOD_G_RST	LPSC3	Main NAVSS reset. Same as EMAC reset (LPSC3).

NOTE: For more information about the device interrupt controllers, see Chapter 9, *Interrupts*.

11.13.2.3 Operational Concepts

This section introduces the data movement concepts and data structures used by NAVSS. Thorough understanding of these concepts is necessary for effective programming of the device. Low-level (bit field) descriptions are provided in later chapters.

11.13.2.3.1 Packets

A packet is the logical grouping of a descriptor and the payload data attached to it. The payload data may be referred to as *packet data* or a *data buffer*, and depending on the descriptor type, may be contiguous with the descriptor fields, or may be somewhere else in memory with a pointer stored in the descriptor.

11.13.2.3.2 Data Buffers

A data buffer is a byte-aligned contiguous block of memory used to store packet payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 32-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

11.13.2.3.3 Queues

Queues are used to hold pointers to packets while they are being passed between the host and/or any of the ports in the system. Queues are maintained within the Queue Manager module.

11.13.2.3.3.1 Packet Queuing

Queuing of packets onto a packet queue is accomplished by writing a pointer to the Packet Descriptor (and in some cases the length of the packet) into a specific set of addresses within the Queue Manager module. Packets may be queued either onto the head or the tail of the queue and this is selected based on a bit in the QM_QUEUE_REG_C_0. By default, packets will be added to the tail of a Queue if the QM_QUEUE_REG_C_0 has not been written. The Queue Manager provides a unique set of addresses for adding packets for each queue that it manages.

See Section 11.13.2.4.1, *Queue Manager Operation* for more details.

11.13.2.3.3.2 Packet De-queuing

De-queuing of packets from a packet queue is accomplished by reading the head packet pointer from the corresponding address in the Queue Manager. After the head pointer has been read, the Queue Manager will invalidate the head pointer and will replace it with the next packet pointer in the queue. This functionality which is implemented in the Queue Manager prevents the ports from needing to traverse linked lists and allows for certain optimizations to be performed within the Queue Manager.

See Section 11.13.2.4.1, *Queue Manager Operation* for more details.

11.13.2.3.4 Queue Types

This section describes the various types of queues that are used for transmitting and receiving packets through NAVSS.

11.13.2.3.4.1 Transmit Queues

These special queues are called *transmit queues* (the mappings are described in Table 11-1974) used to store the packets that are waiting to be transmitted. Tx ports will require one or more packet queues dedicated to each transmit channel for this purpose. Multiple queues per channel may facilitate Quality of Service (QoS) in some applications.

11.13.2.3.4.2 Transmit Completion Queues

Tx ports also use packet queues referred to as *transmit completion queues* to return packets to the host after they are transmitted. The number of queues required by the port or system for this purpose is driven by the requirements of the garbage collection software within the driver. Tx completion queues are only used when the packet descriptor indicates that the packet should be returned to a queue instead of directly recycling the descriptors to their queues of origin.

11.13.2.3.4.3 Receive Queues

Rx ports use packet queues referred to as *receive queues* to forward completed received packets to the host or another peer port entity. Rx ports may be configured in various ways to forward the received packets onto any number of receive queues. Rx ports may choose to queue their receive packets based strictly on Rx channel, protocol type, priority, direct forwarding requirements (that is, to another ports Tx queue) or any combination of these and this is application specific. In many cases the receive queue is in fact also a transmit queue for another peer entity. It is just a matter of semantics with respect to which port is referenced in the system.

11.13.2.3.4.4 Free Descriptor Queues

Rx ports use queues referred to as *free descriptor queues* to allocate empty monolithic descriptors. The entries on the Free Descriptor Queues do not have any buffers attached as buffers are allocated as part of the descriptor for monolithic type packets.

11.13.2.3.4.5 Free Descriptor/Buffer Queues

Rx ports use queues referred to as *free descriptor/buffer queues* to allocated empty host type descriptors. The entries on the Free Descriptor/Buffer Queues have pre-attached empty buffers whose size and location are described in the *original buffer information* fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding a descriptor to a free descriptor/buffer queue.

11.13.2.3.5 Descriptors

Descriptors are small memory areas that describe the packet of data to be transferred through the system.

Descriptor types are discussed and shown in bit-level detail in Section 11.13.2.5, *Descriptor Layouts*, but briefly, the descriptor types are:

11.13.2.3.5.1 Host Packet Descriptor

Host packet descriptors have a fixed size information (or description) area that contains a pointer to a data buffer, and optionally, a pointer to link one or more host buffer descriptors. Host packets are linked in TX by the host application, and by the RX DMA in RX (host packets should not be prelinked when creating an RX FDQ during initialization).

11.13.2.3.5.2 Host Buffer Descriptor

Host buffer descriptors are interchangeable in descriptor size with host packets, but are never placed as the first link of a packet (this is referred to as *start of packet*). They can contain links to other host buffer descriptors.

11.13.2.3.5.3 Monolithic Packet Descriptor

Monolithic packet descriptors differ from host packet descriptors in that the descriptor area also contains the payload data, whereas the host packet contains a pointer to buffer located elsewhere. Monolithic packets are simpler to deal with, but are not as flexible as host packets.

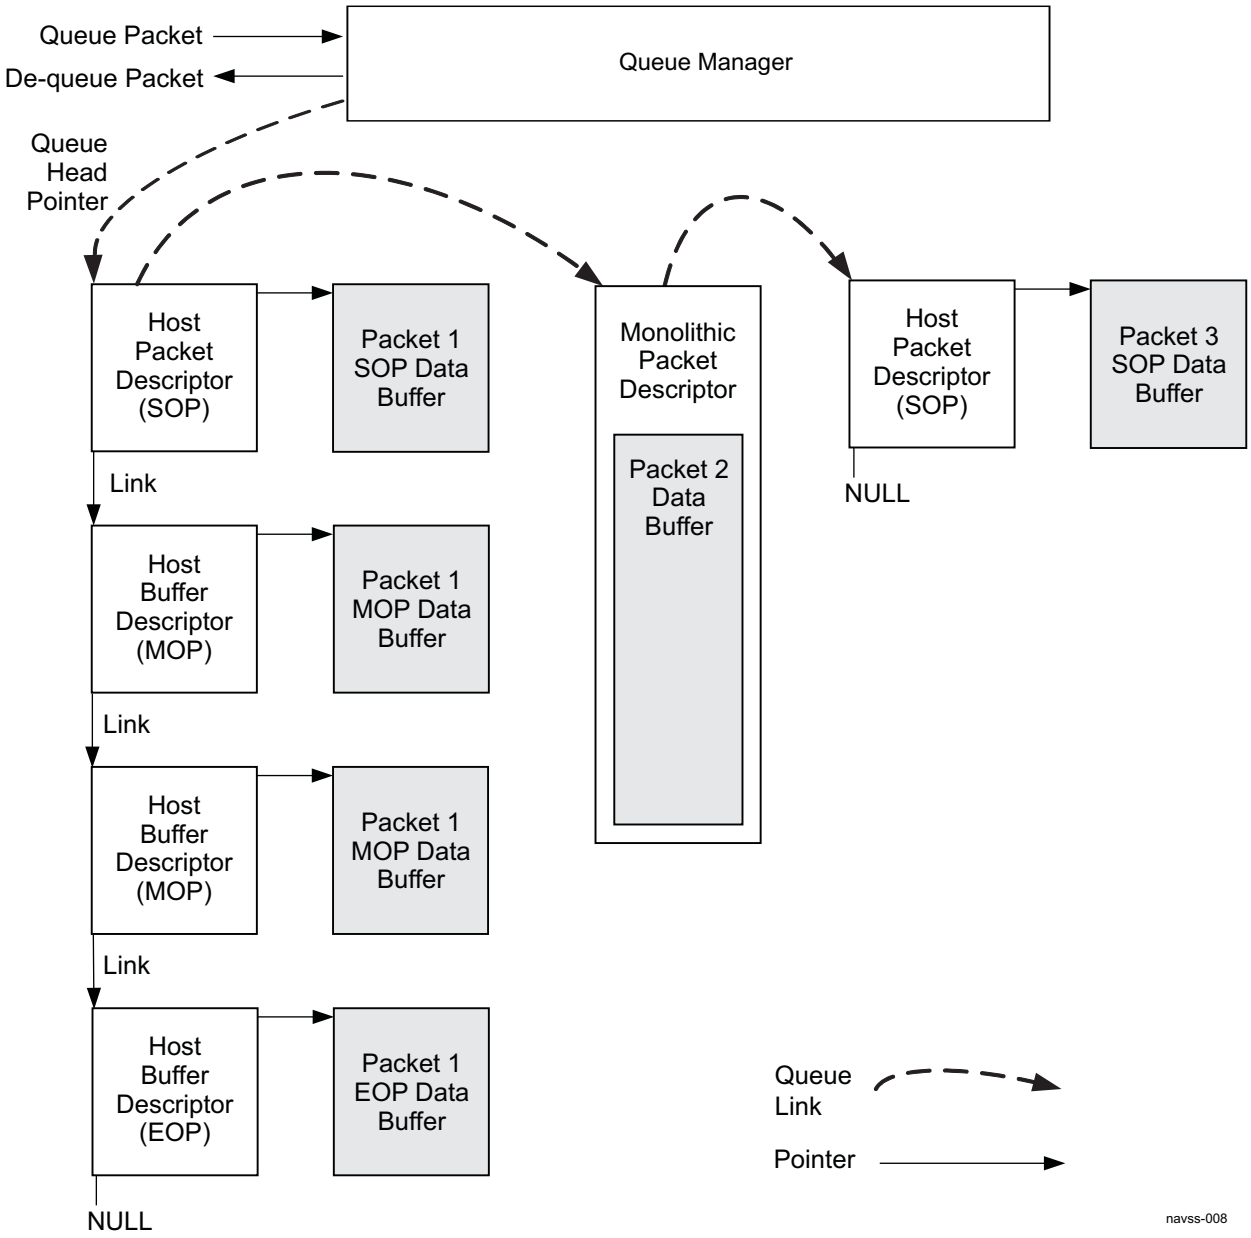
Table 11-1975 shows the different types of descriptors and their characteristics.

Table 11-1975. Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provided Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1		✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.
Host Buffer Descriptor		1			✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures
Monolithic Packet Descriptor	✓	0	✓	✓		Used to provide descriptor and data information in one contiguous data structure

Figure 11-903 shows how the various types of descriptors are queued. For Host type descriptors, it illustrates how Host Buffers are linked to a Host Packet, while only the Host Packet is pushed and popped from a queue. Both Host and Monolithic descriptors may be pushed into the same queue, though in practice they are usually kept separate.

Figure 11-903. Packet Queuing Data Structure Diagram



11.13.2.3.6 Packet Transmit Operation

Refer to Section 11.13.2.4.3, *Transmit Operation (Host Packet Type)* and Section 11.13.2.4.4, *Transmit Operation (Monolithic Packet)*.

11.13.2.3.7 Packet Receive Operation

Refer to Section 11.13.2.4.8, *Receive Operation (Host Packet)* and Section 11.13.2.4.9, *Receive Operation (Monolithic Packet)*

11.13.2.3.8 CPPI DMA

The CPPI DMA (or CDMA) used within NAVSS is like most DMAs in that it is primarily concerned with moving data from point to point. It is unlike some DMAs in that it is unaware of the payload data's structure. To the CDMA, all payloads are simple one-dimensional byte streams. Programming the CDMA is accomplished through correct initialization of descriptors, CDMA RX/TX channels, and RX flows.

11.13.2.3.8.1 Channels

Each CDMA in the system is configured with a number of receive (RX) and transmit (TX) channels (seeSection 11.13.5.2.3.4 and Section 11.13.5.2.3.3 for details). A channel may be thought of a pathway through the CDMA. Once the CDMA has started a packet on a channel, that channel cannot be used by any other packet until the current packet is completed. Because there are multiple channels for RX and TX, multiple packets may be in-flight simultaneously, and in both directions, because each CDMA contains separate DMA engines for RX and TX.

11.13.2.3.8.2 RX Flows

For transmit, the TX DMA engine uses the information found in the descriptor fields to determine how to process the TX packet. For receive, the RX DMA uses a *flow*. A flow is a set of instructions that tells the RX DMA how to process the RX packet. It is important to note that there is not a correspondence between RX channel and RX flow, but rather between RX packet and RX flow. For example, one peripheral may create a single RX flow for all packets across all channels, and another may create several flows for the packets on each channel.

For loopback CDMA modes (that is, infrastructure cases), the RX flow is specified in the TX descriptor, in the SOURCE_TAG_LO field. The CDMA will pass this value to the streaming I/F as *flow index*. In non-loopback cases, the RX flow is specified in the packet info structure of the Streaming I/F. In the event no RX flow is specified, the RX DMA will use RX flow *N* for RX channel *N*.

11.13.2.3.9 Port Data Structures

11.13.2.3.9.1 Transmit Channel State

The port stores and maintains state information for each transmit channel. The state information is referred to as the Tx Channel State. The Tx Channel State is a collection of persistent variables which are used by the port state machine during the transmit operation. The contents of the Tx Channel State generally needs to contain all of the required fields in the packet descriptor as well as current data pointers, status flags, etc. The Host is not required to initialize the Tx Channel State. On channel setup, the port is required to clear it's own state to a known initialization value.

11.13.2.3.9.2 Transmit Channel Real Time Control/Status

Each Tx DMA channel in the port requires some control and status bits that are allowed to be modified independent of the current processing state of the channel. Enabling and disabling of a channel are key examples of tasks which inherently occur asynchronously to the packet processing on the channel. The following register contains these Real Time Control and Status fields that must be provided in the port for each Tx DMA Channel:

- CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_0 to CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_8

11.13.2.3.9.3 Transmit Channel Configuration

Each Tx DMA channel in the port also requires some control fields to be initialized before a channel is enabled. Unlike the Tx Real Time Channel Control fields, these fields cannot be changed while the channel is enabled or active (including the time period where run-out operations may occur after a channel is disabled). The following register contains these Channel Configuration Fields:

- CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_B_0 to CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_B_8

11.13.2.3.9.4 Receive Port DMA State

The port stores and maintains state information for each receive channel. The state information is referred to as the Rx DMA State. The Rx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures in order to receive packets.

11.13.2.3.9.5 Rx DMA Real-Time Control/Status

Each Tx DMA channel in the port requires some control and status bits that are allowed to be modified independent of the current processing state of the channel. Enabling and disabling of a channel are key examples of tasks which inherently occur asynchronously to the packet processing on the channel. The following register contains these Real Time Control and Status fields that must be provided in the port for each Rx DMA Channel:

- CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0 to CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_25

11.13.2.3.9.6 Receive Flow Configuration

Unlike the Tx channels, each Rx channel does not necessarily have a single dedicated set of configuration registers that configure of the optional channel parameters. Instead, the port provides an array of *flow configurations* that contain the default values for the channel behaviors. Each Rx packet provided by the application provides both a DMA channel ID and a Flow ID to instruct the DMA controller how to properly process the packet. The DMA channel ID is used to select which parallel processing thread is to be used in the DMA controller. The DMA flow ID is used to select which flow configuration should be used during the packet reception.

In a simple use case, the port DMA controller may choose to provide the same number of flow configuration entries as it provides DMA channels. In more complex cases, more flow configuration entries may be provided to enable complex chaining operations between multiple CPPI ports connected in series. Like the Tx static channel control information, the information in the Rx Flow Configuration entries can only be changed with all of the channels that use that particular flow entry are disabled.

The fields contained within an Rx Flow Configuration Entry are described in the following registers:

- CDMA_RX_FLOW_CONFIG_REG_A_0 to CDMA_RX_FLOW_CONFIG_REG_A_31
- CDMA_RX_FLOW_CONFIG_REG_B_0 to CDMA_RX_FLOW_CONFIG_REG_B_31
- CDMA_RX_FLOW_CONFIG_REG_C_0 to CDMA_RX_FLOW_CONFIG_REG_C_31
- CDMA_RX_FLOW_CONFIG_REG_D_0 to CDMA_RX_FLOW_CONFIG_REG_D_31
- CDMA_RX_FLOW_CONFIG_REG_E_0 to CDMA_RX_FLOW_CONFIG_REG_E_31
- CDMA_RX_FLOW_CONFIG_REG_F_0 to CDMA_RX_FLOW_CONFIG_REG_F_31
- CDMA_RX_FLOW_CONFIG_REG_G_0 to CDMA_RX_FLOW_CONFIG_REG_G_31
- CDMA_RX_FLOW_CONFIG_REG_H_0 to CDMA_RX_FLOW_CONFIG_REG_H_31

11.13.2.4 Operational Description

11.13.2.4.1 Queue Manager Operation

11.13.2.4.1.1 Queuing Descriptors

Descriptors are queued onto a logical queue by writing a burst of information to the corresponding Queue N Registers. This burst contains optional control information, an optional descriptor size, and a required pointer to the descriptor that is being added. The control and packet size information (if present) is written to the QM_QUEUE_REG_C_0–63. The descriptor pointer is written to QM_QUEUE_REG_D_0–63. When QM_QUEUE_REG_D_0–63 is written, this kicks off the queue manager causing it to add the descriptor either onto the head or the tail of the queue as specified in QM_QUEUE_REG_C_0–63.

To accomplish this linking, the queue manager will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking and queue pointer purposes. This address to index computation is performed by the queue manager in a fixed number of clock cycles. Once the physical index information is determined, the queue manager will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. The queue manager will also update the queue head and tail pointers appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

11.13.2.4.1.2 De-queuing Descriptors

Descriptors are de-queued from a logical queue by reading a descriptor pointer value from the corresponding QM_QUEUE_REG_D_0–63. When QM_QUEUE_REG_D_0–63 is read, if it is not empty it will return the 32-bit descriptor pointer that is on the head of the queue. If the queue is empty it will return a value of 0x0. If other information is desired it must be read from registers A–C in the same burst in which QM_QUEUE_REG_D_0–63 is read.

In order to populate the mailboxes with a 32-bit descriptor address, the queue manager resolve the 16-bit index into a 32-bit descriptor pointer. This index to address lookup is performed by the queue manager in a fixed number of clock cycles. When the 32-bit pointer is resolved and loaded into the mailbox register, the queue manager will assert the qmgr_slv_ready signal until the burst transfer is completed.

11.13.2.4.1.3 Diverting Queued Packets from One Queue to Another

The host can move the entire contents of one queue to another queue by writing the source queue number and the destination queue number to QM_QUEUE_DIVERSION_REG. When diverting packets, the host can choose whether the source queue contents should be pushed onto the tail (default) or head of the destination queue.

11.13.2.4.2 Transmit DMA Controller Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by writing to CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_0–8. The Host may choose to write the TX_ENABLE bit at the same time or after it has written all of the channel parameters but note that every write will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

11.13.2.4.3 Transmit Operation (Host Packet Type)

After a TX DMA channel has been initialized, it can begin to be used to transmit packets. Packet transmission involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.

2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to Host)
   b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. Buffer Pointer with the byte aligned address of the first chunk of buffer data
   h. Buffer Length with the number of bytes in the first chunk of buffer data
   i. Descriptor reclamation policy fields indicating the mode, queue manager, and queue number for recycling the packet after transmission is complete
   j. The Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
   k. Any protocol specific descriptor sections that are required for the given packet type or system configuration
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:
   a. Buffer Descriptor reclamation policy fields (if the intention is to have the DMA automatically recycle the buffer descriptors as they are transmitted).
   b. Buffer Pointer with the byte aligned address of the given chunk of buffer data
   c. Buffer Length with the number of bytes in the given chunk of buffer data
   d. The Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
4. The Host writes the pointer to the Packet Descriptor into a specific memory mapped location inside the Queue Manager which corresponds to one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
5. The Queue Manager provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
7. The DMA controller reads the packet descriptor pointer and descriptor size hint information from the Queue Manager.
8. The DMA controller reads the packet descriptor from memory
9.
   - If the return policy bit (PD Word 2, bit 15) is cleared– The DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves. As each buffer is emptied, the DMA will read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.
   - If the return policy bit is set– The DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves.
10.
    - If the return policy bit (PD Word 2, bit 15) is cleared– When all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue manager/return queue number fields of the packet descriptor.

- If the return policy bit is set– As each buffer is emptied the DMA will write the buffer descriptor pointer to the queue specified in the return queue manager/return queue number fields of the buffer descriptor. The DMA will also read the next buffer descriptor to obtain the pointer and size of the data buffer, the return queue information for the descriptor, as well as the pointer to the next descriptor in the chain.

11. After the Packet Descriptor pointer has been written, the Queue Manager will indicate the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.
12.
    - If the return policy bit (PD Word 2, bit 15) is cleared– While most types of peer entities and embedded processors are able to directly and efficiently use these level sensitive status lines, cached processors may require a hardware block to convert the level status into pulsed interrupts and to perform some level of aggregation of the descriptor pointers from the completion queues into lists.
    - If the return policy bit is set– When all data for the packet has been transmitted as specified in the packet size field, if the current buffer is not marked as end of packet (via a null next descriptor pointer), the DMA will continue to walk the list returning buffer descriptors to the appropriate queues as described in step 10.
13.
    - If the return policy bit (PD Word 2, bit 15) is cleared– Host responds to status change from Queue Manager and performs garbage collection as necessary for packet.
    - If the return policy bit is set– When all buffers have been returned, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue manager/return queue number fields of the packet descriptor.

With the return policy bit (PD Word 2, bit 15) cleared, the complete process is shown in Figure 11-904

With the return policy bit set, the complete process is shown in Figure 11-905

Figure 11-904. Host Packet Tx Operation – Complete Packet Return

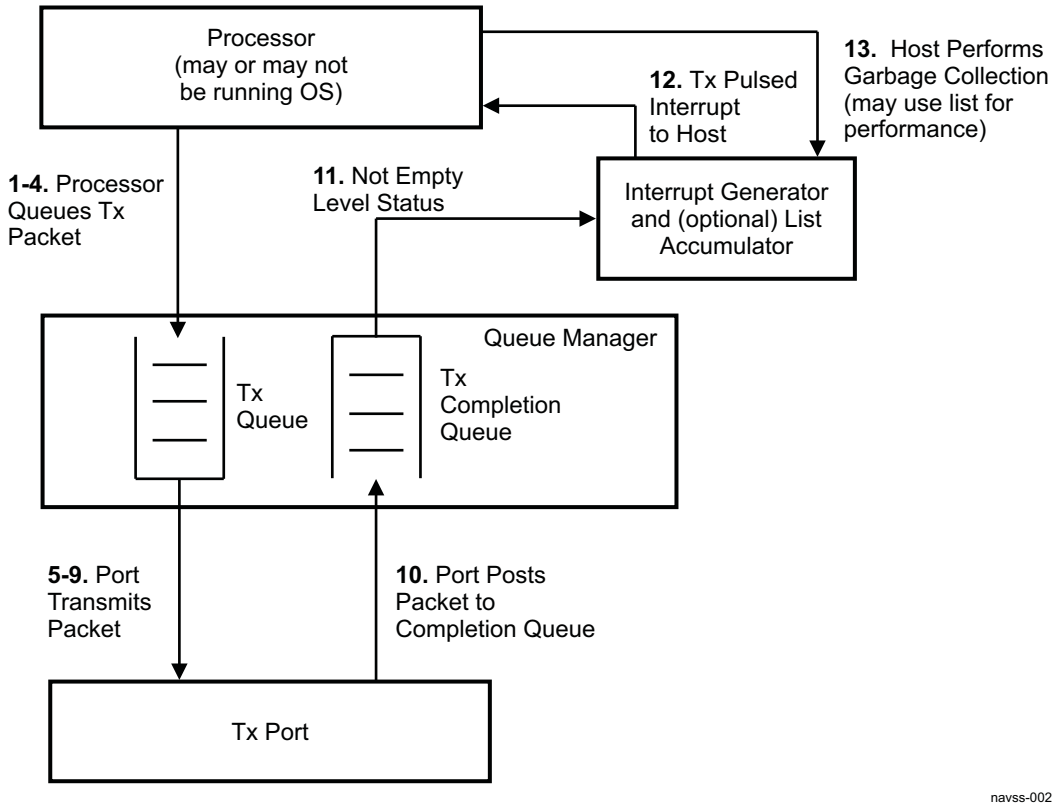


Figure 11-905. Host Packet Tx Operation – Automatic Buffer Recycling Packet Return

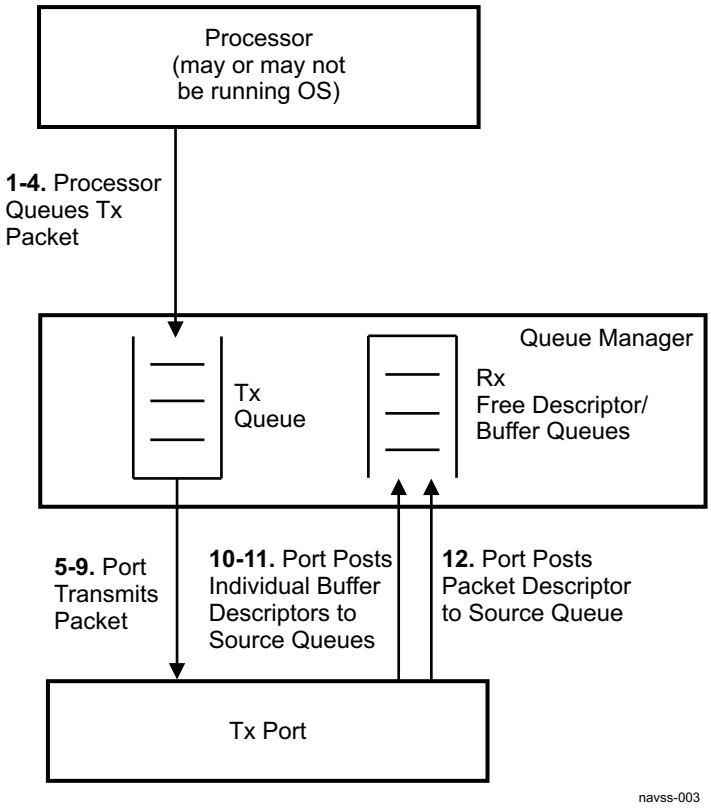


11.13.2.4.4 Transmit Operation (Monolithic Packet)

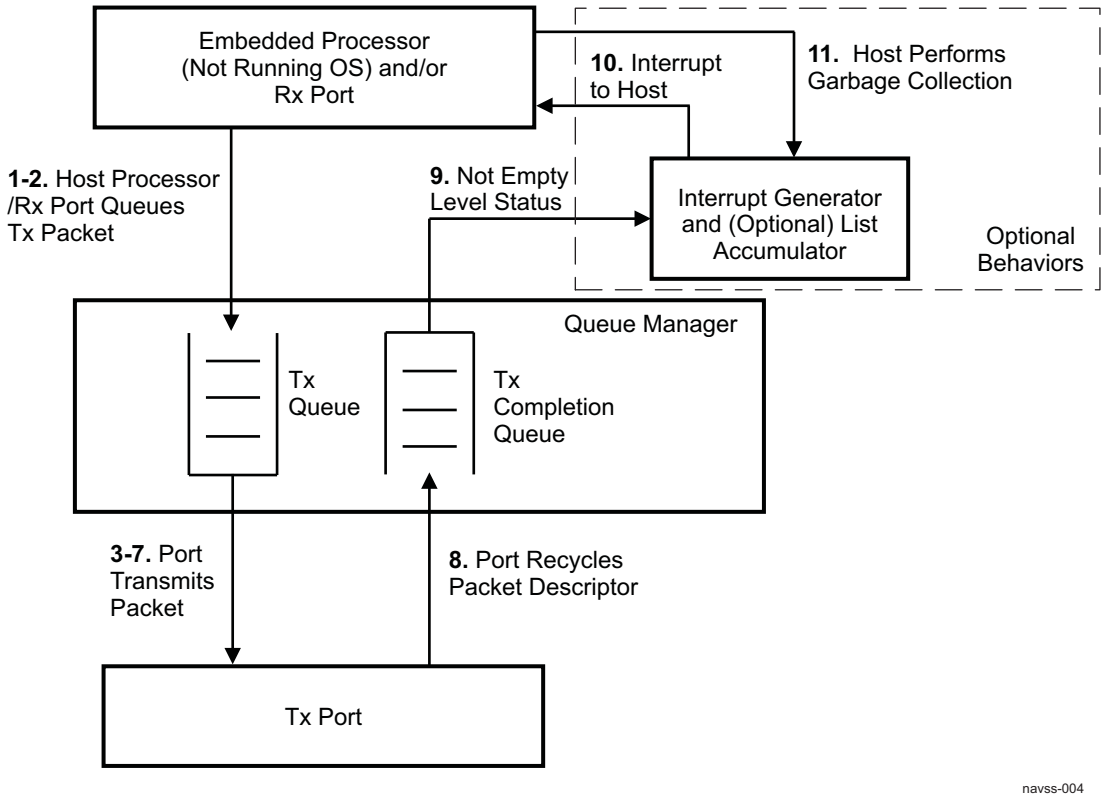
Packet transmission in Monolithic mode involves the following steps:

1. The Host allocates and populates a monolithic packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to Monolithic)
   b. Packet Length indicating the total number of bytes in the packet
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. Offset to payload data
   h. Descriptor reclamation policy fields indicating the mode, queue manager, and queue number for recycling the packet after transmission is complete.
   i. Networking Stack Information (application specific and optional)
   j. Any protocol specific words that are required for the given packet type
2. The Host writes the pointer to the Packet Descriptor into a specific memory mapped location inside the Queue Manager which corresponds to one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues.
3. The Queue Manager provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.

5. The DMA controller reads the packet descriptor pointer and descriptor size from the Queue Manager.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by transmitting the contents in one or more block data moves.
8. When all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue manager/return queue number fields of the packet descriptor.
9. After the Packet Descriptor pointer has been written, the Queue Manager indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

   Whether or not any further processing is required on the packet at this point depends on the nature of the queue that the packet was returned to. The most common case is that the monolithic descriptor will be returned to the Rx Free Descriptor queue that it was allocated from originally. If this is the case, the Tx processing is complete at this point. Alternatatively, the queue may also be a Tx Completion Queue in which case, the following optional steps may also be performed:
10. While most types of peer entities and embedded processors are able to directly and efficiently use these level sensitive status lines, cached processors may require a hardware block to convert the level status into pulsed interrupts and to perform some level of aggregation of the descriptor pointers from the completion queues into lists.
11. Host responds to status change from Queue Manager and performs garbage collection as necessary for packet.

Figure 11-906. Monolithic Packet Tx Operation



11.13.2.4.5 Transmit Channel Teardown (All Packet Types)

A channel teardown is commanded by the host to gracefully terminate an active channel from transmitting packets. The host writes the TX_TEARDOWN bit in CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_0–8 in order to initiate channel teardown. Upon reception of a channel teardown command, the port performs the following operations:

1. Gracefully terminates or completes any packet that is in transmission on the channel
2. Clears the channel enable in CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_0–8

The host may issue a teardown command on any channel at any time, regardless of whether the channel has active queue(s) or not. Note that the host should not clear the enable bit when issuing the teardown command. Doing so may prevent the teardown operation from completing since the channel will be removed from transmit scheduling operations.

The Host determines that a teardown is complete by periodically polling the TX_TEARDOWN and TX_ENABLE bits for the channel.

11.13.2.4.6 Receive Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0–25. The Host may choose to write the RX_ENABLE bit at the same time or after it has written all of the channel parameters but note that every write to CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0–25 will overwrite the channel state for all bytes that are enabled for the write transaction.

11.13.2.4.7 Receive Free Descriptor/Buffer Queue Setup (Host Packets)

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. For Rx Free Descriptor/Buffer queues, descriptors are allocated in a large block by the Host and then initialized and linked with buffers before being given matched pairs where the Host initializes the descriptor to point to its corresponding buffer before being pushed onto a Receive Free Descriptor/Buffer queue. Once the host has allocated both a descriptor and a buffer, it adds them to an Rx Free Descriptor/Buffer Queue by writing the pointer to QM_QUEUE_REG_D_0–63 for the desired queue.

Before the Host adds each Rx buffer descriptor to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Original Buffer Pointer with the byte aligned address of the buffer data
- Write the Original Buffer Size
- Write the Return Queue Number and Return Queue Manager fields in the descriptor to appropriate values (required if auto-recycling is intended)
- Write the On Chip/ Off Chip indicator in the descriptor

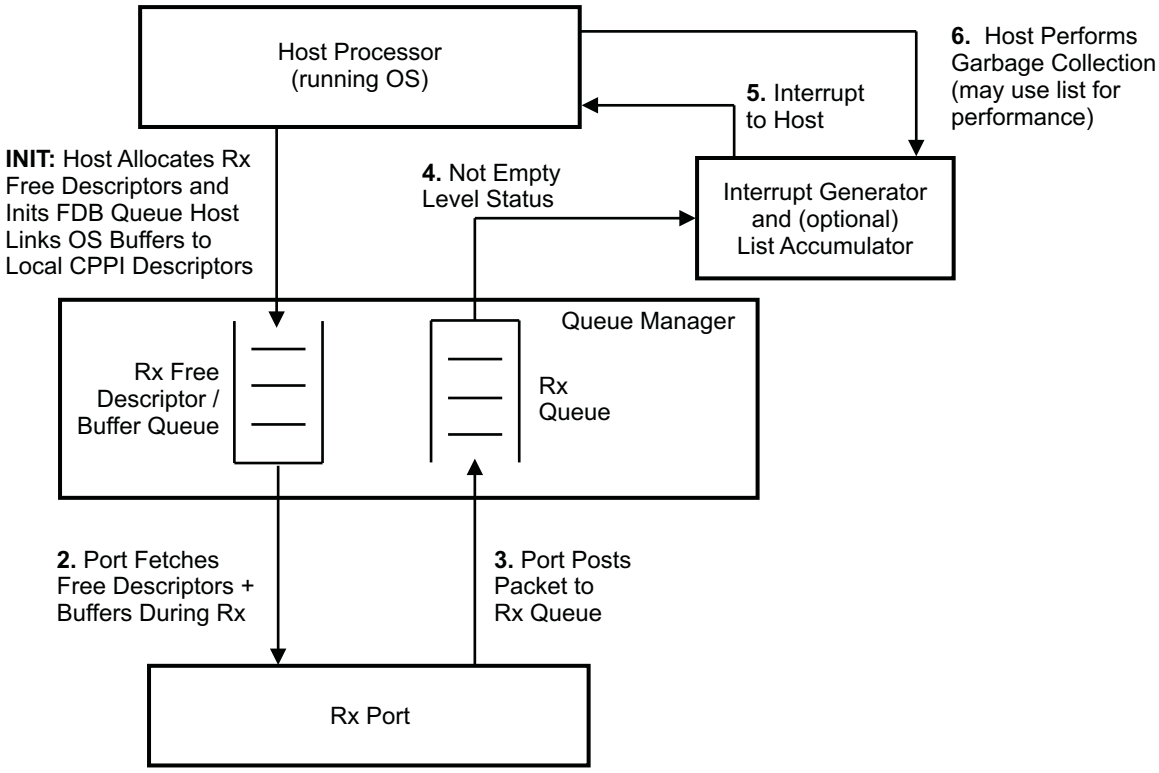
Depending on the software architecture, the Host may also desire to write the return policy bit in the descriptor at this point as well. The DMA will not overwrite any of these listed fields (including return policy) during reception.

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

11.13.2.4.8 Receive Operation (Host Packet)

Figure 11-907 shows a diagram of the overall receive operation.

Figure 11-907. Packet Receive Operation (Host Packet)



When packet reception begins on a given channel, the port will begin by fetching the first descriptor + buffer from the Queue Manager using the Free Descriptor/Buffer Queue 0 Index that was initialized in the Rx Port DMA State for the channel. If the SOP Buffer Offset in the Rx DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fetch additional descriptors + buffers as needed using the Free Descriptor/Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet. The port performs the following operations when each buffer is filled on receive:

1. Fetches next descriptor + buffer (if End of Packet has not been reached)
2. Writes the buffer descriptor to memory. This includes the following fields:
    a. Buffer information
        i. Buffer Pointer with the byte aligned address of the chunk of buffer data
        ii. Buffer Length with the number of bytes in the chunk of buffer data
    b. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

The port performs the following operations when the entire packet has been received:

1. Writes the packet descriptor to memory. This includes the following fields:
    a. Descriptor Type (set to Host)
    b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
    c. Source Tag
    d. Destination Tag (application specific)
    e. Packet Type
    f. Any protocol specific flags for the given packet type
    g. SOP buffer information
        i. Buffer Pointer with the byte aligned address of the chunk of buffer data

ii. Buffer Length with the number of bytes in the chunk of buffer data

h. Any protocol specific words that are required for the given packet type

i. Networking Stack Information (application specific and optional)

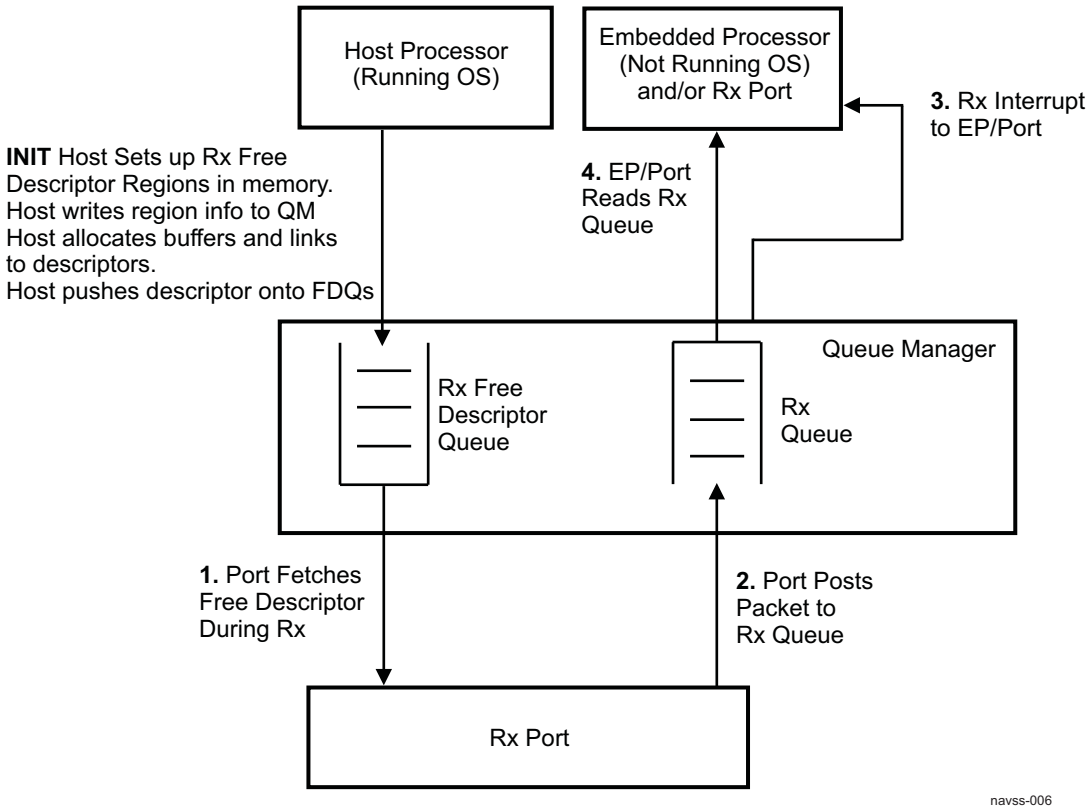
j. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

2. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the RX_DEST_QMGR and RX_DEST_QNUM fields in the Rx Flow Entry or can be overridden using an application specific value.

11.13.2.4.9 Receive Operation (Monolithic Packet)

Error! Reference source not found. shows a diagram of the overall Receive operation for a monolithic descriptor type.

Figure 11-908. Monolithic Packet Receive Operation



When packet reception begins on a given channel, the port will begin by fetching a single descriptor for the packet from the Queue Manager using the Monolithic Type Free Descriptor Queue Index that was initialized in the Rx Port DMA State for the channel. If the Monolithic Type Data Offset in the Rx DMA State is non-zero, then the port will begin writing data after the offset number of bytes in the payload portion of the monolithic descriptor. The port will then continue filling the payload portion of the descriptor until the entire packet has been received.

The port performs the following operations when each buffer is filled on receive:

1. Writes the packet descriptor to memory. This includes the following fields:
   a. Descriptor Type (set to Monolithic)
   b. Packet Length indicating the total number of bytes in this packet.
   c. Source Tag
   d. Destination Tag (application specific)

e. Packet Type
f. Any protocol specific flags for the given packet type
g. Networking Stack Information (application specific and optional)
h. Any protocol specific words that are required for the given packet type

2. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the RX_DEST_QMGR and RX_DEST_QNUM fields in the Rx Flow Entry or can be overridden using an application specific value.

11.13.2.4.10 Receive Error Processing

Several types of errors/exceptions may be encountered during reception of a host packet. These errors can be broken into these basic types:

- Descriptor Starvation
- Protocol errors
- Dropped packets

11.13.2.4.10.1 Descriptor Starvation

Descriptor starvation occurs when the Port attempts to fetch a free descriptor from an Rx Free Descriptor Queue or Rx Free Descriptor/Buffer Queue and none are available. When no descriptor is available, the Queue Manager will return a value of 0x0 for the descriptor pointer. When the port detects that descriptor starvation has occurred it will react based on the value of the RX_ERROR_HANDLING bit which was programmed into CDMA_RX_FLOW_CONFIG_REG_A_0–31.

- If the RX_ERROR_HANDLING bit is cleared:

The Port will assert a descriptor starvation indicator and will then return any descriptors that it has already used in the reception of the current packet back to the appropriate Free Descriptor or Free Descriptor / Buffer queue that they were fetched from. This is performed by writing the pointers for each descriptor to the Rx Free Descriptor Queue N Register in sequence using the queue indexes in the Rx DMA state. The port may choose to implement a counter that counts the number of packets that were dropped due to descriptor starvation and may also desire to distinguish between whether the starvation occurred on the packet descriptor (SOP) or on a buffer starvation.

- If the RX_ERROR_HANDLING bit is set:

The Port will assert a descriptor starvation indicator (which may cause an interrupt to the Host) and will then behave as if it had not performed the current data block transfer which caused the starvation. The Port is required to pause it's current processing saving the state of the transfer. The next time that the channel comes into context it will again try to allocate a descriptor with the intention being that if buffers/descriptors have been added that the operation will complete successfully on a subsequent retry.

11.13.2.4.10.2 Protocol Errors

specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors. When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

11.13.2.4.10.3 Dropped Packets

Packets can be dropped within an Rx Port for any number for reasons which with the exception of the starvation case which was covered above,are application specific. When a Port determines that it needs to drop a packet, it should return any descriptors to the queues they were allocated from in the appropriate Queue Manager(s). Returning the descriptors to their source queues involves simply performing a write of the appropriate pointer which was allocated from the queue back to the address from which the pointer was originally read.

11.13.2.4.11 Receive Channel Teardown

An Rx channel teardown is commanded by the host to gracefully terminate an active channel from receiving packets. The host initiates a teardown by setting the RX_TEARDOWN bit in the channel's CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0–25.

Upon reception of a channel teardown command (as indicated by setting the bit in the control register) the port performs the following operations:

1. Completes any packets which may be pending in the ingress port buffers (what the port considers as pending packets is application specific)
2. Clears the channel enable in CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0–25

The host may issue a teardown command on any channel at any time, regardless of whether the channel is actively receiving a packet or not. Note that the host must not clear the enable bit when issuing the teardown command.

The Host determines that a teardown is complete by periodically polling the TEARDOWN and ENABLE bits for the channel.

11.13.2.5 Descriptor Layouts

Descriptors are memory areas that describe the contents of a packet. This memory may be co-located with the packet data, or may contain pointers to the data.

11.13.2.5.1 Host Packet Descriptor

Host packet descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather-type operations. The host packet descriptor contains the following information:

- Indicator that identifies the descriptor as a host packet descriptor
- Source and destination tags
- Packet type
- Packet length
- Protocol-specific region size
- Protocol-specific control/status bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software-specific information

Host packet descriptors always contain 32 bytes of required information and may also contain optional software-specific information and protocol-specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application-dependent. The descriptor layout is shown in Table 11-1976.

Table 11-1976. Host Packet Descriptor Layout

Packet info (12 bytes)
Buffer info (8 bytes)
Linking info (4 bytes)
Original buffer info (8 bytes)
Extended packet info block (optional) Includes timestamp and software data (16 bytes)
Protocol-specific data (optional) (0 to *M* bytes where *M* is a multiple of 4)
Other software data (optional and user defined)

Host packet descriptors may be linked with zero or more additional host buffer descriptors in a singly-linked-list fashion to form packets. Each host packet consists of a single host packet descriptor followed by a chain of zero or more host buffer descriptors linked together using the next descriptor pointer fields in the descriptors. The last descriptor in a host packet has a 0 next descriptor pointer.

The other software data portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by the DMA or queue manager modules in a NAVSS system and these modules will not modify any bytes within this region.

The contents of the host packet descriptor words are detailed in the following tables:

Table 11-1977. Host Packet Descriptor Packet Information Word 0 (PD Word 0)

Bits	Name	Description	RX Overwrite
31-30	Packet Id	Host packet descriptor type identifier. Value is always 0 (0x0) for Host Packet descriptors.	Yes
29-25	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = To Be Assigned	Yes

Table 11-1977. Host Packet Descriptor Packet Information Word 0 (PD Word 0) (continued)

Bits	Name	Description	RX Overwrite
24-23	Reserved	Unused	Yes
22	Protocol Specific Region Location	This field indicates the location of the protocol-specific words: • 0 = PS words are located in the descriptor • 1 = PS words are located in the SOP Buffer immediately prior to the data.	Yes
21-0	Packet Length	The length of the packet data in bytes. If the packet length is less than the sum of the buffer lengths, then the packet data will be truncated. A packet length greater than the sum of the buffers is an error. The valid range for the packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer / descriptor reclamation as instructed in the return information in word 2.	Yes

Table 11-1978. Host Packet Descriptor Packet Information Word 1 (PD Word 1)

Bits	Name	Description	RX Overwrite
31-24	Source Tag - Hi	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_SRC_TAG_HI_SEL field in the flow configuration table entry.	Configurable
23-16	Source Tag - Lo	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_SRC_TAG_LO_SEL field in the flow configuration table entry. For TX, this value supplies the RX flow index to the Streaming I/F for infrastructure use.	Configurable
15-8	Dest Tag – Hi	This field is application specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_DEST_TAG_HI_SEL field in the flow configuration table entry.	Configurable
7-0	Dest Tag - Lo	This field is application specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_DEST_TAG_LO_SEL field in the flow configuration table entry.	Configurable

Table 11-1979. Host Packet Descriptor Packet Information Word 2 (PD Word 2)

Bits	Name	Description	RX Overwrite
31	Extended Packet Info Block Present	This field indicates the presence of the extended packet info block in the descriptor. • 0 = EPIB is not present • 1 = 16 byte EPIB is present	Yes
30	Reserved	Unused	Yes
29-24	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol-specific region. This is encoded in increments of 4 bytes as follows: • 0 = 0 bytes • 1 = 4 bytes … • 16 = 64 bytes … 32 = 128 bytes 33-63 = Reserved	Yes
23-20	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
19-16	Protocol Specific Flags	This field contains protocol-specific flags / information that can be assigned based on the packet type.	Yes
15	Return Policy	• This field indicates the return policy for this packet. • 0 = Entire packet (still linked together) should be returned to queue specified in bits 13-0 below. • 1 = Each buffer should be returned to queue specified in bits 13-0 of Word 2 in their respective descriptors. The TX DMA will return each buffer in sequence.	No

Table 11-1979. Host Packet Descriptor Packet Information Word 2 (PD Word 2) (continued)

Bits	Name	Description	RX Overwrite
14	Return Push Policy	This field indicates how a transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: • 0 = Descriptor must be returned to tail of queue • 1 = Descriptor must be returned to head of queue This bit is used only when the Return Policy bit is set to 1.	No
13-12	Packet Return Queue Mgr Num	This field indicates which of the four potential queue managers in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and should be initialized by the host.	No
11-0	Packet Return Queue Num	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. The value 0xFFF is reserved.	No

Table 11-1980. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 3)

Bits	Name	Description	RX Overwrite
31-22	Reserved	Unused	Yes
21-0	Buffer 0 Length	The buffer length field indicates how many valid data bytes are in the buffer. Unused or protocol-specific bytes at the beginning of the buffer are not counted in the buffer length field. This value will be overwritten during reception.	Yes

Table 11-1981. Host Packet Descriptor Buffer 0 Info Word 1 (PD Word 4)

Bits	Name	Description	RX Overwrite
31-0	Buffer 0 Pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. If the protocol-specific words are placed at the beginning of the SOP buffer, this pointer will point to the PS words. The offset to the data in that case must be calculated by the consumer using the protocol-specific valid word count from word 2. **Usage note**: For TX, it is a good practice to initialize this field and the Original Ptr field in word 7 with the actual buffer address, but this is the field that is used. For RX, this field may be left uninitialized, or set to 0.	Yes

Table 11-1982. Host Packet Descriptor Linking Word (PD Word 5)

Bits	Name	Description	RX Overwrite
31-0	Next Descriptor Pointer	The 32-bit word-aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is 0, then the current buffer is the last buffer in the packet. The host sets the next descriptor pointer.	Yes

Table 11-1983. Host Packet Descriptor Original Buffer Info Word 0 (PD Word 6)

Bits	Name	Description	RX Overwrite
31-28	Original Buffer 0 Pool Index	This field is used to identify which pool the attached buffer was originally allocated from. This is distinct from the descriptor pool/queue index because a single buffer may be referenced by more that one descriptor. This is a software-only field that is not touched by the hardware.	No
27-22	Original Buffer 0 Reference Count	This field is used to indicate how many references have been made to the attached buffer by different descriptors. Multiple buffer references are commonly used to implement broadcast and multicast packet forwarding when zero packet data copies are desired. This is a software-only field that is not touched by the hardware.	No
21-0	Original Buffer 0 Length	The buffer length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer size as allocated by the host at initialization. Because the buffer length in Word 3 is overwritten by the RX port during reception, this field is necessary to permanently store the buffer size information. **Usage Note:** It is good practice to always set this field during initialization.	No

Table 11-1984. Host Packet Descriptor Original Buffer Info Word 1 (PD Word 7)

Bits	Name	Description	RX Overwrite
31-0	Original Buffer 0 Pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Because the buffer pointer in word 4 is overwritten by the RX port during reception, this field is necessary to permanently store the buffer pointer information. **Usage Note**: It is good practice to always set this field during initialization, but is used only in RX.	No

Table 11-1985. Host Packet Descriptor Extended Packet Info Block Word 0 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Timestamp Info	This field contains an application-specific timestamp that can be used for traffic shaping in a QoS enabled system.	Configurable

(1) This word is present only if the extended packet info block present bit is set in word 2.

Table 11-1986. Host Packet Descriptor Extended Packet Info Block Word 1 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Software Info 0	This field stores software-centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in Word 2.

Table 11-1987. Host Packet Descriptor Extended Packet Info Block Word 2 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Software Info 1	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in Word 2.

Table 11-1988. Host Packet Descriptor Extended Packet Info Block Word 3 (Optional) [1]

Bits	Name	Description	RX Overwrite
31-0	Software Info 2	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in Word 2.

Table 11-1989. Host Packet Descriptor Protocol Specific Word N (Optional)

Bits	Name	Description	RX Overwrite
31-0	Protocol Specific Data N	This field stores information that varies depending on the block and packet type.	Configurable

11.13.2.5.2 Host Buffer Descriptor

The host buffer descriptor is identical in size and organization to a host packet descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol-specific information. Host buffer descriptors are designed to be linked onto a host packet descriptor or another host buffer descriptor to provide support for unlimited scatter / gather type operations. Host buffer descriptors provide information about a single corresponding data buffer. Every host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data buffer
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Host buffer descriptors always contain 32 bytes of required information. Because it is a requirement that it is possible to convert a host descriptor between a buffer descriptor and a packet descriptor (by filling in the appropriate fields), in practice, host buffer descriptors will be allocated using the same sizes as host packet descriptors. The descriptor layout is shown in Table 11-1990.

Table 11-1990. Host Buffer Descriptor Layout

Reserved (10 bytes)
Buffer reclamation info (2 bytes)
Buffer info (8 bytes)
Linking info (4 bytes)
Original buffer info (8 bytes)

A host packet descriptor and zero or more host buffer descriptors may be linked together using the next descriptor pointer fields to form packets. The last descriptor in a packet has a 0 next descriptor pointer. Each host buffer descriptor also points to a single data buffer.

The contents of the host buffer descriptor words are detailed in Table 11-1991 through Table 11-1998. The host buffer descriptor is designed to be interchangeable with host packet descriptors, with common fields residing in the same locations.

Table 11-1991. Host Buffer Descriptor Reserved Word 0 (BD Word 0)

Bits	Name	Description	RX Overwrite
31-0	Reserved	Reserved for host packet fields	No

Table 11-1992. Host Buffer Descriptor Reserved Word 1 (BD Word 1)

Bits	Name	Description	RX Overwrite
31-0	Reserved	Reserved for host packet fields	No

Table 11-1993. Host Buffer Descriptor Buffer Reclamation Info (BD Word 2)

Bits	Name	Description	RX Overwrite
31-15	Reserved	Reserved for host packet fields	No
14	Return Push Policy	This field indicates how a transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: • 0 = Descriptor must be returned to tail of queue • 1 = Descriptor must be returned to head of queue This bit is used only when the Return Policy bit is set to 1.	No
13-12	Packet Return Queue Mgr #	This field indicates which of the four potential queue managers in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and should be initialized by the host.	No
11-0	Packet Return Queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete.	No

Table 11-1994. Host Buffer Descriptor Buffer N Info Word 0 (BD Word 3)

Bits	Name	Description	RX Overwrite
31-22	Reserved	Reserved for host packet fields	Yes
21-0	Buffer N Length	The buffer length field indicates how many valid data bytes are in the buffer. Unused or protocol-specific bytes at the beginning of the buffer are not counted in the buffer length field. This value will be overwritten during reception.	Yes

Table 11-1995. Host Buffer Descriptor Buffer N Info Word 1 (BD Word 4)

Bits	Name	Description	RX Overwrite
31-0	Buffer N Pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception.	Yes

Table 11-1996. Host Buffer Descriptor Linking Word (BD Word 5)

Bits	Name	Description	RX Overwrite
31-0	Next Descriptor Pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is 0, then the current buffer is the last buffer in the packet. This value will be overwritten during reception.	Yes

Table 11-1997. Host Buffer Descriptor Original Buffer Info Word 0 (BD Word 6)

Bits	Name	Description	RX Overwrite
31-28	Original Buffer 0 Pool Index	This field is used to identify which pool the attached buffer was originally allocated from. This is distinct from the descriptor pool/queue index because a single buffer may be referenced by more that one descriptor. This is a software-only field that is not touched by the hardware.	No
27-22	Original Buffer 0 Reference Count	This field is used to indicate how many references have been made to the attached buffer by different descriptors. Multiple buffer references are commonly used to implement broadcast and multicast packet forwarding when zero packet data copies are desired. This is a software-only field that is not touched by the hardware.	No

Table 11-1997. Host Buffer Descriptor Original Buffer Info Word 0 (BD Word 6) (continued)

Bits	Name	Description	RX Overwrite
21-0	Original Buffer 0 Length	The buffer length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer size as allocated by the host at initialization. Because the buffer length in word 3 is overwritten by the RX port during reception, this field is necessary to permanently store the buffer size information.	No

Table 11-1998. Host Buffer Descriptor Original Buffer Info Word 1 (BD Word 7)

Bits	Name	Description	RX Overwrite
31-0	Original Buffer 0 Pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Because the buffer pointer in word 4 is overwritten by the RX port during reception, this field is necessary to permanently store the buffer pointer information.	No

11.13.2.5.3 Monolithic Descriptor

The monolithic packet descriptor contains the following information:

- Indicator that identifies the descriptor as a monolithic packet descriptor
- Source and destination tags
- Packet type
- Packet length
- Packet error indicator
- Packet return information
- Protocol-specific region size
- Protocol-specific region offset
- Protocol-specific control / status bits
- Packet data

The maximum size of a monolithic packet descriptor is 65535 bytes. Of this, monolithic packet descriptors always contain 12 bytes of required information and may also contain 16 bytes of software-specific tagging information and up to 128 bytes (indicated in 4-byte increments) of protocol-specific information. How much protocol-specific information (and therefore the allocated size of the descriptors) is application dependent. The descriptor layout is shown in Table 11-1999.

Table 11-1999. Monolithic Packet Descriptor Layout

Packet info (12 bytes)
Extended packet info block (optional) Includes PS bits, timestamp, and software data words (20 bytes)
Protocol-Specific data (optional) (0 to *M* bytes where *M* is a multiple of 4)
Null region (0 to (511-12) bytes)
Packet data (0 to 64K – 1)
Other software data (optional and user defined)

The other software data portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store private data. This region is not used in any way by the DMA or queue manager modules in a NAVSS system and these modules will not modify any bytes within this region.

A note on the placement of data with respect to the optional EPIB block: If EPIB is present, the 16 bytes of EPIB data begins at byte offset 16, and PS or packet data may begin at byte offset 32 (from the descriptor address). If EPIB is not present, PS or packet data may begin at byte offset 12 (from the descriptor address).

The contents of the monolithic packet descriptor words are detailed in the following tables:

Table 11-2000. Monolithic Packet Descriptor Word 0

Bits	Name	Description	RX Overwrite
31-30	Packet Id	Monolithic packet descriptor type. Value is always 2 (0x02) for monolithic descriptors.	Yes
29-25	Packet Type	This field indicates the type of this packet and is encoded as follows: • 0-31 = To Be Assigned	Yes
24-16	Data Offset	This field indicates the byte offset from byte 0 of this descriptor to the location where the valid data begins. On RX, this value is set equal to the value for the SOP offset given in the RX DMA channel's monolithic control register. When a monolithic packet is processed, this value may be modified in order to add or remove bytes to or from the beginning of the packet. The value for this field can range from 0-511 bytes, which means that the maximum NULL region can be 511-12 bytes, because byte 0 is the start of the 12 byte packet info area. Note that the value of this field must always be greater than or equal to 4 times the value given in the Protocol Specific Valid Word Count field.	Yes
15-0	Packet Length	The length of the packet data in bytes. The valid range is from 0 to 65535 bytes. NOTE: The sum of the data offset field and the packet length must not exceed 64KB or the defined size of the descriptor. To do so is an error, and may cause transmission problems through the Streaming Interface.	Yes

Table 11-2001. Monolithic Packet Descriptor Word 1

Bits	Name	Description	RX Overwrite
31-24	Source Tag - Hi	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_SRC_TAG_HI_SEL field in the flow configuration table entry.	Configurable
23-16	Source Tag - Lo	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_SRC_TAG_LO_SEL field in the flow configuration table entry. For TX, this value supplies the RX flow index to the streaming I/F for infrastructure use.	Configurable
15-8	Dest Tag – Hi	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_DEST_TAG_HI_SEL field in the flow configuration table entry.	Configurable
7-0	Dest Tag - Lo	This field is application-specific. During packet reception, the DMA controller in the port will overwrite this field as specified in the RX_DEST_TAG_LO_SEL field in the flow configuration table entry.	Configurable

Table 11-2002. Monolithic Packet Descriptor Word 2

Bits	Name	Description	RX Overwrite
31	Extended Packet Info Block Present	This field indicates the presence of the extended packet info block in the descriptor. • 0 = EPIB is not present • 1 = 16 byte EPIB is present	Yes
30	Reserved	Unused	Yes

Table 11-2002. Monolithic Packet Descriptor Word 2 (continued)

Bits	Name	Description	RX Overwrite
29-24	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol-specific region. This is encoded in increments of 4 bytes as follows: • 0 = 0 bytes • 1 = 4 bytes • … • 16 = 64 bytes • … • 32 = 128 bytes • 33-63 = Reserved	Yes
23-20	Error Flags	This field contains error flags that can be assigned based on the packet type.	Yes
19-16	Protocol Specific Flags	This field contains protocol-specific flags / information that can be assigned based on the packet type.	Yes
15	Reserved	Unused	No
14	Return Push Policy	This field indicates how a transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: • 0 = Descriptor must be returned to tail of queue • 1 = Descriptor must be returned to head of queue	No
13-12	Packet Return Queue Mgr #	This field indicates which of the four potential queue managers in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and should be initialized by the host.	No
11-0	Packet Return Queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete.	No

Table 11-2003. Monolithic Extended Packet NULL Word (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Reserved	This field is present only to align the extended packet words to a 128-bit boundary in memory. This word can be used for host software scratchpad because it will not be copied or overwritten by the DMA components.	No

(1) This word is present only if the Extended Packet Info Block present bit is set in word 2.

Table 11-2004. Monolithic Extended Packet Info Word 0 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Timestamp Info	This field contains an application-specific timestamp that can be used for traffic shaping in a QoS-enabled system.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in word 2.

Table 11-2005. Monolithic Extended Packet Info Word 1 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Software Info 0	This field stores software-centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in word 2.

Table 11-2006. Monolithic Extended Packet Info Word 2 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Software Info 1	This field stores software-centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in word 2.

Table 11-2007. Monolithic Extended Packet Info Word 3 (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Software Info 2	This field stores software-centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

(1) This word is present only if the Extended Packet Info Block present bit is set in word 2.

Table 11-2008. Monolithic Packet Descriptor Protocol Specific Word M (Optional) (1)

Bits	Name	Description	RX Overwrite
31-0	Protocol Specific Data N	This field stores information that varies depending on the packet type.	Configurable

(1) These words, if present, immediately follow the software data block information.

Table 11-2009. Monolithic Packet Descriptor Payload Data Words 0-N (1) (2)

Bits	Name	Description	RX Overwrite
31-0	Packet Data N	These words store the packet payload data.	Yes

(1) The payload data follows the protocol-specific words at an offset specified in the data offset field of word 0.
(2) This field is endian-specific. In other words, this is the only field in the descriptor that changes based on the endianess of the system.

11.13.3 Memory Error Detection and Correction

The CPSW_2U error detection and correction logic uses the ECC Aggregator Module (Section 11.14.4.19.1).

The ECC_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in Table 11-2010. The ECC_ENABLE bit in the ECC_CONTROL register is not used (ECC is always enabled). The CPSW_2U FIFO RAMs implement ECC only on packet headers. The packet data is protected by Castignoli (regardless of the input packet CRC type or output CRC type).

Table 11-2010. ECC RAM to EMAC RAM Mapping

ECC RAM Number	EMAC RAM
0	Reserved
1	FIFO RAM

11.13.3.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC_ERROR_CONTROL1 register ECC_ROW is not implemented – ECC_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC_CRC_MODE bit is cleared in the CPSW_CONTROL register. The ECC status registers return the RAM address that was flipped (ECC_ROW) along with the ECC_BIT1 value. Forcing double bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW_2U and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC_CRC_MODE is set to one.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code.

11.13.3.2 Packet Protect CRC

Each packet received without error is passed through the CPSW_2U memories with a generated Castignoli protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT_PEND if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC_CRC_MODE bit in the CPSW_CONTROL register is set, the ECC_BIT1 aggregator bits will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC_CRC_MODE is set.

11.13.3.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in Table 11-2011. The ECC_BIT1[15:0] value returned on error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is, (26×3) + 8).

Table 11-2011. ECC Submodule Header Data Bit to Encoder/Decoder Mapping

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:52	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

11.13.3.4 ECC Wrapper and ECC Aggregator

The ECC wrapper implements SECDED code for single bit error detection and correction and double bit error detection. ECC Aggregator module gathers level pending status from the ECC RAMs into a single interrupt to the host. Software interface is provided for status and control.

There are three types of ECC registers:

1. *Global registers* that are common to all ECC RAMs. This includes the ECC_REVISION, ECC_VECTOR, and ECC_MISC_STATUS registers. Every ECC RAM serviced by the aggregator module is assigned a unique ID by the module. Writing this ID to the ECC_VECTOR register selects the ECC RAM to be controlled or read the ECC status from.
2. *ECC control and status registers.* These are specific to each ECC RAM and selected by the RAM_ID written to the ECC_VECTOR register. The accesses to these registers are done via the serial VBUSP protocol. Note that due to the long latencies on the serial VBUS, the reads to the ECC control and status registers are triggered by a write to the ECC_VECTOR register. This is described in detail in Section 11.14.4.19.1.1.
3. *Interrupt registers.* These include the standard interrupt status, interrupt enable, interrupt clear and EOI registers that are part of a standard interrupt module.

   ECC registers are described in Section 11.13.5.1.6, *NSS_0_CFG_ECC Registers*.

11.13.3.4.1 Reads to ECC Control and Status Registers

Due to the long latencies on the serial VBUS, the reads to the ECC control and status registers for each ECC RAM are triggered by writing a *read* message to the ECC_VECTOR register as described below:

1. Software writes the RAM_ID in ECC_VECTOR[10-0], sets bit [15] TRIGGER_READ, and writes [23-16] READ_ADDRESS. The READ_ADDRESS corresponds to any of the ECC control or status registers (at offset 0x10, that is, ECC_WRAPPER_REVISION through 0x24, that is, ECC_ERROR_STATUS2) which require serial VBUS access to the ECC RAM(s).
2. Software then polls the ECC_VECTOR[24] READ_DONE bit waiting for setting to 1. This indicates that the read operation has completed on the serial VBUS.

3. Software reads the data from the ECC control or status register. Read data is returned on the following clock cycle.

11.13.3.4.2 ECC Interrupts

The ECC aggregator module aggregates all the level pending status from the ECC RAMs to a single EOI-handshake based interrupt to the host. Software is expected to follow the sequence described below:

1. Software enables the interrupts for the ECC RAM(s) by writing to the Interrupt Enable register (ECC_INT_ENABLE_0 to ECC_INT_ENABLE_15).
2. On receiving an interrupt, software checks the Interrupt Status Register (ECC_INT_STATUS_0 to ECC_INT_STATUS_15) to see which ECC RAM(s) caused the error. Note that this status read is not a serial VBUS operation.
3. Software writes the RAM_ID in the ECC_VECTOR register along with the read message that includes setting bit [15] TRIGGER_READ, writing the ECC_ERROR_STATUS1 register's address (that is, 0x20) to bits [23-16] READ_ADDRESS. Software needs to load the read message in the ECC_VECTOR register again if it needs to read also the ECC_ERROR_STATUS2.
4. Software polls the ECC_VECTOR[24] READ_DONE bit. When this is set to 1, it can read the ECC_ERROR_STATUS1 and ECC_ERROR_STATUS2 registers.
5. After the interrupt has been serviced, software must clear the interrupt status by writing to bits 8, 9, or 10 depending on the type of ECC error in the ECC_ERROR_STATUS1 register.
6. Software must poll the ECC_ERROR_STATUS1 register to guarantee that the status bit has been cleared. Otherwise there is no indication that the write has actually completed over the serial VBUS
7. Software must write to the ECC_EOI register to clear the aggregated interrupt output.

11.13.4 Gigabit Ethernet MAC (EMAC) Subsystem

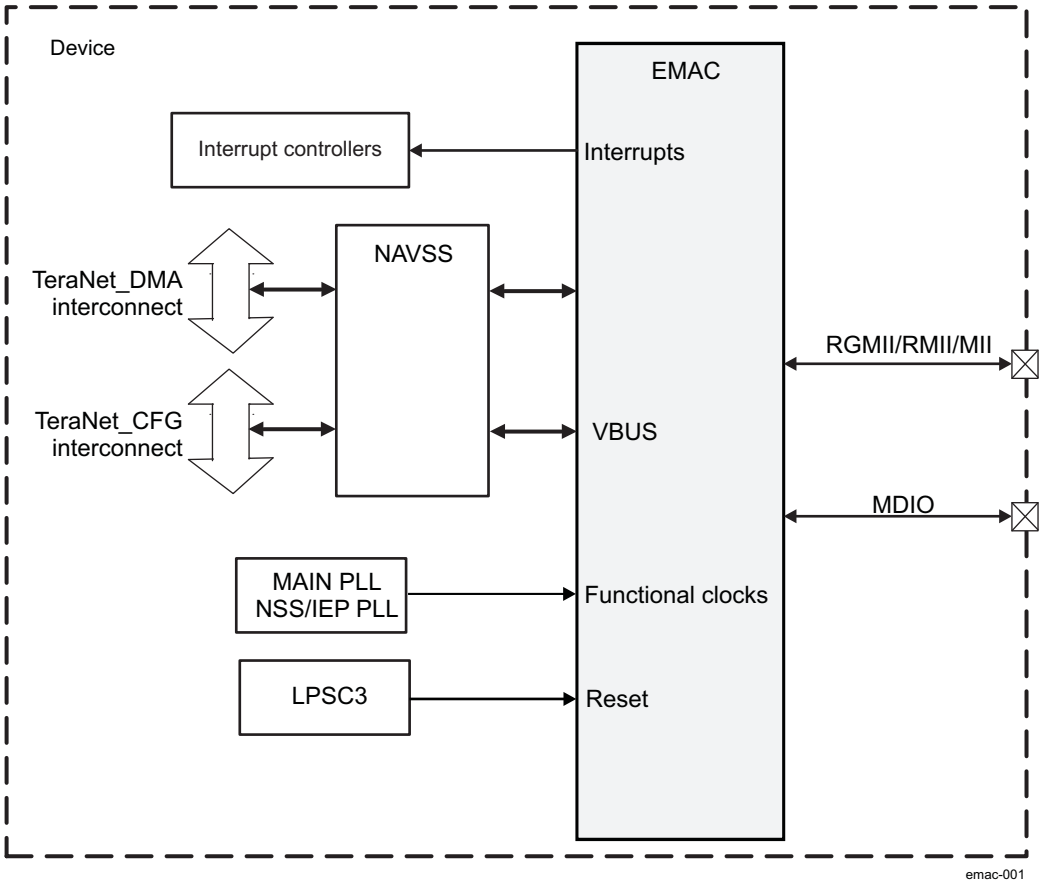
This section describes the gigabit ethernet subsystem in the device.

11.13.4.1 EMAC Overview

The three-port Gigabit Ethernet MAC subsystem (EMAC) provides ethernet packet communication for the device. EMAC features the Gigabit Media Independent Interface (G/MII), Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

Figure 11-909 shows the EMAC subsystem overview.

Figure 11-909. EMAC Overview



11.13.4.1.1 Features

The EMAC subsystem provides the following features:

- One Ethernet port (port 1) with selectable RGMII, RMII, and G/MII interfaces and an internal (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
  - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
  - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events

and generation of compare output pulses

- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
  - 64 total address entries plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging and/or auto-aging
  - Multiple spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- Management Data Input/Output (MDIO) module for PHY Management
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- RAM Error Detection and Correction (SECDED)

Terminology:

AVB— Audio Video Bridging

AVBTP— Audio Video Bridging Trasport Protocol

BMCA— Best Master Clock Algorithm

CFI— Canonical Format Indicator

CPPI— Communications Port Programming Interface

DLR— Device Level Ring

DSCP— Differentiated Services Code Point

EEE— Energy Efficient Ethernet

EMAC— Ethernet Media Access Control

EOP— End of Packet

EOQ— End of Queue

IPG— Inter-Packet Gap

LPI— Low Power Indicator

MDIO— Management Data Input/Output

MOF— Middle of Frame

OUI— Organizationally Unique Identifier

PTP— Precision Time Protocol

RMON— Remote Monitoring

RTCP— RTP Control Protocol

RTP— Real-time Transport Protocol

SCR— Switched Central Resource

SRP— Stream Reservation Protocol

TOS— Type of Service

VLAN— Virtual Local Area Network

11.13.4.2 EMAC Environment

11.13.4.2.1 G/MII Interface

NOTE: G/MII interface in this device functions only in MII mode. In MII Mode (100/10 Mbps) EMAC operates in full-duplex and half-duplex.

The pin connections of the G/MII Interface is shown in Figure 11-910. The detailed description of the signals are listed in the following tables.

Figure 11-910. MII Interface Typical Application

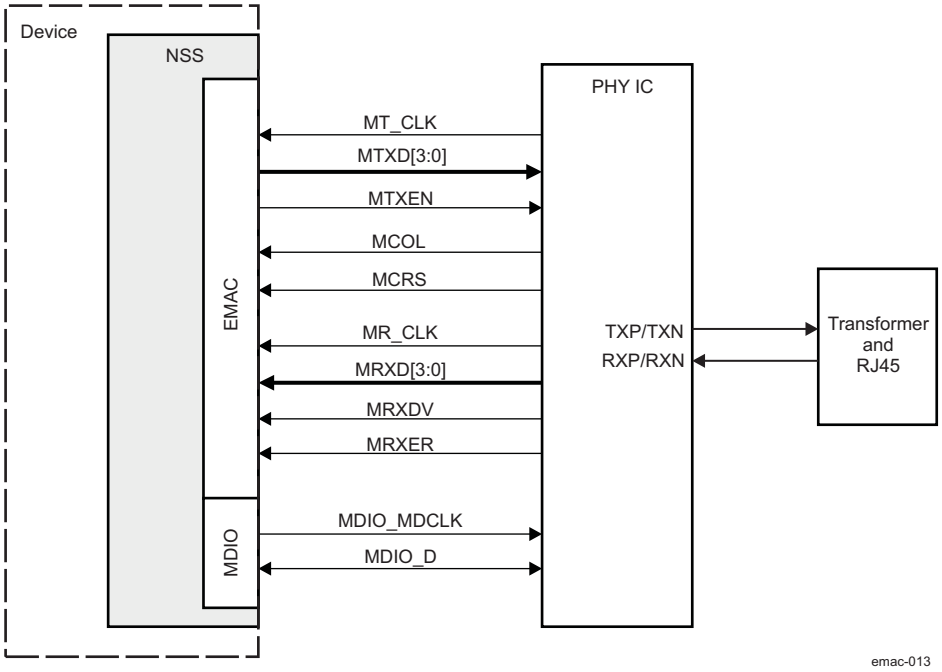


Table 11-2012. G/MII I/O Description in MII Mode

Signal	Device Pin	I/O[1]	Description
MT_CLK	MII_TXCLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD[3:0]	MII_TXD[3:0]	O	The transmit data pins are a collection of 4 data signals MTXD[3:0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MT_CLK and valid only when MTXEN is asserted.
MTXEN	MII_TXEN	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MT_CLK.
MTXER	MII_TXER	O	Transmit data error. Used only for EEE to request PHY for low power transition.
MCOL	MII_COL	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.

(1) I = Input; O = Output

Table 11-2012. G/MII I/O Description in MII Mode (continued)

Signal	Device Pin	I/O[1]	Description
MCRS	MII_CRS	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCRS pin should be held low.
MR_CLK	MII_RXCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD[3:0]	MII_RXD[3:0]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB).The signals are synchronized by MR_CLK and valid only when MRXDV is asserted.
MRXDV	MII_RXDV	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the EMAC. It is driven synchronously to MR_CLK.
MRXER	MII_RXER	I	Receive Data Error input
MDIO_MDCLK	MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

11.13.4.2.2 RMII Interface

Figure 11-911 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 11-2013.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 11-911. RMII Interface Typical Application

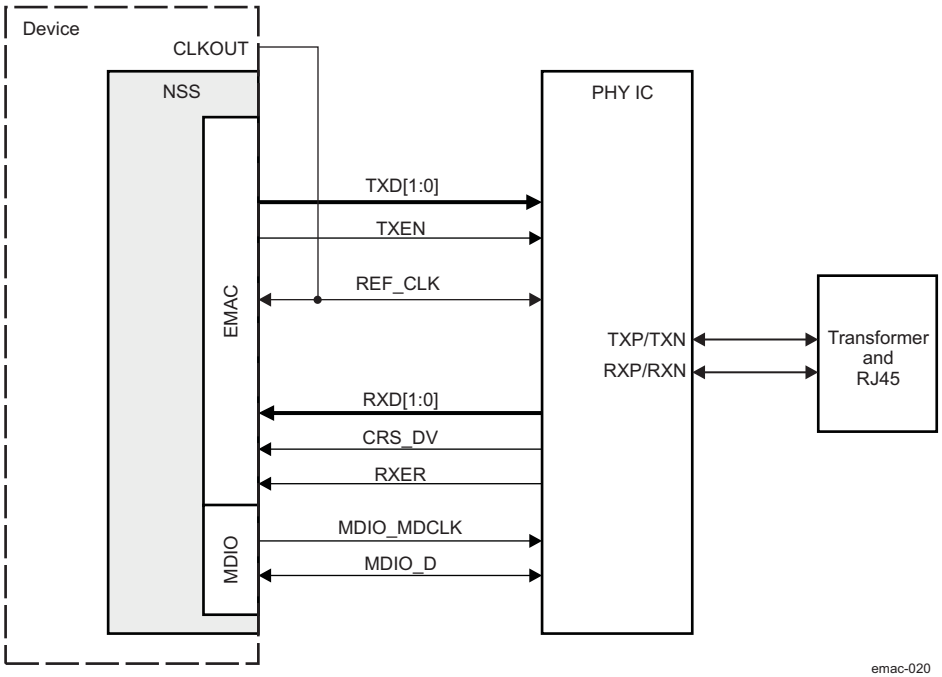

Table 11-2013. RMII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
TXD[1:0]	RMII_TXD[1:0]	O	Transmit data . The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when TXEN is asserted.
TXEN	RMII_TXEN	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK
RMII0_MHZ_50_CLK	RMII_REFCLK	O	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RXD[1:0]	RMII_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when CRS_DV is asserted and RXER is de-asserted.
CRS_DV	RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RXER	RMII_RXER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	MDIO_CLK	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

11.13.4.2.3 RGMII Interface

Figure 11-912 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 11-2014.

Figure 11-912. RGMII Interface Typical Application

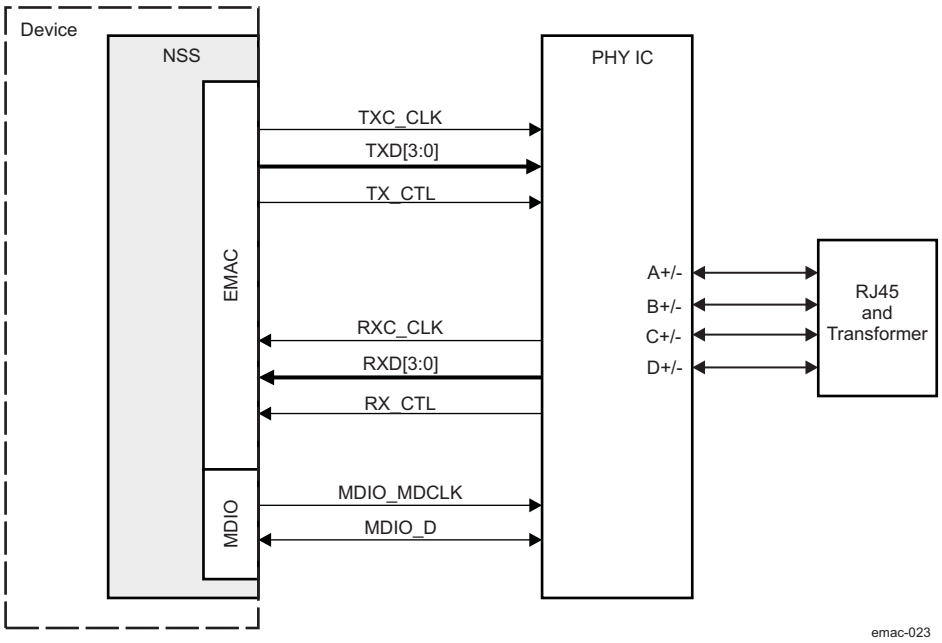

Table 11-2014. RGMII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
TXD[3:0]	RGMII_TXD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.
TX_CTL	RGMII_TXCTL	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	RGMII_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	RGMII_RXD[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted
RX_CTL	RGMII_RXCTL	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the EMAC.
RXC_CLK	RGMII_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	MDIO_CLK	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_D	MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

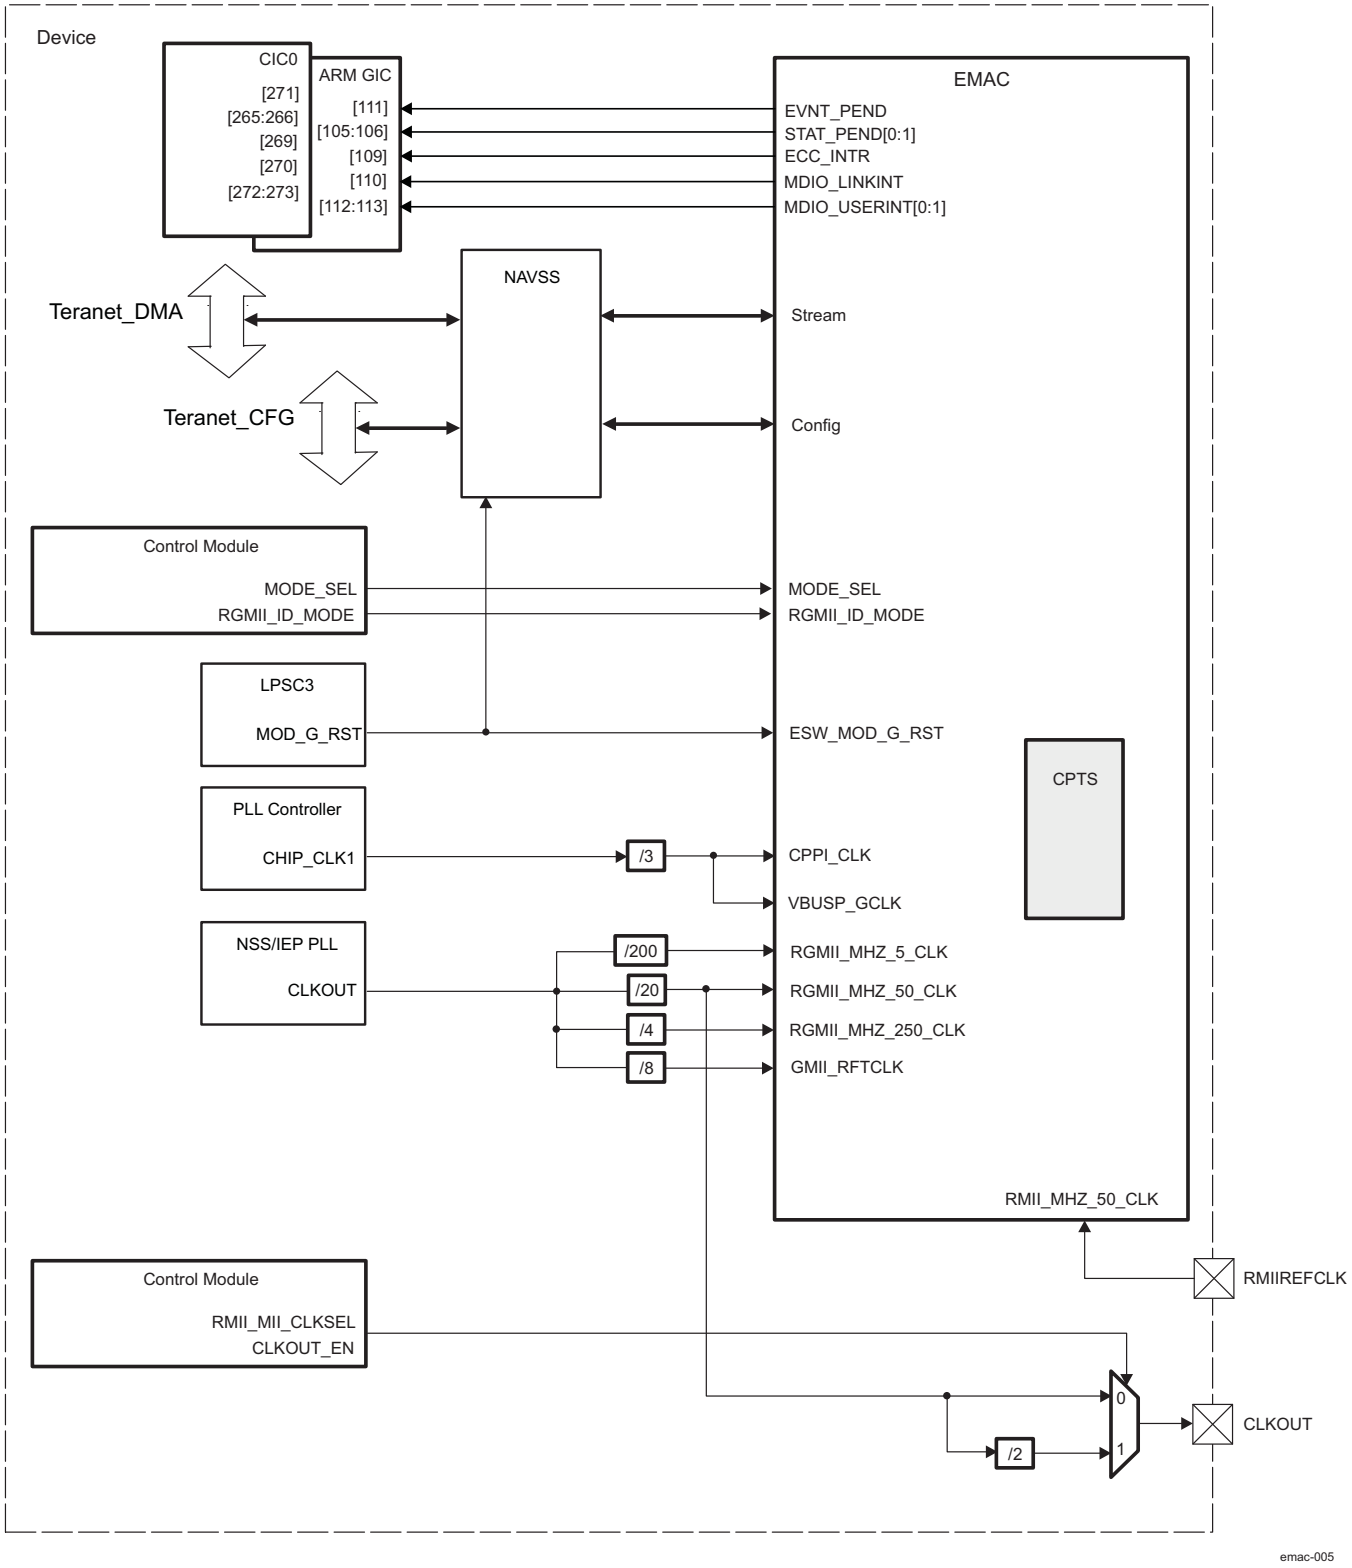
(1) I = Input; O = Output

NOTE: The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 5.1.3.1.1, *Pad Configuration Registers* in *Section 5.1, Control Module (BOOT_CFG)* and Device *Data Manual*.

11.13.4.3 EMAC Integration

Figure 11-913 shows the integration of the EMAC module in the device.

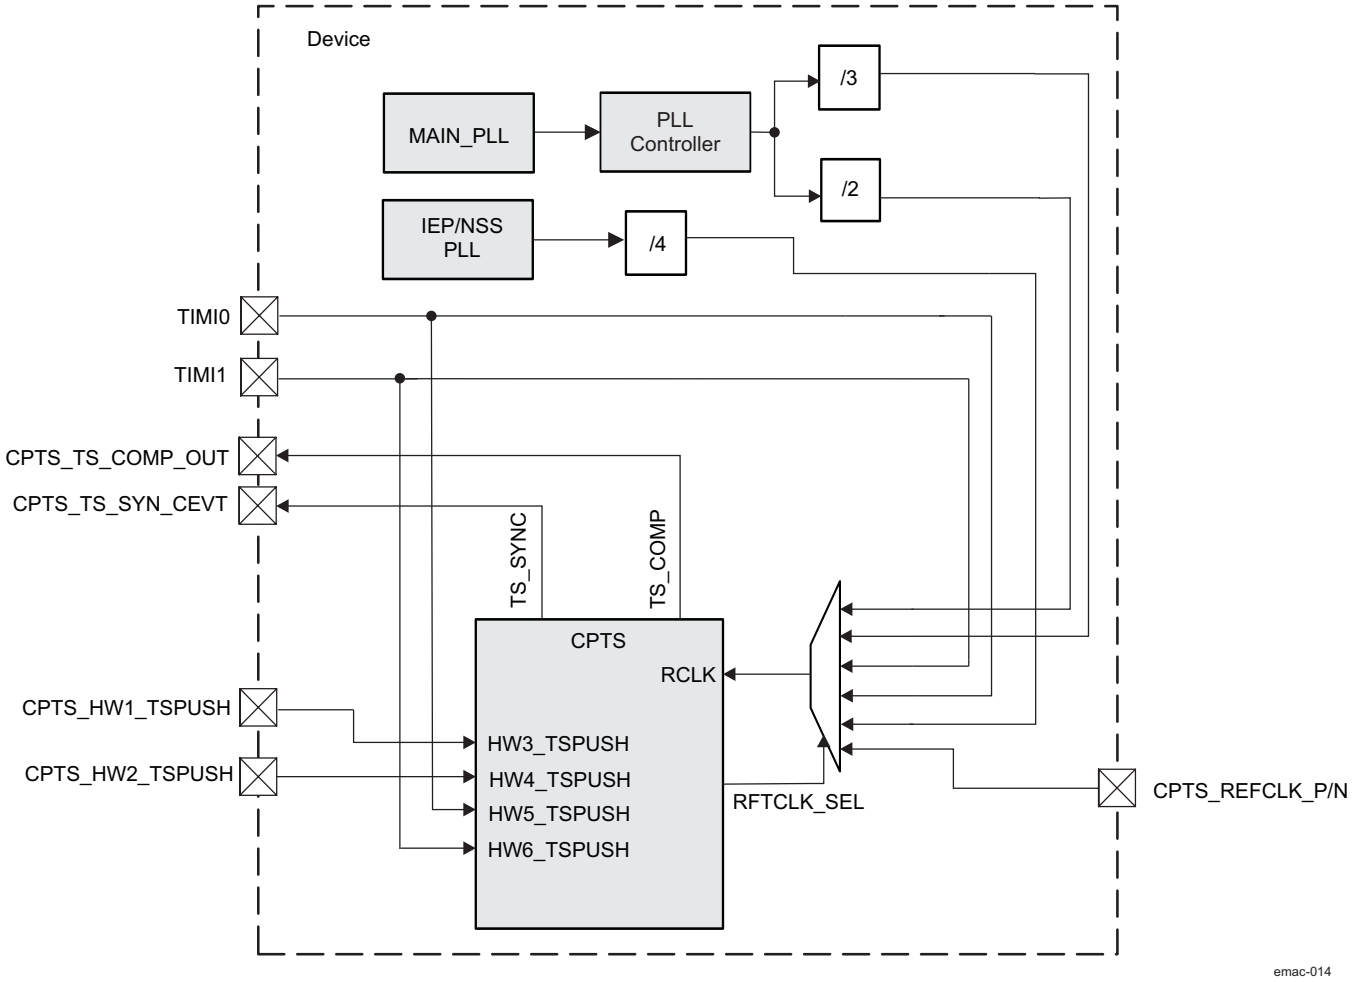
Figure 11-913. EMAC Integration



BOOT_CFG register references: ETHERNET_CFG, ETHERNET_CLKCTL, MACID0, MACID1.

Figure 11-914 shows CPTS integration in the device.

Figure 11-914. CPTS Integration



CPTS IEEE 1588 clock (RCLK) is selected through the CPTS_RFTCLK_SEL register.

NOTE: For CPTS functional description, see Section 11.13.4.4.7, *Common Platform Time Sync (CPTS)*.

Table 11-2015 through Table 11-2017 summarize the integration of the EMAC module in the device.

Table 11-2015. EMAC Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
EMAC	PD2 (NSS)	LPSC3	TeraNet_DMA TeraNet_CFG

Table 11-2016. EMAC Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
EMAC	CPPI_CLK	CHIP_CLK1/3	PLL Controller	CPPI packet streaming interface clock. Main clock for EMAC.
	VBUSP_GCLK	CHIP_CLK1/3	PLL Controller	VBUS interface clock. Min. 125 MHz for Gigabit mode.
	G/MII_RFTCLK	NSS/IEP PLLOUT/8	NSS/IEP PLL	125-MHz G/MII Gigabit mode clock
	RGMII_MHZ_5_CLK	NSS/IEP PLLOUT/200	NSS/IEP PLL	5-MHz RGMII clock
	RGMII_MHZ_50_CLK	NSS/IEP PLLOUT/20	NSS/IEP PLL	50-MHz RGMII clock
	RGMII_MHZ_250_CLK	NSS/IEP PLLOUT/4	NSS/IEP PLL	250-MHz RGMII clock
	RMII_MHZ_50_CLK	RMII_REFCLK	RMII_REFCLK pin	50-MHz RMII clock. Typically sourced from the CLKOUT pin
	CPTS_RFTCLK	CHIP_CLK1/2	PLL Controller	CPTS IEEE 1588 clock. Selected through the CPTS_RFTCLK_SEL register
		CHIP_CLK1/3	PLL Controller	
		TIMI0	TIMI0 pin	
		TIMI1	TIMI1 pin	
		NSS/IEP PLLOUT/4	NSS/IEP PLL	
		CPTS_REFCLK	CPTS_REFCLK_P/N pins	
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
EMAC	ESW_MOD_G_RST	MOD_G_RST	LPSC3	EMAC main reset

Table 11-2017. EMAC Hardware Requests

Interrupt Requests				
Module Instance	**Event Name**	**Mapped To Input Event [Number]**		**Description**
		ARM GIC	**CIC**	
EMAC	EVNT_PEND	[111]	[271]	CPTS Event Pending Interrupt
	STAT_PEND[0:1]	[105:106]	[265:266]	Statistics Pending Interrupts
	ECC_INTR	[109]	[269]	ECC Interrupt
	MDIO_LINKINT	[110]	[270]	MDIO Link Interrupt
	MDIO_USERINT[0:1]	[112:113]	[272:273]	MDIO User Interrupts

NOTE: For more information about the device interrupt controllers, see Chapter 9, *Interrupts*.

NOTE: For the description of the interrupt source, see Section 11.13.4.4.5, *Interrupt Functionality*.

11.13.4.4 EMAC Functional Description

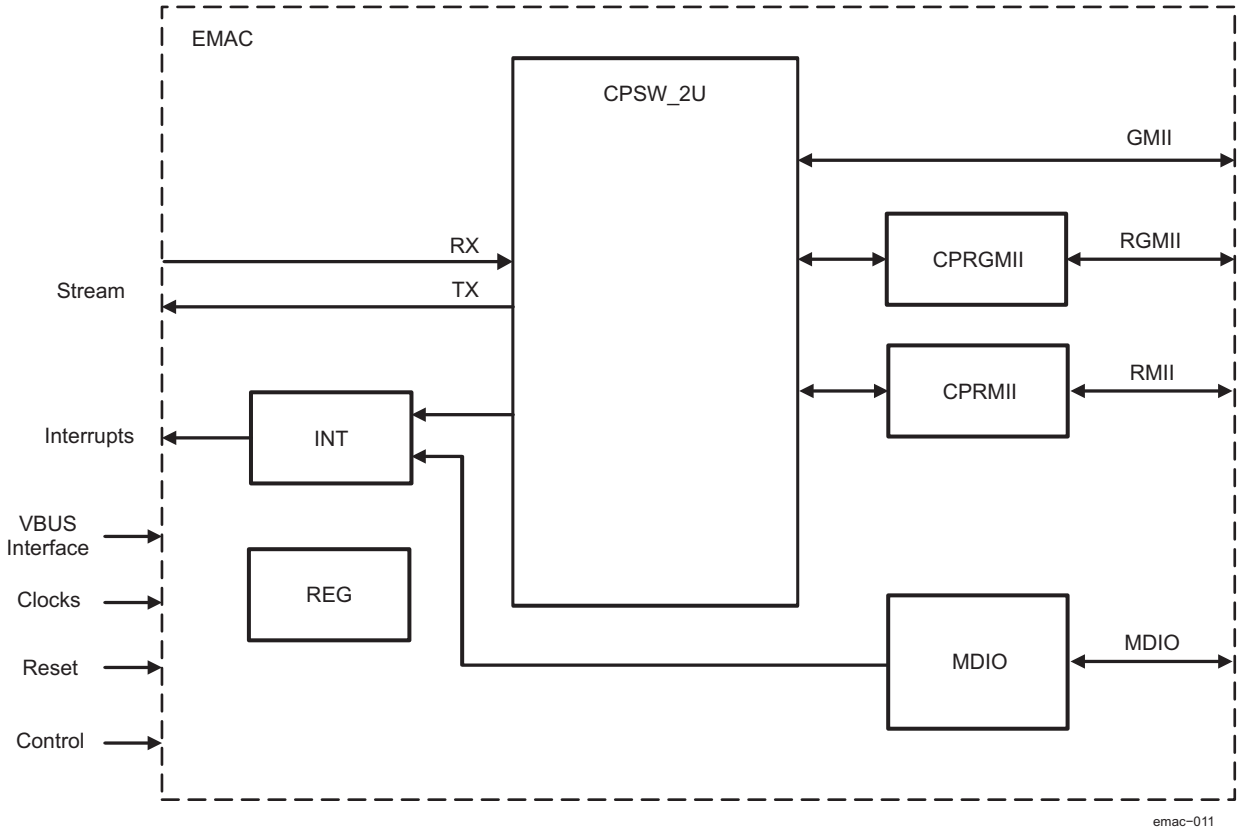
The EMAC subsystem modules are compliant to the IEEE Std 802.3 Specification. EMAC is shown in Figure 11-915.

11.13.4.4.1 Functional Block Diagram

The EMAC subsystem consists of:

- CPSW_2U which features one G/MII interface
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- One MDIO interface module
- One Interrupt Controller module

Figure 11-915. EMAC Top Level Block Diagram



11.13.4.4.2 EMAC Ports

Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this section:

- Port0 is referred to the CPPI Host Port
- Port1 is referred to the interfaces GMII/RGMII/RMII

11.13.4.4.2.1 Interface Mode Selection

The EMAC Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the ethernet interface mode selection bitfield (MODE_SEL) in the ETHERNET_CFG register.

See the device Data Manual for configuring the pin mux mode as per the interface selected.

11.13.4.4.3 Clocking

11.13.4.4.3.1 Subsystem Clocking

EMAC clocking summary is shown in Section 11.13.4.3, *EMAC Integration*.

11.13.4.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

11.13.4.4.3.2.1 G/MII Interface Clocking

GMII1_MR_CLK and GMII1_MT_CLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

NOTE: G/MII interface functions only in MII mode (10/100 Mbps).

11.13.4.4.3.2.2 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

11.13.4.4.3.2.3 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

RMII_MII_CLKOUT_EN and RMII_MII_CLKSEL bits in the ETHERNET_CLKCTL enable the clocking of RMII interface. See Section 5.1, *Control Module (BOOT_CFG).*

11.13.4.4.3.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (VBUSP_GCLK) clock, running at 125 MHz. The application software or driver must control the divide-down value.

See the MDIO_CONTROL register for configuring the Clock Divider (CLKDIV) value.

11.13.4.4.4 Software IDLE

The submodule software idle register bits enable CPSW_2U operation to be completely or partially suspended by software control. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_SOFT_IDLE[0] SOFT_IDLE bit may be set if desired. The CPSW SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch. Idle status is determined by reading or polling the idle bit.

11.13.4.4.5 Interrupt Functionality

EMAC Ethernet Subsystem has four Interrupt outputs:

- CPTS_PEND – CPTS Event Pending Interrupt
- STAT_PEND[0:1] – Statistics Pending Interrupts
- ECC_INTR – ECC Interrupt
- MDIO_LINKINT - MDIO Link Interrupt
- MDIO_USERINT[0:1] – MDIO User Interrupts

11.13.4.4.5.1 EVNT_PEND (CPTS_PEND) Interrupt

See Section 11.13.4.4.7, *Common Platform Time Sync (CPTS)* for more details on this interrupt.

11.13.4.4.5.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the CPTS_INTSTAT_RAW and CPTS_INTSTAT_MASKED registers, respectively.

The Statistics interrupt is enabled by setting to 1 the TS_PEND_EN bit in the CPTS_INT_ENABLE register

11.13.4.4.5.3 MDIO Interrupts

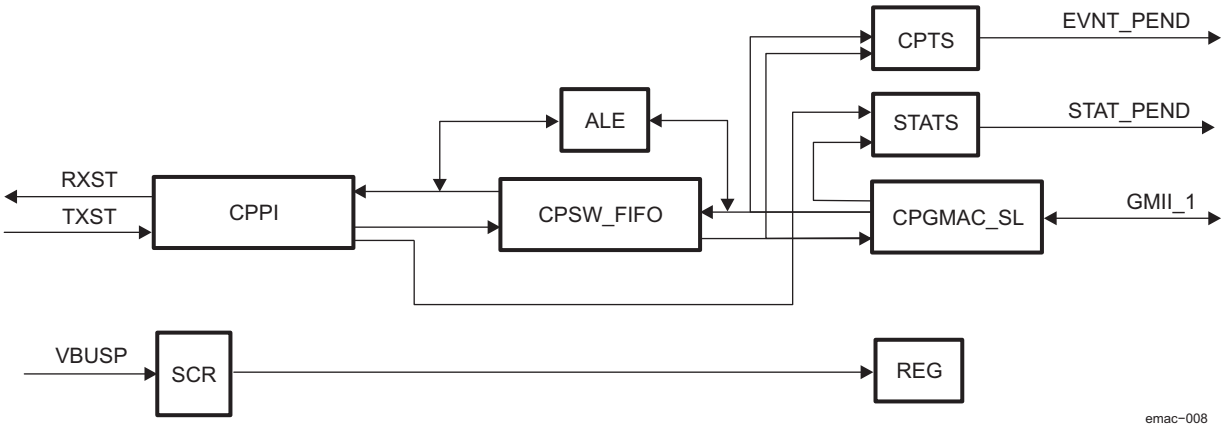
MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the MDIO_USER_PHY_SEL_0 register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO_LINK_INT_MASKED register. When the GO bit in the MDIO_USER_ACCESS_0 register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIO_USER_INT_MASK_SET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the MDIO_USER_INT_MASKED register.

11.13.4.4.6 CPSW_2U

The CPSW_2U G/MII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_2U contains one CPGMAC_SL interface (Ethernet port 1), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_2U is shown in Figure 11-916.

Figure 11-916. CPSW_2U Block Diagram



11.13.4.4.6.1 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPSW_P1_MAC_CONTROL configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no vlan untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

11.13.4.4.6.1.1 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 11-2018. Learned Address Control Bits

Bit(s)	Value
unicast_type	11
block	0
secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40.**

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**

11.13.4.4.6.1.1.1 Free Table Entry

Table 11-2019. Free (Unused) Address Table Entry Bit Values

70:62	61:60	59:0
Reserved	ENTRY_TYPE (00)	Reserved

11.13.4.4.6.1.1.2 Multicast Address Table Entry

Table 11-2020. Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

11.13.4.4.6.1.1.3 VLAN/Multicast Address Table Entry

Table 11-2021. VLAN/Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASk has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

11.13.4.4.6.1.1.4 Unicast Address Table Entry

Table 11-2022. Unicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

11.13.4.4.6.1.1.5 OUI Unicast Address Table Entry

Table 11-2023. OUI Unicast Address Table Entry Bit Values

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

11.13.4.4.6.1.1.6 VLAN/Unicast Address Table Entry

Table 11-2024. Unicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

11.13.4.4.6.1.1.7 VLAN Table Entry

Table 11-2025. VLAN Table Entry

70:68	67	66	65	64:62	61:60	59:48	47:46	45:44
Reserved	NO_LEARN_MASK	Reserved	VLAN_FORCE_INGRESS_CHECK	Reserved (000)	ENTRY_TYPE (10)	VLAN_ID	Reserved	REG_MCAST_FLOOD_INDEX

43:26	25:24	23:22	21:20	19:2	1:0
Reserved	FORCE_UNTAGGED_EGRESS	Reserved	UNREG_MCAST_FLOOD_INDEX	Reserved	VLAN_MEMBER_LIST

No Learn Mask (NO_LEARN_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

VLAN Force Ingress Check (VLAN_FORCE_INGRESS_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the VID_INGRESS_CHECK bit in the ALE_PORT_CONTROL_0 registers except this check is for this VLAN only (not all VLANs).

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Registered Multicast Flood Index (REG_MCAST_FLOOD_INDEX)

Index into ALE_VLAN_MASK_MUX_0 to ALE_VLAN_MASK_MUX_3 register array that is used to create the registered multicast flood mask.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_INDEX)

Index into ALE_VLAN_MASK_MUX_0 to ALE_VLAN_MASK_MUX_3 register array that is used to create the unregistered multicast flood mask.

VLAN Member List (VLAN_MEMBER_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

11.13.4.4.6.1.2 ALE Policing and Classification

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate limiting functions. A policer is a hardware engine that is used for policing. The POLICERS_DIV_8 field in the ALE_STATUS register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - OUI
- Destination Address - DA
- Source Address - SA
- VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking
- IP Destination Address - IPSA with full CIDR masking
- Support Host Thread/Flow ID mapping based on any packet classification above

11.13.4.4.6.1.2.1 ALE Classification

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

11.13.4.4.6.1.2.2 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (ALE_THREAD_DEF, ALE_THREAD_CTL, and ALE_THREAD_VAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The ALE_THREAD_CTL register allows the ALE_THREAD_VAL register contents to be written to the selected classifier. There is a single ALE_THREAD_DEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

11.13.4.4.6.1.3 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW_P0_RX_DSCP_MAP_0 and CPSW_P1_RX_DSCP_MAP_0 registers in the Register Manual section for DSCP mapping.

11.13.4.4.6.1.4 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, *VLAN_Unaware Lookup*, and *Egress.*

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set. Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW_P1_MAC_CONTROL register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

11.13.4.4.6.1.5 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

11.13.4.4.6.1.6 VLAN Aware Mode

The CPSW_2U is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT_TYPE), packet priority (PKT_PRI), and VLAN information.

11.13.4.4.6.1.7 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN_AWARE bit in the CPSW_CONTROL register is cleared to zero. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

11.13.4.4.6.2 Packet Priority Handling

Packets are received on two ports, one CPGMAC_SL Ethernet port and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = 0x8100 then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL or CPSW_P1_CONTROL, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL or

CPSW_P1_CONTROL, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).

4. Else the received packet priority is the source (ingress) port priority.

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

11.13.4.4.6.3 Packet CRC Handling

11.13.4.4.6.3.1 Ethernet Port Ingress Packet CRC

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC_TYPE bit in the CPSW_P1_MAC_CONTROL register.

11.13.4.4.6.3.2 Ethernet Port Egress Packet CRC

Ethernet ports transmit each egress packet with the CRC selected by the CRC_TYPE bit in the CPSW_P1_MAC_CONTROL register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

11.13.4.4.6.3.3 CPPI Port Ingress Packet CRC

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the PASSED_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED_CRC bit is set then the packet is received and forwarded unchanged. The PASSED_CRC bit is set via bit 3 of "Protocol Specific Flags" (ps_flags) in the packet descriptor. The CRC_TYPE is set via bit 2 of "Protocol Specific Flags" (ps_flags) in the packet descriptor and must be Ethernet CRC (CRC_TYPE=0).

11.13.4.4.6.3.4 CPPI Port Egress Packet CRC

The P0_TX_CRC_REMOVE bit in the CPSW_CONTROL register determines if CPPI egress packet have an Ethernet CRC included or not.

11.13.4.4.6.4 Audio Video Bridging

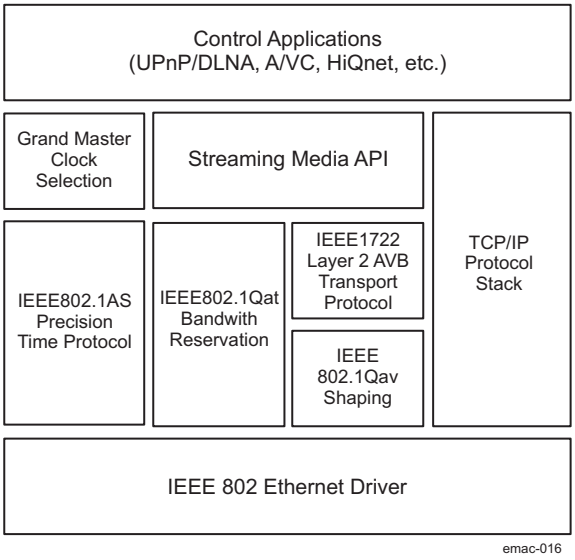
Audio Video Bridging is a project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks.* "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks:* Forwarding and Queuing for Time-Sensitive Streams."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9:* Stream Reservation Protocol (SRP)."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

Figure 11-917. The Network Static with AVB



The following sections describe the media transport protocols that work within the AVB framework.

11.13.4.4.6.4.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

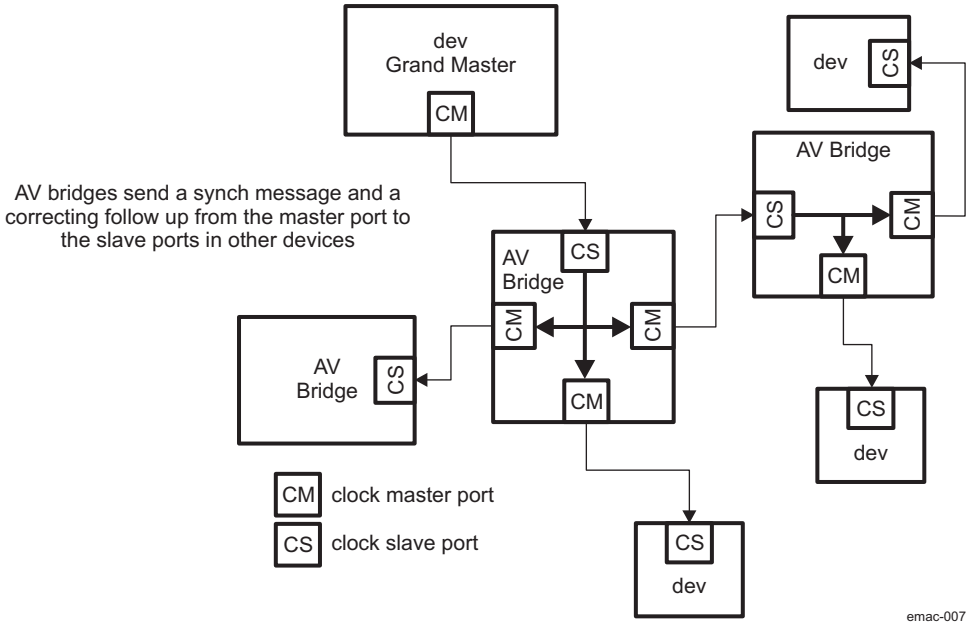
NOTE: The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002,Â PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1-µs accuracy over seven network hops.

Figure 11-918. AVB Network & PTP Clock Entities

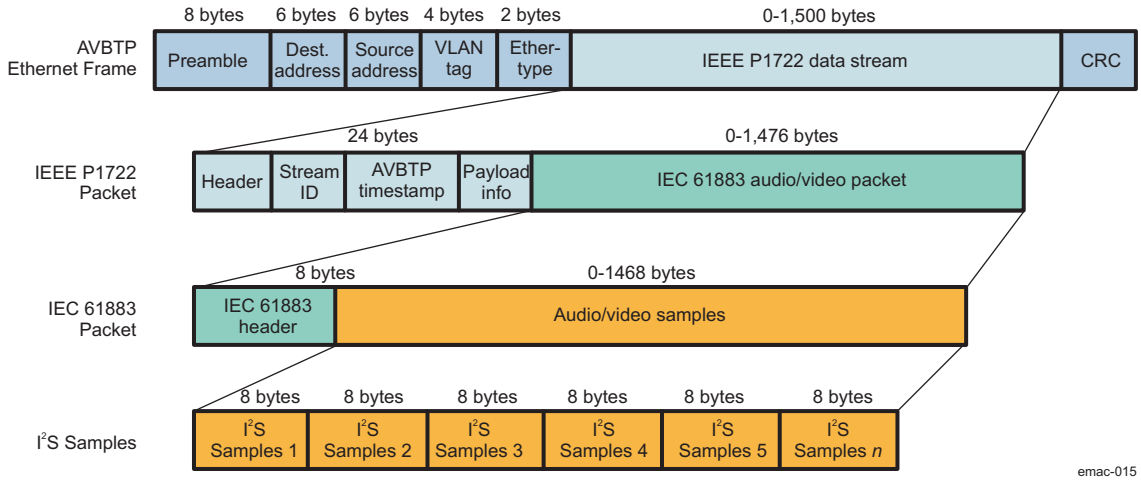


The media transport protocols that work within the AVB framework are:

11.13.4.4.6.4.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 11-919 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

Figure 11-919. IEEE 1722 Packets



1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

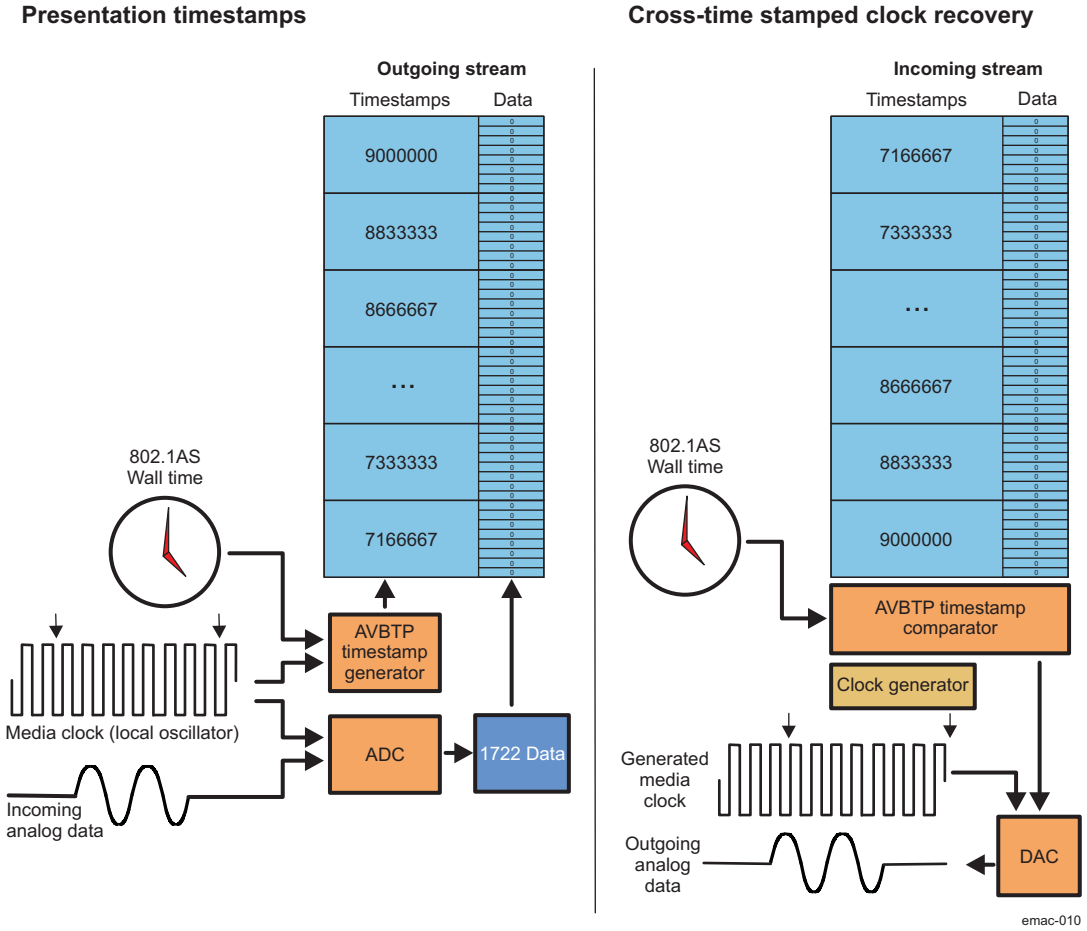
A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 11-920 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

11.13.4.4.6.4.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

Figure 11-920. Cross Time Stamping and Presentation Timestamps



11.13.4.4.6.4.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing and
  - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like Figure 11-921.

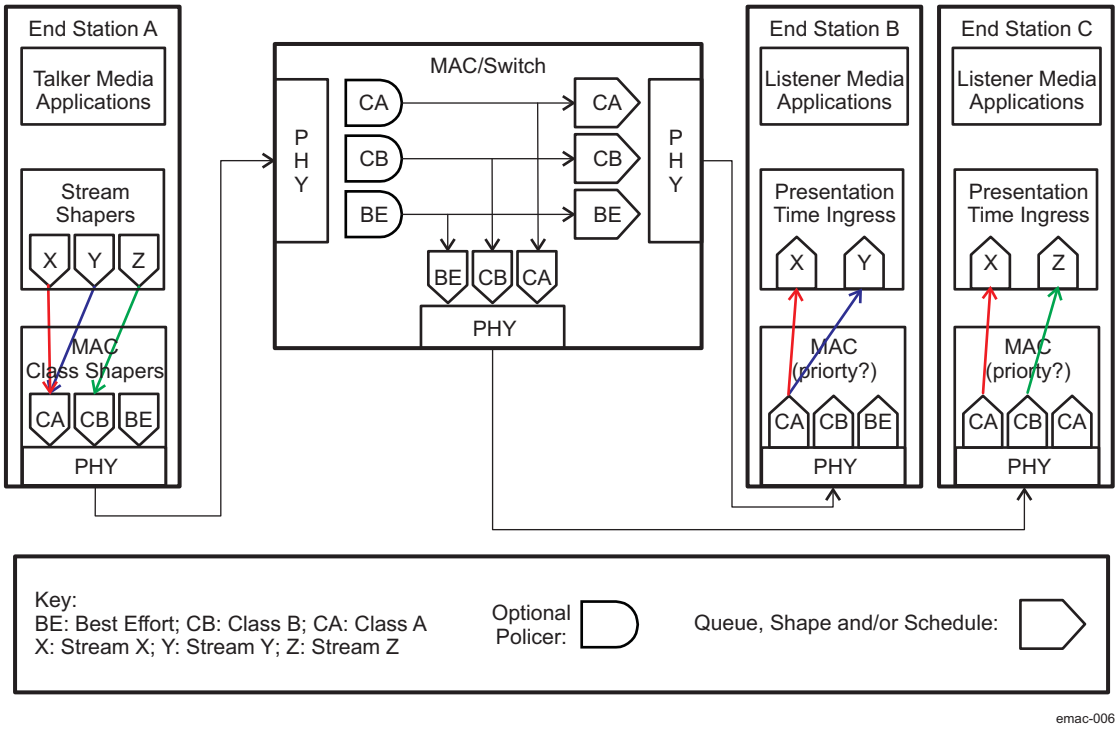
Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

Figure 11-921. AV Stream Queuing/Policing



11.13.4.4.6.4.2.1 Configuring the Device for 802.1Qav Operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_2U that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

Table 11-2026. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 11-2027. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

11.13.4.4.6.5 Ethernet MAC Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

11.13.4.4.6.5.1 G/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

11.13.4.4.6.5.1.1 Data Reception

11.13.4.4.6.5.1.2 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

11.13.4.4.6.5.1.3 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 G/MII clocks (96 bit times) for 10/100 Mbit modes, and 12 G/MII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 G/MII clocks in 10/100 mode and 5 G/MII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

11.13.4.4.6.5.1.4 Data Transmission

The Gigabit Ethernet Mac Sliver (G/MII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

11.13.4.4.6.5.1.5 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

11.13.4.4.6.5.1.6 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

11.13.4.4.6.5.1.7 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

11.13.4.4.6.5.1.8 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the CPSW_P1_MAC_CONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

11.13.4.4.6.5.1.9 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

11.13.4.4.6.5.1.10 Back Off

The Gigabit Ethernet Mac Sliver (G/MII) implements the 802.3 binary exponential back-off algorithm.

11.13.4.4.6.5.1.11 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the CPSW_P1_MAC_TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

11.13.4.4.6.5.1.12 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

11.13.4.4.6.5.2 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

11.13.4.4.6.5.2.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

11.13.4.4.6.5.2.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCRSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCRSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

11.13.4.4.6.5.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the EMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The EMAC does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

11.13.4.4.6.5.3 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

11.13.4.4.6.5.3.1 Features

- Supports 1000/100/10 Mbps speed
- Internal TXC delay on transmit (enabled/disabled in BOOT_CFG)
- MII mode is not supported

11.13.4.4.6.5.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

11.13.4.4.6.5.3.3 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

11.13.4.4.6.5.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW_P0_RX_MAXLEN/CPSW_P1_RX_MAXLEN register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.

- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

11.13.4.4.6.6 Embedded Memories

Table 11-2028. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 512-word × 256-bit RAM	1	(CPPI)

11.13.4.4.6.7 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

11.13.4.4.6.7.1 CPPI Port Flow Control

The CPPI FIFO port has flow control for receive operations (packet ingress). CPPI receive flow control is always enabled and is initiated when triggered. CPPI Receive flow control is accomplished through pushback. The pushback will cause the CPPI port logical receive FIFO to fill up with packet data. Flow control is accomplished with a de-asserted RXST_THREAD_SREADY on the receive packet streaming interface.

11.13.4.4.6.7.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in CPSW_P1_MAC_CONTROL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

11.13.4.4.6.7.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the CPSW_P1_MAC_CONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the CPSW_P1_MAC_CONTROL register.

11.13.4.4.6.7.2.2 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW_P1_MAC_CONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

11.13.4.4.6.7.2.3 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in CPSW_P1_MAC_CONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

11.13.4.4.6.7.2.4 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the CPSW_P1_MAC_CONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the CPSW_P1_MAC_CONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in CPSW_P1_MAC_CONTROL register, and
- the frame's length is 64 to SL_RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in CPSW_P1_MAC_CONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01
  - , or the CPGMAC_SL SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

11.13.4.4.6.8 Latency

When CPSW_2U is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Table 11-2029. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 µs
10	6.5 µs

11.13.4.4.6.9 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_2U operation to be completely or partially suspended. There are two CPSW_2U submodules that contain emulation control registers (CPGMAC_SL and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_2U emulation control. The CPSW_2U module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPSW_P1_MAC_EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CDMA_EMULATION_CONTROL_REG register) allow CDMA operation to be suspended. When the emulation suspend state is entered, the CDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the PDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 11-2030 shows the operations of the emulation control input and register bits.

Table 11-2030. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

11.13.4.4.6.10 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the PSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE register. The pre-

scaler is used to clock all EEE-related counters

2. The port Idle to LPI count values (Px_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px_LPI2WAKE) are written with the desired values
4. The EEE_EN bit is set in the switch CPSW_CONTROL register
5. Set the SS_CONTROL[8] SS_EEE_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PSC) the CPSW_2U to enter a low power state by asserting the EEE_CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE_CLKSTOP_REQ to the CPSW_2U.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW_2U G/MII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time (P0_IDLE2LPI). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

NOTE: The procedure above is described for the G/MII interfaces at the CPSW_2U boundary. External PHY signaling has the following conditions:

- G/MII interface is used only in MII mode. Therefore, only MRXD[3:0] and MTXD[3:0] are pinned out
- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC_CLK edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC_CLK edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE_CLKSTOP_ACK signal is asserted, and the PSC is allowed to stop the module clock. When EEE_CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW_2U memory address space, and then turn off the clock again while EEE_CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE_CLKSTOP_REQ. The host may queue transmit packets at any time including without regard to the CPSW_2U LPI state (the clock must be restarted in order to write the CPSW_2U slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP_WAKEUP signal to be asserted if the CPSW_2U is in the low power state (if CLKSTOP_ACK is asserted).

The external Ethernet PHY's can also wakeup the PSC by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP_ACK asserted and the receive LPI indication is removed, the CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the PSC restarts the clock and de-assert the EEE_CLKSTOP_REQ signal. The CLKSTOP_WAKEUP signal will be synchronously deasserted with CLKSTOP_ACK. Upon the deassertion of CLKSTOP_REQ, the Ethernet ports will count the Px_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP_REQ, the CPDMA transmit will count the P0_LPI2WAKE count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

11.13.4.4.6.11 CPSW_2U Network Statistics

The CPSW_2U has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC_RST. When port enable (P0_STAT_EN or/and P1_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

NOTE: Statistics start at physical address 0423 A000h for CPPI port 0.

Statistics start at physical address 0423 A200h for Ethernet port 1.

Table 11-2031 and Table 11-2032 summarize network statistics.

11.13.4.4.6.11.1 Rx-only Statistics Descriptions

11.13.4.4.6.11.1.1 Good Rx Frames (Offset = 0h)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.2 Broadcast Rx Frames (Offset = 4h)

All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.3 Multicast Rx Frames (Offset = 8h)

All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive

- Had no CRC error, alignment error or code error

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.4 Pause Rx Frames (Offset = Ch)

Ethernet port 1

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX_FLOW_EN = 1).

The port could have been in either half or full-duplex mode.

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.5 Rx CRC Errors (Offset = 10h)

All ports

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

11.13.4.4.6.11.1.6 Rx Align/Code Errors (Offset = 14h)

Ethernet port 1

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

NOTE: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

11.13.4.4.6.11.1.7 Oversize Rx Frames (Offset = 18h)

All ports

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.8 Rx Jabbers (Offset = 1Ch)

All ports

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.9 Undersize (Short) Rx Frames (Offset = 20h)

All ports

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.10 Rx Fragments (Offset = 24h)

Ethernet port 1

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.11 ALE Drop (Offset = 28h)

All ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT_MASK

11.13.4.4.6.11.1.12 ALE Overrun Drop (Offset = 2Ch)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX_CSF_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

11.13.4.4.6.11.1.13 Rx Octets (Offset = 30h)

All ports

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the Section 11.13.4.4.6.11.1.6, *Rx Align/Code Errors* and Section 11.13.4.4.6.11.1.5, *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

11.13.4.4.6.11.1.14 Rx Bottom of FIFO Drop (Offset = 84h)

Ethernet port 1

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

NOTE: This statistic should be zero if proper flow control is being followed.

Host port 0

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 63 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 64 bytes.

11.13.4.4.6.11.1.15 Portmask Drop (Offset = 88h)

All ports

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT_MASK=0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

NOTE: This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT_MASK.

11.13.4.4.6.11.1.16 Rx Top of FIFO Drop (Offset = 8Ch)

All ports

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

11.13.4.4.6.11.1.17 ALE Rate Limit Drop (Offset = 90h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any

destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

11.13.4.4.6.11.1.18 ALE VLAN Ingress Check Drop (Offset = 94h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

11.13.4.4.6.11.1.19 ALE DA=SA Drop (Offset = 98h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

11.13.4.4.6.11.1.20 ALE Unknown Unicast (Offset = A8h)

All ports

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

11.13.4.4.6.11.1.21 ALE Unknown Unicast Bytecount (Offset = ACh)

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

11.13.4.4.6.11.1.22 ALE Unknown Multicast (Offset = B0h)

The total number of frames received on a port that had a multicast destination address with an unknown source address.

11.13.4.4.6.11.1.23 ALE Unknown Multicast Bytecount(Offset = B4h)

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

11.13.4.4.6.11.1.24 ALE Unknown Broadast (Offset = B8h)

The total number of frames received on a port that had a broadcast destination address with an unknown source address.

11.13.4.4.6.11.1.25 ALE Unknown Broadast Bytecount(Offset = BCh)

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

11.13.4.4.6.11.1.26 ALE Policer/Classifier Match (Offset = C0h)

All ports

The total number of frames received on a port that had a matched a policer.

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

11.13.4.4.6.11.2 Tx-only Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

11.13.4.4.6.11.2.1 Good Tx Frames (Offset = 34h)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

11.13.4.4.6.11.2.2 Broadcast Tx Frames (Offset = 38h)

All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

11.13.4.4.6.11.2.3 Multicast Tx Frames (Offset = 3Ch)

All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

11.13.4.4.6.11.2.4 Pause Tx Frames (Offset = 40h)

Ethernet port 1

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

11.13.4.4.6.11.2.5 Deferred Tx Frames (Offset = 44h)

Ethernet port 1

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.6 Collisions (Offset = 48h)

Ethernet port 1

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
   - Was destined for any unicast, broadcast or multicast address
   - Was any size
   - Had no carrier loss and no underrun
   - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

     CRC errors have no effect upon this statistic.
2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

11.13.4.4.6.11.2.7 Single Collision Tx Frames (Offset = 4Ch)

Ethernet port 1

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.8 Multiple Collision Tx Frames (Offset = 50h)

Ethernet port 1

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size

- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.9 Excessive Collisions (Offset = 54h)

Ethernet port 1

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.10 Late Collisions (Offset = 58h)

Ethernet port 1

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple- , and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.11 Carrier Sense Errors (Offset = 60h)

Ethernet port 1

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don’t care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

11.13.4.4.6.11.2.12 Tx Octets (Offset = 64h)

All ports

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

11.13.4.4.6.11.2.13 Tx Memory Protect Errors (Offset = 17Ch)

All ports

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

NOTE:

1. Frames to the host with memory protect errors are dropped via TXST_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
2. This statistic is 8-bits wide only and will not rollover but will saturate at 0xFF.
3. A non-zero value in this statistic will issue a STAT_PEND interrupt for the associated port.

11.13.4.4.6.11.3 Rx- and Tx-Shared Statistics Descriptions

11.13.4.4.6.11.3.1 Rx + Tx 64 Octet Frames (Offset = 68h)

All ports

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.2 Rx + Tx 65–127 Octet Frames (Offset = 6Ch)

All ports

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.3 Rx + Tx 128–255 Octet Frames (Offset = 70h)

All ports

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.4 Rx + Tx 256–511 Octet Frames (Offset = 74h)

All ports

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.5 Rx + Tx 512–1023 Octet Frames (Offset = 78h)

All ports

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.6 Rx + Tx 1024_Up Octet Frames (Offset = 7Ch)

All ports

The total number of frames of size 1024 to RX_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

11.13.4.4.6.11.3.7 Net Octets (Offset = 80h)

All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of ethernet utilization.

Table 11-2031. Rx Statistics Summary

Rx Statistic	Frame /Oct	Rx/Rx +Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data[1]															
			Pause frame	Non-pause [3]	Multi cast	Broad cast	Uni cast	<64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	>rx_maxlen	Flow Coll.[2]	CRC Error	Align/ Code	Overrun	Addr. Disc.
Good Rx Frames	F	R	(y|[4]	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-[5]	n	n	-	n
Broadcast Rx Frames	F	R	(%|[6]	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	R	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	R	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	R	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	R	n	n	(y|	y|	y)	y^[7]	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns[8]	F	R	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	R+T[9]	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

(1) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).

(2) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.

(3) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.

(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.

(5) "-" indicates conditions which are ignored in the formations of the statistic.

(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

(7) "y^" Frame fragments are not counted if less than 8 bytes.

(8) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

(9) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

Table 11-2032. Tx Statistics Summary

Tx Statistic[1]	Frame/Oct	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event										
			MAC control[2]		Data											Collision Type									
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast	64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Flow[3]	1	2-15	16	Late	No Carrier	Queued	Deferred	Underrun
Good Tx Frames	F	T	(y|[4]	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-[5]	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	T	n	(%|[6]	n	y)	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	T	(y|	%|	y)	n	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	T	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-	-
Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	(+[7]	+	+	+	+)	n	-	-	-
Single Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	T	n	(y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	R+T[8]	(y|	y|	y|	y|	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-

(1) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.
(2) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
(3) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See Table 11-2031.)
(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
(5) "-" indicates conditions which are ignored in the formations of the statistic.
(6) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
(7) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
(8) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

Table 11-2032. Tx Statistics Summary (continued)

Tx Statistic[1]	Frame/Oct	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event										
			MAC control[2]		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Collision Type					No Carrier	Queued	Deferred	Underrun
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast									Flow[3]	1	2-15	16	Late				
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	$[9]	$	$	$	$	-	-	-

[9] "$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.

11.13.4.4.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

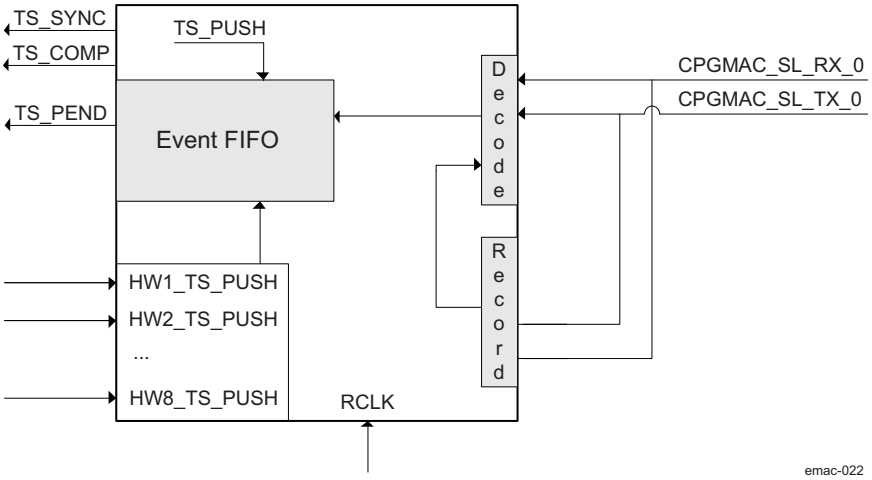
- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports up to 8 hardware timestamp push inputs
- Supports timestamp counter compare output (TS_COMP)
- Supports timestamp counter bit output (TS_SYNC)
- 32-bit and 64-bit timestamp modes

11.13.4.4.7.1 CPTS Architecture

Figure 11-922 shows the architecture of the CPTS module inside the EMAC Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the EMAC are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO. The reference clock used for the time stamp (CPTS_RFTCLK) can be derived from several sources.

Figure 11-922. CPTS Block Diagram



NOTE: See Figure 11-914, *CPTS Integration* for CPTS integration in the device.

11.13.4.4.7.2 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the RFTCLK_SEL value in the CPTS_RFTCLK_SEL register with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

11.13.4.4.7.3 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFTCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_LOW_VAL and CPTS_TS_LOAD_EN registers).

11.13.4.4.7.4 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS_RFTCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

64-bit mode is selected via CPTS_CONTROL[5] MODE_64BIT bit set to 1.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_LOW_VAL, CPTS_TS_LOAD_HIGH_VAL, and CPTS_TS_LOAD_EN registers).

11.13.4.4.7.5 Event FIFO

All time sync events are push onto the Event FIFO. There are 10 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

11.13.4.4.7.6 Timestamp Compare Output

CPTS features one Time Stamp Compare (TS_COMP) output.

11.13.4.4.7.6.1 Non-Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN[23-0] RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_LOW_VAL[31-0] and the length value is non-zero. The TS_COMP rising edge occurs three RCLK periods after the values compare. A timestamp compare event is pushed into the event FIFO when TS_COMP is asserted. The polarity of the TS_COMP output is determined by the CPTS_CONTROL[2] TS_POLARITY bit. The output is asserted low when the polarity bit is 0.

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME_STAMP[63-0] are used instead of only the lower 32-bits.

11.13.4.4.7.6.2 Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_LOW_VAL[31-0] and the length value is non-zero. The TS_COMP toggles thereafter on CPTS_TS_COMP_LEN[23-0] RCLK periods. The length high or low can be adjusted by writing the CPTS_TS_COMP_NUDGE[7-0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK from the CPTS_TS_COMP_LEN value. A value of 0x01 will add one RCLK to the CPTS_TS_COMP_LEN value. Only a single high or low time is adjusted (nudged) and the CPTS_TS_COMP_NUDGE value is cleared to zero when the nudge has occurred. The TS_COMP output is asserted low when the CPTS_CONTROL[2] TS_COMP_POLARITY bit is 0.

No compare events and no CPTS_EVNT interrupts are generated in toggle mode.

The CPTS_CONTROL[6] TS_COMP_TOG bit must be set for toggle mode, and must be set before writing a non-zero value to TS_COMP_LEN[23-0].

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIMESTAMP[63-0] are used instead of only the lower 32-bits.

11.13.4.4.7.7 Timestamp Sync Output

The TS_SYNC output is a selected bit of the TIME_STAMP counter value. One of bits 17-31 can be selected in CPTS_CONTROL[31-28] TS_SYNC_SEL. The TS_SYNC output is disabled when CPTS_CONTROL[31-28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the TS_SYNC output. A rising edge will occur on the TS_SYNC output upon the next transition-to-1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the TS_SYNC operation. The TS_SYNC output is two RCLK periods after the actual count value.

11.13.4.4.7.8 Time Sync Events

Time Sync events are 96-bit or 128-bit (for 32-bit and 64-bit time stamp respectively) values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPTS_EVENT_0 throught CPTS_EVENT_3 hold the data of a time sync event. There are eight types of sync events:

- Time stamp push event
- Time stamp counter rollover event (32-bit mode only)
- Time stamp counter half-rollover event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet receive event
- Ethernet transmit event
- Time Stamp Compare Event
- Host Event

11.13.4.4.7.8.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code.

11.13.4.4.7.8.2 Time Stamp Counter Rollover Event (32-bit mode only)

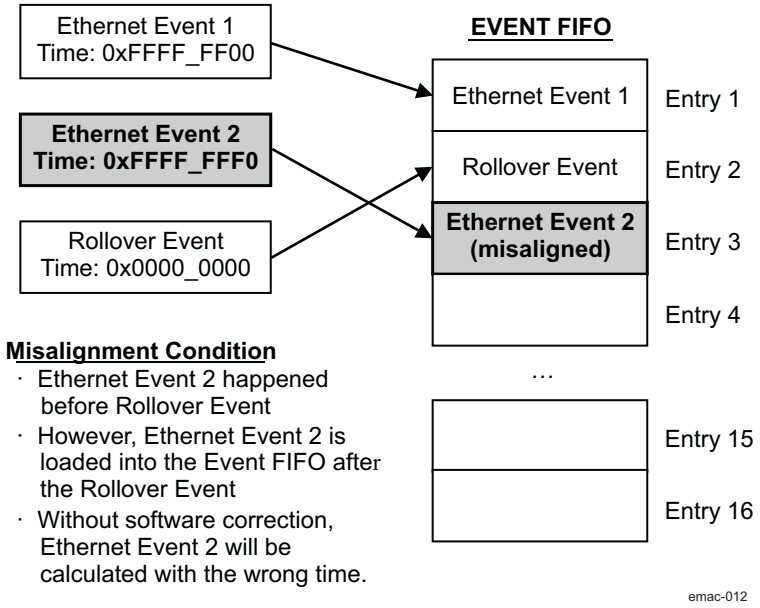
The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented.

11.13.4.4.7.8.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 11-923 shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

Figure 11-923. Event FIFO Misalignment Condition



11.13.4.4.7.8.4 Hardware Time Stamp Push Event

There are eight hardware time stamp inputs (HW1/8_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in Figure 11-914.

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_1 register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

11.13.4.4.7.8.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

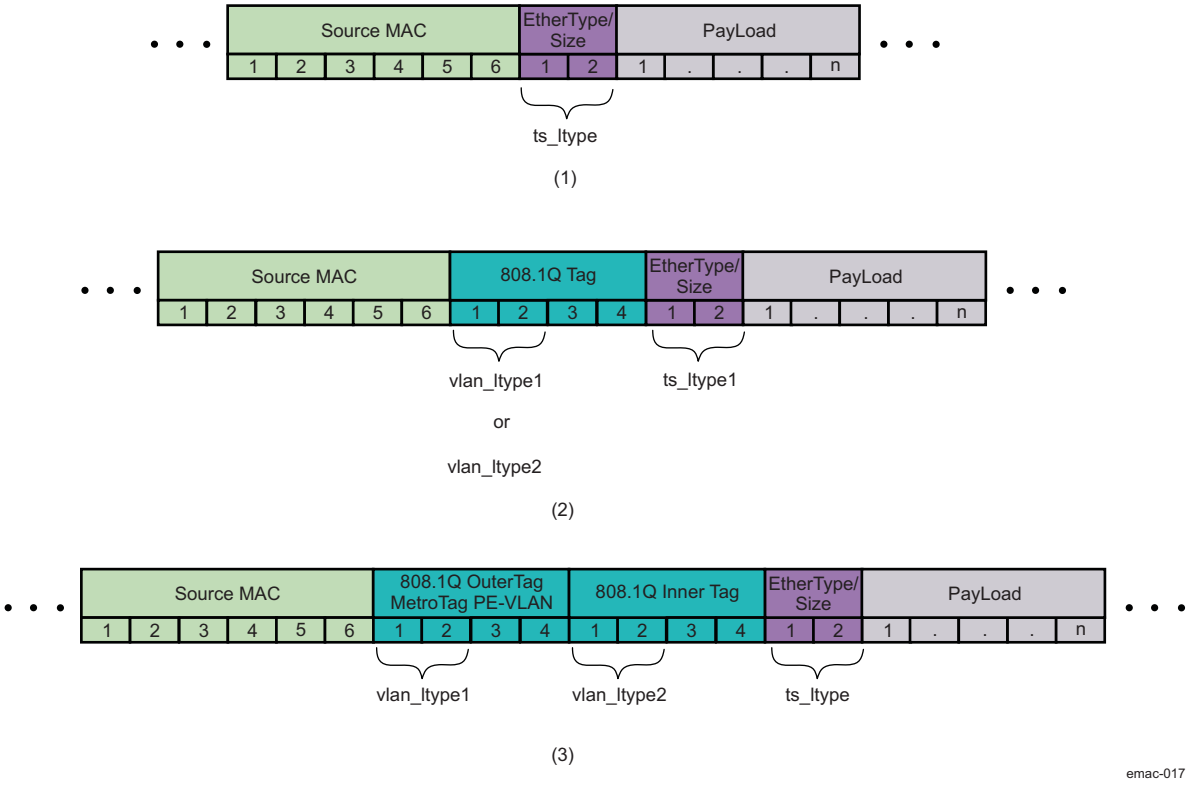
According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 11-924. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field or the TS_LTYPE2 field (depending on which enable bit was set) in CPSW_P1_TS_SEQ_LTYPE or CPSW_P1_TS_CTL_LTYPE2 register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 11-924. To indicate to the CPTS hardware that a virtual LAN is in use, the VLAN_LTYPE1_EN (or VLAN_LTYPE2_EN) enable bit must be set in the CPSW_P1_TS_CTL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN_LTYPE1 (or VLAN_LTYPE2 depending on which enable bit was set) field in the

CPSW_P1_TS_VLAN_LTYPE register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 11-924. In this case, both VLAN_LTYPE1 and VLAN_LTYPE2 must be enabled. The outer tag must match the value of the VLAN_LTYPE1 field, and the inner tag must match the value of the VLAN_LTYPE2 field.

Figure 11-924. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)



11.13.4.4.7.8.5.1 Ethernet Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RCLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (Ethernet Receive)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_P1_TS_CTL register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x0800
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x0800

c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x0800

d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches 0x0800

3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

NOTE: The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x00 if the TS_TTL_NONZERO_EN bit in the switch CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 -OR- byte 22 contains any value if TS_TTL_NONZERO_EN is set to 1. Byte 22 is the time to live field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 and Bytes 30 through 33 contain:
   a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set

   -OR-

   The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   a. Decimal 0x01 and 0x3f respectively and the TS_319 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set -OR-
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (Ethernet Receive)

1. Receive annex E time sync is enabled (RX_ANNEXE_EN bit is set in the switch CPSW_P1_TS_CTL register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE

matches 0x86dd

3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1).
6. The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 and Bytes 38 through 53 contain:
   a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set

   NOTE: All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_P1_TS_CTL2 register.

   -OR-

   The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is set to 1 and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   a. Decimal 0x01 and 0x3f respectively and the TS_319 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
10. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex F (Ethernet Receive)

1. Receive Annex F time sync is enabled (TS_RX_ANNEX_F_EN is set in the switch CPSW_P1_TS_CTL register).
2. One of the sequences below is true:
   a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
   b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register.
   f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and

TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register.

h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register

3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

11.13.4.4.7.8.5.2 Ethernet Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use to the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (Ethernet Transmit)

1. Transmit annex D time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_P1_TS_CTL register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x0800
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x0800
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x0800
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

NOTE: The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x00 if the TS_TTL_NONZERO_EN bit in the switch CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 -OR- byte 22 contains any value if TS_TTL_NONZERO_EN is set to 1. Byte 22 is the time to live field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 and Bytes 30 through 33 contain:

a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
f. The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is set and Bytes 30 through 33 contain any values.

8. Bytes 36 and 37 contain:
   a. Decimal 0x01 and 0x3f respectively and the TS_319 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set -OR-
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
11. The packet was sent by host port 0.

Annex E (Ethernet Transmit)

1. Transmit annex E time sync is enabled (TS_TX_ANNEX_E_EN bit is set in the switch CPSW_P1_TS_CTL register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN register and RX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1).
6. The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is cleared to 0 and Bytes 38 through 53 contain:
   a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or
   e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set

   NOTE: All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_P1_TS_CTL2 register.

   -OR-

   The TS_UNI_EN bit in the CPSW_P1_TS_CTL_LTYPE2 register is set to 1 and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):

a. Decimal 0x01 and 0x3f respectively and the TS_319 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set, or

b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_P1_TS_CTL_LTYPE2 register is set.

8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
10. The packet was sent by host port 0.

Annex F (Ethernet Transmit)

1. Transmit Annex F time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_P1_TS_CTL register).
2. One of the sequences below is true:
   a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
   b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and RX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register.
   f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register.
   g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN register and TX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_P1_TS_SEQ_LTYPE register.
   h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_P1_TS_VLAN register and TX_VLAN_LTYPE1_EN is set in the CPSW_P1_TS_CTL register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_P1_TS_VLAN_LTYPE register and TX_VLAN_LTYPE2_EN is set in the CPSW_P1_TS_CTL register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_P1_TS_CTL_LTYPE2 register and LTYPE2_EN is set in the CPSW_P1_TS_CTL register
3. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_P1_TS_CTL register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RCLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

Table 11-2033. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1

Table 11-2033. Values of Message Type Field (continued)

Message Type	Value (hex)
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPTS_EVENT_1 register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_0 (and CPTS_EVENT_3) register contains the time stamp value when the packet arrived at the corresponding port.

11.13.4.4.7.9 Timestamp Compare Event

NOTE: Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode. The TS_COMP output is also asserted when the event is generated. The event is generated when the TIME_STAMP value compares with the CPTS_TS_COMP_LOW_VAL/CPTS_TS_COMP_HIGH_VAL register and the CPTS_TS_COMP_LEN value is non-zero. The CPTS_TS_COMP_LEN value should be written by software after the CPTS_TS_COMP_LOW_VAL/CPTS_TS_COMP_HIGH_VAL register(s) is written and should be zero when the comparison value is written.

11.13.4.4.7.10 Host Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TIMESTAMP_EN bit and sends the DOMAIN, MSG_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW_2U (see *Receive Streaming Packet Interface (Host Port 0 Switch Ingress)*). An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

11.13.4.4.7.11 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_0 through CPTS_EVENT_3 registers values.
3. Set the CPTS_EVENT_POP[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_0 through CPTS_EVENT_3 registers values.

3. Set the CPTS_EVENT_POP[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS_RFTCLK periods plus four VBUSP_GCLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, proceed to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

11.13.4.4.8 CPPI Packet Streaming Interface

The receive streaming interface on port 0 of the CPSW_2U is responsible for receiving packets from the packet streaming switch in the NAVSS. The CPSW_2U has one receive streaming packet interface for port 0. The CPPI receive port is equivalent to a MAC port with the difference being that the data is provided to the CPSW_2U in the 128-bit streaming interface data format instead of 8-bit GMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW_2U.

The tables below show the information that may be passed along with which descriptor information word to put it in. See Section 11.13.2, *Navigator Subsystem* as well as the descriptor structure definitions in the CPPI LLD (Low Level Driver) for more information on these bits.

11.13.4.4.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW_2U Egress)

The CPSW_2U makes use of CPPI descriptor fields to communicate additional information about the packet being transmitted by the switch (and being received by the DMA). Table 11-2034 details the CPSW_2U information field, and corresponding CPPI descriptor field, and the information conveyed.

Table 11-2034. Port 0 CPPI Transmit Packet Streaming Interface

CPPI Descriptor Field	Contents	Description
PS Flags Bit 3	PASSED_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW_CONTROL register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.
PS Flags Bit 2	CRC_TYPE	CRC Type – The packet CRC type. The type of CRC passed is determined by the P0_TX_CRC_TYPE bit in the CPSW_CONTROL register (not by the type of CRC the packet had on Ethernet port ingress). 0 – Ethernet CRC 1 – Castagnoli CRC
Configurable	SRC_ID	The packet SRC_ID value comes from the PN_SRC_ID field in the CPSW_P0_SRC_ID_A register. This field can be optionally written to the packet descriptor in the source or destination tag, based on DMA channel configuration.
Configurable	FLOW_ID	The default flow ID is the remapped received packet priority plus the FLOW_ID_OFFSET. The default flow ID can be overridden by ALE classification match. This is also called “flow index” by the DMA. This field can be optionally written to the packet descriptor in the source or destination tag, based on DMA channel configuration.
Timestamp Info	TIMESTAMP[31:0]	64-bit Timestamp Low
Software Info 0	TIMESTAMP[63:32]	64-bit Timestamp High

11.13.4.4.8.2 CPPI Receive Packet Streaming Interface (CPSW_2U Ingress)

The CPSW_2U makes use of CPPI descriptor fields to communicate additional information about the packet being sent by the DMA (and being received by the CPSW_2U). Table 11-2035 details the CPSW_2U information field, and corresponding CPPI descriptor field, and the information conveyed.

Table 11-2035. Port 0 CPPI Transmit Packet Streaming Interface

CPPI Descriptor Field	Contents	Description
PS Flags Bit 3	PASSED_CRC	The PASSED_CRC bit indicates that the CRC is passed with the packet data. 0 - CRC is not passed with packet (CRC_TYPE is don't care) 1 - CRC of type CRC_TYPE is passed with the packet.
PS Flags Bit 2	CRC_TYPE	Must be set to zero when PASSED_CRC is set.
Dest_Tag[4:0]	TO_PORT	Port number to send the directed packet to. This field is set by the host. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode. 0 - Not directed 1 - Send the packet to port 1 2 - Send the packet to port 2
Software Info 0 [31]	TIMESTAMP_EN	Software Info 0 [31] TIMESTAMP_EN When set, this bit indicates that the packet will generate a timesync event on Ethernet egress (if the CPTS is configured properly) with the associated DOMAIN, MSG_TYPE, and SEQUENCE_ID.
Software Info 0 [27:20]	DOMAIN	Timesync domain
Software Info 0 [19:16]	MSG_TYPE	Timesync message type
Software Info 0 [15:0]	SEQUENCE_ID	Timesync sequence ID

11.13.4.4.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

11.13.4.4.9.1 MDIO Frame Formats

Table 11-2036 shows the read format and Table 11-2037 shows the write format of the 32-bit MII Management interface frames.

Table 11-2036. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 11-2037. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

11.13.4.4.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the MDIO_CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO_LINK register. The LINKSEL bit in the MDIO_USER_PHY_SEL_0 register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO_LINK_INT_RAW register and the MDIO_LINK_INT_MASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO_USER_PHY_SEL_0 register.

The MDIO_ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO_ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO_USER_ACCESS_0 register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO_USER_INT_RAW register corresponding to the MDIO_USER_ACCESS_0 register being used. The corresponding bit in the MDIO_USER_INT_MASKED register may also be set depending on the mask setting in the MDIO_USER_INT_MASK_SET and MDIO_USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO_USER_ACCESS_0 registers. The host should check the status of the GO bit in the MDIO_USER_ACCESS_0 register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO_USER_ACCESS_0 register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW_P1_MAC_CONTROL register in the corresponding MAC.

11.13.4.5 EMAC Programming Guide

11.13.4.5.1 Initialization and Configuration of EMAC Subsystem

To configure the EMAC Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (G/MII, RGMII, or RMII) Mode. See the ETHERNET_CFG register.
2. Configure pads (pin muxing), as per the interface selected. Refer to Section 5.1.3.1.1, *Pad Configuration Registers* and the device data manual.
3. Lock the NSS PLL if in bypass. Enable the EMAC Ethernet Subsystem clocks. Refer to Section 5.4, *Clock Management* and Section 5.2, *Power Management*
4. Apply Soft Reset to CPGMAC_SL. See CPSW_P1_MAC_SOFT_RESET register.
5. Ensure that at least 2000 VBUSP_CLK periods are run after reset is de-asserted.
6. Configure the CPSW_CONTROL register
7. Configure the Ethernet Port Source Address registers (CPSW_P1_SA_L and CPSW_P1_SA_H)
8. Configure the CPSW_STAT_PORT_EN register
9. Configure the ALE (Section 11.13.4.4.6.1, *Address Lookup Engine*)
10. Configure the MDIO (Section 11.13.4.5.3.1, *Initializing the MDIO Module*)
11. Configure Navigator Subsystem
12. Configure CPGMAC_SL, as per the desired mode of operations

11.13.4.5.2 Ethernet MAC Reset

To reset the CPMAC_SL, the host must perform the following:

1. Set CMD_IDLE in the Ethernet port CPSW_P1_MAC_CONTROL register
2. Wait for Idle to be indicated in the Ethernet port CPSW_P1_MAC_STATUS register
3. Set SOFT_RESET in the Ethernet port CPSW_P1_MAC_SOFT_RESET register
4. Wait for SOFT_RESET in the CPSW_P1_MAC_SOFT_RESET to be cleared to confirm reset completion
5. Configure the Ethernet ports.

11.13.4.5.3 MDIO Software Interface

11.13.4.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (MDIO_CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in MDIO_CONTROL.
3. The MDIO PHY alive status register (MDIO_ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO_LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIO_USER_PHY_SEL_0/1), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO_USER_INT_MASK_SET) to use the MDIO user access register (MDIO_USER_ACCESS_0/1). Since only one PHY is used in this device, the application software can use one MDIO_USER_ACCESS_0/1 to trigger a completion interrupt; the other MDIO_USER_ACCESS_0/1 is not setup.

11.13.4.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO_USER_ACCESS_0/1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USER_ACCESS_0/1) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO_USER_ACCESS_0/1 corresponding to the PHY and PHY register software wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO_USER_ACCESS_0/1 for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USER_INT_RAW) corresponding to MDIO_USER_ACCESS_0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USER_INT_MASK_SET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USER_INT_MASKED) and an interrupt is triggered on the host processor.

11.13.4.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO_USER_ACCESS_0/1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USER_ACCESS_0*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIO_USER_ACCESS_0/1 corresponding to the PHY and PHY register software wants to read.
3. The read data value is available in the DATA bits in MDIO_USER_ACCESS_0/1 after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIO_USER_ACCESS_0/1. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USER_INT_RAW) corresponding to MDIO_USER_ACCESS_0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USER_INT_MASK_SET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USER_INT_MASKED) and an interrupt is triggered on the host processor.

11.13.5 NSS Registers

For NSS top level memory map, please refer to Section 11.13.1.3, *NSS Memory Map*.

11.13.5.1 EMAC Registers

11.13.5.1.1 NSS_0_CFG_EMAC Registers

Table 11-2039 lists the memory-mapped registers for the NSS_0_CFG_EMAC. All register offset addresses not listed in Table 11-2039 should be considered as reserved locations and the register contents should not be modified.

Table 11-2038. NSS_0_CFG_EMAC Instances

Instance	Base Address
NSS_0_CFG_EMAC	0420 0000h

Table 11-2039. NSS_0_CFG_EMAC Registers

Offset	Acronym	Register Name	NSS_0_CFG_EMAC Physical Address	Section

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Read as zero.
23-0	LPI2WAKE	R/W	0h	EEE LPI to wake counter load value – When the port is in the transmit LPI state and the EEE_CLKSTOP_REQ signal is deasserted, this value is loaded into the LPI to wake counter. Transmit packet operations may begin (resume) when the LPI to wake count decrements to zero (on the pre-scale count). This is the time waited before Ethernet transmit operations resume after wakeup.

Table 11-2178. CPSW_P1_MAC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reads return 0 and writes have no effect.
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable – Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of RX_CMF_EN. Frames transferred to memory due toRX_CMF_EN will have the control bit set in their EOP buffer descriptor. • 0 – MAC control frames are filtered (but acted upon if enabled). • 1 – MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to rx_csf_en will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. • 0 –Short frames are filtered • 1 –Short frames are transferred to memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable – Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when rx_cef _en is not set. • 0 – Frames containing errors are filtered. • 1 – Frames containing errors are transferred to memory.
21	RESERVED	R	0h	Reserved
20	EXT_TX_FLOW_EN	R/W	0h	External Transmit Flow Control Enable Enables the tx_flow_en to be selected from the EXT_TX_FLOW_EN input signal and not from the TX_FLOW_EN bit in this register.

Table 11-2178. CPSW_P1_MAC_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	EXT_RX_FLOW_EN	R/W	0h	External Receive Flow Control Enable – Enables the rx_flow_en to be selected from the EXT_RX_FLOW_EN input signal and not from the RX_FLOW_EN bit in this register.
18	CTL_EN	R/W	0h	Control Enable – Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the fullduplex and gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected.
17	GIG_FORCE	R/W	0h	Gigabit Mode Force – This bit is used to force the Enet Mac into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	IFCTL_B	R/W	0h	Interface Control B
15	IFCTL_A	R/W	0h	Interface Control A.Determines the RMII speed • 0 – 10 Mbps • 1 – 100 Mbps
14-13	RESERVED	R	0h	Reserved
12	CRC_TYPE	R/W	0h	Port CRC Type • 0 –Ethernet CRC • 1 – Castagnoli CRC
11	CMD_IDLE	R/W	0h	Command Idle • 0 – Idle not commanded • 1 – Idle Commanded (read idle in Enet_Pn_Mac_Status)
10-8	RESERVED	R	0h	Reserved
7	GIG	R/W	0h	Gigabit Mode • 0 – 10/100 mode • 1 – Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.
6	TX_PACE	R/W	0h	Transmit Pacing Enable • 0 – Transmit Pacing Disabled • 1 – Transmit Pacing Enabled
5	GMII_EN	R/W	0h	GMII Enable • 0 – GMII RX and TX held in reset • 1 – GMII RX and TX released from reset.
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable – Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. • 0 – Transmit Flow Control Disabled. Full-duplex mode – Incoming pause frames are not acted upon. • 1 – Transmit Flow Control Enabled . Full-duplex mode – Incoming pause frames are acted upon.
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable • 0 – Receive Flow Control Disabled Half-duplex mode – No flow control generated collisions are sent. Full-duplex mode – No outgoing pause frames are sent. • 1 – Receive Flow Control Enabled Half-duplex mode – Collisions are initiated when receive flow control is triggered. Full-duplex mode – Outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	R/W	0h	Manufacturing Test Mode – This bit must be set to allow writes to the BACKOFF_TEST and PAUSETIMER registers.

Table 11-2178. CPSW_P1_MAC_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	LOOPBACK	R/W	0h	Loop Back Mode – Loopback mode forces internal fullduplex mode regardless of whether the fullduplex bit is set or not. The loopback bit should be changed only when GMII_EN is de-asserted. • 0 – Not looped back • 1 – Loop Back Mode enabled
0	FULLDUPLEX	R/W	0h	Full Duplex mode – Gigabit mode forces fullduplex mode regardless of whether the fullduplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit • 0 – half duplex mode • 1 – full duplex mode

Table 11-2179. Register Call Summary for CPSW_P1_MAC_CONTROL

Table 11-2181. CPSW_P1_MAC_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	0h	Enet IDLE – The Ethernet port is in the idle state (valid after an idle command) • 0 – The port is not in the idle state. • 1 - The port is in the idle state.
30-7	RESERVED	R	0h	Reserved
6	EXT_RX_FLOW_EN	R	-	External Receive Flow Control Enable – This is the value of the EXT_RX_FLOW_EN input bit.
5	EXT_TX_FLOW_EN	R	-	External Receive Flow Control Enable – This is the value of the EXT_TX_FLOW_EN input bit.
4	EXT_GIG	R	-	External GIG mode – This is the value of the EXT_GIG input bit.
3	EXT_FULLDUPLEX	R	-	External Fullduplex – This is the value of the EXT_FULLDUPLEX input bit.
2	RESERVED	R	0h	Reserved
1	RX_FLOW_ACT	R	0h	Receive Flow Control Active – When asserted, indicates that receive flow control is enabled and triggered.
0	TX_FLOW_ACT	R	0h	Transmit Flow Control Active When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-2187. CPSW_P1_MAC_BOFFTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30-26	PACEVAL	R/W	0h	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes paceval to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause paceval to be decremented down to zero. When paceval is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce “capture” effects improving overall network bandwidth.
25-16	RNDNUM	R/W	0h	Backoff Random Number Generator – This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator’s current value. The value is reset to zero and begins counting on the clock after the de-assertion of reset
15-12	COLL_COUNT	R	0h	Collision Count – The number of collisions the current frame has experienced.
11-10	RESERVED	R	0h	Reserved
9-0	TX_BACKOFF	R	0h	Backoff Count – This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

Table 11-2190. CPSW_P1_MAC_RX_PAUSETIMER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	RX_PAUSETIMER	R/W	0h	RX Pause Timer Value – This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with 0xFF00 when the Enet port sends an outgoing pause frame (with pause time of 0xFFFF). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated. This register is for 802.3 Based flow control and is not used for 802.1qbb Priority Based Flow Control (PFC).

Table 11-2210. ALE_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	Enable ALE • 0 – Drop all packets • 1 – Enable ALE packet processing
30	CLEAR_TABLE	R/W	0h	Clear ALE address table – Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W	0h	Age Out Address Table Now – Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.
28-24	RESERVED	R	0h	Reserved

Table 11-2210. ALE_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-21	UPD_BW_CTL	R/W	0h	The upd_bw_ctrl field allows for up to 8 times the rate in which adds, updates, touches, writes, and aging updates can occur • 0 - 350Mhz, 5M • 1 - 359Mhz, 11M • 2 - 367Mhz, 16M • 3 - 375Mhz, 22M • 4 - 384Mhz, 28M • 5 - 392Mhz, 34M • 6 - 400Mhz, 39M • 7 - 409Mhz, 45M
20-14	RESERVED	R	0h	Reserved
13	UVLAN_NO_LEARN	R/W	0h	Unknown VLAN No Learn – when set this will prevent source addresses of unknown VLANIDs from being automatically added into the look up table if learning is enabled.
12-10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Read as zero
8	UNI_FLOOD_TO_HOST	R/W	0h	Enable Port 0 Unicast Flood • 0 – unknown unicast packets are dropped to the host • 1 – unknown unicast packets flood to host also.
7	LEARN_NO_VID	R/W	0h	Learn No VID • 0 – VID is learned with the source address • 1 – VID is not learned with the source address (source address is not tied to VID). Determines the entry type.
6	EN_VID0_MODE	R/W	0h	Enable VLAN ID = 0 Mode • 0 – Process the priority tagged packet with VID = PORT_VLAN[11:0]. • 1 – Process the priority tagged packet with VID = 0.
5	ENABLE_OUI_DENY	R/W	0h	Enable OUI Deny Mode
4	BYPASS	R/W	0h	ALE Bypass • 0 – no bypass • 1 – bypass the ALE
3	RATE_LIMIT_TX	R/W	0h	Rate Limit Transmit Mode • 0 – Broadcast and multicast rate limit counters are received port based • 1 – Broadcast and multicast rate limit counters are transmit port based.
2	VLAN_AWARE	R/W	0h	ALE VLAN Aware • 0 – Simple switch rules. • 1 – VLAN aware rules. Packets forwarded based on VLAN membership.
1	ENABLE_AUTH_MODE	R/W	0h	Enable MAC Authorization Mode – Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found and the destination address is not an address with the super table entry bit set. • 0 – The ALE is not in MAC authorization mode • 1 – The ALE is in MAC authorization mode
0	ENABLE_RATE_LIMIT	R/W	0h	Enable Broadcast and Multicast Rate Limit • 0 – Broadcast/Multicast rates not limited • 1 – Broadcast/Multicast packet reception limited to the port control register rate limit fields.

Table 11-2216. ALE_AGING_TIMER Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PRESCALE_1_DISABLE	R/W	0h	ALE Prescaler 1 Disable: When set, removes 1,000 from the auto aging multiplier.
30	PRESCALE_2_DISABLE	R/W	0h	ALE Prescaler 2 Disable: When set, removes 1,000 from the auto aging multiplier.
29-24	RESERVED	R	0h	Reserved
23-0	AGING_TIMER	R/W	0h	ALE Aging Timer: When non-zero, auto-aging is enabled. The ale_aging_timer value (minus 1) times 1,000,000 is the number of clock cycles after which auto-aging will automatically be initiated. If either prescale_1_disable or prescale_2_disable is set then the multiplier is 1,000 instead of 1,000,000. If both prescale_1_disable and prescale_2_disable are set then the multiplier is 1 instead of 1,000,000. Auto aging is initiated each time the count reaches zero. When the ale_aging_timer is zero, auto-aging is disabled (but software can still initiate aging by setting age_out_now). There is no auto-aging if ale_enable is zero or if clear_table is set or if age_out_now is set (while the events are occurring).

Table 11-2231. ALE_PORT_CONTROL_0 to ALE_PORT_CONTROL_7 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W	0h	Broadcast Packet Rate Limit Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field.
23-16	MCAST_LIMIT	R/W	0h	Multicast Packet Rate Limit Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
15-13	RESERVED	R	0h	Reserved
12	DISABLE_AUTH_MODE	R/W	0h	Disable MAC Authorization Mode When set, this bit disables MAC authorization mode for this port (when enable_auth_mode in ALE_Control is set).
11-6	RESERVED	R	0h	Reads return 0.
5	NO_SA_UPDATE	R/W	0h	No Source Address Update When set an ingress packet on this port will not cause a matching source address entry port number to be changed (to this port). When cleared, an ingress packet on this port will cause a matching source address entry port number to be changed to this port number (if it was previously a different port).

Table 11-2231. ALE_PORT_CONTROL_0 to ALE_PORT_CONTROL_7 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	NO_LEARN	R/W	0h	No Learn Mode When set the port is disabled from learning source addresses.
3	VID_INGRESS_CHECK	R/W	0h	VLAN ID Ingress Check If VLAN found and the receive port is not a VLAN member then drop the packet.
2	DROP_UNTAGGED	R/W	0h	Drop Untagged Packets - Drop non-VLAN tagged ingress packets
1-0	PORT_STATE	R/W	0h	Port State • 0 – Disabled • 1 – Blocked • 2 – Learn • 3 – Forward

Table 11-2287. CPTS_TS_PUSH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Read as zero.
0	TS_PUSH	W	0h	Time stamp event push – When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

Table 11-2288. Register Call Summary for CPTS_TS_PUSH

Gigabit Ethernet MAC (EMAC) Subsystem • Time Sync Events: [0]
EMAC Registers • NSS_0_CFG_CPTS Registers: [0]

11.13.5.1.4.5 CPTS_TS_LOAD_LOW_VAL Register (Offset = 10h) [reset = 0h]

CPTS_TS_LOAD_LOW_VAL is shown in Figure 11-1006 and described in Table 11-2290.

TS_LOAD_VAL																															
RW-0h																															

LEGEND: RW = Read/Write; *-n* = value after reset

Table 11-2329. CPTS_TS_LOAD_HIGH_VAL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TS_LOAD_VAL	RW	0h	Time Stamp Load high Value – Writing the ts_load_en bit causes the value contained in this register (and the CPTS_TS_LOAD_VAL[63:0]) to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register. This value is unused in 32-bit mode

Table 11-2330. Register Call Summary for CPTS_TS_LOAD_HIGH_VAL

Gigabit Ethernet MAC (EMAC) Subsystem • 64-bit Time Stamp Value: [0]
EMAC Registers • CPTS_TS_LOAD_HIGH_VAL Register (Offset = 44h) [reset = 0h]: [0] • NSS_0_CFG_CPTS Registers: [0]

11.13.5.1.4.19 CPTS_TS_COMP_HIGH_VAL Register (Offset = 48h) [reset = 0h]

CPTS_TS_COMP_HIGH_VAL is shown in Figure 11-1017 and described in Table 11-2323.

Table 11-2340. MDIO_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine idle indicator. 0: State machine is running. 1: State machine is in idle state.
30	ENABLE	R/W	0h	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the IDLE bit. If using byte access, the ENABLE bit has to be the last bit written in this register. 0: Disables the MDIO state machine. 1: Enable the MDIO state machine.
29	RESERVED	R	0h	Reserved
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest user access channel that is available in the module. E.g. 0 = channel 0 only. 1 = channels 0 and 1, and so on. The device itself may not pin out all channels. See Environment section for details.
23-21	RESERVED	R	0h	Reserved
20	PREAMBLE	R/W	0h	Preamble disable. 0: Standard MDIO preamble is used. 1: Disables this device from sending MDIO frame preambles.
19	FAULT	R/W	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0: No failure. 1: Physical layer fault; the MDIO state machine is reset.
18	FAULT_DETECT_ENABLE	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0: Disables the physical layer fault detection. 1: Enables the physical layer fault detection.

Table 11-2340. MDIO_CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	INT_TEST_ENABLE	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0: Interrupt bits are not set. 1: Enables the host to set the USERINT and LINKINT bits for test purposes.
16	RESERVED	R	0h	Reserved
15-0	CLKDIV	R/W	FFh	Clock divider. This field specifies the division ratio between ICLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is set to 0. MDCLK frequency = ICLK frequency/(CLKDIV+1).

Table 11-2341. Register Call Summary for MDIO_CONTROL

Gigabit Ethernet MAC (EMAC) Subsystem • MDIO Functional Description: [0] • Initializing the MDIO Module: [0][1] • Interface Clocking: [0]
EMAC Registers • NSS_0_CFG_MDIO Registers: [0] • MDIO_CONTROL Register (Offset = 4h) [reset = 810000FFh]: [0] • MDIO_USER_INT_MASKED Register (Offset = 24h) [reset = 0h]: [0] • MDIO_LINK_INT_MASKED Register (Offset = 14h) [reset = 0h]: [0] • MDIO_USER_INT_RAW Register (Offset = 20h) [reset = 0h]: [0]

11.13.5.1.5.3 MDIO_ALIVE Register (Offset = 8h) [reset = 0h]

MDIO_ALIVE is shown in Figure 11-1023 and described in Table 11-2343.

Table 11-2358. MDIO_USER_INT_MASKED Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	Reserved
1-0	USERINTMASKED	R/W	0h	Masked value of MDIO user command complete interrupt for the MDIO_USERACCESS register. When asserted 1, a bit indicates that the previously scheduled PHY read or write command using MDIO_USERACCESS register has completed and the corresponding USERINTMASKSET bit is set to 1. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIO_CONTROL register is set, the host may set the USERINTMASKED bits to a 1. This mode may be used for test purposes.

Table 11-2367. MDIO_USER_ACCESS_0 to MDIO_USER_ACCESS_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	GO	R/W	0h	Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIO_USERACCESS register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.
30	WRITE	R/W	0h	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.
29	ACK	R/W	0h	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	RESERVED	R	0h	Reserved
25-21	REGADR	R/W	0h	Register address. Specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	R/W	0h	PHY address. Specifies the PHY to be accesses for this transaction.
15-0	DATA	R/W	0h	User data. The data value read from or to be written to the specified PHY register.

Table 11-2387. ECC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R		Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the force_sec/force_ded will inject an error to the specified row only once. The force_sec bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the force_ded bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0h	Force single/double-bit error on the next RAM read
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if error_once is asserted.
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if error_once is asserted
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes
1	ECC_CHECK	R/W	1h	Enable ECC check. ECC is completely bypassed if both ecc_enable and ecc_check are 0
0	ECC_ENABLE	R/W	1h	Enable ECC generation

Table 11-2396. ECC_ERROR_STATUS1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_ROW	R	0h	Indicates the row/address where the single or double-bit error occurred
15-11	RESERVED	R		Reserved
10	CLR_ECC_OTHER	W1toCl	0h	1 indicates a pending double-bit error. Writing a 1 clears the status bit.
9	CLR_ECC_DED	W1toCl	0h	1 indicates a pending successive single-bit error. Writing a 1 clears the status bit.
8	CLR_ECC_SEC	W1toCl	0h	1 indicates a pending single-bit error. Writing a 1 clears the status bit.
7-3	RESERVED	R		Reserved
2	ECC_OTHER	R/W	0h	1 indicates that successive single-bit errors have occurred while a writeback is still pending. Software can also write a 1 to set the pending status.
1	ECC_DED	R/W	0h	1 indicates a double-bit error. Software can also write a 1 to set the pending status.
0	ECC_SEC	R/W	0h	1 indicates a single-bit error. Software can also write a 1 to set the pending status.

Table 11-2449. CDMA_PERF_CONTROL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved
21-16	WARB_FIFO_DEPTH	R/W	20h	This field sets the depth of the write arbitration FIFO which stores write transaction information between the command arbiter and write data arbiters in the Bus Interface Unit. This value can be set to a range of 1 to 32. Setting this field to smaller values will cause prevent the CDMAHP from having an excess of write transactions outstanding whose data is still waiting to be transferred. System performance can suffer if write commands are allowed to be issued long before the corresponding write data will be transferred. This field allows the command count to be optimized based on system dynamics.
15-0	TIMEOUT_CNT	R/W	0h	This field sets the timeout duration in clock cycles. This field controls the minimum amount of time that an Rx channel will be required to wait when it encounters a buffer starvation condition and the Rx error handling bit is set to 1 (packet is to be preserved - no discard). If the Rx error handling bit in the flow table is cleared, this field will have no effect on the Rx operation. When this field is set to 0, the Rx engine will not force an Rx channel to wait after encountering a starvation event (the feature is disabled). When this field is set to a value other than 0, the Rx engine will force any channel whose associated flow had the Rx error handling bit asserted and which encounters starvation to wait for at least the specified # of clock cycles before coming into context again to retry the access to the QM. This is intended to control potentially debilitating effects on the QM performance that can becaused by the CDMAHP modules continually polling the QM. The exact # of clock cycles between QM access attempts is not important and will not be exact. The only guarantee is that the # of cycles waited will be at least as large as the TIMEOUT_CNT.

Table 11-2468. CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_0 to CDMA_TX_CHANNEL_GLOBAL_CONFIG_REG_A_8 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TX_ENABLE	R/W	0h	Tx channel enable: • 0 = Channel is disabled • 1 = Channel is enabled Disabling a channel halts operation on the channel after the current block transfer is completed. Disabling a channel in the middle of a packet transfer may result in underflow conditions in the attached application block and data loss.
30	TX_TEARDOWN	R/W	0h	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
29	TX_PAUSE	R/W	0h	Setting this bit will request the channel to pause processing at the next packet boundary. This is a more graceful method of halting processing than disabling the channel as it will not allow any current packets to underflow.
28-0	RESERVED	R	0h	Reserved

Table 11-2476. CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_0 to CDMA_RX_CHANNEL_GLOBAL_CONFIG_REG_25 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	Tx channel enable: • 0 = Channel is disabled • 1 = Channel is enabled
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit will request the channel to pause processing at the next packet boundary. This is a more graceful method of halting processing than disabling the channel as it will not allow any current packets to overflow.
28-0	RESERVED	R	0h	Reserved

Table 11-2481. CDMA_RX_FLOW_CONFIG_REG_A_0 to CDMA_RX_FLOW_CONFIG_REG_A_31 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30	RX_EINFO_PRESENT	W	0h	Rx extended packet info block present. This bit controls whether or not the Extended Packet Info Block will be present in the Rx Packet Descriptor. If this bit is clear, the port DMA will clear the Extended Packet Info Present bit in the PD and will drop any Timestamp or SW Data words that are presented from the back end application. If this bit is set, the port DMA will set the Extended Packet Info Block Present bit in the PD and will copy any Timestamp or SW Data words that are presented across the Rx streaming interface into the Extended Packet Info Block words in the descriptor. If no Timestamp or SW Data words are presented from the back end application, the port DMA will overwrite the fields in the PD with zeroes.
29	RX_PSINFO_PRESENT	W	0h	Rx protocol specific words present. This bit controls whether or not the Protocol Specific words will be present in the Rx Packet Descriptor. If this bit is clear, the port DMA will set the PS word count to 0 in the PD and will drop any PS words that are presented from the back end application. If this bit is set, the port DMA will set the PS word count to the value given by the back end application and will copy the PS words from the back end application to the location.

Table 11-2481. CDMA_RX_FLOW_CONFIG_REG_A_0 to CDMA_RX_FLOW_CONFIG_REG_A_31 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	RX_ERROR_HANDLING	W	0h	Rx error handling mode: • 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to • 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation In this mode, the DMA will save it's internal operational state back to the internal state RAM without issuing an advance operation to it's internal FIFO buffers. This results in the DMA reinitiating the data transfer at a later time with the intention that additional free buffers and/or descriptors will have been added.
27-26	RX_DESC_TYPE	W	0h	Rx descriptor type: • 00 = RESERVED • 01 = Host • 10 = Monolithic • 11 = RESERVED
25	RX_PS_LOCATION	W	0h	Rx protocol specific location. If this bit is cleared, the DMA will clear the Protocol Specific Region Location bit in the PD and will place the Protocol Specific Words at the end of the Packet Descriptor. If this bit is set, the DMA will set the Protocol Specific Region Location bit in the PD and will place the Protocol Specific Words at the beginning of the data buffer. When this mode is used, it is required that the resulting target data buffer pointer (which is calculated by adding theHOST_RX_SOP_OFFSET to the original buffer pointer in the Packet Descriptor) is aligned to a 32-bit boundary to avoid unwanted buffer truncation as the DMA will round up to the next 32-bit aligned boundary.
24-16	RX_SOP_OFFSET	W	0h	Rx start of packet offset. This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload or protocol specific bytes(if they are in the sop buffer). This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes. Note that for monolithic packets the value of this field must always be initialized to be greater than or equal to 4 times the maximum number of protocol specific 32-bit words that are required by any of the packet types that will be transferred by this channel. This is important as the primary purpose of this field is to ensure that space is left in the descriptor to place the protocol specific information without overwriting or being overwritten by the Rx data. The secondary purpose of this field is to allow space to be left prior to the data in the descriptor in case header information needs to be added as the packet is passed thorough the system.
15-14	RESERVED	R	0h	Reserved
13-12	RX_DEST_QMGR	W	0h	Rx destination queue manager. This field indicates the default receive queue manager that this channel should use.
11-0	RX_DEST_QNUM	W	0h	Rx destination queue. This field indicates the default receive queue that packets on this flow should be placed onto.

Table 11-2496. CDMA_RX_FLOW_CONFIG_REG_F_0 to CDMA_RX_FLOW_CONFIG_REG_F_31 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RX_SIZE_THRESH0	W	0h	Rx packet size threshold 0. This value is left shifted by 5 bits and compared against the packet size to determine which free descriptor queue should be used for the SOP buffer in the packet. If the packet size is less than or equal to the value given in this threshold, the DMA controller in the port will allocate the SOP buffer from the queue given by the RX_FDQ0_SZ0_QMGR and RX_FDQ0_SZ0_QNUM fields. This field is OPTIONAL.
15-0	RX_SIZE_THRESH1	W	0h	Rx packet size threshold 1. This value is left shifted by 5 bits and compared against the packet size to determine which free descriptor queue should be used for the SOP buffer in the packet. If the packet size is greater than theRX_SIZE_THRESH0 but is less than or equal to the value given in this threshold, the DMA controller in the port will allocate the SOP buffer from the queue given by the RX_FDQ0_SZ1_QMGR and RX_FDQ0_SZ1_QNUM fields. If enabled, this value must be greater than the value given in theRX_SIZE_THRESH0 field. This field is optional.

Table 11-2533. QM_MEMORY_REGION_DESCRIPTOR_SETUP_REG_0 to QM_MEMORY_REGION_DESCRIPTOR_SETUP_REG_15 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reserved
28-16	DESC_SIZE	R/W	0h	This field indicates the size of each descriptor in this memory region. The value programmed is the multipler minus one that needs to be applied to 16 to get the actual descriptor size.So, for 16 and 64 byte descriptors, value programmed will be 0 and 3 respectively.
15-4	RESERVED	R	0h	Reserved
3-0	REG_SIZE	R/W	0h	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as 2^\[5+reg_size\] number of descriptors.

11.14 Peripheral Component Interconnect Express Subsystem (PCIe SS)

This section describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) Controllers which provide a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

11.14.1 PCIe SS Overview

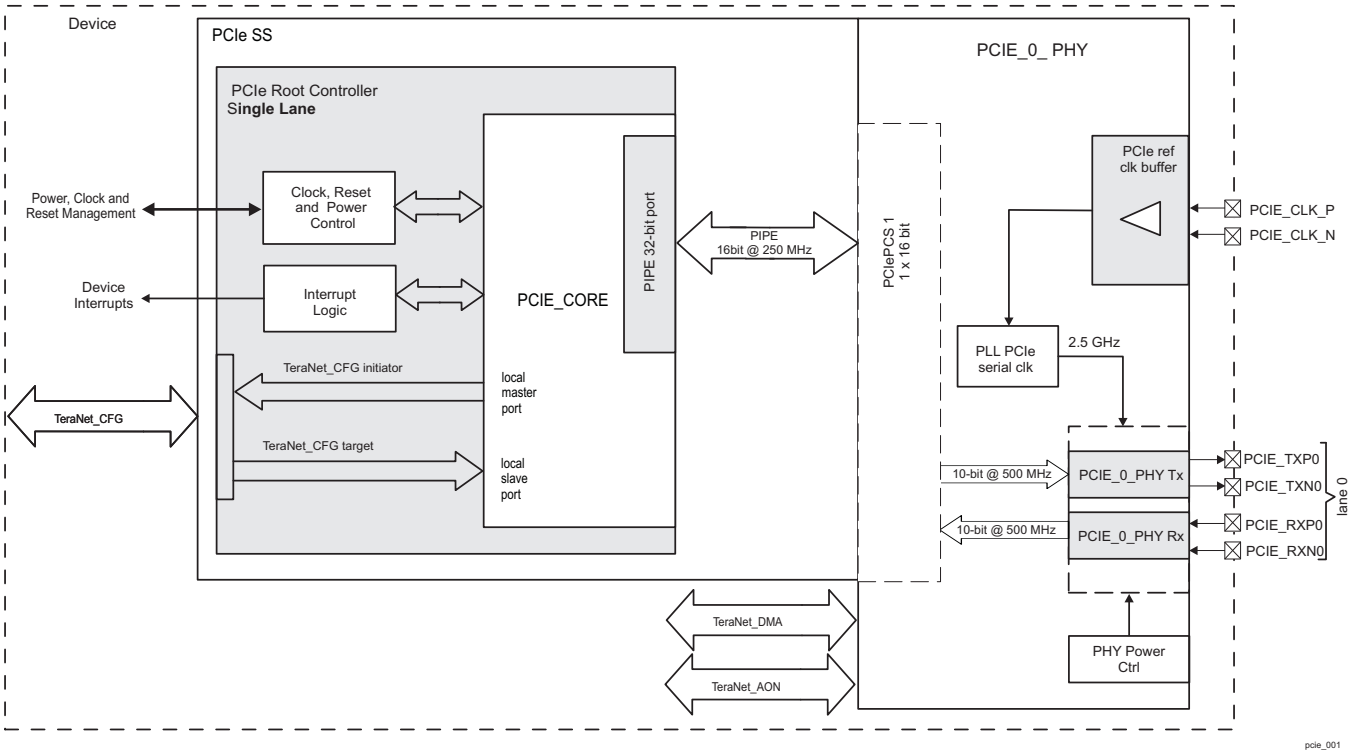
PCIe module is a multi-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane, per direction, for serial links on backplanes and printed curcuit boards. It is a 2nd generation I/O interconnect technology succeeding PCI and ISA bus designed to be used as a general-purpose serial I/O interconnect. It is also used as a bridge to other interconnects such as SATA, USB2/3.0, GbE MAC, and so forth.

The PCI Express standard's predecessor - PCI, is a parallel bus architecture that is increasingly difficult to scale-up in bandwidth, which is usually performed by increasing the number of data signal lines. The PCIe architecture was developed to help minimize I/O bus bottlenecks within systems and to provide the necessary bandwidth for high-speed, chip-to-chip, and board-to-board communications within a system. It is designed to replace the PCI-based shared, parallel bus signaling technology that is approaching its practical performance limits while simplifying the interface design.

NOTE: The device instantiates one PCIe subsystem supporting a single lane.

Figure 11-1089 shows the PCIe module overview.

Figure 11-1089. PCIe Controller Subsystem Overview



11.14.1.1 PCIe SS Features

PCIe module supports the following features:

- Dual operation mode: Root Complex (RC) or End Point (EP), see Section 11.14.4.6.1, *PCI Express Topology*
- Supports a single bidirectional link interface (a single input port and a single output port) with one lane
- Operated at a raw speed of 2.5 Gbps or 5.0 Gbps per lane per direction
- Maximum outbound payload size of 128 bytes
- Maximum inbound payload size of 256 bytes
- Maximum remote read request size of 256 bytes
- Ultra-low transmit and receive latency
- Support for dynamic-width conversion
- Automatic lane reversal
- Polarity inversion on receive
- Single virtual channel (VC)
- Single traffic class (TC)
- Single function in End Point (EP) mode
- Automatic credit management
- ECRC generation and checking
- PCI device power management with the exception of D3cold with Vaux
- PCI Express active state power management (ASPM) state L0s and L1
- PCI Express link power management states, except L2 state
- PCI Express advanced error reporting
- PCI Express messages for both transmit and receive
- Filtering for posted, non-posted, and completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering, and completion lookup/timeout
- Access to configuration space registers and external application memory-mapped registers through BAR0 and through configuration access
- Legacy interrupts reception (in RC) and generation (in EP)
- MSI generation and reception
- PHY loopback in RC mode

PCIe module does not support the following features:

- No support for multiple lanes
- No support for multiple VCs
- No support for multiple TCs
- No support for function-level reset
- No support for PCI Express beacon for in-band wake
- No built-in hardware support for hot-plug
- No support for vendor messaging
- No support for I/O access in inbound direction in RC or EP mode
- No support for addressing modes other than incremental for burst transactions. Thus, the PCIe addresses cannot be in cacheable memory space
- No auxiliary power to maintain controller context when rezuming from D3cold state
- No support for L2 link state

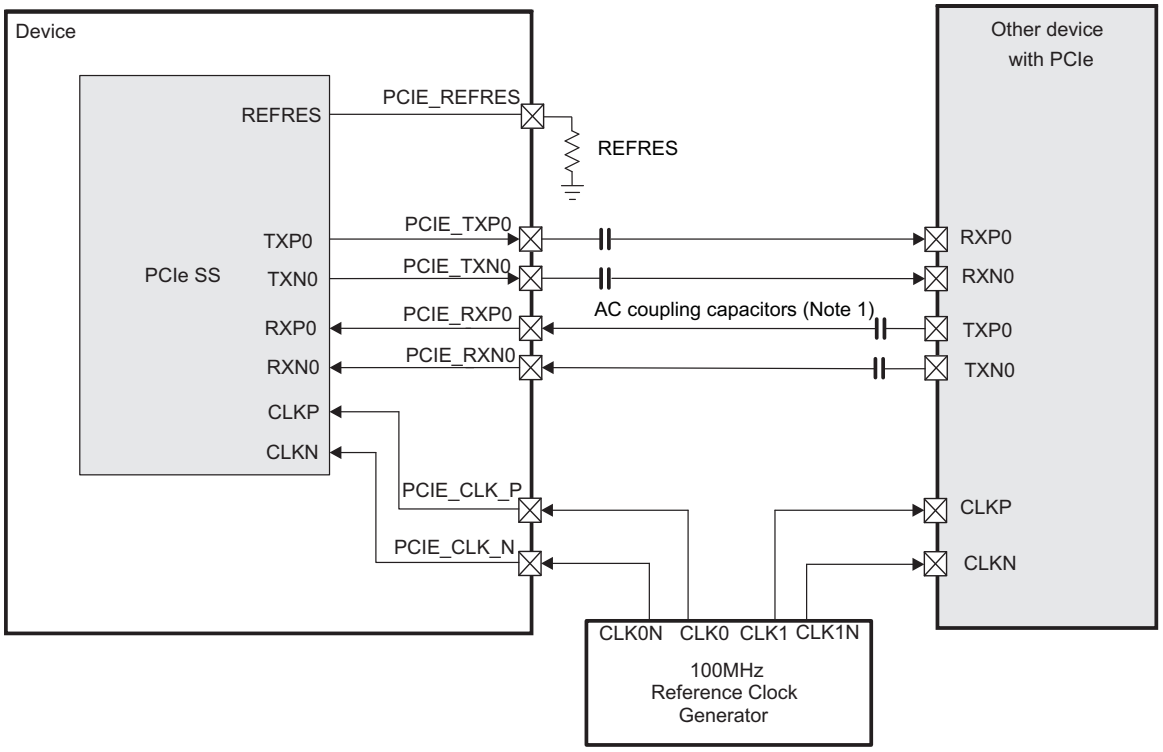
11.14.2 PCIe SS Environment

This section describes PCIe SS connection with an external device.

11.14.2.1 PCIe SS Interface

Figure 11-1090 shows the I/O interface signals of PCIe SS.

Figure 11-1090. PCIe SS Enviroment



Note 1 - For more information about the values of AC Coupling capacitor see PCIe specification

Table 11-2563 lists the PCIe SS interface input/output (I/O) signals.

Table 11-2563. PCIe Interface Signals

Device Signal	Module Signal	I/O[1]	Description
PCIE_RXN0	RXNO	I	RX input of the PCIe port 0 PHY differential transmission line (negative by default)
PCIE_RXP0	RXPO	I	RX input of the PCIe port 0 PHY differential transmission line (positive by default)
PCIE_TXN0	TXNO	O	TX output of the PCIe port 0 PHY differential transmission line (negative by default)
PCIE_TXP0	TXPO	O	TX output of the PCIe port 0 PHY differential transmission line (positive by default)
PCIE_CLK_P	CLKP	I	PCIe Clock Input (positive)
PCIE_CLK_N	CLKN	I	PCIe Clock Input (negative)
PCIE_REFRES	REFRES	A	PCIe SerDes Reference Resistor input (3kΩ ± 1%), see the device Data Manual for more information

(1) I = Input; O = Output; A = Analog

11.14.3 PCIe SS Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-1091 shows the device internal connections with related modules for PCIe functions.

Figure 11-1091. PCIe SS Integration

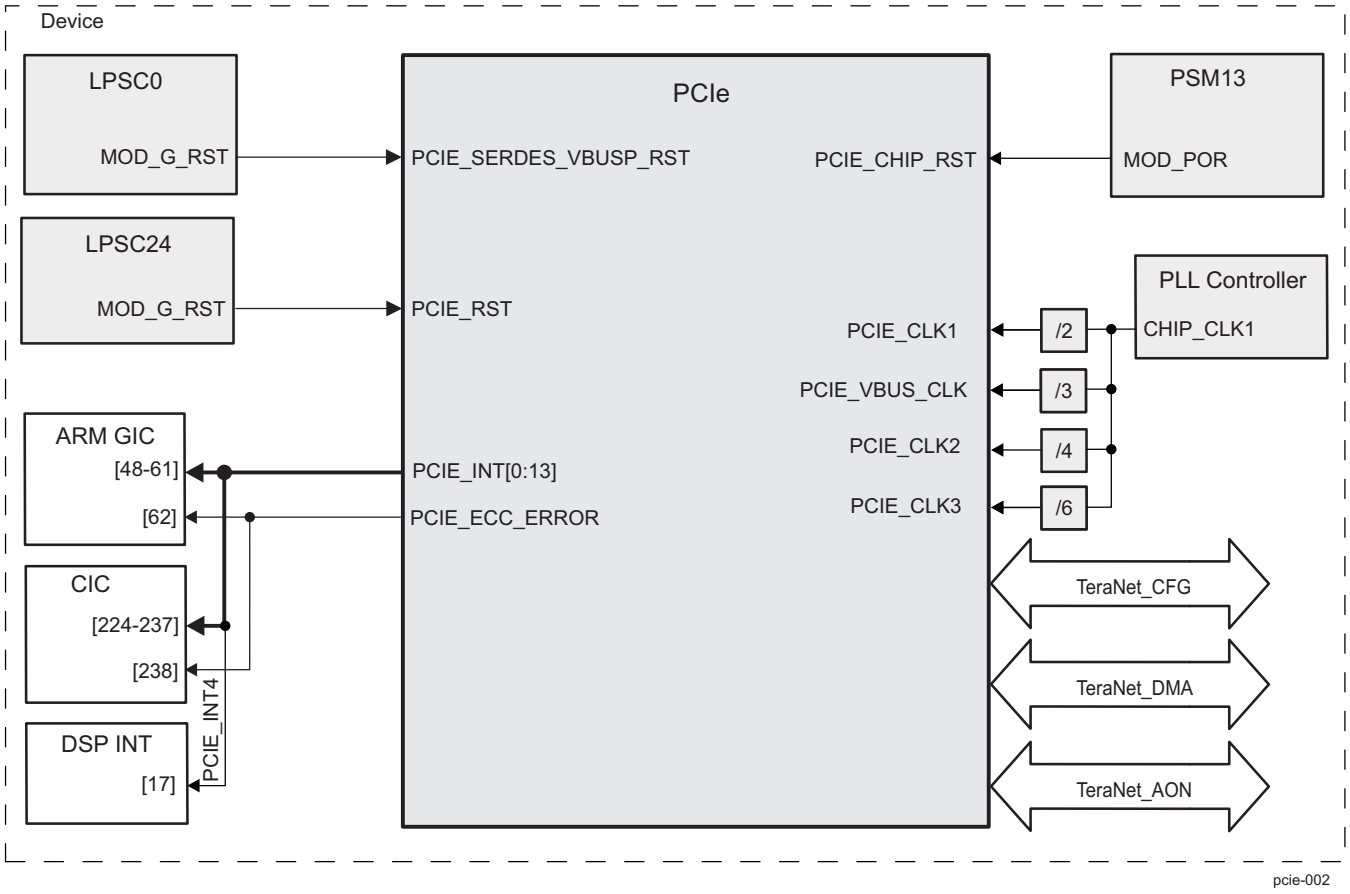


Table 11-2564 through Table 11-2566 summarize the integration of the module in the device.

Table 11-2564. PCIe SS Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect

NOTE: PCIe interrupts are described in Section 11.14.4.4, *Interrupts*.

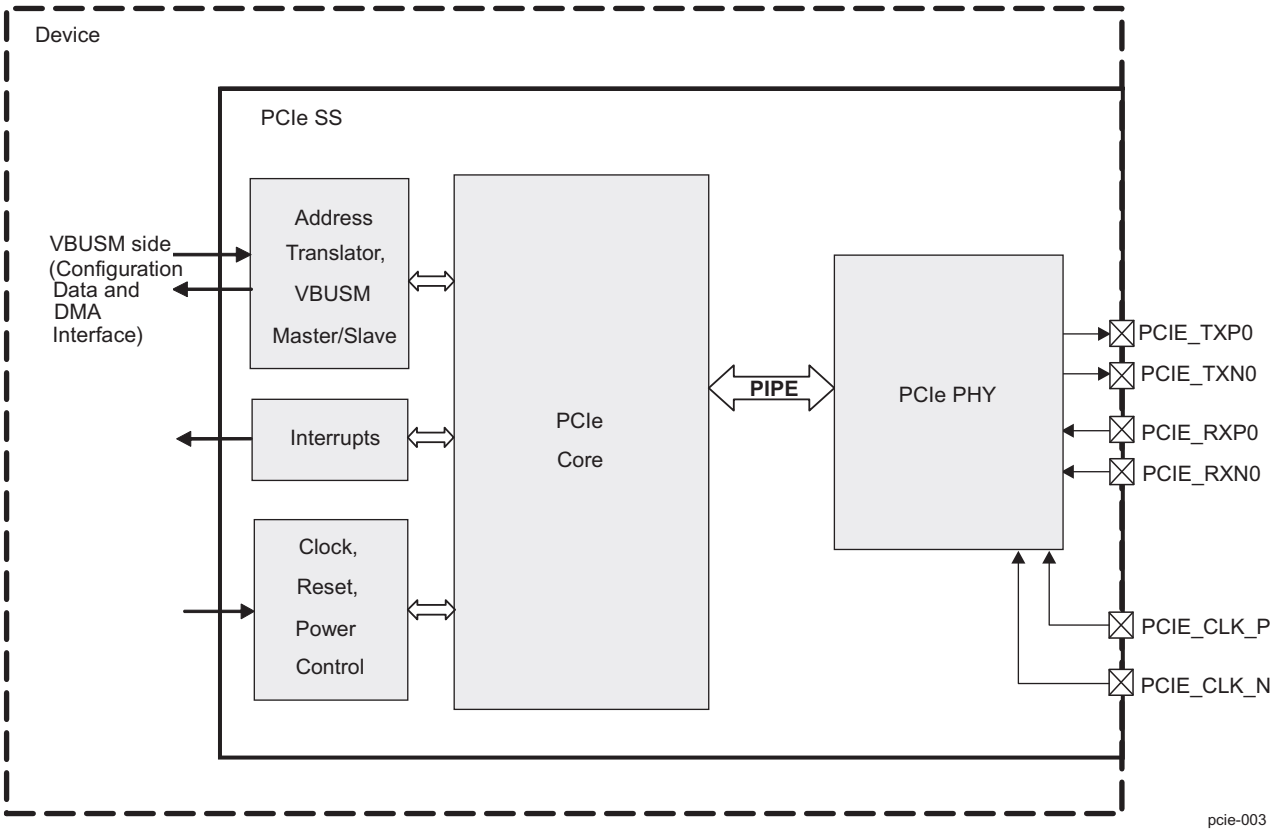
11.14.4 PCIe SS Functional Description

PCIe SS complies with the industry standards listed below:

- PCI Express Base Specification Revision 1.1
- PCI Express Base Specification Revision 2.0

Figure 11-1092 shows the block diagram of the PCIe SS.

Figure 11-1092. PCIe SS Block Diagram



11.14.4.1 PCIe PHY Interface

The PCIE_0_PHY (SERDES PHY) contains the analog portion of the PHY, which is the transmission line channel that is used to transmit and receive data. It contains a phase locked loop, CBA to SB Bridge, Local Registers, CFG/STS Overrides, Clock Gen, Rx Comma Align, and test logic.

11.14.4.2 PCIe Core

11.14.4.2.1 PCIe Core Module

The PCIe core contains the Transaction Layer, Data Link Layer, and MAC part of the PHY. The PCIe core is a Dual Mode core allowing it to operate as RC or EP. As an EP, it can operate as a legacy end point or native PCIe end point. Software can set the PCIe mode (EP, Legacy EP, RC) by writing to the BOOTCFG_DEVCFG[2-1] register, see Section 5.1, *Control Module (BOOT_CFG)* for details. The PCIe Core implements all PCIe specific protocol functionality.

11.14.4.3 Clock, Reset, Power Control Logic

Several clock domains exist within the PCIe SS. These clocks are functional clocks used by the PCIe controller and interface bridges as well as receive and transmit clocks used to clock data in and out. The clocks required for clocking data and PHY functional clocks are generated by the PHY through the supplied input differential clock.

The PCIe SS supports the conventional reset mechanism that is specified within the PCIe Specification. The reset shown in Figure 11-1092 pertains to a hardware reset (cold or warm reset).

In addition to automatic power down mode executed and entered by the hardware (Active State Power Management) when no activity is present, the PCIe SS supports higher level power down mode that is controlled by user software.

11.14.4.4 Interrupts

The PCIe SS is capable of generating up to 14 interrupts (INTA/B/C/D-legacy interrupts combined, MSI, error, power management, and reset) connected to the Interrupt Controller. The user software is required to acknowledge the serviced interrupt by writing to the corresponding vector onto the PCIE_IRQ_EOI register.

11.14.4.5 Differential Data Lines

A pair of differential data lines exists, for both transmit and receive paths lane.

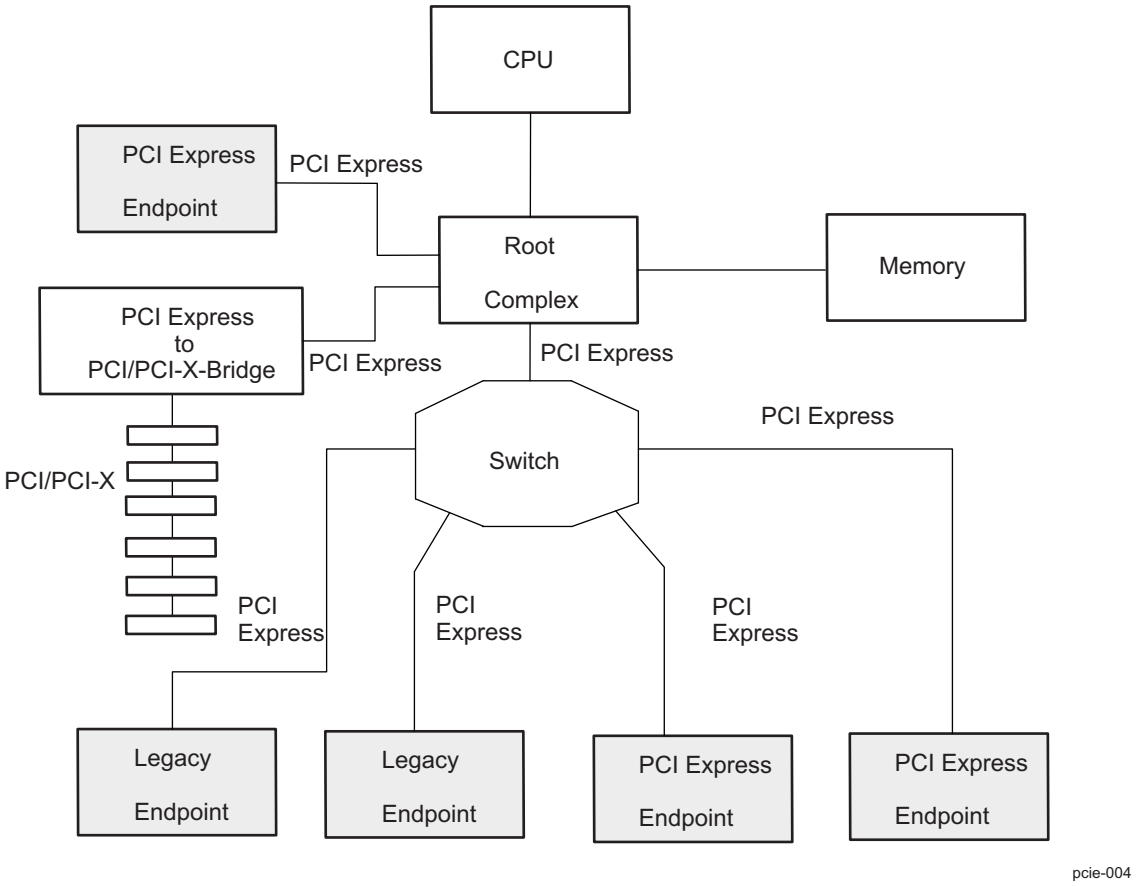
11.14.4.6 Protocol Description

11.14.4.6.1 PCIe Topology

The PCI Express fabric looks like a tree structure with nodes connected to each other via point-to-point links. The root node is called the *root complex* (RC), the leaf nodes are called *end points* (EP) and the nodes that connect multiple devices to each other are called *switches* (SW). The RC can have multiple downstream ports but that still requires multiple instances of the PCIe protocol stack for each RC port.

NOTE: Having one RC port in the PCIe SS does not imply that more than one EP can be connected to the PCIe SS without adding a PCIe switch.

Figure 11-1093. PCIe Example Topology



11.14.4.6.2 Serial Link

PCIe is a point-to-point serial signaling protocol. Each link consists of one TX and one RX differential pair. On each link, depending upon the protocol version, 2.5 Gbps or 5.0 Gbps can be transported in each direction. Accounting for the 8-bit or 10-bit encoding used over the serial link, the data rates translate to 2.0 Gbps and 4.0 Gbps of throughput at higher layers of PCIe protocol. Data is transferred in packets, which include an address and a variable size data payload.

11.14.4.6.3 Supported PCIe Transactions

All of the PCIe transactions defined, Posted and Non-posted, are supported except the Locked Memory Read request transaction and its subsequent completion Locked response transaction. Inbound I/O read and write transactions are also not supported.

Table 11-2567 summarizes the supported PCIe transactions.

Table 11-2567. Supported PCIe Transactions

Transaction Packet Types	Posted/Non-posted
Memory read	Non-posted
Memory write	Posted
I/O read	Non-posted
I/O write	Non-posted
Configuration read (type 0 and type 1)	Non-posted
Configuration write (type 0 and type 1)	Non-posted
Message request without data	Posted
Message request with data	Posted
Completion without data	-
Completion with data	-
Completion without data for locked access	-
Completion with data for locked access	-

The non-posted transactions comprise of a transaction layer packet (TLP) from the requester to completer. The completer, at a later time, sends a completion TLP to the requester. The completion TLP is used to inform the requester that the completer has received the request. In addition, the completion TLP also contains the data if the transaction was a read transaction. Non-posted write transactions contain the data in request TLP.

For posted transactions, the request TLP is sent but there is no response TLP sent from the completer to the requester.

11.14.4.7 Clock Control

The PCIe SS uses multiple clock domains. At the top level, there are only two functional clocks of relevance – a reference clock to the PCIE_0_PHY and a clock for VBUSM interfaces of the subsystem.

The VBUSM interface functional clock is generated from the PLL Controller, see Section 5.4, *Clock Management*, for details.

The other clock input to the PCIe SS is the differential clock. This differential clock is used by the PCIE_0_PHY PLL to generate the necessary functional and bit clock required by the PHY.

To comply with the PCIe Specifications, it is acceptable that a reference clock of 100 MHz that meets the requirements for REFCLK as described in the PCIe Card Electromechanical Specification be driven as a differential signal into PCIe reference clock pads of the device. Greater fluctuation tolerance can be achieved by using one of the higher frequency reference clock values specified in the device Data Manual.

It is recommended that the reference clock be synchronous between the two link partners. To achieve this, a common clock source should be used in the system to provide REFCLK to both ends of each PCIe link.

If common clock architecture is not used, then the software driver must setup appropriate bit (COMMON_CLK_CFG bit in PCIE_LINK_STAT_CTRL register) in the PCIe Configuration registers to indicate so to the system. The number of training sequences is significantly increased if reference clock is not shared between devices on a PCIe link.

The PCIe SS operation is completely dependent upon availability of clock from the PLL that is inside the PHY. All registers in the PCIe SS are located in the clock domain that is dependent upon PLL to be properly configured and in lock. Therefore, for transactions that have been initiated before ensuring that the PLL is locked, the subsystem does not operate. The IP registers are used to enable PLL and verify lock status, see Section 11.14.4.8, *SERDES Configuration*, for more details.

11.14.4.8 SERDES Configuration

The physical layer SERDES has a built-in PLL, which is used for the clock recovery circuitry. The PLL is responsible for clock multiplication of a slow speed reference clock (REFCLKP/N). And the reference clock is the input to PCIe clock pins PCIE_CLK_N and PCIE_CLK_P. This reference clock has no timing relationship to the serial data and is asynchronous to any VBUS clock. The multiplied high-speed clock is routed only within the SERDES block. It is not distributed to the remaining blocks of the peripheral, nor is it a boundary signal to the core of the device. It is extremely important to have a good quality reference clock, and to isolate it and the PLL from all noise sources.

For more information about SERDES Configuration Registers, see Section 11.14.5.1, *SERDES Configuration Registers*.

For more information about implementation instructions for the serializer/deserializer (SerDes)-based interfaces on this device, see SPRUHO3, *KeyStone II Architecture Serializer/Deserializer (SerDes)*.

11.14.4.8.1 Enabling the PLL

Setting of PLL_ENABLE_VAL and PLL_ENABLE_OVL bits of PCIE_PHY_PLL_CTRL enables the internal PLL. For more datails about the stabilization of provided REFCLKP/N, see the device Data Manual.

The PLL_OK bit of PCIE_PHY_PLL_CTRL register will be driven high by the digital lock detector. The software can sample this bit during the PLL initialization to indicate the PLL signal is stable.

11.14.4.8.2 Reference Clock Multiplication

Table 11-2568 summarizes the calculation of the line rate versus PLL output clock frequency.

Table 11-2568. Line Rate versus PLL Output Clock Frequency

Rate	Line Rate	PLL Output Frequency	RATESCALE
Full	x Gbps	0.5x GHz	0.5
Half	x Gbps	1x GHz	1
Quarter	x Gbps	2x GHz	2
REFCLKP/N = (LINERATE*RATESCALE)/MPY			

NOTE: The targeted PLL output frequency (line rate) is 2.5 GHz in both PCIe Gen1 and Gen2 modes. The PCIe PHY performs data bus width conversion from 8-bit to 16-bit when the module switches from Gen1 speed to Gen2 speed. The output frequency of the PLL stays constant irrespective of whether it is operating in Gen1 or Gen2 mode. Set the DIR_SPD bit to 1 in the PCIE_PL_GEN2 register during the initialization to switch the PCIe link speed mode from Gen1 (2.5 Gbps) to Gen2 (5.0 Gbps).

11.14.4.9 Address Translation

PCIe TLP transactions use PCIe addresses. There is a mapping requirement between a PCIe address and a local internal bus address and to accommodate this address mapping, built-in hardware address translation mechanisms exist. That is, if the *Type* field of an outgoing or received TLP indicates the use of address routing, then an outbound or inbound address translation is required and is performed accordingly to map internal bus address to PCIe address or vice-versa using hardware address translators. Address translations for outbound and inbound transactions are discussed below.

PCIe recognizes four address spaces – Memory, I/O, Configuration, and Message. Messages do not consume any Memory or I/O resource. I/O addressing is used by PCIe that supports legacy device operation capabilities; this is not a mandatory feature by PCIe and when supported the I/O spaces is memory mapped to system memory. This implies that only two types of device address spaces, Configuration and Memory spaces, need to map between PCIe address and internal bus address.

The device address space is divided into two spaces (Range 0 and Range 1). Address space (Range 0) that is used for PCIe configuration task is referred to as Configuration space, and a second address space (Range 1) that is used for accessing memory (non-configuration related) is referred to as Memory space.

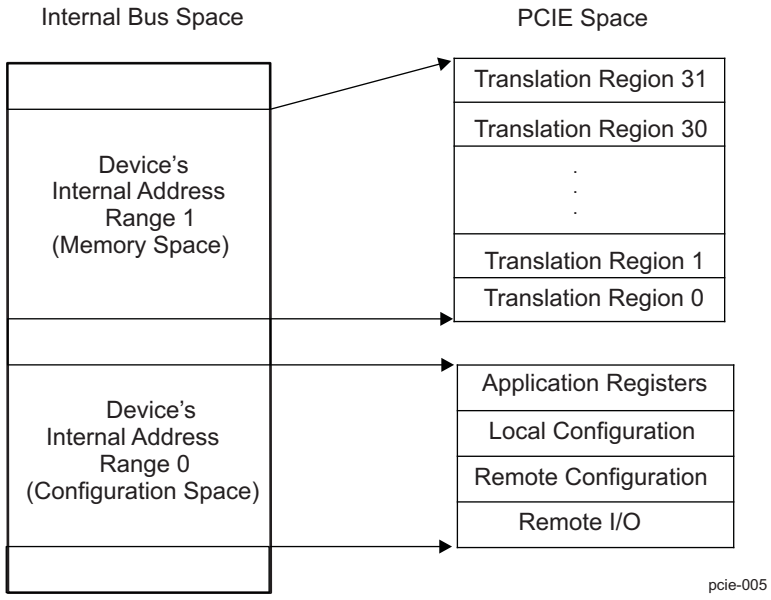
NOTE: All I/O accesses use address routing. There is no support for I/O access in inbound direction. That is, when it comes to a transaction that performs I/O access only TLPs with outbound transactions are supported.

11.14.4.9.1 Outbound Address Translation

The PCIe SS allows mapping of internal bus address to or from PCIe address on outbound TLPs. This is accomplished by using outbound address translation logic. For each outbound read or write request, the address translation module within the PCIe SS can convert an internal bus address to a PCIe address of memory read or write type.

The address translation logic uses information in address translation registers to perform the mapping. The registers, PCIE_OB_SIZE, PCIE_OB_OFFSET_INDEXn and PCIE_OB_OFFSETn_HI are used in conjunction with outbound address translator.

Figure 11-1094. Outbound Address Translation



The memory range that the PCIe SS occupies in the devices internal address range is divided into 32 equally-sized translation regions (Regions 0 to 31). These regions can be programmed to be of 1, 2, 4, or 8MB in size via the PCIE_OB_SIZE register. Each such region can be remapped to a PCIe address range of same size as the size of translation region itself. The address translation logic identifies and extracts the 5 bits (32 regions) of the device's internal address and determines which of the 32 regions it belongs to. The bit address positions of these 5 bits depend on the range size. Once the region is identified, the address translation logic then generates PCIe base address, from the values provided within the corresponding configuration registers for that region, which are the registers PCIE_OB_OFFSET_INDEXn (n = [1,31]) and PCIE_OB_OFFSETn_HI (n = [1,31]). If 32-bit addressing is used, PCIE_OB_OFFSETn_HI will always be programmed with zero.

Once the PCIe base address has been identified, the offset that is to be added to this base address is derived from the lower bit fields of the internal bus address and the bit fields that make up this offset correspond to the size of the regions.

Application software is required to identify the desired internal bus memory that is to be accessible by PCIe module and initialize the corresponding registers prior to enabling PCIe transactions.

To accomplish address translation, each region uses three registers content values:

1. **Outbound Size Register (PCIE_OB_SIZE)** – Application software initializes this register with the size value. This field is used to identify the size of all equally spaced regions and identify one of the 32 regions based on the size value. OB_SIZE field = 0, 1, 2 and 3 corresponds to region sizes of 1MB, 2MB, 4MB and 8MB and the corresponding indexed regions for these sizes are bits[24-20], bits [25-21], bits[26-22] and bits[27-23]. So, index identification is done based on the size of regions and the values of these 5-bit fields identify one of the 32 Regions that are used for mapping. This affects the meaningful bit fields used within PCIE_OB_OFFSET_INDEXn register. The index value will be extracted from the device internal bus address and will be matched to one of the 32 regions. The lower bit fields corresponding to the size of the region are masked and not used in the mapping.
2. **Outbound Translation Region n Offset Low and Index Register (PCIE_OB_OFFSET_INDEXn)** – Application software initializes this register with the 32-bit PCIe address. Not all bits in this field are used in all cases. The number of bits used changes depending upon the size of each address translation region. If each region is 1MB, 2MB, 4MB or 8MB, then this field will be used to create bits[31-20], bits[31-21], bits[31-22] or bits[31-23] of the translated address.
3. **Outbound Address Offset High Register (PCIE_OB_OFFSETn_HI)** – Application software initializes this register and this is a 32-bit field that represents bits [63-32] of translated PCIe space address if using 64-bit addressing. This register is required to be programmed with a Zero value if using 32-bit addressing.

Example 11-5 demonstrates the mapping of a given internal bus address to a PCIe address.

Example 11-5. Outbound Address Translation

For a given device internal bus address of 0x9D3A1234, what would be the corresponding PCIe address that would be used on an outgoing TLP header (assume a 2MB region partition)?

For this example, further assume the following:

- 64-bit addressing is to be used
- Translation Region 9 high offset PCIE_OB_OFFSET9_HI = 0x33445566
- Translation Region 9 low offset PCIE_OB_OFFSET9_INDEX = 0x56E00001 (Region 9 is enabled)

For an internal address 0x9D3A1234, the translated address is calculated based as outlined below:

1. Extract the 5-bit index and offset from given internal bus address of 0x9D3A1234. Because the region partition is 2MB (PCIE_OB_SIZE = 1), bits [25-21] of address 0x9D3A1234 is extracted as 01001b, which is 9.
2. Match it to one of the region index fields. In this example, it matches translation region 9 as internal address bits [25-21] are equal to value of index 9. So the translation registers contents for region 9 will be used.
3. Use programmed offsets 0x33445566 (from PCIE_OB_OFFSET9_HI) for 64-bit addressing bits[63-32] and 0x56E (from PCIE_OB_OFFSET9_INDEX) for bits[31-21]. The translated PCIe base address =

Example 11-5. Outbound Address Translation (continued)

0x33445566 56E00000.

4. Map the offset (bits[20-0]) of the internal bus address directly to PCIe address. Bits[20-0] of 0x9D3A1234 is 0x1A1234.
5. Compute translated address = translated base address + offset = 0x33445566 56E00000+0x1A1234 = 0x33445566 56FA1234.

In Example 11-5, 2MB size region will allow a total of 2MB*32 = 64MB unique internal bus address location to be mapped onto a corresponding PCIe address, values 0x0000 0000 to 0x03FF FFFF. Any internal bus address outside this 64MB space will not be uniquely mapped and the internal bus address will be truncated to fall in within the 64MB region, which happens to be for this example. In other words, bits [31-26] of the given example internal bus address is masked and does not contribute to the PCIe translated address generation (for example, internal bus address 0x9D3A 1234 will have the same PCIe translated address as 0x913A 1234 or 0x953A 1234, and so forth).

NOTE: The outbound translation is used only for memory read and write transactions and not for PCIe configuration or I/O read and write transactions. Outbound translation may not be necessary in all applications.

11.14.4.9.1.1 Transactions Violating Address Translation Boundaries

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation works only at the time a command is issued. So, a memory write for example, does not automatically go to the next translation region if the write has started in the previous one and is larger than the remaining size in the starting translation region.

11.14.4.9.2 Inbound Address Translation

Inbound address translation is used to remap accepted incoming accesses from other PCIe devices to locations within the device's memory map.

The PCIe SS is aware of two internal bus address spaces. The first address space (Address Space 0) is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote I/O accesses (RC only). The second one (Address Space 1) is dedicated for data transfer. Details on this are covered in Section 11.14.4.10, *PCIe Address Spaces*.

Address Space 0 occupies a contiguous 16KB of location, where 4KB of 16KB is the configuration space. Address Space 1 is used for data transfer and is large in size and not necessarily contiguous. To perform a mapping of a PCIe addresses that would land within Address Space 1, 4 dedicated regions (Region[0-3] are to be used by the inbound address translator to achieve the desired address mapping. Otbound translation has 32 regions while inbound translation has 4 regions.

Any accepted incoming address should match one of the BARs (Base Address Registers). If the PCIe SS is configured as EP, PCIE_BAR0÷PCIE_BAR5 will be mapped to one of the two address spaces (Address Space 0/1). If the PCIe SS is configured as RC, only PCIE_BAR0 and PCIE_BAR1 will be used to be mapped to the address spaces. See Section 11.14.4.9.3, *Use of Base Address Registers (BARs)*, for details of BAR usage.

In 32-bit addressing, PCIE_BAR0 is dedicated to Address Space 0 and PCIE_BAR1÷PCIE_BAR5 are dedicated to Address Space 1. Region0, Region1, Region2, and Region3 should be associated only with PCIE_BAR1÷PCIE_BAR5.

In 64-bit addressing, a pair of adjacent BARs concatenated is required to hold the 64-bit address. This means PCIE_BAR0 and PCIE_BAR1 hold 64-bit address with PCIE_BAR0 holding the lower 32-bit address to match while PCIE_BAR1 holding the higher 32-bit address to match. And PCIE_BAR0 and PCIE_BAR1 are dedicated to Address Space 0. The same holds for Address Space 1 association. The two pairs of registers - PCIE_BAR2 and PCIE_BAR3, and PCIE_BAR4 and PCIE_BAR5, hold the accepted 64-bit address that is associated to Address Space 1 where mapping takes place via the use of Region0, Region1, Region2, and Region3.

Address translation for Address Space 0 does not exist because the internal location is unique and is contiguous. The PCIe address should be within the received TLP address matches PCIE_BAR0 for 32-bit addressing, and PCIE_BAR0, PCIE_BAR1 for 64-bit addressing.

In 64-bit addressing, PCIE_BAR0 and PCIE_BAR1 are concatenated and dedicated to Address Space 0. There is no other BAR available in RC mode to map packets with 64-bit addressing to any other internal memory regions with inbound address translation.

However, address translation for Address Space 1 requires the use of one of the four regions (Region0, Region1, Region2, and Region3 to map accepted TLPs to internal memory. Four memory mapped registers that are region specific are used by the inbound address translator.

1. **Inbound Translation Bar Match Register (PCIE_IB_BARn (n = [1,3]))** – This field indicates which BAR the inbound transaction must be targeted to for the translation rule specified to activate.
2. **Inbound Translation Start Address High Register (PCIE_IB_START_HIn (n = [1,3]))** – This field indicates the starting address bits [63-32] as seen in PCIe address. Typically, this field will match the BAR value and is used as the reference for this address translation region in 64-bit addressing. This register is required to be programmed with a Zero value if using 32-bit addressing.
3. **Inbound Translation Start Address Low Register (PCIE_IB_START_LOn (n = [1,3]))** – This field indicates the starting address bits [31-8] as seen in PCIe address. Typically, this field will match the BAR value and is used as the reference for this address translation region in both of 32-bit and 64-bit addressing.
4. **Inbound Translation Address Offset Register (PCIE_IB_OFFSETn (n = [1,3]))** – This is the VBUSM address that will be the starting point of the mapped or translated PCIe address region.

The procedure used by the inbound address translator to perform the mapping between the PCIe address and internal bus address as follows:

1. Extract the offset: PCIe address – (PCIE_IB_STARTn_HI : PCIE_IB_STARTn_LO).
2. Compute internal address: add PCIE_IB_OFFSETn to the offset extracted on step 1.

Example 11-6 demonstrates the mapping of a given PCIe address to an internal bus address.

Example 11-6. Inbound Address Translation

For a given 64-bit PCIe address of 0x12345678 ABC50000, which qualifies for acceptance, what would be the corresponding internal bus address (assume that Region1 registers are programmed to match PCIE_BAR2, PCIE_BAR3 programmed addresses)?

For this example, further assume that application software has programmed the set of registers corresponding to Region1 as follows:

- PCIE_IB_BAR1 = 2. This assignment associates Region1 with PCIE_BAR2, PCIE_BAR3 for 64-bit addressing. The programmed value 2 here associate the match between Region1 (PCIE_IB_BAR1) and configuration register PCIE_BAR2.
- PCIE_IB_START1_HI = 0x12345678
- PCIE_IB_START1_LO = 0xABC00000
- PCIE_IB_OFFSET1 = 0x33400000

The internal bus address is computed by extracting the offset from the PCIe address (address within the TLP header) and add the resultant to the start address of the internal address.

- Extract the offset from the PCIe address:
  - Extracted offset = PCIe address – (PCIE_IB_STARTn_HI : PCIE_IB_STARTn_LO) =
  - = 0x12345678 ABC50000 - 0x12345678 ABC00000 =
  - = 0x00050000
- Compute internal device address:
  - Internal address = PCIE_IB_OFFSET + extracted offset =
  - = 0x33400000 + 0x00050000 =
  - = 0x33450000

In this example, PCIe address 0x12345678 ABC50000 is translated or mapped to internal bus address 0x33450000.

11.14.4.9.2.1 Mapping Multiple Non-Contiguous Memory Ranges To One Region

A single inbound address translation region can be used to map accesses to multiple non-contiguous internal address ranges, within Address Space 1, by ensuring that the start addresses of these regions are programmed in ascending order in the inbound start address registers.

Example 11-7. Mapping Multiple Non-Contiguous Memory Ranges to One Region

In this example, two BARs (PCIE_BAR1 and PCIE_BAR2) are remapped to four separate locations that are non-contiguous using 32-bit addressing. The first two regions (Region0 and Region1) remap accesses landing in PCIE_BAR1 space and the following two regions (Region2 and Region3) remap accesses landing in PCIE_BAR2 space. Each BAR is treated as a 32-bit BAR and therefore, the higher 32-bits of start address are zero.

Programmed value of Base Address Registers in configuration space:

- PCIE_IB_BAR1: 0x11110000
- PCIE_IB_BAR2: 0x22220000

Table 11-2569. Mapping Multiple Non-Contiguous Memory Ranges to One Region

IB Region	PCIE_IB_BAR	PCIE_IB_START_ADDR	PCIE_IB_OFFSET	TLP Address	Translated Address
0	1	0x11110000	0x33330000	0x11110080	[0x11110080 - 0x11110000] + 0x33330000 = 0x33330080
1	1	0x11118000	0x44440000	0x11119000	[0x11119000 - 0x11118000] + 0x44440000 = 0x44441000
2	2	0x22220000	0x55550000	0x22220400	[0x22220400 - 0x22220000] + 0x55550000 = 0x55550400
3	2	0x22220800	0x66660000	0x22231000	[0x22231000 - 0x22220800] + 0x66660000 = 0x66670800

In case there are more than one matching BAR, then the highest start address that is less than the PCIe TLP address is the one that is considered for translation.

11.14.4.9.2.2 PCIE_IB_BAR0 Exception for In-Bound Address Translation

The memory space covered by PCIE_BAR0 in inbound direction is completely dedicated to accessing the application registers, Address Space 0, in both RC and EP modes. It implies that the PCIE_BAR0 cannot be remapped to any other location but to application registers. Any remote inbound access matching the PCIE_BAR0 region will automatically be routed to these registers. It allows RC devices to control EP devices in absence of dedicated software running on EP. For RC and EP, this mapping of PCIE_BAR0 to registers allows the message signaled interrupts to work. There is no support to disable PCIE_BAR0 accesses from reaching the application registers.

11.14.4.9.2.3 Using PCIE_IB_BAR1 Value As Start Address

The inbound address translation for PCIE_BAR1 has additional capability of using the value of PCIE_BAR1 register (from PCIe configuration space) as the start address for inbound address translation. This feature can be activated by leaving the start address of the corresponding inbound translation region (one of the four regions associated to PCIE_BAR1) programmed with zero. When an incoming read/write access matches PCIE_BAR1 and the inbound region's BAR match (PCIE_IB_BARn) is set to 1 with start address programmed to zero, the PCIE_BAR1 value is used to compute the translated address.

NOTE: If this feature is used, only one inbound translation window is available and it is relative to PCIE_BAR1 programmed value. No other BARs or inbound translation windows can be used if PCIE_BAR1 is designated as the reference for inbound address translation.

11.14.4.9.3 Use of Base Address Registers (BARs)

Base address registers (BARs) are treated differently depending upon the type, Type 0 or Type 1, of the configuration space supported by the device. Typically, a RC module uses Type 1 and EP configuration uses Type 0 configuration space.

The main difference between Type 0 and Type 1 configuration space is in regarding TLP filtering. When a TLP is to be routed by its address, the address range in the BAR will decide whether the TLP is rejected or accepted. In the case of an EP, if the address is in the range configured in the BAR, the EP will accept the TLP and pass it to the internal bus side. In the case of RC, if the address is in the range configured in the BAR or is outside of the range defined by the three Base/Limit register sets (non-prefetchable memory, prefetchable memory, and I/O), and then that TLP is accepted.

These three Base/Limit registers contain the address ranges setup for all of the downstream devices:

- Memory Limit and Base Register (PCIE_MEMSPACE)
- Prefetchable Memory Limit and Base Register (PCIE_PREFETCH_MEM). Prefetchable Memory Base Upper 32 bits Register (PCIE_PREFETCH_BASE) and Prefetchable Limit Upper 32 bits Register (PCIE_PREFETCH_LIMIT) are used as well for 64-bit addressing.
- I/O Base and Limit Upper 16 bits Register (PCIE_IOSPACE)

Therefore, any TLP coming into the RC with the downstream address within the range means that it is intended for a device somewhere downstream of RC, and therefore it has been misrouted and will be rejected by the RC filter. TLPs with an address outside the range of the Base/Limit registers are given to the RC application.

For an RC port, the use of BAR register is applicable only when the RC port itself has a memory that can be targeted from the PCIe link. The BAR range in the RC is normally must be outside of the three Base/Limit regions. In a normal system setup, the system memory would be connected on the host/CPU bus. This host/CPU is the initiator/completer for TLPs. To access a downstream device, the host/CPU would initiate a request that is forwarded by the RC port to either a switch or an EP device. Completions (if any), for this request are given to the host/CPU application. If a downstream EP wants to access the system memory, it would initiate a request with an address range outside of the RC port Base/Limit registers. That TLP will be forwarded to the host/CPU interface. If the BAR range in RC is inside of the three Base/Limit regions, the TLP with the address targeted to the RC BAR range will still be accepted by RC.

11.14.4.9.3.1 BAR Mask Registers

The BARs are accessible in both EP and RC modes by the device itself via internal bus. The BARs in EP devices are usually programmed by RC during the PCIe configuration process. Because the PCIe SS is a Dual Mode (DM) core, prior to the time when PCIe configuration starts, the PCIe SS EP device has the opportunity to modify the behavior of BAR registers prior to RC starts the enumeration process and assignment of PCIe Base Address. Using the BAR Mask registers, which are overlaid on the BAR registers, the software on the EP device can configure the amount of address space that the EP will request from the RC during configuration for each of its BARs. The software can also modify the BAR types and can enable/disable the BARs. That is, the read-only bit fields of BARs are user-programmable and is required to be programmed prior to the enumeration process begins.

NOTE: The BAR Mask registers are accessible, for configuration purposes of the BARs, in both EP and RC mode and only when DBI_CS2 bit in PCIE_CMD_STATUS is enabled.

The software needs to clear PCIE_CMD_STATUS [DBI_CS2] after initial configuration prior to RC starts enumeration. The software needs to always read back the written value to DBI_CS2 after modification to ensure that the write has completed because the read will not happen until the write completion. And the read back should be done in both cases of enabling and disabling the DBI_CS2 bit.

The BAR Mask registers are writable but not readable. The read back value will be the BAR registers values instead of BAR Mask registers.

In order to verify if the BAR Mask registers have been set correctly, software writes test pattern into BAR registers and then sees if the bits have been masked correctly.

For example, if PCIE_BAR0 is 32-bit BAR, enable DBI_CS2 bit, write PCIE_BAR0_MASK = 0x00003FFF, disable DBI_CS2 bit, write PCIE_BAR0 = 0xFFFFFFF0, then PCIE_BAR0 should be read as 0xFFFFC000, as the lower bits of PCIE_BAR0 have been masked.

It is important to not attempt modification of BAR Mask registers from serial link side as unpredictable behavior may occur and the system would become unusable.

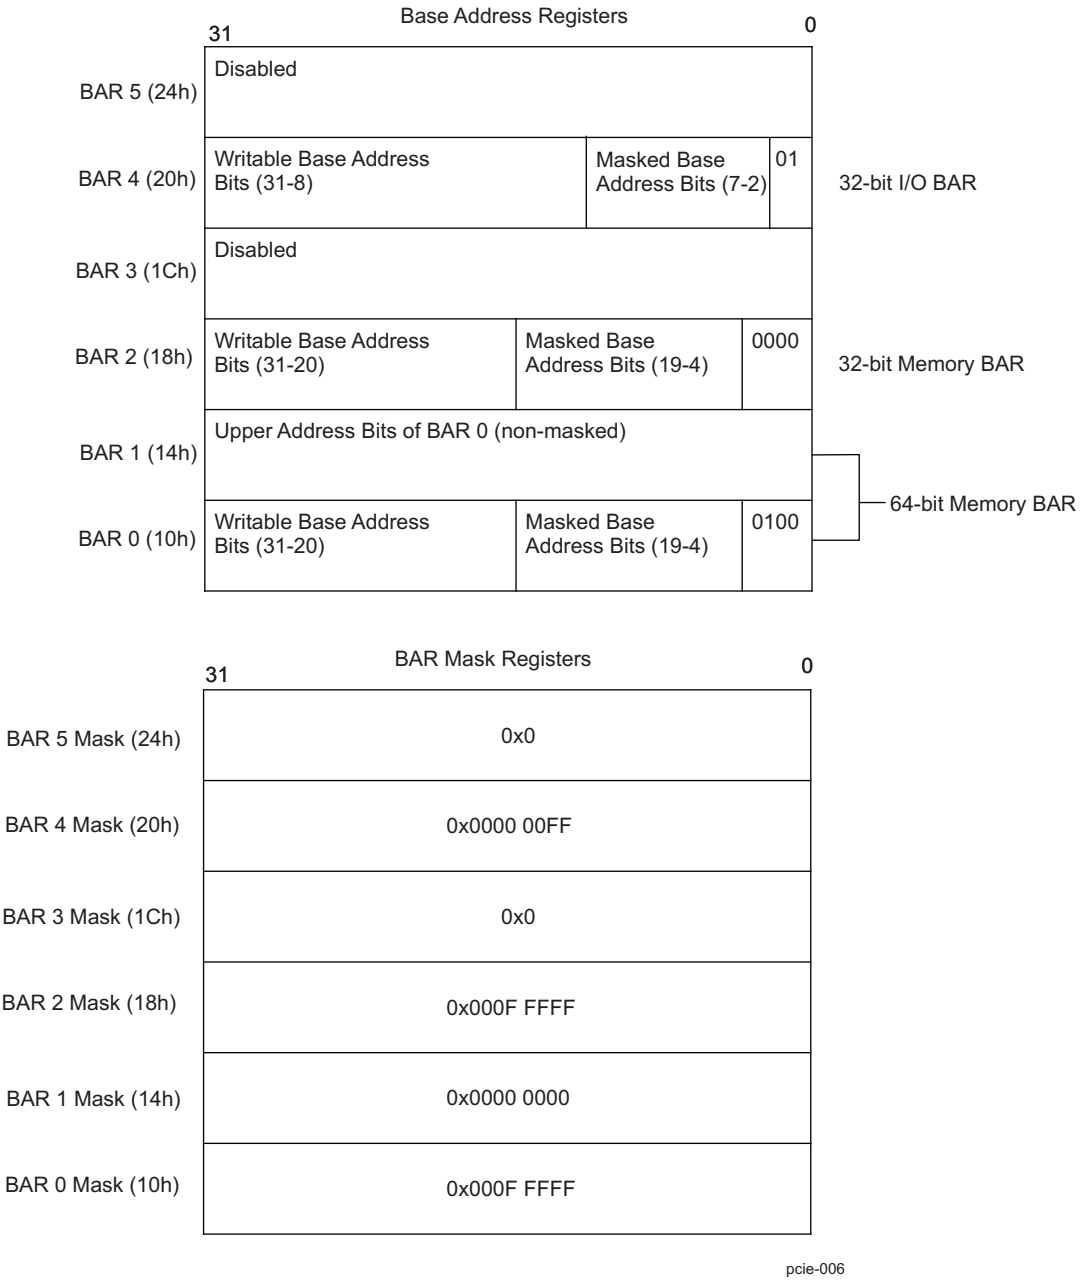
The PCIE_BAR0 Mask register in both RC and EP modes is fixed because PCIE_BAR0 is completely dedicated to accessing the application registers. Only bits [31-20] in PCIE_BAR0 are configurable. Refer to section Section 11.14.4.9.2.2 for more details.

11.14.4.9.3.2 Example BAR Setup

Figure 11-1095 shows an example configuration of the six BARs and their corresponding BAR Mask Registers (EP mode). The example configuration includes:

- One 64-bit memory BAR (non-prefetchable)
- One 32-bit memory BAR (non-prefetchable)
- One 32-bit I/O BAR

Figure 11-1095. Example Base Address Register Configuration



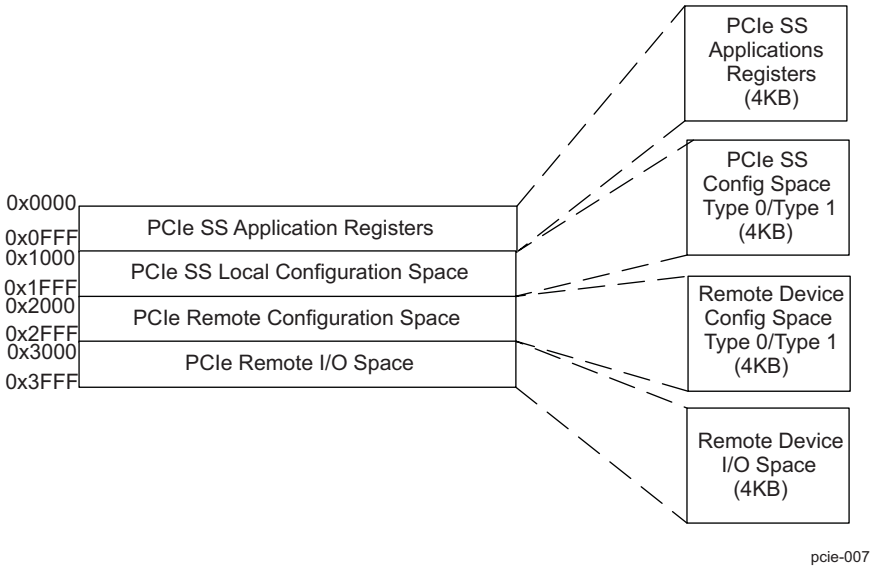
11.14.4.10 PCIe Address Spaces

PCIe SS has two VBUSM regions.The first (Address Space 0) is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote I/O accesses (RC only). The second (Address Space 1) is dedicated for data transfer.

11.14.4.10.1 Address Space 0

Address Space 0 occupies a contiguous 16KB of memory partitioned into 4 regions with equal sizes (each 4KB long). Figure 11-1096 illustrates the relationship of the various address regions within the Address Space 0.

Figure 11-1096. Mapping of the PCIe SS Address Space 0



Each of the four regions is meant for accessing a set of registers.

1. **PCIe SS Application Registers** – These registers are used to configure and monitor various settings within the PCIe SS. These registers are specific to the application needs and are not related to the PCIe configuration registers. All PCIe SS application registers should be accessed in 32-bit mode even if the PCIe SS data bus is wider than 32 bits.

   The application registers are accessible in multiple ways depending on the point of origin of such accesses. When accessed from the device internal bus slave, these registers are accessed via the 4KB space in Address Space 0. When accessed from the PCIe serial link side, the application registers are mapped to PCIE_BAR0 of an EP as well as RC. In addition, a RC can access these registers in a PCIe EP via the upper 1KB space of the PCIe configuration space. The offsets of the registers do not change irrespective of what the mode of accessing these registers is.
2. **PCIe Local Configuration Registers** – These registers are used to read the settings of configuration registers of the local PCIe device. Prior to PCIe configuration is complete, these registers can also be written to. Depending upon whether the PCIe SS is configured as RC or EP, the layout of these registers is either Config Space Type 0 or Type 1. All accesses on PCIe local configuration registers must be made in 32-bit mode even if the PCIe SS data bus is wider than 32 bits.
3. **PCIe Remote Configuration Registers** – PCIe remote configuration registers are accessed by first setting up the bus number, device number and function number of the remote PCIe device in one of the application register (PCIE_CFG_SETUP) and then accessing the PCI remote configuration registers as if it were the PCIe configuration space of a single PCIe function. The layout of the remote configuration registers varies based upon whether the device is an end point or a PCIe switch.
4. **PCIe I/O Access Window** – A 4KB region is dedicated for remote I/O accesses when the PCIe SS is in RC mode. Any access made on this space becomes an I/O access. The actual address in the TLP gets its base address from the PCIE_IOBASE Register value and an offset that is directly derived from the address of the internal bus access in this 4KB space.

NOTE: None of the four address ranges described support burst transactions. Only single 32-bit transactions should be issued to these addresses. These addresses should also be configured as non-cacheable address space.

CAUTION

The remote configuration and I/O transaction windows are directly mapped to internal bus space, which is why software must not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

11.14.4.10.1.1 Organization of Configuration Registers

As showed in Table 11-2570, the registers for various PCIe capabilities are linked to each other via address offsets specified in the registers themselves.

Table 11-2570. Layout of PCIe Configuration Registers

Offset From Start of Configuration Space	Register Block
0x000	PCI-Compatible Header (Type 0/1)
0x040	Power Management Capabilities Registers
0x050	MSI Capabilities Registers
0x070	PCIe Capabilities Registers
0x100	PCIe Extended Capabilities Registers
0x700	Port Logic Registers

11.14.4.10.2 Address Space 1

The second address space is used for data transfer. The BAR values setup in PCIe local configuration registers define where within the memory map of the CPU on root complex side the EPs are located. All locations other than what is setup in BAR registers of the EPs are on the RC side.

The Address Space 1 is mapped to multiple devices in RC mode. Each remote device could be allocated a portion of this memory space and any transaction that is targeted to this address space gets converted to a PCIe transaction targeted to the appropriate remote PCIe device.

11.14.4.11 DMA Support

The PCIe SS does not have DMA capabilities built into it. It has internal bus interface slave and master ports connected to the chip-level interconnect. If the PCIe SS is accessing the external PCIe device, a DMA engine can make burst-data reads and writes on the slave port of the PCIe SS. And the master port on the PCIe SS can initiate reads and writes to memory on behalf of a remote PCIe device without need of DMA. Both of the master and slave ports can be used, no matter the PCIe SS is in RC or EP mode.

11.14.4.11.1 DMA Support in RC Mode

When operating in root complex mode, a DMA controller internal to the device (outside of the PCIe SS) can perform DMA to and from any remote device located on the PCIe fabric. The memory address of such devices is available to the software via the PCIe bus enumeration procedure. In addition, PCIe SS has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

There are bandwidth implications of using an external DMA. If the PCIe core has been programmed to establish a link in the PCIe 2.5 Gbps rate, then the DMA controller that drives the PCIe SS slave port must be able to write/read data at about 85% of 2 Gbps bandwidth per PCIe link. For a PCIe link speed of 5.0 Gbps, the DMA controller must be able to provide bandwidth of about 85% of 4 Gbps per PCIe link.

In addition, the master port on PCIe port can issue read/write accesses that have been initiated by a remote PCIe device. The interconnect fabric should provide sufficient capacity to serve 85% of 2 Gbps (4 Gbps in Gen2 mode) per PCIe link in each direction.

11.14.4.11.2 DMA Support in EP Mode

When operating as a PCIe EP, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe RC device. Any PCIe transactions destined for the device from the upstream ports get transferred to the master port on PCIe SS. Similarly, any transactions originating from the software is sent over to PCIe link.

In end point mode, the PCIe SS provides address translation functionality. It is possible to map I/O, config and memory accesses originating on PCIe side to memory accesses with different address on the internal bus side. These address ranges are configurable through application registers.

The approximate data rate for each of these transactions will be about 85% of 2 Gbps (4 Gbps in Gen2 mode) in each direction on each PCIe lane.

11.14.4.11.3 EDMA Transfer Examples

11.14.4.11.3.1 Memory Write Transfer

Example 11-8 details how to perform an EDMA transfer from the device source (for example, L2 or EMIF) to PCIe memory. For the EDMA configuration, see Chapter 10, *Enhanced Direct Memory Access (EDMA) Controller*.

Example 11-8. Memory Write

```
/* Configure PCIe SS module and prepare transfer parameters*/
/* Initialize the PCIe SS module */
/* Define payload size and buffer size */
PCIE_max_payload = 128; /* Assume PCIe maximum payload size is 128 bytes */
buff_size = 2048; /* Assume the transfer buffer size 2048 bytes */
/* Define PCIe data starting address for EDMA transfer */
PCIEAddr = <PCIe data address defined in the device Data Manual>
...
```

Example 11-8. Memory Write (continued)

```
/* Setup EDMA module and enable the DMA region */
/* setup EDMA PARAM */
/* The OPT register contains following bit fields:
ITCCHEN = 0x0; TCCHEN = 0x0; ITCINTEN = 0x0; TCINTEN = 0x1;
TCC = 0x0; TCCMODE = 0x0; FWID = 0x0; STATIC = 0x0; SYNCDIM = 0x1; DAM = 0x0; SAM = 0x0 */
paramSetup_PCIE.option = CSL_EDMA3_OPT_MAKE(0,0,0,1,0,0,0,0,1,0,0);
paramSetup_PCIE.aCntbCnt = CSL_EDMA3_CNT_MAKE(PCIE_max_payload,
buff_size/PCIe_max_payload);
paramSetup_PCIE.srcDstBidx = CSL_EDMA3_BIDX_MAKE(PCIE_max_payload,PCIe_max_payload);
paramSetup_PCIE.srcDstCidx = CSL_EDMA3_CIDX_MAKE(0,0); paramSetup_PCIE.cCnt = 1;
paramSetup_PCIE.linkBcntrld = CSL_EDMA3_LINKBCNTRLD_MAKE(CSL_EDMA3_LINK_NULL,0);
paramSetup_PCIE.srcAddr = (Uint32)srcAddr;
paramSetup_PCIE.dstAddr = (Uint32)PCIEAddr;
/* Setup EDMA Channel */
/* Enable the EDMA Channel */
/* Wait for a transmit completion */
```

11.14.4.11.3.2 Memory Read Transfer

Example 11-9 details how to perform an EDMA transfer from PCIe memory to the device destination (for example, L2 or EMIF). For the EDMA configuration, see Chapter 10, *Enhanced Direct Memory Access (EDMA) Controller*.

Example 11-9. Memory Read

```
/* Configure PCIe SS module and prepare transfer parameters*/
/* Initialize the PCIe SS module */
/* Define payload size and buffer size */
PCIE_max_payload = 128; /* Assume PCIe maximum payload size is 128 bytes */
buff_size = 2048; /* Assume the transfer buffer size 2048 bytes */
/* Define PCIe data starting address for EDMA transfer */
PCIeAddr = <PCIe data starting address defined in the device Data Manual>
...
/* Setup EDMA module and enable the DMA region */
/* Setup EDMA PARAM */
/* The OPT register contains following bit fields:
ITCCHEN = 0x0; TCCHEN = 0x0; ITCINTEN = 0x0; TCINTEN = 0x1;
TCC = 0x0; TCCMODE = 0x0; FWID = 0x0; STATIC = 0x0; SYNCDIM = 0x1; DAM = 0x0; SAM = 0x0 */
paramSetup_PCIE.option = CSL_EDMA3_OPT_MAKE(0,0,0,1,0,0,0,0,1,0,0);
paramSetup_PCIE.aCntbCnt = CSL_EDMA3_CNT_MAKE(PCIE_max_payload,
buff_size/PCIe_max_payload);
```

Example 11-9. Memory Read (continued)

```
paramSetup_PCIE.srcDstBidx = CSL_EDMA3_BIDX_MAKE(PCIE_max_payload,PCIe_max_payload);
paramSetup_PCIE.srcDstCidx = CSL_EDMA3_CIDX_MAKE(0,0); paramSetup_PCIe.cCnt = 1;
paramSetup_PCIE.linkBcntrld = CSL_EDMA3_LINKBCNTRLD_MAKE(CSL_EDMA3_LINK_NULL,0);
paramSetup_PCIE.srcAddr = (Uint32)PCIeAddr;
paramSetup_PCIE.dstAddr = (Uint32)dstAddr;
/* Setup EDMA Channel */
/* Enable the EDMA Channel */
/* Wait for a transmit completion */
```

11.14.4.12 PCIe Transactions

11.14.4.12.1 Transaction Requirements

There are some requirements that must be adhered to when issuing transactions to the PCIe SS internal bus interface.

11.14.4.12.1.1 Bus Mastering

An end point that is capable of becoming a bus master and initiate transactions in upstream direction must have its Bus Master Enable bit set in configuration space registers (PCIE_STATUS_COMMAND[BUS_MASTER]). If transactions are initiated (while assuming the role of a RC or EP) before enabling bus mastering capability, then transactions will not start until the bus master enable is set. There is no timeout or error response generated when transactions does not go out because of bus master bit not being set.

11.14.4.12.1.2 Address Alignment Requirements

The limit on transaction size on the internal bus interface is 128 bytes. Therefore, the transactions must be 128 bytes or smaller on the internal bus interface. If a transaction received in the inbound direction crosses a 128-byte-aligned address, then the PCIe SS master interface can split such transaction into two transactions at the 128-byte boundary.

If the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. Unspecified behavior will occur if misaligned transactions in outbound direction are not limited to 120 bytes.

11.14.4.12.1.3 Burst Type Requirements

The PCIe SS does not support *fixed* or *wrap* burst types. Transactions that required any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

11.14.4.12.1.4 Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). PCIe core is guaranteed to not interleave read responses if the outbound read command/transaction size does not exceed the max transaction size configured in the PCIe core. Currently this is configured as 128 bytes.

11.14.4.12.1.5 Byte Strobe Requirements

For any type of write transactions, the byte enables can have only a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. *Holes* or *0s* in between the byte enables are not allowed.

Because the internal bus width is greater that 32-bit, the TLP size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

11.14.4.12.2 Support for Endian Modes

The PCIe core supports only little-endian mode (at the pins). The PCIe SS of the device also supports only little-endian mode.

11.14.4.13 Operations

11.14.4.13.1 PCIe as Root Complex

11.14.4.13.1.1 Initialization Sequence

The initialization sequence is as follows:

1. Make sure PLL reference clock is running.
2. Turn on the power domain and clock domain of PCIe module. See Section 5.2, *Power Management*, for more details.
3. Set PCIE_DEV_TYPE to 0b10 in the device level register BOOTCFG_DEVCFG to operate the PCIe SS in RC mode, see Section 5.1, *Control Module (BOOT_CFG)*.
4. Enable PLL using PCIE_PHY_PLL_CTRL register, see Section 11.14.4.8.1, *Enabling the PLL*, for details.
5. Wait until PLL is locked by sampling PLL_OK bit in the PCIE_PHY_PLL_CTRL register. See Section 11.14.4.8.1, *Enabling the PLL*, for details.
6. Disable link training by de-asserting the LTSSM_EN bit in the PCIe SS Command Status Register (PCIE_CMD_STATUS[LTSSM_EN] = 0). Upon reset, the LTSSM_EN is de-asserted automatically by hardware.
7. Program the configuration registers in the PCIe SS to desired values.
8. Initiate link training can be initiated by asserting LTSSM_EN bit in the PCIE_CMD_STATUS register (PCIE_CMD_STATUS[LTSSM_EN] = 1).
9. Insure link training completion and success by observing LTSSM_STATE field in PCIE_DEBUG0 register change to 0x11.
10. In conjunction with the system software, start bus enumeration and setup configuration space on downstream ports.
11. Continue software handshake and initialization on the remote devices. This includes setting up DMA protocols, interrupt procedures, and so forth.
12. With the completion of software initialization, DMA accesses can be started on various end points.

11.14.4.13.1.2 Configuration Accesses

Configuration accesses are made by RC port to individual function in each downstream EP device to program the PCIe specific operating parameters. In particular, the configuration accesses are used to allocate memory ranges for each downstream device, configure those memory ranges as I/O or Memory type, enable bus master capability on the device if necessary and also build a software database of PCIe attributes and capabilities of each downstream device. Each downstream device can be configured through the configuration access region of the PCIe SS. The PCIe SS converts memory reads and writes on the configuration region of internal bus interface into configuration access on the serial link.

11.14.4.13.1.3 Memory Accesses

There are two types of memory accesses – inbound and outbound memory accesses. The outbound memory accesses that are initiated by the DMA on the PCIe SS slave port and the inbound memory accesses that are initiated by the PCIe SS master port targeted to internal memory regions within the internal bus interconnect.

The outbound PCIe memory read and write accesses are made through the PCIe SS slave port through the device memory range that is dedicated to data transfers. The read and write transactions on this region are directly mapped to PCIe space by the PCIe SS in conjunction with the outbound address translation mechanism.

The completions to the bus transactions are generated by the PCIe SS when it receives completions from remote devices. In case of errors or timeouts, an error response is provided. For reads, the error responses span as many phases as there would be data phases if the error had not occurred.

The inbound memory accesses received by the PCIe SS on the serial link are initiated by remote PCIe end points that are capable of bus mastership. Such accesses are converted to bus transactions on the PCIe SS master port and once a response/completion is received, the PCIe SS sends data/response back to the PCIe bus master over the serial links. Typically, the inbound accesses will be targeted to memory space resident on the bus side of the RC port. The locations to which inbound memory accesses map are determined by software. The software must inform the remote devices about what protocol is to be followed so that the remote device will access the relevant memory regions to read or write data/control information. Not all end points have the capability to initiate inbound accesses.

An inbound access cannot cross a 4-KB boundary as per PCIe Specifications. In addition, any access that spans a 128-byte boundary in the device memory map can get split into two transactions at the 128-byte boundary.

11.14.4.13.1.4 I/O Accesses

The PCIe SS supports outbound I/O accesses in RC mode. These accesses are initiated through a 4-KB memory space and a programmable register. All accesses made to the 4-KB space become I/O accesses and the I/O base register determines the target address for such accesses. The I/O accesses cannot be for more than 32-bits of data aligned at a 4-byte boundary. See Chapter 2, *Memory Map*, for location of the I/O access address range. Inbound I/O accesses are not supported in the PCIe SS RC mode.

11.14.4.13.2 PCIe as End Point

11.14.4.13.2.1 Initialization Sequence

Upon de-assertion of reset, the PCIe SS is configured as end point by chip-level setting in DEVCFG register, see Section 5.1, *Control Module (BOOT_CFG)*. Before a root complex is allowed to access the configuration space of the end point, the following initialization sequence should be followed:

1. Make sure PLL reference clock is running.
2. Turn on the power domain and clock domain of PCIe module. See Section 5.2, *Power Management*, for mare details.
3. Set PCIE_DEV_TYPE to 0b0 in the device level register BOOTCFG_DEVCFG to operate the PCIe SS in RC mode, see Section 5.1, *Control Module (BOOT_CFG)*.
4. Enable PLL using PCIE_PHY_PLL_CTRL register, see Section 11.14.4.8.1, *Enabling the PLL*, for details.
5. Wait until PLL is locked by sampling PLL_OK bit in the PCIE_PHY_PLL_CTRL register, see Section 11.14.4.8.1, *Enabling the PLL*, for details.
6. Disable link training by de-asserting the LTSSM_EN bit in the PCIe SS Command Status Register (PCIE_CMD_STATUS[LTSSM_EN] = 0). Upon reset, the LTSSM_EN is de-asserted automatically by hardware.
7. Program the configuration registers in the PCIe SS to desired values.
8. Initiate link training can be initiated by asserting LTSSM_EN bit in the PCIE_CMD_STATUS register (PCIE_CMD_STATUS[LTSSM_EN] = 1).
9. Insure link training completion and success by observing LTSSM_STATE field in PCIE_DEBUG0 register change to 0x11.
10. If further configuration register initialization is required, the application request retry bit (APP_RETRY_EN) should be set in PCIE_CMD_STATUS register. This will lead to incoming accesses to be responded with the retry response. This feature allows slow devices extra time before the root port assumes the devices to be inactive. Once programming is complete, de-assert the APP_RETRY_EN bit to allow transactions from the root complex
11. Once configuration setup is complete, DMA transactions can begin.
12. Inbound PCIe transactions will arrive at the master port of the PCIe SS end point. These will be responded to by the target slave devices and the PCIe SS will relay the response back to the PCIe device that initiated the transaction.
13. Outbound PCIe transactions will be targeted to the slave port of the PCIe SS end point. These transactions will be serviced only if the PCIe SS end point has been given bus master capability by the

root complex.

11.14.4.13.2.2 Configuration Accesses

As an end point, the PCIe SS can be only a target of configuration accesses from upstream. Until the link is established and APP_RETRY_EN is disabled, the PCIe SS will not respond to configuration accesses. When enabled, the PCIe SS will respond to configuration accesses automatically and these accesses do not get relayed to the master interface on the device interconnect side.

End point is not capable of accessing configuration space of devices other than its own. The system software can initialize the read-only fields in the PCIe SS configuration space via the slave port before the link training has been initiated. Once the configuration is complete by the PCIe root complex, the system software should not modify the PCIe SS configuration parameters. There is no explicit prevention mechanism in hardware to disallow such accesses though.

11.14.4.13.2.3 Memory Accesses

There are two types of memory accesses – inbound and outbound memory accesses.

An inbound access is typically initiated by a RC port or by another EP that is reaching the PCIe SS via a PCIe switch that supports peer-to-peer access. In either case, the incoming PCIe transaction results in an access on the PCIe SS master port. The response to such accesses is relayed back to the originating PCIe device.

In an outbound access, a DMA module or a host CPU initiates a read/write access on the PCIe SS slave port. This request is converted into a PCIe memory read/write transaction over the PCIe link. Once the PCIe SS receives completion from the remote device, it generates a completion on the internal bus slave port. The software/hardware that initiates the request on the slave port must perform it in a memory region that has been determined previously through software protocols. For example, the software may get information about applicable memory regions from the software that is running on the root complex device.

11.14.4.13.2.4 I/O Accesses

The PCIe SS in EP mode does not support inbound or outbound I/O accesses.

11.14.4.13.3 Accessing Read-Only Registers in Configuration Space

Some of the register fields provided in the configuration space can be written to prior to bus enumeration via the slave interface of the PCIe SS.

NOTE: The hardware does not prevent modification of read-only fields after bus enumeration but it is strongly advised that read-only fields not be written once the bus enumeration is complete.

In addition, the BAR Mask registers can also be programmed by first enabling the DBI_CS2 bit in PCIE_CMD_STATUS register and then performing writes on the BAR registers. The BAR Mask registers are overlaid on BAR registers. For the BAR Mask registers to be writable, the respective BAR must first be enabled.

11.14.4.13.4 Accessing EP Application Registers from PCIe RC

The application registers are also mapped at 2K and above address in the configuration space. The RC software can access these registers over the PCIe link provided the registers are programmed to some default values by the boot code in the PCIe SS host device that enables link training and TLP exchange.

11.14.4.14 PCIe Loopback

The PCIe Specifications provides loopback support in two ways:

- Through PIPE interface (Link Layer)
- Through PHY loopback capability (PHY Layer)

The PIPE interface loopback requires for two PCIe devices/components to attached to each other in a loopback master and a loopback slave configuration. A loopback master is the component requesting loopback. A loopback slave is the component looping back the data. Regardless with the PCIe SS role it assumes (RC or EP), it can assume a role of a loopback master or a loopback slave.

11.14.4.14.1 PIPE Loopback

The procedure depends upon whether the device is operating in RC or EP mode. In either case, the PCIe SS can be loopback master or loopback slave as outlined in the PCIe Specifications. These modes are to be used with PCIe test equipment only for symbol level loopback.

NOTE: PIPE loopback mode cannot be used for looping back transactions.

11.14.4.14.1.1 Loopback Master

The loopback path when PCIe SS is loopback master is:

1. PCIe SS
2. PIPE (TX)
3. PCIe Link
4. Loopback
5. PCIe Link
6. PIPE (RX)
7. PCIe SS

The loopback entry procedure when the PCIe SS is a loopback master:

RC Mode

1. Set Loopback Enable bit (LPBK_EN) in the Port Link Control Register (PCIE_PL_LINK_CTRL).
2. The link retraining sequence must be initiated by setting Retrain Link bit (RETRAIN_LINK) in the Link Status and Control Register (PCIE_LINK_STAT_CTRL).

EP Mode

1. Set Loopback Enable bit (LPBK_EN) in the PCIE_PL_LINK_CTRL Register.
2. Force the LTSSM to be in recovery state via the Link State field (LINK_STATE) in Port Force Link Register (PCIE_PL_FORCE_LINK).
3. Set Force Link bit (FORCE_LINK) in PCIE_PL_FORCE_LINK Register.

Once this is done, devices at the ends of a PCIe link enter the PCIe LTSSM loopback state. The initiator of loopback state is the loopback master and the other device is the loopback slave.

NOTE: Sending TLPs in Loopback Master EP mode and returning them via the loopback state of the other device are not possible.

11.14.4.14.1.2 Loopback Slave

The loopback path when the PCIe SS is loopback slave is:

1. Remote device
2. PCIe Link
3. PIPE (RX)

4. Loopback
5. PIPE (TX)
6. PCIe Link
7. Remote device

If the PCIe SS is a loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition the PCIe SS into the loopback slave state following which the inbound transactions will be looped back to the test equipment. There is no programming required on the PCIe SS to enter loopback in slave mode. PHY support is not required to use this loopback mode.

11.14.4.14.2 PHY Loopback

The PHY loopback is accomplished by switching the PHY to loopback where the transmitted data is looped back to the receive path at the PHY level. This mode can be used to perform TLP loopback even if there is no link partner. It is, however, possible to set up only when the PCIe SS is used in RC mode. This limitation is because of the fact that link training cannot occur between two upstream ports; at least one port must be a downstream port.

The loopback path in PHY loopback is:

1. Slave interface (TX)
2. PCIe SS
3. PHY (TX)
4. PHY (RX)
5. PCIe SS
6. Master Interface (RX)

The procedure is similar to the one for PIPE (Link Layer) interface but the PHY programming is used instead. This mode is entered by configuring the SERDES configuration registers. Both the Transmit and Receive paths must be set in loopback mode to enable PHY loopback mode.

PHY loopback configuration for the device:

- Follow the steps (up to Step 7) described in Section 11.14.4.13.1.1, *Initialization Sequence*, for RC mode.
- Before executing Step 8, the software should configure the SERDES configuration registers to set Transmit and Receive paths to be in loopback mode, see Section 11.14.5.1, *SERDES Configuration Registers*.
- Then initialize link training (Step 8 in Section 11.14.4.13.1.1, *Initialization Sequence*).
- Before checking link training status (Step 9 in Section 11.14.4.13.1.1, *Initialization Sequence*), it is required to skip Detect state in LTSSM and force link to begin with POLL_ACTIVE state.
  - Set 0x2 (POLL_ACTIVE state) in LNK_STATE field of PCIE_PL_FORCE_LINK Register PCIE_PL_FORCE_LINK[LINK_STATE] = 0x2).
  - Set 0x1 in FORCE_LINK field of PCIE_PL_FORCE_LINK register to force the link to the state specified by LINK_STATE field (PCIE_PL_FORCE_LINK[FORCE_LINK] = 0x1).
- Then insure link training completion (Step 9 in Section 11.14.4.13.1.1, *Initialization Sequence*).
- With the initialization above, the PCIe SS should be configured in PHY loopback mode.

For proper operation the following requirements should also be observed:

1. The PHY should be configured to operate in loopback mode before any transaction is sent out. Recommended approach is to set loopback before link training. Otherwise, any transactions that were not looped back will cause sequence numbers to increment on transmitter but not on receiver and all following transactions will be dropped because of sequence number mismatch.
2. The PCIE_BAR0 and PCIE_BAR1 values (if programmed) should not match the address for the transaction that is issued on slave interface. Otherwise, it will not get to the master port but to internal registers.
3. The memory Base/Limit registers should not be configured such that the address of the transaction lies

in the range specified by the memory Base/Limit registers. Otherwise, the transaction will be discarded as a misrouted packet.

4. It is not possible to use configuration type transactions in this mode as RC cannot be a target of configuration transactions. Such transactions will be invalid and loopback will not work.

11.14.4.15 Reset Considerations

The PCIe SS supports the conventional reset mechanism that is specified within the PCIe Specification. Both hardware and software resets are supported.

No support for the functional level reset is needed because the PCIe SS supports a single function.

11.14.4.15.1 Hardware Reset Considerations

11.14.4.15.1.1 Power-On Reset

The power-on reset is used as cold reset of the PCIe SS. The entire device is reset when power-on reset is asserted. The device level power-on reset acts as the power-on reset for the PCIe SS.

NOTE: The PCIe SS requires power-on reset in case the device software transitions the subsystem to certain power-down states that mandate power-on reset to exit.

11.14.4.15.1.2 System Reset

The PCIe system reset is a warm reset, which can be hard reset or soft reset. The hard reset resets the entire PCIe SS. Soft reset resets the entire PCIe SS except the sticky bits in registers and power management logic inside the PCIe. See Section 5.3, *Reset Management*, for details.

11.14.4.15.2 Software Reset Considerations

The PCIe SS module contains a software reset (INIT_RST) bit in the Reset Command Register (PCIE_RSTCMD) that is used to issue a hot reset. In general, this reset is software controlled procedure and can be issued only by a root complex in a PCIe network as the propagation is downstream only. As a result of a reset, the PCIe SS module register values go to their reset state except the sticky bits. The default states of the registers are shown in Section 11.14.5, *PCIe Registers*.

NOTE: After a reset, the software must wait a determinate period of time before attempting any PCIe transaction on the device that has been reset. See the device Data Manual for the concrete value.

11.14.4.15.3 Power Domain and Module State Transitions Considerations

Turning off the PCIe power domain and module state and turning them back on reset PCIe module to initial state. However, the user must ensure that all of the outbound and inbound traffic on PCIe link is stopped from both the local device and the remote device. If a system hang occurs from improperly turning off PCIe module, the user may need to apply device power-on reset to recover the system.

To turn on and off the power domain and module state, the user must follow the transition sequence and check the transition status bit field (GOSTAT), see Section 5.2.2, *Power Sleep Controller (PSC)*. There is no additional delay requirements from when the PCIe power domain is turned on until it is ready for use.

After turning PCIe module back on, the link training must be restarted following any internal configuration that software may need to perform.

11.14.4.16 Interrupt Support

The PCIe SS provides a total of fourteen interrupts to the device interrupt controller.

Both message signaled interrupt (MSI) and legacy interrupt are handled by the PCIe SS. When operating as an EP, the PCIe SS is capable of generating MSI or legacy interrupt, depending on the role it is assuming.

NOTE: One PCIe component can not generate both types of interrupts.

It is either one or the other. The interrupt type an EP generates is configured during configuration time. When operating as RC, the PCIe SS is capable of handling both MSI and legacy interrupts. This is because when operating as RC it should be able to service both PCIe end points as well as legacy end points.

11.14.4.16.1 Interrupt Allocation

Multiple events from the PCIe SS are mapped to CPU subsystem in the device. The PCIe SS provides a total of fourteen interrupts to the device interrupt controller. Some of the events are meaningful based on the role the PCIe SS assumes (RC or EP). The interrupts and their underlying events are listed below.

Table 11-2571. PCIe SS Interrupt Events

Interrupt Event Number	Interrupt Description
0	PCIe legacy interrupt mode – INTA (RC mode only)
1	PCIe legacy interrupt mode – INTB (RC mode only)
2	PCIe legacy interrupt mode – INTC (RC mode only)
3	PCIe legacy interrupt mode – INTD (RC mode only)
4	MSI interrupts 0, 8, 16, 24 (EP/RC modes)
5	MSI interrupts 1, 9, 17, 25 (EP/RC modes)
6	MSI interrupts 2, 10, 18, 26 (EP/RC modes)
7	MSI interrupts 3, 11, 19, 27 (EP/RC modes)
8	MSI Interrupts 4, 12, 20, 28 (EP/RC modes)
9	MSI Interrupts 5, 13, 21, 29 (EP/RC modes)
10	MSI Interrupts 6, 14, 22, 30 (EP/RC modes)
11	MSI Interrupts 7, 15, 23, 31 (EP/RC modes)
12	Error Interrupts • [0] System error (OR of fatal, nonfatal, correctable errors) (RC mode only) • [1] PCIe fatal error (RC mode only) • [2] PCIe non-fatal error (RC mode only) • [3] PCIe correctable error (RC mode only) • [4] AXI Error due to fatal condition in AXI bridge (EP/RC modes) • [5] PCIe advanced error (RC mode only)
13	Power management and reset event interrupts • [0] Power management turn-off message interrupt (EP mode only) • [1] Power management ack message interrupt (RC mode only) • [2] Power management event interrupt (RC mode only) • [3] Link request reset interrupt (hot reset or link down) (RC mode only)

11.14.4.16.2 Interrupt Generation in EP Mode

When the PCIe SS is operating as an EP, either the legacy interrupts or the MSI interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RC device). As per PCIe Specifications, each PCIe function may generate only one of the legacy or MSI interrupt types as decided during configuration period.

11.14.4.16.2.1 Legacy Interrupt Generation in EP Mode

The end point can trigger generation of a PCI legacy interrupt at the root complex via an in-band Assert_INTx/Deassert_INTx message. The actual interrupt that is generated on RC port is based on the configuration of the EP that generates the interrupt and it could be one of INTA, INTB, INTC, or INTD. See the interrupt-related registers in configuration space registers for details Section 11.14.5.3, *Application Registers*.

To generate an interrupt, following steps are required:

1. Legacy interrupt generation should be enabled via PCIE_LEGACY_A_IRQ_ENABLE_SET, PCIE_LEGACY_B_IRQ_ENABLE_SET, PCIE_LEGACY_C_IRQ_ENABLE_SET or PCIE_LEGACY_D_IRQ_ENABLE_SET.
2. Write 0x1 to PCIE_EP_IRQ_SET register to enable the legacy interrupt
3. An assert INTA/B/C/D message is automatically sent.
4. Write 0x1 to PCIE_EP_IRQ_CLR register to disable the legacy interrupt by sending a deassert INT A/B/C/D message.

Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time. The pending status can be checked in PCIE_EP_IRQ_STATUS register.

There is no hardware input port provided that allows generation of legacy interrupts on the EP port.

NOTE: The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

11.14.4.16.2.2 MSI Interrupt Generation in EP Mode

MSI interrupts are generated by a PCIe 32-bit memory write transaction to a pre-determined address with pre-determined data. The PCIe system software configures the address and the data that is to be used in the memory write transaction at the time of initialization of the EP device. The MSI scheme supports multiple interrupts and each device can request up to 32 interrupt vectors even though the allotted interrupts may be less than the requested number.

To generate MSI interrupts, the following steps are required:

1. Ensure that the MSI support has been enabled in the device (Set MSI_EN bit in MSI Capabilities Register (PCIE_MSI_CAP). Legacy interrupt must be disabled).
2. Read the value of the MSI Address Register in the local PCIe configuration space (Read the value of MSI Lower 32 Bits Register (PCIE_MSI_LOW32) for 32-bit addressing or MSI Upper 32 Bits Register (PCIE_MSI_UP32) and MSI_LOW32 together for 64-bit addressing (64BIT_EN bit is enabled in PCIE_MSI_CAP register)).
3. Read the value of the MSI Data Register in the local PCIe configuration space (Read the value of MSI Data Register (PCIE_MSI_DATA)).
4. Determine the number of MSI vectors allocated (and the number requested) to the device.
5. Depending upon the number of MSI interrupts allocated, issue a memory write transaction with the address the same as PCIE_MSI_LOW32 and PCIE_MSI_UP32 and the data the same as the PCIE_MSI_DATA. In the data, the LSBs can be modified to reflect the appropriate MSI event that needs to be notified to root complex.
6. The memory write transaction can also be optionally routed through the outbound address translation interface if the destination PCIe address is not directly accessible.

The memory write transactions to generate MSI interrupts in RC are actually targeted at PCIE_MSI_IRQ register. The MSI interrupt is generated as a result of the one of 32 events that is triggered by a write of MSI vector value to PCIE_MSI_IRQ register in RC. Before the end point devices can issue MSI interrupts, the MSI address and data registers must be configured by system software to make sure the PCIE_MSI_IRQ registers could be accessed correctly with proper MSI vector value.

If there is no system software supported, the user application needs to make sure EP could issue memory write transaction to PCIE_MSI_IRQ register in RC with proper MSI vector value to generate MSI interrupt in RC.

For more details about how MSI interrupts are expected to behave, see the PCIe standard specifications.

As per the PCIe Specification, an EP device can generate MSI interrupts only to RC. However, the PCIe SS has a provision to allow generation of MSI interrupts from an EP to another EP. To generate an interrupt to another EP, instead of doing the memory write to a register in RC memory space, an EP can target this memory write to an analogous register in another EP device that integrates a PCIe SS. This memory write would be to the PCIE_BAR0 memory space where all registers are located.

NOTE: There is no hardware input port to allow generation of MSI interrupts on the EP port.

11.14.4.16.3 Interrupt Generation in RC Mode

In accordance with PCIe base specifications, root complex ports only receive interrupts. There is no mechanism to generate interrupts from RC port to EP mode as per PCIe Specification. However, the PCIe SS does support generation of interrupts from RC to EP. The behavior is similar to generation and reception of MSI interrupts in RC mode except for the fact that this functionality is enabled in EP mode as well.

The RC device can perform a memory write into the PCIE_MSI_IRQ register over the PCIe link to generate one of 32 EP interrupts.

NOTE: The PCIe SS follows PCIe MSI rules and does not necessarily accumulate multiple writes to the same MSI vector. Only one of such writes is guaranteed to be processed and subsequent writes on the same vector arriving before the interrupt status is cleared may be lost.

11.14.4.16.4 Interrupt Reception in EP Mode

The PCIe Specification does not have provision for end points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts. The MSI interrupts are not supported on EP devices as per PCIe Specification but the PCIe SS does support these interrupts. The MSI interrupt is generated as a result of the one of 32 events that is triggered by a write of MSI vector value to PCIE_MSI_IRQ register in EP.

These interrupts, delivered via register writes over the serial link, could also be coming from another end point that performs a write to the appropriate interrupt registers in the EP's PCIE_BAR0 space. It is up to software designers to implement a way to determine the actual source of the interrupt.

Among the 32 MSI interrupt events, every four MSI interrupts share the same interrupt event number in the PCIe SS, which could generate interrupt event to CPU. See Table 11-2571 for details. The MSI interrupts can be enabled by setting corresponding bits in PCIE_MSI0_IRQ_ENABLE_SET to PCIe_MSI7_IRQ_SET registers. They can be disabled by setting corresponding bits in PCIE_MSI0_IRQ_ENABLE_CLR to PCIE_MSI7_IRQ_ENABLE_CLR registers.

When EP receives the MSI interrupt, the corresponding status bit is set in PCIE_MSI0_IRQ_STATUS to PCIE_MSI7_IRQ_STATUS registers. Before the same MSI interrupt event to be generated again, the MSI interrupt status should be cleared by writing one to the corresponding bit in PCIE_MSI0_IRQ_STATUS to PCIE_MSI7_IRQ_STATUS registers and writing the interrupt event number in PCIE_IRQ_EOI register to indicate the end of the interrupt event. See Table 11-2571 for the interrupt event number of each MSI interrupt.

11.14.4.16.4.1 Hot Reset Request Interrupt

When the link is down, the upstream port may request reset of the end point. This request is terminated as an interrupt to the end point host software. The PCIe SS automatically disables LTSSM by de-asserting the LTSSM_EN bit in the PCIE_CMD_STATUS register and suspends LTSSM in the *detect quiet* state. All outstanding transactions are errored out on the slave port and further transactions are not generated on the master port. Once the transactions are completely stopped through the internal bus disconnect protocol, the software should issue a local reset to the PCIe SS. The re-initialization process may then be started.

11.14.4.16.5 Interrupt Reception in RC Mode

11.14.4.16.5.1 Legacy Interrupts Reception in RC Mode

Any of the four legacy interrupts may be generated by the PCIe SS. Each interrupt can originate from multiple end point devices. The software should service these by probing the interrupt registers in each downstream device's configuration space. When all devices have been serviced, the last device serviced will send an interrupt deassert message, which will clear the interrupt.

The interrupt request signal at the PCIe SS boundary is a pulse signal that is triggered each time an assert interrupt message is received. The interrupt pending signal is a level signal that is high as long as the interrupt has not be serviced and the interrupt status not cleared through a register write.

The traditional EOI procedure, although implemented, may not operate as expected if the deassert message arrives after the EOI has been issued. This cannot be corrected but only worked around by doing a read on the interrupt register downstream before issuing an EOI. If the EOI register is written to before the deassert message has reached the interrupt logic, the interrupt pending status will not have cleared and the interrupt will retrigger.

In addition, the software drivers for downstream devices must ensure that the data transaction that is expected to complete before interrupt is triggered in RC device's CPU has completed. Because PCIe write transactions are posted, it is not necessary that a write from EP to system memory in RC has completed before a write to MSI interrupt generation register has completed. This could create a potential race condition.

The reason is that the PCIe RC or switch could reorder the memory write transactions just posted ahead of previously posted memory write transactions or message transactions. Similarly, message transactions just posted may be ordered ahead of previously posted memory write or message transactions due to the relax ordering feature in PCIe. The relaxed ordering could improve the performance of the post transactions while it could potentially cause issues if the reordering is not permitted in some circumstances.

In the RC mode, the user could disable the relaxed ordering feature by clearing the RELAXED field to 0 in DEV_STAT_CTRL register. The RC could also clear RELAXED field to 0 in TLPCFG register to disable the reordering request for all outgoing TLPs.

11.14.4.16.5.2 MSI Interrupts Reception in RC Mode

A total of 32 MSI interrupts can be generated from one or more downstream devices. These MSI interrupts represent the MSI interrupts that have been allocated to various downstream devices during PCIe configuration/enumeration procedure. The MSI interrupt is generated as a result of the one of 32 events that is triggered by a write of MSI vector value to MSI_IRQ register in RC.

Among the 32 MSI interrupt events, every four MSI interrupts share the same interrupt event number in the PCIe SS, which could generate interrupt event to CPU. See Table 11-2571 for details. The MSI interrupts can be enabled by setting corresponding bits in PCIE_MSI0_IRQ_ENABLE_SET to PCIE_MSI7_IRQ_ENABLE_SET registers. They can be disabled by setting corresponding bits in PCIE_MSI0_IRQ_ENABLE_CLR to PCIE_MSI7_IRQ_ENABLE_CLR registers.

When RC receives the MSI interrupt, the corresponding status bit will be set in PCIE_MSI0_IRQ_STATUS to PCIE_MSI7_IRQ_STATUS registers. Before the same MSI interrupt event to be generated again, the MSI interrupt status needs to be cleared by writing one to the corresponding bit in PCIE_MSI0_IRQ_STATUS to PCIE_MSI7_IRQ_STATUS registers and writing the interrupt event number in PCIE_IRQ_EOI register to indicate the end of the interrupt event. See Table 11-2571 for the interrupt event number of each MSI interrupt.

Each end point can use either MSI interrupts or legacy interrupts, but not both at the same time. MSI interrupts have the same race condition hazard as the legacy interrupts. Hence, software drivers should take precaution.

11.14.4.16.5.3 Advanced Error Reporting Interrupt

If enabled by software at the time of enumeration, the PCIe SS will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable advanced error reporting. But if it is enabled, it must process the interrupt as per PCIe Specifications. The error message reporting enable bit must be set in the Root Error Command Register (PCIE_RC_ERR_CMD) to generate this interrupt. This interrupt can originate either via an MSI message or via an INTx internally in the root complex.

11.14.4.16.6 Interrupt Reception in RC and EP Mode

These interrupts are common to both RC and EP modes of operation.

11.14.4.16.6.1 Link down Interrupt

If the PHY link is disconnected, this interrupt will be generated. The expected course of action is to reset the entire PCIe SS subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

11.14.4.16.6.2 Transaction Error Interrupts

If there is a timeout on PCIe or an abort, this interrupt will be issued. These errors should be handled based upon the severity of the error. For more details, see the PCIe standard specifications.

11.14.4.16.6.3 Power Management Event Interrupt

This interrupt is generated to let the software know of power management events.

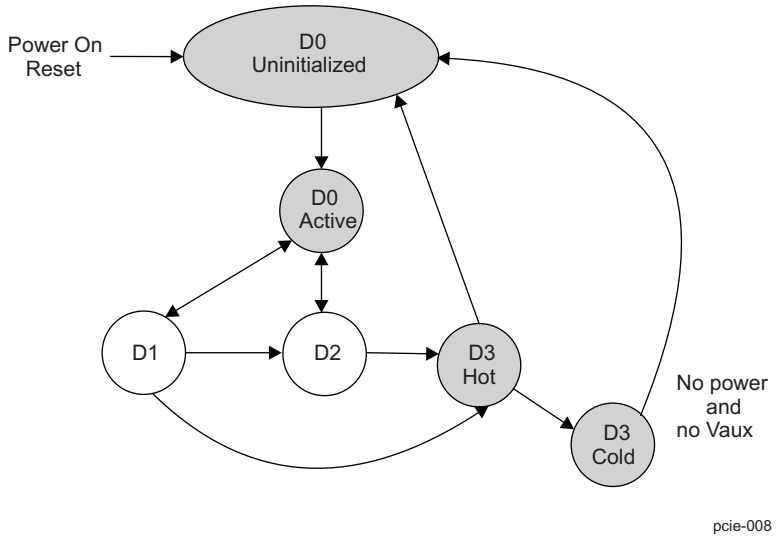
11.14.4.17 Power Management

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

11.14.4.17.1 Device Power Management

The PCIe protocol is compatible with all PCI power management functionality. The power states specified are D0, D1, D2, D3hot, and D3cold. All functions must support D0 and D3 states.

Figure 11-1097. PCIe Power Management State Transitions



11.14.4.17.1.1 D0 State

Upon completion of a reset such as a power-on or hot reset, the function is considered to be in the D0 uninitialized state. Once the function is enumerated, configured, and one or more of the memory spaces are enabled, and I/O space enable or bus master enable bits are set, it is considered to be in D0 active state. The D0 active state is the full-operation state of a PCIe function.

11.14.4.17.1.2 D1 State

Support for the D1 state is optional and is primarily driven by software. It is considered to be a light sleep state that provides some power savings compared to D0 state while still allowing transition to D0 state. While in the D1 state, a function must not initiate any request TLPs on the link except for a power management event (PME) message. Configuration and message requests are the only TLPs accepted by a function in the D1 state. All other received requests must be handled as unsupported requests, and all received completions may optionally be handled as unexpected completions. A function's software driver participates in the process of transitioning the function from D0 to D1. It contributes to the process by saving any functional state (if necessary), and otherwise preparing the function for the transition to D1. As part of this quiescence process the function's software driver must ensure that any mid-transaction TLPs (that is requests with outstanding completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D1.

11.14.4.17.1.3 D2 State

Support for the D2 state is optional in PCIe and is primarily driven by software. It provides significant power savings while still retaining capability to transition back to a previous condition. In this state, the PCI function can only initiate power management events and it can only respond to configuration accesses.

11.14.4.17.1.4 D3hot and D3cold State

All PCIe functions are required to support D3 state. In the D3hot state, power is still present while in D3cold there is no power. Devices in the D3hot state may be transitioned back to the D0 state while the devices in the D3cold state need re-initialization to be brought back to the D0 state.

NOTE: All PCIe devices support D3cold state. This state is a power off state.

Functions in D3hot respond to configuration space accesses as long as power and clock are supplied so that they can be returned to D0 by software. When programmed to D0, the function may return to the D0 Initialized or D0 Uninitialized state without PCIe reset being asserted. There is an option of either performing an internal reset or not performing an internal reset. If not performing an internal reset, upon completion of the D3hot to D0 Initialized state, no additional operating system intervention is required beyond writing the power state bits. If the internal reset is performed, devices return to the D0 Uninitialized and a full re-initialization is performed on the device. The full re-initialization sequence returns the device to D0 Initialized, where normal operation may resume.

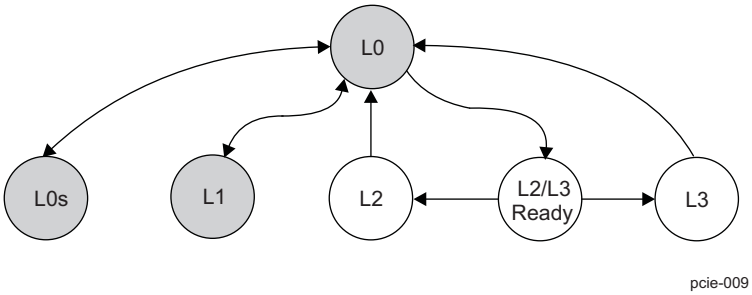
11.14.4.17.2 Link State Power Management

There are multiple states for the physical layer – L0, L0s, L1, L2, and L3 states, that provide incrementally higher power savings as the states transition from L0 toward L3. The PCIe SS supports the L0, L0s, and L1 states. The L3 state is a power–off state and is supported by default.

NOTE: The PCIe SS does not support L2 power down states.

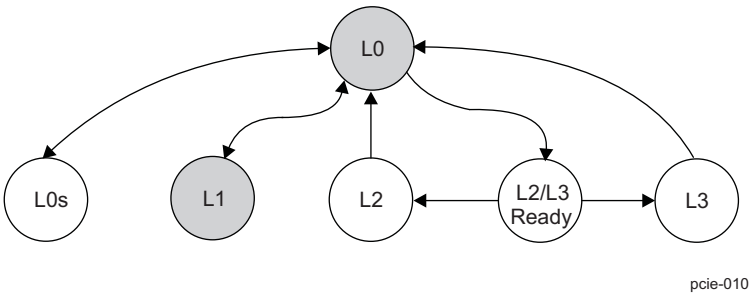
Some of the link power states are autonomously managed by hardware – ASPM. Figure 11-1098 illustrates the transitions between states L0, L0s, and L1 that are managed by ASPM. The transitions between gray states are allowed in ASPM. These transitions can be enabled through registers in the PCIe configuration space to allow either just L0s transition or both L0s and L1 transitions.

Figure 11-1098. ASPM Link State Transitions



The L1 power state can also be entered via software control. When the device power state is D1, D2, or D3hot, then the link state must transition to L1 state. Figure 11-1099 shows such state transitions.

Figure 11-1099. Software–driven Link Power State Transition



11.14.4.17.2.1 L0s State

L0s is a lower power state enabled by ASPM. Each device can control its L0s transition on its transmitter. Receiver side is controlled by the remote device.

11.14.4.17.2.2 L1 State

The L1 state is reached either through ASPM timer mechanism or via the software initiated transition to a D state other than the D0 state. In the L1 state, the link is in an idle state and both receiver and transmitter in devices on both ends of a link are able to conserve energy.

11.14.4.17.2.3 L2/L3 Ready State

This state is a transitional state reached from L1, from which the link must either transition to the L2 or to the L3 state. The L3 state is a full power off state. The L2 state is also a power off state except that the wake signal can be used by end point devices to request power and clock from the system.

11.14.4.17.2.4 L2 State

The L2 state is appropriate when a device needs to monitor an external event while in deep power down mode. In the L2 state, auxiliary power is supplied and a minimal amount of current is drawn from the power source. Almost all of the logic is without power. To recover, the wake signal is used.

11.14.4.17.2.5 L3 State

In this state, device does not supply any power to the PCIe fabric. There is no mechanism to communicate in the L3 state. To recover, the system must re–establish power and reference clock followed by a fundamental reset.

11.14.4.17.3 Relationship Between Device and Link Power States

The device D–states are correlated to the link power states. For each D state, there are specific states that the PCIe link or interconnect can transition to. Table 11-2572 shows the permissible state combinations.

Table 11-2572. Device and Link Power States Combinations

Downstream Device State	Permissible Upstream Device State	Permissible Link State
D0	D0	L0 (required), L0s (required), L1 ASPM (optional)
D1	D0 – D1	L1
D2	D0 – D2	L1
D3hot	D0 – D3hot	L1, L2/L3 Ready
D3cold	D0 – D3cold	L2aux, L3

11.14.4.17.4 CBA Power Management

The power management for PCIe SS WITH CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe SS will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe SS will guarantee that in the event there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA fabric power management logic.

NOTE: The PCIe SS does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe SS.

11.14.4.17.5 PCIe SS Power Management

PCIe SS supports several device and link power management states. The sections below outline the sequence involved in entering and exiting these states that is specific to PCIe SS architecture. For each state, entry and exit conditions are described along with their correlation with CBA power management procedures and protocols.

11.14.4.17.5.1 L0 State

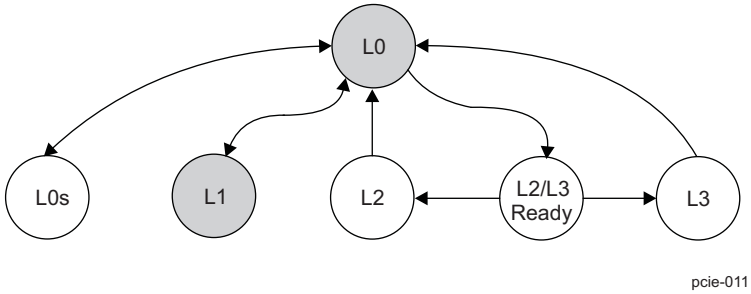
The state of normal operation (no power saving) is the L0 state. In this state, the transmitter and the received in the physical layer are both switched on and actively operating.

11.14.4.17.5.2 L0s State

The L0s transition is fully managed by PCIe SS as documented by the ASPM specifications. Based on a timer monitoring the activity on transmitter, the ASPM L0s state is reached whenever there has been no pending transmission for a specified period of time. The timeout interval for entering L0s can be controlled via L0S_ENTRY_LATENCY field in PCIE_ACK_FREQ register in Port Logic registers. The entry into L0s can be enabled or disabled by the AS_LINK_PM field in PCIE_LINK_CAP register PCIe Configuration space. The power saving in this state is due to the transmitters in SERDES being switch off. In the L0s state, there is no logic power saving except what is accomplished by lack of switching activity in the sequential logic.

Figure 11-1100 presents the ASPM L0s transaction.

Figure 11-1100. ASPM L0s Transition



11.14.4.17.5.2.1 Entry Conditions for ASPM L0s Stat

The following conditions must be met before L0s state is entered:

- ASPM L0s is enabled by the AS_LINK_PM field in PCIE_LINK_CAP register.
- The specified duration of time since last transmission has elapsed and no other higher state of power down is requested.

Whether or not a device enters L0s is configurable by Root Complex software.

11.14.4.17.5.2.2 Exit Conditions for ASPM L0s State

Any of the following conditions will bring the PCIe SS out of L0s state:

- The conditions to enter L1 state are met.
- A DLLP or TLP is pending to be transmitted. Since the device is in D0 state, there is no need for a PME message to be transmitted.
- The PCIe link partner requests link recovery.

11.14.4.17.5.2.3 CBA Power States

There is no correlation between CBA power management and L0s power state. If clock stop protocol has been initiated, the PCIe SS may acknowledge the clock stop request. If there have been any forthcoming transactions, PCIe SS is not able to service those if clock has been stopped and transactions have been received after that from the remote link partner.

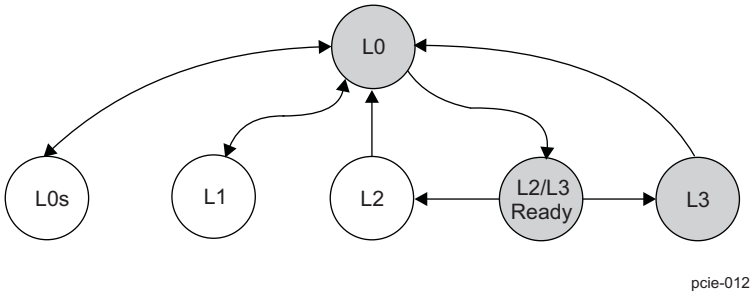
NOTE: It is not recommended to stop clocks in this state.

11.14.4.17.5.3 ASPM L1 State

The L1 state can also be reached by software controlled D1, D2 or D3 states. This section describes the ASPM L1 power down state. Both link partners are involved in this transition and negotiate to transition the link to L1 state. A link will transition back to L0 when there is a transaction level packet or Data link layer packet to be sent, application/software requests transition or if the link partner makes a request. The entry into L1 can be enabled or disabled by the ASPM Link Power Management Support field in the Link Capabilities Register and Link Control Register in PCIe Configuration space. The timeout value is controlled by the L1 Entry Latency field in Port Logic registers.

Figure 11-1101 presents the Link Power States L0 and L1.

Figure 11-1101. Link Power States L0 and L1



11.14.4.17.5.3.1 Entry Conditions for ASPM L1 State

There are two possible transition sequences for L1 state. All conditions listed must be met for entry to L1 to occur.

The first sequence is L1 Idle Timeout from L0s:

1. Both L1 and L0s modes of ASPM are enabled by ACTIVE_LINK_PM field in PCIE_LINK_STAT_CTRL register.
2. Link state is in L0s for both transmitter and receiver of the link. Alternatively, by setting ASPM_L1 bit in PCIE_ACK_FREQ, it is possible to override this and require that only the transmitter is in L0s before L1 transition is initiated.
3. There is no higher stage of power down requested and L1 enter conditions defined by PCIe spec regarding no pending TLPs or completions and availability of flow control credits are met.
4. A pre-specified period of time has elapsed in L0s state.

The second sequence is L1 Idle Timeout from L0:

1. ASPM L1 is enabled and L0s is not enabled in the PCIE_LINK_STAT_CTRL register.
2. Link state is in L0.
3. There is no higher stage of power down requested and L1 enter conditions defined by PCIe spec regarding no pending TLPs or completions and availability of flow control credits are met.
4. A pre-specified period of time has elapsed in L0 state.

11.14.4.17.5.3.2 Exit Conditions from ASPM L1 State

Any of the following conditions can occur to cause transition out of L1 state.

- Software initiates a higher stage of power down.
- Any pending DLLP or TLP.
- Link partner requesting exit from L1.

11.14.4.17.5.3.3 CBA Power States

In ASPM L1 state, the PCIe SS will acknowledge clock stop request if there are no pending transactions on CBA interface. The link is guaranteed to not have pending transactions in L1 state. Like in L0s state, clock stop procedure should be performed only if it is guaranteed that the CBA masters have already completed all transactions and are not going to schedule any new transactions. The same condition applies to remote device as well.

It is recommended that the clock stop sequence not be used without ensuring higher level protocols have been suspended. The ASPM states can be seen as a way to reduce system level power consumption in situations of transient inactive periods that are in order of microseconds at a time.

11.14.4.17.5.4 Software Initiated L1 State

The software initiated power management states in PCIe are managed via the Device states – D0, D1, D2 and D3. In L1 power down state, both link partners are involved and negotiate to transition to L1 state. A link will transition back to L0 when there is a transaction level packet or Data link layer packet to be sent, application/software requests transition or if the link partner makes a request.

11.14.4.17.5.4.1 Entry Conditions for L1 State on EP and RC

The L1 state is entered when the RC software writes the Power Management Control and Status Register (PMCSR) to change state of EP to D1, D2 or D3. The EP must be capable of transitioning to these states based on the values programmed in Power Management Capabilities Register (PMCAP).

The sequence followed to move PCIe SS EP to L1 state is:

- RC changes EP's state to D1, D2 or D3 through a Configuration Write to EP's PMCSR
- EP ensures the following conditions are true before it sends PM_ENTER_L1 DLLPs to RC
  - No new TLPs to be sent and any TLPs received will be discarded
  - Last TLP Ack received (retry buffer empty)
  - Flow Control Credits are available
- RC receives PM_ENTER_L1 DLLP
- RC ensures no new TLPs to be sent downstream and that last TLP ack received and FC credits available.
- RC sends PM_REQUEST_ACK continuously.
- Upon receiving PM_REQUEST_ACK, the EP transmits Electrical Idle ordered set. This indicates successful transition to L1 state.
- RC software may decide to either stay in D0 or switch to higher state such as D1 or D2.
- As an EP, any outbound transactions on PCIe SS slave port arriving after the PM_ENTER_L1 DLLP transmission has begun are blocked.

NOTE: If the software fails to ensure that configuration write to transition to a power saving D state is done only after all completions and read/write requests are completed, the EP may fail to process such transactions and may issue Error messages to the RC. This behavior is not a malfunction but it is compliance to PCIe protocol.

11.14.4.17.5.4.2 Exit Conditions for L1 State on EP

The following sequence outlines exit from L1 when in EP mode:

1. When the EP is in L1 mode, there are two possible ways to exit – if there is pending traffic on the slave port or if the link partner initiated transition back to L0 mode.

- If there is pending traffic on slave port, then the PCIe SS generates a PME message automatically. It is possible for a transaction to be generated on the link in response to a register write on the local PCIe memory map. In such cases as well, a PME message will be generated by PCIe SS automatically. The reception of PME message is used by RC software to change the D-state of the EP back to D0. Unless the D0 state is written by RC, the EP cannot send the TLP out on the serial link.
- Alternatively, if there is pending traffic in the inbound direction, the RC will first renegotiate link state to L0 on itself and on EP. Then, it will do a configuration write to switch the D-state back to D0. In the meantime, detecting transition out of electrical idle on the PHY, the PCIe SS will request the bus fabric to supply clocks if they were gated.

2. Once the EP and RC are back in D0 device state and L0 link state, the normal operation resumes.

11.14.4.17.5.4.3 Exit Conditions for L1 State on RC

The RC can exit L1 and D1/D2 state in the following sequence:

1. The execution of this step depends on the current state of RC:
   a. If the RC needs to transmit packets, it needs to get out of D1 state via a configuration write to its own config space.
   b. This step is skipped if RC stayed in D0 state.
2. The link is transitioned to L0.
3. The EP mode is changed by RC to D0 state.
4. The normal transfers can resume.

11.14.4.17.5.4.4 CBA Power States

After the link has transitioned to L1 as a result of software power state transition to D1 or a higher state, the clock stop sequence can be initiated. If there are no outstanding transactions, the PCIe SS will acknowledge and be prepared for removal of CBA clocks.

If there is activity on the wire and the link is no longer in electrical idle state (because of activity initiated by link partner), the PCIe SS will not be able to respond. The software architecture must comprehend this limitation and transition to this state only when a pre-determined wake sequence is established between the two link partners. Such wake sequence, implemented outside the PCIe SS, would ensure availability of clocks on both devices for resumption of normal operation.

To resume operation, the Root Complex can modify D-state on the End Point by initiating a configuration write. Alternatively, the software on End Point can request generation of PME message by writing to application registers. In response to this PME Message, the Root Complex will change the D-state of End Point through a configuration write. In either method, link would transition to L0 and be ready for normal operation.

NOTE: PCIe SS with CBA interface does not generate PME message automatically.

It is important to recognize that the software can successfully transition the PCIe SS to a software initiated power down mode followed by a clock stop request/acknowledge sequence only if prior steps have been taken to ensure that the activity on both ends of a PCIe link has been suspended. While the PCIe SS will guarantee that the clock stop request is not acknowledged if there are pending transfers, it cannot, on its own, force exit from D1 or higher states. For example, if the RC forces D1 state on an EP that has outgoing commands pending, the EP will not acknowledge clock stop request. Secondly, it will not automatically send a PME to the RC to let it know of pending transmission. So, it is important that the EP software driver running on RC implement safeguards against such situations.

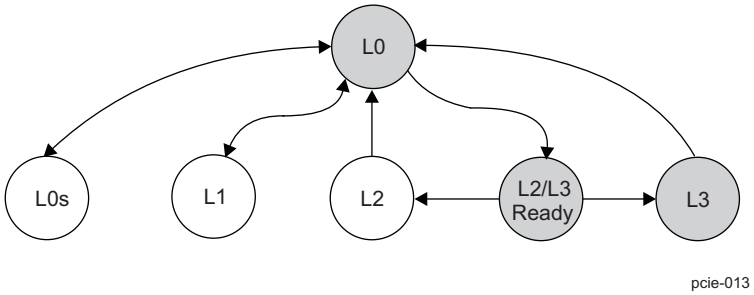
11.14.4.17.5.5 Software Initiated L2/L3 Ready state

The L2 and L3 states are reached via the L2/L3 ready state. Depending on whether the device has auxiliary power source, it will enter L2 state. Otherwise, it enters L3 state which is a full off power state.

NOTE: PCIe SS does not support L2 state with auxiliary power.

Figure 11-1102 presents the Link states L2/L3 Ready, L2 and L3 states.

Figure 11-1102. Link states L2/L3 Ready, L2 and L3 states



The L2/L3 Ready is a pseudo state. It is a transitional state for a PCIe device that leads to L2 or L3 state.

L2 state is reached when auxiliary power is available and the system controller switches the PCIe device from main power to auxiliary power on the PCIe connector.

L3 state is reached when auxiliary power is not available and the system controller switches a PCIe device off with no power supply at all.

11.14.4.17.5.5.1 Entry Conditions for L2/L3 Ready State on EP/RC

The entry conditions and sequence is as follows:

1. RC sets D3 state on all EP devices. This causes L0 –L1 transition on EP devices.
2. RC then sends PME_TURNOFF to EP device. This causes L1–L0 transition on EP devices to enable L2/L3 Ready handshake.
3. The message transmission causes the EP to wake from L1 and switch to L0
4. When the message is received, the PM_TURNOFF interrupt is generated. When the EP device is ready to get its PCIe SS shutdown, it must acknowledge the turn off message by asserting the ENTR_L23 bit in PCIE_PMCFG at some point in time. This time cannot be indefinite.
5. The PCIe SS EP automatically transmits PME_TO_ACK message while still in D3 state. The message is turned into PME_TO_ACK interrupt if PCIe SS is in RC mode and has enabled the interrupt.
6. Once the EP software has written the bit ENTR_L23, it is presumed that the PCIe SS is ready to get its power and reference clock removed. Then, the EP PCIe SS will automatically transmit a PM_ENTER_L23 DLLP. It is continued until the RC sends PM_REQUEST_ACK to EP.
7. Reception of PM_REQUEST_ACK causes the transition to L2/L3 Ready state.
8. The L3 state is reached if Aux power is not requested by the device.

11.14.4.17.5.5.2 Exit Conditions from L2/L3 on EP/RC

Since Wake from D3cold is not supported, the PCIe SS goes to L3 and the recovery to L0 is accomplished through supply of clock and power followed by a reset. System designers may be able to keep PCIe SS on a separate power domain and actually shut of power supply to PCIe SS. During recovery from L3, the power on reset must be provided to PCIe SS or some bits required to be reset for the recovery will not be reset.

11.14.4.17.5.5.3 CBA Power States

The L2/L3 Ready state is a preparation to turn off (completely power off) a PCIe device. It is expected that the PCIe SS will not be used for a long period of time (at least several minutes).

The clock stop request protocol can be executed after the L2/L3 state is reached. After the clock stop protocol is completed, power can be removed from PCIe SS.

To resume, the power should be restored, reset should be issued and link training restarted following any internal configuration that software may want to perform.

NOTE: The PCIe link activity must be stopped before preparation to turn the device off via L3/L3 Ready transition is performed. Without that, the clock stop request may not be acknowledged successfully.

11.14.4.17.5.6 Limitations and Exceptions

While the hardware makes best effort decisions for power state transitions, it is still susceptible to certain actions that are not in its control. Following is a list of events where unexpected behavior can occur.

11.14.4.17.5.6.1 L1 State

For PCIe SS variants that use GS70 technology, the SERDES does not support asynchronous loss of signal detect circuit. As a result, specifically in Gen2 mode, there is a dependency on clock for a squelch circuit in loss-of-signal-detect circuit. This dependency prevents the PCIe SS from correctly issuing interface wake signal. The implication of this limitation is that PCIe SS subsystems that operate in Gen2 mode should not use L1 power down state if it is expected that the PCIe SS would make a request to wake up via Interface Wake when there is activity on the link.

11.14.4.17.5.6.2 L2 and L3 States

NOTE: L2 state is not supported by PCIe SS.

Upon entry into L2/L3 Ready, the next state will be L3 which is a complete power off state. It is strongly recommended to transition to L3 only if required. A power cycle with a power on reset will be required for PCIe SS to recover to L0 state on resumption of power. The system software should use L1 state for power savings while the device is powered on.

PCIe SS does not have the ability to transmit in-band beacon because the SERDES does not support beacon.

11.14.4.17.5.6.3 PME Transmission

PCIe SS will transmit more than one PME message even though only one PME Message is expected to be transmitted. This is a known issue with the behavior of the third party PCIe IP and is not necessarily a malfunction.

11.14.4.18 Error Handling

11.14.4.18.1 Error Reporting

PCIe provides three mechanisms for establishing the error reporting policy. These mechanisms are controlled and reported through configuration registers mapped into three distinct regions of configuration space.

The various error reporting features are enabled as follows:

- PCI-compatible Registers — this error reporting mechanism provides backward compatibility with existing PCI compatible software and is enabled via the PCIE_CMD_STATUS register.
- PCIe Capability Registers — this mechanism is available only to software that has knowledge of PCIe. This required error reporting is enabled via the PCIE_DEV_STAT_CTRL register mapped within PCI-compatible configuration space.
- PCIe Advanced Error Reporting Registers — this mechanism involves registers mapped into the extended configuration address space. PCIe compatible software enables error reporting for individual errors via the Error Mask Registers.

PCIe includes two methods of reporting errors:

- Error message transactions — used to report errors to the host
  The conventional PCI reports errors via the PERR# and SERR# signals. But PCIe eliminates these error-related signals and error messages have been defined to replace these signals by acting as virtual wires. Furthermore, these messages provide additional information that could not be conveyed directly via the PERR# and SERR# signals. This includes identification of the device that detected the error and an indication of the severity of each error.
- Completion status — used by the completer to report errors to the requester
  PCIe defines a completion status field within the completion header that enables the transaction completer to report errors back to the requester.

11.14.4.18.2 Error Detection and Handling

This section defines the required support for detecting and handling PCIe errors.

11.14.4.18.2.1 PCI-Compatible Error Handling

Each PCIe must map required PCIe error support to the PCI-related error registers. This involves enabling error reporting and setting status bits that can be read by PCI-compliant software. The PCIe errors tracked by the PCI compatible registers are:

- Transaction Poisoning
- Completer Abort (CA) detected by a completer
- Unrecognizable Request (UR) detected by a completer

The PCI mechanism for reporting errors is the assertion of PERR# (data parity errors) and SERR# (unrecoverable errors). The PCIe mechanisms for reporting these events are via the split transaction mechanism (transaction completions) and virtual SERR# signaling via error messages.

The Status and Command Register (PCIE_STATUS_COMMAND) has error-related bits to understand the features available from the PCI-compatible point of view. While the Status and Command Register bits have the PCI name, some of the field definitions have been modified to reflect the related PCIe error conditions and reporting mechanisms. See Section 11.14.5.4.3, *PCIE_STATUS_COMMAND Register*, for the details of this register.

The following bits are set to enable baseline error reporting under control of PCI-compatible software.

- SERR Enable (bit 8)
- Parity Error Response (bit 6)

The following bits are set under certain error circumstances:

- Detected Parity Error (bit 31)
- Signalled System Error (bit 30)

- Received Master Abort (bit 29)
- Received Target Abort (bit 28)
- Signalled Target Abort (bit 27)
- Master Data Parity Error (bit 24)

11.14.4.18.2.2 PCIe Baseline Error Handling

The PCIE_DEV_STAT_CTRL register permits software to enable generation of error messages for four error-related events and to check status information to determine which type of error has been detected:

- Correctable Errors
- Non-Fatal Errors
- Fatal Errors
- Unsupported Request Errors

11.14.4.18.2.2.1 Enabling Error Reporting

Setting the corresponding bit in the PCIE_DEV_STAT_CTRL register enables the generation of the corresponding error message, which reports errors associated with each classification. Unsupported Request errors are specified as Non-Fatal errors and are reported via a Non-Fatal error message, but only when the Unsupported Request Enable bit is set.

- Unsupported Request Reporting Enable (bit 3)
- Fatal Error Reporting Enable (bit 2)
- Non-Fatal Error Reporting Enable (bit 1)
- Correctable Error Reporting Enable (bit 0)

11.14.4.18.2.2.2 Error Status

An error status bit is set any time an error associated with its classification is detected. These bits are set irrespective of the setting of the Error Reporting Enable bits within the PCIE_DEV_STAT_CTRL register. Because Unsupported Request errors are by default considered Non-Fatal errors, when these errors occur both the Non-Fatal error status bit and the Unsupported Request status bit will be set.

NOTE: Both the Non-Fatal error status bit and the Unsupported Request status bit are cleared by software when writing a one (1) to the bit field.

- Unsupported Request Detected (bit 19)
- Fatal Error Detected (bit 18)
- Non-Fatal Error Detected (bit 17)
- Correctable Error Detected (bit 16)

11.14.4.18.2.2.3 Link Errors

The physical link connecting two devices may fail causing a variety of errors. Because the link has incurred errors, the error cannot be reported to the host via the failed link. Therefore, link errors must be reported via the upstream port of switches or by the Root Port itself. Also the related fields in the PCIE_LINK_STAT_CTRL are valid only in RC (not applicable within EP device). This permits system software to access link-related error registers on the port that is closest to the host.

The PCIE_LINK_STAT_CTRL register includes a RETRAIN_LINK bit (bit 5) that when set forces the RC to retrain the link. If transaction (upon completion of the retraining) can once again traverse the link without errors, the problem will have been solved.

Software can monitor the LINK_TRAINING bit (bit 27) in the PCIE_LINK_STAT_CTRL register to determine when retraining has completed.

11.14.4.18.2.2.4 Root's Response to Error Message

When a message is received by the RC the action that it takes when reporting the error message to the host system is determined in part by the PCIE_ROOT_CTRL_CAP register settings. There are three bit fields that specify whether an error should be reported as a fatal System Error (SERR set enables generation of a system error):

- SERR on Fatal Error Enable (bit 2)
- SERR on Non-Fatal Error Enable (bit 1)
- SERR on Correctable Error Enable (bit 0)

The PME Interrupt Enable bit (bit 3) allows software to enable and disable interrupt generation upon the RC detecting a PME Message transaction.

11.14.4.18.2.3 PCIe Advanced Error Reporting

Advanced Error Reporting requires implementation of the Advanced Error Reporting registers. These registers provide several additional error reporting features.

11.14.4.18.2.3.1 ECRC Generation and Checking

End-to-End CRC (ECRC) generation and checking can be enabled by PCIE_ACCR

- ECRC Check Enable (bit 8)
- ECRC Check Capable (bit 7)
- ECRC Generation Enable (bit 6)
- ECRC Generation Capable (bit 5)

In some cases, multiple uncorrectable errors may be detected prior to software reading and clearing the register. The First Error Pointer field (bit[4-0]) identifies the bit position within the PCIe Uncorrectable Error Status Register (PCIE_UNCERR) corresponding to the error that occurred first.

NOTE: When connecting KeyStone PCIe device to another external PCIe device, it is worth checking if the external PCIe device supports the ECRC feature. The ECRC should be disabled by clearing bits ECRC_CHK_EN and ECRC_GEN_EN in the PCIE_ACCR register if the external PCIe device does not support it, especially if the KeyStone PCIe device is configured as RC.

11.14.4.18.2.3.2 Advanced Correctable Error Handling

Advanced error reporting provides the ability to pinpoint specific correctable errors. These errors can selectively cause the generation of a Correctable Error Message being sent to the host system:

- Advanced Correctable Error Status
- When a correctable error occurs the corresponding bit within the PCIe Correctable Error Status Register (PCIE_CERR) is set. These bits are automatically set by hardware and are cleared by software when writing a 1 to the bit position. These bits are set whether or not the error is reported via an error message.
  - Replay Timer Timeout Status (RPLY_TMR_ST) (bit 12)
  - REPLAY_NUM Rollover Status (RPLT_RO_ST) (bit 8)
  - Bad DLLP Status (BAD_DLLP_ST) (bit 7)
  - Bad TLP Status (BAD_TLP_ST) (bit 6)
  - Receiver Error Status (RCVR_ERR_ST) (bit 0)
- Advanced Correctable Error Reporting
- Whether a particular correctable error is reported to the host is specified by the PCIe Correctable Error Mask Register (PCIE_CERR_MASK). The default state of the mask bits are cleared (0), thereby causing a Correctable Error message to be delivered when any of the correctable errors are detected. Software may choose to set one or more bits to prevent a Correctable Error Message from being sent

when the selected error is detected.

- Replay Timer Timeout Mask (RPLY_TMR_MSK) (bit 12)
- REPLAY_NUM Rollover Mask (RPLT_RO_MSK) (bit 8)
- Bad DLLP Mask (BAD_DLLP_MSK) (bit 7)
- Bad TLP Mask (BAD_TLP_MSK) (bit 6)
- Receiver Error Mask (RCVR_ERR_MSK) (bit 0)

11.14.4.18.2.3.3 Advanced Uncorrectable Error Handling

Advanced error reporting provides the ability to pinpoint which uncorrectable error has occurred. Furthermore software can specify the severity of each error and select which errors will result in an error message being sent to the host system (Root Complex).

- **Advanced Uncorrectable Error Status:** When an uncorrectable error occurs the corresponding bit within the PCIe Uncorrectable Error Status Register (PCIE_UNCERR) is set. These bits are automatically set by hardware and are cleared by software when writing a 1 to the bit position. Bits [4,12-20] are set whether or not the error is reported via an error message.
- **Advanced Uncorrectable Error Reporting:** Software can mask out specific errors so that they never cause an error message to be generated. The default condition in the PCIe Uncorrectable Error Mask Register (PCIE_UNCERR_MASK) is to generate error messages for each type of error (all bits are cleared). The same numbers of bits [4,12-20] , as in PCIE_UNCERR are used.
- **Selecting the Severity of Each Uncorrectable Error:** Advanced error handling permits software to select the severity of each error within the PCIe Uncorrectable Error Severity Register (PCIE_UNCERR_SVRTY). This gives software the opportunity to treat errors according to the severity associated with a given application. For example, Poisoned TLP data associated with audio data being sent to a speaker, while not correctable has no serious side effects relative to the integrity of the system. However, if real-time status information is being retrieved that will help make critical decisions, any errors in this data can be very serious. The values in the individual bit fields represent the default severity levels for each type of error (0 = Non-Fatal,1 = Fatal).

11.14.4.18.2.3.4 Error Logging

A four double-word portion (PCIE_HDR_LOG0÷PCIE_HDR_LOG3) of the PCIe Extended Capabilities Registers block is reserved for storing the header of the transaction that has incurred a failure. Only a select group of transaction layer errors result in the transaction header being logged. Table 11-2573 lists the transactions that are logged.

Table 11-2573. Transaction Layer Error That are Logged

Name of Error	Default Classification
Poisoned TLP Received	Uncorrectable - Non-Fatal
ECRC Check Failed	Uncorrectable – Non-Fatal
Unsupported Request	Uncorrectable – Non-Fatal
Completion Abort	Uncorrectable – Non-Fatal
Unexpected Completion	Uncorrectable – Non-Fatal
Malformed TLP	Uncorrectable – Fatal

11.14.4.18.2.3.5 Root Complex Error Tracking and Reporting

The Root Complex is the target of all error messages issued by devices within the PCIe fabric. Errors received by the RC result in status registers being updated and the error being conditionally reported to the appropriate software handler or handlers.

- **Root Error Status Registers:** When the Root Complex receives an error message, it sets status bits within the Root Error Status Register (PCIE_RC_ERR_ST). This register indicates the types of errors received and also indicates when multiple errors of the same type have been received.
  - Fatal Error Messages Received (bit 6)

  - Non-Fatal Error Messages Received (bit 5)
  - First Uncorrectable Fatal Received (bit 4)
  - Multiple Uncorrectable Error Received (bit 3)
  - Uncorrectable Error Received (bit 2)
  - Multiple Correctable Error Received (bit 1)
  - Correctable Error Received (bit 0)
- **Root Error Command Register:** The Root Error Status Register sets status bits that determines whether a Correctable, Fatal, or Non-Fatal error has occurred. In conjunction with these status bits the Root Complex can also generate separate interrupts that call handlers for each of the error categories. The Root Error Command register (PCIE_RC_ERR_CMD) enables interrupt generation for all three categories as follows:
  - Fatal Error Reporting Enable (bit 2)
  - Non-Fatal Error Reporting Enable (bit 1)
  - Correctable Error Reporting Enable (bit 0)
- **Error Source ID Register:** Software error handlers may need to read and clear error status registers within the device that detected and reported the error. The error messages contain the ID of the device reporting the error. The Error Source Identification Register (PCIE_ERR_SRC_ID) captures the error message ID associated with the first Fatal/Non-Fatal and correctable Error message received by the Root Complex.

11.14.4.18.2.4 Read Completion with an Error Completion Status

When a Read Completion is received with a Completion Status other than Successful Completion:

- No data is included with the Completion.
- Cpl (Completion without Data) encoding is used instead of CplD (Completion with Data). PCIe SS will return all the data as 0's to the host with an error status indicated on the bus.
- This Completion is the final Completion for the Request.
- The Requester must consider the Request terminated, and not expect additional Completions.

NOTE: Some system configuration software depends on reading a data value of all 1’s when a Configuration Read Request is terminated as an Unsupported Request, particularly when probing to determine the existence of a device in the system. A Root Complex intended for use with software that depends on a read-data value of all 1’s must synthesize this value when UR Completion Status is returned for a Configuration Read Request.

11.14.4.19 Memory Error Detection and Correction

11.14.4.19.1 ECC Wrapper and ECC Aggregator

The ECC wrapper implements SECDED code for single bit error detection and correction and double bit error detection. ECC Aggregator module gathers level pending status from the ECC RAMs into a single interrupt to the host. Software interface is provided for status and control.

There are three types of ECC registers:

1. *Global registers* that are common to all ECC RAMs. This includes the PCIE_ECC_REVISION, PCIE_ECC_VECTOR, and PCIE_ECC_MISC_STATUS registers. Every ECC RAM serviced by the aggregator module is assigned a unique ID by the module. Writing this ID to the PCIE_ECC_VECTOR register selects the ECC RAM to be controlled or read the ECC status from.
2. *ECC control and status registers.* These are specific to each ECC RAM and selected by the RAM_ID written to the PCIE_ECC_VECTOR register. The accesses to these registers are done via the serial VBUSP protocol. Note that due to the long latencies on the serial VBUS, the reads to the ECC control and status registers are triggered by a write to the PCIE_ECC_VECTOR register. This is described in detail in Section 11.14.4.19.1.1.
3. *Interrupt registers.* These include the standard interrupt status, interrupt enable, interrupt clear and EOI registers that are part of a standard interrupt module.

   ECC registers are described in Section 11.14.5.2, *PCIE_ECC Registers*.

11.14.4.19.1.1 Reads to ECC Control and Status Registers

Due to the long latencies on the serial VBUS, the reads to the ECC control and status registers for each ECC RAM are triggered by writing a *read* message to the PCIE_ECC_VECTOR register as described below:

1. Software writes the RAM_ID in PCIE_ECC_VECTOR[10-0] , sets bit [15] TRIGGER_READ, and writes [23-16] READ_ADDRESS. The READ_ADDRESS corresponds to any of the ECC control or status registers (at offset 0x10, that is, PCIE_ECC_WRAPPER_REVISION through 0x24, that is, PCIE_ECC_ERROR_STATUS2) which require serial VBUS access to the ECC RAM(s).
2. Software then polls the PCIE_ECC_VECTOR[24] READ_DONE bit waiting for setting to 1. This indicates that the read operation has completed on the serial VBUS.
3. Software reads the data from the ECC control or status register. Read data is returned on the following clock cycle.

11.14.4.19.1.2 ECC Interrupts

The ECC aggregator module aggregates all the level pending status from the ECC RAMs to a single EOI-handshake based interrupt to the host. Software is expected to follow the sequence described below:

1. Software enables the interrupts for the ECC RAM(s) by writing to the Interrupt Enable register (PCIE_ECC_INT_ENABLE_0 to PCIE_ECC_INT_ENABLE_15).
2. On receiving an interrupt, software checks the Interrupt Status Register (PCIE_ECC_INT_STATUS_0 to PCIE_ECC_INT_STATUS_15) to see which ECC RAM(s) caused the error. Note that this status read is not a serial VBUS operation.
3. Software writes the RAM_ID in the PCIE_ECC_VECTOR register along with the read message that includes setting bit [15] TRIGGER_READ, writing the PCIE_ECC_ERROR_STATUS1 register's address (that is, 0x20) to bits [23-16] READ_ADDRESS. Software needs to load the read message in the PCIE_ECC_VECTOR register again if it needs to read also the PCIE_ECC_ERROR_STATUS2.
4. Software polls the PCIE_ECC_VECTOR[24] READ_DONE bit. When this is set to 1, it can read the PCIE_ECC_ERROR_STATUS1 and PCIE_ECC_ERROR_STATUS2 registers.
5. After the interrupt has been serviced, software must clear the interrupt status by writing to bits 8, 9, or 10 depending on the type of ECC error in the PCIE_ECC_ERROR_STATUS1 register.
6. Software must poll the PCIE_ECC_ERROR_STATUS1 register to guarantee that the status bit has been cleared. Otherwise there is no indication that the write has actually completed over the serial VBUS

7. Software must write to the PCIE_ECC_EOI register to clear the aggregated interrupt output.

11.14.4.20 Emulation Considerations

The emulation suspend interface is not supported on PCIe SS.

11.14.4.21 Encoding of LTSSM State in DEBUG Registers

This appendix contains the following supplementary information:

11.14.4.21.1 LTSSM States

The LTSSM state value that is read from DEBUG registers is an encoded value. The literal names of the LTSSM states corresponding to the encoded values are tabulated below.

Table 11-2574. Encoding of LTSSM State in DEBUG registers

Code	LTSSM State
0x00	DETECT_QUIET
0x01	DETECT_ACT
0x02	POLL_ACTIVE
0x03	POLL_COMPLIANCE
0x04	POLL_CONFIG
0x05	PRE_DETECT_QUIET
0x06	DETECT_WAIT
0x07	CFG_LINKWD_START
0x08	CFG_LINKWD_ACEPT
0x09	CFG_LANENUM_WAIT
0x0A	CFG_LANENUM_ACEPT
0x0B	CFG_COMPLETE
0x0C	CFG_IDLE
0x0D	RCVRY_LOCK
0x0E	RCVRY_SPEED
0x0F	RCVRY_RCVRCFG
0x10	RCVRY_IDLE
0x11	L0
0x12	L0s
0x13	L123_SEND_EIDLE
0x14	L1_IDLE
0x15	L2_IDLE
0x16	L2_WAKE
0x17	DISABLED_ENTRY
0x18	DISABLED_IDLE
0x19	DISABLED
0x1A	LPBK_ENTRY

0x1C	LPBK_EXIT
0x1D	LPBK_EXIT_TIMEOUT
0x1E	HOT_RESET_ENTRY
0x1F	HOT_RESET

11.14.5 PCIe SS Registers

This section describes the PCIe registers. They are divided into 10 subsection based on their specific use.

11.14.5.1 SERDES Configuration Registers

11.14.5.1.1 Register Summary

Table 11-2576 shows the configuration registers of the SERDES.

Table 11-2575. PCIe Instances

Instance	Base Address
PCIE_0_PHY_CFG	0232 1FC0h

Table 11-2576. SERDES Configuration Registers

Offset	Acronym	Register Name	PCIE_0_PHY_CFG Physical Address	Section
0h	PCIE_PHY_MOD_VER	Identifies revision of SERDES	0232 1FC0h	Section 11.14.5.1.2
14h	PCIE_PHY_LANE_PLL_STS	Current configuration of REFCLK and LANE Mux selection	0232 1FD4h	Section 11.14.5.1.3
20h	PCIE_PHY_LANExCTL_STS	Override SERDES configuration settings.	0232 1FE0h	Section 11.14.5.1.4
34h	PCIE_PHY_PLL_CTRL	PLL Control register	0232 1FF4h	Section 11.14.5.1.5
38h	PCIE_PHY_COMMA_LINK_DELAY	Comma Link delay register	0232 1FF8h	Section 11.14.5.1.6
3Ch	PCIE_PHY_CMU_WAIT	CMU Wait Register	0232 1FFCh	Section 11.14.5.1.7

11.14.5.1.2 PCIE_PHY_MOD_VER Register (Offset = 0h) [reset = 4EBE2101h]

The Module and Version Register PCIE_PHY_MOD_VER identifies the module identifier and revision of the WIZ8B2M4SB module.

Table 11-2577. PCIE_PHY_MOD_VER Register

Table 11-2581. PCIE_PHY_LANE_PLL_STS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
27	PLL0_PWR_ON	R	1h	Indicates the state of the PLL0 REFCLK supplies: • 0 - REFCLK power is off • 1 - REFCLK power is on
26	PLL0_LEFT_SEL	R	1h	Indicates the REFCLK source used for PLL0. This bit indicates that the left refclk input is used for the PLL0. When both PLL0_LEFT_SEL and PLL0_RIGHT_SEL are zero, the REFCLK pads are used for the PLL0. • 0 - disabled left clock • 1 - enable left clock
25	PLL0_CHAIN_EN	R	0h	Indicates the refclk chaining is enabled: • 0 - REFCLK right and left are driven from the REFCLK pads of this macro • 1 - REFCLK right or left is driven from left or right respectively.
24	PLL0_RIGHT_SEL	R	0h	Indicates the refclk source used for PLL0. This bit indicates that the right REFCLK Input is used for the PLL0. When bothPLL0_LEFT_SEL and PLL0_RIGHT_SEL are zero, the REFCLK pads are used for the PLL0. • 0 - disabled left clock • 1 - enable left clock
23-4	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
3	LANE0_PLL_LOCK	R	0h	Indicates that the lane 0 TX clock is valid
2	LANE0_RST_ISO	R	0h	Indicates that the selected IP has the Lane 0 reset isolation signal set.

Table 11-2581. PCIE_PHY_LANE_PLL_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	LANE0_IP_SEL	R	0h	Indicates which IP interface is used for lane 0. • 00 - IP1 is selected for lane 0. • 01 - IP2 is selected for lane 0. • 10 - IP3 is selected for lane 0. • 11 - IP4 is selected for lane 0.

Table 11-2584. PCIE_PHY_LANExCTL_STS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	TX0_ENABLE_OVL	R/W	0h	The Tx Enable Overlay bit when set allows the Tx Enable Value to override the CFGTX Enable input.
30-29	TX0_ENABLE_VAL	R/W	0h	The Tx Enable Value when used allows the Tx lane to be placed in • 00 - Disable state • 01 - Sleep state • 10 - Snooze state • 11 - Enabled state
28	TX0_RATE_OVL	R/W	0h	The Tx Rate Overlay bit when set allows the Tx Rate Value to override the CFGTX Rate input.
27-26	TX0_RATE_VAL	R/W	0h	The Tx Rate Value when used allows the Tx lane to be placed into: • 00 - Full Rate mode • 01 - Half Rate mode • 10 - Quarter Rate mode • 11 - Reserved
25	TX0_IDLE_OVL	R/W	0h	The Tx Idle Overlay bit when set allows the Tx Idle Value to override the CFGTX.Idle input.
24	TX0_IDLE_VAL	R/W	0h	The Tx Idle Value when used allows the Tx lane to be placed electrical Idle state in non PCIE mode.
23	TX0_WIDTH_OVL	R/W	0h	The Tx Width Overlay bit when set allows the Tx Width Value to override the CFGTX.Width input.

Table 11-2584. PCIE_PHY_LANExCTL_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22-21	TX0_WIDTH_VAL	R/W	0h	The Tx Width Value when used allows the Tx lane to be placed into: • 00 - 10 bit mode • 01 - Reserved • 10 - 20 bit mode • 11 - 16 bit mode
20-16	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
15	RX0_ENABLE_OVL	R/W	0h	The Rx Enable Overlay bit when set allows the Rx Enable Value to override the CFGRX Enable input.
14-13	RX0_ENABLE_VAL	R/W	0h	The Rx Enable Value when used allows the Rx lane to be placed in: • 00 - Disable state • 01 - Sleep state • 10 - Snooze state • 11 - Enabled state
12	RX0_RATE_OVL	R/W	0h	The Rx Rate Overlay bit when set allows the Rx Rate Value to override the CFGRX Rate input.
11-10	RX0_RATE_VAL	R/W	0h	The Rx Rate Value when used allows the Rx lane to be placed into: • 00 - Full Rate mode • 01 - Half Rate mode • 10 - Quarter Rate mode • 11 - Reserved
9	RX0_POLARITY_OVL	R/W	0h	The Rx Polarity Overlay bit when set allows the Rx Polarity Value to override the CFGRX.Polarity input.
8	RX0_POLARITY_VAL	R/W	0h	The Rx Polarity Value when used allows the lane Rx Polarity to be inverted.
7	RX0_ALIGN_OVL	R/W	0h	The Rx Align Overlay bit when set allows the Rx Align Value to override the CFGRX.Align input.
6	RX0_ALIGN_VAL	R/W	0h	The Rx Align Value when used allows the Rx lane to align to K28.1, K28.5 and K28.7 characters otherwise known as Comma Characters.
5	RX0_WIDTH_OVL	R/W	0h	The Rx Width Overlay bit when set allows the Rx Width Value to override the CFGRX Width input.
4-3	RX0_WIDTH_VAL	R/W	0h	The Rx Width Value when used allows the Rx lane to be placed into • 00 - 10 bit mode • 01 - Reserved • 10 - 20 bit mode • 11 - 16 bit mode
2	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
1	RX0_OK	R	0h	The Rx OK indicate that the lane is in a functional state.
0	RX0_LOSS	R		The Rx Signal Loss Indicates that the data has not been detected or the CDR is not locked. • 0 - data detected or CDR locked • 1 - data not detected or CDR not locked

Table 11-2587. PCIE_PHY_PLL_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PLL_ENABLE_OVL	R/W	0h	The PLL Enable Overlay bit when set allows the PLL Enable Value to override the CFGPLL.Enable input.
30-29	PLL_ENABLE_VAL	R/W	0h	The PLL Enable Value when used allows the PLL to be placed in • 00 - Disable state • 01 - Sleep state • 10 - Snooze state • 11 - Enabled state
28	PLL_OK	R	0h	The PLL Ok indicate that the transmit clocks are valid and the PLL circuits are ready for use.
27-18	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
17	LN_WAFTER_OK	R/W	0h	The LN_WAFTER_OK field will cause the lane OK indication to be Blocked until the LNX_CONT_OK is set. This allows code to run after the lane OK but before the hardware can use the lane.
16	LN_WAFTER_SD	R/W	0h	The LN_WAFTER_SD field will cause the Rx signal indication to be Blocked until the LNX_CONT_SD is set. This allows code to run after signal detect but before the hardware can use the data.
15-13	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
12	LN0_CONT_OK	R/W	0h	The LN0_CONT_OK allows the Blocked lane OK for lane 0 to now pass to the controlling PCS IP. This bit is auto cleared when LN0_OK_STATE is driven inactive.
11-9	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
8	LN0_OK_STATE	R	0h	The LN0_OK_STATE indicate the current state of the lane OK signal for lane 0.
7-5	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.

Table 11-2587. PCIE_PHY_PLL_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	LN0_CONT_SD	R/W	0h	The LN0_CONT_SD allows the Blocked signal detect for lane 0 to now pass to the controlling PCS IP. This bit is auto cleared when LN0_SD_STATE is driven inactive.
3-1	Reserved	R	0h	Reserved - writes are ignored, always reads zeros.
0	LN0_SD_STATE	R	0h	The LN0_SD_STATE indicate the current state of the signal detect signal for lane 0.

Table 11-2610. PCIE_ECC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R		Reserved
6	ERROR_ONCE	R/W	0	If this bit is set, the force_sec/force_ded will inject an error to the specified row only once. The force_sec bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the force_ded bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0	Force single/double-bit error on the next RAM read
4	FORCE_DED	R/W	0	Force double-bit error. Cleared the cycle following the error if error_once is asserted.
3	FORCE_SEC	R/W	0	Force single-bit error. Cleared on a writeback or the cycle following the error if error_once is asserted
2	ENABLE_RMW	R/W	1	Enable read-modify-write on partial word writes
1	PCIE_ECC_CHECK	R/W	1	Enable ECC check. ECC is completely bypassed if both PCIE_ECC_enable and PCIE_ECC_check are 0
0	PCIE_ECC_ENABLE	R/W	1	Enable ECC generation

11.14.5.3 Application Registers

The application registers are accessible in multiple ways depending on the point of origin of such accesses. When accessed from the internal bus slave, these registers are accessed via the 4KiB space in Address Space 0. When accessed from the PCIE serial link side, the application registers are mapped to PCIE_BAR0 of an EP as well as a RC. In addition, a RC can access these registers in a PCIESS EP via the upper 1KiB space of the PCIE configuration space. The offsets of the registers do not change irrespective of what the mode of accessing these registers is.

Table 11-2642. PCIE_CMD_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reads return 0 and writes have no effect.
5	DBI_CS2	R/W	0h	Set to enable writing to BAR mask registers that are overlaid on BAR registers. • 0 = Disable writing to BAR mask registers. • 1 = Enable writing to BAR mask registers.
4	APP_RETRY_EN	R/W	0h	Application request retry enable. This feature can be used if initialization can take longer than PCIe stipulated time frame. • 0 = Disable all incoming PCIe transactions to be returned with a retry response. • 1 = Enable all incoming PCIe transactions to be returned with a retry response.
3	POSTED_WR_EN	R/W	0h	Posted write enable. Default is 0 with all internal bus master writes defaulting to non-posted. • 0 = Disable the internal bus master to use posted write commands. • 1 = Enable the internal bus master to use posted write commands. NOTE: This bit is not applicable for KeyStone device.
2	IB_XLT_EN	R/W	0h	Inbound address translation enable. • 0 = Disable translation of inbound memory/IO read/write requests into memory read/write requests. • 1 = Enable translation of inbound memory/IO read/write requests into memory read/write requests.
1	OB_XLT_EN	R/W	0h	Outbound address translation enable. • 0 = Disable translation of outbound memory read/write requests into memory/IO/configuration read/write requests. • 1 = Enable translation of outbound memory read/write requests into memory/IO/configuration read/write requests.

Table 11-2642. PCIE_CMD_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	LTSSM_EN	R/W	0h	Link training enable. • 0 = Disable LTSSM in PCI Express core. • 1 = Enable LTSSM in PCI Express core and link negotiation with link partner will begin.

Table 11-2932. PCIE_STATUS_COMMAND Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PARITY_ERROR	R/W1C	0h	Set if function receives poisoned TLP.
30	SIG_SYS_ERROR	R/W1C	0h	Set if function sends an ERR_FATAL or ERR_NONFATAL message and SERR enable bit is set to one.
29	RX_MST_ABORT	R/W1C	0h	Set when a requester receives a completion with unsupported request completion status.
28	RX_TGT_ABORT	R/W1C	0h	Set when a requester receives a completion with completer abort status.
27	SIG_TGT_ABORT	R/W1C	0h	Set when a function acting as a completer terminates a request by issuing completer abort completion status to the requester.
26-25	RESERVED	R	0h	Reads return 0 and writes have no effect.
24	DAT_PAR_ERROR	R/W1C	0h	This bit is set by a requester if the Parity Error Enable bit is set in its Command register and either the condition that the requester receives a poisoned completion or the condition that the requester poisons a write request is true.
23-21	RESERVED	R	0h	Reads return 0 and writes have no effect.
20	CAP_LIST	R	1h	For PCIe, this field must be set to 1.
19	INT_STAT	R	0h	Indicates that the function has received an interrupt.
18-11	RESERVED	R	0h	Reads return 0 and writes have no effect.
10	INTX_DIS	R/W	0h	Setting this bit disables generation of INTx messages.
9	RESERVED	R	0h	Reads return 0 and writes have no effect.
8	SERR_EN	R/W	0h	When set, it enables generation of the appropriate PCI Express error messages to the Root Complex.
7	RESERVED	R	0h	Reads return 0 and writes have no effect.

Table 11-2932. PCIE_STATUS_COMMAND Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	PAR_ERR_RESP	R/W	0h	This bit controls whether or not the device responds to detected parity errors (poisoned TLP). This error is typically reported as an unsupported request and may also result in a non-fatal error message if SERR_EN=1. If this bit is set, the PCIESS will respond normally to parity errors. If this bit is cleared, the PCIESS will ignore detected parity errors.
5-3	RESERVED	R	0h	Reads return 0 and writes have no effect.
2	BUS_MS	R/W	0h	Enables mastership of the bus.
1	MEM_SP	R/W	0h	This bit is set to enable the device to respond to memory accesses.
0	IO_SP	R/W	0h	This bit is set to enable the device to respond to I/O accesses. This functionality is not supported in PCIESS and therefore this bit is set to 0.

Table 11-3035. PCIE_SECSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	DTCT_PERROR	R/W1C	0h	Detected Parity Error. Set if the function receives a poisoned TLP.
30	RX_SYS_ERROR	R/W1C	0h	Received System Error. Set if the function receives an ERR_FATAL or ERR_NONFATAL message.
29	RX_MST_ABORT	R/W1C	0h	Received Master Abort. Set if the function receives a completion with unsupported request completion status.
28	RX_TGT_ABORT	R/W1C	0h	Received Target Abort. Set if the function receives a completion with completer abort completion status.
27	TX_TGT_ABORT	R/W1C	0h	Signaled Target Abort. Set if the function completes a posted or non-posted request as a completer abort error.
26-25	RESERVED	R	0h	Reads return 0 and writes have no effect.
24	MST_DPERR	R/W1C	0h	Master Data Parity Error. Set if the parity error enable bit is set in the Bridge Control Register and either the condition that the requester receives a poisoned completion or the condition that the requester poisons a write request is true.
23-16	RESERVED	R	0h	Reads return 0 and writes have no effect.
15-12	IO_LIMIT	R/W	0h	Upper 4 bits of 16bit IO Space Limit Address.
11-9	RESERVED	R	0h	Reads return 0 and writes have no effect.
8	IO_LIMIT_ADDR	R	0h	Indicates addressing for IO Limit Address. Writable from internal bus interface. • 0 = 16-bit IO addressing. • 1 = 32-bit IO addressing.
7-4	IO_BASE	R/W	0h	Upper 4 bits of 16bit IO Space Base Address.
3-1	RESERVED	R	0h	Reads return 0 and writes have no effect.

Table 11-3035. PCIE_SECSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	IO_BASE_ADDR	R	0h	Indicates addressing for the IO Base Address. Writable from internal bus interface. • 0 = 16-bit IO addressing. • 1 = 32-bit IO addressing.

LEGEND: R = Read Only; *-n* = value after reset

Table 11-3064. PCIE_PMCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	PME_SUPP_N	R	0h	PME Support. Identifies the power states from which generates PME Messages. A value of 0 for any bit indicates that the device (or function) is not capable of generating PME Messages while in that power state. Writable from internal bus interface. • Bit 31 = If set, PME Messages can be generated from D3cold. • Bit 30 = If set, PME Messages can be generated from D3hot. • Bit 29 = If set, PME Messages can be generated from D2. • Bit 28 = If set, PME Messages can be generated from D1. • Bit 27 = If set, PME Messages can be generated from D0.
26	D2_SUPP_N	R	0h	D2 Support. Writable from internal bus interface.
25	D1_SUPP_N	R	0h	D1 Support. Writable from internal bus interface.
24-22	AUX_CURR_N	R	0h	Auxiliary Current. Writable from internal bus interface.
21	DSI_N	R	0h	Device Specific Initialization. Writable from internal bus interface.
20	RESERVED	R	0h	Reads return 0 and writes have no effect.
19	PME_CLK	R	0h	PME Clock. Hardwired to zero.
18-16	PME_SPEC_VER	R	3h	Power Management Specification Version. Writable from internal bus interface.
15-8	PM_NEXT_PTR	R	50h	Next capability pointer. By default, it points to Message Signaled Interrupt structure.Writable from internal bus interface.
7-0	PM_CAP_ID	R	1h	Power Management Capability ID.

Table 11-3067. PCIE_PM_CTL_STAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	DATA_REG	R	0h	Data register for additional information. Not supported.
23	CLK_CTRL_EN	R	0h	Bus Power/Clock Control Enable. Hardwired to zero.
22	B2_B3_SUPPORT	R	0h	B2 and B3 support. Hardwired to zero.
21-16	RESERVED	R	0h	Reads return 0 and writes have no effect.
15	PME_STATUS	R/W1C	0h	PME Status. Indicates if a previously enabled PME event occurred or not.
14-13	DATA_SCALE	R	0h	Data Scale. Not supported.
12-9	DATA_SELECT	R	0h	Data Select. Not supported.
8	PME_EN	R/W	0h	PME Enable. Value of 1 indicates device is enabled to generate PME. Writable from internal bus interface.
7-4	RESERVED	R	0h	Reads return 0 and writes have no effect.
3	NO_SOFT_RST	R	0h	No Soft Reset. It is set to disable reset during a transition from D3 to D0. Writable from internal bus interface.
2	RESERVED	R	0h	Reads return 0 and writes have no effect.
1-0	PWR_STATE	R/W	0h	Power State. Controls the device power state. Writes are ignored if the state is not supported. Writable from internal bus interface. • 0 = D0 power state • 1h = D1 power state • 2h = D2 power state • 3h = D3 power states

Bit	Field	Type	Reset	Description
14-12	LOS_EXIT_LAT	R	5h	L0s Exit Latency. Writable from internal bus interface. • 0 = Less than 64 ns • 1h = 64 ns to less than 128 ns • 2h = 128 ns to less than 256 ns • 3h = 256 ns to less than 512 ns • 4h = 512 ns to less than 1 µs • 5h = 1 µs to less than 2 µs • 6h = 2 µs to less than 4 µs • 7h = More than 4 µs
11-10	AS_LINK_PM	R	1h	Active State Link Power Management Support. Writable from internal bus interface. • 1h = L0s entry supported. • 3h = L0s and L1 supported. • Others = Reserved.
9-4	MAX_LINK_WIDTH	R	2h	Maximum Link Width (×N – corresponding to N Lanes). Writable from internal bus interface. • 1h = ×1 • 2h = ×2 • Others = Reserved.
3-0	MAX_LINK_SPEED	R	2h	Maximum Link Speed. Writable from internal bus interface. • 1h = 2.5GT/s Link speed supported. • 2h = 5.0 GT/s and 2.5 GT/s Link speeds supported. • Others = Reserved.

Table 11-3098. PCIE_LINK_STAT_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	LINK_BW_STATUS	R/W1C	0h	Link Autonomous Bandwidth Status. This bit is Set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the downstream component that was indicated as an autonomous change. Not applicable and reserved for EP.
30	LINK_BW_MGMT_STATUS	R/W1C	0h	Link Bandwidth Management Status. This bit is Set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status: • A Link retraining has completed following a write of 1b to the Retrain Link bit • Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process. This bit must be set if the Physical Layer reports a speed or width change was initiated by the downstream component that was not indicated as an autonomous change. Not applicable and reserved for EP.
29	DLL_ACTIVE	R	0h	Data Link Layer Active This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1 to indicate the DL_Active state, 0 otherwise. Not applicable and reserved for EP.

Table 11-3098. PCIE_LINK_STAT_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	SLOT_CLK_CFG	R	1h	Slot Clock Configuration. Writable from internal bus interface. This bit indicates that the component uses the same physical reference clock that the platform provides on the connector.
27	LINK_TRAINING	R	0h	Link Training. Not applicable to EP.
26	RESERVED	R	0h	Reserved
25-20	NEGOTIATED_LINK_WD	R	1h	Negotiated Link Width. Set automatically by hardware after link initialization.
19-16	LINK_SPEED	R	1h	Link Speed. Set automatically by hardware after link initialization.
15-12	RESERVED	R	0h	Reads return 0 and writes have no effect.
11	LINK_BW_INT_EN	R	0h	Link Autonomous Bandwidth Interrupt Enable. Not applicable and is reserved for EP.
10	LINK_BW_MGMT_INT_EN	R	0h	Link Bandwidth Management Interrupt Enable. Not applicable and is reserved for EP.
9	HW_AUTO_WIDTH_DIS	R	0h	Hardware Autonomous Width Disable. Not supported and hardwired to zero.
8	CLK_PWR_MGMT_EN	R/W	0h	Enable Clock Power Management.
7	EXT_SYNC	R/W	0h	Extended Synchronization.
6	COMMON_CLK_CFG	R/W	0h	Common Clock Configuration. • 0 = Indicates that this device and the device at the opposite end of the link are operating with separate reference clock sources. • 1 = Indicates that this device and the device at the opposite end of the link are operating with a common clock source.
5	RETRAIN_LINK	R/W	0h	Retrain Link. Not applicable and reserved for EP.
4	LINK_DISABLE	R/W	0h	This bit disables the link by directing the LTSSM to the Disabled state when set. Not applicable and is reserved for EP.
3	RCB	R	1h	Read Completion Boundary. Writable via internal bus interface for RC. • 0 = 64 bytes • 1 = 128 bytes
2	RESERVED	R	0h	Reads return 0 and writes have no effect.
1-0	ACTIVE_LINK_PM	R/W	0h	Active State Link Power Management Control • 0 = Disabled. • 1h = L0s entry enabled. • 2h = L1 entry enabled. • 3h = L0s and L1 entry enabled.

Table 11-3101. PCIE_SLOT_CAP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	SLOT_NUM	R	0h	Physical Slot Number. Writable from internal bus interface.
18	CMD_COMP_SUPP	R	0h	No Command Complete Support. Writable from internal bus interface. When Set, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot-Plug Controller.
17	EML_PRESENT	R	0h	Electromechanical Interlock Present. Writable from internal bus interface. When Set, this bit indicates that an Electromechanical Interlock is implemented on the chassis for this slot.
16-15	PWR_LMT_SCALE	R	0h	Slot Power Limit Scale. Writable from internal bus interface.
14-7	PWR_LMT_VALUE	R	0h	Slow Power Limit Value. Writable from internal bus interface.
6	HP_CAP	R	1h	Hot Plug Capable. Writable from internal bus interface.
5	HP_SURPRISE	R	0h	Hot Plug Surprise. Writable from internal bus interface.
4	PWR_IND	R	0h	Power Indicator Present. Writable from internal bus interface.
3	ATTN_IND	R	0h	Attention Indicator Present. Writable from internal bus interface.
2	MRL_SENSOR	R	0h	MRL Sensor Present. Writable from internal bus interface.
1	PWR_CTL	R	0h	Power Controller Present. Writable from internal bus interface. If there is no power controller, software must ensure that system power is up before reading Presence Detect state.
0	ATTN_BUTTON	R	0h	Attention Indicator Present. Writable from internal bus interface.

Table 11-3119. PCIE_LINK_CTRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	Reads return 0 and writes have no effect.
16	DE_EMPH	R	1h	Current De-emphasis level • 0 = -6 dB • 1 = -3.5 dB
15-13	RESERVED	R	0h	Reads return 0 and writes have no effect.
12	POLL_DEEMPH	R/W	0h	De-emphasis level in polling-compliance state This bit sets the de-emphasis level in Polling Compliance state if the entry occurred due to the Enter Compliance bit being 1. • 0 = -6 dB • 1 = -3.5 dB
11	CMPL_SOS	R/W	0h	Compliance SOS. When this bit is set to 1, the LTSSM is required to send SKP Ordered Sets periodically in between the modified compliance patterns.
10	ENTR_MOD_COMPL	R/W	0h	Enter modified compliance. When this bit is set to 1, the device transmits Modified Compliance Pattern if the LTSSM enters Polling Compliance substate.
9-7	TX_MARGIN	R/W	0h	Value of non-de-emphasized voltage level at transmitter pins.
6	SEL_DEEMPH	R/W	0h	Selectable De-emphasis. When the Link is operating at 5.0 GT/s speed, this bit selects the level of de-emphasis for an upstream component. When the Link is operating at 2.5 GT/s speed, the setting of this bit has no effect. • 0 = -6 dB • 1 = -3.5 dB

Table 11-3119. PCIE_LINK_CTRL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HW_AUTO_SPEED_DIS	R/W	0h	Hardware Autonomous Speed Disable. • 0 = Enable hardware to change the link speed. • 1 = Disables hardware from changing the Link speed for device specific reasons other than attempting to correct unreliable Link operation by reducing Link speed.
4	ENTR_COMPL	R/W	0h	Enter Compliance. Software is permitted to force a Link to enter Compliance mode at the speed indicated in the Target Link Speed field by setting this bit to 1 in both components on a Link and then initiating a hot reset on the Link.
3-0	TGT_SPEED	R/W	2h	Target Link Speed. • 1h = 2.5 GT/s Target Link Speed. • 2h = 5.0 GT/s Target Link Speed. • Others = Reserved.

Table 11-3177. PCIE_ACK_FREQ Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reads return 0 and writes have no effect.
30	ASPM_L1	R/W	0h	Set to allow entering ASPM L1 even when link partner did not to L0s. When cleared, the ASPM L1 state is entered only after idle period during which both RX and TX are in L0s.
29-27	L1_ENTRY_LATENCY	R/W	3h	L1 entrance latency. The latency is set to 2^L1_ENTRY_LATENCY microseconds with the max being 64 microseconds. • 0 = 1 µs • 1h = 2 µs • 2h = 4 µs • 3h = 8 µs • 4h = 16 µs • 5h = 32 µs • 6h or 7h = 64 µs
26-24	L0S_ENTRY_LATENCY	R/W	3h	L0s entrance latency. The latency is set to L0S_ENTRY_LATENCY+1 microseconds. Maximum is 7 microseconds. • 0 = 1 µs • 1h = 2 µs • 2h = 3 µs • 3h = 4 µs • 4h = 5 µs • 5h = 6 µs • 6h or 7h = 7 µs
23-16	COMM_NFTS	R/W	Fh	Number of fast training sequences when common clock is used and when transitioning from L0s to L0.
15-8	NFTS	R/W	64h	Number of fast training sequences to be transmitted when transitioning from L0s to L0. Value of 0is not supported.

Table 11-3177. PCIE_ACK_FREQ Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	ACK_FREQ	R/W	0h	Ack Frequency. The value range is 0x0-0xFF. A value of 0 in the ACK Frequency field indicates that this ACK frequency control feature is disabled. A value of N (N>0) indicates that the module will ack N TLPs received by sending an ACK DLLP.

Table 11-3178. Register Call Summary for PCIE_ACK_FREQ

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reads return 0 and writes have no effect.
21-16	LNK_MODE	R/W	3h	Link Mode Enable. (×N – corresponding to N Lanes). • 1h = ×1 • 3h = ×2 • 7h = ×4 • Fh = ×8 • 1Fh = ×16 • 3Fh = ×32 • Others = Reserved
15-12	RESERVED	R	0h	Reads return 0 and writes have no effect.
11-8	LINK_RATE	R/W	1h	Default link rate. For 2.5 GT/s it is 0x1. This register does not affect any functionality.
7	FLNK_MODE	R/W	0h	Fast link mode. Set all internal timers to fast mode for simulation purposes.
6	RESERVED	R	0h	Reads return 0 and writes have no effect.
5	DLL_EN	R/W	1h	DLL Link Enable. Enable link initialization.
4	RESERVED	R	0h	Reads return 0 and writes have no effect.
3	RST_ASRT	R/W	0h	Reset assert. Triggers a recovery and forces the LTSSM to the Hot Reset state. Downstream ports (RC ports) only.
2	LPBK_EN	R/W	0h	Loopback Enable. Turn on loopback.
1	SCRM_DIS	R/W	0h	Scramble Disable. Turn off data scrambling.
0	OMSG_REQ	R/W	0h	Other message request. Set to transmit the message contained in the Other Message Register (PCIE_PL_OMSG).

11.15 Quad Serial Peripheral Interface (QSPI)

This section describes the Quad Serial Peripheral Interface (QSPI™) module for the device.

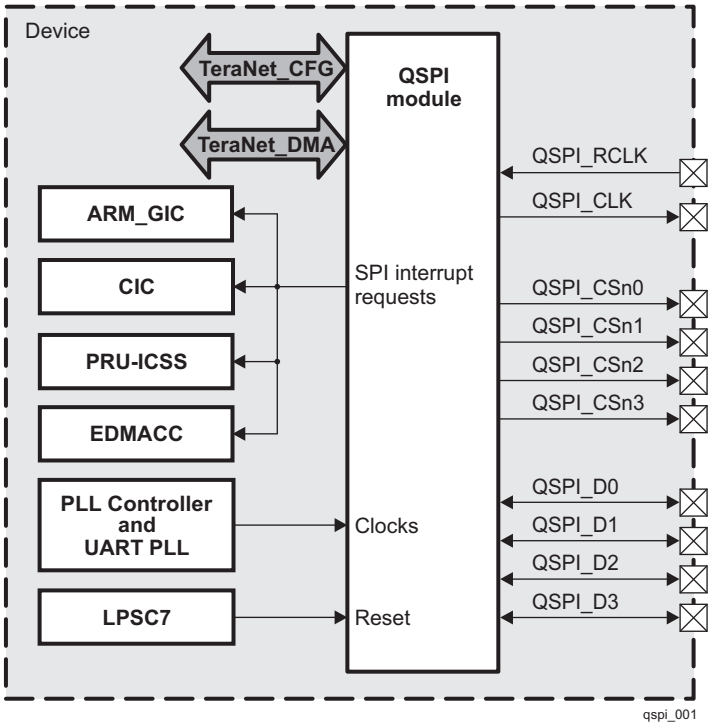
NOTE: This section contains information that is Copyright ©2010-2015 Cadence Design Systems, Inc. All rights reserved.

11.15.1 QSPI Overview

The Quad Serial Peripheral Interface (QSPI™) module (see Figure 11-1305) is a kind of Serial Peripheral Interface (SPI) module which allows single, dual or quad read and write access to external flash devices. This module has a memory mapped register interface, which provides a direct memory interface for accessing data from external flash devices, simplifying software requirements.

The QSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling its completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device master at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM should be accessed using user programmable configuration registers.

Figure 11-1305. QSPI Module



The QSPI module has the following features:

- Memory mapped 'direct' mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM to reduce bus overhead and buffer flash data during indirect transfers.
- Set of software accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Supports any device clock frequency, including frequencies of 96 MHz (QSPI mode 0 only).

- Supports XIP (Execute in Place), also referred to as continuous mode.
- Supports single, dual or quad I/O instructions.
- Supports 16/32/64 byte cacheline wrap accesses.
- Supports ECC for its internal SRAM buffer.
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.
- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs bypassing the higher layer processes.
- Independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Serial clock with programmable polarity.
- Programmable baud rate generator to generate QSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external chip selects.
- Supports Little-endian operation only.

The following features are not supported:

- DMA peripheral interface.
- High speed performance (greater than 50 MHz) for QSPI modes 1, 2 and 3.
- Continuous addressing mode for each of the connected devices and auto-detection of boundaries between them.

NOTE: The QSPI module does not provide any busy or idle status. Software needs to ensure that the QSPI module is idle before clocks can be shut off. Otherwise a lockup condition may occur.

11.15.2 QSPI Environment

The QSPI module is primarily intended for fast booting from Quad-SPI flash memories. Figure 11-1306 shows a typical connection of the QSPI module to an external Quad-SPI flash memory.

Figure 11-1306. QSPI Connected to an External Quad-SPI Flash Memory

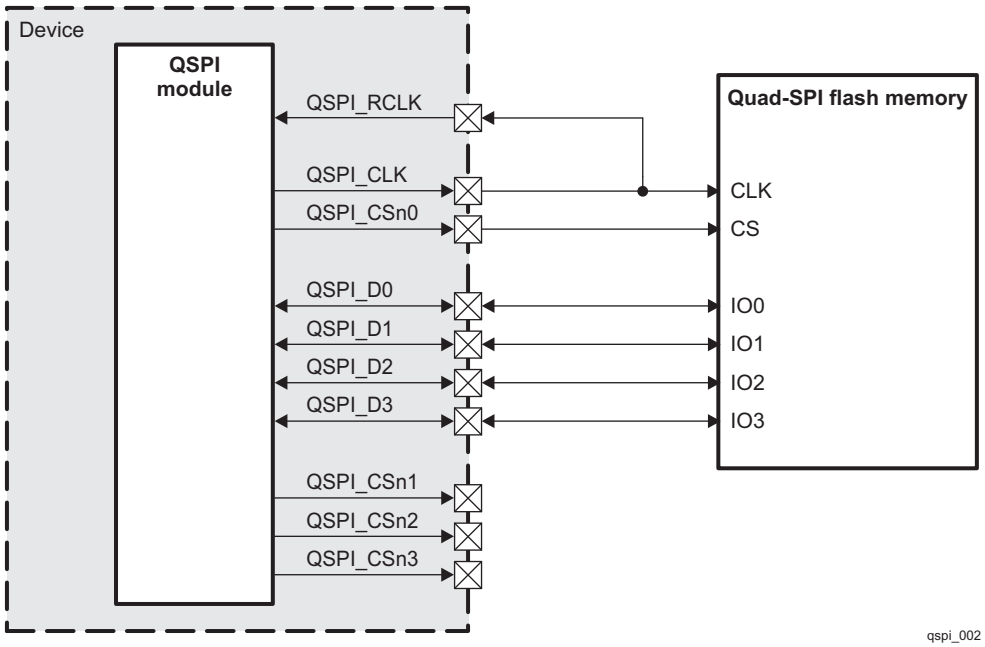


Table 11-3203 lists and describes the QSPI I/O signals.

Table 11-3203. QSPI I/O Signals

Signal Name	I/O[1]	Description
QSPI_D0	IO	QSPI data input/output 0
QSPI_D1	IO	QSPI data input/output 1
QSPI_D2	IO	QSPI data input/output 2
QSPI_D3	IO	QSPI data input/output 3
QSPI_CSn0	O	External flash device chip select 0
QSPI_CSn1	O	External flash device chip select 1
QSPI_CSn2	O	External flash device chip select 2
QSPI_CSn3	O	External flash device chip select 3
QSPI_CLK	O	QSPI clock output for the external flash device
QSPI_RCLK	I	QSPI return clock input (looped back clock of QSPI_CLK)[2]

(1) I = Input; O = Output

(2) The clock input signal is a looped back version of QSPI_CLK and facilitates easier timing closure at higher speeds. The loop back has to be at board level in order to support higher QSPI speeds.

11.15.3 QSPI Integration

This section describes the module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-1307 shows the QSPI module integration.

Figure 11-1307. QSPI Integration

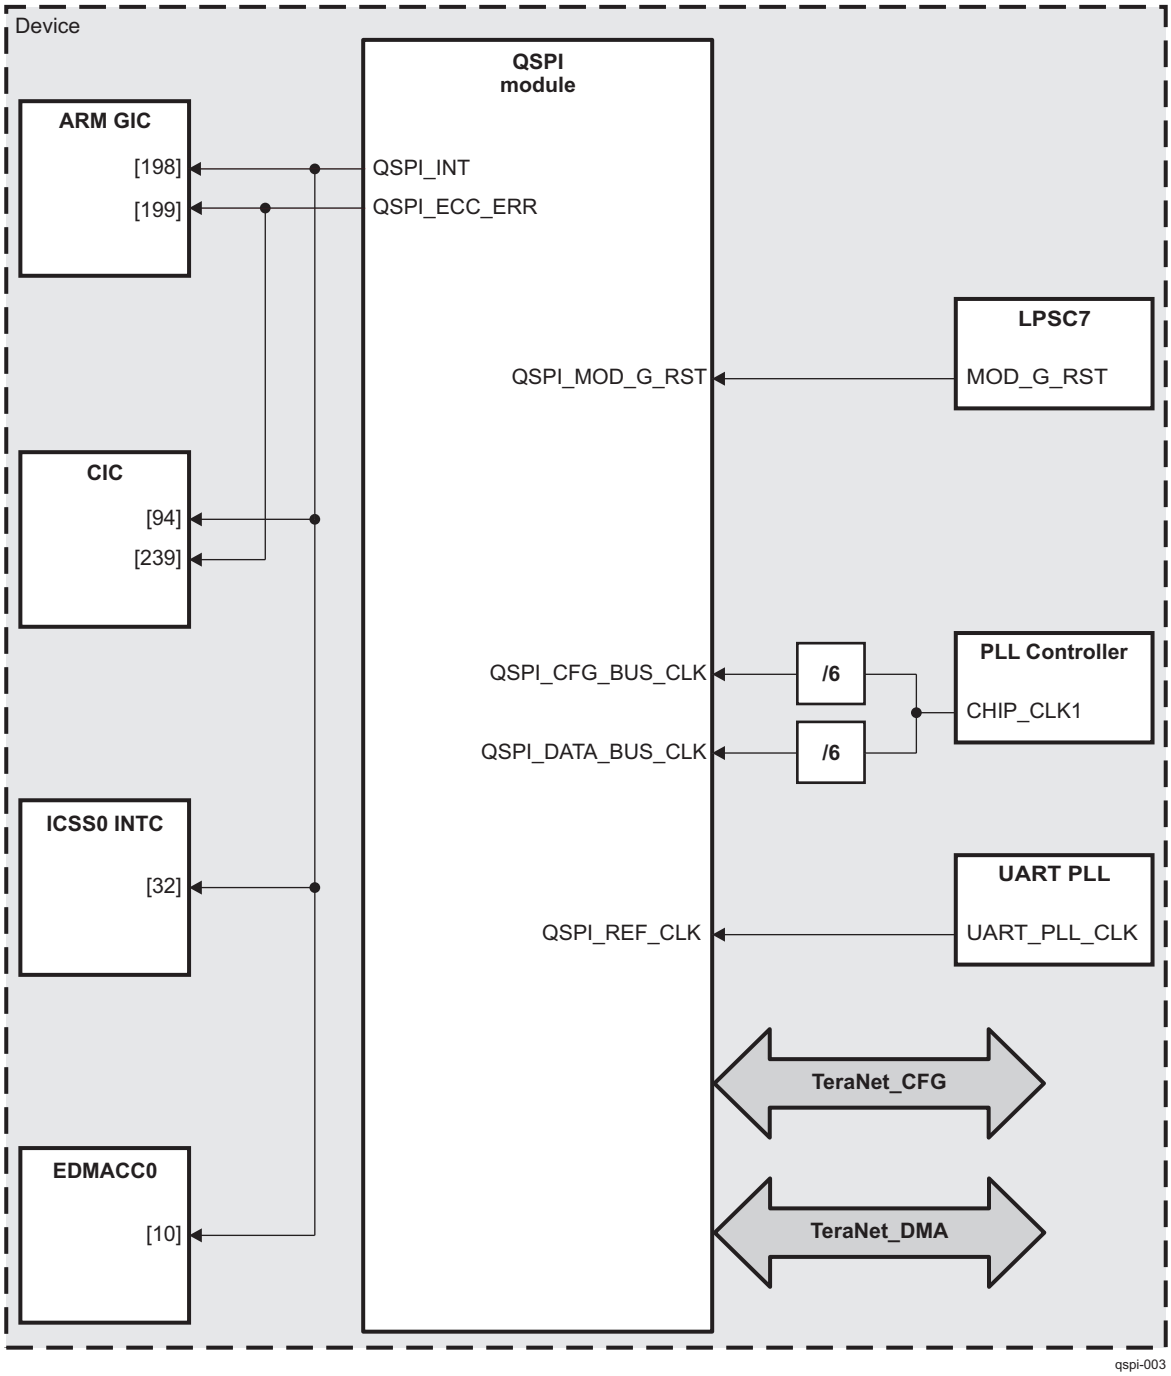

Table 11-3204 through Table 11-3206 summarize the integration of the module in the device.

Table 11-3204. QSPI Integration Attributes

Module Instance	Attributes

	QSPI_ECC_ERR	[199]	[239]	-	-	QSPI ECC Interrupt Request

11.15.3.1 QSPI Clock Domains

The QSPI module has three clock domains:

- Config bus clock domain.
- Data bus clock domain.
- SPI reference clock domain.

All of these clocks are asynchronous to each other. The first two clock domains correspond to the configuration and data busses respectively. The data bus clock (QSPI_DATA_BUS_CLK) is used to transfer data over the data bus between a master on the system interconnect and the QSPI module. The data bus clock also drives the internal QSPI SRAM. The config bus clock (QSPI_CFG_BUS_CLK) is used to access the QSPI configuration registers and for interrupt handling. The SPI reference clock (QSPI_REF_CLK) drives the SPI transmit and receive logic in the QSPI module. It is also used to generate the output SPI protocol clock (QSPI_CLK) and for oversampling of the input data (QSPI_RCLK). Using the QSPI_REF_CLK allows the QSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

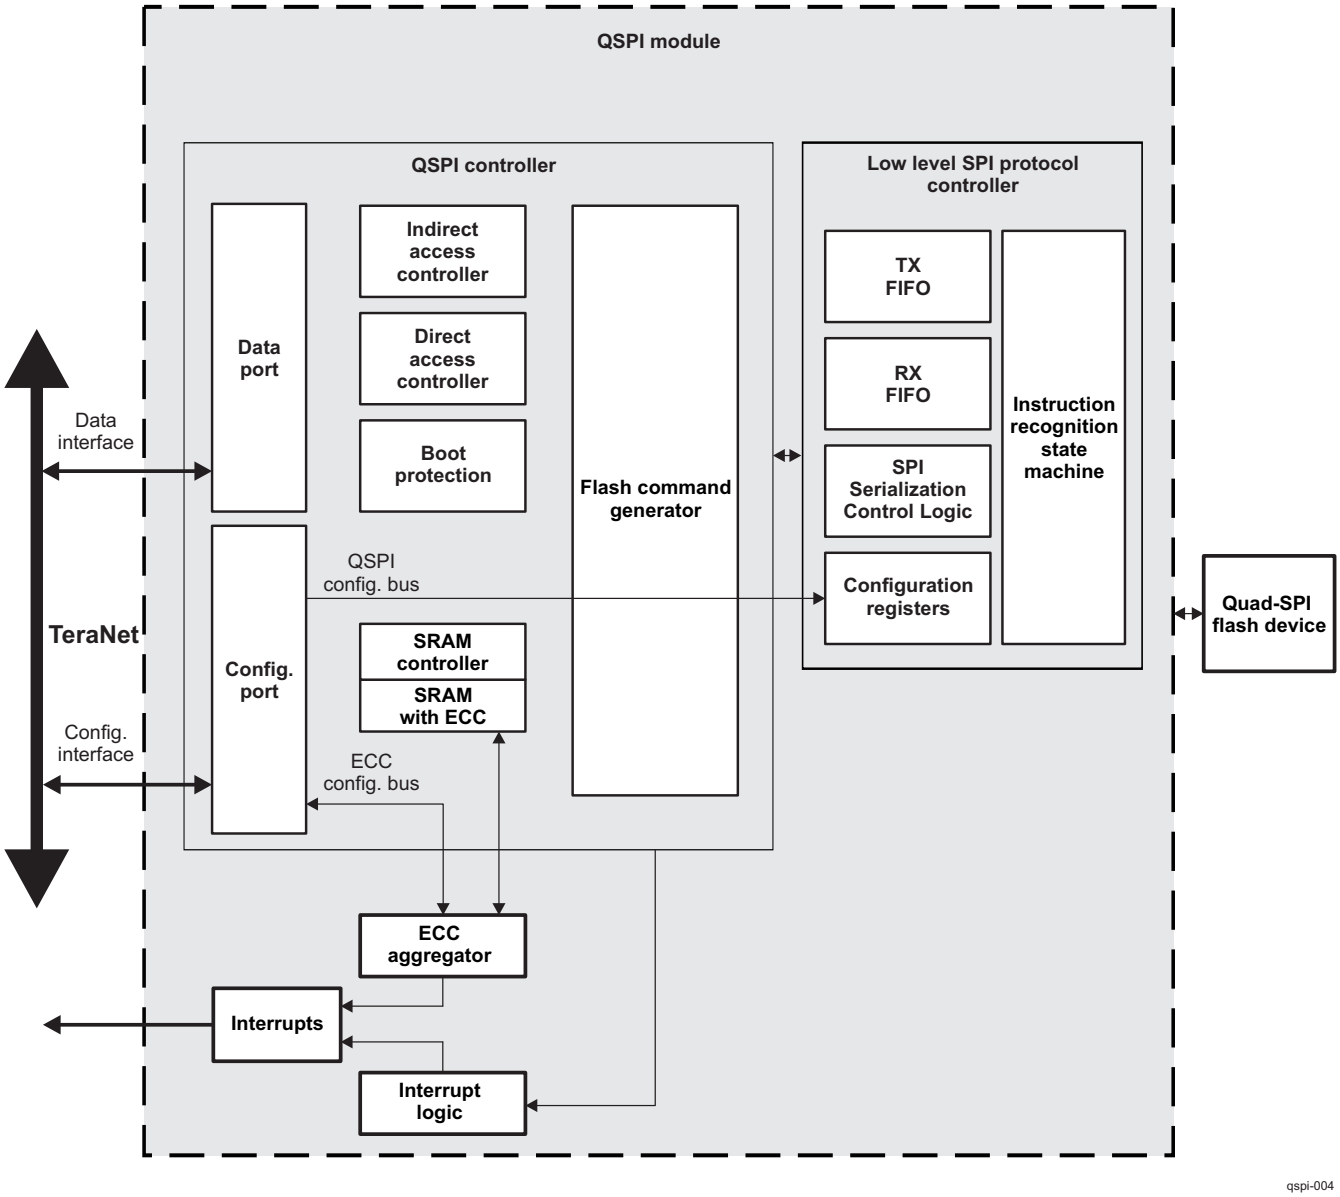
NOTE: There is no particular clock ratio requirement between QSPI_DATA_BUS_CLK and QSPI_CFG_BUS_CLK. But QSPI_REF_CLK has to be 2 times greater than QSPI_DATA_BUS_CLK and 4 times greater than QSPI_CLK.

11.15.4 QSPI Functional Description

11.15.4.1 QSPI Block Diagram

Figure 11-1308 shows the QSPI module block diagram.

Figure 11-1308. QSPI Block Diagram



The QSPI module is composed of two main blocks. The first one is the QSPI controller and the second one is the Low level SPI protocol controller.

The QSPI module has the following two slave ports:

- Data slave port intended for data transfer.
- Configuration slave port intended for accessing the programmable set of registers.

11.15.4.1.1 Data Slave Port

The data port is used for data transfer to external flash devices in direct and indirect mode of operation. It validates the incoming data accesses, responds to invalid requests, performs any required byte and half-word reordering, blocks writes violating the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC). The data interface bus is 32-bit wide. Therefore only byte, half-word and word accesses are permitted.

NOTE: Cache line wrap accesses over the data slave port should be word aligned.

Data slave port does't support cache line wrap bursts of 128 bytes.

11.15.4.1.2 Configuration Slave Port

The configuration port is used to configure the QSPI module and perform software controlled flash accesses using the QSPI_FLASH_CMD_CTRL_REG register (for more information refer to Section 11.15.4.10, *Software Triggered Instruction Generator (STIG)*). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the QSPI configuration and SRAM ECC registers.

NOTE: The configuration port supports only 32-bit accesses. For single byte or half word manipulations software should perform read-modify-write operations.

11.15.4.2 QSPI Modes

The QSPI module supports four SPI modes. These modes are defined through the QSPI_CONFIG_REG[1] SEL_CLK_POL_FLD and QSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD bits. The SEL_CLK_POL_FLD bit defines the clock polarity and the SEL_CLK_PHASE_FLD bit defines the data launch and data capture relation to the QSPI_CLK edges. Table 11-3207 gives a brief description of these modes.

Table 11-3207. QSPI Modes

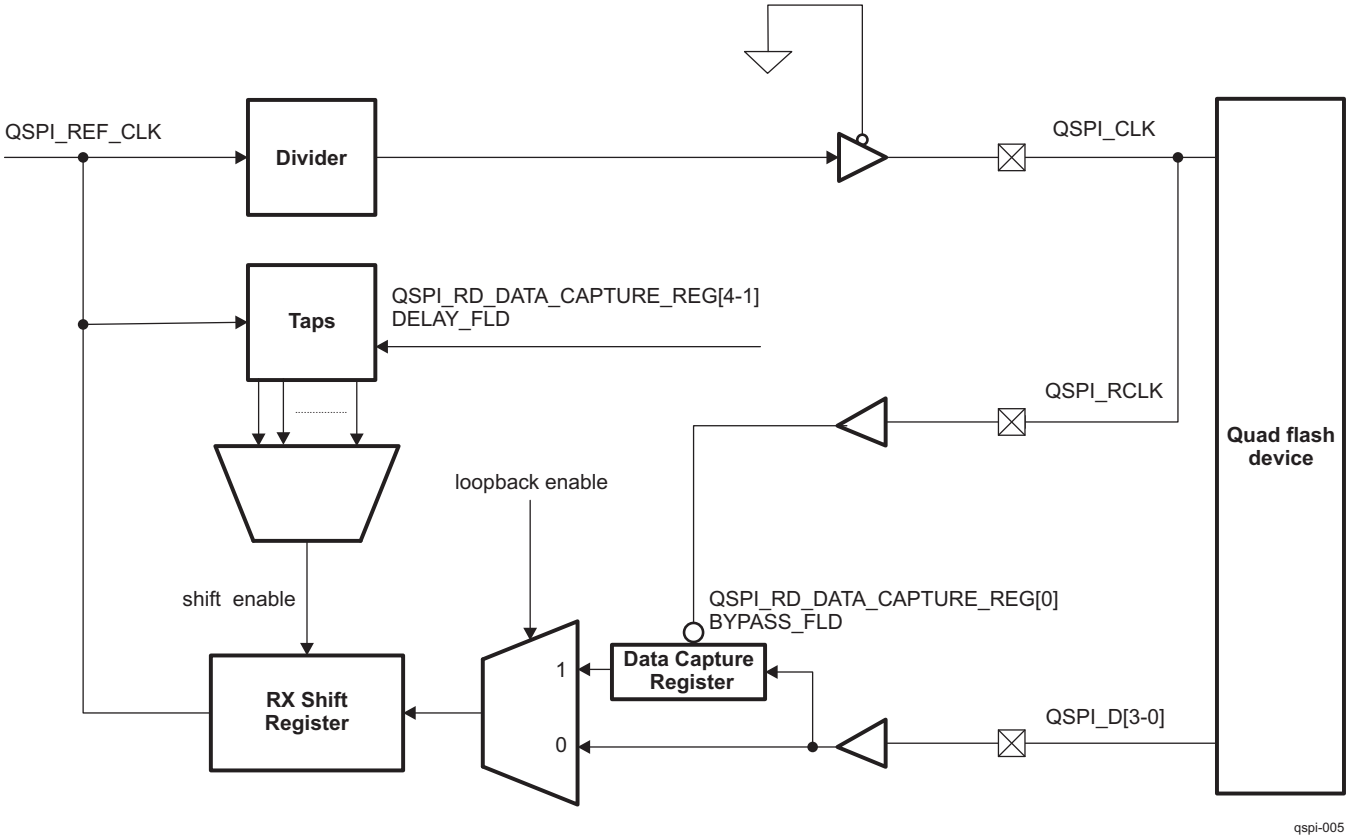
QSPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state : low
			Data launch edge : clock falling edge
			Data capture edge : clock rising edge
1	0	1	Clock inactive state : low
			Data launch edge : clock rising edge
			Data capture edge : clock falling edge
2	1	0	Clock inactive state : high
			Data launch edge : clock rising edge
			Data capture edge : clock falling edge
3	1	1	Clock inactive state : high
			Data launch edge : clock falling edge
			Data capture edge : clock rising edge

The QSPI module has a loopback mode in which a clock, looped back at board level, is used for registering the input data. And the edge used is same as the launch edge (for more information see Section 11.15.4.2.1, *Read Data Capture*).

11.15.4.2.1 Read Data Capture

Figure 11-1309 shows the Read Data Capture Logic in the QSPI module.

Figure 11-1309. Read Data Capture Logic



The loopback mode is enabled by writing 0 to QSPI_RD_DATA_CAPTURE_REG[0] BYPASS_FLD bit. The taps are selected by programming QSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD field. The taps delay the read data capturing logic by the programmed number of QSPI_REF_CLK cycles.

There are three programmable features allowing software to tune the logic that captures the read data from the device. After POR, the adapted loopback clock circuit and the QSPI_DEV_DELAY_REG register line both wake in a disabled state. This should be valid for most applications, and can be used for device enumeration, where the device clock will be configured slowly. The QSPI_RD_DATA_CAPTURE_REG register provides the control for these features. The QSPI_RD_DATA_CAPTURE_REG[5] SAMPLE_EDGE_SEL_FLD bit selects the edge of the QSPI_REF_CLK signal, on which data outputs from flash memory are sampled. The QSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD field controls the additional number of read data capture cycles (this is the fast QSPI_REF_CLK signal, running at least x4 times of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less.

11.15.4.3 QSPI Memory Regions

A total of 256 B space is allocated to the configuration port and data port is 64 MB. Table 11-3208 shows QSPI memory map.

Table 11-3208. QSPI Memory Map

Address Range	Size	Description
2400 0000h to 27FF FFFFh	64 MB	Data register space
0294 0000h to 0294 00FFh	256 B	Configuration register space
0294 0100h to 0294 03FFh	768 B	Reserved
0294 0400h to 0294 07FFh	1 KB	SRAM ECC
0294 0800h to 0294 0FFFh	2 KB	Reserved

11.15.4.4 QSPI Interrupt Requests

The QSPI module generates two interrupts. The ECC interrupt (QSPI_ECC_ERR) is generated by the ECC aggregator. The other interrupt (QSPI_INT) is generated by the QSPI module.

Table 11-3209 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 11-3209. QSPI Events

Event Flag	Event Mask	Description
QSPI_IRQ_STATUS_REG[0] MODE_M_FAIL_FLD	QSPI_IRQ_MASK_REG[0] MODE_M_FAIL_MASK_FLD	Event Flag and Event Mask for the QSPI Interrupts.

11.15.4.5 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address will be forwarded. A remap feature is available to remap all incoming AHB addresses to ADDRESS + N, where N is the value stored in the QSPI_REMAP_ADDR_REG[31-0] VALUE_FLD bit field. It is enabled via the QSPI_CONFIG_REG[16] ENB_AHB_ADDR_REMAP_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

11.15.4.6 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, will be not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first QSPI_LOWER_WR_PROT_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second QSPI_UPPER_WR_PROT_REG register defines the FLASH block that is located at the top of the region to be protected. The third QSPI_WR_PROT_CTRL_REG register is a control register consisting of 2 bits. The QSPI_WR_PROT_CTRL_REG[0] INV_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The QSPI_WR_PROT_CTRL_REG[1] ENB_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the QSPI_DEV_SIZE_CONFIG_REG register.

NOTE: The write protection feature is supported for DAC mode only. For INDAC mode this feature is not supported.

11.15.4.7 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the QSPI_CONFIG_REG[7] ENB_DIR_ACC_CTRL_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in Section 11.15.4.9, *Indirect Controller (INDAC)*. If DAC is disabled, any incoming access that can't be forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

11.15.4.8 Direct Access Controller (DAC)

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see QSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD and QSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD bits).

11.15.4.9 Indirect Controller (INDAC)

11.15.4.9.1 Indirect Read Controller

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (for more information see the following registers: QSPI_INDIRECT_READ_XFER_CTRL_REG, QSPI_INDIRECT_READ_XFER_WATERMARK_REG, QSPI_INDIRECT_READ_XFER_START_REG, and QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG). This block will communicate with an embedded Low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external TeraNet master.

By default, the indirect read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in QSPI_INDIRECT_READ_XFER_START_REG and QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG registers respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to Section 11.15.4.9.3, *Indirect Access Queuing*.

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external master will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the QSPI module. The address of the incoming read access must be in the range of Indirect trigger address programmed via the QSPI_IND_AHB_ADDR_TRIGGER_REG register to Indirect trigger address + 15. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the Indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH Memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the QSPI_INDIRECT_READ_XFER_START_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the QSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with minimum latency. Once the data has been read from the SRAM, the QSPI module will free up the associated resource in it.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external master may issue a 16-bit (HalfWord) or byte access to complete the transfer. It is also permitted for the external master to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the QSPI_SRAM_FILL_REG register.

An indirect operation may be cancelled at any time by setting 1 to QSPI_INDIRECT_READ_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The QSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see QSPI_INDIRECT_READ_XFER_WATERMARK_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the QSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the QSPI module.

Setting the QSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit starts an indirect read operation. QSPI_INDIRECT_READ_XFER_CTRL_REG[2] RD_STATUS_FLD bit is available to check the status.

11.15.4.9.1.1 Indirect Read Transfer Process

The following sequence can be followed:

- 1. Set-up QSPI_CONFIG_REG register.
- 2. Set-up the indirect transfer's FLASH start address in the QSPI_INDIRECT_READ_XFER_START_REG register.
- 3. Set-up the number of bytes to be transferred in the QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG register.
- 4. Set-up the indirect transfer's trigger address in the QSPI_IND_AHB_ADDR_TRIGGER_REG register.
- 5. If the watermark interrupt feature is to be used, set the SRAM fill level watermark register (QSPI_INDIRECT_READ_XFER_WATERMARK_REG register) which will cause an interrupt to be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.
- 6. Trigger Indirect Read access by setting the QSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit to 1.
- 7. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the QSPI_SRAM_FILL_REG register to decide when sufficient data is in the SRAM to trigger data fetches.
- 8. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 7. Otherwise continue to step 9.
- 9. The completion status of the indirect read operation can be polled via the QSPI_INDIRECT_READ_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD bit.
- 10. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

11.15.4.9.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more

information see the following registers: QSPI_INDIRECT_WRITE_XFER_CTRL_REG, QSPI_INDIRECT_WRITE_XFER_WATERMARK_REG, QSPI_INDIRECT_WRITE_XFER_START_REG, and QSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG). This block will await delivery of the write data via the external TeraNet master, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in QSPI_INDIRECT_WRITE_XFER_START_REG and QSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG registers respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to Section 11.15.4.9.3, *Indirect Access Queuing*.

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external TeraNet master. In the case of SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable QSPI_SRAM_FILL_REG register and this can be used to avoid this situation.

An external master will provide the write data and will transfer this to the QSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the QSPI_IND_AHB_ADDR_TRIGGER_REG register to Indirect trigger address + 15. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be popped, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the QSPI_INDIRECT_WRITE_XFER_START_REG register. Assuming the SRAM is not full at the point the data interface access is received by the QSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external master may issue a 32-bit word, 16-bit (half-word) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the master is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the QSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the QSPI module will initiate a write burst to the flash command generator.

An indirect operation may be cancelled at any time by setting 1 to the QSPI_INDIRECT_WRITE_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The QSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see QSPI_INDIRECT_WRITE_XFER_WATERMARK_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the QSPI module.

Setting the QSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit starts an indirect write operation. The QSPI_INDIRECT_WRITE_XFER_CTRL_REG[2] WR_STATUS_FLD bit is available to check the status.

11.15.4.9.2.1 Indirect Write Transfer Process

The following sequence can be followed:

- 1. Set-up the indirect transfer's FLASH start address in the QSPI_INDIRECT_WRITE_XFER_START_REG register.
- 2. Set-up the number of bytes to be transferred in the QSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register.
- 3. Set-up the indirect transfer's trigger address in the QSPI_IND_AHB_ADDR_TRIGGER_REG register.
- 4. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the QSPI module to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write data in one block transfer, the software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, the software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a choise as to when is the most practical time to send the next part of the transfer.
- 5. If the watermark interrupt feature is to be used, set the SRAM fill level watermark register (see QSPI_INDIRECT_WRITE_XFER_WATERMARK_REG and QSPI_SRAM_FILL_REG registers) which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. If the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
- 6. Trigger Indirect Write access by setting the QSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit to 1.
- 7. If the remaining number of bytes still to be transferred into the QSPI SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to the SRAM.
- 8. If all the data in the indirect transfer has now been sent to the SRAM, then goto step 10 and await indirect complete status. Otherwise if there is more data still to be transferred then either
  - If the watermark interrupt feature is being used, then wait for watermark interrupt.
  - Alternatively the SRAM fill level can be checked to identify a convenient time to send more data.
- 9. Loop back to step 7.
- 10. Optional: The completion status of the Indirect write operation can be polled via the QSPI_INDIRECT_WRITE_XFER_CTRL_REG[2] WR_STATUS_FLD bit.
- 11. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

11.15.4.9.3 Indirect Access Queuing

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (QSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit or QSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit) twice in short succession. The indirect number of bytes register (QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG or QSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register) and the indirect FLASH start address register (QSPI_INDIRECT_READ_XFER_START_REG or QSPI_INDIRECT_WRITE_XFER_START_REG register) must be set-up with the relevant transfer data before START_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG and QSPI_INDIRECT_READ_XFER_START_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

11.15.4.9.4 Consecutive Writes and Reads Using Indirect Transfers

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

11.15.4.9.5 Accessing the SRAM

The SRAM is separated in two segments. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the QSPI_SRAM_PARTITION_CFG_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 00h, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 01h, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 02h, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to FDh, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.
- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to FEh, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the QSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to FFh, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

NOTE: A value of FFh or 00h in the QSPI_SRAM_PARTITION_CFG_REG should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the QSPI_SRAM_FILL_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. Table 11-3210 shows priority allocated to these sources.

Table 11-3210. SRAM Access Priority

SRAM Access Priority		
Indirect Write	Write to SRAM (From System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (From QSPI Module)	2nd
Indirect Read	Write to SRAM (From QSPI Module)	1st
	Read from SRAM (From System Data Bus)	3rd (exclusive with Data Bus Write Request)

NOTE: With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

11.15.4.10 Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the QSPI_FLASH_CMD_CTRL_REG register by setting up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH Devices could cause unpredicted behavior of the controller. The QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit is used to trigger the command. The QSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (QSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the QSPI_FLASH_RD_DATA_LOWER_REG and QSPI_FLASH_RD_DATA_UPPER_REG registers. For writes, the write data should be placed in the QSPI_FLASH_WR_DATA_LOWER_REG and QSPI_FLASH_WR_DATA_UPPER_REG registers.

11.15.4.10.1 Servicing a STIG Request

A STIG request will cause the QSPI Flash controller to interrogate the QSPI_FLASH_CMD_CTRL_REG register to determine what and how many bytes it should send to the FLASH device. The QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size of which is also programmed in the same register) is sent next. The address itself is stored in the QSPI_FLASH_CMD_ADDR_REG register. If there are any dummy bytes to send (the size of which is also programmed in QSPI_FLASH_CMD_CTRL_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in QSPI_FLASH_CMD_CTRL_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers,

QSPI_FLASH_WR_DATA_LOWER_REG and QSPI_FLASH_WR_DATA_UPPER_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the QSPI Flash Controller stores that in the Flash Command Read Data Registers (QSPI_FLASH_RD_DATA_LOWER_REG and QSPI_FLASH_RD_DATA_UPPER_REG registers). When the QSPI Flash controller starts to service a STIG request, it sets the QSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit to indicate a command execution is in progress. When the QSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the QSPI_POLLING_FLASH_STATUS_REG[8] DEVICE_STATUS_VALID_FLD bit, which indicate active auto-polling phase. After requesting a STIG, the QSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by MSB of QSPI_WRITE_COMPLETION_CTRL_REG register). This feature is implemented to free up SPI bandwidth if needed.

NOTE: The QSPI data is sent LSB first, while address is sent MSB first.

NOTE: The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

11.15.4.11 Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write
- The STIG
- The Direct Access Read
- The Indirect Access Read

11.15.4.12 SPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (QSPI_DEV_INSTR_RD_CONFIG_REG and QSPI_DEV_INSTR_WR_CONFIG_REG registers).

For writes, the Write Enable Latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The QSPI Flash Controller will automatically issue the write enable latch command before triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by set-up bit 8th into the QSPI_DEV_INSTR_WR_CONFIG_REG register. The op-code for WREN is typically 06h and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The QSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit [0] has cleared to zero and the write enable latch bit has also cleared to zero). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

11.15.4.13 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the QSPI_DEV_INSTR_RD_CONFIG_REG register and the QSPI_DEV_INSTR_WR_CONFIG_REG register. These registers include fields to set-up the required instruction op-codes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type and whether the instruction uses single, dual or quad pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the controller can operate from a reset state, the registers will be reset to an op-code compatible with SIO devices.

Despite being applicable for both READs and WRITEs, the QSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD field only appears once – it is not included in the QSPI_DEV_INSTR_WR_CONFIG_REG register. If software sets this to anything other than '0', then the address xfer type and the data xfer type bits of both QSPI_DEV_INSTR_RD_CONFIG_REG and QSPI_DEV_INSTR_WR_CONFIG_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions). Also note that for devices that support instructions that can send the OPCODE over 2/4 lanes, the name for these instructions are not consistently named in the FLASH datasheets.

One of the devices that support these instructions is the Numonyx (Micron) N25Q128. The extra READ instructions are called DCFR and QCFR. The WRITE instructions are DCPP and QCPP. Table 11-3211 shows how software should configure the QSPI module for each specific READ and WRITE instruction supported by the N25Q128 device.

Table 11-3211. READ and WRITE Instruction Configuration

READS						
OPCODE	OPCODE sent over how many lanes?	ADDRESS/ DUMMY/ MODE sent over how many lanes?	DATA bytes sent over how many lanes?	QSPI Instruction TYPE (Device Read Instruction Configuration Register)	QSPI Address Xfer type (Device Read Instruction Configuration Register)	QSPI Data Xfer type (Device Read Instruction Configuration Register)
READ	1	1	1	0	0	0
FAST_READ	1	1	1	0	0	0
DOFR (Dual O/p Fast Read)	1	1	2	0	0	1
DIOFR (Dual I/O Fast Read)	1	2	2	0	1	1
QOFR (Quad O/p Fast Read)	1	1	4	0	0	2
QIOFR (Quad I/O Fast Read)	1	4	4	0	2	2

Table 11-3211. READ and WRITE Instruction Configuration (continued)

DCFR (Dual Command Fast Read)	2	2	2	1	Don't care	Don't care
QCFR (Quad Command Fast Read)	4	4	4	2	Don't care	Don't care
WRITE						
OPCODE	OPCODE sent over how many lanes?	ADDRESS/ DUMMY/ MODE sent over how many lanes?	DATA sent over how many lanes?	QSPI Instruction TYPE (Device Read Instruction Configuration Register)	QSPI Address Xfer type (Device Write Instruction Configuration Register)	QSPI Data Xfer type (Device Write Instruction Configuration Register)
PP	1	1	1	0	0	0
DIFP (Dual Input Fast Program)	1	1	2	0	0	1
DIEFP (Dual Input Extended Fast Program)	1	2	2	0	1	1
QIFP (Quad Input Fast Program)	1	1	4	0	0	2
QIEFP (Quad Input Extended Fast Program)	1	4	4	0	2	2
DCPP (Dual Command Fast Program)	2	2	2	1	Don't care	Don't care
QCPP (Quad Command Fast Program)	4	4	4	2	Don't care	Don't care

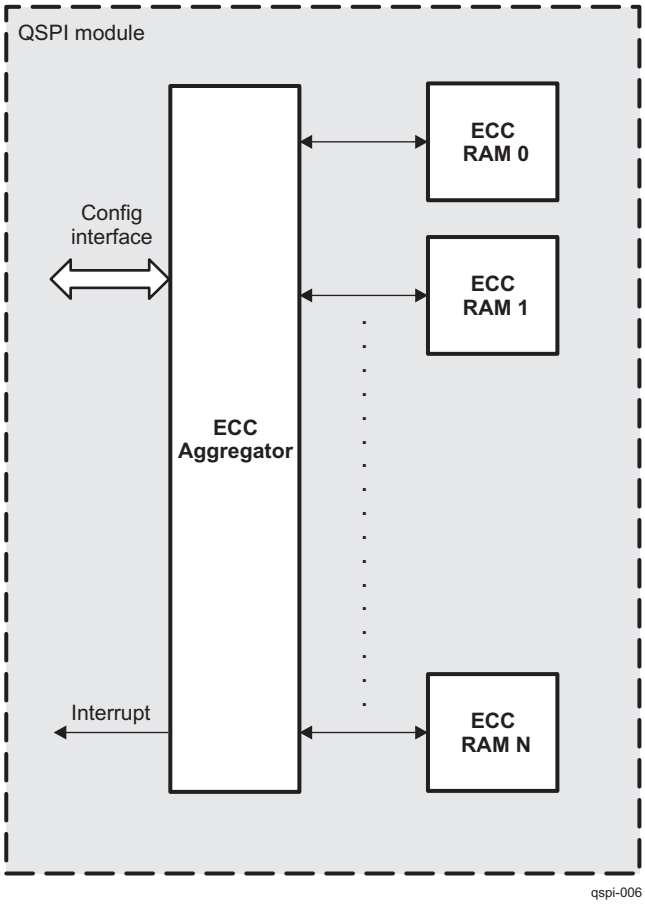
11.15.4.14 ECC Aggregator module

This section describes the architecture and functional details of the ECC Aggregator module.

11.15.4.14.1 Overview

Figure 11-1310 shows the ECC Aggregator module block diagram.

Figure 11-1310. ECC Aggregator Block Diagram



The ECC Aggregator module supports the following general features:

- Automatically detects and connects all the RAM ECC interfaces in the QSPI module.
- Provides a mechanism to control and monitor the ECC RAMs in the QSPI module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAMs into a single interrupt to the host.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed these operations can be handled by software.

11.15.4.14.2 ECC Aggregator Registers

The ECC Aggregator module supports all the ECC control, status and interrupt registers for all the ECC RAMs in the QSPI module. The ECC registers are memory mapped to a 1 KB address space in the configuration port of the QSPI module (address range: from 0294 0400h to 0294 07FFh).

There are 3 types of register accesses in the ECC aggregator module:

- Global registers that are common to all ECC RAMs. This includes the revision and ECC vector registers. Every ECC RAM serviced by the ECC Aggregator module is assigned a unique ID by the module. Writing this ID to the ECC vector register selects the ECC RAM to be controlled or read the ECC status from.
- ECC control and status registers. These are specific to each ECC RAM and selected by the RAM ID written to the ECC vector register. The accesses to these registers are done via the configuration interface.
- Interrupt registers. These include the standard interrupt status, interrupt enable, clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module.

11.15.4.14.3 Reads to ECC Control and Status Registers

Due to the long latencies in the order of several thousands of clock cycles on the configuration interface, the reads to the ECC control and status registers for each ECC RAM are triggered by writing a 'read message' to the ECC vector register as described below:

- Software writes the ECC ID to the QSPI_ECC_VECTOR[10-0] RAM_ID bit field, the 'read message' to the QSPI_ECC_VECTOR[15] TRIGGER_READ bit, and the read address to the QSPI_ECC_VECTOR[23-16] READ_ADDRESS bit field. The read address corresponds to any of the ECC control or status registers (QSPI_ECC_WRAPPER_REVISION, QSPI_ECC_CONTROL, QSPI_ECC_ERROR_CONTROL1, QSPI_ECC_ERROR_CONTROL2, QSPI_ECC_ERROR_STATUS1, QSPI_ECC_ERROR_STATUS2) which require configuration interface access to the ECC RAM(s).
- Software then polls the QSPI_ECC_VECTOR[24] READ_DONE bit to check if it is '1'. This indicates that the read operation has completed on the configuration interface.
- Software reads the data from the ECC control or status register. The following clock cycle returns the read data.

11.15.4.14.4 ECC Interrupts

The ECC aggregator module aggregates all the level pending status from the ECC RAMs to a single EOI-handshake based interrupt to the host. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM(s) by writing to the QSPI_ECC_INT_ENABLE register.
- On receiving an interrupt, software checks the QSPI_ECC_INT_STATUS to see which ECC RAM(s) caused the error.
- Software writes the RAM ID in the QSPI_ECC_VECTOR[10-0] RAM_ID field along with the 'read message' to the QSPI_ECC_VECTOR[15] TRIGGER_READ bit (to trigger the read), writing the QSPI_ECC_ERROR_STATUS1 register address to the QSPI_ECC_VECTOR[23-16] READ_ADDRESS field. Software will need to load the 'read message' in the QSPI_ECC_VECTOR register again if it needs to read the QSPI_ECC_ERROR_STATUS2 register.
- Software polls the QSPI_ECC_VECTOR[24] READ_DONE bit. When this is set, it does a read of the QSPI_ECC_ERROR_STATUS1/QSPI_ECC_ERROR_STATUS2 registers.
- After the interrupt has been serviced, software will clear the interrupt status by writing to bits 8, 9 or 10 in the QSPI_ECC_ERROR_STATUS1 register depending on the type of ECC error.
- Software has to poll the QSPI_ECC_ERROR_STATUS1 register to guarantee that the status bit has been cleared. Otherwise there is no indication that the write has actually completed over the configuration interface.
- Software will write to the QSPI_ECC_EOI register to clear the interrupt.

11.15.5 QSPI Programming Guide

11.15.5.1 QSPI Configuration Sequence

The following sequence assumes the QSPI module is enabled and the SPI protocol mode is correctly configured (see Table 11-3212).

Table 11-3212. QSPI Configuration Sequence

Step
1. Set baud rate to correspond to < 25 MHz operation.
2. Issue a RDID (Read ID) command in STIG mode of operation. Store the returned data for future reference.
3. Bump up baud rate to desired speed.
a. If the desired rate is < 25 MHz, there is no need of data training (step 4).
b. If the desired rate is > 25 MHz but < 50 MHz then data training is required. Clock loopback mode is not required in this case and should not be used.
c. If the desired rate is > 50 MHz, loopback clock needs to be enabled and data training is required as well.
4. For data training the software should sweep through the 16 read capture delay values, 0 to 15, and for every value issue a RDID (Read ID) command in STIG mode of operation. Compare the returned value with the reference value read during slow MHz operation. Mark the delay value as valid or invalid based on the comparison result. The complete sweep operation should fetch atleast 3 valid taps. Select the central tap in the valid window for future flash accesses.

11.15.5.2 Direct Access Controller Programming Sequence

The following sequence assumes that QSPI module is enabled, baud rate programmed and data training, if required, done for the given baud rate (see Table 11-3213).

Table 11-3213. Direct Access Controller Programming Sequence

Step	Register/Bit Field/Programming Model	Value
1. Set address remap enable to 1 and chip select decode to 0 (in the QSPI Configuration Register).	QSPI_CONFIG_REG[16] ENB_AHB_ADDR_REMAP_FLD	1h
	QSPI_CONFIG_REG[9] PERIPH_SEL_DEC_FLD	0h
2. Program the remap address register with a byte aligned value, so that the final remap address is byte aligned (in the Remap Address Register).	QSPI_REMAP_ADDR_REG[31-0] VALUE_FLD	-h
3. Set DAC enable to 1 (in the QSPI Configuration Register).	QSPI_CONFIG_REG[7] ENB_DIR_ACC_CTRL_FLD	1h
4. Program chip select value (in QSPI Configuration Register).	QSPI_CONFIG_REG[13-10] PERIPH_CS_LINES_FLD	-h
5. Set the SPI modes by programming clock phase and clock polarity (in the QSPI Configuration Register).	QSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD	-h
	QSPI_CONFIG_REG[1] SEL_CLK_POL_FLD	-h
6. Program the QSPI Device Delay Register with required values (in the QSPI Device Delay Register).	QSPI_DEV_DELAY_REG	-h
7. Set number of bytes per block. Use 10h for Micron and Spansion as both have 65535 bytes per block (in the Device Size Configuration Register).	QSPI_DEV_SIZE_CONFIG_REG[20-16] BYTES_PER_SUBSECTOR_FLD	10h
8. Set number of bytes per page. Use 100h for Micron and Spansion since both have 256 bytes per page (in the Device Size Configuration Register).	QSPI_DEV_SIZE_CONFIG_REG[15-4] BYTES_PER_DEVICE_PAGE_FLD	100h
9. Set number of address bytes. Use 2h for Micron and Spansion since both memories accept 24 bit address (in the Device Size Configuration Register).	QSPI_DEV_SIZE_CONFIG_REG[3-0] NUM_ADDR_BYTES_FLD	2h

Table 11-3213. Direct Access Controller Programming Sequence (continued)

Step	Register/Bit Field/Programming Model	Value
10. Program the write and read opcode with proper values based on the flash memories being accessed. Make sure the values programmed for data transfer type, address transfer type and instruction type matches the opcode value programmed (in the Device Read Instruction Configuration Register and the Device Write Instruction Configuration Register).	QSPI_DEV_INSTR_RD_CONFIG_REG	-h
	QSPI_DEV_INSTR_WR_CONFIG_REG	-h
11. Set write dummy cycle to 0 and read dummy cycle to a value based on the opcode. If Micron then 15, if Spansion the 4,6 or 8 (in the Device Read Instruction Configuration Register and the Device Write Instruction Configuration Register).	QSPI_DEV_INSTR_RD_CONFIG_REG[28-24] DUMMY_RD_CLK_CYCLES_FLD	-h
	QSPI_DEV_INSTR_WR_CONFIG_REG[28-24] DUMMY_WR_CLK_CYCLES_FLD	0h
12. Set mode bit to 0 (in the Device Read Instruction Configuration Register).	QSPI_DEV_INSTR_RD_CONFIG_REG[20] MODE_BIT_ENABLE_FLD	0h
13. If the WEL Disable bit in the Device Write Instruction Configuration Register is '0', enable the flash for write operation. This is done through STIG. (in the Flash Command Control Register).	QSPI_DEV_INSTR_WR_CONFIG_REG	WEL Disable bit is '0'
	QSPI_FLASH_CMD_CTRL_REG[15] ENB_WRITE_DATA_FLD	1h
a. Set command opcode to 06h, with rest of the fields programmed to default values.	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	06h
b. Then set execute command, in order to initiate STIG transaction to the flash.	QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD	1h
14. In order to perform a transaction to the flash in Dual I/O mode or Quad I/O mode, following sequence needs to be followed.		
a. Set command opcode to 61h, with write data enabled (in the Flash Command Control Register).	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	61h
b. Program the write data register with a value BFh if Dual and 7Fh if Quad, and number of bytes to 1 byte (in the Flash Command Write Data Register (Lower)).	QSPI_FLASH_WR_DATA_LOWER_REG[31-0] DATA_FLD	BFh (Dual mode)
		7Fh (Quad mode)
c. Then set execute command, in order to initiate STIG transaction to the flash (in the Flash Command Control Register). The above opcode and data values are for Micron memories. For Spansion memories, replace the opcode with 01h and value with 0200h for Quad I/O operation. No programming is required for SERIAL and Dual I/O operation.	QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD	1h
	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	01h
	QSPI_FLASH_WR_DATA_LOWER_REG[31-0] DATA_FLD	0200h (Quad mode)
15. Check the flash memory register, to see if it has been programmed as required.		
a. Set command opcode to 65h, and read data enable to 1 (in the Flash Command Control Register).	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	65h
	QSPI_FLASH_CMD_CTRL_REG[15] ENB_WRITE_DATA_FLD	1h
b. Read the value from the read data register, and compare if the value matches with the written data (in the Flash Command Read Data Register (Lower)).	QSPI_FLASH_RD_DATA_LOWER_REG	
16. Initiate a data bus read/write burst/single transactions. Make sure the data bus address is byte aligned.		

NOTE: As long as direct access is enabled, and even though the address lies within the trigger address range with indirect access disabled, the transaction goes as direct access.

NOTE: For direct accesses, the transaction cannot be started immediately after programming the write and read opcode in the device configuration register. Due to synchronization delays software is expected to wait 3 QSPI_DATA_BUS_CLK cycles before starting the DAC operation.

NOTE: DAC mode needs to be enabled for proper legacy mode operation.

11.15.5.3 Indirect Access Controller Programming Sequence

The following sequence assumes that QSPI is enabled, baud rate programmed and data training, if required, done for the given baud rate (see Table 11-3214).

Table 11-3214. Indirect Access Controller Programming Sequence

Step	Register/Bit Field/Programming Model	Value
1. Program chip select (in the QSPI Configuration Register).	QSPI_CONFIG_REG[13-10] PERIPH_CS_LINES_FLD	-h
2. Set SPI mode by setting clock phase and clock polarity as required (in the QSPI Configuration Register).	QSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD	-h
	QSPI_CONFIG_REG[1] SEL_CLK_POL_FLD	-h
3. Program the QSPI Device Delay Register with necessary values (in the QSPI Device Delay Register).	QSPI_DEV_DELAY_REG	-h
4. Set number of bytes per block. Use 10h for both Micron and Spansion as they have 65535 bytes per block (in the Device Size Configuration Register 14h).	QSPI_DEV_SIZE_CONFIG_REG[20-16] BYTES_PER_SUBSECTOR_FLD	10h
5. Set number of bytes per page. Use 100h for Micron and Spansion as they both have 256 bytes per page (in the Device Size Configuration Register).	QSPI_DEV_SIZE_CONFIG_REG[15-4] BYTES_PER_DEVICE_PAGE_FLD	100h
6. Set number of address bytes. Use 2h since both memories accept 24 bit address (in the Device Size Configuration Register).	QSPI_DEV_SIZE_CONFIG_REG[3-0] NUM_ADDR_BYTES_FLD	2h
7. Program the write and read opcode with proper values based on the flash memories being accessed. Make sure the values programmed for data transfer type, address transfer type and instruction type matches the opcode value programmed (in the Device Read Instruction Configuration Register and the Device Write Instruction Configuration Register).	QSPI_DEV_INSTR_RD_CONFIG_REG	-h
	QSPI_DEV_INSTR_WR_CONFIG_REG	-h
8. Set write dummy cycle to 0 and read dummy cycle to a value based on the opcode. If Micron then 15, if Spansion the 4, 6 or 8 (in the Device Read Instruction Configuration Register and the Device Write Instruction Configuration Register).	QSPI_DEV_INSTR_RD_CONFIG_REG[28-24] DUMMY_RD_CLK_CYCLES_FLD	-h
	QSPI_DEV_INSTR_WR_CONFIG_REG[28-24] DUMMY_WR_CLK_CYCLES_FLD	0h
9. Set mode bits to 0 (in the Device Read Configuration Instruction Register).	QSPI_DEV_INSTR_RD_CONFIG_REG[20] MODE_BIT_ENABLE_FLD	0h
10. If the WEL Disable bit in the Device Write Instruction Configuration Register is '0', enable the flash for write operation. This is done through STIG (in the Flash Command Control Register).	QSPI_DEV_INSTR_WR_CONFIG_REG	WEL Disable bit is '0'
	QSPI_FLASH_CMD_CTRL_REG[15] ENB_WRITE_DATA_FLD	1h
a. Set command opcode to 06h, with reset of the fields programmed to default value.	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	06h
b. Then set execute command, in order to initiate STIG transaction to the flash.	QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD	1h
11. In order to perform a transaction to the flash in Dual I/O mode or Quad I/O, following sequence needs to be followed.		
a. Set command opcode to 61h, with write data enabled in the flash command control register (in the Flash Command Control Register).	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	61h
b. Program the write data register with a value BFh if Dual and 7Fh if Quad, and number of bytes to 1 byte (in the Flash Command Write Data Register (Lower)).	QSPI_FLASH_WR_DATA_LOWER_REG[31-0] DATA_FLD	BFh (Dual mode)
		7Fh (Quad mode)

Table 11-3214. Indirect Access Controller Programming Sequence (continued)

Step	Register/Bit Field/Programming Model	Value
c. Then set execute command, in order to initiate STIG transaction to the flash (in the Flash Command Control Register). The above opcode and data values are for Micron memories. For Spansion memories, replace the opcode with 01h and value with 0200h for Quad I/O operation. No programming is required for SERIAL and Dual I/O operation).	QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD	1h
	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	01h
	QSPI_FLASH_WR_DATA_LOWER_REG[31-0] DATA_FLD	0200h (Quad mode)
12. Check the flash memory register, to see if it has been programmed as required.		
a. Set command opcode to 65h, and read data enable to 1 (in the Flash Command Control Register).	QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD	65h
	QSPI_FLASH_CMD_CTRL_REG[15] ENB_WRITE_DATA_FLD	1h
b. Read the value from the read data register, and compare if the value matches with the written data (in Flash Command Read Data Register (Lower)).	QSPI_FLASH_RD_DATA_LOWER_REG	
13. If targeting the flash (Micron memory) to perform transaction in EXTENDED I/O mode or Spansion memory in SERIAL or Dual I/O mode, then the above three steps can be skipped.		
14. Program the SRAM partition and watermark registers with appropriate values.	QSPI_SRAM_PARTITION_CFG_REG	-h
	QSPI_INDIRECT_READ_XFER_WATERMARK_REG	-h
	QSPI_INDIRECT_WRITE_XFER_WATERMARK_REG	-h
15. Program the INDAC write control and read control register with proper start address, trigger address, write and read number of bytes.	QSPI_INDIRECT_READ_XFER_CTRL_REG	-h
	QSPI_INDIRECT_WRITE_XFER_CTRL_REG	-h
	QSPI_INDIRECT_READ_XFER_START_REG	-h
	QSPI_INDIRECT_WRITE_XFER_START_REG	-h
	QSPI_IND_AHB_ADDR_TRIGGER_REG	-h
	QSPI_INDIRECT_READ_XFER_NUM_BYTES_REG	-h
	QSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG	-h
16. For writes:		
a. Set the start INDAC write field of the INDAC write control register to 1. Wait for couple of cycles of QSPI_REF_CLK (since this bit is internally synchronized by the QSPI module).	QSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD	1h
b. Initiate a data bus Write burst/single transaction in order to start the write transaction. The transactions are recommended to start at the trigger address and shouldn't be longer than 64 bytes.		
c. Poll indirect write completion status bit, then wait until the transaction is complete at the SPI end.	QSPI_INDIRECT_WRITE_XFER_CTRL_REG[2] WR_STATUS_FLD	
17. For reads:		
a. Set start INDAC read field of the INDAC read control register to 1. Wait for couple of cycles of QSPI_REF_CLK until this bit is internally synchronized by the QSPI module.	QSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD	1h
b. Monitor SRAM fill level.	QSPI_SRAM_FILL_REG	
c. Initiate a data bus Read burst/single transaction when enough data is available. The transactions are recommended to start at the trigger address and shouldn't be longer than 64 bytes.		
d. Poll for indirect read completion status bit to be set.	QSPI_INDIRECT_READ_XFER_CTRL_REG[2] RD_STATUS_FLD	
Make sure that the trigger address is 64 byte aligned, and the complete transaction is always within the trigger boundary (trigger address to trigger address + 16). Also make sure the INDAC start address is word aligned.		

NOTE: For INDAC burst accesses, the address of every data bus phase should be within the trigger range. Burst start address should be within trigger and trigger + 64 byte limit and burst start address + byte-count should never exceed trigger + 64 byte limit. Recommended access scheme would be to always start at trigger address and not do bursts greater than 64 bytes.

NOTE: Indirect write status bit gets set before the last 12 bytes of SPI transaction are sent. Hence the software should wait for about 2.5 us before starting another transaction.

NOTE: In indirect access, execute QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit has to be set before data bus transaction is pushed through.

11.15.5.4 Write Completion Polling for Both DAC and INDAC

If polling for write completion at the flash end is required then following steps needs to be flowed, before initiating any transaction (in the QSPI_WRITE_COMPLETION_CTRL_REG register). The following sequence assumes that QSPI module is enabled, baud rate programmed and data training, if required, done for the given baud rate (see Table 11-3215).

Table 11-3215. Write Completion Polling for Both DAC and INDAC

Step	Register/Bit Field/Programming Model	Value
1. For Micron memory:		
a. Program the opcode value to 70h	QSPI_WRITE_COMPLETION_CTRL_REG[7-0] OPCODE	70h
b. Polling bit index to value 7h	QSPI_WRITE_COMPLETION_CTRL_REG[10-8] POLLING_BIT_INDEX	7h
c. Polling polarity to 1	QSPI_WRITE_COMPLETION_CTRL_REG[13] POLLING_POLARITY	1h
d. Disable polling to 0 by default	QSPI_WRITE_COMPLETION_CTRL_REG[14] DISABLE_POLLING	0h
e. Poll count to 1	QSPI_WRITE_COMPLETION_CTRL_REG[23-16] POLL_COUNT	1h
2. For Spansion memory:		
a. Program the opcode value to 05h	QSPI_WRITE_COMPLETION_CTRL_REG[7-0] OPCODE	05h
b. Polling bit index to value 0h	QSPI_WRITE_COMPLETION_CTRL_REG[10-8] POLLING_BIT_INDEX	0h
c. Polling polarity to 0	QSPI_WRITE_COMPLETION_CTRL_REG[13] POLLING_POLARITY	0h
d. Disable polling to 0 by default	QSPI_WRITE_COMPLETION_CTRL_REG[14] DISABLE_POLLING	0h
e. Poll count to 1	QSPI_WRITE_COMPLETION_CTRL_REG[23-16] POLL_COUNT	1h
The controller polls until the poll count value programmed in the Polling Expiration Register is reached. An interrupt gets generated when Poll count reaches the value programmed in the register.		

NOTE: Flash write status poll is done more times than the programmed value in the QSPI_WRITE_COMPLETION_CTRL_REG[23-16] POLL_COUNT field. The status value, though, is discarded if polling is disabled.

11.15.5.5 ECC Programming Sequence

Table 11-3216. ECC Programming Sequence

Step	Register/Bit Field/Programming Model	Value
1. Write into ECC Interrupt Enable register to set the interrupt bit if needed in ECC Interrupt Set Register (address: 480h).	QSPI_ECC_INT_ENABLE[N-1:0] BITMASK	1h
2. Set the ECC enable, ECC Check bits to 1 (enabled by default) and force sec/ded bits in ECC Control Register (address: 414h).	QSPI_ECC_CONTROL[0] ECC_ENABLE	1h
	QSPI_ECC_CONTROL[1] ECC_CHECK	1h
	QSPI_ECC_CONTROL[3] FORCE_SEC	1h
	QSPI_ECC_CONTROL[4] FORCE_DED	1h
3. Then write to ECC Vector Register (address: 408h) with bits [23-16] set to the actual address to be updated which in this case is the ECC Control register and bit 15 to 0 to indicate a write.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	414h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	0h

Table 11-3216. ECC Programming Sequence (continued)

Step	Register/Bit Field/Programming Model	Value
4. Set the bit position1 to be corrupted and the ecc row to be corrupted in ECC Control1 register (address: 418h).	QSPI_ECC_ERROR_CONTROL1[31-16] ECC_BIT1	1h
	QSPI_ECC_ERROR_CONTROL1[15-0] ECC_ROW	1h
5. Then write to ECC Vector Register (address: 408h) with bits [23-16] set to the actual address to be updated which in this case is the ECC Control1 register and bit 15 to 0 to indicate a write.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	418h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	0h
6. Set the bit position2 to be corrupted in ECC Control2 register (address: 81Ch).	QSPI_ECC_ERROR_CONTROL2[15-0] ECC_BIT2	1h
7. Then write to ECC Vector Register (address: 408h) with bits [23-16] set to the actual address to be updated which in this case is the ECC Control2 register and bit 15 to 0 to indicate a write.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	81Ch
	QSPI_ECC_VECTOR[15] TRIGGER_READ	0h
8. To ensure that writes are complete, write into ECC Vector register with [23-16] set to ECC Control register and bit 15 to 1 to initiate a read.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	414h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
9. Keep Polling the ECC Vector register till the 23rd bit (read_done) bit becomes a 1.	QSPI_ECC_VECTOR[24] READ_DONE	1h (polling)
10. Then, read the ECC Control register to get the read value.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	414h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
11. If SRAM read is performed on the particular row in the ECC Control1 register (by either the flash controller or the software) and if force_sec/force_ded bits are set, an interrupt is raised if enabled.		
12. Read the ECC status registers by using the ECC Vector register method as mentioned in steps 8-10.	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	420h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
	QSPI_ECC_VECTOR[24] READ_DONE	1h (polling)
	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	420h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	424h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
	QSPI_ECC_VECTOR[24] READ_DONE	1h (polling)
	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	424h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	1h
13. Clear the status bits by writing back 1 into ECC status register using the ECC Vector register method as in steps 2-3.	QSPI_ECC_CONTROL[0] ECC_ENABLE	1h
	QSPI_ECC_CONTROL[1] ECC_CHECK	1h
	QSPI_ECC_CONTROL[3] FORCE_SEC	1h
	QSPI_ECC_CONTROL[4] FORCE_DED	1h
	QSPI_ECC_VECTOR[23-16] READ_ADDRESS	420h
	QSPI_ECC_VECTOR[15] TRIGGER_READ	0h
14. Finally, write into EOI register to clear the interrupt.	QSPI_ECC_EOI[0] EOI_WR	0h

11.15.6 QSPI Registers

Table 11-3218 lists the memory-mapped registers for the QSPI module. All register offset addresses not listed in Table 11-3218 should be considered as reserved locations and the register contents should not be modified.

Table 11-3220. QSPI_CONFIG_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	QSPI_IDLE_FLD	R	1h	Serial interface and QSPI pipeline is IDLE: This is a STATUS read-only bit. Note this is a retimed signal, so there will be some inherent delay on the generation of this status signal.
30-23	RESERVED	R	0h	Reserved
22-19	MSTR_BAUD_DIV_FLD	R/W	Fh	Master Mode Baud Rate Divisor (2 to 32): SPI baud rate = QSPI_REF_CLK / BD. Where Baud Devisor (BD) is: 0000 = 2 0001 = 4 0010 = 6 0011 = 8 0100 = 10 0101 = 12 0110 = 14 0111 = 16 1000 = 18 … 1111 = 32 Set this register field up before enabling the QSPI module.

Table 11-3220. QSPI_CONFIG_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	ENTER_XIP_MODE_IMM_FLD	R/W	0h	Enter XIP Mode immediately: 0h: If XIP is enabled, then setting to 0 will cause the controller to exit XIP mode on the next READ instruction. 1h: Operate the device in XIP mode immediately. Use this register bit when the external device wakes up in XIP mode (as per the contents of its non- volatile configuration register). The controller will assume the next READ instruction will be passed to the device as an XIP instruction, and therefore will not require the READ opcode to be transferred. NOTE: To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only after the next READ instruction is executed. Software therefore should ensure that at least one READ instruction is requested after resetting this bit in order to be sure that XIP mode is exited.
17	ENTER_XIP_MODE_FLD	R/W	0h	Enter XIP Mode on next READ: 0h: If XIP is enabled, then setting to 0 will cause the controller to exit XIP mode on the next READ instruction, 1h: If XIP is disabled, then setting to 1 will inform the controller that the device is ready to enter XIP on the next READ instruction. The controller will therefore send the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register bit after the controller has ensured the FLASH device has been configured to be ready to enter XIP mode. NOTE: To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only after the next READ instruction is executed. Software should therefore ensure that at least one READ instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited.
16	ENB_AHB_ADDR_REMAP_FLD	R/W	0h	Enable AHB Address Re-mapping (Direct Access Mode Only): When set to 1, the incoming AHB address will be adapted and sent to the FLASH device as address + N, where N is the value stored in the QSPI_REMAP_ADDR_REG register.
15-14	RESERVED	R	0h	Reserved
13-10	PERIPH_CS_LINES_FLD	R/W	0h	Peripheral Chip Select Lines: If QSPI_CONFIG_REG[9] PERIPH_SEL_DEC_FLD is set to 0, ss[3:0] are output thus: ss[3:0] → n_ss_out[3:0] xxx0 → 1110 xx01 → 1101 x011 → 1011 0111 → 0111 1111 → 1111 (no peripheral selected) else ss[3:0] directly drives n_ss_out[3:0]
9	PERIPH_SEL_DEC_FLD	R/W	0h	Peripheral select decode: 0h: only 1 of 4 selects n_ss_out[3:0] is active, 1h: allow external 4-to-16 decode (n_ss_out = ss).
8	ENB_LEGACY_IP_MODE_FLD	R/W	0h	Legacy QSPI Mode Enable: 0h: Use Direct Access Controller / Indirect Access Controller. 1h: Legacy Mode is enabled. In this mode, any write to the controller via the AHB is serialized and sent to the FLASH device. Any valid AHB read will pop the internal RX-FIFO, retrieving data that was forwarded by the external FLASH device on the SPI lines, 4 , 2 or 1 byte transfers are permitted.

Table 11-3220. QSPI_CONFIG_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	ENB_DIR_ACC_CTLR_FLD	R/W	1h	Enable Direct Access Controller: 0h: disable the Direct Access Controller once current transfer of the data word is complete, 1h: enable the Direct Access Controller. When the Direct Access Controller and Indirect Access Controller are both disabled, all AHB requested are completed with an error response.
6-3	RESERVED	R	0h	Reserved
2	SEL_CLK_PHASE_FLD	R/W	0h	Clock phase: If SEL_CLK_POL_FLD = 0h: 0h: Data launched on falling edge and captured on rising edge (Mode 0), 1h: Data launched on rising edge and captured on falling edge (Mode 1). If SEL_CLK_POL_FLD = 1h: 0h: Data launched on rising edge and captured on falling edge (Mode 2). 1h: Data launched on falling edge and captured on rising edge (Mode 3).
1	SEL_CLK_POL_FLD	R/W	0h	Clock polarity outside SPI word: 0h: the SPI clock is static low, 1h: the SPI clock is static high.
0	ENB_QSPI_FLD	R/W	1h	QSPI Enable: 0h: Disable the QSPI module. This should be done after the current data word transfer has already been completed, 1h: Enable the QSPI module.

Table 11-3229. QSPI_DEV_DELAY_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	D_NSS_FLD	R/W	0h	Clock Delay for Chip Select Deassert: Delay in master reference clocks for the length that the master mode chip select outputs are de-asserted between transactions. The minimum delay is always QSPI_CLK period to ensure the chip select is never re-asserted within an QSPI_CLK period.
23-16	D_BTWN_FLD	R/W	0h	Clock Delay for Chip Select Deactivation: Delay in master reference clocks between one chip select being de-activated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.
15-8	D_AFTER_FLD	R/W	0h	Clock Delay for Last Transaction Bit: Delay in master reference clocks between last bit of current transaction and deasserting the device chip select (n_ss_out). By default, the chip select will be deasserted on the cycle following the completion of the current transaction.
7-0	D_INIT_FLD	R/W	0h	Clock Delay with n_ss_out: Delay in master reference clocks between setting n_ss_out low and first bit transfer.

Table 11-3265. QSPI_IRQ_STATUS_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12	INDRD_SRAM_FULL_FLD	R/W	0h	Indirect Read Partition overflow: Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation.
11	RX_FIFO_FULL_FLD	R/W	0h	Small RX FIFO full: Current FIFO status can be ignored in non-SPI legacy mode. 0h: FIFO is not full. 1h: FIFO is full.
10	RX_FIFO_NOT_EMPTY_FLD	R/W	0h	Small RX FIFO not empty: Current FIFO status can be ignored in non-SPI legacy mode. 0h: FIFO has less than RX THRESHOLD entries. 1h: FIFO has >= THRESHOLD entries.
9	TX_FIFO_FULL_FLD	R/W	0h	Small TX FIFO full: Current FIFO status can be ignored in non-SPI legacy mode. 0h: FIFO is not full. 1h: FIFO is full.

Table 11-3265. QSPI_IRQ_STATUS_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	TX_FIFO_NOT_FULL_FLD	R/W	1h	Small TX FIFO not full: Current FIFO status can be ignored in non-SPI legacy mode. 0h: FIFO has >= THRESHOLD entries. 1h: FIFO has less than THRESHOLD entries.
7	RECV_OVERFLOW_FLD	R/W	0h	Receive Overflow: This should only occur in Legacy SPI mode. Set if an attempt is made to push the RX FIFO when it is full. This bit is reset only by a system reset and cleared only when this register is read. If a new push to the RX FIFO occurs coincident with a register read this flag will remain set. 0h: no overflow has been detected. 1h: an overflow has occurred.
6	INDIRECT_XFER_LEVEL_BREACH_FLD	R/W	0h	Transfer Watermark Breach: Indirect Transfer Watermark Level Breached.
5	ILLEGAL_ACCESS_DET_FLD	R/W	0h	Illegal AHB Access Detected: AHB wrapping bursts and the use of SPLIT/RETRY accesses will cause this error interrupt to trigger.
4	PROT_WR_ATTEMPT_FLD	R/W	0h	Protected Area Write Attempt: Write to protected area was attempted and rejected.
3	INDIRECT_READ_REJECT_FLD	R/W	0h	Indirect Read Reject: Indirect operation was requested but could not be accepted. Two indirect operations already in storage.
2	INDIRECT_OP_DONE_FLD	R/W	0h	Indirect Operation Complete: Controller has completed last triggered indirect operation.
1	UNDERFLOW_DET_FLD	R/W	0h	Underflow Detected: 0h: no underflow has been detected. 1h: underflow is detected and an attempt to transfer data is made when the small TX FIFO is empty. This may occur when AHB write data is being supplied too slowly to keep up with the requested write operation This bit is reset only by a system reset and cleared only when the register is read.
0	MODE_M_FAIL_FLD	R/W	0h	Mode M Failure: Mode M failure indicates the voltage on pin n_ss_in is inconsistent with the SPI mode. Set =1 if n_ss_in is low in master mode (multi-master contention). These conditions will clear the QSPI_CONFIG_REG[0] ENB_QSPI_FLD bit and disable the SPI. This bit is reset only by a system reset and cleared only when this register is read. 0h: no mode fault has been detected. 1h: a mode fault has occurred.

Table 11-3266. Register Call Summary for QSPI_IRQ_STATUS_REG

QSPI Functional Description • QSPI Interrupt Requests: [0][1][2][3][4][5][6][7][8][9][10][11][12]
QSPI Registers • QSPI_IRQ_STATUS_REG Register (Offset = 40h) [reset = 100h]: [0] • QSPI Registers: [0]

11.15.6.17 QSPI_IRQ_MASK_REG Register (Offset = 44h) [reset = 0h]

QSPI_IRQ_MASK_REG is shown in Figure 11-1327 and described in Table 11-3268.

0h: the interrupt for the corresponding interrupt status register bit is disabled.
1h: the interrupt for the corresponding interrupt status register bit is enabled.

Table 11-3280. QSPI_INDIRECT_READ_XFER_CTRL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-6	NUM_IND_OPS_DONE_FLD	R	0h	Completed Indirect Operations: This field contains the number of indirect operations which have been completed. This is used in conjunction with the QSPI_INDIRECT_READ_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD bit. It is incremented by hardware when an indirect operation has completed. Write a 1 to QSPI_INDIRECT_READ_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD bit to decrement it.
5	IND_OPS_DONE_STATUS_FLD	R/W	0h	Indirect Completion Status: This field is set to 1 when an indirect operation has completed. Write a 1 to this field to clear it.
4	RD_QUEUED_FLD	R	0h	Queued Indirect Read Operations: Two indirect read operations have been queued.
3	SRAM_FULL_FLD	R/W	0h	SRAM Full: SRAM full and unable to immediately complete an indirect operation. Write a 1 to this field to clear it.
2	RD_STATUS_FLD	R	0h	Indirect Read Status: Indirect read operation in progress (status).
1	CANCEL_FLD	W	0h	Cancel Indirect Read: Writing a 1 to this bit will cancel all ongoing indirect read operations.
0	START_FLD	W	0h	Start Indirect Read: Writing a 1 to this bit will trigger an indirect read operation. The assumption is that the indirect start address and the indirect number of bytes register is set-up before triggering the indirect read operation.

Table 11-3304. QSPI_FLASH_CMD_CTRL_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	CMD_OPCODE_FLD	R/W	0h	Command Opcode: The command opcode field should be set-up before triggering the command. For example, 20h maps to SubSector Erase. Writing to the QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit launches the command. NOTE: Using this approach to issue commands to an external flash device makes use of the instruction type of the device instruction configuration register. ·If this field is set to 0h, then the command opcode, command address, command dummy bytes and command data will all be transferred in a serial fashion. ·If this field is set to 1h, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using QSPI_D0 and QSPI_D1 pins. ·If this field is set to 2h, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using QSPI_D0, QSPI_D1, QSPI_D2 and QSPI_D3 pins.
23	ENB_READ_DATA_FLD	R/W	0h	Read Data Enable: Set to 1 if the command specified in the QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD field requires read data bytes to be received from the external flash device.
22-20	NUM_RD_DATA_BYTES_FLD	R/W	0h	Number of Read Data Bytes: Up to 8 data bytes may be read using this command. Set to 0 for 1 byte and 7 for 8 bytes.

Table 11-3304. QSPI_FLASH_CMD_CTRL_REG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	ENB_COMD_ADDR_FLD	R/W	0h	Command Address Enable: Set to 1 if the QSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD field requires an address. This should be set-up before triggering the command via writing a 1 to the QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit.
18	ENB_MODE_BIT_FLD	R/W	0h	Mode Bit Enable: Set to 1 to ensure the mode bits defined in the QSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD field are sent following the address bytes.
17-16	NUM_ADDR_BYTES_FLD	R/W	0h	Number of Address Bytes: Set to the number of address bytes required (the address itself is programmed in the QSPI_FLASH_CMD_ADDR_REG register). This should be set-up before triggering the command via QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit of this register. 0h: 1 address byte, 1h: 2 address bytes, 2h: 3 address bytes, 3h: 4 address bytes.
15	ENB_WRITE_DATA_FLD	R/W	0h	Write Data Enable: Set to 1 if the command specified in the command opcode field (CMD_OPCODE_FLD) of this register requires write data bytes to be sent to the external flash device.
14-12	NUM_WR_DATA_BYTES_FLD	R/W	0h	Number of Write Data Bytes: Up to 8 Data bytes may be written using this command. Set to 0 for 1 byte, 7 for 8 bytes.
11-7	NUM_DUMMY_BYTES_FLD	R/W	0h	Number of Dummy Bytes: Set to the number of dummy bytes required. This should be set-up before triggering the command via the QSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit of this register.
6-2	RESERVED	R	0h	Reserved
1	CMD_EXEC_STATUS_FLD	R	0h	Command Execution Status: 1h: Command execution in progress.
0	CMD_EXEC_FLD	W	0h	Execute Command: 1h: Execute the command.

Table 11-3340. QSPI_ECC_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error.
5	FORCE_N_ROW	R/W	0h	Force single/double-bit error on the next RAM read.
4	FORCE_DED	R/W	0h	Force double-bit error: Cleared the cycle following the error if ERROR_ONCE is asserted.
3	FORCE_SEC	R/W	0h	Force single-bit error: Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted.
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes.
1	ECC_CHECK	R/W	1h	Enable ECC check: ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are 0.
0	ECC_ENABLE	R/W	1h	Enable ECC generation.

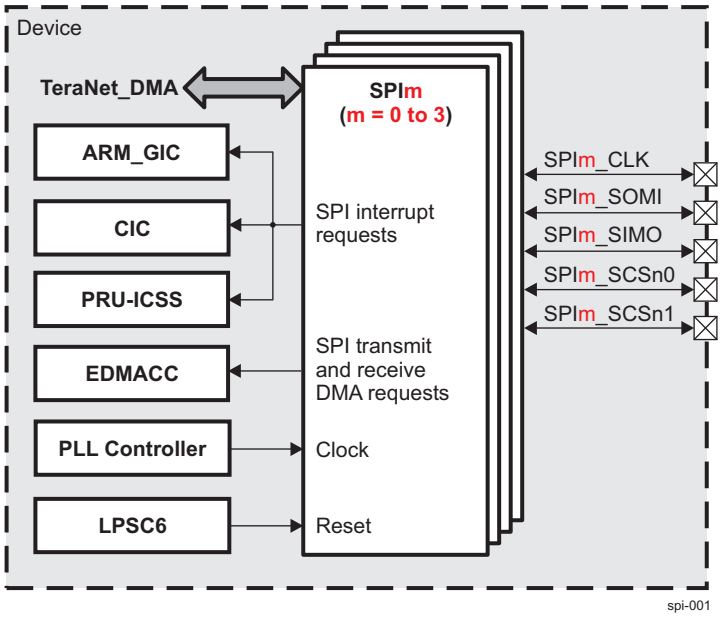
11.16 Serial Peripheral Interface (SPI)

This section describes the Serial Peripheral Interface (SPI) module for the device.

11.16.1 SPI Overview

The SPI module is a master/slave high-speed synchronous serial input/output interface that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted in and out of the device at a programmed bit-transfer rate. There are four separate SPI modules (SPI0, SPI1, SPI2, and SPI3) in the device (see Figure 11-1360). All these four modules support up to two external devices (two chip selects) and are able to work as both master and slave. The SPI module allows multiple programmable chip-selects. It is normally used for communication between the device and external peripherals. Typical applications include interface to external I/O or peripheral expansion via devices such as shift registers, display drivers, SPI EEPROMS, and analog-to-digital converters. The SPI module may be used to connect to serial flash memory devices for booting. The SPI module supports EDMA events and can be used in conjunction with EDMA for data transfer with minimal CPU overhead.

Figure 11-1360. SPI Modules SPI0, SPI1, SPI2, and SPI3



The SPI module has the following features:

- 16-bit Shift register
- 16-bit Receive buffer register (SPIBUF) and 16-bit Receive buffer emulation *alias* register (SPIEMU)
- 16-bit Transmit data register (SPIDAT0) and 16-bit Transmit data and format selection register (SPIDAT1)
- 8-bit Baud clock generator
- Serial clock (SPIm_CLK) I/O pin
- Slave in, master out (SPIm_SIMO) I/O pin
- Slave out, master in (SPIm_SOMI) I/O pin
- 2 Chip select signals (SPIm_SCSn0 and SPIm_SCSn1)
- Programmable SPI clock frequency range
- Programmable character length (2 to 16 bits)
- Programmable clock phase (delay or no delay)
- Programmable clock polarity (high or low)
- Interrupt capability
- DMA support (read/write synchronization events)

- Operates at up to 50 MHz in master mode and 25 MHz in slave mode (actual speed depends on SPI functional clock and SPI clock divider)

The SPI module allows software to program the following options:

- SPIm_CLK frequency (SPI functional clock / 2 through SPI functional clock / 256)
- 3-pin and 4-pin options
- Character length (2 to 16 bits) and shift out direction (MSB/LSB first)
- Clock phase (delay or no delay) and polarity (high or low)
- Delay between transmissions in master mode
- Chip select setup and hold times in master mode
- Chip select hold in master mode

The SPI module does not support the following features:

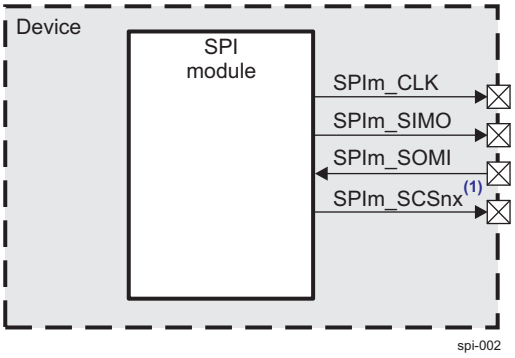
- Multibuffer mode
- Parallel mode and parity
- GPIO mode

11.16.2 SPI Environment

11.16.2.1 Basic SPI Pins for Master Mode

Figure 11-1361 shows all of the SPI interface signals in master mode.

Figure 11-1361. SPI Interface Signals in Master Mode



(1) x = 0 to 1

Table 11-3366 describes the SPI I/O in master mode.

Table 11-3366. SPI I/O Description (Master Mode)

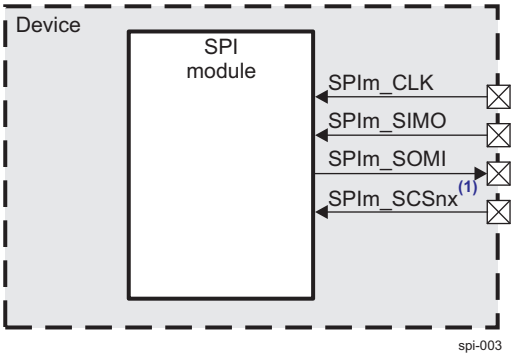
Signal Name(1)	I/O(2)	Description
SPIm_CLK	O	Serial clock output for master mode
SPIm_SIMO	O	Serial data output in master mode
SPIm_SOMI	I	Serial data input in master mode
SPIm_SCSnx(3)	O	Chip-select output for master mode

(1) m = 0 to 3
(2) I = Input; O = Output
(3) x = 0 to 1

11.16.2.2 Basic SPI Pins for Slave Mode

Figure 11-1362 shows all of the SPI interface signals in slave mode.

Figure 11-1362. SPI Interface Signals in Slave Mode



(1) x = 0 or 1

Table 11-3367 describes the SPI I/O in slave mode.

Table 11-3367. SPI I/O Description (Slave Mode)

Signal Name[1]	I/O[2]	Description
SPIm_CLK	I	Serial clock input for slave mode
SPIm_SIMO	I	Serial data input in slave mode
SPIm_SOMI	O	Serial data output in slave mode
SPIm_SCSnx[3]	I	Chip-select input for slave mode

(1) m = 0 to 3
(2) I = Input; O = Output
(3) x = 0 or 1

11.16.2.3 Data Formats

The SPI module provides the capability to configure four independent data formats. These formats are configured by programming the corresponding SPI data format registers (SPIFMTn, where n = 0 to 3). In each data format register, the following characteristics of the SPI operation are selected:

- Character length from 2 to 16 bits: The character length is configured by the SPIFMTn[4-0] CHARLEN field.
- Shift out direction (MSB first or LSB first): The shift out direction is configured by the SPIFMTn[20] SHIFTDIR bit.
- Clock polarity: The clock polarity is configured by the SPIFMTn[17] POLARITY bit.
- Clock phase: The clock phase is configured by the SPIFMTn[16] PHASE bit.

The data format is chosen on each transaction. Transmit data is written to the SPI transmit data register 1 (SPIDAT1) and in the same write the SPIDAT1[25-24] DFSEL field indicates which data format is to be used for the next transaction. Alternatively, the data format can be configured once and applies to all transactions that follow until the data format is changed.

11.16.2.3.1 Character Length

The character length is configured by the SPIFMTn[4-0] CHARLEN field. Legal values are 2 bits (2h) to 16 bits (10h). The character length is independently configured for each of the four data formats; and it must be programmed in both master mode and slave mode.

Transmit data is written to the SPIDAT1 register. The transmit data must be written right-justified irrespective of the character length. The SPI module automatically sends out the data correctly based on the chosen data format.

Figure 11-1363 shows how a 12-bit word (EC9h) must be written to the transmit buffer in order to be transmitted correctly.

Figure 11-1363. Format for Transmitting 12-Bit Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
x	x	x	x	1	1	1	0	1	1	0	0	1	0	0	1

The data received in the SPIBUF register is right-justified irrespective of the character length and is padded with 0s when character length is less than 16.

Figure 11-1364 shows how a 10-bit word (3A2h) is stored in the buffer once it is received.

Figure 11-1364. Format for 10-Bit Received Word

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	1	1	1	0	1	0	0	0	1	0

11.16.2.3.2 Shift Direction

The shift out direction is configured as most-significant bit (MSB) first or least significant bit (LSB) first. The SPI module supports automatic right-alignment of receive data independent of shift direction and data word length. Transmit data has to be written right-aligned and the internal shift register will sort them out according to selected shift direction and data word length for correct transfer.

The shift out direction is selected by the SPIFMTn[20] SHIFTDIR bit. The shift out direction is independently configured for each of the four data formats.

- When SPIFMTn[20] SHIFTDIR bit is set to '0h', the transmit data is shifted out with MSB first.
- When SPIFMTn[20] SHIFTDIR bit is set to '1h', the transmit data is shifted out with LSB first.

11.16.2.3.3 Clock Phase and Polarity

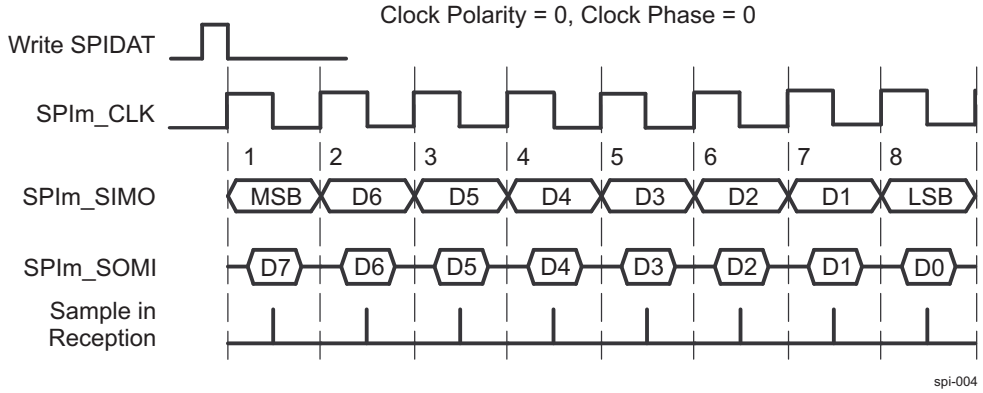
The SPI module provides the flexibility to program four different clock mode combinations in which the SPIm_CLK signal may operate enabling a choice of the clock phase (delay or no delay) and the clock polarity (rising edge or falling edge). When operating with PHASE bit active, the SPI module makes the first bit of data available after the SPIDAT1 register is written and before the first edge of the SPIm_CLK signal. The data input and output edges depend on the values of both the SPIFMTn[17] POLARITY and SPIFMTn[16] PHASE bits as shown in Table 11-3368.

Table 11-3368. Clocking Modes

SPIFMTn[17] POLARITY	SPIFMTn[16] PHASE	Action
0	0	Data is output on the rising edge of SPIm_CLK. Input data is latched on the falling edge.
0	1	Data is output one half-cycle before the first rising edge of SPIm_CLK and on subsequent falling edges. Input data is latched on the rising edge of SPIm_CLK.
1	0	Data is output on the falling edge of SPIm_CLK. Input data is latched on the rising edge.
1	1	Data is output one half-cycle before the first falling edge of SPIm_CLK and on subsequent rising edges. Input data is latched on the falling edge of SPIm_CLK.

Figure 11-1365 to Figure 11-1368 show the four possible modes of the SPIm_CLK signal. Having four signal options allows the SPI module to interface with different types of serial devices. Also shown are the SPIm_CLK control bit polarity and phase values corresponding to each signal.

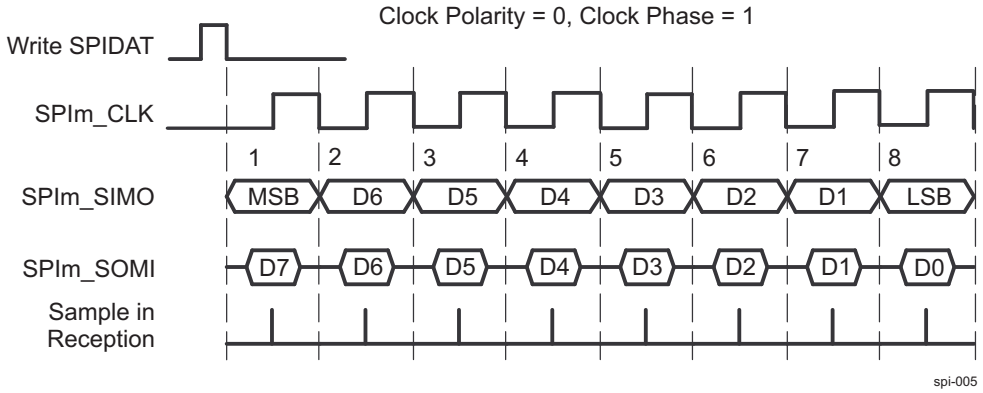
Figure 11-1365. Clock Mode with POLARITY = 0 and PHASE = 0(1)



(1) Clock phase = 0 (SPIm_CLK without delay)

- Data is output on the rising edge of SPIm_CLK.
- Input data is latched on the falling edge of SPIm_CLK.
- A write to the SPIDAT register starts SPIm_CLK.

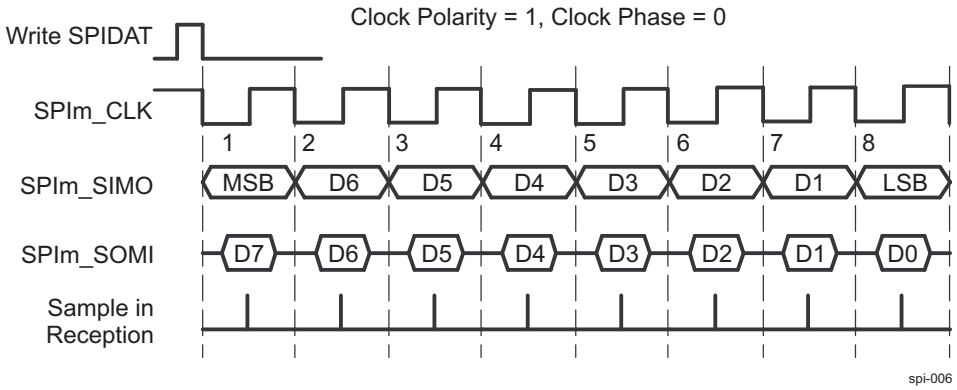
Figure 11-1366. Clock Mode with POLARITY = 0 and PHASE = 1(1)



(1) Clock phase = 1 (SPIm_CLK with delay)

- Data is output one-half cycle before the first rising of SPIm_CLK and on subsequent falling edges of SPIm_CLK.
- Input data is latched on the rising edge of SPIm_CLK.

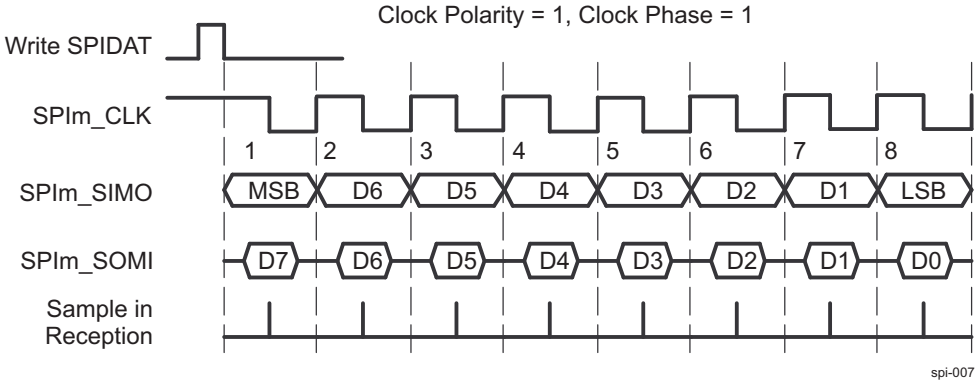
Figure 11-1367. Clock Mode with POLARITY = 1 and PHASE = 0(1)



(1) Clock phase = 0 (SPIm_CLK without delay)

- Data is output on the falling edge of SPIm_CLK.
- Input data is latched on the rising edge of SPIm_CLK.
- A write to the SPIDAT register starts SPIm_CLK.

Figure 11-1368. Clock Mode with POLARITY = 1 and PHASE = 1(1)



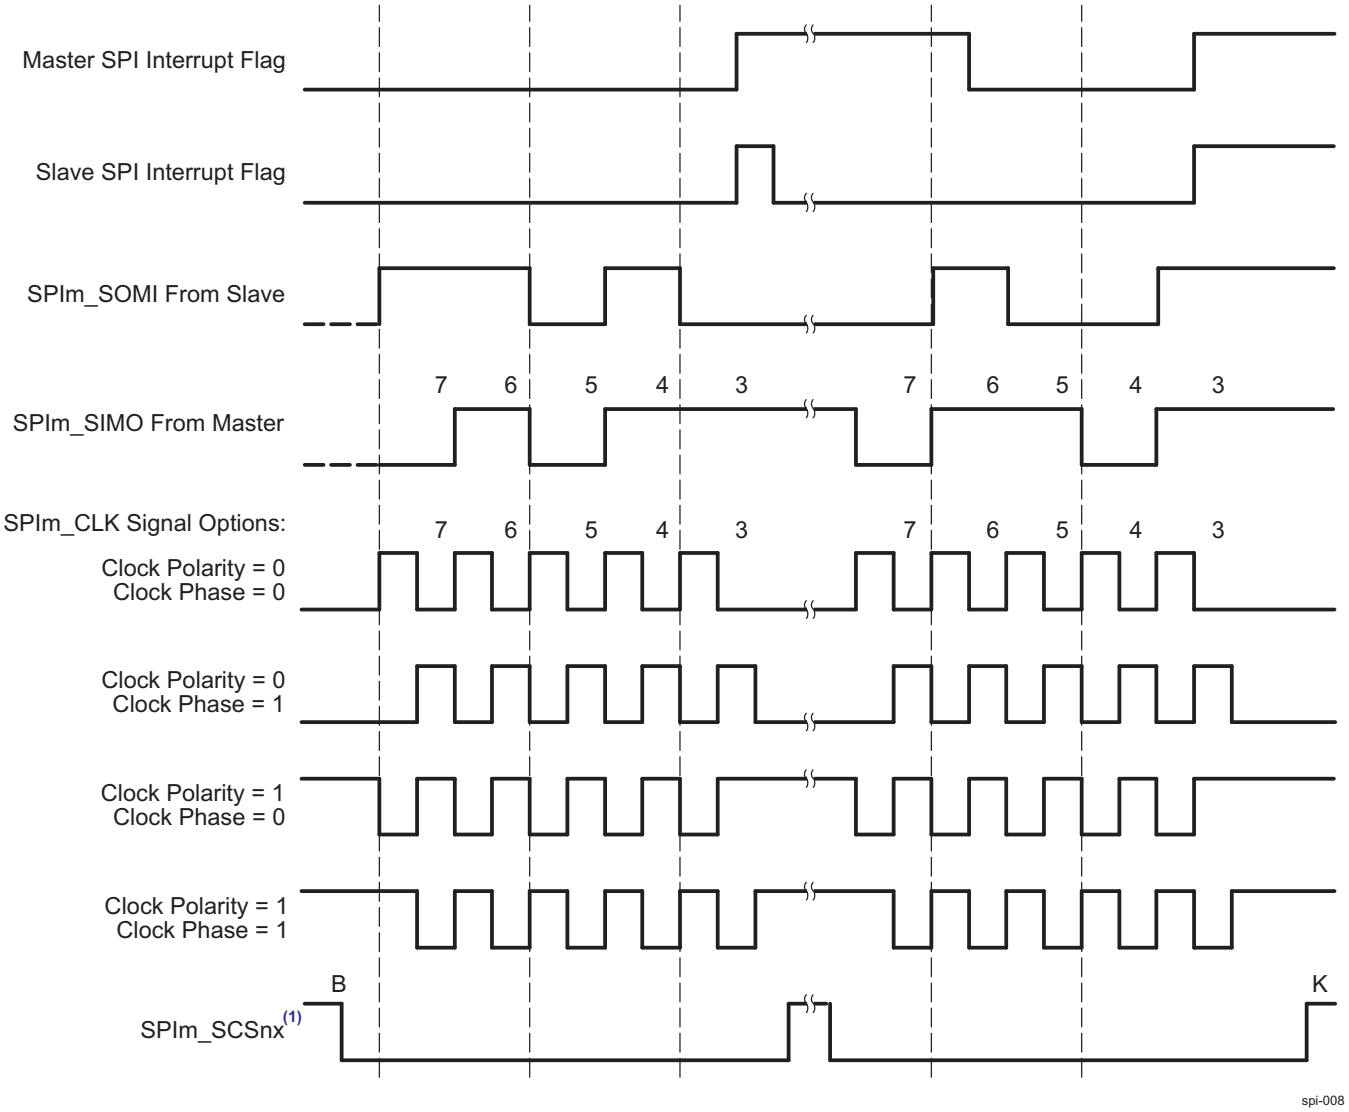
(1) Clock phase = 1 (SPIm_CLK with delay)

- Data is output one-half cycle before the first falling edge of SPIm_CLK and on the subsequent rising edges of SPIm_CLK.
- Input data is latched on the falling edge of SPIm_CLK.

11.16.2.3.4 SPI Data Transfer Example

Figure 11-1369 shows a SPI data transfer between two devices using a character length of five bits.

Figure 11-1369. SPI Data Transfer, Five Bits per Character (4-Pin with Chip Select Option)



(1) x = 0 to 1 (for master mode); x = 0 or 1 (for slave mode)

11.16.3 SPI Integration

This section describes the module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-1370 shows the SPI module integration.

Figure 11-1370. SPI Integration

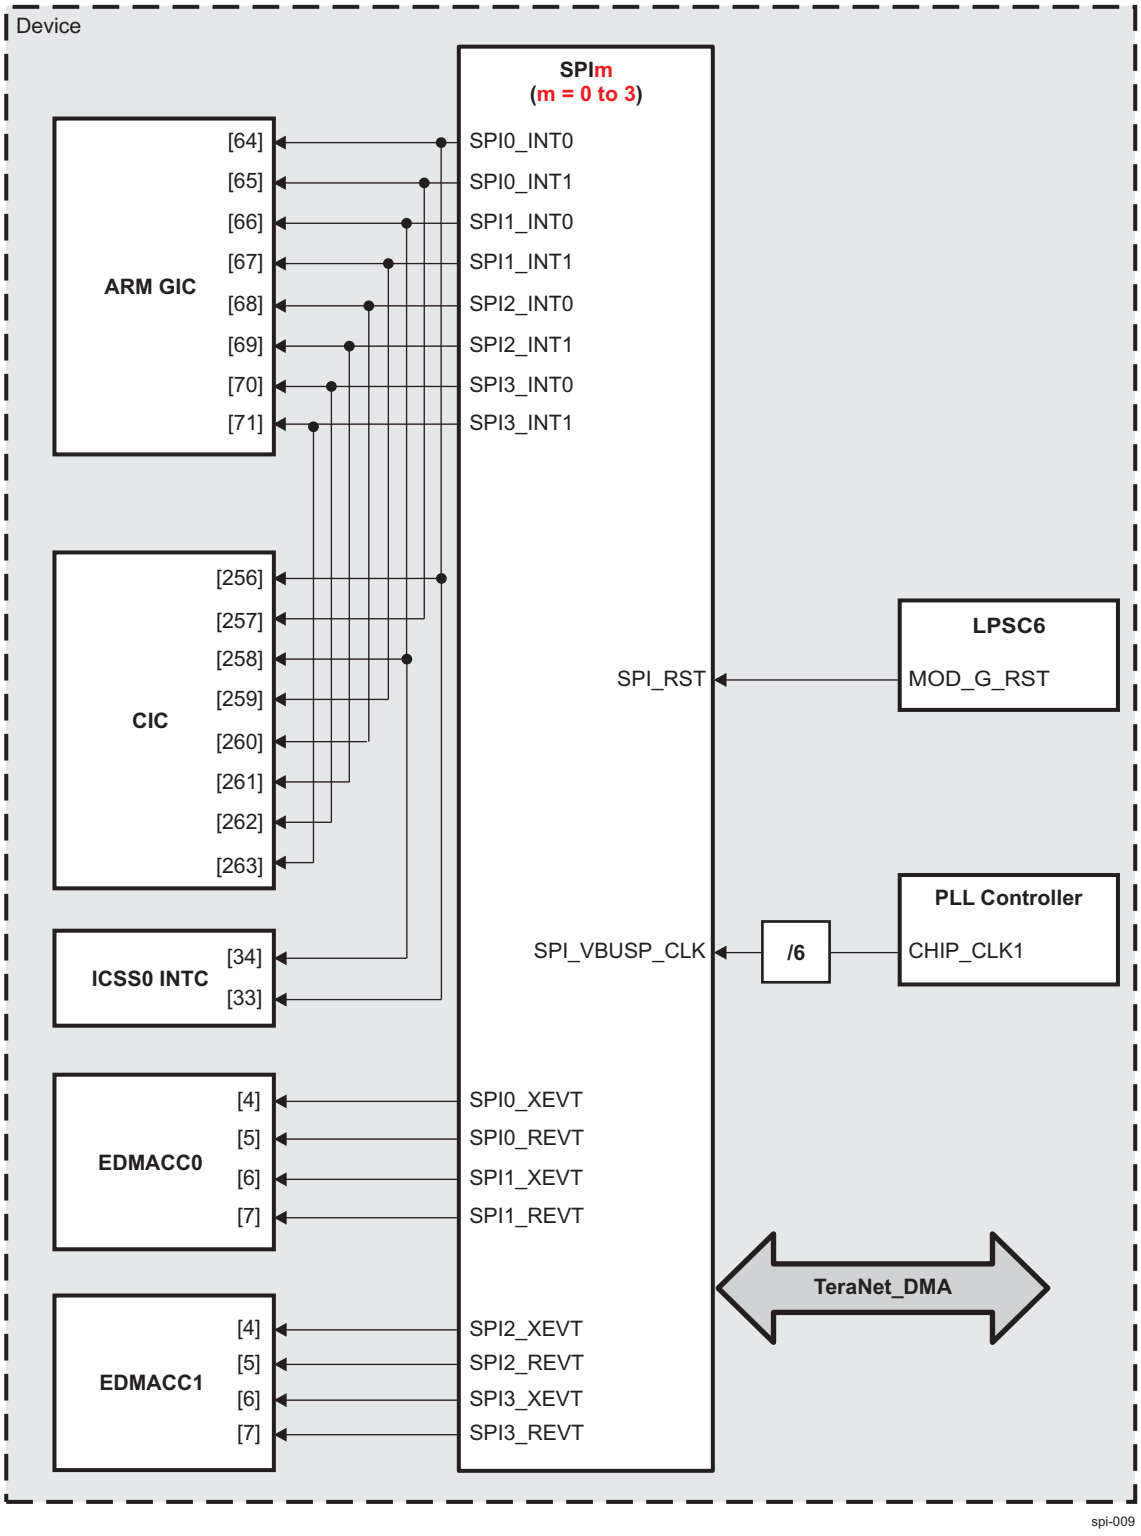


Table 11-3369 through Table 11-3371 summarize the integration of the module in the device.

Table 11-3369. SPI Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
SPI0	PD5	LPSC6	TeraNet_DMA
SPI1	PD5	LPSC6	TeraNet_DMA
SPI2	PD5	LPSC6	TeraNet_DMA
SPI3	PD5	LPSC6	TeraNet_DMA

Table 11-3370. SPI Clocks and Resets

Clocks

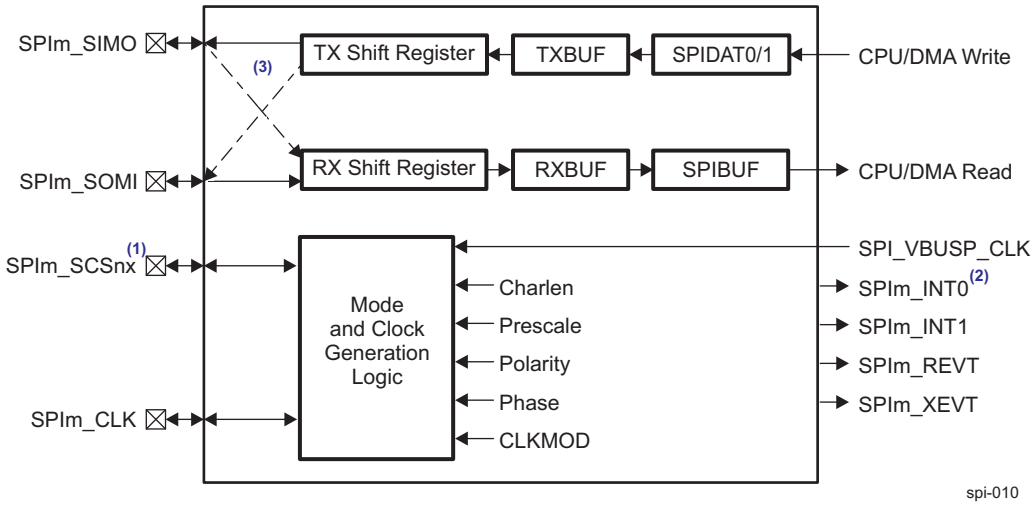
For more information about the DMA requests, see Section 11.16.4.6, *DMA Events Support*.

11.16.4 SPI Functional Description

11.16.4.1 SPI Block Diagram

Figure 11-1371 shows the SPI module.

Figure 11-1371. SPI Block Diagram



(1) x = 0 to 1 (for master mode); x = 0 or 1 (for slave mode)

(2) m = 0 to 3

(3) Solid line represents data flow for SPI master mode and dashed line represents data flow for SPI slave mode.

11.16.4.2 Operation Modes

The SPI module operates in a master or slave mode. The SPIGCR1[0] MASTER bit selects the configuration of the SPIm_SIMO and SPIm_SOMI pins and the SPIGCR1[1] CLKMOD bit determines whether an internal or external clock source will be used. The chip select (SPIm_SCSnx) pins are used as outputs when communicating with multiple slave devices. When the SPI module operates in master mode a write to the SPIDAT1 register activates the SPIm_SCSnx pin which allows a slave connected to that signal to be selected. In slave mode, only one chip select can be used. In this case it is input.

NOTE: Note: Although there are two different bits which control the Master/Slave mode functions, only two of their combinations are valid. For Master mode of operation: MASTER = '1h', CLKMOD = '1h'. For Slave mode of operation: MASTER = '0h', CLKMOD = '0h'. Any other combinations of these two bits may not yield any desirable operation of the module and must be avoided.

The SPI module supports two options:

- 3-pin option
- 4-pin with chip select option

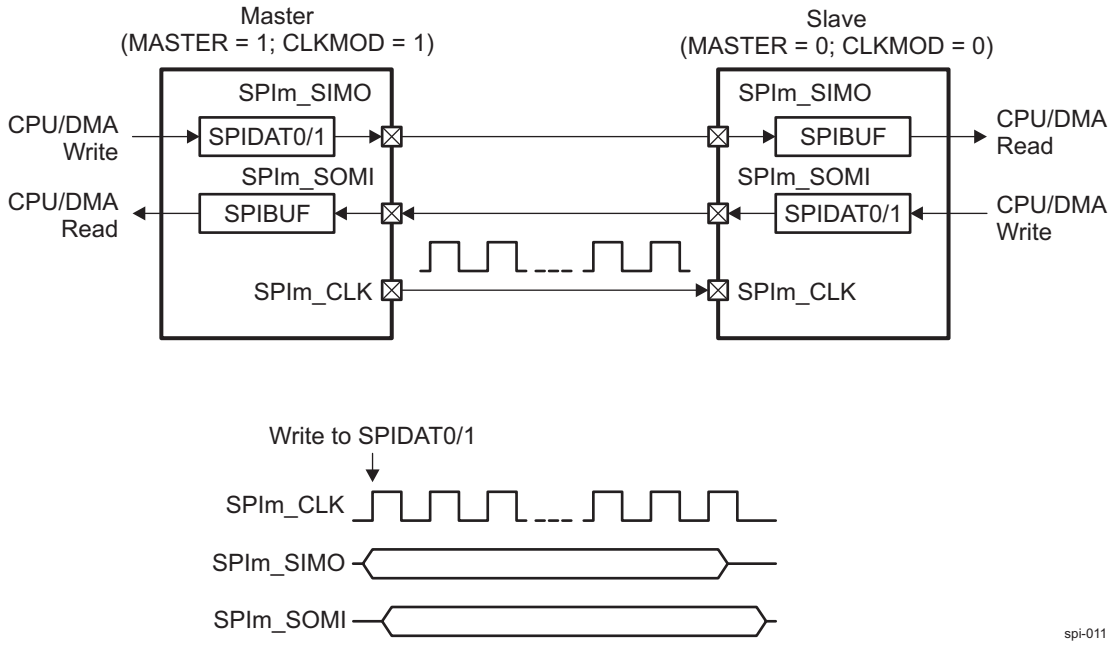
The 3-pin option is the basic clock, data in, and data out SPI interface and uses the SPIm_CLK, SPIm_SIMO, and SPIm_SOMI pins. The 4-pin with chip select option adds the SPIm_SCSnx pin that is used to support multiple SPI slave devices on a single SPI bus.

11.16.4.2.1 SPI Operation: 3-Pin Mode

NOTE: If only unidirectional communication is required, the SPIm_CLK pin and the two data pins (SPIm_SOMI and SPIm_SIMO) must all be configured as functional pins. A 2-pin unidirectional mode is not supported.

In master mode configuration (SPIGCR1[0] MASTER and SPIGCR1[1] CLKMOD bits are set to '1h'), the SPI module provides the serial clock on the SPIm_CLK pin for the entire serial communications network. Data is output on the SPIm_SIMO pin and latched in from the SPIm_SOMI pin (see Figure 11-1372). Data written to the shift register (SPIDAT1) initiates data transmission on the SPIm_SIMO pin, most significant bit (MSB) first. Simultaneously, received data is shifted through the SPIm_SOMI pin. When the selected number of bits has been transmitted, the recevied data in the RX Shift Register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in the SPIBUF register.

Figure 11-1372. SPI 3-Pin Option



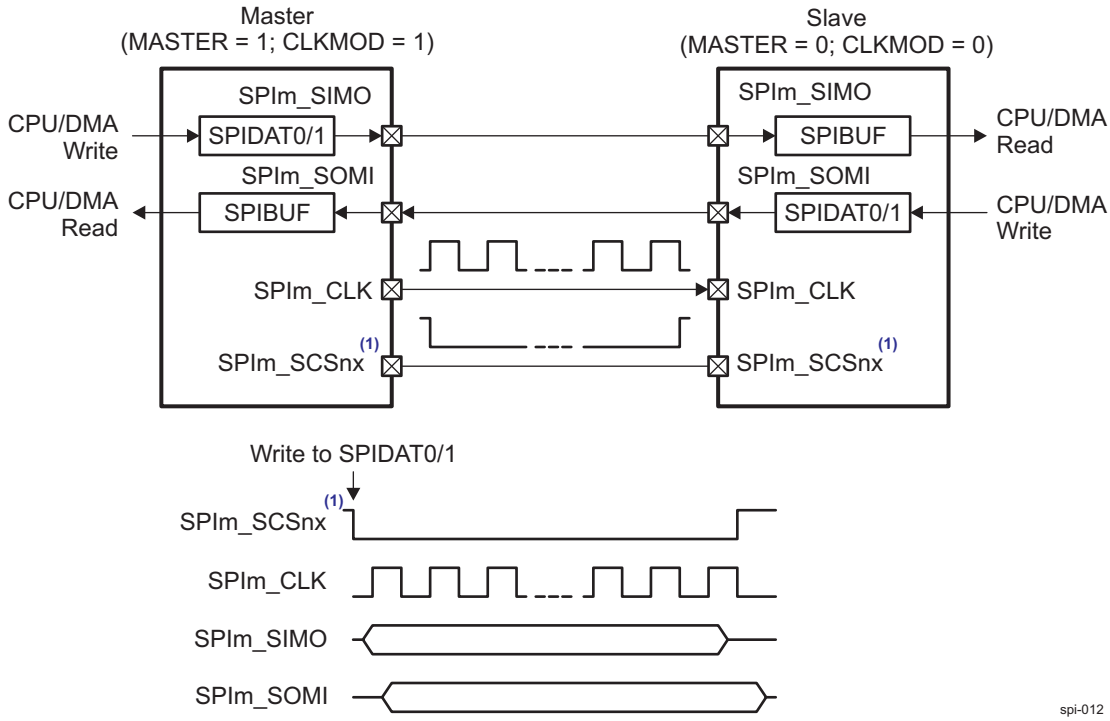
In slave mode configuration (SPIGCR1[0] MASTER and SPIGCR1[1] CLKMOD bits are set to '0h'), data is shifted out on the SPIm_SOMI pin and in on the SPIm_SIMO pin. The SPIm_CLK pin is used as an input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. Data written to the SPIDAT1 register is transmitted to the network when the SPIm_CLK signal is received from the network master. To receive data, the SPI module waits for the network master to send the SPIm_CLK signal and then shifts the data present on the SPIm_SIMO pin into the RX Shift Register. If data has to be transmitted by the slave while receiving, the data must be written to the SPIDAT1 register before the beginning of the SPIm_CLK signal.

NOTE: Either the SPIDAT0 or SPIDAT1 register can be used on both master and slave sides.

11.16.4.2.2 SPI Operation: 4-Pin Mode

The three-pin option and the four-pin options of the SPI module are identical in the master mode (SPIGCR1[1] CLKMOD bit is set to '1h'), except that the four-pin option uses SPIm_SCSnx pins. Figure 11-1373 shows SPI 4-Pin Option with SPIm_SCSnx pin.

Figure 11-1373. SPI 4-Pin Option with SPIm_SCSnx pin



(1) x = 0 to 1 (for master mode); x = 0 or 1 (for slave mode)

NOTE: Either the SPIDAT0 or SPIDAT1 register can be used on both master and slave sides.

11.16.4.2.2.1 Multiple Chip Selects

The SPIm_SCSnx pins that are going to be used must be configured as functional (SPIPC0[1-0] SCSFUN). The default value for the SPIm_SCSnx pins when all slaves are deactivated can be configured through the SPIDEF register. There is a separate bit for each chip select signal within this register. This functionality allows different slaves with different chip-select polarity to be activated by the SPI module. During transmission, the value of the SPIDAT1[23-16] CSNR field is applied on the chip select pins. Depending on this value certain chip select is activated to establish data transmission to the associated slave. When in slave mode the SPI module can be selected only by an active value of '0h' on its SPIm_SCSnx pin. However, when in master mode the SPI module is capable of driving both '0h' or '1h' as the active value of any of the SPIm_SCSnx pins. This is fully controlled by the SPIDAT1[23-16] CSNR field.

NOTE: In slave mode, only one chip select pin can be used.

11.16.4.2.3 Master Mode Settings

The two master mode options are defined by the configuration bit settings listed in Table 11-3372. Other configuration bits may take any value in the range listed in Table 11-3373. The values listed in Table 11-3372 and Table 11-3373 should not be changed while the SPIGCR1[24] ENABLE bit is set to '1h'. Note that in certain cases the allowed values may still be ignored. For example, Table 11-3373 indicates that the SPIDELAY register may take a range of values in Master 3-pin mode; however, the SPIDELAY register has no effect in Master 3-pin mode. For complete details on each mode, see Section 11.16.4.2.1, *SPI Operation: 3-Pin Mode*, Section 11.16.4.2.2 *SPI Operation: 4-Pin Mode*, and Section 11.16.4.2.3.1, *Master Mode Timing Options*.

Table 11-3372. SPI Register Settings Defining Master Modes

Register	Bit(s)	Master 3-pin	Master 4-pin Chip Select
SPIGCR0	RESET	1h	1h
SPIGCR1	ENABLE	1h	1h
SPIGCR1	LOOPBACK	0h	0h
SPIGCR1	CLKMOD	1h	1h
SPIGCR1	MASTER	1h	1h
SPIPC0	SOMIFUN	1h	1h
SPIPC0	SIMOFUN	1h	1h
SPIPC0	CLKFUN	1h	1h
SPIPC0	SCSFUN	0h	1h, 2h, 3h

Table 11-3373. Allowed SPI Register Settings in Master Modes

Register	Bit(s)	Master 3-pin	Master 4-pin Chip Select
SPIFMTn	WDELAY	0h to 3Fh	0h to 3Fh
SPIFMTn	SHIFTDIR	-h	-h
SPIFMTn	DISCSTIMERS	-h	-h
SPIFMTn	POLARITY	-h	-h
SPIFMTn	PHASE	-h	-h
SPIFMTn	PRESCALE	0h to FFh	0h to FFh
SPIFMTn	CHARLEN	2h to 10h	2h to 10h
SPIDELAY	C2TDELAY	0h to FFh	0h to FFh
SPIDELAY	T2CDELAY	0h to FFh	0h to FFh

11.16.4.2.3.1 Master Mode Timing Options

In master mode the SPI module supports several options to modify the timing of its generation of the chip select signal (SPIm_SCSnx). This allows the SPI module to support the timing requirements of various slave devices without adding additional overhead to the CPU by generating the appropriate delays automatically.

11.16.4.2.3.1.1 Chip Select Setup Time

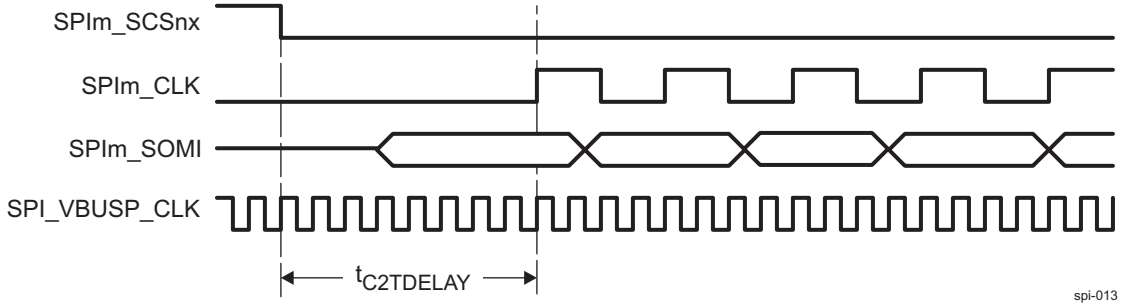
In order to support slow slave devices the SPI module can be configured to delay the data transmission after the chip select is activated. This delay is controlled by the SPIDELAY[31-24] C2TDELAY field and can be configured between 2 and 257 SPI_VBUSP_CLK cycles. The C2TDELAY is applicable only in 4-pin with chip select mode. The C2TDELAY begins when the SPI master asserts SPIm_SCSnx signal. The C2T delay period is specified by:

duration of C2TDELAY period = (SPIDELAY[31-24] C2TDELAY + 2) * SPI_VBUSP_CLK Period

The previous value of the SPIDAT1[28] CSHOLD bit must be set to '0h' for the C2T delay to be enabled.

Figure 11-1374 shows C2TDELAY example.

Figure 11-1374. Example: $t_{C2TDELAY}$ = 8 SPI_VBUSP_CLK Cycles



NOTE: The chip select setup delay configured through the SPIDELAY[31-24] C2TDELAY field is not applied between transactions which have the SPIDAT1[28] CSHOLD bit set to '1h'.

11.16.4.2.3.1.2 Chip Select Hold Time

In order to support slow slave devices the SPI module can also be configured to delay the chip select deactivation after the last data bit transfer. This delay is controlled by the SPIDELAY[23-16] T2CDELAY bit and can be configured between for 1 and 256 SPI_VBUSP_CLK cycles. The T2CDELAY is applicable only in 4-pin with chip select mode. The T2CDELAY begins after the data shifting period ends. The T2C delay period is specified by:

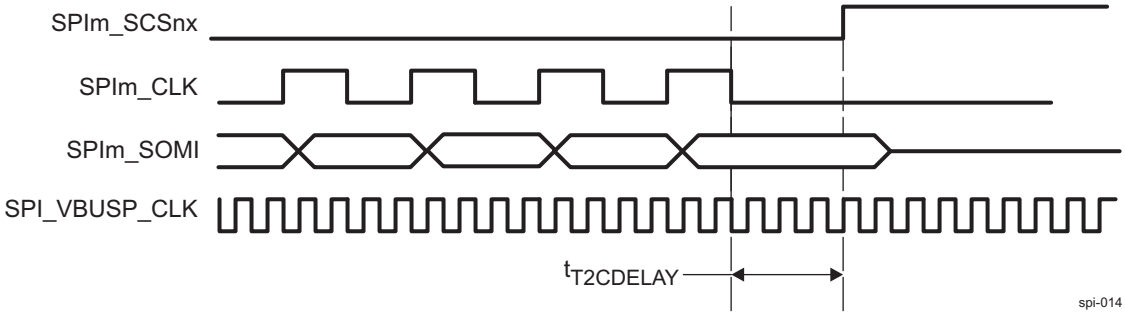
duration of T2CDELAY period = (SPIDELAY[32-16] T2CDELAY + 1) * SPI_VBUSP_CLK Period

If the SPIFMTn[16] PHASE bit is '0h', then the T2CDELAY period lasts for an additional ½ SPIm_CLK signal time over that specified by the above equation.

The current value of the SPIDAT1[28] CSHOLD bit must be set to '0h' for T2C delay to be enabled.

Figure 11-1375 shows T2CDELAY example.

Figure 11-1375. Example: $t_{T2CDELAY}$ = 4 SPI_VBUSP_CLK Cycles



NOTE: The chip select hold delay configured through the SPIDELAY[23-16] T2CDELAY field is not applied between transactions which have the SPIDAT1[28] CSHOLD bit set to '1h'.

11.16.4.2.3.1.3 Automatic Delay Between Transfers

The SPI master can automatically insert a delay of between 2 and 65 SPI_VBUSP_CLK cycles between transmissions. This delay is controlled by the SPIFMTn[29-24] WDELAY field and is enabled by setting the SPIDAT1[26] WDEL bit to '1h'. The WDELAY period begins when the T2CDELAY period terminates (if T2C delay period was enabled) or when the master deasserts SPIm_SCSnx signal (if T2C delay periods is disabled). If a transfer is initiated by writing a 32-bit value to the SPIDAT1 register, then the new values of SPIDAT1[26] WDEL and SPIFMTn[29-24] WDELAY bits are used; otherwise, the old values of SPIDAT1[26] WDEL and SPIFMTn[29-24] WDELAY are used. The WDELAY delay period is specified by:

duration of WDELAY period = (SPIFMTn[29-24] WDELAY + 2) * SPI_VBUSP_CLK Period

11.16.4.2.3.1.4 Chip Select Hold Option

There are slave devices available that require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers. The SPI module supports both types of slave devices. The SPIDAT1[28] CSHOLD bit selects between the two options.

If the chip select hold option is enabled, the chip select will not toggle between two consecutive accesses. Therefore, the SPIDELAY[23-16] T2CDELAY of the first transfer and the SPIDELAY[31-24] C2TDELAY of the second transfer will not be applied. However, the wait delay could still be applied between the two transactions, if the SPIDAT1[26] WDEL bit is set to '1h'.

When the SPIDAT1[28] CSHOLD bit is '0h', during the data transmission, the value of the SPIDAT1[23-16] CSNR field is put on the chip select SPIm_SCSnx pins. When the transmission finishes, the value of the SPIDEF[1-0] CSDEF field is put on the SPIm_SCSnx pins.

The current and previous values of the SPIDAT1[28] CSHOLD bit are retained. Although the current value of the SPIDAT1[28] CSHOLD bit is initialized to '0h' when the SPIGCR0[0] RESET bit is set to '0h', the previous value of the SPIDAT1[28] CSHOLD bit is not initialized. The previous value of the SPIDAT1[28] CSHOLD bit must be explicitly initialized by writing twice to the SPIDAT1[28] CSHOLD bit.

11.16.4.3 Slave Mode Settings

The two slave mode options are defined by the configuration bit settings listed in Table 11-3374. Other configuration bits may take any value in the range listed in Table 11-3375. The values listed in Table 11-3374 and Table 11-3375 should not be changed while the SPIGCR1[24] ENABLE bit is set to '1h'. For complete details on each mode, see Section 11.16.4.2.1, *SPI Operation: 3-Pin Mode*, Section 11.16.4.2.2 *SPI Operation: 4-Pin Mode*.

Table 11-3374. SPI Register Settings Defining Slave Modes

Register	Bit(s)	Slave 3-pin	Slave 4-pin Chip Select
SPIGCR0	RESET	1h	1h
SPIGCR1	ENABLE	1h	1h
SPIGCR1	CLKMOD	0h	0h
SPIGCR1	MASTER	0h	0h
SPIPC0	SOMIFUN	1h	1h
SPIPC0	SIMOFUN	1h	1h
SPIPC0	CLKFUN	1h	1h
SPIPC0	SCSFUN	0h	1h, 2h

Table 11-3375. Allowed SPI Register Settings in Slave Modes

Register	Bit(s)	Slave 3-pin	Slave 4-pin Chip Select
SPIFMTn	CHARLEN	2h to 10h	2h to 10h
SPIFMTn	SHIFTDIR	-h	-h

11.16.4.4 Clock

The SPI clock signal (SPIm_CLK) is derived from the SPI functional clock (SPI_VBUSP_CLK) divided by 2. The maximum clock rate supported is SPI_VBUSP_CLK / 2, as determined by the SPIFMTn[15-8] PRESCALE field. The SPIm_CLK frequency is calculated as:

SPIm_CLK frequency = SPI_VBUSP_CLK / [SPIFMTn[15-8] PRESCALE + 1]

When SPIFMTn[15-8] PRESCALE is set to '0h', the SPIm_CLK frequency defaults to SPI_VBUSP_CLK / 2.

11.16.4.5 Interrupt Support

The SPI module generates two interrupt requests. The SPI interrupt system is controlled by three registers:

- The SPI interrupt level register (SPILVL) controls which interrupt events to be mapped to INT0 and INT1 interrupt request lines.
- The SPI interrupt register (SPIINT0) contains bits to selectively enable/disable each interrupt event.
- The SPI flag register (SPIFLG) contains flags indicating when each of the interrupt conditions have occurred.

Multiple interrupt sources can be assigned to the same interrupt request line. To identify the interrupt source in the SPI peripheral the SPIFLG register or the INTVECn[5-1] INTVECTn (n = 0 to 1) field must be read. For more details, see SPI_INTVEC0 and SPI_INTVEC1 registers.

11.16.4.6 DMA Events Support

If handling the SPI message traffic on a character-by-character basis requires too much CPU overhead, then the CPU can configure the system DMA to handle the SPI data transfer.

The SPI module has two DMA synchronization event outputs for receive (REVT) and transmit (XEVT), allowing DMA transfers to be triggered by SPI read receive and write transmit events. The SPI module enables DMA requests by enabling the SPIINT0[16] DMAREQEN bit.

When a character is to be transmitted the SPI module signals the DMA via the XEVT signal. The DMA controller then transfers the data from the source buffer into the SPI transmit data register (SPIDAT1). When a character is received, the SPI module signals the DMA via the REVT signal. The DMA controller then reads the data from the SPI receive buffer register (SPIBUF) and transfers it to a destination buffer for read access.

In most cases, if the DMA is being used to service received data from the SPI module, the SPIINT0[8] RXINTEN bit should be set to '0h'. This prevents the CPU from responding to the received data in addition to the DMA.

11.16.4.7 Robustness Features

The SPI module includes many features to make the SPI communication link robust. An internal loopback test mode can be used to facilitate a power on self test routine. Additionally, the SPI master continually monitors the bus for faults on its data line. Section 11.16.4.7.1, *SPI Internal Loopback Test Mode (Master Only)* and Section 11.16.4.7.2, *SPI Transmission Continuous Self-Test* describe these robustness features in more detail.

11.16.4.7.1 SPI Internal Loopback Test Mode (Master Only)

CAUTION

The internal loop-back self-test mode should not be entered during a normal data transaction or unpredictable operation may occur.

To select the loopback mode, the SPIm_CLK, SPIm_SOMI, SPIm_SIMO pins should be configured as functional pins by configuring the SPIPC0 register and by setting the SPIGCR1[16] LOOPBACK bit. The internal loop-back self-test mode can be used to test the SPI transmit and receive paths including the transmit and receive buffers. In this mode, the transmit signal is internally fed back to the receiver and the SPIm_SIMO, SPIm_SOMI, and SPIm_CLK pins are in a high-impedance state. This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

11.16.4.7.2 SPI Transmission Continuous Self-Test

During a data transfer, the SPI module captures the value from its data output pin on the appropriate SPIm_CLK signal edge. This value is compared against the expected value and any difference indicates a fault on the SPI bus. If a fault is detected, then the SPIBUF[28] BITERR and the SPIFLG[4] BITERRFLG bits are set and an error interrupt is generated if enabled. The SPI continuous self-test mode is not available in SPI loopback mode.

11.16.4.8 Reset Considerations

This section describes the software and hardware reset considerations.

11.16.4.8.1 Software Reset Considerations

The SPI module contains a software reset bit (SPIGCR0[0] RESET) that is used to reset the SPI module. As a result of a reset, the SPI module register values go to their reset state. The SPIGCR0[0] RESET bit must be set before beginning of any SPI operation.

11.16.4.8.2 Hardware Reset Considerations

In the event of a hardware reset, the SPI module register values go to their reset state and the application software needs to reprogram the registers to the desired values.

11.16.4.9 Power Management

The SPI module can be put in local low-power mode. The SPI local low-power mode is activated by setting the SPIGCR1[8] POWERDOWN bit. Setting this bit stops the clocks to the SPI internal logic and the SPI registers. Setting the SPIGCR1[8] POWERDOWN bit causes the SPI module to enter local low-power mode and clearing the SPIGCR1[8] POWERDOWN bit causes SPI module to exit from local low-power mode. All registers are accessible during local power-down mode as any register access enables the clock to SPI module for that particular access alone.

Because entering a low-power mode has the effect of suspending all state machine activities, care must be taken when entering such mode to ensure that a valid state is entered when low-power mode is active. As a result, application software must ensure that a low-power mode is not entered during a transmission or reception of data.

11.16.4.10 Emulation Considerations

CAUTION

Viewing or otherwise reading the following SPI registers: SPIBUF, SPIFLG, SPI_INTVEC0, and SPI_INTVEC1 through the JTAG debugger will cause their contents to change, possibly invalidating the results of the debug session. Be sure to set up the debugger to avoid reading these registers.

The SPI module does not support soft or hard stop during emulation breakpoints. The SPI module will continue to run if an emulation breakpoint is encountered.

In addition, any status registers that are cleared after reading will be affected if viewed in a memory or watch window of the debugger because the emulator will read these registers to update the value displayed in the window.

11.16.5 SPI Programming Guide

11.16.5.1 Global Initialization

Table 11-3376 shows the basic steps needed for configuration of the SPI module in master or slave mode.

Table 11-3376. SPI Master and Slave Mode Initialization

Step	Register/Bit Field/Programming Model	Value	
		Master Mode	Slave Mode
1. Reset the SPI module	SPIGCR0[0] RESET	0h	0h
2. Take the SPI module out of reset	SPIGCR0[0] RESET	1h	1h
3. Configure the SPI module for master or slave mode	SPIGCR1[0] MASTER	1h	0h
	SPIGCR1[1] CLKMOD	1h	0h
4. Configure the SPI module for 3-pin or 4-pin with chip select mode	SPIPC0[11] SOMIFUN	1h	1h
	SPIPC0[10] SIMOFUN	1h	1h
	SPIPC0[9] CLKFUN	1h	1h
	SPIPC0[1-0] SCSFUN	0h for Master 3-pin mode	0h for Slave 3-pin mode
		1h, 2h, 3h for Master 4-pin with Chip Select	1h, 2h for Slave 4-pin with Chip Select
5. Choose the SPI data format register n (SPIFMTn) to be used	SPIDAT1[25-24] DFSEL	0h - SPIFMT0 is used	0h - SPIFMT0 is used
		1h - SPIFMT1 is used	1h - SPIFMT1 is used
		2h - SPIFMT2 is used	2h - SPIFMT2 is used
		3h - SPIFMT3 is used	3h - SPIFMT3 is used
6. Configure the SPI data rate, character length, shift direction, phase, polarity and other format options using SPIFMTn selected in step 5.	SPIFMTn	-h	-h[(1)]
7. In master mode, configure the master delay options	SPIDELAY	-h	NA
8. Select the error interrupt notifications	SPIINT0	-h	-h
	SPILVL	-h	-h
9. Enable the SPI communication	SPIGCR1[24] ENABLE	1h	1h
10. Setup and enable the DMA for SPI data handling and then enable the DMA servicing for the SPI data requests	SPIINT0[16] DMAREQEN	1h	1h
11. Handle SPI data transfer requests using DMA and service any SPI error conditions using the interrupt service routine.			

(1) In slave mode configure character length and shift direction only.

11.16.6 SPI Registers

Table 11-3378 lists the memory-mapped registers for the SPI module. All register offset addresses not listed in Table 11-3378 should be considered as reserved locations and the register contents should not be modified.

Table 11-3377. SPI Instances

Instance	Base Address
SPI0	2180 5400h
SPI1	2180 5800h
SPI2	2180 5C00h
SPI3	2180 6000h

Table 11-3378. SPI Registers

Offset	Acronym	Register Name	SPI0 Physical Address	SPI1 Physical Address	SPI2 Physical Address	SPI3 Physical Address	Section

Table 11-3383. SPIGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved
24	ENABLE	R/W	0h	SPI enable. This bit enables the SPI transfers. The other SPI configuration registers except SPIINT0[16] DMAREQEN bit should be configured before writing 1 to this bit. This will prevent the SPI from responding to bus operations erroneously while it is in the process of being configured. The SPIINT0[16] DMAREQEN bit should be enabled after setting SPIGCR1[24] ENABLE bit. If SPIINT0[16] DMAREQEN bit is enabled before setting SPIGCR1[24] ENABLE bit then the first DMA request that occurs before the SPI is ready for data transfer may get dropped. When SPIGCR1[24] ENABLE bit is set to 0h, the following SPI registers get forced to their default states (to 0s except for SPIBUF[31] RXEMPTY bit): • Both TX and RX shift registers. • The SPIDAT0[15-0] TXDATA and SPIDAT1[15-0] TXDATA fields. • All the fields of the SPIFLG register. • Contents of SPIBUF and the internal RXBUF registers. • 0 = SPI is not activated for transfers. • 1 = Activates SPI.
23-17	RESERVED	R	0h	Reserved

Table 11-3383. SPIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	LOOPBACK	R/W	0h	Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPIm_SIMO and SPIm_SOMI pins are configured with SPI functionality, then the SPIm_SIMO pin is internally connected to the SPIm_SOMI pin. The transmit data is looped back as receive data and is stored in the receive field of the concerned buffer. Externally, during loop-back operation, the SPIm_CLK pin outputs an inactive value, SPIm_SIMO and SPIm_SOMI pins remain in high-impedance state. The SPI has to be initialized in master mode before the loop-back can be selected. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result. • 0 = Internal loop-back test mode disabled. • 1 = Internal loop-back test mode enabled.
15-9	RESERVED	R	0h	Reserved
8	POWERDOWN	R/W	0h	When active, the SPI state machine enters a power-down state. • 0 = The SPI is in active mode. • 1 = The SPI is in power-down mode.
7-2	RESERVED	R	0h	Reserved
1	CLKMOD(1)	R/W	0h	Clock mode. Selects either an internal or external clock source. This bit also determines the I/O direction of the chip select (SPIm_SCSnx) pins in functional mode. • 0 = Clock is external, SPIm_SCSnx is an input. • 1 = Clock is internal, SPIm_SCSnx is an output.
0	MASTER(1)	R/W	0h	SPIm_SIMO/SPIm_SOMI pin direction determination. Determines the direction of the SPIm_SIMO and SPIm_SOMI pins. This bit determines whether the SPI is in Master mode or Slave mode. • 0 = SPIm_SIMO pin an input, SPIm_SOMI pin an output. • 1 = SPIm_SOMI pin an input, SPIm_SIMO pin an output.

(1) Although there are two different bits which control the Master/Slave mode functions, only two of their combinations are valid. For Master mode of operation: MASTER = '1', CLKMOD = '1'. For Slave mode of operation: MASTER = '0', CLKMOD = '0'. Any other combinations of these two bits may not yield any desirable operation of the module and must be avoided.

Table 11-3392. SPIFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	Reserved
9	TXINTFLG	R	0h	Transmitter empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new data can be written to it. This flag is set when a data is copied to the shift register either directly or from the TXBUF register. This bit is cleared by one of following ways: • Writing a new data to either SPIDAT0 or SPIDAT1 registers. • Writing a 0 to SPIGCR1[24] ENABLE bit. • 0 = Transmit buffer is now full. No interrupt pending for transmitter empty. • 1 = Transmit buffer is empty. An interrupt is pending to fill the transmitter.

Table 11-3392. SPIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	RXINTFLG	R/W1C	0h	Receiver full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). This bit is cleared under the following ways: • Reading the SPIBUF register. During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit. • Reading SPI_INTVEC0 or SPI_INTVEC1 register when there is a receive buffer full interrupt. • Writing a 1 to this bit. • Writing a 0 to SPIGCR1[24] ENABLE bit. • System reset. • 0 = No new received data pending. Receive buffer is empty. • 1 = A newly received data is ready to be read. Receive buffer is full. • **Note:** Clearing SPIFLG[8] RXINTFLG bit by writing a 1 before reading the SPIBUF register sets the SPIBUF[31] RXEMPTY bit too. This way, one can ignore a received data. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF register and the SPIBUF[31] RXEMPTY bit will be cleared again. The SPIBUF register contents should be read first if this situation needs to be avoided.
7	RESERVED	R	0h	Reserved
6	OVRNINTFLG	R/W1C	0h	Receiver overrun flag. The bit is set when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. This bit is cleared under the following conditions: • Reading SPI_INTVEC0 or SPI_INTVEC1 register when there is a receive buffer overrun interrupt. • Writing a 1 to this bit. • 0 = Overrun condition did not occur. • 1 = Overrun condition has occurred. • **Note:** Reading SPIBUF register does not clear the SPIFLG[6] OVRNINTFLG bit. If an overrun interrupt is detected, then the SPIBUF register may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF register will result in RXBUF contents (if it is full) getting copied to SPIBUF register. • **Note:** A special condition under which SPIFLG[6] OVRNINTFLG bit gets set. If both SPIBUF register and RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR and DLENERR occur, then SPIFLG[6] OVRNINTFLG bit will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receiver overrun.
5	RESERVED	R	0h	Reserved
4	BITERRFLG	R/W1C	0h	This bit is set when a mismatch of internal transmit data and transmitted data is detected. The SPI samples the signal of the transmit pin (master: SPIm_SIMO, slave: SPIm_SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag is set. A possible reason for a bit error can be a too high bit rate/capacitive load or another master/slave trying to transmit at the same time. This flag can be cleared by one of the following ways: • Write a 1 to this bit. • Set SPIGCR1[24] ENABLE bit to 0. • 0 = No bit error occurred. • 1 = A bit error occurred.
3-0	RESERVED	R	0h	Reserved

Table 11-3401. SPIDAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	Reserved
28	CSHOLD	R/W	0h	Chip select hold mode. The SPIDAT1[28] CSHOLD bit is supported in master mode only. In slave mode, this bit is ignored. SPIDAT1[28] CSHOLD bit defines the behavior of the chip select lines at the end of a data transfer. • 0 = The SPIm_SCSnx pins are restored to SPIDEF[1-0] CSDEF field at the end of a transfer after the T2CDELAY time has passed. • 1 = The SPIm_SCSnx pins are continued as SPIDAT1[23-16] CSNR field at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1 register. The setup and hold delays in SPIDELAY register (SPIDELAY[31-24] C2TDELAY and SPIDELAY[23-16] T2CDELAY fields) are not applied between transactions which have SPIDAT1[28] CSHOLD = 1. • **Note:** If a transfer with SPIDAT1[28] CSHOLD = 0 is followed by a transfer with SPIDAT1[28] CSHOLD = 1, then SPIDELAY[31-24] C2TDELAY field will be applied at the beginning of the second transfer. To do multiple transactions to a slave without deactivating chip select between transfers, maintain SPIDAT1[28] CSHOLD of 1 and same SPIDAT1[23-16] CSNR field information to keep the same slave selected in the transfers.
27	RESERVED	R	0h	Reserved

Table 11-3401. SPIDAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	WDEL	R/W	0h	Enable the delay counter at the end of the current transaction. The SPIDAT1[26] WDEL bit is supported in master mode only. In slave mode, this bit is ignored. • 0 = No delay will be inserted. However, SPIm_SCSnx pin will still be deactivated for at least 2 SPI module clock cycles if SPIDAT1[28] CSHOLD = 0. • 1 = After a transaction, SPIFMTn[29-24] WDELAY field of the selected data format will be loaded into the delay counter. No transaction will be performed until the SPIFMTn[29-24] WDELAY counter overflows. The SPIm_SCSnx pin will be deactivated for at least (WDELAY + 2) × SPI module clock period.
25-24	DFSEL	R/W	0h	Data word format select: • 0h = Data word format 0 is selected. • 1h = Data word format 1 is selected. • 2h = Data word format 2 is selected. • 3h = Data word format 3 is selected.
23-16	CSNR	R/W	0h	Chip select number (value = 0-FFh). The SPIDAT1[23-16] CSNR field defines the chip select that will be activated during the data transfer. In slave mode, this field must be written as 00h; in master mode, the value of this field is driven on the chip select pins. Bits [23-18] are not used. Bits [17-16] are put out on SPIm_SCSn[1-0] during a transfer. For more information about supported number of the chip select pins, see Section 11.16.1, *SPI Overview*.
15-0	TXDATA	R/W	0h	Transfer data (value = 0-FFFFh). When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, the TXBUF will hold the written values. SPIGCR1[24] ENABLE bit must be set to 1 before this register can be written to. Writing a 0 to the SPIGCR1[24] ENABLE bit forces the lower 16 bits of the SPIDAT1 register to 0. • **Note:** Irrespective of the character length, the transmit data should be right-justified before writing to SPIDAT1 register.

LEGEND: R = Read Only; RC = Read to Clear; RS = Read to Set; *-n* = value after reset

Table 11-3404. SPIBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RXEMPTY	RS	1h	Receive data buffer empty. When the host reads the SPIBUF field or the whole SPIBUF register, this will automatically set the SPIBUF[31] RXEMPTY bit. When a data transfer is completed, the received data is copied into SPIBUF register, the SPIBUF[31] RXEMPTY bit is cleared. This flag is set to 1 under following conditions: • Reading the SPIBUF[15-0] RXDATA field. • Writing 1 to clear the SPIFLG[8] RXINTFLG bit. • 0 = New data has been received and copied into the SPIBUF register. • 1 = No data received since last reading of SPIBUF register. Write-clearing the SPIFLG[8] RXINTFLG bit before reading the SPIBUF register indicates the received data is being ignored. Conversely, SPIFLG[8] RXINTFLG bit can be cleared by reading the SPIBUF[15-0] RXDATA field or the entire SPIBUF register.

Table 11-3404. SPIBUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
30	RXOVR	RC	0h	Receive data buffer overrun. When a data transfer is completed and the received data is copied into the RXBUF while it is already full, SPIBUF[30] RXOVR bit is set. An overrun always occurs to the RXBUF, and SPIBUF register contents never get overwritten until after it is read by the CPU/DMA. Reading SPIBUF register does not clear the SPIBUF[30] RXOVR bit. If an overrun interrupt is detected, then the SPIBUF register may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF register will result in RXBUF contents (if it is full) getting copied to SPIBUF register. • **Note:** A special condition under which SPIBUF[30] RXOVR bit gets set. If both SPIBUF register and RXBUF are already full and while another buffer receive is underway, if any errors like TIMEOUT, BITERR and DLENERR occur, then SPIBUF[30] RXOVR bit will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receiver overrun. • 0 = No receive data overrun condition occurred since last time reading the data field. • 1 = A receive data overrun condition occurred since last time reading the data field.
29	TXFULL	R	0h	Transmit data buffer full. This flag is a read-only flag. Writing into SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the SPIBUF[29] TXFULL bit. Once the data is copied to the shift register, the SPIBUF[29] TXFULL bit will be cleared. Writing to the SPIDAT0/SPIDAT1 register when both TXBUF and the TX shift register are empty does not set the SPIBUF[29] TXFULL bit. • 0 = The transmit buffer is empty; SPIDAT0/SPIDAT1 register is ready to accept a new data. • 1 = The transmit buffer is full; SPIDAT0/SPIDAT1 register is not ready to accept a new data.
28	BITERR	RC	0h	Bit error. There was a mismatch of internal transmit data and transmitted data. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the flag BITERR is set. A possible reason for a bit error can be noise, a too-high bit rate/capacitive load, or another master/slave trying to transmit at the same time. • **Note:** This flag is set to 0h when the SPIBUF[15-0] RXDATA field is read. • 0 = No bit error occurred. • 1 = A bit error occurred.
27-16	RESERVED	R	0h	Reserved
15-0	RXDATA	R	0h	SPI receive data (value = 0-FFFFh). This is the received data, transferred from the receive shift-register at the end of a transfer completion. Irrespective of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.

LEGEND: R = Read Only; R/W = Read/Write; *-n* = value after reset

Table 11-3410. SPIDELAY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	C2TDELAY	R/W	0h	Chip-select-active-to-transmit-start delay (value = 0-FFh). SPIDELAY[31-24] C2TDELAY bit is used in master mode only. It defines a setup time for the slave device that delays the data transmission from the chip select active edge by a multiple of SPI module clock cycles. C2TDELAY can be configured between 2 and 257 SPI module clock cycles (See Section 11.16.4.2.3.1.1). The setup time value is calculated as follows: $t_{C2TDELAY}$ = (C2TDELAY + 2) × SPI module clock period • **Note:** If C2TDELAY = 0, then $t_{C2TDELAY}$ = 0. • ***Example:*** SPI module clock = 25 MHz -> SPI module clock period = 40 ns; C2TDELAY = 06h; then $t_{C2TDELAY}$ = 320 ns; When the chip select signal becomes active, the slave has to prepare for data transfer within 320 ns. • **Note:** If phase = 1, the delay between SPIm_SCSnxfalling edge to the first edge of SPIm_SCSnx will have an additional 0.5 SPIm_CLK period delay. This delay is as per the SPI protocol.

Table 11-3410. SPIDELAY Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-16	T2CDELAY	R/W	0h	Transmit-end-to-chip-select-inactive delay (value = 0-FFh). SPIDELAY[23-16] T2CDELAY is used in master mode only. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of SPI module clock cycles after the last bit is transferred. T2CDELAY can be configured between 2 and 256 SPI module clock cycles (See Section 11.16.4.2.3.1.2). The hold time value is calculated as follows: $t_{T2CDELAY}$ = (T2CDELAY + 1) × SPI module clock period Note: If T2CDELAY = 0, then $t_{T2CDELAY}$ = 0 • ***Example:*** VBUSPCLK = 25 MHz -> VBUSPCLK period = 40 ns; T2CDELAY = 03h; then $t_{T2CDELAY}$ = 160 ns; After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns. • **Note:** If phase = 0, then between the last edge of SPIm_CLK and rise-edge of SPIm_SCSnx there will be an additional delay of 0.5 SPIm_CLK period. This is as per the SPI protocol.

Table 11-3416. SPIFMT0 to SPIFMT3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved
29-24	WDELAY	R/W	0h	Delay in between transmissions. Idle time that will be applied at the end of the current transmission if the SPIDAT1[26] WDEL bit is set in the current buffer. The delay to be applied is equal to: WDELAY × $P_{SPI\ module\ clock}$ + 2 × $P_{SPI\ module\ clock}$ $P_{SPI\ module\ clock}$ -> Period of SPI module clock
23-21	RESERVED	R	0h	Reserved
20	SHIFTDIR	R/W	0h	Shift direction. • 0 = Most significant bit is shifted out first. • 1 = Least significant bit is shifted out first. • **Note:** Shift direction must be programmed in both master mode and slave mode.
19	RESERVED	R	0h	Reserved
18	DISCSTIMERS	R/W	0h	Disable chip select timers for this format register. The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format if not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip select delay timers for any slaves. • 0 = Both C2TDELAY and T2CDELAY counts are inserted for the chip selects. • 1 = No C2TDELAY or T2CDELAY is inserted in the chip select timings.

Table 11-3416. SPIFMT0 to SPIFMT3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	POLARITY	R/W	0h	SPI clock polarity. • 0 = SPI clock signal is low-inactive (before and after data transfer the clock signal is low). • 1 = SPI clock signal is high-inactive (before and after data transfer the clock signal is high).
16	PHASE	R/W	0h	SPI clock delay. • 0 = SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge. • 1 = SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.
15-8	PRESCALE	R/W	0h	SPI prescaler (value = 0-FFh). It determines the bit transfer rate if the SPI is the network master and is directly derived from the SPI module clock. If the SPI is configured as slave, SPIFMTn[15-8] PRESCALE does not need to be configured. The clock rate can be calculated as: SPI clock frequency = SPI module clock/(PRESCALE + 1) • **Note:** When PRESCALEx is set to 0h, the SPI clock rate defaults to SPI module clock/2.
7-5	RESERVED	R	0h	Reserved
4-0	CHARLEN	R/W	0h	SPI data word length (value = 0-1Fh). Legal values are 2h (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 0 or 1Fh are not detected and their effect is indeterminate. • **Note:** Data word length must be programmed in both master mode and slave mode.

Table 11-3419. SPI_INTVEC0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5-1	INTVECT0	R	0h	Interrupt vector for interrupt line INT0. SPI_INTVEC0[5-1] INTVECT0 field returns the vector of the pending interrupt at interrupt line INT0. If more than one interrupt is pending, SPI_INTVEC0[5-1] INTVECT0 field always references the highest priority interrupt source first. The interrupts available for SPI in the descending order of their priorities are as given below. • Transmission error Interrupt. • Receive buffer overrun interrupt. • Receive buffer full interrupt. • Transmit buffer empty interrupt. The SPI_INTVEC0[5-1] INTVECT0 field just reflects the status of SPIFLG register in a vectorized format. So, any updates to SPIFLG register will automatically reflect in the vector value in this register. Vectors for each of these interrupts will be reflected on the SPI_INTVEC0[5-1] INTVECT0 field, when they occur. Reading the vectors for the receive buffer overrun and receive buffer full interrupts will automatically clear the respective flags in the SPIFLG register. Reading the vector register when transmitter empty is indicated does not clear the SPIFLG[9] TXINTFLG bit. Writing a new data to SPIDAT0/SPIDAT1 register clears the transmitter empty interrupt. On reading the SPI_INTVEC0[5-1] INTVECT0 field, the vector of the next highest priority interrupt (if any) will be then reflected on the INTVECT0 bits. If two or more interrupts occur simultaneously, the vector for the highest priority interrupt will be reflected on the SPI_INTVEC0[5-1] INTVECT0 field. The following are the SPI interrupt vectors for line INT0: • 0h = No interrupt pending. • 1h-10h = Reserved. • 11h = Error interrupt pending. See the lower halfword of SPIINT0 register to determine more details about the type of error. • 12h = The pending interrupt is receive buffer full interrupt. • 13h = The pending interrupt is receive buffer overrun interrupt. • 14h = The pending interrupt is transmit buffer empty interrupt. • 15h-1Fh = Reserved.

11.17 Timers

This chapter describes the Timer modules for the device.

11.17.1 Timers Overview

There are total of 7 chip-level timers.

The device includes several types of timers used by the system software, including general-purpose (GP) timers, watchdog timers, and a wake-up timer, as it follows:

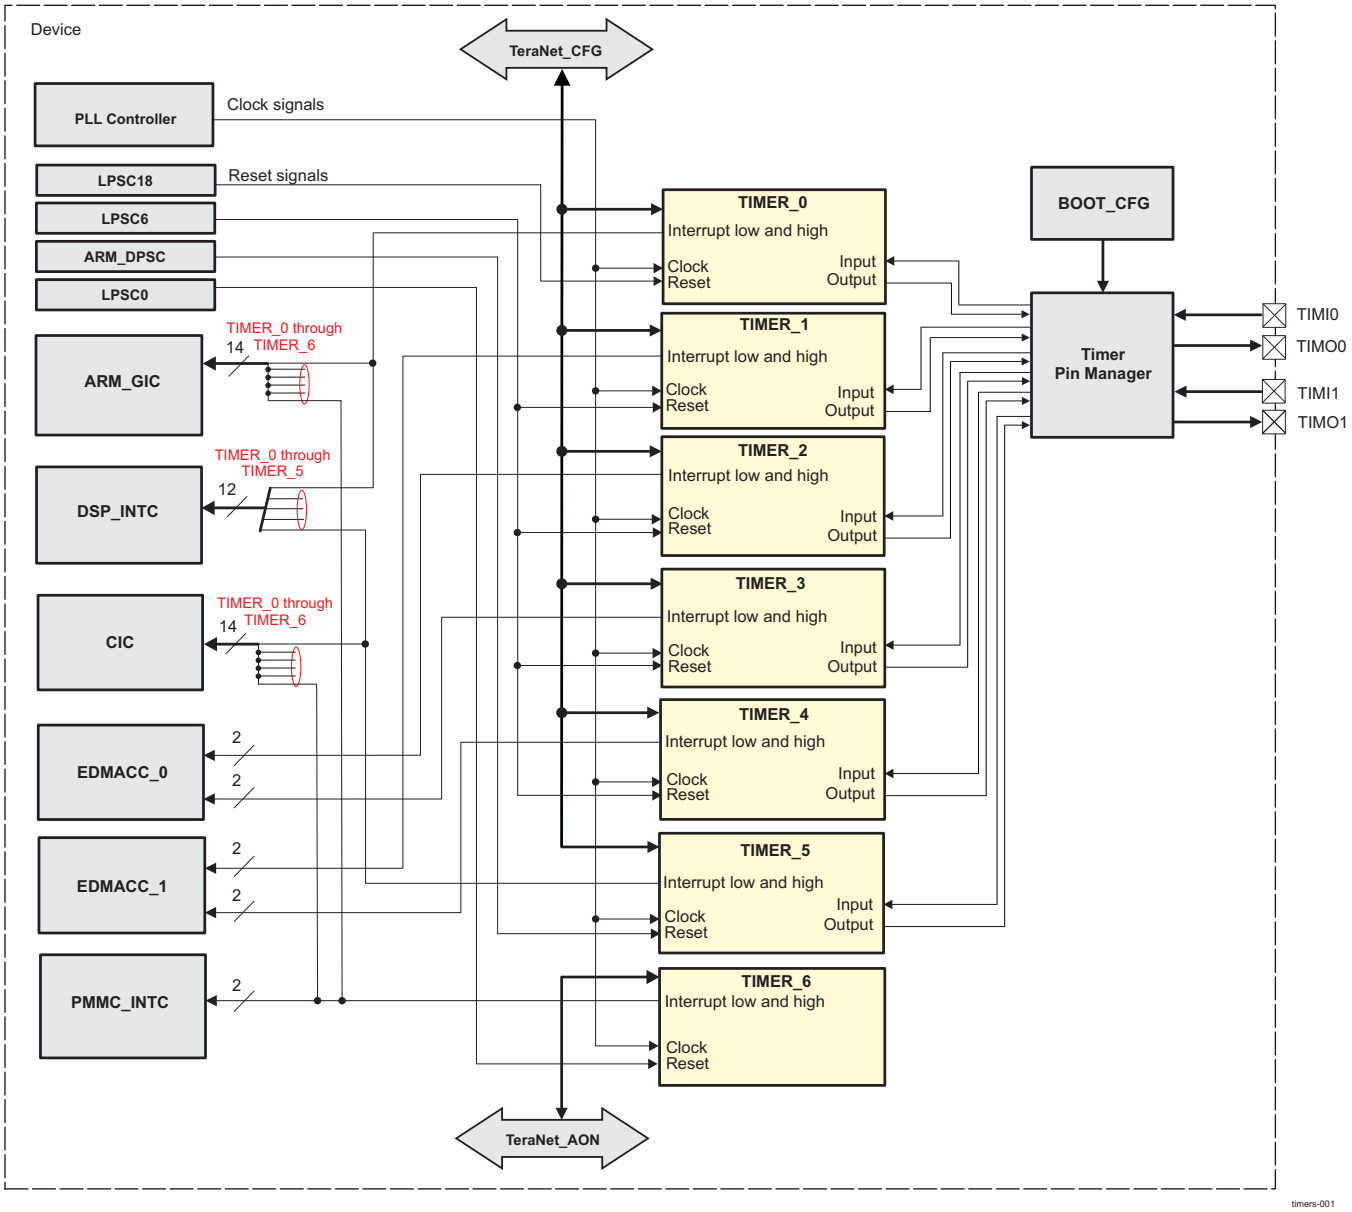
- TIMER_0 is dedicated/tightly coupled for C66x CorePac. TIMER_0 can be used as general-purpose timer or watchdog timer
- TIMER_1 through TIMER_4 are general-purpose timers
- TIMER_5 is dedicated/tightly coupled for the Arm core 0. TIMER_5 can be used as general-purpose timer or watchdog timer
- TIMER_6 is dedicated as device wake-up timer by interrupting PMMC CPU. TIMER_6 cannot be used by high-level software as a general-purpose timer or watchdog. TIMER_6 is neither connected to Timer pin manager block nor to Timer IOs.

Each timer has two input pins (TINPL and TINPH) and two output pins (TOUTL and TOUTH).

At the chip level there are 4 timer pins — two input pins (TIMI[1:0]) and two output pins (TIMO[1:0]). Each of TIMER_0 through TIMER_5 input can be configured to be driven by the timer input pins. Each of TIMO[1:0] output pin can be driven by any of the timer outputs. The selection of timer inputs and outputs is controlled by Timer pin manager. The Timer pin manager block is controlled by registers in BOOT_CFG module. For more information see Section 5.1.3.1.9, *Timer Pin Manager Control Registers*.

Figure 11-1392 shows a high-level block diagram of the timer circuitry.

Figure 11-1392. Timers Overview



The timer can be driven by an external clock at the timer input pin (TINPL) or by the divide-down clock rate of the internal clock. TINPH can be used to drive the higher 32-bit timer, TIMHI, in unchained mode. The internal clock is generated by the PLL Controller and is a divided-down version of the CHIP_CLK1 clock. For more information, see Section 5.4, *Clock Management*.

11.17.1.1 Timers Features

Timer modules are identical instances of hardware supporting three modes. The modes are selected in TIMER_TGCR[3-2] TIMMODE bits:

- 64-bit general-purpose (GP) timer
- Dual 32-bit timers (TIMLO and TIMHI in chain mode or unchained mode)
- Watchdog timer

Timer integration in this device implies timer usage as described in Section 11.17.1, *Timers Overview*.

11.17.2 Timers Environment

11.17.2.1 Timers External System Interface

Figure 11-1393 shows the external system interface for the timers, and Table 11-3427 describes the GP timer inputs and outputs.

NOTE: Software control (Timer pin manager) must ensure that MUX mode is configured to select the TIMER_i (where i = 0 to 5) signal on four different pads.

Note that TIMER_6 is not connected to Timer pin manager block nor to Timer IOs.

For more information about the configuration of the TIMER_i I/O pads, see Section 5.1.3.1.1, *Pad Configuration Registers*.

Table 11-3430. Timers Hardware Requests

Interrupt Requests						
Module Instance	**Event Name**	**Mapped To Input Event [Number]**				**Description**
		ARM GIC	**CIC**	**DSP INTC**	**PMMC INTC**	
TIMER_0[(1)]	TIMER_0_INTL	[16]	[72]	[32]	-	TIMER_0 Interrupt low
	TIMER_0_INTH	[17]	[73]	[33]	-	TIMER_0 Interrupt high
TIMER_1	TIMER_1_INTL	[18]	[74]	[34]	-	TIMER_1 Interrupt low
	TIMER_1_INTH	[19]	[75]	[35]	-	TIMER_1 Interrupt high
TIMER_2	TIMER_2_INTL	[20]	[76]	[36]	-	TIMER_2 Interrupt low
	TIMER_2_INTH	[21]	[77]	[37]	-	TIMER_2 Interrupt high
TIMER_3	TIMER_3_INTL	[22]	[78]	[38]	-	TIMER_3 Interrupt low
	TIMER_3_INTH	[23]	[79]	[39]	-	TIMER_3 Interrupt high
TIMER_4	TIMER_4_INTL	[24]	[80]	[40]	-	TIMER_4 Interrupt low
	TIMER_4_INTH	[25]	[81]	[41]	-	TIMER_4 Interrupt high

(1) Because TIMER_0 is used as DSP watchdog timer additionally to TIMER_0_INTL and TIMER_0_INTH there is WDT_RSTN signal. This watchdog timer signal is controlled by the registers in the RSTMUX. For more information about RSTMUX registers, see Section 5.1.3.1.8, *Reset Mux Control Registers*.

Table 11-3430. Timers Hardware Requests (continued)

TIMER_5[(2)]	TIMER_5_INTL	[26]	[82]	[42]	-	TIMER_5 Interrupt low
	TIMER_5_INTH	[27]	[83]	[43]	-	TIMER_5 Interrupt high
TIMER_6	TIMER_6_INTL	[28]	[84]	-	[3]	TIMER_6 Interrupt low
	TIMER_6_INTH	[29]	[85]	-	[4]	TIMER_6 Interrupt high

DMA Requests

Module Instance	Event Name	Mapped To Input Event [Number]		Description
		EDMACC_0	EDMACC_1	
TIMER_1	TIMER_1_INTL	-	[2]	TIMER_1 Interrupt low
	TIMER_1_INTH	-	[3]	TIMER_1 Interrupt high
TIMER_2	TIMER_2_INTL	[0]	-	TIMER_2 Interrupt low
	TIMER_2_INTH	[1]	-	TIMER_2 Interrupt high
TIMER_3	TIMER_3_INTL	[2]	-	TIMER_3 Interrupt low
	TIMER_3_INTH	[3]	-	TIMER_3 Interrupt high
TIMER_4	TIMER_4_INTL	-	[0]	TIMER_4 Interrupt low
	TIMER_4_INTH	-	[1]	TIMER_4 Interrupt high

(2) Because TIMER_5 is used as Arm watchdog timer additionally to TIMER_5_INTL and TIMER_5_INTH there is WDT_RSTN signal. This watchdog timer signal is controlled by the registers in the RSTMUX. For more information about RSTMUX registers, see Section 5.1.3.1.8, *Reset Mux Control Registers*.

NOTE: For the description of the interrupt source, see Section 11.17.4.9, *Timer Interrupt Rate*.

11.17.3.1 Watchdog Timer Integration

When in watchdog timer mode, an extra active-low signal called WDT_RSTN is provided to ease the chip-level integration. This signal is an exact duplication and inversion of the TOUTL pin but only valid in watchdog timer mode. In GP timer mode, this signal is inactive (stays high).

In Aem, watchdog event for TIMER_5 (Arm dedicated) is routed to the chip level Arm interrupt controller (ARM_INTC) and also to DSP interrupt controller (via INTC) to enable multiple options to handle watchdog timeout exception. As Arm does not support a local CPU reset input like the DSP do, the only options are to do a device reset or in certain situations DSP core can power cycle the errant Arm core.

The first option is to enable device reset on watchdog reset which can be configured using RSTMUX8. Here no interrupt handling or other software intervention after watchdog timeout event is required.

In the second option the DSP software can power cycle Arm core (dynamic power down) or entire Arm domain when watchdog times out, based on device level interrupt to DSP (either directly or via INTC).

For more information about Watchdog Timer Mode refer to Section 11.17.4.12, *Watchdog Timer Mode*.

11.17.3.1.1 RSTMUX

Timer can be configured to act as a watchdog timer or a general purpose timer. When configured as a watchdog timer, the software periodically writes the appropriate value in the specified register so that the watchdog timer does not time out. The timer output is routed to the reset input of the DSP LPSC through the RSTMUX block.

In order for the timers to reset the CPU, there needs to be a register that controls the routing of the events to the CPU. This is done in the RSTMUX registers. RSTMUX0 register correspond to DSP_INTC. RSTMUX8 register correspond to ARM_GIC.

For more information about RSTMUX block and registers refer to Section 5.1.3.1.8, *Reset Mux Control Registers*.

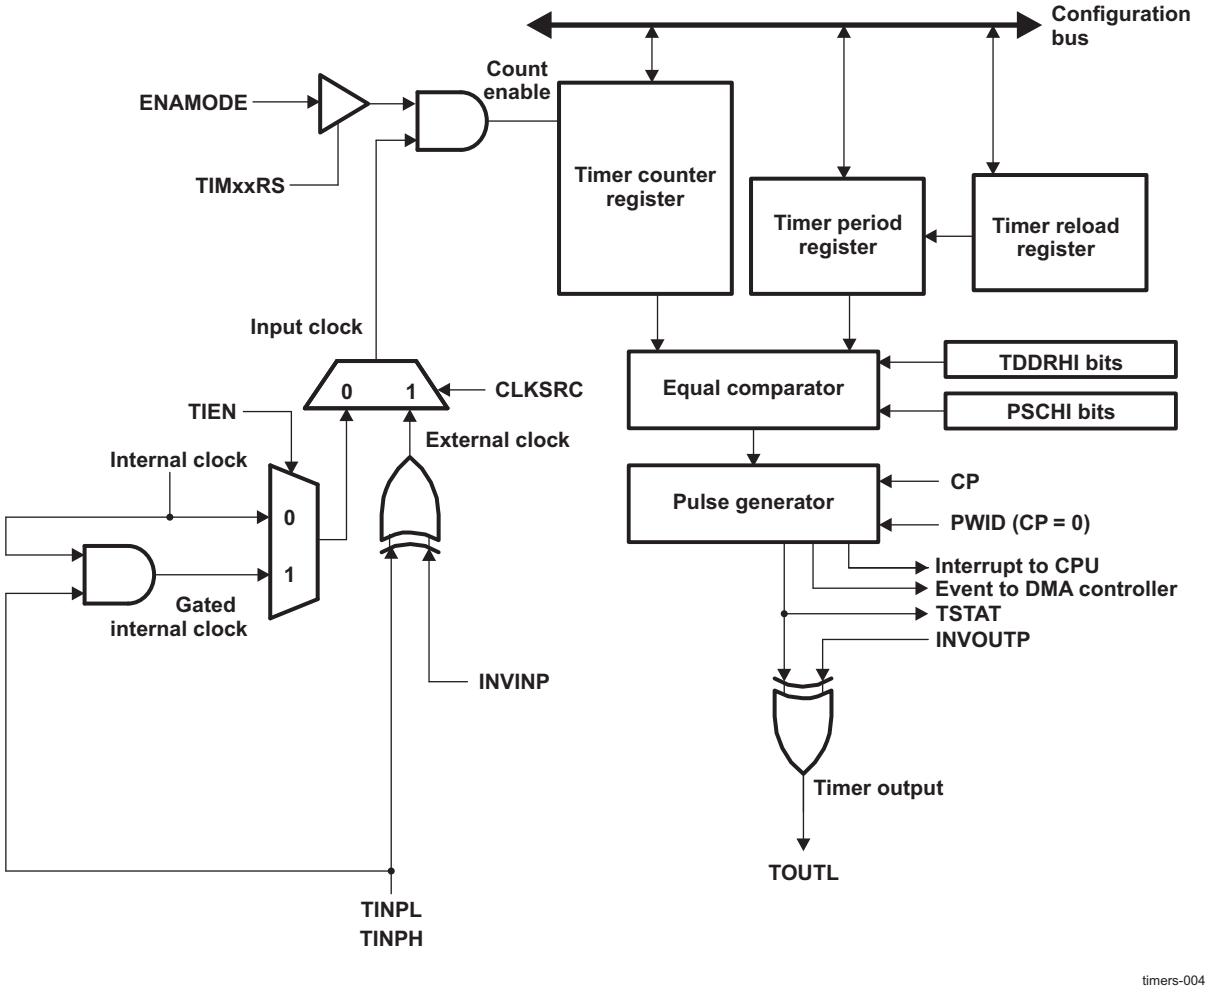
11.17.4 Timers Functional Description

This section describes the functional description of the timers.

11.17.4.1 Timers Block Diagram

Figure 11-1395 is a block diagram of the timers in the device.

Figure 11-1395. Timers Block Diagram



11.17.4.2 Timer Modes

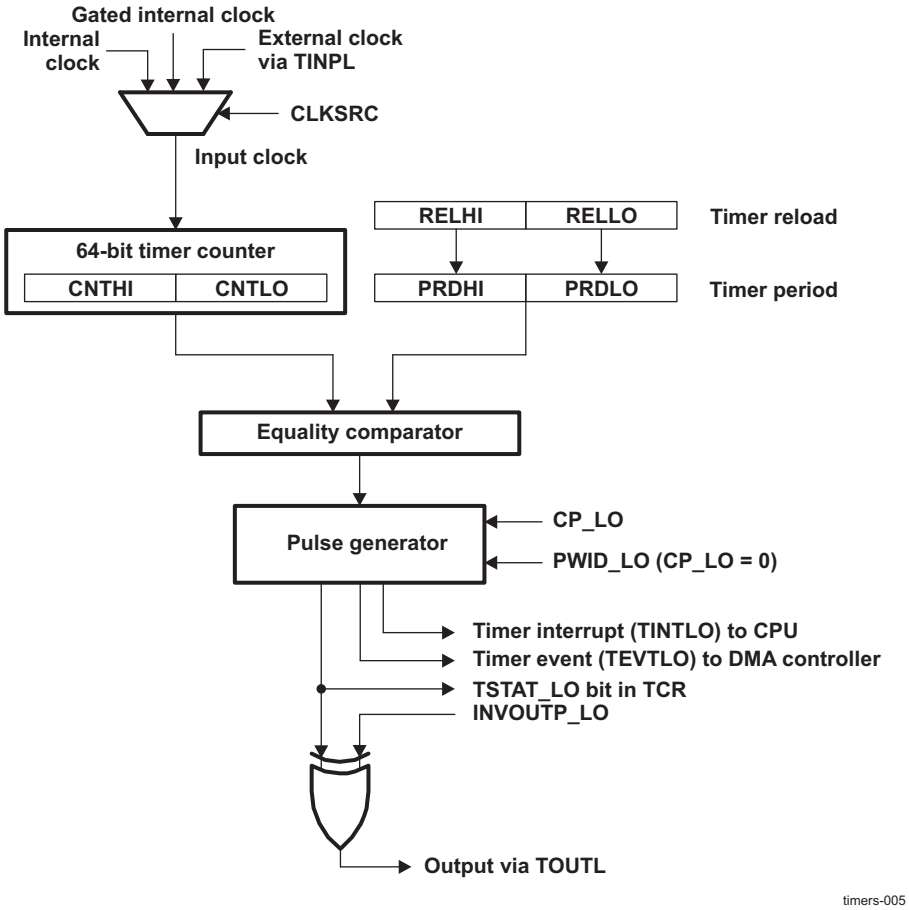
11.17.4.2.1 64-Bit Timer Mode

The timer can be configured as a 64-bit general-purpose (GP) timer, using the TIMER_TGCR[3-2] TIMMODE bit. At reset, the timer is in 64-bit GP timer mode.

In this mode, the timer operates as a 64-bit up-counter, as shown in Figure 11-1396. The counter registers (TIMER_CNTLO, TIMER_CNTHI) and the period registers (TIMER_PRDLO, TIMER_PRDHI) form a 64-bit timer counter register and a 64-bit timer period register, respectively. When the timer is enabled (see Table 11-3433), the timer counter starts incrementing by 1 at every timer input clock cycle. When the timer counter matches the timer period, it generates a maskable timer interrupt (TINTLO), a timer event (TEVTLO), and an output signal on the timer output pin, TOUTL.

When in pulse mode (CP_LO = 0), the timer output pin (TOUTL) asserts a pulse that is 1, 2, 3, or 4 timer clock cycles wide, depending on the setting of the pulse width bits TIMER_TCR[5-4] PWID_LO. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. When the timer counter matches the timer period, the period registers will be loaded with the values in the reload registers (TIMER_RELLO, TIMER_RELHI) if TIMER_TCR[7-6] ENAMODE_LO = 3h. The timer can be stopped, restarted, reset, or disabled using the bits of the timer control register.

Figure 11-1396. 64-Bit Timer Mode Block Diagram



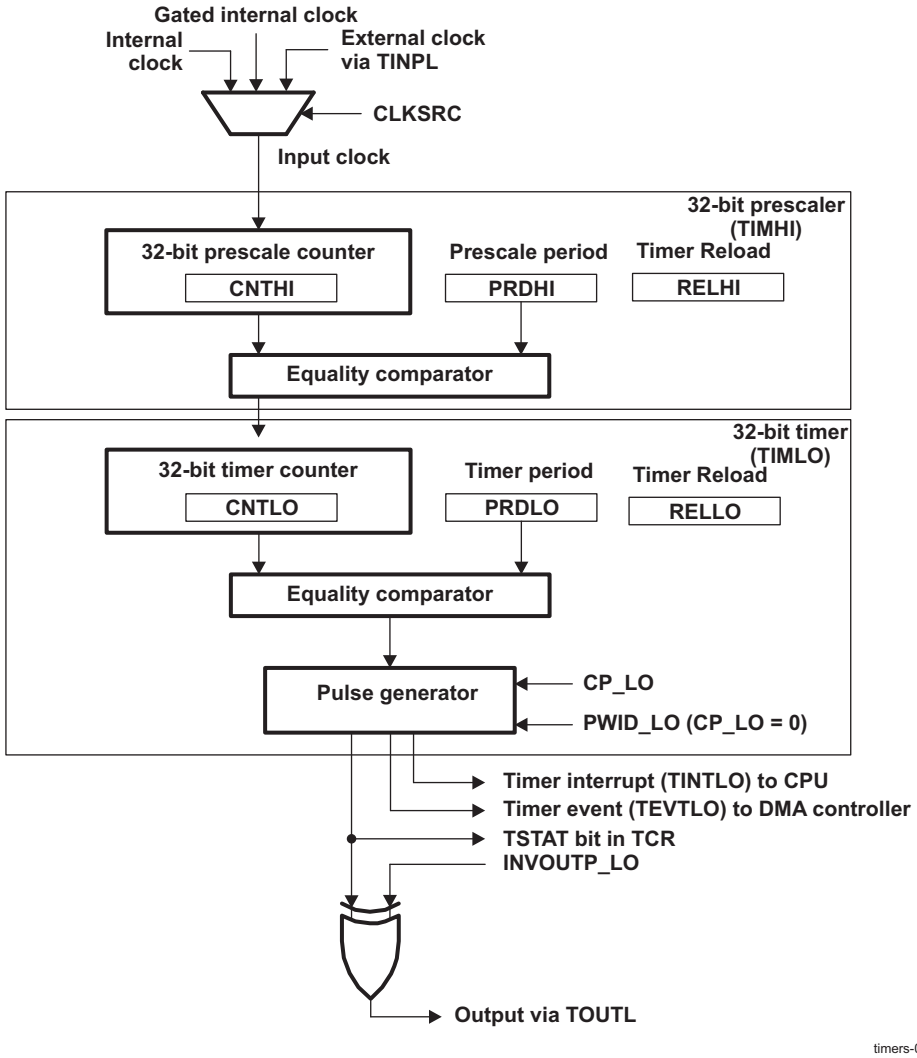
11.17.4.2.2 Dual 32-bit Timer Mode

The timer can be broken down into two 32-bit timers, using the TIMER_TGCR[3-2] TIMMODE. In this mode, the two 32-bit timers can be operated in conjunction with each other (chained mode) or independently.

11.17.4.2.2.1 Chained Mode

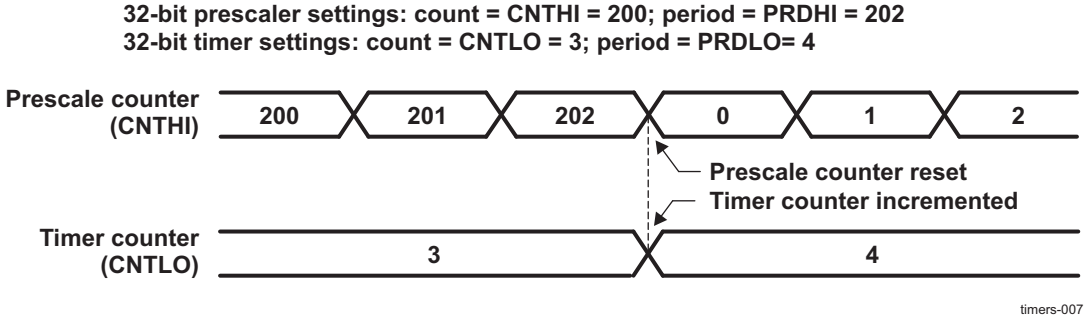
In the chained mode, shown in Figure 11-1397, one 32-bit timer (TIMHI) is used as a 32-bit prescaler to a second timer (TIMLO).

Figure 11-1397. Dual 32-Bit Timers Chained Mode Block Diagram



The 32-bit prescaler (TIMHI) uses the counter register (TIMER_CNTHI) and the period register (TIMER_PRDHI) to form a 32-bit prescale counter register and a 32-bit prescale period register, respectively. When the timer is enabled, the prescale counter starts incrementing by 1 at every timer input clock cycle. On the cycle after the prescale counter matches the prescale period, a clock signal is generated and the prescale counter register is reset to 0 (see the example in Figure 11-1398).

Figure 11-1398. Dual 32-Bit Timers Chained Mode Example



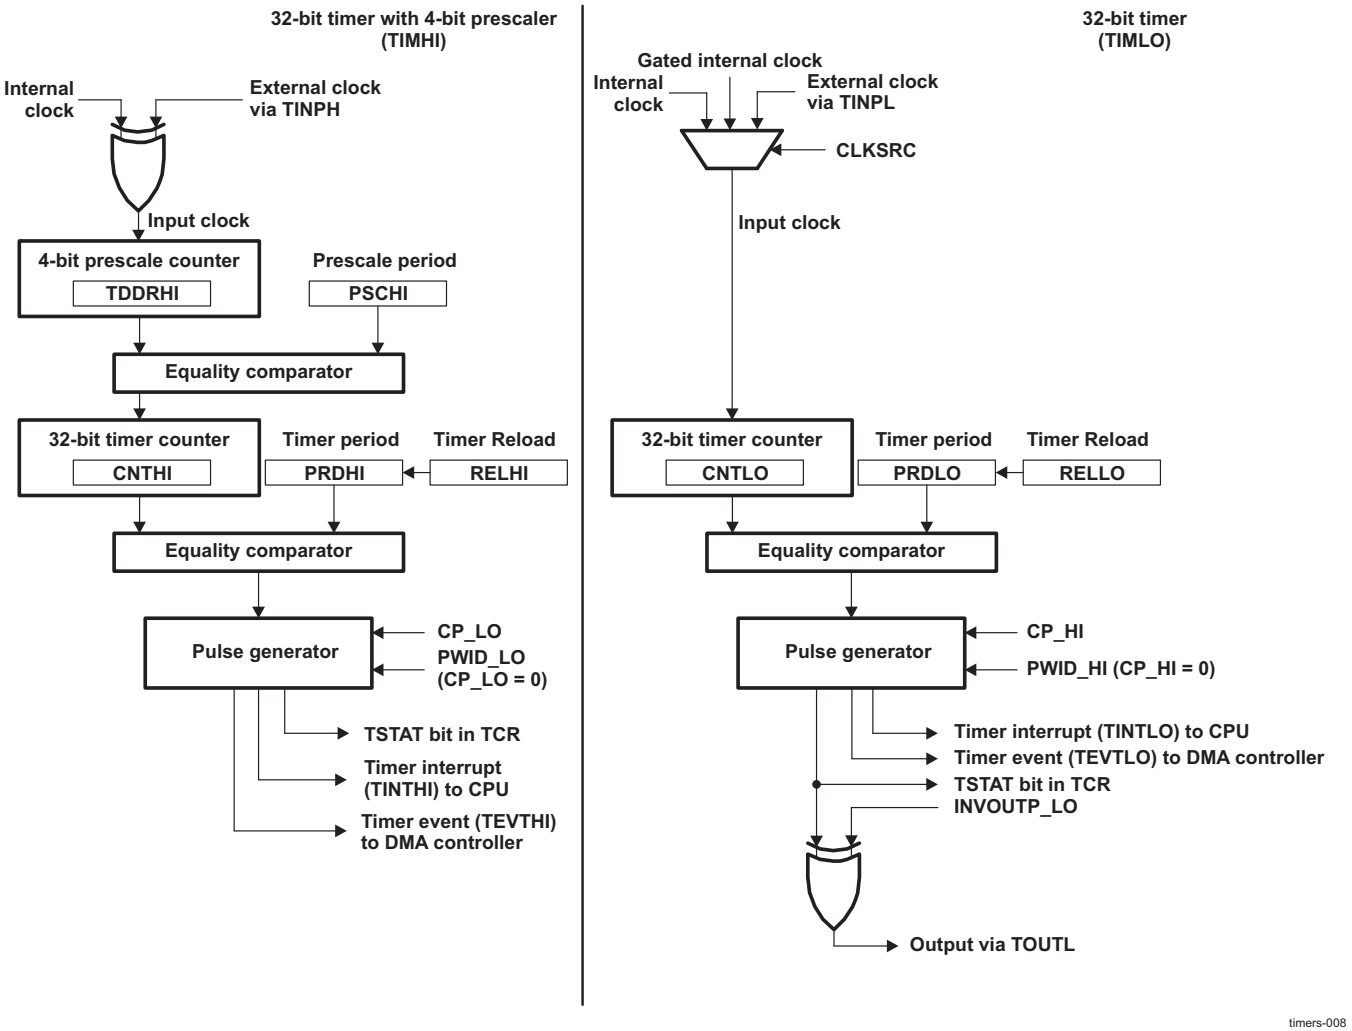
The other 32-bit timer (TIMLO) uses the counter register (TIMER_CNTLO) and the period register (TIMER_PRDLO) to form a 32-bit timer counter register and a 32-bit timer period register, respectively. This timer is clocked by the output clock from the prescaler (see the example in Figure 11-1398). The timer counter increments by 1 at every prescaler output clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINTLO), a timer DMA event (TEVTLO), and an output signal are generated.

When in pulse mode (CP_LO = 0), the timer output (TOUTL) asserts a pulse that is 1, 2, 3, or 4 timer clock cycles wide, depending on the setting of the pulse width bits TIMER_TCR[5-4] PWID_LO. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. The timer can be stopped, restarted, reset, or disabled using the bits of the timer control register. The timer control register (TIMER_TCR) does not control the TIMHI in this mode.

11.17.4.2.2.2 Unchained Mode

In the unchained mode, shown in Figure 11-1399, the timer can operate as two independent 32-bit timers. One 32-bit timer (TIMHI) can be configured as a 32-bit timer being clocked by a 4-bit prescaler. The other (TIMLO) can be used as a 32-bit timer.

Figure 11-1399. Dual 32-Bit Timers Unchained Mode Block Diagram



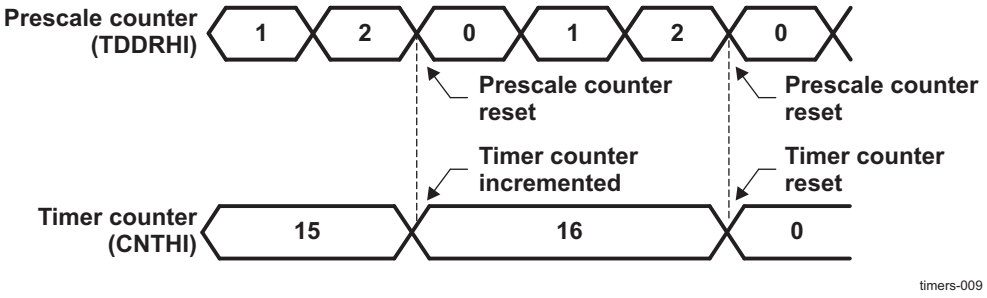
11.17.4.2.2.1 32-Bit Timer With a 4-Bit Prescaler (TIMHI)

In the unchained mode, the 4-bit prescaler can be clocked by either the internal clock or the external clock source (TINPH) for TIMHI. The 4-bit prescaler uses the timer divide-down ratio bits TIMER_TGCR[15-12] TDDRHI and the prescale counter bits TIMER_TCR[11-8] PSCHI to form a 4-bit prescale counter register and a 4-bit prescale period register, respectively.

The 32-bit timer uses the counter register (TIMER_CNTHI) and the period register (TIMER_PRDHI) to form a 32-bit timer counter register and a 32-bit timer period register, respectively. The 32-bit timer is clocked by the output clock from the 4-bit prescaler (see the example in Figure 11-1400). When the timer is enabled, the timer counter increments by 1 at every prescaler output clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINTHI) and a timer DMA event (TEVTHI) are generated. The state of the output signal is read in the timer status TIMER_TCR[16] TSTAT_HI bit. When in pulse mode (CP_HI = 0), TIMER_TCR[16] TSTAT_HI stays high or low for 1, 2, 3, or 4 timer clock cycles. The pulse width depends on the setting of the pulse width TIMER_TCR[21-20] PWID_HI bits. When in clock mode (CP_HI = 1), the TSTAT bit changes state (high-to-low or low-to-high) every time the timer counter matches the timer period. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period (see the example in Figure 11-1400). Note that when the timer counter matches the timer period, the period register (TIMER_PRDHI) will be loaded with the value in the reload register (TIMER_RELHI) if TIMER_TCR[23-22] ENAMODE_HI = 3h.The timer can be stopped, restarted, reset, or disabled using TIMER_TCR and the timer global control register (TIMER_TGCR).

Figure 11-1400. Dual 32-Bit Timers Unchained Mode Example

4-bit prescaler settings: count = TDDRHI = 1; period = PSCHI = 2
32-bit timer settings: count = CNTHI= 15; period = PRDHI = 16



11.17.4.2.2.2 32-Bit Timer (TIMLO)

The other 32-bit timer (TIMLO) uses the counter register (TIMER_CNTLO) and the period register (TIMER_PRDLO) to form a 32-bit timer counter register and a 32-bit timer period register, respectively. When the timer is enabled, the timer counter increments by 1 at every timer input clock cycle. When the timer counter matches the timer period, a maskable timer interrupt (TINTLO), a timer DMA event (TEVTLO), and an output signal (TOUTL) are generated. The state of the output signal is also read in the timer status (TSTAT) bit of the timer control register (TIMER_TCR). When in pulse mode (CP_LO = 0) and depending on the timer output inverter control (INVOUTP) bit in TIMER_TCR, the timer output pin (TOUTL) stays high or low for 1, 2, 3, or 4 timer clock cycles.

The pulse width depends on the setting of the pulse width TIMER_TCR[5-4] PWID_LO bits. When in clock mode (CP_LO = 1), the timer output and the TIMER_TCR[0] TSTAT_LO bit change state (high-to-low or low-to-high) every time the timer counter matches the timer period. When the timer is configured in continuous mode, the timer counter is reset to 0 on the cycle after the timer counter reaches the timer period. When the timer counter matches the timer period, the period register will be loaded with the value in the reload register (TIMER_RELLO) if TIMER_TCR[7-6] ENAMODE_LO = 3h. The timer can be stopped, restarted, reset, or disabled using TIMER_TCR and the timer global control register (TIMER_TGCR).

11.17.4.2.3 Counter, Reload and Period Registers Used in GP Timer Modes

Table 11-3431 summarizes the counter registers (TIMER_CNTLO and TIMER_CNTHI), reload registers (TIMER_RELLO and TIMER_RELHI) and period registers (TIMER_PRDLO and TIMER_PRDHI) used in each GP timer mode.

Table 11-3431. Counter and Period Registers Used in GP Timer Modes

Timer Mode		Counter Registers	Reload Registers	Period Registers
64-bit general-purpose		TIMER_CNTHI: TIMER_CNTLO	TIMER_RELHI: TIMER_RELLO	TIMER_PRDHI: TIMER_PRDLO
Dual 32-bit chained	Prescaler (TIMHI)	TIMER_CNTHI	-	TIMER_PRDHI
	Timer (TIMLO)	TIMER_CNTLO	-	TIMER_PRDLO
Dual 32-bit unchained	Timer (TIMLO)	TIMER_CNTLO	TIMER_RELLO	TIMER_PRDLO
	Timer with prescaler (TIMHI)	PSCHI bits and TIMER_CNTHI	TIMER_RELHI	TDDRHI bits and TIMER_PRDHI

11.17.4.2.4 Timer Plus/Additional Modes

The Timer supports the following additional features:

- Period reload
- External event capture mode
- Timer counter register read reset mode

By default, period reload, external event capture mode, timer counter register read reset mode, timer counter capture registers, and interrupt/DMA/TOUTL generation control and status are not available. Setting the TIMER_TGCR[4] PLUSEN bit enables these features.

11.17.4.2.4.1 Timer Capture Registers

When the timer has a timeout due to a normal expiration of timer, external input event in Event Capture Mode, or read of timer counter registers in Read Reset Mode, the values of the timer counter registers (TIMER_CNTLO and TIMER_CNTHI) are copied onto the timer counter capture registers (TIMER_CAPLO and TIMER_CAPHI). Note that the value in TDDR is not captured when a read of TIMER_CNTHI happens.

11.17.4.2.4.2 Event Capture Mode

When the TIMER_TGCR[4] PLUSEN bit is set, Event Capture Mode is available for TIMER_CNTLO when the timer is configured in 32-bit unchained mode. When Event Capture Mode is enabled, the timer cycle is restarted when an external input event occurs on pin TINPL. In particular, when an external input event occurs, the timer stops counting, generates output CPU interrupts and DMA events, copies values from the timer counter register TIMER_CNTLO to the timer capture register TIMER_CAPLO, reloads the timer period register TIMER_PRDLO if in continuous mode with period reload (ENAMODE = 3h), resets the timer counter register TIMER_CNTLO and then restarts counting in continuous mode. Event Capture Mode is available only when the timer clock source is the internal timer (CLKSRC = 0) and the timer is in continuous mode (ENAMODE = 2h or 3h). Capture mode is enabled using the Capture mode enable bit TIMER_TCR[11] CAPMODE_LO. The type of input event is selected by the capture event mode bit TIMER_TCR[13-12] CAPEVTMODE_LO. All of the following input event types are available:

- Rising edge of input signal
- Falling edge of input signal
- Rising or falling edge of input signal

11.17.4.2.4.3 Timer Counter Register Read Reset Mode

Read Reset Mode is available when the TIMER_TGCR[4] PLUSEN bit is set and the timer is configured in 32-bit unchained mode. When Read Reset Mode is enabled, the timer cycle will restart when the timer counter registers are read (TIMER_CNTLO and/or TIMER_CNTHI). In particular, when the timer registers are read, the timer stops counting, copies values from the timer counter registers (TIMER_CNTLO and/or TIMER_CNTHI) to the timer capture registers (TIMER_CAPLO and/or TIMER_CAPHI), reloads the timer period registers (TIMER_PRDLO and/or TIMER_PRDHI) if in continuous mode with period reload (ENAMODE = 3h), and then restarts counting in continuous mode. Timer output events (TINTn, TEVTn, and TOUTn) are not generated during this process. Read Reset Mode is enabled using the read reset mode enable bit (READRSTMODE) in the timer control register (TIMER_TCR).

11.17.4.3 Timer Operation

The following sections describe the overall timer operation. For specific details on the watchdog timer operation, see Section 11.17.4.12.

11.17.4.3.1 Timer Mode Selection

The timer can be configured as a 64-bit general-purpose timer or dual 32-bit timers (chained or unchained), or as a watchdog timer using the timer mode (TIMMODE) bits in timer global control register (TIMER_TGCR) (see Table 11-3432). At reset, the timer is configured as a 64-bit GP timer by default. These bits can be written to select the respective function as shown in Table 11-3432.

Table 11-3432. Timer Mode Selection

TIMMODE Bits		Timer Mode
Bit 3	Bit 2	
0	0	64-bit general-purpose timer (default)
0	1	Dual 32-bit timers (unchained)
1	0	64-bit watchdog timers
1	1	Dual 32-bit timers (chained)

11.17.4.3.2 Timer Enabling

In the 64-bit timer mode or the dual 32-bit timers chained mode, the timer can be enabled by setting the TIMER_TGCR[0] TIMLORS and TIMER_TGCR[1] TIMHIRS bits to 1 and setting the TIMER_TCR[7-6] ENAMODE_LO bits to 1h, 2h or 3h.

In the dual 32-bit timers unchained mode, the 32-bit timer (TIMLO) can be enabled by setting the TIMER_TGCR[0] TIMLORS bit to 1 and the TIMER_TCR[7-6] ENAMODE_LO bits to 1h, 2h or 3h. The 32-bit timer with prescaler (TIMHI) can be enabled by setting the TIMER_TGCR[1] TIMHIRS to 1 and the TIMER_TCR[23-22] ENAMODE_HI to 1h, 2h or 3h.

Table 11-3433 is a summary of timer enabling.

Table 11-3433. Timer Enabling

Timer Mode	TIMER_TCR ENAMODE bits				TIMER_TGCR		Timer Status
	Bit 23	Bit 22	Bit 7	Bit 6	TIMHIRS	TIMLORS	
64-bit general-purpose	X	X	0	0	X	X	Disabled (default)
	X	X	0	1	1	1	Enabled one time
	X	X	1	0	1	1	Enabled continuously
	X	X	1	1	1	1	Enabled continuously with period reload
Dual 32-bit chained	X	X	0	0	X	X	Disabled (default)
	X	X	0	1	1	1	Enabled one time
	X	X	1	0	1	1	Enabled continuously
	X	X	1	1	1	1	Reserved

Table 11-3433. Timer Enabling (continued)

Timer Mode	TIMER_TCR ENAMODE bits				TIMER_TGCR		Timer Status
	Bit 23	Bit 22	Bit 7	Bit 6	TIMHIRS	TIMLORS	
Dual 32-bit unchained	0	0	0	0	X	X	Both timers disabled (default)
• 32-bit timer	X	X	0	1	1	1	32-bit timer enabled one time
	1	0	1	0	1	1	32-bit timer enabled continuously
	1	1	1	1	1	1	Enabled continuously with period reload
• 32-bit timer with prescaler	0	1	X	X	1	X	32-bit timer enabled one time
	1	0	X	X	1	X	32-bit timer enabled continuously
	1	1	X	X	1	X	Enabled continuously with period reload

11.17.4.3.3 Timer Clock Source Selection

As shown in Table 11-3434 and Figure 11-1401, the timer clock sources for TIMLO and TIMHI is selected using the clock source (CLKSRC) bit and timer input enable TIMER_TCR[9] TIEN_LO bit.

Three clock sources are available to drive the timer clock:

- Internal clock, by setting TIMER_TCR[8] CLKSRC_LO = 0 and TIMER_TCR[9] TIEN_LO = 0.
- Internal clock gated by the timer input signal, by setting TIMER_TCR[8] CLKSRC_LO = 0 and TIMER_TCR[9] TIEN_LO = 1.
- External clock on the timer input pins (TINPL and TINPH), by setting TIMER_TCR[8] CLKSRC_LO = 1. This input signal is synchronized internally and can be inverted by setting the timer inverter control bit TIMER_TCR[2] INVINP_LO to 1.

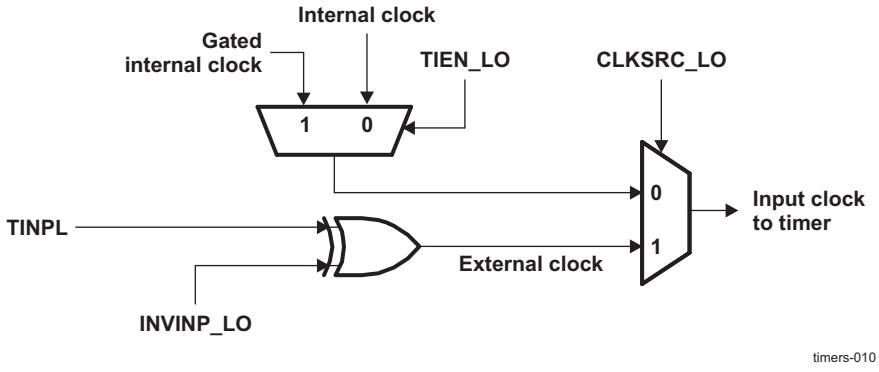
At reset, the clock source is the internal clock. The internal clock is derived from the DSP clock generator.

When the clock source is the gated internal clock, the timer starts counting when the timer input transitions from low to high and the timer stops counting when the timer input transitions from high to low.

Table 11-3434. Timer Clock Source Selection

CLKSRC_LO	TIEN_LO	Input Clock
0	0	Internal clock (default)
0	1	Gated internal clock
1	X	External clock on timer input (TINPL and TINPH)

Figure 11-1401. Timer Clock Source Block Diagram



11.17.4.4 Timer Output Mode Selection

The two basic timer output modes are pulse mode and clock mode. The timer output mode is selected using the clock/pulse mode bits TIMER_TCR[3] CP_LO and TIMER_TCR[19] CP_HI.

When in the pulse mode (TIMER_TCR[3] CP_LO or TIMER_TCR[19] CP_HI = 0), the pulse width bits (TIMER_TCR[5-4] PWID_LO or TIMER_TCR[21-20] PWID_HI) set the pulse width to 1, 2, 3, or 4 timer clock cycles. This pulse can be inverted by setting the timer output inverter control bits (TIMER_TCR[1] INVOUTP_LO or TIMER_TCR[17] INVOUTP_HI) to 1.

When in the clock mode (TIMER_TCR[3] CP_LO or TIMER_TCR[19] CP_HI = 1), the timer output signal has a 50% duty cycle. The signal toggles (from high-to-low or from low-to-high) each time the timer counter reaches the timer period.

The output signal of TIMLO is driven on both TIMER_TCR[0] TSTAT_LO and the timer output pin TOUTL. The output signal of TIMHI is driven on TIMER_TCR[16] TSTAT_HI only.

11.17.4.5 Timer Counting

The timer counter runs at the timer clock rate specified by the clock source bit (CLKSRC) in the timer control register (TIMER_TCR). Counting is enabled by setting the enabling mode (ENAMODE) bits in TIMER_TCR to 1h or 2h. When enabled, the timer counter starts incrementing until the counter reaches a value equal to the value in the timer period register. Once the timer counter matches the timer period:

- If the timer is set to enable one time (ENAMODE = 1h), the timer counter is reset to 0, then stops.
- If the timer is set to enable continuously (ENAMODE = 2h), the timer counter is reset to 0, then continues counting.
- If the timer is set to enable continuously with period reload (ENAMODE = 3h), the timer counter is reset to zero, reloads the period registers (TIMER_PRDLO and TIMER_PRDHI) with the value in the period reload registers (TIMER_RELLO and TIMER_RELHI), then continues counting.

Once the timer stops, if an external clock is used as the timer clock, the disable period must last at least one external clock period or the timer will not start counting again. When using the external clock, the count value is synchronized to the internal clock.

Note that when both the timer counter and timer period are cleared to 0, the timer can be enabled but the timer counter does not increment because the timer period is 0.

11.17.4.6 Timer Pulse Generation

The two basic timer output modes are pulse mode and clock mode. These modes can be select via the C/P_ bit. In the pulse mode, the PWID can set the pulse width to one or two or three or four timer clocks. This provides minimum pulse widths in the case in which TSTATx drives the timer output pin. This pulse can be inverted by setting INVOUT=1. The TSTATx directly drives the timer output. TSTATx and TOUTPx will be generated only when a compare of PRDx and TIMx register succeeds. They will not be generated when timeout happens due to external event when CAPMODE = 1 or due to TIMx read when READRSTMODE = 1.

11.17.4.7 Timer Reset Sources

The timer has two reset sources: hardware reset (TIMER_i_RST) and the timer reset bits (TIMER_TGCR[0] TIMLORS and TIMER_TGCR[1] TIMHIRS) in the timer global control register (TIMER_TGCR).

- When a hardware reset is asserted (TIMER_i_RST is set to 0), all the registers are set to their default values.
- When TIMER_i_RST = 1 and TIMER_TGCR[0] TIMLORS is cleared to 0, TIMER_TCR[0] TSTAT_LO is reset to 0 and TOUTL is in the high-impedance state.
- When TIMER_i_RST = 1 and TIMER_TGCR[1] TIMHIRS is cleared to 0, TIMER_TCR[16] TSTAT_HI is reset to 0.

11.17.4.8 Timer Input/ Output and TSTAT in GPIO

NOTE: In GPIO mode output for TINPL / TINPH and input for TOUTL / TOUTH is not supported.

Upon device reset, the timer input (TINPL / TINPH) and output (TOUTL / TOUTH) are not GPIO. But the timer input and output can operate as GPIO if being configured as GPIO function.

- When both timer input and output pins are configured in GPIO mode and both are the sources of interrupt and event, the input pin has higher priority than the output pin.
- Writing 1 to GPIO_ENILO(HI) or GPIO_ENOLO(HI) are ignored when TIMLO(HI)RS is 1.
- Writing 1 to TIMLO(HI)RS is ignored when GPIO_ENILO(HI) or GPIO_ENOLO(HI) is 1.
- TSTAT in GPIO mode holds the previous value.
- In GP Interrupt mode, one vbus clock period pulse of TINT is asserted when TINP goes to high (when GPINTx_INVI is 0), that is TINP doesn't drive TINT directly.
- GPIOLO(HI)_DIRI(DIRO) must be set to 0 when GPIO interrupt is used (GPINTLO(HI)_ENI(ENO) = 1).

11.17.4.9 Timer Interrupt Rate

To receive periodic interrupts, configure the timer to run in the continuous mode (ENAMODE = 2h or 3h). Each time the timer finishes counting, it can generate a timer interrupt for the CPU and a timer event for the DMA controller. The rate at which this occurs (the timer interrupt rate) depends on whether the timer has a prescaler.

If the timer does not have a prescaler, there is only one counter. When the timer counter reaches the programmed timer period, the timer generates an interrupt and a DMA event. Because the timer is in the continuous mode, one cycle after the timer counter matches the timer period, the timer counter is reset to 0 and starts counting again. The timer interrupt rate is:

$$TINT\ rate = \frac{Timer\ input\ clock\ rate}{Programmed\ timer\ period + 1}$$

timers-011

If a timer has a prescaler, there are two counters. One cycle after the prescale counter reaches the programmed prescale period, the timer counter is incremented by 1, and the prescale counter is reset to start counting again.

If the prescaler continues long enough, it increments the timer counter to the programmed timer period. At that time, the timer generates an interrupt and a DMA event. One cycle later (assuming the continuous mode), the timer counter is reset to 0 and starts counting again. The timer interrupt rate in this case is:

$$TINT\ rate = \frac{Timer\ input\ clock\ rate}{(Programmed\ prescale\ period + 1) \cdot (Programmed\ timer\ period + 1)}$$

timers-012

11.17.4.10 Timer Emulation Modes

The timer has an emulation management and clock speed register (TIMER_EMUMGT_CLKSPD). As shown in Table 11-3435, the TIMER_EMUMGT_CLKSPD[0] FREE and TIMER_EMUMGT_CLKSPD[1] SOFT bits determine how the timer responds to an emulation suspend event. An emulation suspend event corresponds to any type of emulator access to the DSP, such as a hardware or software breakpoint, a probe point, or a printf instruction.

Table 11-3435. Timer Emulation Modes Selection

FREE	SOFT	Emulation Mode
0	0	Default: The timer stops immediately.
0	1	The timer stops when the timer counter value increments and reaches the value in the timer period register.

Table 11-3435. Timer Emulation Modes Selection (continued)

FREE	SOFT	Emulation Mode
1	X	The timer runs free regardless of TIMER_EMUMGT_CLKSPD[1] SOFT bit status.

When using an internal clock as the timer clock source, the timer counter increments properly when single stepping. For example, the timer increments by one for each single step if the timer clock is equal to the CPU clock; or increments by one for every six single steps if the timer clock is equal to one-sixth of the CPU clock.

11.17.4.11 Timer Operation Boundary Conditions

Section 11.17.4.11.1 through Section 11.17.4.11.7 describe the boundary conditions affecting the timer operation.

11.17.4.11.1 Writing to and Reading From the Reserved Registers

Write the reset value to the reserved registers. Reading from the reserved registers returns zeros.

11.17.4.11.2 Timer Count = 0 and Timer Period = 0 (No Prescaler)

Consider a timer that has no prescaler:

- The 64-bit GP timer.
- TIMLO in the 32-bit dual timers configuration (unchained mode).

In the special case when timer count = 0 and timer period = 0:

- After a hardware reset and before the timer starts counting (ENAMODE bits = 0h), the timer output signal is held low.
- Once the timer is enabled, its behavior depends on the selected enabling mode (ENAMODE bits = 1h, 2h or 3h in the timer control register) and the selected timer output mode (CP bits = 0 or 1 in the timer control register). The options are summarized in Table 11-3436.
- The timer interrupt is not generated.

Table 11-3436. Timer Operation When Timer Count = 0 and Timer Period = 0

Timer Enabling Mode	Timer Output Mode	Timer Operation When Timer Count = 0 and Timer Period = 0 No Prescaler)
One-time mode (ENAMODE bits = 1h)	Pulse mode (CP bits = 0)	The timer output pulses once at the first timer clock cycle, and the timer stops counting at the next timer clock cycle. The pulse width is defined by the PWID bits of the TIMER_TCR.
	Clock mode (CP bits = 1)	The timer output toggles once at the first timer clock cycle. The timer stops counting at the next timer clock cycle.
Continuous mode (ENAMODE bits = 2h)	Pulse mode (CP bits = 0)	The timer output pulses once at the first timer clock cycle, and the timer continues to count up. Whenever the timer counter reaches its maximum value, it rolls around to 0, generating another pulse. The pulse width is defined by the PWID bits of the TIMER_TCR.
	Clock mode (CP bits = 1)	The timer output toggles once at the first timer clock cycle and then toggles with a frequency of half the timer clock frequency as the timer continues to count.
Continuous mode with reload (ENAMODE bits = 3h)	Pulse mode (CP bits = 0)	The timer output pulses once at the first timer clock cycle, and the timer continues to count up. Whenever the timer counter reaches its maximum value, it rolls around to 0, generating another pulse. The pulse width is defined by the PWID bits of the TIMER_TCR. The period registers are loaded with the reload registers.
	Clock mode (CP bits = 1)	The timer output toggles once at the first timer clock cycle and then toggles with a frequency of half the timer clock frequency as the timer continues to count. The period registers are loaded with the reload registers.

11.17.4.11.3 Timer Count = 0, Timer Period = 0, Prescale Count = 0, and Prescale Period = 0

Consider a timer that has a prescaler:

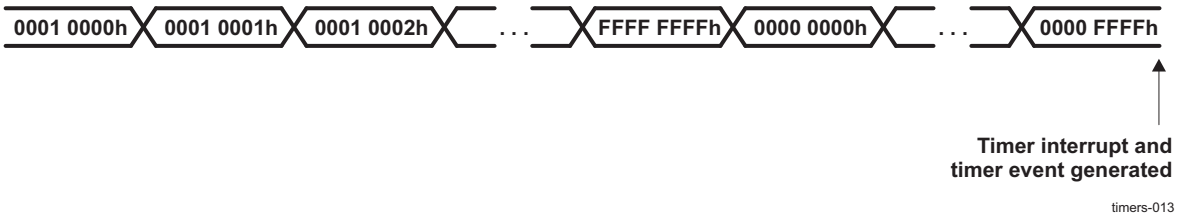
- The combination timer in the 32-bit dual timers chained mode.
- TIMHI in the 32-bit dual timer configuration (unchained mode).

In the special case when timer count = 0, timer period = 0, prescale count = 0, and prescale period = 0, the timer operates in the same manner as a non-prescaled timer with timer count = 0 and timer period = 0 (see Section 11.17.4.11.2).

11.17.4.11.4 Timer Counter Overflow

Timer counter overflow can happen when the timer counter register is set to a value greater than the value in the timer period register. The counter reaches its maximum value (FFFF FFFFh or FFFF FFFF FFFF FFFFh), rolls over to 0, and continues counting until it reaches the timer period. An example is shown in Figure 11-1402.

Figure 11-1402. 32-Bit Timer Counter Overflow Example



11.17.4.11.5 Writing to Registers of an Active Timer

Writes from the configuration bus to the timer registers are not allowed when the timer is active, except for stopping or resetting the timers. In the 64-bit and dual 32-bit timer modes, registers that are protected by hardware include TIMER_CNTLO, TIMER_CNTHI, TIMER_PRDLO, TIMER_PRDHI, TIMER_TGCR (except the TIMER_TGCR[0] TIMLORS and TIMER_TGCR[1] TIMHIRS bits), and TIMER_TCR (except the ENAMODE bits).

11.17.4.11.6 Small Timer Period Value in Pulse Mode

Small timer periods in pulse mode (CP = 0) can cause TSTAT to remain high when ENAMODE is not 0. This condition can occur when PRD . PWID + 1.

11.17.4.11.7 Reading the Counter Registers

Table 11-3437 summarizes how to read the counter registers. When reading the timer counter in 64-bit GP timer mode, the CPU must read the first 32-bit word from the TIMER_CNTLO registers. When this occurs, the timer takes a snapshot of the TIMER_CNTHI register and copies it into a shadow register CNTHIS. Note that reading TIMER_CNTHI instead of TIMER_CNTLO will not cause the timer to take a snap shot of the timer counters and copy them into the shadow registers.

Table 11-3437. Reading Counter Registers

Timer Mode	CPU	
64-bit timer	Read TIMER_CNTLO	Read TIMER_CNTLO Copy TIMER_CNTHI to CNTHIS
	Read TIMER_CNTHI	Read from CNTHIS
32-bit timer	Read TIMER_CNTLO	Read TIMER_CNTLO
	Read TIMER_CNTHI	Read TIMER_CNTHI

11.17.4.12 Watchdog Timer Mode

This subsection describes the capability of the timers to be configured as watchdog timer.

The timer can be configured also as a 64-bit watchdog timer. As a watchdog timer, it can be used to prevent system lock-up when the software becomes trapped in loops with no controlled exit. After a hardware reset, the timer is configured as a 64-bit GP timer and the watchdog mode is disabled. The timer then can be reconfigured as a watchdog timer using the timer mode bits TIMER_TGCR[3-2] TIMMODE and the Watchdog timer enable bit TIMER_WDTCR[14] WDEN. In the watchdog timer mode, the timer requires a special service sequence to be executed periodically. Without this periodic servicing, the timer counter increments until it matches the timer period and causes a watchdog timeout event or module reset.

When operating in Watchdog mode, the timer counts down to zero and generates an event. It is a requirement that software writes to the timer before the count expires, after which the count begins again. If the count ever reaches zero, the timer event output is asserted. This event can be used as a CPU exception (routed to the CPU interrupt controller), which requires a software exception handler. If routed as an exception to a DSP, software can post a request to the PLL Controller or the DSP LPSC to do a device or local reset.

Once the timer is configured as a watchdog timer, it cannot be reconfigured as a GP timer until a device reset occurs. When the timer counter matches the timer period, the timer generates two signals: an output signal and an interrupt signal (described in Section 11.17.4.12.1). Typically, one or the other is used, depending on whether an external or internal trigger is desired.

11.17.4.12.1 Timer Output Signal and Timer Interrupt Signal in Watchdog Timer Mode

When the periodic service sequence is not met, the timer counter increments until it matches the period and times out. During a timeout, a pulse is asserted on the timer output pin, and an internal maskable interrupt (INTL) is triggered. The timer output pin can be externally connected to the interrupt pin of an external device. Note that the timer pulse width must be configured to generate an active low pulse long enough for the external device to recognize it as an interrupt pulse. The pulse width is configured using the PWID bits of the timer control register (TIMER_TCR).

11.17.4.12.2 Watchdog Timer Mode Restrictions

The watchdog timer mode is selected and enabled when TIMER_TGCR[3-2] TIMMODE = 2h and TIMER_WDTCR[14] WDEN = 1. This mode has the following restrictions:

- No dual 32-bit timers mode
- No gated clock
- No external clock
- No one-time enabling
- No clock mode (only pulse mode)

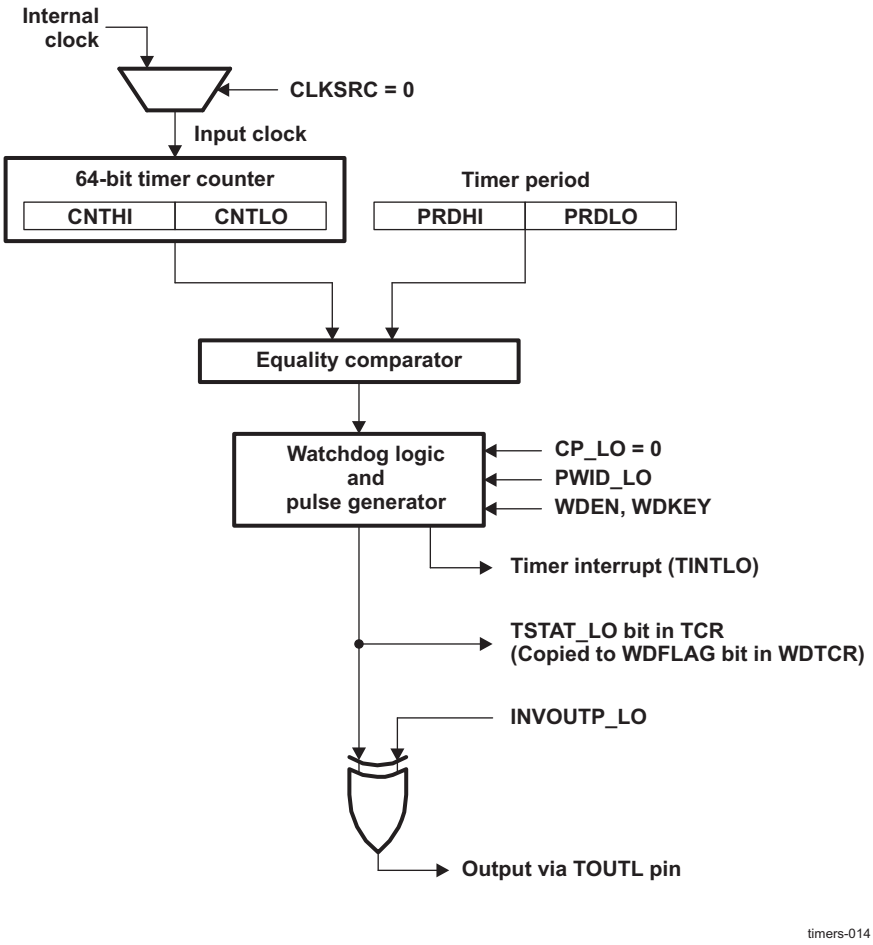
11.17.4.12.3 Watchdog Timer Mode Operation

Figure 11-1403 shows the timer when it is used in the watchdog timer mode. Note that in this mode, the timer clock must be set to the internal clock (TIMER_TCR[8] CLKSRC_LO = 0). The TIMER_TCR[3] CP_LO bit is forced to 0 because the pulse mode is required for the watchdog timer operation. The counter registers (TIMER_CNTLO and TIMER_CNTHI) form a 64-bit timer counter register and the period registers (TIMER_PRDLO and TIMER_PRDHI) form a 64-bit period register.

When the timer counter matches the timer period, the timer generates a watchdog timeout event. This event:

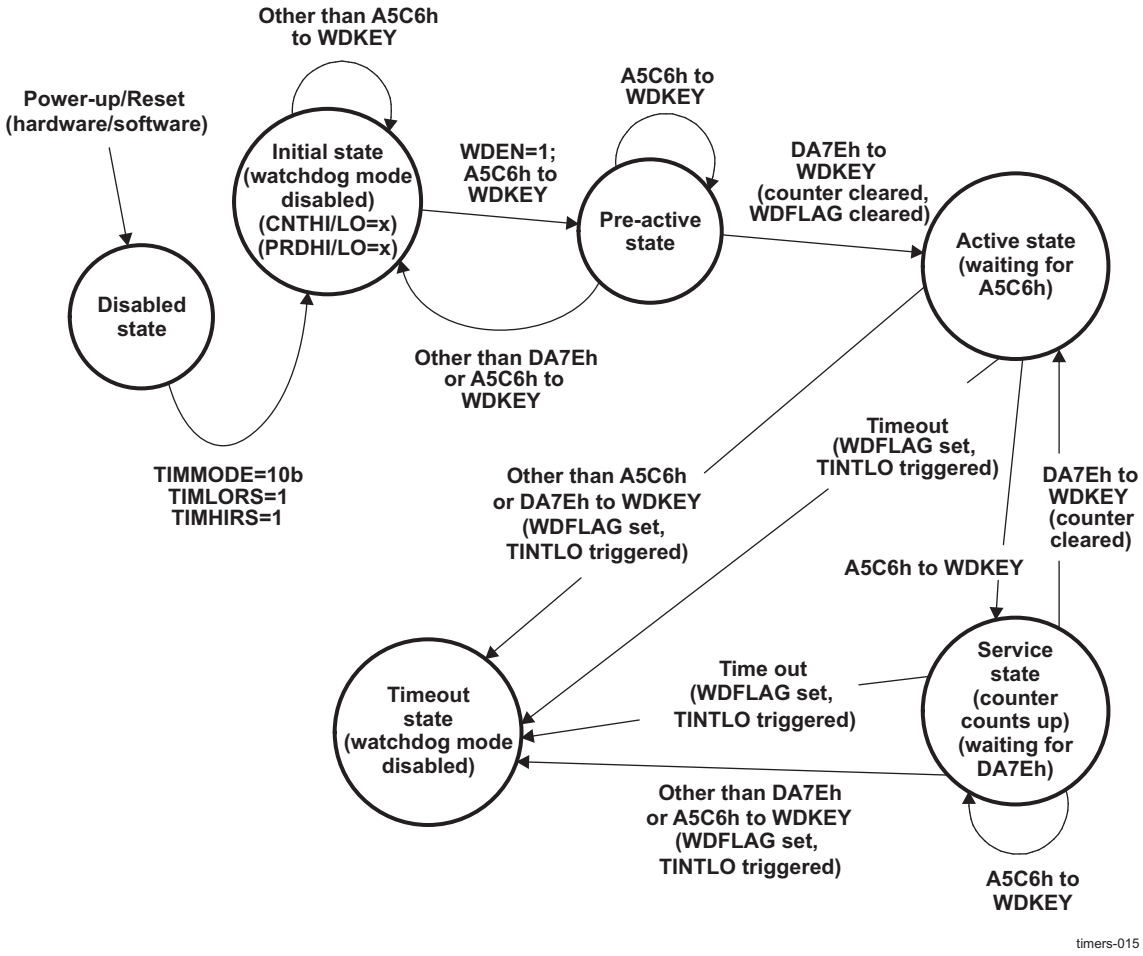
- Drives the timer output signal (TOUTL) and/or the timer interrupt signal (INTL).
- Resets the timer counter to 0.
- Sets the TIMER_TCR[0] TSTAT_LO bit, which is copied to the TIMER_WDTCR[15] WDFLAG bit.

Figure 11-1403. Timer in Watchdog Timer Mode



To activate the watchdog timer, a certain sequence of events must be followed, as shown in state diagram Figure 11-1404.

Figure 11-1404. Watchdog Timer Operation State Diagram



Once the watchdog timer is activated, it can be disabled only by a watchdog timeout event or by a hardware reset. A special key sequence is required to prevent the watchdog timer from being accidentally serviced while the software is trapped in a dead loop or by some other software failure.

To prevent a watchdog timeout event, the timer has to be serviced periodically by writing A5C6h followed by DA7Eh to the watchdog timer service key TIMER_WDTCR[31-16] WDKEY bits before the timer finishes counting up. Both A5C6h and DA7Eh are allowed to be written to the TIMER_WDTCR[31-16] WDKEY bits, but only the correct sequence of A5C6h followed by DA7Eh to the TIMER_WDTCR[31-16] WDKEY bits services the watchdog timer. Any other writes to the TIMER_WDTCR[31-16] WDKEY bits triggers the watchdog timeout event immediately. Writes to other bits in the TIMER_WDTCR are ignored when the watchdog timer is active (see Section 11.17.4.12.4).

When the watchdog timer is in the timeout state, the watchdog timer is disabled, the TIMER_WDTCR[14] WDEN bit is cleared to 0, and the timer is reset. After entering the timeout state, the watchdog timer cannot be enabled again until a hardware reset occurs.

After a hardware reset, the watchdog timer is disabled; however, reads or writes to the watchdog timer registers are allowed. Once the TIMER_WDTCR[14] WDEN bit is set and A5C6h is written to the TIMER_WDTCR[31-16] WDKEY bits, the watchdog timer enters the pre-active state. In the pre-active state:

- A write to TIMER_WDTCR is allowed only when the write comes with the correct key (A5C6h or DA7Eh) to the TIMER_WDTCR[31-16] WDKEY bits.
- A write of DA7Eh to the TIMER_WDTCR[31-16] WDKEY bits when the TIMER_WDTCR[14] WDEN bit is set to 1 resets the counters and activates the watchdog timer.

The TIMER_PRDHI, TIMER_PRDLO, TIMER_TCR, and TIMER_WDTCR registers must be configured before the watchdog timer enters the active state. The TIMER_WDTCR[14] WDEN bit must be set to 1 before writing DA7Eh to the TIMER_WDTCR[31-16] WDKEY bits in the pre-active state. Every time the watchdog timer is serviced by the correct TIMER_WDTCR[31-16] WDKEY sequence, the watchdog timer counter is automatically reset.

Before the watchdog timer enters the active state, the timer output signal is never asserted. Only the timer interrupt is asserted when the timer finishes counting up. In this case, the timer interrupt can be used to:

- Indicate that the watchdog timer is counting but is not in the active state.
- Generate a periodic interrupt, without having to service the watchdog timer.

The watchdog timer can always be disabled before entering the active state.

11.17.4.12.4 Watchdog Timer Register Write Protection

Once the watchdog timer enters the pre-active state, writes to registers TIMER_CNTHI, TIMER_CNTLO, TIMER_PRDHI, TIMER_PRDLO, TIMER_TCR, and TIMER_WDTCR (except for the TIMER_WDTCR[31-16] WDKEY bits) will have no effect. Writes to WDEN when the watchdog timer is in the timeout state have no effect.

The value A5C6h or DA7Eh must be written to the WDKEY bits depending on the current state (see Figure 11-1404). After the watchdog timer has entered the initial state, clearing the TIMER_TGCR[0] TIMLORS and TIMER_TGCR[1] TIMHIRS bits is prohibited.

11.17.5 Timers Programming Guide

11.17.5.1 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

11.17.5.1.1 Global Initialization

11.17.5.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the timers are to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the timers. For more information, see Section 11.17.3, *Timers Integration*, and Section 11.17.2, *Timers Environment*. Table 11-3438 summarizes the surrounding modules.

Table 11-3438. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
DSP_INTC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling DSP interrupts, see Section 6.2, *C66x DSP Subsystem*.
CIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling CIC interrupts, see Chapter 9, *Interrupts*.
ARM_GIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling ARM GIC interrupts, see Section 6.1, *Arm Cortex-A15 Subsystem*.
EDMACC_0 and EDMACC_1	DMA controllers (EDMACC_0 and EDMACC_1) configuration must be done to enable the module DMA channel request. See Chapter 10, *Enhanced Direct Memory Access (EDMA) Controller*.
PLL Controller	PLL Controller configuration must be done to enable the module clocks. See Section 5.4.5.3, *PLL Controller*.
Timer pin manager	Timer pin manager configuration must be done to enable the module output pins multiplexing. See Section 5.1.3.1.9, *Timer Pin Manager Control Registers*.

11.17.5.1.1.2 Timers Module Global Initialization

11.17.5.1.1.2.1 Main Sequence – Timers Module Global Initialization

After a hardware reset, the enabling mode bits TIMER_TCR[23-33] ENAMODE are cleared to 0 and the timer is disabled. The timer counter and period registers are cleared to 0. The timer can be configured to the desired mode by programming the control registers, TIMER_TCR and (in the case of the watchdog timer mode) TIMER_WDTCR.

Table 11-3439 identifies the main steps for initializing the timers module when the module is to be used for the first time.

Table 11-3439. Timers Module Global Initialization

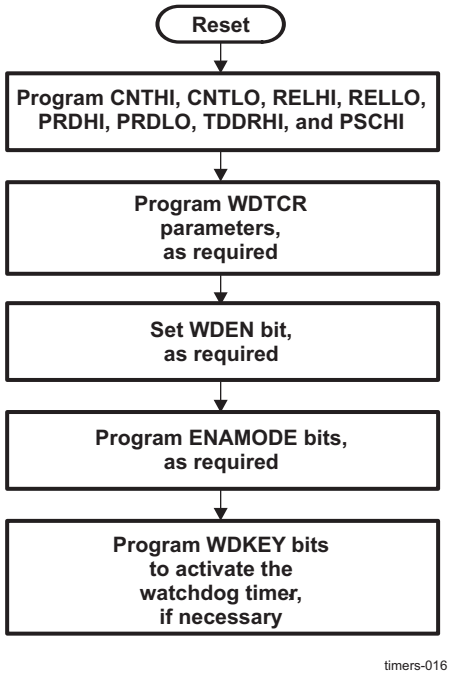
Step	Register/Bit Field/Programming Model	Value
Execute hardware reset.	TIMER_TCR[23-22] ENAMODE	0h
Write the timer counter, period reload (if used) and period values	Write the values to TIMER_CNTHI and/or TIMER_CNTLO, TIMER_RELHI, TIMER_RELLO and TIMER_PRDHI and/or TIMER_PRDLO registers	-h
Is the 4-bit prescaler to be used?	Write the values to the TIMER_TGCR[15-12] TDDRHI bits and TIMER_TGCR[11-8] PSCHI bits	-h
Set the remaining control bits to the required state		-h
Is the timer to be used as watchdog timer?	Set TIMER_WDTCR[14] WDEN bit	1h

Table 11-3439. Timers Module Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
To start the timer, set the ENAMODE bits to use the timer as a continuous interrupt generator	ENAMODE bits	2h or 3h
or	or	
as a one-time counter.	ENAMODE bits	1h
Is the watchdog timer mode to be selected?	Program the TIMER_WDTCR[31-16] WDKEY bits	A5C6h DA7Eh

Figure 11-1405 shows a typical timer initialization:

Figure 11-1405. Timer Initialization



11.17.5.2 Additional requirements to Watchdog Timer Mode

Few additional requirements apply to watchdog timer mode:

1. When CPU is in emulation halt mode, the corresponding watchdog timer must be suspended. This is to ensure no watchdog resets during debug. Emulation suspend outputs from CPU (DSP or A15 core) are connected to TIMER_0 and TIMER_5 to enable this feature.
2. When CPU is reset, the corresponding watchdog timer also needs to be reset. For DSP this is ensured by using the same LPSC to control both the DSP and the corresponding watchdog timer. The Arm internal PSC supports a reset and clock stop handshake interface is connected to Timer clock stop/clock gating control.
3. When CPU is clock gated or powered down using the LPSC, the corresponding watchdog timer should also be clock gated. For DSP this is ensured by using the same LPSC to control both the DSP and the corresponding watchdog timer.
4. For A15 core internal clock gating mode like WFI mode, it is the responsibility of software to put the corresponding timer in the clock gated state.

11.17.6 Timers Registers

Table 11-3441 and Table 11-3442 list the memory-mapped registers for the Timers. All register offset addresses not listed in Table 11-3441 and Table 11-3442 should be considered as reserved locations and the register contents should not be modified.

NOTE: Timers' IDLE mode is not supported in this family of devices.

Table 11-3440. Timers Instances

Instance	Base Address

11.17.6.1 TIMER_PID12 Register (Offset = 0h) [reset = 4472 020Ch]

TIMER_PID12 is shown in Figure 11-1406 and described in Table 11-3444.

This register is intended to store versioning information used to identify the specific GP/WD timer peripheral implemented in a particular device. All bits within this register are read only.

11.17.6.2 TIMER_EMUMGT_CLKSPD Register (Offset = 4h) [reset = 0h]

TIMER_EMUMGT_CLKSPD is shown in Figure 11-1407 and described in Table 11-3447.

The TIMER_EMUMGT_CLKSPD register contains the FREE and SOFT bits that determine how the timer responds to an emulation suspend event. An emulation suspend event corresponds to any type of emulator access to the DSP, such as a hardware or software breakpoint, a probe point, or a printf instruction. For additional emulation information, see Section 11.17.4.10.

The CLKDIV field of this register also can be read to identify the ratio of the CPU clock to the timer input clock. For example, in devices where the internal timer clock frequency is equal to the CPU frequency divided by 6, the CLKDIV field will read as 6 on those devices.

Table 11-3447. TIMER_EMUMGT_CLKSPD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R/W	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

(1) The reset value of this field is based on the ratio of the CPU clock to the timer internal clock.

Table 11-3447. TIMER_EMUMGT_CLKSPD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-16	CLKDIV	R	-h	Clock divide-down ratio bits. Defines the ratio of the CPU clock to the timer input clock. The CLKDIV bits are read-only bits. • 1h = Internal clock source for the timer is the CPU clock divided by 1. • 2h = Internal clock source for the timer is the CPU clock divided by 2. • 3h = Reserved • 4h= Internal clock source for the timer is the CPU clock divided by 4. • 5h = Reserved • 6h = Internal clock source for the timer is the CPU clock divided by 6. • 7h = Reserved • 8h = Internal clock source for the timer is the CPU clock divided by 8. • 9h-15h = Reserved
15-2	RESERVED	R/W	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1	SOFT	R/W	0h	Used in conjunction with FREE bit to determine how the timer responds to an emulation suspend event. When the FREE bit is 0, the SOFT bit selects the timer response. • 0 = The timer stops immediately. • 1 = The timer stops when the timer counter register increments and reaches the value in the timer
0	FREE	R/W	0h	Used in conjunction with SOFT bit to determine how the timer responds to an emulation suspend event. When the FREE bit is 0, the SOFT bit selects the timer response. • 0 = The SOFT bit selects the timer response. • 1 = The timer runs free, regardless of the value of the SOFT bit.

Bit	Field	Type	Reset	Description
31-26	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
25	GPIO_ENO34	R/W	0h	Enable the timer output TOUTH in GPIO mode. GPIO_ENO34=0: timer output functions as a timer output. GPIO_ENO34=1: the timer output is enabled as GPIO.
24	GPIO_ENI34	R/W	0h	Enable the timer input TINPH in GPIO mode. GPIO_ENI34=0: timer input functions as a timer input. GPIO_ENI34=1: the timer input is enabled as GPIO.
23-18	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
17	GPIO_ENO12	R/W	0h	Enable the timer output TOUTL in GPIO mode. GPIO_ENO12=0: timer output functions as a timer output. GPIO_ENO12=1: the timer output is enabled as GPIO.
16	GPIO_ENI12	R/W	0h	Enable the timer input TINPL in GPIO mode. GPIO_ENI12=0: timer input functions as a timer input. GPIO_ENI12=1: the timer input is enabled as GPIO.
15-14	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.

Table 11-3450. TIMER_GPINT_EN Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	GPINT34_INVO	R/W	0h	Invert bit for timer output TOUTH when it is used to source an interrupt or event (GPINT34_ENO=1). GPINT34_INVO=0: Rising of Timer output generate interrupt or event. GPINT34_INVO=1: Falling of Timer output generate interrupt or event. This bit has no effect when GPINT34_ENO=0.
12	GPINT34_INVI	R/W	0h	Invert bit for timer input TINPH when it is used to source an interrupt or event (GPINT34_ENI=1). GPINT34_INVI=0: Rising of Timer input generate interrupt or event. GPINT34_INVI=1: Falling of Timer input generate interrupt or event. This bit has no effect when GPINT34_ENI=0.
11-10	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
9	GPINT34_ENO	R/W	0h	Enable the timer output TOUTH to source the interrupt or event in GPIO mode. GPINT34_ENO=0: causes the interrupt or event to be sourced normally by the timer. GPINT34_ENO=1: causes the timer output to source an interrupt or event.
8	GPINT34_ENI	R/W	0h	Enable the timer input TINPH to source the interrupt or event in GPIO mode. GPINT34_ENI=0: causes the interrupt or event to be sourced normally by the timer. GPINT34_ENI=1: causes the timer input to source an interrupt or event.
7-6	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
5	GPINT12_INVO	R/W	0h	Invert bit for timer output TOUTL when it is used to source an interrupt or event (GPINT12_ENO=1). GPINT12_INVO=0: Timer output interrupt or event is not inverted. GPINT12_INVO=1: Timer output interrupt or event is inverted. This bit has no effect when GPINT12_ENO=0.
4	GPINT12_INVI	R/W	0h	Invert bit for timer input TINPL when it is used to source an interrupt or event (GPINT12_ENI=1). GPINT12_INVI=0: Timer input interrupt or event is not inverted. GPINT12_INVI=1: Timer input interrupt or event is inverted. This bit has no effect when GPINT12_ENI=0.
3-2	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
1	GPINT12_ENO	R/W	0h	Enable the timer output TOUTL to source the interrupt or event in GPIO mode. GPINT12_ENO=0: causes the interrupt or event to be sourced normally by the timer. GPINT12_ENO=1: causes the timer output to source an interrupt or event.
0	GPINT12_ENI	R/W	0h	Enable the timer input TINPL to source the interrupt or event in GPIO mode. GPINT12_ENI=0: causes the interrupt or event to be sourced normally by the timer. GPINT12_ENI=1: causes the timer input to source an interrupt or event.

Bit	Field	Type	Reset	Description
31-26	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
25	GPIO_DIRO34	R/W	0h	Controls the direction of the timer output TOUTH in GPIO mode. It must be set to 0 to be used as input in GPIO interrupt mode. GPIO_DIRO34=0: timer output functions as a GPIO input. GPIO_DIRO34=1: timer output functions as a GPIO output.
24	GPIO_DIRI34	R/W	0h	Controls the direction of the timer input TINPH in GPIO mode. It must be set to 0 to be used as input in GPIO interrupt mode. GPIO_DIRI34=0: timer input functions as a GPIO input. GPIO_DIRI34=1: timer input functions as a GPIO output.
23-18	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
17	GPIO_DIRO12	R/W	0h	Controls the direction of the timer output TOUTL in GPIO mode. It must be set to 0 to be used as input in GPIO interrupt mode. GPIO_DIRO12=0: timer output functions as a GPIO input. GPIO_DIRO12=1: timer output functions as a GPIO output.
16	GPIO_DIRI12	R/W	0h	Controls the direction of the timer input TINPL in GPIO mode. It must be set to 0 to be used as input in GPIO interrupt mode. GPIO_DIRI12=0: timer input functions as a GPIO input. GPIO_DIRI12=1: timer input functions as a GPIO output.

Table 11-3453. TIMER_GPDIR_DAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-10	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
9	GPIO_DATO34	R/W	0h	When GPIO_DIRO34=0: timer output TOUTH functions as a GPIO input, the logic value read in this bit is equal to the logic level present at the timer input. Writes to this bit have no effect. The GP input is sampled with the VBUS clock. When GPIO_DIRO34=1: timer output TOUTH functions as a GPIO output, the GP output is driven to the logic level which is written to and stored in this bit. The logic level of the GP output can also be read back at this bit.
8	GPIO_DATI34	R/W	0h	When GPIO_DIRI34=0: timer input TINPH functions as a GPIO input, the logic value read in this bit is equal to the logic level present at the timer input. Writes to this bit have no effect. The GP input is sampled with the VBUS clock. When GPIO_DIRI=1: timer input functions as a GPIO output, the GP output is driven to the logic level which is written to and stored in this bit. The logic level of the GP output can also be read back at this bit.
7-2	RESERVED	R/W	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
1	GPIO_DATO12	R/W	0h	When GPIO_DIRO12=0: timer output TOUTL functions as a GPIO input, the logic value read in this bit is equal to the logic level present at the timer input. Writes to this bit have no effect. The GP input is sampled with the VBUS clock. When GPIO_DIRO=1: timer output TOUTL functions as a GPIO output, the GP output is driven to the logic level which is written to and stored in this bit. The logic level of the GP output can also be read back at this bit.
0	GPIO_DATI12	R/W	0h	When GPIO_DIRI12=0: timer input TINPL functions as a GPIO input, the logic value read in this bit is equal to the logic level present at the timer input. Writes to this bit have no effect. The GP input is sampled with the VBUS clock. When GPIO_DIRI12=1: timer input TINPL functions as a GPIO output, the GP output is driven to the logic level which is written to and stored in this bit. The logic level of the GP output can also be read back at this bit.

- TIMER_GPDIR_DAT Register (Offset = Ch) [reset = 0h]: [0]

11.17.6.5 TIMER_CNTLO Register (Offset = 10h) [reset = 0h]

TIMER_CNTLO is shown in Figure 11-1410 and described in Table 11-3456.

The timer counter registers (TIMER_CNTLO and TIMER_CNTHI) are 32-bit-wide registers that can be used in conjunction to form a 64-bit counter, or separately as 32-bit counters. The use of these registers depends on the configuration of the timer. In the 64-bit general-purpose timer mode and watchdog mode, the two registers work as a single 64-bit counter. The 64-bit counter increments when the timer is enabled to count.

In a dual 32-bit timer mode, the counter registers work as separate 32-bit registers. These two register pairs can be configured as chained or unchained.

A hardware reset clears both counter registers, but software resets do not affect them. When the TIMLORS bit is cleared, TIMER_CNTLO keeps its current value, and when the TIMHIRS bit is cleared, TIMER_CNTHI keeps its current value.

11.17.6.7 TIMER_PRDLO Register (Offset = 18h) [reset = 0h]

TIMER_PRDLO is shown in Figure 11-1412 and described in Table 11-3462.

The timer period registers (TIMER_PRDLO and TIMER_PRDHI) are 32-bit-wide registers which can be used in conjunction to form a single 64-bit period register or separately as 32-bit period registers.

In a 64-bit general-purpose timer mode and watchdog mode, all 64 period bits contain the number of timer input clock cycles to count. This number controls the frequency of the timer output. In a 32-bit dual timer mode, the period registers work as separate 32-bit registers.

These two registers are used in conjunction with the two counter-registers, TIMER_CNTHI and TIMER_CNTLO.

11.17.6.9 TIMER_TCR Register (Offset = 20h) [reset = 0h]

TIMER_TCR is shown in Figure 11-1414 and described in Table 11-3468.

The lower 16 bits of the timer control register (TIMER_TCR) determine the operating mode and monitor the status of TIMLO, as well as control the function of TINPL and TOUTL. The upper 16 bits determine the operating mode and monitor the status of TIMHI. The upper 16 bits of the TIMER_TCR are used only when the timer is configured in dual 32-bit timers unchained mode (TIMMODE = 1h in TIMER_TGCR).

Table 11-3468. TIMER_TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved. The reserved bit location is always read as 0.
29-28	CAPEVTMODE_HI	R/W	0h	Capture event mode for TIMHI. Uses these bits to specify the type of event for Capture mode. • 0h = Event occurs on timer input rising edge. • 1h = Event occurs on time input falling edge. • 2h = Event occurs on both rising and falling edges. • 3h = Reserved
27	CAPMODE_HI	R/W	0h	Capture mode enable bit for TIMHI. Determines if external event can reset timer. Capture mode is only available in dual 32-bit unchained mode and when CLKSRC = 0 and ENAMODE = 2h or 3h. Output events (interrupt/DMA/other) are generated when capture mode event occurs. • 0 = Timer is not in capture mode. • 1 = Timer is in capture mode. External event can reset timer.

Table 11-3468. TIMER_TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	READRSTMODE_HI	R/W	0h	Read reset mode enable bit for TIMHI. Determines the effect of a timer counter read on TIMER_CNTHI. Read reset mode is only available in dual 32-bit unchained. Output events (interrupt/DMA/other) are not generated when read reset occurs. • 0 = There is no effect when timer counter register TIMER_CNTHI is read. • 1 = Timer counter is reset when timer counter register TIMER_CNTHI is read.
25	TIEN_HI	R/W	0h	Timer input enable bit determines if the timer clock is gated by the timer input. Applicable only when CLKSRC_HI = 0. • 0 = Timer clock is not gated by the timer input. • 1 = Timer clock is gated by a high state of the timer input synchronized with the internal clock. Timer starts counting when timer input transitions from low to high. Timer stops counting when timer input transitions from high to low.
24	CLKSRC_HI	R/W	0h	Clock source bit determines the clock source for the timer. • 0 = The clock source is the internal clock. • 1 = The clock source is the signal on the timer pin.
23-22	ENAMODE_HI	R/W	0h	A value written to this Enabling mode bits determine the timer mode for TIMHI. • 0h = The timer is disabled (not counting) and maintains the current value. • 1h = The timer is enabled one time. The timer stops after the timer counter reaches the timer period. • 2h = The timer is enabled continuously. The timer counter increments until it reaches the timer period. One timer clock cycle later, the timer counter is reset to 0 and continues counting. • 3h = The timer is enabled continuously. The timer counter increments until it reaches the timer period. One timer clock cycle later, the timer counter is reset to 0, the period registers (TIMER_PRDHI and TIMER_PRDLO) reload with the reload registers (TIMER_RELHI and TIMER_RELLO) and continues counting when TIMMODE is either set to 0h (64-bit timer mode) or 1h (32-bit timers unchained mode).
21-20	PWID_HI	R/W	0h	Pulse width bits for TIMHI. PWID_HI is only used in pulse mode (CP_HI = 0). PWID_HI controls the width of the timer output signal. The polarity of the pulse is controlled by the INVOUTP_HI bit. The timer output signal is recorded in the TSTAT_HI bit and can be made visible on the timer output pin. • 0h = The pulse width is 1 timer clock cycle. • 1h = The pulse width is 2 timer clock cycles. • 2h = The pulse width is 3 timer clock cycles. • 3h = The pulse width is 4 timer clock cycles.
19	CP_HI	R/W	0h	Clock/pulse mode bit for TIMHI. In the watchdog timer mode (TIMMODE = 2h), the pulse mode is selected automatically and the CP_HI bit is a don't care. • 0 = Pulse mode. When the timer counter reaches the timer period, the timer output appears as a pulse with the width defined by the PWID_HI bits and the polarity defined by the INVOUTP_HI bits. • 1 = Clock mode. The timer output signal has a 50% duty cycle signal. When the timer counter reaches the timer period, the level of the timer output signal is toggled (from high to low or from low to high).
18	INVINP_HI	R/W	0h	Timer input inverter control bit for TIMHI. Only affects operation if CLKSRC_HI = 1. • 0 = A non-inverted timer input drives the timer. • 1 = An inverted timer input drives the timer.
17	INVOUTP_HI	R/W	0h	Timer output inverter control bit for TIMHI. • 0 = The timer output is not inverted. • 1 = The timer output is inverted.

Table 11-3468. TIMER_TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	TSTAT_HI	R/W	0h	Timer status bit for TIMHI. This is a read-only bit that shows the value of the timer output. • 0 = Timer output is low. • 1 = Timer output is high.
15-14	RESERVED	R	0h	The reserved bit location is always read as 0. A value written to this field has no effect.
13-12	CAPEVTMODE_LO	R/W	0h	Capture event mode. Uses these bits to specify the type of event for Capture mode. • 0h = Event occurs on timer input rising edge. • 1h = Event occurs on time input falling edge. • 2h = Event occurs on both rising and falling edges. • 3h = Reserved
11	CAPMODE_LO	R/W	0h	Capture mode enable bit. Determines if external event can reset timer. Capture mode is only available in dual 32-bit unchained mode and when CLKSRC = 0 and ENAMODE = 2h or 3h. Output events (interrupt/DMA/other) are generated when capture mode event occurs. • 0 = Timer is not in capture mode. • 1 = Timer is in capture mode. External event can reset timer.
10	READRSTMODE_LO	R/W	0h	Read reset mode enable bit. Determines the effect of a timer counter read on TIMER_CNTLO. Read reset mode is only available in dual 32-bit unchained. Output events (interrupt/DMA/other) are not generated when read reset occurs. • 0 = There is no effect when timer counter register TIMER_CNTLO is read. • 1 = Timer counter is reset when timer counter register TIMER_CNTLO is read.
9	TIEN_LO	R/W	0h	Timer input enable bit determines if the timer clock is gated by the timer input. Applicable only when CLKSRC_LO = 0. • 0 = Timer clock is not gated by the timer input. • 1 = Timer clock is gated by a high state of the timer input synchronized with the internal clock. Timer starts counting when timer input transitions from low to high. Timer stops counting when timer input transitions from high to low.
8	CLKSRC_LO	R/W	0h	Clock source bit determines the clock source for the timer. • 0 = The clock source is the internal clock. • 1 = The clock source is the signal on the timer pin.
7-6	ENAMODE_LO	R/W	0h	Enabling mode bits determine the timer mode. • 0h = The timer is disabled (not counting) and maintains the current value. • 1h = The timer is enabled one time. The timer stops after the timer counter reaches the timer period. • 2h = The timer is enabled continuously. The timer counter increments until it reaches the timer period. One timer clock cycle later, the timer counter is reset to 0 and continues counting. • 3h = The timer is enabled continuously. The timer counter increments until it reaches the timer period. One timer clock cycle later, the timer counter is reset to 0, the period registers (TIMER_PRDHI and TIMER_PRDLO) reload with the reload registers (TIMER_RELHI and TIMER_RELLO) and continues counting when TIMMODE is either set to 0h (64-bit timer mode) or 1h (32-bit timers unchained mode).

Table 11-3468. TIMER_TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-4	PWID_LO	R/W	0h	Pulse width bits. PWID_LO is only used in pulse mode (CP_LO = 0). PWID_LO controls the width of the timer output signal. The polarity of the pulse is controlled by the INVOUTP_LO bit. The timer output signal is recorded in the TSTAT_LO bit and can be made visible on the timer output pin. • 0h = The pulse width is 1 timer clock cycle. • 1h = The pulse width is 2 timer clock cycles. • 2h = The pulse width is 3 timer clock cycles. • 3h = The pulse width is 4 timer clock cycles.
3	CP_LO	R/W	0h	Clock/pulse mode bit for timer output. In the watchdog timer mode (TIMMODE = 2h), the pulse mode is selected automatically and the CP_LO bit is a don't care. • 0 = Pulse mode. When the timer counter reaches the timer period, the timer output appears as a pulse with the width defined by the PWID_LO bits and the polarity defined by the INVOUTP_LO bits. • 1 = Clock mode. The timer output signal has a 50% duty cycle signal. When the timer counter reaches the timer period, the level of the timer output signal is toggled (from high to low or from low to high).
2	INVINP_LO	R/W	0h	Timer input inverter control bit. Only affects operation if CLKSRC_LO = 1. • 0 = A non-inverted timer input drives the timer. • 1 = An inverted timer input drives the timer.
1	INVOUTP_LO	R/W	0h	Timer output inverter control bit. • 0 = The timer output is not inverted. • 1 = The timer output is inverted.
0	TSTAT_LO	R/W	0h	Timer status bit. This is a read-only bit that shows the value of the timer output. TSTAT_LO drives the timer pin (TOUTL) when the pin is used as a timer output pin and may be inverted by setting INVOUTP_LO = 1. • 0 = Timer output is low. • 1 = Timer output is high.

Table 11-3471. TIMER_TGCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	Reserved. The reserved bit location is always read as 0.
15-12	TDDRHI	R/W	0h	Timer divide-down ratio bits. This field is the prescale counter for TIMHI in the dual 32-bit timers unchained mode (TIMMODE = 1h). When the timer is enabled, TDDRHI increments every timer clock cycle. The timer counter (TIMER_CNTHI) increments on the cycle after the TDDRHI matches the value of PSCHI. TDDRHI resets to 0 and continues. If enabled one time, when TIMER_CNTHI matches the TIMER_PRDHI, the timer stops; if the timer is enabled continuously, TIMER_CNTHI resets to 0 on the cycle after matching the TIMER_PRDHI and the timer continues counting. The default value is 0000h.
11-8	PSCHI	R/W	0h	Prescale period bits. This field specifies the prescale period for TIMHI in the dual 32-bit timers unchained mode (TIMMODE = 1h). The default value is 0000h.
7-5	RESERVED	R/W	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

Table 11-3471. TIMER_TGCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	PLUSEN	R/W	0h	Enable Timer Plus features. • 0 = Enable backward compatibility. Disable Timer Plus features (Timer Plus features are unavailable). • 1 = Disable backward compatibility. Enable Timer Plus features (Timer Plus features are available).
3-2	TIMMODE	R/W	0h	Timer mode bits determine the timer operating mode. • 0h = The timer is in the 64-bit general-purpose timer mode. • 1h = The timer is in the dual 32-bit timers unchained mode. • 2h = The timer is in the 64-bit watchdog timer mode. • 3h = The timer is in the dual 32-bit timers chained mode.
1	TIMHIRS	R/W	0h	TIMHI reset bit. Note that in order for the timer to function properly in 64-bit general-purpose timer mode both the TIMHIRS and TIMLORS bits must be set to 1. If the timer is in the watchdog timer active state, changing this bit does not affect the timer. • 0 = TIMHI is in reset. The TSTAT_HI bit of TIMER_TCR is reset to 0. However, the counter register TIMER_CNTHI keeps its current value. • 1 = TIMHI is not in reset. TIMHI can be used as a 32-bit timer.
0	TIMLORS	R/W	0h	TIMLO reset bit. Note that in order for the timer to function properly in 64-bit general-purpose timer mode both the TIMHIRS and TIMLORS bits must be set to 1. If the timer is in the watchdog timer active state, changing this bit does not affect the timer. • 0 = TIMLO is in reset. The TSTAT_LO bit of TIMER_TCR is reset to 0, and the timer output signal is in the high-impedance state. However, the counter register TIMER_CNTLO keeps its current value. • 1 = TIMLO is not in reset. TIMLO can be used as a 32-bit timer.

11.17.6.11 TIMER_WDTCR Register (Offset = 28h) [reset = 0h]

TIMER_WDTCR is shown in Figure 11-1416 and described in Table 11-3474. This register determines the state of the watchdog timer and monitors the watchdog timer status.

Table 11-3473. TIMER_WDTCR Instances

Instance	Physical Address
TIMER_0	0220 0028h

Table 11-3474. TIMER_WDTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	WDKEY	R/W	0h	Value = 0000h-FFFFh Watchdog timer service key bits. Before a watchdog timeout event occurs, only a write sequence of a A5C6h followed by a DA7Eh services the watchdog timer. Any other write triggers a watchdog timeout event immediately. The default value of WDKEY is 0000h. WDKEY is not applicable in the general-purpose timer mode.
15	WDFLAG	R/W	0h	Watchdog timer flag bit. WDFLAG is cleared when the watchdog timer is moved to the active state, when a hardware reset occurs, and when 1 is written to WDFLAG. • 0 = No watchdog timer timeout event occurred. • 1 = Watchdog timer timeout event occurred.
14	WDEN	R/W	0h	Watchdog timer enable bit. WDEN must be set to move the watchdog timer to the pre-active state (see Figure 11-1404). • 0 = Watchdog timer is disabled. Watchdog timer output pin is disconnected from the watchdog timer timeout event, and the timer counter starts to count. The timer is in the general-purpose timer mode. • 1 = Watchdog timer is enabled. The watchdog timer output pin is connected to the watchdog timeout event. The watchdog timer can be disabled by a watchdog timeout event or by a hardware reset.

Table 11-3474. TIMER_WDTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-12	WDIKEY	R/W	0h	Value = 0h-3h Watchdog idle enable key bits. A write sequence of 1h followed by 2h is required before the watchdog timer can enter the idle mode. Writing 0h to WDIKEY prevents the watchdog timer from entering the idle mode. WDIKEY is not applicable in the general-purpose timer mode.
11-0	RESERVED	R/W	0h	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

11.17.6.12 TIMER_RELLO Register (Offset = 34h) [reset = 0h]

TIMER_RELLO is shown in Figure 11-1417 and described in Table 11-3477. The timer reload registers (TIMER_RELLO and TIMER_RELHI) are 32-bit-wide registers which can be used in conjunction to form a single 64-bit reload register or separately as 32-bit reload registers. These two registers are used in conjunction with the two counter-registers, TIMER_CNTHI and TIMER_CNTLO.

11.17.6.14 TIMER_CAPLO Register (Offset = 3Ch) [reset = 0h]

TIMER_CAPLO is shown in Figure 11-1419 and described in Table 11-3483. The timer capture registers (TIMER_CAPLO and TIMER_CAPHI) are 32-bit-wide registers which can be used to store the timer counter bits. When the timer has a timeout (due to external event or read of counter register) the value of TIMER_CNTHI and TIMER_CNTLO registers are copied onto the TIMER_CAPHI and TIMER_CAPLO registers. These two registers are used in conjunction with the two counter-registers, TIMER_CNTHI and TIMER_CNTLO.

11.18 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART) module in the device.

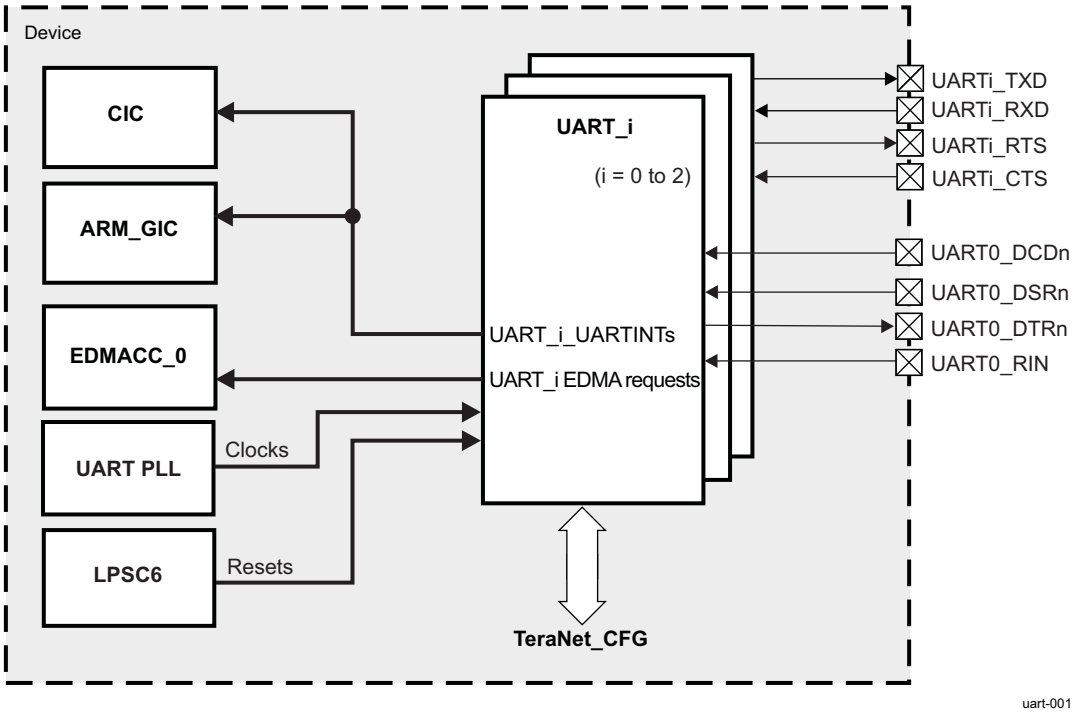
11.18.1 UART Overview

The Universal Asynchronous Receiver/Transmitter peripheral is 16550 standard compatible asynchronous communications element. The UART can be placed in an alternate FIFO mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

There are 3 UART (UART_0, UART_1 and UART_2) modules in the device. Only UART_0 supports full modem control functions. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 11-1422 shows the UART module overview.

Figure 11-1422. UART Overview



11.18.1.1 UART Features

The UART_i (where i = 0 to 2) include the following features:

- 16550 standard compatible
- 16-byte FIFO buffer for receiver and 16-byte FIFO for transmitter
- Baud generation based on programmable divisors operating from a fixed functional clock of 192 MHz
- Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:
  - Baud rate = (functional clock / 16) / N
  - Baud rate = (functional clock / 13) / N
- Break character detection and generation
- Configurable data format:
  - Data bit: 5, 6, 7, or 8 bits

  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS)
- The 192 MHz functional clock option allows baud rates up to 12Mbps

The UART performs serial-to-parallel conversions on data received from a peripheral device or modem and parallel-to-serial conversion on data received from the CPU. The CPU can read the UART status at any time. The UART includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

11.18.2 UART Environment

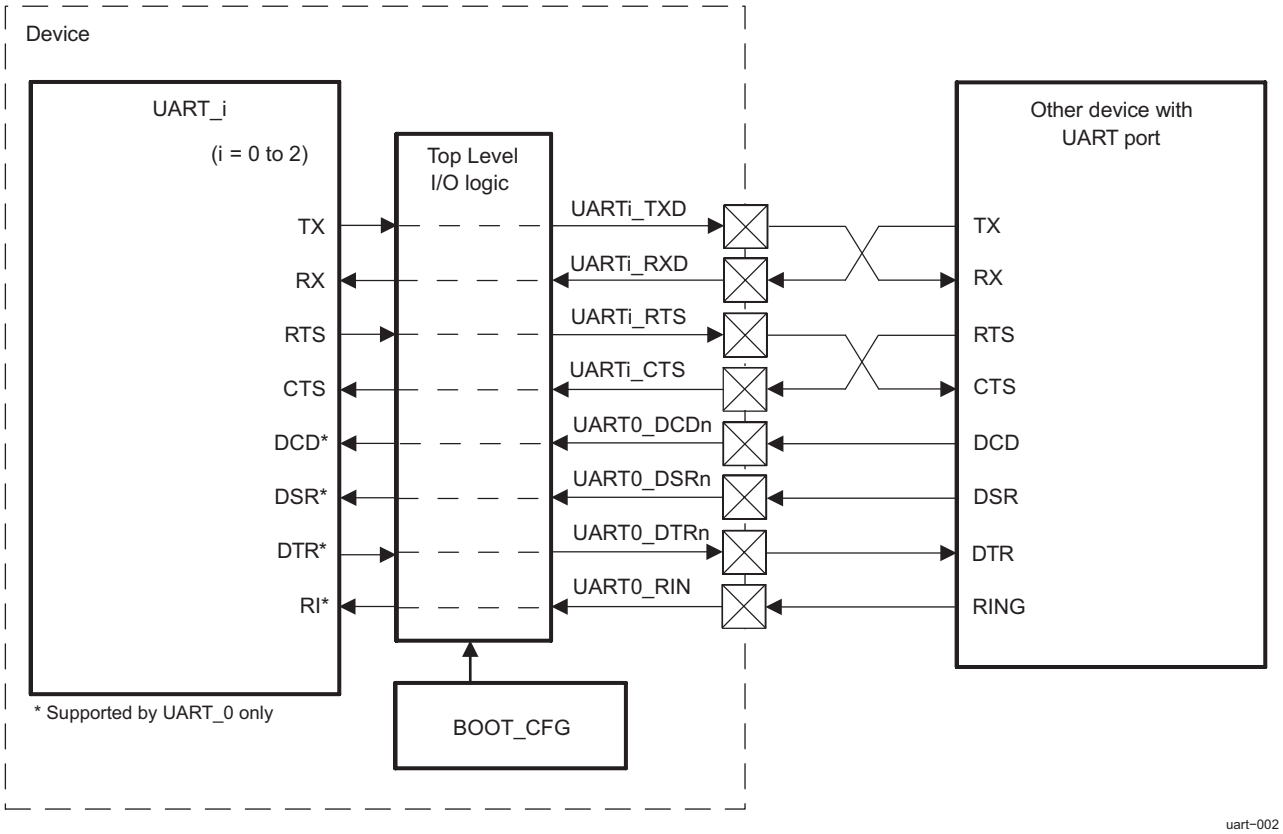
This section describes the UART connection with an external device.

11.18.2.1 UART Interface

11.18.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see Figure 11-1423).

Figure 11-1423. UART Mode Bus System Overview



11.18.2.1.1.1 UART Interface Description

Table 11-3491 lists the UART interface input/output (I/O) signals.

Table 11-3491. UART Interface Signals

Device Signal	Module Signal	I/O[1]	Description	Module Level Reset Value
UART_0 Interface Signals				
UART0_RXD	RX	I	UART_0 Serial data input	HiZ
UART0_TXD	TX	O	UART_0 Serial data output This pin is set to high on reset.	1
UART0_CTSn	CTS	I	UART_0 Clear to send. Active low	HiZ
UART0_RTSn	RTS	O	UART_0 Request to send. Active low	1
UART_0 Modem Signals				
UART0_DCDn	DCD	I	UART_0 Data Carrier Detect. Active low	HiZ
UART0_DSRn	DSR	I	UART_0 Data Set Ready. Active low	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

Table 11-3491. UART Interface Signals (continued)

Device Signal	Module Signal	I/O[1]	Description	Module Level Reset Value
UART0_DTRn	DTR	O	UART_0 Data Terminal Ready. Active low	1
UART0_RIN	RI	I	UART_0 Ring Indicator. Active low	HiZ
UART_1 Interface Signals				
UART1_RXD	RX	I	UART_1 Serial data input	HiZ
UART1_TXD	TX	O	UART_1 Serial data output This pin is set to high on reset.	1
UART1_CTSn	CTS	I	UART_1 Clear to send. Active low	HiZ
UART1_RTSn	RTS	O	UART_1 Request to send. Active low	1
UART_2 Interface Signals				
UART2_RXD	RX	I	UART_2 Serial data input	HiZ
UART2_TXD	TX	O	UART_2 Serial data output This pin is set to high on reset.	1
UART2_CTSn	CTS	I	UART_2 Clear to send. Active low	HiZ
UART2_RTSn	RTS	O	UART_2 Request to send. Active low	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the BOOT_CFG module registers. For more information on control module settings, see Section 5.1.3.1.1, *Pad Configuration Registers*, in Section 5.1, *BOOT_CFG*.

11.18.2.1.1.2 UART Protocol and Data Format

The UART device operates in two modes:

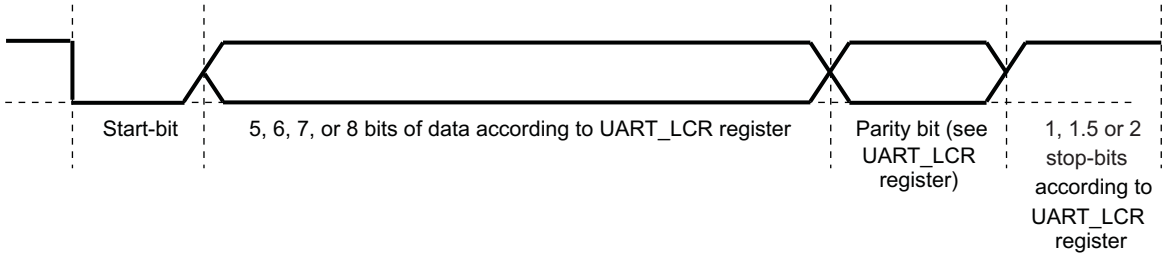
- UART 16×
- UART 13×

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the 16550 UART

Figure 11-1424 shows the UART frame data format.

Figure 11-1424. UART Frame Data Format



11.18.3 UART Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-1425 shows the device internal connections with related modules for UART functions.

Figure 11-1425. UART Integration

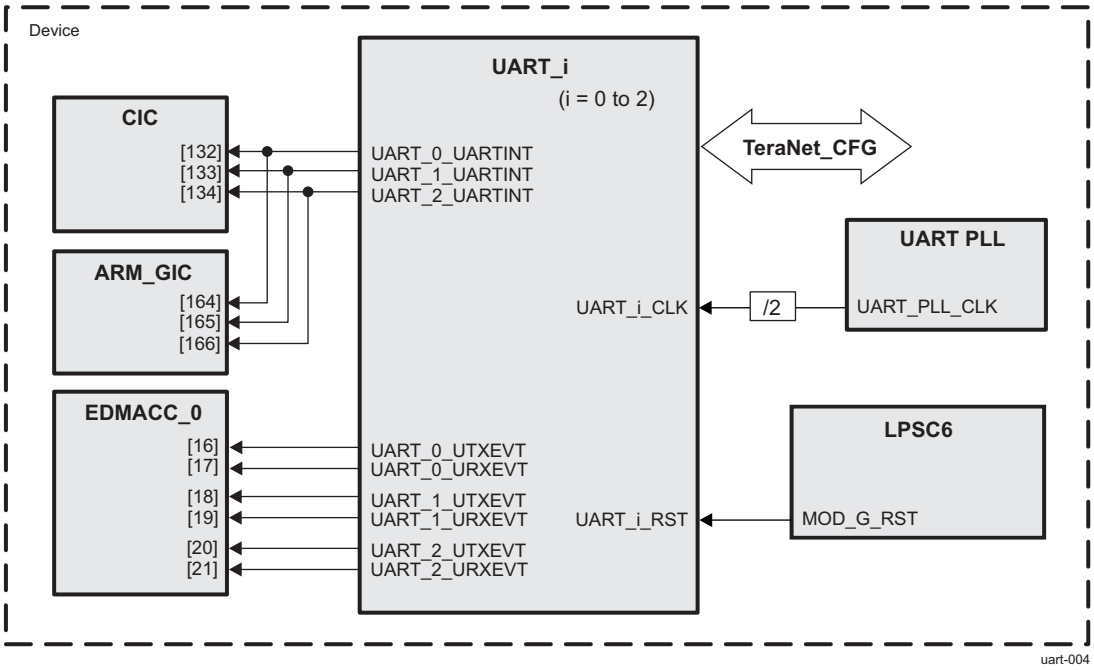


Table 11-3492 through Table 11-3494 summarize the integration of the module in the device.

Table 11-3492. UART Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
UART_0	PD5	LPSC6	TeraNet_CFG
UART_1	PD5	LPSC6	TeraNet_CFG

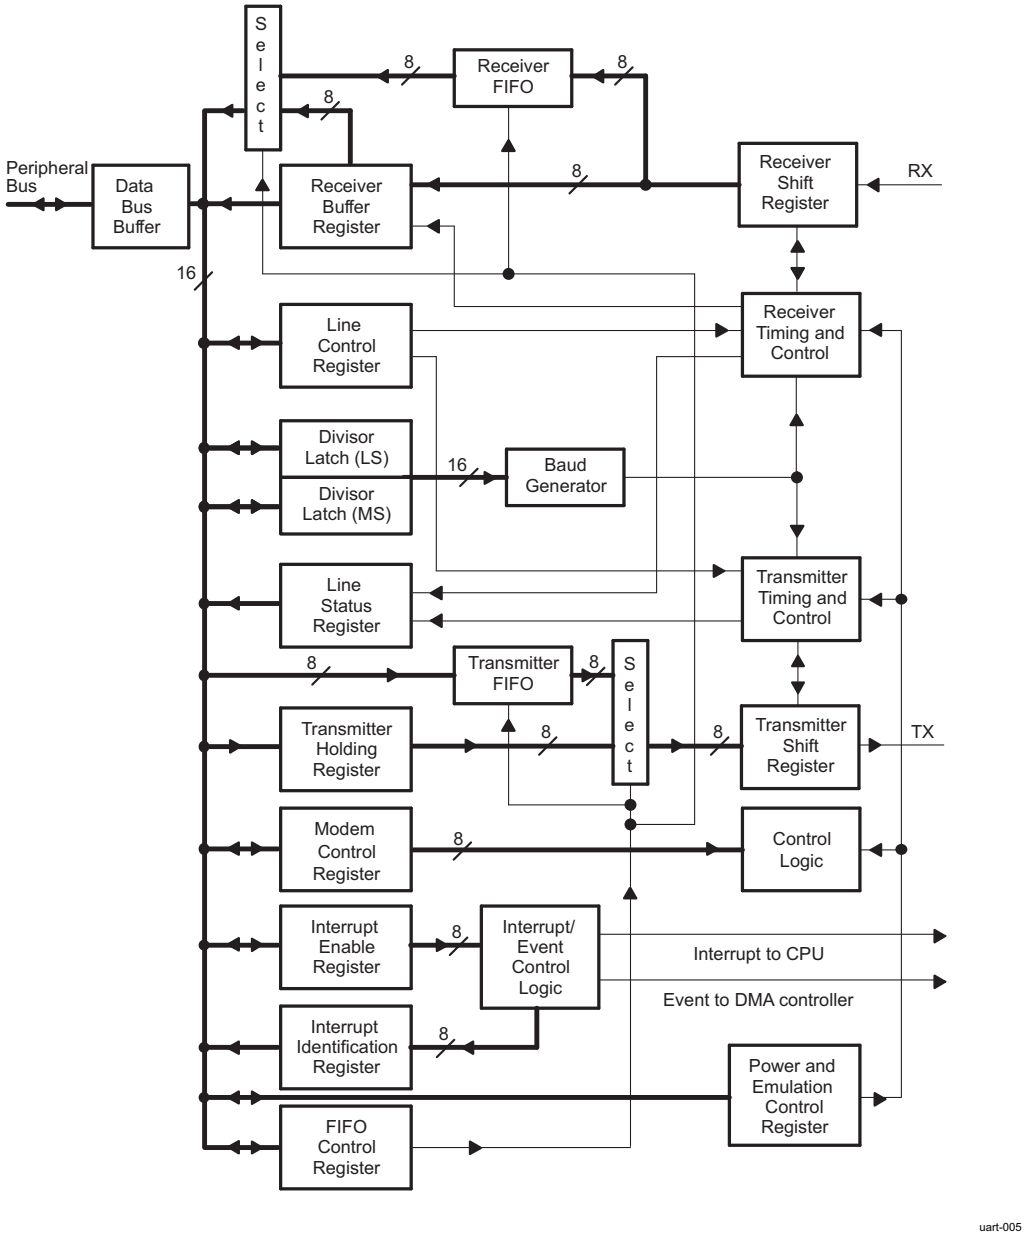
NOTE: UART interrupts are described in Section 11.18.4.3, *Interrupt Requests*.

11.18.4 UART Functional Description

11.18.4.1 Block Diagram

Figure 11-1426 is the UART block diagram.

Figure 11-1426. UART Functional Block Diagram

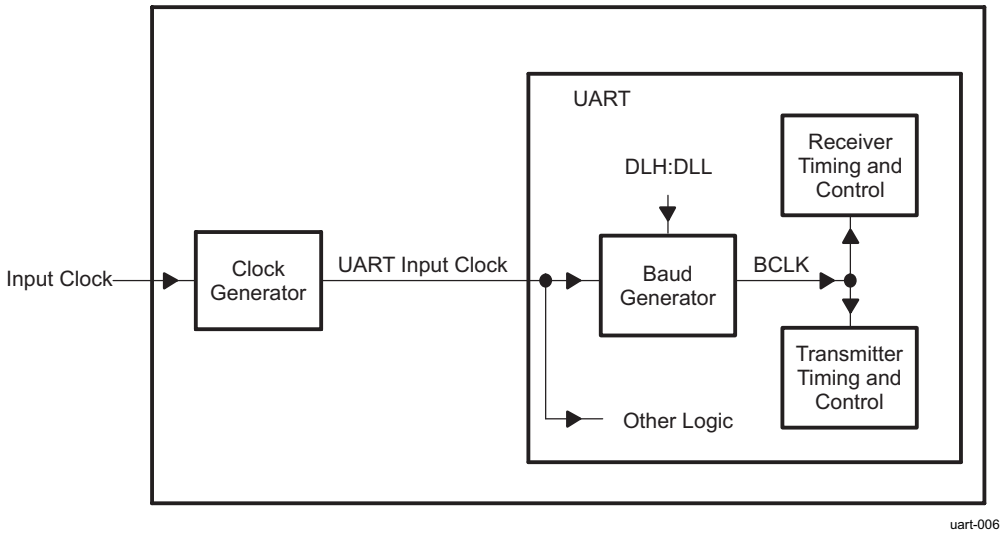


11.18.4.2 Clock Configuration

The UART bit clock is derived from an input clock to the UART.

Figure 11-1427 is a conceptual clock generation diagram for the UART. The processor clock generator receives a signal from an external clock source and produces a UART input clock with a programmed frequency. The UART contains a programmable baud generator that takes an input clock and divides it by a divisor in the range between 1 and (2^{16} - 1) to produce a baud clock (BCLK). The frequency of BCLK is sixteen times (16×) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times (13×) the baud rate (each received or transmitted bit lasts 13 BCLK cycles). When the UART is receiving, the bit is sampled in the eighth BCLK cycle for 16× over sampling mode and on the sixth BCLK cycle for 13× oversampling mode.

Figure 11-1427. UART Clock Generation Diagram



The 16× or 13× reference clock is selected by configuring the UART_MDR[0] OSM_SEL bit. The formula to calculate the divisor is:

$$\text{Divisor} = \frac{\text{UART Input Clock Frequency}}{\text{Desired Baud Rate} \times 16} \quad \text{[MDR.OSM\_SEL = 0]}$$

$$\text{Divisor} = \frac{\text{UART Input Clock Frequency}}{\text{Desired Baud Rate} \times 13} \quad \text{[MDR.OSM\_SEL = 1]}$$

uart-007

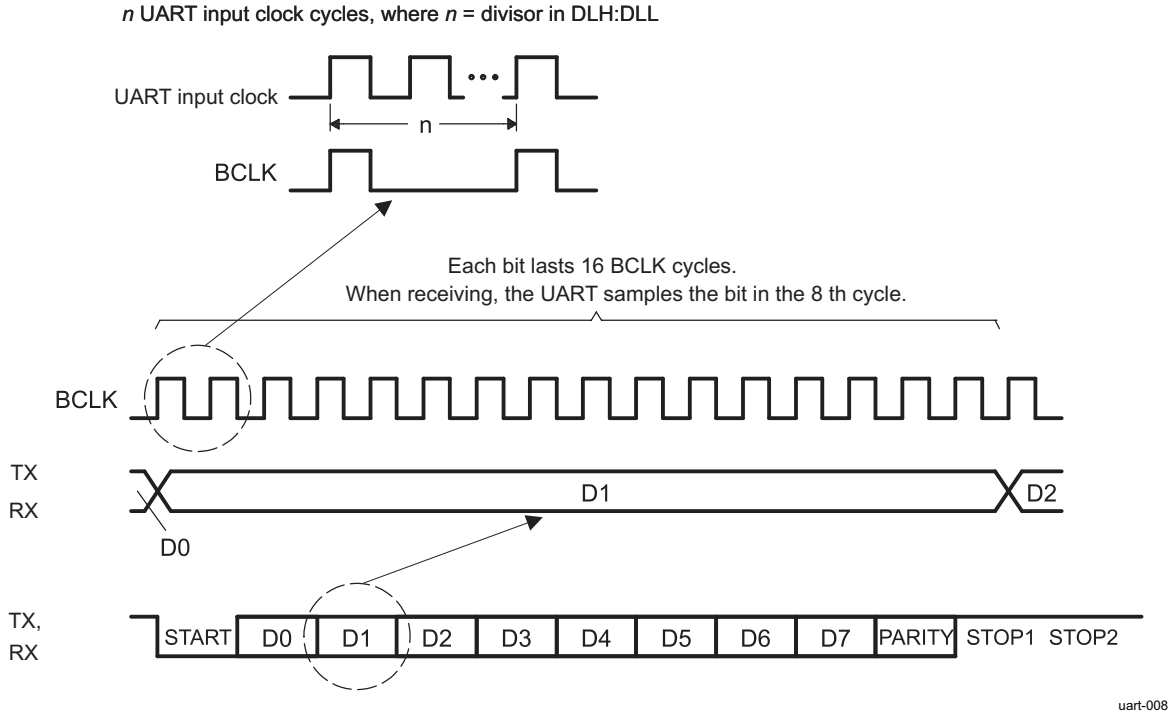
Two 8-bit register fields:

- Divisor MSB Latch [7-0] DLH
- Divisor LSB Latch [7-0] DLL,

called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see Section 11.18.6.11 and Section 11.18.6.12. These divisor latches must be loaded during initialization of the UART to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 11-1428 summarizes the relationship between the transferred data bit, BCLK, and the UART input clock. Note that the timing relationship in Figure 11-1428 shows that each bit lasts for 16 BCLK cycles. This is in case of 16× oversampling mode. For 13× oversampling mode each bit lasts for 13 BCLK cycles.

Figure 11-1428. Relationships Between Data Bit, BCLK, and UART Input Clock



11.18.4.3 Interrupt Requests

11.18.4.3.1 UART Interrupt Management

11.18.4.3.1.1 UART Interrupts

UART includes five possible interrupts prioritized to four levels.

When an interrupt is generated, the UART_IIR[0] IPEND bit is set to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART_IIR[3-1] INTID bit field. Table 11-3495 summarizes the interrupt control functions.

Table 11-3495. Interrupt Identification and Interrupt Clearing Information

Priority Level	UART_IIR Bits				Interrupt Type	Interrupt Source	Event That Clears Interrupt
	3	2	1	0			
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the UART_LSR clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The UART_RBR is read.
						FIFO mode: Trigger level reached. If four character times (see Table 11-3496) pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level. (1)
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 11-3496), and there is at least one character in the receiver FIFO during this time.	One of the following events: A character is read from the receiver FIFO (1), OR A new character arrives in the receiver FIFO, OR The UART_PWREMU_MGMT[13] URRST bit is loaded with 0.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: UART_THR is empty.	A character is written to the UART_THR.
						FIFO mode: Transmitter FIFO is empty.	
4	0	0	0	0	Modem status	Clear to send, data set ready, ring indicator, or data carrier detect	Reading the modem status register.

(1) In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

11.18.4.3.1.2 FIFO Management

The FIFO is accessed by reading and writing the UART_RBR and UART_THR registers. Parameters are controlled using the FIFO control register (UART_FCR).

The UART_FCR register controls the FIFO trigger level, which enables DMA and interrupt generation.

11.18.4.3.1.2.1 FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

11.18.4.3.1.2.1.1 FIFO Interrupt Mode

When the receiver FIFO is enabled in the UART_FCR and the receiver interrupts are enabled in the UART_IER, the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in UART_FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see Section 11.18.4.4.2, *Interrupt Support*.
- The UART_LSR[0] DR bit (data-ready) indicates the presence or absence of characters in the receiver FIFO. The UART_LSR[0] DR bit is set when a character is transferred from the receiver shift register (UART_RSR) to the empty receiver FIFO. The UART_LSR[0] DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:

  - At least one character is in the FIFO.
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit, n data bits, 1 PARITY bit, and 1 STOP bit, where n depends on the word length selected with the UART_LCR[1-0] WLS bits. See Table 11-3496.
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the UART_PWREMU_MGMT[13] URRST is cleared.
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in UART_FCR and the transmitter holding register empty interrupt is enabled in UART_IER, the interrupt mode is selected for the transmitter FIFO. The transmitter holding register empty interrupt occurs when the transmitter FIFO is empty. It is cleared when the UART_THR is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt).

Table 11-3496. Character Time for Word Lengths

Word Length (n)	Character Time	Four Character Times
5	Time for 8 bits	Time for 32 bits
6	Time for 9 bits	Time for 36 bits
7	Time for 10 bits	Time for 40 bits
8	Time for 11 bits	Time for 44 bits

11.18.4.3.1.2.1.2 FIFO Poll Mode

When the receiver FIFO is enabled in the UART_FCR and the receiver interrupts are disabled in the UART_IER, the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled and the transmitter interrupts are disabled, the transmitted FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the UART_LSR:

- The UART_LSR[7] RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The UART_LSR[6] TEMT bit indicates that both the transmitter holding register (UART_THR) and the transmitter shift register (UART_TSR) are empty.
- The UART_LSR[5] THRE bit indicates when UART_THR is empty.
- The UART_LSR[4] BI (break indicator), UART_LSR[3] FE (framing error), UART_LSR[2] PE (parity error), and UART_LSR[1] OE (overrun error) bits specify which error or errors have occurred.
- The UART_LSR[0] DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

Also, in the FIFO poll mode:

- The UART_IIR is not affected by any events because the interrupts are disabled.
- The UART does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

11.18.4.4 Protocol Formatting

The UART transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

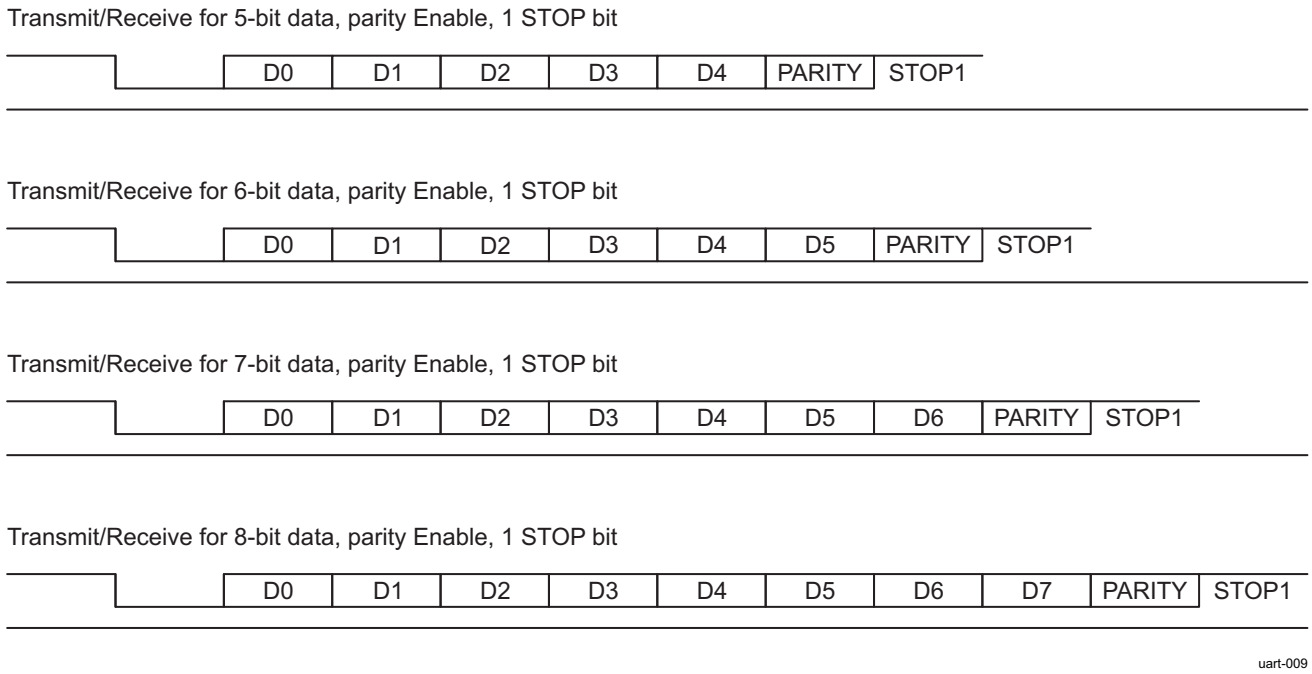
The UART receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in Figure 11-1429.

Figure 11-1429. UART Protocol Formats



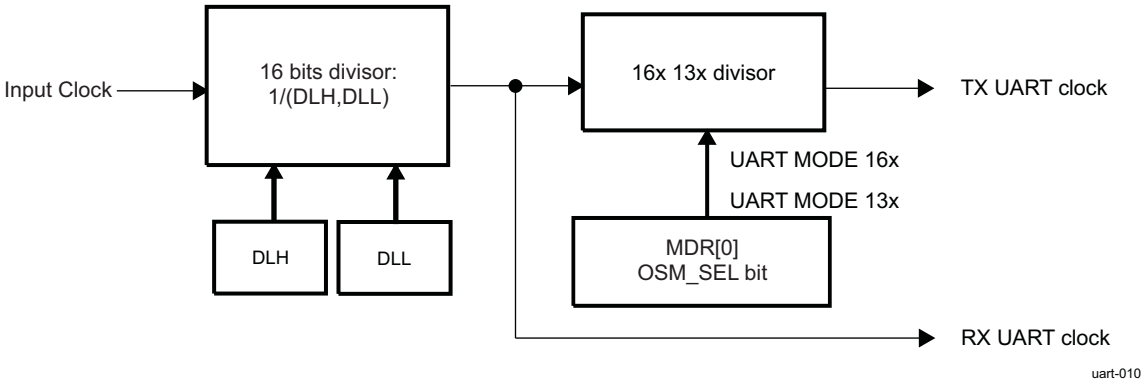
11.18.4.4.1 UART Mode

11.18.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the functional clock input down to the expected baud rate.

Figure 11-1430 shows the baud rate generator and associated controls.

Figure 11-1430. Baud Rate Generation



11.18.4.4.1.2 Choosing the Appropriate Divisor Value

Table 11-3497 describes the UART baud rate settings (192-MHz Clock).

Table 11-3497. UART Baud Rate Settings (192-MHz Clock)

Baud Rate	Baud Multiple	DLH, DLL (Decimal) (Divisor value)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)

11.18.4.4.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

11.18.4.4.1.3.1 Frame Formatting

Character length is specified using the UART_LCR[1-0] WLS bit field (see Table 11-3499).

The number of stop-bits is specified using the UART_LCR[2] STB bit (see Table 11-3499).

The parity bit is programmed using the UART_LCR[5-3] PEN, EPS, and SP bits (see Table 11-3498).

Table 11-3498. Relationship Between ST, EPS, and PEN Bits in UART_LCR

ST Bit	EPS Bit	PEN Bit	Parity Option
x	x	0	Parity disabled: No PARITY bit is transmitted or checked.
0	0	1	Odd parity selected: Odd number of logic 1s.
0	1	1	Even parity selected: Even number of logic 1s.
1	0	1	Stick parity selected with PARITY bit transmitted and checked as set.
1	1	1	Stick parity selected with PARITY bit transmitted and checked as cleared.

Table 11-3499. Number of STOP Bits Generated

ST Bit	WLS Bit	Word Length Selected with WLS Bits	Number of STOP Bits Generated	Baud Clock (BCLK) Cycles
0	x	Any word length	1	16
1	0h	5 bits	1.5	24
1	1h	6 bits	2	32
1	2h	7 bits	2	32
1	3h	8 bits	2	32

11.18.4.4.1.4 Operation

11.18.4.4.1.4.1 Transmission

The UART transmitter section includes a transmitter hold register (UART_THR) and a transmitter shift register (UART_TSR). When the UART is in the FIFO mode, UART_THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (UART_LCR). Based on the settings chosen in UART_LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

UART_THR receives data from the internal data bus, and when UART_TSR is ready, the UART moves the data from UART_THR to UART_TSR. The UART serializes the data in UART_TSR and transmits the data on the TX pin. In the non-FIFO mode, if UART_THR is empty and the UART_THR empty interrupt is enabled in the UART_IER, an interrupt is generated. This interrupt is cleared when a character is loaded into UART_THR. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO.

11.18.4.4.1.4.2 Reception

The UART receiver section includes a receiver shift register (UART_RSR) and a receiver buffer register (UART_RBR). When the UART is in the FIFO mode, UART_RBR is a 16-byte FIFO. Receiver section control is a function of the UART line control register (UART_LCR). Based on the settings chosen in UART_LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

UART_RSR receives the data bits from the RX pin. Then UART_RSR concatenates the data bits and moves the resulting value into UART_RBR (or the receiver FIFO). The UART also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in UART_RBR and the receiver data-ready interrupt is enabled in the UART_IER, an interrupt is generated. This interrupt is cleared when the character is read from UART_RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the UART_FCR, and it is cleared when the FIFO contents drop below the trigger level.

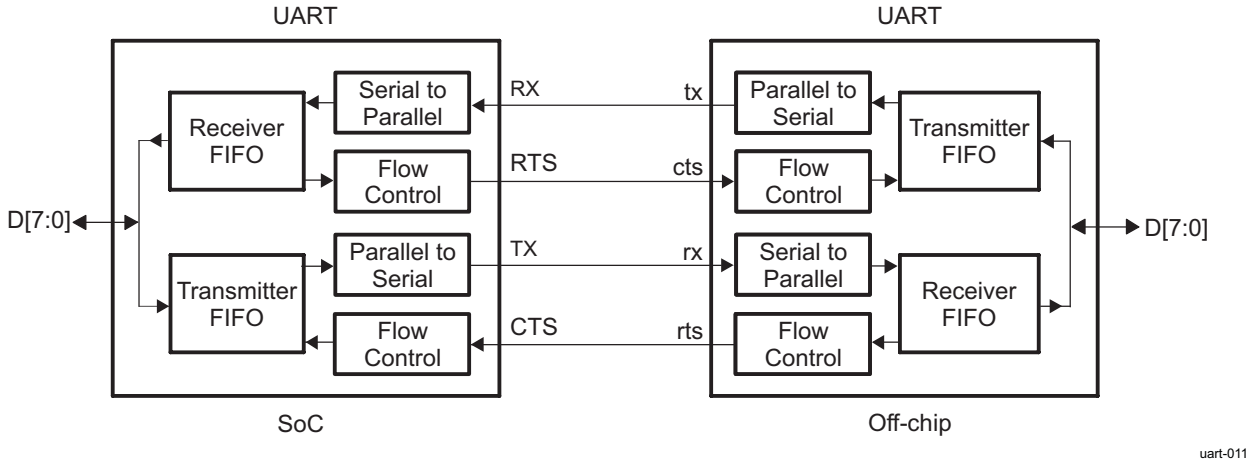
11.18.4.4.1.5 Hardware Flow Control

Hardware flow control is composed of RTS and CTS signals. They can be enabled and disabled by programming the UART_MCR[1] RTS and UART_MCR[5] AFE bit fields.

11.18.4.4.1.5.1 Autoflow Control

The UART can employ autoflow control by connecting the CTS and RTS signals. The CTS input must be active before the transmitter FIFO can transmit data. The RTS becomes active when the receiver needs more data and notifies the sending device. When RTS is connected to CTS, data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 11-1431 with autoflow enabled, overrun errors are eliminated.

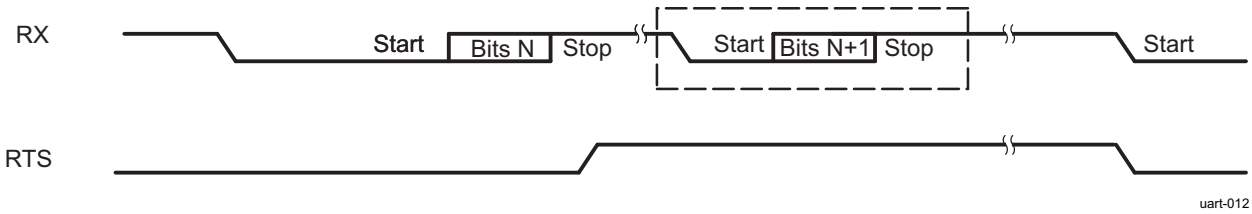
Figure 11-1431. Autoflow Control Example



11.18.4.4.1.5.1.1 RTS Behavior

The RTS data flow control originates in the receiver block (see Figure 11-1426). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see Figure 11-1432), RTS is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of RTS until after it has begun sending the additional byte. For trigger level 1, 4, and 8, RTS is automatically reasserted after the receiver FIFO is emptied. For trigger level 14, RTS is automatically reasserted when the receiver FIFO drops below the trigger level.

Figure 11-1432. Autoflow Functional Timing Waveforms for RTS



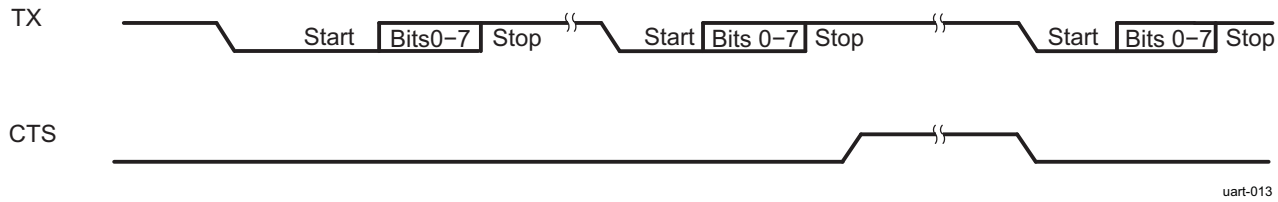
A The N = Receiver FIFO trigger level.

B The two blocks in dashed lines cover the case in which an additional byte is sent.

11.18.4.4.1.5.1.2 CTS Behavior

The transmitter checks CTS before sending the next data byte. If CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, CTS must be released before the middle of the last STOP bit that is currently being sent (see Figure 11-1433). When flow control is enabled, CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.

Figure 11-1433. Autoflow Functional Timing Waveforms for CTS



A When CTS is active (low), the transmitter keeps sending serial data out.

B When CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.

C When CTS goes from high to low, the transmitter begins sending data again.

11.18.4.4.1.5.2 Loopback Control

The UART can be placed in the diagnostic mode using the LOOP bit in the modem control register (UART_MCR), which internally connects the UART output back to the UART input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

11.18.4.4.1.5.3 Modem Signal Control

Modem signals RTS, DTR, OUT1, and OUT2 can be controlled and the modem signals CTS, DCD, DSR and RI can be observed by using the Modem Control Register (UART_MCR) and the Modem Status Register (UART_MSR), respectively. Modem control function of these inputs and outputs except for RTS and CTS must be implemented in software. RTS and CTS are used for autoflow control (see Section 11.18.4.4.1.5.1, *Autoflow Control* for details) and controlled by UART hardware in that mode.

11.18.4.4.1.6 Reset Considerations

11.18.4.4.1.6.1 Software Reset Considerations

Three bits in the UART_PWREMU_MGMT control resetting the parts of the UART:

- The UART_PWREMU_MGMT[15] URST bit resets both transmitter and receiver.
- The UART_PWREMU_MGMT[14] UTRST bit controls resetting the transmitter only.
- The UART_PWREMU_MGMT[13] URRST bit controls resetting the receiver only.

For backward compatibility, the UART_PWREMU_MGMT[14] UTRST and UART_PWREMU_MGMT[13] URRST are automatically set when the UART_PWREMU_MGMT[15] URST is set. Table 11-3500 shows truth table and functions of the three software reset bits. These software bits affect only transmitter and receiver, and they don't affect modem control signals. The control of modem signals are responsibility of software.

Table 11-3500. Software Reset Bit Truth Table

Write Data[15-13]	URST	UTRST	URRST	Transmitter	Receiver
000	0	0	0	Disabled	Disabled
001	0	0	1	Disabled	Enabled
010	0	1	0	Enabled	Disabled

Table 11-3500. Software Reset Bit Truth Table (continued)

Write Data[15-13]	URST	UTRST	URRST	Transmitter	Receiver
1xx	0	1	1	Enabled	Enabled

NOTE: RTS in auto-flow control mode must be taken care of especially. User must set UART_MCR[1] RTS bit after setting UART_PWREMU_MGMT[15] URST or UART_PWREMU_MGMT[13] URRST bit. Otherwise, UART_MCR[1] RTS output goes to low indicating the UART is read to receive data while the receiver of the UART is actually disabled.

11.18.4.4.2 Interrupt Support

11.18.4.4.2.1 Interrupt Events and Requests

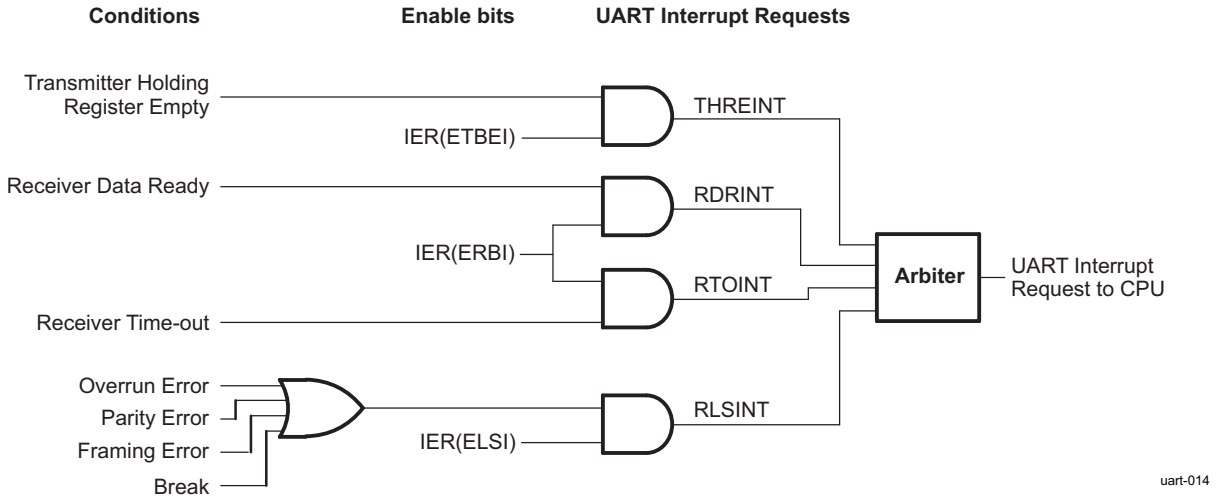
The UART generates the interrupt requests described in Table 11-3501. All requests are multiplexed through an arbiter to a single UART interrupt request to the CPU, as shown in Figure 11-1434. Each of the interrupt requests has an enable bit in the UART_IER and is recorded in the UART_IIR.

If an interrupt occurs and the corresponding enable bit is set to 1, the interrupt request is recorded in UART_IIR and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0, the interrupt request is blocked. The interrupt request is neither recorded in UART_IIR nor forwarded to the CPU.

Table 11-3501. UART Interrupt Requests Descriptions

UART Interrupt Request	Interrupt Source	Comment
THREINT	THR-empty condition: The UART_THR or the transmitter FIFO is empty. All of the data has been copied from UART_THR to the transmitter shift register (UART_TSR).	• If THREINT is enabled by setting the UART_IER[1] ETBEI bit, it is recorded in UART_IIR. • As an alternative to using THREINT, the CPU can poll the UART_LSR[5] THRE bit.
RDAINT	Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.	• If RDAINT is enabled by setting the UART_IER[0] ERBI bit, it is recorded in UART_IIR. • As an alternative to using RDAINT, the CPU can poll the UART_LSR[0] DR bit. In the FIFO mode, this is not a functionally equivalent alternative because the UART_LSR[0] DR bit does not respond to the FIFO trigger level. The UART_LSR[0] DR bit indicates only the presence or absence of unread characters.
RTOINT	Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 11-3496), and there is at least one character in the receiver FIFO during this time.	• The receiver time-out interrupt prevents the UART from waiting indefinitely when the receiver FIFO level is below the trigger level and, therefore, does not generate a receiver data-ready interrupt. • If RTOINT is enabled by setting the UART_IER[0] ERB bit, it is recorded in UART_IIR. • There is no status bit to reflect the occurrence of a time-out condition.
RLSINT	Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.	• If RLSINT is enabled by setting the UART_IER[2] ELSI bit, it is recorded in UART_IIR. • As an alternative to using RLSINT, the CPU can poll the following bits UART_LSR[1] OE, UART_LSR[2] PE, UART_LSR[3] FE, and UART_LSR[4] BI.

Figure 11-1434. UART Interrupt Request Enable Paths



11.18.4.4.3 DMA Event Support

In the FIFO mode, the UART generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the UART_FCR[7-6] RXFIFTL bit. Every time the trigger level is reached or a receiver time-out occurs, the UART sends a receive event to the EDMA controller. In response, the EDMA controller reads the data from the receiver FIFO by way of the UART_RBR.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the UART sends an UTXEVT signal to the EDMA controller. In response, the EDMA controller refills the transmitter FIFO by way of the UART_THR. The UTXEVT signal is also sent to the DMA controller when the UART is taken out of reset using the UART_PWREMU_MGMT[14] UTRST bit.

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the UART generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the UART event is generated. Otherwise, the DMA channel will miss the event and, unless the UART generates a new event, no data transfer will occur.

11.18.4.4.4 Module Power Management

The UART peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the UART peripheral is controlled by the Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device. When PSC requests the UART to be in idle, if a data is transferred, the UART transfers the data completely, asserts an interrupt or a DMA event if it is set up as it does so, and enter IDLE state. If no data is transferred, the UART enters IDLE state immediately. In the IDLE state, the UART holds state machines in the transmitter and the receiver to prevent them starting the next transfer. The transmitter and the receiver go into IDLE state independently except in loop back mode. For detailed information on power management procedures using the PSC, see Section 5.2, *Power Management* in *Device Configuration*.

11.18.4.4.5 Emulation Considerations

The UART_PWREMU_MGMT[0] FREE bit determines how the UART responds to an emulation suspend event such as an emulator halt or breakpoint. If UART_PWREMU_MGMT[0] FREE = 0 and a transmission is in progress, the UART halts after completing the one-word transmission; if UART_PWREMU_MGMT[0] FREE = 0 and a transmission is not in progress, the UART halts immediately. If UART_PWREMU_MGMT[0] FREE = 1, the UART does not halt and continues operating normally.

Note also that emulator accesses are essentially transparent to UART operation. Emulator read operations do not affect any register contents, status bits, or operating states. Emulator writes, however, may affect register contents and may affect UART operation, depending on what register is accessed and what value is written.

The UART registers can be read from or written to during emulation suspend events, even if the UART activity has stopped.

11.18.4.5 Exception Processing

11.18.4.5.1 Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

11.18.4.5.2 Changing Operating Mode During Busy Serial Communication

Since the serial link characteristics are based on how the control registers are programmed, the UART will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

11.18.5 UART Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This procedure ensures the quick start of the UART. It does not cover every UART feature.

11.18.5.1 Global Initialization

11.18.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the UART. Refer to the UART Module Integration and Environment Sections for further information.

Table 11-3502. Global Initialization of Surrounding Modules for UART

Surrounding Modules	Comments
CIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling CIC interrupts, see Chapter 9, *Interrupts*.
ARM_GIC	Device INTCs must be configured to enable the interrupt request generation. For information about enabling ARM_GIC interrupts, see Section 6.1, *Arm Cortex-A15 Subsystem*.
EDMACC_0	DMA controllers configuration must be done to enable the module DMA channel request. See Chapter 10, *DMA Controllers*.
LPSC6	Module reset must be enabled. For more information about the module configuration, see Section 5.2, *Power Management*.
UART PLL	UART PLL configuration must be done to enable the clocks to the UART modules. See Section 5.4.5.3, *PLL Controller*.

11.18.5.1.1.1 UART Module Global Initialization

The following steps are required to initialize the UART:

Table 11-3503. Global Initialization of UART

Step	Register/Bit Field/Programming Model	Value
Set the desired baud rate by writing the appropriate clock divisor values.	UART_DLL[7-0] DLL and UART_DLH[7-0] DLH See Table 11-3497, *UART Baud Rate Settings (192-MHz Clock)*	-h and -h
If the FIFOs will be used, select the desired trigger level and enable the FIFOs by writing the appropriate values to the UART_FCR. **NOTE:** UART_FCR[0] FIFOEN bit must be set first, before the other bits in UART_FCR are configured.	UART_FCR[7-6] RXFIFTL	-h
Choose the desired protocol settings by writing the appropriate values to the UART_LCR.	See Table 11-3498 and Table 11-3499	-h
If autoflow control is desired set Autoflow control enable bit.	UART_MCR[5] AFE	1h
Also write the appropriate values to the RTS control bit.	UART_MCR[1] RTS	-h
Choose the desired response to emulation suspend events.	Configure UART_PWREMU_MGMT[0] FREE bit	-h
Enable the UART.	Set the UART_PWREMU_MGMT[15] URST and UART_PWREMU_MGMT[14] UTRST bits	-h

11.18.6 UART Registers

Table 11-3505 lists the memory-mapped registers for the UART. All register offset addresses not listed in Table 11-3505 should be considered as reserved locations and the register contents should not be modified.

Table 11-3504. UART Instances

11.18.6.1 UART_RBR Register (Offset = 0h) [reset = 0h]

UART_RBR is shown in Figure 11-1435 and described in Table 11-3507.

The UART receiver section consists of a receiver shift register (UART_RSR) and a receiver buffer register (UART_RBR). When the UART is in the FIFO mode, UART_RBR is a 16-byte FIFO. Timing is supplied by the 16× receiver clock or 13× receiver clock by programming UART_MDR[0] OSM_SEL bit. Receiver section control is a function of the UART_LCR.

The UART_RSR receives serial data from the RX pin. Then the UART_RSR concatenates the data and moves it into the UART_RBR (or the receiver FIFO). In the non-FIFO mode, when a character is placed in UART_RBR and the receiver data-ready interrupt is enabled (UART_IER[0] DR = 1), an interrupt is generated. This interrupt is cleared when the character is read from the UART_RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the UART_FCR, and it is cleared when the FIFO contents drop below the trigger level.

Access considerations:

- The UART_RBR, UART_THR, and UART_DLL share one address. To read the UART_RBR, write 0 to the UART_LCR[7] DLAB bit, and read from the shared address. When UART_LCR[7] DLAB = 0, writing to the shared address modifies the UART_THR. When UART_LCR[7] DLAB = 1, all accesses at the shared address read or modify the UART_DLL.
- The UART_DLL also has a dedicated address. If the dedicated address is used, UART_LCR[7] DLAB can = 0, so that the UART_RBR and UART_THR are always selected at the shared address.

11.18.6.2 UART_THR Register (Offset = 0h) [reset = 0h]

UART_THR is shown in Figure 11-1436 and described in Table 11-3510.

The UART transmitter section consists of a transmitter hold register (UART_THR) and a transmitter shift register (UART_TSR). Transmitter control is a function of the UART_LCR.

The UART_THR receives data from the internal data bus. When the UART_TSR is idle the UART then moves the data from the UART_THR to the UART_TSR. The UART serializes the data in the UART_TSR and transmits the data on the TX pin.

In the non-FIFO mode, if the UART_THR and UART_TSR is empty and the THRE interrupt is enabled (UART_IER[1] ETBEI = 1), then an interrupt is generated. This interrupt is cleared when a character is loaded into the UART_THR.

When the UART is in the FIFO mode, the UART_THR is a 16-byte FIFO. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO.

Access considerations:

- The UART_RBR, UART_THR, and UART_DLL share one address. To load the UART_THR, write 0 to the UART_LCR[7] DLAB bit, and write to the shared address. When UART_LCR[7] DLAB = 0, reading from the shared address gives the content of the UART_RBR. When UART_LCR[7] DLAB = 1, all accesses at the address read or modify the UART_DLL.
- The UART_DLL also has a dedicated address. If the dedicated address is used, UART_LCR[7] DLAB can = 0, so that the UART_RBR and the UART_THR are always selected at the shared address.

11.18.6.3 UART_IER Register (Offset = 4h) [reset = 0h]

UART_IER is shown in Figure 11-1437 and described in Table 11-3513.

The interrupt enable register (UART_IER) is used to individually enable or disable each type of interrupt request that can be generated by the UART. Each interrupt request that is enabled in the UART_IER is forwarded to the CPU.

Access considerations:

- The UART_IER and UART_DLH share one address. To read or modify the UART_IER, write 0 to the UART_LCR[7] DLAB bit. When UART_LCR[7] DLAB = 1, all accesses at the shared address read or modify the UART_DLH.
- The UART_DLH also has a dedicated address. If the dedicated address is used, UART_LCR[7] DLAB can = 0, so that the UART_IER is always selected at the shared address.

11.18.6.4 UART_IIR Register (Offset = 8h) [reset = 1h]

UART_IIR is shown in Figure 11-1438 and described in Table 11-3516.

The interrupt identification register (UART_IIR) is a read-only register at the same address as the UART_FCR, which is a write-only register. When an interrupt is generated and enabled in the UART_IER, the UART_IIR indicates that an interrupt is pending in the UART_IIR[0] IPEND bit and encodes the type of interrupt in the UART_IIR[3-1] INTID bits.

The UART has an on-chip interrupt generation and prioritization capability that permits flexible communication with the CPU. The UART provides four priority levels of interrupts:

- Priority 1 - Receiver line status (highest priority)
- Priority 2 - Receiver data ready or receiver timeout
- Priority 3 - Transmitter holding register empty
- Priority 4 - Modem status (lowest priority)

The UART_IIR[7-6] FIFOEN bit field can be checked to determine whether the UART is in the FIFO mode or the non-FIFO mode.

Access considerations:

- The UART_IIR and UART_FCR share one address. Regardless of the value of the UART_LCR[7] DLAB bit, reading from the address gives the content of the UART_IIR, and writing to the address modifies the UART_FCR.

UART Functional Description • FIFO Management: [0] • Interrupt Events and Requests: [0][1][2][3][4][5][6]

11.18.6.5 UART_FCR Register (Offset = 8h) [reset = 0h]

UART_FCR is shown in Figure 11-1439 and described in Table 11-3519.

The FIFO control register (UART_FCR) is a write-only register at the same address as the interrupt identification register (UART_IIR), which is a read-only register. Use the UART_FCR to enable and clear the FIFOs and to select the receiver FIFO trigger level. The FIFOEN bit must be set to 1 before other UART_FCR bits are written to or the UART_FCR bits are not programmed.

Access considerations:

- The UART_IIR and UART_FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of the UART_IIR, and writing to the address modifies the UART_FCR.

CAUTION

For proper communication between the UART and the EDMA controller, the DMAMODE1 bit must be set to 1. Always write a 1 to the DMAMODE1 bit, and after a hardware reset, change the DMAMODE1 bit from 0 to 1.

Table 11-3518. UART_FCR Instances

Instance	Physical Address

11.18.6.6 UART_LCR Register (Offset = Ch) [reset = 0h]

UART_LCR is shown in Figure 11-1440 and described in Table 11-3522.

The system programmer controls the format of the asynchronous data communication exchange by using the line control register (UART_LCR). In addition, the programmer can retrieve, inspect, and modify the content of the UART_LCR. This eliminates the need for separate storage of the line characteristics in system memory.

Table 11-3521. UART_LCR Instances

Instance	Physical Address

Table 11-3522. UART_LCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved.
7	DLAB	R/W	0h	Divisor latch access bit. The divisor latch registers (UART_DLL and UART_DLH) can be accessed at dedicated addresses or at addresses shared by UART_RBR, UART_THR, and UART_IER. Using the shared addresses requires toggling DLAB to change which registers are selected. If the dedicated addresses are used, DLAB can = 0. 0 = Allows access to the receiver buffer register (UART_RBR), the transmitter holding register (UART_THR), and the interrupt enable register (UART_IER) selected. At the address shared by UART_RBR, UART_THR, and UART_IER, the CPU can read from UART_RBR and write to UART_THR. At the address shared by UART_IER and UART_DLH, the CPU can read from and write to UART_IER. 1 = Allows access to the divisor latches of the baud generator during a read or write operation (UART_DLL and UART_DLH). At the address shared by UART_RBR, UART_THR, and UART_DLL, the CPU can read from and write to UART_DLL. At the address shared by UART_IER and UART_DLH, the CPU can read from and write to UART_DLH.
6	BC	R/W	0h	Break control. 0 = Break condition is disabled. 1 = Break condition is transmitted to the receiving UART. A break condition is a condition in which the TX signal is forced to the spacing (cleared) state.

Table 11-3522. UART_LCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SP	R/W	0h	Stick parity. The SP bit works in conjunction with the EPS and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0 = Stick parity is disabled. 1 = Stick parity is enabled. When odd parity is selected (EPS = 0), the PARITY bit is transmitted and checked as set. When even parity is selected (EPS = 1), the PARITY bit is transmitted and checked as cleared.
4	EPS	R/W	0h	Even parity select. Selects the parity when parity is enabled (PEN = 1). The EPS bit works in conjunction with the SP and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0 = Odd parity is selected (an odd number of logic 1s is transmitted or checked in the data and PARITY bits). 1 = Even parity is selected (an even number of logic 1s is transmitted or checked in the data and PARITY bits).
3	PEN	R/W	0h	Parity enable. The PEN bit works in conjunction with the SP and EPS bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 11-3498. 0 = No PARITY bit is transmitted or checked. 1 = Parity bit is generated in transmitted data and is checked in received data between the last data word bit and the first STOP bit.
2	STB	R/W	0h	Number of STOP bits generated. STB specifies 1, 1.5, or 2 STOP bits in each transmitted character. When STB = 1, the WLS bit determines the number of STOP bits. The receiver clocks only the first STOP bit, regardless of the number of STOP bits selected. The number of STOP bits generated is summarized in Table 11-3499. 0 = One STOP bit is generated. 1 = WLS bit determines the number of STOP bits: • When WLS = 0, 1.5 STOP bits are generated. • When WLS = 1h, 2h, or 3h, 2 STOP bits are generated.
1-0	WLS	R/W	0h	Word length select. Number of bits in each transmitted or received serial character. When STB = 1, the WLS bit determines the number of STOP bits. 0h = 5 bits 1h = 6 bits 2h = 7 bits 3h = 8 bits

11.18.6.7 UART_MCR Register (Offset = 10h) [reset = 0h]

UART_MCR is shown in Figure 11-1441 and described in Table 11-3525.

The modem control register (UART_MCR) provides the ability to enable/disable the autoflow functions, and enable/disable the loopback function for diagnostic purposes.

Table 11-3524. UART_MCR Instances

Instance	Physical Address
UART_0	0253 0C10h
UART_1	0253 1010h
UART_2	0253 1410h

Table 11-3525. UART_MCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	Reserved
5	AFE	R/W	0h	Autoflow control enable. Autoflow control allows the RTS and CTS signals to provide handshaking between UARTs during data transfer. When AFE = 1, the RTS bit determines the autoflow control enabled. 0 = Autoflow control is disabled. 1 = Autoflow control is enabled: • When RTS = 0, only CTS is enabled. • When RTS = 1, RTS and CTS are enabled.
4	LOOP	R/W	0h	Loopback mode enable. LOOP is used for the diagnostic testing using the loopback feature. 0 = Loopback mode is disabled. 1 = Loopback mode is enabled. When LOOP is set, the following occur: • The TX signal is set high. • The RX pin is disconnected • The output of the transmitter shift register (UART_TSR) is looped back in to the receiver shift register (UART_RSR) input.
3	OUT2	R/W	0h	OUT2 Control Bit.
2	OUT1	R/W	0h	OUT1 Control Bit.
1	RTS	R/W	0h	RTS control. When AFE = 1, the RTS bit determines the autoflow control enabled. 0 = RTS is disabled, only CTS is enabled. 1 = RTS and CTS are enabled.

11.18.6.8 UART_LSR Register (Offset = 14h) [reset = 60h]

UART_LSR is shown in Figure 11-1442 and described in Table 11-3528.

The line status register (UART_LSR) provides information to the CPU concerning the status of data transfers. It is intended for read operations only — do not write to this register. Bits 1 through 4 record the error conditions that produce a receiver line status interrupt.

Table 11-3527. UART_LSR Instances

Instance	Physical Address

Table 11-3528. UART_LSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7	RXFIFOE	R	0h	Receiver FIFO error. **In non-FIFO mode:** 0 = There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver buffer register (UART_RBR). 1 = There is a parity error, framing error, or break indicator in the receiver buffer register (UART_RBR). **In FIFO mode:** 0 = There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver FIFO and there are no more errors in the receiver FIFO. 1 = At least one parity error, framing error, or break indicator in the receiver FIFO.

Table 11-3528. UART_LSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	TEMT	R	1h	Transmitter empty (TEMT) indicator. **In non-FIFO mode:** 0 = Either the transmitter holding register (UART_THR) or the transmitter shift register (UART_TSR) contains a data character. 1 = Both the transmitter holding register (UART_THR) and the transmitter shift register (UART_TSR) are empty. **In FIFO mode:** 0 = Either the transmitter FIFO or the transmitter shift register (UART_TSR) contains a data character. 1 = Both the transmitter FIFO and the transmitter shift register (UART_TSR) are empty.
5	THRE	R	1h	Transmitter holding register empty (THRE) indicator. If the THRE bit is set and the corresponding interrupt enable bit is set (ETBEI = 1 in UART_IER), an interrupt request is generated. **In non-FIFO mode:** 0 = Transmitter holding register (UART_THR) is not empty. UART_THR has been loaded by the CPU. 1 = Transmitter holding register (UART_THR) is empty (ready to accept a new character). The content of UART_THR has been transferred to the transmitter shift register (UART_TSR). **In FIFO mode:** 0 = Transmitter FIFO is not empty. At least one character has been written to the transmitter FIFO. The transmitter FIFO may be written to if it is not full. 1 = Transmitter FIFO is empty. The last character in the FIFO has been transferred to the transmitter shift register (UART_TSR).
4	BI	R	0h	Break indicator. The BI bit is set whenever the receive data input (RX) was held low for longer than a fullword transmission time. A full-word transmission time is defined as the total time to transmit the START, data, PARITY, and STOP bits. If the BI bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in UART_IER), an interrupt request is generated. **In non-FIFO mode:** 0 = No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver buffer register (UART_RBR). 1 = A break has been detected with the character in the receiver buffer register (UART_RBR). **In FIFO mode:** 0 = No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver FIFO and the next character to be read from the FIFO has no break indicator. 1 = A break has been detected with the character at the top of the receiver FIFO.

Table 11-3528. UART_LSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	FE	R	0h	Framing error (FE) indicator. A framing error occurs when the received character does not have a valid STOP bit. In response to a framing error, the UART sets the FE bit and waits until the signal on the RX pin goes high. When the RX signal goes high, the receiver is ready to detect a new START bit and receive new data. If the FE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in UART_RBR), an interrupt request is generated. **In non-FIFO mode:** 0 = No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver buffer register (UART_RBR). 1 = A framing error has been detected with the character in the receiver buffer register (UART_RBR). **In FIFO mode:** 0 = No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no framing error. 1 = A framing error has been detected with the character at the top of the receiver FIFO.
2	PE	R	0h	Parity error (PE) indicator. A parity error occurs when the parity of the received character does not match the parity selected with the EPS bit in the line control register (UART_LCR). If the PE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in UART_IER), an interrupt request is generated. **In non-FIFO mode:** 0 = No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver buffer register (UART_RBR). 1 = A parity error has been detected with the character in the receiver buffer register (UART_RBR). **In FIFO mode:** 0 = No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no parity error. 1 = A parity error has been detected with the character at the top of the receiver FIFO.
1	OE	R	0h	Overrun error (OE) indicator. An overrun error in the non-FIFO mode is different from an overrun error in the FIFO mode. If the OE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in UART_IER), an interrupt request is generated. **In non-FIFO mode:** 0 = No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (UART_LSR). 1 = Overrun error has been detected. Before the character in the receiver buffer register (UART_RBR) could be read, it was overwritten by the next character arriving in UART_RBR. **In FIFO mode:** 0 = No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (UART_LSR). 1 = Overrun error has been detected. If data continues to fill the FIFO beyond the trigger level, an overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. An overrun error is indicated to the CPU as soon as it happens. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.

Table 11-3528. UART_LSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DR	R	0h	Data-ready (DR) indicator for the receiver. If the DR bit is set and the corresponding interrupt enable bit is set (ERBI = 1 in UART_IER), an interrupt request is generated. **In non-FIFO mode:** 0 = Data is not ready, or the DR bit was cleared because the character was read from the receiver buffer register (UART_RBR). 1 = Data is ready. A complete incoming character has been received and transferred into the receiver buffer register (UART_RBR). **In FIFO mode:** 0 = Data is not ready, or the DR bit was cleared because all of the characters in the receiver FIFO have been read.. 1 = Data is ready. There is at least one unread character in the receiver FIFO. If the FIFO is empty, the DR bit is set as soon as a complete incoming character has been received and transferred into the FIFO. The DR bit remains set until the FIFO is empty again.

11.18.6.9 UART_MSR Register (Offset = 18h) [reset = 000000-0h]

UART_MSR is shown in Figure 11-1443 and described in Table 11-3531.

The modem status register (UART_MSR) provides information to the CPU concerning the status of modem control signals. It is intended for read operations only — do not write to this register.

Table 11-3530. UART_MSR Instances

Instance	Physical Address
UART_0	0253 0C18h
UART_1	0253 1018h

Table 11-3531. UART_MSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7	CD	R	-h	Complement of the Carrier Detect input. When the UART is in the diagnostic test mode (loopback mode UART_MCR[4] = 1), this bit is equal to the UART_MCR bit 3 (OUT2).
6	RI	R	-h	Complement of the Ring Indicator input. When the UART is in the diagnostic test mode (loopback mode UART_MCR[4] = 1), this bit is equal to the UART_MCR bit 2 (OUT1)
5	DSR	R	-h	Complement of the Data Set Ready input. When the UART is in the diagnostic test mode (loopback mode UART_MCR[4] = 1), this bit is equal to the UART_MCR bit 0 (DTR).
4	CTS	R	-h	Complement of the Clear To Send input. When the UART is in the diagnostic test mode (loopback mode UART_MCR[4] = 1), this bit is equal to the UART_MCR bit 1 (RTS).
3	DCD	R	0h	Change in DCD indicator bit. DCD indicates that the DCD input has changed state since the last time it was read by the CPU. When DCD is set and the modem status interrupt is enabled, a modem status interrupt is generated.
2	TERI	R	0h	Trailing edge of RI (TERI) indicator bit. TERI indicates that the RI input has changed from a low to a high. When TERI is set and the modem status interrupt is enabled, a modem status interrupt is generated.
1	DDSR	R	0h	Change in DSR indicator bit. DDSR indicates that the DSR input has changed state since the last time it was read by the CPU. When DDSR is set and the modem status interrupt is enabled, a modem status interrupt is generated.

Table 11-3531. UART_MSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	DCTS	R	0h	Change in CTS indicator bit. DCTS indicates that the CTS input has changed state since the last time it was read by the CPU. When DCTS is set (autoflow control is not enabled and the modem status interrupt is enabled), a modem status interrupt is generated. When autoflow control is enabled, no interrupt is generated.

Table 11-3535. Register Call Summary for UART_SCR

UART Registers
- UART Registers: [0]
- UART_SCR Register (Offset = 1Ch) [reset = 0h]: [0][1]

11.18.6.11 UART_DLL Register (Offset = 20h) [reset = 0h]

UART_DLL is shown in Figure 11-1445 and described in Table 11-3537.

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. The latches are in the UART_DLH and UART_DLL. The UART_DLH holds the most-significant bits of the divisor, and the UART_DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Access considerations:

- The UART_RBR, UART_THR, and UART_DLL share one address. When DLAB = 1 in the UART_LCR, all accesses at the shared address are accesses to the UART_DLL. When DLAB = 0, reading from the shared address gives the content of the UART_RBR, and writing to the shared address modifies the UART_THR.
- The UART_IER and UART_DLH share one address. When DLAB = 1 in the UART_LCR, accesses to the shared address read or modify the UART_DLH. When DLAB = 0, all accesses at the shared address read or modify the UART_IER.

The UART_DLL and UART_DLH also have dedicated addresses. If dedicated addresses are used, the DLAB bit can be kept cleared, so that the UART_RBR, UART_THR, and UART_IER are always selected at the shared addresses.

11.19 Universal Serial Bus Subsystem (USB)

This section describes the USB 2.0 Dual-Role-Device (DRD) subsystem of the device.

NOTE: This chapter serves to describe the integration of the third party USB subsystem and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact your TI sales representative for more information on how to obtain the third party documentation under NDA.

NOTE: The supported set of features and peripherals is device part number dependent. For more information, see the device Data Manual.

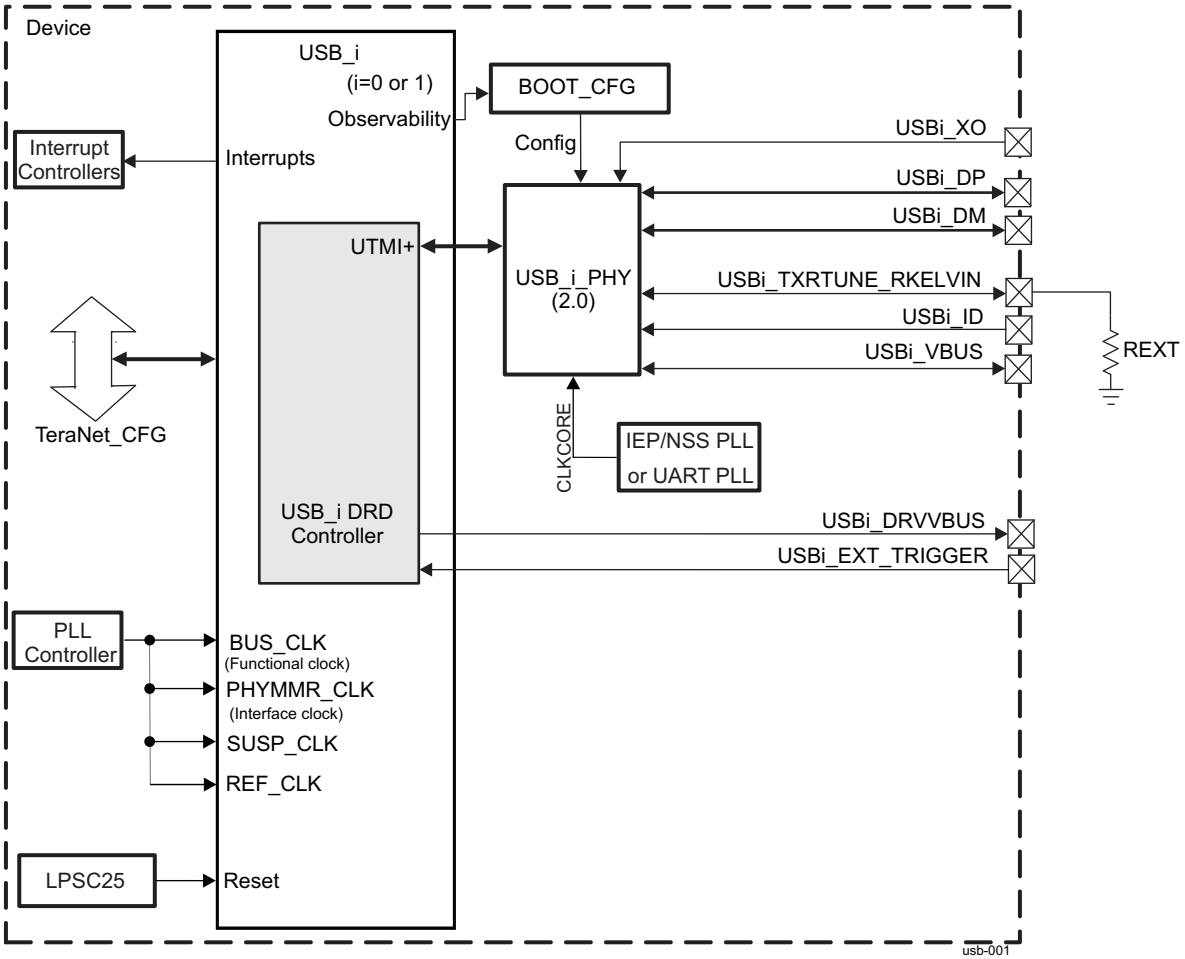
11.19.1 USB Overview

Similar to earlier versions of USB bus, USB 2.0 is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals.

The device supports two USB 2.0 subsystems with High Speed Dual-Role-Device (DRD) ports with integrated PHY.

Figure 11-1450 shows the USB module highlights.

Figure 11-1450. USB Overview



11.19.1.1 Terminology

The following acronyms and abbreviations are used in the document.

Term	Definition
A-dev	A USB device with an A-plug connected to its port (ID pin grounded). Default host
ACA	Accessory Charger Adaptor
ADP	Attach Detection Protocol: detects USB OTG attach/detach events.
B-dev	A USB device with a B-plug connected to its port (ID pin floating). Default peripheral.
BER	Bit Error Rate.
CDC	Communication Device Class: USB device class.
DRD	Dual Role Device: USB Host and Peripheral capable.
DS	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
EOP	End of Packet
EP	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
FS	Full-Speed USB data rate (12 Mbps).
HCD	Host Controller Driver, designates the USB SW.
HNP	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
HS	High-Speed USB data rate (480 Mbps).
ISOCH	Isochronous transfer type.
ITP	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
J	Logical USB2 line level: Diff1 in HS/FS, Diff0 in LS. Idle FS/LS bus state.
K	Logical USB2 line level: Diff0 in HS/FS, Diff1 in LS. Resume bus state.
LFPS	Low-Frequency Periodic Signal.
LMP	Link Management Packet.
LS	Low-Speed USB data rate (1.5 Mbps).
MSC	Mass Storage Class.
OTG	On-The-Go extension to USB protocol.
PHY	Physical Layer Device.
PIPE	PHY Interface for PCI Express.
SDR	Single Data Rate.
SE	Single-Ended: USB state based on individual lines' state (D+/D-).
SE0	Single-Ended zero line state where D+=D-=0. Used for reset, FS/LS EOP.
SER	Soft Error Rate.
SOF	Start Of Frame.
SRP	Session Request Protocol. OTG extension to wake-up a system, allowing a B-device to request an A-device to turn on the VBUS power and start session.
SS	Super Speed
TRB	Transfer Request Block.
TX	Transmit.
UAS	USB-Attached SCSI: ANSI standard for USB-attached storage.
ULPI	UTMI+ Low Pin count Interface.
US	Upstream facing from a device (or hub) to the host (or a hub).
USB	Universal Serial Bus.
USB IF	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. www.usb.org
UTMI	USB 2.0 PHY Transceiver Macrocell Interface specification.
UTMI+	UTMI plus extensions to the UTMI spec. Among other improvements, it defines the PHY interface.
xHC	Host Controller, designates the USB HW that implements the xHCI specification.
xHCI	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

11.19.1.2 Main Features

The USB 2.0 subsystem, supports the following USB features:

- Dual-role-device (DRD) capability:
  - Supports USB 2.0 Peripheral (or Device) mode at Highspeed (480 Mbps) and Fullspeed (12 Mbps)
  - Supports USB 2.0 Host mode at Highspeed (480 Mbps), Fullspeed (12 Mbps), and Lowspeed (1.5 Mbps)
  - USB 2.0 static peripheral operation
  - USB 2.0 static host operation
  - xHCI Debug Capability
  - External Buffer Control (EBC) mode for IN (Tx) Endpoint
- Each controller instance contains single xHCI with the following features:
  - Compatible to the xHCI specification (revision 1.1) in Host mode
  - Supports 15 Transmit (TX), 15 Receive (RX) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal DMA controller
  - Interrupt moderation and blocking
  - Supports for all USB transfer modes - Control, Bulk, Interrupt, and Isochronous
  - Supports high bandwidth ISO mode
  - Descriptor caching and data pre-fetching used to improve system performance
  - Dynamic FIFO memory allocation for all endpoints
- Operation flexibility:
  - Uniform programming model for HS, FS, and LS operation
  - Multiple interrupt lines:
    - 16 interrupts associated with 16 programmable Event Rings for multi-core support
    - A MISC interrupt line for all miscellaneous events
- ECC RAM
- External requirements:
  - An external charge pump for VBUS 5 V generation
  - An external reference clock input for USB PHY operation
  - An external high-precision resistor for internal PHY termination calibration

The following are USB features which are not supported:

- USB 3.0 SuperSpeed (5Gbps) or USB3.1 SuperSpeed+ (10Gbps) operation in either host or device modes
- OTG Functionality
- HSIC (High Speed inter-chip)
- ULPI Interface for external PHY
- Battery Charger Support
- Accessory Charger Adaptor Support
- xHCI Virtualization
- Hibernation (separate power domain for wake up from USB and save/ restore on wakeup) mode
- External Buffer Control (EBC) for OUT (Rx) Endpoint

11.19.2 USB Environment

11.19.2.1 USB Subsystem I/O Environment

Figure 11-1451 shows the I/O interface signals of the USB subsystem.

Figure 11-1451. USB Subsystem Environment

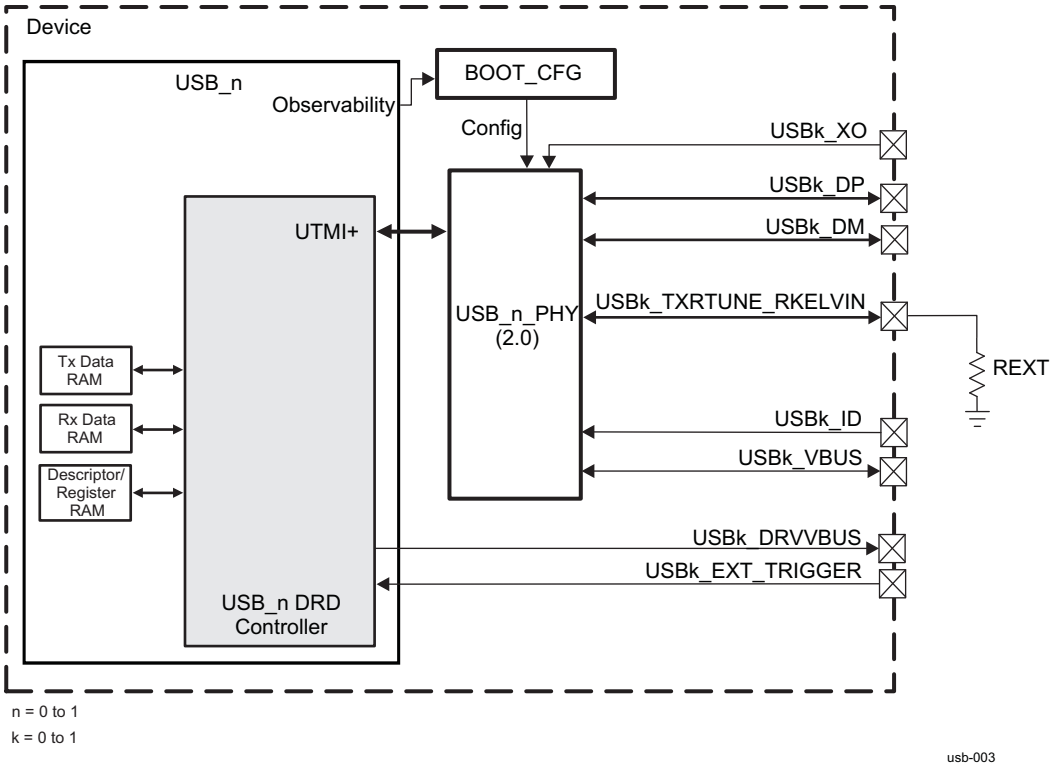


Table 11-3551 describes the external signals of the USB_0 module.

Table 11-3551. USB_0 Input/Output Description

Module Pin	Device Signal	I/O[1]	Description	Value at Reset
USB_0_PHY (2.0)				
USB0XO	USB0_XO	I	Crystal oscillator XO pin or Board Clock Reference Input.	HiZ
USB0DP	USB0_DP	I/O	USB 2.0 and 1.1 specification-compliant signal pins. These are HS/FS/LS bidirectional differential data pins.	HiZ
USB0DM	USB0_DM	I/O		HiZ
USB0ID	USB0_ID	I	USB mini-receptacle identifier. ID Pin with internal pull-up.	A
USBV0BUS	USB0_VBUS	I/O	An analog input for monitoring the voltage on VBUS.	A
USB0RESREF	USB0_TXRTUNE_RKELVIN	I/O	Termination Training Resistor. It is intended to connect an external resistor (REXT) to ground for internal USB 2.0 PHY termination calibration.	A
USB_0 DRD Controller				
USB0DRVVBUS	USB0_DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump to supply +5V power to the VBUS port of the device as well as the VBUS port of the USB receptacle, when appropriate per the USB standard.	0
USB0EXTTRIGGER	USB0_EXT_TRIGGER	I	External trigger for tracing data.	0

(1) I = Input; O = Output

Table 11-3552 describes the external signal of the USB_1 module.

Table 11-3552. USB_1 Input/Output Description

Module Pin	Device Signal	I/O[1]	Description	Value at Reset
USB_1_PHY (2.0)				
USB1XO	USB1_XO	I	Crystal oscillator XO pin or Board Clock Reference Input.	HiZ
USB1DP	USB1_DP	I/O	USB 2.0 and 1.1 specification-compliant signal pins. These are HS/FS/LS bidirectional differential data pins.	HiZ
USB1DM	USB1_DM	I/O		HiZ
USB1ID	USB1_ID	I	USB mini-receptacle identifier. ID Pin with internal pull-up.	A
USBV1BUS	USB1_VBUS	I/O	An analog input for monitoring the voltage on VBUS.	A
USB1RESREF	USB1_TXRTUNE_RKELVIN	I/O	Termination Training Resistor. It is intended to connect an external resistor (REXT) to ground for internal USB 2.0 PHY termination calibration.	A
USB_1 DRD Controller				
USB1DRVVBUS	USB1_DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump to supply +5V power to the VBUS port of the device as well as the VBUS port of the USB receptacle, when appropriate per the USB standard.	0
USB1EXTTRIGGER	USB1_EXT_TRIGGER	I	External trigger for tracing data.	0

(1) I = Input; O = Output

11.19.3 USB2.0 Subsystem Application

As the USB controller modules present in this device are DRD (Dual-Role Devices), they can support operation as either a USB Host or a USB Device. The operational mode determination is made based on the state of the USBn_ID pin; when this pin is grounded, the controller will operate as a USB Host, when this pin is left floating, the controller assumes the role of a USB Device. For implementations that do not require DRD functionality, the USBn_ID pin can either be left floating or can be grounded in the board design depending on the static role required. For implementations that do require DRD functionality, the USBn_ID pin should be connected directly to the corresponding ID pin on a USB Micro-AB socket. In doing so, the USBn_ID pin will be correctly terminated (open or grounded) depending on the cable attached and the controller will enter Host or Device mode accordingly.

Figure 11-1452 shows typical application of the USB_0 controller in the USB2.0 DRD (dual-role-device) mode. The power switch drives 5-V VBUS when required by monitoring the USB0_DRV_VBUS output from the USB controller.

11.19.4 USB Integration

This section describes USB2.0 module integration in the device, including information about clocks, resets, and hardware requests.

NOTE: USB 2.0 OTG is not supported for this device.

Figure 11-1458 shows the integration of the USB_0 module in the device.

Figure 11-1458. USB_0 Integration

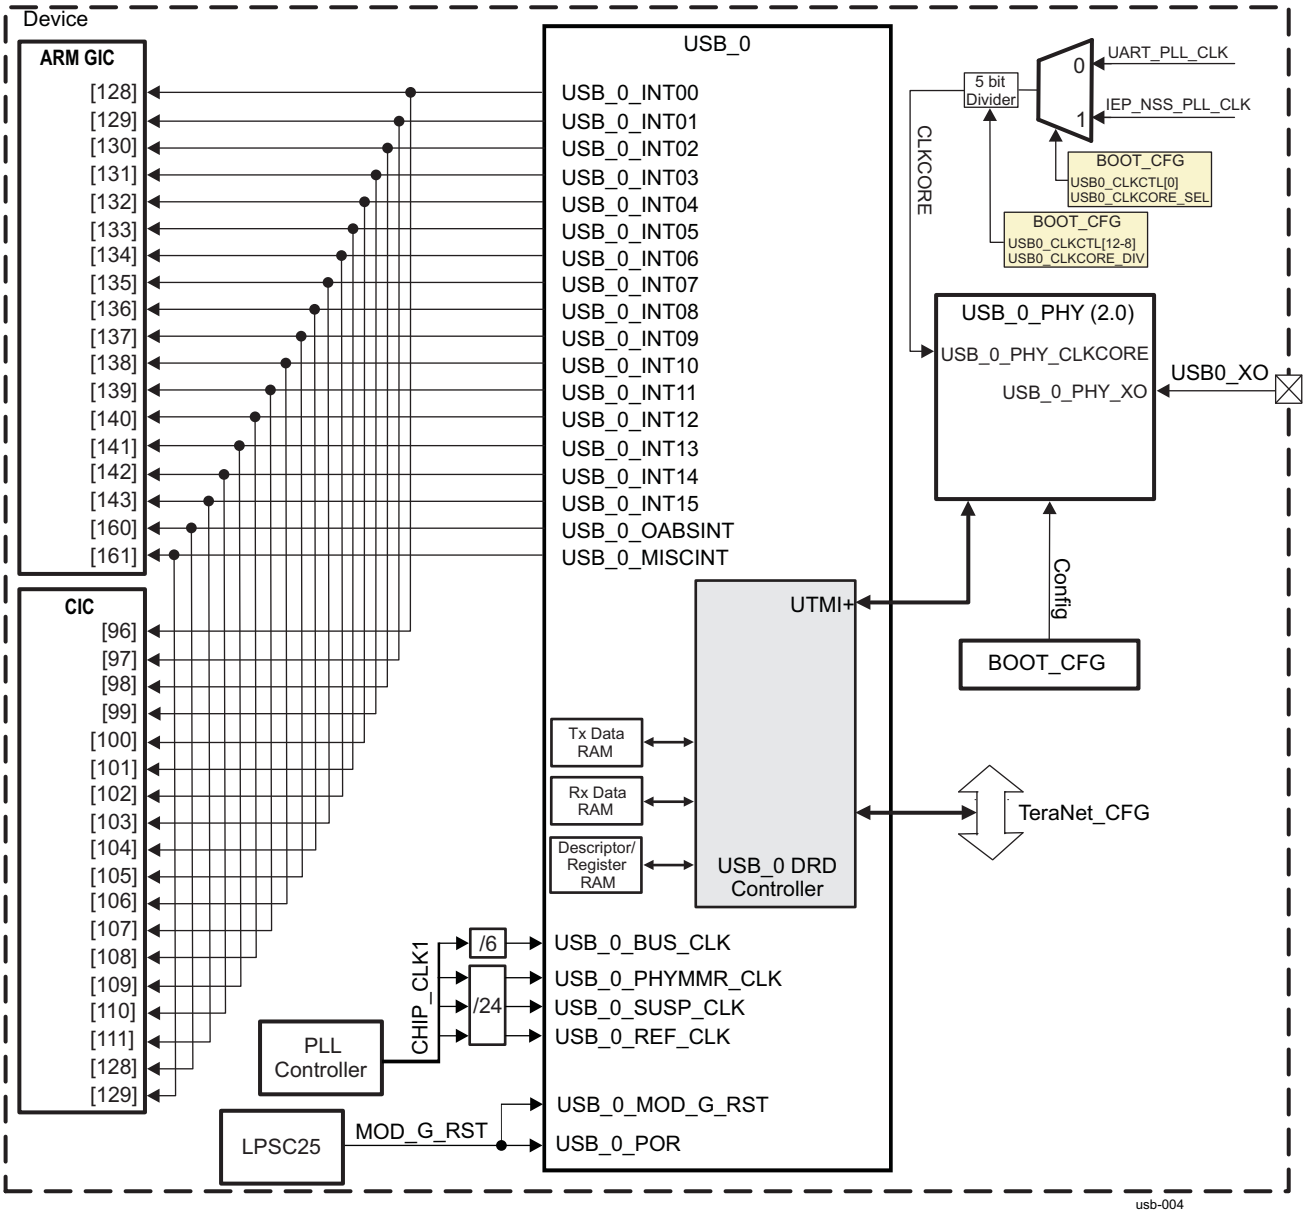

Figure 11-1459 shows the integration of the USB_1 module in the device.

Figure 11-1459. USB_1 Integration

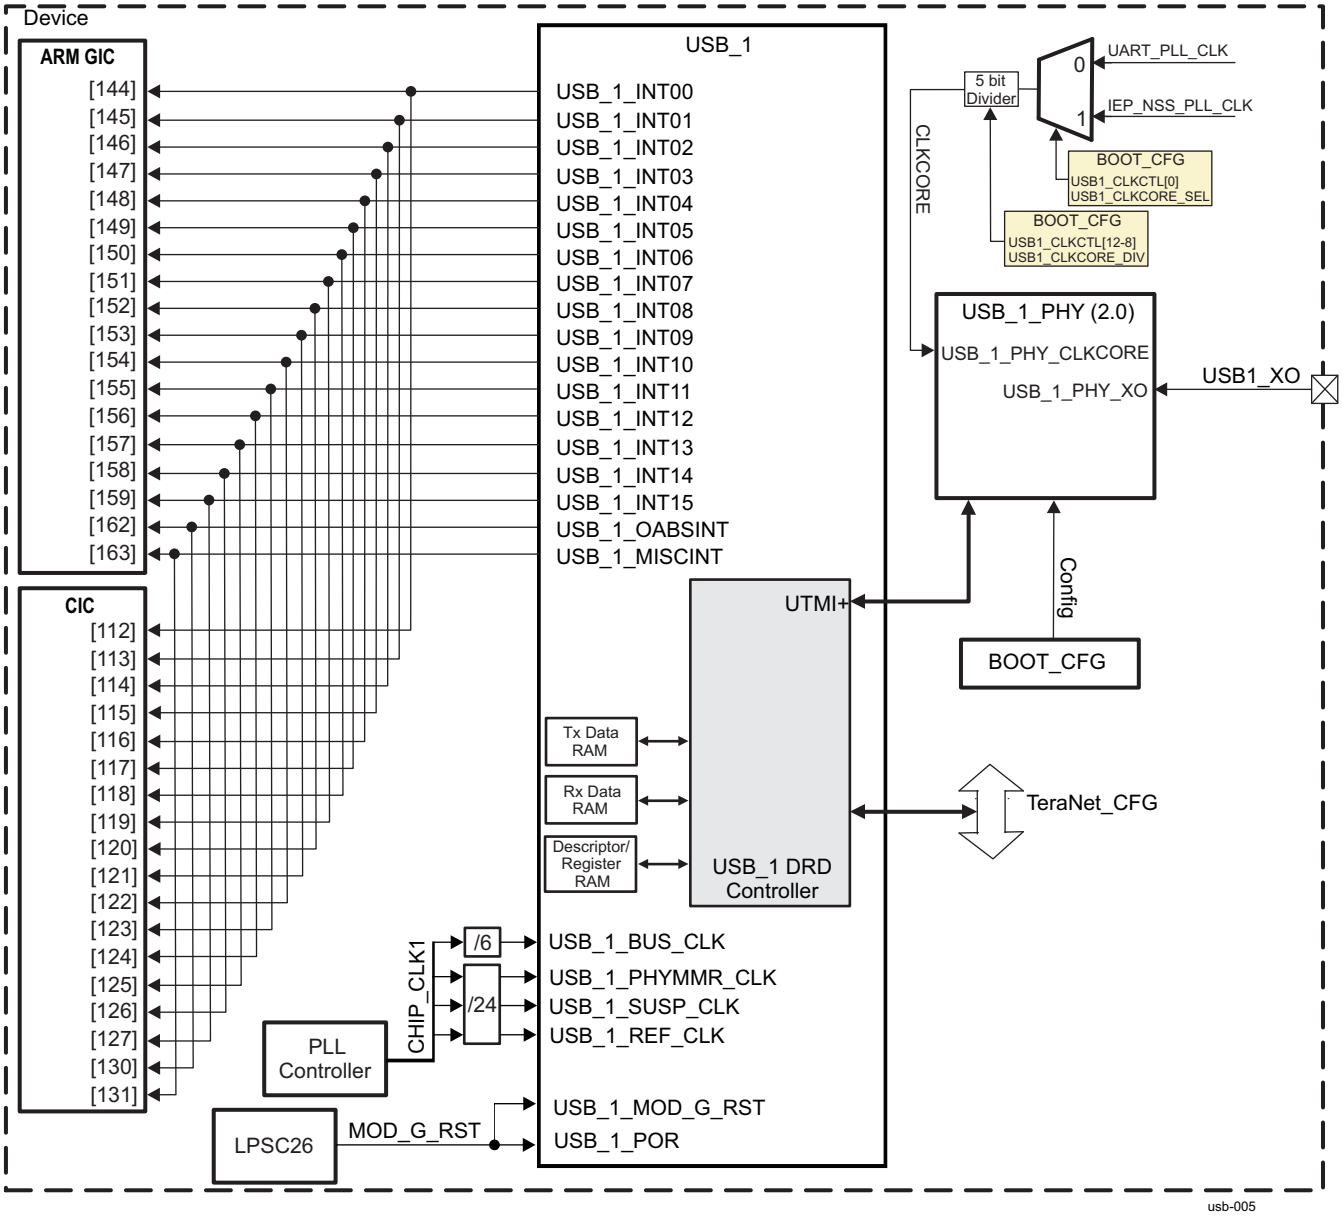

Table 11-3553 through summarize the integration of the USB modules in the device.

Table 11-3553. USB Integration Attributes

Module Instance	Attributes		
	Power Domain	Module Domain	Interconnect
USB_0	PD14	LPSC25	TeraNet_CFG
USB_1	PD14	LPSC26	TeraNet_CFG

Table 11-3554. USB Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
USB_0	USB_0_BUS_CLK	CHIP_CLK1 / 6	PLL Controller	The main BUS_CLK clock to the wrapper module and to the DRD controller module.
	USB_0_PHYMMR_CLK	CHIP_CLK1 / 24	PLL Controller	The PHYMMR_CLK clock is used to access the PHY registers. The Slave Bus-1 interface to PHY registers is completely asynchronous.
	USB_0_SUSP_CLK	CHIP_CLK1 / 24	PLL Controller	The USB_0_SUSP_CLK drives a portion of DRD controller.
	USB_0_REF_CLK	CHIP_CLK1 / 24	PLL Controller	The REF_CLK clock is used to a portion of DRD controller when USB_0 PHY is in the suspended state.
	USB_0_PHY_CLKCORE	CLKCORE	Divided version of UART PLL or IEP / NSS PLL output clocks	On-chip reference clock source for USB_0 PHY.
	USB_0_PHY_XO	USB0XO_REF_CLK	External USB0_XO input pin	Optional USB_0 PHY reference clock. External clock connected to the USB0_XO pin.
USB_1	USB_1_BUS_CLK	CHIP_CLK1 / 6	PLL Controller	The main BUS_CLK clock to the wrapper module and to the DRD controller module.
	USB_1_PHYMMR_CLK	CHIP_CLK1 / 24	PLL Controller	The PHYMMR_CLK clock is used to access the PHY registers. The Slave Bus-1 interface to PHY registers is completely asynchronous.
	USB_1_SUSP_CLK	CHIP_CLK1 / 24	PLL Controller	The USB_1_SUSP_CLK drives a portion of DRD controller. The ADP (Attach Detection Protocol) logic use also the Suspend clock (SUSP_CLK).
	USB_1_REF_CLK	CHIP_CLK1 / 24	PLL Controller	The REF_CLK clock is used to a portion of DRD controller when USB_1 PHY is in the suspended state.
	USB_1_PHY_CLKCORE	CLKCORE	Divided version of UART PLL or IEP / NSS PLL output clocks	On-chip reference clock source for USB_1 PHY.
	USB_1_PHY_XO	USB1XO_REF_CLK	External USB1_XO input pin	Optional USB_1 PHY reference clock. External clock connected to the USB1_XO pin.
Resets				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
USB_0	USB_0_MOD_G_RST	MOD_G_RST	LPSC25	Module Asynchronous Reset. It will reset all regions, except the RAMs within the xHC controller. This signal resets the USB_0 PHY transmit and receive logic.
	USB_0_POR	MOD_G_RST	LPSC25	Module level power on reset (PHY Reset). This signal resets all state machines and registers inside the USB_0 PHY.

Table 11-3554. USB Clocks and Resets (continued)

USB_1	USB_1_MOD_G_RST	MOD_G_RST	LPSC26	Module Asynchronous Reset. It will reset all regions, except the RAMs within the xHC controller. This signal resets the USB_1 PHY transmit and receive logic.
	USB_1_POR	MOD_G_RST	LPSC26	Module level power on reset (PHY Reset). This signal resets all state machines and registers inside the USB_1 PHY.

Table 11-3555. USB Hardware Requests

Interrupt Requests				
Module Instance	**Event Name**	**Mapped To Input Event [Number]**		**Description**
		ARM GIC	**CIC**	
USB_0	USB_0_INT00	[128]	[96]	USB_0 Event ring 0 interrupt
	USB_0_INT01	[129]	[97]	USB_0 Event ring 1 interrupt
	USB_0_INT02	[130]	[98]	USB_0 Event ring 2 interrupt
	USB_0_INT03	[131]	[99]	USB_0 Event ring 3 interrupt
	USB_0_INT04	[132]	[100]	USB_0 Event ring 4 interrupt
	USB_0_INT05	[133]	[101]	USB_0 Event ring 5 interrupt
	USB_0_INT06	[134]	[102]	USB_0 Event ring 6 interrupt
	USB_0_INT07	[135]	[103]	USB_0 Event ring 7 interrupt
	USB_0_INT08	[136]	[104]	USB_0 Event ring 8 interrupt
	USB_0_INT09	[137]	[105]	USB_0 Event ring 9 interrupt
	USB_0_INT10	[138]	[106]	USB_0 Event ring 10 interrupt
	USB_0_INT11	[139]	[107]	USB_0 Event ring 11 interrupt
	USB_0_INT12	[140]	[108]	USB_0 Event ring 12 interrupt
	USB_0_INT13	[141]	[109]	USB_0 Event ring 13 interrupt
	USB_0_INT14	[142]	[110]	USB_0 Event ring 14 interrupt
	USB_0_INT15	[143]	[111]	USB_0 Event ring 15 interrupt
	USB_0_OABSINT	[160]	[128]	USB_0 OTG/ ADP/ BC/ SER interrupt
	USB_0_MISCINT	[161]	[129]	USB_0 Miscellaneous interrupt

	USB_1_INT05	[149]	[117]	USB_1 Event ring 5 interrupt
	USB_1_INT06	[150]	[118]	USB_1 Event ring 6 interrupt
	USB_1_INT07	[151]	[119]	USB_1 Event ring 7 interrupt
	USB_1_INT08	[152]	[120]	USB_1 Event ring 8 interrupt
	USB_1_INT09	[153]	[121]	USB_1 Event ring 9 interrupt
	USB_1_INT10	[154]	[122]	USB_1 Event ring 10 interrupt
	USB_1_INT11	[155]	[123]	USB_1 Event ring 11 interrupt
	USB_1_INT12	[156]	[124]	USB_1 Event ring 12 interrupt
	USB_1_INT13	[157]	[125]	USB_1 Event ring 13 interrupt
	USB_1_INT14	[158]	[126]	USB_1 Event ring 14 interrupt
	USB_1_INT15	[159]	[127]	USB_1 Event ring 15 interrupt
	USB_1_OABSINT	[162]	[130]	USB_1 OTG/ ADP/ BC/ SER interrupt
	USB_1_MISCINT	[163]	[131]	USB_1 Miscellaneous interrupt

11.19.5 USB Registers

NOTE: Details on the registers found in the USB subsystem are not provided in this document. The existing Linux or RTOS drivers should be used for proper USB operation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact your TI sales representative for more information on how to obtain the third party documentation under NDA.

On-chip Debug

This chapter describes the debug and trace features of the device.

Topic **Page**

12.1 Introduction to SoC Debug Architecture

12.1.1 Overview

This chapter describes the capabilities of the various features available through the debug architecture on the device.

The SoC debug capabilities are centered around the Debug Subsystem (DEBUGSS) module. The DEBUGSS module contains the ICEPick module which handles the JTAG TAP and multiple secondary TAPs for the various processing cores of the device. It also provides: DAP port for system wide memory access from debugger, cross-triggering, system trace, peripheral suspend generation, debug port (EMUx) pin management, etc.

The DEBUGSS module works in conjunction with the debug capability integrated in the processing cores (Arm Cortex®-A15, C66x DSP, etc.) to provide a comprehensive hardware platform for a rich debug and development experience.

In addition, the device provides the following debug and trace capabilities to meet the requirement to optimize for power efficiency:

- Ability to turn off the power and clock of the DEBUGSS
- Debug and instrumentation via Instruction Trace Macrocell (ITM) in PMMC

12.1.2 On-chip Debug Features

The SoC implements the following debug features:

- Debug interface
  - Support for 1149.1 standard (JTAG + boundary scan) and 1149.6 (boundary scan extensions). No support for 1149.7 (cJTAG)
  - Supports 20 EMU pins (EMU[19:0]) for exporting system and processor trace data. Some pins may be muxed with other functional pins and thus not always available in all system configurations
  - Supports cross-triggering between devices, and debug boot mode control via EMU[1:0] pins
- ARMSS debug and trace
  - Support for invasive debug like halt mode debugging (breakpoint, watchpoints) and monitor mode debugging
  - Support for non-invasive debugging (program trace, performance monitoring)
  - Support for Cortex-A15 Performance Monitoring Unit (cycle counters)
  - Support for CoreSight Program Trace Module (CS-PTM) with timing
  - Support for an integrated CoreSight System Trace Module (CS-STM) for hardware event and software instrumentation
  - A shared timestamp counter for the Cortex-A15 core and CS-STM is integrated in ARMSS for trace data correlation
  - Support for a 16KB Trace Buffer and Router (TBR) to hold PTM/STM trace. The trace data can be copied by EDMA to external memory for draining by SoC high-speed serial interfaces
  - Support for simultaneous draining of trace stream through EMUx pins and TBR (to achieve higher aggregate trace throughput)
  - Support for debug authentication interface to disable debug accesses in secure devices
  - Support for cross-triggering between Arm core, CS-STM and CT-TBR
  - Support for debug through warm reset
- DSP debug and trace
  - Support for halt mode debug
  - Support for real-time debug
  - Support for monitor mode debug
  - Advanced Event Triggering (AET) for data/PC watchpoints, event monitoring and visibility into external events

- Support for PC/Timing/Data/Event trace
- 4KB TETB (TI Embedded Trace Buffer) for storing PC/Timing/Data/Event trace. The trace data can be copied by EDMA to external memory for draining by SoC high-speed serial interfaces or it can be drained through EMU[19:0] pins
- Support for cross-triggering source/sink to other SoC subsystems

- SoC-level debug and trace:
  - Support debug capability for following processors and hardware accelerators
    - All PRUs in PRU-ICSS modules
    - Cortex-M3 processor in the PMMC, support for ITM trace
  - Support limited debug capabilities (not via CCS) of Hardware Accelerators (HWAs), including:
    - DSS_UL
    - Crypto in the NSS
  - Support emulation mode aware peripherals (suspend features and debug access features)
  - Power domain requirement for DEBUGSS
    - The DEBUGSS resides in its own power domain
    - Domain is ON by default, can be switched OFF by application
    - Domain will automatically wake up upon connection of debugger
    - Automatic turn off when external debugger is disconnected
  - Debug activities will not be interrupted by events of clock-gate or power-down of an individual subsystem
  - Multicore debug
    - Two cross-triggering channels (Trigger0, and Trigger1), shared by:
      - Processor subsystems – ARMSS, DSP. Note that PMMC and PRU-ICSS do not support cross-triggering
      - External device (via EMU[1:0] pins)
      - ARMSS STM, Tracers, CT-TBRs and DEBUGSS STM
    - Synchronized (global) run of C66x DSP, Arm Cortex-A15, PMMC Cortex-M3, and all HWAs
    - Global stop of C66x DSP, Arm Cortex-A15, PMMC Cortex-M3, PRU-ICSS PRUs, and all HWAs
  - Debug access to system resources
    - Support system memory access via the DAP port (natively support 32-bit address, and it can support 36-bit address through configuration of MPAX inside MSMC)
    - Debug access to any invalid memory location (reserved/clock-gated/power-down) will not cause system hang
  - Debug activities does not affect the correctness of an application
    - Peripheral, which is sensitive to a debug access, distinguishes access initiated from debugger versus from application
    - Peripheral, which is sensitive to a debug event (CPU halt), behaves properly during processor suspension
    - Errors triggered by a debug access does not cause any undesired interrupt or exception to the normal execution of a processor
  - Support for debug related reset features, including:
    - Debugger-generated system reset and subsystem resets via ICEPick-D
    - Debugger-generated local resets to individual processor (DSP Subsystem can generate a local reset)
    - Blocking certain system reset generated by applications
    - Blocking subsystem local resets generated by applications
    - Debug logics will survive all resets except global cold resets or TRSTz/TLR
    - TRSTz/TLR resets only affect debug and test logics. It does not affect any functional operation

of the device
- Wait-In-Reset (WIR) debug boot mode

– System trace: support STM-based system trace as following:
  - Software messages generated by application code running on each processor cores
  - Hardware messages generated by Tracers for logging of bus transactions for selected end-points
  - Support 32KB DEBUGSS TBR (Trace Buffer and Router) to hold system trace
  - Support for trace export (from all processor cores and DEBUGSS STM) through Debug Port pins (EMU[19:0])
  - TBR can be drained to on-chip DDR via EDMA
– Debug will be able to get DSP core back to ready after a DSP hang occurs. Note this capability only applies to the DSP core.

12.1.3 Application Integration

TI provides a set of libraries known as CToolsLib that allows for easy integration of debug and trace capabilities into existing software. For more information about CToolsLib, see Section 12.7.

12.2 SoC Debug Interfaces

12.2.1 IEEE1149.1 JTAG Interface

The SoC supports a standard 5-pin JTAG (IEEE1149.1) interface for emulator-based debug. This interface controls the ICEPick module (generic TAP for emulation) to allow the debugger to access several debug resources through its secondary (output) JTAG ports.

Table 12-1 describes the 5-pin JTAG interface.

Table 12-1. JTAG Interface Signals

Pin Name	I/O Type	Internal Pull Type	Description
TRSTz	I	PD	*Test Reset* input. Iinitializes and disables the test interface
TCK	I	PU	*Test Clock* input. Controls the timing of the test interface independently from any system clocks. TCK is pulsed by the equipment controlling the test and not by the tested device.
TMS	I	PU	*Test Mode Select* input. Controls the transitions of the test interface state machine.
TDI	I	PU	*Test Data Input*. Supplies the data to the JTAG registers (Boundary Scan Register, Instruction Register, or other data registers).
TDO	O	PU	*Test Data Output*. Used to serially output the data from the JTAG registers to the equipment controlling the test.

NOTE: The state of all JTAG pins and trace (EMU) pins shall not be affected by the chip-level functional reset. They would only be affected by TRSTz or PORn.

For maximum reliability, the device includes an internal pull-down resistor on the TRSTz pin to ensure that TRSTz will always be asserted upon power-up and the device internal emulation logic will always be properly initialized when this pin is not routed out. JTAG controllers from Texas Instruments actively drive TRSTz high. However, some third-party JTAG controllers may not drive TRSTz high, but expect the use of an external pull-up resistor on TRSTz. When using this type of JTAG controller, assert TRSTz to initialize the device after power-up and externally drive TRSTz high before attempting any emulation or boundary scan operations.

12.2.2 ICEPick Module

12.2.2.1 ICEPick Overview

The debugger is connected to the SoC through its external JTAG interface. The first level of debug interface seen by the debugger is connected to the ICEPick (version D) module embedded in the DEBUGSS. ICEPick is the chip-level TAP, responsible for providing access to the IEEE1149.1 and IEEE1149.6 boundary scan capabilities of the device.

The SoC has multiple processors and debug modules, some with secondary JTAG TAPs (e.g., DSP) and others with an APB memory-mapped interface (e.g., Arm subsystem and CoreSight components). ICEPick manages the TAPs as well as the power/reset/clock controls for the logics associated with the TAPs and the APB ports.

The ICEPick module is visible only from the debugger point of view and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other (secondary) TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  - Serially linking up to 32 TAP controllers
  - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs

- Power, reset and clock management
  - Provides the power and clock status of the domain to the debugger
  - Provides debugger control of the power domain of a processor
    - Force the domain power and clocks on
    - Prohibit the domain from being clock-gated or powered-down
  - Applies system reset
  - Provides wait-in-reset (WIR) boot mode as described in Section 12.6.7
  - Provides global and local WIR release
  - Provides global and local reset block

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key has been properly programmed, ICEPick signals and subsystems emulation logic should be turned on.

12.2.2.2 ICEPick Dynamic Tap Insertion

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the debugger selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

There are two types of components connected through ICEPick to external debug interface:

- Legacy JTAG Components
  - DSPSS (single C66x core) implements a JTAG-compatible port and is directly interfaced with ICEPick and individually attached to an ICEPick secondary TAP
- CoreSight Components
  - The CoreSight components are interfaced with ICEPick through the CS_DAP module. The CS_DAP is attached to an ICEPick secondary TAP and translates JTAG transactions into APBv3 transactions.

Table 12-2 shows the ICEPick secondary TAPs in the system.

Table 12-2. ICEPick Debug Secondary TAPs

Tap #	Type	Name	IR Scan Length	Description
0	N/A	N/A	N/A	Reserved. This is an internal TAP and not exposed at the DEBUGSS boundary
1	JTAG	DSP/C66x	38	Access to DSP
2-7	JTAG	Reserved	N/A	Spare ports
8	JTAG	PMMC/Cortex-M3	4	Access to PMMC[1]
9-13	JTAG	Reserved	N/A	Spare ports
14	CS	CS_DAP (APB-AP)	4	APB-AP is used to access Arm A15 Core and other APB components
		CS_DAP (AHB-AP)		AHB-AP is used to access system memory map.

(1) PMMC/Cortex-M3 is not directly interfaced with ICEPick. There is a DAP instantiated to connect the JTAG pins from ICEPick to the AHB-AP port inside Cortex-M3.

Besides secondary debug TAPs, ICEPick also supports power/reset/clock controls for non-JTAG debug cores. These debug cores are accessible through the CS_DAP.

Table 12-3 summarizes the ICEPick debug core mapping.

Table 12-3. ICEPick Debug Cores

Debug Core #	Name
0	Arm Cortex-A15 core
1	Reserved
2	Reserved
3	Reserved
4	PRU0 in PRU-ICSS_0
5	PRU1 in PRU-ICSS_0
6	PRU0 in PRU-ICSS_1
7	PRU1 in PRU-ICSS_1
8-23	Reserved

12.2.3 Debug Port

The SoC supports a 20-pin emulation dedicated interface – EMU[19:0]. The EMU[19:0] pins are collectively called the "Debug Port" and are shared by the following functions:

- Trace
  - ARMSS/Cortex-A15 trace (via PTM)
  - PMMC/Cortex-M3 trace (via ITM)
  - DSP/C66x trace
  - STM trace
- Cross-triggering
- Debug boot modes

12.2.3.1 Debug Port Configuration

Table 12-4 shows the Debug Port configuration. The application software must make sure to program the Debug Resource Manager (DRM) integrated in the Debug Subsystem to appropriately export trace data to an external trace receiver. The Debug Pin Manager (DPM) of the DRM specifies this configuration by matching each of the EMU pins listed below to a specific function such as: DSP trace, STM trace, cross-triggering, etc.

Table 12-4. Debug Port Configuration

EMU Pins	Cross-Triggering	PTM/ITM Trace (via CS-TPIU)		DSP Trace		STM	Debug Boot Mode
EMU19		TRCDTa[15]	TRCDTb[17]	TRCDTa[15]	TRCDTb[17]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU18		TRCDTa[14]	TRCDTb[16]	TRCDTa[14]	TRCDTb[16]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU17		TRCDTa[13]	TRCDTb[15]	TRCDTa[13]	TRCDTb[15]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU16		TRCDTa[12]	TRCDTb[14]	TRCDTa[12]	TRCDTb[14]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU15		TRCDTa[11]	TRCDTb[13]	TRCDTa[11]	TRCDTb[13]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU14		TRCDTa[10]	TRCDTb[12]	TRCDTa[10]	TRCDTb[12]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	

Table 12-4. Debug Port Configuration (continued)

EMU Pins	Cross-Triggering	PTM/ITM Trace (via CS-TPIU)		DSP Trace		STM	Debug Boot Mode
EMU13		TRCDTa[9]	TRCDTb[11]	TRCDTa[9]	TRCDTb[11]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU12		TRCDTa[8]	TRCDTb[10]	TRCDTa[8]	TRCDTb[10]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU11		TRCDTa[7]	TRCDTb[9]	TRCDTa[7]	TRCDTb[9]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU10		TRCDTa[6]	TRCDTb[8]	TRCDTa[6]	TRCDTb[8]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU9		TRCDTa[5]	TRCDTb[7]	TRCDTa[5]	TRCDTb[7]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU8		TRCDTa[4]	TRCDTb[6]	TRCDTa[4]	TRCDTb[6]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU7		TRCDTa[3]	TRCDTb[5]	TRCDTa[3]	TRCDTb[5]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU6		TRCDTa[2]	TRCDTb[4]	TRCDTa[2]	TRCDTb[4]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU5		TRCDTa[1]	TRCDTb[3]	TRCDTa[1]	TRCDTb[3]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU4		TRCDTa[0]	TRCDTb[2]	TRCDTa[0]	TRCDTb[2]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU3		TRCCLKB	TRCCLKB	TRCCLKB	TRCCLKB	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU2		TRCCLKA	TRCCLKA	TRCCLKA	TRCCLKA	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	
EMU1	Trigger1		TRCDTb[1]		TRCDTb[1]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	Debug boot mode [1]
EMU0	Trigger0		TRCDTb[0]		TRCDTb[0]	TRCDT3, or TRCDT2, or TRCDT1, or TRCDT0, or TRCCLK or Tri-state	Debug boot mode [0]

NOTE: If the EMU[1:0] signals are shared for cross-triggering purposes at board level, they SHOULD NOT be used for trace purposes.

12.2.3.2 Concurrent Use of Debug Port

The following combinations are possible concurrently:

- Trigger 0/1
- Trigger 0/1 and STM Trace (up to 4 data pins)
- Trigger 0/1 and STM Trace (up to 4 data pins) and DSP Trace (up to 11 data pins)
- Trigger 0/1 and STM Trace (up to 4 data pins) and TPIU Trace (up to 11 data pins)
- STM Trace (up to 4 datapins) and TPIU Trace (up to 13 data pins)
- Trigger 0/1 and TPIU Trace (up to 16 data pins)

- Trigger 0/1 and DSP Trace (up to 16 data pins)
- TPIU Trace (up to 18 data pins)
- DSP Trace (up to 18 data pins)

ARMSS/PMMC (via TPIU) and DSP simultaneous trace is not supported.

12.2.4 Board Design Considerations

In order to facilitate correct debug functionality between the SoC emulation signals and a particular board JTAG interface, certain procedures must be followed. More information on board design guidelines for trace advanced emulation can be found in the *Emulation and Trace Headers Technical Reference Manual* (SPRU655i).

Useful guidelines can also be found at the "XDS Target Connection Guide" TI wiki page:

http://processors.wiki.ti.com/index.php/XDS_Target_Connection_Guide

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

12.3 DSP Subsystem Debug Features

The following sections define the types of emulation actions possible for the DSP subsystem (C66x CorePac).

The DSP supports:

- Invasive debug techniques, such as:
  - Halt mode debug (Section 12.3.1.1)
  - Real-time debug (Section 12.3.1.2)
  - Monitor mode debug (Section 12.3.1.3)
- Non-invasive debug mechanisms, such as:
  - Trace (Section 12.3.2)
- Triggering options possible with AET (Advanced Event Triggering) supported by C66x (Section 12.3.3)

12.3.1 DSP Debug Modes

12.3.1.1 Halt Mode Debug

The DSP supports traditional stop-mode emulation, whereby host tooling can halt the C66x core, as well as any of the device peripherals. The C66x core has a direct connection to the JTAG interface. Emulation has full visibility of the DSP memory map, and can access the chip memory through the core.

The core has visibility requirements critical for successful software development and debug in the field.

The following are requirements in a debugger environment (host control through JTAG)

- Run-time execution control (e.g. halt, step, run)
- Accurate reflection of memory and register contents
- Visibility into system stalls
  - Bank conflict
  - Cache miss/coherency overhead
  - Memory latency
  - DMA conflict
  - Cache state (coherency with external memory)
- Shared memory view:
  - Cache state (coherency between cores)
  - Conflict between cores (performance degradation)
- Shared atomic resources (memory structure, IP, etc.)
  - Ownership through Hardware Semaphore – view/force
  - IPC flags – view/force
  - Volatile shared structs – view/update
- Shared multichannel resources (e.g. DMA channels)
  - View/change context without impacting other cores
- Cross-triggering
  - Local halt, step, run
  - Global halt, step, run (synchronized)
  - Local hardware breakpoint
  - Global software breakpoint (assert and receive)
  - Global hardware breakpoint (assert and receive)

12.3.1.2 Real-Time Debug

Real-Time Debug (DSP-only feature) provides a base set of capabilities for real-time execution control (run, step, halt, etc.) and register/memory visibility. This infrastructure component allows the user to debug application code while interrupts designated as real-time continue to be serviced. Registers and memory may be accessed while code is running or stopped. Users define the interrupts that are to be treated as real-time through a special debug interrupt enable register (DIER). The user can also mark code that must not be disturbed by real-time debug memory accesses within the application. These facilities provide the basic execution control and memory/register accessibility needed by the Code Composer Debugger.

Real-time debug encompasses three code execution states. These states generate bus activity that is presented to triggering logic. An applications developer may want to constrain triggering behavior to a limited set of these states. Before triggering behavior can be discussed, it is important to understand the three CPU code execution states related to debug:

- Normal code execution – running code prior to a debug event (normal code and interrupt service routines). Normal code execution is the behavior of the system as if the emulator is not connected to the chip where the peripheral resides. In other words, the CPU is running code without a debug event halting execution with the peripheral operating continuously.
- Secondary code execution – running code related to the service of a real-time interrupt after a debug event has halted code execution. The CPU execution is designated by the applications developer as real-time, allowing the service of interrupts designated as real-time (via the debug interrupt enable register) after code execution is halted.
- No code execution – not running code. This occurs when the emulation functions are enabled, a debug event halts code execution, and no real-time interrupt is being serviced after code execution is halted. Generally, break detection is always enabled for normal code execution. The applications developer may desire to either include or exclude secondary code execution. A programmable option is provided to either include or exclude secondary code execution in trigger generation.

12.3.1.3 Monitor Mode (Run Mode) Debug

It is possible to have a real-time debug thread of execution that provides application-level debugging features at run-time that complement the Stop-Mode/Real-Time Emulation features noted above. The debug thread would respond to commands sent by a host debugger and configure the AET logic to raise an AINT interrupt whenever a user-specified trigger condition occurred. The ISR for the AINT interrupt would be handled by the real-time debugger, which would implement whatever functionality was required to perform the required debug actions requested by the host debugger.

The debug thread software would be implemented as a library that is linked in by the customer application on the device, and would give the ability to:

- Suspend a specified task (on interruptible region)
- Resume execution of a the task
- "Single step" the task (i.e. set a pending interrupt flag, resume execution of the task and suspend execution of the task when the pending interrupt is serviced)
- View/modify memory, CPU registers

12.3.2 DSP Trace

12.3.2.1 DSP Trace Overview

DSP trace provides for the recording of program flow, memory references, and application-specific data with a timestamp. Trace targets the debug of unstable code, performance analysis, and quality assurance. The use of dedicated hardware to both collect, buffer, transfer trace data to the host makes trace non-intrusive. Data is exported via trace packets. These packets are converted to trace transmission packets via the trace export block. Transmission packets can be from 1 to 20-bits wide. This allows all or a percentage of the Debug Port pins to be allocated to trace. This allows the sharing of Debug Port pins between trace and other functions, with the number of pins allocated to trace and the corresponding trace port width varied at run-time.

The trace function can collect and export a record of the program flow and timing at the same rate generated by the CPU. Tracing data references must be restricted, however, as the export mechanism is generally limited to a number of pins insufficient to sustain tracing of all memory references. In the case of data trace, the Advanced Event Triggering facilities provide a means to restrict the trace data exported to data of interest to maintain the non-intrusive aspect of trace. This reduces the export bandwidth needs and facilitates the successful collection of the data of interest. Error indications are embedded in the debug stream in the event the export logic is unable to keep up with the data rate generated by the collection logic. This notification allows the user to scale back the amount of requested data collection.

The user can optionally select the export of all specified trace data. In this case the CPU is stalled to avoid the loss of trace data, with trace becoming intrusive to the application if trace related stalls are generated. The user is notified that trace stalls have occurred although the number of stalls and their location is not recorded.

The trace technology is modular with different collection elements for different types of data (PC, Timing, Memory References). This allows the customization of the trace function if the trace function is not encapsulated in the CPU megamodule. Collection elements for different types of data are modular allowing the customer to trade off functionality versus gates and pins required to meet the bandwidth requirements. Trace export shares debug pins with other functions.

Another option to export the trace data is via TETB buffer. DSP supports one dedicated TETB with 4KB memory. The trace data in TETB can be drained to some other memory (L2, shared, or external) while continuing to trace. Trace data can be further exported by using an application interface such as Ethernet, PCIe and etc. However, these measures introduce some intrusion to the normal operation of the system.

12.3.2.2 DSP Trace Clock

DSP trace clock is derived from the Main PLL in conjuction with the PLL Controller. This clock is used for both:

- Storing DSP trace data on-chip into dedicated trace buffer (TETB)
- Exporting DSP trace data off-chip via Debug Port pins

Note that the DSP trace clock is referenced as "GEM_TRACE_CLK" from PLL perspective, and is referenced as "TRCCLK" from Debug Port perspective (Table 12-4).

For more information about DSP trace clock, Main PLL, and PLL Controller, see section 5.2, *Power Management*.

WARNING

When using TI's provided tools (CCS with an XDDS560T or XDS560v2 Trace Pro), do not modify the PLL used for DSP Core Trace. This will cause conflicts with TI's software that uses a calibration scheme to set the trace data rate at the fastest rate possible the receiver can collect data at.

12.3.2.3 DSP Trace Export Configuration

DSP trace data is formatted into 1 to 20-bit packets. For external capture through the Debug Port, the trace port has a width of 20 bits. This port mapping is software configurable to 16 or 18 data pins (TRCDTa[15:0] and TRCDTb[17:0], respectively) plus two pins dedicated to the export clock (TRCCLKA and TRCCLKB). See Section 12.2.3 for details.

12.3.3 DSP Advanced Event Triggering (AET)

Triggers manage breakpoints, trace acquisition, data collection via an interrupt, timing measurement, and generate external triggers. They also control a state machine and counters used to create the intermediate events (loop counts and state machines). AET uses instruction and data bus comparators, auxiliary event detection, sequencers/state machines, and event counters to identify events of interest. These events can be combined to create simple or complex triggers using modules call trigger builders. AET logic is provided for monitoring program, memory bus, auxiliary input activity, remembering event sequences, counting event occurrences, or measuring the interval between events. Bus comparators can perform range and identity comparisons, detect exact transactions or the mere touching of a byte or range of bytes by memory references. External event detectors provide a means to monitor external triggers or internal states of interest (i.e., cache miss). A state machine with four states that allows transitions from any state to any other state provides for the identification of a sequence of triggers, with counters/timers (16-bit and/or 32-bit) providing for the implementation of loop counts or a predetermined number of events. The state machine and counter components are controlled by triggers and generate events (state number and count equals zero). The state machine and counter events are part of the event pool used to create triggers. Trigger builder components are used to create triggers from the events created by all event generation sources.

Triggering facilities are used to identify specific system activity to generate breakpoints, an interrupt used for the collection of system data, or the identification of program activity that is observed through Trace.

Any system event routed to the C66x core can be routed (through software selection) to the AET. This is controlled through software by configuring the DSP interrupt controller as well as the Chip-level Interrupt Controller (CIC). The DSP interrupt controller supports routing up to eight events to the AET logic for tracking by the emulation hardware. Events that can be routed include the system events, CPU interrupts and exception inputs, and interrupt and exception acknowledges. Likewise, cross-triggering is possible by having an AET trigger on one DSP core signal (through EMU0/1) to cause an action on another core (or STM) within the chip or even on another device (assuming the device pins are connected properly).

For more information on how to program the AET for various application use, see Section 12.7.2.

12.3.4 DSP and Related Debug Components

The DSP debug features are supported by a variety of debug modules as follows:

- The ICEMAKER provides DSP emulation with the classic debug features, such as: download code, access to memory or registers, run/halt/single-step
- DT-DMA is a debug dedicated DMA engine intended for fast block data transfer between a debugger and DSP over JTAG port
- TCU unit is used for trigger management
- AET unit is used to generate debug actions for managing breakpoints, watchpoints, trace, timers/counters, event outputs to external logic of DSP, based on events detected by instruction and data bus comparators or by auxiliary event detectors. DSP AET can also handle complex events with event state machine and event counters
- DSP XMC supports 36-bit addressing and emulation can access the 36-bit address space
- ADTF provides trace formatting to convert the DSP generated trace into a format that is required by the DEBUGSS. The ADTF provides the mechanism for embedded trace with the TETB, or a path to the DRM within DEBUGSS for pin trace
- TETB (TI Embedded Trace Buffer) provides buffering of ADTF formatted trace stream and is capable of generating DMA events to enable EDMA draining of the FIFO. The TETB supports trace during run-time with no intrusion to the application. There are two primary application models that are facilitated by the TETB:
  - Crash analysis: Here, the TETB contents are not accessed during run-time, but rather only at defined points. Typically this would be when an external host detects a system failure. In this case, the TETB can be set to trace continuously, and when a system fault occurs the host reads the TETB contents for offline analysis of the pre-fault execution.
  - Continuous trace: The TETB can be drained during run-time through the use of EDMA channels. This adds some system loading, as EDMA resources and memory bandwidth must be consumed for this purpose. However, continuous trace allows for trace data to be:

- Stored in DDR to extend the size of the embedded trace buffer, which provides a larger history to the host
- Streamed out through a standard peripheral interface such as Ethernet, or PCIe, to be captured by an external host in the actual embedded system for real-time analysis

NOTE: The ADTF and TETB debug components are not part of the DSP subsystem. They are integrated at SoC level.

12.3.5 DSP Debug Summary

Table 12-5 summarizes the DSPSS debug capabilities.

Table 12-5. DSP Subsystem Debug Capabilities

Feature	Usage	DSP Support
Basic Debug	Execution control	Y
	System visibility	Y
Real-Time Debug	Interrupts serviced while halted	Y
	Low/non-intrusive system visibility while running	Y
Advanced Debug	Global start	Y
	Global stop	Y
	Specify targeted memory level(s) during memory accesses	Y
Advanced System Control	Subsystem reset via debug	Y
	Peripheral notification of debug events	Y
	Cache-coherent debug accesses	Y
Security	Configurable levels of security and debug visibility	Y
	Memory accesses prevented to secure memory	Y
	Debug halts prevented during secure mode	Y
Program Trace	Program flow corruption	Y
	Code coverage	Y
	Path coverage	Y
	Thread/interrupt synchronization problems	Y
Data Trace	Memory corruption	Y
Timing Trace	Profiling	Y
Analysis Actions	Stop program execution	Y
	Control trace streams	Y
	Generate debug interrupt	Y
	Benchmarking with counters	Y
	External trigger generation	Y
	Debug state machine state transition	Y
	Combinational and Sequential event generation	Y
Analysis Events	Program event detection	Y
	Data event detection	Y
	External trigger detection (cross-trigger)	Y
	System event detection (i.e., cache miss)	Y
	Debug state machine state detection	Y
Analysis Configuration	Application access	Y
	Debugger access	Y
	Debug state restoration across power cycle	N

Table 12-6 summarizes the DSPSS debug features.

Table 12-6. DSP Subsystem Debug Features

Category	Hardware Feature	DSP Support
Basic Debug	Software breakpoint (SWBP)	Unlimited and DSP also supports embedded SWBP. SWBPs are global, affecting any/all CPUs that execute an instruction with SWBP inserted
	Hardware breakpoint (HWBP)	Up to 10 HWBPs: • 4 HWBPs are in core (HWBP0 is associated with a counter) • 2 dedicated HWBPs are in AET • 4 HWBPs which are shared with watchpoint (also in AET)
Analysis	Watchpoint	4 watchpoints registers are shared with HWBPs, and can also be used as 2 watchpoints with data (32-bits)
	Watchpoint with Data (Data Watchpoint)	2 (they are shared with the 4 watchpoints).
	Counters/Timers	The DSP core has one 64-bit free running time-stamp counter (TSC)
	External Event Trigger In	2 (the two cross-triggering signals. They can be used to halt target as a HWBP (they can be called system HWBPs))
	External Event Trigger Out	
Trace Control	Address range for trace	3
	Data qualification for trace	2 (see "Watchpoint with Data")
	System events for trace control	32 events (directly connected to AET), which include: • 32 CPU memory events (cache) • 32 CPU system events (stall) • 32 others (miscellaneous) events including 8 event inputs which all internal and external interrupts events can be muxed to via the DSP internal INTC, as well as the system INTC module (CIC).
	Counters/Timers for trace control	2x32 bits
	State Machines/Sequencers	1x4-states or 2x2-states state machine(s)
	Context/Thread-ID Comparator	0
	Independent trigger control units	1
On-chip Trace Capture	Capture depth PC	4KB TETB buffer
	Capture depth PC + Timing	4KB TETB buffer
	Application accessible	Y
Performance Monitoring Unit	Application accessible cycle counters	Y (supported by AET)

12.4 Arm Subsystem Debug Features

12.4.1 ARMSS Debug Overview

The Cortex-A15 processor supports the following native features:

- Halt mode and monitor mode debug
- Six hardware breakpoints and four watchpoints
- Asynchronous aborts
- Processor trace and software instrumentation
- Performance monitoring
- Cross-triggering: allows stopping the Cortex-A15 CPU upon debug event (for example, breakpoint) detection in another device CPU or debug/trace component

For more information about Cortex-A15 native debug features, see the *Arm Cortex-A15 Technical Reference Manual*.

12.4.2 ARMSS Debug Modes

The Cortex-A15 CPU supports invasive and non-invasive debug modes.

The invasive debug mode is intended primarily for run-control debugging. Invasive debug mode provides support for:

- Monitor mode: In monitor mode, a debug event causes a debug exception to occur. A debug exception that relates to instruction execution generates a Prefetch Abort exception. A debug exception that relates to a data access generates a Data Abort exception. A software handler can then take control to examine or alter the processor state. Monitor debug mode is essential in real-time systems where the processor cannot be halted to collect debug information.
- Halt mode: In halt mode, a debug event causes the processor to enter Debug state. In Debug state, the processor stops executing instructions from the location indicated by the program counter, but is instead controlled through the external debug interface, in particular using the Instruction Transfer Register (DBGITR)

Non-invasive debug includes all debug features that permit data and program flow to be observed, but that do not permit modification of the main processor state. Non-invasive debug mode support includes Processor Instruction Trace, Sample-based Profiling, and Performance Monitoring.

12.4.3 ARMSS Trace

The Cortex-A15 MPCore integrates a CoreSight Processor Trace Macrocell (PTM or CS-PTM) which performs real-time instruction flow tracing. It generates information that can be used by trace receiver to reconstruct the execution of all or part of a program.

The PTM identifies certain instructions in the program, and certain events, as waypoints. A waypoint is a point where instruction execution by the processor may involve a change in the program flow.

The PTM traces only the following waypoints:

- All indirect branches
- All conditional and unconditional direct branches
- All exceptions
- Any instruction that changes the instruction set state of the processor
- When halting debug mode is enabled, entering or leaving debug state
- Synchronization primitives

The PTM provides the ability to reconstruct the complete instruction flow.

For more information about PTM, see *Arm CoreSight Program Flow Trace Architecture Specification*.

The Cortex-A15 processor trace characteristics are as follows:

- Program trace only (no data trace)

- Two exclusive trace sinks:
  - TPIU: Trace exported to an external trace receiver (via Debug Port)
  - CT-TBR: Trace stored to ARMSS local trace buffer for draining through high-speed serial interfaces
- Trace can be optionally:
  - Cycle accurate (useful for profiling sections of code)
  - Locally time-stamped using a 64-bit free-running graycode counter exported to the PTM

12.4.4 ARMSS Software Instrumentation

The ARMSS software instrumentation is supported by its integrated CoreSight STM (CS-STM). The CS-STM provides 'extended stimulus port' registers designated to be accessible by software with minimum instrumentation cycles overhead.

Each 'extended stimulus port' occupies 256 consecutive bytes in the memory map and is write-only. Up to 64K instrumentation channels are available at ARMSS level.

The CS-STM supports 'guaranteed' or 'invariant timing' transactions:

- Guaranteed transactions are guaranteed to be traced. This might involve stalling the Cortex-A15 core to ensure the transaction is accepted by the CS-STM
- Invariant timing transactions are not guaranteed to be traced. These transactions will take an invariant amount of time regardless of the state of the CS-STM

12.4.5 ARMSS Performance Monitoring

The Cortex-A15 processor includes a Performance Monitoring Unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU gathers statistics about the operation of the processor and memory system.

The Cortex-A15 PMU events are listed in the *Arm Cortex A15 Technical Reference Manual*.

12.4.6 ARMSS Cross-Triggering

The Arm subsystem provides cross-triggering support by implementing CoreSight Cross-Trigger Interface (CTI) and Cross-Trigger Matrix (CTM) modules. The following CTI and CTM modules are integrated in the ARMSS:

- At Cortex-A15 MPCore level:
  - One CTI. The CTI is programmable through AXI bus accesses or by debugger from APB bus directly.
  - One CTM
- At ARMSS level (that is, outside the Cortex-A15 MPCore):
  - One additional CTM to carry cross triggers between the Arm core, integrated CS-STM, integrated CT-TBR and from DEBUGSS outside the ARMSS wrapper

The ARMSS cross-triggering modules provide support for useful cases, such as cross-triggering between PTM and CT-TBR:

- PTM can generate a trigger that can be used to stop CT-TBR data capture
- CT-TBR can send buffer-full or acquisition-complete events to the PTM

12.5 PMMC Debug Features

The PMMC integrates a single Cortex-M3 processor, which supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watchpoint on access to data address, address range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M3 native debug features, see the *Arm Cortex-M3 Technical Reference Manual*.

The PMMC implements an Instruction Trace Macrocell (ITM) unit to provide trace-based debugging, such as PC sampling, data trace, event trace and software instrumentation. ITM supports two data sources:

- Software trace: generated by software application to provide hardware assisted **printf()**-like messages
- Hardware trace: system and application events generated by DWT unit

The Cortex-M3 trace is stored into a dedicated PMMC TraceCell integrated at SoC level. The PMMC TraceCell includes a CT-TBR module with 16KB RAM which can generate a DMA request to the EDMACC_0 controller for further trace draining.

12.6 SoC Level Debug Features

As devices get more complicated and more IPs are integrated into the device (SoC), there is a requirement to provide sufficient hooks in the silicon to provide enough visibility to facilitate debug in the system. Multiple cores (processing engines) executing concurrently and asynchronously stress the system memory in variable fashion during execution in response to system stimulus (events). Multiple 'DMA' transactions move a very large amount of data through the chip concurrently, converging at memory and accelerator endpoints. The data movement is a mixture of synchronous and asynchronous activity, both driving and driven by the program execution.

12.6.1 System Trace

12.6.1.1 Overview

System trace can provide significant debug visibility into how multiple cores and masters are interacting and executing in the SoC. System trace provides visibility on bandwidth consumption by SoC masters as well as transaction trace information. Its purpose is to collect system debug and performance data from the SoC and encapsulate it into a standard format. These features are accomplished on the device through both hardware and software messages.

The on-chip Tracer modules provide the functionality which generate hardware messages (as explained in Section 12.6.2).

System trace also supports the capture of software messages as a minimally intrusive means to log information during run-time. To trigger SW messages, applications write data to be logged to certain memory mapped locations of the CTools System Trace Module (CT-STM) embedded in the Debug Subsystem. The CT-STM provides 256 dedicated channels for simultaneous logging of software messages.

The CT-STM provides support for:

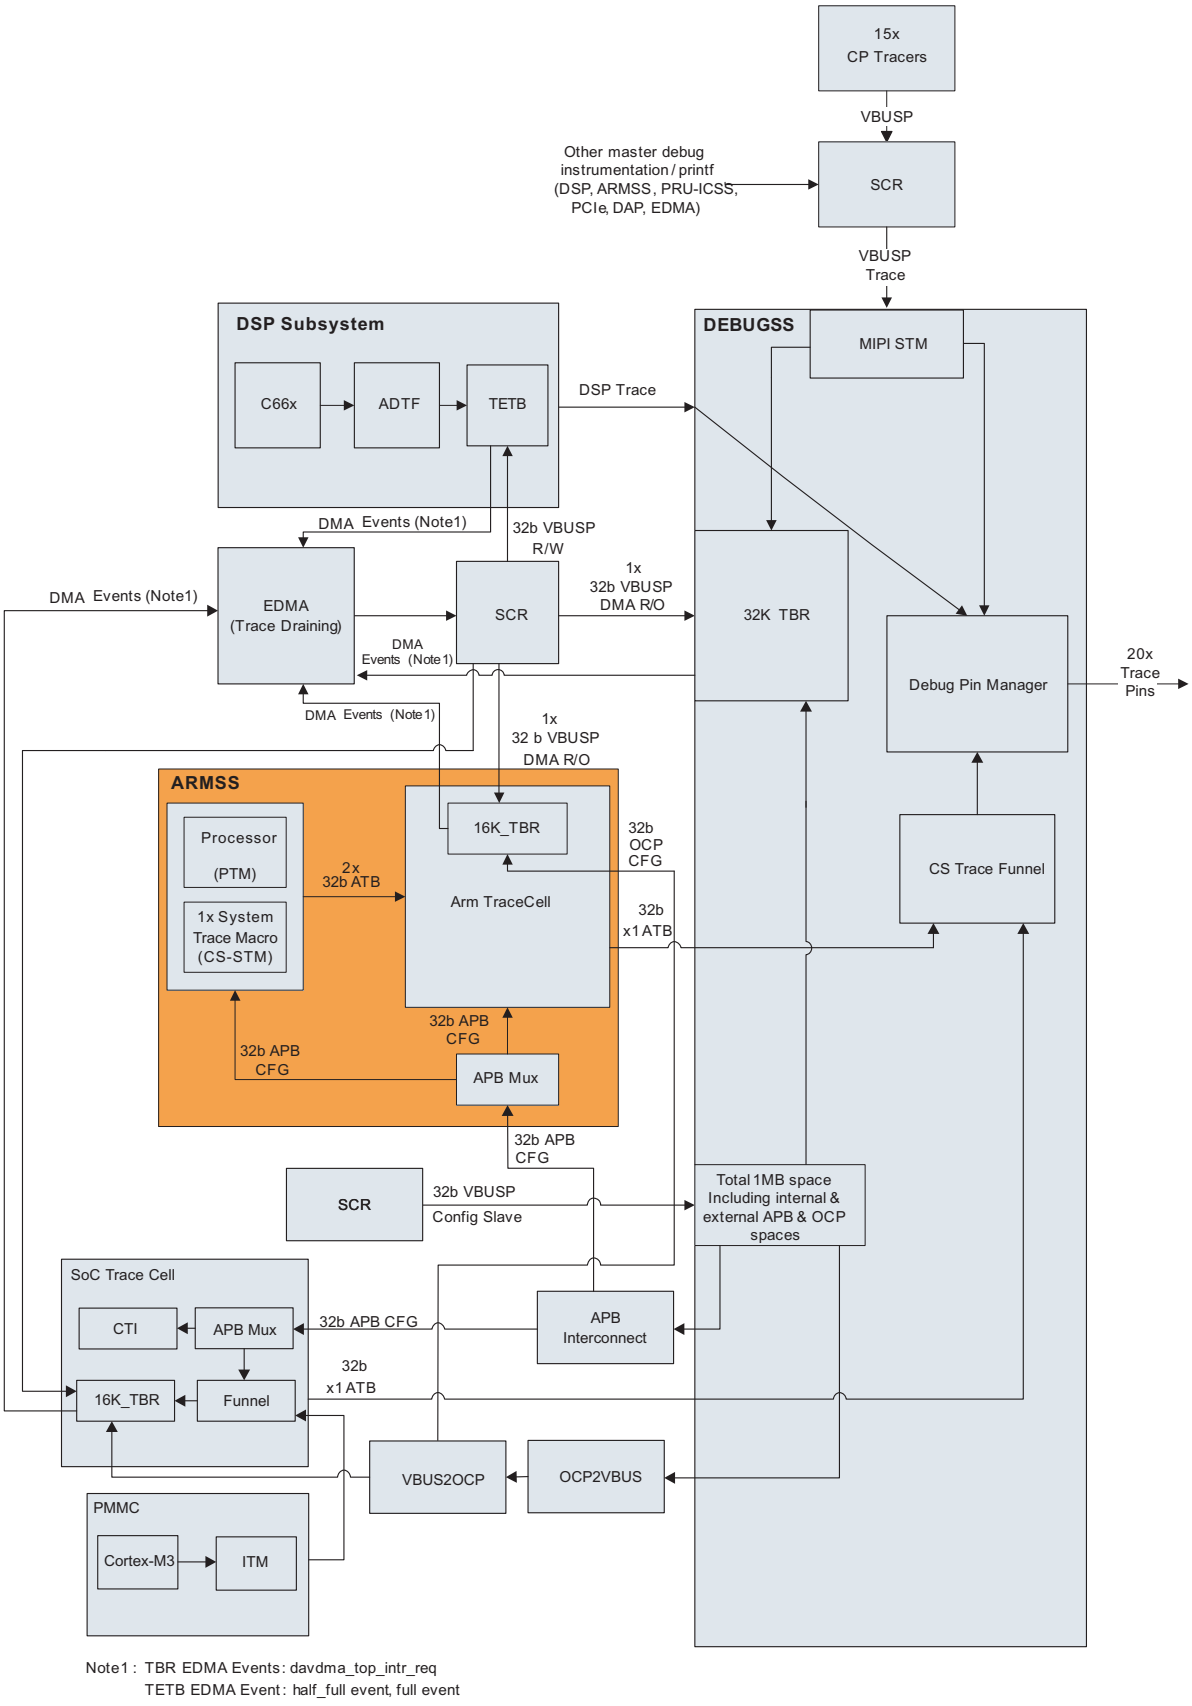
- Storing system trace data on-chip into dedicated CTools Trace Buffer Router (CT-TBR)
- Exporting system trace data off-chip to an external trace receiver via the Debug Port

When storing data on-chip, the CT-STM interfaces with the dedicated CT-TBR through the ATB port.

When exporting data off-chip, the CT-STM interfaces with the Debug Resource Manager (DRM) module through the Parallel Trace Interface (PTI). The system trace port width and clock can both be configured through the PTI. More information on configuring the PTI can be found in Section 12.7.2.

Figure 12-1 shows the overall SoC trace architecture with trace generation of Cortex-A15 core, DSP core, Cortex-M3 core, hardware instrumentation (Tracers), and software instrumentation. The figure also shows the trace draining using EMU pins in addition to on-chip buffers for trace storage (TETB for DSP; CT-TBR(s) for ARMSS, CT-STM, and PMMC).

Figure 12-1. SoC Trace Architecture



Note1 : TBR EDMA Events: davdma_top_intr_req
TETB EDMA Event: half_full event, full event

12.6.1.2 System Trace Module

The Debug Subsystem integrates the CTools System Trace Module (CT-STM) to handle hardware instrumentation/messages (generated by the Tracer modules) and software instrumentation/messages (from various processing cores).

The main features of the CT-STM are as follows:

- Implements MIPI STP protocol (rev 2.0) with the following characteristics:
  - Highly optimized for software-generated traces from ARMSS, DSP, PMMC, PRU-ICSS sources
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from Tracer modules
- Supports following types of trace sinks:
  - Pin trace (EMU pins) through the Parallel Trace Interface
  - Capture of trace into DEBUGSS internal buffer (CT-TBR) through ATB interface
- Pin trace available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver

12.6.1.3 System Trace Sinks

12.6.1.3.1 Trace Capture into CT-TBR

The CT-TBR module residing in the Debug Subsystem provides on-chip storage of system trace data using a 32-KB RAM memory. The CT-TBR receives trace data through its ATB port. The debugger can then access the trace data through the APB port of the CS_DAP module.

The CT-TBR can act like a circular buffer; that is, it can continuously capture and write data into memory when trace capture is enabled and its trigger counter is static at 0 or has not yet decremented to 0.

Trace window can be adjusted around a specific trigger spot using the CT-TBR trigger counter:

- Trace before
- Trace after
- Trace around

Once the capture has been disabled, the trace history can be read from the CS_DAP.

12.6.1.3.2 Trace Export Through Debug Port

For exporting trace data off-chip to an external trace receiver through the Debug Port, the CT-STM has a configurable export width of 1, 2, or 4 data pins (STM_DATA) plus a dedicated export clock (STM_CLK). Data width and clock selection are configured through the PTI and should not be changed on-the-fly.

STM trace export clock is derived from the Main PLL in conjuction with the PLL Controller.

Note that the STM trace export clock is referenced as "STM_CLK" from PLL perspective, and is referenced as "TRCCLK" from Debug Port perspective (Table 12-4).

For more information about STM trace export clock, Main PLL, and PLL Controller, see section 5.2, *Power Management*.

12.6.1.4 Software Messages

STM-based SW message is a software instrumentation method, which is light-weight in term of intrusiveness, and is very easy to use. With it, an application directly writes data to be logged to some memory mapped location of CT-STM, and CT-STM will automatically capture and export the data to external receiver or to the dedicated on-chip CT-TBR buffer. To have this, all SW masters have a write access path to the memory space of CT-STM, and each SW master has a distinguished Master ID.

The list of SW masters supported on this device is as follows:

- DSP C66x
- Arm Cortex-A15
- PMMC Cortex-M3
- PRU-ICSS_0 PRU0/1
- PRU-ICSS_1 PRU0/1

CT-STM supports 256 channels for each SW master. If up to 256 tasks (threads) running on same processor use different channels, they can log data to CT-STM simultaneously without any mutex/semaphore protection.

CT-STM provides multiple registers for configuring which software masters are enabled for generating trace messages. The cTools libraries then provide various APIs for generating the software messages.

12.6.1.5 Hardware Messages

Hardware messages are generated by the Tracer modules. For more information, see Section 12.6.2.

12.6.1.6 Message Interleaving

The CT-STM architecture allows interleaving of software and hardware messages. These flows are typically asynchronous and could result in concurrent or very close accesses arbitrated by the DEBUGSS instrumentation interconnect and signaled by a MASTER message. The CT-STM buffer allows absorbing write accesses peaks resulting from interleaving.

12.6.1.7 Master ID Encoding

The CT-STM uses a Master ID field to differentiate between hardware and software messages. It uses the following field encodings:

- MReqMstID[7]: Differentiates software masters versus hardware masters (0 signifies a software master; 1 signifies a hardware master)
- MReqMstID[6-2]: Signifies the ID that has been assigned to the master by the TeraNet configuration
- MReqMstID[1-0]: Additional qualifier for multicore masters. Unused on this device

For master ID values of all HW and SW masters, see Chapter 3, *Interconnect*.

12.6.1.8 Timestamping

The CT-STM supports automatic timestamping upon receiving system trace messages. The timestamp is exported along with the message.

Table 12-7 shows the structure of the CT-STM memory space for multiple channels.

Table 12-7. CT-STM Channel Memory Space

Byte Address		Channel	Size	Description
0x00000	0x007FF	0	4-KB	Data message (no timestamp)
0x00800	0x00FFF			Data message with timestamp
0x01000	0x017FF	1	4-KB	Data message (no timestamp)
0x01800	0x01FFF			Data message with timestamp
0x02000	0x027FF	2	4-KB	Data message (no timestamp)
0x02800	0x02FFF			Data message with timestamp
0x03000	0x037FF	3	4-KB	Data message (no timestamp)
0x03800	0x03FFF			Data message with timestamp
...	...	...	...	...
0xFF000	0xFF7FF	255	4-KB	Data message (no timestamp)
0xFF800	0xFFFFF			Data message with timestamp

The application software shall write to:

- The lower 2-KB window, to trigger a data message without timestamping
- The upper 2-KB window, to trigger a data message with timestamping

1-KB address spaces can also be allocated for each channel, in which case writing to the upper 512 bytes would trigger a data message with timestamping. The length configuration is not exclusive – one master may instrument its application code through 4-KB channels and another may do so through 1-KB channels simultaneously. Both hardware and software masters may operate this way.

The CT-STM also supports local timestamping where the timestamped messages are stored to the CT-TBR. The user should enable local time-stamping mode to use this feature. In this case, the CT-STM can receive one hardware message (32 bits) per cycle. Considering the hardware message only case, the CT-STM adds 4 bits additional information to each hardware message or 12 bits additional information to each hardware message if the CT-STM is configured to add a timestamp. The CT-STM can send processed hardware messages to the CT-TBR at 32 bits per cycle. Therefore, the sustainable rate is 8/9 hardware messages per cycle, assuming the timestamp is not added. The CT-STM can buffer up to 128 full messages at a time. We can assume the CT-STM consumes 8/9 messages per cycle and buffers 1/9 messages per cycle. Consequently, it can process up to 128*9 = 1152 back-to-back hardware messages. When the timestamp is added to the hardware message, the sustainable rate is 8/11 hardware messages per cycle and the CT-STM should be able to process up to 128 / (1-8/11) = 469 hardware messages back-to-back.

When the CT-STM runs out of buffer space, it will hold the reception of messages from the Tracer modules. This may cause overflow of hardware messages within the Tracer modules. The hardware messages do carry an overflow indication.

12.6.1.9 CT-STM Message Format

Table 12-8 shows the message format for packets processed by the CT-STM.

Table 12-8. CT-STM Message Format

ID	Data	Mnemonic	Description
0001	M[7-0]	MASTER	Master ID
0010	O[7-0]	OVRF	Number of overflows
0011	C[7-0]	C8	Channel
0110	D[31-0]	D32	Data
1010	D[31-0] T[7-0]	D32TS	Data and timestamp

This message format is used by both software and hardware masters. Data words are stored internally in 44-bit packets within an internal FIFO before being exported through the ATB (for CT-TBR) or PTI (for external trace receiver) interfaces.

12.6.1.10 Overflow

When there is overflow of input data to the CT-STM from hardware messages, the CT-STM will stall input from any source to avoid overflowing its buffers.

12.6.1.11 Reset

The CT-STM is reset with a hardware power-on-reset (POR). All CT-STM registers are asynchronously reset. The CT-STM shall remain operational and with its setup preserved when a warm reset is triggered in order to export the trace history to the trace controller. This trace history may contain valuable information from a debug perspective allowing the user to understand the root cause of the warm reset (e.g. security violation). Making the CT-STM unsensitive to warm reset will also allow tracing the transactions processed right after the reset without reconfiguration of the System Trace.

The application or debugger software can reset the CT-STM at any time by writing a 1 to the SOFTRESET bit of the CT-STM System Configuration Register. This will put the CT-STM in the same reset state as a hardware reset.

12.6.2 Tracer Architecture and Operation

This section provides an overview of the Tracer architecture and describes the operational concepts of the Tracer module, including event generation, message formatting/exporting, and integration with both the DEBUGSS System Trace Module (CT-STM) and DEBUGSS Trace Buffer and Router (CT-TBR).

NOTE: The Tracer modules are also referred to as CP_Tracers (Common Platform Tracers).

12.6.2.1 Purpose of the Tracer

Tracer modules are used in conjunction with their supported SoC masters to generate system trace events. Corresponding messages are then generated based on these events and can be read to obtain information about the status and performance of the system.

12.6.2.2 Tracer Features

The following features are available for the Tracer modules:

- One hardware Tracer module for each supported slave interface, each containing the following:
  - Support for events A through G as described in Table 12-9
  - Unique event inputs A, F, and G for each supported master
  - Event inputs B, C, and E shared among supported masters
  - Dedicated FIFOs for events A, B, C, and E
  - Message filters
  - Two throughput counters
  - Accumulated Wait Time counter
  - Num Grant counter
  - Message Formatter
  - VBUSP slave port for CPU access to Tracer MMRs
  - VBUSP master port for access to STM port of Debug Subsystem
- Multiple Tracer modules on the device. Assignment is as follows:
  - TRACER_0 for MSMC SRAM bank 0
  - TRACER_1 for DDR_EMIF
  - TRACER_2 for CORE
  - TRACER_3 for PCIE
  - TRACER_4 is reserved
  - TRACER_5 for MCASP/MCBSP
  - TRACER_6 for GPMC/MMC/QSPI
  - TRACER_7 for EDMACC_0/EDMACC_1
  - TRACER_8 for CFG SCR
  - TRACER_9 for ALWAYSON_CFG
  - TRACER_10 for ARM_GIC
  - TRACER_11 for CIC
  - TRACER_12 for ROM/SPI
  - TRACER_13 for ALWAYSON_MAIN
  - TRACER_14 for PRU-ICSS
- Common Bus Architecture (CBA) event generators embedded in the SCR that generate master events for CorePacs, IPs, SRAMs, and the CFG SCR
- CBA slave event interfaces for each Tracer
- Capability to export three different types of messages from captured event data (event, statistics, and

status messages)

- Tracers run on either CHIP_CLK1/1 (TRACER_0, TRACER_1) or CHIP_CLK1/3 (TRACER_2...14) clock
- Multiple master connections to each slave Tracer module

12.6.2.3 Tracer Architecture

The Tracer module generates and exports system trace messages based on events triggered by the SoC masters that support it. The Tracer module is used to collect real-time data from a system by setting up various counters and filter modes provided by the module. It uses synchronous CBA event generators through four different event interfaces connected to the SCR to format and export trace messages. It also has the capability to provide various filter modes to the events and export the produced messages to the CT-TBR inside the Debug Subsystem.

The Tracer also has statistics counters to monitor the real-time performance of the CBA infrastructure. These counters are also triggered by the CBA event generators built into the SCR. All event messages are sent through a VBUSP interface. Each Tracer connection is specified by a unique SID.

Figure 12-2 shows how the Tracer functional block is connected to other components of the SoC. The Tracer module supports connections from multiple supported masters to its CBA event inputs. Various masters trigger CBA event generators on their own respective modules according to which events are occurring. In addition to the original transaction requests sent from the masters to the targeted slave, these events are sent to the CBA slave interfaces on the Tracer module, where the Tracer forms messages to send to the STM for reformatting. Messages originating from the Tracers are 32-bits wide and are reformatted into larger packets within the STM. An additional 4 bits are used by the STM to signify that the message is a hardware message. The STM then sends messages to the CT-TBR or to an external trace receiver through the Debug Port.

Figure 12-2. Tracer Connection

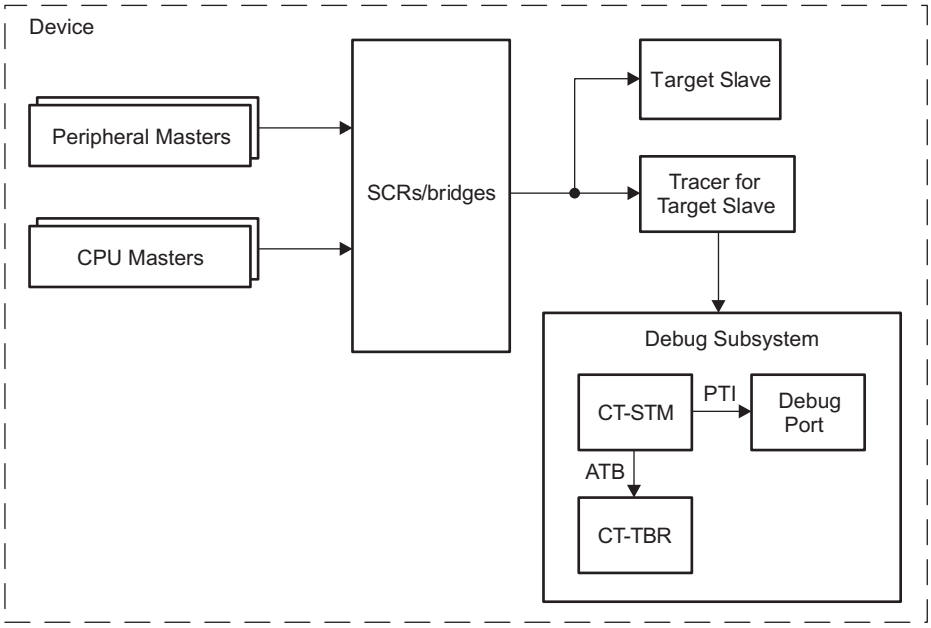


Figure 12-3 shows the individual CBA event connections from multiple IP masters to the Tracer for a particular slave. Each Tracer module has unique event A, F, and G inputs for each IP master it supports. For events B, C, and E, there is only one input for each of these events per Tracer module that is shared among supported IPs.

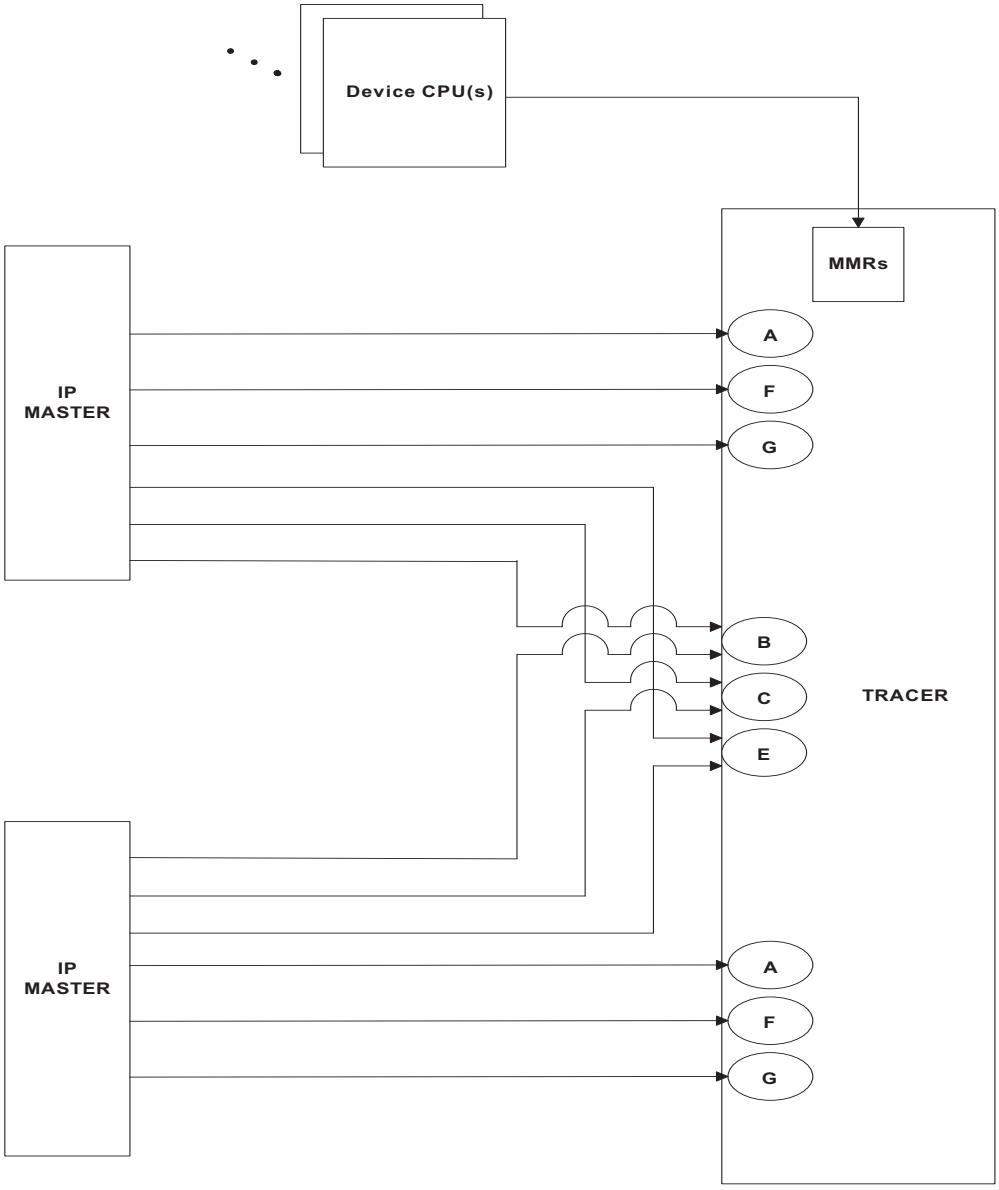
Figure 12-3. CBA Event Connections



12.6.2.3.1 Hardware Instrumentation through Tracers

There is a large number of masters in the SoC, all of which drive data transactions through the switch fabric (system interconnect), a certain minimum amount of visibility is required to balance priority and scheduling for successful system integration and debug. The following are requirements both in a debugger environment (host control through JTAG) and in the embedded system (host control through application software)

- Resource (memory) usage – Ability to track the bandwidth consumed by the system masters.
  - Bandwidth (#bytes/time)
  - Provide two configurable system master groups, and bandwidth tracking for each group
- Transaction trace – Ability to monitor the data transactions occurring by each master, to selected slave interfaces through tracing of key transaction points:
  - Arbitration won
  - Last data phase (transaction complete)
  - Two filtering functions for transaction traces to bring out the specific transactions:
    - Transaction-qualifier-based filtering: read/write
    - Address-range-based filtering
- Cross-triggering to turn on/off exporting capability from DSP/ARMSS.

To support this visibility, the Tracer module is integrated into the chip to monitor and trace the transactions to each of the high-speed memory slave ports of the main SCR(s). The Tracer is also used for tracing and monitoring the transactions sent to the configuration SCR peripherals.

NOTE: There is a bottleneck in the STM, such that it is not possible to activate all Tracer instances in the device at the same time.

The sliding time window specifies the measurement interval for all the CBA statistic counters implemented in the Tracer module. The sliding time window is specified in terms of the Tracer clock cycles. All the counters that are enabled start counting at the first transaction after the sliding window begins. When the sliding window timer expires, the counter values are loaded into the respective registers and the count starts again. If enabled, an interrupt is also generated when the sliding time window expires. The host CPU and/or EDMA can read the statistics counters upon assertion of the interrupt. If enabled, the counter value can also be exported to STM automatically after the sliding time window is expired.

12.6.2.3.2 Event Interface

The CBA event generation logic embedded in an SCR can generate events based on the transaction occurring at a master interface. The events are generated for every transaction targeted towards a particular slave interface. The master interfaces and the target slave interface for which the events are generated can be configured when the SCR is generated. Care should be taken such that the same transaction does not generate multiple events as it traverses through different SCRs in a system.

Tracer has interfaces to monitor and log the following events:

- New request event from master (Event A)
- New request event to slave (Event B)
- Last write data event from master (Event C)
- Last read data event to master (Event E)
- Write Merged (Event F)
- Command Discarded (Event G)

Tracer module provides the following filtering features:

- Filtering based on mstid on events B and E
- Filtering based on read/write on event B
- Filtering based on dtype on event B
- Filtering based on address range (inclusive of addresses within the range and exclusive outside the

range) on event B

- Filtering based on EMU0/1 control inputs on all events B, C and E

12.6.2.4 CBA Event Generation

For any transaction that targets a supported slave interface, an event can be generated to monitor the transaction from the master to the slave through the CBA event generators of Tracer. The user can determine how these events are generated and how they are exported.

When transaction requests are generated from an SoC master to a particular slave, that master can send event signals to the Tracer module for the targeted slave. The Tracer module in turn will route information to the CT-TBR within the Debug Subsystem or to an external trace receiver through the Debug Port. It is important to make sure the same transaction does not generate multiple events as it traverses the different SCRs in a system. Table 12-9 shows the different event types that can be triggered by Tracer.

Table 12-9. Tracer Events

Event	Action	Function
A	Master requesting to slave	This event triggers when there is a new request from the master decoded to the slave.
B	New request to slave	This event triggers when a transaction is sent to the slave.
C	Last write data to slave	This event triggers when the last write data is sent to the slave, thus completing the write burst.
E	Last read data from slave	This event triggers when the last read data arrives at the slave interface, thus completing the read burst.
F	Merge	Indicates that a write request from <mst> to <slv> has been merged with another request
G	Discard	Indicates that a read request from <mst> to <slv> has been discarded.

12.6.2.4.1 Event A - Master Request Event

Event A represents a master request transaction and is used for generating status and statistics messages from the Tracer. For example, consider a master issuing a write request to a target slave. The master could generate a transaction write request and at the same time generate an Event A on its CBA master interface which would then be sent to the CBA slave interface of the Tracer module for the targeted slave.

12.6.2.4.2 Event B - Arbitration Event

Event B represents a standard request to a slave that has been granted arbitration. With this event we can monitor many different transactions, so the user has the ability to establish filter modes to enable monitoring of the following:

- Trigger event when a transaction is sent to a slave. This signal interface does not track which master initiated the transaction. The Tracer uses dedicated event A CBA interfaces for each supported master for tracking the frequency of transactions from specific masters.
- Trigger event when the last transaction is arbitrated for a given command.
- Send the master ID associated with the given transaction.
- Send the arbitration direction associated with the given transaction.
- Send the dtype (0 for CPU Data Access, 1 for CPU Instruction Access, and 2 for DMA Access) associated with the given transaction.
- Send the transaction ID associated with the given transaction.
- Send the destination address associated with the given transaction.
- Send the byte count associated with the given transaction. This byte count is added to one of the throughput counters based upon how we configure the Transaction Qualifier Register. The throughput can be monitored based on a configurable timing window. The throughput gathered during the last timing window can then be read from one of two throughput registers, Throughput0 or Throughput1.
- The Transaction Qualifier Register and the Master ID Select Register N can be used to set any filtering

modes for generating Event B messages.

12.6.2.4.3 Event C - Write Completion Event

Event C is triggered when the last set of write data is sent to the targeted slave. This event also signifies the end of the write burst.

12.6.2.4.4 Event E - Read Completion Event

Event E is triggered when the last set of read data is sent to the targeted slave, completing the read burst. The associated master ID and transaction ID is also sent with this event. The MasterID Select Register N can be used to set any filtering modes required for this event.

12.6.2.4.5 Event F - Write Merge Event

Event F indicates that a write request from <mst> to <slv> has been merged with another request.

12.6.2.4.6 Event G - Read Discard Event

Event G indicates that a read request from <mst> to <slv> has been discarded.

12.6.2.5 Transaction Flow

Figure 12-4 shows the overall transaction flow of a Tracer event. The event is generated from the master interface with the transaction request. The Tracer creates the hardware message from the event that is routed to the STM to be stored on-chip or exported externally.

Figure 12-4. Tracer Generation

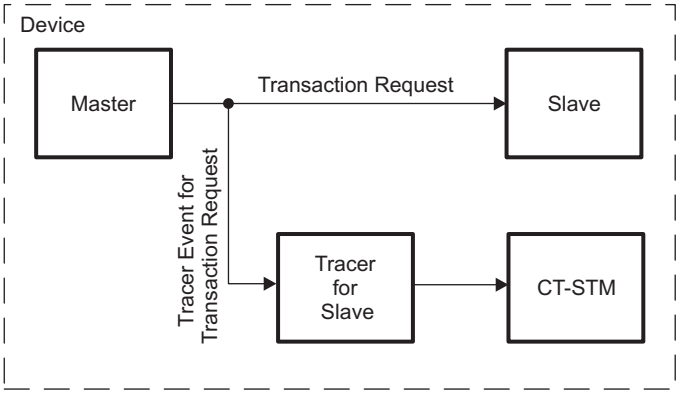


Figure 12-5 illustrates how an Event A can be generated and propagated to a Tracer module through a simple write to L2 memory.

Figure 12-5. Example—Event A to Tracer

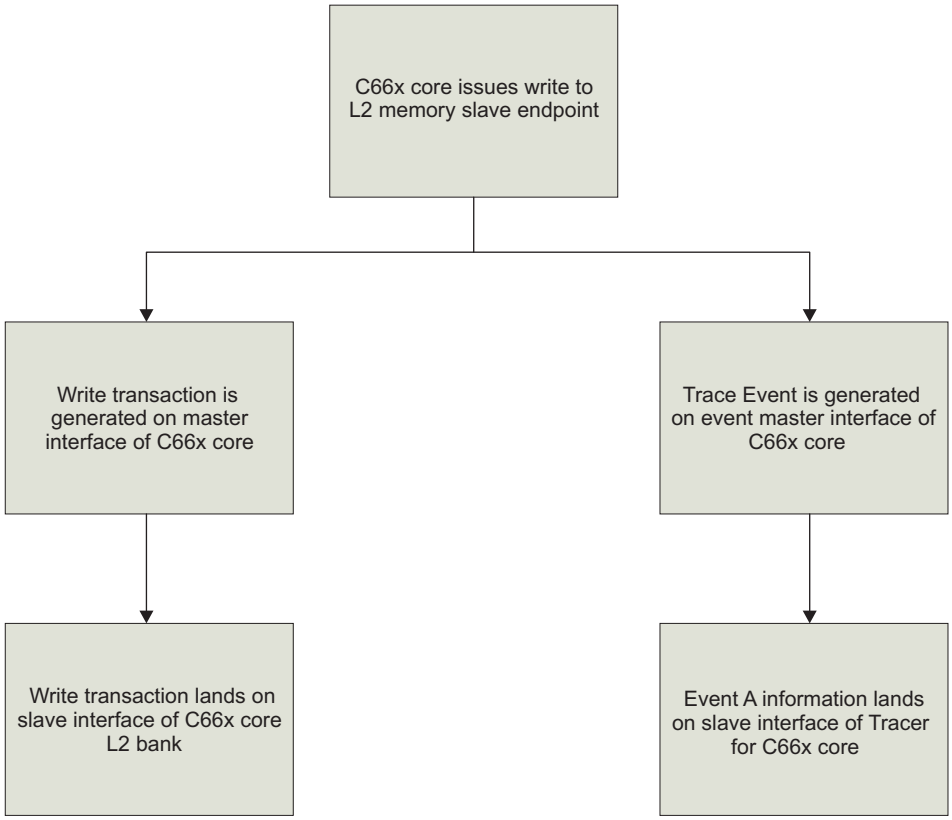

Figure 12-6 illustrates how an Event B is be generated and propagated through the Tracer module through a write to MSMC RAM.

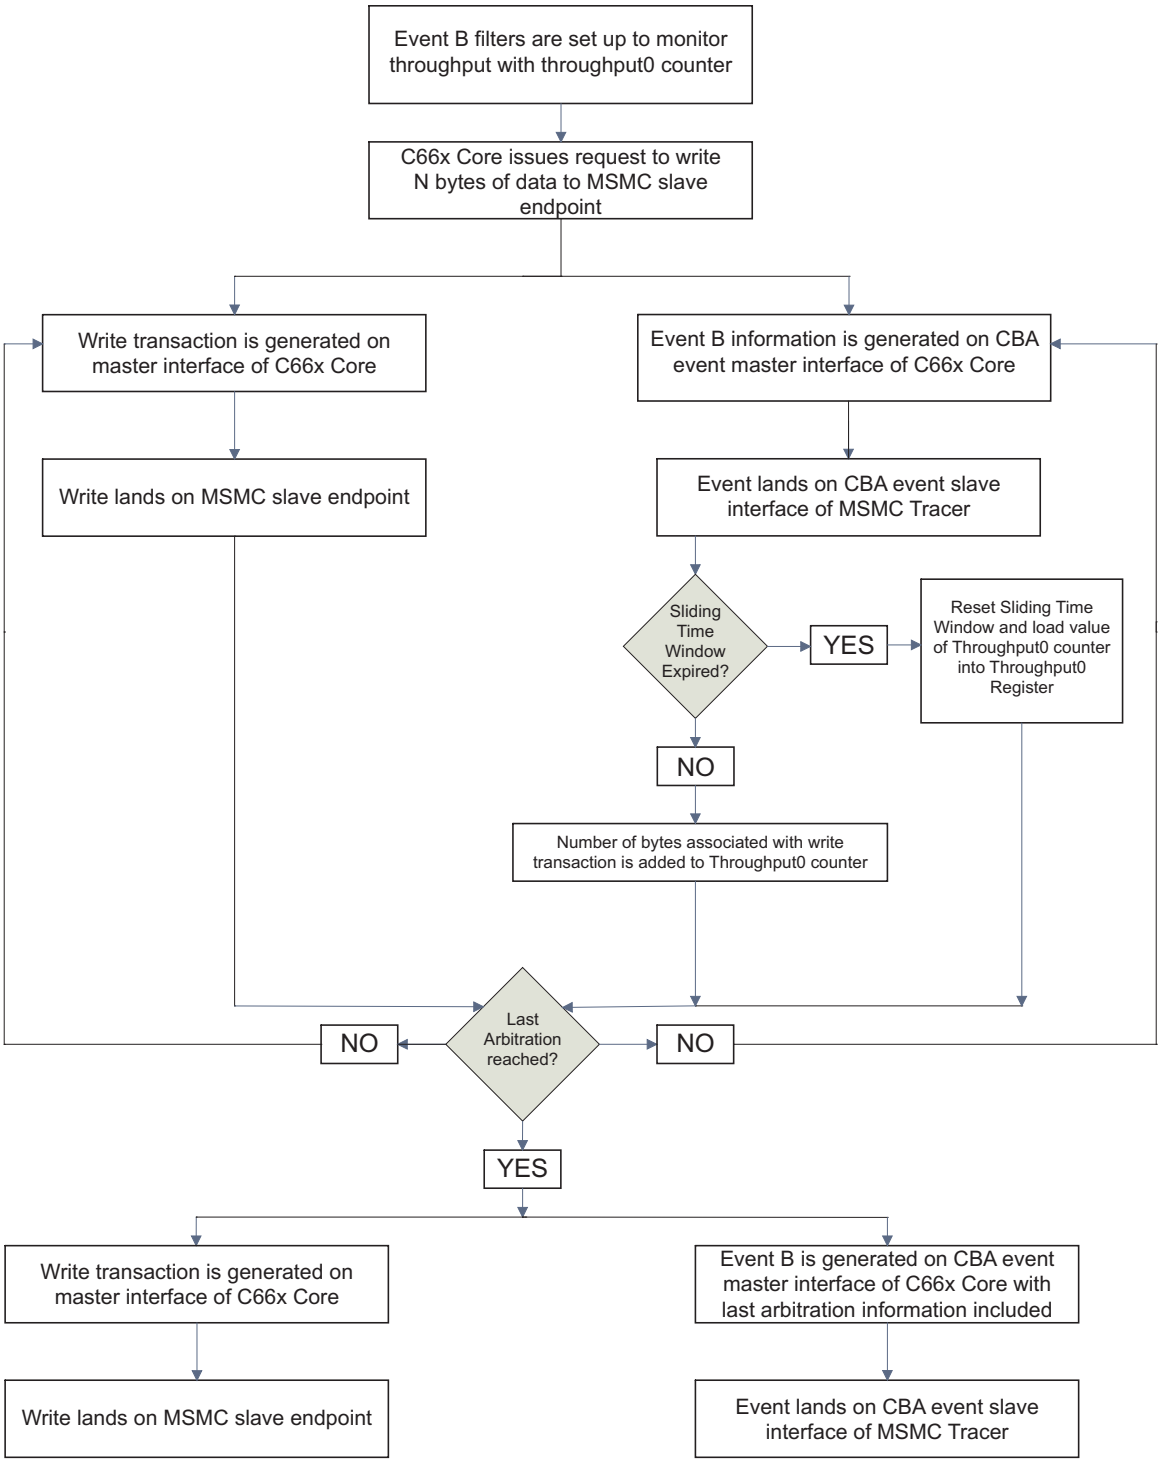
Figure 12-6. Example—Event B to Tracer



NOTE: There is only one Event B interface for the Tracer module for the MSMC target that is shared amongst masters, whereas there are unique Event A interfaces on this module for each supported master.

12.6.2.6 FIFOs

The Tracer modules implement the following FIFOs:

Event FIFO: This FIFO queues the event signals arriving at the CBA event slave interface of the Tracer.

Message FIFO: This FIFO queues the messages that are constructed by the Tracer logic after an event has been received. As long as there is at least one message pending in this FIFO, the VBUSP trace transfer controller will issue a 32-bit transfer to the STM.

12.6.2.7 Trace Message Formats

The Tracer modules generate different message types according to the events they receive at their CBA event interfaces. These messages contain all the information that the corresponding events were generated and filtered on. Event A is recorded through status messages, whereas events B, C, and E are recorded through event messages. The following sections describe the formats for the different messages generated by the Tracers, STM, and TETB.

12.6.2.7.1 Status Messages

Status messages (Figure 12-7) are generated for Event A and provide information on request interaction between masters and slaves.

Figure 12-7. Status Message Format

31 29	28 24	23	22 0
Type=000	SID	G	Access Status

The SID specifies which unique Tracer this message is generated from.

The Access Status field is used to associate the transaction with a particular master event I/F. Each bit of the Access Status field signifies whether a request has happened on that particular Event A interface since the last status message was exported. A '0' means that no request event happened on that Event A interface since the last status message was exported. A '1' means that one or more request event happened on an event A interface since the last status message was exported.

As we can have up to 32 interfaces from which status messages are generated from and a limited amount of bits for representation, the status message can appear in two formats, shown in Figure 12-8.

Figure 12-8. Status Message Format

31	30 29	28 24	23	22 0
0	00	SID	0	Access Status (I/F 22-0)

31	30 29	28 24	23	22 9	8 0
0	00	SID	1	All 0	Access Status (I/F 31-23)

In the first configuration, bits 0-22 represent master interfaces 0-22. In the second, bits 0-8 represent the master interfaces 23-31. The two types are differentiated by the G field, bit 23.

12.6.2.7.2 Event Message

Event messages are generated for events B, C, and E. Figure 12-9 shows the message format for event messages.

Figure 12-9. Event Message Format

31 29	28 24	23 16	15 12	11	10	9 0
Type	SID	MID	XID (3-0)	0	R/W	Address (9-0)

The type field is encoded as following:

- 0b001: event B
- 0b010: event C
- 0b011: event E

The other fields are as follows:

- SID specifies which unique Tracer this message is generated from
- MID specifies the unique master ID from which the transaction originated to this Tracer slave endpoint.
- XID specifies the transaction ID.
- O indicates overflow status.
- R/W can be used to determine whether the transaction was read or write.
- The Address field can be used to determine the 10 bits of the associated 48-bit address that are exported with the event. The Address Mask Register is used to determine which 10 bits are exported.

Not all fields are valid for all event messages. For each event message the following fields are valid. All other fields are read as 0:

- Event B: Type, SID, MID, XID, O, RW, Address
- Event C: Type, SID, O
- Event E: Type, SID, MID, XID, O

12.6.2.7.3 Statistics Message

Each statistics message contains 4*32 bits as shown in Figure 12-10:

Figure 12-10. Statistic Message Format

31 29	28 24	23 0
Type=100	SID	Throughput_count0 (23-0)
Type=101	SID	Throughput_count1 (23-0)
Type=110	SID	Total_wait_time (23-0)
Type=111	SID	Total_granted (23-0)

Throughput_count0—This field equals the throughput from register Throughput0.

Throughput_count1—This field equals the throughput from register Throughput1.

Total_wait_time—This field is read from the Accumulated Wait time counter.

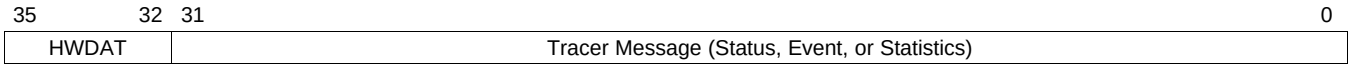
Total_granted—This field gives the reading of the grant counter which counts the number of times arbitration has been granted. The value is essentially equal to the number of B events that have occurred with arb_last asserted and is read from the Num Grant Counter.

Each of these fields is implemented by a dedicated counter in each Tracer and each start counting at the first transaction after the sliding time window begins. The sliding time window is explained in Section 12.6.2.10.

12.6.2.7.4 STM Message

The various messages from the Tracer modules are routed to the STM in the Debug Subsystem. Figure 12-11 shows how the messages originating from the Tracer modules will be encapsulated within STM.

Figure 12-11. STM Message Format



STM will pack incoming Tracer module data into 36-bit messages, 32 of which are data from the Tracer module and the most significant four bits are always 0b0110 to signify a HWDAT (Hardware Data) message.

12.6.2.8 CBA Counters and Statistics

Each Tracer's statistics counters allow the following statistics to be calculated:

- Bus bandwidth to slave used by one or more selected bus masters (bytes/sec.) = throughput for bus master X / sliding time window duration
- Average access size = throughput byte count / num accesses granted
- Bus utilization (transactions per second) = Num accesses granted / sliding time window duration
- Percentage of time there was contention for the bus = (accumulated wait time / sliding window length in cycles) * 100
- Minimum Average Latency = Accumulated Wait Time / number of accesses
- Percentage of bus throughput used by bus master X = (throughput for bus master X / throughput for all bus masters) * 100

, where sliding time window duration = sliding time window period in cycles / # cycles per second.

NOTE: The Tracers cannot measure average latency and average wait time. The Minimum Average Latency is not a true average arbitration latency, since it ignores the cycle counts where multiple bus masters are waiting at the same time. It will typically be lower than the true average latency.

12.6.2.9 Throughput Counters

Each Tracer module contains two throughput counters that can be enabled and filtered individually through specific registers. These counters are used in correspondence with Event B and exported as part of the statistics message. The throughput counters accumulate and record the total number of bytes forwarded to the target slave during the specified time duration. Filtering can be performed by address range, emu type, dtype, read/write transaction type, and master ID.

12.6.2.10 Sliding Time Window

Each Tracer module implements a sliding time window, measured in Tracer clock cycles, which specifies the total interval in which all CBA statistics counters are recorded. The Tracer clock cycles are tied to DMA cycles. In consequence, excluding CPU instruction or Data cycles in calculation will have no affect on the Tracer clock cycles computed. Excluding DMA cycles will exclude all Tracer cycles. When the sliding time window begins, all counters which are configured and enabled begin incrementing. When the sliding time window expires, these counter values are loaded into their respective registers and the counts repeat again based on the sliding time window interval. When a periodic stream is enabled (statistic counters or access status) messages are generated on expiration of the sliding time window even if there was no bus activity.

The interrupt raw bit of the Interrupt Raw Status Register is set when the window expires.

12.6.2.11 Cross-Triggering

By using EMU0 and EMU1 signals from a device CPU, there is the ability to start and stop trace recording at specific times with the STM instead of around transaction events. Both EMU0/1 assert respective signals in the Debug Subsystem that control trace start and stop. The Transaction Qualifier Register is used to determine whether to trace transactions between the assertion of EMU0 and EMU1 with the QUALIF_EMU field.

12.6.2.12 Filtering

For generating statistics and event messages, there are several filtering modes which can be applied before exporting messages. Filtering can be applied based on:

- mstid on events B and E
- read/write on event B
- dtype on event B
- address range (inclusive of addresses within the range and exclusive outside the range) on event B. If any bytes of a transaction fall within an address range then the transaction will pass the inclusive filter or fail the exclusive filter.
- EMU0/1 control inputs on all events B, C and E

12.6.2.13 Accumulated Wait Time Counter

The accumulated-wait-time counter is a 24-bit counter used to accumulate the number of cycles spent waiting for a request to be serviced. It is exported as part of the statistics trace message. When a new request is issued from a master device to a slave, this event will be captured on the Event A interface of the Tracer for the corresponding slave and the number of pending requests will be incremented. When a transaction is sent to the slave for this request, this event will be captured on the Event B interface of the Tracer and the number of pending requests will be decremented. As long as there are pending requests, the accumulation cycle count will be incremented. Events E and F will also decrement the pending count.

12.6.2.14 Num Grant Counter

This is a 24-bit counter that is used to count the number of times arbitration has been granted (the number of event B that occurred with arb_last asserted). This counter is reset when the sliding timer window expires. This counter is enabled by a software register bit. This counter value is exported as part of the statistics trace message.

12.6.2.15 Overflow Status

Due to limits in the Tracer event FIFO size and the STM bandwidth, overflow may occur and event traces could be generated faster than they are drained. To deal with overflow, Tracer modules implement an overflow bit for events B, C, and E. When set to 1 in the corresponding trace message, the bit indicates that there has been some event loss between the current event and the previous event of the same type. A value of 0 indicates that no event loss has occurred.

12.6.3 SoC Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor/subsystem/module to another. For example, a given subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another subsystem B can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events are: processor entering debug state, CS_PTM trigger, TBR full and acquisition complete, etc.

Examples of debug actions are: debug request generation, restart (Cortex-A15 synchronous run), interrupt request generation, start/stop trace, etc.

Subsystems cross-triggering is consolidated at device level by the XTRIG module, which is embedded in the DEBUGSS. XTRIG also supports the off-chip trigger channels (EMU0 and EMU1).

NOTE: XTRIG is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at subsystem level.

12.6.3.1 SoC Cross-Triggering Connection

The cross-trigger lines are shared by all the subsystems implementing cross-triggering. An Arm subsystem trigger event can therefore be propagated to any application subsystem or system trace component. The remote subsystem or system trace component can be programmed to be sensitive to the global SOC trigger lines to either:

- Generate a processor debug request
- Generate an interrupt request
- Start/Stop processor trace
- Start/Stop CBA transaction tracing through CP_Tracers
- Start external logic analyzer trace
- Stop external logic analyzer trace

Table 12-10 summarizes the SoC cross-triggering connections.

Table 12-10. Cross-Triggering Connections

Name	Source Triggers	Sink Triggers
Inside DEBUGSS		
Device-to-device trigger via EMU0/1 pins	Yes	Yes
MIPI-STM	No	Yes
DEBUGSS CT-TBR	Yes	Yes
DEBUGSS CS-TPIU	No	Yes
Outside DEBUGSS		
DSPSS	Yes	Yes
CP_Tracers	Yes	Yes
ARMSS/Cortex-A15	Yes	Yes
PMMC/Cortex-M3	Not supported	Not supported
PRU-ICSS	No	No
CT-TBR in PMMC TraceCell	Yes	Yes

Table 12-11 describes the cross-trigger connection between various cross-trigger sources and TI XTRIG module.

Table 12-11. TI XTRIG Assignment

Name	Assigned XTRIG Channel Number
C66x DSP	XTRIG 0
CP_Tracer 0..14	XTRIG 1.. 15

Table 12-12 describes the CoreSight cross-trigger connection between various cross-trigger sources and the DEBUGSS.

Table 12-12. CoreSight Triggering Assignment

Name	Assigned CoreSight Trigger Channel Number
ARMSS Cortex-A15	0
PMMC TraceCell	1
Reserved	2
Reserved	3

12.6.3.2 DEBUGSS Cross-Triggering Schemes and Components

The DEBUGSS implements two cross-triggering schemes:

- TI cross-triggering scheme
- CoreSight cross-triggering scheme

The DEBUGSS has multiple modules to manage triggering across these cross-triggering schemes:

- XTRIG module (TI cross-trigger module) to support merge and distribution of TI asynchronous triggers (2 channels per interface).
- CS_CTM (CoreSight Cross-Trigger Matrix) to support merge and distribution of CoreSight triggers (up to 4 interfaces and 4 channels per interface) to CoreSight components inside and outside of the DEBUGSS. The following subsystems are connected to the CoreSight Triggering Interface (CTI):
  - ARMSS (Cortex-A15)
  - TBR at the PMMC TraceCell
- CT_CTA module (CTools Cross-Trigger Adapter) to support conversion between TI asynchronous trigger format (2 channels) and CoreSight handshake-based asynchronous trigger format

This cross-triggering architecture of the debug subsystem allows it to provide the following features:

- Migration of a trigger originating from a CoreSight trigger source and ending at a TI trigger sink
- Migration of a trigger originating from a TI trigger source and ending at a CoreSight trigger sink
- Migration of a trigger originating from a CoreSight trigger source and ending at a CoreSight trigger sink
- Migration of a trigger originating from a TI trigger source in to a TI trigger sink

12.6.3.2.1 System Instrumentation Cross-Triggering

The CT_STM module interfaces with the SOC cross-triggering logic and implements two trigger input lines. These triggers can then be programmed by the user to start and stop collecting software instrumentation data:

- The EMU0 trigger line is coupled to software masters trace start
- The EMU1 trigger line is coupled to software masters trace stop

NOTE: The input triggers do not affect hardware masters trace. STM does not generate trigger outputs.

12.6.3.2.2 Cross-Triggering with External Devices

Based on DRM settings, the EMU0 and EMU1 lines may also be used as external triggers. Trigger0 is connected to the EMU0 device pin, and Trigger1 is connected to the EMU1 device pin.

12.6.3.2.3 CT-TBR

CT-TBR, used for hardware and software instrumentation, can generate and receive triggers. It uses the Arm CoreSight cross-triggering scheme.

12.6.3.2.4 TPIU

Trace Port Interface Unit (TPIU) is another Arm CoreSight component which receives trigger using the Arm CoreSight cross-triggering scheme.

12.6.3.3 ARMSS Cross-Triggering Schemes and Components

ARMSS uses the standard Arm embedded cross-trigger network for cross-triggering with other device subsystems/modules. The primary components making up the trigger network are CTIs and CTMs. There are multiple instances of CTI and CTM modules inside ARMSS wrapper. Only CTIs are programmable by software to generate/receive trigger events. They are listed as follows:

- The Cortex-A15 MPCore has one CTI
- At ARMSS level, there is a CTI used as a trigger interface for the CS-STM module
- In the ARMSS TraceCell, there is a CTI used as a trigger interface for the CT-TBR module

12.6.4 Emulation Aware Peripherals

Normal debug actions should not corrupt the correctness of the application and should keep the intrusion to the application to a minimum. This requires that all peripherals that are sensitive to debug events should be emulation aware. Specifically:

- A peripheral that is sensitive to a debug event (CPU halt) should behave properly during processor suspension. This is communicated to the peripheral from the CPU through an Emulation Suspend Event.
- A peripheral that is sensitive to debug access should distinguish accesses initiated from an emulator versus from an application. This is communicated from the debugging master to the peripheral as Emulation Requests
- Errors triggered by debug access should not cause any undesired interrupt or exception to the normal execution of a processor

12.6.4.1 Emulation Suspend Event

The device support a suspend mechanism, which provides a means to stop a closely-coupled hardware process running on a device peripheral when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripherals operate in a lock-step manner with a host processor.

To facilitate the operation of such peripherals, each of the C66x DSP, Arm Cortex-A15, and PMMC Cortex-M3 outputs a group of signals indicating their execution state. Accordingly, an entry is provided for each peripheral that needs to take into account the suspend signals from these processors.

Typically, two bits (SOFT and FREE) are implemented in the corresponding peripheral register dedicated to emulation control. The SOFT bit should be programmed based on whether or not an immediate pause of the peripheral function is required or if the peripheral suspend should occur only after a particular completion point is reached in the normal peripheral operation. The FREE bit should be programmed to enable or disable the emulation suspend functionality.

The DEBUGSS supports up to 32 emulation suspend sources (processor cores) and 64 emulation suspend sinks (peripherals). The assignment of processor cores and peripherals is shown in Table 12-13 and Table 12-14, respectively.

By default, the logical AND of all the processor cores' debug suspend signals is routed to all peripherals except for the tightly-coupled timers dedicated to each core. For these dedicated timers, default routing is such that each timer can be suspended by its associated DSP or Arm core. It is possible to select an individual core to be routed to the peripheral (e.g., used in tightly-coupled peripherals like timers), a logical AND of all cores (global peripherals) or a logical OR of all cores by programming the DRM module residing in the DEBUGSS. The DRM module implements a Suspend Control logic for routing purpose.

Table 12-13 summarizes the suspend sources (device cores) assignment.

Table 12-13. Suspend Sources Assignment

DRM Suspend Control Input	Device Core
0	DSP C66x
1-6	Unused (tied to 0)
7	PMMC Cortex-M3
8	Arm Cortex-A15
9-29	Unused (tied to 0)
30	Logical OR of core # 0,7,8
31	Logical AND of core # 0,7,8

Note that the emulation suspend signals of all the cores are synchronized to CPU/6, which is the frequency of the slowest peripheral that uses these signals.

Table 12-14 summarizes the suspend sinks (device peripherals) assignment.

Table 12-14. Suspend Sinks Assignment

DRM Suspend Control Output	Device Peripheral
0	TIMER_0
1	TIMER_1
2	TIMER_2
3	TIMER_3
4	TIMER_4
5	TIMER_5
6	TIMER_6
7	I2C_0
8	I2C_1
9	I2C_2
10	UART_0
11	UART_1
12	UART_2
13	PRU-ICSS
14	NSS_L
15	DCAN_0
16	DCAN_1
17	ePWM_0
18	ePWM_1
19	ePWM_2
20	ePWM_3
21	ePWM_4
22	ePWM_5
23	SRSS
24	MCBSP
25	eCAP_0
26	eCAP_1
27	eQEP
28-63	Unused

12.6.4.2 Emulation Requests

To make an emulation access to peripheral non-intrusive, some of peripherals need to distinguish accesses from CPU (application code) versus from emulator (debugger). In general, peripheral with following register/state behaviors should distinguish the access from CPU versus from emulator to preserve the peripheral's state:

- An access initiating a flag clear
- An access initiating a pointer update
- An access initiating a peripheral state-machine update
- An access error initiating a bit being set in error register

Otherwise, when a developer opens a memory window in CCS to view peripheral's registers, the application software execution will potentially be corrupted due to unexpected change of the peripheral state.

To facilitate such operation, the protocol of VBUSM and VBUSP buses, which interconnect different units in the system, provides signals *cemudbg* or *emudbg* to differentiate a bus transaction initiated from the CPU or from an external emulator.

All peripherals that need to be aware of the emulation access must make use of the *cemudbg* or *emudbg* signals correctly to prevent side effects from occurring.

12.6.4.3 Peripherals Emulation Support Summary

Table 12-15 lists all the peripherals on this device, and the status of whether or not a peripheral supports emulation suspend or emulation request events.

Table 12-15. Peripherals Emulation Support Summary

Peripheral	Emulation Suspend Support				Emulation Request Support (cemudbg/emudbg)
	Stop Mode	Real-Time Mode	FREE Bit	SOFT Bit	
EDMA_x (x=0,1)	N	N	N	N	Y

PMMC	N	N	N	N	Y
MSGMNGR	N	N	N	N	Y

Refer to the corresponding peripheral chapters for more details.

12.6.5 DMA Tooling

The EDMA is a powerful tool that can provide detailed visibility to the data flow through the device with minimal intrusiveness on real-time operation. Through the EDMACC, any event can be used to trigger a DMA transfer, or sequence of transfers. Additionally, any DMA transfer can generate an event back to the EDMA to chain to a "debug" transaction.

The EDMA has full visibility to the chip memory map and can access any location with an address, except the internal DSP configuration registers. The DMA has ability to initiate transactions at any priority level, so that DMA "debug" transactions can be dedicated to priority 7 (low), and completed on a dedicated transfer controller channel (physical channel that performs reads/writes).

Debug transactions triggered by system events, or DMA transfers (chaining) of interest can be used to capture:

- System time
- Transfer information (address, ID, data, etc)
- Statistics transactions can be kicked off periodically

All EDMACC events can be traced through DSP, when configured in the system event router, which allow the application or host tooling to leverage the DSP AET logic. This facilitates:

- Matching DMA activity to CPU activity
- Counting time between events of interest, such as transfer time, time between transfers, etc

12.6.6 Power/Clock/Reset Emulation Support

12.6.6.1 Power/Clock Emulation Support

Debug should not hang when:

- It accesses a target which is under clock-gate or power-down since the access path is not functioning
- During an access, the target gets clock-gated or gets powered-down

To meet the above requirement, the DEBUGSS provides interfaces for a debugger to interact with the system power/clock control module (PSC module). The interface provides the power/clock/reset status of the subsystem under the Debug TAP or Debug Cores, and the controls to force the target active (clock and power back on) or prohibit it from being clock-gated or powered-down.

If an emulation access is made to a peripheral whose clock is gated, the emulation access shall still complete as this should be guaranteed by SCR and PSC infrastructure.

If an emulation access is made to a memory region whose clock is gated, the emulation access shall still complete as this should be guaranteed by SCR and PSC infrastructure.

12.6.6.1.1 Emulation Power Domain

The emulation power domain (PD1) can be switched off in normal operating mode to reduce active power consumption. Emulation power domain includes most of debug modules that are not mandatory in customer applications.

By default, emulation power domain is active after POR. Application software must switch off the domain when no debug is required. The application software can also wake up the emulation domain at any time, even if no debugger is attached to the device. This is typically required to support trace or monitor-based debugging.

12.6.6.1.2 ICEMelter Module

ICEMelter is a small module residing in the ALWAYS_ON power domain (PD0) that controls the wake-up and power-down of the emulation power domain. ICEMelter monitors several system signals and device pins to determine if the emulation logic should be active or in a dormant state.

ICEMelter includes:

- Monitoring of the EMU0 and EMU1 device pins
- Monitoring of the JTAG device pins
- Interaction with the ICEPick module
- Interaction with the device PSC module

ICEMelter is designed to support the following activities:

- Wake-up of the emulation power domain when an external debugger is first attached
- Power-down of the emulation power domain after an external debugger is disconnected

When a debugger is attached after the emulation power domain is switched off by the application software, based on the activity of the debug interface pins, ICEMelter can send a request to the PSC module to ramp-up the emulation power domain.

ICEMelter is not programmatically visible from the JTAG interface or any device processor.

12.6.6.2 Reset Emulation Support

Software developers often would like to debug the behavior of their program from a reset condition, or even through reset. In both cases, the emulator must continue to be able to connect to and communicate with on-chip emulation logic while the chip is held in reset. The following features are supported through the ICEPick interface of the DEBUGSS:

- Support for debugger-generated global reset (CHIP_0_RST) via ICEPick and a way to block this reset generated by applications, such as the watchdog timer reset
- Support for debugger-generated local reset via either ICEPick or individual processor's local resets, as

well as the way of blocking such subsystem reset

- TRSTz/TLR reset applies only to test logic and some security related logic. TRSTz/TLR reset does not affect any functional operation of the device

NOTE: Any warm reset that leads to a CHIP_0_RST causes power cycling of DSP subsystem including the debug logic. The workaround to this issue is to require the debug driver to assert the "Force Active" command during a debug session to keep the PSC from power cycling the DSP subsystem.

For more information about the reset emulation support in the device, see Chapter 5.3, *Reset Management*.

12.6.7 Debug Boot Modes

The DEBUGSS supports debug boot modes determined from its input signals EMU[1:0] upon a rising edge of POR reset. Table 12-16 shows the details:

Table 12-16. Debug Boot Modes

EMU[1:0] Pins	TAPs in TDI->TDO path	Comment
0xb	N/A	Reserved
10b	ICEPick	Hardware Wait-In-Reset (WIR)
11b	ICEPick	Default condition

This feature is used to debug run-away boot code on the device.

12.6.7.1 Default Condition

None of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

12.6.7.2 Hardware Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

12.7 Programming Guidelines

12.7.1 Application Support

TI includes a set of system level debug facilities in the Debug Subsystem of devices known as Chip Tools (CTools). For easy integration of DSP Core Trace and System Trace into applications, a set of libraries commonly referred to as CToolsLib are provided. CToolsLib is a collection of embedded target APIs/libraries focused on enabling easy access to the CTools. CToolsLib encompasses the following libraries to assist in trace integration:

- DSP Trace Library
- AET Library
- STM Library
- CP Tracer Library
- ETB/TBR Library
- PTM/ETM Library
- CTools Use-Case Library

For more information about these libraries, downloadable files, and other useful links, please visit the CToolsLib Wiki site:

http://processors.wiki.ti.com/index.php/CToolsLib

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

12.7.2 Programming Overview

The following sections demonstrate the capabilities of the cTools libraries for various debug tools. Care should be taken to make sure the power and sleep controller for the Debug Subsystem is enabled before proceeding with further debug configuration.

12.7.2.1 DSP Core Trace Specific Configuration

DSPTraceLib enables the user to do the following:

- Claim ownership of the Trace Export Block
- Configure Pin Manager
- Claim and enable trace streams
- Configure type of trace capture
- Start/stop trace recording

12.7.2.2 AET Specific Configuration

CToolsLib for AET provides APIs for configuring the AET logic for various trace jobs. The AET library enables the user to do the following:

- Initialize AET
- Claim AET
- Set up AET to trigger on a certain set of conditions
- Start/Stop triggering with AET

12.7.2.3 STM Specific Configuration

CToolsLib provides various APIs for STM configuration as follows:

- Sending various types of software messages.
- Configuring the Tracers and generating various types of hardware messages

In addition, the STM can be configured for the following features:

1. Setting STM for optimized or unoptimized operation. In optimized operation only a pointer to the message string is transported, unlike in unoptimized operation where the entire null terminated string is transported.
2. Configuring STM channel resolution to either 1024 or 4096 bytes for specified channels

12.7.2.4 Debug Pin Manager Configuration

To export trace data off chip to an external trace receiver, the Debug Pin Manager of the DRM must be programmed to specify which pins will be used for export and for what purpose. With TI's CToolsLib, this configuration is performed automatically.
