The AWR2944P/AWR2E44P is a single chip radar transceiver with integrated 76-81 GHz LO, 4 RXs, and 4 TXs, along with an integrated DSP and main MCU that are both accessible for customer use. The AWR2944P/AWR2E44P is a new silicon design based of AWR2944 SOC to achieve enhanced system performance (range) and optimized area. It is a seamless upgrade from AWR2944 with full hardware compatibility (pin to pin for AWR2944P) and maximum SW reuse for fast time to market. This chip is targeted for applications such as blind spot detection, lane change assist, low cost automatic cruise control and automated emergency braking. This chapter introduces the features, subsystems, and architecture of AWR2944P/AWR2E44P Systems on Chip (SoCs).

Note

AWR2x44P device name will be used further in this document which correlates to both AWR2944P and AWR2E44P device variants.

1.1 Device Overview

The AWR2x44P is targeted for Advanced Driver Assistance System (ADAS). These SoCs aims to meet the complex processing needs of end equipment such as High End corner Radar, Entry level/Mid end Front Radar, and Blind Spot Detection (BSD).

The SoC has been designed as a low power, high performance, and highly integrated device architecture, adding significant enhancement on processing power and coherent memory support. In addition, they support state of art security and functional safety features.

Some of the main distinguished characteristics of the device are:

- Frequency-modulated Continuous Wave (FMCW) Radio Frequency Transceiver
 - Integrated PLL, Transmitter, Receiver, Baseband and A2D
 - 76-81 GHz Coverage with 5GHz available Bandwidth
 - 4 Receive channels
 - 4 Transmit channels
 - Per Transmit Phase Shifter
 - Ultra-accurate Chirp engine based on Fractional-n PLL
- Wide IF bandwidth up to 20 MHz to decrease range/Doppler ambiguity
- Highly programmable chirp generation
- 12, 14, and 16-bit I-Only ADC With Variable Baseband ADC Sampling Rates up to 45 Msps.
- High Performance Radar Processing Accelerators having capability to offload the DSP/CPU almost all the pre-processing functions.
- High Performance C66x DSP to perform high end post-processing function such as statistical beam forming or high-end classification algorithms.
- Hardware Security Module (HSM) – To provide secure execution environment.
- High Performance/Cost ratio. Highly optimized, area efficient infrastructure to support the radar data flow with maximum cost effectiveness and efficiency.
- High Temperature operating range (>125°C) for Industrial use cases (with relaxed profile).
- 4.5 Mbytes of 'on Chip' RAM .

- Dedicated M4 core to configure/control the HWA operations. This core is part of the DSP Subsystem. In this document, this core is referred to as either HWA_M4 or DSS_M4; both terms denote the same core.

The device is composed of the following main subsystems:

- One Lock-step Cortex R5F microcontroller at up to 400 MHz.
- One TI C66x variant Single Core Floating point DSP at up to 450 MHz
- Radar Hardware Accelerators running at 400 MHz
- Cortex M4-based (200MHz) Hardware Security Module (HSM) for running security services in a secure island.
- Cortex M4 to control/configure HWA running at 200MHz
- Radar Subsystem (RSS) comprises of a lockstep CR4 microcontroller at up to 200 MHz, Digital front end (DFE) at up to 200 MHz, and Analog-RF subsystem. This group of modules is referred as BIST SubSystem(BSS) and in the later chapters BSS or RSS will be used interchangeably as and when required.

Note

For MSS_TCMA_CR5A 0xC100 0000, 192 KB size includes size of TCMA RAM (64kb) and TCMA ROM (128KB). ROM-to-RAM (RBL to SBL) switching causes TCMA_ROM_CR5A eclipse to TCMA_RAM_CR5A i.e. 0x0000 0000 now maps to TCMA_RAM_CR5A memory area.

Note

TCMB are 0x0002 0000 and 0x0008 0000 respectively as per R5A view. For AXI slave (EDMA or other processors) view addresses are 0xC100 0000 and 0xC180 0000.

The device implements a system interconnect based on TI's common bus architecture, comprising of VBUSM and VBUSP protocols.

The system interconnect is designed for the high-performance needs of the system. The interconnect structure is a full crossbar implementation, wherein every controller has an independent communication path with every target such that transactions from each controllers have access to full interconnect bandwidth. Arbitration only happens at target end point. It's divided into interconnect systems local to each subsystem: the Main R5F subsystem, DSP subsystem, and Radar Subsystem .

3.1 Main Subsystem R5F Infrastructure

In the main subsystem, the primary VBUSM SCR is responsible for managing the arbitration priority between accesses from multiple controllers to each of the targets. The arbitration priority is always round-robin.

The main subsystem has PCR interconnect that manages the accesses to the peripheral registers and peripheral memories, and provides a global reset for all peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device clocks, interrupts, and so forth.

The system module registers include status flags for indicating exception conditions – resets, aborts, errors, and interrupts.

General description about the PCR

The Peripheral Central Resource (PCR) provides decoding and multiplexing between the peripheral bridge and the peripherals and memories. The peripheral bridge is connected to the PCR using the VBUSP. The VBUSP protocol is used to communicate with the peripherals selects (PS), the peripheral memory frame (PCS). Each PS, PPSE (for system peripherals) frame can be fractioned into 4 quadrants, that can occupy 256 bytes each. For PCS, there is no provision of quadrants.

Different ways to protect a peripheral using PCR

1. **Using the PMPROT (peripheral memory protection) and PPROT (peripheral protection) registers** - using these registers, it is possible to restrict writes to each one of the non-system peripherals individually to only the privilege mode. Here, PMPROT is being used for PCS region and PPROT registers are being used to protect the PS region.
2. **Using the master-id registers** - using these registers, access to a slave can be restricted for a particular master (maximum 16 masters) using master-id register bits. PCR will respond with an address error (AERROR) for requests from masters which does not have access privilege through master-id registers. To utilize the master-id protection for the peripherals, the Software should first program master-id registers for all generated frames by enabling writes to master-id registers through master-id protect write enable register (MSTIDWRENA). Then enable the master-id check through the master-id enable register (MSTIDENA).

Register size	Number of assigned quadrant	Quadrant 0	Quadrant 1	Quadrant 2	Quadrant 3
<256	1	✓	✓	✓	✓
512> >256	2	✓	-	✓	-
1K> >512	4	✓	-	-	-
>1K	N/A	-	-	-	-

How the quadrants are being used in a PS frame

The following are the ways in which quadrants are used within a PS frame:

1. The slave uses all the four quadrants: Only the bit corresponding to the quadrant 0 of PS_n is implemented. It protects the whole 1K-byte frame. The remaining three bits are not implemented.
2. The slave uses two quadrants: Each quadrant has to be in one of these groups: (Quad 0 and Quad 1) or (Quad 2 and Quad 3). For the group Quad0/Quad1, the bit quadrant 0 protects both quadrants 0 and 1. The bit quadrant 1 is not implemented. For the group Quad2/Quad3, the bit quadrant 2 protects both quadrants 2 and 3. The bit quadrant 3 is not implemented.
3. The slave uses only one quadrant: In this case, the bit, for that specific quadrant will protect the whole peripheral.

Figure 4-1. Device Initialization

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

4.2 Boot Process

4.2.1 ROM Code Overview

To accommodate various system scenarios, the ROM code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host through the selected interface (such as UART). Either the host writes the application code directly into internal memory over UART, or the ROM code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

- Hardware initialization phase
- Boot process

During initialization, the ROM code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements. During the boot process, the boot image can be loaded into device memory and executed, depending on the boot peripheral. HSM ROM code performs code verification and allows or forbids the image execution.

The main configuration source for boot after power-up are the SOP mode pins sampled automatically after reset release and stored in device status registers. At ROM code startup, these pin values are read from the registers to create the boot peripheral list, and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

4.2.2 Boot Modes

MCU ROM supports the functionality of loading the secondary boot loader (SBL). The SBL can be loaded through QSPI (primary/secondary SBL) and UART mode. The primary use case of QSPI programming through UART interface is to support the uniFlash utility. This mode programming may be applicable for certain use

cases, such as initial FLASH programming in volume mass production, that can also be achieved with special in-circuit gung programming tools.

Primary functional boot mode is through QSPI FLASH. MCU ROM supports managing multiple (primary and backup) QSPI SBL images. It can identify the primary image, and switch to secondary image load if primary image load fails.

Table 4-1. Boot Modes and Boot Media

Boot Mode/Peripheral	Boot Media/Host	Notes
QSPI	QSPI flash	Download and boot SBL from QSPI flash. Attempt Primary SBL, followed by Secondary SBL if primary loading fails: If above is not successful
UART	External host	Download and boot SBL from UART. Device is expected to get SBL from UART. We will support the XMODEM protocol for download over UART.

For more information about various bootmode and flash device support please refer to [application note](#).

4.2.3 SOP Mode Pins

Table 4-2 lists the functional mode pin settings to be done for the SOP lines of the device to boot using different peripheral. New SOP modes will be added later.

Table 4-2. Functional Mode Pin Settings

Functional Mode	SOP Mode	PMIC_OUT	SYNC_OUT	TDO
Func Mode –QSPI	SOP_MODE4	0	0	1
Func Mode –UART	SOP_MODE5	1	0	1

4.2.4 BOOT-ROM Architecture (RBL)

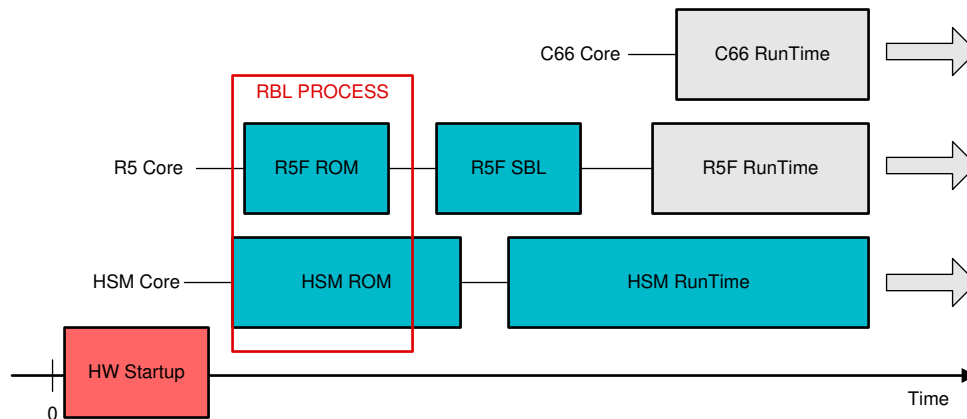

Figure 4-2. Boot Flow and Boot ROM Architecture

The RBL process goal is to load, verify, optionally decrypt, and launch an authentic R5F software image that accomplishes general-purpose/secure boot goals. The RBL process is implemented jointly by the R5F and HSM ROM as illustrated in Figure 4-2.

HSM ROM

This HSM ROM contains the first set of software instructions that is executed by any processor core on all AWR2944P devices. All state changes in the device after the external reset is released but prior to the beginning of the HSM ROM code execution are purely a function of hardware logic. This hardware logic must perform sufficient ramp up and initialization to allow the Cortex M4 core of the HSM to leave reset and begin execution from its reset vector. The HSM ROM code is “time zero” software. The HSM ROM code is only intended to be

used during the initial load of the secondary boot loader (SBL) and HSM RunTime image. HSM ROM is also responsible for providing Test/Debug capabilities when functional boot is interrupted.

R5F ROM

The R5F ROM code is only intended to be used during the initial load of the secondary boot loader (SBL). RBL can load the SBL content only to MSS_L2 area and at the end copies SBL's IVT (interrupt vector table) of 640B size to TCMA_RAM_CR5A before switching to SBL. This ROM-to-RAM (RBL to SBL) switching causes TCMA_ROM_CR5A eclipse to TCMA_RAM_CR5A i.e. 0x0000_0000 now maps to TCMA_RAM_CR5A memory area. Use of RBL at any other time in the lifecycle of a system is not supported. R5F ROM executes set of self-tests: PBIST (DATA SRAM, PROGRAM SRAM, and ROM Code Integrity) using a hardware-defined interface. If unsuccessful, the error condition is indicated, external ESM signal asserted, and boot does not proceed.

R5F SBL

This SBL can perform complete boot sequence on general purpose devices. Customers are expected to develop their own SBLs, supporting a wider range of requirements (such as different interfaces, additional protocols, different image formats, future update flow and so forth).

HSM RunTime/R5F Runtime/C66 RunTime

HSM RunTime is only applicable in case of Secured (HS) variant and out of scope of this document. R5F and C66 RunTime are user developed applications and loaded/executed by SBL.

4.2.5 R5F SBL Loading

The SBL process starts with R5F executing loaded and verified R5F SBL code.

The only service exposed to R5F SBL by HSM ROM is the API to load the HSM RunTime. All other HSM services are outside of the HSM ROM. The R5 Boot ROM and HSM Boot ROM work together to load the R5F SBL. When the R5F SBL has been successfully validated and loaded, the R5F Boot-ROM is eclipsed and the R5F SBL executes.

Figure 4-3 is the simplified sequence of the boot process. It is provided for illustration purposes only. An illustration of the SBL and HSM RunTime is similar to what is shown in Figure 4-3.

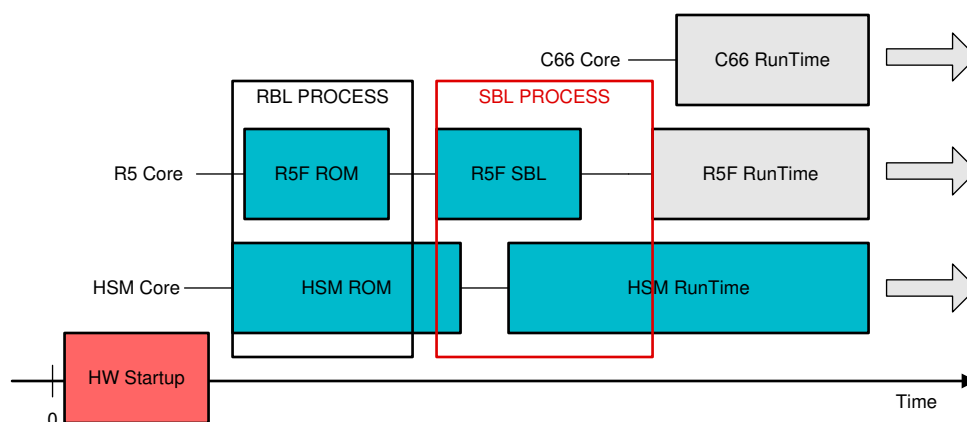

Figure 4-3. R5F SBL

HSM ROM configures the IPC interface, unhalts the R5F core, and then waits for a confirmation message from the R5F Core (over IPC). The R5F core sends a confirmation to the HSM ROM. The R5F ROM then configures the QSPI interface and reads the R5F SBL image from FLASH. The SBL image might or might not have integrity check enabled (based on the certificate). HSM ROM switches the memory map for R5F from ROM to RAM and resets the R5F to execute the SBL image. The HSM-ROM for GP devices is now locked (black-boxed). SBL can now load the multicore image (containing MSS & DSS application and RSS firmware/patch images)

to the corresponding RAMs and core soft-reset to jump to R5F RunTime. SBL or R5F RunTime can release out-of-reset & unhalt RadarSS and C66x subsystems.

For more information about SBL and bootloading please refer to the [application note](#)

Note

R5F SBL is user spaced application, so SBL can be written as per customer requirement but within device capability. [MMWAVE-MCUPLUS-SDK](#) provides reference SBL implementation for AWR2x44P device.

5.1 Overview

PRCM manages clocks, resets, and power domain control of subsystems and modules inside the device. Additionally, configuration of certain device-level features is also performed through this module. PRCM has control and status registers to achieve this functionality. The Clock and Reset Management in AWR2944P is distributed. The Main subsystem TOPRCM module controls all the Subsystem Resets and Clocks. The SubSystem RCM modules control their respective subsystem IPs

The available address space of PRCM is divided as in [Figure 5-1](#).
