

## ADS125H01 $\pm 20$ -V Input, 40-kSPS, 24-Bit, Delta-Sigma ADC

### 1 Features

- $\pm 20$ -V input, 24-bit delta-sigma ADC
- Programmable data rate: 2.5 SPS to 40 kSPS
- High-voltage, 1-G $\Omega$  input impedance PGA:
  - Differential input range: up to  $\pm 20$  V
  - Absolute input range: up to  $\pm 15.5$  V
  - Programmable attenuation and gain:
    - 0.125 to 128
- High-performance ADC:
  - Noise: 45 nV<sub>RMS</sub> (gain = 128, 20 SPS)
  - CMRR: 105 dB
  - 50-Hz and 60-Hz rejection: 95 dB
  - Offset drift: 10 nV/ $^{\circ}$ C
  - Gain drift: 1 ppm/ $^{\circ}$ C
  - INL: 2 ppm
- Integrated features and diagnostics:
  - Internal oscillator
  - Signal and reference voltage monitors
  - Cyclic redundancy check (CRC)
- Power supplies:
  - AVDD: 4.75 V to 5.25 V
  - DVDD: 2.7 V to 5.25 V
  - HVDD:  $\pm 5$  V to  $\pm 18$  V
- Operating temperature:  $-40^{\circ}$ C to  $+125^{\circ}$ C
- 5-mm  $\times$  5-mm VQFN package

### 2 Applications

- [PLC analog input modules](#):
  - Voltage ( $\pm 10$  V or 0 V to 5 V)
  - Current (4 mA to 20 mA with shunt)
- [Data acquisition \(DAQ\)](#):
  - High common-mode voltage inputs
  - High-side current measurement
- [Battery tests](#)

### 3 Description

The ADS125H01 is a  $\pm 20$ -V input, 24-bit, delta-sigma ( $\Delta\Sigma$ ) analog-to-digital converter (ADC). The ADC features a low-noise programmable gain amplifier (PGA), a clock oscillator, and signal or reference out-of-range monitors.

The integration of a wide input range,  $\pm 18$ -V supply PGA and an ADC into a single package reduces board area up to 50% compared to discrete solutions.

Programmable attenuation and gain of 0.125 to 128 (corresponding to an equivalent input range from  $\pm 20$  V to  $\pm 20$  mV) eliminates the need for an external attenuator or external gain stages. A 1-G $\Omega$  minimum input impedance reduces error resulting from sensor loading. Additionally, the low-noise and low-drift performance allow direct connections to strain-gauge bridge and thermocouple sensors that are affected by high common-mode voltage.

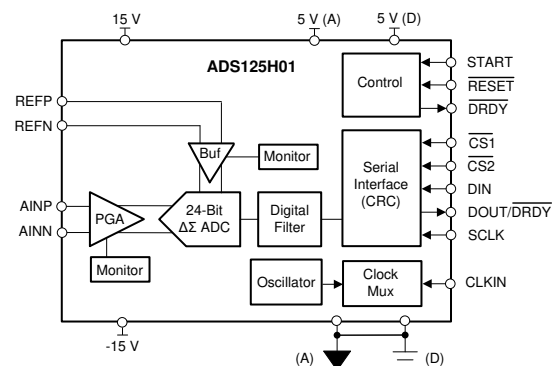

The digital filter is programmable over a wide range from 2.5 SPS to 40 kSPS. Attenuation of 50-Hz and 60-Hz line cycle noise for data rates  $\leq 50$  SPS or 60 SPS reduces measurement error. In most data rates, the filter provides no-latency conversion data for high data throughput during external channel sequencing.

The ADS125H01 is housed in a 5-mm  $\times$  5-mm VQFN package and is fully specified over the  $-40^{\circ}$ C to  $+125^{\circ}$ C temperature range.

#### Device Information (1)

PART NUMBER	PACKAGE	BODY SIZE (NOM)
ADS125H01	VQFN (32)	5.00 mm $\times$ 5.00 mm

- (1) For all available packages, see the orderable addendum at the end of the data sheet.

## 5 Device Comparison Table

FEATURE	ADS125H01	ADS125H02
Resolution	24 bits	24 bits
Data rate	40 kSPS	40 kSPS
Analog input pins	2	3
Voltage reference	—	Yes
Temperature sensor	—	Yes
Auto-zero mode	—	Yes
Sinc2 filter mode	—	Yes
GPIO pins	—	4
Current sources	—	2

## 6 Pin Configuration and Functions

**Figure 6-1. RHB Package, 32-Pin VQFN, Top View**

**Table 6-1. Pin Functions**

NO.	NAME	I/O	DESCRIPTION
1	REFP	Analog input	Positive reference input
2	CAPP	Analog output	PGA output P; connect a 1-nF C0G dielectric capacitor from CAPP to CAPN
3	CAPN	Analog output	PGA output N; connect a 1-nF C0G dielectric capacitor from CAPP to CAPN
4	AVDD	Analog	Low-voltage analog power supply
5	AGND	Analog	Analog ground; connect to the ADC ground plane
6	NC	—	No connection; electrically float or tie to AGND
7	RESET	Digital input	Reset; active low
8	START	Digital input	Conversion start, active high
9	CS2	Digital input	Serial interface chip-select 2 to select the PGA for communication
10	CS1	Digital input	Serial interface chip-select 1 to select the ADC for communication
11	SCLK	Digital input	Serial interface shift clock

**Table 6-1. Pin Functions (continued)**

NO.	NAME	I/O	DESCRIPTION
12	DIN	Digital input	Serial interface data input
13	DRDY	Digital output	Data ready; active low
14	DOUT/DRDY	Digital output	Serial interface data output or data-ready output, active low
15	BYPASS	Analog output	2-V subregulator output; connect a 1- $\mu$ F capacitor to DGND
16	DGND	Digital	Digital ground; connect to the ADC ground plane
17	DVDD	Digital	Digital power supply
18	CLKIN	Digital input	External clock input; connect to DGND for internal oscillator operation
19	HV_AVSS	Analog	High-voltage negative analog power supply
20	HV_AVDD	Analog	High-voltage positive analog power supply
21 – 25	NC	—	No connection; electrically float or tie to AGND
26	AINN	Analog input	Negative analog input
27	AINP	Analog input	Positive analog input
28 – 31	NC	—	No connection; electrically float or tie to AGND
32	REFN	Analog input	Negative reference input
Thermal pad		—	Exposed thermal pad; connect to DGND; see the recommended PCB land pattern at the end of the document

## 7 Specifications

### 7.1 Absolute Maximum Ratings

see (1)

		MIN	MAX	UNIT
Power-supply voltage	HV_AVDD to HV_AVSS	-0.3	38	V
	HV_AVSS to AGND	-19	0.3	
	AVDD to AGND	-0.3	6	
	DVDD to DGND	-0.3	6	
	AGND to DGND	-0.1	0.1	
Analog input voltage	AINP, AINN	HV_AVSS - 0.3	HV_AVDD + 0.3	V
	REFP, REFN	AGND - 0.3	AVDD + 0.3	
Digital input voltage	CS1, CS2, SCLK, DIN, START, RESET, CLKIN, DRDY, DOUT/ DRDY	DGND - 0.3	DVDD + 0.3	V
Input current	Continuous(2)	-10	10	mA
Temperature	Junction, T <sub>J</sub>		150	°C
	Storage, T <sub>stg</sub>	-60	150	

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Input and output pins are diode-clamped to the internal power supplies. Limit the input current to 10 mA in the event the analog input voltage exceeds HV\_AVDD + 0.3 V or HV\_AVSS - 0.3 V, or if the reference input exceeds AVDD + 0.3 V or AGND - 0.3 V, or if the digital input voltage exceeds DVDD + 0.3 V or DGND - 0.3 V.

### 7.2 ESD Ratings

			VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001(1)	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101(2)	±250	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 7.3 Recommended Operating Conditions

over operating ambient temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
<b>POWER SUPPLY</b>						
	High-voltage analog power supplies	HV_AVDD to HV_AVSS	10		36	V
		HV_AVSS to AGND	-18		0	
		HV_AVDD to AGND <sup>(1)</sup>	5		36	
	Low-voltage analog power supply	AVDD to AGND	4.75	5	5.25	V
	Digital power supply	DVDD to DGND	2.7		5.25	V
<b>SIGNAL INPUTS</b>						
V <sub>(AINx)</sub>	Absolute input voltage		See the <a href="#">PGA Operating Range</a> section			
V <sub>IN</sub>	Differential input voltage range <sup>(2)</sup>	V <sub>IN</sub> = V <sub>AINP</sub> - V <sub>AINN</sub>	-20	±V <sub>REF</sub> / Gain	20	V
<b>VOLTAGE REFERENCE INPUTS</b>						
V <sub>REF</sub>	Reference voltage input	V <sub>REF</sub> = V <sub>(REFP)</sub> - V <sub>(REFN)</sub>	0.9		AVDD	V
V <sub>(REFN)</sub>	Negative reference voltage		AGND - 0.05		V <sub>(REFP)</sub> - 0.9	V
V <sub>(REFP)</sub>	Positive reference voltage		V <sub>(REFN)</sub> + 0.9		AVDD + 0.05	V
<b>DIGITAL INPUTS</b>						
	Input voltage		DGND		DVDD	V
<b>EXTERNAL CLOCK<sup>(3)</sup></b>						
f <sub>CLK</sub>	Frequency	f <sub>DATA</sub> ≤ 25.6 kSPS	1	7.3728	8	MHz
		f <sub>DATA</sub> = 40 kSPS	1	10.24	10.75	
	Duty cycle		40%		60%	
<b>TEMPERATURE RANGE</b>						
T <sub>A</sub>	Operating ambient temperature		-45		125	°C

(1) HV\_AVDD can be connected to AVDD if AVDD ≥ 5 V.

(2) The full available differential input voltage range is limited under certain conditions. See the [PGA Operating Range](#) section for details.

(3) Data rates scale with clock frequency.

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		ADS125H01	UNIT
		RHB (VQFN)	
		32 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	35.2	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	19.0	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	15.8	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	0.3	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	15.7	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	8.0	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

## 7.5 Electrical Characteristics

minimum and maximum specifications apply from  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ ; typical specifications are at  $T_A = 25^\circ\text{C}$ ; all specifications are at  $HV\_AVDD = 15\text{ V}$ ,  $HV\_AVSS = -15\text{ V}$ ,  $AVDD = 5\text{ V}$ ,  $DVDD = 3.3\text{ V}$ ,  $V_{REF} = 2.5\text{ V}$ ,  $f_{CLK} = 7.3728\text{ MHz}$ , data rate = 20 SPS, and gain = 1 (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT	
<b>ANALOG INPUTS</b>						
Absolute input current	$V_{(AINx)} = 0\text{ V}$ , $T_A \leq 105^\circ\text{C}$	-15	$\pm 0.5$	15	nA	
Absolute input current drift			20		$\text{pA}/^\circ\text{C}$	
Differential input current	$V_{IN} = 2.5\text{ V}$		$\pm 0.1$		nA	
Differential input current drift	$V_{IN} = 2.5\text{ V}$		10		$\text{pA}/^\circ\text{C}$	
Differential input impedance		1	20		$\text{G}\Omega$	
<b>PGA</b>						
Gain settings		0.125, 0.1875, 0.25, 0.5, 1, 2, 4, 8, 16, 32, 64, 128			V/V	
Antialias filter frequency			230		kHz	
<b>PERFORMANCE</b>						
Resolution	No missing codes	24			Bits	
$e_n$	Noise performance	See the <a href="#">Noise Performance</a> section				
$f_{DATA}$	Data rate	2.5			40000	SPS
INL	Integral nonlinearity	Gain = 0.125 to 32	2		10	$\text{ppm}_{FSR}$
		Gain = 64, 128	4		12	
$V_{OS}$	Offset error <sup>(4)</sup>	$T_A = 25^\circ\text{C}$	$-30 - 300 / \text{Gain}$	$\pm 10 + 100 / \text{Gain}$	$30 + 300 / \text{Gain}$	$\mu\text{V}$
	Offset error drift	Gain = 0.125 to 8	$150 / \text{Gain}$		$700 / \text{Gain}$	$\text{nV}/^\circ\text{C}$
		Gain = 16 to 128	10		50	
GE	Gain error <sup>(4)</sup>	$T_A = 25^\circ\text{C}$ , all gains	-0.7%	$\pm 0.1\%$	0.7%

		$f_{DATA} = 40\text{ kSPS}$	-3.5%	$\pm 0.5\%$	3.5%	

## 7.5 Electrical Characteristics (continued)

minimum and maximum specifications apply from  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ ; typical specifications are at  $T_A = 25^\circ\text{C}$ ; all specifications are at  $HV\_AVDD = 15\text{ V}$ ,  $HV\_AVSS = -15\text{ V}$ ,  $AVDD = 5\text{ V}$ ,  $DVDD = 3.3\text{ V}$ ,  $V_{REF} = 2.5\text{ V}$ ,  $f_{CLK} = 7.3728\text{ MHz}$ , data rate = 20 SPS, and gain = 1 (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>DIGITAL INPUTS/OUTPUTS</b>						
$V_{OH}$	High-level output voltage	$I_{OH} = 1\text{ mA}$	$0.8 \times DVDD$			V
		$I_{OH} = 8\text{ mA}$	$0.75 \times DVDD$			
$V_{OL}$	Low-level output voltage	$I_{OL} = -1\text{ mA}$	$0.2 \times DVDD$			V
		$I_{OL} = -8\text{ mA}$	$0.2 \times DVDD$			
$V_{IH}$	High-level input voltage		$0.7 \times DVDD$		DVDD	V
$V_{IL}$	Low-level input voltage				$0.3 \times DVDD$	V
	Input hysteresis			0.1		V
	Input leakage		-10		10	$\mu\text{A}$
<b>POWER SUPPLY</b>						
$I_{HV\_AVDD}$ , $I_{HV\_AVSS}$	HV_AVDD, HV_AVSS supply current			1.1	1.8	mA
$I_{AVDD}$	AVDD supply current	$f_{DATA} \leq 25.6\text{ kSPS}$		2.8	4.6	mA
		$f_{DATA} = 40\text{ kSPS}$		3.6		
$I_{DVDD}$	DVDD supply current	Internal oscillator active		0.5	0.7	mA
		$f_{DATA} = 40\text{ kSPS}$		0.7	1	
$P_D$	Power dissipation			49	79	mW

- (1) Normal-mode rejection ratio performance is dependent on the digital filter configuration.
- (2) Common-mode rejection ratio is specified at  $f_{IN} = 50\text{ Hz}$  and  $60\text{ Hz}$ .
- (3) Power-supply rejection ratio is specified at DC.
- (4) Offset and gain errors are reduced to the level of noise by calibration.

## 7.6 Timing Requirements

over operating ambient temperature range and  $DVDD = 2.7\text{ V}$  to  $5.25\text{ V}$  (unless otherwise noted)

		MIN	MAX	UNIT
<b>SERIAL INTERFACE</b>				
$t_{d(CSSC)}$	Delay time, first SCLK rising edge after $\overline{CS1}$ or $\overline{CS2}$ falling edge	50		ns
$t_{su(DI)}$	Setup time, DIN valid before SCLK falling edge	25		ns
$t_{h(DI)}$	Hold time, DIN valid after SCLK falling edge	25		ns
$t_c(SC)$	SCLK period	97		ns
$t_w(SCH)$ , $t_w(SCL)$	Pulse duration, SCLK high or low	40		ns
$t_{d(SCCS)}$	Delay time, last SCLK falling edge before $\overline{CS1}$ or $\overline{CS2}$ rising edge	50		ns
$t_w(CSH)$	Pulse duration, $\overline{CS1}$ or $\overline{CS2}$ high to reset interface	25		ns
<b>RESET</b>				
$t_w(RSTL)$	Pulse duration, RESET low	4		$1/f_{CLK}$
<b>CONVERSION CONTROL</b>				
$t_w(STH)$	Pulse duration, START high	4		$1/f_{CLK}$
$t_w(STL)$	Pulse duration, START low	4		$1/f_{CLK}$
$t_{su(STDR)}$	Setup time, START low or STOP command before $\overline{DRDY}$ falling edge to stop the next conversion (continuous-conversion mode)		100	$1/f_{CLK}$
$t_{h(DRSP)}$	Hold time, START low or STOP command after $\overline{DRDY}$ falling edge to continue the next conversion (continuous-conversion mode)	150		$1/f_{CLK}$

## 7.7 Switching Characteristics

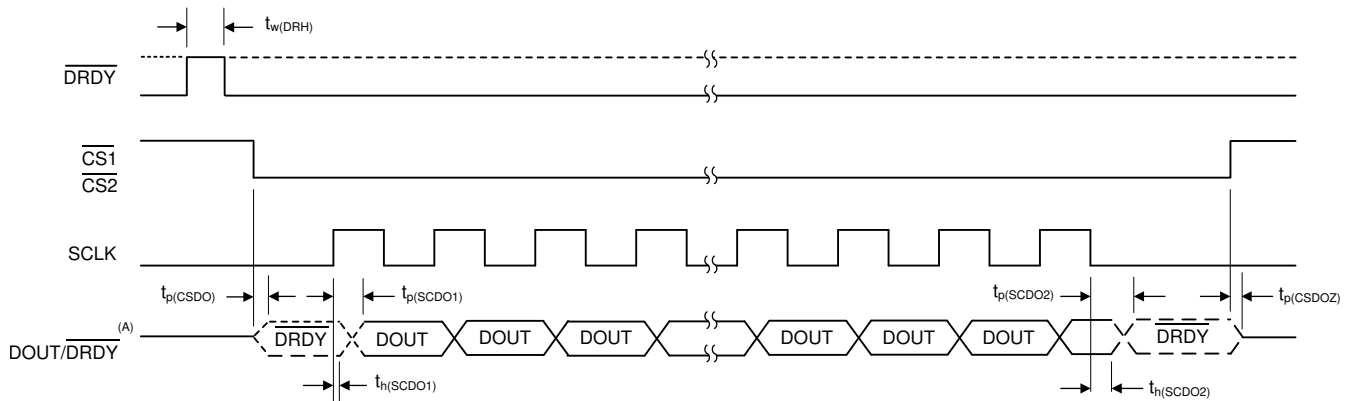

over operating ambient temperature range and DVDD = 2.7 V to 5.25 V, and DOUT/DRDY load = 20 pF || 100 kΩ to DGND (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>SERIAL INTERFACE</b>					
$t_{w(DRH)}$	Pulse duration, $\overline{DRDY}$ high	16			$1/f_{CLK}$
$t_{p(CSDO)}$	Propagation delay time, $\overline{CS1}$ or $\overline{CS2}$ falling edge to DOUT/DRDY driven	0		50	ns
$t_{p(SCDO1)}$	Propagation delay time, SCLK rising edge to valid DOUT/DRDY			40	ns
$t_{h(SCDO1)}$	Hold time, SCLK rising edge to invalid DOUT/DRDY	0			ns
$t_{h(SCDO2)}$	Hold time, last SCLK falling edge to invalid DOUT/DRDY data output function	15			ns
$t_{p(SCDO2)}$	Propagation delay time, last SCLK falling edge to DOUT/DRDY data-ready function			110	ns
$t_{p(CSDOZ)}$	Propagation delay time, $\overline{CS1}$ or $\overline{CS2}$ rising edge to DOUT/DRDY high impedance			50	ns
<b>RESET</b>					
$t_{p(RSCN)}$	Propagation delay time, RESET rising edge or RESET command to conversion start	512			$1/f_{CLK}$
$t_{p(PRCM)}$	Propagation delay time, power-on threshold voltage to ADC communication		2 <sup>16</sup>		$1/f_{CLK}$
$t_{p(CMCN)}$	Propagation delay time, ADC communication to conversion start	512			$1/f_{CLK}$
<b>CONVERSION CONTROL</b>					
$t_{p(STDR)}$	Propagation delay time, START pin high or START command to $\overline{DRDY}$ high			2	$1/f_{CLK}$

## 7.8 Timing Diagrams

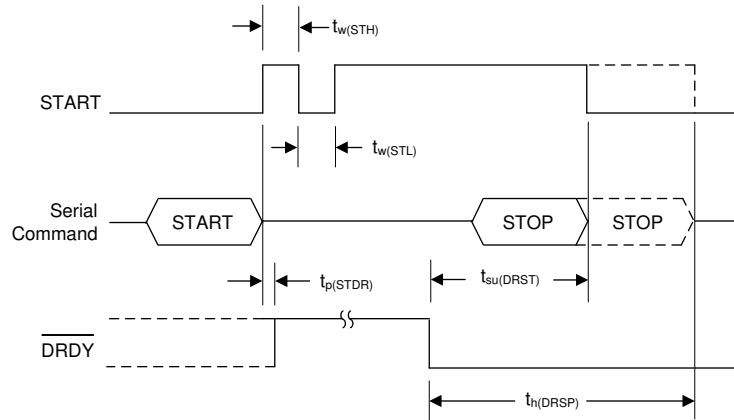

**Figure 7-1. Serial Interface Timing Requirements**

A.  $\overline{DRDY}$  indicates the data-ready function in the interval between  $\overline{CS1}$  low and the first SCLK rising edge, and in the interval between the last SCLK falling edge of the command to  $\overline{CS1}$  high.  $DOUT$  indicates the data output function during the data read operation.

## 8 Parameter Measurement Information

### 8.1 Noise Performance

Noise performance depends on the device configuration: data rate, input gain, and digital filter mode. Two significant factors affecting noise performance are data rate and input gain. Decreasing the data rate lowers the noise because the measurement bandwidth is reduced. Increasing the gain reduces noise (when noise is treated as an input-referred quantity) because the noise of the PGA is lower than that of the ADC. Noise performance also depends on the digital filter mode. As the digital filter order is increased, the bandwidth decreases, which results in lower noise.

Figure 8-1 shows noise data versus data rate as input-referred values ( $\mu\text{V}_{\text{RMS}}$ ) in gains 0.125 to 2, (corresponding input ranges of  $\pm 20\text{ V}$  to  $\pm 1.25\text{ V}$ ) in the sinc3 filter mode. Figure 8-2 shows noise data versus data rate as input-referred values ( $\mu\text{V}_{\text{RMS}}$ ) in gains 4 to 128, (corresponding input ranges of  $\pm 625\text{ mV}$  to  $\pm 19.5\text{ mV}$ ) in the sinc3 filter mode. The noise data represent typical ADC performance at  $T_A = 25^\circ\text{C}$  and the 2.5-V reference voltage.

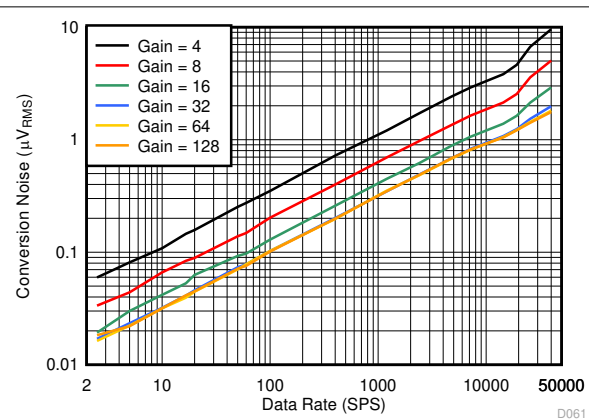

Peak-to-peak noise performance is typically 6.6 times the RMS value. Relative to the noise in the sinc3 filter mode, noise typically increases 30% in the finite-impulse response (FIR) and sinc1 filter mode because of the increased bandwidth of the sinc1 and FIR modes. Noise typically decreases 6% in the sinc4 filter mode because of the decreased bandwidth of the sinc4 filter mode.

The noise data are the standard deviation of the ADC data scaled in microvolts. The data are acquired with inputs shorted and based on consecutive ADC readings for a period of ten seconds or 8192 data points, whichever occurs first. Because of the statistical nature of noise, repeated measurements may yield higher or lower noise results.

Gain = 0.125 to 2,  $V_{\text{REF}} = 2.5\text{ V}$ , sinc3 filter  
(sinc5 filter for  $f_{\text{DATA}} \geq 14.4\text{ kSPS}$ )

Figure 8-1. Conversion Noise vs Data Rate

Gain = 4 to 128,  $V_{\text{REF}} = 2.5\text{ V}$ , sinc3 filter  
(sinc5 filter for  $f_{\text{DATA}} \geq 14.4\text{ kSPS}$ )

Figure 8-2. Conversion Noise vs Data Rate

ADC noise performance can also be expressed as *effective resolution* and *noise-free resolution* (bits). Effective resolution is based on the RMS value of the noise data and noise-free resolution is based on the peak-to-peak noise data; therefore, the noise-free resolution is the resolution with no code flicker. Equation 1 is used to compute effective resolution based on the noise values plots of Figure 8-1 and Figure 8-2.

$$\text{Effective Resolution or Noise-Free Resolution (Bits)} = 3.32 \log (\text{FSR} / e_n) \quad (1)$$

where:

- FSR = Full-scale range =  $2 V_{\text{REF}} / \text{Gain}$
- $e_n$  = Input-referred noise (RMS value for *effective resolution*, peak-to-peak value for *noise-free resolution*)

For example, using full-scale range = ±13.3 V, data rate = 20 SPS, and sinc3 filter mode, the RMS noise value (from Figure 8-1) is 2.1 μV. The effective resolution is:  $3.32 \log(26.6 \text{ V} / 2.1 \text{ } \mu\text{V}) = 23.6$  bits.

Figure 8-3 and Figure 8-4 show effective resolution (bits) versus data rate. Figure 8-5 and Figure 8-6 show noise-free resolution (bits) versus data rate. When  $f_{\text{DATA}} \leq 14.4$  kSPS, effective resolution and noise-free resolution improve by 0.7 bits by increasing the reference voltage from 2.5 V to 4.096 V because of the increased input signal range.

**Figure 8-3. Effective Resolution vs Data Rate**

**Figure 8-4. Effective Resolution vs Data Rate**

**Figure 8-5. Noise-Free Resolution vs Data Rate**

**Figure 8-6. Noise-Free Resolution vs Data Rate**

## 9 Detailed Description

### 9.1 Overview

The ADS125H01 is a  $\pm 20$ -V signal input, 40-kSPS, 24-bit, delta-sigma ( $\Delta\Sigma$ ) analog-to-digital converter (ADC). The ADC provides a compact one-chip measurement solution for a wide range of input voltages, including typical current and voltage inputs of industrial programmable logic controllers (PLCs), such as  $\pm 10$ -V and 4-mA to 20-mA transmitters (using an external shunt resistor). The ADC provides the resolution necessary for direct interface to low-level sensors such as strain-gauge sensors and thermocouples.

The device features a programmable gain amplifier (PGA) with an attenuation range from 0.125 to 0.5 and a gain range from 1 to 128. The combination of attenuation and gain provide an overall input voltage range of  $\pm 20$  V to  $\pm 20$  mV (when  $V_{REF} = 2.5$  V). The PGA is low-noise and low-drift with high input impedance, and includes internal monitors for detection of overload conditions.

In summary, the ADC features:

- 24-bit resolution
- Low-noise, 1-G $\Omega$  input impedance PGA
- Selectable attenuation and gain: overall full-scale range from  $\pm 20$  mV to  $\pm 20$  V
- Internal or external clock operation
- PGA and voltage reference monitors
- SPI-compatible serial interface with cyclic redundancy check (CRC) error check

Analog inputs (AINP and AINN) connect to the PGA via an input switch. The switch selects between the input signal and an internal test voltage ( $V_{CM}$ ). Internal diodes protect the analog and reference inputs from ESD events.

The PGA is a high-impedance, differential-input and differential-output amplifier providing both gain and attenuation modes. In attenuation mode, the input voltage is reduced to the range of the ADC. In gain mode, the input voltage is amplified to the range of the ADC. The PGA output connects to the CAPP and CAPN pins. The ADC antialias filter is provided by the combination of the internal PGA output resistors and the external capacitor connected to these pins.

The PGA is monitored for signal overload conditions. Status bits in the STATUS1 register indicate possible PGA overload conditions.

The  $\Delta\Sigma$  modulator measures the input voltage relative to the reference voltage to produce a 24-bit conversion result. The input range of the ADC is  $\pm V_{REF} / \text{Gain}$ , where gain is programmable from 0.125 to 128.

The reference voltage is either external (pins REFP, REFN) or the AVDD power supply. The reference input includes a monitor to detect low voltage conditions. The status is reflected in the conversion data STATUS byte.

The digital filter averages and decimates the modulator data to provide the output conversion result. For data rates  $\leq 7.2$  kSPS, the digital filter provides programmable sinc orders allowing optimization of conversion latency, conversion noise, and line-cycle rejection. The finite-impulse response (FIR) filter mode provides no-latency conversion data with simultaneous rejection of 50-Hz and 60-Hz interference at data rates of 20 SPS or less.

User-programmable offset- and gain-calibration registers correct the conversion data to provide the final conversion result.

The SPI-compatible serial interface is used to read the conversion data and for device configuration. SPI I/O communication is validated by CRC error checking. The serial interface consists of the following signals:  $\overline{CS1}$ ,  $\overline{CS2}$ , SCLK, DIN, and DOUT/DRDY (see the [Chip-Select Pins \( \$\overline{CS1}\$  and  \$\overline{CS2}\$ \)](#) section for details). The dual-function DOUT/DRDY pin combines the functions of the serial data output and data-ready indication into one pin. DRDY is the data-ready output signal.

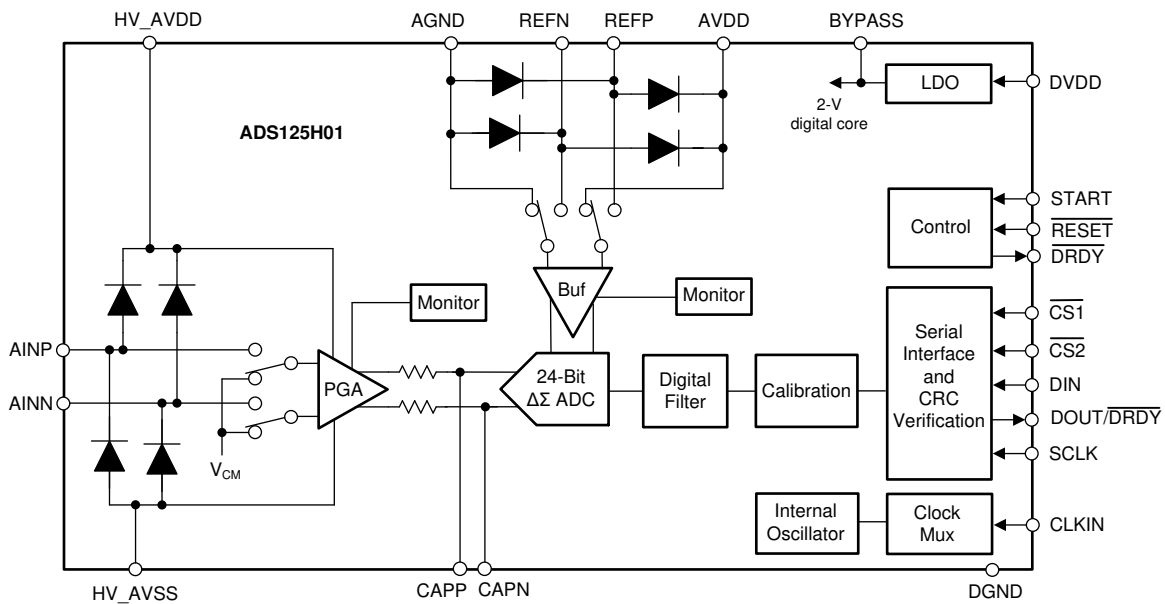

Clock operation is either by the internal oscillator or by an external clock source. The external clock is automatically detected by the ADC. The nominal clock frequency is 7.3728 MHz (10.24 MHz for  $f_{DATA} = 40$  kSPS).

Conversions are controlled by the START pin or by the START command. Conversions are programmable for either continuous or one-shot (pulse) mode of operation.

The ADC is reset at power-on, or manually reset by the  $\overline{\text{RESET}}$  input or by the RESET command.

The HV\_AVDD and HV\_AVSS power supplies allow either bipolar or unipolar configuration (bipolar:  $\pm 5$  V to  $\pm 18$  V, unipolar: 10 V to 36 V). The 5-V analog supply (AVDD) powers the ADC. The digital I/Os are powered by DVDD (3-V to 5-V range). An internal 2-V subregulator powers the ADC digital core from the DVDD supply. An external bypass capacitor is required at the subregulator output (BYPASS pin).

## 9.2 Functional Block Diagram

## 9.3 Feature Description

### 9.3.1 Input Voltage Range

Equation 2 defines the full-scale input voltage range of the ADC. Table 9-1 lists the input voltage range corresponding to the attenuation and gain setting when operating with a 2.5-V reference voltage. The input voltage range is limited under certain operating conditions due to the required headroom of the PGA and the ADC. See the [PGA Operating Range](#) section for details.

$$\text{Input Voltage Range} = \pm V_{\text{REF}} / \text{Gain} \quad (2)$$

**Table 9-1. Input Voltage Range**

GAIN[2:0] BITS <sup>(1)</sup>	GAIN	INPUT VOLTAGE RANGE	
		DIFFERENTIAL	SINGLE-ENDED
0000	0.125	±20 V	0 V to ±15.5 V
0001	0.1875	±13.3 V	0 V to ±13.3 V
0010	0.25	±10 V	0 V to ±10 V
0011	0.5	±5 V	0 V to ±5 V
0100	1	±2.5 V	0 V to ±2.5 V
0101	2	±1.25 V	0 V to ±1.25 V
0110	4	±0.625 V	0 V to ±0.625 V
0111	8	±0.312 V	0 V to ±0.312 V
1000	16	±0.156 V	0 V to ±0.156 V
1001	32	±0.0781 V	0 V to ±0.0781 V
1010	64	±0.0391 V	0 V to ±0.0391 V
1011	128	±0.0195 V	0 V to ±0.0195 V

(1) Reference voltage = 2.5 V and HV power supply = ±18 V.

### 9.3.2 Analog Inputs (AINP, AINN)

#### 9.3.2.1 ESD Diodes

ESD diodes are used to protect the ADC inputs from possible ESD events occurring during the manufacturing process and during printed circuit board (PCB) assembly when manufactured in an ESD-controlled environment. For system-level ESD protection, consider the use of external ESD protection devices for pins that are exposed to possible ESD, including the analog inputs.

If an analog input is driven below HV\_AVSS – 0.3 V, or above HV\_AVDD + 0.3 V, the internal ESD protection diodes can conduct. If this condition is possible, current can flow through the inputs and flow out from the HV\_AVDD or HV\_AVSS pins. Use external clamp diodes, series resistors, or both to limit the input current to the specified value.

#### 9.3.2.2 Input Switch

The input switch selects between an internal test voltage and the external input signal. The internal test voltage ( $V_{\text{CM}}$ ) is the mid-point of the HV\_AVDD and HV\_AVSS power-supply voltage. The internal voltage is used to verify the offset and noise of the ADC measurement path. The input switch is programmed by the MUX[2:0] bits of the [MODE4](#) register (address = 10h). [Table 9-2](#) lists the input switch settings.

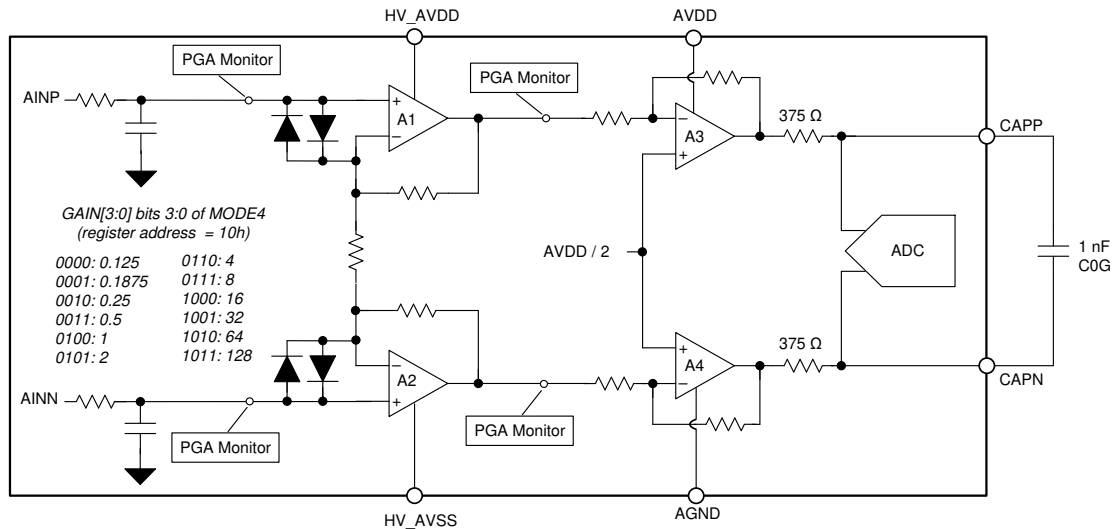

**Table 9-2. Input Switch Settings**

MUX[2:0] BITS OF REGISTER MODE4 (10h)	INPUT SELECTION
000	AINP to AINN
101	$V_{\text{CM}}$ : (HV_AVDD + HV_AVSS) / 2 (default)

### 9.3.3 Programmable Gain Amplifier (PGA)

The PGA is a low-noise, programmable gain (attenuation), CMOS differential-input, differential-output amplifier. The PGA operates in gain or attenuation mode depending on the selected gain. Typically, the PGA is programmed for gain when the expected input signal voltage is  $\leq V_{REF}$  and is programmed for attenuation when the expected input signal voltage is  $\geq V_{REF}$ .

Figure 9-1 shows the block diagram of the PGA.

**Figure 9-1. PGA Block Diagram**

The signal inputs are RC filtered to reduce sensitivity to radio frequency interference (RFI) and electromagnetic interference (EMI). The first PGA stage is a high input-impedance, noninverting differential amplifier (amplifiers A1 and A2) and provides gain. Inverse-parallel connected diodes across the inputs of A1 and A2 clamp the amplifier input voltage if they are driven out-of-range. If the amplifier is out-of-range, the diodes can conduct, resulting in current flow through the analog input pins. High  $dV/dt$  input signals, such as those generated from the switching of a multiplexer, can lead to transient turn-on of the clamp diodes. In some cases, an RC filter at the PGA inputs may be necessary to limit the  $dV/dt$  of the signal to prevent the clamp diodes from turning on.

The second stage (amplifiers A3 and A4) is an inverting, differential amplifier. This stage provides attenuation of high-amplitude signal levels. The common-mode voltage of this stage is  $AVDD / 2$ . The second stage drives the modulator input of the ADC and is also connected to the CAPP and CAPN pins. An external 1-nF capacitor filters the modulator input sample pulses and also provides the antialias filter for the ADC. Place the capacitor close to the pins using short, direct traces. Avoid running clock traces or other digital traces underneath or in the vicinity of these pins. Gain is programmed by the GAIN[3:0] bits of the **MODE 4** register.

Monitors verify the voltage headroom of the PGA input and output nodes. See the [PGA Monitors](#) section for details.

### 9.3.3.1 PGA Operating Range

The *absolute input voltage* range of the PGA must not be exceeded in order to maintain linear operation. The maximum and minimum absolute input voltage is determined by the PGA gain setting, the maximum differential input voltage ( $V_{IN}$ ), and the minimum value of the high-voltage power supply. The absolute voltage is the combined differential and common-mode voltages. Maintain the absolute input voltage ( $V_{AINx}$ ) within the range as shown in Equation 3, otherwise incorrect conversion data can result.

$$HV\_AVSS + 2.5\text{ V} + V_{IN} \times (\text{Gain} - 1) / 2 < V_{(AINx)} < HV\_AVDD - 2.5\text{ V} - V_{IN} \times (\text{Gain} - 1) / 2 \quad (3)$$

where:

- Gain = PGA gain. For gain < 1, use value = 1
- $V_{(AINx)}$  = Absolute input voltage
- $V_{IN} = V_{AINP} - V_{AINN} =$  Maximum expected differential input voltage

Additionally, the *differential input signal* is limited in two conditions. The first condition is when the reference voltage exceeds  $AVDD - 1\text{ V}$  (nominally  $V_{REF} > 4\text{ V}$ ). In this case, the differential input signal is limited to:  $V_{IN} = \pm (AVDD - 1\text{ V}) / \text{Gain}$ , instead of the ideal  $V_{IN} = \pm V_{REF} / \text{Gain}$ . The second condition applies to gains of 0.125 and 0.1875. In this case, the differential input signal range is limited to:  $V_{IN} = \pm 20\text{ V}$ , regardless of the reference voltage value.

Figure 9-2 and Figure 9-3 show the relationship between the PGA input voltage and the PGA output voltage. In attenuation mode, the first PGA stage is configured as a unity-gain follower. The second PGA stage attenuates the differential input voltage and shifts the signal common-mode voltage to  $AVDD / 2$  to drive the ADC input.

In gain mode, the first PGA stage amplifies the differential signal. The second PGA stage is configured as a unity-gain follower with level-shift. Figure 9-2 and Figure 9-3 show the corresponding output voltage of the PGA stages that must have operating voltage headroom.

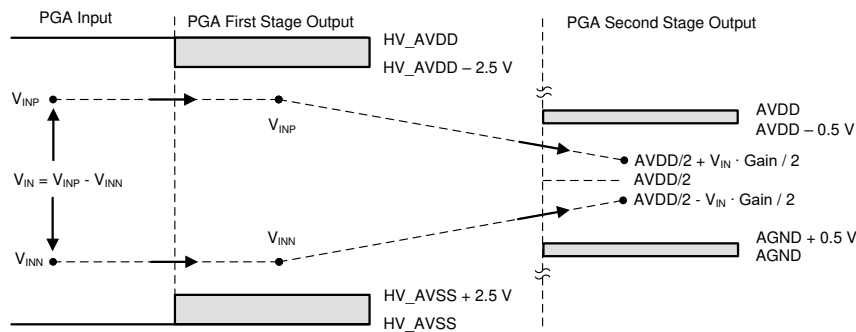

Figure 9-2. PGA Attenuation Mode

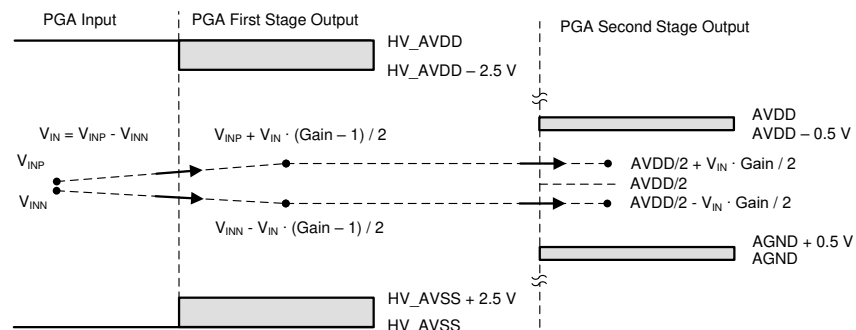

Figure 9-3. PGA Gain Mode

### 9.3.3.2 PGA Monitors

The PGA requires operating voltage headroom at the input and output nodes. The operating headroom must be maintained; otherwise the conversion data may not be valid. Use the internal PGA monitors to detect PGA out-of-range conditions. The PGA has four monitors (two monitors for the input and two monitors for the output) with high and low thresholds for each, for a total of eight possible alarms. The status of each PGA monitor is read in the STATUS1 register. The PGA monitoring points are illustrated in Figure 9-1. Figure 9-4 shows the operation of the high and low thresholds of each of the four PGA monitors.

**Figure 9-4. PGA Monitor Thresholds**

Detect PGA out-of-range operating conditions by polling the STAT12 bit (bit 4 of the STATUS conversion byte or STATUS0 register). The STAT12 bit is the logical OR of all PGA error flags with the CRC2 error flag. When the STAT12 bit asserts, poll the STATUS1 and STATUS2 registers (address 11h and 12h) to determine the source of the STAT12 error. The PGA out-of-range flags latch in the STATUS1 register and remain latched after the overload condition is removed. Read the STATUS1 register to clear the PGA out-of-range bits (clear-on-read operation). The PGA overload flags *and* the CRC2 flag must be reset in order for the STAT12 bit to clear. See the STATUS1 register for a description of the PGA overload bits.

The PGA monitors are analog comparators that respond to transient out-of-range conditions.

### 9.3.4 Reference Voltage

A reference voltage is required for operation. An internal reference voltage switch selects between the external reference and the AVDD power supply voltage (default). Program the reference switch using the RMUX[3:0] bits to select the reference (see the REF register for details).

Apply the reference voltage to the REFP and REFN pins. The reference inputs are differential defined by:  $V_{REF} = (V_{REFP} - V_{REFN})$ , where  $V_{REFP}$  and  $V_{REFN}$  are the positive and negative absolute reference voltages. Follow the specified absolute and differential operating conditions. Use a 10-nF or larger bypass capacitor across the reference input pins to filter noise. The reference input current can lead to a voltage error if large reference impedances are present. If a reference impedance is present, the reference voltage may have an error.

#### 9.3.4.1 Reference Monitor

The reference monitor detects a low or missing reference voltage. As illustrated in Figure 9-5, when the differential reference voltage is  $\leq 0.4$  V (typical), the REFALM bit is set in the STATUS0 register. The alarm is read-only and resets at the next conversion after the fault condition is cleared. To implement the reference monitor, place a 100-k $\Omega$  resistor across the reference inputs. If either positive or negative reference inputs become disconnected, the reference inputs are differentially biased to 0 V, thereby triggering the low reference alarm. Poll bit 3 (REFALM) of the STATUS0 register to determine if the reference alarm has triggered.

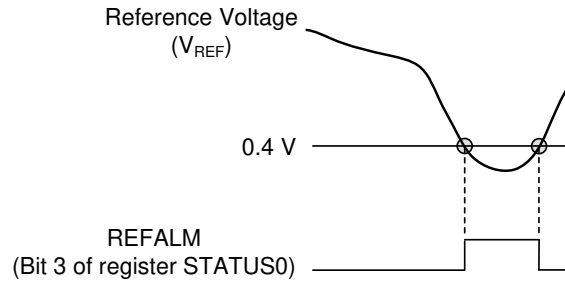

Figure 9-5. Reference Monitor Operation

### 9.3.5 ADC Modulator

The modulator is an inherently stable, fourth-order, 2 + 2 pipelined  $\Delta\Sigma$  modulator. The modulator samples the analog input voltage at a high sample rate ( $f_{MOD} = f_{CLK} / 8$ ) and converts the analog input to a 1's-density bit stream that is processed by the digital filter.

### 9.3.6 Digital Filter

The digital filter has two operating modes, as shown in Figure 9-6:  $\sin(x) / x$  (sinc) mode and finite impulse response (FIR) mode. The sinc mode provides data rates of 2.5 SPS to 40 kSPS, and selectable sinc1, sinc3, and sinc4 filter orders for  $f_{DATA} \leq 7.2$  kSPS. The FIR filter provides single-cycle settled conversions and simultaneous rejection of 50-Hz and 60-Hz signal interference frequencies with data rates of 2.5 SPS to 20 SPS.

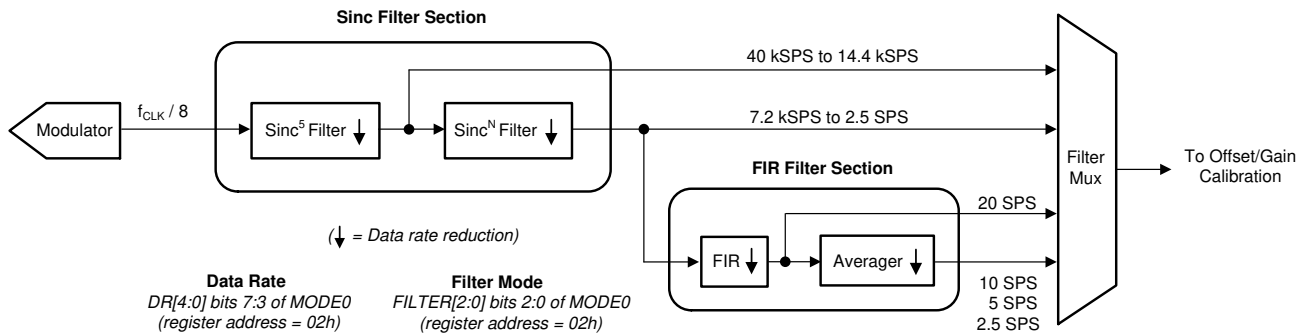

Figure 9-6. Digital Filter Block Diagram

#### 9.3.6.1 Sinc Filter Mode

The sinc filter consists of a variable-decimation sinc5 filter followed by a variable-decimation, variable-order sinc filter. The sinc5 filter averages and down-samples the modulator data ( $f_{CLK} / 8$ ) to provide 40 kSPS, 25.6 kSPS, 19.2 kSPS, and 14.4 kSPS data rates by using decimation ratios of 32, 36, 48, and 64. These data rates bypass the second filter stage and as a result are sinc5 output only. The second stage receives data at 14.4 kSPS and performs additional filtering and decimation to provide data rates of 7.2 kSPS to 2.5 SPS. The second stage has programmable sinc order. The data rate is programmed by the DR[4:0] bits and the filter mode is programmed by the FILTER[2:0] bits of the MODE0 register.

### 9.3.6.1.1 Sinc Filter Frequency Response

As shown in [Figure 9-7](#) and [Figure 9-8](#), the first-stage sinc5 filter has frequency response nulls occurring at  $N \times f_{\text{DATA}}$  (where  $N = 1, 2, 3,$  and so on). At the null frequencies, the filter has zero gain.

The second stage filter superimposes additional nulls to the nulls produced by the first stage. The first of the nulls occurs at the output data rate with additional nulls occurring at data rate multiples.

[Figure 9-9](#) shows the frequency response at 2.4 kSPS. This data rate has five equally spaced nulls between the first stage 14.4-kHz nulls  $[(14.4 \text{ kHz} / 2.4 \text{ kHz}) - 1 = 5]$ . This frequency response is similar to that of data rates 2.5 SPS to 7.2 kSPS. [Figure 9-10](#) shows the frequency response nulls at 10 SPS.

Figure 9-11 and Figure 9-12 show the frequency response of data rates 50 SPS and 60 SPS. 50-Hz or 60-Hz rejection is increased by increasing the order of the sinc filter.

Figure 9-13 and Figure 9-14 show the detailed frequency response of the 50-SPS and 60-SPS data rates.

The sinc filter has an overall low-pass response that rolls off high-frequency components of the signal. The filter bandwidth depends on the output data rate and the filter order. The *system* bandwidth is the combined bandwidths of the digital filter, the PGA antialias filter, and external signal filters. Table 9-3 lists the –3-dB bandwidth of the sinc filter.

**Table 9-3. Sinc Filter Bandwidth**

–3-dB BANDWIDTH (Hz)				
DATA RATE (SPS)	SINC1	SINC3	SINC4	SINC5
2.5	1.10	0.65	0.58	—
5	2.23	1.33	1.15	—
10	4.43	2.62	2.28	—
16.6	7.38	4.37	3.80	—
20	8.85	5.25	4.63	—
50	22.1	13.1	11.4	—
60	26.6	15.7	13.7	—
100	44.3	26.2	22.8	—
400	177	105	91.0	—
1200	525	314	273	—
2400	1015	623	544	—
4800	1798	1214	1077	—
7200	2310	1750	1590	—
14400	—	—	—	2940
19200	—	—	—	3920
25600	—	—	—	5227
40000	—	—	—	8167

**9.3.6.2 FIR Filter**

The finite impulse response (FIR) filter provides simultaneous rejection of 50-Hz and 60-Hz line cycle frequencies and related harmonics at data rates of 2.5 SPS, 5 SPS, 10 SPS, and 20 SPS. The conversion latency of the FIR filter is a single cycle; see Table 9-6 for detailed latency values. As illustrated in Figure 9-6, the FIR filter section receives data from the second-stage sinc filter. The FIR filter section decimates the data to yield the output data rate of 20 SPS. A variable averaging filter (sinc1) yields 10 SPS, 5 SPS, and 2.5 SPS.

As shown in Figure 9-15 and Figure 9-16, the frequency response has nulls that are positioned near 50 Hz and 60 Hz.

Similar to the response of the sinc filter, the overall FIR filter frequency has a low-pass response that rolls off high frequencies. The signal bandwidth depends on the output data rate. [Table 9-4](#) lists the –3-dB filter bandwidth of the FIR filter. The total system bandwidth is the combined response of the digital filter, the PGA antialias filter, and external filters.

**Table 9-4. FIR Filter Bandwidth**

DATA RATE (SPS)	–3-dB BANDWIDTH (Hz)
2.5	1.2
5	2.4
10	4.7
20	13

### 9.3.6.3 50-Hz and 60-Hz Normal-Mode Rejection

To reduce the effects of 50-Hz and 60-Hz interference, optimize the filter mode and data rate selection, and the accuracy of the ADC clock to provide the required 50-Hz and 60-Hz rejection. [Table 9-5](#) summarizes the 50-Hz and 60-Hz noise rejection versus filter mode and data rate. The table values are based on a 2% and 6% tolerance of the 50-Hz and 60-Hz input frequencies relative to the ADC clock frequency. Common-mode noise is also rejected at 50 Hz and 60 Hz.

**Table 9-5. 50-Hz and 60-Hz Normal-Mode Rejection**

DIGITAL FILTER AMPLITUDE (dB)					
DATA RATE (SPS)	FILTER TYPE	50 Hz (±2%)	50 Hz (±6%)	60 Hz (±2%)	60 Hz (±6%)
2.5	FIR	–113	–88	–99	–80
2.5	Sinc1	–36	–40	–37	–37
2.5	Sinc3	–108	–120	–111	–111

## 9.4 Device Functional Modes

### 9.4.1 Conversion Control

The START pin or the START command controls the conversions. If using commands to control conversions, keep the START pin low to avoid contention between pin control and command control. Commands take effect on the 32nd falling SCLK edge. See the [Switching Characteristics](#) table for details on conversion-control timing.

The ADC has two conversion-control operating modes: continuous-conversion mode and pulse-conversion mode. The continuous-conversion mode performs conversions indefinitely until conversions are stopped. Pulse-conversion mode performs one conversion and then stops. The CONVRT (bit 4 of the [MODE1](#) register) programs the conversion mode.

#### 9.4.1.1 Continuous-Conversion Mode

This conversion mode performs continuous conversions until the conversion process is stopped. To start conversions, take the START pin high or send the START command.  $\overline{\text{DRDY}}$  is driven high when the conversion is started.  $\overline{\text{DRDY}}$  is driven low when the conversion data are ready. Conversion data are available to read at that time. Take the START pin low or send a STOP command to stop conversions. When conversions are stopped, any conversion in progress runs to completion. To restart a conversion that is in progress, toggle the START pin low-then-high or send a new START command.

#### 9.4.1.2 Pulse-Conversion Mode

In pulse-conversion mode, the ADC performs one conversion when the START pin is taken high or when the START command is sent. When the conversion completes, further conversions stop automatically. The  $\overline{\text{DRDY}}$  output is driven high to indicate the conversion is actively in progress and is driven low when the conversion data are ready. Conversion data are available to read at that time. To restart a conversion in progress, toggle the START pin low-then-high or send a new START command. Driving START low or sending the STOP command does not interrupt the current conversion.

#### 9.4.1.3 Conversion Latency

The digital filter averages data from the modulator to produce the conversion result. The internal stages of the digital filter must be settled to provide fully settled output data. The order and the decimation ratio of the digital filter determine the amount of data averaged that, in turn, affects the latency of the conversion result. The FIR and sinc1 filter modes are zero latency because the ADC provides the conversion result in one conversion cycle. Latency time is an important consideration for overall data throughput in multiplexed applications.

[Table 9-6](#) lists the conversion latency values of the ADC. Conversion latency is defined as the time from the start of the first conversion by taking the START pin high or sending the START command to the time of the first conversion data. The ADC is designed to provide fully settled data under this condition. The conversion latency values listed in [Table 9-6](#) include the programmable start-conversion delay that delays the digital filter start. After the first conversion in continuous-conversion mode, the periods of the following conversions are equal to  $1 / f_{\text{DATA}}$ .

**Table 9-6. Conversion Latency Time**

DATA RATE (SPS)	CONVERSION LATENCY TIME ( $t_{\text{STDR}}$ ) <sup>(1)</sup> , ms				
	SINC1	SINC3	SINC4	SINC5	FIR
2.5	400.4	1,200	1,600	—	402.2
5	200.4	600.4	800.4	—	202.2
10	100.4	300.4	400.4	—	102.2
16.6	60.43	180.4	240.4	—	—
20	50.43	150.4	200.4	—	52.22
50	20.43	60.43	80.43	—	—
60	17.09	50.43	67.09	—	—
100	10.43	30.43	40.43	—	—
400	2.925	7.925	10.43	—	—
1200	1.258	2.925	3.758	—	—
2400	0.841	1.675	2.091	—	—
4800	0.633	1.050	1.258	—	—
7200	0.564	0.841	0.980	—	—
14400	—	—	—	0.423	—
19200	—	—	—	0.336	—
25600	—	—	—	0.271	—
40000	—	—	—	0.179	—

(1) Conversion-start time delay = 50  $\mu\text{s}$  (36  $\mu\text{s}$  at  $f_{\text{CLK}} = 10.24 \text{ MHz}$ ) using DELAY[3:0] = 0001). Conversion latency scales with  $f_{\text{CLK}}$ .

As shown in [Figure 9-17](#), if the input-step change occurs during an active conversion, the conversion data are a mix of old and new data. After an input-step change, the number of conversion periods required to provide fully settled output data are determined dividing the conversion latency time by the conversion period plus one additional conversion period.

**Figure 9-17. Input Change During Conversions**

#### 9.4.1.4 Start-Conversion Delay

At the start of a conversion, the ADC provides a programmable delay time to allow for PGA settling and to provide a delay time for the possible effects of settling of external components (such as multiplexers and R-C filters). The default value is 50  $\mu\text{s}$  ( $f_{\text{CLK}} = 7.3728 \text{ MHz}$ ) to provide settling time for the PGA antialiasing filter after an input step change. Use additional delay time as needed to provide settling time for the settling effects of external components. As an alternative to this parameter, delay the start of conversion manually after an input change. See [Table 9-27](#) for start-conversion delay values.

#### 9.4.2 Clock Mode

The ADC is operated with an external clock or with the internal oscillator. For external clock operation, apply the clock signal to the CLKIN pin. The ADC detects the presence of the external clock and selects the clock automatically. Read the CLOCK bit in the STATUS0 register to verify the clock mode. As described in [Table 9-7](#), the clock frequency depends on the data rate used. Be sure the external clock is free of overshoot and glitches. A source-termination resistor placed at the clock buffer often helps reduce overshoot.

To operate the ADC by the internal oscillator, connect CLKIN to DGND. Be aware of the accuracy of the internal oscillator as described in the [Electrical Characteristics](#). The internal oscillator begins operating immediately at device power-on.

**Table 9-7. External Clock Frequency**

CLOCK FREQUENCY	DATA RATE
7.3728 MHz	2.5 SPS – 25.6 kSPS
10.24 MHz	40 kSPS

### 9.4.3 Reset

The ADC is reset in three ways: automatic at power-on, manually via the  $\overline{\text{RESET}}$  pin, or manually by the RESET command.

At reset, the serial interface, conversion-control logic, digital filter, and register map values are reset. The RESET bit of the STATUS0 register is set after a reset occurs. Clear the bit to detect the next device reset. If the START pin is high after reset, the ADC immediately begins conversions after reset.

#### 9.4.3.1 Power-On Reset

After the supply voltages cross the respective reset thresholds at power-up, the ADC is reset and after  $2^{16} f_{\text{CLK}}$  cycles the ADC is ready for communication. Until this time,  $\overline{\text{DRDY}}$  is held low.  $\overline{\text{DRDY}}$  is then driven high to indicate when ADC communication can begin. The conversion cycle starts 512  $f_{\text{CLK}}$  cycles after  $\overline{\text{DRDY}}$  asserts high if START is high. See [Figure 7-4](#) for power-on reset behavior.

#### 9.4.3.2 Reset by $\overline{\text{RESET}}$ Pin

Reset the ADC by taking the  $\overline{\text{RESET}}$  pin low for a minimum of four  $f_{\text{CLK}}$  cycles, and then return the pin high. After reset, the conversion starts 512  $f_{\text{CLK}}$  cycles later if START is high. See [Figure 7-5](#) for  $\overline{\text{RESET}}$  pin timing requirements.

#### 9.4.3.3 Reset by Command

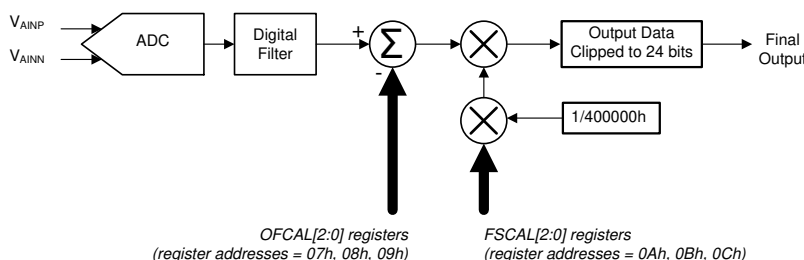

Reset the ADC through the serial interface by the RESET command. Bring  $\overline{\text{CS1}}$  high-then-low to first reset the serial interface, ensuring the ADC is ready for the RESET command. After reset, the conversion starts 512  $f_{\text{CLK}}$  cycles later if START is high. See [Figure 7-5](#) for RESET command timing.

### 9.4.4 Calibration

The ADC incorporates calibration registers to calibrate offset and full-scale errors. Calibrate the ADC by using calibration commands, or calibrate by writing to the calibration registers directly (user calibration). To calibrate by command, send the offset or full-scale calibration commands. To user calibrate, write to the calibration registers with values based on the acquired conversion data. Perform the offset calibration operation before the full-scale calibration operation.

#### 9.4.4.1 Offset and Full-Scale Calibration

Use the offset and full-scale (gain) registers to correct offset or full-scale errors, respectively. As illustrated in [Figure 9-18](#), the offset calibration register is subtracted from the output data before multiplication by the full-scale register, which is divided by 400000h. After the calibration operation, the final value of the output data is clipped to 24 bits.

**Figure 9-18. Calibration Block Diagram**

Equation 4 shows the internal calibration.

$$\text{Final Output Data} = (\text{Pre Data} - \text{OFCAL}[2:0]) \times \text{FSCAL}[2:0] / 400000h \quad (4)$$

#### 9.4.4.1.1 Offset Calibration Registers

The offset calibration word is 24 bits consisting of three 8-bit registers. The offset value is subtracted from the conversion result. The offset value is two's-complement format with a maximum positive value equal to 7FFFFFFh and a maximum negative value equal to 800000h. A register value equal to 000000h has no offset correction. Although the calibration registers provide a wide offset value range, the input signal cannot exceed  $\pm 106\%$  of the precalibrated range; otherwise the ADC is overranged. Table 9-8 lists example values of the offset register.

**Table 9-8. Offset Calibration Register Values**

OFCAL[2:0] REGISTER VALUE	CALIBRATED OUTPUT VALUE <sup>(1)</sup>
000001h	FFFFFFh
000000h	000000h
FFFFFFh	000001h

(1)  $V_{IN} = 0$  V, ideal ADC with no offset error or noise.

#### 9.4.4.1.2 Full-Scale Calibration Registers

The full-scale calibration word is 24 bits consisting of three 8-bit registers. The full-scale calibration value is straight binary and normalized to unity-gain at value = 400000h. Table 9-9 lists register values for selected gain factors. Gain errors greater than unity are corrected by full-scale values less than 400000h. Although the calibration registers provide a wide range of possible values, the input signal must not exceed  $\pm 106\%$  of the precalibrated input range; otherwise the ADC is overranged.

**Table 9-9. Full-Scale Calibration Register Values**

FSCAL[2:0] REGISTER VALUE	GAIN FACTOR
433333h	1.05
400000h	1
3CCCCCh	0.95

#### 9.4.4.2 Offset Calibration Command (OFSCAL)

The offset calibration command corrects offset errors. To calibrate offset errors, short the inputs to the ADC or to calibrate the system, short the signal inputs to the system. When the command is sent, the ADC averages 16 conversion results to reduce conversion noise for improved calibration accuracy. When calibration is complete, the ADC performs one conversion using the new calibration value. The new calibration value is written to the offset calibration register.

#### 9.4.4.3 Full-Scale Calibration Command (GANCAL)

The full-scale calibration command corrects gain errors. To calibrate, apply a positive calibration voltage to the ADC, or apply the voltage to the signal inputs of the system, wait for the signal to settle, and then send the command. The ADC averages 16 conversion results to reduce conversion noise to improve calibration accuracy. The ADC computes the full-scale calibration value so that the applied calibration voltage is scaled to an equal positive full-scale output code. The computed result is written to the calibration register. The ADC then performs one new conversion using the new calibration value.

#### 9.4.4.4 Calibration Command Procedure

Use the following calibration procedure using the calibration commands. When calibrating at power-on, make sure the reference voltage has stabilized. Perform an offset calibration operation prior to full-scale calibration.

1. Set the ADC configurations as required.
2. Apply the appropriate calibration signal (zero or full-scale) to the ADC or to the system inputs.
3. Take the START pin high or send the START command to start conversions.  $\overline{\text{DRDY}}$  is driven high.

4. Before the first conversion completes, send the appropriate calibration command. Keep  $\overline{CS1}$  low until  $\overline{DRDY}$  is driven low (calibration complete); otherwise the command is cancelled. Do not send other commands during the calibration period.
5.  $\overline{DRDY}$  is driven low when calibration is complete. The calibration time, as described in Table 9-10, depends on the data rate and digital filter mode. The calibration registers are updated with new values. New conversion data are available immediately using the new calibration value.

**Table 9-10. Calibration Time (ms)**

DATA RATE (SPS) <sup>(1)</sup>	FILTER MODE				
	SINC1	SINC3	SINC4	SINC5	FIR
2.5	6801	8401	9201	—	6805
5	3401	4201	4601	—	3405
10	1701	2101	2300	—	1705
16.6	1021	1261	1381	—	—
20	850.9	1051	1151	—	854.5
50	340.9	421	460.9	—	—
60	284.2	350.9	384.2	—	—
100	170.9	210.9	230.9	—	—
400	43.36	53.36	58.36	—	—
1200	15.02	18.36	20.02	—	—
2400	7.938	9.605	10.44	—	—
4800	4.397	5.230	5.647	—	—
7200	3.216	3.772	4.050	—	—
14400	—	—	—	1.892	—
19200	—	—	—	1.458	—
25600	—	—	—	1.133	—
40000	—	—	—	0.738	—

(1) Actual calibration time can vary depending on the accuracy of  $f_{CLK}$ .

#### 9.4.4.5 User Calibration Procedure

To user calibrate, apply the calibration voltage, acquire conversion data, and compute the calibration value. Write the computed value to the corresponding calibration registers. Before starting calibration, preset the offset and full-scale registers to 000000h and 400000h, respectively.

To offset calibrate, short the inputs to the system and average  $n$  number of the conversion data. Averaging conversion data reduces noise to increase calibration accuracy. Write the average value of the conversion data to the offset registers.

To gain calibrate using a full-scale calibration signal, temporarily reduce the full-scale register by 95% to avoid any output clipped codes (set FSCAL[2:0] to 3CCCCCh). Acquire  $n$  number of conversions and average the conversions to increase calibration accuracy. Equation 5 describes how to compute the full-scale calibration value:

$$\text{Full-Scale Calibration Value} = (\text{Expected Code} / \text{Actual Code}) \times 400000\text{h} \quad (5)$$

where:

- Expected code = 799998h using full-scale calibration signal and 95% precalibration scale factor

## 9.5 Programming

### 9.5.1 Serial Interface

The SPI-compatible serial interface is used to read conversion data, configure the device registers, and control ADC operation. The CRC is used to validate error-free transmission of the input and output data flow. The serial interface consists of the following control signals:  $\overline{CS1}$ ,  $\overline{CS2}$ , SCLK, DIN, and DOUT/ $\overline{DRDY}$ . Most microcontroller SPI peripherals can operate with the ADC. The interface operates in SPI mode 1, where CPOL = 0 and CPHA = 1. In SPI mode 1, SCLK idles low and data are updated or changed on the SCLK rising edges; data are latched or read on the SCLK falling edges. Timing details of the SPI protocol are provided in [Figure 7-1](#) and [Figure 7-2](#).

#### 9.5.1.1 Chip-Select Pins ( $\overline{CS1}$ and $\overline{CS2}$ )

The ADC consists of discrete PGA and ADC sections with each section selected for communication by separate chip-select inputs ( $\overline{CS1}$  and  $\overline{CS2}$ ). Most commands require the use of  $\overline{CS1}$  to control the ADC section. However, for control of the PGA section, use  $\overline{CS2}$  for register access commands at address 10h and above. Communicate to the device by taking either  $\overline{CS1}$  or  $\overline{CS2}$  low corresponding to the type of command and whether addressing the ADC or PGA registers.

$\overline{CS1}$  and  $\overline{CS2}$  are active low inputs. In normal operation, take one chip-select input low at a time and keep that input low for the duration of the command operation. Take the chip-select input high after the command operation completes. When the chip-select input is taken high, the serial interface resets and SCLK activity is ignored (thus blocking commands). When both chip-select inputs are high, DOUT/ $\overline{DRDY}$  enters a high-impedance state.  $\overline{CS1}$  must be low in order to poll the data-ready function provided by DOUT/ $\overline{DRDY}$ . The  $\overline{DRDY}$  pin remains active regardless of the state of the chip-select inputs.

#### 9.5.1.2 Serial Clock (SCLK)

SCLK is the serial interface shift clock input that clocks data into and out of the device. Output data are updated on the rising edge of SCLK and input data are latched on the falling edge of SCLK. Return SCLK low after the data operation completes. SCLK is a Schmidt-triggered input designed to provide noise immunity. Even though SCLK is noise resistant, keep SCLK noise-free as possible to avoid unintentional SCLK transitions. Avoid ringing and overshoot on the SCLK input. Use a series termination resistor at the SCLK drive pin to reduce ringing.

#### 9.5.1.3 Data Input (DIN)

DIN is the serial interface data input. DIN inputs commands and register data to the device. Input data are latched on the falling edge of SCLK.

#### 9.5.1.4 Data Output/Data Ready (DOUT/ $\overline{DRDY}$ )

The DOUT/ $\overline{DRDY}$  pin is the serial interface data output. This pin also provides the conversion-data ready output. The function of the pin changes whether a read data (or read register) operation is in progress. With  $\overline{CS1}$  low and when not reading register or conversion data, the pin indicates when data are ready by asserting low. For conversion data and register read operations, the pin function changes to data output. When the read operation is completed, the function changes back to the data-ready signal. In the data output mode, data are updated on the SCLK rising edge and the data is therefore latched by the host on the SCLK falling edge.  $\overline{CS1}$  must be low for DOUT/ $\overline{DRDY}$  to provide the data-ready function. When both chip-select pins are high, DOUT/ $\overline{DRDY}$  is in high-impedance mode (tri-state).

### 9.5.2 Data Ready ( $\overline{DRDY}$ )

$\overline{DRDY}$  asserts low to indicate that new conversion data are ready for readback. The operation of  $\overline{DRDY}$  depends on the conversion mode (continuous or pulse) and whether or not the conversion data are retrieved. The  $\overline{DRDY}$  output remains functional regardless of the state of the chip-select inputs.

#### 9.5.2.1 $\overline{DRDY}$ in Continuous-Conversion Mode

In continuous-conversion mode,  $\overline{DRDY}$  is driven high when a conversion is started and is driven low when conversion data are ready. During data readback,  $\overline{DRDY}$  is driven high, which indicates completion of the read

operation. If the conversion data are not read,  $\overline{\text{DRDY}}$  remains low then pulses high 16  $f_{\text{CLK}}$  cycles prior to the next falling edge.

To read back the current conversion data before the next conversion completes, send the read data command at least 16  $f_{\text{CLK}}$  cycles prior to the  $\overline{\text{DRDY}}$  falling edge. If the readback command is sent *less than* 16  $f_{\text{CLK}}$  cycles prior to the  $\overline{\text{DRDY}}$  falling edge, *either* the previous or new conversion data are provided. The timing of the command determines whether previous or new data are provided. In the event that previous data are provided,  $\overline{\text{DRDY}}$  transitioning to low is temporarily suspended until after the read data operation completes. In this case, the DRDY bit of the STATUS0 byte is low to indicate that the previous data have already been read. In the event that new conversion data are provided,  $\overline{\text{DRDY}}$  transitions low as normal. The DRDY bit of the STATUS0 byte is high to indicate the conversion data are new. To ensure readback of new conversion data, wait until  $\overline{\text{DRDY}}$  asserts low before starting the data read operation.

### 9.5.2.2 $\overline{\text{DRDY}}$ in Pulse-Conversion Mode

$\overline{\text{DRDY}}$  is driven high at conversion start and is driven low when the conversion data are ready.  $\overline{\text{DRDY}}$  remains low until a new conversion is started.

Figure 9-19 shows the  $\overline{\text{DRDY}}$  operation with and without data retrieval in pulse- and continuous-conversion modes.

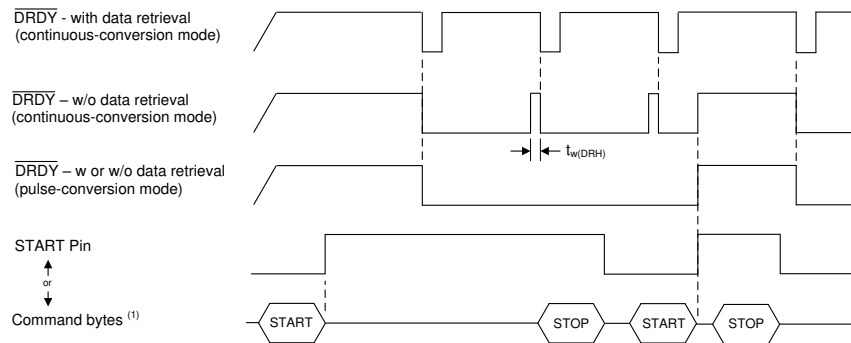

Figure 9-19.  $\overline{\text{DRDY}}$  Operation

### 9.5.2.3 Data Ready by Software Polling

As an option to polling the  $\overline{\text{DRDY}}$  pin or the DOUT/ $\overline{\text{DRDY}}$  pin, poll the DRDY bit in the STATUS byte (sent with the conversion data) or the STATUS0 register byte. If the bit is high, the conversion data are new from the last data read operation. If the bit is low, conversion data are not new from the last data read operation. If  $\text{DRDY} = 0$ , the previous (old) conversion data are returned. In order to avoid missing conversion data in continuous-conversion mode, poll the bit at least as often as the period of the data rate.

## 9.5.3 Conversion Data

Conversion data are read by the RDATA command. To read conversion data, take  $\overline{\text{CS1}}$  low and issue the read data command. The conversion data field consists of an optional STATUS0 byte, three data bytes, and the CRC byte. The CRC byte is computed over the combined STATUS0 byte (if enabled) and three conversion data bytes. See the [RDATA Command](#) section for details on reading conversion data.

### 9.5.3.1 Status Byte (STATUS0)

The status byte contains information on the operating status of the ADC. During the conversion data read operation, the contents of the STATUS0 register is transmitted together with the conversion data by setting the STATENB bit of the [MODE3](#) register. Alternatively, read the [STATUS0](#) register directly by the register read command without having to read conversion data.

### 9.5.3.2 Conversion Data Format

The conversion data are 24 bits, in two's-complement format to represent positive and negative values. The data begin with the most significant bit (sign bit) first. The data are scaled so that  $V_{IN} = 0\text{ V}$  results in an ideal code value of 000000h, the positive full-scale input is equal to an ideal value of 7FFFFFFh, and the negative full-scale input is equal to an ideal code value of 800000h. [Table 9-11](#) lists the code values. The data are clipped to 7FFFFFFh and 800000h during positive and negative signal overdrive, respectively.

**Table 9-11. ADC Conversion Data Codes**

DESCRIPTION	INPUT SIGNAL (V)	24-BIT CONVERSION DATA <sup>(1)</sup>
Positive full scale	$\geq V_{REF} / \text{Gain} \times (2^{23} - 1) / 2^{23}$	7FFFFFFh
1 LSB	$V_{REF} / (\text{Gain} \times 2^{23})$	000001h
Zero scale	0	000000h
-1 LSB	$-V_{REF} / (\text{Gain} \times 2^{23})$	FFFFFFh
Negative full scale	$\leq -V_{REF} / \text{Gain}$	800000h

(1) Ideal output code excluding noise, offset, gain, and linearity errors.

### 9.5.4 Cyclic Redundancy Check (CRC)

Cyclic redundancy check (CRC) is an error detection byte that detects communication errors to and from the host and ADC. CRC is the division remainder of the payload data by the prescribed CRC polynomial. The payload data are 1, 2, 3, or 4 bytes depending on the data transfer operation.

The host computes the CRC over the two command bytes and appends the CRC to the command string (third byte). A fourth, zero-value byte completes the command field to the ADC. The ADC performs the CRC calculation and compares the result to the CRC transmitted by the host. If the host and ADC CRC values match, the command executes and the ADC responds by transmitting the valid CRC during the fourth byte of the command. If the CRC is error free and the operation is a data read, the ADC responds with a second CRC that is computed for the requested data byte payload. The response data payload is 1, 3, or 4 bytes depending on the type of operation.

If the host and ADC CRC values *do not* match, the command does not execute and the ADC responds with an *inverted* CRC value, calculated over the received command bytes. The inverted CRC is intended to signal the host of the failed operation. The host terminates transmission of further bytes to stop the command operation. The CRC1 bit is set in the [STATUS0](#) register when an error pertaining to ADC commands occurs. The STAT12 and CRC2 flags are set when an error pertaining to PGA register access occurs.

The ADC is ready to accept the next command after all required bytes are transmitted when no CRC error occurs, or after a CRC error occurs when terminated at the end of the fourth command byte.

The CRC data byte is the 8-bit remainder of the bitwise exclusive-OR (XOR) of the argument by a CRC polynomial. The CRC polynomial is based on the CRC-8-ATM (HEC) polynomial:  $X^8 + X^2 + X + 1$ . The nine binary polynomial coefficients are 100000111b. The following sections detail the input and output data of each command.

See the example C code for the CRC calculation in the [ADS125H02 Example C Code software](#). Also see the [ADS125H02 Design Calculator software](#) to calculate specific CRC code values.

In the command descriptions from the [Commands](#) section, these CRC mnemonics apply:

- **CRC-2:** Input CRC of command byte 1 and command byte 2
- **Out CRC-1:** Output CRC of one register data byte
- **Out CRC-2:** Output CRC of two command bytes, inverted value if an input CRC error is detected
- **Out CRC-3:** Output CRC of three conversion data bytes
- **Out CRC-4:** Output CRC of three conversion data bytes plus the STATUS0 byte
- **Echo Byte 1:** Echo out of input byte 1
- **Echo Byte 2:** Echo out of input byte 2

### 9.5.5 Commands

Commands are used to read conversion data, control the device, and read and write register data. [Table 9-12](#) provides a list of commands and the corresponding command byte sequence. Only send commands listed in [Table 9-12](#).

The column labeled  $\overline{CSx}$  shows the use of  $\overline{CS1}$  or  $\overline{CS2}$  for the particular command type. Most commands use  $\overline{CS1}$ . Only activate  $\overline{CS2}$  to access register data at addresses 10h, 11h, and 12h. See the [Chip-Select Pins \( \$\overline{CS1}\$  and  \$\overline{CS2}\$ \)](#) section for details of the chip-select operation.

**Table 9-12. Command Byte Summary**

MNEMONIC	$\overline{CSx}$	DESCRIPTION	BYTE 1	BYTE 2 <sup>(2)</sup>	BYTE 3	BYTE 4
<b>CONTROL COMMANDS</b>						
NOP	$\overline{CS1}$ or $\overline{CS2}$	No operation	00h	Arbitrary	CRC-2	00h
RESET	$\overline{CS1}$	Reset	06h	Arbitrary	CRC-2	00h
START	$\overline{CS1}$	Start conversion	08h	Arbitrary	CRC-2	00h
STOP	$\overline{CS1}$	Stop conversion	0Ah	Arbitrary	CRC-2	00h
<b>READ DATA COMMAND</b>						
RDATA	$\overline{CS1}$	Read conversion data	12h	Arbitrary	CRC-2	00h
<b>CALIBRATION COMMANDS</b>						
OFSCAL	$\overline{CS1}$	Offset calibration	16h	Arbitrary	CRC-2	00h
GANCAL	$\overline{CS1}$	Gain calibration	17h	Arbitrary	CRC-2	00h
<b>REGISTER COMMANDS</b>						
RREG	$\overline{CS1}$ or $\overline{CS2}$	Read register data	20h + rrh <sup>(1)</sup>	Arbitrary	CRC-2	00h
WREG	$\overline{CS1}$ or $\overline{CS2}$	Write register data	40h + rrh <sup>(1)</sup>	Register data	CRC-2	00h

(1) rrh = 5-bit register address.

(2) Excluding the write-register command, the value of the second byte is arbitrary (any value) but is included in the CRC calculation.

#### 9.5.5.1 General Command Format

[Figure 9-20](#) shows an example register write operation to register address 02h (command = 42h). For this register address (02h), take  $\overline{CS1}$  low. The first byte output from the ADC is always FFh. The host calculates the CRC of the two input command bytes. The Out CRC-2 byte is the ADC-calculated, output CRC based on the received command bytes. If the CRC values match, the command is executed beginning at the last SCLK of the fourth byte in the sequence. Forcing the chip select high before the command completes results in command termination. Toggle the chip select low-to-high between command operations.

**Figure 9-20. Register Write Command Sequence (Address = 02h)**

The following sections detail the input and output byte sequence corresponding to each command. See the [Cyclic Redundancy Check \(CRC\)](#) section for the notation used for the CRC.

### 9.5.5.2 NOP Command

This command has no operation. Use the NOP command to validate the CRC response byte and error detection without affecting normal operation. [Table 9-13](#) shows the NOP command byte sequence.

**Table 9-13. NOP Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	00h	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.3 RESET Command

The RESET command resets the ADC operation and resets all registers to default. See the [Reset by Command](#) section for details. [Table 9-14](#) lists the RESET command byte sequence.

**Table 9-14. RESET Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	06h	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.4 START Command

This command starts conversions. See the [Conversion Control](#) section for details. [Table 9-15](#) lists the START command byte sequence.

**Table 9-15. START Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	08h	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.5 STOP Command

This command is used to stop conversions. See the [Conversion Control](#) section for details. [Table 9-16](#) lists the STOP command byte sequence.

**Table 9-16. STOP Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	0Ah	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.6 RDATA Command

This command reads conversion data. Because the data are buffered, the data can be read at any time during the conversion sequence. If data are read *near* the completion of the conversion phase, old or new conversion data are returned. See the [Data Ready \(DRDY\)](#) section for details.

The response data of the ADC varies in length depending if the optional STATUS0 byte is included. See the [Conversion Data Format](#) section for details of the format of the conversion data. [Table 9-17](#) and [Figure 9-21](#) describe the RDATA command byte sequence that includes the STATUS0 byte.

**Table 9-17. RDATA Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4	BYTE 5	BYTE 6	BYTE 7	BYTE 8	BYTE 9
DIN	12h	Arbitrary	CRC-2	00h	00h	00h	00h	00h	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2	STATUS0 <sup>(1)</sup>	MSB data	MID data	LSB data	Out CRC-3 or Out CRC-4 <sup>(2)</sup>

- (1) Optional STATUS0 byte shown.
- (2) Out CRC-4 (4-byte CRC = STATUS0 + data) if the STATUS0 byte is included in the data packet.

**Figure 9-21. Conversion Data Read Operation**

### 9.5.5.7 OFSCAL Command

This command is used for offset calibration. See the [Calibration](#) section for details. [Table 9-18](#) lists the OFSCAL command byte sequence.

**Table 9-18. OFSCAL Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	16h	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.8 GANCAL Command

This command is used for gain calibration. See the [Calibration](#) section for details. [Table 9-19](#) lists the GANCAL command byte sequence.

**Table 9-19. GANCAL Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	17h	Arbitrary	CRC-2	00h
DOUT/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

### 9.5.5.9 RREG Command

Use the RREG command to read register data. Take  $\overline{CS1}$  low to access registers within the ADC register block. Take  $\overline{CS2}$  low to access registers within the PGA register block (see the [Register Map](#) section for the register block map). Register data are read one byte at a time using the RREG command for each operation. Add the register address (rrh) to the base value (20h) to complete the command byte (20h + rrh). [Table 9-20](#) lists the RREG command byte sequence. The ADC responds with the register data byte, most significant bit first. Data for registers addressed outside the range is 00h. Out CRC-2 is the output CRC corresponding to the received command bytes. Out CRC-1 is the output CRC corresponding to the single register data byte.

**Table 9-20. RREG Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4	BYTE 5	BYTE 6
DIN	20h + rrh	Arbitrary	CRC-2	00h	00h	00h
DOU/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2	Register data	Out CRC-1

### 9.5.5.10 WREG Command

Use the WREG command to write register data. Take  $\overline{CS1}$  low to access registers within the ADC register block. Take  $\overline{CS2}$  low to access registers within the PGA register block (see the [Register Map](#) section for the register block map). The WREG command writes the register data one byte at a time using the WREG command for each operation. Add the register address (rrh) to the base value (40h) to complete the command byte (40h + rrh). [Table 9-21](#) lists the WREG command byte sequence. Writing to certain registers results in conversion restart. [Table 9-22](#) lists the affected registers. Do not write to registers outside the address range.

**Table 9-21. WREG Command**

DIRECTION	BYTE 1	BYTE 2	BYTE 3	BYTE 4
DIN	40h + rrh	Register data	CRC-2	00h
DOU/DRDY	FFh	Echo byte 1	Echo byte 2	Out CRC-2

## 9.6 Register Map

Table 9-22 shows the device register map consisting of a series of byte-wide registers. Collectively, the registers are used to configure the device. Access the registers by using the RREG and WREG commands (register-read and register-write, respectively). Data are accessed one register byte at a time for each command operation. The address of the register corresponds to using either CS1 or CS2 for the register command operation. The CSx column shows the correlation of CS1 or CS2 to the register address. Changing the data of certain registers will result in restart of conversions. The Restart column lists these registers.

**Table 9-22. Register Map Summary**

ADDRESS	REGISTER	DEFAULT	RESTART	CSx	BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
00h	ID	4xh		CS1	DEV_ID[3:0]				REV_ID1[3:0]			
01h	STATUS0	01h		CS1	0	CRC1	0	STAT12	REFALM	DRDY	CLOCK	RESET

12h	STATUS2	0xh		CS2	0	0	0	CRC2	REV_ID2[3:0]			

Table 9-23 lists the access codes for the ADS125H01 registers.

**Table 9-23. ADS125H01 Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R/W	R-W	Read or write
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

### 9.6.1 Device Identification (ID) Register (address = 00h) [reset = 4xh]

ID is shown in [Figure 9-22](#) and described in [Table 9-24](#).

Return to [Register Map Summary](#).

**Figure 9-22. ID Register**

<sup>(1)</sup> 7	6	5	4	3	2	1	0
DEV_ID[3:0]				REV_ID1[3:0]			
R-4h				R-xh			

(1) Reset values are device dependent.

**Table 9-24. ID Register Field Descriptions**

Bit	Field	Type	Reset	Description
7:4	DEV_ID[3:0]	R	4h	<b>Device ID</b> 0100 = ADS125H01
3:0	REV_ID1[3:0]	R	xh	<b>Revision ID1</b> There are two revision ID fields: REV_ID1 and REV_ID2. The revision IDs can change without notification.

### 9.6.2 Main Status (STATUS0) Register (address = 01h) [reset = 01h]

STATUS0 is shown in [Figure 9-23](#) and described in [Table 9-25](#).

Return to [Register Map Summary](#).

**Figure 9-23. STATUS0 Register**

7	6	5	4	3	2	1	0
RESERVED	CRC1	RESERVED	STAT12	REFALM	DRDY	CLOCK	RESET
R/W-0h	R/W-0h	R/W-0h	R-0h	R-0h	R-0h	R-xh	R/W-1h

**Table 9-25. STATUS0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	RESERVED	R/W	0h	<b>Reserved</b> Always write 0.
6	CRC1	R/W	0h	<b>CRC1 Error</b> Indicates if a CRC error occurred during commands when $\overline{CS1}$ is active. Write 0 to clear the CRC error. 0: No CRC error during commands using $\overline{CS1}$ 1: CRC error occurred during commands using $\overline{CS1}$ See the <a href="#">STATUS2</a> register for the CRC error status for commands using $\overline{CS2}$ .
5	RESERVED	R/W	0h	<b>Reserved</b> Always write 0.
4	STAT12	R	0h	<b>STAT12 Error Flag</b> Indicates one or more error events have been logged in the STATUS1 or STATUS2 registers. Read the STATUS1 and STATUS2 registers to determine the error. This bit clears automatically after all errors are cleared. 0: No error 1: Error logged in the STATUS1 or STATUS2 registers
3	REFALM	R	0h	<b>Reference Voltage Alarm</b> This bit sets when the reference voltage falls below < 0.4 V (typical). The alarm updates at each new conversion cycle (auto-reset). 0: No reference low alarm 1: Reference low alarm
2	DRDY	R	0h	<b>Data Ready</b> Indicates new conversion data. 0: Conversion data are not new from the last data read 1: Conversion data are new from the last data read
1	CLOCK	R	xh	<b>Clock</b> Indicates internal or external clock mode. The ADC automatically selects the clock mode. 0: ADC clock is internal 1: ADC clock is external
0	RESET	R/W	1h	<b>Reset</b> Indicates an ADC reset has occurred. Clear the bit to detect the next device reset. 0: No reset 1: Reset (default)

### 9.6.3 Mode 0 (MODE0) Register (address = 02h) [reset = 24h]

MODE0 is shown in [Figure 9-24](#) and described in [Table 9-26](#).

Return to [Register Map Summary](#).

**Figure 9-24. MODE0 Register**

7	6	5	4	3	2	1	0
DR[4:0]				FILTER[2:0]			
R/W-4h				R/W-4h			

**Table 9-26. MODE0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7:3	DR[4:0]	R/W	4h	<b>Data Rate</b> These bits select the data rate. 00000: 2.5 SPS 00001: 5 SPS 00010: 10 SPS 00011: 16. $\bar{6}$ SPS 00100: 20 SPS (default) 00101: 50 SPS 00110: 60 SPS 00111: 100 SPS 01000: 400 SPS 01001: 1.2 kSPS 01010: 2.4 kSPS 01011: 4.8 kSPS 01100: 7.2 kSPS 01101: 14.4 kSPS 01110: 19.2 kSPS 01111: 25.6 kSPS 10000 - 11111: 40 kSPS
2:0	FILTER[2:0]	R/W	4h	<b>Digital Filter</b> See the <a href="#">Digital Filter</a> section for details. <sup>(1)</sup> These bits select the digital filter mode. 000: Sinc1 001: Reserved 010: Sinc3 011: Sinc4 100: FIR (default) 101-111: Reserved

(1) For  $f_{DATA} \geq 14.4$  kSPS, the filter mode is sinc5 only. In this case, the filter bits are don't care. The FIR filter option is available for  $f_{DATA} = 2.5$  SPS, 5 SPS, 10 SPS, and 20 SPS only.

### 9.6.4 Mode 1 (MODE1) Register (address = 03h) [reset = 01h]

MODE1 is shown in [Figure 9-25](#) and described in [Table 9-27](#).

Return to [Register Map Summary](#).

## 10 Application and Implementation

### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

### 10.1 Application Information

#### 10.1.1 Example to Determine the PGA Linear Operating Range

Linear operation of the PGA requires that the absolute input voltage does not exceed the specified range. The following example shows how to verify the absolute input voltage is within the valid range. In this example, the input signal is  $\pm 10$  V using a chosen 15% overrange capability. The negative input lead of the sensor is connected to AGND and AINN. The ADC gain is chosen at 0.1875 using a 2.5-V reference voltage and  $\pm 15$ -V power supplies with a 5% voltage tolerance. The summary of conditions to verify PGA operating conformance are:

- $V_{(A\text{INP\_MAX})} = 10 \text{ V} \times 115\% = 11.5 \text{ V}$
- $V_{(A\text{INP\_MIN})} = -10 \text{ V} \times 115\% = -11.5 \text{ V}$
- $V_{(A\text{INN})} = \text{AGND}$
- $\text{HV\_AVDD}_{\text{MIN}} = 15 \text{ V} \times 95\% = 14.25 \text{ V}$
- $\text{HV\_AVSS}_{\text{MAX}} = -15 \text{ V} \times 95\% = -14.25 \text{ V}$
- Gain = 0.1875
- $V_{\text{REF}} = 2.5 \text{ V}$

The evaluation of [Equation 3](#) (for gain < 1) results in:

$$-11.75 \text{ V} < -11.5 \text{ V} \text{ and } 11.5 \text{ V} < 11.75 \text{ V}$$

The inequality is satisfied, and as a result, the absolute input voltage is within the PGA input range.

#### 10.1.2 Input Signal Rate of Change (dV/dt)

A high dV/dt signal at the ADC input can lead to transient turn-on of the PGA inverse-parallel protection diodes (see [Figure 9-1](#) for details). Turn-on of the PGA diodes can result in current flow in the analog inputs that can cause a disturbance in the measurement channel. For example, a high dV/dt voltage can be generated at the output of a signal multiplexer after a channel selection, leading to a possible flow of transient currents through the ADC inputs. Filter the ADC input voltage to limit the rate of voltage change (dV/dt).

#### 10.1.3 Unused Inputs and Outputs

##### • Digital I/O

ADC operation is possible using a subset of the digital I/Os. However, tie any unused digital input high or low (DVDD or DGND, as appropriate). Do not float (tri-state) the digital inputs or unpredictable operation can result. The following is a summary of an optional digital I/O:

- **CLKIN:** Tie CLKIN to DGND to operate the ADC using the internal oscillator. The internal oscillator stops operation if CLKIN is connected to DVDD, resulting in loss of ADC functionality. Connect CLKIN to an external clock source to operate with an external clock.
- **START:** Tie START low in order to control conversions entirely by command. Tie START high to free-run conversions (only when programmed to continuous-conversion mode). Connect START to the host controller to control conversions directly by the pin.
- **RESET:** Tie  $\overline{\text{RESET}}$  high if desired. An external RC delayed-reset or a reset device connected to the RESET pin is not necessary because the ADC automatically resets at power on. The ADC can be reset by the RESET command. Connect the RESET pin to the host controller to reset the ADC by hardware.

- **DRDY**: The data-ready indicator is also provided by the DOUT/ $\overline{\text{DRDY}}$  pin.  $\overline{\text{CS1}}$  must be low to use DOUT/ $\overline{\text{DRDY}}$  to provide the data-ready function. Data-ready is also determined by polling the DRDY bit of the STATUS0 byte. Using these alternate methods, the connection of  $\overline{\text{DRDY}}$  to the host controller is not necessary and the pin can be left unconnected.

## 10.2 Typical Application

Figure 10-1 illustrates an example of the ADS125H01 used in a  $\pm 10\text{-V}$  analog input programmable logic controller (PLC) module. The ADC inputs are protected by external ESD diodes to provide system-level protection. The external 100-M $\Omega$  resistor is used to pull the positive analog input to 15 V if the field-wiring connection is open or the transmitter connected the ADC inputs has a failed open circuit. A failed input results in a full-scale code value.

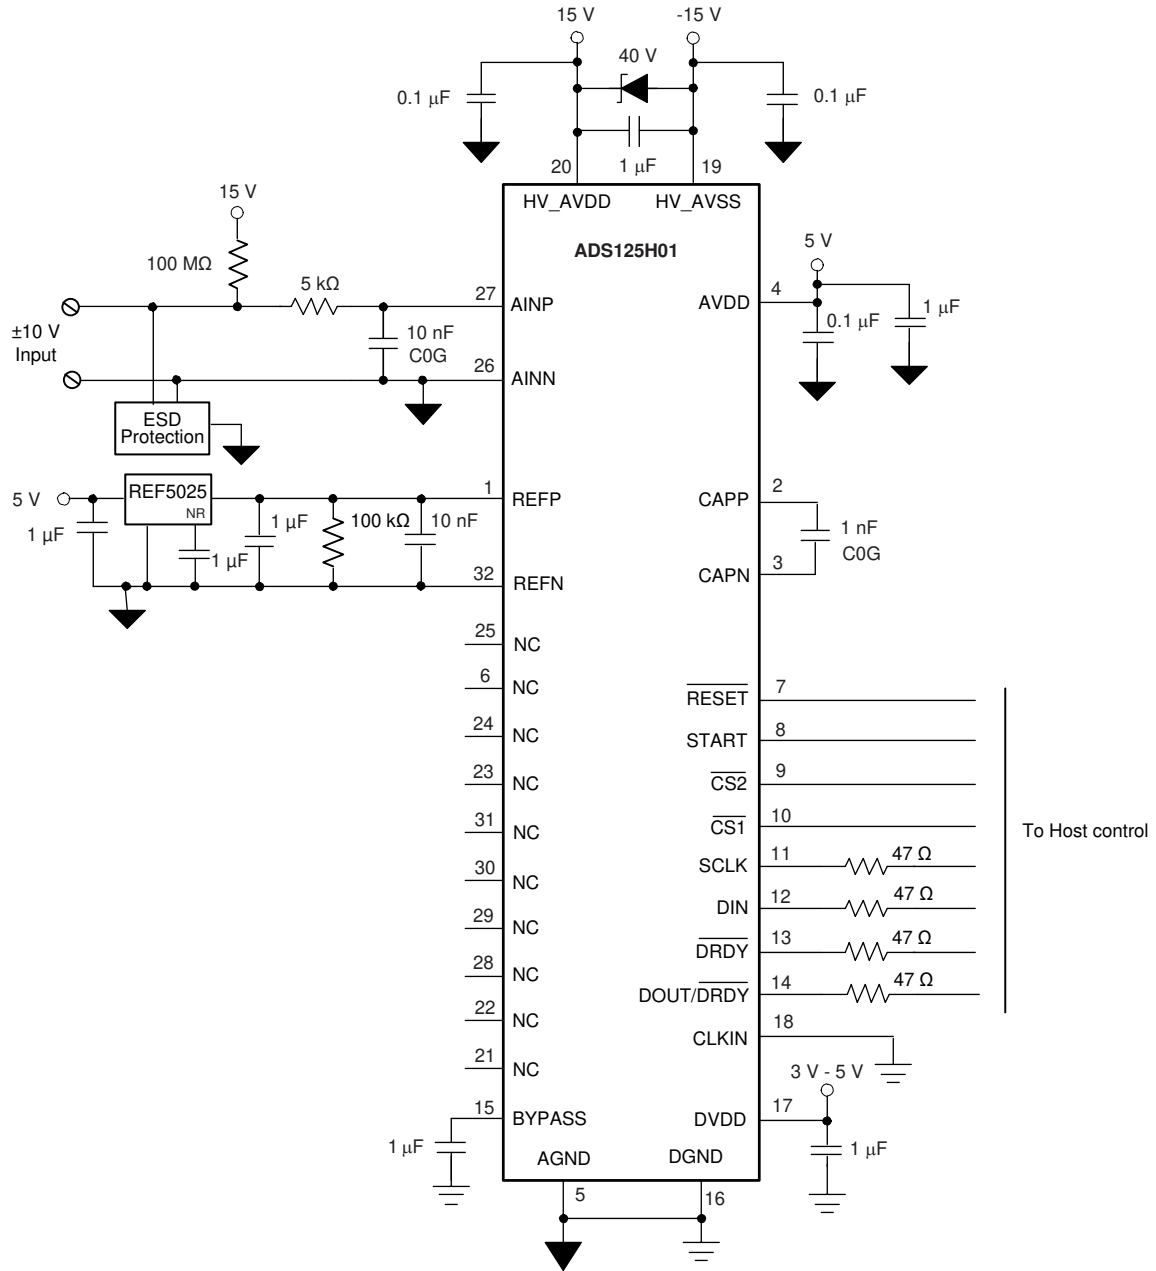

The signal from the transmitter is filtered to remove EMI and RFI interference to enhance noise immunity. The resistor also serves to limit input current in the event of a DC overvoltage, including if the module loses power while the input signal is present. The negative input is connected to AINN, which is also connected to AGND. Connection to AGND is necessary if the sensor power supply is not referenced to the ADC ground.

The input configuration is single-ended with the input voltage driven to 0 V and  $-10\text{ V}$  relative to AINN (AGND).

The reference voltage is applied to the REFP and REFN pins. A 100-k $\Omega$  resistor biases the differential reference voltage to 0 V when either reference input is open circuit. With the resistor, a failed or missing reference voltage is detected by the internal monitor.

The internal oscillator is selected by grounding the CLKIN pin. The serial interface and digital control lines of the ADC connect to the host.

The Zener diode clamps the high-voltage supply (HV\_AVDD – HV\_AVSS) to 40 V to provide overvoltage protection if an input signal is applied with module power off.

**Figure 10-1.  $\pm 10\text{-V}$  Analog Input PLC Module**

## 10.2.1 Design Requirements

Table 10-1 shows the design goals of the analog input PLC module. The ADC programmability allows various tradeoffs of sample rate, conversion noise, and conversion latency. Table 10-2 shows the design parameters of the analog input PLC module.

**Table 10-1. Design Goals**

DESIGN GOAL	VALUE
Accuracy	±0.1%
Temperature range (internal module)	0°C to +105°C
Update rate	50 $\mu$ s
Effective resolution	18 bits

**Table 10-2. Design Parameters**

DESIGN PARAMETER	VALUE
Nominal signal range	±10 V
Extended range	±12 V
Input impedance	100 M $\Omega$
Overvoltage rating	±35 V

## 10.2.2 Detailed Design Procedure

A key consideration in the design of an analog input module is the error over the ambient temperature range resulting from the drift of gain, offset, reference voltage, and linearity error. This example assumes the initial offset and gain (including reference voltage error) are user calibrated at  $T_A = 25^\circ\text{C}$ . Table 10-3 shows the maximum drift error of the ADC over the 0°C to +105°C temperature range.

**Table 10-3. Error Over Temperature**

PARAMETER	ERROR (0°C to +105°C)
Offset drift error	0.00125%
Gain drift error	0.032%
Nonlinearity error (over temperature)	0.001%
Reference drift error (REF5025IDGK external reference)	0.024%
Total drift error	0.05825%

As shown in Table 10-3, the total drift error is 0.058% when using the REF5025IDGK reference, which satisfies the 0.1% total error design goal.

The ADC gain is programmed to 0.1875. With a 2.5-V reference voltage, the ADC input range is  $\pm 2.5 \text{ V} / 0.1875 = \pm 13.3 \text{ V}$ . However, using  $\pm 15\text{-V}$  power supplies, the required headroom of the PGA limits the range to  $\pm 12.5 \text{ V}$  (which excludes the tolerance of the  $\pm 15\text{-V}$  power supplies). The input range satisfies the extended range design target of  $\pm 12 \text{ V}$ .

The 1-G $\Omega$  minimum input impedance of the ADC and the 100-M $\Omega$  external pullup resistor meets the input impedance goal of 100 M $\Omega$ . The input fault overvoltage requirement (35 V) is met by limiting the input current to the 10-mA maximum specification. The external 5-k $\Omega$  series input resistor limits the input current to 7 mA.

The data rate that meets the continuous-conversion, 50- $\mu$ s acquisition period is 25600 SPS (39  $\mu$ s actual). If a precise 50- $\mu$ s conversion period is desired, reduce the clock frequency to the ADC with an external clock source. The clock frequency that produces a precise 50- $\mu$ s conversion period is 5.76 MHz.

Referring to the data illustrated in Figure 8-3, the effective resolution is 18 bits at data rate = 25600 SPS and gain = 0.1875.

### 10.2.3 Application Curve

Figure 10-2 shows 100,000 consecutive conversions over a four-second interval with the ADC inputs shorted using the ADC configuration given in this example. 100,000 conversions demonstrate the consistency of the ADC conversion results over time. The conversion noise in this example is  $107 \mu\text{V}_{\text{RMS}}$ . Based on this measurement data, the equivalent effective resolution is 18 bits, which meets the design requirement.

**Figure 10-2. Conversion Noise**

## 11 Power Supply Recommendations

The ADC requires three analog power supplies (high-voltage supplies HV\_AVDD and HV\_AVSS, and a low-voltage supply AVDD) and a digital power supply (DVDD). The high-voltage analog power-supply configuration is either bipolar ( $\pm 5$  V to  $\pm 18$  V) or unipolar (10 V to 36 V). The AVDD power supply is 5 V. The digital supply range is 2.7 V to 5.25 V. AVDD and DVDD can be tied together as long as the 5-V power supply is free from noise and glitches that can affect conversion results. An internal low-dropout regulator (LDO) powers the digital core from the DVDD power supply. DVDD sets the digital I/O voltage.

Voltage ripple produced by switch-mode power supplies can interfere with the ADC conversion accuracy. Use LDOs at the switching regulator output to reduce power-supply ripple.

### 11.1 Power-Supply Decoupling

Good power-supply decoupling is important in order to achieve optimum performance. Power supplies must be decoupled close to the device supply pins. For the high-voltage analog supply (HV\_AVDD and HV\_AVSS), place a 1- $\mu$ F capacitor between the pins and place 0.1- $\mu$ F capacitors from each supply to the ground plane. Connect 0.1- $\mu$ F and 1- $\mu$ F capacitors in parallel at AVDD to the ground plane. Connect a 1- $\mu$ F capacitor from DVDD to the ground plane. Connect a 1- $\mu$ F capacitor from the BYPASS pin to the ground plane. Use multilayer ceramic chip capacitors (MLCCs) that offer low equivalent series resistance (ESR) and equivalent series inductance (ESL) characteristics for power-supply decoupling purposes.

### 11.2 Analog Power-Supply Clamp

Circumstances must be evaluated when an input signal is present while the ADC is unpowered. When the input signal exceeds the forward voltage of the internal ESD diodes, the diodes conduct resulting in backdrive of the analog power-supply voltage through the internal ESD diodes. Backdriving the ADC power supply can also occur when the power supply is on. If the power supply is not able to sink current during a backdrive condition, the power-supply voltage can rise and can ultimately exceed the breakdown rating of the ADC. The maximum supply voltage rating of the ADC must not be exceeded under any condition. One solution is to clamp the analog supply using a Zener diode placed across HV\_AVSS and HV\_AVDD.

### 11.3 Power-Supply Sequencing

The power supplies can be sequenced in any order, but do not allow analog or digital voltage inputs to exceed the respective analog or digital power supplies without limiting the input current.

## 12 Layout

### 12.1 Layout Guidelines

Good layout practices are crucial to realize the full performance of the ADC. Poor grounding can quickly degrade the ADC noise performance. This section discusses layout recommendations that help provide the best results.

For best performance, dedicate an entire PCB layer to a ground plane and do not route any other signal traces on this layer. However, depending on layout restrictions, a dedicated ground plane may not be practical. If ground plane separation is necessary, make a single, direct connection to the planes at the ADC. Do not connect individual ground planes at multiple locations because this configuration creates ground loops.

Route digital signals away from the CAPP and CAPN pins and away from all analog inputs and associated components to prevent crosstalk.

Because large capacitance on DOUT/ $\overline{\text{DRDY}}$  can lead to increased ADC noise levels, minimize the length of the PCB trace. Use a series resistor or a buffer if long traces are used.

Use C0G capacitors for the analog input filter and for the CAPP to CAPN capacitor. Use ceramic capacitors (for example, X7R grade) for the power-supply decoupling capacitors. High-K capacitors (Y5V) are not recommended. Place the required capacitors as close as possible to the device pins using short, direct traces. For optimum performance, use low-impedance connections with multiple vias on the ground-side connections of the bypass capacitors.

When applying an external clock, be sure the clock is free of overshoot and glitches. A source-termination resistor placed at the clock buffer often helps reduce overshoot. Glitches present on the clock input can lead to noisy conversion data.

### 12.2 Layout Example

[Figure 12-1](#) illustrates an example layout of the ADS125H01, requiring a minimum of three PCB layers. The example circuit is shown with bipolar supply operation ( $\pm 15$  V). In this example, the inner layer is dedicated to the ground plane and the outer layers are used for signal and power traces. If a four-layer PCB is used, dedicate an additional inner layer for the power planes. In this example, the ADC is oriented in such a way to minimize crossover of the analog and digital signal traces.

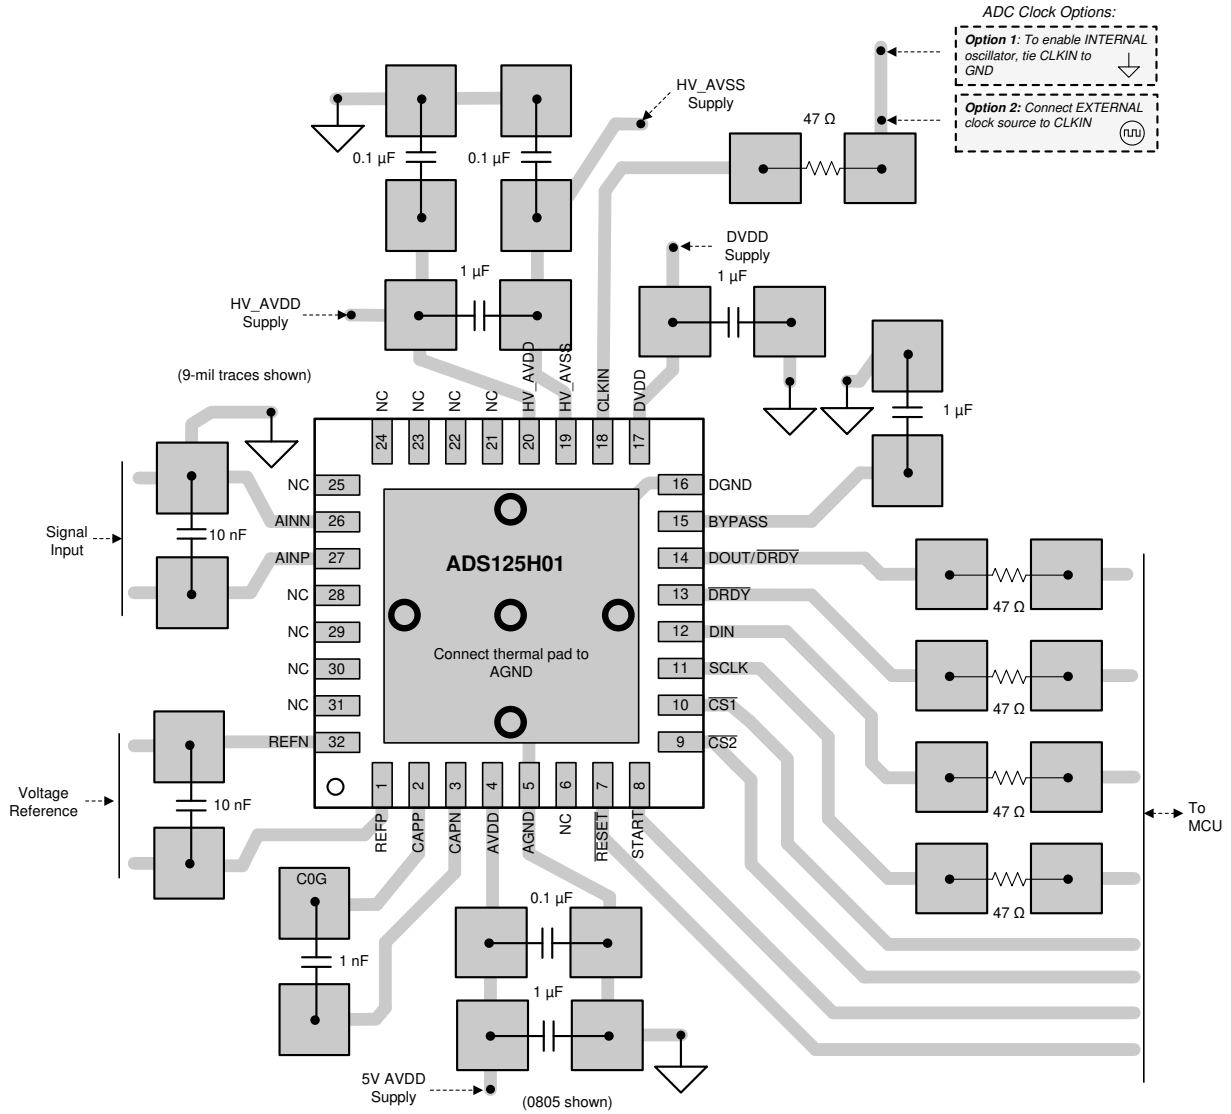

Figure 12-1. Example Top-Layer PCB Layout

## 13 Device and Documentation Support

### 13.1 Documentation Support

#### 13.1.1 Related Documentation

For related documentation see the following:

- Texas Instruments, [ADS125H02  \$\pm\$ 20-V Input, 40-kSPS, 24-Bit, Delta-Sigma ADC with Voltage Reference data sheet](#)
- Texas Instruments, [ADS125H02 Example C Code software](#)
- Texas Instruments, [ADS125H02 Design Calculator software](#)
- Texas Instruments, [REF50xx Low-Noise, Very Low Drift, Precision Voltage Reference data sheet](#)

#### 13.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](#). Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

#### 13.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

#### 13.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.

All trademarks are the property of their respective owners.

#### 13.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

#### 13.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## 14 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
ADS125H01IRHBR	ACTIVE	VQFN	RHB	32	3000	RoHS & Green	NIPDAU	Level-3-260C-168 HR	-40 to 125	ADS 125H01	Samples

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSELETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

**TAPE AND REEL INFORMATION**
