

OPAx323 20MHz High Bandwidth, 114dB CMRR, Low Voltage (1.7V to 5.5V), RRIO Zero-Cross Operational Amplifier

1 Features

- Zero cross amplifier for 1.7V to 5.5V applications
- High rail-to-rail CMRR: 114dB typical
- High gain-bandwidth product: 20MHz
- Fast slew-rate: 33V/μs typical
- Fast 0.01% settling: 200ns typical for 2V step
- Low input offset voltage: ±150μV typical
- Low noise floor: 5.5nV/√Hz typical at 10kHz
- High output current: ±110mA typical I_{SC} at 5.5V
- Quiescent current: 1.6mA/ch typical
- Rail-to-rail input and output
- Unity-gain stable
- Drives up to 150pF without sustained oscillations
- Internal RFI and EMI filtered input pins
- Operating temperature range: –40°C to 125°C

2 Applications

- [Amplifier driver for ADCs](#)
- [High side current sensing](#)
- [Motor rotary encoders](#)
- [Transimpedance photodiode amplifiers](#)
- [Audio microphone pre-amplifiers](#)
- [Ultrasonic transducers](#)

3 Description

The OPAx323 family of op amps includes single (OPA323), dual (OPA2323), and quad-channel (OPA4323), low-voltage (1.7V to 5.5V), high-bandwidth (20MHz) amplifiers (op amps) with a zero-crossover input stage and a rail-to-rail output stage. The zero-crossover input stage enables OPAx323 to achieve high linearity and low distortion for input signals with rail-to-rail swing that are typical in ADC driver applications. Gain-bandwidth of 20MHz provides a fast settling response for ADC sampling speeds between 0.5MSPS to 5MSPS depending on the settling performance required. The OPAx323 is well-optimized for power savings as the device consumes just 1.6mA typical quiescent current.

The OPAx323 easily supports precision performance in high gain voltage sensing applications such as the wheatstone bridge, as it features maximum offset drift of 2μV/°C and thermal noise floor of 5.5nV/rt-Hz with a minimum of 100dB CMRR. This unique combination of higher precision (low offset, drift, noise, distortion, and CMRR) and higher gain-bandwidth (fast settling and slewing) enables use in multiple applications such as the motor rotary encoders, microphone audio pre-amplifiers and ultrasonic transducers.

The OPAx323 achieves a high slew-rate of 33V/μs allowing for fast detection of faults in motor current sensing applications. Unlike traditional amplifiers, the zero-cross over input stage allows for identical precision performance for both low and high-side sensing applications, thus making OPAx323 the best choice for current sensing in a variety of end equipments such as the solar string inverters, power delivery, grid and EV infrastructure. OPAx323S devices provide shutdown functionality for additional power savings and help disable the amplifier when idle. The family features standard and small size as well as leaded and QFN packages across all the channel variants.

Device Information

PART NUMBER ⁽¹⁾	CHANNEL COUNT	PACKAGE ⁽⁴⁾	PACKAGE SIZE ⁽⁵⁾

6 Specifications

6.1 Absolute Maximum Ratings

over operating ambient temperature range (unless otherwise noted) ⁽¹⁾

		MIN	MAX	UNIT
Supply voltage, $V_S = (V+) - (V-)$	Supply voltage, $V_S = (V+) - (V-)$	0	7.0	V
Signal input pins	Common-mode voltage ^{(2) (3)}	-0.5	6.0	V
	Differential voltage ^{(2) (3)}		±6.0	V
	Current ⁽³⁾	-10	10	mA
Output short-circuit ⁽⁴⁾		Continuous		
Operating ambient temperature, T_A		-55	150	°C
Junction temperature, T_J			150	°C
Storage temperature, T_{stg}		-65	150	°C

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) Input pins can swing beyond (V+) as long as they stay within 6V. No diode structure from input pins to (V+).
- (3) Input pins are diode-clamped to (V-). Input signals that 0.3V below (V-) must be current-limited to 10mA or less.
- (4) Short-circuit to ground, one amplifier per package.

6.2 ESD Ratings

			VALUE	UNIT	
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±4000	V	
		Charged-device model (CDM), per ANSI/ESDA/JEDEC JS-002 ⁽²⁾	OPA4323	±500	V
			OPA323, OPA2323	±250	V

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating ambient temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V_S	Supply voltage, (V+) – (V–)	1.7	5.5	V
C_{BYP}	Bypass capacitor on the power supply pins ⁽¹⁾	0.1		µF
T_A	Specified temperature	-40	125	°C

- (1) For C_{BYP} , use low-ESR ceramic capacitors between each supply pin and ground. Only one C_{BYP} is sufficient for single supply operation. Ensure that C_{BYP} is placed as close to the device as possible and the supply trace routes through C_{BYP} before reaching the supply pin.

6.4 Thermal Information for Single Channel

(1) Max or min limit is specified based on characterization results.

(2) Typical input current noise data to be specified based on design simulation results

(3) Third-order filter; bandwidth = 80kHz at -3dB.

- (4) Short circuit current specified here is average of sourcing and sinking short circuit currents
- (5) Disable time (t_{OFF}) and enable time (t_{ON}) are defined as the time interval between the 50% point of the signal applied to the \overline{SHDN} pin and the point at which the output voltage reaches the 10% (disable) or 90% (enable) level.
- (6) Full shutdown refers to the dual device having both channels 1 and 2 disabled ($\overline{SHDN1} = \overline{SHDN2} = V-$) and the quad device having all channels 1 to 4 disabled ($\overline{SHDN12} = \overline{SHDN34} = V-$). For partial shutdown, only one \overline{SHDN} pin is exercised; in this mode, the internal biasing circuitry remains operational and the enable time is shorter.
- (7) Shutdown section is on preview

7 Detailed Description

7.1 Overview

The OPAX323 family of op amps includes single / dual / quad channel (OPA323, OPA2323, OPA4323), ultra low-voltage (1.7V to 5.5V), high-bandwidth (20MHz) amplifiers. This family of amplifiers feature a zero-crossover input stage and a rail-to-rail output stage that can be used for variety of applications across industrial and automotive markets. The input common-mode voltage range includes signal swing beyond the supply rails, and allows the OPAX323 to be used in many single-supply or dual supply configurations. Rail-to-rail output swing significantly increases dynamic range, especially in low-supply applications with the class AB output stage capable of driving smaller resistive loads.

The OPAX323 family of zero-cross input stage amplifiers achieve high linearity for input signals with rail-to-rail swing that are typical in ADC driver applications in comparison to the complementary input stage amplifiers. Gain-bandwidth of 20MHz helps provide a fast settling response for ADC sampling speeds between 0.5 to 5MSPS depending on the settling performance required. The OPAX323 easily supports precision performance in high gain voltage sensing applications (such as the wheatstone bridge), as the device features maximum offset of 1.25mV and drift of 1.8 μ V/ $^{\circ}$ C. This unique combination of high precision and high gain-bandwidth enables use in multiple applications such as the motor rotary encoders, microphone audio pre-amplifiers and ultrasonic transducers.

The OPAX323 family consumes only 1.6mA supply current per channel for 20MHz gain bandwidth, thus providing a good AC performance at a very low power consumption. These devices achieve a high slew-rate of 33V/ μ s allowing for fast detection of faults in motor current sensing applications. The zero-cross over input stage provides identical AC and DC performance for both low and high-side sensing applications, thus making the OPAX323 the best choice for current sensing in a variety of end equipments such as the solar string inverters, power delivery, grid, and EV infrastructure. Precision transimpedance and voltage gain applications are well served with a low input bias current (0.5pA typical, 20pA maximum), a good PSRR (20 μ V/V maximum), CMRR (100dB minimum), and A_{OL} (114dB minimum). The device has 60 $^{\circ}$ of typical phase margin with no load and drives up to 75pF with a phase margin of 35 $^{\circ}$.

The OPAX323 has an internal current limit that enables additional robustness when operating with high output current while driving smaller output impedance like 68 Ω , 128 Ω , and 256 Ω loads in audio applications. The OPAX323 can swing very close to the rails and has a short circuit current of \pm 80mA minimum at 5.5V power supply. The OPAX323S devices provide shutdown functionality for additional power savings and help disable the amplifier when idle. These op amps feature an integrated radio frequency immunity (RFI) and electro-magnetic interference (EMI) rejection filter, unity-gain stability, and no-phase reversal in input overdrive conditions.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Operating Voltage

The OPAx323 series of operational amplifiers is fully specified from 1.8V to 5.5V and is designed for amplifier operation from 1.7V to 1.8V. In addition, many specifications apply from -40°C to 125°C . Parameters that vary significantly with operating voltages or temperature are provided in the [Typical Characteristics](#) section. TI highly recommends to add low-ESR ceramic bypass capacitors (C_{BYP}) between each supply pin and ground. Only one C_{BYP} is sufficient for single supply operation. Make sure that C_{BYP} is placed as close to the device as possible and the power supply trace routes through C_{BYP} before reaching the amplifier power supply terminals.

7.3.2 Rail-to-Rail Input

The input common-mode voltage range of the OPAx323 series extends beyond the supply rails with a common-mode rejection ratio (CMRR) of 100dB minimum at 5.5V as specified in [Electrical Characteristics](#). The device is designed to have a good performance of 85dB minimum CMRR even when operating at an ultra-low supply voltage of 1.8V. This is made possible by using a zero-cross input stage architecture for the amplifier input pair.

Most commercial amplifiers employ a complementary input stage architecture which often limits the rail-to-rail CMRR to less than 65dB. This is because the offset performance across the rail-to-rail input common-mode range is not linear. One of the input pairs, usually, the P-channel pair with better offset, noise performance is designed to cover the majority of the common-mode range with the N-channel pair slated to slowly take over at a certain threshold voltage from the positive rail. This creates a big jump in the offset voltage across common mode when transitioning across the input pairs as shown in [TLV900x Offset Voltage vs Common-Mode](#). This offset jump not only affects CMRR but also limits linearity / THD for rail-to-rail input signals.

The OPAx323 achieves linear offset performance over the entire rail-to-rail input range by extending the common-mode-range of a single P-channel input pair using an internal charge pump as shown in the [Functional Block Diagram](#). This eliminates the need for the N-channel input pair and the resulting offset jump caused by input pair transitions.

The OPAx323 exhibits near to zero shift in offset voltage across the entire common-mode voltage as shown in [Figure 7-1](#). This is crucial to achieving high linearity in ADC driver and audio driver applications.

Figure 7-1. OPAx323 Offset Voltage vs Common-Mode

Figure 7-2. TLV900x Offset Voltage vs Common-Mode

7.3.3 Rail-to-Rail Output

The OPAx323 delivers a robust output drive capability. An output stage with common-source transistors is used to achieve full rail-to-rail output swing capability. The device is designed to have a minimum output short circuit current of $\pm 80\text{mA}$, making the device an excellent choice for audio driver applications at room temperature and

at 5.5V. For resistive loads up to 2k Ω and a power supply of 5.5V, the output swings within a maximum of 55mV to either supply rail, thereby using almost the entire input range of an ADC in ADC driver applications.

7.3.4 Common-Mode Rejection Ratio (CMRR)

The OPAx323 achieves excellent DC and AC CMRR performance. The device is designed to have a DC CMRR performance at two supply voltages (5.5V and 1.8V) for the entire operating temperature range (-40°C to 125°C). DC CMRR is specified for common-mode beyond rails over a input voltage range of $(V-) - 0.2\text{V} \leq V_{\text{CM}} \leq (V+) + 0.15\text{V}$ for 5.5V operation and $(V-) - 0.1\text{V} \leq V_{\text{CM}} \leq (V+) + 0.05\text{V}$ for 1.8V operation. AC CMRR is shown in [Typical Characteristics](#) and is subject to the routing of input traces on the PCB board. For good performance, maintain a short and symmetrical input trace for the two amplifier input terminals.

7.3.5 Capacitive Load and Stability

The OPAx323 is designed for use in applications where driving a capacitive load is required. As with all operational amplifiers, there can be specific instances where the device can become unstable. The particular operational amplifier circuit configuration, layout, gain, and output loading are some of the factors to consider when establishing whether or not an amplifier is stable in operation.

An operational amplifier in the unity-gain (1V/V) buffer configuration that drives a capacitive load exhibits a greater tendency to be unstable than an amplifier operating at a higher noise gain. The capacitive load, in conjunction with the operational amplifier output resistance, creates a pole within the feedback loop that degrades the phase margin. The degradation of the phase margin increases when capacitive loading increases. When operating in the unity-gain configuration, the OPAx323 has a phase margin of 50° with 30pF of capacitive load. The device remains stable with pure capacitive loads up to approximately 75pF with acceptable phase margin of 35° and has no sustained oscillations up to 150pF. The equivalent series resistance (ESR) of some very large capacitors (greater than 1 μF) is sometimes sufficient to alter the phase characteristics in the feedback loop such that the amplifier remains stable. Increasing the amplifier closed-loop gain allows the amplifier to drive increasingly larger capacitance. This increased capability is evident when measuring the overshoot response of the amplifier at higher voltage gains.

One technique for increasing the capacitive load drive capability of the amplifier operating in a unity-gain configuration is to insert a small resistor (typically 10 Ω to 50 Ω) in series with the output, as shown in [Figure 7-3](#). This resistor significantly reduces the overshoot and ringing associated with large capacitive loads. This is usually the circuit configuration used in ADC driver application with C_{load} serving as a charge bucket for the ADC sampling capacitor.

Figure 7-3. Improving Capacitive Load Drive

7.3.6 Overload Recovery

Overload recovery is defined as the time required for the operational amplifier output to recover from a saturated state to a linear state. The output stage of the operational amplifier enters a saturation region when the output voltage exceeds the rated operating voltage, because of the high input voltage or high gain. After one of the outputs enters the saturation region, the output stage requires additional time to return to the linear operating state which is referred to as overload recovery time. After the output stage returns to linear operating state, the

amplifier begins to slew at the specified slew rate. Therefore, the propagation delay (in case of an overload condition) is the sum of the overload recovery time and the slew time.

The overload recovery time for the OPAx323 family is designed to be approximately 130ns typical.

7.3.7 EMI Rejection

The OPAx323 uses integrated electromagnetic interference (EMI) filtering to reduce the effects of EMI from sources such as wireless communications (radio frequency interference - RFI) and densely-populated boards with a mix of analog signal chain and digital components. EMI immunity can be improved with circuit design techniques; the OPAx323 benefits from these design improvements. Texas Instruments has developed the ability to accurately measure and quantify the immunity of an operational amplifier over a broad frequency spectrum extending from 10MHz to 6GHz. [Figure 7-4](#) shows the results of this testing on the OPAx323. [Table 7-1](#) shows the EMIRR IN+ values for the OPAx323 at particular frequencies commonly encountered in real-world applications. The [EMI Rejection Ratio of Operational Amplifiers application report](#) contains detailed information on the topic of EMIRR performance relating to op amps and is available for download from www.ti.com.

Figure 7-4. EMIRR Testing

Table 7-1. OPAX323 EMIRR IN+ for Frequencies of Interest

FREQUENCY	APPLICATION OR ALLOCATION	EMIRR IN+
400MHz	Mobile radio, mobile satellite, space operation, weather, radar, ultra-high frequency (UHF) applications	48dB
900MHz	Global system for mobile communications (GSM) applications, radio communication, navigation, GPS (to 1.6GHz), GSM, aeronautical mobile, UHF applications	56dB
1.8GHz	GSM applications, mobile personal communications, broadband, satellite, L-band (1GHz to 2GHz)	60dB
2.4GHz	802.11b, 802.11g, 802.11n, Bluetooth®, mobile personal communications, industrial, scientific and medical (ISM) radio band, amateur radio and satellite, S-band (2GHz to 4GHz)	61dB
3.6GHz	Radiolocation, aero communication and navigation, satellite, mobile, S-band	67dB
5GHz	802.11a, 802.11n, aero communication and navigation, mobile communication, space and satellite operation, C-band (4GHz to 8GHz)	70dB

7.3.8 ESD and Electrical Overstress

Designers often ask questions about the capability of an operational amplifier to withstand electrical overstress. These questions tend to focus on the device inputs, but can involve the supply voltage pins or even the output pin. Each of these different pin functions have electrical stress limits determined by the voltage breakdown characteristics of the particular semiconductor fabrication process and specific circuits connected to the pin. Additionally, internal electrostatic discharge (ESD) protection is built into these circuits to protect them from accidental ESD events both before and during product assembly.

Having a good understanding of this basic ESD circuitry and relevance to an electrical overstress event is helpful. Figure 7-5 shows the ESD circuits contained in the OPAX323 devices. The ESD protection circuitry involves several current-steering diodes connected from the input and output pins and routed back to the internal power supply lines, where the input and output pins meet at an absorption device internal to the operational amplifier. This protection circuitry is intended to remain inactive during normal circuit operation.

Note that the OPAX323 features no current-steering diodes connected between the input and positive power-supply pin.

Figure 7-5. Equivalent Internal ESD Circuitry

7.3.9 Input ESD Protection

The OPAX323 family incorporates internal ESD protection circuits on all pins. For inputs, this protection primarily consists of fail safe ESD input structures which feature no current-steering diodes connected between the input and positive power-supply pin as shown in the Figure 7-5. This feature is very useful during power sequencing scenarios where input signal can be present before the positive power supply rail. A fail safe input ESD

structure prevents any short between inputs and positive power supply. For further details, refer to [Op Amp ESD Protection Structures](#) application note.

7.3.10 Shutdown Function

The OPAx323S devices feature $\overline{\text{SHDN}}$ pins that disable the op amp, placing the op amp into a low-power standby mode. In this mode, the op amp typically consumes less than 1000nA at room temperature. The SHDN pins are active low, meaning that shutdown mode is enabled when the input to the $\overline{\text{SHDN}}$ pin is a valid logic low.

The $\overline{\text{SHDN}}$ pins are referenced to the negative supply voltage of the op amp. The threshold of the shutdown feature lies around 500mV (typical) and does not change with respect to the supply voltage. Hysteresis has been included in the switching threshold to provide for smooth switching characteristics. For optimal shutdown behavior, the $\overline{\text{SHDN}}$ pins must be driven with valid logic signals. A valid logic low is defined as a voltage between V_- and $(V_-) + 0.2V$. A valid logic high is defined as a voltage between $(V_-) + 1V$ and V_+ . To enable the amplifier, the $\overline{\text{SHDN}}$ pins must be driven to a valid logic high. To disable the amplifier, the $\overline{\text{SHDN}}$ pins must be driven to a valid logic low. TI highly recommends to not leave the shutdown pin floating, but to connect the shutdown pin to a valid high or low voltage. The maximum voltage allowed at the SHDN pins is $(V_+) + 0.5V$. Exceeding this voltage level damages the device.

The $\overline{\text{SHDN}}$ pins are high-impedance CMOS inputs. Dual op amp versions are independently controlled and quad op amp versions are controlled in pairs with logic inputs. For battery-operated applications, this feature can be used to greatly reduce the average current and extend battery life. The enable and disable time is targeted to be under 1 μ s for full shutdown of all channels. When disabled, the output assumes a high-impedance state. This architecture allows the OPAx323S to operate as a gated amplifier (or to have the device output multiplexed onto a common analog output bus). Shutdown time (t_{OFF}) depends on loading conditions as any charge on the output capacitor needs to be discharged by any external resistive load or the op-amp. To achieve the 1 μ s shutdown time, the specified 10k Ω load to midsupply ($V_S / 2$) is required with no capacitive load.

7.3.11 Packages with an Exposed Thermal Pad

The OPAx323 family is available in packages such as the WQFN-16 (RTE) and WSON-8 (DSG), which feature an exposed thermal pad. Inside the package, the die is attached to this thermal pad using an electrically conductive compound. For this reason, when using a package with an exposed thermal pad, the thermal pad must be connected to V₋. Attaching the thermal pad to a potential other than V₋ is not allowed, and the performance of the device may not be consistent with the [Electrical Characteristics](#) table when doing so.

7.4 Device Functional Modes

The OPAx323 devices have one functional mode. These devices are powered on as long as the power-supply voltage is between 1.7V ($\pm 0.85V$) and 5.5V ($\pm 2.75V$).

The OPAx323S devices feature a shutdown pin, which can be used to place the op amp into a low-power mode. For more information, see the [Shutdown Function](#) section.

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The OPAx323 family of rail-to-rail input and output operational amplifiers is specifically designed for variety of high gain and high speed applications. These devices operate from 1.7V to 5.5V, are unity-gain stable, and are also an excellent choice for a wide range of general-purpose applications. The output stage is capable of driving small resistive loads connected to any point between $V+$ and $V-$ as long as the device is not forced into short circuit mode. The input common-mode voltage range includes beyond the rail signal swing and allows the OPAx323 series to be used in many single-supply or dual supply configurations.

8.2 Typical Application

8.2.1 OPAx323 in Low-Side, Current Sensing Application

Figure 8-1 shows the OPA323 configured in a low-side current sensing application.

Figure 8-1. OPA323 in a Low-Side, Current-Sensing Application

8.2.1.1 Design Requirements

The design requirements for this design are:

- Load current: 0A to 1A
- Maximum output voltage: 4.9V
- Maximum shunt voltage: 100mV

8.2.1.2 Detailed Design Procedure

The transfer function of the circuit in [Figure 8-1](#) is given in [Equation 1](#).

$$V_{OUT} = I_{LOAD} \times R_{SHUNT} \times \text{Gain} \quad (1)$$

The load current (I_{LOAD}) produces a voltage drop across the shunt resistor (R_{SHUNT}). The load current is set from 0A to 1A. To keep the shunt voltage below 100 mV at maximum load current, the largest shunt resistor is defined using [Equation 2](#).

$$R_{SHUNT} = \frac{V_{SHUNT_MAX}}{I_{LOAD_MAX}} = \frac{100\text{ mV}}{1\text{ A}} = 100\text{ m}\Omega \quad (2)$$

Using [Equation 2](#), R_{SHUNT} is calculated to be 100mΩ. The voltage drop produced by I_{LOAD} and R_{SHUNT} is amplified by the OPA323 to produce an output voltage of approximately 0V to 4.9V. The gain needed by the OPA323 to produce the necessary output voltage is calculated using [Equation 3](#).

$$\text{Gain} = \frac{V_{OUT_MAX} - V_{OUT_MIN}}{V_{IN_MAX} - V_{IN_MIN}} \quad (3)$$

Using [Equation 3](#), the required gain is calculated to be 49V/V, which is set with resistors R_F and R_G . [Equation 4](#) sizes the resistors R_F and R_G , to set the gain of the OPA323 to 49V/V.

$$\text{Gain} = 1 + \frac{R_F}{R_G} \quad (4)$$

Selecting R_F as 57.6kΩ and R_G as 1.2kΩ provides a combination that equals 49V/V. [Figure 8-2](#) shows the measured transfer function of the circuit shown in [Figure 8-1](#). Notice that the gain is only a function of the feedback and gain resistors. This gain is adjusted by varying the ratio of the resistors and the actual resistors values are determined by the impedance levels that the designer wants to establish. The impedance level determines the current drain, the effect that stray capacitance has, and a few other behaviors. There is no optimal impedance selection that works for every system; choose an impedance that is best for the system parameters.

8.2.1.3 Application Curve

Figure 8-2. Low-Side, Current-Sense Transfer Function

8.3 Power Supply Recommendations

The OPAx323 is tested for amplifier operation at 1.7V and is fully specified from 1.8V to 5.5V ($\pm 0.9V$ to $\pm 2.75V$); many specifications apply from -40°C to 125°C . [Electrical Characteristics](#) presents parameters that can exhibit significant variance regarding operating voltage or temperature.

CAUTION

Supply voltages larger than 7V can permanently damage the device; for more information, see the [Absolute Maximum Ratings](#) table.

TI highly recommends to add low-ESR ceramic bypass capacitors (C_{BYP}) between each supply pin and ground. Only one C_{BYP} is sufficient for single supply operation. Place the C_{BYP} as close to the device as possible to reduce coupling errors from noisy or high-impedance power supplies. Make sure the power supply trace routes through C_{BYP} before reaching the amplifier power supply terminals. For more information, see [Layout Guidelines](#).

8.4 Layout

8.4.1 Layout Guidelines

For best operational performance, use good printed circuit board (PCB) layout practices, including:

- Noise can propagate into analog circuitry through the power connections of the board and propagate to the power pins of the op amp itself. Bypass capacitors are used to reduce the coupled noise by providing a low-impedance path to ground.
 - Connect low-ESR, 0.1 μF ceramic bypass capacitors between each supply pin and ground, placed as close to the device as possible. One bypass capacitor from $V+$ to ground is adequate for single-supply applications.
- Separate grounding for analog and digital portions of circuitry is one of the simplest and most effective methods of noise suppression. One or more layers on multilayer PCBs are usually devoted to ground planes. A ground plane helps distribute heat and reduces electromagnetic interference (EMI) noise pickup. Take care to physically separate digital and analog grounds, paying attention to the flow of the ground current.
- To reduce parasitic coupling, run the input traces as far away from the supply or output traces as possible. If these traces cannot be kept separate, then cross the sensitive trace at a 90 degree angle, which is much better as opposed to running the traces in parallel with the noisy trace.
- Place the external components as close to the device as possible, as shown in [Layout Example](#). Keeping R_1 and R_2 close to the inverting input minimizes parasitic capacitance.
- Keep the length of input traces as short as possible. Remember that the input traces are the most sensitive part of the circuit.
- Consider a driven, low-impedance guard ring around the critical traces. A guard ring can significantly reduce leakage currents from nearby traces that are at different potentials.
- TI recommends cleaning the PCB following board assembly for best performance.
- Any precision integrated circuit can experience performance shifts resulting from moisture ingress into the plastic package. Following any aqueous PCB cleaning process, TI recommends baking the PCB assembly to remove moisture introduced into the device packaging during the cleaning process. A low-temperature, post-cleaning bake at 85°C for 30 minutes is sufficient for most circumstances.

8.4.2 Layout Example

Note: C3 and C4 are C_{BYP} capacitors

9 Device and Documentation Support

9.1 Documentation Support

9.1.1 Related Documentation

For related documentation see the following:

- Texas Instruments, [QFN/SON PCB Attachment application note](#)
- Texas Instruments, [Quad Flatpack No-Lead Logic Packages application note](#)

9.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](#). Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

9.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

Trademarks

TI E2E™ is a trademark of Texas Instruments.

Bluetooth® is a registered trademark of Bluetooth SIG, Inc.

All trademarks are the property of their respective owners.

9.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

9.5 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

10 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision A (November 2023) to Revision B (April 2024)	Page
• Changed the status of the DGK (VSSOP, 8), DDF (SOT23-THN) OPA2323 and DYY (SOT23-THN) OPA4323 from: <i>preview</i> to <i>active</i>	1
• Changed the CMRR value in the data sheet title from <i>100dB</i> to <i>114dB</i>	1
• Changed the DYY (SOT-23) package option from <i>16</i> to <i>14</i> pins and moved the package from OPA4323S to OPA4323 in <i>Device Information</i> table.....	1
• Changed the DYY (SOT-23) package option from <i>16</i> to <i>14</i> pins and moved the package from OPA4323S to OPA4323 in <i>Device Comparison</i> table.....	2
• Removed OPA4310 information from the data sheet.....	11
• Changed the <i>Typical Characteristics</i> section to add more plots.....	14
• Changed the <i>Rail-to-Rail input</i> section.....	28
• Changed the EMIRR Testing plot in <i>EMI Rejection</i> section.....	30
• Changed the EMIRR IN+ values for the 900MHz, 1.8GHz, 2.4GHz, 3.6GHz, and 5GHz frequency options in <i>OPAx323 EMIRR IN+ for Frequencies of Interest</i> table.....	30

Changes from Revision * (October 2023) to Revision A (November 2023)	Page
• Changed the status of the DCK (SC70, 5) OPA323 from: <i>preview</i> to: <i>active</i>	1
• Changed the status of the D (SOIC, 8) OPA2323 from: <i>preview</i> to: <i>active</i>	1

11 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
OPA2323IDDFR	ACTIVE	SOT-23-THIN	DDF	8	3000	RoHS & Green	NIPDAU	Level-1-260C-UNLIM	-40 to 125	23DDF	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided.
