

TPS61378-Q1 25-µA Quiescent Current Synchronous Boost Converter with Load **Disconnect**

1 Features

- AEC-Q100 qualified for automotive applications
 - Device temperature grade 1: –40°C to 125°C ambient operating temperature range
- TPS61378-Q1 Wettable Flank
- TPS61378L-Q1 Immersion Sn
 - Provides shorter production cycle time and longer shelf life
- **Function Safety-Capable**
 - Documentation available to aid functional safety system design
- Flexible input and output operation range
 - Input voltage range: 2.3V to 14V
 - Programmable output voltage: 4.0V to 18.5V
 - Input voltage range: 2.3V to 14V
 - Fixed output options: 5V, 5.25V, and 5.5V
 - Programmable peak current limit: 1A to 4.8A
- Avoid AM band interference and crosstalk
 - Dynamically programmable switching frequency: 200kHz to 2.2MHz
 - Spread spectrum frequency modulation at FPWM mode
 - Optional clock synchronization
- Minimize solution size for space constraint applications
 - Integrated LS/HS/ISO FET: $R_{DS(ON)} 50 m\Omega/50 m\Omega/100 m\Omega$
 - Support up to 2.2MHz with small L-C
- Minimized light load and idle state current consumption
 - 25µA quiescent current into VIN pin
 - 0.5µA shutdown current into VIN pin
 - Selectable auto PFM and forced PWM mode
 - True load disconnect during shutdown or fault conditions
- Integrated protection features
 - Supports VIN close to VOUT operation
 - Input undervoltage lockout and output overvoltage protection
 - Hiccup output short circuit protection
 - Power good indicator
 - Thermal shutdown protection at 165°C
- Higher than 90% efficiency under 0.8A load from 3.3V to 9V conversion

2 Applications

- Advanced driver-assistance system (ADAS)
- Automotive infotainment and cluster
- Body electronics and lighting

Emergency call (eCall)

3 Description

The TPS61378-Q1 is a fully-integrated synchronous boost converter with an integrated load disconnect function. The input voltage covers 2.3V to 14V while the maximal output voltage covers up to 18.5V. The switching current limit is programmable from 1A to 4.8A. The device consumes 25µA quiescent current from V_{IN}.

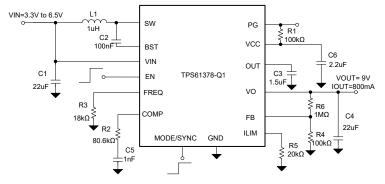

The TPS61378-Q1 employs peak current mode control with the switching frequency programmable from 200kHz to 2.2MHz. The device works in fixed frequency PWM operation in medium to heavy loads. There are two optional modes in light load by configuring the MODE pin: auto PFM mode and forced PWM to balance the efficiency and noise immunity in light load. The switching frequency can be synchronized to an external clock. The TPS61378-Q1 uses the spread spectrum of the internal clock to be more EMI friendly at FPWM mode. In addition, there is an internal soft-start time to limit the inrush current.

The TPS61378-Q1 has various fixed output voltage versions to save the external feedback resistor. It supports the external loop compensation so that the stability and transient response can be optimized at wider V_{OUT}/V_{IN} ranges. It also integrates robust protection features including output short protection, output overvoltage protection, and thermal shutdown protection. The TPS61378-Q1 is available in a 3mm × 3mm 16-pin QFN package with wettable flank.

Device Information

PART NUMBER	PACKAGE ⁽¹⁾	BODY SIZE (NOM)
TPS61378-Q1	WQFN-16	3.0mm × 3.0mm

For all available packages, see the orderable addendum at the end of the data sheet.

⁽¹⁾ Product Preview. Contact TI factory for more information.

⁽²⁾ R_{FB} is the sensed resistor from FB pin. Please refer to *Section 8.2.2.1* for details. Avoid using resistors other than the recommended values, otherwise the output voltage value cannot be guaranteed.

5 Pin Configuration and Functions

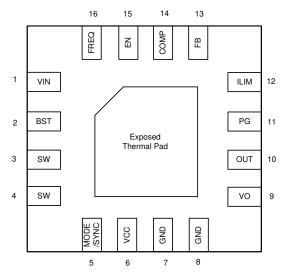

Figure 5-1. 16-Pin WQFN RTE Package (Transparent Top View)

Table 5-1. Pin Functions

PI	N	1/0	DESCRIPTION	
NAME	NO.	- I/O	DESCRIPTION	
VIN	1	I	IC power supply input	
BST	2	I	Power supply for high-side N-MOSFET gate drivers. A capacitor must be connected between this pin and the SW pin.	
sw	3, 4	PWR	The switching node pin of the converter. It is connected to the drain of the internal low-side FET and the source of the high-side FET.	
MODE/SYNC	5	I	Mode selection pin. MODE = high, forced PWM mode MODE = low or floating, auto PFM mode This pin can also be used to synchronize the external clock. Refer to Table 7-2 for details.	
vcc	6	0	Output of internal regulator. A ceramic capacitor with more than 1 μF must be connected between this pin and GND.	
GND	7, 8	PWR	Power ground of the IC. It is connected to the source of the low-side FET.	
VO	9	PWR	Output of the isolation FET. Connect load to this pin to achieve input/output isolation.	
ОИТ	10	PWR	Output of the drain of the HS FET. Connect this pin because the output can disable the load disconnect/short protection feature (or short this pin with the VO pin).	
PG	11	0	Power good indicator and open drain output	
ILIM	12	I	Current limit setting pin. Use a resistor to set the desired peak current limit. Refer to Section 7.3.7 for details.	
FB	13	ı	Feedback pin. Use a resistor divider to set the desired output voltage. Refer to <i>Section</i> 8.2.2.1 for details.	
СОМР	14	ı	Output of the internal transconductance error amplifier. An external RC network is connected to this pin to optimize the loop stability and response time.	
EN	15	1	Enable logic input	
FREQ	16	I	Frequency setting pin. Connect a resistor between this pin and GND pin to set the desired frequency.	
Thermal Pad	-	-	The thermal pad must be connected to the power ground plane for good power dissipation.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
Voltage range at terminals (2)	VIN	-0.3	16	V
Voltage range at terminals ⁽²⁾	VO, SW, OUT	-0.3	23	V
	BST	-0.3	SW + 6	V
	MODE/SYNC, FB, FREQ, ILIM, VCC, COMP, EN	-0.3	6	V
	PG	-0.3	20	V
T _J ⁽³⁾ Operating junction temperature		-40	150	°C
T _{stg}	Storage temperature	-65	150	°C

- (1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to network ground terminal.
- (3) High junction temperatures degrade operating lifetime. Operating lifetime is de-rated for junction temperatures greater than 125°C

6.2 ESD Ratings

				VALUE	UNIT
	V _(ESD) (1) Electrostatic discharge		Human-body model (HBM), per AEC Q100-002 ⁽²⁾	±2000	V
`	V _(ESD) (1) Electrostatic discharge	Charged-device model (CDM), per AEC Q100-011, all pins ⁽³⁾	±500	v	
١	/ _(ESD) (1)	Electrostatic discharge	Charged-device model (CDM), per AEC Q100-011, corner pins (1,4,5,8,9,12,13,16) ⁽³⁾	±750	V

- (1) Electrostatic discharge (ESD) to measure device sensitivity and immunity to damage caused by assembly line electrostatic discharges in to the device.
- (2) Level listed above is the passing level per ANSI, ESDA, and JEDEC JS-001. JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 500-V HBM is possible with the necessary precautions.
- (3) Level listed above is the passing level per EIA-JEDEC JESD22-C101. JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 250-V CDM is possible with the necessary precautions.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage	2.3		14	V
V _{OUT}	Outputvoltage	4		18.5	V
TJ	Operating junction temperature ⁽¹⁾	-40		150	°C

1) High junction temperatures degrade operating lifetimes. Operating lifetime is de-rated for junction temperatures greater than 125°C.

6.4 Thermal Information

		TPS61378-Q1	
	THERMAL METRIC ⁽¹⁾	RTE	UNIT
		16 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	46.2	°C/W
R _{0JC(top)}	Junction-to-case (top) thermal resistance	43.5	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	18.5	°C/W
ΨЈТ	Junction-to-top characterization parameter	1.1	°C/W
ΨЈВ	Junction-to-board characterization parameter	18.5	°C/W
R _{0JC(bot)}	Junction-to-case (bottom) thermal resistance	8.8	°C/W

(1) For more information about traditional and new thermal metrics, see the Semiconductor and IC Package Thermal Metrics application report.

6.5 Electrical Characteristics

 $T_J = -40$ to 125°C, L = 1 μ H, $V_{IN} = 3.3$ V and $V_{OUT} = 9$ V (VO pin). Typical values are at $T_J = 25$ °C, (unless otherwise noted)

7 Detailed Description

7.1 Overview

The TPS61378-Q1 is a fully-integrated synchronous boost converter with load disconnect function. It supports output voltage up to 18.5 V with a maximum of a 4.8-A programmable switching peak current limit. The input voltage ranges from 2.3 V to 14 V while consuming 25-µA quiescent current.

The TPS61378-Q1 utilizes the fixed-frequency peak current control scheme, which has an internal oscillator and supports adjustable switching frequency from 200 kHz to 2.2 MHz.

The TPS61378-Q1 operates with fixed-frequency pulse width modulation (PWM) from medium to heavy load. At the beginning of each switching cycle, the low-side N-MOSFET switch is turned on. The inductor current ramps up to a peak current that is determined by the output of the internal error amplifier (EA). Once the switching peak current triggers the output of the EA, the low-side N-MOSFET is turned off and the high-side N-MOSFET is turned on after a short dead time. The high-side N-MOSFET switch is not turned off until the next cycle as determined by the internal oscillator. The low-side switch turns on again after a short dead time and the switching cycle is repeated.

The TPS61378-Q1 provides either auto PFM or forced PWM for the light load operation by configuring the MODE/SYNC pin. In forced PWM mode, the switching frequency remains constant across the entire load range, which helps avoid frequency variation with load. The internal oscillator can be synchronized to an external clock applied on the MODE/SYNC pin. Spread spectrum modulation of the frequency in forced PWM mode helps optimize the EMI performance for automotive applications. In auto PFM mode, the switching frequency can decrease, resulting in higher efficiency.

The TPS61378-Q1 implements a cycle-by-cycle current limit to protect the device from overload during the boost operation phase. If the output current further increases and triggers the output voltage to fall below the input voltage, the TPS61378-Q1 enters into hiccup mode short protection.

There is a built-in soft-start time, which prevents the inrush current during the start-up. The TPS61378-Q1 also provides a power good (PG) indicator to enable the power sequence control for start-up.

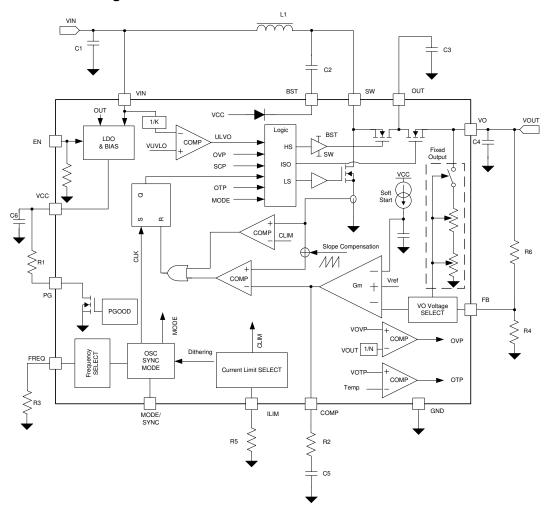

The TPS61378-Q1 also has a number of protection features including output short protection, output overvoltage protection (OVP), and thermal shutdown protection (OTP).

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 VCC Power Supply

The internal LDO in the TPS61378-Q1 outputs a regulated voltage of 4.8 V with 10-mA output current capability. A ceramic capacitor is connected between the VCC pin and GND pin to stabilize the VCC voltage and also decouple the noise on the VCC pin. The value of this ceramic capacitor should be above 1 μ F. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating higher than 10 V is recommended.

7.3.2 Input Undervoltage Lockout (UVLO)

An undervoltage lockout (UVLO) circuit stops the operation of the converter when the input voltage drops below the UVLO threshold of 2.04 V (typical). A hysteresis of 160 mV (typical) is added so that the device cannot be enabled again until the input voltage exceeds 2.2 V (typical). This function is implemented to prevent the device from malfunctioning when the input voltage is between 2.04 V and 2.2 V.

7.3.3 Enable and Soft Start

When the input voltage is above the UVLO threshold and the EN pin is pulled above 1.2 V, the TPS61378-Q1 is enabled. The device starts to monitor the FB pin. With a typical 400-µs delay time after EN is pulled high, the TPS61378-Q1 starts switching. There is an internal built-in start-up time, typically 2.5 ms, to limit the inrush current during start-up.

Submit Document Feedback

Copyright © 2024 Texas Instruments Incorporated

7.3.4 Shut Down

When the input voltage is below the UVLO threshold or the EN pin is pulled low, The TPS61378-Q1 is in shutdown mode and all the functions are disabled. The input voltage is isolated from the output to minimize the leakage currents.

7.3.5 Switching Frequency Setting

The TPS61378-Q1 uses a fixed-frequency control scheme. The switching frequency can be programmed between 200kHz and 2.2Mhz using a resistor from the FREQ pin to GND. The resistor must be connected when the oscillator is synchronized by external clock. The resistance is defined by Equation 1.

$$F_{SW}(MHz) = \frac{41.9}{R_{FREO}(k\Omega) + 1.05} \tag{1}$$

where

R_{FRQE} is the resistance between the FREQ pin and the GND pin

For example, the switching frequency is 2.2 MHz if the resistance between FREQ pin and GND is $18k\Omega$. This pin cannot be left floating or tied to VCC.

7.3.6 Spread Spectrum Frequency Modulation

The TPS61378-Q1 uses a triangle waveform to spread the switching frequency with ±10% of normal frequency. The frequency of the triangle waveform is typically 0.4% of the switching frequency. For example, if the normal switching frequency of the TPS61378-Q1 is programmed to 2.2MHz, the spread spectrum function modulates the switching frequency in the range of 1.98MHz to 2.42MHz in a triangle behavior with an 8.8kHz rate.

The spread spectrum is only available while the clock of the TPS61378-Q1 is free running at its natural frequency in FPWM mode. Any of the following conditions overrides spread spectrum, turning it off:

- · An external clock is applied to the MODE/SYNC pin.
- The MODE/SYNC pin is configured to be logic low or floating.

7.3.7 Adjustable Peak Current Limit

The TPS61378-Q1 adopts a cycle-by-cycle peak current limit internally and changes its current limit with different working conditions. The low-side switch is turned off immediately as soon as the switch peak current triggers the peak current limit. The peak switch current limit can be set by a resistor from the ILIM pin to ground. The relationship between the peak current limit and the resistor is shown in Equation 2.

$$R_{LIM}(k\Omega) = 1.184 + \frac{90.56}{I_{LIM}(A)}$$
 (2)

where

- R_{ILIM} is the resistance between the ILIM pin and the GND. This pin cannot be left floating or connected to VCC.
- I_{LIM} is switch peak current limit

For instance, the current limit is set to 4.8 A if the R_{LIM} is 20 k Ω .

Table 7-1 summarizes the peak current limit under various conditions. The current limit applies to the start-up phase.

Table 7-1. Switch Peak Current Limit

Behavior	Switch Peak Current Limit
Vin < VO (Not in Down Mode)	I _{LIM} ⁽¹⁾
Vin < VO (In Down Mode)	2/3 I _{LIM}
3V > Vin - VO > 0V	4/9 I _{LIM}
6V > Vin - VO > 3V	1/4 I _{LIM}

Copyright © 2024 Texas Instruments Incorporated

Submit Document Feedback

Table 7-1. Switch Peak Current Limit (continued)

Behavior	Switch Peak Current Limit
Vin - VO > 6V	1/4 I _{LIM} & Fsw Clamp to 1.1MHz if FREQ pin setting is > 1.1MHz
FB ≤ 0.1V	1/5 I _{LIM} & Fsw Clamp to 1.1MHz if FREQ pin setting is > 1.1MHz

(1) I_{LIM} is switch peak current limit programmed in Equation 2.

7.3.8 Bootstrap

The TPS61378-Q1 has an integrated bootstrap regulator circuit. A small ceramic capacitor is needed between the BST pin and SW pin to provide the gate drive supply voltage for high-side switches. The bootstrap capacitor is charged during the time when the low-side switch is in the ON state. The value of this ceramic capacitor should be above $0.1~\mu F$. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating higher than 6.3~V is recommended.

7.3.9 Load Disconnect

The TPS61378-Q1 integrates a load disconnect function when the input source is DC, completely cutting off the path between the input side and output side during shutdown.

The output disconnect function also allows the output short protection and minimizes the inrush current at start-up.

7.3.10 MODE/SYNC Configuration

Table 7-2 summarizes the MODE/SYNC function and the entry condition.

Table 7-2. MODE/SYNC Configuration

MODE/SYNC PIN CONFIGURATION	MODE
Logic Low or Floating	Auto PFM Mode
Logic High	Forced PWM Mode
External Synchronization	Forced PWM Mode

The TPS61378-Q1 can be synchronized to an external clock applied to the MODE/SYNC pin.

7.3.11 Overvoltage Protection (OVP)

If the output voltage exceeds the OVP threshold (typically 20 V), the TPS61378-Q1 immediately stops switching until the output voltage drops below the recovery threshold (typically 19.5 V). This function protects the device against excessive voltage.

7.3.12 Output Short Protection/Hiccup

In addition to the cycle-by-cycle current limit function, the TPS61378-Q1 also has output short protection.

During normal working condition, when output draws an excessive amount of current, causing the low-side FET to reach peak current limit and the output voltage is pulled below the input voltage, the device enters short circuit protection mode, triggering the hiccup timer. When the hiccup timer is active, the device limits the current for 1.8 ms and then shuts down. After 67 ms, it restarts.

During start-up, whether normal start-up or hiccup restart, the device can trigger short protection. The device has limited loading capacity at start up phase because of smaller peak current limit, which is list in Table 7-1.

Starting up with heavy load or very large capacitors at output side may causes short hiccup protection.

7.3.13 Power-Good Indicator

The TPS61378-Q1 integrates a power-good function. The power-good output consists of an open-drain NMOS, requiring an external pullup resistor connect to a suitable voltage supply like VCC. The PG pin goes high with a typical 3.4-ms delay time after VOUT reaches 90% of the target output voltage. When the output voltage drops below 85% of the target output voltage, the PG pin immediately goes low without delay.

Product Folder Links: TPS61378-Q1

7.3.14 Thermal Shutdown

A thermal shutdown is implemented to prevent damage due to excessive heat and power dissipation. Typically, the thermal shutdown occurs at junction temperatures exceeding 165°C. When the thermal shutdown is triggered, the device stops switching and recovers when the junction temperature falls below 145°C (typical).

7.4 Device Functional Modes

7.4.1 Forced PWM Mode

The TPS61378-Q1 enters forced PWM mode by pulling the MODE/SYNC pin to logic high for more than five switching cycles. In forced PWM mode, the TPS61378-Q1 keeps the switching frequency constant at light load condition. When the load current decreases, the output of the internal error amplifier also decreases to keep the inductor peak current down. When the output current decreases further, the high-side switch is not turned off even if the current of the high-side switch goes negative to keep the frequency constant.

7.4.2 Auto PFM Mode

The TPS61378-Q1 enters auto PFM Mode by pulling the MODE/SYNC pin to logic low for more than five switching cycles or leaving the pin floating. The TPS61378-Q1 improves the efficiency at light load when operating in PFM mode. When the output current decreases to a certain level, the output voltage of the error amplifier is clamped by the internal circuit. If the output current reduces further, the inductor current through the high-side switch will be clamped but not lowered further. Pulses are skipped to improve the efficiency at light load.

7.4.3 External Clock Synchronization

The TPS61378-Q1 supports external clock synchronization with a range of 200 kHz to 2.2 MHz. The external clock needs to be within -+20% of the setting frequency to ensure a reliable synchronization. The TPS61378-Q1 remains in forced PWM mode and operates in CCM across the entire load range if the oscillator is synchronized by an external clock. The spread spectrum feature is disabled when external synchronization is used.

7.4.4 Down Mode

The TPS61378-Q1 features down mode operation when input voltage is close to or higher than output voltage. In down mode, output voltage is regulated at target value, even when $V_{IN} > V_O$. The TPS61378-Q1 high-side and low-side FETs are switching devices that always work in boost operation, where the isolation FET always works as a linear device.

For boost circuits, on-time or duty cycle is reduced as input voltage approaches output voltage. The TPS61378-Q1 enters down mode when V_{IN} reaches 85% (typical) of V_O voltage at 2.2 MHz. Exiting down mode requires V_{IN} to be reduced below 85% (typical) of V_O voltage at 2.2 MHz.

In normal operation, the isolation FET is fully on.

When down mode is triggered and V_{IN} is less than VO pin voltage, the OUT pin has a fixed 2 V (typical) above VO pin voltage. An isolation FET works in LDO mode to regulate VO pin voltage with a 2-V constant voltage drop.

When down mode is triggered and V_{IN} is 100 mV (typical) higher than VO pin voltage, the OUT pin has an approximated 3 V (typical) above the V_{IN} pin voltage. As V_{IN} keeps rising, the OUT pin continues rising with 3 V on top of V_{IN} . In addition, an isolation FET works in LDO mode to regulate VO pin voltage with a voltage differential of the OUT pin and VO pin.

Refer to Figure 7-1.

Submit Document Feedback

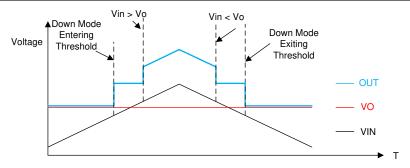

Figure 7-1. Down Mode

Take care during short-to-ground condition when operation V_{IN} is above 6 V. During hiccup on, the device operates in down mode and the isolation FET voltage drop is V_{IN} + 3 V (OUT pin to VO pin).

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The TPS61378-Q1 is a 25-μA quiescent current boost converter that supports a 2.3-V to 14-V input voltage range. The device also supports load disconnect to minimize the leakage current. The following design procedure can be used to select component values for the TPS61378-Q1.

8.2 Typical Application

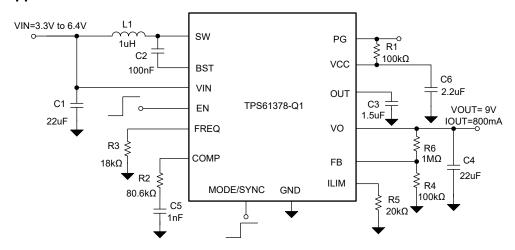

Figure 8-1. Typical Application

8.2.1 Design Requirements

A typical application example is dual cameras powered through a coax cable, which normally requires 9.0-V output as its bias voltage and consumes less than 600 mA current. 800-mA load current is designed to provide margin. The following design procedure can be used to select external component values for the TPS61378-Q1.

PARAMETERS	VALUES
Input Voltage	3.3 V to 6.4 V
Output Voltage	9.0 V
Switching Frequency	2.2 MHz
Output Current	800 mA
Output Voltage Ripple	± 25 mV

Table 8-1. Design Requirements

8.2.2 Detailed Design Procedure

8.2.2.1 Programming the Output Voltage

The output voltage is determined by the resistor sensed from FB pin before device is enabled.

There are two ways to set the output voltage of the TPS61378-Q1, adjustable output voltage(for TPS61378-Q1 and TPS613783-Q1 only) and fixed output voltage.

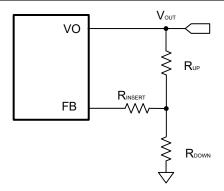

Figure 8-2. Typical Connection of FB Pin For Adjustable Output Voltage

Figure 8-2 shows the typical circuit of the FB pin conncetion for adjustable output voltage. The FB resistor R_{FB} is defined as Equation 3:

$$R_{FB} = R_{INSERT} + \frac{R_{UP} \times R_{DOWN}}{R_{UP} + R_{DOWN}} \tag{3}$$

When selected for adjustable output voltage, R_{FB} must be above 14.4k Ω . The FB pin is connected to the negative input of the internal error amplifier directly. The output voltage can be programmed by adjusting the external resistor divider R_{UP} and R_{DOWN} according to Equation 4.

$$V_{OUT} = V_{REF} \times \frac{(R_{UP} + R_{DOWN})}{R_{DOWN}} \tag{4}$$

Equation 4 shows that the output voltage setting is only influenced by R_{UP} and R_{DOWN} . In normal application, R_{INSERT} can be 0Ω , that is, directly connect FB pin to middle point of feedback voltage divider.

For automotive application that do not prefer to use resistors more than 100 k Ω , R_{INSERT} (>15k Ω) can be used so that calculated R_{UP} and R_{DOWN} feedback resistor value could be less than 100k Ω .

When working with adjustable voltage, for the best accuracy, R_{DOWN} is recommended to be smaller than 160 $k\Omega$ to ensure that the current flowing through R_{DOWN} is at least 100 times larger than FB pin leakage current. Changing R_{DOWN} towards the lower value increases the robustness against noise injection. Changing R_{DOWN} to higher values reduces the quiescent current to achieve higher efficiency at light load.

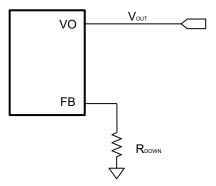

Figure 8-3. Typical Connection of FB Pin For Fixed Output Voltage

Figure 8-3 shows the typical circuit of the FB pin conncetion for fixed output voltage. The FB resistor R_{FB} is defined as Equation 5:

$$R_{FB} = R_{DOWN} \tag{5}$$

When designed for fixed output voltage, the TPS61378-Q1 uses the internal resistor divider and works with fixed output voltage. The TPS61378-Q1 subdivides the voltage due to R_{FB} and device part number. See Device Comparison Table for detailed information.

Submit Document Feedback

8.2.2.2 Setting the Switching Frequency

The switching frequency of the TPS61378-Q1 is set at 2.2 MHz. Use Equation 1 to calculate the required resistor value. The calculated value is 18 k Ω to get the frequency of 2.2 MHz.

8.2.2.3 Setting the Current Limit

The current limit of the TPS61378-Q1 can be programmed by an external resistor. For a target current limit of 4.8 A, use Equation 2. The calculated resistor value is 20 k Ω .

8.2.2.4 Selecting the Inductor

A boost converter normally requires two main passive components for storing energy during power conversion: an inductor and an output capacitor. The inductor affects the steady state efficiency (including the ripple and efficiency), transient behavior, and loop stability, which makes the inductor the most critical component in application.

When selecting the inductor and the inductance, the other important parameters are:

- The maximum current rating (RMS and peak current should be considered)
- · The series resistance
- · Operating temperature

The TPS61378-Q1 has built-in slope compensation to avoid subharmonic oscillation associated with current mode control. If the inductor value is too low and makes the inductor peak-to-peak ripple higher than 2 A, the slope compensation may not be adequate, and the loop can be unstable. Therefore, it is recommended to make the peak-to-peak current ripple between 800 mA to 2 A when selecting the inductor.

The inductance can be calculated by Equation 6, Equation 7, and Equation 8:

$$\Delta I_{L} = \frac{V_{IN} \times D}{L \times f_{SW}}$$
(6)

$$\Delta I_{L_R} = Ripple\% \times \frac{V_{OUT} \times I_{OUT}}{\eta \times V_{IN}}$$
 (7)

$$L = \frac{1}{\text{Ripple }\%} \times \frac{\eta \times V_{\text{IN}}}{V_{\text{OUT}} \times I_{\text{OUT}}} \times \frac{V_{\text{IN}} \times D}{f_{\text{SW}}}$$
(8)

where

- Δ_{II} is the peak-peak inductor current ripple
- V_{IN} is the input voltage
- D is the duty cycle
- · L is the inductor
- f_{SW} is the switching frequency
- Ripple % is the ripple ration versus the DC current
- V_{OUT} is the output voltage
- I_{OUT} is the output current
- η is the efficiency

The current flowing through the inductor is the inductor ripple current plus the average input current. During power up, load faults, or transient load conditions, the inductor current can increase above the peak inductor current calculated.

Inductor values can have $\pm 20\%$, or even $\pm 30\%$, tolerance with no current bias. When the inductor current approaches the saturation level, the inductance can decrease 20% to 35% from the value at 0-A bias current, depending on how the inductor vendor defines saturation. When selecting an inductor, make sure the rated current, especially the saturation current, is larger than its peak current during the operation.

Copyright © 2024 Texas Instruments Incorporated

Submit Document Feedback

The inductor peak current varies as a function of the load, switching frequency, and input and output voltages. The peak current can be calculated with Equation 9 and Equation 10.

$$I_{PEAK} = I_{IN} + \frac{1}{2} \times \Delta I_{L}$$
(9)

where

- I_{PEAK} is the peak current of the inductor
- I_{IN} is the input average current
- Δ_{IL} is the ripple current of the inductor

The input DC current is determined by the output voltage. The output current can be calculated by:

$$I_{IN} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta}$$
(10)

where

- I_{IN} is the input current of the inductor
- V_{OUT} is the output voltage
- V_{IN} is the input voltage
- η is the efficiency

While the inductor ripple current depends on the inductance, the frequency, the input voltage, and duty cycle are calculated by Equation 6. Replace Equation 6 and Equation 10 into Equation 9 and get the inductor peak current:

$$I_{PEAK} = \frac{I_{OUT}}{(1-D) \times \eta} + \frac{1}{2} \times \frac{V_{IN} \times D}{L \times f_{SW}}$$
(11)

where

- · I_{PEAK} is the peak current of the inductor
- · I_{OUT} is the output current
- · D is the duty cycle
- η is the efficiency
- V_{IN} is the input voltage
- L is the inductor
- f_{SW} is the switching frequency

The heat rating current (RMS) is can be calculated with Equation 12:

$$I_{L_RMS} = \sqrt{I_{IN}^2 + \frac{1}{12} (\Delta I_L)^2}$$
 (12)

where

- I_{L RMS} is the RMS current of the inductor
- I_{IN} is the input current of the inductor
- Δ_{II} is the ripple current of the inductor

It is important that the peak current does not exceed the inductor saturation current and the RMS current is not over the temperature-related rating current of the inductors.

For a given physical inductor size, increasing inductance usually results in an inductor with lower saturation current. The total losses of the coil consists of the DC resistance (DCR) loss and the following frequency-dependent loss:

Submit Document Feedback

Copyright © 2024 Texas Instruments Incorporated

Instruments www.ti.com

- The losses in the core material (magnetic hysteresis loss, especially at high switching frequencies)
- Additional losses in the conductor from the skin effect (current displacement at high frequencies)
- Magnetic field losses of the neighboring windings (proximity effect)

For a certain inductor, the larger current ripple (smaller inductor) generates the higher DC and also the frequency-dependent loss. An inductor with lower DCR is basically recommended for higher efficiency. However, it is usually a tradeoff between the loss and foot print. Table 8-2 lists some recommended inductors.

Table 8-2. Recommended Inductors

PART NUMBER	L (µH)	DCR TYP (mΩ) MAX	SATURATION CURRENT (A) SIZE (L × W × H mm)		VENDOR ⁽¹⁾

8.2.2.5 Selecting the Output Capacitors

The output capacitor is mainly selected to meet the requirements at load transient or steady state. The loop is compensated for the output capacitor selected. The output ripple voltage is related to the equivalent series resistance (ESR) of the capacitor and its capacitance. Assuming a capacitor with zero ESR, the minimum capacitance needed for a given ripple can be calculated by Equation 13:

$$C_{OUT} = \frac{I_{OUT} \times (V_{OUT} - V_{IN})}{f_{SW} \times \Delta V \times V_{OUT}}$$
(13)

where

- C_{OUT} is the output capacitor
- I_{OUT} is the output current
- V_{OUT} is the output voltage
- V_{IN} is the input voltage
- Δ_V is the output voltage ripple required
- f_{SW} is the switching frequency

The additional output ripple component caused by ESR is calculated by Equation 14:

$$\Delta V_{ESR} = I_{OUT} \times R_{ESR} \tag{14}$$

where

- ΔV_{ESR} is the output voltage ripple caused by ESR
- R_{ESR} is the resistor in series with the output capacitor

For the ceramic capacitor, the ESR ripple can be neglected. However, for the tantalum or electrolytic capacitors, it must be considered if used.

The minimum ceramic output capacitance needed to meet a load transient requirement can be estimated using Equation 15:

$$C_{OUT} = \frac{\Delta I_{STEP}}{2\pi \times f_{BW} \times \Delta V_{TRAN}}$$
 (15)

where

- ΔI_{STEP} is the transient load current step
- ΔV_{TRAN} is the allowed voltage dip for the load current step
- $f_{\rm BW}$ is the control loop bandwidth (that is, the frequency where the control loop gain crosses zero)

For the output capacitor on the OUT pin, the effective capacitance is recommended between 0.22 µF to 1 µF.

Take care when evaluating the derating of a ceramic capacitor under the DC bias. Ceramic capacitors can derate by as much as 70% of the capacitance at the respective rated voltage. Therefore, enough margins on the voltage rating must be considered to ensure adequate capacitance at the required output voltage.

8.2.2.6 Selecting the Input Capacitors

Multilayer ceramic capacitors are an excellent choice for the input decoupling of the step-up converter since they have extremely low ESR and are available in small footprints. Input capacitors must be located as close as possible to the device. While a 22-µF input capacitor or equivalent is sufficient for the most applications, larger values can be used to reduce input current ripple.

Take care when using only ceramic input capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the VIN pin. This ringing can couple to the output and be mistaken as loop instability or can even damage the device. Additional "bulk" capacitance (electrolytic or tantalum) in this circumstance, must be placed between CIN and the power source lead to reduce ringing that can occur between the inductance of the power source leads and C_{IN}.

8.2.2.7 Loop Stability and Compensation

8.2.2.7.1 Small Signal Model

The TPS61378-Q1 uses the fixed frequency peak current mode control. There is an internal adaptive slope compensation to avoid subharmonic oscillation. With the inductor current information sensed, the small-signal model of the power stage reduces from a two-pole system, created by L and C_{OUT}, to a single-pole system, created by R_{OUT} and C_{OUT}. The single-pole system is easily used with the loop compensation. Figure 8-4 shows the equivalent small signal elements of a boost converter.

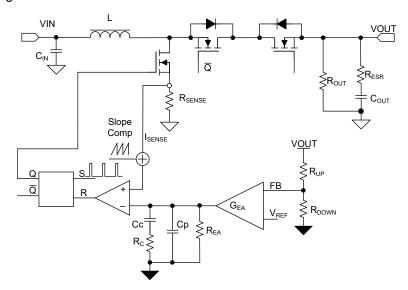

Figure 8-4. TPS61378-Q1 Control Equivalent Circuitry Model

The small signal of power stage is:

$$K_{PS}(S) = \frac{R_{OUT} \times (1 - D)}{2 \times R_{SENSE}} \times \frac{(1 + \frac{S}{2\pi \times f_{ESR}})(1 - \frac{S}{2\pi \times f_{RHP}})}{(1 + \frac{S}{2\pi \times f_{P}})}$$
(16)

Submit Document Feedback Product Folder Links: TPS61378-Q1

where

- · D is the duty cycle
- R_{OUT} is the output load resistor
- R_{SENSE} is the equivalent internal current sense resistor, which is typically 118 m Ω

The single pole of the power stage is:

$$f_{P} = \frac{2}{2\pi \times R_{OUT} \times C_{OUT}}$$
(17)

where

 C_{OUT} is the output capacitance. For a boost converter having multiple identical output capacitors in parallel, simply combine the capacitors with the equivalent capacitance

The zero created by the ESR of the output capacitor is:

$$f_{ESR} = \frac{1}{2\pi \times R_{ESR} \times C_{OUT}}$$
 (18)

where

R_{ESR} is the equivalent resistance in series of the output capacitor

The right-hand plane zero is:

$$f_{RHP} = \frac{R_{OUT} \times (1 - D)^2}{2\pi \times L} \tag{19}$$

where

- · D is the duty cycle
- R_{OUT} is the output load resistor
- · L is the inductance

Equation 20 shows the equation for feedback resistor network and the error amplifier.

$$H_{EA}(S) = G_{EA} \times R_{EA} \times \frac{R_{DOWN}}{R_{UP} + R_{DOWN}} \times \frac{1 + \frac{S}{2 \times \pi \times f_Z}}{(1 + \frac{S}{2 \times \pi \times f_{P1}}) \times (1 + \frac{S}{2 \times \pi \times f_{P2}})}$$
(20)

where

- R_{EA} is the output impedance of the error amplifier, typically R_{EA} = 500 $M\Omega$
- f_{P1} , f_{P2} is the pole's frequency of the compensation
- f_Z is the zero's frequency of the compensation network

$$f_{P1} = \frac{1}{2\pi \times R_{EA} \times C_c} \tag{21}$$

where

C_C is the zero capacitor compensation

$$f_{P2} = \frac{1}{2\pi \times R_C \times C_P} \tag{22}$$

where

- C_P is the pole capacitor compensation
- R_C is the resistor of the compensation network

$$f_Z = \frac{1}{2\pi \times R_C \times C_C} \tag{23}$$

8.2.2.7.2 Loop Compensation Design Steps

With the small signal models coming out, the next step is to calculate the compensation network parameters with the given inductor and output capacitance.

1. Set the Crossover Frequency, $f_{\rm C}$

The first step is to set the loop crossover frequency, $f_{\rm C}$. The higher the crossover frequency, the faster the loop response is. It is generally accepted that the loop gain crosses over no higher than the lower of either 1/10 of the switching frequency, $f_{\rm SW}$, or 1/5 of the RHPZ frequency, $f_{\rm RHPZ}$. Then, calculate the loop compensation network values of R_C, C_C, and C_P by the following equations.

2. Set the Compensation Resistor, R_C.

By placing f_Z below f_C , for frequencies above f_C , $R_C \mid R_{EA} = R_C$, so $R_C \times G_{EA}$ sets the compensation gain. Setting the compensation gain, $K_{COMP-dB}$, at f_Z results in the total loop gain, $K_{COMP-dB} = K_{PS(s)} \times K_{EA(s)}$, being zero at f_C .

Therefore, to approximate a single-pole rolloff up to f_{P2} , rearrange Equation 20 to solve for RC so that the compensation gain, K_{EA} , at f_C is the negative of the gain, K_{PS} . Read at frequency f_C for the power stage bode plot or more simply:

$$K_{EA}(f_C) = 20 \times log(G_{EA} \times R_C \times \frac{R_{DOWN}}{R_{UP} + R_{DOWN}}) = -K_{PS}(f_C)$$
(24)

where

- · K_{EA} is gain of the error amplifier network
- K_{PS} is the gain of the power stage
- G_{EA} is the transconductance of the amplifier, the typical value of G_{EA} = 70 μ A / V

3. Set the Compensation Zero capacitor, C_C.

Place the compensation zero at the power stage R_{OUT} ,C_{OUT} pole's position to get:

$$f_Z = \frac{1}{2\pi \times R_C \times C_C} \tag{25}$$

$$C_{C} = \frac{R_{OUT} \times C_{OUT}}{2R_{C}}$$
 (26)

4. Set the Compensation Pole Capacitor, Cp.

Place the compensation pole at the zero produced by R_{ESR} and C_{OUT} . It is useful for canceling unhelpful effects of the ESR zero.

$$f_{P2} = \frac{1}{2\pi \times R_C \times C_P} \tag{27}$$

Submit Document Feedback

$$f_{ESR} = \frac{1}{2\pi \times R_{ESR} \times C_{OUT}}$$
 (28)

Set $f_{P2} = f_{ESR}$, and get:

$$C_{P} = \frac{R_{ESR} \times C_{OUT}}{R_{C}}$$
 (29)

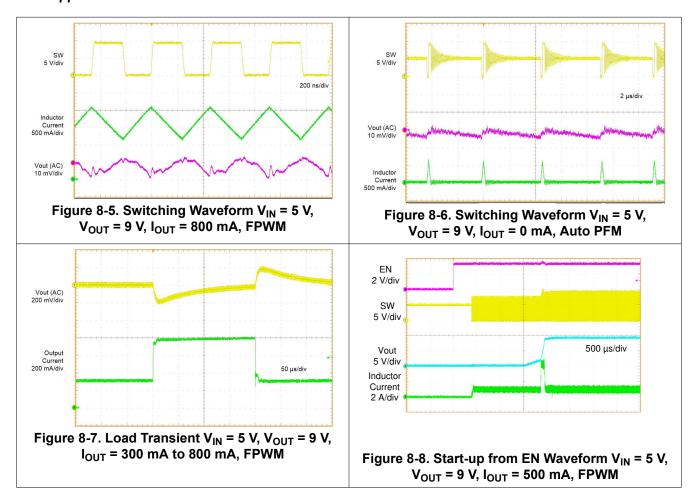

8.2.2.7.3 Selecting the Bootstrap Capacitor

The bootstrap capacitor between the BST and SW pin supplies the gate current to charge the high-side FET device gate during the turnon of each cycle. The gate current also supplies charge for the bootstrap capacitor. The recommended value of the bootstrap capacitor is 0.1 μ F to 1 μ F. C_{BST} must be a good quality, low-ESR ceramic capacitor located at the pins of the device to minimize potentially damaging voltage transients caused by trace inductance. A value of 0.1 μ F was selected for this design example.

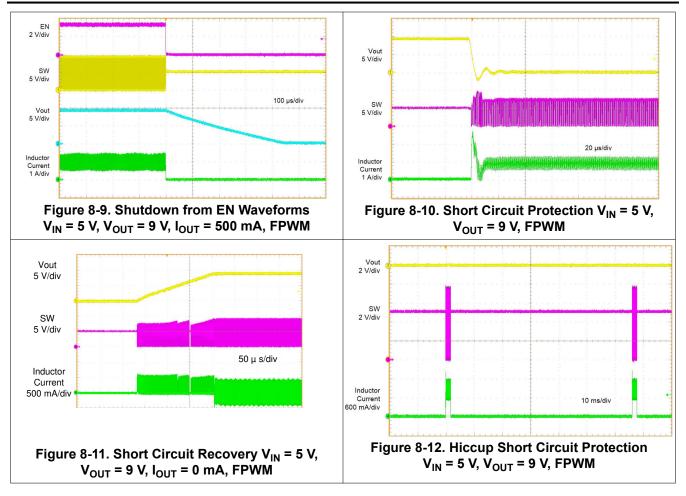

8.2.2.7.4 V_{CC} Capacitor

The primary purpose of the V_{CC} capacitor is to supply the peak transient currents of the driver and bootstrap capacitor and provide stability for the V_{CC} regulator. The value of C_{VCC} must be at least 10 times greater than the value of C_{BST} , and must be a good quality, low-ESR ceramic capacitor. C_{VCC} must be placed close to the pins of the IC to minimize potentially damaging voltage transients caused by the trace inductance. A value of 2.2 μ F was selected for this design example.

8.2.3 Application Curves

9 Power Supply Recommendations

The TPS61378-Q1 is designed to operate from an input voltage supply range between 2.3 V to 14 V. This input supply must be well regulated. If the input supply is located more than a few inches from the device, the bulk capacitance can be required in addition to the ceramic bypass capacitors. An electrolytic capacitor with a value of $47 \, \mu F$ is a typical choice.

10 Layout

10.1 Layout Guidelines

As for all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator can show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground paths. The input and output capacitor, as well as the inductor must be placed as close as possible to the IC.

10.2 Layout Example

The bottom layer is a large GND plane connected by vias.

11.5 Glossary

TI Glossary This glossary

This glossary lists and explains terms, acronyms, and definitions.

11.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

12 Revision History

Changes from Revision D (October 2021) to Revision E (October 2024)	Page
Added TPS61378L	1
Added additional features	1
Updated Package to WQFN-16	1
Updated Output Voltage Selection Resistor in the Device Comparison Table	
Updated Error Amplifier units	
Updated Figure 6-8	
Added additional information to Spread Spectrum Frequency Modulation	
Added Table 7-1	13
Added additional information to Output Short Protection/Hiccup	14
• Added "The external clock needs to be within -+20% of the setting frequency to ensure a reliable	
synchronization."	15
Updated Figure 8-1	17
Added additional information and Figure 8-2 and Figure 8-3	
.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead finish/Ball material Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

3 x 3, 0.5 mm pitch

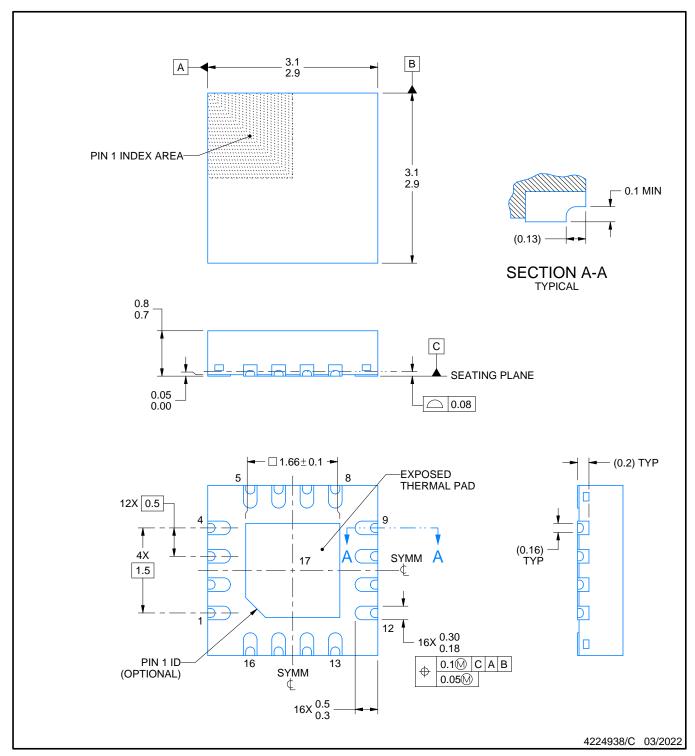

PLASTIC QUAD FLATPACK - NO LEAD

This image is a representation of the package family, actual package may vary. Refer to the product data sheet for package details.

PLASTIC QUAD FLATPACK - NO LEAD

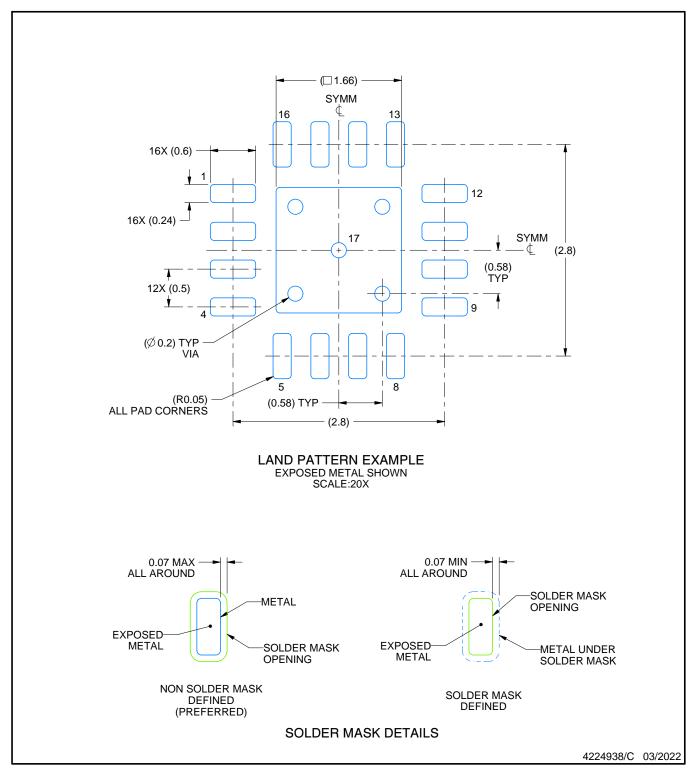

NOTES:

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
 2. This drawing is subject to change without notice.
- 3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

PLASTIC QUAD FLATPACK - NO LEAD

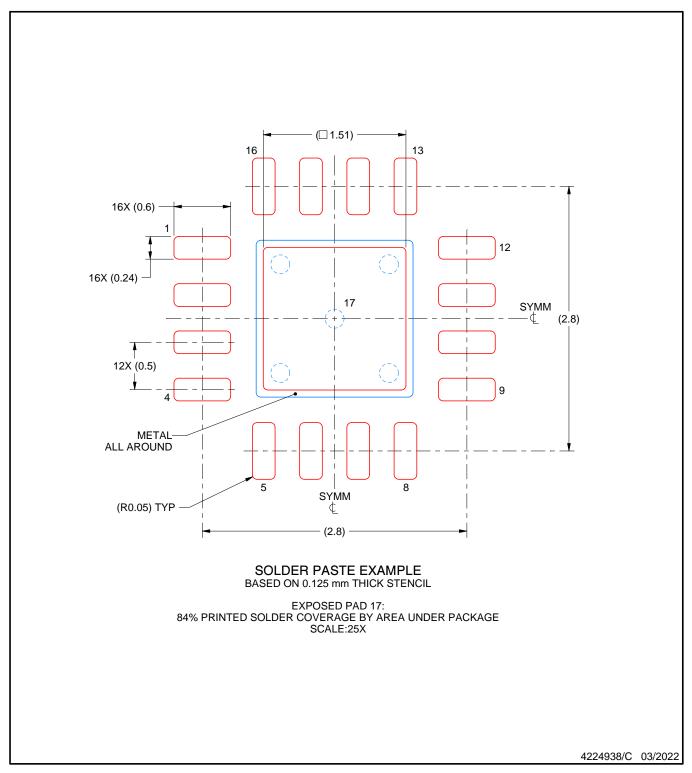

NOTES: (continued)

- 4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
- Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to TI's Terms of Sale or other applicable terms available either on ti.com or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
