## SN6507-Q1 Low-Emissions, 36-V Push-Pull Transformer Driver with Duty Cyle Control for Isolated Power Supplies

## 1 Features

- Functional Safety-Capable
- Documentation available to aid functional safety system design: SN6507-Q1
- AEC-Q100 (Grade 1) qualified for automotive applications
- Create a custom design using the SN6507-Q1 with the WEBENCH ${ }^{\circledR}$ Power Designer
- Push-pull driver for isolation transformers
- Wide input voltage range: 3 V to 36 V
- Input voltage tolerance up to 60 V
- Duty-cycle control for line regulation
- 0.5-A switches with programmable current limit
- Wide switching frequency range: 100 kHz to 2 MHz
- Compatible with small-footprint transformers
- Programmable switching frequency
- External clock synchronization option
- Low noise and emissions
- Symmetric push-pull topology
- Spread sprectrum clocking
- Pin-configurable slew-rate control
- Protection Features
- Adjustable under voltage lockout (UVLO)
- Programmable over-current protection (OCP)
- Over voltage lockout (OVLO)
- Thermal shutdown (TSD)
- Wide temperature range: $-55^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$
- Programmable soft-start to reduce in-rush current
- 10-Pin HVSSOP (DGQ) package with thermal pad

## 2 Applications

Isolated power supplies for:

- Battery management system (BMS)
- On-board charger
- DC/DC converter
- Inverter and motor control

## 3 Description

The SN6507-Q1 is a high voltage, high frequency push-pull transformer driver providing isolated power in a small solution size. The device comes with the push-pull topology's benefits of simplicity, low EMI, and flux cancellation to prevent transformer saturation. Further space savings are achieved through duty-cycle control, which reduces component count for wide-input ranges, and by selecting a high switching frequency, reducing the size of the transformer.

The device integrates a controller and two 0.5-A NMOS power switches that switch out of phase. Its input operating range is programmed with precision undervoltage lockouts. The device is protected from fault conditions by over-current protection (OCP), adjustable under-voltage lockout (UVLO), over voltage lockout (OVLO), thermal shutdown (TSD), and break-before-make circuitry.

The programmable Soft Start (SS) minimizes inrush currents and provides power supply sequencing for critical power up requirements. Spread Spectrum Clocking (SSC) and pin-configurable Slew Rate Control (SRC) further reduces radiated and conducted emissions for ultra-low EMI requirements.

The SN6507-Q1 is available in a 10-pin HVSSOP DGQ package. The device operation is characterized for a temperature range from $-55^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

## 5 Pin Configuration and Functions

Figure 5-1. DGQ Package, 10-Pin HVSSOP (Top View)
Table 5-1. Pin Functions

| PIN |  |  | DESCRIPTION |
| :---: | :---: | :---: | :---: |
| NAME | NO. | TYPE ${ }^{(1)}$ |  |
| SW1 | 1 | 0 | Open drain output of the first power MOSFET, switch 1. Typically connected to either of the outer terminals of the center tap transformer. Because large currents flow through these pins, their external traces should be kept short. |
| GND | 2 | GND | Ground connection of internal control circuits and power MOSFET. Pin 2 and Pin 9 must be shorted on PCB for optimzed emissions and efficiency. |
| VCC | 3 | P | The VCC pin is the main supply pin for the power and analog circuits. Short duration, high-current pulses are produced during the turn on and turn off of the power switches. |
| EN/UVLO | 4 | 1 | Enable input and undervoltage lockout (UVLO) programming pin. <br> - If the pin voltage is above EN_UVLO threshold, the device is enabled and will start switching when VCC is above VCC_UVLO threshold. <br> - If the pin is shorted to VCC, the device is self-started when VCC is above VCC_UVLO threshold. <br> - If the pin is floating, or the pin voltage is below EN_UVLO threshold, the device stops switching. |
| DC | 5 | 1 | Duty cycle control pin to compensate input variation. A resistor on this pin to GND sets the duty cycle. If unused, leave the pin floating, the duty cycle is set to the default value (48\%). Duty cyle control is disabled in SYNC mode. |
| SR | 6 | 1 | Slew rate control pin to further optimize emission performance. This pin adjusts slew rate of SW1 and SW2 by connecting a resistor to GND. If the pin is left floating, the device switches at the default slew rate. |
| CLK | 7 | 1 | This pin is used to sync the device with an external clock (SYNC mode) or program the switching frequency by connecting the pin to ground through a resistor. If shorted to GND, the device will switch at its default frequency ( 1 MHz typical). If left floating, the device will stop switching. |
| SS/ILIM | 8 | 1 | Multifunction Soft-Start (SS) and Current-Limit (ILIM) input pin. <br> - A capacitor to GND is needed to set the output soft-start time and input inrush current. <br> - A resistor to GND is needed to protect the device through the programmable current limit. |
| GND | 9 | GND | Ground connection of internal control circuits and power MOSFET. Pin 2 and Pin 9 must be shorted on PCB for optimized emissions and efficiency. |
| SW2 | 10 | 0 | Open drain output of the second power MOSFET, switch 2 . Typically connected to either of the outer terminals of the center tap transformer. Because large currents flow through these pins, their external traces should be kept short. |
| PowerPAD | 11 | GND | GND pins (Pin 2 and Pin 9) must be electrically connected to the power pad (Pin 11) on the printed circuit board for proper operation. |

(1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
(2) All voltage values are with respect to the local ground terminal (GND) and are peak voltage values.

## 8 Detailed Description

### 8.1 Overview

The SN6507-Q1 is a 36-V, 0.5-A push-pull transformer driver with two integrated n -channel power MOSFETs. It is designed for low cost, small size, low EMI isolated DC/DC power supplies.

The device includes an oscillator that feeds a gate-drive circuit. The gate-drive, comprising a frequency divider and a break-before-make (BBM) logic, provides two complementary output signals which alternately turn the two output NMOS transistors on and off. A subsequent break-before-make logic inserts a dead-time between the high-pulses of the two signals to avoid shorting out both ends of the transformer's primary windings. The resulting output signals drive an isolation transformer and rectifier, converting the input voltage to an isolated output voltage.
To improve performance at wide-input applications, the device implements a Duty Cycle Control (DCC) feature that the duty cyle is dynamically adjusted to compensate for the input variation. It removes the need of preregulation if the input variation is within a certain degree. Or even if at wide input conditions where the input variation is out of regulation range, it saves secondary-side LDO size and power loss. The wide switching frequency range allows for better efficiency and smaller output ripple, as well as size optimization when selecting the transformers.

The transformer driver comes with multiple protection features to ensure robust operation, such as programmable overcurrent protection (OCP), input OVP, input UVLO and TSD. The device minimizes excessive output overvoltage transients by taking advantage of the overvoltage comparator. When the overvoltage comparator is activated, the MOSFETs are turned off and prevented from turning on until the overvoltage condition is removed. The device implements overload protection for both MOSFETs which help control the transformer current and avoid transformer saturation. It also shuts down if the junction temperature is higher than the thermal shutdown trip point. A programmable soft-start period reduces the inrush current during start-up and fault recovery.

For ultra-low EMI applications, the slew rate control feature provides design flexibility and simplicity to further improve emissions with a resistor-programmable option.

### 8.2 Functional Block Diagram

### 8.3 Feature Description

### 8.3.1 Push-Pull Converter

Push-pull converters require transformers with center-taps to transfer power from the primary to the secondary as shown in Figure 8-1. When $\mathrm{Q}_{1}$ conducts, $\mathrm{V}_{\mathbb{I N}}$ drives a current through the lower half of the primary to ground, thus creating a negative voltage potential at the lower primary end with regards to the $\mathrm{V}_{\mathrm{IN}}$ potential at the center-tap. .

Figure 8-1. Switching Cycles of a Push-Pull Converter
At the same time the voltage across the upper half of the primary is such that the upper primary end is positive with regards to the center-tap in order to maintain the previously established current flow through $Q_{2}$, which now has turned high-impedance. The two voltage sources, each of which equaling $\mathrm{V}_{\mathbb{I}}$, appear in series and cause a voltage potential at the open end of the primary of $2 \times \mathrm{V}_{\text {IN }}$ with regards to ground.

Per dot convention the same voltage polarities that occur at the primary also occur at the secondary. The positive potential of the upper secondary end therefore forward biases diode $\mathrm{CR}_{1}$. The secondary current starting from the upper secondary end flows through $\mathrm{CR}_{1}$, charges capacitor C , and returns through the load impedance $R_{\mathrm{L}}$ back to the center-tap.

When $Q_{2}$ conducts, $Q_{1}$ goes high-impedance and the voltage polarities at the primary and secondary reverse. Now the lower end of the primary presents the open end with a $2 \times \mathrm{V}_{\mathbb{I N}}$ potential against ground. In this case $\mathrm{CR}_{2}$ is forward biased while $\mathrm{CR}_{1}$ is reverse biased and current flows from the lower secondary end through $\mathrm{CR}_{2}$, charging the capacitor and returning through the load to the center-tap.

### 8.3.2 Core Magnetization

Figure $8-2$ shows the ideal magnetizing curve for a push-pull converter with $B$ as the magnetic flux density and $H$ as the magnetic field strength. When $Q_{1}$ conducts the magnetic flux is pushed from $A$ to $A^{\prime}$, and when $Q_{2}$ conducts the flux is pulled back from $A^{\prime}$ to $A$. The difference in flux and thus in flux density is proportional to the product of the primary voltage, $V_{P}$, and the time, $t_{O N}$, it is applied to the primary: $B \approx V_{P} \times t_{O N}$.

Figure 8-2. Core Magnetization and Self-Regulation Through Positive Temperature Coefficient of $\mathrm{R}_{\mathrm{DS}(o n)}$
This volt-seconds (V-t) product is important as it determines the core magnetization during each switching cycle. If the V-t products of both phases are not identical, an imbalance in flux density swing results with an offset from the origin of the B-H curve. If balance is not restored, the offset increases with each following cycle and the transformer slowly creeps toward the saturation region.
Fortunately, due to the positive temperature coefficient of a MOSFET's on-resistance, the output FETs of the SN6507-Q1 have a self-correcting effect on V-t imbalance. In the case of a slightly longer on-time, the prolonged current flow through a FET gradually heats the transistor which leads to an increase in $\mathrm{R}_{\mathrm{DS} \text {-on }}$. The higher resistance then causes the drain-source voltage, VDS, to rise. Because the voltage at the primary is the difference between the constant input voltage, $\mathrm{V}_{\mathbb{I N}}$, and the voltage drop across the MOSFET, $\mathrm{V}_{\mathrm{P}}=\mathrm{V}_{\mathbb{I N}}-\mathrm{V}_{\mathrm{DS}}$, $V_{\text {pis }}$ gradually reduced and V-t balance restored.

### 8.3.3 Duty Cycle Control

The SN6507-Q1 implements a duty cycle control feature to provide line regulation to a certain degree through a resistor on DC pin. By making the DC pin voltage a function of the input, the duty cycle will adjust with $\mathrm{V}_{\mathbb{I}}$, so that $\mathrm{V}_{\text {OUt }}$ can be kept constant. Compared to fixed duty cycle transformer drivers, this dynamic duty cycle control feature reduces LDO power loss for wide $\mathrm{V}_{\mathbb{I N}}$ variations by pseudo-regulating the output. For applications where input variation is within a certain range, this feature can eliminate the post-regulation LDO. Another benefit of duty cycle control is to reduce the transformer cost and size because of the limited input range to primary side of the transformer.

Figure 8-3. Schematic with duty cycle control
The calculation of $D C$ pin resistor is shown in Equation 1, where both $R_{D C}$ and $R_{C L K}$ are in $k \Omega$.

$$
\begin{equation*}
R_{D C}=0.816 \times D \times V C C \times\left(R_{C L K}+1\right)-1 \tag{1}
\end{equation*}
$$

For fixed oscillator cases where $R_{\text {CLK }}$ is shorted to $G N D$, a value of $R_{\text {CLK }}=9.6 \mathrm{k} \Omega$ should be used in the equation above to calculate $\mathrm{R}_{\mathrm{DC}}$.

The duty cycle control can compensate for input variation up to $\pm 35 \%$, where line regulation within $\pm 5 \%$ can be achieved. To achieve this range, it is recommended that duty cycle at nominal $\mathrm{V}_{\text {IN }}$ is centered at $25 \%$ ( $\mathrm{D}=0.25$ ). The transformer turns ratio needs take this duty cycle into calculation to ensure the expected output voltage level at all $\mathrm{V}_{\mathrm{IN}}$ voltages, as discussed in Section 9.2.2.5.
The duty cycle control features supports up to a certain duty cycle and $\mathrm{V}_{\mathbb{I N}}$ range. The minimum duty cycle is determined by the charge and discharge time of the gate capacitance of Power FETs, while the maximum duty cycle is limtied by the dead time ( 70 ns typical). For example, at 1 MHz , the adjustable duty cycle is between $10 \%$ and $43 \%$. Exceeding above duty cycle range, the line regulation may saturate and input compensation does not work anymore. Meanwhile, if the duty cycle is lower than the minimum spec, the part may hit current limit at heavy loads. The $\mathrm{V}_{\mathbb{I N}}$ range that duty cycle feature is applicable is from 6 V to 36 V .

To enable the duty cycle control feature, an inductor is required on the output side. The selection of the output inductor should make sure the inductor current will not go into discountinous conduction mode (DCM), meaning the inductor current ramp should not drop to zero at any time. The minimum inductance $\mathrm{L}_{\mathrm{MIN}}$ is therefore calculated by the conditions that the part stays in continuous conduction mode (CCM) where the load DC current is smaller than half the current ramp amplitude seen on the inductor. Therefore $L_{\text {MIN }}$ is a function of the load current and switching frequency as shown by below equation where $I_{\text {load }}$ is in $A, f_{S w}$ is in $\mathrm{Hz}, \mathrm{D}$ is the duty cycle as a decimal (for $25 \%$ duty cycle, 0.25 would be used), and $\mathrm{L}_{\text {min }}$ is in H .

$$
\begin{equation*}
L_{M I N}=V_{\text {OUT }} \times \frac{1-2 \times D \times\left(V_{I N T Y P} / V_{I N ~ M A X}\right)}{\left.4 \times I_{\text {LOAD }}\right)} \tag{2}
\end{equation*}
$$

## Programmable Switching Frequency

SN6507-Q1 has an internal oscillator to set the switching frequency of the power stage. As the two power switches are out of phase, the oscillator frequency is twice of the actual switching frequency of each power
switch. The duty cycle is fixed with 70 ns deadtime to avoid shoot-through. The duty cycle is changeable if duty cycle feature is enabled. Please refer to Section 8.3.3.
SN6507-Q1 has a wide switching frequency range from 100 kHz up to 2 MHz , which is pin-programmable through a resistor ( $\mathrm{R}_{\text {CLK }}$ ) to GND. Below table lists the value of $\mathrm{R}_{\text {CLK }}$ to achieve certain operating frequencies ( $\mathrm{f}_{\mathrm{Sw}}$ ). The choice of switching frequency is a trade-off between power efficiency and size of capacitive and inductive components. For example, when operating at higher switching frequency, the size of the transformer and inductor is reduced, resulting in a smaller design footprint and lower cost. However, higher frequency increases switching losses and consequently degrades the overall power supply efficiency.

Table 8-1. Recommended 1\% $R_{\text {CLK }}$ values and $f_{\text {Sw }}$ Look-up Table

| $\mathbf{R}_{\mathbf{C L K}}$ | $\mathbf{f}_{\text {Sw }}$ (Typical) |
| :---: | :---: |
| $111 \mathrm{k} \Omega$ | 105 kHz |
| $21 \mathrm{k} \Omega$ | 523 kHz |
| $9.6 \mathrm{k} \Omega$ | 1.07 MHz |
| $4.1 \mathrm{k} \Omega$ | 2.13 MHz |
| $0 \mathrm{k} \Omega$ (Short to GND) | Default (1 MHz) |

Figure 8-6 can also be used to estimate the programmable switching frequency, $\mathrm{f}_{\mathrm{SW}}$, using an external resistor value, $R_{\text {CLK }}$, where $R_{\text {CLK }}$ is in $k \Omega$ and $f_{S w}$ is in $k H z$ :

Figure 8-6. Approximate SN6507-Q1 Switching Frequency, $\mathrm{F}_{\text {SW }}$, for $\mathbf{R}_{\text {CLK }}$ Range
If CLK pin is shorted to GND, the part switches at its default frequency, $\mathrm{F}_{\text {sw }}$. CLK pin floating is not a valid state of operation and will cause the part to stop switching until an external clock signal is present.

### 8.3.4 Spread Spectrum Clocking

Radiated emissions is an important concern in high current switching power supplies. Due to the periodicity of the digital clock signals, the energy concentrates in one particular frequency and also in its odds harmonics, causing EMI issues. SN6507-Q1 implements Spread spectrum clocking (SSC) to reduce the radiated emissions of digital clock signals. The device modulates its internal clock in such a way that the emitting energy is spread

over multiple frequency bins. This feature greatly improves the emissions performance of the entire power supply block and hence relieves the system designer from one major concern in isolated power supply design.

### 8.3.5 Slew Rate Control

To allow optimization of EMI with respect to efficiency, the SN6507-Q1 is designed to allow a resistor ( $\mathrm{R}_{\mathrm{SR}}$ ) to select the strength of the driver of PowerFETs turning on. As shown in Figure 8-7 below, the slew rate of the switching edges is controllable with the resistor. Rolling off harmonics through slew rate control can eliminate the need for shielding and common mode chokes in many applications.

The EMI benefit of slew rate control may result in slightly reduced efficiency and higher peak current (ISW_SR). When the feature slows down the charging and discharging of the gate capacitance, the extended transition times of the FETs increases the transition losses during each switching cycle. This increases power dissipation, which decreases efficiency and exacerbates thermal concerns. This will limit how much the slew rate can be reduced. Another cost is the peak current of each cyle will be increased. It is because the slow edges reduce the on-time (lon_SR) and eventually the peak current (ISW_SR) will increase to deliver the same average current to the load on each cycle.

Figure 8-7. Slew Rate Control Scheme
The slew rate at different $\mathrm{V}_{I N}$ is programmed by $\mathrm{R}_{\mathrm{SR}}$. Higher $\mathrm{R}_{\mathrm{SR}}$ values configure $\mathrm{SN6507-Q1}$ for slower slew rates across $V_{C C}$ levels while lower $R_{S R}$ values configure $\mathrm{SN6507-Q1}$ for faster slew rates. The relationship between $\mathrm{V}_{\mathrm{CC}}$ and the slew rate for 12 V and 24 V cases are listed in Table $8-2$ below. As the slew rate is independent of the switching frequency, care must be taken that at high frequencies, the slew rate should be fast enough to maximize the output power delivery to the load. If the SR pin is left floating, the slew rate will be set to the default value. An SR pin short to GND is read as a fault condition, and the device will stop switching.

### 8.3.6 Protection Features

SN6507-Q1 is protected by multiple protection features to improve the system level robustness and reliability. The protection features include programmable input undervoltage protection (UVLO), input over-voltage protection (OVP), programmable over current protection (OCP), and over-temperature protection (TSD).

### 8.3.6.1 Over Voltage Protection (OVP)

As SN6507-Q1 is a open-loop transformer driver, the over voltage protection feature is implemented to prevent the output voltage from rising too high. The overvoltage protection threshold is a fixed value and cannot be programmed. If the VCC pin voltage exceeds the overvoltage rising threshold, device stops switching after a 550 ns (typical) response time. To recover from an over voltage event, the input voltage must drop below the OVP falling threshold.

### 8.3.6.2 Over Current and Short Circuit Protection (OCP)

The SN6507-Q1 is protected from overcurrent conditions with cycle-by-cycle current limiting on both NMOS switches. OCP is disabled during soft-start. After soft-start finishes, the OCP is enabled, and the threshold is set at the programmed value. The switch current is sensed and compared to the current threshold that is programmed by the external resistor on SS/ILIM pin, $\mathrm{R}_{\text {ILIM }}$. Common current limit thresholds ( $\mathrm{I}_{\text {LIM }}$ ) and their corresponding resistor values for $R_{\text {IIIM }}$ are listed in Table 8-3 below. Leaving the ILIM/SS pin floating is not recommended for this device.

Table 8-3. Recommended 1\% $\mathrm{R}_{\text {ILIM }}$ values

| $\mathbf{R}_{\text {ILIM }}$ | $\mathbf{l}_{\text {LIM }}$ (Typical) |
| :---: | :---: |
| $18 \mathrm{k} \Omega$ | 1.3 A |
| $20 \mathrm{k} \Omega$ | 1.2 A |
| $22 \mathrm{k} \Omega$ | 1.1 A |
| $24 \mathrm{k} \Omega$ | 1.0 A |
| $27 \mathrm{k} \Omega$ | 900 mA |
| $30 \mathrm{k} \Omega$ | 800 mA |
| $35 \mathrm{k} \Omega$ | 700 mA |
| $40 \mathrm{k} \Omega$ | 600 mA |
| $50 \mathrm{k} \Omega$ | 500 mA |
| $62 \mathrm{k} \Omega$ | 400 mA |
| $85 \mathrm{k} \Omega$ | 300 mA |
| $127 \mathrm{k} \Omega$ | 200 mA |
| $261 \mathrm{k} \Omega$ | 100 mA |

In case of an extreme over-load condition on the isolated output due to a short circuit, the device behaves as follows:

- In the event of a transient overload or short circuit, if the resulting voltage dip is lower than 2.5 V (typical) on the SS/I ${ }_{\text {LIM }}$ pin, the device considers it as a "soft-short" condition. In soft-shorts, the converter goes into hiccup mode: on hitting the programmed OCP threshold, the driver will be shut-off for 100 ns (typical), and then retry driving. If the OCP trips again, the cycle continues. This retry keeps occurring for entire $\mathrm{T}_{\mathrm{ON}}$ time of SW1 and SW2 until OCP does not trip or a "hard-short" is triggered. During the OCP retry events, both FETs are turned OFF, and the transient peak current may go higher than OCP limit.
- If the voltage dip is more than 2.5 V (typical), the devices considers it as a "hard-short" condition. The hard-short OCP threshold is fixed at 5 A (typical). If a hard-short condition lasts more than $200 \mu \mathrm{~s}$, it indicates that the system is in a serious short-circuit fault condition, the device will fully discharge the soft-start cap
and enters soft start once the short circuit is cleared. Note there is a 65 ns (typ.) response time to trigger hard-short OCP.

### 8.3.6.3 Under Voltage Lock-Out (UVLO)

Start-up and shutdown are controlled by the both EN/UVLO pin and VCC pin. For the device to remain in shutdown mode, apply a voltage below EN UVLO to the EN/UVLO pin. In shutdown mode, the quiescent current is less than $0.8 \mu \mathrm{~A}$ (typical). If EN/UVLO pin sees a voltage higher than $\mathrm{EN}_{\text {UVLO }}$, but $\mathrm{V}_{\text {IN }}$ is still below $\mathrm{VCC}_{U V L O}$, the SW node is inactive. Once the $\mathrm{V}_{\mathbb{I N}}$ is above $\mathrm{VCC}_{U V L O}$, the chip begins to switch normally, provided the EN/UVLO voltage is above 1.5 V .

There are three ways to enable the device operation. The simplest way is to connect the EN/UVLO pin to VCC pin, allowing self-start-up of the device when VCC pin voltage is above VCC ${ }_{\text {UVLo }}$ level. However, many applications benefit from an input UVLO level different than that provided internal UVLO. So another way is to employ an enable resistor divider network as shown in Figure below, which establishes a programmable UVLO threshold. The thrid way is to connect an external logic output to drive this pin, allowing user-defined system power sequencing.
EN/UVLO pin has a $5 \mu \mathrm{~s}$ (typical) glitch filter to help avoid false turn-on and turn-off due to noise coupling. It also comes with an internal pull down design to ensure the device is in shutdown mode when the pin is left floating.

Programmable UVLO using EN/UVLO pin

Resistor values can be calculated using Equation below, where the input turn on threshold $\mathrm{V}_{\text {IN_UVLO }}$ is the desired typical start-up input voltage, EN UVLO is 1.5 V typical, and $R_{\text {ENT }}$ and $R_{\text {ENB }}$ are in $\Omega$.

$$
\begin{equation*}
V_{I N_{-} U V L O}=\left(1+\frac{R_{E N T}}{R_{E N B}}\right) \times E N_{U V L O} \tag{3}
\end{equation*}
$$

### 8.3.6.4 Thermal Shut Down (TSD)

Thermal shutdown prevents the device from reaching extreme junction temperatures by turning off the internal switches when the IC junction temperature exceeds $180^{\circ} \mathrm{C}$ (typical). In TSD, the switching stops immediately to prevent the internal MOSFETs from failing in either high ambient temperature operation conditions or due to self-heating from high switching current. To recover from thermal shut down condition, the junction temperature must be below the overtemperature protection falling threshold. When the junction temperature falls below $147^{\circ} \mathrm{C}$ (typical), the power FET switching is enabled.

### 8.4 Device Functional Modes

The functional modes of the device are divided into start-up, operating, and off-mode.

### 8.4.1 Start-Up Mode

When VCC pin voltage ramps up to VCC VVLo , and EN/UVLO pin voltage is over EN ${ }_{\text {UVLo }}$ the internal oscillator starts operating. The output stage begins switching but the amplitude of the drain signals at SW1 and SW2 have not reached its full maximum yet.

### 8.4.1.1 Soft-Start

SN6507-Q1 device supports soft-start feature. Upon power up or when EN/UVLO pin transitions from Low to High, the gate drive of the output powerFET is gradually increased over a period of time from 0 V to full driving
strength. Soft-start prevents high inrush current from VCC while charging large secondary side decoupling capacitors, and also prevents overshoot in secondary voltage during power-up.
The sort-start time to ramp to the peak switch current is calculated by the capacitor and resistor on SS/ILIM pin with the following formula.

$$
\begin{equation*}
T_{S S}=\frac{C_{S S}}{275 \mu A-\frac{0.6}{R_{\text {ILIM }}}} \tag{4}
\end{equation*}
$$

During soft-start, the over-current protection is disabled. To ensure a smooth transition between soft-start and the steady state, it's recommended to have a $\mathrm{C}_{S S}$ value between 50 nF and $5 \mu \mathrm{~F}$ with an output capacitor, Cout, of less than 10 times the value of $\mathrm{C}_{\mathrm{ss}}$.

### 8.4.2 Operation Mode

The SN6507-Q1 driver is in operation mode when EN pin is above ENUVLo, VIN pin is above VCC ${ }_{\text {UVLO }}$, and soft-start completes. In normal operation mode, the switching frequency is fixed, determined either by the CLK pin resistor or external Clock signal.

### 8.4.3 Shutdown Mode

The device has a dedicated EN/UVLO pin to put the device in very low power mode to save power when not in use. EN/UVLO pin has an internal pull down resistor which keeps device disabled when not driven. When disabled or when $\mathrm{V}_{\mathrm{CC}}$ is $<2.8 \mathrm{~V}$, both drain outputs, SW 1 and SW 2 , are tri-stated.

### 8.4.4 SYNC Mode

The SN6507-Q1 has a CLK pin which can be used to synchronize the device with system clock and in turn with other SN6507-Q1 devices so that the system can control the exact switching frequency of the device. In SYNC mode, the CLK frequency is divided by two to drive the gates of powerFETs. Figure $9-2$ shows the timing diagram for the same.
The device cannot automatically change from SYNC mode to switching frequency control using the internal oscillator or resistor-programmable switching frequency mode. If a valid external CLK signal is not present, the output will stop switching, and a power cycle will be required to change the switching mode back to using the internal oscillator or the adjustable switching frequency using $R_{\text {CLK }}$.
When the device is in SYNC mode, duty cycle control and SSM are not supported, therefore it's recommended to leave DC pin floating in SYNC mode to reduce the solution size.

Note that it is recommended that the SN6507-Q1 V the initial state of external clock should be high-impedance.

## 9 Application and Implementation

## Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. Tl's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

The SN6507-Q1 is a transformer driver designed for low-cost, small form-factor, isolated DC/DC converters using the push-pull topology. The device includes an oscillator that feeds a gate-drive circuit. The gate-drive, comprising a frequency divider and a break-before-make (BBM) logic, provides two complementary output signals which alternately turn the two output transistors on and off.

Figure 9-1. Block Diagram With Break-Before-Make Action

Figure 9-2. Output timing with Break-Before-Make Action

The output frequency of the oscillator is divided down by an asynchronous divider that provides two complementary output signals, $S$ and $\bar{S}$, with a $50 \%$ duty cycle. A subsequent break-before-make logic inserts a dead-time between the high-pulses of the two signals. The resulting output signals, $G_{1}$ and $G_{2}$, present the gate-drive signals for the output transistors $Q_{1}$ and $Q_{2}$. As shown in Figure $9-2$, before either one of the gates can assume logic high, there must be a short time period during which both signals are low and both transistors are high-impedance. This short period, known as break-before-make time, is required to avoid shorting out both ends of the primary.

### 9.2 Typical Application

Two application cases are discussed. One is for Fixed input with slew rate control. The other is for wide-ranging input with duty cycle control.

### 9.2.2 Detailed Design Procedure

This section presents a detailed design procedures using the SN6507-Q1 transformer driver. The following recommendations on components selection focus on the design of an efficient push-pull converter with high current drive capability. Two cases are discussed: wide input range with duty cycle control, and a compact design with a fixed input voltage.
The pin configuration of SN6507-Q1 are discussed by 5 simple steps, followed by the selection of external components, including diodes, capacitors, inductor, LDO and transformers.

### 9.2.2.1 Pin Configuration

Here is an example of how to configure the SN6507-Q1 pins in 5 simple steps.

## Step 1: Set the Switching Frequency

First, set the driver switching frequency with $\mathrm{R}_{\text {CLK }}$ using Table 8-1.
For example: $R_{\text {CLK }}=9.6 \mathrm{k} \Omega$ or shorted to GND, sets typical $\mathrm{f}_{\text {Sw }}$ at about 1 MHz .

## Step 2: Set the Input UVLO

The EN/UVLO (undervoltage lockout) pins are used to set minimum input voltage that the driver starts switching. The resister divider value can be calculated by Equation 3.
For example, if the input threshold $\left(\mathrm{V}_{\mathrm{ON}}\right)$ is expected to be at 9 V , the resistors are calculated as $\mathrm{R}_{\mathrm{ENT}} / R_{\mathrm{ENB}}=5$
Therefore,the resistors values are chosen as:
$R_{\mathrm{ENT}}=5 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{ENB}}=1 \mathrm{k} \Omega$
To make the device self-start at default UVLO thresold ( 2.8 V typical), users can skip Step 2 and directly short the EN/UVLO pin to VCC.

## Step 3: Set the Current Limit and Soft-Start Time

The current limit can be set by a resistor on SS/LLIM pin according to Table 8-3. Peak currents may be very high during operation of the overcurrent protection system until the fault is cleared.
For example, to set the current limit is set at 500 mA (typical), the recommended $R_{\text {ILIM }}$ is $50 \mathrm{k} \Omega$.
Once $R_{\text {ILIM }}$ is determined, substitue $R_{\text {IIIM }}$ into Equation 4, the soft-time calculation is:

$$
T_{S S}=\frac{C_{S S}}{275 \mu A-\frac{0.6}{50 \mathrm{k}}}
$$

Taking 2 ms (typical) soft-start time as an example, the capacitor on SS/ILIM pin : $\mathrm{C}_{\mathrm{SS}}=0.5 \mathrm{uF}$.
Note that both $\mathrm{R}_{\text {ILIM }}$ and $\mathrm{C}_{\text {SS }}$ are required on SS/ILIM pin to ensure the robust operation of this device. Missing the RC connection or leaving the pin floating should be avoided.

## Step 4: Set the Duty Cycle

For fixed input cases, the duty cycle feature is not needed. This step can be skipped by leaving DC pin floating, so that the device will operate at default maximum duty ( $48 \%$ typical). The maximum duty cycle is determined by the switching period and the deadtime ( 70 ns typical) to avoid overlap of two power switches.
For wide-input cases, the duty cycle feature can be enabled by connecting a resistor $R_{D C}$ on $D C$ pin, and an inductor at the output side. The inductor selection is presented in Section 9.2.2.4.
To achieve maximum input compensation, the DC is set close to 0.25 ( $25 \%$ duty cycle) at typical $\mathrm{V}_{\mathrm{CC}}(24 \mathrm{~V})$. The $R_{D C}$ is calculated as $50.9 \mathrm{k} \Omega$ by substituting $D C=0.25, V_{C C}=24 \mathrm{~V}$, and $R_{C L K}=9.6$ into Equation 1, where both $R_{C L K}$ and $R_{D C}$ are in $k \Omega$.

### 9.2.2.2 LDO Selection

SN6507-Q1 is an open-loop transformer driver without load regulation capability. The output voltage may vary over a wide range load current. Therefore, if a high-accuracy, load independent supply is required, the implementation of a low dropout regulator (LDO) on the output side is strongly advised.
The minimum requirements for a suitable low dropout regulator are:

- Its current drive capability should slightly exceed the specified load current of the application to prevent the LDO from dropping out of regulation. Therefore, for a load current of 200 mA , choose a 200 mA to 300 mA LDO. While regulators with higher drive capabilities are acceptable, they also usually possess higher dropout voltages that will reduce overall converter efficiency.
- The internal dropout voltage, $\mathrm{V}_{\mathrm{DO}}$, at the specified load current should be as low as possible to maintain efficiency. For a low-cost 300 mA LDO, a $\mathrm{V}_{\mathrm{DO}}$ of 600 mV at 300 mA is common. Be aware; however, that this lower value is usually specified at room temperature and can increase by a factor of 2 over temperature, which in turn will raise the required minimum input voltage.
- The required minimum input voltage preventing the regulator from dropping out of line regulation is given with:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{I}-\min }=\mathrm{V}_{\mathrm{DO}-\max }+\mathrm{V}_{\mathrm{O}-\max } \tag{5}
\end{equation*}
$$

This means in order to determine $\mathrm{V}_{\mathrm{I}}$ for worst-case condition, the user must take the maximum values for $\mathrm{V}_{\mathrm{DO}}$ and $\mathrm{V}_{\mathrm{O}}$ specified in the LDO data sheet for rated output current (that is, 200 mA ) and add them together. Also specify that the output voltage of the push-pull rectifier at the specified load current is equal or higher than $\mathrm{V}_{1 \text {-min. }}$. If it is not, the LDO will lose line-regulation and any variations at the input passes straight through to the output. Hence, below $\mathrm{V}_{1 \text {-min }}$ the output voltage follows the input and the regulator behaves like a simple conductor.

- The maximum regulator input voltage must be higher than the rectifier output under no-load. Under this condition there is no secondary current reflected back to the primary, thus making the voltage drop across $R_{\text {DS-on }}$ negligible and allowing the entire converter input voltage to drop across the primary. At this point, the secondary reaches its maximum voltage of

$$
\begin{equation*}
\mathrm{V}_{\mathrm{S}-\max }=\mathrm{V}_{\text {IN-max }} \times \mathrm{N} \tag{6}
\end{equation*}
$$

with $\mathrm{V}_{\mathbb{I N}-\max }$ as the maximum converter input voltage and n as the transformer turns ratio. Thus to prevent the LDO from damage the maximum regulator input voltage must be higher than $\mathrm{V}_{\mathrm{S} \text {-max. }}$. Table 9-2 lists the maximum secondary voltages for various turns ratios commonly applied in push-pull converters.

### 9.2.2.3 Diode Selection

A rectifier diode should always possess low-forward voltage to provide as much voltage to the converter output as possible. However, when SN6507-Q1 is used in high-frequency switching applications, the diode must also possess a low total capacitance, a short recovery time and a current rating greater than the load current. Schottky diodes meet these requirements and are therefore strongly recommended in SN6507-Q1 push-pull converter designs.
The necessary diode reverse voltage rating, $\mathrm{V}_{\mathrm{R}}$, is determined by the transformer secondary side voltage plus any voltage ringing. The voltage ringing, however, is difficult to predict, because it depends on multiple factors, such as loop resistance, the leakage inductance of the transformer, and the diode junction capacitance. As a rule of thumb, the diode voltage rating should be greater than 1.5 times the transformer turns ratio multiplied by the maximum input voltage. Because the two secondary windings are connected across the rectifier bridge, a factor of two is needed, producing the diode maximum DC blocking voltage rating:

$$
\begin{equation*}
\text { Diode } V_{R}>1.5 \times 2 \times N \times V_{I N(M A X)} \tag{7}
\end{equation*}
$$

For high-efficiency designs, diodes with low forward voltage, $V_{F}$, and diode capacitance, $C_{T}$, can be used, like BAT165E6327HTSA1 or equivalent can be used for high-efficiency 15-V outputs. Diode parameters like these parasitics and reverse recovery will impact system efficiency and can affect emissions. For low-emissions designs, low-emissions diodes can be used, like PMEG200G20ELRX or equivalent can be used for lowemissions outputs up to 100 V .

### 9.2.2.4 Capacitor and Inductor Selection

## Capacitor Selection

The capacitors in the push-pull converter circuits are normally multi-layer ceramic chip (MLCC) capacitors. As with many high speed CMOS ICs, the device requires a bypass capacitor of 100 nF . Ensure this capacitor is placed within 2 mm of the SN6507-Q1 VCC pin.
The input bulk capacitor at the center-tap of the transformer primary side supports large currents into the primary winding during the fast switching transients. For minimum ripple make this capacitor $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$, where $10 \mu \mathrm{~F}$ is preferred. Place this capacitor close to the transformer primary winding center-tap to minimize trace inductance. If placed on the opposite side of the PCB from the transformer, an additional 100 nF capacitor can be placed on the same layer and close to the transformer center tap. Use two vias in parallel for each connection between these capacitors to the transformer center tap to ensure low-inductance paths.

The bulk capacitor at the rectifier output smooths the output voltage. Make this capacitor 500 nF to $10 \mu \mathrm{~F}$. To avoid hitting OCP at the transistion from soft-start to steady state, the output capacitor $\mathrm{C}_{\text {OUT }}$ is recommended to be less than 10 times of $C_{S S}$ connected to the SS/ILIM pin. Otherwise, if there is a short soft-start time due to a small $C_{S S}$ value, the output capacitor is only partially charged and sees high current spikes on the first switching cycles after the device exits soft start mode.

Optional capacitors of values between 1 nF to 4.7 nF can be connected to the control pins of SN6507-Q1 for filtering if operating in noisy environments.
If an LDO is used, an additional small capacitor at the LDO input is not necessarily required. However, good analog design practice suggests using a small value of 47 nF to 100 nF improves the regulator's transient response and noise rejection.
If an LDO is used, an additional capacitor at the LDO output buffers the regulated output supply for the subsequent isolator and transceiver circuitry. The choice of output capacitor depends on the LDO stability requirements specified in the data sheet. However, in most cases, a low-ESR ceramic capacitor in the range of $4.7 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ will satisfy these requirements.

## Inductor Selection

The inductor is required only for duty cycle feature. The minimum inductor value ( $\mathrm{L}_{\text {MIN }}$ ) is is calculated by Equation 2. Higher inductance produces better regulation and lower voltage ripple, but requires a correspondingly larger size inductor. The optimum inductor value is determined by taking into account the tradeoff between the regualtion performance and the size.
For example, when $\mathrm{V}_{\text {OUT }}=15 \mathrm{~V}, \mathrm{~V}_{\text {IN TYP }}=15 \mathrm{~V}, \mathrm{~V}_{\text {IN MAX }}=18 \mathrm{~V}$, $\mathrm{I}_{\text {LOAD MIN }}=250 \mathrm{~mA}, \mathrm{f}_{\mathrm{SW}}=1 \mathrm{MHz}, \mathrm{D}=0.25$, the minimum inductance is calculated to be $50 \mu \mathrm{H}$.

$$
\begin{equation*}
L_{M I N}=15 \mathrm{~V} \times \frac{1-2 \times 0.25 \times(15 \mathrm{~V} / 18 \mathrm{~V})}{4 \times 0.25 \mathrm{~A} \times 1 \mathrm{MHz}}=8.75 \mu \mathrm{H} \tag{8}
\end{equation*}
$$

### 9.2.2.5 Transformer Selection

### 9.2.2.5.1 V-t Product Calculation

To prevent a transformer from saturation its V-t product must be greater than the maximum V-t product applied by the device: the maximum time this voltage is applied to the primary for half the period of the lowest frequency at the specified input voltage. For designs using duty cycle control, the maximum V-t applied by the device can be calculated by the typical voltage applied for one quarter of the period of the lowest switching frequency. For systems using a clock frequency set by $R_{C L K}, f_{\text {min }}$ can be estimated as $15 \%$ below the typical or approximate
switching frequency value, $\mathrm{f}_{\mathrm{SW}}$, for the corresponding $\mathrm{R}_{\mathrm{CLK}}$ from Section Programmable Switching Frequency. For systems where the CLK pin is connected to GND, the minimum specified $\mathrm{F}_{\text {SW }}$ from Section 6 should be used. Therefore, the transformer's minimum V-t product is determined through Equation 9 for fixed inputs and Equation 10 for wide-ranging inputs using duty cycle control:

$$
\begin{align*}
& \mathrm{V} t_{\text {min }} \geq V_{I N(\max )} \times \frac{T_{\max }}{2}=\frac{V_{I N(\max )}}{2 \times f_{\text {min }}}  \tag{9}\\
& \mathrm{V} t_{\text {min }} \geq V_{I N(t y p)} \times \frac{T_{\max }}{4}=\frac{V_{I N(t y p)}}{4 \times f_{\text {min }}} \tag{10}
\end{align*}
$$

## Example of Fixed Input:

For a fixed input system with $\mathrm{f}_{\mathrm{SW}(\text { min })}$ of 780 kHz and a $\mathrm{V}_{\mathbb{I N}}=24 \mathrm{~V}$ supply with $\pm 10 \%$ tolerance, Equation 9 yields the minimum V -t product of:

$$
\begin{equation*}
\mathrm{V} t_{\min } \geq \frac{26.4 \mathrm{~V}}{2 \times 780 \mathrm{kHz}}=16.9 \mathrm{~V} \mu \mathrm{~s} \tag{11}
\end{equation*}
$$

## Example of Wide-Ranging Input:

Taking the assumption of $\mathrm{f}_{\mathrm{SW}(\text { min })}$ as 780 kHz with a $\mathrm{V}_{\mathrm{IN}(\mathrm{typ})} 24 \mathrm{~V}$ supply, Equation 10 yields the minimum V - t product of:

$$
\begin{equation*}
\mathrm{V} t_{\min } \geq \frac{24 \mathrm{~V}}{4 \times 780 \mathrm{kHz}}=7.7 \mathrm{~V} \mu \mathrm{~s} \tag{12}
\end{equation*}
$$

While Vt-wise all of these transformers can be driven by the device, other important factors such as isolation voltage, transformer wattage, and turns ratio must be considered before making the final decision.

### 9.2.2.5.2 Turns Ratio Estimate

From previous section, it has been determined that the transformer chosen must have a V-t product of $15 \mathrm{~V} \mu \mathrm{~s}$. However, before searching the manufacturer web sites for a suitable transformer, the user still needs to know its minimum turns ratio that allows the push-pull converter to operate flawlessly over the specified current and temperature range. This minimum transformation ratio is expressed through the ratio of minimum secondary to minimum primary voltage multiplied by a correction factor that takes the transformer's typical efficiency of $97 \%$ into account:

$$
\begin{equation*}
V_{P-\min }=V_{I N-\min }-V_{D S-\max } \tag{13}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{S} \text {-min }}$ must be large enough to allow for a maximum voltage drop, $\mathrm{V}_{\mathrm{F} \text {-max }}$, across the rectifier diode and still provide sufficient input voltage for the regulator to remain in regulation. From the Section 9.2.2.2 section, this minimum input voltage is known and by adding $\mathrm{V}_{\mathrm{F} \text {-max }}$ gives the minimum secondary voltage with:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{S}-\min }=\mathrm{V}_{\mathrm{F}-\max }+\mathrm{V}_{\mathrm{DO}-\max }+\mathrm{V}_{\mathrm{O}-\max } \tag{14}
\end{equation*}
$$

Figure 9-5. Establishing the Required Minimum Turns Ratio Through $\mathbf{N}_{\text {min }}=1.03 \times \mathrm{V}_{\text {S-min }} / \mathrm{V}_{\text {P-min }}$
Then calculating the available minimum primary voltage, $\mathrm{V}_{\mathrm{P} \text {-min }}$, involves subtracting the maximum possible drain-source voltage of the device, $\mathrm{V}_{\mathrm{DS} \text {-max }}$, from the minimum converter input voltage $\mathrm{V}_{\mathbb{I N} \text {-min }}$ :

$$
\begin{equation*}
V_{P-\text { min }}=V_{I N-\text { min }}-V_{D S-\text { max }} \tag{15}
\end{equation*}
$$

$V_{D S \text {-max }}$ however, is the product of the maximum $R_{D S(o n)}$ and $I_{D}$ values for a given supply specified in the data sheet:

$$
\begin{equation*}
V_{D S-\text { max }}=R_{D S-\text { max }} \times I_{D \text { max }} \tag{16}
\end{equation*}
$$

Then inserting Equation 16 into Equation 15 yields:

$$
\begin{equation*}
V_{P-\text { min }}=V_{I N-\text { min }}-R_{D S \text {-max }} \times I_{I_{\text {max }}} \tag{17}
\end{equation*}
$$

and inserting Equation 17 and Equation 14 into Equation 13 provides the minimum turns ration with:

$$
\begin{equation*}
N_{\min }=1.03 \times \frac{V_{F-\max }+V_{D O-\max }+V_{O-\max }}{V_{I N-\min }-R_{D S}-\max \times I_{D}-\max } \tag{18}
\end{equation*}
$$

Examples are given on the calculation method. One is for the fixed input case without duty cycle control. The other is for the wide-ranging input, with or without duty cycle control.

## Example of Fixed Input:

For a fixed $24 \mathrm{~V} \mathrm{~V}_{\text {IN }}$ to $15 \mathrm{~V}_{\text {OUt }}$ converter using the rectifier diode PMEG200G20ELRX and the LM317A LDO, the data sheet values taken for a load current of 500 mA and a maximum temperature of $85^{\circ} \mathrm{C}$ are $\mathrm{V}_{\mathrm{F} \text {-max }}=0.5 \mathrm{~V}$, $\mathrm{V}_{\text {DO-max }}=0.7 \mathrm{~V}$, and $\mathrm{V}_{\mathrm{O} \text {-max }}=15.15 \mathrm{~V}$.

Then assuming that the converter input voltage is taken from a 24 V regulated supply with a maximum $\pm 2 \%$ accuracy makes $\mathrm{V}_{\mathrm{IN} \text {-min }}=23.52 \mathrm{~V}$. Finally the maximum values for drain-source resistance and drain current at 24 V are taken from the data sheet with $\mathrm{R}_{\mathrm{DS}-\max }=1 \Omega$ and $\mathrm{I}_{\mathrm{D}-\mathrm{max}}=0.5 \mathrm{~A}$. Inserting the values above into the Equation above yields a minimum turns ratio of:

$$
\begin{equation*}
N_{\min }=1.03 \times \frac{0.5 \mathrm{~V}+0.7 \mathrm{~V}+15.1 \mathrm{~V}}{23.52 \mathrm{~V}-1 \Omega \times 0.5 \mathrm{~A}}=0.72 \tag{19}
\end{equation*}
$$

## Example of Wide-Ranging Input:

## - Wide-Ranging Input without Duty-Cycle Control

For converter designs with wide-input range but no duty cycle control, the turns ratio needs to take the minimum input voltage into consideration.

Assuming the same diode and LDO are used, the calculation, so $\mathrm{V}_{\mathrm{F}-\max }=0.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{DO}-\max }=0.7 \mathrm{~V}$, and $\mathrm{V}_{\mathrm{O}-\max }=$ 15.15 V .

The input range from 18 V up to 30 V makes $\mathrm{V}_{\mathrm{IN}-\text { min }}=18 \mathrm{~V}$. The input range from 18 V up to 30 V with 24 V typical makes $\mathrm{V}_{\mathbb{I N}-\min }=18 \mathrm{~V}$. Substituting the same $\mathrm{R}_{\mathrm{DS}-\max }=1 \Omega$ and $\mathrm{I}_{\mathrm{D}-\mathrm{max}}=0.5 \mathrm{~A}$ into the Equation above yields to a minimum turns ratio of:

$$
\begin{equation*}
N_{\min }=1.03 \times \frac{0.5 \mathrm{~V}+0.7 \mathrm{~V}+15.1 \mathrm{~V}}{18 \mathrm{~V}-1 \Omega \times 0.5 \mathrm{~A}}=0.96 \tag{20}
\end{equation*}
$$

## - Wide-Ranging Input with Duty-Cycle Control

For converter designs with wide-input range, the duty cycle feature is useful to compensate input variaton. But care must be taken to make sure that high turns ratios don't lead to primary currents that exceed the specified current limits of the device.

$$
\begin{equation*}
N_{\min }=1.03 \times \frac{V_{F-\max }+V_{D O}-\max +V_{O-\max }}{V_{I N-t y p}-R_{D S}-\max \times I_{D}-\max } \times \frac{1}{2 D_{t y p}} \tag{21}
\end{equation*}
$$

Assuming the same diode and LDO are used, so $\mathrm{V}_{\mathrm{F}-\max }=0.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{DO}-\max }=0.7 \mathrm{~V}$, and $\mathrm{V}_{\mathrm{O}-\max }=15.15 \mathrm{~V}$.
It's recommends the use to set the $\mathrm{DC}=25 \%$ at typical $\mathrm{V}_{\text {IN-typ }}=24 \mathrm{~V}$. Substituting the same $\mathrm{R}_{\mathrm{DS} \text {-max }}=1 \Omega$ and $\mathrm{I}_{\mathrm{D}-\max }=0.5 \mathrm{~A}$ into the Equation above yields to a minimum turns ratio of:

$$
\begin{equation*}
N_{\min }=1.03 \times \frac{0.5 V+0.7 V+15.1 \mathrm{~V}}{24 V-1 \Omega \times 0.5 \mathrm{~A}} \times \frac{1}{2 \times 0.25}=1.38 \tag{22}
\end{equation*}
$$

### 9.2.2.6 Low-Emissions Designs

For isolated power supply designs requiring low levels of radiated and conducted emissions, the following recommendations can help minimize emissions from SN6507-Q1 and its surrounding components:

- Ensure a push-pull isolation transformer with low parasitics, like leakage inductance and parasitic capacitances, is used to minimize common-mode currents across the isolation barrier and antenna effects in the system.
- Use low-emissions rectifier diodes with low recovery times, like PMEG200G20ELRX or equivalent.
- Configure SN6507-Q1 for its slowest slew-rate setting to minimize high-frequency content in the switching paths.
- Include a snubber circuit on the secondary-side of the isolation transformer to filter high-frequency content in the switching paths.
Using these configurations may each affect system-level efficiency. The SN6507DGQEVM can be used to evaluate these design options.

### 9.3 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 3 V and 36 V nominal. If the input supply is located more than a few inches from the device, a $0.1 \mu \mathrm{~F}$ by-pass capacitor should be connected as close as possible to the device $\mathrm{V}_{\mathrm{Cc}}$ pin and a $10 \mu \mathrm{~F}$ capacitor should be connected close to the transformer center-tap pin.

### 9.4 Layout

### 9.4.1 Layout Guidelines

- The power supply input, $\mathrm{V}_{\mathbb{I N}}$, must be buffered to ground with a low-ESR ceramic bypass-capacitor. The recommended capacitor value can range from $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$, and is typically $10 \mu \mathrm{~F}$. The capacitor must have a voltage rating greater than the $\mathrm{V}_{\mathbb{I N}}$ voltage level and an X5R or X7R dielectric.
- The optimum placement of the $\mathrm{V}_{\mathbb{I N}}$ capacitor is closest to the $\mathrm{V}_{\mathbb{I N}}$ and $G N D$ pins at the board entrance to minimize the loop area formed by the bypass-capacitor connection, the $\mathrm{V}_{\mathrm{IN}}$ terminal, and the GND pin. See Figure 9-10 for a PCB layout example.
- To help ensure reliable operation, a $0.1-\mu \mathrm{F}$ low-ESR ceramic bypass-capacitor is recommended at the device $\mathrm{V}_{\mathrm{Cc}}$ pin. The capacitor should be placed as close to the supply pins as possible in the PCB layout and on the same layer. The capacitor must have a voltage rating greater than the $\mathrm{V}_{\mathbb{I N}}$ voltage level.
- The connections between the device SW1 and SW2 pins and the transformer primary endings and the connection of the device $\mathrm{V}_{\mathrm{CC}}$ pin and the transformer center-tap must be as short as possible for minimum trace inductance.
- The connection of the device $\mathrm{V}_{\mathrm{CC}}$ pin and the transformer center-tap must be buffered to ground with a low-ESR ceramic bypass-capacitor. The recommended capacitor value can range from $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$, and is typically $10 \mu \mathrm{~F}$. The capacitor must have a voltage rating greater than the $\mathrm{V}_{\mathbb{I N}}$ voltage level and an X5R or X7R dielectric.
- The device GND pins must be tied to the PCB ground plane using two vias to help minimize inductance.
- The ground connections of the capacitors and other connections to the ground plane should use two vias for minimum inductance.
- The rectifier diodes should be Schottky diodes with low forward voltage and low capacitance to maximize efficiency.
- The $\mathrm{V}_{\text {OUt }}$ pin must be buffered to ISO-Ground with a low-ESR ceramic bypass-capacitor. The typical capacitor value can range from 500 nF to $10 \mu \mathrm{~F}$ and should be less than 10 times the value of $\mathrm{C}_{\mathrm{SS}}$ to ensure a smooth transition between soft-start and the steady state.

${ }^{(1)}$ The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.
${ }^{(2)}$ RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed $0.1 \%$ by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: Tl defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the $<=1000$ ppm threshold requirement.
${ }^{(3)}$ MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
${ }^{(4)}$ There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
${ }^{(5)}$ Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a " $\sim$ " will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
${ }^{(6)}$ Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-187, variation BA-T.

6 . Features may differ or may not be present.

SOLDER MASK DETAILS

NOTES: (continued)
7. Publication IPC-7351 may have alternate designs.
8. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
9. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 (www.ti.com/lit/sIma002) and SLMA004 (www.ti.com/lit/sIma004).
10. Size of metal pad may vary due to creepage requirement.
