

# TPS54538 3.8V to 28V, 5A, Synchronous Buck Converter With User Selectable Mode

## 1 Features

- Configured for a wide range of applications
  - 3.8V to 28V input voltage range
  - 0.6V to 22V output voltage range
  - Up to 5A continuous output current
  - 0.6V  $\pm$ 1% reference voltage ( $-40^{\circ}\text{C}$  to  $150^{\circ}\text{C}$ )
  - 70ns and 114ns minimum switching on and off-time
  - 8us maximum switching on-time
  - 98% maximum duty cycle
- High efficiency
  - Integrated 47m $\Omega$  and 21m $\Omega$  MOSFETs
  - Low quiescent current of 28uA (typical)
- Ease of use and small design size
  - Peak current control mode with internal compensation
  - 200kHz to 2.2MHz selectable frequency
  - Synchronizable to an external clock (support phase shift) : 200kHz to 2.2MHz
  - Selectable PFM / FCCM at light load condition
  - Selectable adjustable soft-start time, power-good indicator function
  - Good EMI performance with frequency spread spectrum and optimized pinout
  - Hiccup OC limit for both high-side and low-side MOSFETs
  - Non-latched protections for OTP, OCP, OVP, UVP, and UVLO
  - Integrated bootstrap capacitor to support single-layer PCB layout
  - $-40^{\circ}\text{C}$  to  $150^{\circ}\text{C}$  operating junction temperature
  - 1.5mm  $\times$  2.0mm QFN package
- Create a custom design with the TPS54538 using the [WEBENCH® Power Designer](#)

## 2 Applications

- Medical and healthcare, building automation, test and measurement
- Multifunction printers, enterprise projectors
- Portable electronics, connected peripherals
- Wired networking, wireless infrastructure
- Distributed power systems with 5V, 12V, 19V, and 24V input

## 3 Description

The TPS54538 is a high efficiency, high voltage input, and easy-to-use synchronous buck converter with high design flexibility. With the wide operating input voltage range of 3.8V to 28V, the TPS54538 is designed for systems powered from 5V, 12V, 19V, 24V power-bus rails. The device supports up to 5A/4A/3A continuous output current and 98% maximum duty cycle.

TPS54538 uses fixed frequency peak current control with internal compensation for fast transient response and good line and load regulation. With the optimized internal loop compensation, the device eliminates the need for external compensation over a wide output voltage range and switching frequency. Integrated bootstrap capacitor helps achieve single layer PCB and reduce external component count.

### Package Information

PRT NUMBER	PACKAGE <sup>(1)</sup>	PACKAGE SIZE <sup>(2)</sup>
TPS54538	RQF (VQFN-HR, 9)	2mm $\times$ 1.5mm

(1) For more information, see [Section 10](#).

(2) The package size (length  $\times$  width) is a nominal value and includes pins, where applicable.

### Simplified Schematic

TPS54538 Efficiency,  $V_{IN} = 24\text{V}$ ,  $f_{SW} = 500\text{kHz}$

TPS54538 allows high design flexibility with wide supported switching frequency of 200kHz – 2.2MHz set by the RT/SYNC pin. The device has the option for pulse frequency modulation (PFM), forced continuous conduction modulation (FCCM) at light load condition and adjustable soft-start (SS) time / power-good (PG) indicator with different configuration of the MODE pin.

TPS54538 provides protection functions including thermal shutdown, input undervoltage lockout, cycle-by-cycle current limit, and hiccup short-circuit protection. TPS54538 is available in 9-pin 1.5mm × 2.0mm QFN package and the pinout is available for single-layer PCB layout and the junction temperature is specified from –40°C to 150°C.

## 4 Pin Configuration and Functions

Figure 4-1. 9-Pin RQF VQFN-HR, 1.5mm × 2mm Package (Top View)

Table 4-1. Pin Functions

PIN		TYPE <sup>(1)</sup>	DESCRIPTION
NAME	NO.		
RT/SYNC	1	A	Frequency select and external clock synchronization. A resistor to ground sets the switching frequency of the device. An external clock can also be applied to this pin to synchronize the switching frequency. See <a href="#">Section 6.3.5</a> for details.
EN	2	A	Enable input to the converter. Driving EN high or leaving this pin floating enables the converter. An external resistor divider can be used to implement an adjustable $V_{IN}$ UVLO function.
FB	3	A	Output feedback input. Connect FB to the tap of an external resistor divider from the output to GND to set output voltage.
GND	4	G	Ground pin. Connected to the source of the low-side FET as well as the ground pin for the controller circuit. Connect to system ground and the ground side of $C_{IN}$ and $C_{OUT}$ . The path to $C_{IN}$ must be as short as possible.
VIN	5, 6	P	Supply input pin to internal LDO and high-side FET. Input bypass capacitors must be directly connected to this pin and GND.
Mode	7	A	Mode selection pin in light load condition and Power-Good / Soft-Start function. See Mode Selection for details.
SW	8	P	Switching output of the convertor. Internally connected to the source of the high-side FET and drain of the low-side FET. Connect to the power inductor.
SS/PG	9	A	This pin can be a soft-start function or Power-Good function depending on the mode pin configuration. If the soft-start function is selected, an external capacitor connected from this pin to GND defines the rise time for the internal reference voltage. If Power-Good function is selected, this is an open drain power-good indicator, which is asserted low if output voltage is out of PG threshold, overvoltage, or if the device is under thermal shutdown, EN shutdown, or during soft start.

## 5 Specifications

### 5.1 Absolute Maximum Ratings

Over the recommended operating junction temperature range of  $-40^{\circ}\text{C}$  to  $+150^{\circ}\text{C}$ , unless otherwise noted<sup>(1)</sup>

		MIN	MAX	UNIT
Input voltage	V <sub>IN</sub>	-0.3	30	V
	EN	-0.3	6	
	FB	-0.3	6	
Output voltage	SW, DC	-0.3	30	
	SW, transient < 10ns	-5	34	
	SS/PG	-0.3	6	
	MODE	-0.3	6	
	RT/SYNC	-0.3	6	
T <sub>J</sub>	Operating junction temperature <sup>(2)</sup>	-40	150	°C
T <sub>stg</sub>	Storage temperature	-65	150	

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) Operating at junction temperatures greater than  $150^{\circ}\text{C}$ , although possible, degrades the lifetime of the device.

### 5.2 ESD Ratings

			VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	±3000	V
		Charged device model (CDM), per ANSI/ESDA/JEDEC JS-002, all pins <sup>(2)</sup>	±1000	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

### 5.3 Recommended Operating Conditions

Over the recommended operating junction temperature range of  $-40^{\circ}\text{C}$  to  $+150^{\circ}\text{C}$ , unless otherwise noted<sup>(1)</sup>

		MIN	NOM	MAX	UNIT
Input voltage	V <sub>IN</sub>	3.8		28	V
	EN	-0.1		5.5	
	FB	-0.1		5.5	
	SS/PG	-0.1		5.5	
	MODE	-0.1		5.5	
Output voltage	V <sub>OUT</sub>	0.8		22	V
	SW, DC	-0.1		28	
Output current	I <sub>OUT</sub>	TPS54538		0	5
Temperature	Operating junction temperature, T <sub>J</sub>	-40		150	°C

- (1) The *Recommended Operating Conditions* indicate conditions for which the device is intended to be functional, but do not specify specific performance limits. For compliant specifications, see the *Electrical Characteristics*.

## 5.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		TPS54538		UNIT
		QFN-HR, 9 PINS		
		JEDEC <sup>(2)</sup>	EVM <sup>(3)</sup>	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	89.9	N/A	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	79.6	N/A	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	23.1	N/A	°C/W
Ψ <sub>JT</sub>	Junction-to-top characterization parameter	2.5	N/A	°C/W
Ψ <sub>JB</sub>	Junction-to-board characterization parameter	23	N/A	°C/W
R <sub>θJA_EVM</sub>	Junction-to-ambient thermal resistance on official EVM board	N/A	46.5	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application note.
- (2) The value of R<sub>θJA</sub> given in this table is only valid for comparison with other packages and can not be used for design purposes. These values were simulated on a standard JEDEC board. They do not represent the performance obtained in an actual application.
- (3) The real R<sub>θJA</sub> is tested on TI EVM.

## 5.5 Electrical Characteristics

The electrical ratings specified in this section apply to all specifications in this document, unless otherwise noted. These specifications are interpreted as conditions that do not degrade the device parametric or functional specifications for the life of the product containing it. Typical values correspond to T<sub>J</sub> = 25°C, V<sub>IN</sub> = 12V. Minimum and maximum limits are based on T<sub>J</sub> = -40°C to +150°C, V<sub>IN</sub> = 3.8V to 28V, unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>POWER SUPPLY (VIN PIN)</b>						
V <sub>IN</sub>	Operation input voltage		3.8		28	V
I <sub>Q</sub>	Nonswitching quiescent current	EN = 5V, V <sub>FB</sub> = 0.65V, V <sub>IN</sub> = 12V, PFM		28	34	μA
		EN = 5V, V <sub>FB</sub> = 0.65V, V <sub>IN</sub> = 12V, FCCM		40	47	
I <sub>SHDN</sub>	Shutdown supply current	V <sub>EN</sub> = 0V, V <sub>IN</sub> = 12V		3	5.5	μA
V <sub>IN_UVLO</sub>	Input undervoltage lockout thresholds	Rising threshold	3.4	3.6	3.8	V
		Falling threshold	3.2	3.4	3.6	V
		Hysteresis		200		mV
<b>ENABLE (EN PIN)</b>						
V <sub>EN_RISE</sub>	Enable threshold	Rising enable threshold		1.15	1.22	V
V <sub>EN_FALL</sub>	Disable threshold	Falling disable threshold	0.9	1		V
I <sub>p</sub>	EN pullup current	V <sub>EN</sub> = 1.0V		0.7		μA
I <sub>h</sub>	EN pullup hysteresis current			1.76		μA
<b>VOLTAGE REFERENCE (FB PIN)</b>						
V <sub>FB</sub>	FB voltage	T <sub>J</sub> = 25°C	596	600	604	mV
		T <sub>J</sub> = 0°C to 85°C	595	600	605	mV
		T <sub>J</sub> = -40°C to 150°C	594	600	606	mV
I <sub>FB</sub>	Input leakage current	V <sub>IN</sub> = 12V, V <sub>FB</sub> = 0.8V, T <sub>J</sub> = 25°C			0.1	μA
<b>INTEGRATED POWER MOSFETS</b>						
R <sub>DSON_HS</sub>	High-side MOSFET on-resistance	T <sub>J</sub> = 25°C		47		mΩ
R <sub>DSON_LS</sub>	Low-side MOSFET on-resistance	T <sub>J</sub> = 25°C		21		mΩ
<b>CURRENT LIMIT</b>						
I <sub>HS_LIMIT</sub>	High-side MOSFET current limit	V <sub>IN</sub> = 12V, TPS54538	7	8.1	9.4	A
I <sub>LS_LIMIT</sub>	Low-side MOSFET current limit	V <sub>IN</sub> = 12V, TPS54538	5	6	7	A
I <sub>LS_NOC</sub>	Reverse current limit	V <sub>IN</sub> = 12V	2	3	4.2	A
I <sub>PEAK_MIN</sub>	Minimum peak inductor current	V <sub>IN</sub> = 12V		0.7		A

## 5.5 Electrical Characteristics (continued)

The electrical ratings specified in this section apply to all specifications in this document, unless otherwise noted. These specifications are interpreted as conditions that do not degrade the device parametric or functional specifications for the life of the product containing it. Typical values correspond to  $T_J = 25^\circ\text{C}$ ,  $V_{IN} = 12\text{V}$ . Minimum and maximum limits are based on  $T_J = -40^\circ\text{C}$  to  $+150^\circ\text{C}$ ,  $V_{IN} = 3.8\text{V}$  to  $28\text{V}$ , unless otherwise noted.

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT		
<b>SOFT START (SS PIN)</b>							
$I_{SS}$	Soft-start charge current	3.5	5.5	6.5	$\mu\text{A}$		
$T_{SS}$	Fixed internal soft-start time	Mode with PG function. Time from 0% $V_{out}$ -90% $V_{out}$		3.6	ms		
<b>POWER GOOD (PG PIN)</b>							
$V_{PGTH}$	PG threshold, $V_{FB}$ percentage	$V_{FB}$ falling, PG high to low		85%			
		$V_{FB}$ rising, PG low to high		90%			
		$V_{FB}$ falling, PG low to high		107%			
		$V_{FB}$ rising, PG high to low		115%			
$T_{PG\_R}$	PG delay time	PG from low to high		70	$\mu\text{s}$		
$T_{PG\_F}$	PG delay time	PG from high to low		13	$\mu\text{s}$		
$V_{IN\_PG\_VALID}$	Minimum $V_{IN}$ for valid PG output	Measured when PG < 0.5V with 100k $\Omega$ pullup to external 5V		2	2.5	V	
$V_{PG\_OL}$	PG output low-level voltage	$I_{PG} = 0.5\text{mA}$		0.3	V		
$I_{PG\_LK}$	PG leakage current when open drain is high	$V_{PG} = 5.5\text{V}$		-1	1	$\mu\text{A}$	
<b>OSCILLATOR FREQUENCY (RT PIN)</b>							
$f_{SW}$	Switching center frequency	RT = floating		450	500	550	kHz
		RT = GND		870	1000	1130	
$V_{SYNC\_HI}$	SYNC clock high level threshold			1.7		V	
$V_{SYNC\_LO}$	SYNC clock low level threshold				0.9	V	
$t_{ON\_MIN}^{(1)}$	Minimum ON pulse width			70		ns	
$t_{OFF\_MIN}^{(1)}$	Minimum OFF pulse width			114		ns	
$t_{ON\_MAX}^{(1)}$	Maximum ON pulse width			8		$\mu\text{s}$	
<b>OUTPUT OVERVOLTAGE AND UNDERVOLTAGE PROTECTION</b>							
$V_{OVP}$	Output OVP threshold	OVP detect (L→H)		112%	115%	118%	
		Hysteresis			8%		
$V_{UVP}$	Output UVP threshold	UVP detect (H→L)			65%		
		Hysteresis			6%		
$t_{hiccup\_ON}$	UV hiccup ON time before entering hiccup mode after soft start ends				256		$\mu\text{s}$
$t_{hiccup\_OFF}$	UV hiccup OFF time before restart				9.8		cycles
<b>THERMAL SHUTDOWN</b>							
$T_{SHDN}^{(1)}$	Thermal shutdown threshold	Shutdown temperature			165		$^\circ\text{C}$
$T_{HYS}^{(1)}$		Hysteresis			30		$^\circ\text{C}$
<b>SPREAD SPECTRUM FREQUENCY</b>							
$f_m^{(1)}$	Modulation frequency				10		kHz
$f_{spread}$	Internal spread oscillator frequency				$\pm 8\%$		

(1) Not production tested, specified by design.

## 6 Detailed Description

### 6.1 Overview

The TPS54538 is a high efficiency, high voltage input, and easy-to-use synchronous buck converter with high design flexibility. With the wide operating input voltage range of 3.8V to 28V, the TPS54538 is designed for systems powered from 5V, 12V, 19V, 24V power-bus rails. The device supports up to 5A continuous output current and 98% maximum duty cycle.

TPS54538 uses peak current mode control with internal compensation for fast transient response and good line and load regulation. With the internal adaptive loop adjustment, the device eliminates the need for external compensation over a wide output voltage range and switching frequency. The integrated boostcap and the related circuit helps achieve single layer PCB and further reduce the external component count.

With different configuration of MODE pin, the device has option for pulse frequency modulation (PFM), forced continuous current modulation (FCCM) at light load condition and adjustable soft-start time / power-good indicator. When working at PFM mode, the device can attain high efficiency at light load. The FCCM mode helps TPS54538 have low output ripple in all load conditions. A small value capacitor or resistor divider is connected to the SS/PG pin for soft-start time setting or voltage tracking when the device is set to have SS function. When PG function is selected, the device can indicate power good through SS/PG pin.

The EN pin has an internal pullup current that can be used to adjust the input voltage undervoltage lockout (UVLO) with two external resistors. In addition, the EN pin can be floating for the device to operate with the internal pullup current.

The switching frequency can be set by the configuration of the RT/SYNC pin in the range of 200kHz to 2.2MHz, which allows for efficiency and design size optimization when selecting the output filter components. The frequency spread spectrum feature helps the device lower down EMI noise.

TPS54538 has the on-time extension function with a maximum on time of 8 $\mu$ s (typical). During low dropout operation, the high-side MOSFET can turn on up to 8 $\mu$ s, then the high-side MOSFET turns off and the low-side MOSFET turns on with a minimum off time of 114ns (typical). The devices support the maximum 98% duty cycle.

Cycle-by-cycle current limiting on the high-side MOSFET protects the device in overload situations and is enhanced by a low-side sourcing current limit, which prevents current runaway. The TPS54538 provides output undervoltage protection (UVP) when the regulated output voltage is lower than 65% of the nominal voltage due to overcurrent being triggered, approximately 256 $\mu$ s (typical) deglitch time later, both the high-side and low-side MOSFET turn off, the device steps into hiccup mode.

The devices minimize excessive output overvoltage transient by taking advantage of the overvoltage comparator. When the regulated output voltage is greater than 115% of the nominal voltage, the overvoltage comparator is activated, and the high-side MOSFET is turned off and keep off until the output voltage is lower than 104%.

Thermal shutdown disables the devices when the die temperature,  $T_J$ , exceeds 165°C and enables the devices again after  $T_J$  decreases below the hysteresis amount of 30°C.

## 6.2 Functional Block Diagram

## 6.3 Feature Description

### 6.3.1 Fixed Frequency Peak Current Mode

The following operation description of the TPS54538 refers to the functional block diagram and to the waveforms in Figure 6-1. The TPS54538 is a synchronous buck converter with integrated high-side (HS) and low-side (LS) MOSFETs (synchronous rectifier). The TPS54538 supplies a regulated output voltage by turning on the HS and LS NMOS switches with controlled duty cycle. During high-side switch on time, the SW pin voltage swings up to approximately  $V_{IN}$ , and the inductor current,  $i_L$ , increases with linear slope  $(V_{IN} - V_{OUT}) / L$ . When the HS switch is turned off by the control logic, the LS switch is turned on after an anti-shoot-through dead time. Inductor current discharges through the low-side switch with a slope of  $-V_{OUT} / L$ . The control parameter of a buck converter is defined as Duty Cycle  $D = t_{ON} / t_{SW}$ , where  $t_{ON}$  is the high-side switch on time and  $t_{SW}$  is the switching period. The converter control loop maintains a constant output voltage by adjusting the duty cycle  $D$ . In an ideal buck converter where losses are ignored,  $D$  is proportional to the output voltage and inversely proportional to the input voltage:  $D = V_{OUT} / V_{IN}$ .

**Figure 6-1. SW Node and Inductor Current Waveforms in Continuous Conduction Mode (CCM)**

The TPS54538 employs the fixed-frequency peak current mode control. A voltage feedback loop is used to get accurate DC voltage regulation by adjusting the peak current command based on voltage offset. The peak inductor current is sensed from the HS switch and compared to the peak current threshold to control the on time of the HS switch. The voltage feedback loop is internally compensated, which allows for fewer external components, makes design easy, and provides stable operation with almost any combination of output capacitors.

### 6.3.2 Mode Selection

With different configuration of MODE pin, the device is featured with selectable PFM/FCCM at light load, adjustable soft-start time function / power good indicator function for SS/PG pin and user-selectable spread spectrum feature for EMI enhancement. Table shows different MODE pin configurations, TI recommends using 1% tolerance resistors with a low temperature coefficient for MODE selection.

**Table 6-1. MODE Pin Configuration Table**

Recommended Mode Resistor / kΩ	Operation in Light Load	Function of SS/PG Pin	Frequency Spread Spectrum Fss
< 4kΩ / short	PFM	SS	Yes
18kΩ	PFM	PG	Yes
180kΩ	FCCM	SS	Yes
330kΩ	FCCM	PG	Yes
680kΩ	FCCM	SS	No
> 1.3MΩ / floating	FCCM	PG	No

### 6.3.3 Voltage Reference

The internal reference voltage,  $V_{REF}$ , is designed at 0.6V (typical). The negative feedback system of converter produces a precise  $\pm 1\%$  feedback voltage,  $V_{FB}$ , over full temperature by scaling the output of a temperature-stable internal band-gap circuit.

### 6.3.4 Output Voltage Setting

A precision 0.6V reference voltage,  $V_{REF}$ , is used to maintain a tightly regulated output voltage over the entire operating temperature range. The output voltage is set by a resistor divider from the output voltage to the FB pin. TI recommends using 1% tolerance resistors with a low temperature coefficient for the FB divider. Select the bottom-side resistor,  $R_{FBB}$ , for the desired divider current and use Equation 1 to calculate the top-side resistor,  $R_{FBT}$ . Lower  $R_{FBB}$  increases the divider current and reduces efficiency at very light load. Larger  $R_{FBB}$  makes the FB voltage more susceptible to noise, so larger  $R_{FBB}$  values require a more carefully designed feedback path on the PCB. TI recommends setting  $R_{FBB} = 10k\Omega$  and  $R_{FBT}$  in the range of 10kΩ to 300kΩ for most applications.

The tolerance and temperature variation of the resistor dividers affect the output voltage regulation.

**Figure 6-2. Output Voltage Setting**

$$R_{FBT} = \frac{V_{OUT} - V_{REF}}{V_{REF}} \times R_{FBB} \quad (1)$$

where

- $V_{REF}$  is the 0.6V (the internal reference voltage).
- $R_{FBB}$  is 10kΩ (recommended).

### 6.3.5 Switching Frequency Selection / Synchronization

TPS54538 can work under RT mode and SYNC mode by different configuration of the RT/SYNC pin. The condition of this input is detected when the device is first enabled. After the converter is running, the switching frequency selection is fixed and cannot be changed until the next power-on cycle or EN toggle.

In RT mode, the switching frequency of TPS54538 can be set with RT selection programming. Table 6-2 shows the RT selection programming. When RT is connected with resistor, the switching frequency can be set between 200kHz and 2200kHz using Equation 2.

$$R_T = \frac{44500}{f_{SW}} - 2 \quad (2)$$

where

- $R_T$  is the value of RT timing resistor in k $\Omega$ .
- $f_{SW}$  is the switching frequency in kHz.

**Table 6-2. RT/SYNC Pin Resistor Settings**

RT / SYNC Pin	Resistance	Switching Frequency
Floating	85k $\Omega$	500kHz
GND	40k $\Omega$	1000kHz
Resistor	18k $\Omega$ to 220k $\Omega$	200kHz to 2200kHz

There are four cases where the switching frequency does not conform to the condition set by the RT/SYNC pin:

- Light load operation (PFM mode)
- Low dropout operation
- Minimum on-time operation
- Current limit tripped

Under all of these cases, the switching frequency folds back, meaning the switching frequency is less than that programmed by the RT/SYNC pin. During these conditions, the output voltage remains in regulation, except for current limit operation.

An internal Phase Locked Loop (PLL) has been implemented to allow synchronization from 200kHz to 2200kHz, and to easily switch from RT mode to SYNC mode. To implement the synchronization feature, connect a square wave clock signal to the RT/SYNC pin with a on time  $\geq 100$ ns. The clock signal amplitude must transition lower than 0.9V and higher than 1.7V.

In applications where both RT mode and SYNC mode are needed, an RC circuit as shown in Figure 6-3 can be used to interface the RT/SYNC pin but the capacitive load slows down the transition back to RT mode. The RT/SYNC pin must not be left connect to GND / floating and 100pF capacitor is recommended. When using the series RC circuit, verify the amplitude of the signal at the RT/SYNC pin must transition lower than 0.9V and higher than 1.7V.

**Figure 6-3. SYNC Mode Configuration**

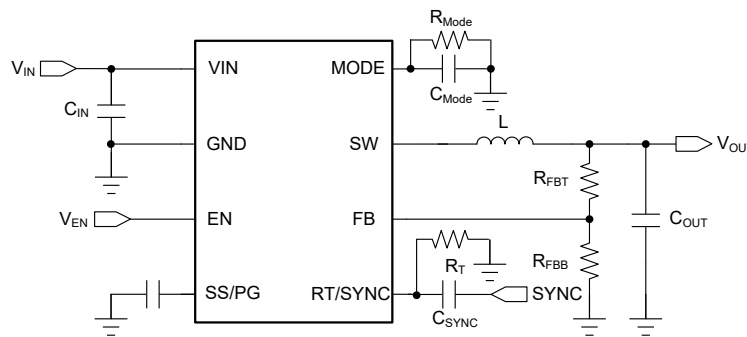

**Note**

- If SYNC is active before start-up, TPS54538 works in SYNC clock.
- If SYNC not active before start-up, TPS54538 works at default clock (based on RT resistor). When SYNC clock active, TPS54538 works in SYNC mode.
  - If SYNC clock is out of range (200k to approximately 2.2MHz), TPS54538 works at the end frequency (200k, 2.2Mhz).
  - SYNC clock is not locked during operation.

**6.3.6 Phase Shift**

When the TPS54538 works in FCCM mode with SYNC to external clock, phase shift function can be activated by adding a capacitor connect to MODE pin, as is shown in Figure 6-4. When phase shift function is disabled, let the capacitor floating. The phase shift function is designed to reduce the input ripple and improve EMI performance for multi rails, where step-down converters share the same input. Figure 6-5 shows how phase shift reduce input ripple with three buck converters sharing the same input. The capacitor value can be calculated using Equation 3, where  $C_{MODE}$  is the MODE capacitor,  $\theta$  is the degree of phase shift. Table 6-3 shows the typical capacitor value for phase shift configuration.

$$C_{MODE} = \frac{\theta - 28^\circ}{1.3585} \tag{3}$$

**Figure 6-4. Phase Shift Operation Schematic**

**Figure 6-5. Phase Shift Operation Application**

**Table 6-3. Phase Shift Configuration Table**

Recommended Mode Capacitor / pF	Phase shift / degree
47pF	90°
68pF	120°
120pF	180°
180pF	270°

### 6.3.7 Enable and Adjusting Undervoltage Lockout

The EN pin provides electrical ON and OFF control of the device. When the EN pin voltage exceeds the enable threshold voltage,  $V_{EN\_RISE}$ , the TPS54538 begins operation. If the EN pin voltage is pulled below the disable threshold voltage,  $V_{EN\_FALL}$ , the converter stops switching and enters shutdown mode.

The EN pin has an internal pullup current source, which allows the user to float the EN pin to enable the device. If an application requires control of the EN pin, use an open-drain or open-collector or GPIO output logic to interface with the pin.

The TPS54538 implements internal undervoltage lockout (UVLO) circuitry on the VIN pin. The device is disabled when the VIN pin voltage falls below the internal  $V_{IN\_UVLO}$  threshold. The internal  $V_{IN\_UVLO}$  threshold has a hysteresis of typical 200mV. If an application requires a higher UVLO threshold on the VIN pin, the EN pin can be configured as shown in [Figure 6-6](#). When using the external UVLO function, TI recommends setting the hysteresis at a value greater than 500mV.

The EN pin has a small pullup current,  $I_p$ , which sets the default state of the EN pin to enable when no external components are connected. The pullup hysteresis current,  $I_h$ , is used to control the hysteresis voltage for the UVLO function when the EN pin voltage crosses the enable threshold. Use [Equation 4](#) and [Equation 5](#) to calculate the values of R1 and R2 for a specified UVLO threshold. After R1 and R2 are settled down,  $V_{EN}$  can be calculated by [Equation 6](#), which must be lower than 5.5V with the maximum  $V_{IN}$ .

**Figure 6-6. Adjustable  $V_{IN}$  Undervoltage Lockout**

$$R_1 = \frac{V_{START} \times \frac{V_{EN\_FALL}}{V_{EN\_RISE}} - V_{STOP}}{I_p \times \left(1 - \frac{V_{EN\_FALL}}{V_{EN\_RISE}}\right) + I_h} \quad (4)$$

$$R_2 = \frac{R_1 \times V_{EN\_FALL}}{V_{STOP} - V_{EN\_FALL} + R_1 \times (I_p + I_h)} \quad (5)$$

$$V_{EN} = \frac{R_2 \times V_{IN} + R_1 \times R_2 \times (I_p + I_h)}{R_1 + R_2} \quad (6)$$

where

- $I_p$  is 0.7 $\mu$ A.
- $I_h$  is 1.76 $\mu$ A.
- $V_{EN\_FALL}$  is 1V.
- $V_{EN\_RISE}$  is 1.15V.
- $V_{START}$  is the input voltage enabling the device.
- $V_{STOP}$  is the input voltage disabling the device.

### 6.3.8 External Soft Start and Prebiased Soft Start

When the TPS54538 is configured to the SS function by the MODE pin, the SS/PG pin of TPS54538 is used to minimize inrush current when driving capacitive load. The devices use the lower voltage of the internal voltage reference,  $V_{REF}$ , or the SS/PG pin voltage as the reference voltage and regulates the output accordingly. A capacitor on the SS/PG pin to ground implements a soft-start time. The device has an internal pullup current source that charges the external soft-start capacitor. Use Equation 7 to calculate the soft-start time ( $t_{SS}$ , 0% to 100%) and soft-start capacitor ( $C_{SS}$ ).

$$t_{SS} = \frac{C_{SS} \times V_{REF}}{I_{SS}} \quad (7)$$

where

- $V_{REF}$  is 0.6V (the internal reference voltage).
- $I_{SS}$  is 5.5 $\mu$ A (typical), the internal pullup current.

If the output capacitor is prebiased at start-up, the devices initiate switching and start ramping up only after the internal reference voltage becomes greater than the feedback voltage,  $V_{FB}$ . This scheme makes sure that the converters ramp up smoothly into regulation point. A resistor divider connected to the SS/PG pin can implement voltage tracking of the other power rail.

### 6.3.9 Power Good

When the TPS54538 is configured to PG function, the SS/PG pin is used to indicate whether the output voltage has reached the appropriate level or not. The PG signal can be used for start-up sequencing of multiple rails. The PG pin is an open-drain output that requires a pullup resistor to any voltage below 5.5V. TI recommends a pullup resistor of 10k $\Omega$  – 100k $\Omega$ . The device can sink approximately 4mA of current and maintain the specified logic low level. After the FB pin voltage is between 90% and 107% of the internal reference voltage ( $V_{REF}$ ) and after a deglitch time of 70 $\mu$ s, the PG turns to high impedance status. The PG pin is pulled low after a deglitch time of 13 $\mu$ s when FB pin voltage is lower than 85% of the internal reference voltage or greater than 115% of the internal reference voltage, or in events of thermal shutdown, EN shutdown, or UVLO conditions.  $V_{IN}$  must remain present for the PG pin to stay low.

**Table 6-4. PG Status**

Device State		PG Logic Status	
		High Impedance	Low
Enable (EN = High)	$V_{FB}$ does not trigger $V_{PGTH}$	√	
	$V_{FB}$ triggers $V_{PGTH}$		√
Shutdown (EN = Low)			√
UVLO	$2.5V < V_{IN} < V_{UVLO}$		√
Thermal shutdown	$T_J > T_{SD}$		√
Power supply removal	$V_{IN} < 2.5V$	√	

### 6.3.10 Minimum On Time, Minimum Off Time, and Frequency Foldback

Minimum on time ( $t_{ON\_MIN}$ ) is the smallest duration of time that the high-side switch can be on.  $t_{ON\_MIN}$  is typically 70ns in the TPS54538. Minimum off time ( $t_{OFF\_MIN}$ ) is the smallest duration that the high-side switch can be off.  $t_{OFF\_MIN}$  is typically 114ns. In CCM operation,  $t_{ON\_MIN}$ , and  $t_{OFF\_MIN}$ , limit the voltage conversion range without switching frequency foldback.

The minimum duty cycle without frequency foldback allowed is:

$$D_{MIN} = t_{ON\_MIN} \times f_{SW} \quad (8)$$

The maximum duty cycle without frequency foldback allowed is:

$$D_{MAX} = 1 - t_{ON\_MIN} \times f_{SW} \quad (9)$$

Given a required output voltage, the maximum  $V_{IN}$  without frequency foldback is:

$$V_{IN\_MAX} = \frac{V_{OUT}}{t_{ON\_MIN} \times f_{SW}} \quad (10)$$

The minimum  $V_{IN}$  without frequency foldback is:

$$V_{IN\_MIN} = \frac{V_{OUT}}{1 - t_{ON\_MIN} \times f_{SW}} \quad (11)$$

In TPS54538, a frequency foldback scheme is employed once  $t_{ON\_MIN}$  or  $t_{OFF\_MIN}$  is triggered, which can extend the maximum duty cycle or lower the minimum duty cycle.

The on time decreases while  $V_{IN}$  voltage increases. Once the on time decreases to  $t_{ON\_MIN}$ , the switching frequency starts to decrease while  $V_{IN}$  continues to go up, which lowers the duty cycle further to keep  $V_{OUT}$  in regulation according to [Equation 8](#).

The frequency foldback scheme also works once larger duty cycle is needed under low  $V_{IN}$  condition. The frequency decreases after the device hits the  $t_{OFF\_MIN}$ , which extends the maximum duty cycle according to [Equation 9](#). A wide range of frequency foldback allows the TPS54538 output voltage to stay in regulation with a much lower supply voltage  $V_{IN}$ , which allows a lower effective dropout. With frequency foldback,  $V_{IN\_MAX}$  is raised, and  $V_{IN\_MIN}$  is lowered by decreased  $f_{SW}$ .

### 6.3.11 Frequency Spread Spectrum

To reduce EMI, the TPS54538 introduces frequency spread spectrum. The jittering span is typically  $\Delta f_c = \pm 8\%$  of the switching frequency with the modulation frequency of 10kHz. The purpose of spread spectrum is to eliminate peak emissions at specific frequencies by spreading emissions across a wider range of frequencies than a part with fixed frequency operation. [Figure 6-7](#) shows the frequency spread spectrum modulation. [Figure 6-8](#) shows the energy is spread out at the center frequency,  $f_c$ .

**Figure 6-7. Frequency Spread Spectrum Diagram**

Figure 6-8. Energy vs Frequency

### 6.3.12 Overvoltage Protection

The device incorporates an output overvoltage protection (OVP) circuit to minimize output voltage overshoot. The OVP feature minimizes the overshoot by comparing the FB pin voltage to the OVP threshold. If the FB pin voltage is greater than the OVP threshold of 115%, the high-side MOSFET is turned off, which prevents current from flowing to the output and minimizes output overshoot. When the FB pin voltage drops lower than the OVP threshold minus hysteresis, the high-side MOSFET is allowed to turn on at the next clock cycle. This function is a non-latch operation.

### 6.3.13 Overcurrent and Undervoltage Protection

The TPS54538 incorporates both peak and valley inductor current limits to provide protection to the device from overloads and short circuits and limit the maximum output current. Valley current limit prevents inductor current runaway during short circuits on the output, while both peak and valley limits work together to limit the maximum output current of the converter. Hiccup mode is also incorporated for sustained short circuits.

The high-side switch current is sensed when turned on after a set blanking time ( $t_{ON\_MIN}$ ), the peak current of high-side switch is limited by the peak current threshold,  $I_{HS\_LIMIT}$ . The current going through low-side switch is also sensed and monitored. When the low-side switch turns on, the inductor current begins to ramp down.

As the device is overloaded, a point is reached where the valley of the inductor current cannot reach below  $I_{LS\_LIMIT}$  before the next clock cycle, then the low-side switch is kept on until the inductor current ramps below the valley current threshold,  $I_{LS\_LIMIT}$ , then the low-side switch is turned off and the high-side switch is turned on after a dead time. When this action occurs, the valley current limit control skips that cycle, causing the switching frequency to drop. Further overload causes the switching frequency to continue to drop, but the output voltage remains in regulation. As the overload is increased, both the inductor current ripple and peak current increase until the high-side current limit,  $I_{HS\_LIMIT}$ , is reached. When this limit is tripped, the switch duty cycle is reduced and the output voltage falls out of regulation. This action represents the maximum output current from the converter and is given approximately by Equation 12. The output voltage and switching frequency continue to drop as the device moves deeper into overload while the output current remains at approximately  $I_{OMAX}$ . There is another situation, if the inductor ripple current is large, the high-side current limit can be tripped before the low-side limit is reached. In this case, Equation 13 gives the approximate maximum output current.

$$I_{OMAX} \approx \frac{I_{HS\_LIMIT} + I_{LS\_LIMIT}}{2} \quad (12)$$

$$I_{OMAX} \approx I_{HS\_LIMIT} - \frac{(V_{IN} - V_{OUT})}{2 \times L \times f_{SW}} \times \frac{V_{OUT}}{V_{IN}} \quad (13)$$

Furthermore, if a severe overload or short circuit causes the FB voltage to fall below the  $V_{UVP}$  threshold, 65% of the  $V_{REF}$ , and triggering current limit, and the condition occurs for more than the hiccup on time (typical 256 $\mu$ s), the converter enters hiccup mode. In this mode, the device stops switching for hiccup off time,  $10.5 \times t_{SS}$ , and then goes to a normal restart with soft-start time. If the overload or short-circuit condition remains, the device runs in current limit and then shuts down again. This cycle repeats as long as the overload or short-circuit condition persists. This mode of operation reduces the temperature rise of the device during a sustained overload or short circuit condition on the output. Once the output short is removed, the output voltage recovers normally to the regulated value.

For FCCM version, the inductor current is allowed to go negative. When this current exceed the LS negative current limit  $I_{LS\_NEG}$ , the LS switch is turned off and HS switch is turned on immediately, which is used to protect the LS switch from excessive negative current.

### 6.3.14 Thermal Shutdown

The junction temperature ( $T_J$ ) of the device is monitored by an internal temperature sensor. If  $T_J$  exceeds 165°C (typical), the device goes into thermal shutdown, both the high-side and low-side power FETs are turned off. When  $T_J$  decreases below the hysteresis amount of 30°C (typical), the converter resumes normal operation, beginning with a soft start.

## 6.4 Device Functional Modes

### 6.4.1 Modes Overview

The TPS54538 moves between CCM, DCM, PFM, and FCCM mode as the load changes. Depending on the load current, the TPS54538 is in one of below modes:

- Continuous conduction mode (CCM) with fixed switching frequency when load current is above half of the peak-to-peak inductor current ripple
- Discontinuous conduction mode (DCM) with fixed switching frequency when load current is lower than half of the peak-to-peak inductor current ripple in CCM operation
- Pulse frequency modulation mode (PFM) when switching frequency is decreased at very light load
- Forced continuous conduction mode (FCCM) with fixed switching frequency even at light load

### 6.4.2 Heavy Load Operation

The TPS54538 operates in continuous conduction mode (CCM) when the load current is higher than half of the peak-to-peak inductor current. In CCM operation, the output voltage is regulated by switching at a constant frequency and modulating the duty cycle to control the power to the load. Regulating the output voltage provides excellent line and load regulation and minimum output voltage ripple, and the maximum continuous output current of 3A /4A/5A can be supplied by the TPS54538.

### 6.4.3 Pulse Frequency Modulation

The TPS54538 is designed to operate in pulse frequency modulation (PFM) mode at light load currents to boost light load efficiency when MODE pin is configured to PFM mode.

When the load current is lower than half of the peak-to-peak inductor current in CCM, the devices operate in discontinuous conduction mode (DCM). In DCM operation, the low-side switch is turned off when the inductor current drops to  $I_{LS\_ZC}$  to improve efficiency. Both switching losses and conduction losses are reduced in DCM, compared to forced CCM operation at light load.

At even lighter current load, pulse frequency modulation (PFM) mode is activated to maintain high-efficiency operation. When either the minimum high-side switch on time,  $t_{ON\_MIN}$ , or the minimum peak inductor current  $I_{PEAK\_MIN}$  is reached, the switching frequency decreases to maintain regulation. In PFM mode, the switching frequency is decreased by the control loop to maintain output voltage regulation when load current reduces. Switching loss is further reduced in PFM operation due to less frequent switching actions. Since the integrated current comparator catches the peak inductor current only, the average load current entering PFM mode varies with the applications and external output LC filters.

In PFM mode, the high-side MOSFET is turned on in a burst of one or more pulses to provide energy to the load. The duration of the burst depends on how long the feedback voltage takes to catch  $V_{REF}$ . The periodicity of these bursts is adjusted to regulate the output, while zero current crossing detection turns off the low-side MOSFET to maximize efficiency. This mode provides high light-load efficiency by reducing the amount of input supply current required to regulate the output voltage at small loads. This trades off very good light-load efficiency for larger output voltage ripple and variable switching frequency.

#### 6.4.4 Forced Continuous Conduction Modulation

When the TPS54538 is configured to operate in FCCM under light load conditions, the switching frequency is maintained at a constant level over the entire load range, which is an excellent choice for applications requiring tight control of the switching frequency and output voltage ripple at the cost of lower efficiency under light load. For some audio application, this mode can help avoid switching frequency drop into audible range that can introduce some "noise". Proper capacitor, inductor, and layout can help to avoid audible noise as well.

#### 6.4.5 Dropout Operation

The dropout performance of any buck converter is affected by the  $R_{DS(ON)}$  of the power MOSFETs, the DC resistance of the inductor, and the maximum duty cycle that the controller can achieve. As the input voltage level approaches the output voltage, the off time of the high-side MOSFET starts to approach the minimum value. Beyond this point, the switching frequency becomes erratic and the output voltage can fall out of regulation. To avoid this problem, the TPS54538 automatically reduces the switching frequency (on-time extension function) to increase the effective duty cycle and maintain in regulation until the switching frequency reach to the lowest limit.

#### 6.4.6 Minimum On-Time Operation

Every switching converter has a minimum controllable on time dictated by the inherent delays and blanking times associated with the control circuits, which imposes a minimum switch duty cycle and, therefore, a minimum conversion ratio. The constraint is encountered at high input voltages and low output voltages. To help extend the minimum controllable duty cycle, the TPS54538 automatically reduces the switching frequency when the minimum on-time limit is reached. This way, the converter can regulate the lowest programmable output voltage at the maximum input voltage. Use [Equation 14](#) to find an estimate for the approximate input voltage for a given output voltage before frequency foldback occurs. The values of  $t_{ON\_MIN}$  and  $f_{SW}$  can be found in [Section 5.5](#).

$$V_{IN} \leq \frac{V_{OUT}}{t_{ON\_MIN} \times f_{SW}} \quad (14)$$

As the input voltage is increased, the switch on time (duty-cycle) reduces to regulate the output voltage. When the on time reaches the minimum on time,  $t_{ON\_MIN}$ , the switching frequency drops while the on time remains fixed.

#### 6.4.7 Shutdown Mode

The EN pin provides electrical ON and OFF control for the device. When  $V_{EN}$  is below typical 1.15V, the TPS54538 is in shutdown mode. The device also employs VIN UVLO protection. If  $V_{IN}$  voltage is below the respective UVLO level, the converter is turned off too.

## 7 Application and Implementation

### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

### 7.1 Application Information

The TPS54538 is a highly integrated, synchronous, step-down, DC-DC converter. This device is used to convert a higher DC input voltage to a lower DC output voltage, with a maximum output current of 5A.

### 7.2 Typical Application

The application schematic of the following figure was developed to meet the requirements of the device. This circuit is available as the TPS54538EVM evaluation module. The design procedure is given in this section.

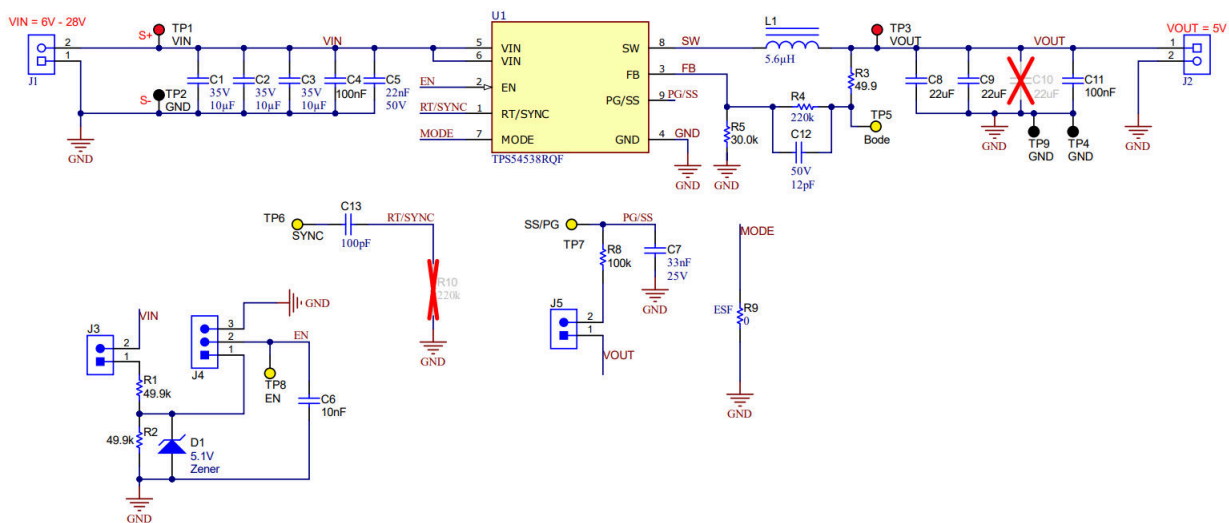

Figure 7-1. TPS54538 5V Output, 5A Reference Design

## 7.2.1 Design Requirements

Table 7-1 shows the design parameters for this application.

**Table 7-1. Design Parameters**

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNIT
V <sub>IN</sub>	Input voltage	5.5	24	28	V
V <sub>OUT</sub>	Output voltage		5		V
I <sub>OUT</sub>	Output current rating		5		A
V <sub>IN(ripple)</sub>	Input ripple voltage		400		mV
V <sub>OUT(ripple)</sub>	Output ripple voltage		30		mV
F <sub>SW</sub>	Switching frequency	RT = floating	500		kHz
t <sub>SS</sub>	Soft-start time	C <sub>SS</sub> = 33nF	4		mS
T <sub>A</sub>	Ambient temperature		25		°C

## 7.2.2 Detailed Design Procedure

### 7.2.2.1 Custom Design With WEBENCH® Tools

Create a custom design with the TPS54538 using the [WEBENCH® Power Designer](#).

1. Start by entering the input voltage (V<sub>IN</sub>), output voltage (V<sub>OUT</sub>), and output current (I<sub>OUT</sub>) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at [www.ti.com/WEBENCH](http://www.ti.com/WEBENCH).

### 7.2.2.2 Output Voltage Resistors Selection

The output voltage is set with a resistor divider from the output node to the FB pin. TI recommends using 1% tolerance or better divider resistors. Referring to the application schematic of [Figure 7-1](#), start with 30kΩ for R5 and use [Equation 15](#) to calculate R4 = 220kΩ. To improve efficiency at light loads, consider using larger value resistors. If the values are too high, the converter is more susceptible to noise and voltage errors from the FB input leakage current are noticeable.

$$R_4 = \frac{V_{OUT} - V_{REF}}{V_{REF}} \times R_5 \quad (15)$$

[Table 7-2](#) shows the recommended components value for common output voltages.

### 7.2.2.3 Choosing Switching Frequency

The choice of switching frequency is a compromise between conversion efficiency and overall design size. Higher switching frequency allows the use of smaller inductors and output capacitors, and hence, a more compact design. However, lower switching frequency implies reduced switching losses and usually results in higher system efficiency, so the 500kHz switching frequency was chosen for this example, remove R10 and leave RT pin floating.

Please note the switching frequency is also limited by the following as mentioned in [Section 6.3.10](#):

- Minimum on time of the integrated power switch
- Input voltage

- Output voltage
- Frequency shift limitation

#### 7.2.2.4 Soft-Start Capacitor Selection

The large  $C_{SS}$  can reduce inrush current when driving large capacitive load. 33nF is chosen for C7, which sets the soft-start time,  $t_{SS}$ , to approximately 3.6ms.

#### 7.2.2.5 Output Inductor Selection

The most critical parameters for the inductor are the inductance, saturation current, and the RMS current. The inductance is based on the desired peak-to-peak ripple current,  $\Delta I_L$ , which can be calculated by [Equation 16](#).

$$\Delta I_L = \frac{V_{OUT}}{V_{IN\_MAX}} \times \frac{V_{IN\_MAX} - V_{OUT}}{L \times f_{SW}} \quad (16)$$

Usually, define K coefficient represents the amount of inductor ripple current relative to the maximum output current of the device, a reasonable value of K is 20% to 60%. Experience shows that the best value of K is 30% to approximately 40%. Because the ripple current increases with the input voltage, the maximum input voltage is always used to calculate the minimum inductance L. Use [Equation 17](#) to calculate the minimum value of the output inductor.

$$L = \frac{(V_{IN} - V_{OUT})}{K \times f_{SW} \times I_{OUT\_MAX}} \times \frac{V_{OUT}}{V_{IN}} \quad (17)$$

where

- K is the ripple ratio of the inductor current ( $\Delta I_L / I_{OUT\_MAX}$ ).

In general, choosing lower inductance in switching power supplies is preferable because this choice usually corresponds to faster transient response, smaller DCR, and reduced size for more compact designs. Too low of an inductance can generate too large of an inductor current ripple such that overcurrent protection at the full load can be falsely triggered. The device also generates more inductor core loss since the current ripple is larger. Larger inductor current ripple also implies larger output voltage ripple with the same output capacitors.

After inductance L is determined, the maximum inductor peak current and RMS current can be calculated by [Equation 18](#) and [Equation 19](#).

$$I_{L\_PEAK} = I_{OUT} + \frac{\Delta I_L}{2} \quad (18)$$

$$I_{L\_RMS} = \sqrt{I_{OUT}^2 + \frac{\Delta I_L^2}{12}} \quad (19)$$

Ideally, the saturation current rating of the inductor is at least as large as the high-side switch current limit,  $I_{HS\_LIMIT}$  (see [Section 5.5](#)). This size makes sure that the inductor does not saturate even during a short circuit on the output. When the inductor core material saturates, the inductance falls to a very low value, causing the inductor current to rise very rapidly. Although the valley current limit,  $I_{LS\_LIMIT}$ , is designed to reduce the risk of current runaway, a saturated inductor can cause the current to rise to high values very rapidly, this can lead to component damage, so do not allow the inductor to saturate. In any case, the inductor saturation current must not be less than the maximum peak inductor current at full load.

For this design example, choose the following values:

- K = 0.3
- $V_{IN\_MAX} = 28V$
- $f_{SW} = 500kHz$
- $I_{OUT\_MAX} = 5A$

The inductor value is calculated to be 5.3 $\mu$ H. Choose the nearest standard value of 5.6 $\mu$ H. The maximum  $I_{HS\_LIMIT}$  is 7A, the calculated peak current is 5.7A, and the calculated RMS current is 5.02A. The chosen

inductor is a Würth Elektronik, [74439346056](#), 5.6µH, which has a saturation current rating of 12.1A and a RMS current rating of 6.9A.

The maximum inductance is limited by the minimum current ripple required for the peak current mode control to perform correctly. To avoid subharmonic oscillation, the minimum inductor ripple current must be no less than approximately 10% of the device maximum rated current (5A) under nominal conditions.

### 7.2.2.6 Output Capacitor Selection

The device is designed to be used with a wide variety of LC filters, so using as little output capacitance as possible to keep cost and size down is desired. Choose the output capacitance,  $C_{OUT}$ , with care because the output capacitance directly affects the following specifications:

- Steady state output voltage ripple
- Loop stability
- Output voltage overshoot and undershoot during load current transient

The output voltage ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance (ESR) of the output capacitors:

$$\Delta V_{OUT\_ESR} = \Delta I_L \times ESR = K \times I_{OUT} \times ESR \quad (20)$$

The other is caused by the inductor current ripple charging and discharging the output capacitors:

$$\Delta V_{OUT\_C} = \frac{\Delta I_L}{8 \times f_{SW} \times C_{OUT}} = \frac{K \times I_{OUT}}{8 \times f_{SW} \times C_{OUT}} \quad (21)$$

where

- K is the ripple ratio of the inductor current ( $\Delta I_L / I_{OUT\_MAX}$ ).

The two components in the voltage ripple are not in phase, so the actual peak-to-peak ripple is smaller than the sum of the two peaks.

Output capacitance is usually limited by the load transient requirements rather than the output voltage ripple if the system requires tight voltage regulation with presence of large current steps and fast slew rate. When a large load step happens, output capacitors provide the required charge before the inductor current can slew up to the appropriate level. The control loop of the converter usually needs eight or more clock cycles to regulate the inductor current equal to the new load level. The output capacitance must be large enough to supply the current difference for about eight clock cycles to maintain the output voltage within the specified range. [Equation 22](#) shows the minimum output capacitance needed for specified  $V_{OUT}$  overshoot and undershoot.

$$C_{OUT} > \frac{1}{2} \times \frac{\Delta I_{OUT}}{\Delta V_{OUT\_SHOOT}} \left( \frac{6}{f_{SW}} - \frac{1}{SR_{\Delta I_{OUT}}} \right) \quad (22)$$

where

- D is  $V_{OUT} / V_{IN}$ , duty cycle of steady state.
- $\Delta V_{OUT\_SHOOT}$  is the output voltage change.
- $\Delta I_{OUT}$  is the output current change.
- $SR_{\Delta I_{OUT}}$  is the slew rate of output current change

For this design example, the target output ripple is 30mV. Presuppose  $\Delta V_{OUT\_ESR} = \Delta V_{OUT\_C} = 30\text{mV}$  and choose  $K = 0.3$ . [Equation 20](#) yields ESR no larger than 25mΩ and [Equation 21](#) yields  $C_{OUT}$  no smaller than 10µF. For the overshoot and undershoot limitation of this design,  $\Delta V_{OUT\_SHOOT} < 5\% \times V_{OUT} = 250\text{mV}$  for an output current step of  $\Delta I_{OUT} = 4\text{A}$  with  $SR_{\Delta I_{OUT}} = 0.8\text{A}/\mu\text{s}$ .  $C_{OUT}$  is calculated to be no smaller than 38µF by [Equation 22](#). In summary, the most stringent criterion for the output capacitor is 38µF. By considering the ceramic capacitor has DC bias derating, it can be achieved with a bank of  $2 \times 22\mu\text{F}$ , 35V, ceramic capacitor C3216X5R1V226M160AC in the 1206 case size.

More output capacitors can be used to improve the load transient response. Ceramic capacitors can easily meet the minimum ESR requirements. In some cases, an aluminum electrolytic capacitor can be placed in parallel with the ceramics to build up the required value of capacitance. When using a mixture of aluminum and ceramic capacitors, use the minimum recommended value of ceramics and add aluminum electrolytic capacitors as needed.

The recommendations given in [Table 7-2](#) provide typical values of output capacitance for the given conditions. Large values of output capacitance can adversely affect the start-up behavior of the converter as well as the loop stability. If values larger than noted here must be used, then a careful study of start-up at full load and loop stability must be performed.

In practice, the output capacitor has the most influence on the transient response and loop phase margin. Load transient testing and bode plots are the best way to validate any given design and must always be completed before the application goes into production. In addition to the required output capacitance, a small ceramic placed on the output can reduce high frequency noise. Small case size ceramic capacitors in the range of 1nF to 100nF can help reduce spikes on the output caused by inductor and board parasitics.

[Table 7-2](#) shows the recommended LC combination.

**Table 7-2. Recommended LC Combination for TPS54538**

V <sub>OUT</sub> (V)	f <sub>SW</sub> (kHz)	R <sub>TOP</sub> (kΩ)	R <sub>DOWN</sub> (kΩ)	Typical Inductor L (μH)	Typical C <sub>OUT</sub> (μF)
3.3	500	45	10.0	4.7	44
	1000			1.5	44
5	500	73.3	10.0	5.6	44
	1000			2.2	44
12	500	190	10.0	5.6	66

### 7.2.2.7 Input Capacitor Selection

The TPS54538 device requires an input decoupling capacitor and, depending on the application, a bulk input capacitor. The typical recommended value for the decoupling capacitor is 10μF, and TI recommends an additional 0.1μF capacitor from the VIN pin to ground to provide high frequency filtering.

The value of a ceramic capacitor varies significantly over temperature and the amount of DC bias applied to the capacitor. TI recommends X5R and X7R ceramic dielectrics because X5R and X7R ceramic dielectrics have a high capacitance-to-volume ratio and are fairly stable over temperature. The capacitor must also be selected with the DC bias taken into account. The effective capacitance value decreases as the DC bias increases.

The capacitor voltage rating needs to be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum input current ripple. The input ripple current can be calculated using [Equation 23](#).

$$I_{CIN\_RMS} = I_{OUT} \times \sqrt{\frac{V_{OUT}}{V_{IN\_MIN}} \times \frac{V_{IN\_MIN} - V_{OUT}}{V_{IN\_MIN}}} \quad (23)$$

For this example design, three Murata [GRM32ER7YA106KA12K](#) (10μF, 35V, 1210, X7R) capacitors have been selected. The effective capacitance under input voltage of 24V for each one is 6.16μF. The input capacitance value determines the input ripple voltage of the converter. The input voltage ripple can be calculated using [Equation 24](#). Using the design example values, I<sub>OUT\_MAX</sub> = 5A, C<sub>IN\_EFF</sub> = 3 × 6.16 = 18.48μF, and f<sub>SW</sub> = 500kHz, yields an input voltage ripple of 113mV and a RMS input ripple current of 2.03A.

$$\Delta V_{IN} = \frac{I_{OUT\_MAX} \times 0.25}{f_{SW} \times C_{IN}} + (I_{OUT\_MAX} \times R_{ESR\_MAX}) \quad (24)$$

where

- R<sub>ESR\_MAX</sub> is the maximum series resistance of the input capacitor, which is approximately 1mΩ of three capacitors in parallel.

### 7.2.2.8 Feedforward Capacitor C<sub>FF</sub> Selection

In some cases, a feedforward capacitor can be used across R<sub>F<sub>BT</sub></sub> to improve the load transient response or improve the loop phase margin. This is especially true when values of R<sub>F<sub>BT</sub></sub> > 100kΩ are used. Large values of R<sub>F<sub>BT</sub></sub> in combination with the parasitic capacitance at the FB pin can create a small signal pole that interferes with the loop stability. A C<sub>FF</sub> helps mitigate this effect. Use lower values to determine if any advantage is gained by the use of a C<sub>FF</sub> capacitor.

The [Optimizing Transient Response of Internally Compensated DC-DC Converters with Feedforward Capacitor application report](#) is helpful when experimenting with a feedforward capacitor.

For this example design, a 10pF capacitor C9 can be mounted to boost load transient performance.

### 7.2.2.9 Maximum Ambient Temperature

As with any power conversion device, the TPS54538 dissipates internal power while operating. The effect of this power dissipation is to raise the internal temperature of the converter above ambient. The internal die temperature (T<sub>J</sub>) is a function of the following:

- Ambient temperature
- Power loss
- Effective thermal resistance, R<sub>θJA</sub>, of the device
- PCB combination

The maximum internal die temperature must be limited to 150°C. This limit establishes a limit on the maximum device power dissipation and, therefore, the load current. [Equation 25](#) shows the relationships between the important parameters. It is easy to see that larger ambient temperatures (T<sub>A</sub>) and larger values of R<sub>θJA</sub> reduce the maximum available output current. The converter efficiency can be estimated by using the curves provided in this data sheet. Note that these curves include the power loss in the inductor. If the desired operating conditions cannot be found in one of the curves, then interpolation can be used to estimate the efficiency. Alternatively, the EVM can be adjusted to match the desired application requirements and the efficiency can be measured directly. The correct value of R<sub>θJA</sub> is more difficult to estimate. As stated in the [Semiconductor and IC Package Thermal Metrics application note](#), the value of R<sub>θJA</sub> given in the [Thermal Information](#) table is not valid for design purposes and must not be used to estimate the thermal performance of the application. The values reported in that table were measured under a specific set of conditions that are rarely obtained in an actual application. The data given for R<sub>θJC(bott)</sub> and Ψ<sub>JT</sub> can be useful when determining thermal performance. See the [Semiconductor and IC Package Thermal Metrics application note](#) for more information and the resources given at the end of this section.

$$I_{OUT\_MAX} = \frac{(T_J - T_A)}{R_{\theta JA}} \times \frac{\eta}{1 - \eta} \times \frac{1}{V_{OUT}} \quad (25)$$

where

- η is efficiency.

The effective R<sub>θJA</sub> is a critical parameter and depends on many factors such as the following:

- Power dissipation
- Air temperature and flow
- PCB area
- Copper heat-sink area
- Number of thermal vias under the package
- Adjacent component placement

### 7.2.3 Application Curves

$V_{IN} = 24V$ ,  $V_{OUT} = 5V$ ,  $L_1 = 5.6\mu H$ ,  $C_{OUT} = 44\mu F$ ,  $T_A = 25^\circ C$  (unless otherwise noted)

### 7.3 Best Design Practices

- Do not exceed the [Absolute Maximum Ratings](#).
- Do not exceed the [Recommended Operating Conditions](#).
- Do not exceed the [ESD Ratings](#).
- Do not allow the SS pin floating.
- Do not allow the output voltage to exceed the input voltage, nor go below ground.
- Do not use the value of  $R_{\theta JA}$  given in the [Thermal Information](#) table to design your application. See [Section 7.2.2.9](#).
- Follow all the guidelines and suggestions found in this data sheet before committing the design to production. TI application engineers are ready to help critique your design and PCB layout to help make your project a success.
- Use a 100nF capacitor connected directly to the VIN and GND pins of the device. See [Section 7.2.2.7](#) for details.

### 7.4 Power Supply Recommendations

The devices are designed to operate from an input voltage supply range between 3.8V and 30V. This input supply must be well regulated and compatible with the limits found in the [specifications](#) of this data sheet. In addition, the input supply must be capable of delivering the required input current to the loaded converter. The average input current can be estimated with [Equation 26](#).

$$I_{IN} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} \quad (26)$$

where

- $\eta$  is efficiency.

If the converter is connected to the input supply through long wires or PCB traces, special care is required to achieve good performance. The parasitic inductance and resistance of the input cables can have an adverse effect on the operation of the converter. The parasitic inductance, in combination with the low-ESR, ceramic input capacitors, can form an under-damped resonant circuit, resulting in overvoltage transients at the input to the converter. The parasitic resistance can cause the voltage at the VIN pin to dip whenever a load transient is applied to the output. If the application is operating close to the minimum input voltage, this dip can cause the converter to momentarily shutdown and reset. The best way to solve these kind of issues is to reduce the distance from the input supply to the converter and use an aluminum or tantalum input capacitor in parallel with the ceramics. The moderate ESR of these types of capacitors help damp the input resonant circuit and reduce any overshoots. A value in the range of 20 $\mu$ F to 100 $\mu$ F is usually sufficient to provide input damping and help hold the input voltage steady during large load transients.

TI recommends that the input supply must not be allowed to fall below the output voltage by more than 0.3V. Under such conditions, the output capacitors discharge through the body diode of the high-side power MOSFET. The resulting current can cause unpredictable behavior, and in extreme cases, possible device damage. If the application allows for this possibility, then use a Schottky diode from VIN to VOUT to provide a path around the converter for this current.

In some cases, a transient voltage suppressor (TVS) is used on the input of converters. One class of this device has a snap-back characteristic (thyristor type). The use of a device with this type of characteristic is not recommended. When the TVS fires, the clamping voltage falls to a very low value. If this voltage is less than the output voltage of the converter, the output capacitors discharge through the device, as mentioned above.

Sometimes, for other system considerations, an input filter is used in front of the converter, which can lead to instability as well as some of the effects mentioned above, unless designed carefully. The [AN-2162 Simple Success with Conducted EMI from DCDC Converters application note](#) provides helpful suggestions when designing an input filter for any switching converter.

## 7.5 Layout

### 7.5.1 Layout Guidelines

The PCB layout of any DC/DC converter is critical to the excellent performance of the design. Bad PCB layout can disrupt the operation of a good schematic design. Even if the converter regulates correctly, bad PCB layout can mean the difference between a robust design and one that cannot be mass produced. Furthermore, the EMI performance of the converter is dependent on the PCB layout to a great extent. In a buck converter, the most critical PCB feature is the loop formed by the input capacitors and power ground, as shown in [Figure 7-17](#). This loop carries large transient currents that can cause large transient voltages when reacting with the trace inductance. These unwanted transient voltages disrupt the proper operation of the converter. Because of this, the traces in this loop must be wide and short, and the loop area as small as possible to reduce the parasitic inductance.

TI recommends a 4-layer board with 2oz copper thickness of top and bottom layer, 1oz copper thickness of mid layer, and proper layout provides low current conduction impedance, proper shielding, and lower thermal resistance. [Figure 7-18](#) and [Figure 7-19](#) show the recommended layouts for the critical components of the TPS54538.

- Place the inductor, input and output capacitors, and the IC on the same layer.
- Place the input and output capacitors as close as possible to the IC. The VIN and GND traces must be as wide as possible and provide sufficient vias on them to minimize trace impedance. The wide areas are also of advantage from the view point of heat dissipation.
- Place a 0.1 $\mu$ F ceramic decoupling capacitor or capacitors as close as possible to VIN and GND pins, which is key to EMI reduction.
- Keep the SW trace as physically short and wide as practical to minimize radiated emissions.
- Place the feedback divider as close as possible to the FB pin. TI recommends a > 10-mil width trace for heat dissipation. Connect a separate V<sub>OUT</sub> trace to the upper feedback resistor. Place the voltage feedback loop away from the high-voltage switching trace. The voltage feedback loop preferably has ground shield.

- Place the SS capacitor resistor close to the IC and routed with minimal lengths of trace. TI recommends a > 10-mil width trace for heat dissipation.

## 8 Device and Documentation Support

### 8.1 Device Support

#### 8.1.1 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

#### 8.1.2 Development Support

##### 8.1.2.1 Custom Design With WEBENCH® Tools

Create a custom design with the TPS54538 using the [WEBENCH® Power Designer](#).

1. Start by entering the input voltage ( $V_{IN}$ ), output voltage ( $V_{OUT}$ ), and output current ( $I_{OUT}$ ) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at [www.ti.com/WEBENCH](http://www.ti.com/WEBENCH).

### 8.2 Documentation Support

#### 8.2.1 Related Documentation

For related documentation, see the following:

- Texas Instruments, [AN-2162 Simple Success with Conducted EMI from DCDC Converters application note](#)
- Texas Instruments, [Optimizing Transient Response of Internally Compensated DC-DC Converters with Feedforward Capacitor application note](#)

### 8.3 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](http://ti.com). Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

### 8.4 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

### 8.5 Trademarks

TI E2E™ is a trademark of Texas Instruments.

WEBENCH® is a registered trademark of Texas Instruments.

All trademarks are the property of their respective owners.

## 8.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## 8.7 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## 9 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

DATE	REVISION	NOTES
November 2024	*	Initial Release

## 10 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.
