

# TPS61088 10-A Fully-Integrated Synchronous Boost Converter

## 1 Features

- 2.7-V to 12-V input voltage range
- 4.5-V to 12.6-V output voltage range
- 10-A switch current
- Up to 91% efficiency at  $V_{IN} = 3.3\text{ V}$ ,  $V_{OUT} = 9\text{ V}$ , and  $I_{OUT} = 3\text{ A}$
- Mode selection between PFM mode and forced PWM mode at light load
- 1.0- $\mu\text{A}$  current into the VIN pin during shutdown
- Resistor-programmable switch peak current limit
- Adjustable switching frequency: 200 kHz to 2.2 MHz
- Programmable soft start
- Output overvoltage protection at 13.2 V
- Cycle-by-cycle overcurrent protection
- Thermal shutdown
- 4.50-mm  $\times$  3.50-mm 20-pin VQFN package
- Create a custom design using the TPS61088 with the [WEBENCH Power Designer](#)

## 2 Applications

- [Portable POS terminal](#)
- [Bluetooth™ speaker](#)
- [E-cigarette](#)
- [Thunderbolt interface](#)
- [Quick charge power bank](#)

## 3 Description

The TPS61088 is a high-power density, fully-integrated synchronous boost converter with a 11-m $\Omega$  power switch and a 13-m $\Omega$  rectifier switch to provide a high efficiency and small size solution in portable systems. The TPS61088 has a wide input voltage range from 2.7 V to 12 V to support applications with single-cell or two-cell Lithium batteries. The device has 10-A switch current capability and is capable of providing an output voltage up to 12.6 V.

The TPS61088 uses adaptive constant off-time peak current control topology to regulate the output voltage. In moderate to heavy load condition, the TPS61088 works in pulse width modulation (PWM) mode. In light load condition, the device has two operation modes selected by the MODE pin. One is the pulse frequency modulation (PFM) mode to improve the efficiency and another one is forced PWM mode to avoid application problems caused by low switching frequency. The switching frequency in PWM mode is adjustable, ranging from 200 kHz to 2.2 MHz by an external resistor. The TPS61088 also implements a programmable soft-start function and an adjustable switching peak current limit function. In addition, the device provides 13.2-V output overvoltage protection, cycle-by-cycle overcurrent protection, and thermal shutdown protection.

The TPS61088 is available in a 4.50-mm  $\times$  3.50-mm 20-pin VQFN package.

## 5 Pin Configuration and Functions

**Figure 5-1. 20-Pin VQFN With Thermal Pad RHL Package(Top View)**

**Table 5-1. Pin Functions**

PIN		I/O	DESCRIPTION
NAME	NUMBER		
VCC	1	O	Output of the internal regulator. A ceramic capacitor of more than 1.0 $\mu\text{F}$ is required between this pin and ground.
EN	2	I	Enable logic input. Logic high level enables the device. Logic low level disables the device and turns it into shutdown mode.
FSW	3	I	The switching frequency is programmed by a resistor between this pin and the SW pin.
SW	4, 5, 6, 7	I	The switching node pin of the converter. It is connected to the drain of the internal low-side power MOSFET and the source of the internal high-side power MOSFET.
BOOT	8	O	Power supply for high-side MOSFET gate driver. A ceramic capacitor of 0.1 $\mu\text{F}$ must be connected between this pin and the SW pin.
VIN	9	I	IC power supply input
SS	10	O	Soft-start programming pin. An external capacitor sets the ramp rate of the reference voltage of the internal error amplifier during soft start.
NC	11, 12	—	No connection inside the device. Connect these two pins to the ground plane on the PCB for good thermal dissipation.
MODE	13	I	Operation mode selection pin for the device in light load condition. When this pin is connected to ground, the device works in PWM mode. When this pin is left floating, the device works in PFM mode.
VOUT	14, 15, 16	O	Boost converter output
FB	17	I	Voltage feedback. Connect to the center tape of a resistor divider to program the output voltage.
COMP	18	O	Output of the internal error amplifier, the loop compensation network must be connected between this pin and the AGND pin.
ILIM	19	O	Adjustable switch peak current limit. An external resistor must be connected between this pin and the AGND pin.
AGND	20	—	Signal ground of the IC
PGND	21	—	Power ground of the IC. It is connected to the source of the low-side MOSFET.

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature (unless otherwise noted) <sup>(1)</sup>

		MIN	MAX	UNIT
Voltage <sup>(2)</sup>	BOOT	-0.3	SW + 7	V
	VIN, SW, FSW, VOUT	-0.3	14.5	
	EN, VCC, SS, COMP, MODE	-0.3	7	
	ILIM, FB	-0.3	3.6	
T <sub>J</sub>	Operating junction temperature	-40	150	°C
T <sub>stg</sub>	Storage temperature	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to network ground terminal.

### 6.2 ESD Ratings

			VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	±2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins <sup>(2)</sup>	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V <sub>IN</sub>	Input voltage range	2.7		12	V
V <sub>OUT</sub>	Output voltage range	4.5		12.6	V
L	Inductance, effective value	0.47	2.2	10	μH
C <sub>i</sub>	Input capacitance, effective value	10			μF
C <sub>O</sub>	Output capacitance, effective value	6.8	47	1000	μF
T <sub>J</sub>	Operating junction temperature	-40		125	°C

## 7 Detailed Description

### 7.1 Overview

The TPS61088 is a fully-integrated synchronous boost converter with a 11-m $\Omega$  power switch and a 13-m $\Omega$  rectifier switch to output high power from a single-cell or two-cell Lithium batteries. The device is capable of providing an output voltage of 12.6 V and delivering up to 30-W power from a single-cell Lithium battery.

The TPS61088 uses adaptive constant off-time peak current control topology to regulate the output voltage. In moderate-to-heavy load condition, the TPS61088 works in the quasi-constant frequency pulse width modulation (PWM) mode. The switching frequency in PWM mode is adjustable ranging from 200 kHz to 2.2 MHz by an external resistor. In light load condition, the device has two operation modes selected by the MODE pin. When the MODE pin is left floating, the TPS61088 works in pulse frequency modulation (PFM) mode. The PFM mode brings high efficiency at the light load. When the MODE pin is short to ground, the TPS61088 works in forced PWM mode (FPWM). The FPWM mode can avoid the acoustic noise and other problems caused by the low switching frequency. The TPS61088 implements cycle-by-cycle current limit to protect the device from overload conditions during boost switching. The switch peak current limit is programmable by an external resistor. The TPS61088 uses external loop compensation, which provides flexibility to use different inductors and output capacitors. The adaptive off-time peak current control scheme gives excellent transient line and load response with minimal output capacitance.

## 7.2 Functional Block Diagram

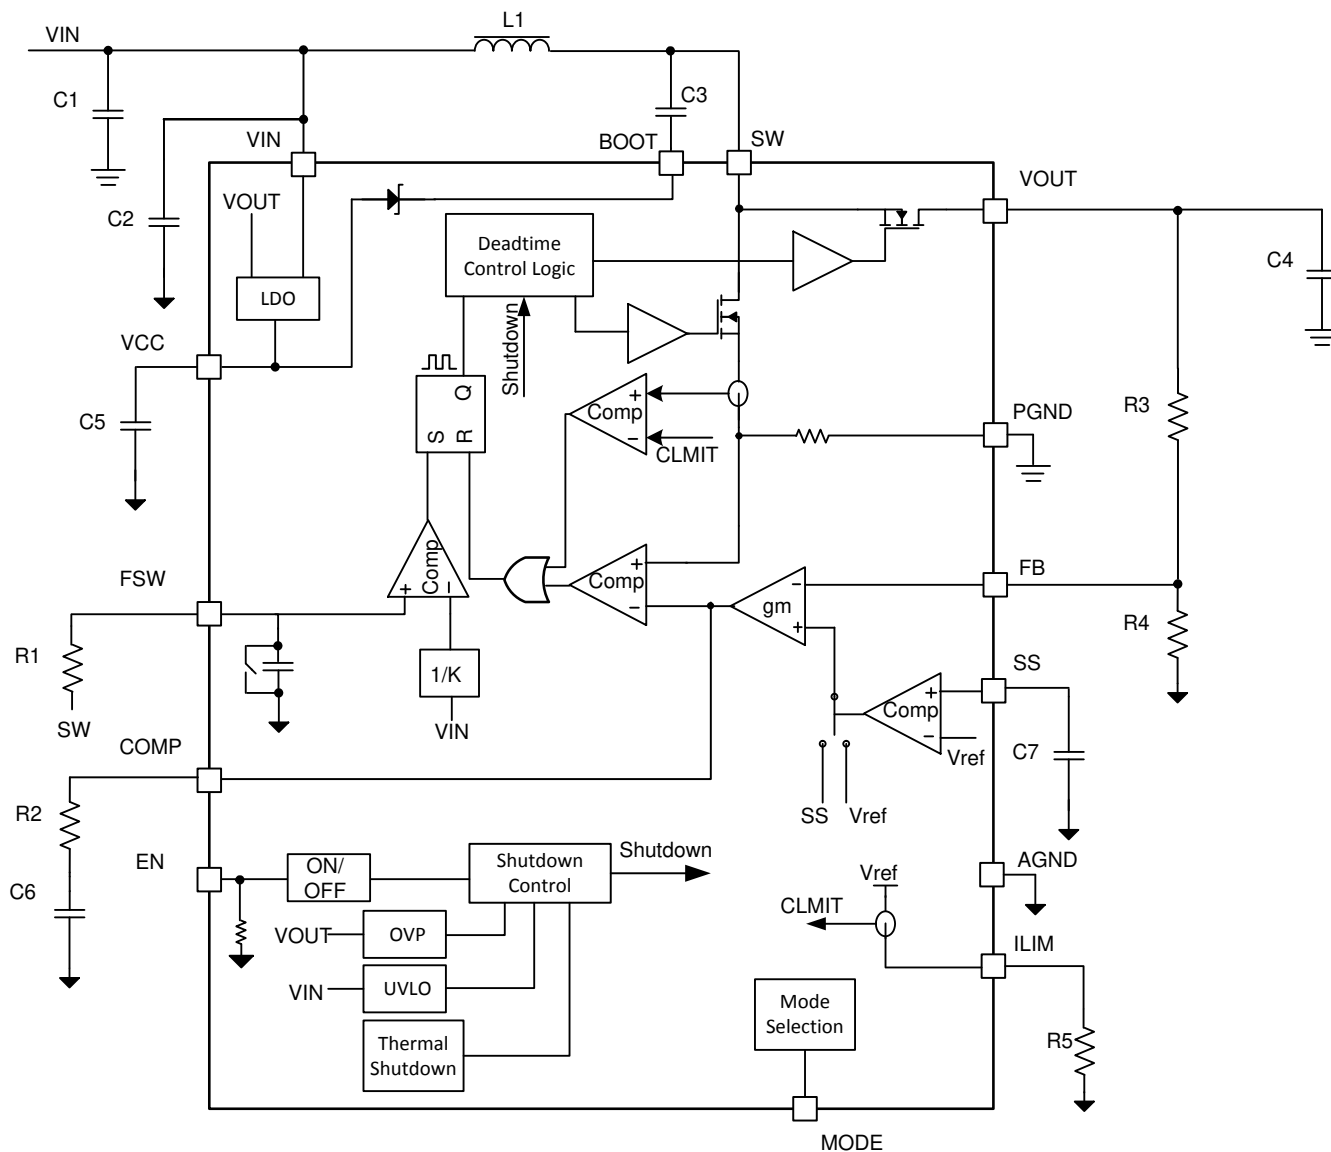

Figure 7-1. Functional Block Diagram

## 7.3 Feature Description

### 7.3.1 Enable and Start-up

The TPS61088 has an adjustable soft start function to prevent high inrush current during start-up. To minimize the inrush current during start-up, an external capacitor, connected to the SS pin and charged with a constant current, is used to slowly ramp up the internal positive input of the error amplifier. When the EN pin is pulled high, the soft-start capacitor  $C_{SS}$  (C7 in Figure 8-1) is charged with a constant current of 5  $\mu$ A typically. During this time, the SS pin voltage is compared with the internal reference (1.204 V), the lower one is fed into the internal positive input of the error amplifier. The output of the error amplifier (which determines the inductor peak current value) ramps up slowly as the SS pin voltage goes up. The soft-start phase is completed after the SS pin voltage exceeds the internal reference (1.204 V). The larger the capacitance at the SS pin, the slower the ramp of the output voltage and the longer the soft-start time. A 47-nF capacitor is usually sufficient for most applications. When the EN pin is pulled low, the voltage of the soft-start capacitor is discharged to ground.

Use Equation 1 to calculate the soft-start time.

$$t_{SS} = \frac{V_{REF} \times C_{SS}}{I_{SS}} \quad (1)$$

where

- $t_{SS}$  is the soft start time
- $V_{REF}$  is the internal reference voltage of 1.204 V
- $C_{SS}$  is the capacitance between the SS pin and ground
- $I_{SS}$  is the soft-start charging current of 5  $\mu$ A

### 7.3.2 Undervoltage Lockout (UVLO)

The UVLO circuit prevents the device from malfunctioning at low input voltage and the battery from excessive discharge. The TPS61088 has both VIN UVLO function and VCC UVLO function. It disables the device from switching when the falling voltage at the VIN pin trips the UVLO threshold  $V_{IN\_UVLO}$ , which is typically 2.4 V. The device starts operating when the rising voltage at the VIN pin is 200 mV above  $V_{IN\_UVLO}$ . It also disables the device when the falling voltage at the VCC pin trips the UVLO threshold  $V_{CC\_UVLO}$ , which is typically 2.1 V.

### 7.3.3 Adjustable Switching Frequency

This device features a wide adjustable switching frequency ranging from 200 kHz to 2.2 MHz. The switching frequency is set by a resistor connected between the FSW pin and the SW pin of the TPS61088. A resistor must always be connected from the FSW pin to SW pin for proper operation. The resistor value required for a desired frequency can be calculated using [Equation 2](#).

$$R_{FREQ} = \frac{4 \times \left( \frac{1}{f_{SW}} - t_{DELAY} \times \frac{V_{OUT}}{V_{IN}} \right)}{C_{FREQ}} \quad (2)$$

where

- $R_{FREQ}$  is the resistance connected between the FSW pin and the SW pin
- $C_{FREQ}$  is 23 pF
- $f_{SW}$  is the desired switching frequency
- $t_{DELAY}$  is 89 ns
- $V_{IN}$  is the input voltage
- $V_{OUT}$  is the output voltage

### 7.3.4 Adjustable Peak Current Limit

To avoid an accidental large peak current, an internal cycle-by-cycle current limit is adopted. The low-side switch is turned off immediately as soon as the switch current touches the limit. The peak switch current limit can be set by a resistor at the ILIM pin to ground. The relationship between the current limit and the resistance depends on the status of the MODE pin.

When the MODE pin is floating, namely the TPS61088, is set to work in the PFM mode at light load, use [Equation 3](#) to calculate the resistor value:

$$I_{LIM} = \frac{1190000}{R_{ILIM}} \quad (3)$$

where

- $R_{ILIM}$  is the resistance between the ILIM pin and ground
- $I_{LIM}$  is the switch peak current limit

When the resistor value is 100 k $\Omega$ , the typical current limit is 11.9 A.

When the MODE pin is connected to ground, namely the TPS61088 is set to work in forced PWM mode at light load, use [Equation 4](#) to calculate the resistor value.

$$I_{LIM} = \frac{1190000}{R_{LIM}} - 1.6 \quad (4)$$

When the resistor value is 100 k $\Omega$ , the typical current limit is 10.3 A.

Considering the device variation and the tolerance over temperature, the minimum current limit at the worst case can be 1.3 A lower than the value calculated by above equations.

### 7.3.5 Overvoltage Protection

If the output voltage at the VOUT pin is detected above 13.2 V (typical value), the TPS61088 stops switching immediately until the voltage at the VOUT pin drops the hysteresis value lower than the output overvoltage protection threshold. This function prevents overvoltage on the output and secures the circuits connected to the output from excessive overvoltage.

### 7.3.6 Thermal Shutdown

A thermal shutdown is implemented to prevent damages due to excessive heat and power dissipation. Typically, the thermal shutdown happens at a junction temperature of 150°C. When the thermal shutdown is triggered, the device stops switching until the junction temperature falls below typically 130°C, then the device starts switching again.

## 7.4 Device Functional Modes

### 7.4.1 Operation

The synchronous boost converter TPS61088 operates at a quasi-constant frequency pulse width modulation (PWM) in moderate-to-heavy load condition. Based on the  $V_{IN}$  to  $V_{OUT}$  ratio, a circuit predicts the required off-time of the switching cycle. At the beginning of each switching cycle, the low-side N-MOSFET switch, as shown in [Section 7.2](#), is turned on, and the inductor current ramps up to a peak current that is determined by the output of the internal error amplifier. After the peak current is reached, the current comparator trips. It turns off the low-side N-MOSFET switch and the inductor current goes through the body diode of the high-side N-MOSFET in a dead-time duration. After the dead-time duration, the high-side N-MOSFET switch is turned on. Since the output voltage is higher than the input voltage, the inductor current decreases. The high-side switch is not turned off until the fixed off-time is reached. After a short dead-time duration, the low-side switch turns on again and the switching cycle is repeated.

In light load condition, the TPS61088 implements two operation modes, PFM mode and forced PWM mode, to meet different application requirements. The operation mode is set by the status of the MODE pin. When the MODE pin is connected to ground, the device works in forced PWM mode. When the MODE pin is left floating, the device works in PFM mode.

#### 7.4.1.1 PWM Mode

In forced PWM mode, the TPS61088 keeps the switching frequency unchanged in light load condition. When the load current decreases, the output of the internal error amplifier decreases as well to keep the inductor peak current down, delivering less power from input to output. When the output current further reduces, the current through the inductor decreases to zero during the off-time. The high-side N-MOSFET is not turned off even if the current through the MOSFET is zero. Thus, the inductor current changes its direction after it runs to zero. The power flow is from output side to input side. The efficiency is low in this mode. But with the fixed switching frequency, there is no audible noise and other problems which might be caused by low switching frequency in light load condition.

#### 7.4.1.2 PFM Mode

The TPS61088 improves the efficiency at light load with PFM mode. When the converter operates in light load condition, the output of the internal error amplifier decreases to make the inductor peak current down, delivering less power to the load. When the output current further reduces, the current through the inductor decrease to zero during the off-time. Once the current through the high side N-MOSFET is zero, the high-side MOSFET is turned off until the beginning of the next switching cycle. When the output of the error amplifier continuously goes down and reaches a threshold with respect to the peak current of  $I_{LIM} / 12$ , the output of the error amplifier

is clamped at this value and does not decrease any more. If the load current is smaller than what the TPS61088 delivers, the output voltage increases above the nominal setting output voltage. The TPS61088 extends its off-time of the switching period to deliver less energy to the output and regulate the output voltage to 0.7% higher than the nominal setting voltage. With PFM operation mode, the TPS61088 keeps the efficiency above 80% even when the load current decreases to 1 mA. In addition, the output voltage ripple is much smaller at light load due to low peak current. Refer to [Figure 7-2](#).

**Figure 7-2. PFM Mode Diagram**

## 8 Application and Implementation

### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

### 8.1 Application Information

The TPS61088 is designed for outputting voltage up to 12.6 V with 10-A switch current capability to deliver more than 30-W power. The TPS61088 operates at a quasi-constant frequency pulse-width modulation (PWM) in moderate-to-heavy load condition. In light load condition, the converter can either operate in PFM mode or in forced PWM mode according to the mode selection. The PFM mode brings high efficiency over entire load range, but PWM mode can avoid the acoustic noise as the switching frequency is fixed. The converter uses the adaptive constant off-time peak current control scheme, which provides excellent transient line and load response with minimal output capacitance. The TPS61088 can work with different inductor and output capacitor combination by external loop compensation. It also supports adjustable switching frequency ranging from 200 kHz to 2.2 MHz.

### 8.2 Typical Application

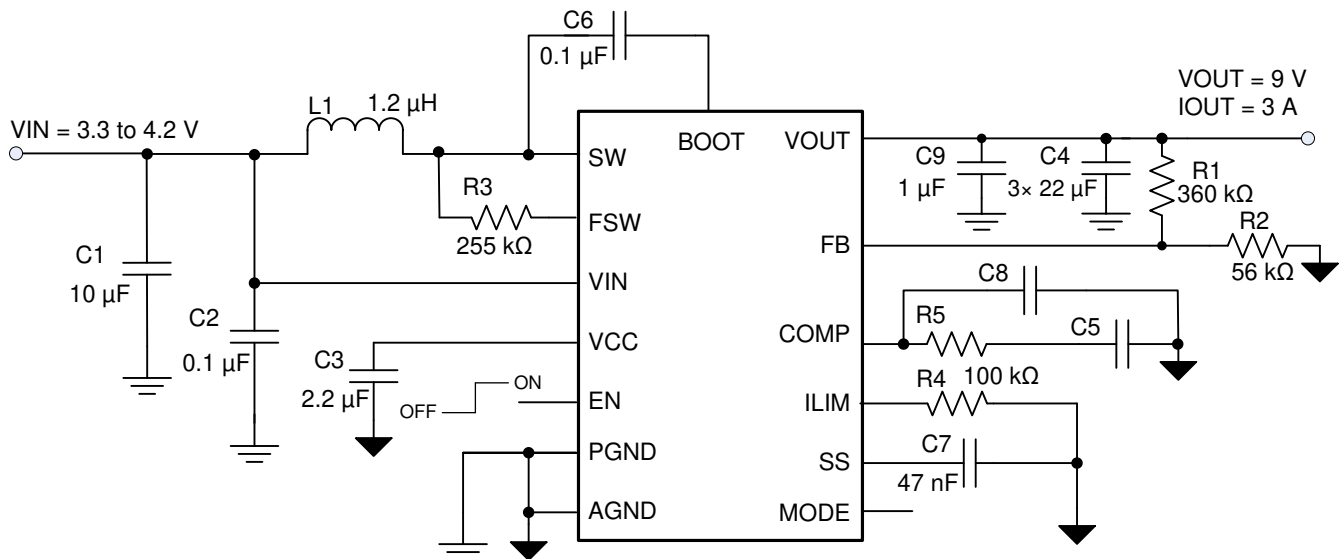

Figure 8-1. TPS61088 3.3 V to 9-V/3-A Output Converter

#### 8.2.1 Design Requirements

Table 8-1. Design Parameters

DESIGN PARAMETERS	EXAMPLE VALUES
Input voltage range	3.3 to 4.2 V
Output voltage	9 V
Output voltage ripple	100 mV peak to peak
Output current rating	3 A
Operating frequency	600 kHz
Operation mode at light load	PFM

## 8.2.2 Detailed Design Procedure

### 8.2.2.1 Custom Design with WEBENCH Tools

[Click here](#) to create a custom design using the TPS61088 device with the WEBENCH® Power Designer.

1. Start by entering your  $V_{IN}$ ,  $V_{OUT}$  and  $I_{OUT}$  requirements.
2. Optimize your design for key parameters like efficiency, footprint and cost using the optimizer dial and compare this design with other possible solutions from Texas Instruments.
3. WEBENCH Power Designer provides you with a customized schematic along with a list of materials with real time pricing and component availability.
4. In most cases, you will also be able to:
  - Run electrical simulations to see important waveforms and circuit performance,
  - Run thermal simulations to understand the thermal performance of your board,
  - Export your customized schematic and layout into popular CAD formats,
  - Print PDF reports for the design, and share your design with colleagues.
5. Get more information about WEBENCH tools at [www.ti.com/webench](http://www.ti.com/webench).

### 8.2.2.2 Setting Switching Frequency

The switching frequency is set by a resistor connected between the FSW pin and the SW pin of the TPS61088. The resistor value required for a desired frequency can be calculated using [Equation 5](#).

$$R_{FREQ} = \frac{4 \times \left( \frac{1}{f_{SW}} - t_{DELAY} \times \frac{V_{OUT}}{V_{IN}} \right)}{C_{FREQ}} \quad (5)$$

where

- $R_{FREQ}$  is the resistance connected between the FSW pin and the SW pin
- $C_{FREQ}$  is 23 pF
- $f_{SW}$  is the desired switching frequency
- $t_{DELAY}$  is 89 ns
- $V_{IN}$  is the input voltage
- $V_{OUT}$  is the output voltage

### 8.2.2.3 Setting Peak Current Limit

The peak input current is set by selecting the correct external resistor value correlating to the required current limit. Since the TPS61088 is configured to work in PFM mode in light load condition, use [Equation 6](#) to calculate the correct resistor value:

$$I_{LIM} = \frac{1190000}{R_{ILIM}} \quad (6)$$

where

- $R_{ILIM}$  is the resistance connected between the ILIM pin and ground
- $I_{LIM}$  is the switching peak current limit

For a typical current limit of 11.9 A, the resistor value is 100 kΩ. Considering the device variation and the tolerance over temperature, the minimum current limit at the worst case can be 1.3 A lower than the value calculated by [Equation 6](#). The minimum current limit must be higher than the required peak switch current at the lowest input voltage and the highest output power to make sure the TPS61088 does not hit the current limit and can still regulate the output voltage in these conditions.

### 8.2.2.4 Setting Output Voltage

The output voltage is set by an external resistor divider ( $R_1$ ,  $R_2$  in [Figure 8-1](#)). Typically, a minimum current of 20 μA flowing through the feedback divider gives good accuracy and noise covering. A standard 56-kΩ resistor is typically selected for low-side resistor  $R_2$ .

The value of R1 is then calculated as:

$$R_1 = \frac{(V_{OUT} - V_{REF}) \times R_2}{V_{REF}} \quad (7)$$

### 8.2.2.5 Inductor Selection

Because the selection of the inductor affects the steady state operation of the power supply, transient behavior, loop stability, and boost converter efficiency, the inductor is the most important component in switching power regulator design. Three most important specifications to the performance of the inductor are the inductor value, DC resistance, and saturation current.

The TPS61088 is designed to work with inductor values between 0.47 and 10  $\mu$ H. A 0.47- $\mu$ H inductor is typically available in a smaller or lower-profile package, while a 10- $\mu$ H inductor produces lower inductor current ripple. If the boost output current is limited by the peak current protection of the IC, using a 10- $\mu$ H inductor can maximize the output current capability of the controller.

Inductor values can have  $\pm 20\%$  or even  $\pm 30\%$  tolerance with no current bias. When the inductor current approaches saturation level, its inductance can decrease 20% to 35% from the value at 0-A current depending on how the inductor vendor defines saturation. When selecting an inductor, make sure its rated current, especially the saturation current, is larger than its peak current during the operation.

Follow [Equation 8](#) to [Equation 10](#) to calculate the peak current of the inductor. To calculate the current in the worst case, use the minimum input voltage, maximum output voltage, and maximum load current of the application. To leave enough design margin, TI recommends using the minimum switching frequency, the inductor value with  $-30\%$  tolerance, and a low-power conversion efficiency for the calculation.

In a boost regulator, calculate the inductor DC current as in [Equation 8](#).

$$I_{DC} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} \quad (8)$$

where

- $V_{OUT}$  is the output voltage of the boost regulator
- $I_{OUT}$  is the output current of the boost regulator
- $V_{IN}$  is the input voltage of the boost regulator
- $\eta$  is the power conversion efficiency

Calculate the inductor current peak-to-peak ripple as in [Equation 9](#).

$$I_{PP} = \frac{1}{L \times \left( \frac{1}{V_{OUT} - V_{IN}} + \frac{1}{V_{IN}} \right) \times f_{SW}} \quad (9)$$

where

- $I_{PP}$  is the inductor peak-to-peak ripple
- $L$  is the inductor value
- $f_{SW}$  is the switching frequency
- $V_{OUT}$  is the output voltage
- $V_{IN}$  is the input voltage

Therefore, the peak current,  $I_{Lpeak}$ , seen by the inductor is calculated with [Equation 10](#).

$$I_{Lpeak} = I_{DC} + \frac{I_{PP}}{2} \quad (10)$$

Set the current limit of the TPS61088 higher than the peak current  $I_{L,peak}$ . Then select the inductor with saturation current higher than the setting current limit.

Boost converter efficiency is dependent on the resistance of its current path, the switching loss associated with the switching MOSFETs, and the core loss of the inductor. The TPS61088 has optimized the internal switch resistance. However, the overall efficiency is affected significantly by the DC resistance (DCR) of the inductor, equivalent series resistance (ESR) at the switching frequency, and the core loss. Core loss is related to the core material and different inductors have different core loss. For a certain inductor, larger current ripple generates higher DCR and ESR conduction losses and higher core loss. Usually, a data sheet of an inductor does not provide the ESR and core loss information. If needed, consult the inductor vendor for detailed information. Generally, TI would recommend an inductor with lower DCR and ESR. However, there is a tradeoff among the inductance of the inductor, DCR and ESR resistance, and its footprint. Furthermore, shielded inductors typically have higher DCR than unshielded inductors. [Table 8-2](#) lists recommended inductors for the TPS61088. Verify whether the recommended inductor can support your target application with the previous calculations and bench evaluation. In this application, the Sumida's inductor CDMC8D28NP-1R2MC is selected for its small size and low DCR.

**Table 8-2. Recommended Inductors**

PART NUMBER	L (μH)	DCR MAX (mΩ)	SATURATION CURRENT / HEAT RATING CURRENT (A)	SIZE MAX (L × W × H mm)	VENDOR
CDMC8D28NP-1R2MC	1.2	7.0	12.2 / 12.9	9.5 × 8.7 × 3.0	Sumida
744311150	1.5	7.2	14.0 / 11.0	7.3 × 7.2 × 4.0	Würth
PIMB104T-2R2MS	2.2	7.0	18 / 12	11.2 × 10.3 × 4.0	Cyntec
PIMB103T-2R2MS	2.2	9.0	16 / 13	11.2 × 10.3 × 3.0	Cyntec
PIMB065T-2R2MS	2.2	12.5	12 / 10.5	7.4 × 6.8 × 5.0	Cyntec

### 8.2.2.6 Input Capacitor Selection

For good input voltage filtering, TI recommends low-ESR ceramic capacitors. The VIN pin is the power supply for the TPS61088. A 0.1-μF ceramic bypass capacitor is recommended as close as possible to the VIN pin of the TPS61088. The VCC pin is the output of the internal LDO. A ceramic capacitor of more than 1.0 μF is required at the VCC pin to get a stable operation of the LDO.

For the power stage, because of the inductor current ripple, the input voltage changes if there is parasite inductance and resistance between the power supply and the inductor. It is recommended to have enough input capacitance to make the input voltage ripple less than 100mV. Generally, 10-μF input capacitance is sufficient for most applications.

#### Note

DC bias effect: High-capacitance ceramic capacitors have a DC bias effect, which has a strong influence on the final effective capacitance. Therefore, the right capacitor value must be chosen carefully. The differences between the rated capacitor value and the effective capacitance result from package size and voltage rating in combination with material. A 10-V rated 0805 capacitor with 10 μF can have an effective capacitance of less 5 μF at an output voltage of 5 V.

### 8.2.2.7 Output Capacitor Selection

For small output voltage ripple, TI recommends a low-ESR output capacitor like a ceramic capacitor. Typically, three 22-μF ceramic output capacitors work for most applications. Higher capacitor values can be used to improve the load transient response. Take care when evaluating the derating of a capacitor under DC bias. The bias can significantly reduce capacitance. Ceramic capacitors can lose most of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance. From the required output voltage ripple, use the following equations to calculate the minimum required effective capacitance  $C_{OUT}$ :

$$V_{\text{ripple\_dis}} = \frac{(V_{\text{OUT}} - V_{\text{IN\_MIN}}) \times I_{\text{OUT}}}{V_{\text{OUT}} \times f_{\text{SW}} \times C_{\text{OUT}}} \quad (11)$$

$$V_{\text{ripple\_ESR}} = I_{\text{Lpeak}} \times R_{\text{C\_ESR}} \quad (12)$$

where

- $V_{\text{ripple\_dis}}$  is output voltage ripple caused by charging and discharging of the output capacitor
- $V_{\text{ripple\_ESR}}$  is output voltage ripple caused by ESR of the output capacitor
- $V_{\text{IN\_MIN}}$  is the minimum input voltage of boost converter
- $V_{\text{OUT}}$  is the output voltage
- $I_{\text{OUT}}$  is the output current
- $I_{\text{Lpeak}}$  is the peak current of the inductor
- $f_{\text{SW}}$  is the converter switching frequency
- $R_{\text{C\_ESR}}$  is the ESR of the output capacitors

### 8.2.2.8 Loop Stability

The TPS61088 requires external compensation, which allows the loop response to be optimized for each application. The COMP pin is the output of the internal error amplifier. An external compensation network comprised of resistor R5, ceramic capacitors C5 and C8 is connected to the COMP pin.

The power stage small signal loop response of constant off-time (COT) with peak current control can be modeled by [Equation 13](#).

$$G_{\text{PS}}(S) = \frac{R_{\text{O}} \times (1 - D)}{2 \times R_{\text{sense}}} \times \frac{\left(1 + \frac{S}{2 \times \pi \times f_{\text{ESRZ}}}\right) \left(1 - \frac{S}{2 \times \pi \times f_{\text{RHPZ}}}\right)}{1 + \frac{S}{2 \times \pi \times f_{\text{P}}}} \quad (13)$$

where

- D is the switching duty cycle
- $R_{\text{O}}$  is the output load resistance
- $R_{\text{sense}}$  is the equivalent internal current sense resistor, which is 0.08  $\Omega$

$$f_{\text{P}} = \frac{2}{2\pi \times R_{\text{O}} \times C_{\text{O}}} \quad (14)$$

where

- $C_{\text{O}}$  is output capacitor

$$f_{\text{ESRZ}} = \frac{1}{2\pi \times R_{\text{ESR}} \times C_{\text{O}}} \quad (15)$$

where

- $R_{\text{ESR}}$  is the equivalent series resistance of the output capacitor

$$f_{\text{RHPZ}} = \frac{R_{\text{O}} \times (1 - D)^2}{2\pi \times L} \quad (16)$$

The COMP pin is the output of the internal transconductance amplifier. [Equation 17](#) shows the small signal transfer function of compensation network.

$$G_C(S) = \frac{G_{EA} \times R_{EA} \times V_{REF}}{V_{OUT}} \times \frac{\left(1 + \frac{S}{2 \times \pi \times f_{COMZ}}\right)}{\left(1 + \frac{S}{2 \times \pi \times f_{COMP1}}\right) \left(1 + \frac{S}{2 \times \pi \times f_{COMP2}}\right)} \quad (17)$$

where

- $G_{EA}$  is the transconductance of the amplifier
- $R_{EA}$  is the output resistance of the amplifier
- $V_{REF}$  is the reference voltage at the FB pin
- $V_{OUT}$  is the output voltage
- $f_{COMP1}$ ,  $f_{COMP2}$  are the poles' frequency of the compensation network
- $f_{COMZ}$  is the zero's frequency of the compensation network

The next step is to choose the loop crossover frequency,  $f_C$ . The higher in frequency that the loop gain stays above zero before crossing over, the faster the loop response is. It is generally accepted that the loop gain cross over no higher than the lower of either 1/10 of the switching frequency,  $f_{SW}$ , or 1/5 of the RHPZ frequency,  $f_{RHPZ}$ .

Then set the value of R5, C5, and C8 (in [Figure 8-1](#)) by following these equations.

$$R5 = \frac{2\pi \times V_{OUT} \times R_{sense} \times f_C \times C_O}{(1 - D) \times V_{REF} \times G_{EA}} \quad (18)$$

where

- $f_C$  is the selected crossover frequency

The value of C5 can be set by [Equation 19](#).

$$C5 = \frac{R_O \times C_O}{2R5} \quad (19)$$

The value of C8 can be set by [Equation 20](#).

$$C8 = \frac{R_{ESR} \times C_O}{R5} \quad (20)$$

If the calculated value of C8 is less than 10 pF, it can be left open.

Designing the loop for greater than 45° of phase margin and greater than 10-dB gain margin eliminates output voltage ringing during the line and load transient.

### 8.2.3 Application Curves

## 9 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 2.7 V to 12 V. This input supply must be well regulated. If the input supply is located more than a few inches from the converter, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. A typical choice is an electrolytic or tantalum capacitor with a value of 47  $\mu$ F.

## 10 Layout

### 10.1 Layout Guidelines

As for all switching power supplies, especially those running at high switching frequency and high currents, layout is an important design step. If layout is not carefully done, the regulator could suffer from instability and noise problems. To maximize efficiency, switch rise and fall times are very fast. To prevent radiation of high-frequency noise (for example, EMI), proper layout of the high-frequency switching path is essential. Minimize the length and area of all traces connected to the SW pin, and always use a ground plane under the switching regulator to minimize interplane coupling.

The input capacitor needs to be close to the VIN pin and GND pin in order to reduce the  $I_{input}$  supply ripple.

The layout should also be done with well consideration of the thermal as this is a high power density device. A thermal pad that improves the thermal capabilities of the package should be soldered to the large ground plate, using thermal vias underneath the thermal pad.

### 10.2 Layout Example

The bottom layer is a large ground plane connected to the PGND plane and AGND plane on top layer by vias.

Figure 10-1. Bottom Layer

### 10.3 Thermal Considerations

The maximum IC junction temperature should be restricted to 125°C under normal operating conditions. Calculate the maximum allowable dissipation,  $P_{D(max)}$ , and keep the actual power dissipation less than or equal to  $P_{D(max)}$ . The maximum-power-dissipation limit is determined using [Equation 21](#).

$$P_{D(max)} = \frac{125 - T_A}{R_{\theta JA}} \quad (21)$$

where

- $T_A$  is the maximum ambient temperature for the application.
- $R_{\theta JA}$  is the junction-to-ambient thermal resistance given in the *Thermal Information* table.

The TPS61088 comes in a thermally-enhanced VQFN package. This package includes a thermal pad that improves the thermal capabilities of the package. The real junction-to-ambient thermal resistance of the package greatly depends on the PCB type, layout, and thermal pad connection. Using thick PCB copper and soldering the thermal pad to a large ground plate enhance the thermal performance. Using more vias connects the ground plate on the top layer and bottom layer around the IC without solder mask also improves the thermal capability.

## 11 Device and Documentation Support

### 11.1 Device Support

#### 11.1.1 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

#### 11.1.2 Development Support

##### 11.1.2.1 Custom Design with WEBENCH Tools

[Click here](#) to create a custom design using the TPS61088 device with the WEBENCH® Power Designer.

1. Start by entering your  $V_{IN}$ ,  $V_{OUT}$  and  $I_{OUT}$  requirements.
2. Optimize your design for key parameters like efficiency, footprint and cost using the optimizer dial and compare this design with other possible solutions from Texas Instruments.
3. WEBENCH Power Designer provides you with a customized schematic along with a list of materials with real time pricing and component availability.
4. In most cases, you will also be able to:
  - Run electrical simulations to see important waveforms and circuit performance,
  - Run thermal simulations to understand the thermal performance of your board,
  - Export your customized schematic and layout into popular CAD formats,
  - Print PDF reports for the design, and share your design with colleagues.
5. Get more information about WEBENCH tools at [www.ti.com/webench](http://www.ti.com/webench).

#### 11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](http://ti.com). Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

#### 11.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

#### 11.4 Trademarks

Bluetooth™ is a trademark of Bluetooth SIG.

TI E2E™ is a trademark of Texas Instruments.

WEBENCH® are registered trademarks of Texas Instruments.

All trademarks are the property of their respective owners.

#### 11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

#### 11.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## 12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

**PACKAGING INFORMATION**

Orderable part number	Status (1)	Material type (2)	Package   Pins	Package qty   Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)

TPS61088RHILT.A	Active	Production	VQFN (RHL)   20	250   SMALL T&R	Yes	NIPDAU	Level-1-260C-UNLIM	-40 to 125	S61088A

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
