Some register settings in the PHY are both chip select based and frequency based. For them, the PHY_PER_CS_TRAINING_INDEX_0/1/2/3 bits and the DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX field apply to the register access. The DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN bit applies as well. Table 8-19 shows the chip select based and frequency based register settings.

8.2.3.7.8 Low-Power Modes

The DDR PHY provides a means to reduce the operational power when it is not actively transferring read or write data for an extended periond of time. This is done using the DFI low power interface. Using this interface, the DDR controller communicates to the PHY that it may enter its own low-power state and informs the PHY how quickly it requires the PHY to recover if a low-power state is entered. This DDR PHY has the following power modes:

- **Idle**: This is a period in which no read or write activity is being performed by the DDR controller. The PHY is not in any low power state, and is ready to accept commands at any time.
- **Read/Write**: This describes the time period when the PHY is actively performing a read or write operation triggered by the DDR controller.
- **Light Sleep**: This is a low-power state in which the master delay lines and their logic receive a clock, but all other slice logic is gated off. The PHY PLLs remain in an active state. Register reads and writes to data and address slices are not permitted. The PHY returns quickly to functional operation after an exit from light sleep. After exiting the PHY initializes the slave delay settings automatically. The master delay line macro maintains lock. This mode is entered if the dfi_lp_wakeup signal is driven with a value less than or equal to the programmed value in bits [3:0] of the the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field. If low power idle state is enabled, the value must also be greater than the value of bits [7:4] in the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.
- **Deep Sleep**: This is an ultra low-power state in which clocking to the data, address, and address/control slices is disabled. The PLLs are in a power down state. Pad calibration functions are frozen. When in this mode, no DFI accesses or register reads and writes can be performed. This mode is entered if the dfi_lp_wakeup signal is driven with a value greater than the programmed value in bits [3:0] of the the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.
- **Low Power Idle**: This is a low power version of idle where the data slices are placed in a light sleep mode while still allowing accesses to the data slice register address space. The DDRSS_PHY_1318[16] PHY_LS_IDLE_EN bit enables this low power idle state. The mode is entered if the dfi_lp_wakeup signal is driven with a value less than or equal to the programmed value of bits [7:4] in the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.

In general, if the SDRAM is placed into a power-down mode, the DDR PHY should enter light sleep. If the SDRAM is placed in a self-refresh mode, the DDR PHY could enter deep sleep.

The DDRSS_PHY_1319[9-0] PHY_LP_CTRLUPD_CNTR_CFG field controls the number of clock controller cycles between de-assertion of the dfi_lp_req signal and de-assertion of the dfi_lp_ack signal during exit of light sleep and low power idle modes.

Within each data slice, the DQ, DM and DQS I/O's are disabled when not being written to or read from. The gate feedback pads are constantly enabled to control the read DQS gate open logic. The following fields control disabling the gate feedback pad for the corresponding slice during deep sleep mode:

- DDRSS_PHY_79[26-24] PHY_FDBK_PWR_CTRL_0
- DDRSS_PHY_335[26-24] PHY_FDBK_PWR_CTRL_1
- DDRSS_PHY_591[26-24] PHY_FDBK_PWR_CTRL_2
- DDRSS_PHY_847[26-24] PHY_FDBK_PWR_CTRL_3

8.2.3.7.9 Training Support

Training of the DDR PHY and SDRAM is necessary to support high-speed operation. The general training flow as follows:

Copyright © 2023 Texas Instruments Incorporated

1. I/O calibration
2. CA/CS training (VREF CA)
3. Write leveling
4. Read DQS gate training
5. Read data eye training
6. Write data eye training (VREF DQ)

8.2.3.7.9.1 Write Leveling

When the write leveling algorithm has completed, the final write DQS delay settings can be found in the following fields:

- DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0
- DDRSS_PHY_376[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_1
- DDRSS_PHY_632[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_2
- DDRSS_PHY_888[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_3
- DDRSS_PHY_121[1-0] PHY_WRLVL_THRESHOLD_ADJUST_0
- DDRSS_PHY_377[1-0] PHY_WRLVL_THRESHOLD_ADJUST_1
- DDRSS_PHY_633[1-0] PHY_WRLVL_THRESHOLD_ADJUST_2
- DDRSS_PHY_889[1-0] PHY_WRLVL_THRESHOLD_ADJUST_3

After write leveling is complete, the following fields can be checked to obtain the leveling status:

- DDRSS_PHY_50[16-0] PHY_WRLVL_STATUS_OBS_0
- DDRSS_PHY_306[16-0] PHY_WRLVL_STATUS_OBS_1
- DDRSS_PHY_562[16-0] PHY_WRLVL_STATUS_OBS_2
- DDRSS_PHY_818[16-0] PHY_WRLVL_STATUS_OBS_3

After write leveling is complete, software can always override the results by writing directly to the following fields:

- DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0
- DDRSS_PHY_376[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_1
- DDRSS_PHY_632[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_2
- DDRSS_PHY_888[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_3

If the clock path to the SDRAM is longer than the DQS path to the SDRAM, the leveling result from the first SDRAM along the memory clock path always returns a small value greater than zero because the DQS signal needs to be moved slightly to the right to line up with the memory clock. If the clock path to the SDRAM is shorter than the DQS path to the SDRAM, the DQS signal may need to be moved close to a cycle before it lines up with the memory clock. The leveling result indicates to the slice that the DQS needs to be delayed almost a cycle. This would then result in the write data being a cycle later than expected by the SDRAM based on when the write command is received. In reality, the DQS needs to be negatively delayed to align to the memory clock in the proper cycle. To create this “negative” delay, the command bus needs to be delayed one cycle so that when the DQS is delayed almost one cycle, the DQS appears “early” with respect to the write command. For example, if the memory clock path for slice 0 is expected to be about 1/16th cycle shorter than the DQS path, a write leveling result of 0x1E0 would be expected. The DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field enables the data slice 0 to understand if this is an expected delay or if this is a “negative” delay condition. When the result contained in DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0 field is greater than the DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field, the command bus is delayed by one cycle.Table 8-20 shows examples of programming this field for various expected delays. The following fields are associated with the other data slices:

- DDRSS_PHY_387[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_1
- DDRSS_PHY_643[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_2
- DDRSS_PHY_889[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_3

Table 8-20. PHY Write Level Delay Values

Expected Delay	PHY_WRLVL_DELAY_EARLY_THRESHOLD_x x = 0, 1, 2, 3	Command Bus Impact
0.25 cycle	0x200 (off)	None
1.00 cycle	0x200 (off)	None

Copyright © 2023 Texas Instruments Incorporated

Table 8-20. PHY Write Level Delay Values (continued)

Expected Delay	PHY_WRLVL_DELAY_EARLY_THRESHOLD_x x = 0, 1, 2, 3	Command Bus Impact
0.00 cycles	0x1E0	1 cycle delay if result is > 0x1E0

The DDRSS_PHY_132[16] PHY_WRLVL_EARLY_FORCE_ZERO_0 bit works with the DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field for slice 0. The following fields are associated with the other slices:

- DDRSS_PHY_388[16] PHY_WRLVL_EARLY_FORCE_ZERO_1 and DDRSS_PHY_387[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_1
- DDRSS_PHY_644[16] PHY_WRLVL_EARLY_FORCE_ZERO_2 and DDRSS_PHY_643[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_2
- DDRSS_PHY_900[16] PHY_WRLVL_EARLY_FORCE_ZERO_3 and DDRSS_PHY_899[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_3

When the write leveling result satisfies the early threshold condition, the DQS is ideally aligned to clock but there is a cycle of latency added to the command path. Setting the PHY_WRLVL_EARLY_FORCE_ZERO_x bit to 0x1 forces the PHY_CLK_WRDQS_SLAVE_DELAY_x value to 0x0 so there is no command latency impact.

The PHY_WRLVL_THRESHOLD_ADJUST_x fields contain the results of the PHY_WRLVL_DELAY_PERIOD_THRESHOLD_x and PHY_WRLVL_DELAY_EARLY_THRESHOLD_x calculations from the write leveling process. This allows for direct observation of the leveling results. It also allows to rewrite leveling results if desired. This can be useful in case leveling is performed once and the same results are used in the future. The PHY_WRLVL_DELAY_EARLY_THRESHOLD_x and PHY_WRLVL_DELAY_PERIOD_THRESHOLD_x results can be applied through the PHY_WRLVL_THRESHOLD_ADJUST_x fields without having to go through the leveling process again.

The previously mentioned PHY_WRLVL_DELAY_PERIOD_THRESHOLD_x fields are accessed through the following registers:

- DDRSS_PHY_132[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_0
- DDRSS_PHY_388[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_1
- DDRSS_PHY_644[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_2
- DDRSS_PHY_900[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_3

8.2.3.7.9.2 Read Gate Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS_PHY_130[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_0 (cycle fraction)
- DDRSS_PHY_386[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_1 (cycle fraction)
- DDRSS_PHY_642[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_2 (cycle fraction)
- DDRSS_PHY_898[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_3 (cycle fraction)
- DDRSS_PHY_131[3-0] PHY_RDDQS_LATENCY_ADJUST_0 (cycle offset)
- DDRSS_PHY_387[3-0] PHY_RDDQS_LATENCY_ADJUST_1 (cycle offset)
- DDRSS_PHY_643[3-0] PHY_RDDQS_LATENCY_ADJUST_2 (cycle offset)
- DDRSS_PHY_899[3-0] PHY_RDDQS_LATENCY_ADJUST_3 (cycle offset)

After read gate training is complete, the following fields can be checked to obtain the training status:

- DDRSS_PHY_54[17-0] PHY_GTLVL_STATUS_OBS_0
- DDRSS_PHY_310[17-0] PHY_GTLVL_STATUS_OBS_1
- DDRSS_PHY_566[17-0] PHY_GTLVL_STATUS_OBS_2
- DDRSS_PHY_822[17-0] PHY_GTLVL_STATUS_OBS_3

After read gate training is complete, software can always override the results by writing directly to the PHY_RDDQS_GATE_SLAVE_DELAY_x and PHY_RDDQS_LATENCY_ADJUST_x fields.

Copyright © 2023 Texas Instruments Incorporated

8.2.3.7.9.3 Read Data Eye Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS_PHY_121[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_0
- DDRSS_PHY_122[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_0
- DDRSS_PHY_123[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_0
- DDRSS_PHY_124[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_0
- DDRSS_PHY_125[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_0
- DDRSS_PHY_126[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_0
- DDRSS_PHY_127[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_0
- DDRSS_PHY_128[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_0
- DDRSS_PHY_377[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_1
- DDRSS_PHY_378[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_1
- DDRSS_PHY_379[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_1
- DDRSS_PHY_380[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_1
- DDRSS_PHY_381[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_1
- DDRSS_PHY_382[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_1
- DDRSS_PHY_383[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_1
- DDRSS_PHY_384[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_1
- DDRSS_PHY_633[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_2
- DDRSS_PHY_634[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_2
- DDRSS_PHY_635[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_2
- DDRSS_PHY_636[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_2
- DDRSS_PHY_637[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_2
- DDRSS_PHY_638[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_2
- DDRSS_PHY_639[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_2
- DDRSS_PHY_640[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_2
- DDRSS_PHY_889[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_3
- DDRSS_PHY_890[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_3
- DDRSS_PHY_891[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_3
- DDRSS_PHY_892[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_3
- DDRSS_PHY_893[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_3
- DDRSS_PHY_894[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_3
- DDRSS_PHY_895[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_3
- DDRSS_PHY_896[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_3
- DDRSS_PHY_122[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_0
- DDRSS_PHY_123[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_0
- DDRSS_PHY_124[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_0
- DDRSS_PHY_125[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_0
- DDRSS_PHY_126[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_0
- DDRSS_PHY_127[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_0
- DDRSS_PHY_128[9-0] PHY_RDDQS_DQ6_FALL_SLAVE_DELAY_0
- DDRSS_PHY_129[9-0] PHY_RDDQS_DQ7_FALL_SLAVE_DELAY_0
- DDRSS_PHY_378[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_1
- DDRSS_PHY_379[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_1
- DDRSS_PHY_380[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_1
- DDRSS_PHY_381[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_1
- DDRSS_PHY_382[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_1
- DDRSS_PHY_383[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_1

- DDRSS_PHY_642[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_2
- DDRSS_PHY_898[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_3

Read data eye training for LPDDR4 devices does return data on the DM pin so the DBI data is trained along with the other DQ pins. In this case, the PHY_RDDQS_DM_RISE_SLAVE_DELAY_x and PHY_RDDQS_DM_FALL_SLAVE_DELAY_x fields receive their own unique values.

After read data eye training is complete, no error condition is noted in the read leveling status fields. The RISE and FALL field results in the previously described registers can be checked to look for values that appear out of place (for example, near 0x000, near 0x100 or greater) or to look for a DQ that is much different than the rest. After read data eye training is complete, software can always override the results by writing directly to the PHY_RDDQS_DQy_RISE_SLAVE_DELAY_x, PHY_RDDQS_DQy_FALL_SLAVE_DELAY_x, PHY_RDDQS_DM_RISE_SLAVE_DELAY_x and PHY_RDDQS_DM_FALL_SLAVE_DELAY_x fields.

8.2.3.7.9.4 Write DQ Training

The data that is written to the SDRAM during training is created within the data slice. The following data pattern options are available:

- Clock pattern - An alternating pattern of "1" and "0" is applied to each DQ/DM. The phase of the 1/0 pattern is identical on the DQ/DM pins.
- LFSR pattern - The same LFSR pattern that is used for data loopback can be applied to the DQ/DM pins. The LFSR is reset at the start of the pattern and each burst of data is different according to the progression of the LFSR.
- User defined pattern - A user defined pattern can also be applied to the DQ/DM pins. Independent data for each bit covering a full burst of 16 can be loaded into register fields to supply the training data. The same data pattern is repeated for every burst. The pattern is defined through the following fields:
  - DDRSS_PHY_36[31-0] PHY_USER_PATT0_0
  - DDRSS_PHY_292[31-0] PHY_USER_PATT0_1
  - DDRSS_PHY_548[31-0] PHY_USER_PATT0_2
  - DDRSS_PHY_804[31-0] PHY_USER_PATT0_3
  - DDRSS_PHY_37[31-0] PHY_USER_PATT1_0
  - DDRSS_PHY_293[31-0] PHY_USER_PATT1_1
  - DDRSS_PHY_549[31-0] PHY_USER_PATT1_2
  - DDRSS_PHY_805[31-0] PHY_USER_PATT1_3
  - DDRSS_PHY_38[31-0] PHY_USER_PATT2_0
  - DDRSS_PHY_294[31-0] PHY_USER_PATT2_1
  - DDRSS_PHY_550[31-0] PHY_USER_PATT2_2
  - DDRSS_PHY_806[31-0] PHY_USER_PATT2_3
  - DDRSS_PHY_39[31-0] PHY_USER_PATT3_0
  - DDRSS_PHY_295[31-0] PHY_USER_PATT3_1
  - DDRSS_PHY_551[31-0] PHY_USER_PATT3_2
  - DDRSS_PHY_807[31-0] PHY_USER_PATT3_3

Copyright © 2023 Texas Instruments Incorporated

- DDRSS_PHY_40[15-0] PHY_USER_PATT4_0
- DDRSS_PHY_296[15-0] PHY_USER_PATT4_1
- DDRSS_PHY_552[15-0] PHY_USER_PATT4_2
- DDRSS_PHY_808[15-0] PHY_USER_PATT4_3

These patterns can be used in any combination and if multiple patterns are requested, the final results are based on the largest leading edge found and the smallest trailing edge found across the patterns selected.

8.2.3.7.9.5 CA Training

CA bits can be swizzled between any bit positions via the DDRSS_PHY_1053[23-0] PHY_ADR_ADDR_SEL_0 field.

When the memory subsystem consists of more than one LPDDR device on the full bus width (two 16 bit devices on a 32 bit bus), all devices receive the same CA bits at some timing relative to each other depending on board placement and routing. In these cases, the DDR PHY can only supply a single CA training value for all devices to use together. Since each device may not receive ideal timing, the CA timing margin is reduced in the overall memory subsystem. Either a single one (any of them) or any combination of the devices participating in the training can be individually selected via the DDRSS_PHY_1357[20-16] PHY_CALVL_DEVICE_MAP field.

In case of two channels, each one can be assigned to a specific chip select and data slices. The DDRSS_PHY_1293[31-24] PHY_CALVL_CS_MAP field is used to map each CS rank to the appropriate DQ slice for training data return.

Bit 1 of the DDRSS_PHY_1038[25-24] PHY_ADR_CALVL_RANK_CTRL_0 field enables current training results to be taken into account along with new training results, instead of discarding previous results. This can be used to train each rank or channel and construct an aggregate for all of them. Each rank or channel then receives the same CA training timing that is the best case possible for all of them. This may result in the setup/hold margin for the CA bits being narrower than any single rank or channel could achieve by itself.

Note

When multiple frequency sets are supported, then all ranks for a given frequency set must be trained before changing to a new frequency. Failure to do so results in rank aggregation not being performed completely with possible data corruption due to rank training being improper.

In case of multiple channels each rank of a channel must use the same CA swizzle. Each rank of a channel must also use the same DQ swizzle.

If the memory device DQ bits are not received in the same order at the PHY as the LPDDR device sent them, then the DQ data has been swizzled, and must be reordered back to its original form before CA training can interpret the results. The following fields specify the DQ swizzling in the corresponding data slice:

- DDRSS_PHY_114[31-0] PHY_DQ_DM_SWIZZLE0_0
- DDRSS_PHY_370[31-0] PHY_DQ_DM_SWIZZLE0_1
- DDRSS_PHY_626[31-0] PHY_DQ_DM_SWIZZLE0_2
- DDRSS_PHY_882[31-0] PHY_DQ_DM_SWIZZLE0_3
- DDRSS_PHY_115[3-0] PHY_DQ_DM_SWIZZLE1_0
- DDRSS_PHY_371[3-0] PHY_DQ_DM_SWIZZLE1_1
- DDRSS_PHY_627[3-0] PHY_DQ_DM_SWIZZLE1_2
- DDRSS_PHY_883[3-0] PHY_DQ_DM_SWIZZLE1_3

The PHY_DQ_DM_SWIZZLE0_x fields contain the bit position to map the received read DQ bits for proper comparison with the training pattern bits.

After CA training is complete the DDRSS_PHY_1043[31-0] PHY_ADR_CALVL_OBS1_0 field can be read to obtain training status information.

After CA training is complete, software can always override the results by writing to the following fields:

- DDRSS_PHY_1065[18-8] PHY_ADR0_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1066[10-0] PHY_ADR1_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1067[10-0] PHY_ADR2_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1068[10-0] PHY_ADR3_CLK_WR_SLAVE_DELAY_0

Copyright © 2023 Texas Instruments Incorporated

- DDRSS_PHY_1069[10-0] PHY_ADR4_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1070[10-0] PHY_ADR5_CLK_WR_SLAVE_DELAY_0

Note

The PHY_ADRx_CLK_WR_SLAVE_DELAY_0 fields can be programmed between 0x000 and 0x600. While training is permitted to set these fields below 0x0C0, the final result is always greater than 0x0C0. If software overrides training results, values less than 0x0C0 should never be programmed. The same restriction applies also to the PHY_GRPy_SLAVE_DELAY_x fields.

8.2.3.7.9.6 CS Training

When the CS training algorithm has completed, the final CS slave delay settings can be found in the following fields:

- DDRSS_PHY_1399[10-0] PHY_GRP0_SLAVE_DELAY_0
- DDRSS_PHY_1399[26-16] PHY_GRP1_SLAVE_DELAY_0
- DDRSS_PHY_1400[10-0] PHY_GRP2_SLAVE_DELAY_0
- DDRSS_PHY_1400[26-16] PHY_GRP3_SLAVE_DELAY_0
- DDRSS_PHY_1401[10-0] PHY_GRP0_SLAVE_DELAY_1
- DDRSS_PHY_1402[10-0] PHY_GRP1_SLAVE_DELAY_1
- DDRSS_PHY_1403[10-0] PHY_GRP2_SLAVE_DELAY_1
- DDRSS_PHY_1404[10-0] PHY_GRP3_SLAVE_DELAY_1

After CS training is complete, the DDRSS_PHY_1289[31-0] PHY_CSLVL_OBS1 field can be read to obtain training status information.

After CS training is complete, software can always override the results by writing directly to the PHY_GRPy_SLAVE_DELAY_x fields.

8.2.3.7.10 Data Bus Inversion (DBI)

Data bus inversion is supported in the DDR PHY. The PHY only passes the DBI information between the DDR controller and SDRAM devices. It does not perform DBI generation and decode. If the DDRSS_PHY_102[8] PHY_DBI_MODE_0 bit is set to 0x1 the SDRAM DBI information for slice 0 is passed to the DDR controller. The following bits are associated with the other slices:

- DDRSS_PHY_358[8] PHY_DBI_MODE_1
- DDRSS_PHY_614[8] PHY_DBI_MODE_2
- DDRSS_PHY_870[8] PHY_DBI_MODE_3

8.2.3.7.11 I/O Pad Calibration

I/O pad calibration runs at initialization time by default but it can also be programmed to operate in a background mode after initialization. Bits [3:1] of the DDRSS_PHY_1330[12-0] PHY_CAL_MODE_0 field enable the periodic calibration mechanism and determine the base clock frequency of the interval counter. The DDRSS_PHY_1331[31-0] PHY_CAL_INTERVAL_COUNT_0 field then sets a timer to indicate how frequently calibration is performed. When the timer expires, the calibration runs in background, independent of other traffic running through the PHY. When the calibration is complete, the updated PVTP/PVTN/PVTR codes are transferred to the PHY I/O cells. Whether or not the update of the memory clock PVTP/PVTN/PVTR codes is applied at the same time as the remaining I/O cells is controlled through the DDRSS_PHY_1298[8] PHY_CONTINUOUS_CLK_CAL_UPDATE bit. If the automatic update of the memory clock codes is disabled through the PHY_CONTINUOUS_CLK_CAL_UPDATE bit, the DDRSS_PHY_1298[0] SC_PHY_UPDATE_CLK_CAL_VALUES bit can be used to trigger a manual update.

8.2.3.7.12 DQS Error

A DQS error results from a mismatch between the expected number of read DQS pulses and the actual number of read DQS pulses. Counters exist at DDR PHY level to track the number of DQS errors in each data slice. Counter information can be obtained by reading the following fields:

- DDRSS_PHY_1363[31-0] PHY_DS0_DQS_ERR_COUNTER
- DDRSS_PHY_1364[31-0] PHY_DS1_DQS_ERR_COUNTER
- DDRSS_PHY_1365[31-0] PHY_DS2_DQS_ERR_COUNTER
- DDRSS_PHY_1366[31-0] PHY_DS3_DQS_ERR_COUNTER

Copyright © 2023 Texas Instruments Incorporated

The DQS error signals from each data slice are accumulated at PHY level and can be used to generate a dfi_error signal. Bit 2 of the DDRSS_PHY_1361[26-24] PHY_ERR_MASK_EN field is used to mask the DQS error from generating a dfi_error or being reported on dfi_error_ info[2].

8.2.3.8 PI Functional Description

The PHY Independent (PI) module is part of the DDR PHY and can perform PHY independent leveling and SDRAM BIST without involvement of the DDR controller. The PI can also initialize the SDRAM independent of the DDR controller. The PI module provides an interface between the PHY core logic and the DDR controller.

8.2.3.8.1 PI Initialization

The PI module can be used to perform SDRAM initialization before training instead of the DDR controller. The following steps represent the main actions of the initialization process:

1. Set to 0x1 the DDRSS_PI_139[8] PI_DRAM_INIT_EN bit.
2. Enable the PI by setting to 0x1 the DDRSS_PI_0[0] PI_START bit.
3. Enable the DDR controller.
4. The PI, DDR controller and PHY core are involved in a process of specific hardware communication between them that does not require software intervention.
5. The PI starts the power-up sequence which includes the SDRAM initialization timing, the SDRAM mode register programming and training.
6. After completion of the power-up sequence, the PI notifies the DDR controller through the dfi_init_complete signal.
7. The DDR controller can now access the SDRAM.

8.2.4 DDRSS Registers

Note

Refer to the DDRSS Registers section of the DRA821 TRM (https://www.ti.com/lit/pdf/spruiu1) for register offset information to be combined with the base address listed below (where applicable for this Device):

- DDRSS0 = 0x02990000
- DDRSS1 = 0x029B0000
- DDRSS2 = 0x029D0000
- DDRSS3 = 0x029F0000

8.3 Peripheral Virtualization Unit (PVU)

This chapter describes the PVU module, part of the main NAVSS.

8.3.1 PVU Overview

The Peripheral Virtualization Unit (PVU) module provides TLBs (translation look-aside buffers) for a static virtual address translation on a CBA VBUSM bus.

Figure 8-9 shows a top-level overview of the PVU module.

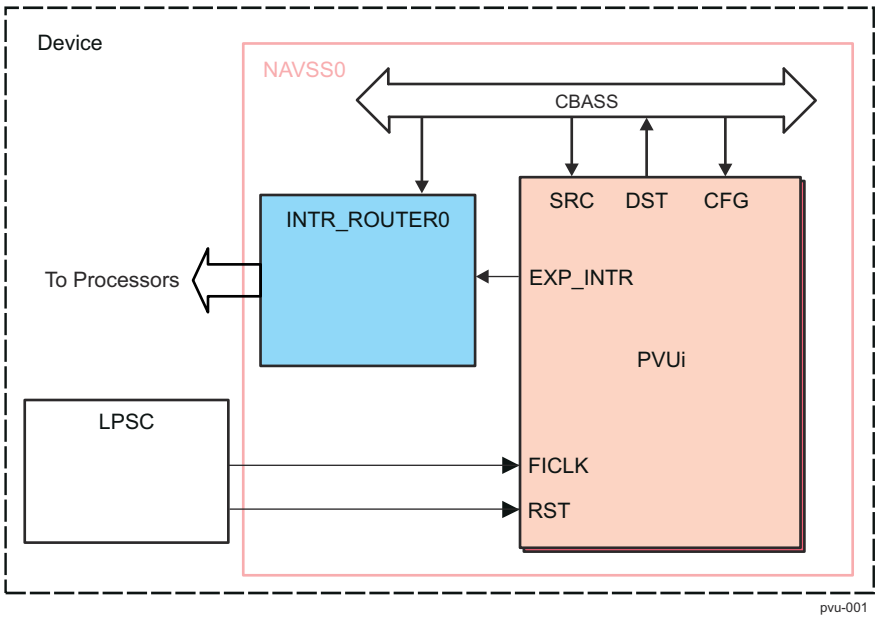

Figure 8-9. PVU Overview

8.3.1.1 PVU Features

Each PVU supports the following features:

- Implements a channelized TLB for virtual address translation
- Supports a pre-configured number of virtIDs (channels). See Section 8.3.1.2.
- Supports mapping of virtIDs to TLBs with a programmable number of DMA channel support
- Supports a pre-configured number of entries per channel of the TLB. See Section 8.3.1.2
- Supports TLB chaining to extend the search but at a latency penalty
- Supports a 48-bit address size
- Supports page sizes of 4 KB, 16 KB, 64 KB, 2 MB, 32 MB, 512 MB, 1 GB, and 16 GB
- Support TLBs in software mode, where they are maintained by software only
- Produces a fault interrupt when the TLB misses or upon a permission error.

8.3.1.2 PVU Parameters

shows the PVU configuration parameters set during SoC design.

Copyright © 2023 Texas Instruments Incorporated

8.3.2 PVU Functional Description

8.3.2.1 Functional Operation Overview

The Peripheral Virtualization Unit, PVU, module provides TLBs, translation look-aside buffers, for a static virtual address translation on a CBA VBUSM bus. This is in contrast to a dynamic translation TLB that works with an MMU, such as the Arm® processor SMMU. The module acts as a VBUSM retiming bridge that also performs the address translation. Each of the TLBs has its own set of private entries. It is a static translation because all the entries must be programmed by software and there is no hardware to fetch new translation entries when a transaction does not match any of the provided entries.

The entire PVU can be enabled or disabled via the PVU_ENABLE register.

8.3.2.2 PVU Channels

The module supports a number of channels (see Section 8.3.1.2), each having its own independent TLB and translation entries. This allows a single PVU to handle the translations for many masters, as well as keep their translations from interfering with each other.

The mapping of transactions to TLBs is made using mapping registers (PVU_VIRTID_MAP1 and PVU_VIRTID_MAP2). Each channel can be mapped to a virtID, or as a sub range of a DMA virtID. This allows the software to decide how the transactions are mapped to TLBs. It can be purely based on virtID, so that each virtual space has its own TLB. Or, it can be partly based on a highly channelized master, such as a DMA, can have 4 TLBs dedicated for channels where the sub-class on the upper chanid bits determine which of the 4 TLBs to use. This DMA mode allows for different classes of DMA traffic, such as descriptors or buffers, to be in their own TLBs and not interfere with each other. Since the TLB mapping is relatively simple, it is software's responsibility to control the definition of virtIDs in peripherals and DMAs so that they map to TLBs as required.

8.3.2.3 TLB

Each PVU channel contains a single traditional TLB. The TLB contains a number of entries that store the translation recipes, and these entries are used only for this TLB. Any activity for other TLBs or PVU channels will not impact this TLB.

8.3.2.4 TLB Entry

A TLB entry consists of the virtual address base and LPAE (Large Physical Address Extension) fields defined by Arm® architecture, stored in TLB Entry registers. This entry then includes the translated base address, size of the page, and other attributes of the page. When written by software, these fields must be written in the same way for correct operation.

The base addresses must be aligned to the defined page size.

8.3.2.5 TLB Selection

The first step of the module is to map the transaction to a specific TLB by comparing the virtID, chanID upper bits, and those programmed in PVU_VIRTID_MAP1 and PVU_VIRTID_MAP2. This mapping determines which TLB to select from the virtID. That TLB is used for the remainder of the pipeline. If there is no match then the PVU automatically misses.

8.3.2.6 DMA Classes

The first N virtIDs can be reserved for DMA class usage in the PVU_VIRTID_MAP1 register. These virtIDs map to TLBs along with classes that are defined in the chanID bits 10 to 11 on the bus. This creates four classes per virtID, that can select from four TLBs, allowing the transaction to restrict its translations to smaller sets from known distinct memory segments (such as the DMA accessing descriptors or buffers). A set of bitfields define the class mapping, which defines the final class value to use for an input class, and can be used to restrict the number of classes if all four are not used (by mapping 2 to 0 and 3 to 1 for example to limit to two classes). Then the final TLB selection is calculated as:

virtID × 4 + final class value

The unused classes cause unused TLBs as entry points, but they can be used in chaining.

Copyright © 2023 Texas Instruments Incorporated

8.3.2.7 General virtIDs

After the first N virtIDs for DMA class usage, the remaining virtIDs up to the maximum allowed (as set in PVU_VIRTID_MAP2) are for general usage. Each of these map one to one to a TLB, where the calculation is:

dma_cnt × 4 + (virtID - dma_cnt)

There are no classes used for this range of virtIDs. An input virtID that is beyond the MAX_CNT bitfield value will produce an error.

8.3.2.8 TLB Lookup

The next step of the module is to check the input address, which uses the bits just above the 4-kB size, bits 12 and up, as the virtual address base. This is compared against all the TLB entries for that TLB, given the size in each entry. The size affects which address bits need comparing for an entry. The minimum size of 4 kB, so address bits 12 and up are compared. But if the size is 64 kB, then bits 16 and up are compared, as the lower bits fall into the size of the page. In addition to the address, the psecure bit is used to match against the secure level of the transaction. Only secure transaction are allowed to match an entry with psecure set, while only non-secure transactions are allowed to match an entry with psecure clear. If the entry is valid and the base compare matches and the secure level matches then the entry is used for the translation and checks.

8.3.2.9 TLB Miss

If the TLB lookup results in no matches and there is no chaining to another TLB (described later), then this is called a TLB miss. If the TLB misses, since there is no back-fill (such as from an MMU), the result is that the translation fails and will fault (a fault is when there is no physical address available). The transaction will be marked as in error with the flush signal, and a later slave will perform the flush that will return a bus error and read data as zeros. The PVU will record the fault as an interrupt and log the fault in the exception logging read-only registers.

8.3.2.10 Multiple Matching Entries

The PVU does not support multiple entries in a TLB that match the same virtual address. This is an illegal condition for software to program, as there is no mechanism to select one over the other. The PVU will have unpredictable results if this occurs, with the one requirement that the input transactions will never transition from a non-secure attribute to a secure attribute even in this illegal condition. This means that there is no support for background and foreground translating entries in the same TLB (which would be the result if a real MMU were used also). If software user wants to use a foreground and background method (that is not MMU compliant), he can place the foreground entries in earlier TLBs that are chained together, and the background entries are in the later TLBs, so that no single TLB has overlapping entries. The background entry would only be hit when the address falls within the background range but not any of the foreground ranges.

8.3.2.11 TLB Disable

A special case is when a TLB should go through a lookup but is disabled through the PVU_CHAIN_j[31] EN bit, or the entire PVU is disabled through the PVU_ENABLE[0] EN bit. If a lookup is requested when the TLB or PVU is disabled, then the transaction will pass and no translation will occur (output address is the same as the input address). Also, if the atype=1 then it will change to atype=0 on the output so that the resulting bypass transaction does not get routed right back to the PVU. Any other atype value will be maintained on the output. Any entries set in the disabled TLB are ignored as well as the chaining setting (described in Section 8.3.2.12) is also ignored, so once a disabled TLB is used then the chain is ended. Software must take care to not include any disabled TLBs in chains that must be fully searched – if a TLB must be disabled then the chain must be updated first to skip over that TLB and any virtIDs that directly map to that TLB initially must not be used.

8.3.2.12 TLB Chaining

If the TLB has a chain enabled by writing a non-zero chain value, then the TLB lookup will continue for the transaction using the chained TLB number. There is a latency penalty to resume the lookup at the chained TLB, but it allows more TLB resources to be used for virtIDs that might need more translations. If a TLB misses and has a chain value of zero then the overall result is a miss. Any TLB logs are always applied to the original TLB of the chain, and not the chained TLB.

TLB chaining can be defined in the PVU_CHAIN_j[11:0] CHAIN register bitfield.

Copyright © 2023 Texas Instruments Incorporated

8.3.2.13 TLB Permissions

The TLB entry contains permissions for the page that must be checked before the translation can be used. These include if the page has *supervisor* access for read, write, or execute, and has *user* access for read, write, or execute. The supervisor or user is based on the transaction priv[0] signal (0 = user, 1 = supervisor). The access type is based on the transaction dtype[0] and dir signals (dtype[0] = 0 and dir = 1 is a read, dtype[0] = 0 and dir = 0 is a write, dtype[0] = 1 and dir = 1 is an execute). The transaction signals are checked against these permissions. If they are allowed then the translation continues. If the page does not allow this transaction then the check fails and flush signal set is on the bus, like for a firewall, indicating that the transaction is no longer valid and must return an error. PVU does not perform the error signaling, so a later module must support it. A fault interrupt is produced.

The pperm entry bits define four additional checks. If pperm[0] is clear then user privilege access is not allowed, and a matching transaction with the CBA bus priv signal set to 0 (indicating user access) will result in an error. If pperm[1] is set then write access is not allowed, and a matching transaction that is a write will result in an error. If pperm[2] is set then instruction execute is not allowed, and a matching transaction that has the CBA bus dtype signal set to 1 (instruction fetch) will result in an error. If pperm[3] is set then supervisor instruction execute is not allowed, and a matching transaction that has the CBA bus priv signal non-zero (above user) and the CBA bus dtype signal set 1 (instruction fetch) will result in an error. If all these checks pass then the translation is allowed.

The pprefetch entry bit determines whether the translation allows prefetch transactions. If set, then any transaction with the pfable signal set are allowed. But if pprefetch=0 then those transactions with pfable set will fault as prefetch is defined as not supported.

8.3.2.14 Translation

If all the checks pass, then the translated address is replaced and the transaction can proceed to the output. Only the address bits above the page size are replaced, and all the lower bits are copied from the transaction. The memory attributes are also replaced on the transaction. These attributes include the memory type, shareability, and allocation policies. In addition, the prefetchable request is only copied if the page allows prefetch, and otherwise it is forced clear, but the transaction is still allowed to continue (just the prefetch will not occur).

8.3.2.15 Memory Attributes

Table 8-21 shows the mapping of page attributes to the bus memory attributes.

Table 8-21. Page Attributes to Bus Memory Attributes Mapping

Bus Signal	Page Attribute	Translated Bus Signal
cinner	piallocpol	cinner = piallocpol
couter	poallocpol	couter = poallocpol
memtype	pmemtype	memtype = pmemtype
sdomain	posable, pisable	sdomain[1] = posable, sdomain[0] = pisable
pable	pprefetch	pable = pable AND pprefetch

8.3.2.16 Faulted Transactions

A faulted transaction will have the flush bit set on the outgoing transaction so that it will return errors by the interconnect. The atype will be set to 0 since the memory attributes have not been replaced. And the outgoing transaction address will have the upper bits set to the fault_addr parameter value (see Section 8.3.1.2), which defines an interconnect address that will always return errors and not interfere with any valid slave traffic (such as to memory).

8.3.2.17 Non-Virtual Transactions

The module must not receive a transaction that does not have the atype set to an intermediate address, but if it does, there is no translation performed for that transaction. The transaction is simply copied to the output without modification.

Copyright © 2023 Texas Instruments Incorporated

8.3.2.18 Allowed virtIDs

Software can control the limit of usable virtIDs in the PVU by PVU_VIRTID_MAP2[11:0] MAX_CNT register. This sets the maximum virtID allowed value. If the PVU receives a transaction with a higher virtID signal, then the transaction will be treated as a fault and error, and no TLB lookup will be performed.

8.3.2.19 Software Control

The software can control all the TLB entries directly. The TLB can be programmed at any time by software, and writes to the TLB take precedence over lookups. This allows the update to be reflected as soon as possible in the translations. But there is no guarantee about the timing of the update against any bus transactions, so the only way to guarantee an endpoint uses the updated table is to stall the endpoint until the update has been completed (using the write status). This allows software to directly populate TLB entries for known translation as well as locking entries down so that they cannot be replaced.

8.3.2.20 Fault Logging

The module will log faults into exception logging registers. It will capture that type of fault, the address that faulted, and the attributes of the transaction that faulted. It will also set an interrupt. The module can only store one fault. When the software clears the interrupt status then the fault is also cleared and another can be captured. If another fault occurs while one is pending then that fault log is lost.

There is a logging Enable/Disable bit per TLB and if disabled then faults from that TLB will not be logged. PVU_EXCEPTION_LOGGING_DISABLE register allows to disable types of faults, and when disabled that type of fault will not be logged. There are additional fault status fields per TLB that capture fault status that would have been logged but could not because another fault was already logged. These status bits stay set until cleared by software.

A TLB fault that occurs after chaining will set the fault status of the original TLB, and not of the last TLB in the chain.

8.3.2.21 Alignment Restrictions

All accesses through the module must not cross 4-kB page boundaries. The module does not perform any checks for this requirement.

Both the input and output addresses must be aligned with the configured size for the TLB.

Copyright © 2023 Texas Instruments Incorporated

8.4 Region-based Address Translation (RAT) Module

This section describes the RAT functionality.

8.4.1 RAT Functional Description

8.4.1.1 RAT Availability

lists the device modules and subsystems which have RAT module.

8.4.1.2 RAT Operation

The RAT module performs a region based address translation. It translates a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

RAT has 16 regions, with each region having dedicated registers that define its attributes:

- Base address of the region, via the RAT_BASE_k register.
- Size of the region, via the RAT_CTRL_k register.
- Translated base address (48-bit). It is defined by 32-bit lower address via the RAT_TRANS_L_k register, and 16-bit upper address via the RAT_TRANS_U_k register.

The input addresses are compared against all the enabled regions in parallel. The region size defines how many of the lowest address bits are included in the region space, starting from a 1B space to a 4GB space. Then the upper bits not part of the region are used for the lookup and comparison, matching those bits of the input addresses against the region base address. The region matches when it is enabled and the compare matches. The first region that matches has the output address set with the region translated base address upper bits. The lower bits that are part of the region size are copied from the input address to the output address. If there are no region matches then the input address is copied to the output address entirely.

RAT does not automatically correct transactions that cross region boundaries, that is, start inside of a region and end outside of it, or start outside of a region and end inside of it. If a boundary crossing transaction is detected, then RAT annuls the transaction as illegal, generates an interrupt and logs an error, as explained in *RAT Error Logging*.

Note

The region base address and translated base address must be aligned to the defined region size. For example, if the defined region size is 64KB, then the two addresses must be 64KB aligned. This is software responsibility as RAT does not perform such alignment check. Regions that are not aligned have unpredictable results.

Moreover, multiple region definitions must not overlap in their covered address space. RAT does not check for this, so it is software responsibility to take care of it. Overlapping regions may lead to unpredictable results.

8.4.1.3 RAT Error Logging

The error log consists of a series of registers that capture the details of the transaction, including the input address that caused the error. These registers are the following:

- RAT_EXCEPTION_LOGGING_HEADER0 and RAT_EXCEPTION_LOGGING_HEADER1
- RAT_EXCEPTION_LOGGING_DATA0 through RAT_EXCEPTION_LOGGING_DATA3

The RAT module can capture one error before it is cleared by software. The error logging is enabled by default, but can be disabled via the RAT_EXCEPTION_LOGGING_CONTROL[0] DISABLE_F bit. Upon error logging an interrupt is also generated. To clear the log, software must either read the final error logging register, or manually clear the RAT_EXCEPTION_PEND_CLEAR[0] PEND_CLR bit by setting it to 0x1. This will clear the error status, and not the actual log registers, but it does allow the next error to be captured into the log registers. If the status is not cleared and additional errors are detected, they are not logged.

After an error occurs and is cleared (whether by reading the final error logging register or by clearing the status bit), the RAT_EOI_REG register must be written to guarantee the next interrupt pulse will be produced.

Copyright © 2023 Texas Instruments Incorporated

See the RAT section of the Module Integration chapter of this document for the RAT Source ID mapping which is associated with the EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field for each RAT module.

9 Interrupts

9.1 Interrupt Architecture

The SoC has many peripherals and a large number of event sources (interrupt, time sync or DMA). The use of events is completely dependent on a user's specific application, which drives a need for maximum flexibility in which event sources are used in the system. It is also completely up to software control as to how the events are serviced.

The SoC includes the following interrupt servicing modules (hosts):

- Security Management Subsystem (WKUP_SMS0):
  - 2 Arm Cortex-M4F cores
  - 2 Nested vectored interrupt controller (NVIC)
- Compute cluster:
  - Three processor subsystems:
    - Dual-core Arm Cortex-A72 microprocessor unit (A72SS0)
    - 2 Single-core C71x DSP subsystems (C71SS0, C71SS1)
  - Two interrupt controllers, both integrated inside the MSMC wrapper:
    - Arm generic interrupt controller (GIC-500) supports both cores in the dual-A72 cluster
    - Cluster level event controller (CLEC) supports the C71x DSPs
- Microcontroller units (R5FSS0, R5FSS1, MCU_R5FSS0), each implementing:
  - Two Arm Cortex-R5F cores
  - Vectored interrupt manager (VIM)

Most of the system events are routed directly to the various proccesing elements but in some cases it is impractical to route all events of a certain group (for example, GPIO events) to each processing element. For this purpose, the SoC integrates several interrupt router (INTRTR) instances. Each interrupt router aggregates a number of system events and can route each event to a given processing element by using simple combinational logic (a set of multiplexors). Event selection is controlled through the associated registers within each interrupt router.

The following interrupt router instances are part of the SoC interrupt architecture:

- WKUP domain GPIO interrupt router (WKUP_GPIOMUX_INTRTR0):
  - Provides selection of active module interrupts for the WKUP_GPIOx modules
- MAIN domain GPIO interrupt router (GPIOMUX_INTRTR0):
  - Provides selection of active module interrupts for the MAIN domain GPIOx modules
- MAIN-to-MCU domain level interrupt router (MAIN2MCU_LVL_INTRTR0):
  - Provides selection of active MAIN domain module *level* interrupts for routing to MCU domain processing elements
  - Reduces the number of event voltage domain crossings
- MAIN-to-MCU domain pulse interrupt router (MAIN2MCU_PLS_INTRTR0):
  - Provides selection of active MAIN domain module *pulse* interrupts for routing to MCU domain processing elements
  - Reduces the number of event voltage domain crossings

In addition, the following interrupt router instances are part of the SoC time sync architecture:

- Time sync event router (TIMESYNC_INTRTR0):
  - Provides selection of active common platform time synchronization (CPTS) events for routing to CPTS capable modules
- Compare event router (CMPEVT_INTRTR0):
  - Provides selection of active CPTS counter compare events for routing as processor interrupts or DMA events

For more details on time sync routers, see *Time Sync Routers*.

Copyright © 2023 Texas Instruments Incorporated

9.2 Interrupt Controllers

9.2.1 Generic Interrupt Controller (GIC)

This section describes the Generic Interrupt Controller (GIC) module in the device.

9.2.1.1 GIC Overview

The device GIC is a TI module that is based on the Arm GIC-500 interrupt controller. The Arm GIC-500 is a high-performance, area-optimized, built-time configurable interrupt controller which detects, manages, and distributes system interrupts to the Arm® Cortex®-A72 processors in the Compute Cluster.

The Arm GIC-500 is compliant to the Arm GICv3 standard. It only supports cores that implement the Armv8 architecture and the GIC CPU interface with the standard GIC Stream Protocol Interface (such as A72).

The GIC includes additional logic (TI wrapper) to fully integrate the Arm GIC-500 into the SoC.

The GIC module is located inside the MSMC_WRAP logical block in the Compute Cluster, along with the cluster level interrupt controller (CLEC), which serves the C71x DSPs.

9.2.1.1.1 GIC Features

Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

The Arm GIC-500 supports the following features in the device:

- Module revision: r1p1
- Supports all A72 cores
- 16 software generated interrupts (SGIs) per core
- 16 private peripheral interrupts (PPIs) per core
- 960 shared peripheral interrupts (SPIs)
- Locality-specific peripheral interrupts (LPIs), used for message-based interrupts
- Interrupt translation service (ITS)
  - Device isolation
  - ID translation for message-based interrupts
  - This allows virtual machines to program devices directly
- Interrupt masking and prioritization
- Programmable, affinity-based interrupt routing
- 32 priorities for each interrupt
- Three different interrupt groups
  - Group 0
  - Non-secure group 1
  - Secure group 1

Additionally, the GIC wrapper logic provides the following features:

- Synchronizes interrupt inputs to GIC clock
- Implements AXI2VBUSM and VBUSM2AXI bridges
  - Used for bus protocol conversion (AXI-to-VBUSM and VBUSM-to-AXI, respectively)
- Implements an integrated ECC aggregator
  - Only used to inject errors (for testing purposes)

9.2.1.1.2 GIC Not Supported Features

The GIC does not support the following features:

- GICv2 backwards compatibility
- AWID-based LPI mapping

Copyright © 2023 Texas Instruments Incorporated

9.2.1.2 GIC Functional Description

Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

9.2.1.2.1 Arm GIC-500

The Arm GIC-500 is responsible for detecting, managing and communicating system interrupts to all A72 cores in the device. The main difference between the Arm GIC-500 and previous Arm GIC versions is the direct communication with the CPU(s). Previously, an interrupt controller would set a pending bit to a CPU and that CPU would then have to query an interrupt controller MMR to find out what to do. Now, the Arm GIC-500 sends interrupts to a CPU via a dedicated message interface and the CPU communicates back about interrupts through the same interface. The CPU now uses writes and reads to system registers instead of over the memory interface. This leads to reduced latency and the ability to route interrupts to different CPUs based on a set of rules.

The Arm GIC-500 is divided into three main sections:

- **Distributor**: The Distributor receives interrupts from the wire interrupts and the programming interface. It is responsible for prioritizing these interrupts and sending them to the CPU interface via the GIC Stream Protocol Interface.
- **Redistributor**: There is one Redistributor per core. Each Redistributor holds the state that is individual to a particular core (such as the settings for PPIs and SGIs). It also stores the LPIs for that core after they have been generated using the ITS.
- **ITS**: The ITS is responsible for translating message-based interrupts from device peripherals into LPIs. The user can also use the ITS to manage existing LPIs. Note that the ITS is not used for other types of interrupt

9.2.1.2.2 GIC Interrupt Types

The GIC supports four types of interrupts:

- *Software Generated Interrupts (SGIs)*: There are 16 SGIs (ID0-ID15). These are inter-processor interrupts. SGIs can be sent using either Arm system registers or by writing to the Software Generated Interrupt Register (GICD_SGIR).
- *Private Peripheral Interrupts (PPIs)*: There are 16 PPIs (ID16-ID31). These are wired interrupts dedicated to a specific CPU. Many are reserved to specific functions via convention. These can be either active-low levels (by default), or rising edge triggered (software programmable).
- *Shared Peripheral Interrupts (SPIs)*: There are 960 SPIs (ID32-ID991). These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC. These are active-high levels (by default), or rising edge triggered (software programmable).
- *Locality-Specific Peripheral Interrupts (LPIs)*: There are 57,344 of these. These interrupts are used for message-based interrupts from a peripheral. They are generated through writes to the GIC slave interface. The information associated with these is located in memory. The GIC keeps a small 64-entries cache on-board in order to reduce latency either for specific interrupts or for most-recently-used. LPIs can be routed to different CPUs based on programmed rules.

The mapping of PPIs and SPIs can be found in section TBD .

9.2.1.2.3 GIC Interfaces

The GIC has the following main interfaces:

- A pair of 64-bit VBUSM write-only and read-only master interfaces
  - AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into this pair of interfaces
  - The AXI4 master interface allows the GIC ITS and redistributors to access main memory
- 32-bit VBUSM slave interface
  - Provides access to Arm GIC-500 internal resources
  - Handles all message-based interrupts. Message-based interrupts can generate SPIs or LPIs, depending on the register that is written

Copyright © 2023 Texas Instruments Incorporated

  - VBUSM2AXI bridge converts this interface into an 32-bit AXI4 slave interface
- 32-bit VBUSP slave interface
  - Provides access to internal ECC aggregator
- Physical interrupt and power signals
  - Inputs: CPU active signals, SPIs and PPIs (can be programmed as either level-sensitive, or edge-triggered)
  - Outputs: Error signals and wake-up requests
- GIC Stream Protocol Interface
  - Consists of a pair of AXI4-Stream interfaces (one upstream and one downstream 16-bit AXI4-Stream interface) that the GIC uses to send interrupts to the core and receive notifications when the core activates interrupts
  - There is a pair of physical interfaces, one in each direction, for each cluster

9.2.1.2.4 GIC Interrupt Outputs

Table 9-1 lists the interrupts that are generated by the GIC.

Table 9-1. GIC Interrupt Outputs

Interrupt Name	Description
GIC_AXIM_ERR	GIC bus error interrupt. This interrupt is triggered if the GIC receives an error on a bus transaction, such as a decode or protection error. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GIC_ECC_FATAL	GIC uncorrectable ECC error interrupt. Indicates an uncorrectable 2-bit error detected in one of the ITS cache memories. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GIC_PWRm_WAKE_REQUEST_n	GIC wake requests for A72 cores. Asserted state indicates that an interrupt is pending for a processor that has set the PROCESSORSLEEP bit in the GICR_WAKER register. This bit indicates that the SoC should wake up the indicated CPU so that it can process the interrupt.
GIC_PWRm_WAKE_REQUEST_n	

9.2.1.2.5 GIC ECC Support

The Arm GIC-500 has built-in SECDED ECC on its memories to protect against errors. The syndrome generation and checking is done internally.

Additionally, the TI GIC wrapper integrates an ECC aggregator (GIC_ECC_AGGR) in order to allow errors to be injected for testing purposes. The generic ECC aggregator functionality is described in Section 12.10.4, *ECC Aggregator*. Note that the GIC_ECC_AGGR supports only a subset of this functionality.

9.2.1.2.6 GIC AXI2VBUSM and VBUSM2AXI Bridges

The GIC uses the AXI4 master interface to allow the ITS and redistributors to access main memory. It is expected that the main memory (attached to a CBASS VBUSM port) holds the following:

- ITS translation tables
- ITS command queue, which is written by software in order to program the ITS
- LPI configuration table, which holds the priorities and enable bits for LPIs
- LPI pending tables, which can hold information on whether each LPI is pending on each core

The AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into a pair of 64-bit VBUSM write-only and read-only master interfaces. AXI4 has a separate command channel for read and write, and the AXI2VBUSM bridge keeps them separate, so that the system may prioritize or arbitrate the traffic between them as appropriate.

The GIC uses the AXI4 slave interface to provide access to the programming interfaces of all its parts (distributor, redistributors, ITS). The VBUSM2AXI bridge converts the standard 32-bit VBUSM master interface into an 32-bit AXI4 slave interface.

9.2.2 Cluster Level Event Controller (CLEC)

9.2.2.1 CLEC Overview

The CLEC supports the following features:

- Supports software scalable event routing mechanism
  - RAM-based interrupt event routing table
- Supports aggregation of incoming interrupt events from:
  - SoC peripherals
  - MSMC
  - DRU
  - C71SS
- Supports distribution of each aggregated interrupt event to one or more of the following:
  - SoC (could be routed to the GIC externally)
  - DRU
  - A72SS
  - C71SS
- Supports originating interrupt events through the following mechanisms:
  - MMR writes to trigger new events
  - Reporting errors detected by the CLEC
- 2048 input events
- 128 output events
- Can handle both level and pulse input interrupts
  - SoC out interrupt is always level regardless of input interrupt type (pulse or level)
- Can be used for inter-processor communication (IPC) between A72 and C71
- Shares SPI (shared peripheral interrupt) input events with GIC

Copyright © 2023 Texas Instruments Incorporated

9.2.2.2 CLEC Functional Description

9.2.2.2.1 CLEC Interrupt Event Routing

The CLEC routes events according to a RAM-based interrupt event routing table. This table holds one entry for each supported external interrupt/event number, plus some additional entries for CLEC internal events. External in this context means "external to the CLEC", and corresponds to all interrupt events arriving at the CLEC from other sources. Internal refers to events that the CLEC generates internally, or in response to an MMR write that triggers the event.

The routing table memory has 2048 entires in size. Each routing table entry contains the following details:

- Outgoing event number: Each incoming event can be mapped to any outgoing event number
- Secure / Non-secure: Each incoming event can be claimed as a secure event
- Destination port configuration: This configuration allows for both single-cast and broadcast events

For each incoming interrupt event, the CLEC does the following processing:

- Validates the interrupt event number. For out-of-range event numbers, the CLEC triggers an "invalid event number" event
- Non-secure read/write to registers associated with a secure event will generate a privilege error
- Looks up the event in the routing table
- For each port in the destination bitmap that has a bit set, it queues the event to that destination
  - Queuing to multiple destinations happens in parallel, not sequentially, to minimize latency
  - If no bits are set, the event is dropped silently, but an interrupt dropped event is asserted. This event gets routed as determined by the routing table

Note

For events mapped to DRU and ARM, only event mapping number is looked at and they are not qualified by CLEC_MRR_j[21-16] RTMAP. Hence, this bit field is "don’t care" for events that have CLEC_MRR_j[15-8] EXT_EVNUM set to 128 or higher.

Since the routing table is a shared resource, the CLEC only routes one new event per cycle. The routing state machine arbitrates among all incoming event sources round-robin, with the exception that internally generated error events have priority over all other event sources.

The CLEC routes events to their destinations and also maintains pending interrupt information in an CLEC_EFR_k register. Firmware needs to clear this pending interrupt bit in an interrupt service routine (ISR).

9.2.2.2.2 CLEC Virtualization, Isolation and Access Control

The CLEC provides direct support for virtual-machine isolation via a hypervisor. Each event’s register window is deliberately spaced 64KB apart. This enables allocating individual event numbers to virtual machines via stage-2 translation. The 64KB spacing allows this to work even with the largest translation granule supported by ARM (64KB).

Individual functions associated with an event within each event’s window are spaced 4KB apart. This allows a standard operating system to open up, for instance, write access to an CLEC_ESR_j register for a single task, while blocking access to the event routing details in CLEC_MRR_j register.

The CLEC implements event lock registers (CLEC_GELRS / CLEC_GELRNS) that allow hypervisor to lock down the configuration of events, while still permitting write access to the event send register (CLEC_ESR_j) for that event.

In current implementation, the CLEC provides basic support for isolating virtual machines by partitioning incoming events in the address map. However, it does not provide any support for limiting event numbers assigned for outgoing events in CLEC_MRR_j[15-8] EXT_EVNUM. If such isolation is necessary, software can implement it in the hypervisor via para-virtualization calls, via trap-and-emulate for full virtualization.

Copyright © 2023 Texas Instruments Incorporated

9.2.2.2.3 CLEC Memory Protection

The CLEC implements minimal memory protection checks. It relies on protection mechanisms outside to control accesses from various masters. Chip-level firewalls control which masters may access the CLEC. MMUs provide finer-grain control for programmable processors that access the CLEC.

Specifically, the CLEC returns the following errors:

- Address error on a read or write to unimplemented space
- Address error on a read to a write-only register
- Address error on a write to a read-only register
- Privilege error on a non-secure read or write to registers associated with a secure event (CLEC_MRR_j[31] S = 1 for that event)
- Privilege error on a write to CLEC_ESR_j on an event whose CLEC_MRR_j[30] ESE = 0
- Privilege error on a write to CLEC_MRR_j on an event when CLEC_GELRS[0] LOCK = 1

Any further access control must be implemented with firewalls and/or MMU configuration outside the CLEC.

9.2.2.2.4 CLEC ECC Support

Standard ECC aggregator strategy is used to implement ECC protection on the SRAM used to implement the CLEC routing table. The CLEC has two ports connected to the ECC_AGGR at the MSMC_WRAP level. For RAM_ID values of CLEC ECC-protected memories, see , *Compute Cluster ECC Aggregators*. For details on the generic ECC_AGGR functionality, see Section 12.10.4, *ECC Aggregator*.

9.2.2.2.5 CLEC Intra-Core Communication

In order to support intra-core synchronization inside Compute Cluster, associated C71/A72 events are routed through the CLEC.

9.2.2.2.6 CLEC Event Maps

See *Interrupt Sources* for CLEC event mapping.

9.2.2.2.6.1 CLEC ESM Event Routing

9.3 Interrupt Routers

9.3.1 INTRTR Overview

The interrupt router (INTRTR) module provides a mechanism to mux *M* interrupt inputs to *N* interrupt outputs, where all *M* inputs are selectable to be driven per *N* ouput. There is one register per output (MUXCNTL_N) that controls the selection.

There are several INTRTR modules in the device. Their purpose is described in *Interrupt Architecture*.

The user should take the following into account when programming the MUXCNTL_N register:

- Avoid programming this register when input interrupts are active. This could lead to spurious asynchronous output toggles which may lead to unpredictable behavior.

The recommended general programming sequence is as follows:

1. Disable interrupt by writing '0' to the INT_ENABLE bit field. Do not change mux control configuration settings (ENABLE bit field) at this time.
2. Change the mux control configuration settings. INT_ENABLE needs to remain '0' at this time.
3. Enable interrupt by writing '1' to INT_ENABLE. Do not change mux control configuration settings at this time.

10.1 DMA Architecture

This section describes the DMA (data movement) architecture in the device.

10.1.1 Overview

The DMA architecture specifies the data structures used by Texas Instruments standard communications modules to facilitate direct memory access (DMA) and to provide a consistent application programming interface (API) to the host software in multi-core devices. The data structures and the API used to manipulate them will be jointly referred to as NAVSS.

Frequent tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the host software and communication module interface. In networking systems, packet transmission and reception are critical tasks. Texas Instruments has developed the NAVSS standard, which is aimed at maximizing the efficiency of interaction between the host software and communications modules.

The design goals for NAVSS are as follows:

- Minimize host interaction
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections, buffer sizes, queue sizes, and protocols supported
- Minimize protocol specific features
- Minimize complexity

NAVSS architecture is shown on Figure 10-1.

Figure 10-1. NAVSS Overview

10.1.1.1 Navigator Subsystem

The Navigator Subsystem (NAVSS hardware) is a container which groups together as much as possible the components which provide the Hardare to Software boundary for data movement control in the system. All of the components which control work handoff (queuing, interrupts, monitoring and debugging) are included in the NAVSS which in turn is located as close as possible to the various host processors to which services are provided. Other DMA components such as DRUs, UTC, and PDMAs exist outside the NAVSS but all are controlled by the root complexes provided in NAVSS.

The SoC has two NAVSSes: one in main and one in MCU domain.

10.1.1.2 Ring Accelerator (RA)

The ring accelerator (RINGACC or RA) is a hardware module that is responsible for accelerating management of various types of queues in the system. The RA accelerates passing of packets between a producer and consumer in normal system memory (including cached memory). The RA is capable of accelerating the read/write pointer maintenance and occupancy tracking operations.

The ring accelerator operates like a bus infrastructure bridge in that it passes transactions through it between a source and destination interface. As transactions are passed, the RA modifies the address, byte count, and transaction identifiers and internally updates the occupancies/pointers.

Each queue that the RA provides can operate in either exposed-ring-mode or private-queue-mode.

- The exposed ring mode allows software to directly access the underlying ring structure to add or remove items from the tail or head of the ring respectively. Whenever items are added or removed from a ring, the host software is required to write to a corresponding doorbell register to increment or decrement the ring occupancy. When using the exposed ring mode, no proxy is required between the software and the RA but all queue add operations require a memory fence to be performed to ensure that the data has landed in a snoopable cache before the doorbell register is written.
- The private queue mode provides an abstract view of the ring so that the host software does not need to know the actual physical address location or current read or write indexes of the ring. The private queue mode provides a memory window for each ring which when written redirects the write to the address pointed

Copyright © 2023 Texas Instruments Incorporated

to by the write pointer and when read redirects the read to the address pointed to by the read pointer. The same address range is always used to push or pop elements from a given queue.

Rings are an implementation of a logical queue with the following limitations:

- Each ring has a finite size. When rings are used in exposed ring mode the following conditions apply:
  - A separate operation is required to write/read the contents of a ring and to update the occupancy of the ring
  - It is not straightforward to allow multiple producers to write to a ring or multiple consumers to read from a ring. Additional synchronization and pointer passing is required since rings require software to manage one of the pointers for the queue.
  - An exposed ring cannot be used when software or hardware needs to both read and write the same queue (such as for a DMA RX free queue where errors can have the DMA write the element back onto the same RX free queue). Since software owns one side of the pointers and hardware owns the other, they cannot be kept coherent if either side needs to update either at any time.

The RA allows each ring to be configured to a different primary element size. Element sized chunks of data are placed onto and retrieved from rings when queuing or de-queueing occurs. Element sizes can be as small as 4 bytes or as large as 256 bytes.

10.1.1.3 Proxy

The proxy provides a mechanism for software to access the RA coherently when the processor does not support large bursts. The RA requires a single burst for each operation so that it maintains atomicity and coherence by relying on the atomicity of the bursts on the bus interconnect fabric, since it only delivers a single burst to the RA before the next. Since processors are usually limited in the size of a burst they can deliver natively, such as 32 to 128 bits, they cannot be used directly with the data access region of the RA for larger element sizes. The proxy solves this gap by providing a temporary space for the software to form a larger burst of data before it is sent to the RA. The proxy allows smaller processor accesses to the data and only forwards to the RA when the entire data burst is complete, as directed by the software. Each proxy hardware can support multiple threads of software (whether on the same or different processors) operating on bursts at the same time, and they do not interfere with each other, as long as each thread of software only operates on its thread in the proxy. Each proxy thread also supports access to any RA queue via different offsets similar to how the RA provides access to the queues via different offsets.

For writing data to the RA, the software will write the data in native sized writes to the proxy thread it has been assigned. The proxy simply accepts the writes into a buffer reserved for that thread. Only when the software writes to the completion byte offset (last byte of the burst) then will the proxy take the entire burst of data written (including the final write data) and send it to the RA as a single write burst. After the completion write, the software can begin building a new data burst. For reading data from the RA, the software will read the data in native sized reads to the proxy thread. For the first read, the proxy will read the entire burst from the RA, so that it atomically gets the next element off the queue. This entire data is stored in the proxy thread buffer, and the requested portion is returned to software. Then software can read any location within the burst and the proxy will read it from the buffer. When software is done reading the data, it must read the completion byte offset so that the proxy 'knows' that the read burst is completed, and that for the next read it must read a burst from the RA queue again. A single proxy thread can only be used for a single data burst at a time, so once starting a write it should complete before starting another write or a read, and similarly once starting a read, it should complete before starting another read or a write. If software needs to read and write at the same time, it should use two proxy threads. Similarly if there are multiple threads of software that need to access RA at the same time, they should use separate proxy threads.

10.1.1.4 Secure Proxy

A special version of a proxy is the secure proxy that provides secured access to RA queues for communication to the security master of the system. The secure proxy provides basically the same function as a normal proxy. The data burst size is fixed for message sizes to the security master, so there is no support for all the element sizes of the RA. The security master locks down the RA queue to access and direction for each proxy thread so that the software cannot access anything they shouldn’t, so the software only sees a single queue (unlike the normal proxy), and any attempts to access another queue or access it in violation of how the security master defined and an error will be flagged. This allows for a much more controlled setup for passing messages to the security master.

10.1.1.5 Interrupt Aggregator (INTA)

The interrupt aggregator (INTR_AGGR or INTA) is a hardware module which provides a persistent view of the real time status of various DMA components within the overall SoC DMA system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

The INTA block provides the following functions:

- Conversion of local event signal lines into global events
- Performing an 'Y-split' operation of global events
- Counting global events
- Steering and aggregation of global events into specified bit positions in one of N interrupt cause registers
- SoC interrupt-achitecture-compliant set/clear and mask set/clear functionality to cover interrupt cause registers
- Output of virtual interrupt sources to the Interrupt Router module

10.1.1.6 Interrupt Router (IR)

The interrupt router (INTR_ROUTER or IR) is a hardware module which allows for virtual interrupt sources which were output from the INTA block to be crossbar switched onto physical interrupts which are connected to the system level Interrupt Controller (ARM GIC or other interrupt controller).

10.1.1.7 Unified DMA – Third Party Channel Controller (UDMA-C)

Note

In this SoC, UDMA-P (see Section 10.1.1.10) serves UDMA-C functions. That is, there is no discrete UDMA-C controller in this SoC device.

The Unified DMA 3rd-Party Channel Controller is intended to perform similar (but significantly upgraded) functions to the EDMA Channel Controller engine on previous SoC devices. The UDMA-C module supports the transmission of Transfer Request packets from memory mapped data structures to data channels within UTCs in the system and reception of Transfer Response packets from data channels in UTCs in the system into memory mapped data structures. Up to 512 (configuration specific) third-party DMA control channels are provided within the UDMA-C. Each control channel corresponds to a single third party DMA data channel in a separate UTC. Transfer Request messages provide transfer parameters which are to be used by the UTC channels to move data in the system (previously implemented as PARAM entries). Transfer Response messages are sent back from the UTC in a one to one relationship with Transfer Request packets and provide an indication of both completion of a data transfer and whether or not any exception or error occurred during the data transfer.

The UDMA-C controller maintains state information for each of its channels which allows Transfer Request packet transmission and Transfer Response packet reception operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for the transmission of Transfer Request packets. The ordering and rate of Transfer Response receive operations is directly controlled by the order in which those packets are received on the Rx PSI-L interface. A block diagram of a UDMA-C module is shown Figure 10-2.

Copyright © 2023 Texas Instruments Incorporated

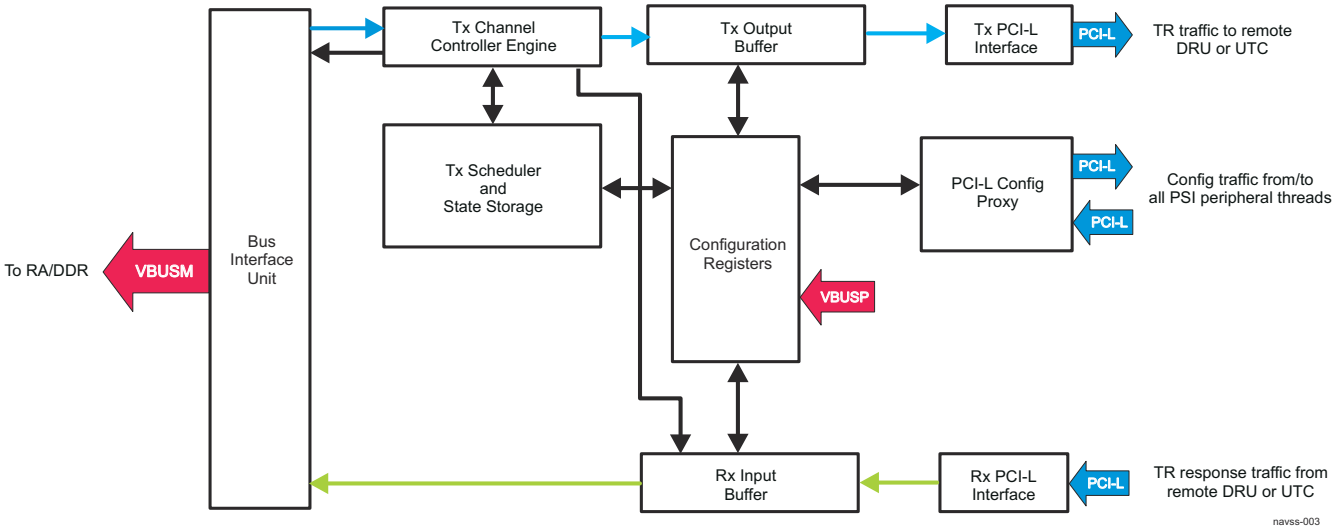

Figure 10-2. UDMA-C Block Diagram

10.1.1.8 Unified Transfer Controller (UTC)

The Unified Transfer Controller is intended to perform similar functions to the EDMA Transfer Controller engine used on previous devices. The UTC engine is generally classified as a third-party DMA. This designation comes from the fact that the engine is not actually the source or sink of the data which is being moved but is instead an intermediary 3rd-party that performs the data move on behalf of the source and sink.

The UTC engine accepts Transfer Response messages from the UDMA-P via a PSI-L interface which provide instructions to copy data between a source read interface and a destination write interface. The sequence of operations that can be instructed includes up to 4-dimensional nested loops. Multiple types of Transfer Request messages are specified and each UTC instance in the system may support all types or any specified subset. The TR formats are specified in detail in a later section. When a Transfer Request has been completed, the UTC returns a Transfer Response message back to the originating UDMA-P. The UTC has the ability to generate events at specified completion points when processing a Transfer Request. These events are sent back to the Interrupt Aggregator block.

An UTC instance may be configured to only support VBUSM to VBUSM block copies or they may also optionally support ‘split’ operations where a read engine is instructed by a TR to read data from a VBUSM interface and send the data to the Packet Streaming fabric via a PSI-L master interface. A similar split operation is supported for writes where data is received into a PSI-L slave interface and is then routed to a write engine which has been instructed by a TR to move the data into a set of memory locations.

10.1.1.9 Data Routing Unit (DRU)

For purposes of the K3 Data Movement architecture, the DRU is essentially a UTC which supports only the block copy mode subset of the Transfer Request message formats. The DRU typically will provide the highest performance block copy data movement capability of any DMA engine within the SoC. The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CC_ARMSS frequency.

10.1.1.10 Unified DMA – Peripheral Root Complex (UDMA-P)

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices. The UDMA-P module supports the transmission and reception of various packet types. The UDMA-P is architected to facilitate the segmentation and reassembly of SoC DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An external DMA scheduler is used to

Copyright © 2023 Texas Instruments Incorporated

control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA-P also supports acting as both a UTC and UDMA-C for its internal channels. Channels in the UDMA-P can be configured to be either Packet-Based or Third-Party channels on a channel by channel basis.

A block diagram of the UDMA-P Controller is shown in Figure 10-3.

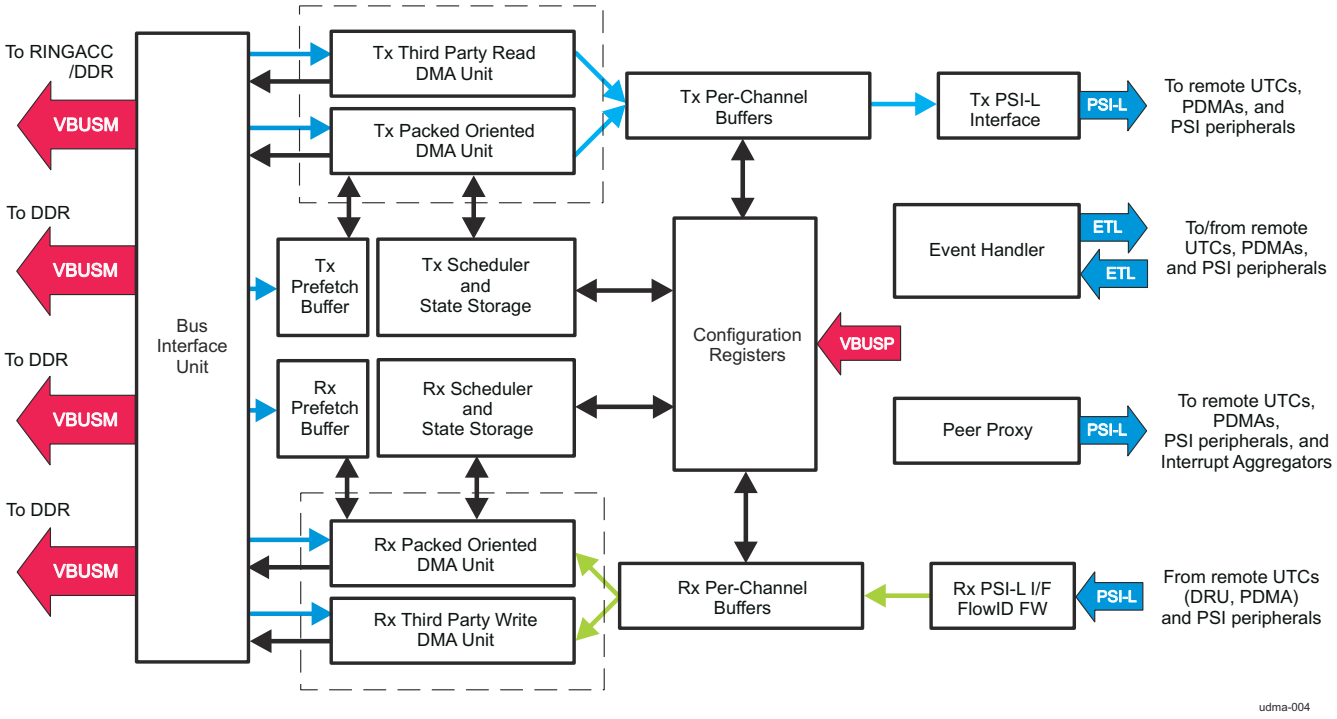

Figure 10-3. UDMA-P Block Diagram

10.1.1.11 Peripheral DMA (PDMA)

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals which perform data transfers using memory mapped registers accessed via a standard non-coherent bus fabric. The PDMA module is intended to be located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request operations. The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The Peripheral DMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

10.1.1.12 Embedded DMA

Embedded DMA refers to a DMA-capable master module which either follows an industry standard hardware/ software Application Programming Interface (API) or is a module which does not natively comply with the TI

Copyright © 2023 Texas Instruments Incorporated

DMA architecture requirements. It is assumed that modules which include Embedded DMA will provide their own dedicated software drivers and interoperability with other DMA entities in the system will be accomplished with software bridging code. None of the remainder of this chapter has any effect on the operation or architecture of Embedded DMA functions.

10.1.1.13 Definition of Terms

Host	The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.
Channel	A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.
Data Buffer	A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.
Buffer Descriptor	A buffer descriptor is a single data structure that contains information about one or more data buffers.
Packet Descriptor	A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).
Queue	A queue is a list of strongly ordered entries which is typically used to pass work between a producer and a consumer. Queue entries in most cases are references to a work payload which is being passed but in some cases (Transfer Request Packets for example) queue entries may actually contain data which is being transferred. Queues are used throughout UDMA whenever communication is required between entities. Queues can have multiple different implementations and UDMA uses two of the most common: linked lists and rings.
Linked list	A linked list is a data structure in which each entry stores not only the entry data but also a chaining pointer to the next entry in the list. The last entry in each list has its chaining pointer set to NULL (typically encoded as 0x0). The list manager maintains a pointer to the head element on the list and to the tail element on the list. Since the chaining pointer is stored with the entry data, linked lists have a length which is dynamically changeable and limited only by the ability to allocate additional entries which are to be queued/de-queued. Linked lists are present in Host Descriptors to chain multiple descriptors to form a packet
Ring	A ring is a data structure in which a contiguous memory block defined by M N-byte entries (total size is M × N bytes) is statically allocated and sequentially written/read in order to pass data or data references. Rings are also referred to as circular buffers because when the last element in the contiguous memory array is written, the pointers wrap back to the beginning address for the ring and start the process all over again. The Ring Accelerator component uses rings in order to implement logical queues
Free Descriptor/ Buffer Queue	A free descriptor/buffer queue is a list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Ring Accelerator.
Free Descriptor Queue	A free descriptor queue is a list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Ring Accelerator.
Packet Queue	A packet queue is a list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes. Packet Queues are implemented by the Ring Accelerator.
Memory	Memory is an area of data storage managed by the host. This area is visible to the port as a 64-bit addressable area.
Device Driver	A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without knowing every bit field location or initialization sequence.. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

Copyright © 2023 Texas Instruments Incorporated

SOP Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

MOP Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

EOP End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

10.1.2 UDMA Hardware/Software Interface

The intent of the TI Data Movement (DMA) architecture is to provide a uniform hardware/software interface which includes a rich set of mechanisms that software can make use of to transfer data with low overhead and reasonable complexity. To this goal, the number of components which software is required to interact with on an ongoing real time basis has been kept to a minimum and is as follows (in order of anticipated frequency of access):

- Interrupt Aggregator
- Ring Accelerator
- UDMA-P/C (for managed flow control and error/exception handling only)

When interrupts are used, the interrupt aggregator will provide the vast majority of interrupt sources from all DMA components in the system. All non-exception/non-debug packet and TR completion signaling originates from the Interrupt Aggregator and the INTA provides a uniform set of registers that can be queried to quickly determine the cause of a specific interrupt. Events from PSI-L/ETL components are all routed to the host via the Interrupt Aggregator.

The Ring Accelerator provides the primary means by which work is sent to or received from the UDMA-P DMA engines (and the UTC/DRU, and PDMA engines whose control operations are proxied by the UDMA-P).

The UDMA-P are primarily fronted by the RA and the INTA but for real time operations like software controlled flow control (via pause) some registers in the UDMA-P blocks may be directly manipulated.

Data structures are used to pass anytime information between components in the system. These components may be hardware or software. The following sections describe the data structures which are used within a UDMA based system for passing information. These data structures include data buffers, packet descriptors, buffer descriptors, queues (including transmit queues, transmit completion queues, and receive queues) and the configuration registers that are provided in the various components. The following sections provide a detailed description of these data structures.

10.1.2.1 Data Buffers

A data buffer is a byte aligned contiguous block of memory used to store packet payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 64-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

10.1.2.2 Descriptors

Descriptors are so named because their primary function is to describe other data structures.

The UDMA architecture provides 4 basic types of descriptors each of which has specific characteristics intended to address different requirements. Table 10-1 shows the different types of descriptors and their characteristics.

Table 10-1. UDMA Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provided Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1		✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.

Copyright © 2023 Texas Instruments Incorporated

Table 10-1. UDMA Descriptor Types and Attributes (continued)

Descriptor Type	Includes Valid Packet Info	Provided Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Buffer Descriptor		1			✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures
Monolithic Packet Descriptor	✓	0	✓	✓		Used to provide descriptor and data information in one contiguous data structure.
Transfer Request Packet Descriptor		0				Used to feed transfer request sequences to the UDMA third party channel controller

As Table 10-1 shows, two of the four different descriptor types (the Host Packet Descriptor and Monolithic Packet Descriptor) provide packet level information that is useful to both the ports and the Host in order to properly process the packet. These descriptors are referred to as Packet Descriptors and will always appear as the first descriptor (or only descriptor in the case of Monolithic types) within a packet.

Software must allocate descriptors on 16-byte address boundaries. 16-byte is the minimum granularity that UDMA supports. This is intended for better memory utilization by allowing on-chip descriptors which are not a power of 2 in length to be packed into arrays with little wasted memory space.

Even though descriptors and buffers may be allocated on any 16-byte alignment, careful consideration of the alignment effects should be made based on the storage location and any cache related affects that may exist. If data structures are placed in off-chip SDRAM the burst size and alignment restrictions of the memory devices must be considered in order to avoid performance issues related to continually fetching mis-aligned blocks. In this case, the memory efficiency can be reduced to 50% because two memory bank lines are read for every line sized data fetch. Similarly, placing more than one descriptor or buffer object within a single cache line can cause the adjacent object to become corrupted during cache line writeback operations.

Software/application specific control information may be added to the end of any of the packet descriptor types using as many extra words as necessary but the above alignment rules still apply.

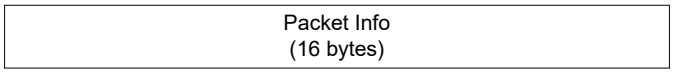
10.1.2.2.1 Host Packet Descriptor

Host Packet Descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control/Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software specific information

Host Packet Descriptors always contain 48 bytes of required information and may also contain optional software specific information and protocol specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application dependent.

The Host Packet descriptor layout is shown below.



Copyright © 2023 Texas Instruments Incorporated

Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)
Extended Packet Info Block (Optional) Includes Timestamp and Software Data (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Other Software Data (Optional and User Defined)

Host Packet Descriptors may be linked with zero or more additional Host Buffer Descriptors in a singly linked list fashion to form packets. Each Host Packet consists of a single Host Packet Descriptor followed by a chain of zero or more Host Buffer Descriptors linked together using the Next Descriptor Pointer fields in the descriptors. The last descriptor in a Host packet has a zero Next Descriptor Pointer.

The 'Other Software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Host Packet Descriptor words are detailed in Table 10-2 through Table 10-18.

Table 10-2. Host Packet Descriptor Packet Information Word 0 (PD Word 0)

Bits	Name	Description	Rx Overwrite
31:30	2'd1	64-bit Host Packet Descriptor Type Identifier	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	Protocol Specific Region Location	This field indicates the location of the Protocol Specific Words: 0 = PS Words are located in the descriptor 1 = PS Words are located in the SOP Buffer immediately prior to the data.	Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes … 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error unless the packet length is set to 0x3FFFFF. If the packet length is set to all 1s (0x3FFFFF) the Tx port will disable truncation and will transmit as much data as is specified in the Buffer Length fields. On Rx, if the received data exceeds 4M-1 bytes, the packet length field will saturate to a value of 0x3FFFFF. The valid range for an exact packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

Table 10-3. Host Packet Descriptor Packet Information Word 1 (PD Word 1)

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes

Copyright © 2023 Texas Instruments Incorporated

Table 10-3. Host Packet Descriptor Packet Information Word 1 (PD Word 1) (continued)

Bits	Name	Description	Rx Overwrite
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 10-4. Host Packet Descriptor Packet Information Word 2 (PD Word 2)

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = Application specific	Yes
26:19	RESERVED	Reserved	No
18	Return Policy	This field indicates the return policy for this packet. 0 = Entire packet (still linked together) should be returned to queue specified in bits 15:0. 1 = Each buffer should be returned to queue specified in bits 15:0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.	No
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit or Receive DMA should return the descriptor pointers to the free queues This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. The Rx DMA will only use this field when an error occurs during reception and the DMA must return descriptors back to the free queue from which they came. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue/ Ring Num	This field indicates the ring number in the RA that the descriptor is to be returned to after transmission is complete. The value 0xFFFF is reserved.	No

Table 10-5. Host Packet Descriptor Packet Information Word 3 (PD Word 3)

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

Table 10-6. Host Packet Descriptor Linking Word 0 (PD Word 4)

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit, 16-byte aligned (min), memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	Yes

Table 10-7. Host Packet Descriptor Linking Word 1 (PD Word 5)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.	Yes
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer	Yes

Table 10-8. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 6)

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. If the protocol specific words are placed at the beginning of the SOP buffer, this pointer will point to the PS words. The offset to the data in that case must be calculated by the consumer using the Protocol Specific Valid Word Count from Word 2. These are the 32 LSBs of the 48-bit buffer pointer.	Yes

Table 10-9. Host Packet Descriptor Buffer 0 Info Word 1 (PD Word 7)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.	Yes
15:0	Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit buffer pointer	Yes

Table 10-10. Host Packet Descriptor Buffer 0 Info Word 2 (PD Word 8)

Bits	Name	Description	Rx Overwrite
31:22	RESERVED	Written to 0	Yes
21:0	Buffer 0 Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	Yes

Table 10-11. Host Packet Descriptor Original Buffer Info Word 0 (PD Word 9)

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		No
21:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in PD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

Table 10-12. Host Packet Descriptor Original Buffer Info Word 1 (PD Word 10)

Bits	Name	Description	Rx Overwrite
31:0	Original Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Since the buffer pointer in PD Words 6/7 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. This field contains the 32 LSBs of the 48-bit original buffer pointer	No

Table 10-13. Host Packet Descriptor Original Buffer Info Word 2 (PD Word 11)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Original Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Original Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit original buffer pointer	No

Table 10-14. Host Packet Descriptor Extended Packet Info Block Word 0 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Timestamp Info	This field contains an application specific timestamp which can be used for traffic shaping in a QoS enabled system.	Configurable

Table 10-15. Host Packet Descriptor Extended Packet Info Block Word 1 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 0	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-16. Host Packet Descriptor Extended Packet Info Block Word 2 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 1	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-17. Host Packet Descriptor Extended Packet Info Block Word 3 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 2	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-18. Host Packet Descriptor Protocol Specific Word N (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Protocol Specific Data N	This field stores information which varies depending on the block and packet type.	Configurable

10.1.2.2.2 Host Buffer Descriptor

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter/gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer.

Every Host buffer descriptor stores the following information:

Copyright © 2023 Texas Instruments Incorporated

1. Pointer to the first valid byte in the data buffer
2. Length of the data buffer
3. Pointer to the next buffer descriptor in the packet

Host Buffer Descriptors always contain 48 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors.

The Host Buffer Descriptor layout is shown below.

Buffer Reclamation Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)

A Host Packet Descriptor and zero or more Host Buffer Descriptors may be linked together using the Next Descriptor Pointer fields to form packets. The last descriptor in a packet has a zero Next Descriptor Pointer. Each Host Buffer descriptor also points to a single data buffer.

The contents of the Host Buffer Descriptor words are detailed in Table 10-19 through Table 10-30.

Table 10-19. Host Buffer Descriptor Reserved Word 0 (BD Word 0)

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

Table 10-20. Host Buffer Descriptor Reserved Word 1 (BD Word 1)

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

Table 10-21. Host Buffer Descriptor Buffer Reclamation Info (BD Word 2)

Bits	Name	Description	Rx Overwrite
31:18	RESERVED		No
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit or Receive DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. The Rx DMA will only use this field when an error occurs during reception and the DMA must return descriptors back to the free queue from which they came. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue Num	This field indicates the ring number within the Ring Accelerator that the descriptor is to be returned to after transmission is complete.	No

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

Table 10-23. Host Buffer Descriptor Linking Word 0 (BD Word 4)

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit, 16-byte aligned (min), memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	Yes

Table 10-24. Host Buffer Descriptor Linking Word 1 (BD Word 5)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		Yes
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.	Yes
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer	Yes

Table 10-25. Host Buffer Descriptor Buffer N Info Word 1 (BD Word 6)

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. If the protocol specific words are placed at the beginning of the SOP buffer, this pointer will point to the PS words. The offset to the data in that case must be calculated by the consumer using the Protocol Specific Valid Word Count from Word 2. These are the 32 LSBs of the 48-bit buffer pointer.	Yes

Table 10-26. Host Buffer Descriptor Buffer N Info Word 1 (BD Word 7)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		Yes
19:16	Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.	Yes
15:0	Buffer 0 Pointer MSB	The MSBs of the 48-bit buffer pointer	Yes

Table 10-27. Host Buffer Descriptor Buffer N Info Word 2 (BD Word 8)

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		Yes
21:0	Buffer N Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	Yes

Table 10-28. Host Buffer Descriptor Original Buffer Info Word 0 (BD Word 9)

Bits	Name	Description	Rx Overwrite
31:28	RESERVED		No
27:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in BD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		Yes
19:16	Original Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address – treated special by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other ‘tiles’ on large devices.	Yes
15:0	Original Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit original buffer pointer	No

10.1.2.2.3 Monolithic Packet Descriptor

The Monolithic Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Monolithic Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Packet Error Indicator
- Packet Return Information
- Protocol Specific Region Size
- Protocol Specific Region Offset
- Protocol Specific Control/Status Bits
- Packet Data

The maximum size of a Monolithic Packet Descriptor is 4 MB. Of this, Monolithic Packet Descriptors always contain 16 bytes of required information and may also contain 16 bytes of software specific tagging information and up to 128 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent.

The Monolithic Packet descriptor layout is shown below.

Packet Info (16 bytes)
Extended Packet Info Block (Optional) Includes Timestamp, and software Data Words (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Null Region (0 to 511 bytes)
Packet Data (0 to 4M – 1)
Other software Data (Optional and User Defined)

The 'Other software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store private data. This region is not used in any way by the hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Monolithic Packet Descriptor words are detailed in Table 10-31 through Table 10-40

Copyright © 2023 Texas Instruments Incorporated

Table 10-31. Monolithic Packet Descriptor Word 0

Bits	Name	Description	Rx Overwrite
31:30	2'd2	Monolithic Packet Descriptor type.	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	RESERVED		Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes … 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. The valid range for the packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

Table 10-32. Monolithic Packet Descriptor Word 1

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 10-33. Monolithic Packet Descriptor Word 2

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = To Be Assigned	Yes
26:18	Data Offset	This field indicates the byte offset from byte 0 of this descriptor to the location where the valid data begins. On Rx, this value is set equal to the value for the SOP offset given in the Rx DMA channel's Monolithic control register. When a monolithic packet is processed, this value may be modified in order to add or remove bytes to from the beginning of the packet. The value for this field can range from 0-511 bytes. Note that the value of this field must always be greater than or equal to 4 times the value given in the Protocol Specific Valid Word Count field.	Yes
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No

Table 10-39. Monolithic Packet Descriptor Protocol Specific Word M (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Protocol Specific Data N	This field stores information which varies depending on the packet type.	Configurable

The payload data follows the protocol specific words at an offset specified in the data offset field of Word 0.

Table 10-40. Monolithic Packet Descriptor Payload Data Words 0-N

Bits	Name	Description	Rx Overwrite
31:0	Packet Data N	These words store the packet payload data.	Yes

This field is endian specific. In other words, this is the only field in the descriptor which changes based on the endianness of the system.

10.1.2.2.4 Transfer Request Descriptor

The Transfer Request Descriptor contains the following information:

- Indicator which identifies the descriptor as a TR Descriptor
- Source and Destination Tags
- Packet Error Indicator
- Packet Return Information
- Set of one or more Transfer Request Records
- Set of one or more Transfer Response Records

Transfer Request Packet Descriptors always contain 16 bytes of required information and a variable number of Transfer Request/Transfer Response Records (request and response counts match).

The Transfer Request descriptor layout is shown below.

Packet Info (16 bytes)
Null (0-102 bytes to bring start of TR request array into natural alignment for memory fetch efficiency)
Array of Transfer Request Records (M bytes)
Array of Transfer Response Records (4 bytes per)

Table 10-41. Transfer Request Packet Descriptor Word 0

Bits	Name	Description	Rx Overwrite
31:30	2'd3	TR Packet Descriptor type.	Yes
29	RESERVED		Yes
28:20	Reload Count	Specifies what to do when the last entry is processed in this packet. This field specifies how many times to return to the Reload Index upon reaching the Last Entry. When an internal count is incremented to this value and the TR indicated by the Last Entry has been processed, this packet will be considered complete and the descriptor will be placed back on the return queue specified in Word 2. A value of 0x1FF indicates that a perpetual loop is desired. In this case, the loop count is considered infinite and the internal count will not be incremented. A teardown operation on the channel will cause the loop to be broken at the nearest iteration boundary.

Table 10-41. Transfer Request Packet Descriptor Word 0 (continued)

Bits	Name	Description	Rx Overwrite
19:14	Reload Index	Specifies the value to set the current processing index to when the last entry is processed and the Reload Enable is set to 1. This is basically an absolute index to jump to on the 2nd and following passes through the TR packet.	
13:0	Last Entry	Specifies the index of the last valid entry in this packet	Yes

Table 10-42. Transfer Request Packet Descriptor Word 1

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27	RESERVED		Yes
26:24	Transfer Request Nominal Element Size	Specifies the stride between TR entries. The value in this field must be set large enough that any TR in the buffer will fit within the given dimension. TRs are expected to be placed on boundaries as given in this dimension. This field is also used to calculate the location where the Transfer Responses will be written back. This field is encoded as follows: 0 = 16 byte Transfer Request record size 1 = 32-byte Transfer Request record size 2 = 64-byte Transfer Request record size 3 = 128-byte Transfer Request record size 4-7 = RESERVED	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 10-43. Transfer Request Packet Descriptor Word 2

Bits	Name	Description	Rx Overwrite
31:17	RESERVED		No
16	Return Push Policy	This field indicates how a Transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator	No
15:0	Packet Return Queue Num	This field indicates the queue number that the descriptor is to be returned to after transmission is complete.	No

15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

Table 10-45. Transfer Request Packet Descriptor Payload Words 0-N

Bits	Name	Description	Rx Overwrite
31:0	Transfer Control Record Array	Transfer Control Records. This is an array of records which encapsulate the Transfer Request and Transfer Response messages which are used by the UTC	Yes (partial)

10.1.2.3 Transfer Request Record

10.1.2.3.1 Overview

This section describes the standard transfer request (TR) format to initiate a DMA transfer. The TRs can support both half and full duplex with multiple dimensions as well as cache warms. The UTC (Universal Transfer Controller) does not have to support all types of TRs. Each TR will also generate a TR response. A TR can be sent to the UTC either through a PSI-L interface or an optionally supported Direct TR submission (previously QDMA) which will have Memory Mapped TR submission registers that can be written. The Memory Mapped TR submission registers further be classified by submission type either a single burst (atomic write) or multiple burst (non-atomic). The non-atomic TR will be sent when the submission register with word 0 is written.

Table 10-46. Terms and Definitions

Term	Definition
TR	A transfer request to move data.
CR	A cache operation request. A request to send messages to a specified cache controller to prepare the cache for a future operation.
UTC	Universal Transfer Controller the module in the UDMA architecture that handled the actual movement of data requested in the TR.

10.1.2.3.2 Addressing Algorithm

For a basic TR request the same algorithm is used. The innermost loop always consumes physically contiguous elements from memory. Its implicit dimension is 1 byte, this can be changed if the TR contains the formatting flags field and it is supported by the UTC. The pointer itself moves from fetch to fetch on the maximum byte alignments specified for the UTC, in increasing order. In each level outside the inner loop, the loop moves the pointer to a new location based on the size of that loop level's dimension.

10.1.2.3.2.1 Linear Addressing (Forward)

The following code illustrates the basic algorithm for a 4-level loop nest block move. This model assumes that it transfers data 1 byte at a time and the input and output block are the same size in all dimensions.

```
// sptr is a byte pointer.
// dptr is a byte pointer.
// Source address is indirect
if (TR_ISA) {
```

Copyright © 2023 Texas Instruments Incorporated

```
  sptr = *sptr;
}
// Destination address is indirect
if (TR_IDA) {
  dptr = *dptr;
}
// TR_TRIGX can be selected to come from Global events, Local event, or none.
// Check for trigger of TYPE0
if (TR_TRIG0_TYPE == TYPE0)  while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE0)  while(!TR_TRIG1);
for (i3 = 0; i3 < ICNT3; i3++)
{
sptr3 = sptr; // save current position before entering next level
dptr3 = dptr; // save current position before entering next level
// Check for trigger of TYPE1
if (TR_TRIG0_TYPE == TYPE1)  while(!TR_TRIG0);
If (TR_TRIG1_TYPE == TYPE1)  while(!TR_TRIG1);
for (i2 = 0; i2 < ICNT2; i2++) {
sptr2 = sptr; // save current position before entering next level
dptr2 = dptr; // save current position before entering next level
// Check for trigger of TYPE2
if (TR_TRIG0_TYPE == TYPE2)  while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE2)  while(!TR_TRIG1);
for (i1 = 0; i1 < ICNT1; i1++) {
sptr1 = sptr; // save current position before entering next level
dptr1 = dptr; // save current position before entering next level
// Check for trigger of TYPE3
if(TR_TRIG0_TYPE == TYPE3)  while(!TR_TRIG0);
if(TR_TRIG1_TYPE == TYPE3)  while(!TR_TRIG1);
for (i0 = 0; i0 < ICNT0; i0++) {
// UTC can combine these in optimized burst aligned accesses.
*dptr = *sptr;
sptr = sptr++;
dptr = dptr++;
}
// Update based on saved pointer for this level
sptr = sptr1 + SDIM1;
dptr = dptr1 + DDIM1;
}
// Update based on saved pointer for this level
sptr = sptr2 + SDIM2;
dptr = dptr1 + DDIM2;
}
// Update based on saved pointer for this level
sptr = sptr3 + SDIM3;
dptr = dptr1 + DDIM3;
}
```

This form of addressing allows programs to specify regular paths through memory in a small number of parameters. Additionally, it allows for various stall points through the loop to allow for hardware or software induced pausing of the transfer. The following table defines these parameters more explicitly.

Table 10-47. Addressing Parameters for a Basic Stream

Parameter	Definition
ICNT0	Number of iterations for the innermost loop dimension, loop level 0. That is, DIM0 = BYTES.
ICNT1	Number of iterations for the first level above the innermost loop, loop level 1.
SDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the source.
DDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the destination.
ICNT2	Number of iterations for loop level 2.
SDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the source.
DDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the destination.
ICNT3	Number of iterations for loop level 3.
SDIM3	Number of bytes between starting points for consecutive iterations of loop level 3 for the source.

Copyright © 2023 Texas Instruments Incorporated

Table 10-47. Addressing Parameters for a Basic Stream (continued)

Parameter	Definition
DDIM3	Number of bytes between the starting points for consecutive iterations of loop level 3 for the destination.

10.1.2.3.3 Transfer Request Formats

The Transfer Request format builds on the same structure adding fields to the TR to give more configuration options. The structure in Table 10-48 shows the 512-bit data structure that makes up the maximum sized UTC Transfer request.

Table 10-48. Transfer Request Template

word 15		word 14		word 13		word 12
DICNT3	DICNT2	DICNT1	DICNT0	DDIM3		DDIM2
word 11		word 10		word 9		word 8
DADDR				DDIM1		FMTFLAGS
word 7		word 6		word 5		word 4
DIM3		DIM2		ICNT3	ICNT2	DIM1
word3		word 2		word 1		word0
ADDR				ICNT1	ICNT0	FLAGS

The UTC defines a four-level loop nest for addressing elements within the TR, using the algorithms described in the Addressing algorithm. Most of the fields in the TR template map directly to the parameters in those algorithms.

Table 10-49. Transfer Request Fields

Field Name	Description	Size (bits)
FLAGS	TR flags that specify type of TR and how the TR should be handled. It also supports the TR triggering and output events.	32
ICNT0	Total loop iteration count for level 0 (innermost)	16
ICNT1	Total loop iteration count for level 1	16
ADDR	Starting address for the source data or destination data if it is a half-duplex write	64
DIM1	Signed dimension for loop level 1 for the source data	32
ICNT2	Total loop iteration count for level 2	16
ICNT3	Total loop iteration count for level 3 (outermost)	16
DIM2	Signed dimension for loop level 2	32
DIM3	Signed dimension for loop level 3	32
FMTFLAGS	Flags that tell how the data is formatted either between the input and the output or if the data should use different addressing schemes or sizes. These flags are OPTIONAL and only specific features may be supported by a given DMA implementation. The UDMA/UTC capabilities register specifies which features are supported.	32
DDIM1	Signed dimension for loop level 1 for the destination data	32
DADDR	Starting address for the destination of the data	64
DDIM2	Signed dimension for loop level 2 for the destination data	32
DDIM3	Signed dimension for loop level 3 for the destination data	32
DICNT0	Total loop iteration count for level 0 (innermost) used for destination	16
DICNT1	Total loop iteration count for level 1 used for destination	16
DICNT2	Total loop iteration count for level 2 used for destination	16
DICNT3	Total loop iteration count for level 3 used for destination	16

The TR assumes all iteration counts as unsigned integers, and all dimensions as signed integers representing byte offsets.

The template above fully specifies the type of elements, length, and dimensions of the transfer.

Copyright © 2023 Texas Instruments Incorporated

Since all transfers will not require all the fields the TRs have the type field which allow the number of words required to be sent for the TR to be reduced.

10.1.2.3.4 Flags Field Definition

Table 10-50 expands the 32-bit FLAGS field. The numbers above each field here indicate bit numbers within the field.

Table 10-50. Transfer Request Template FLAGS Field

31							24	23							16
CONFIGURATION SPECIFIC FLAGS								CMD ID							
15	14	13	12	11	10	9	8	7	6	5	4	3			0
TRIGGER1_TYPE		TRIGGER1		TRIGGER0_TYPE		TRIGGER0		EVENT_SIZE		WAIT	STATIC	TYPE			

The flags field fills in the remaining details about the stream, as follows:

Table 10-51. FLAGS Field Descriptions

Bit	Field	Description
0-3	TYPE	The TYPE of TR that is being sent 0: One dimensional data move 1: Two dimensional data move 2: Three dimensional data move 3: Four dimensional data move 4: Four dimensional data move with data formatting 5: Four dimensional Cache Warm 6-7: Reserved 8: Four Dimensional Block Move 9: Four Dimensional Block Move with Repacking 10: Two Dimensional Block Move 11: Two Dimensional Block Move with Repacking 12-14: Reserved 15: Four Dimensional Block Move with Repacking and Indirection
4	STATIC	This field is only valid on Type 8 and type 9 TRs The TR is static and will continually reload into the channel upon completion of the TR until a channel tear down.
5	WAIT	This field is only valid on Type 15 TRs. This field indicates whether or not this TR should ensure it completes before allowing the next TR to start on this channel. The encoding is as follows: 0 = Allow next TR to start immediately 1 = Wait for this TR to complete before allowing next TR to start When set, the next TR will not be considered triggered (regardless of any other trigger conditions) until all write status responses for the current TR have landed.
6-7	EVENT_SIZE	This is how often the TR will generate an output event. 0: Event is only generated with the TR is complete 1: Event is generated when the second inner most loop (ICNT1) is decremented by 1. 2: Event is generated when the third inner most loop (ICNT2) is decremented by 1. 3: Event is generated when the outer most loop (ICNT3) is decremented by 1.

Copyright © 2023 Texas Instruments Incorporated

Table 10-51. FLAGS Field Descriptions (continued)

Bit	Field	Description
8-9	TRIGGER0	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER0_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel
10-11	TRIGGER0_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
12-13	TRIGGER1	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER1_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel This field is reserved for a Direct TR.
14-15	TRIGGER1_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
16-23	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR. For a Direct TR this is the event number that will be generated based on the event trigger.
24-31	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC implementation.

The following sections expand on each of these fields.

10.1.2.3.4.1 Type: TR Type Field

The TR Type field gives the size of the TR and which fields are expected in the TR. Based on the type the number of words required to be sent to complete the TR can be decreased. The tables below show the minimum size for each TR as well if any fields will be treated as reserved.

Table 10-52. Transfer Request Minimum Size Type 0 One Dimensional Transfer

10.1.2.3.4.2 STATIC: Static Field Definition

The static field is used to allow for a single TR to be reused repeatedly. If the static bit is set then the UTC upon completing the specified TR will restart the TR with the same values as were in the initial TR. This TR will stay

Copyright © 2023 Texas Instruments Incorporated

active until the channel is torn down. The initiating of a tear down of the channel will clear the STATIC field in the active TR and it will be removed from the channel FIFO after the TR completion.

Note

If a TR is submitted to a channel FIFO with the STATIC field set then any TRs placed in the FIFO after that will NOT be run until the teardown has been initiated.

10.1.2.3.4.3 EVENT_SIZE: Event Generation Definition

The UTC allows for an event to be generated at specified intervals for each TR. As the TR passes through the various loops in the addressing algorithm it will generate an event that then can be routed to other event receivers, such as other channels or interrupts to processors.

Table 10-63. Event Size Encoding

Value	Event Type	When it Fires
0	Completion Event	When the TR is complete and all status for the TR has been received.
1	ICNT1 Decrement	Type 0: When the last data transaction is sent for the TR. Type 1-11: When ICNT1 is decremented
2	ICNT2 Decrement	Type 0 – 1,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT2 is decremented
3	ICNT3 Decrement	Type 0 – 2,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT3 is decremented

10.1.2.3.4.4 TRIGGER INFO: TR Triggers

The TR allows for two different triggers to be set to allow for the data transfer to be prevented or halted through the process of transferring the data. The triggers are specified by selecting a type of trigger and the size of the transfer that can be allowed for the receipt of a given trigger. The triggers themselves in the UTC are collected on a per channel basis and for each of three sources. Anytime the trigger event is received the internal counter is incremented. The trigger event will not be cleared until the specified block has started its transfer and it will **only** clear the triggers that are active.

CAUTION

This does allow for one TR in the channel to use global event 0 and the next TR to use global event 1. If while the first TR is running global event 0 can increment and will decrement each time the TR reaches the specified level. At the same time global event 1 will be incremented whenever it is received but it will not decrement until the next TR runs. If the global event 1 counter reaches overflows then an error event will NOT be generated but the event will be lost.

10.1.2.3.4.5 TRIGGERX_TYPE: Trigger Type

The trigger type sets the value of TR_TRIGX as shown in the addressing algorithm description. The TR_TRIGX value allows for the temporary halting of the TR until the expected event has been received. After the given loop has been entered the selected trigger will be decremented.

10.1.2.3.4.6 TRIGGERX: Trigger Selection

The TR is able to select up to 2 of 3 trigger sources for a given TR. The events can come from the dedicated local event on the UTC itself or from two assigned global events that come from the PSI-L interface on the UTC. The trigger counters are always enabled so that events can be received prior to the TR getting loaded. The trigger counters are only decremented when the trigger is active and the TR has scheduled the first transfer of the transaction.

10.1.2.3.4.7 CMD ID: Command ID Field Definition

The command ID is used as a unique identifier for the TR. The value is not used during the data transfer but is only used by the TR Completion Response to allow for hardware and software to identify the specific TR.

Copyright © 2023 Texas Instruments Incorporated

10.1.2.3.4.8 Configuration Specific Flags Definition

The configuration specific flags are specific to a given TR type. If a TR type does not require additional flags the field should be filled with 0's. Currently only Types 0-4 and Type 15 support the following configuration specific flags:

Table 10-64. Configuration Specific Flags

Bit	Field	Description
0	ISA	Indirect Source Address 0: Source address in TR is a directly usable pointer to the data 1: Source address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
1	IDA	Indirect Destination Address 0: Destination address in TR is a directly usable pointer to the data 1: Destination address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
2	SUPR_EVT	Suppress Event Output: 0 = Output events will be generated according to FLAGS.EVENT_SIZE field 1 = No output events will be generated for the duration of this TR execution This field is only valid on split and type 15 TRs (Type 0-3,15)
3	Reserved	Reserved for Future use.
6:4	EOL	This field is only valid on split TRs (Type 0-3). On source (Read) split TRs, this field specifies whether or not the EOL delimiters should be produced on the Tx PSI-L bus. The encodings of this field for source split TRs is as follows: 0 = SOL/EOL match SOP/EOP 1 = SOL/EOL boundaries are each ICNT0 bytes 2 = SOL/EOL boundaries are each ICNT0×ICNT1 bytes 3 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2 bytes 4 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2×ICNT3 bytes On destination (Write) split TRs, this field specifies how to handle EOL delimiters when they are encountered on the Rx (write) side of a TR. EOL delimiters can be produced from the Tx (read) side of a block copy operation or from a remotely paired peripheral when operating in split TR mode. The encodings of this field are as follows: 0: Ignore EOL 1: Clear any remaining ICNT0 bytes and increment ICNT1 by 1 2: Clear any remaining ICNT0/1 bytes and increment ICNT2 by 1 3: Clear any remaining ICNT0/1/2 bytes and increment ICNT3 by 1 -7: RESERVED
7	EOP	This TR should generate an EOP on the streaming interface for any downstream packet oriented consumers to denote that a 'packet' of data is complete 0: No EOP flag will accompany the last PSI-L data phase associated with transfers from this TR 1: On egress the DMA will set the EOP flag coincident with transferring the last of the data for this TR. If the TR data does not complete an entire PSI-L data phase then the remaining bytes in the data phase will be skipped and the internal FIFO pointer will be updated to begin packing new data on a new data phase boundary.

10.1.2.3.5 TR Address and Size Attributes

The fields described below all describe the data transfer that needs to be made as described in the Linear Memory Addressing Block Move Algorithm.

10.1.2.3.5.1 ICNT0

The ICNT0 is the number of elements to transfer in the inner loop of the TR. If the TR type does not contain a FMTFLAGS field then this count is assumed to be the number of bytes to transfer. If the FMTFLAGS field is included in the types then the number of bytes to be transferred will be ICNT0 times the Element size rounded up to the nearest byte.

Copyright © 2023 Texas Instruments Incorporated

10.1.2.3.5.2 ICNT1

The ICNT1 field is the loop count for the second innermost loop count as defined in the Addressing algorithm.

10.1.2.3.5.3 ADDR

The address location is the initial address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register.

While the ADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4-bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the ADDR field is given in Table 10-65.

Table 10-65. ADDR Field Format

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit source or source/destination starting address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype or rx_atype field in the DMA Tx/Rx channel's Configuration Register.

10.1.2.3.5.4 DIM1

This is the offset of the address from the initial address for the first access of the second loop. This will be added to the address from the loop before. This is a signed value so that the address can be both above and below the initial address.

10.1.2.3.5.5 ICNT2

This is the count for the third innermost loop in the addressing algorithm.

10.1.2.3.5.6 ICNT3

This is the count for the outermost loop in the addressing.

10.1.2.3.5.7 DIM2

This is the offset of the address from the initial address to the next address in the third innermost loop. This is a signed vales so that the address can be both above and below the previous address.

10.1.2.3.5.8 DIM3

This is the offset of the address from the initial address to the next address in the outermost loop. This is a signed values so that the address can be both above and below the previous address.

10.1.2.3.5.9 DDIM1

This is the offset of the destination address from the initial destination address for the first access of the second loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.10 DADDR

The destination address location is the initial destination address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register

While the DADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4 bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the DADDR field is given as follows:

Copyright © 2023 Texas Instruments Incorporated

Table 10-66. DADDR Field Format

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit starting destination address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype field in the DMA Tx channel's Configuration Register.

10.1.2.3.5.11 DDIM2

This is the offset of the destination address from the initial destination address for the first access of the third loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.12 DDIM3

This is the offset of the destination address from the initial destination address for the first access of the outer loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.13 DICNT0

This is the number of elements to use in the destination if the TR is repacking the data. This number reflects the number of elements to be transferred.

10.1.2.3.5.14 DICNT1

This is the number of times to execute the second loop to use in the destination transfer.

10.1.2.3.5.15 DICNT2

This is the number of times to execute the third loop to use in the destination transfer.

10.1.2.3.5.16 DICNT3

This is the number of times to execute the fourth loop to use in the destination transfer. The value of DICNT0 × DICNT1 × DICNT2 × DICNT3 must equal ICNT0 × ICNT1 × ICNT2 × ICNT3. If any of the values are zero they are NOT included in the multiplication.

10.1.2.3.6 FMTFLAGS

The format flags are used to specify special formatting of the transfer. Table 10-67 shows the definition of the sub-fields in the FMTFLAGS field.

Table 10-67. Transfer Request Template FMTFLAGS Field

31															16
AMODE SPECIFIC															
15	14	13	12	11			8	7			4	3	2		0
RESERVED		SECTR		DFMT				ELTYPE				DIR	AMODE		

The flags field fills in the remaining details about the stream, as follows:

Table 10-68. FMTFLAGS Field Descriptions

Bit	Field	Description
16-31	AMODE SPECIFIC	This 16-bit field is defined based on the addressing mode used as selected in the AMODE field.
14-15	Reserved	Reserved for Future use
12-13	SECTR	A secondary TR is required and the format of the secondary TR.
8-11	DFMT	The data reformatting function to apply in the middle of the TR

Copyright © 2023 Texas Instruments Incorporated

Table 10-68. FMTFLAGS Field Descriptions (continued)

Bit	Field	Description
4-7	ELTYPE	The type of element and its size and potential output size for the innermost loop. If this is not specified in the TR then a byte is the assumed element.
3	DIR	For a block type transfer does the addressing mode apply for source or destination. The other one will use linear. If it is a non-block type TR then this field is ignored
0-2	AMODE	The Addressing Mode of TR that is being sent 0: Linear Addressing 1: Circular Addressing 2-7: Reserved for future use

10.1.2.3.6.1 AMODE: Addressing Mode Definition

The addressing mode field allows for different algorithms to be used other than the default linear addressing mode described in the Addressing algorithm.

10.1.2.3.6.1.1 Linear Addressing

This is the addressing that is used if there is no FMTFLAGS field in the TR.

10.1.2.3.6.1.2 Circular Addressing

Circular addressing modifies how the UTC performs address arithmetic so that addresses remain within a power-of-2 sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default—linear addressing—which allows all of the address bits to vary.

The UTC TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

Conceptually, selectable addressing mode support replaces all address arithmetic with a function similar to the following.

```
enum addr_mode_t
{
LINEAR,// Linear addressing mode
CIRC0,// Circular addressing with block size 0
CIRC1// Circular addressing with block size 1
};
uint64_t circ_mask_0;// Circular addressing mask for block size 0
uint64_t circ_mask_1;// Circular addressing mask for block size 1
uint64_t address_add( uint64_t base, int32_t offset, addr_mode_t mode )
{
uint64_t new_addr = base + offset;
if ( mode == LINEAR )
return new_addr;
// Look up address mask based on selected circular buffer size.
// Mask contains 1s for bits that remain fixed, and 0s elsewhere.
uint64_t addr_mask = mode == CIRC0 ? circ_mask_0 : circ_mask_1;
return ( base & addr_mask ) | ( new_addr & ~addr_mask );
}
```

The address_add primitive then takes the place of plain addition for all TR address computations in this mode. The following example illustrates address_add.

```
for (i3 = 0; i3 < ICNT3; i3++)
{
ptr3 = ptr; // save current position before entering next level
for (i2 = 0; i2 < ICNT2; i2++)
{
ptr2 = ptr; // save current position before entering next level
for (i1 = 0; i1 < ICNT1; i1++)
{
ptr1 = ptr; // save current position before entering next level
for (i0 = 0; i0 < ICNT0; i0++)
{
```

Copyright © 2023 Texas Instruments Incorporated

```
fetch( ptr, ELEM_BYTES );
ptr = address_add( ptr, ELEM_BYTES, addr_mode_0 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr1, DIM1, addr_mode_1 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr2, DIM2, addr_mode_2 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr3, DIM3, addr_mode_3 );
}
```

The values for the circular addressing can be selected by using the 16 bits of the AMODE specific Field as described in the AMODE SPECIFIC Addressing Mode Field.

10.1.2.3.6.2 DIR: Addressing Mode Direction Definition

This field is used if the TR TYPE specifies the TR is for a block move if the addressing mode specified in the AMODE field applies to the source addressing or the destination addressing. A value of 0 means the source addressing will use the method selected in the AMODE field and the destination address will use the default linear addressing. A value of 1 means that the destination addressing will use the method selected in the AMODE field and the source addressing will use the default linear addressing. If the TR TYPE is not a block transfer then this field will be ignored.

10.1.2.3.6.3 ELTYPE: Element Type Definition

The Element Type field allows the user to specify the basic unit that is used for the innermost loop. If the FMTFLAGS field is not present then the UTC will assume a value of 0 which is a byte size element. The element type also allows for the some expansion or contraction of the element size from the source to the destination.

Table 10-69. ELTYPE Encoding

Encoding	Definition
0	1 Byte per element
1	1.5 Bytes(12 bits) per element
2	2 Bytes per element
3	3 Bytes per element
4	4 Bytes per element
5	8 Bytes per element

10.1.2.3.6.4 DFMT: Data Formatting Algorithm Definition

The Data Formatting Algorithm is a method to specify a manipulation of the data between how it is read and how it is sent. If the TR Type is not a block operation TR then this field will be ignored. Otherwise Table 10-70 specifies what the encodings meaning.

Table 10-70. DFMT Encoding

Encoding	Definition
0	No Change. The input and output block will remain identical
1	Constant Copy. The input block is not an address but the address is up to a 64-bit constant
2	Transpose. The inner and second most inner loops are swapped so that rows become columns and columns become rows.

Copyright © 2023 Texas Instruments Incorporated

Table 10-70. DFMT Encoding (continued)

Encoding	Definition
3	Reverse. The data in the row will be accessed in the reverse of the order that it is read. So the largest address read in a row will be the first address written.
4	Reverse Transpose. The data will be written in the reverse of the order that is read as well as transposed. So the largest address read in a row will be the address in the first line being written out.
5-15	Reserved for Future Use

10.1.2.3.6.5 SECTR: Secondary Transfer Request Definition

The Secondary Transfer Request field allows the user to specify if the TR requires an additional TR located in memory. If this is used then the address given in the TR is the pointer to the Secondary TR and the secondary TR will have a pointer to the actual final TR.

Table 10-71. Secondary Transfer Request Format

Encoding	Size	Definition
0	0	The TR does not require a secondary TR
1	64 bytes	The TR will fetch a 64-byte Secondary TR prior to the initial read.
2	128 bytes	The TR will fetch a 128-byte Secondary TR prior to the initial read.
3	TBD	Reserved for future use

10.1.2.3.6.5.1 Secondary TR Formats

The secondary TR format is a TR that is fetched by the UTC when it is executing a TR to fill in additional information that does not fit in the original TR. It is not included in the standard TR as the information required in it is not required until execution time and is kept separate so the Channel FIFO space can be minimized. The first four words of the Secondary TR are always the real start address of the transfer followed by a Secondary TR Flags field. The remaining words in the secondary TR are defined by the Secondary TR TYPE from the Secondary TR Flags field.

Table 10-74. FLAGS Field Descriptions

Bit	Field	Description
31-4	SEC_TR_TYPE_SPECIFIC	Reserved for the SEC_TR_TYPE to define based on its requirements
3-0	SEC_TR_TYPE	The TYPE of SEC_TR 0: Multiple Buffer Interleave 1-15: Reserved

The following sections expand on each of these fields.

10.1.2.3.6.5.2.1 SEC_TR_TYPE: Secondary TR Type Field

The Secondary TR Type field is used to state the purpose of the secondary TR. This can be defined

10.1.2.3.6.5.2.2 Multiple Buffer Interleave

The multiple buffer interleave is used to have a single TR plus Secondary TR that can define a fetch where a single line is selected from multiple buffers and then sent as a single buffer. This can be used along with transpose of the data to present data in slices optimal for processing the same algorithm on different data sets at the same time. An example of this can be seen in Figure 10-4.

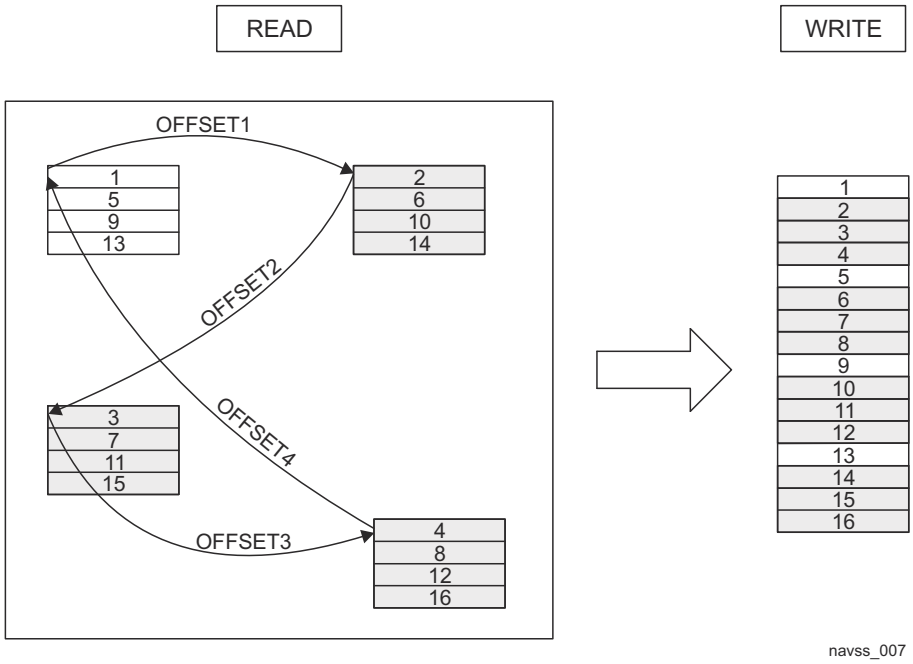

Figure 10-4. Example of Multiple Buffer Interleaving Read with 4 Offsets

The case above provides the ability to minimize the number of TRs submitted to make the transfer but the interleaved Read main advantage comes when used with the transpose mode enabled. Figure 10-5 shows the advantage of the interleaved mode along with the transpose mode to allow for maximum size transfer on both read and write transactions.

Copyright © 2023 Texas Instruments Incorporated

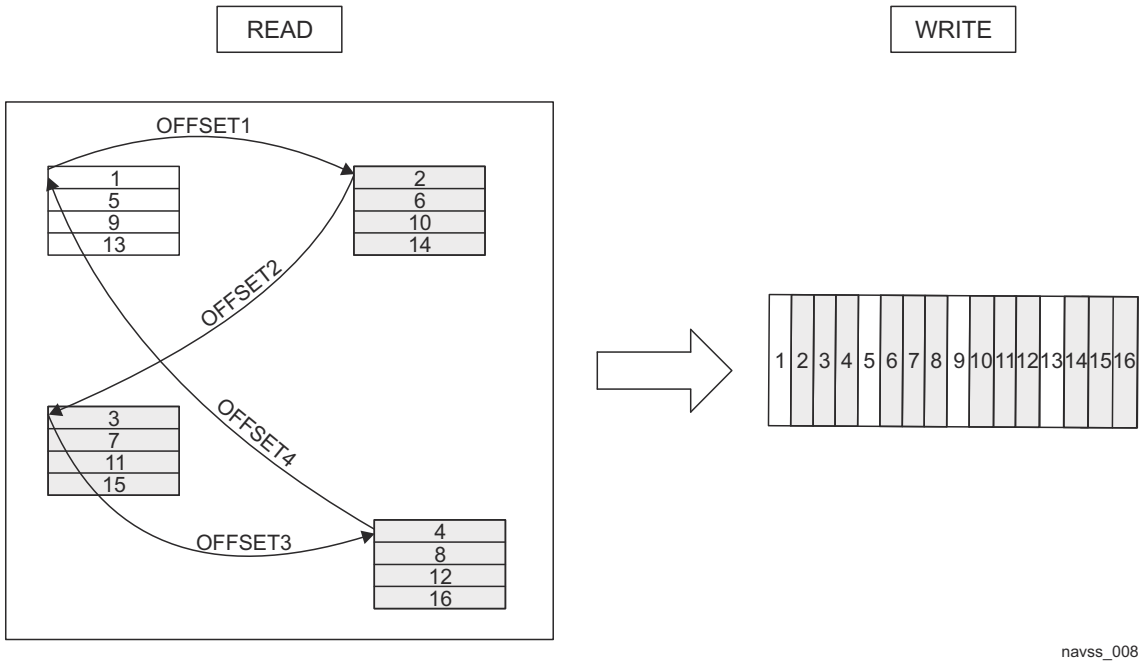

Figure 10-5. Example of Interleaved Read with 4 Offsets and Transpose Enabled

As the figure shows the data that is written out now contains one element from each block of memory and can be read in directly to processing units.

RESERVED	SECONDARY TR FLAGS	ADDR	

Multiple Buffer Interleave will work by setting the SECTR field in the TR presented to the channel to be either 64 or 128 bytes depending on the number of offsets required. An offset number of 4 or 8 will require 64 bytes while 16 offsets will require 128 bytes. When the channel becomes active it will see that the SECTR field is nonzero and fetch the SECTR of the size specified. The first access from the channel will be a read of the secondary TR as specified in the address field of the TR. Upon receiving the Secondary TR the channel will parse the type field and seeing that it is a Multiple Buffer interleave will load the offset index fields for the channel. Additionally it will load the ADDRESS field from the secondary TR into the Address of the actual TR to allow it to process as normal.

The first address fetch will then be to this SEC_TR_ADDRESS. After finishing the inner loop the next address will be SEC_TR_ADDRESS + OFFSET0.

Note

ICNT1 should be equal to the height of the transfer blocks times the number of offsets.

10.1.2.3.6.6 AMODE SPECIFIC: Addressing Mode Field

The AMODE Specific Fields are defined based upon the Addressing Mode being used as specified in AMODE: Addressing Mode Definition.

10.1.2.3.6.6.1 Circular Address Mode Specific Flags

If the circular addressing mode is selected in AMODE the definition of the upper 16 bits of the FMTFLAGS field are used to select the type of addressing for each entry in the loop and to define 2 unique masks that can be used for the circular buffering.

The following example code shows the method used to compute the masks referred to by the address_add function described in the‘ Address Arithmetic with Selectable Linear/Circular Addressing Modes section.

```
// Circular addressing masks.
// 1 bits in the mask indicate address bits that remain fixed.
// 0 bits in the mask indicate address bits that are allowed to vary.
uint64_t circ_mask_0;// mask for circular addressing block 0
uint64_t circ_mask_1;// mask for circular addressing block 1
void compute_circular_address_masks( int cbk0, int cbk1 )
{
int block_size_0 = cbk0 + 9;// power-of-2 of block size in bytes
int block_size_1 = cbk0 + cbk1 + 10;
if ( block_size_1 > 31 ) block_size_1 = 32;// clamp to 4GB maximum size
circ_mask_0 = (~0ULL) << block_size_0;
circ_mask_1 = (~0ULL) << block_size_1;
}
```

Example 3-4 Circular Address Mask Computation

Table 10-78. Transfer Request Template FMTFLAGS AMODE SPECIFC Circular Addressing Field

26-27	AM1	The address mode to use with ICNT1 loop
28-29	AM2	The address mode to use with ICNT2 loop
30-31	AM3	The address mode to use with ICNT3 loop

10.1.2.3.6.6.1.1 CBK0 and CBK1: Circular Block Size Selection

The CBK0 and CBK1 fields set the circular block sizes for circular addressing. CBK0 directly determines the circular block size for block 0. CBK1 combines with CBK0 to determine the circular block size for block 1. Specifically, the streaming engine sets block 1's size according to CBK0 + CBK1 + 1. Therefore, circular block 1 is always larger than circular block 0.

The following table illustrates the resulting valid block sizes for circular block 0 and 1. For circular block 0, the use the value of CBK0 directly. Circular block 0 supports block sizes ranging from 512 bytes to 16M bytes. For circular block 1, use the value of CBK0 + CBK1 + 1. Circular block 1 supports sizes ranging from 1K bytes to 4G bytes.

Table 10-80. Circular Block Size Decoding

Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size
0	512	8	128K	16	32M	24	Reserved
1	1K	9	256K	17	64M	25	Reserved
2	2K	10	512K	18	128M	26	Reserved
3	4K	11	1M	19	1M	27	Reserved
4	8K	12	1M	20	1M	28	Reserved
5	16K	13	1M	21	1M	29	Reserved
6	32K	14	1M	22	1M	30	Reserved
7	64K	15	1M	23	1M	31	Reserved

10.1.2.3.6.6.1.2 Amx: Addressing Mode Selection

The fields AM0 through AM3 control the addressing modes for each of the 4 dimensions. The UTC supports the following addressing modes:

Table 10-81. AMX Address Mode Selection Encoding

AMX	Meaning
00b	Linear addressing
01b	CKB0 (Circular Buffer 0 is used)
10b	CKB1 (Circular Buffer 1 is used)
11b	Reserved

Each dimension has its own addressing mode, independent of the other dimensions. This permits any mixture of linear and circular addressing among the 4dimensions.

When a given dimension selects linear addressing, the UTC uses unmodified two's complement arithmetic to update addresses for that loop level.

When a given dimension selects circular addressing via CBK0 or CBK1, the UTC uses the circular address arithmetic described above in the Address Arithmetic with Selectable Linear/Circular Addressing Modes section.

10.1.2.3.6.7 Cache Flags

If the TR type is a cache warm the format flags field is replaced with a Cache Flags field.

Table 10-82 shows the breakdown of the 32 bit Cache Flags field.

Copyright © 2023 Texas Instruments Incorporated

Table 10-82. Transfer Request Template CACHEFLAGS Field

31 24	23 16
CACHE OPERATION	RESERVED
15 8	7 0
RESERVED	CACHE ID

The flags field fills in the remaining details about the stream, as follows:

Table 10-83. FMTFLAGS Field Descriptions

Bit	Field	Description
24-31	Cache Operation	0: Prewarm the Cache 1: Prewarm MMU 2-255: Reserved for future use
8-23	Reserved	Reserved for future use
0-7	Cache ID	The Cache number to perform the operation on. 0-254: Cores. 255: L3 Cache

10.1.2.4 Transfer Response Record

Upon completing a TR the UTC will send back a TR Response to the UDMA-C. The UTC TR response format is a single 32-bit word as shown in Table 10-84.

Table 10-84. Transfer Request Response Template STATUS FLAGS Field

31 24	23 16	
CONFIGURATION SPECIFIC STATUS	CMD ID	
15 8	7 4	3 0
RESERVED	STATUS_FIELD	STATUS_TYPE

Table 10-85. STATUS FLAGS Field Descriptions

Bit	Field	Description
31:24	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC implementation. For UDMA channels which are capable of interfacing to endpoint peripherals (or via a PDMA) the format of these flags are as follows: 31:28 error_flags – the error_flags field as is provided across PSI-L 27:24 ps_flags – the ps_flags field as is provided across PSI-L
23:16	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR.
15:8	Reserved	Reserved for Future use
7:4	STATUS_INFO	Information that is unique based on the STATUS_TYPE returned
3:0	STATUS_TYPE	The completion status of the TR.

10.1.2.4.1 STATUS Field Definition

The Status field is made up of two sub-fields STATUS_TYPE and STATUS_INFO. A value of 0 means it completed as requested any other value means an error has occurred. Table 10-86 states the legal STATUS_TYPEs and the use of the STATUS_INFO in each case.

10.1.2.4.1.1 STATUS_TYPE Definition

The STATUS_TYPE field is used to determine what type of status is being returned. Depending on the type of Status it might additionally have information in the STATUS_FIELD to give more details about the specific reason why the status was returned.

Table 10-86. STATUS_TYPE Encoded Values

Value	Error Type	Completion	STATUS FIELD Definition
0	None	Complete	None

Copyright © 2023 Texas Instruments Incorporated

Table 10-86. STATUS_TYPE Encoded Values (continued)

Value	Error Type	Completion	STATUS FIELD Definition
1	Transfer Error	None to Partial	CBA Non-Complete Status Received
2	Aborted Error	None to Partial	None
3	Submission Error	None	Submission Error Type
4	Unsupported Feature	None	Feature Type
5	Transfer Exception	Partial	Exception Type
6	Teardown Flush	None	None
7-15	Reserved	Unknown	Reserved

10.1.2.4.1.1.1 Transfer Error

A transfer ERROR occurs anytime that one of the CBA transactions performed by the UTC returns a status other than complete. The UTC may continue the transfer or may abort the transfer and return back to an IDLE state. Once the transfer is finished (aborted or complete) the UTC will send back the TR Response with the STATUS TYPE of Transfer Error. The STATUS FIELD will contain the 3 bit CBA Status field the upper bit specifies if it was a read status (1) or a write status (0).

10.1.2.4.1.1.2 Aborted Error

An aborted error occurs if the PSI-L interface asserts the drop signal prior to the completion of the TR. The UTC will return back to an IDLE state and send back the TR Response with the STATUS TYPE. If the UTC receives a transfer error after receiving the abort the transfer error should be reported instead of the Abort Error.

10.1.2.4.1.1.3 Submission Error

A submission error is returned for a TR that is received that cannot be run. The STATUS_INFO field specifies the type of submission errors.

Table 10-87. Submission Error STATUS_INFO Encodings

Value	Submission Error Type
0	ICNT0 was 0
1	Channel FIFO was full when TR received
2	Channel is not owned by the submitter. Either CC submitting to Direct or Direct submitting to a CC channel
3-15	Reserved

10.1.2.4.1.1.4 Unsupported Feature

An unsupported feature error is returned for a TR that is received that cannot be run because it specifies a feature that is optional and not supported by the UTC that received the TR. The STATUS FIELD specifies the feature that was not supported. If it specifies multiple features that were not supported the UTC implementation can determine which type it wants to return

Table 10-88. Unsupported Feature STATUS_INFO Encodings

Value	Submission Error Type
0	TR Type not supported
1	STATIC not supported
2	EOL not supported
3	CONFIGURATION SPECIFIC not supported
4	AMODE not supported
5	ELTYPE not supported
6	DFMT not supported
7	SECTR not supported
8	AMODE SPECIFIC Field not supported
9-15	Reserved

Copyright © 2023 Texas Instruments Incorporated

10.1.2.4.1.1.5 Transfer Exception

A transfer exception is returned for a TR that completed but experienced a known exception during reception. The STATUS_INFO field specifies the type of transfer exception that was encountered.

Table 10-89. Transfer Exception STATUS_INFO Encodings

Value	Transfer Exception Type
0	EOP on incoming data stream was encountered prematurely (short packet)
1	EOP on incoming data stream was encountered late (long packet)
2-15	Reserved

10.1.2.4.1.1.6 Teardown Flush

Split mode UTC Rx channels (write channels) can respond with a teardown flush in the case that they have received a teardown message, all data has been transferred , and TRs have been prefetched (in anticipation of more data being received). In this case, the UTC will simply return the prefetched TR to the completion queue with the status type set to teardown flush.

10.1.2.5 Queues

Queues are used to hold either values or references that need to be passed between components in the system. These components could be software or hardware. Queues are implemented by the Ring Accelerator module.

10.1.2.5.1 Queue Types

10.1.2.5.1.1 Transmit Queues (Pass By Reference)

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx channels require one or more packet queues dedicated to each transmit channel for this purpose. Multiple queues per channel may facilitate Quality of Service (QoS) in some applications. Pass by reference Tx Queues only pass a pointer to a descriptor (and optional information like the packet length). Pass by reference Tx Queues can contain pointers to Host, Monolithic, or TR packet descriptors (depending on Tx channel mode configuration).

10.1.2.5.1.2 Transmit Queues (Pass By Value)

Pass by value Tx Queues are used for direct Transfer Request submission on Tx channels which are configured for 3rd party pass by value mode. Entries on a pass by value Tx Queue include the entire Transfer Request message and optional protocol specific information. Pass by value queues are only supported by the Ring Accelerator.

10.1.2.5.1.3 Transmit Completion Queues (Pass By Reference)

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. The number of queues required by the channel or system for this purpose is driven by the requirements of the garbage collection software within the driver. Tx completion queues are only used when the packet descriptor indicates that the packet should be returned to a queue instead of directly recycling the descriptors to their queues of origin. Pass by reference Tx Completion Queues only pass a pointer to a descriptor.

10.1.2.5.1.4 Transmit Completion Queues (Pass By Value)

Pass by value Tx Completion Queues are used to pass the Transfer Response messages that are returned when a channel is configured in 3rd Party pass by value mode. Entries on a pass by value Tx Completion Queue include the Transfer Response message. Pass by value queues are only supported by the Ring Accelerator.

10.1.2.5.1.5 Receive Queues

Rx ports use packet queues referred to as “receive queues” to forward completed received packets to the host or another peer port entity. Rx ports may be configured in various ways to forward the received packets onto any number of receive queues. Rx ports may choose to queue their receive packets based strictly on Rx channel, protocol type, priority, direct forwarding requirements (i.e. to another ports Tx queue) or any combination of these and this is application specific. In many cases the receive queue is in fact also a transmit queue for another peer entity. It is just a matter of semantics with respect to which port is referenced in the system.

Copyright © 2023 Texas Instruments Incorporated

10.1.2.5.1.6 Free Descriptor Queues

Rx ports use queues referred to as “free descriptor queues” to allocate empty monolithic descriptors. The entries on the Free Descriptor Queues do not have any buffers attached as buffers are allocated as part of the descriptor for monolithic type packets.

10.1.2.5.1.7 Free Descriptor/Buffer Queues

Rx ports use queues referred to as “free descriptor/buffer queues” to allocated empty host type descriptors. The entries on the Free Descriptor/Buffer Queues have pre-attached empty buffers whose size and location are described in the “original buffer information” fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding a descriptor to a free descriptor/buffer queue.

10.1.2.5.2 Ring Accelerator Queues Implementation

Work packets which are stored in a pass by reference queue managed by the Ring Accelerator are shown in Figure 10-6.

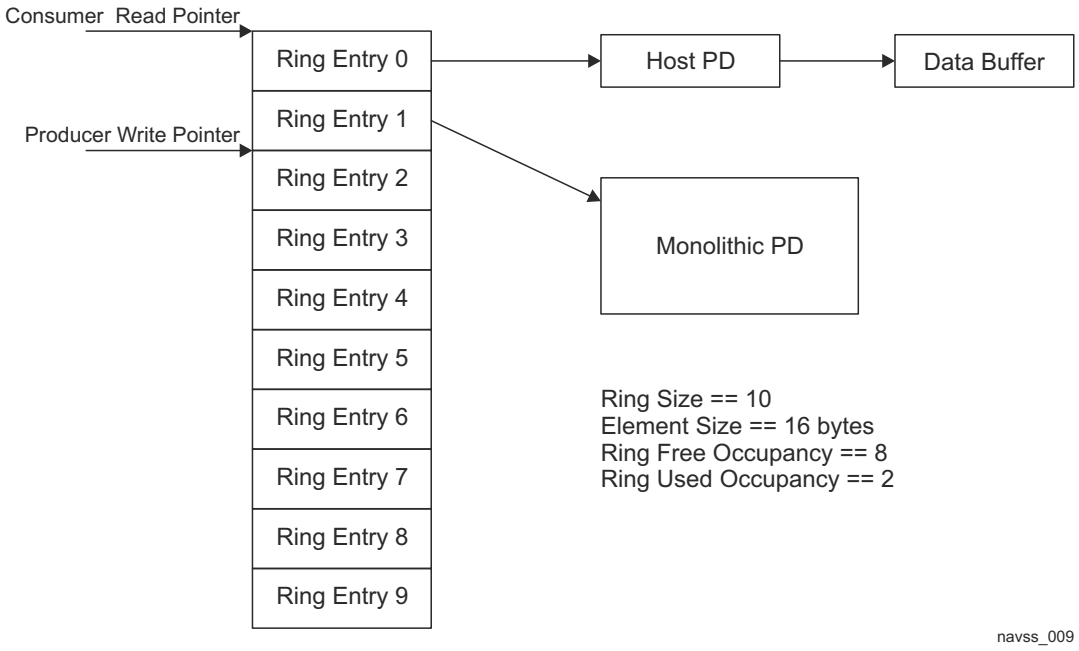

Figure 10-6. Ring Accelerator Based Queue Structure

Work packets stored in a pass by value queue managed by the Ring Accelerator are shown in Figure 10-7.

Copyright © 2023 Texas Instruments Incorporated

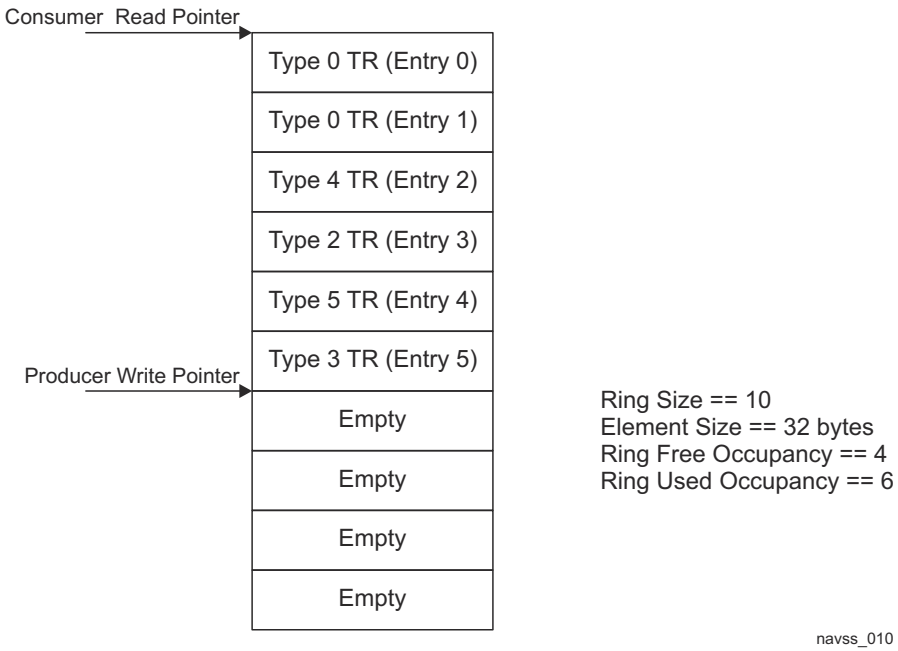

Figure 10-7. Ring Accelerator Based Direct Transfer Request Queue Structure

10.1.3 Operational Description

10.1.3.1 Resource Allocation

Queues, rings, memory, interrupts, DMA channels, and flow table entries are shared resources within the data movement architecture and their ownership and use must be managed in order to provide stable, safe, and secure operation. The K3 platform provides channelized firewalls which can be used to protect arrayed resources (like queues, rings, channel control registers, etc.) from unwanted/unauthorized use as well as restricted access to the firewall configurations themselves. It is outside the scope of this document to define how the resource management system functions but it is assumed that all of these resources are isolate-able and secure-able.

10.1.3.2 Ring Accelerator Operation

10.1.3.2.1 Queue Initialization

The base address, size and element size for each ring must be initialized via the provided registers prior to using the ring. Ring initialization is typically done only on channel setup as once initialized the rings can be used indefinitely. Optionally, an internal initialization machine may be provided to set default values for the ring address, size, and element sizes. This capability enables the rings to be used during boot without configuration. Not all rings will necessarily support this feature and if required must be configured at design time. Whether or not this machine is present, all rings are able to be re-configured at run time through the provided registers.

10.1.3.2.2 Queuing packets (Exposed Ring Mode)

Queuing of packets onto a packet queue using the Ring Accelerator is logically equivalent but requires a different set of transactions from queuing packets in queue mode. The producer (entity which is going to queue an entry onto the ring) maintains a current write pointer and a free entry occupancy count for each ring it controls. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the memory location pointed to by the current write pointer and will decrement its free entry occupancy. After the producer has confirmed that the data has actually landed it memory, it will then write to the doorbell register for the ring to increment the used occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

10.1.3.2.3 De-queuing packets (Exposed Ring Mode)

The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer and a used entry occupancy count for each ring it controls. To de-queue an entry the consumer will read the entry

Copyright © 2023 Texas Instruments Incorporated

contents from the memory location pointed to by the current read pointer and will decrement its used entry occupancy. The consumer will then write to the doorbell register for the ring to increment the free occupancy count for the ring.

10.1.3.2.4 Queuing packets (Queue Mode)

To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the Proxy thread location allocated by the system, with the queue offset for the queue to access. The write within the queue offset to the completion offset (final byte of the data) will cause the entire data to be written to the RA queue.

10.1.3.2.5 De-queuing packets (Queue Mode)

To de-queue an entry the consumer will read the entry contents from the Proxy thread location allocated by the system, with the queue offset for the queue to access. The proxy will read the entry from the RA queue. The consumer can then read the entire contents of the entry. The completion offset (final byte of the data) will cause the proxy to flush that entry (so that it can fetch a new one from the RA upon the next read).

10.1.3.3 UDMA Internal Transmit Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by writing to the Tx Channel Configuration Register A. The Host may choose to write the enable bit in the Tx Channel Configuration Register A at the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

It should be noted that very little configuration information is required for a UDMA Tx channel compared to previous versions of UDMA. This is because UDMA has transitioned to a full modeless model for channel operation where each packet descriptor specifies the descriptor type, packet type, and the packet return parameters. Packet queues in UDMA may include combinations of host and monolithic descriptors in any order.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

10.1.3.4 UDMA Internal Transmit Channel Teardown (All Packet Types)

An Tx channel teardown is initiated by the host by writing the TX_TEARDOWN bit in the Tx Channel N Realtime Control Register. When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the TX_FORCED_TEARDOWN bit in the Tx Channel N Realtime Control Register.

If the TX_FORCED_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR prefetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Realtime Control Register.
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

Copyright © 2023 Texas Instruments Incorporated

If the TX_FORCED_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
3. Clears the channel enable in the Tx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

10.1.3.5 UDMA-P Transmit Channel Pause

Setting the TX_PAUSE bit in the Tx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source.

10.1.3.6 UDMA-P Transmit Operation (Host Packet Type)

After a channel has been set up it can begin to be used to transmit packets. Packet transmission in Host mode involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.
2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to Host)
   b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. Buffer Pointer with the byte aligned address of the first chunk of buffer data
   h. Buffer Length with the number of bytes in the first chunk of buffer data
   i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
   j. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
   k. Any protocol specific descriptor sections that are required for the given packet type or system configuration
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:

Copyright © 2023 Texas Instruments Incorporated

   a. Buffer Descriptor reclamation policy fields (if the intention is to have the DMA automatically recycle the buffer descriptors as they are transmitted).
   b. Buffer Pointer with the byte aligned address of the given chunk of buffer data
   c. Buffer Length with the number of bytes in the given chunk of buffer data
   d. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
4. The Host writes queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
5. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
7. The DMA controller reads the packet descriptor pointer from the Ring Accelerator
8. The DMA controller reads the packet descriptor from memory
9. Step 9:
   - If the return policy bit (PD Word 2, bit 15) is cleared, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves. As each buffer is emptied, the DMA will read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.
   - If the return policy bit is set, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves.
10. Step 10:
    - If the return policy bit (PD Word 2, bit 15) is cleared, when all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
    - If the return policy bit is set, as each buffer is emptied the DMA will write the buffer descriptor pointer to the queue specified in the return queue number field of the buffer descriptor. The DMA will also read the next buffer descriptor to obtain the pointer and size of the data buffer, the return queue information for the descriptor, as well as the pointer to the next descriptor in the chain.
11. Step 11:
    - If the return policy bit (PD Word 2, bit 15) is cleared, after the Packet Descriptor pointer has been written, the Ring Accelerator will indicate the status of the Tx Completion Queue by sending an up event .
    - If the return policy bit is set, when all data for the packet has been transmitted as specified in the packet size field, if the current buffer is not marked as end of packet (via a null next descriptor pointer), the DMA will continue to walk the list returning buffer descriptors to the appropriate queues as described in step 10.
12. Step 12:
    - If the return policy bit (PD Word 2, bit 15) is cleared, the Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
    - If the return policy bit is set, when all buffers have been returned, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
13. If the return policy bit (PD Word 2, bit 15) is cleared, host responds to status change from the Ring Accelerator (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. If the return policy bit (PD Word 2, bit 15) is cleared, once the garbage collection causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register and potentially de-assert the interrupt line.

If the return policy bit (PD Word 2, bit 15) is cleared, the complete process is illustrated on Figure 10-8.

If the return policy bit is set, the complete process is illustrated on Figure 10-9.

Figure 10-8 shows a diagram of the host packet transmit operation – complete packet return.

10.1.3.7 UDMA-P Transmit Operation (Monolithic Packet)

Packet transmission in Monolithic mode involves the following steps:

1. The Host allocates and populates a monolithic packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to Monolithic)
   b. Packet Length indicating the total number of bytes in the packet
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. Offset to payload data
   h. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
   i. Networking Stack Information (application specific and optional)
   j. Any protocol specific words that are required for the given packet type
2. The Host queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the Ring Accelerator.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by transmitting the contents in one or more block data moves. The size of these blocks is application specific. The DMA controller module specification is intended to document the block size used by a given implementation.
8. When all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
9. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

   Whether or not any further processing is required on the packet at this point depends on the nature of the queue that the packet was returned to. The most common case is that the monolithic descriptor will be returned to the Rx Free Descriptor queue that it was allocated from originally. If this is the case, the Tx processing is complete at this point. Alternatively, the queue may also be a Tx Completion Queue in which case, the following optional steps may also be performed:
10. While most types of peer entities and embedded processors are able to directly and efficiently use these level sensitive status lines, cached processors may require a hardware block to convert the level status into pulsed interrupts and to perform some level of aggregation of the descriptor pointers from the completion queues into lists.
11. Host responds to status change from Ring Accelerator and performs garbage collection as necessary for packet.
12. Ring Accelerator sends down event when ring is empty

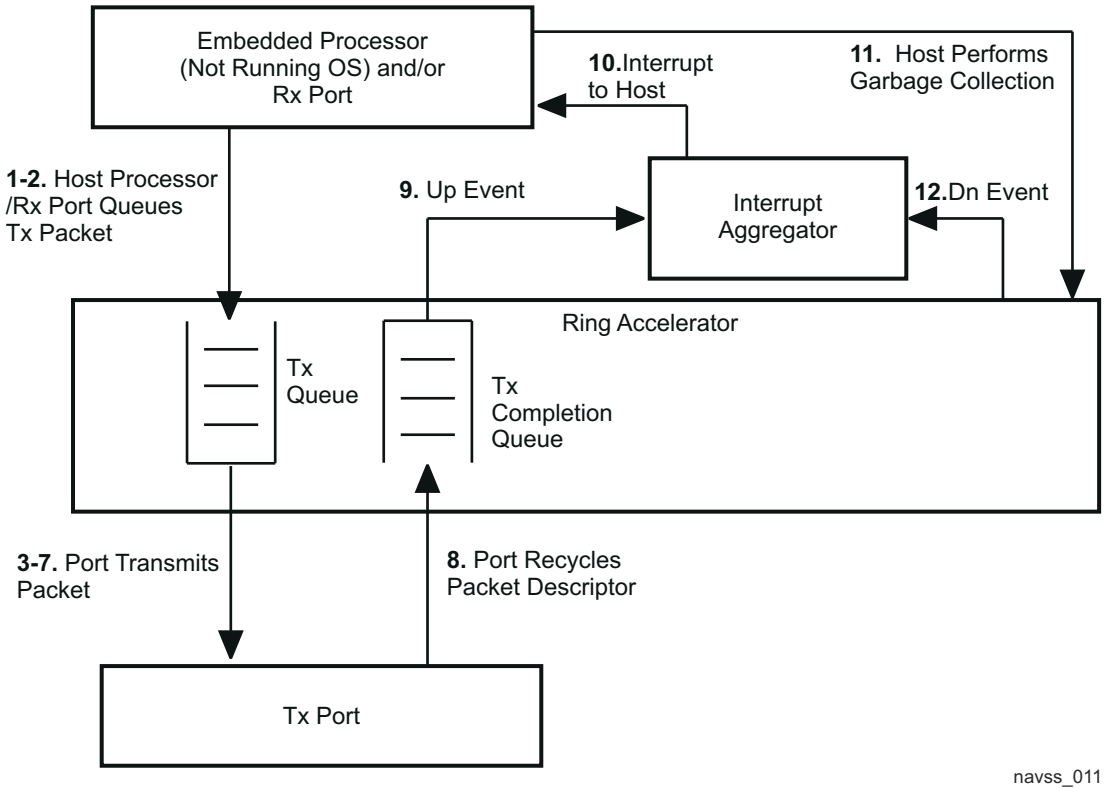

Figure 10-10. Monolithic Packet Tx Operation

10.1.3.8 UDMA Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to TR)
   b. Reload Enable to 1 if looping is required, otherwise 0
   c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
   d. Last Entry to TR count minus 1
   e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
   f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
   g. Source Tag
   h. Destination Tag (application specific)
   i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
   j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired UDMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding Tx channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the RA.
6. The DMA controller reads the packet descriptor from memory

Copyright © 2023 Texas Instruments Incorporated

7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).
8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which is corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.9 UDMA Transmit Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Tx Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).
5. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.10 UDMA Transmit Error/Exception Handling

There are 3 specific errors which may be encountered during Tx operation and which are trapped by the UDMA. The following table lists the errors and how the UDMA will process them:

Table 10-90. UDMA Tx Error/Exception Handling

Condition	Channel Mode	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	All UTC	Selectable(1)	Yes	No	Just that TR	No
Unsupported TR Type	All UTC	Selectable(1)	Yes	No	Just that TR	No
Bus Errors	All	Selectable(1)	Yes	Yes	No	Yes

(1) If PAUSE_ON_ERROR bit is set in channel configuration

Copyright © 2023 Texas Instruments Incorporated

10.1.3.10.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Tx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.10.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Tx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.10.3 Bus Errors

If a bus error is encountered during transmit the DMA will log the error by asserting the TX_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

10.1.3.11 UDMA Receive Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

10.1.3.12 UDMA Receive Channel Teardown

A Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408. This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the UDMA receives a data phase with the tdown attribute asserted it will immediately set the internal RX_TEARDOWN bit in the Rx Channel N Realtime Control Register.

Upon seeing the RX_TEARDOWN bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the RX_FORCED_TEARDOWN bit in the Rx Channel N Realtime Control Register.

If the RX_FORCED_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)
2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

Copyright © 2023 Texas Instruments Incorporated

If the RX_FORCED_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using ‘null’ write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
3. Clears the channel enable in the Rx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode or single ended TR mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the UDMA. If that is not possible, the host may write the RX_TEARDOWN bit directly to a 1.

The Host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

10.1.3.13 UDMA-P Receive Channel Pause

Setting the RX_PAUSE bit in the Rx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source.

10.1.3.14 UDMA-P Receive Free Descriptor/Buffer Queue Setup (Host Packets)

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. For Rx Free Descriptor/Buffer queues, descriptors are allocated in a large block by the Host and then initialized and linked with buffers before being given matched pairs where the Host initializes the descriptor to point to its corresponding buffer before being pushed onto a Receive Free Descriptor/Buffer queue. Once the host has allocated both a descriptor and a buffer, it adds them to an Rx Free Descriptor/Buffer Queue by writing the pointer to the descriptor to the Rx Free Descriptor/Buffer Queue register D for the desired queue.

Before the Host adds each Rx buffer descriptor to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Original Buffer Pointer with the byte aligned address of the buffer data
- Write the Original Buffer Size
- Write the Return Queue Number field in the descriptor to appropriate values (required if auto-recycling is intended)
- Write the On Chip/ Off Chip indicator in the descriptor

Depending on the software architecture, the Host may also desire to write the return policy bit in the descriptor at this point as well. The DMA will not overwrite any of these listed fields (including return policy) during reception.

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

Copyright © 2023 Texas Instruments Incorporated

10.1.3.15 UDMA-P Receive FlowID Firewall Operation

Each incoming packet that enters the UDMA-P will either include an explicitly specified FlowID contained in the info words or it will have an implicitly specified default FlowID which is the same as the channel number. The Rx FlowID firewall checks the incoming FlowID on the received packet to verify that it is either the corresponding default FlowID for the channel or that the FlowID falls within the range specified in the Rx Channel Flow Range register. If the received flowID is not the channel number and it does not fall within the legal range as specified then the packet is dropped, the error is trapped in the Rx Flow ID Firewall Status register, and an optional output event is generated as specified in the Rx Flow ID Firewall Output Event Steering Register.

10.1.3.16 UDMA-P Receive Operation (Host Packet)

Figure 10-11 shows a diagram of the overall Receive operation for Host flow mode.

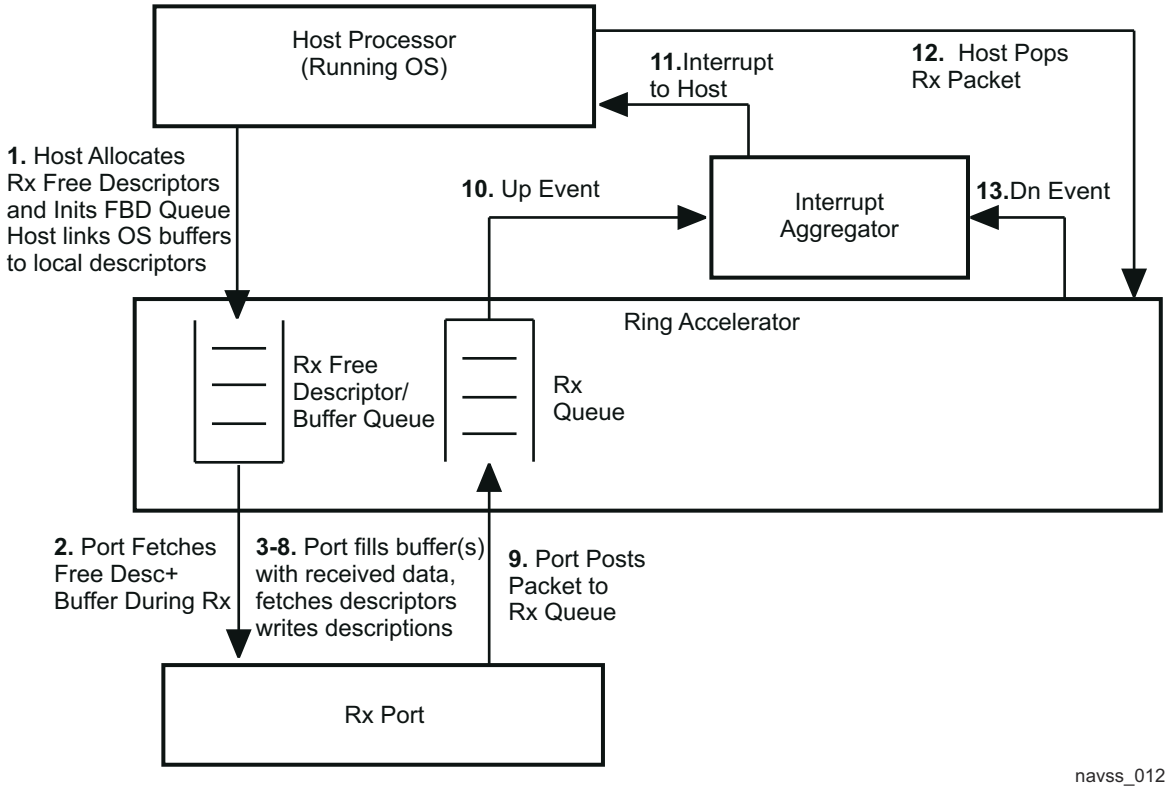

Figure 10-11. Host Packet Receive Operation

When packet reception begins on a given channel, the port will begin by fetching the first descriptor + buffer from the Ring Accelerator using the Free Descriptor/Buffer Queue 0 Index that was initialized in the Rx Flow Table for the flow which is being used by the channel. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fetch additional descriptors + buffers as needed using the Free Descriptor/Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet.

A detailed summary is as follows:

1. Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/ Buffer Queues
2. UDMA-P fetches packet descriptor pointer from RA
3. UDMA-P reads the packet descriptor to obtain the packet info, buffer pointer, and size
4. UDMA-P fills the buffer with received data
5. If packet is not complete, UDMA-P fetches next buffer descriptor pointer from RA
6. UDMA-P fills the buffer with received data

   If the RX_DESC_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the

Copyright © 2023 Texas Instruments Incorporated

RX_DESC_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine will proceed to step 8 skipping step 7.

7. UDMA-P writes previous buffer descriptor to memory. This includes the following fields:
   a. Buffer information
   b. Buffer Pointer with the byte aligned address of the chunk of buffer data
   c. Buffer Length with the number of bytes in the chunk of buffer data
   d. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

   If the RX_DESC_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX_DESC_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine proceeds to step 8 as soon as the first buffer is full. Any remaining data in the packet from the line is then received into one or more additional packets each exactly one Host buffer long.

   The UDMA-P performs the following operations when the entire packet has been received:
8. UDMA-P writes the packet descriptor to memory. This includes the following fields:
   a. Descriptor Type (set to Host)
   b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. SOP buffer information
      i. Buffer Pointer with the byte aligned address of the chunk of buffer data
      ii. Buffer Length with the number of bytes in the chunk of buffer data
   h. Any protocol specific words that are required for the given packet type
   i. Networking Stack Information (application specific and optional)
   j. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.
9. UDMA-P writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx_dest_qnum field in the Rx Flow Table entry or will be a queue which was provided via the PSI-L destination queue number override field.
10. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
11. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
12. The Host will pop the packet pointer from the Rx Queue
13. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/embedded processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

10.1.3.17 UDMA-P Receive Operation (Monolithic Packet)

Figure 10-12 shows a diagram of the overall Receive operation for a monolithic descriptor type.

Copyright © 2023 Texas Instruments Incorporated

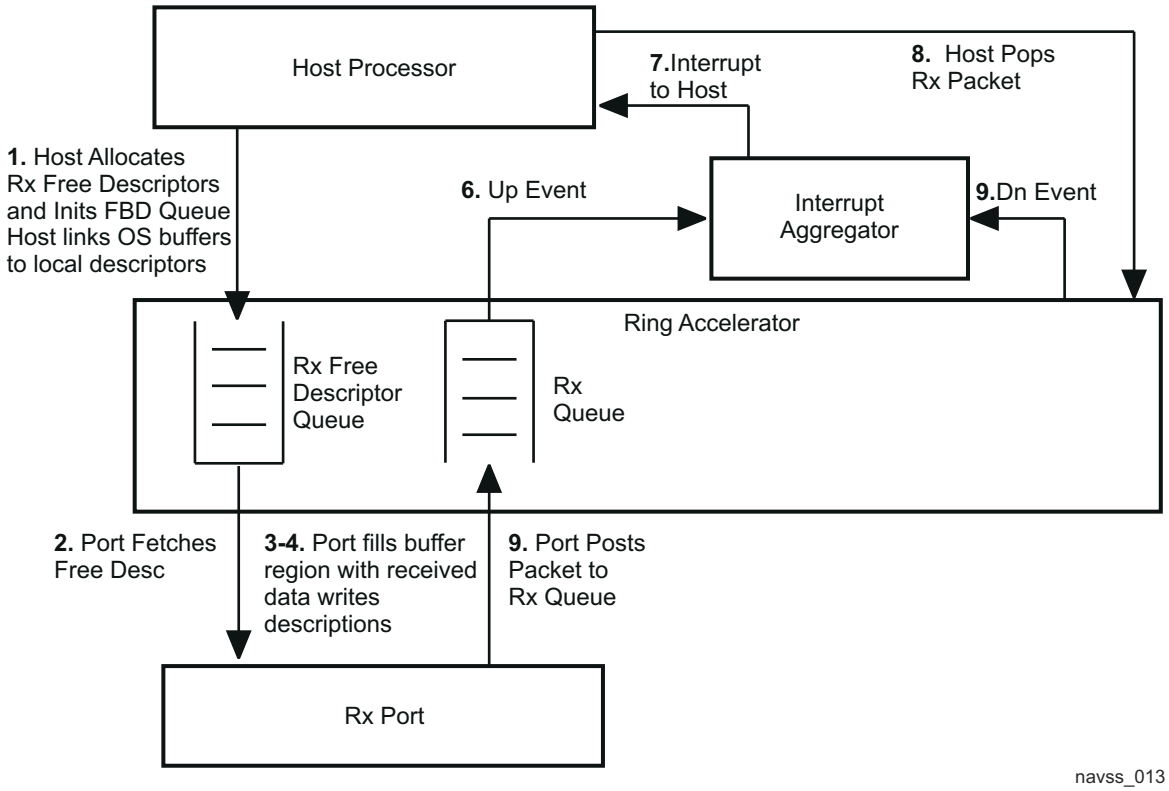

Figure 10-12. Monolithic Packet Receive Operation

The following sequence is a detailed summary of the Monolithic Packet Reception process:

1. The Host initializes free Descriptors and places them on an Rx Free Descriptor Queue
2. The UDMA-P fetches a single descriptor for the packet from the Ring Accelerator using the Monolithic Type Free Descriptor Queue Index that was initialized in the Rx Flow Table entry that is being used for the packet.
3. If the RX_SOP_OFFSET field in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the payload portion of the monolithic descriptor. The port will then continue filling the payload portion of the descriptor until the entire packet has been received.

   The port performs the following operations when the entire packet has been received:
4. Writes the packet descriptor to memory. This includes the following fields:
   a. Descriptor Type (set to Monolithic)
   b. Packet Length indicating the total number of bytes in this packet.
   c. Source Tag
   d. Destination Tag (application specific)
   e. Packet Type
   f. Any protocol specific flags for the given packet type
   g. Networking Stack Information (application specific and optional)
   h. Any protocol specific words that are required for the given packet type
5. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx_dest_qnum fields in the Rx Flow Entry or can be overridden by the value in the PSI-L destination queue override field.
6. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
7. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
8. The Host will pop the packet pointer from the Rx Queue
9. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

Copyright © 2023 Texas Instruments Incorporated

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

10.1.3.18 UDMA Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
   a. Descriptor Type (set to TR)
   b. Reload Enable to 1 if looping is required, otherwise 0
   c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
   d. Last Entry to TR count minus 1
   e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
   f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
   g. Source Tag
   h. Destination Tag (application specific)
   i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
   j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired UDMA channel. Channels may provide more than one Rx TR Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the RA.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted to an internal UTC.
8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which is corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.19 UDMA Receive Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Rx TR Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.

Copyright © 2023 Texas Instruments Incorporated

3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted to an internal UTC (in the case of a UDMA-P).
5. All of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.20 UDMA Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

Table 10-91. UDMA Rx Error/Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial(2)	Until EOP	-	No
	Host – single buffer	Error	Selectable(1)	Yes	Partial(2)	Until EOP(3)	-	No
	Mono	Exception	No	No	Partial(2)	Until EOP	-	No
	UTC–single ended	Exception	No	No	Partial(2)	Until EOP	Until EOP(4)	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	All Packet	Error	Selectable(1)	Yes	No	Yes	-	No
	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP(4)	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable(1)	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable(1)	Yes	No	No	Just that TR	No

(1) If PAUSE_ON_ERROR bit is set in channel configuration
(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.
(3) EOP will only occur when in single buffer mode when teardown is initiated. The data is a (never ending) stream. Drop is never supposed to be asserted during this mode of operation.
(4) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

10.1.3.20.1 Error Conditions

The following sections describe items which fall under an error severity when encountered by the UDMA on Rx:

10.1.3.20.1.1 Bus Errors

If a bus error is encountered during receive the DMA will log the error by asserting the RX_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

Copyright © 2023 Texas Instruments Incorporated

10.1.3.20.1.2 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.20.1.3 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.20.2 Exception Conditions Exception Conditions

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the UDMA packet or TR mode write engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets

10.1.3.20.2.1 Descriptor Starvation

Descriptor starvation occurs when the Port attempts to fetch a free descriptor from an Rx Free Descriptor Queue or Rx Free Descriptor/Buffer Queue and none are available. When no descriptor is available, the Ring Accelerator will return a value of 0x0 for the descriptor pointer (Optionally, some ports may contain internal counters for the free queues which indicate how many elements are currently queued. In this case, no access to the RA is required and starvation is directly detected via a zero element count). When the port detects that descriptor starvation has occurred it will react based on the value of the RX_ERROR_HANDLING bit which was programmed into the Rx Flow N Configuration Register A.

- If the RX_ERROR_HANDLING bit is cleared:

The Port will assert a descriptor starvation indicator and will then return any descriptors that it has already used in the reception of the current packet back to the appropriate Free Descriptor or Free Descriptor/Buffer queue that they were fetched from. This is performed by writing the pointers for each descriptor to the Rx Free Descriptor Queue N Register in sequence using the queue indexes in the Rx DMA state. The port may choose to implement a counter that counts the number of packets that were dropped due to descriptor starvation and may also desire to distinguish between whether the starvation occurred on the packet descriptor (SOP) or on a buffer starvation.

- If the RX_ERROR_HANDLING bit is set:

The Port will assert a descriptor starvation indicator (which may cause an interrupt to the Host) and will then behave as if it had not performed the current data block transfer which caused the starvation. The Port is required to pause its current processing saving the state of the transfer. The next time that the channel comes into context it will again try to allocate a descriptor with the intention being that if buffers/descriptors have been added that the operation will complete successfully on a subsequent retry.

Copyright © 2023 Texas Instruments Incorporated

10.1.3.20.2.2 Protocol Errors

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host or Monolithic descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

10.1.3.20.2.3 Dropped Packets

Packets can be dropped within an Rx Port for any number for reasons which with the exception of the starvation case which was covered above are application specific.

If a split TR mode channel receives instruction to drop a packet on the PSI-L interface, the UDMA/UTC will continue executing the TRs but without data transfer up until a TR is completed for which the EOP condition was set. Events will be generated as normal although data may not be actually transferred.

10.1.3.20.2.4 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

10.1.3.20.2.5 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

10.1.3.20.2.6 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

10.1.3.21 UTC Operation

A UTC accepts Transfer Request records from the UDMA-C and performs a sequence of transactions as specified in the TR record in accordance with the address generation algorithm that is specified in the Transfer Request format specification. The UTC will wait until an optional triggering event has occurred to load the channel state into one of its read or write engines so that the data movement operations can be completed. The UTC will complete the specified transactions until it either has transferred a pre-set number of bytes or until it has reached a point in the sequence where the TR indicates that a trigger is required to continue execution. When either of these two conditions is met, the UTC will save off the current state of the channel and will wait until the channel is re-triggered at which point the TR execution will continue. Once the entire Transfer Request specified sequence of data transfers has completed, the UTC will wait to ensure that all outstanding writes have landed at their respective destination endpoints and will then return a Transfer Response message back to the UDMA-C indicating the success or failure of the Transfer Request. The UTC processes Transfer Request operations on a given channel with strong ordering such that all Transfer Response operations will be returned in an order corresponding to the exact order that Transfer Request operations were issued.

Copyright © 2023 Texas Instruments Incorporated

10.1.3.22 UTC Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

Table 10-92. UTC Rx Error/Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Drop	UTC–single ended	Exception	No	No	Partial(2)	Until EOP	Until EOP(3)	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP(3)	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable(1)	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable(1)	Yes	No	No	Just that TR	No

(1) If pause_on_error bit is set in channel configuration
(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.
(3) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

10.1.3.22.1 Error Handling

If an error occurs during the processing of a Transfer Request, the UTC will discontinue any further operations on the TR and will wait for all outstanding transactions to complete. At that point, the Transfer Response record will be returned to the UDMA-C with the appropriate codes indicating the type of failure as specified in the Transfer Response Format specification.

Depending on the value of the PAUSE_ON_ERROR bit in the UTC configuration register, the UTC will next do one of the following:

If the PAUSE_ON_ERROR bit is clear the channel will move on to the next Transfer Request record that it received from the UDMA-C.

If the PAUSE_ON_ERROR bit is set the channel will halt from processing any new Transfer Request records in order to allow the Host to examine the current channel state in order to determine the potential cause of the failure. The UTC is required to preserve as much of the channel state as possible as soon as a failure is determined. Note that the state will not necessarily provide exact details or a ‘smoking gun’ as the UTC implementation allows for large scale transaction pipelining and error status returns from the bus can occur well after the machine has moved on to other channel tasks.

10.1.3.22.1.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.22.1.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

Copyright © 2023 Texas Instruments Incorporated

10.1.3.22.2 Exception Conditions

There are a few cases which can occur when processing TRs which are not considered errors but which will require handling in order to avoid locking up the UTC read or write engines. Since the UTC performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following outline these scenarios.

10.1.3.22.2.1 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

10.1.3.22.2.2 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

10.1.3.22.2.3 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

10.2 Navigator Subsystem (NAVSS)

This chapter describes the features and functions of the Navigator Subsystem (NAVSS) hardware modules in the device.

The SoC device contains two NAVSSes:

- Main NAVSS (NAVSS0) – See Section 10.2.1, *Main Navigator Subsystem (NAVSS)*
- MCU NAVSS (MCU_NAVSS0) – See Section 10.2.2, *MCU Navigator Subsystem (MCU NAVSS)*.

Copyright © 2023 Texas Instruments Incorporated

10.2.1 Main Navigator Subsystem (NAVSS)

This section describes the top-level integration of the main Navigator Subsystem (NAVSS) in the device.

10.2.1.1 NAVSS Overview

Main SoC Navigator Subsystem (NAVSS0) consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), Peripherals (Module subsystem [MODSS]), Virtualization translation (VirtSS), and a North Bridge (NBSS).

UDMASS – UDMASS is the essential part of the *TI Data Movement Architecture* (see Section 10.1). UDMASS consists of:

- Unified DMA Controller – Section 10.2.3
- Ring Accelerator – Section 10.2.4
- Packet Streaming Interface (PSI-L) – Section 10.2.8
- Block Copy DMA Controller

MODSS – Module subsystem is a collection of peripherals with different system-level functions, for example, interprocessor communication and time sync, among others. NAVSS0 contains the following modules:

- Mailbox – Section 7.1
- Spinlock – Section 7.2
- Two Timer Managers (Timer banks) – Section 11.2
- Time Stamp Module (CPTS) – Section 11.1
- Infrastructure components such as:
  - CBASS – *System Interconnect*
  - Proxies – Section 10.2.5, Section 10.2.6
  - Interrupt aggregators – Section 10.2.7
  - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – Section 10.2.9

VirtSS – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Peripheral Virtualization Units (PVU) – Section 8.3

ECC aggregators – Section 12.10.4

NAVSS0 hardware components and their integration are shows on Figure 10-13.

Copyright © 2023 Texas Instruments Incorporated

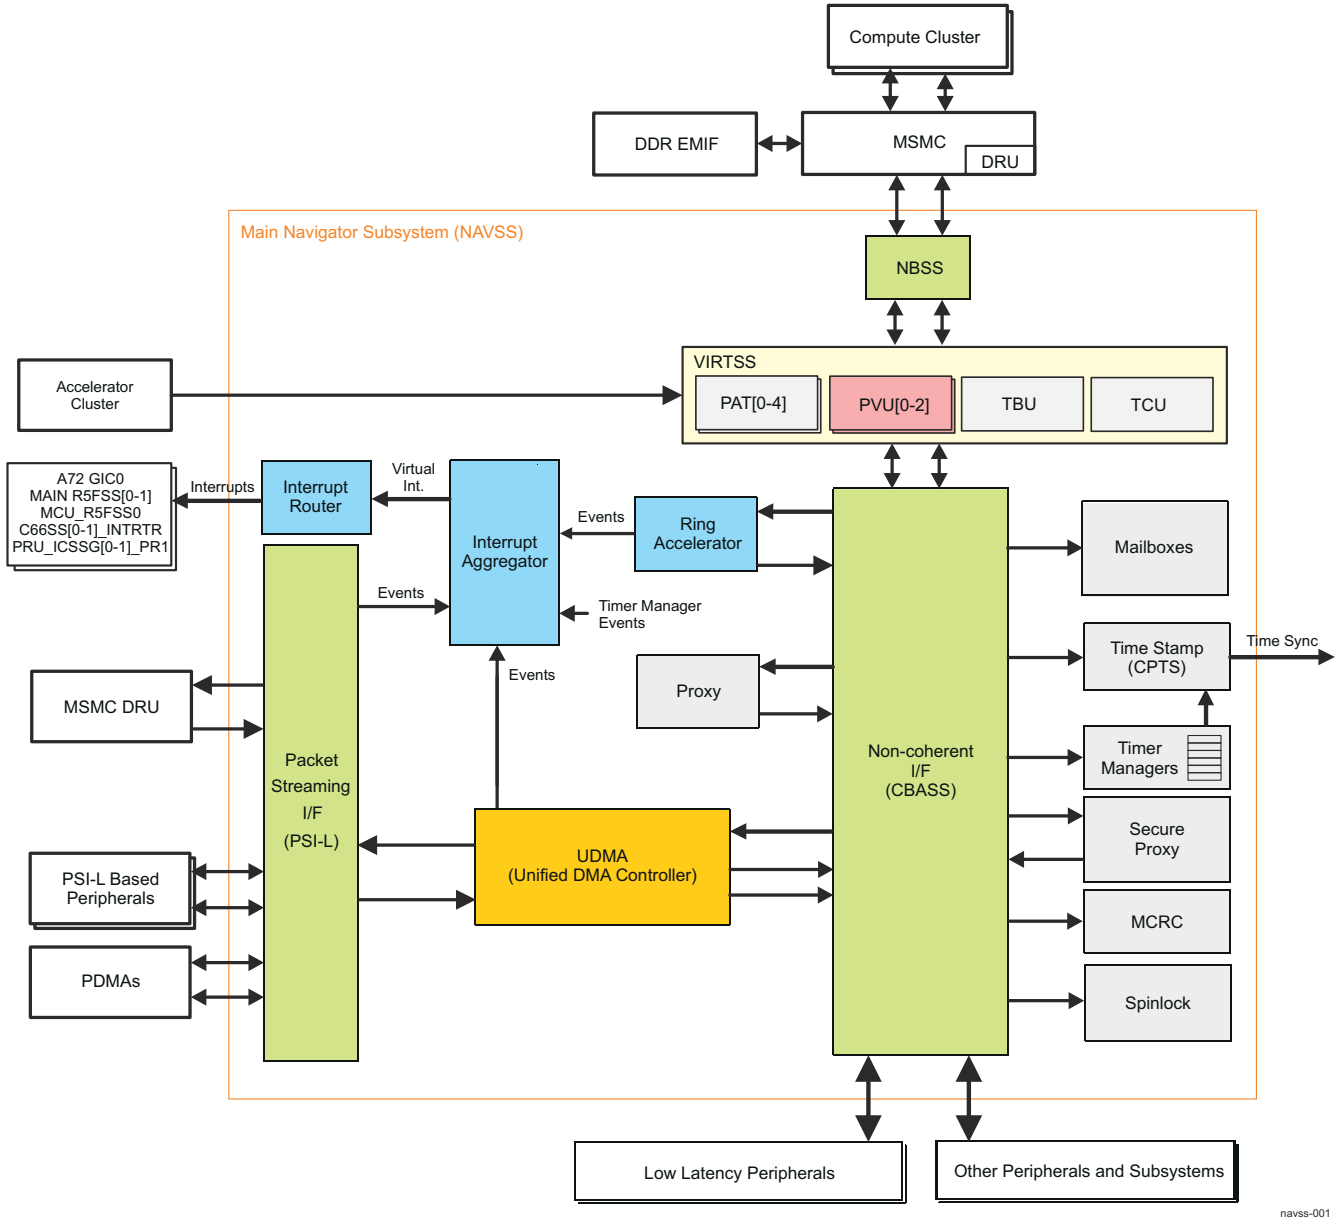

Figure 10-13. NAVSS0 Top-Level Block Diagram

Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed ot fewer peripherals and has reduced bandwidth.

10.2.1.2 NAVSS Functional Description

See Section 10.1, *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:
- Unified DMA Controller – Section 10.2.3
- Ring Accelerator – Section 10.2.4
- Packet Streaming Interface (PSI-L) – Section 10.2.8
- Block Copy DMA Controller

MODSS:
- Mailbox – Section 7.1
- Spinlock – Section 7.2
- Two Timer Managers (Timer banks) – Section 11.2
- Time Stamp Module (CPTS) – Section 11.1
- Infrastructure components:
  - CBASS – *System Interconnect*
  - Proxies – Section 10.2.5
  - Interrupt aggregators – Section 10.2.7
  - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – Section 10.2.9

ECC aggregators – Section 12.10.4

VirtSS – Virtualization sub-system provides all the translation components supported in K3 for virtualization:
- Peripheral Virtualization Units (PVU) – Section 8.3

10.2.1.3 NAVSS Interrupt Configuration

This section describes the actions needed to configure interrupts within the NAVSS. The information provided is applicable to either the NAVSS or MCU_NAVSS subsystems.

Table 10-93 are module-specific hardcoded parameters required to properly configure the NAVSS interrupt support.

Table 10-93. NAVSS Parameters

Parameter	Value NAVSS0	Value MCU_NAVSS0	Description
RA_RING_CNT	1024	286	Number of total rings supported
IA_SEVI	4608	1536	UDMA Interrupt Aggregator Source Event Input (SEVI) count
IA_VINTR	256	256	UDMA Interrupt Aggregator Virtual Interrupt (VINTR) count
IR_IBASE	See *NAVSS Interrupt Router Input Mapping*	See *Interrupt Router Input Mapping*	Interrupt Router input interrupt base number for given module (hardcoded values in interrupt router)
EO	See *Global Event Map*	See *Global Event Map*	Event offset (hardcoded offsets in NAVSS)

Table 10-94 lists software-configurable variables used in the examples and descriptions.

Table 10-94. NAVSS Software Variables

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number
OI#	0 – 407	Interrupt router output CPU interrupt number. See *NAVSS Hardware Requests*

10.2.1.3.1 NAVSS Event and Interrupt Flow

Figure 10-14 illustrates the event and interrupt flow within the NAVSS and output interrupts to a CPU. Information that flows between NAVSS modules is also indicated (in this case, Global Event (GE) information flows between ring accelerator and the PSILSS).

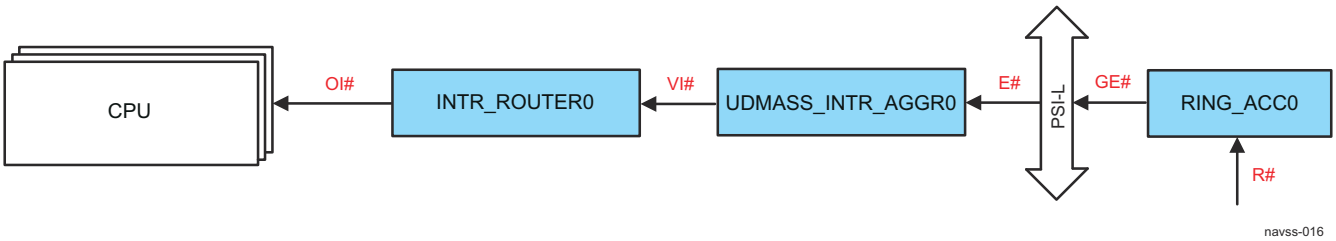

Figure 10-14. NAVSS Interrupt Flow

10.2.1.3.1.1 NAVSS Interrupts Description

This section describes the interrupt-related information that flows within NAVSS and how this information is configured or generated.

1. **Ring Number (R#)**
   - Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, proxy, or secure proxy accesses
   - The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see *RINGACC Ring Mapping*)
2. **Global Event and Event Numbers (GE# and E#)**
   - GE# = EO + E#

Copyright © 2023 Texas Instruments Incorporated

- EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the NAVSS event mapping, removing EO in the process. The destination module sees only E#. See *Global event Map* for details. Examples:
  - GE# in the range 0x0000 – 0x1FFF (EO = 0x0000, E# = 0x0000 – 0x1FFF) would go to NAVSS0_UDMASS_INTR_AGGR0. The INTR_AGGR sees E#.
  - GE# in the range 0x4000 – 0x47FF (EO = 0x4000, E# = 0x0000 – 0x07FF) would go to MCU_NAVSS0_UDMASS_INTR_AGGR0. The INTR_AGGR sees E#.
- For the INTR_AGGR module, E# ranges from 0 to (IA_SEVI - 1)

3. **Virtual Interrupt (VI#)**
   - The INTR_AGGR maps E# (via software configuration) to any SB#
   - SB# ranges from 0 to (IA_SEVI - 1)
   - Each VI# (0 – (IA_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s VI#×64 – (VI#×64)+63)
4. **Output Interrupt (OI#)**
   - The Interrupt Router has a hardwired set of interrupt inputs from various modules (see *NAVSS Interrupt Router Input Mapping*). Examples:
     - In the NAVSS, 256 interrupt inputs from the NAVSS0_UDMASS_INTR_AGGR0 are hardwired to interrupt inputs 0 – 255. The VI# is zero-relative to this range.
     - In the MCU_NAVSS, 4 event interrupt inputs from the MCRC0 are hardwired to interrupt inputs 256 – 259. The VI# is zero-relative to this range.
   - Software configures an interrupt input (based on VI# + IR_IBASE) to an OI#

10.2.1.3.1.2 Application Example

This section uses the following example to illustrate how to configure the NAVSS interrupt support for a specific use-case:

```
Using NAVSS0, use A72 MPU interrupt 7 for UDMAP0 receive ring 16 (assumptions: use up/down event
10, NAVSS0_UDMASS_INTR_AGGR0 for interrupt aggregation, and virtual interrupt 3).
```

Table 10-95 lists the modules' hardcoded parameters used for this example:

Table 10-95. NAVSS Parameters for the Application Example

Parameter	Value NAVSS0	From Table	Description
RA_UDMAP0_RX		*RINGACC Ring Mapping*	Starting ring number for UDMA0 receive channels
RA_RING_CNT	1024	*NAVSS0_RINGACC0 Configuration Parameters*	Number of total rings supported
IA_SEVI	4608	*Interrupt Aggregators Parameters*	NAVSS0_UDMASS_INTR_AGGR0 Steerable Event Input (SEVI) count
IA_VINTR	256	*Interrupt Aggregators Parameters*	NAVSS0_UDMASS_INTR_AGGR0 Virtual Interrupt (VINTR) count
IR_IBASE	0	*NAVSS Interrupt Router Input Mapping*	Interrupt-Router-input-interrupt base for NAVSS0_UDMASS_INTR_AGGR0
EO	0	*Global event Map*	Event offset. Destination is NAVSS0_UDMASS_INTR_AGGR0
CC_IBASE	0	*NAVSS0 Hardware Requests*	Interrupt-requests-to-CC base

Table 10-96 the variables and their respective calculations for this example.

Table 10-96. NAVSS Software Variables for the Application Example

Variable	Calculations/Value	Description
R#	= (RA_UDMAP0_RX + 16) = (+ 16) =	Receive ring 16 translates to ring number
E#	10	Zero-relative event number from PSILSS to NAVSS0_UDMASS_INTR_AGGR0
GE#	= (EO + E#) = (0 + 10) = 10	Global event number (event 10 to be sent to NAVSS0_UDMASS_INTR_AGGR0)

Copyright © 2023 Texas Instruments Incorporated

Table 10-96. NAVSS Software Variables for the Application Example (continued)

Variable	Calculations/Value	Description
VI#	= 3	VI# = 3 is per example assumptions. VI# could get any value 0 – IA_VINTR-1.
SB#	= 200	Must be in the range (VI#×64) – ((VI#×64)+63) = 192 – 255 in order to drive VI# 3. We will use 200 for this example.
OI#	= (A72_IBASE + 7) = (0 + 7) = 7	OI# = 7 is per example assumptions. OI# could get any value 0 – 119 to drive an A72 interrupt.

Table 10-97 shows software register writes that will configure the NAVSS to produce the desired interrupt per the example description.

Table 10-97. NAVSS Register Writes for the Application Example

Module	Register	Value to Write	Description
RINGACC0	RING[R#]_EVT (EVENT_j)	RING[]_EVT = GE# = 10	Ring event number must be specified as a global event number
INTR_AGGR0	ENTRY[E#]_INTMAP (IMAP_j)	ENTRY[10]_INTMAP = (((SB#/64)&0x1FF)<<8) | (SB#%64) = (3<<8) | 8 = 0x308	regnum = SB# / 64 bitnum = SB# % 64
INTR_AGGR0	VINT[SB#/ 64]_ENABLE_SET (ENABLE_SET_j)	VINT[3]_ENABLE_SET = 1<<(SB# % 64) = 1<<8 = 0x100	Enable interrupt
INTR_ROUTER0	INTERRUPT_CONTROL[OI#] (MUXCNTL_y)	INTERRUPT_CONTROL[7] = IR_IBASE + VI# = 0 + 3 = 3	Route interrupt

10.2.2 MCU Navigator Subsystem (MCU NAVSS)

This chapter describes the integration of the MCU Navigator Subsystem (MCU NAVSS) in the device and internal module parameters.

10.2.2.1 MCU NAVSS Overview

MCU Navigator Subsystem (MCU NAVSS) has a subset of the modules of the main NAVSS and is instantiated in the MCU domain.

MCU Navigator Subsystem consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), and Peripherals (Module subsystem [MODSS]).

UDMASS – UDMASS is the essential part of the TI Data Movement Architecture. UDMASS consists of:

- Unified DMA Controller
- Ring Accelerator
- Packet Streaming Interface (PSILSS)

MODSS – MODSS is a collection of peripherals with different system-level functions. NAVSS0 contains the following modules:

- Memory CRC module
- Infrastructure components such as CBASS, proxies, interrupt aggregators, and an interrupt router

ECC aggregators – for SEC/DED memory protection.

Figure 10-15 shows the MCU_NAVSS0 top-level block diagram.

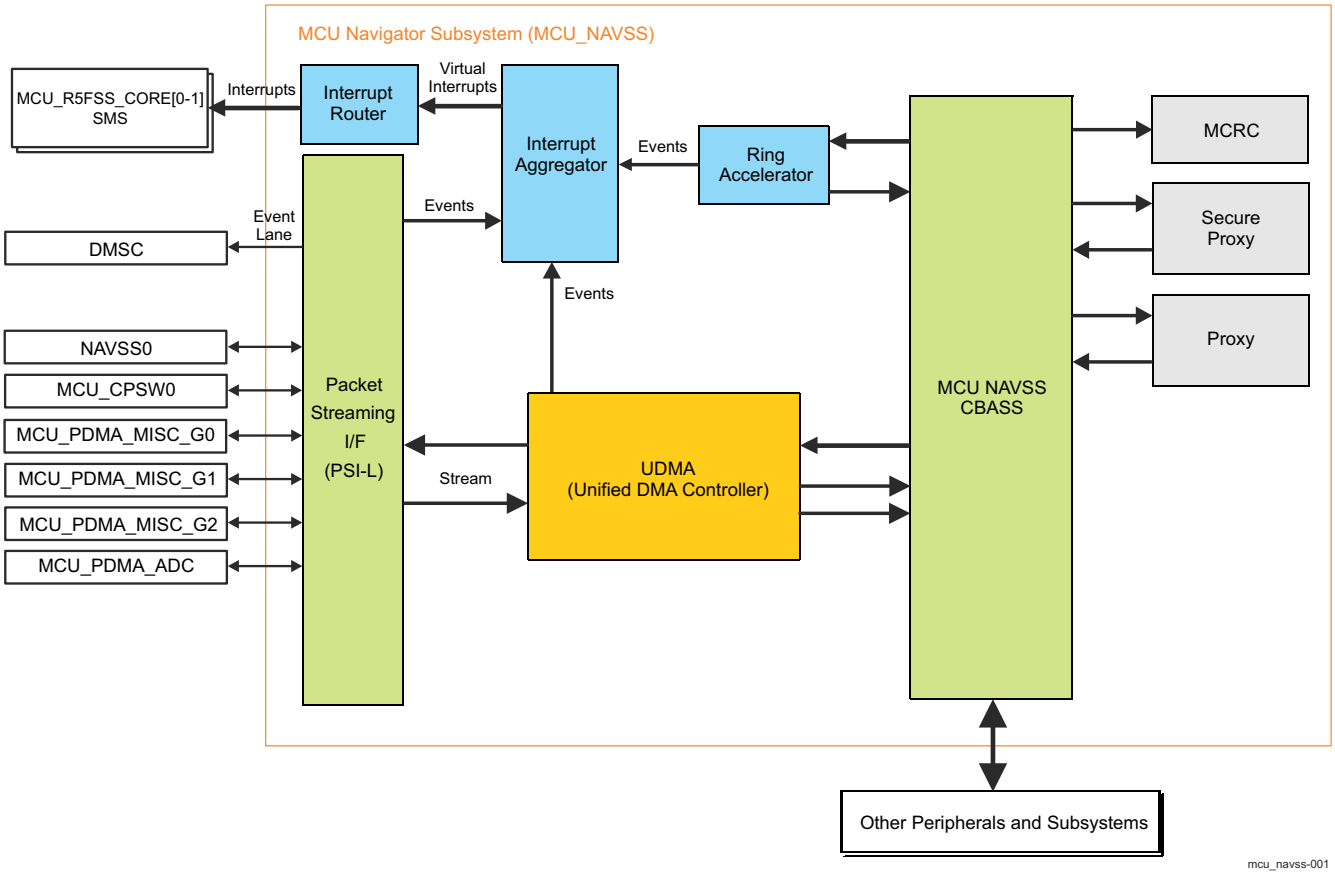

Figure 10-15. MCU NAVSS Top-Level Block Diagram

Copyright © 2023 Texas Instruments Incorporated

Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed ot fewer peripherals and has reduced bandwidth. This chapter describes the integration and parameters specific for MCU NAVSS.

Copyright © 2023 Texas Instruments Incorporated

10.2.2.2 MCU NAVSS Functional Description

See Section 10.1, *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

10.2.3 Unified DMA Controller (UDMA)

This chapter describes the UDMA controller module, part of NAVSS.

10.2.3.1 UDMA Overview

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices.

Table 10-98. UDMA Allocation Across Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_UDMAP0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMAP0	-	✓ (MCU NAVSS)	-

Figure 10-16 shows a top-level overview of the UDMA module.

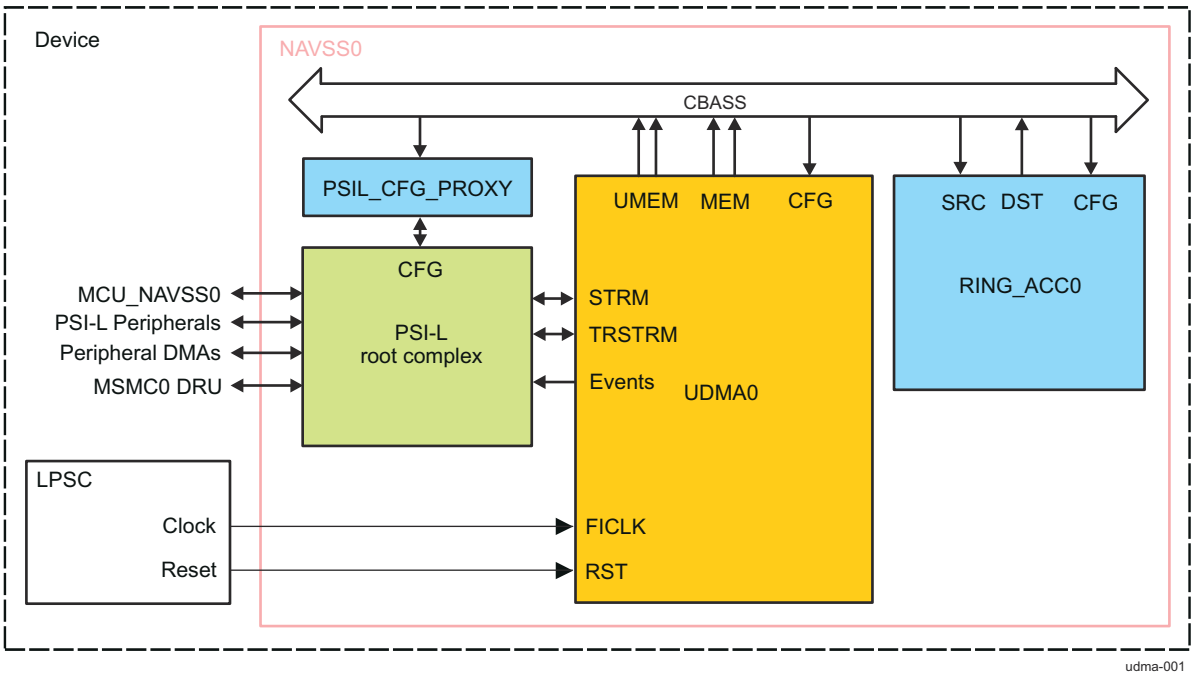

Figure 10-16. UDMA Overview

10.2.3.1.1 UDMA Features

NAVSS0_UDMAP0 controller module supports the following modes and features:

- *TI K3 DMA Architecture* compliant Tx/Rx port implementation (see Section 10.1, *DMA Architecture*)
- Implements *TI DMA Architecture*-compliant Packet-Oriented DMA Functionality (UDMA-P)
  - Provides internal Tx Packet Oriented DMA processing unit
  - Provides internal Rx Packet Oriented DMA processing unit
  - Supports *rflow_cnt* unique Rx flow table entries
  - Supports 1 transmit queue per data connection
  - Supports 1 receive queue per data connection
  - Supports physical separation of buffer control and payload information
  - Supports host and monolithic descriptor formats
  - Supports unlimited buffer scatter/gather for packets using host descriptor type
  - Supports data buffer sizes up to 4 Mbytes
  - Supports variable first valid byte offset within data buffers
  - Supports packet truncation on transmit
  - Provides per-channel buffering:

Copyright © 2023 Texas Instruments Incorporated

    - Provides 16 word deep × 128-bit Packet FIFO for each Tx channel
    - Provides 4 word deep Packet Info FIFO for each Rx channel
    - Provides 8 word deep × 128-bit Packet Data FIFO for each Rx channel
    - Supports up to 32 Protocol Specific words for Tx packets
    - Supports up to 32 Protocol Specific words for Rx packets
- Implements *TI DMA Architecture* compliant Third Party Channel Controller
  - Channel controller is built as a prefetcher engine
  - Provides the same functionality as a discrete UDMA-C/UTC combination
    - Provides a fully integrated *TI DMA Architecture* Third Party DMA compliant solution
  - Can also fetch TRs and writeback TR responses for up to *echan_cnt* external channels which are transported via the TR PSI-L interface
- Implements *TI DMA Architecture* compliant Unified Transfer Controller
  - Provides a memory read access unit
    - Supports read bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Provides a memory write access unit
    - Supports write bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Supports Type 0-4, and Type 15 Transfer Request types
- Provides a set of *TI DMA Architecture* compliant Unified DMA channels which all share the execution hardware using time division multiplexing
  - Supports *tchan_cnt* concurrent Tx channels
    - Each Tx channel can be configured at runtime to be:
      - Packet oriented Tx data channel
      - Third party combination source control and data channel (Third Party channel mode)
  - Supports *rchan_cnt* simultaneous Rx (destination) channels
    - Each Rx channel can be configured at runtime to be:
      - Packet oriented Rx data channel
      - Third party combination destination control and data channel (Third Party channel mode)
  - Provides support for three different groups of internal channels:
    - Ultra-high capacity (UHC) channels
      - Quantity specified by: *uchan_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - UHC channels are the first *uchan_cnt* channels within the Tx and Rx arrays (starting with channel 0 and extending up to channel *uchan_cnt*-1)
      - Tx and Rx UHC channels are specified as a matched pair
        - Still usable as split channels but design must have same number of Tx/Rx UHC channels
    - High-capacity (HC) channels:
      - Quantity specified by: *hchan_cnt - uchan_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - HC channels are the next *hchan_cnt* channels (after any UHC channels) within the Tx and Rx channel arrays (starting with channel *uchan_cnt* and extending up to *uchan_cnt* + *hchan_cnt*-1).
    - Normal capacity (NC) channels:
      - Quantity on Tx specified by: *tchan_cnt - uchan_cnt - hchan_cnt*
      - Quantity on Rx specified by: *rchan_cnt - uchan_cnt - hchan_cnt*
      - Provide standard depth Tx/Rx per channel FIFOs
      - Provide 1 deep descriptor/TR prefetch buffers

Note

User can still use ultra-high capacity and high-capacity channels as general normal-capacity channels though may not be taking advantage of the potential DMA throughput advantages.

  - Provides per-channel buffering:
    - Provides 16 word deep data FIFO for each NC Tx (source) channel
    - Provides 8 word deep data FIFO for each NC Rx (destination) channel

Copyright © 2023 Texas Instruments Incorporated

- Provides single 128-bit read/write VBUSM master interface for prefetcher accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read/write VBUSM master interface for packet DMA and coherency unit accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding reads.
- Provides single 128-bit write only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding writes.
- Provides 128-bit wide PSI-L compliant source interface for sending data to remote UTCs and remote peripherals
  - Includes 1 outgoing event transport lane
- Provides 128-bit wide PSI-L compliant destination interface for receiving data from remote UTCs and remote peripherals
  - Includes 1 incoming event transport lane
- Provides PSI-L interface for sending Transfer Requests to remote UTC channels and receiving back Transfer Responses
  - Provides 32 entry deep unified Transfer Response FIFO for external channels
- Provides 0 local event input buses

10.2.3.1.2 UDMA Parameters

Table 10-99 shows the UDMA configuration parameters in this SoC.

Table 10-99. UDMA Configuration Parameters

Module Instance	Parameters(1)					
	tchan_cnt(2)	rchan_cnt(3)	echan_cnt (4)	hchan_cnt(6)	uchan_cnt(7)	rflow_cnt(5)
NAVSS0_UDMAP0	85	82	256	4	2	224
MCU_NAVSS0_UDMAP0	48	48	0	2	0	96

(1) Parameter values can be read from the capabilities registers. See UDMA_CAP2 and UDMA_CAP3 registers.
(2) Total internal Tx channel count (Normal- + High- + Ultra-high capacities)
(3) Total internal Rx channel count (Normal- + High- + Ultra-high capacities)
(4) External UTC channel count
(5) Rx flow table entry count
(6) High-capacity + Ultra-high capacity channel count
(7) Ultra-high capacity channel count

10.2.3.2 UDMA Functional Description

The UDMA module supports the transmission and reception of various packet types. The UDMA is architected to facilitate the segmentation and reassembly of K3 DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware.

An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA also supports acting as a Unified Channel Controller (UDMA-C)/Unified Transfer Controller (UTC) combined unit which accepts Transfer Request packets from Ring Accelerator and then performs the transfers which the Transfer Request (TR) specifies.

Channels in the UDMA can be configured to be either Packet-based or TR-based Third Party channels on a channel by channel basis.

10.2.3.2.1 Block Diagram

Figure 10-17 shows UDMA main internal components.

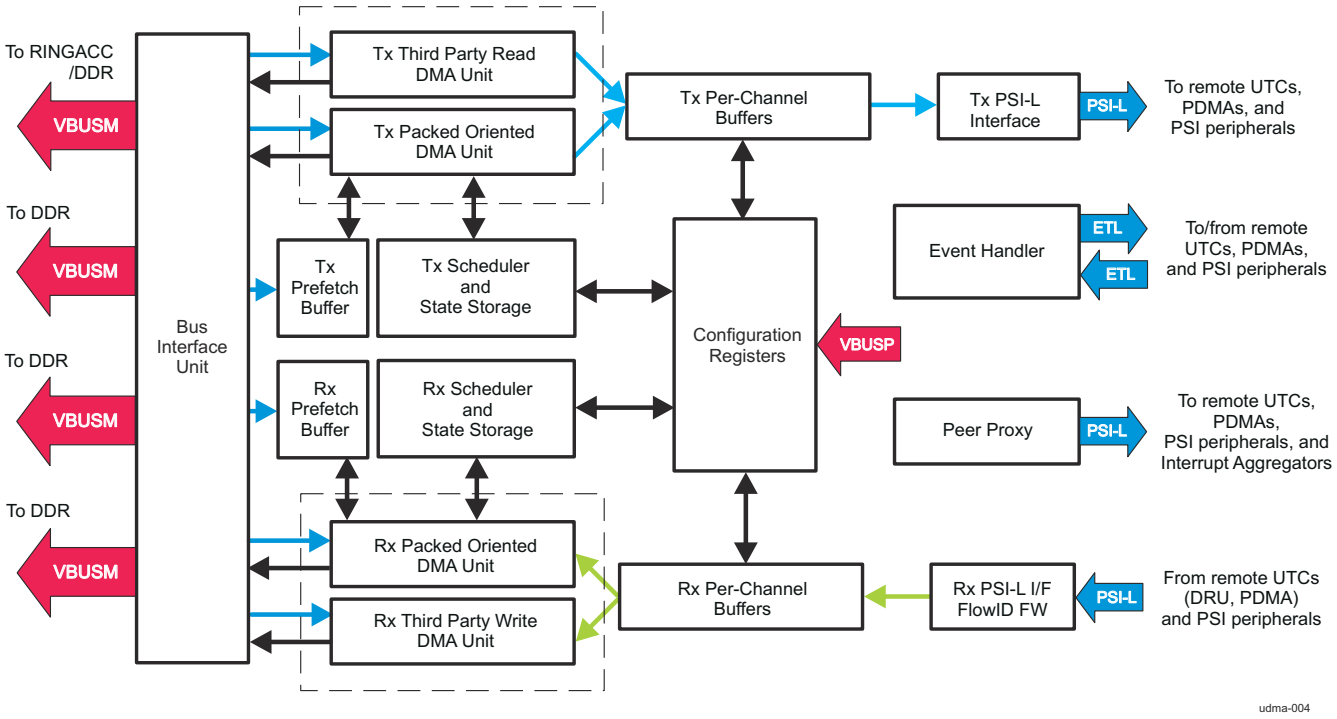

Figure 10-17. UDMA Block-Diagram

Bus Interface Unit

The Bus Interface Unit (BIU) is responsible for merging and buffering all of the transactions that originate from the various master blocks inside the DMA controller into the 4 separate VBUSM master interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A two word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

Tx Prefetcher Configuration Registers

The Tx Prefetcher Configuration Registers block is responsible for providing memory mapped registers for configuration of the Tx DMA function, monitoring the fullness level of the Tx prefetch buffers, maintaining Tx prefetch state information, arbitrating which channel will be allowed to perform prefetch work next, issuing

Copyright © 2023 Texas Instruments Incorporated

scheduler commands to the Tx Prefetch Units, and writing back the updated state returned from those same prefetch units.

Tx Prefetch Unit(s)

The Tx Prefetch Unit block is responsible for performing a fetch of either a Packet Descriptor (packet mode) or a TR to feed the downstream Tx DMA/Tx Read Units.

Tx Configuration Registers

The Tx Configuration Registers block (*UDMASS_UDMAP0_CFG_TCHAN Registers*) is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx Packet and TR based DMA core blocks, and writing back the updated state returned from those same DMA core blocks.

Tx Packet DMA Unit

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Host and Monolithic Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read and write descriptor pointers from the Ring Accelerator, read descriptors from memory, and read data from buffers in memory.

Tx Packet Coherency Unit

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Tx queue. This unit is only used on channels which are in Pass-By-Reference mode

Tx TR Coherency Unit

The Tx TR Coherency Unit is responsible for ensuring that all control structures and data have been read prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

Tx External Channel TR Coherency Unit

The Tx External Channel TR Coherency Unit is responsible for ensuring that TRs received back from remote UTCs are written in strong order to either the Packet Descriptor or a Pass-by-Value queue in the Ring Accelerator. This unit is only used on external UTC channels.

Tx Event Coherency Unit

The Tx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing Event Transport Lane (ETL). This unit is only used on channels which are in TR mode.

Tx Per Channel Buffers

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units or Tx Third Party Read unit modules. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each Tx (source) channel in the UDMA controller maps directly onto a thread in the Tx PSI-L interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler block which it then uses to determine when it must initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

Copyright © 2023 Texas Instruments Incorporated

Rx FlowID Firewall

The Rx FlowID firewall checks the incoming flowID on the received packet from the Rx PSI-L interface to verify that it is either the corresponding flowID for the channel (that is, the default flow ID for the channel which is the same as the channel number) or that the flowID falls within a programmed range that is considered legal for the channel. If the received flowID does not fall within the legal range then the packet is dropped and the error is trapped.

Rx Per Channel Buffers

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel must be serviced next

Rx Configuration Registers

The Rx Configuration Registers block (*UDMASS_UDMAP0_CFG_RCHAN Registers*) is responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Rx Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

Rx Packet DMA Unit

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Rx protocol for Host and Monolithic descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from the Ring Accelerator, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

Rx Packet Coherency Unit

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID. This unit is only used on channels which are in Pass By Reference mode

Rx TR Coherency Unit

The Rx TR Coherency Unit is responsible for ensuring that all control structures have been read and all data has been written prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

Rx Event Coherency Unit

The Rx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing ETL. This unit is only used on channels which are in TR mode.

Third Party Read Unit

The Third Party Read Unit(s) are responsible for sequencing all of the Tx side channel control and data transfers. The Third Party Read Unit is responsible for performing the actual data read operations including sequential address generation and nested loop control. Like the Tx Packet DMA Unit, the Third Party Read Unit receives state information from the Tx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Read Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred, the transfer is completed, or the transfer has reached a point which requires an input trigger event to proceed.

Third Party Write Unit

Copyright © 2023 Texas Instruments Incorporated

The Third Party Write Unit(s) are responsible for sequencing all of the Rx side channel data transfers. The Third Party Write Unit is responsible for performing the actual data write operations including sequential address generation and nested loop control. Like the Rx Packet DMA Unit, the Third Party Write Unit receives state information from the Rx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Write Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred or the transfer is completed or the transfer has reached a point which requires an input trigger event to proceed.

Event Handler

The Event Handler block is responsible for accepting and logging channel triggering events and for generating channel completion and error events.

PSI-L Real Time Proxy

The PSI-L Real Time Proxy block is responsible for allowing tunneled VBUSP transactions to the Real Time Remote Peer registers to generate PSI-L configuration transactions to the paired remote peer for each Tx and Rx channel.

10.2.3.2.2 General Functionality

This section is applicable to all UDMA modes.

10.2.3.2.2.1 Operational States

At any given time the UDMA can be in one of three different states as described in Table 10-100.

Table 10-100. Operational States

Operational State	Description
Init	This is the initial state of UDMA during and immediately after reset. During this state, all of the RAMs inside the UDMA will be initialized to known values including the ECC redundant parity bits. While in the Init state, the DMA will de-assert all ready signals on all applicable slave interfaces and will de-assert all request signals on all applicable master interfaces. The UDMA will automatically transition out of the Init state into the Idle state when all of the RAM initialization has been completed.
Idle	Once the UDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the UDMA interfaces (master or slave). The Idle state is generally a transient state and is used by the UDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the UDMA transitions to the Active state. When no more work is pending, or when the host pauses/disables active channels, or when the SoC power management desires to shut down the UDMA, the UDMA will account for any outstanding transactions and will re-enter the Idle state. The UDMA leaves the Idle state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
Active	The UDMA enters the Active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the UDMA transitions to the Idle state.

10.2.3.2.2.2 Tx Channel Allocation

In NAVSS0, a total of 140 Packet Tx channels are provided within the DMA for concurrent data transfers between memory mapped space and the Tx Per Channel Buffers. Each of these channels can be configured to operate as a packet oriented channel (uses queues/rings/descriptors/buffer) or as a Third Party DMA source channel (uses Transfer Request packets to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to a Tx Packet DMA Unit or a Third Party Read Unit respectively.

The Tx channels are allocated as shown in Table 10-101.

Table 10-101. Internal Tx Channel Allocation

DMA Channel	Function	Tx Queue (Ring)
0	Tx Channel	0 (Starting queue number in RINGACC for Tx channel 0)
...	...	...
139	Tx Channel	139

Copyright © 2023 Texas Instruments Incorporated

10.2.3.2.2.3 Rx Channel Allocation

In NAVSS0, a total of 140 Rx channels are provided within the DMA for concurrent transfers between the Rx Per Channel Buffers and memory mapped space. Each of these channels can be configured to operate as a packet oriented channel (uses rings/descriptors/buffer) or as a Third Party DMA destination channel (uses rings/Transfer Request packets or TR standalone records to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to an Rx Packet DMA Unit or a Third Party Write Unit respectively. The Rx channels are allocated as shown in Table 10-102.

Table 10-102. Rx Channel Allocation

DMA Channel	Function	Src Tag
0	Rx Channel	0
...	...	...
139	Rx Channel	139

10.2.3.2.2.4 Tx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates a Tx DMA channel teardown operation by writing to the TDOWN bit in the TCHANRT UDMA_TRT_CTL_j register. Once a channel teardown is requested, the appropriate Tx DMA unit will complete any packet/TRs that the channel has prefetched or is currently in the process of transferring and will then clear the EN bit, will send a Teardown packet out the outbound Payload Data PSI-L interface, and will push a Teardown Completion Record onto the Tx Default Queue for the channel. If the Tx DMA engine is not currently in a packet/TR for the channel, it will immediately clear the EN, send the Teardown packet, and push the Teardown Completion Record. Once the teardown is complete, no further packet processing will occur until the host software re-enables the channel.

10.2.3.2.2.5 Rx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates an optimal Rx DMA channel teardown operation by shutting down the incoming payload stream at its source (a remote peer peripheral or the Tx side of a block copy channel). Once teardown is initiated at the source, data will eventually drain from the incoming PSI-L stream and when all data is complete, the remote peer entity will send a Teardown packet (either a standalone packet or tdown asserted with eop on the last data phase of the last packet). When the UDMA receives a teardown message, the TDOWN bit will be set in RCHANRT UDMA_RRT_CTL_j. In the case where a remote peer cannot generate a teardown message, the host must ensure that all data has stopped flowing from the remote peer and will then directly set the TDOWN bit. Once the UDMA sees the TDOWN asserted it will wait for any existing packets which are currently held in the Rx Per Channel FIFO to be completed and will then de-assert the EN bit in RCHANRT UDMA_RRT_CTL_j. If the back end application continues to allow new packets to be pushed into the Rx PC FIFO, the DMA will continue to delay marking the channel as torn down as long as the Rx PC FIFO never reaches an empty state

10.2.3.2.2.6 Tx Clock Stop

The Tx clock stop interface allows the Tx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the tcs_clkstop_req input is asserted, the Tx portion of the UDMA will stop processing transmit packets/TRs for each channel at the next packet/TR boundary. Once all of the Tx channels have gracefully stopped transmission, the UDMA will assert the tcs_clkstop_ack output. Once the UDMA Tx engine has entered the IDLE state, it will remain there until the tx_clockstop_req is de-asserted.

10.2.3.2.2.7 Rx Clock Stop

The Rx clock stop interface allows the Rx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the rcs_clkstop_req input is asserted, the Rx portion of the UDMA will stop processing receive packets for each channel at the next packet boundary. Once all of the Rx channels have gracefully stopped reception, the UDMA will assert the rcs_clkstop_ack output. Once the UDMA Rx engine has entered the IDLE state, it will remain there until the rx_clockstop_req is de-asserted.

Copyright © 2023 Texas Instruments Incorporated

10.2.3.2.2.8 Rx Thread Enables

PSI-L threads must first be enabled in order to transfer commands or data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

10.2.3.2.2.9 Events

Events are used in the *TI DMA Architecture* for triggering hardware or software (by being turned into interrupts) processes. Physical (or local) events in the *TI DMA Architecture* are implemented as active-high, single-cycle, long, synchronous pulses which are strobed to communicate that a particular condition has occurred. Virtual (or global) events are implemented as a value which is passed across a shared bus (ETL) - one value per cycle. Physical (local) events can be used by the UDMA to communicate with some local peripherals. Virtual (global) events are used by the UDMA to communicate with remote peripherals, the interrupt aggregator, and other DMA instances in the system.

10.2.3.2.2.9.1 Local Event Inputs

There are no local events routed to the UDMA local event inputs in the current NAVSS implementation.

10.2.3.2.2.9.2 Inbound Tx PSI-L Events

The Tx PSI-L interface includes a single inbound event transport lane (ETL) which allow events to be received from other UDMA/UTC/PDMA instances for synchronization and triggering purposes. Events passed in from this event transport lane will already have been decoded as destined for some event destination index for this particular UDMA. The appropriate LSBs of each event number are extracted and the specified event is asserted.

The event map for inbound events to the UDMA is shown in Table 10-103.

Table 10-103. Inbound Event Map

Event Number	Target
0	Tx Channel 0 Global Trigger 0
1	Tx Channel 0 Global Trigger 1
2	Tx Channel 1 Global Trigger 0
3	Tx Channel 1 Global Trigger 1
...	...
279	Tx Channel 139 Global Trigger 1
280	Rx Channel 0 Global Trigger 0
281	Rx Channel 0 Global Trigger 1
282	Rx Channel 1 Global Trigger 0
283	Rx Channel 1 Global Trigger 1
...	...
559	Rx Channel 139 Global Trigger 1

10.2.3.2.2.9.3 Outbound Rx PSI-L Events

The Rx PSI-L interface includes a single outbound event transport lane (ETL) which allows internal events to be sent to other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes. The destination event number is programmed for each event source within the UDMA. See registers:

- TCHAN UDMA_TOES_j
- TCHAN UDMA_TEOES_j
- RCHAN UDMA_ROES_j
- RCHAN UDMA_REOES_j

10.2.3.2.2.10 Emulation Control

The emulation control input and register bits (SOFT and FREE in the UDMA_EMU_CTRL register) allow DMA operation to be suspended. When the emulation suspend state is entered, the DMA will stop processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or

Copyright © 2023 Texas Instruments Incorporated

transmission will be completed normally without suspension. Emulation control is implemented for compatibility with other peripherals. Table 10-104 shows the operations of the emulation control input and register bits.

Table 10-104. Emulation Behavior Control

Emulation Control Input	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

10.2.3.2.3 Packet Oriented Transmit Operation

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interfaces onto the Transmit Packet Data PSI-L Interface. This movement of data is performed in blocks whose size is specified by the Tx DMA scheduler.

10.2.3.2.3.1 Packet Mode VBUSM Master Interface Command ID Selection

The UDMA keeps a transaction command scoreboard for each specific direction for the Packet Mode VBUSM Master interface. The scoreboard tracks which command indexes are currently outstanding from the DMA on that interface. When a read or write is requested by one of the internal master agents in the UDMA, the scoreboard corresponding to the specified interface and for the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*). The index values for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

10.2.3.2.4 Packet Oriented Receive Operation

Packet reception is accomplished within the UDMA by moving data from the Receive PSI-L Interface to data structures that are located in memory accessible via the VBUSM Memory Interface(s).

10.2.3.2.4.1 Rx Packet Drop

The Rx PSI-L Interface master may assert the rstrmp_drop signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Rx Packet DMA unit will be notified that the packet is to be flushed and recycled rather than passed to the host. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops a packet on a channel configured for Packet mode there is no notification to the host.

10.2.3.2.4.2 Rx Starvation and the Starvation Timer

As described in the *TI DMA Architecture* specification, whenever the Rx DMA engine needs to read a Free Descriptor Pointer from the Ring Accelerator, it is possible that the queue may be empty. When this occurs it is referred to as buffer starvation. The Ring Accelerator provides a message interface to the UDMA which provides increment and decrement information so that the UDMA can keep a local occupancy counter for each ring that it can access from the RINGACC. When the Rx engine requires a free descriptor it will first check to see if the local occupancy for that ring is non-zero. If the occupancy is zero, starvation has occurred. When starvation occurs the Rx DMA will respond in one of two ways depending on the value of the rx_error_handling bit in Rx Flow Table entry that is currently being used for that particular packet reception opportunity. If the rx_error_handling bit is 0, the Rx DMA will drop the packet and will return any descriptors which it may have previously allocated for that packet to the respective queues from which they were allocated. If the rx_error_handling bit is set, the Rx DMA is required to retry checking to see if a Free Descriptor is available at a later time.

A timer is provided in order to control the rate at which the retry attempts will occur. All channels share the same timer and the period of the timer is set using the TIMEOUT_CNT field in the UDMA_PERF_CTRL register. The TIMEOUT_CNT field specifies in clock cycles the minimum delay between subsequent attempts to check if a Free Descriptor is available on each individual channel.

Copyright © 2023 Texas Instruments Incorporated

Example: If the TIMEOUT_CNT is set to 256 and channel 1 finds its Free Descriptor queue empty on cycle 10, it will be required to wait until at least cycle 266 before it can make another attempt check the queue again. The actual number of cycles which will be waited by the DMA will typically be larger than the TIMEOUT_CNT value and this is not intended to be a highly precise operation. The critical requirement is that the DMA will not attempt to bring a channel into context to check if a buffer is available at a more frequent rate than is allowed.

10.2.3.2.5 Third Party Mode Operation

10.2.3.2.5.1 Events and Flow Control

The following sections describe the mechanisms that are provided for supporting flexible flow control between peripherals, the UDMA and other DMA instances.

10.2.3.2.5.1.1 Channel Triggering

Channels which are configured in Third Party mode must be triggered in order for them to perform work. Triggering can be configured to be immediate, one-shot, or periodic at different levels of TR completion and is specified in the TR itself. Each channel in the UDMA is capable of being triggered by two separate events which are mapped at specific offsets in a global event target map (just like an address map for memory mapped slaves). The UDMA maps its channel triggers with Tx side channels first followed by Rx side channels as described in Table 10-103, *Inbound Event Map.*

10.2.3.2.5.1.2 Internal TR Completion Events

Each TR which is processed, provides the ability to assert 1 of 4 possible output events at specific completion levels for the TR. Since the output event is specified directly in the TR and the TRs are written by potentially untrusted software processes, channels are only able to assert *virtual events* when they complete various portions of the TR. These virtual events are then mapped to actual destination events in the global event map by the TCHAN UDMA_TOES_j or RCHAN UDMA_ROES_j event steering registers. These registers are programmed statically by a trusted software process that has determined the channels that should have access to the specified event destination slots.

10.2.3.2.5.2 Transmit Operation

10.2.3.2.5.2.1 Transfer Request

After reset, all channels that are configured in Third Party transfer mode will be idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the host software places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Tx Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification (see Section 10).

10.2.3.2.5.2.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request record, the UDMA will return a Transfer Response record to either the original Transfer Request Descriptor or the Tx Completion Queue, depending on the mechanism which was used to provide the Transfer Request record. If the Transfer Request record originated in a Transfer Request Descriptor then a corresponding slot in the Transfer Request Descriptor will be overwritten with the response status. If the Transfer Request record originated in a pass by value Tx Ring, the Transfer Response record will be placed in a pass by value Tx Completion Ring. The Transfer Response record will only contain a completion code which indicates if the transfer was a success or if a particular type of failure occurred. The exact mechanisms which are used and the contents of the Transfer Response Record are given in the *TI DMA Architecture* specification (see Section 10).

10.2.3.2.5.2.3 Data Transfer

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interface(s) onto the Transmit PSI-L Interface. On the Tx side of the UDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Tx Per Channel FIFO to a remote peer DMA entity via the Tx PSI-L interface.

10.2.3.2.5.2.4 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a

Copyright © 2023 Texas Instruments Incorporated

corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see Section 10.1).

The sequences of data transactions that are performed by the UDMA on the Read Only VBUSM interface during transmit can be described as a sequence of piecewise linear read transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

10.2.3.2.5.2.5 Error Handling

In the case that an error occurs during any Tx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE_ON_ERR bit in the TCHAN UDMA_TCFG_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE_ON_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE_ON_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

10.2.3.2.5.3 Receive Operation

10.2.3.2.5.3.1 Transfer Request

After reset, all channels that are configured in Third Party mode will be Idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the Host places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Rx TR Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification (see Section 10).

10.2.3.2.5.3.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request, the UDMA will send a Transfer Response message back to either the Packet Descriptor (pass by reference channel mode) or to the completion queue in the Ring Accelerator (pass by value channel mode). The contents of this message are described in detail in the *TI DMA Architecture* specification (see Section 10).

10.2.3.2.5.3.3 Error Handling

In the case that an error occurs during any Rx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE_ON_ERR bit in the RCHAN UDMA_RCFG_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE_ON_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE_ON_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

10.2.3.2.5.4 Data Transfer

Third Party mode packet reception is accomplished within the UDMA by unpacking and moving data from the Rx Per Channel FIFOs which were filled via the Rx PSI-L Interface to specified memory mapped address ranges via the write only VBUSM master interface. On the Rx side of the UDMA, these transfers are always writes. Each write transfer which is performed by the Third Party Write Unit is to a destination address and of a size as calculated from parameters specified in the Transfer Request packet which was previously received to control the channel behavior.

10.2.3.2.5.4.1 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work

Copyright © 2023 Texas Instruments Incorporated

queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see Section 10.1).

The sequences of data transactions that are performed by the UDMA on the Write Only Memory interface during receive can be described as a sequence of piecewise linear write transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

10.2.3.2.5.4.2 Rx Packet Drop

The Rx PSI-L Interface master may assert the rstrm_drop signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Third Party write unit will be notified that the packet is to be flushed and no further writes are to be performed. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops the packet on a channel that is in Third Party mode, a 'dropped by source' error code will be placed in the Transfer Response packet which is returned to the Packet Descriptor or completion queue.

10.2.4 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the NAVSS.

10.2.4.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer. There is one RINGACC module per NAVSS.

Table 10-105. RINGACC Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_RINGACC0	-	-	✓ (NAVSS)
MCU_NAVSS0_RINGACC0	-	✓ (MCU NAVSS)	-

Figure 10-18 shows a top-level overview of the RINGACC module.

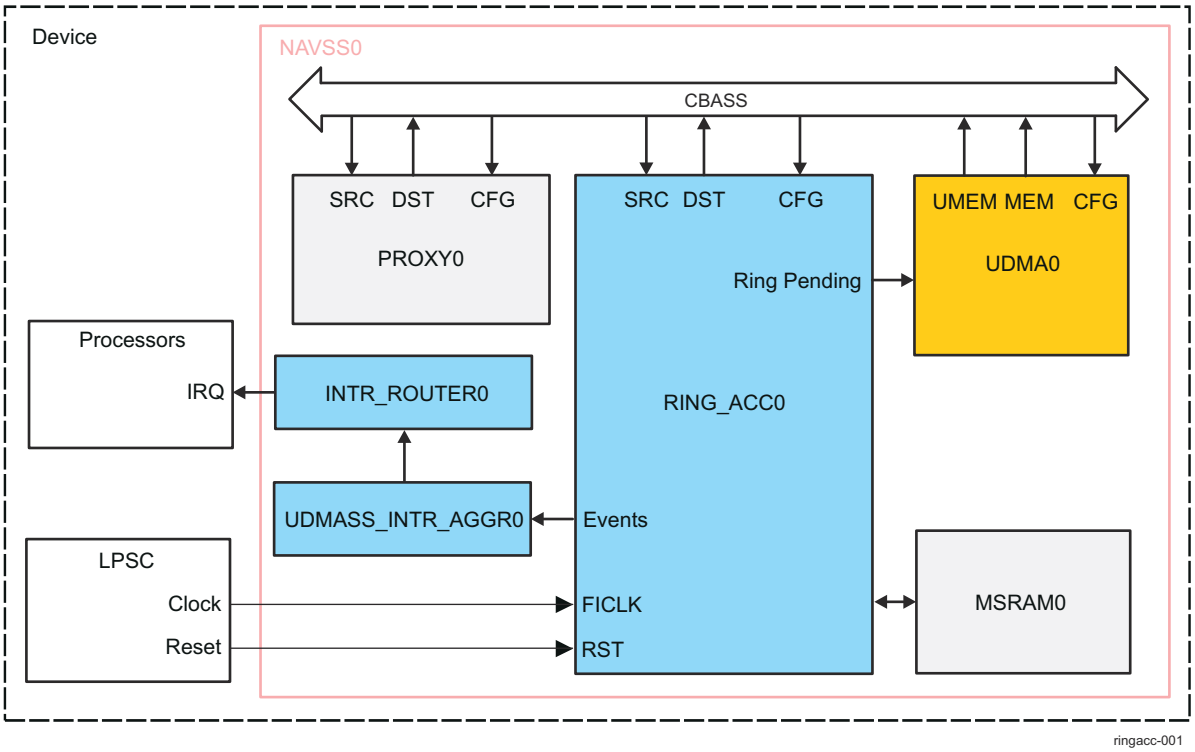

Figure 10-18. RINGACC Overview

10.2.4.1.1 RINGACC Features

NAVSS0_RINGACC0 supports the following features:

- Supports independent memory-mapped ring structures. See ring count in Table 10-106, *RINGACC Configuration Parameters*.
- Supports various modes for each ring based on usage and compatability
- Provides single-word deep shared incoming Transfer Response FIFO
- Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities.
  - Provides 2 word deep command FIFO
  - Provides 2 word deep write data FIFO
  - Provides 2 word deep read data FIFO
  - Provides 2 word deep write status FIFO
- Provides bit-wide destination VBUSM read/write master interface for accesses to ring structures in memory
- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads

Copyright © 2023 Texas Instruments Incorporated

- Source interface provides an array of 1024 × 512-byte long address windows (four for each ring) which are packed into a single contiguous address range
  - Read and write addresses which target a specific window are translated, in order to redirect the read or write transaction, to an effective address calculated from the base address for the ring plus current ring offset
  - Each read or write access presented on VBUSM slave interface is modified and bridged onto the VBUSM master interface

10.2.4.1.2 RINGACC Parameters

Table 10-106 shows the RINGACC configuration parameters in this SoC.

Table 10-106. RINGACC Configuration Parameters

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
NAVSS0_RINGACC0	1024	32	0x000038000000
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

Table 10-107 shows the MSRAM configuration parameters set during SoC design. MSRAM0 is accessible only from the ring accelerator (DST port).

Table 10-107. MSRAM Configuration Parameters

Module Instance	Parameters		
	Depth	Width	Base Address
NAVSS0_MSRAM0	4096	128	0x000030000000
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

10.2.4.2 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

10.2.4.2.1 Block Diagram

Figure 10-19 shows ring accelerator's main internal components.

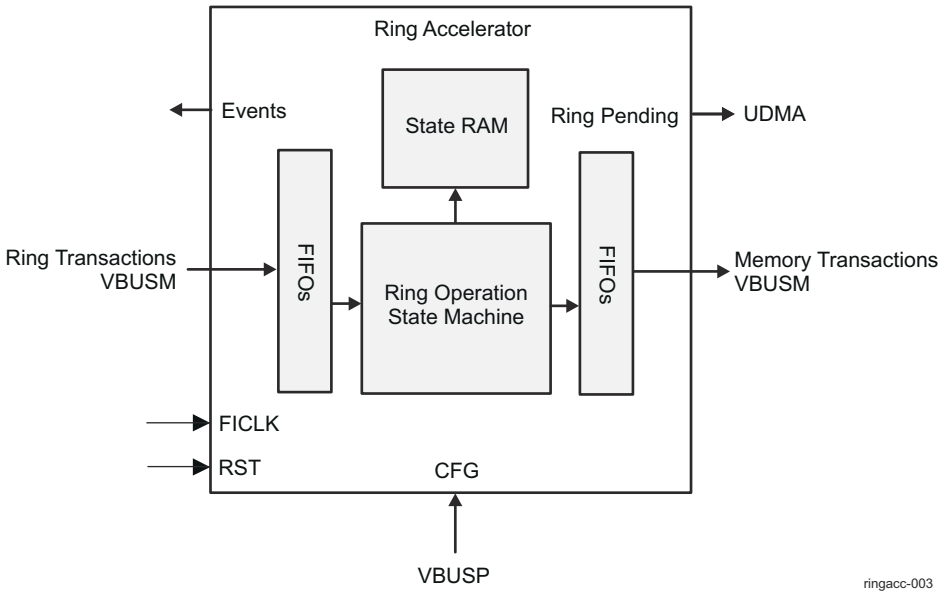

Figure 10-19. Ring Accelerator Block-Diagram

10.2.4.2.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields (NAVSS0_UDMASS_RINGACC0_CFG Registers), which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers (NAVSS0_UDMASS_RINGACC0_CFG_RT Registers), which are modified frequently during runtime.

Configuration registers are listed and described in *RINGACC Register Manual*.

10.2.4.2.1.2 Source Command FIFO

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

10.2.4.2.1.3 Source Write Data FIFO

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

Copyright © 2023 Texas Instruments Incorporated

10.2.4.2.1.4 Source Read Data FIFO

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

10.2.4.2.1.5 Source Write Status FIFO

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

10.2.4.2.1.6 Main State Machine

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to inidicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating master.

10.2.4.2.1.7 Destination Command FIFO

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped fromt the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original *cid* and *crouteid* values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

10.2.4.2.1.8 Destination Write Data FIFO

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

10.2.4.2.1.9 Destination Read Data FIFO

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

10.2.4.2.1.10 Destination Write Status FIFO

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

10.2.4.2.2 RINGACC Functional Operation

10.2.4.2.2.1 Queue Modes

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatability it has with hardware and software.

10.2.4.2.2.1.1 Ring Mode

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing the memory directly rather than going through hardware, and software updates the hardware on any changes

Copyright © 2023 Texas Instruments Incorporated

through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGACC_DB_j) than what is valid in the Ring Occupancy (RINGACC_OCC_j) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGACC_OCC_j register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGACC_OCC_j register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGACC_OCC_j reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

10.2.4.2.2.1.2 Messaging Mode

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no directly control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to tha RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

10.2.4.2.2.1.3 Credentials Mode

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

10.2.4.2.2.1.4 Queue Manager Mode

Queue manager mode makes the queue act like a traditional queue-manager (QM) queue in previous devices.

Note

Queue Manager mode is no longer supported in this device. This section was left for completeness only.

10.2.4.2.2.1.5 Peek Support

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

10.2.4.2.2.1.6 Index Register Operation

In ring mode, the Index (RINGACC_INDX_j) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGACC_HWINDX_j) register follows the hardware access of the ring through bus transactions. It works for a ring in either direction as the doorbell register update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot

Copyright © 2023 Texas Instruments Incorporated

differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

10.2.4.2.2.2 VBUSM Slave Ring Operations

Each ring contains four memory spaces on the VBUSM slave bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in Table 10-108.

Table 10-108. Ring Memory Partition

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reserved	Peeks from tail are not supported in this device
0x800 - 0xFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register .

10.2.4.2.2.3 VBUSM Master Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

10.2.4.2.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using *ring base + ring_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments hardware index and hardware occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments software index and occupancy for ring
3. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

10.2.4.2.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using ring base + ring_index
4. RINGACC increments hardware index and decrements hardware occupancy for ring

Copyright © 2023 Texas Instruments Incorporated

5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC increments software index and decrements software occupancy for ring
3. RINGACC pushes restored *routeid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

10.2.4.2.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGACC_DB_j) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both hardware and software occupancies for ring
4. RINGACC re-evaluates pending bit for ring

10.2.4.2.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring numberfrom incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using ring base + ring_index
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD- and WR-occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and ring number into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

10.2.4.2.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using *ring base + ring_index*
4. RINGACC increments RD index and decrements RD- and WR-occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *rrouteid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

10.2.4.2.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and *occ* are still incremented normally, and any special fields that are unwritten are assumed to be 0 .

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

Copyright © 2023 Texas Instruments Incorporated

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or *occ* increments occur. The only exception is for writes to an 8-byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatability).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and *occ* are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or *occ* decrements occur. Access beyond the credentials word must not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32-bit words, and partial bytes are not supported for all ring modes.

10.2.4.2.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements.

The event number is programmable per queue in the RINGACC_EVENT_j register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

10.2.4.2.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC_ERROR_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC_ERROR_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

10.2.4.2.5 Monitors

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

10.2.4.2.5.1 Threshold Monitor

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

10.2.4.2.5.2 Watermark Monitor

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high.

Copyright © 2023 Texas Instruments Incorporated

Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

10.2.4.2.5.3 Starvation Monitor

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

10.2.4.2.5.4 Statistics Monitor

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

10.2.4.2.5.5 Overflow

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through the RINGACC_OVRFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in *ring* or *message* modes.

10.2.4.2.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, a emudbg pop, a push to a full ring, as those do not update the ring state. When the bus is valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been recevied, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

10.2.4.2.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The *msgtype* field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC_TRACE_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 10-109 shows the trace message for a push.

10.2.5 Proxy

This chapter describes the Proxy module in a NAVSS.

10.2.5.1 Proxy Overview

The Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

Figure 10-20 shows a top-level overview of the Proxy module.

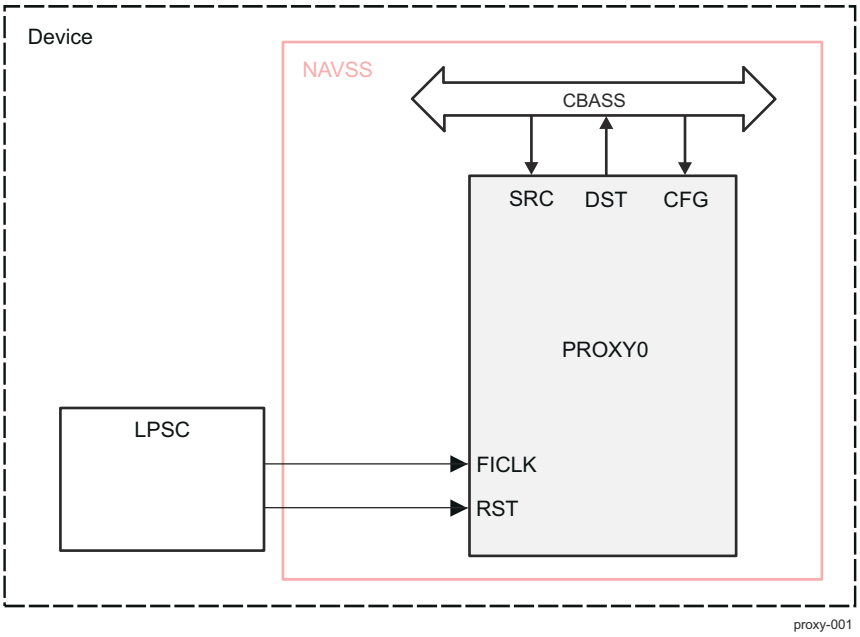

Figure 10-20. Proxy Overview

10.2.5.1.1 Proxy Features

Each Proxy supports the following features:

- Provides proxy buffers to store large data bursts that a host can only access in smaller amounts.
- Keeps the large data coherent until the complete data has been accessed.
- Allows for interleaved access between multiple hosts using multiple proxies.
- Each target has pre-configured number of channels, size of each channel, and address offset. See Table 10-113.

10.2.5.1.2 Proxy Parameters

Table 10-113 shows the Proxy configuration parameters set during SoC design.

(3) Number of channels for the target
(4) Number of bytes per channel supported for the target

10.2.5.2 Proxy Functional Description

This module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are for large Message Manager messages, Queue Manager data that is more than a pointer, or DMA Transfer Requests Messages. All of these require larger data sets, from 12 to 128 bytes, and the modules require the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as hardware registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the module with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but it stays in front of other module (target module) that does contain the resources. The proxy will access the target module with the entire data in a single burst, once the host has completed the data.

10.2.5.2.1 Targets

10.2.5.2.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in Table 10-114, totaling 4 kB space per ring/queue. Each channel has access modes (enabled via PROXY_CTL_j[17-16] MODE field):

- head access
- tail access
- peeks from head

Table 10-114. RINGACC Offsets per Ring/Queue

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored. This mode is not supported in this device.
0x800 - 0xFFF	Reserved

10.2.5.2.2 Proxy Sizes

The number of proxies in the module is configured during SoC design. See Table 10-113. Each proxy has its own address space to the module and determining which proxy is being accessed is simply based on the address bits above the final size of each proxy space. The size of the proxy space is always 4 KB. This is enough to contain the data message, along with controls for which channel, access mode, and element size for the access.

10.2.5.2.3 Proxy Interleaving

Each proxy must have a single owner, as each proxy only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy. Then they will have their own buffer and each can access a different resource at the same time. Each proxy is completely independent and kept coherent regardless of accesses to other proxies or regardless of the order of accesses. So the proxies support interleaving of multiple hosts' accesses.

10.2.5.2.4 Proxy Host States

Each individual proxy per host uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy is in use or not, but also for error detection. The proxy always stays in idle state, when there is no activity. There is a write state for when the proxy has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy has read data from a resource

Copyright © 2023 Texas Instruments Incorporated

and that entire data has not been fully read by the host. When a proxy access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

10.2.5.2.5 Proxy Host Channel Selection

The host must program the PROXY_CTL_j (where j = 0h to 3Fh) prior to accessing the PROXY_DATA_j_y (where j = 0h to 3Fh, y = 0h to 7Fh) unless the previous values are to be reused. This sets the channel within the target, the access mode (head, tail, peek), and the element size. These values will be used when writing the full message to the target, or reading a new message from the target. The target address used will be based on the target base address, the programmed channel, the programmed access mode (for the offset within the 4 kB of the target channel), and the element size (for the offset within the 512 Bytes max size message).

target address = target base + (channel × 4KB) + (mode × 512B) + (512 - element size in bytes)

, for element size in bytes length.

The proxy will detect an error if these fields are changed while in the middle of a message.

10.2.5.2.6 Proxy Host Access

A proxy begins in an idle state, where there is no data in the buffer. In this state the proxy will accept any access to a new resource. If the proxy is in another state, representing a resource is in progress, and the host attempts to access another target or resource, or switches from read to write, then the proxy will detect that as an error and flush the buffer with no final target access and the data is lost and the proxy goes back to idle state.

10.2.5.2.6.1 Proxy Host Writes

The first write to an idle proxy puts the proxy into write mode for the selected target and channel. Further legal writes are stored in the buffer for the enabled bytes and position within the buffer. A write to a previously written location will overwrite the previous data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy is then put back into idle state.

10.2.5.2.6.2 Proxy Host Reads

When in idle state, the first read to the proxy will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy is put back into idle state.

10.2.5.2.7 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target. This will copy the secure, debug, priv, privid, and virtid signals so that they can be firewalled during the target access for the resource.

10.2.5.2.8 Buffer Size

Buffer size is shown in Table 10-113. An attempt to access a larger message will result in the proxy going into error mode. Software must only create messages up to the supported target size.

10.2.5.2.9 Error Events

Each proxy can produce an event when it has detected an error. This error occurs when the host changes the target, resource, or access direction before completing the previous data. An error can also occur for an access to an illegal target, illegal offset within a target, such as beyond the target size or buffer size, or if the access spans multiple channels. This error does not include accessing reserved register locations within the proxy thread, as that results in normal reserved register behavior of ignoring write data and reading 0s. There is a separate status bit per proxy for these errors. The event number is programmed via PROXY_EVT_REG_j (where j = 0h to 3Fh) for each proxy. The event will not be sent if the event is programmed to 0xFFFF.

Copyright © 2023 Texas Instruments Incorporated

10.2.5.2.10 Debug Reads

Since debug reads with emudbg=1 must not cause any side effects or bus errors, any debug read will just read the buffer and never cause a target read. It will also not return any bus errors.

Copyright © 2023 Texas Instruments Incorporated

10.2.6 Secure Proxy

This chapter describes the Secure Proxy module in NAVSS.

10.2.6.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Secure Proxy is a modified version of the Proxy module in NAVSS.

Table 10-115. Secure Proxy Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_SEC_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_SEC_PROXY0	-	✓ (MCU NAVSS)	-

10.2.6.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events.

10.2.6.1.2 Secure Proxy Parameters

Table 10-116 shows the Secure Proxy configuration parameters set during SoC design.

Table 10-116. Secure Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies (1)	Message Size (2)	Target	Channels (3)	Sizes (4)
NAVSS0_SEC_PROXY0	370	64	NAVSS0_RINGACC0	110	4096
MCU_NAVSS0_SEC_PROXY0	90	64	MCU_NAVSS0_RINGACC0	30	4096

(1) Number of proxy threads supported. Can be read off from the SEC_PROXY_CONFIG read-only register
(2) Number of bytes for message. Can be read off from the SEC_PROXY_CONFIG read-only register
(3) Number of channels for the target
(4) Number of bytes per channel supported for the target

10.2.6.2 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)
- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. Therefore the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses.

Figure 10-21 describes Secure Proxy major building blocks.

Copyright © 2023 Texas Instruments Incorporated

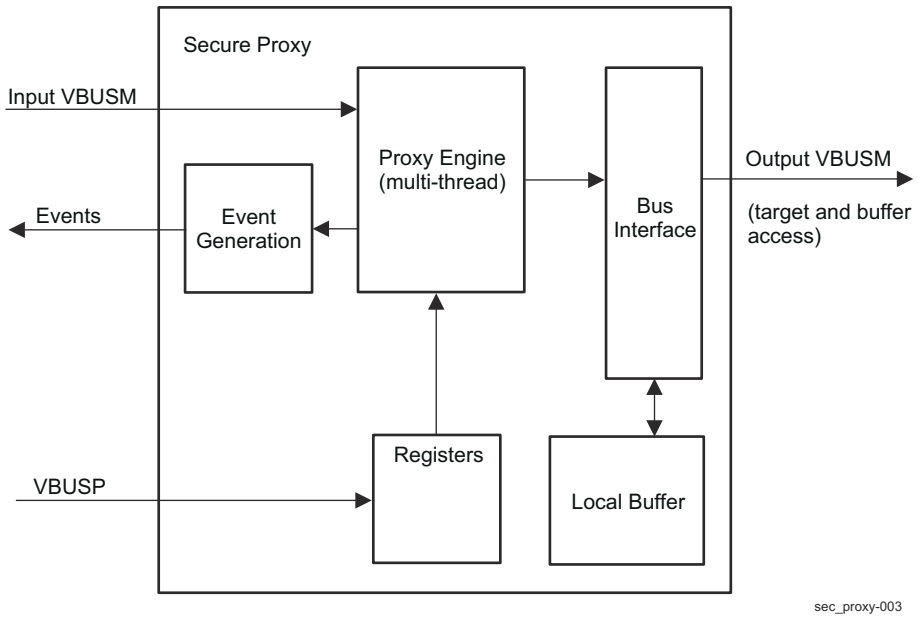

Figure 10-21. Secure Proxy Block Diagram

10.2.6.2.1 Targets

10.2.6.2.1.1 Ring Accelerator

The RING_ACC provides four distinct offsets to use per ring/queue shown in Table 10-117, totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RING_ACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always access the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

Table 10-117. RING_ACC Offsets per Ring/Queue

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored. Not used by Secure Proxy
0x600 - 0x7FF	Reads peek from tail. Writes ignored. Not used by Secure Proxy
0x800 - 0xFFF	Reserved

This means that target writes will use the following calculation:

target base address + (queue × 4KB) + 0x400 - msg_size (17)

,and burst until offset 0x3FF.

And target reads will use the following calculation:

target base address + (queue × 4KB) + 0x200 - msg_size (18)

,and burst until offset 0x1FF.

10.2.6.2.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC_PROXY_BUFFER_L, SEC_PROXY_BUFFER_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one *msg_size* per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target.

Copyright © 2023 Texas Instruments Incorporated

Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

10.2.6.2.2.1 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC_PROXY_CTL_j register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC_PROXY_STATUS_j) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

10.2.6.2.2.2 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC_PROXY_DATA_j).

10.2.6.2.2.3 Completion Byte

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

10.2.6.2.3 Proxy Thread Sizes

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

10.2.6.2.4 Proxy Thread Interleaving

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

10.2.6.2.5 Proxy States

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access

Copyright © 2023 Texas Instruments Incorporated

completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

10.2.6.2.6 Proxy Host Access

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

10.2.6.2.6.1 Proxy Host Writes

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

10.2.6.2.6.2 Proxy Host Reads

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

10.2.6.2.6.3 Buffer Accesses

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

10.2.6.2.6.4 Target Access

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

10.2.6.2.6.5 Error State

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are: an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

10.2.6.2.7 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

10.2.6.2.8 Resource Association

Each proxy thread has a register (SEC_PROXY_CTL_j) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

10.2.6.2.9 Direction

Each proxy thread has a register (SEC_PROXY_CTL_j) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

10.2.6.2.10 Threshold Events

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC_PROXY_EVT_MAP_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

10.2.6.2.11 Error Events

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

10.2.6.2.12 Bus Errors and Credits

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word in contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

10.2.6.2.13 Debug

When the transaction has the *emudbg* set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

10.2.7 Interrupt Aggregator (INTR_AGGR)

This chapter describes the INTR_AGGR module, part of NAVSS.

10.2.7.1 INTR_AGGR Overview

The Interrupt Aggregator (INTR_AGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

Table 10-118. INTR_AGGR Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_INTR_AGGR0	-	-	✓ (NAVSS)
NAVSS0_INTR_AGGR1	-	-	✓ (NAVSS)
NAVSS0_UDMASS_INTR_AGGR0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMASS_INTR_AGGR0	-	✓ (MCU NAVSS)	-

10.2.7.1.1 INTR_AGGR Features

NAVSS0_INTR_AGGR0 supports the following features:

- 64-bit VBUSP slave using 64-bit registers
- Provides a set of *TI Interrupt Architecture* compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Maps a collection of "DMA Messaged Events" which are input through an Event Transport Lane (ETL) into specific bit locations in one or more interrupt cause registers
  - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt_cnt-1)
    - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
    - Tracks a single 'event up'/'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored)
  - Tracked status interrupts are presented to the user through a standard interrupt register interface
    - Provides separate 'enable set' and 'enable clear' registers
    - Provides both masked and unmasked interrupt status
    - Interrupt status bits can be manually cleared using 'write 1 to clear'
- Provides a set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL)
  - Each counted event provides an register by which the count can be read and an register by which a specified amount can be decremented by the host
  - Each counted event generates a egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register
- Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event
- Provides a set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces.

10.2.7.1.2 INTR_AGGR Parameters

Table 10-119 shows the MODSS Interrupt Aggregators 0 and 1, and UDMASS Interrupt Aggregator 0 parameters set during design time. 4 local (LEVI) interrupts are from the MCRC0 module.

Copyright © 2023 Texas Instruments Incorporated

Table 10-119. Interrupt Aggregators Parameters

Module Instance	Parameters				
	VINTR (1)	SEVI (2)	GEVI (3)	LEVI (4)	MEVI (5)
NAVSS0_INTR_AGGR0	64	1024	0	0	0
NAVSS0_INTR_AGGR1	64	1024	0	0	0
NAVSS0_UDMASS_INTR_AGGR0	256	4608	512	132	512
MCU_NAVSS0_UDMASS_INTR_AGGR0	256	1536	256	12	128

(1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
(2) SEVI – Number of Main (Steerable) Events. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
(3) GEVI – Number of Countable Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
(4) LEVI – Number of Local Event inputs. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
(5) MEVI – Number of Multicast Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.

10.2.7.2 INTR_AGGR Functional Description

The Interrupt Aggregator provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Both the signaling and content of K3 system events are incompatible with standard interrupt controllers. The INTR_AGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by the Interrupt Router and all downstream interrupt infrastructure. Events can be presented to the INTR_AGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
  - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
  - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The INTR_AGGR is architected to perform this conversion in an efficient and cost effective manner.

10.2.7.2.1 Submodule Descriptions

10.2.7.2.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the *TI Interrupt Architecture* requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

10.2.7.2.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

10.2.7.2.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI UDMA_INTA_MCMAP_j register, so count status egress events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.2 General Functionality

10.2.7.2.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a

Copyright © 2023 Texas Instruments Incorporated

corresponding raw interrupt status register and bit number within that register which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an *up* event is received, the specified bit in the j Status register will be set. When a *down* event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

10.2.7.2.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register. The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

10.2.7.2.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (INTA_STATUSM_j) contains the value of the interrupt status ANDed with the value of the interrupt enable register. Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

10.2.7.2.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (INTA_ENABLE_SET_j and INTA_ENABLE_CLEAR_j) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the INTA_ENABLE_SET_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the INTA_ENABLE_CLEAR_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

10.2.7.2.2.5 Interrupt Output Generation

Each interrupt masked status register (INTA_STATUSM_j) is accompanied by a single pending bit which indicates if any enabled interrupt source within the corresponding interrupt status register is currently asserted. These pending bits from the interrupt masked status registers are collectively output from the INTR_AGGR as the VINTR_PEND bus. The interrupt status outputs will always be updated to reflect the current values of the INTA_STATUSM_j register. This is accomplished by triggering output updates on write operations to the internal RAM that holds the current raw status and enable masks.

10.2.7.2.2.6 Global Event Counting

When enabled, the INTR_AGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the UDMA_INTA_COUNT_j register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the UDMA_INTA_MAP_j register. The event may be mapped such that it then re-enters INTR_AGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new

Copyright © 2023 Texas Instruments Incorporated

egress event index via the UDMA_INTA_MAP_j register does not alter the stored event count for the ingress event register index.

10.2.7.2.2.7 Local Event to Global Event Conversion

When enabled, the INTR_AGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided levi interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping UDMA_INTA_MAP_j registers. The egress Global events can themselves be mapped to re-enter the INTR_AGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in Section 10.2.7.2.1.3. The event routing is handled by an external event switch fabric.

10.2.7.2.2.8 Global Event Multicast

In UDMASS_INTR_AGGR0, the INTR_AGGR will provide a set of Global event multicast (UDMA_INTA_MCMAP_j) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

10.2.8 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

10.2.8.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to NAVSS0 or MCU_NAVSS0. All switching functions among the PSI-L based interfaces are done inside NAVSS0 and MCU_NAVSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information. Only MCU_NAVSS0 has such event interface. It is connected to WKUP_ and allows MCU_NAVSS0 to send event information to the interrupt aggregator inside WKUP_.

Figure 10-22 shows an overview of all PSI-L connections within the device.

Copyright © 2023 Texas Instruments Incorporated

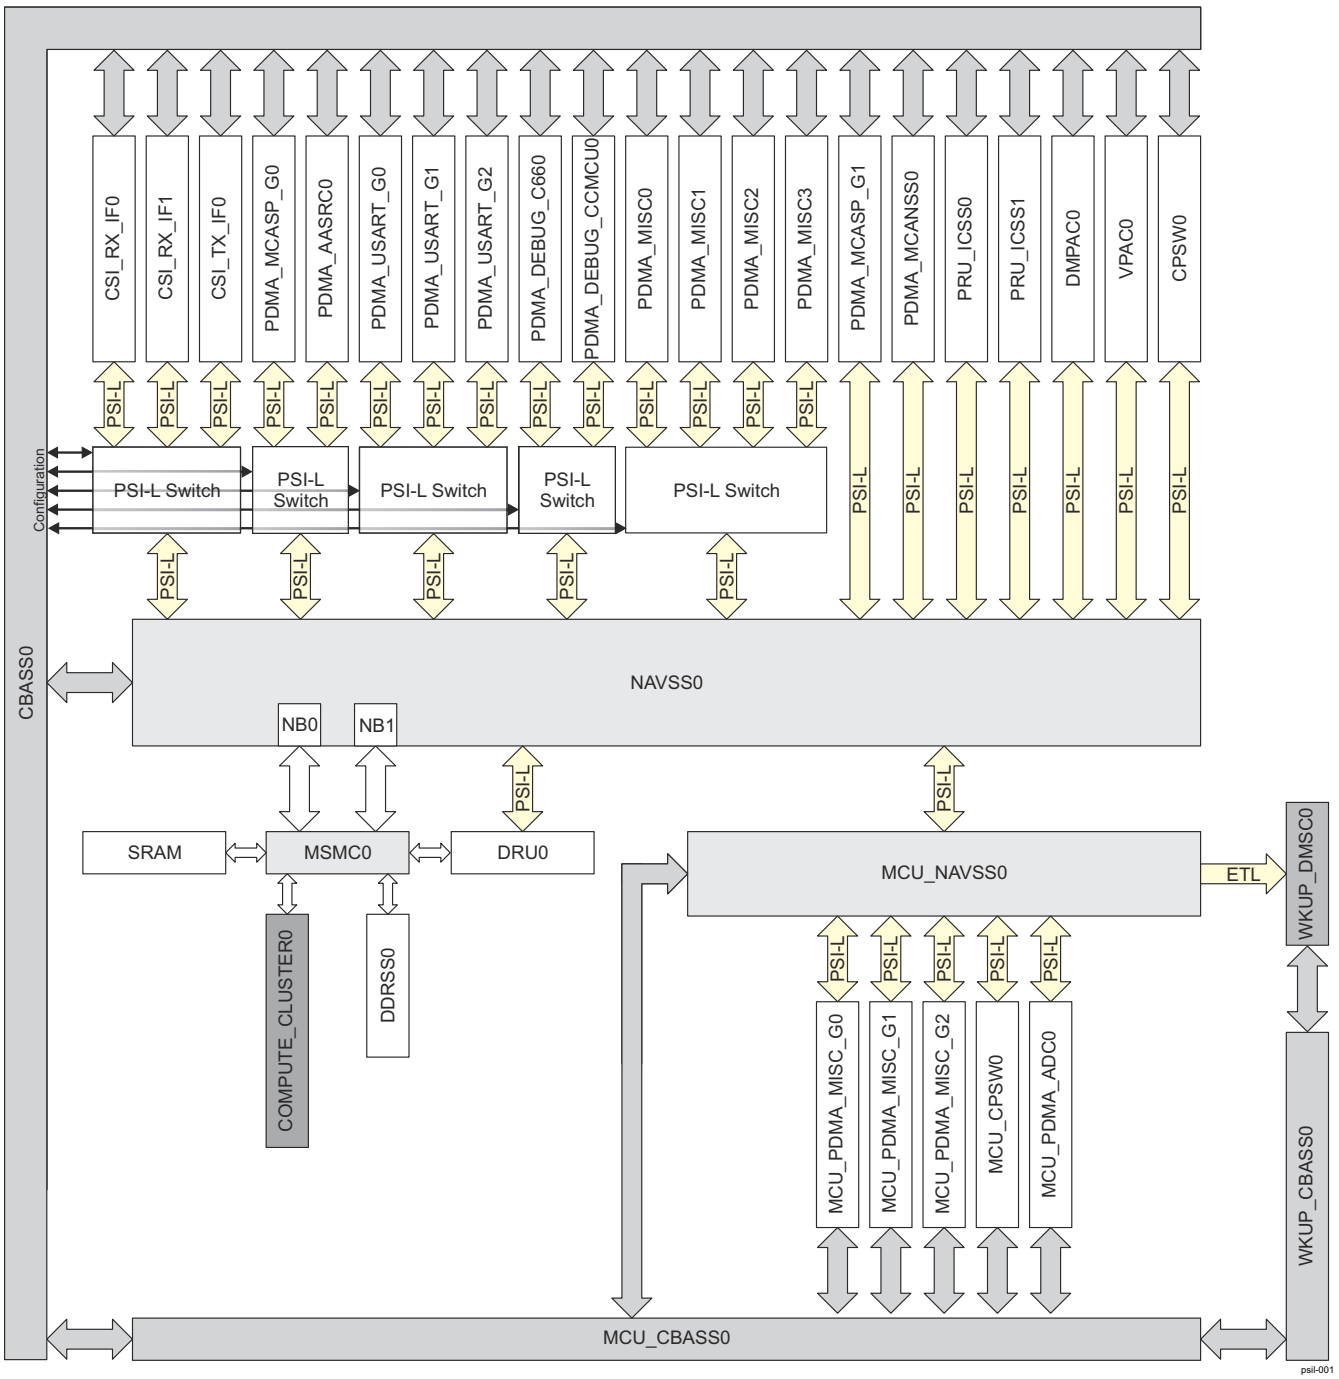

Figure 10-22. PSI-L Overview

Copyright © 2023 Texas Instruments Incorporated

10.2.8.2 PSI-L Functional Description

10.2.8.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single datapath through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L master and slave used for transfering data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

Figure 10-23 illustrates the point to point PSI-L connection.

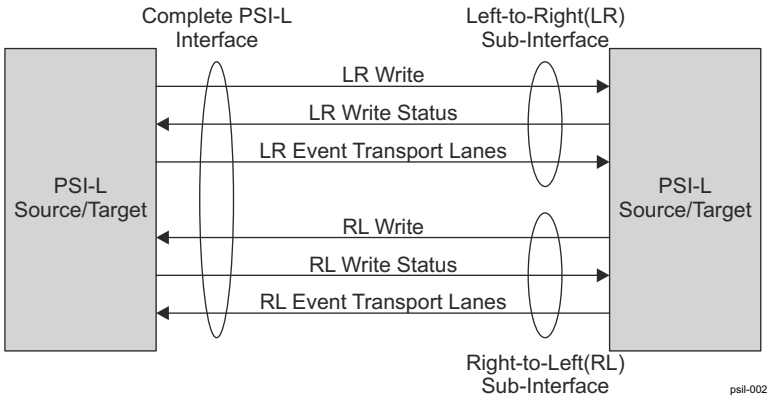

Figure 10-23. PSI-L Connection

PSI-L is intended to be a versatile interface which can carry various types of communications. Table 10-120 describes several types of threads which have been defined.

Table 10-120. Types of PSI-L Threads

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS master to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread master and a single thread slave using a connection oriented transfer mechanism. A thread master and a thread slave are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread master and a thread slave of the same type.

10.2.8.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data

Copyright © 2023 Texas Instruments Incorporated

transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

10.2.8.2.2.1 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional sub-interfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hwardware handshake.

10.2.8.2.2.2 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0x8FFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see Table 10-120). Both source and destination threads may act as masters for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

10.2.8.2.2.3 Arbitration Protocol

On each cycle, an arbiter built into the master side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.
3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

Copyright © 2023 Texas Instruments Incorporated

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

10.2.8.2.2.4 Thread Configuration

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

10.2.8.2.2.4.1 Thread Pairing

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

10.2.8.2.2.4.1.1 Configuration Transaction Pairing

Configuration write and read transactions are only initiated by a special module called configuration proxy (CFG_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The CFG_PROXY registers are described in *PSI-L CFG_PROXY Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

10.2.8.2.2.4.2 Configuration Registers Region

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *PSI-L Configuration Registers*. The thread ID mapping is shown in *Navigator Subsystem (NAVSS)*.

Copyright © 2023 Texas Instruments Incorporated

10.2.9 NAVSS North Bridge (NB)

This section describes the North Bridge (NB) in the main Navigator Subsystem.

10.2.9.1 NB Overview

The North bridge bridges between CBA 4.0 compliant VBUSM interfaces and a three-threaded CBA 4.0 compliant VBUSM.C interface.

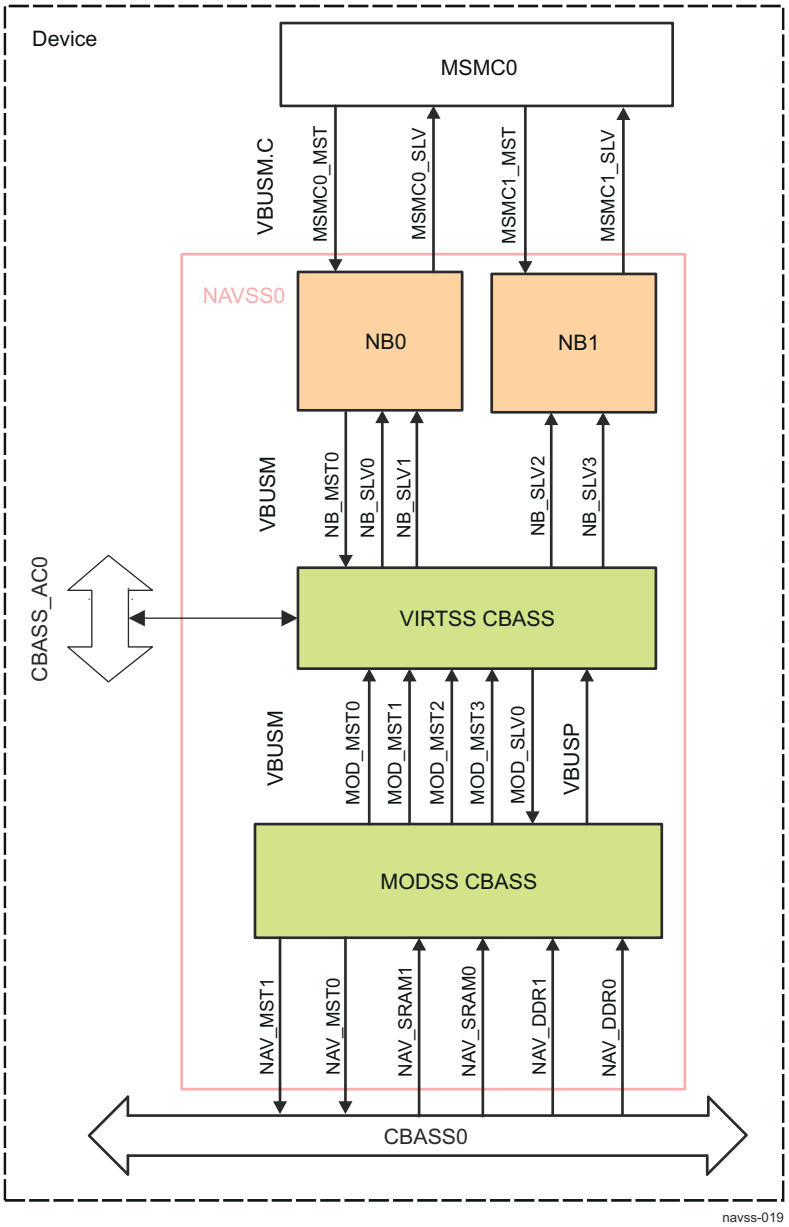

Figure 10-24. NB Overview

10.2.9.1.1 Features Supported

- Implements a CBA 4.0 VBUSM to/from VBUSM.C compliant bridge
- Implements CBA 4.0 VBUSM compliant slave interface(s) to receive traffic from a VBUSM source
- Implements a CBA 4.0 VBUSM compliant master interface to create traffic to a VBUSM destination
- Implements a CBA 4.0 VBUSM.C compliant interface to receive and create traffic to and from a VBUSM.C endpoint using 3 threads
- Can optionally support fragmentation of VBUSM write commands into defined burst aligned sizes

Copyright © 2023 Texas Instruments Incorporated

- Can optionally support fragmentation and reassembly of VBUSM read commands into defined burst aligned sizes
- Can optionally support synchronous or asynchronous clock conversion
- Can optionally support data width conversion
- Can optionally support using the CBA 4.0 VBUSM credit interface for the VBUSM interfaces
- Allows for priority escalation through the bridge, either for higher priority pending commands inside the bridge or requesting into the bridge
- Supports the K3 clkstop idle signal
- Can optionally support a maximum outstanding read byte count to limit the total read data
- Can optionally insert memory attributes for commands
- Can optionally maintain VBUSM order based on orderid
- Allows programming the mapping of the VBUSM source interfaces to VBUSM.C threads

10.2.9.1.2 NB Parameters

North Bridges are implemented in the SoC with the parameters shown in Table 10-121 and Table 10-122.

Table 10-121. NB0 Configuration

Parameter	Value	Description
Number of sources	2	The number of VBUSM source interfaces
Source 0	CBASS MSMC_SLV to MSMC0	Source 0
Source 1		Source 1
source_oidmap[0]	0-7	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	8-15	
start64k	0x0060000000	This defines the starting address of the memory in VBUSM.C that uses the 64-KB table.
num64k	8192	This defines the number of entries in the 64-KB table.

Table 10-122. NB1 Configuration

Parameter	Value	Description
Number of sources	3	The number of VBUSM source interfaces
Source 0	CBASS MSMC_DDR_0 to MSMC1	Source 0
Source 1	CBASS MSMC_DDR_1 to MSMC1	Source 1
Source 2	CBASS MSMC_DDR_2 to MSMC1	Source 2
source_oidmap[0]	0-4	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	5-9	
source_oidmap[2]	10-15	
start16m[0]	0x0080000000	This defines the starting address of the memory in VBUSM.C that uses the 16-MB table. The index is for each of the 16-MB regions.
start16m[1]	0x0800000000	
num16m[0]	128	This defines the number of entries in the 16-MB table. The index is for each 16-MB region.
num16m[1]	8192	

10.2.9.1.2.1 Compliance to Standards

The module is compliant to the CBA 4.0 VBUSM specification and VBUSM.C annex.

10.2.9.1.2.2 Features Not Supported

- Does not support fragmentation of VBUSM.C commands
- Does not support VBUSM.C coherence traffic

Copyright © 2023 Texas Instruments Incorporated

10.2.9.2 NB Functional Description

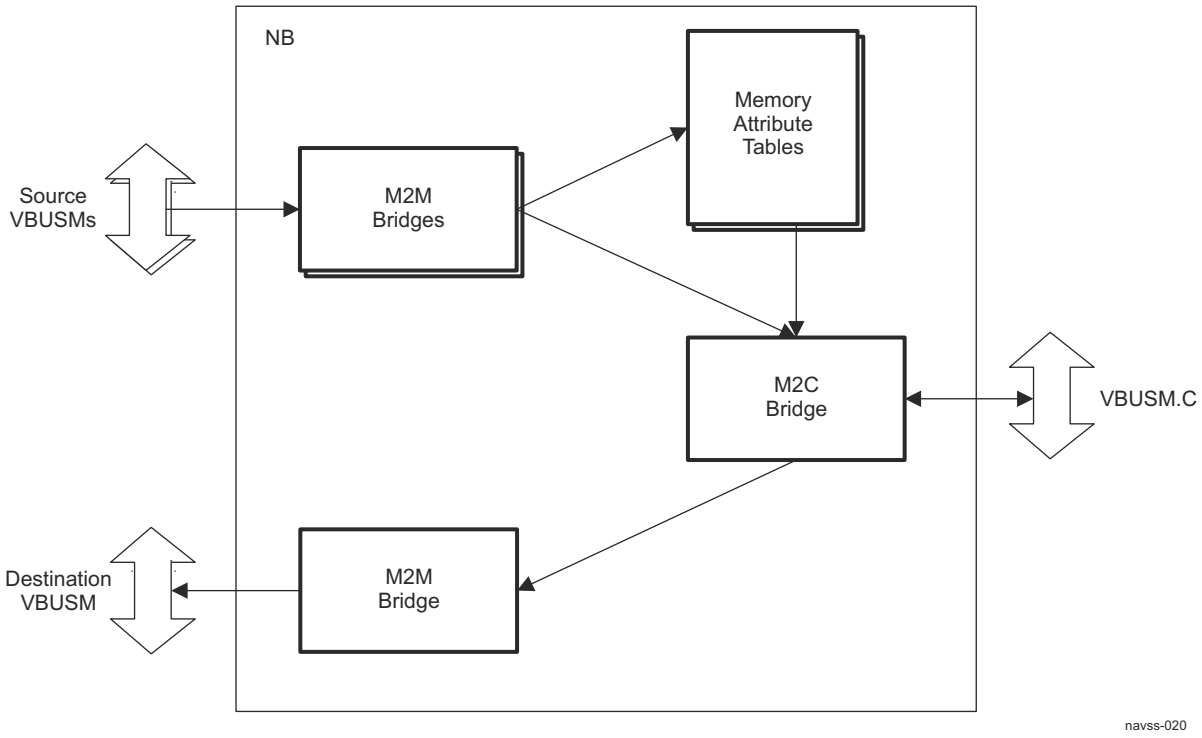

Figure 10-25. NB Block Diagram

The CBA 4.0 North bridge, NB, bridges between CBA 4.0 compliant VBUSM interfaces and a three threaded CBA 4.0 compliant VBUSM.C interface. This is achieved by using M2M bridges to support all the M2M features and then an M2C bridge to convert the VBUSM interfaces to a VBUSM.C interface, which support duplex traffic. The M2M bridges allow for clock frequency conversion, data width conversion and fragmentation for the Source M2M bridge(s). This allows the M2C bridge to remain simple and operate at the VBUSM.C clock frequency and data width, as well as assume all required burst limitations have already been handled. Some additional features needed for the north bridge are implemented, including: adding memory attributes to source VBUSM transactions, and forcing a maximum outstanding read data limit.

10.2.9.2.1 VBUSM Slave Interfaces

The slave interfaces on the bridge is the source VBUSM port to receive commands and return data and status. These ports have the defined prefix, smX (SoC Master, input to bridge), to identify them, where the X is the number to idenfity each port starting from zero. The number of these interfaces and bridges is shown in Table 10-121 and Table 10-122.

10.2.9.2.2 VBUSM Master Interface

The master interface on the bridge is the destination VBUSM port to send commands and receive data and status. These ports have the defined prefix, ss (SoC Slave, output of bridge), to identify them.

It is important to note that any feature not supported in the optional signals for this bus that is supported on the VBUSM.C interface will not be corrected inside the bridge. Examples are excluding the emudbg pin on this bus but expecting VBUSM.C transactions with emudbg set to not create bus status errors on this VBUSM bus outside the bridge (as the bridge will just pass the returned status which could be an error if it does not support the emudbg pin).

10.2.9.2.3 VBUSM.C Interfaces

The pair of interfaces on the bridge is the VBUSM.C port to send and receive commands and send and receive data and status. These ports will have the defined prefix, mm (Memory Master, output of bridge) and ms (Memory Slave, input to bridge), to identify them. These interfaces support three threads for sending and receiving traffic.

Copyright © 2023 Texas Instruments Incorporated

10.2.9.2.3.1 Multi-Threading

The VBUSM.C interfaces use multi-threading to support both input and output traffic on the same data signals. The threads are used to separate that traffic. Thread 0 is used for commands to VBUSM.C, thread 1 is used for commands from VBUSM.C, and thread 2 is used for realtime commands to VBUSM.C. Any responses due to commands must use the same thread when returned.

10.2.9.2.3.2 Write Command Crediting

VBUSM.C interfaces use credits for sending data phases. For writes and read responses to the MSMC (VBUSM.C consumer), there is a requirement that all credits for the write, including the command and all data phases, should be available before sending the command. Since the VBUSM.C data width is always half the max burst size on VBUSM.C, the write command must wait for a TAC credit available and 1 or 2 TDC credits available before the write can be sent.

10.2.9.2.3.3 Early Credit Response

The VBUSM.C interfaces use the credit mechanism available. They do not check for full burst available credits before sending any piece of the burst (command or data). To prevent deadlocks, the connected VBUSM.C device must support sending early credit responses, before the entire burst is received.

10.2.9.2.3.4 Priority Escalation

The VBUSM.C interface does not natively define a mechanism for priority escalation, since the cepriority signal is only valid when a command is sent, and can otherwise be ignored. To support this feature this bridge supports updating the cepriority output even if there is no valid command, so identify the highest priority of any pending commands when the bridge cannot sent a command, such as due to a lack of credits. The VBUSM.C consumer can assume the cepriority output from this bridge is always valid every cycle, and use the cepriority along with the priorities of all pending commands. When there are no pending commands, the cepriority output will be the lowest priority, 7.

10.2.9.2.4 Source M2M Bridges

The source M2M bridges perform all the usual bridging functions from the source VBUSM interface to an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface. It also performs the fragmentation to sizes the VBUSM.C interface requires. It additionally performs full read data reassembly, orderid based ordering, and read data cacheline conversion.

10.2.9.2.5 Destination M2M Bridge

The destination M2M bridge performs all the usual bridging functions to the destination VBUSM interface from an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface.

10.2.9.2.6 M2C Bridge

The M2C bridge performs the protocol conversion and multi-threading of the VBUSM.C interface from the internal VBUSM interfaces. It also handles the cacheline conversion of the write data.

A VBUSM.C write with a dtype of 1 (CPU instruction) will be converted to a VBUSM write with a dtype of 0 (CPU data), as this condition is allowed in VBUSM.C but not in VBUSM.

10.2.9.2.7 Memory Attribute Tables

The bridge can optionally include a memory attribute lookup table to add the coherence memory attributes required for VBUSM.C for VBUSM commands missing them. It is implemented using up to 4 tables, a table of 64-KB regions and 1 to 3 tables of 16-MB regions. The first table is meant to cover an internal memory with smaller granularity, while the second to fourth tables are meant to cover the external memory with a much larger size and larger granularity. The external memory has one to three regions as its address space might be fragmented in the SoC memory map. Starting address and number of table entries for each region are shown in Table 10-121 and Table 10-122.

When a command without memory attributes, an atype = 0, is input to the M2C bridge, this table performs the lookup in parallel and returns the memory attributes to the M2C bridge in the next cycle. If the atype is another value, it is assumed the memory attributes on the VBUSM interface are valid. The lookup is performed by matching the address against the starting addresses, assuming the successive regions always starts at later address, including that the up to three 16-MB regions are given in increasing order. Then the offset from the

Copyright © 2023 Texas Instruments Incorporated

starting address of the region and the region size, 64-KB or 16-MB, is used to calculate the entry of attributes for that address. Then a memory is read to retrieve the attributes and return them to the M2C bridge. An output FIFO is implemented to capture the attributes if they are not accepted immediately.

There is a memory attribute table module for each VBUSM slave interface. If the MAT is enabled, at least one of the 64-KB region and/or the first 16-MB region must be populated, or both. The second and third 16-MB regions are optional.

10.2.9.2.8 Outstanding Read Data Limiter

If a param defines a maximum outstanding read data byte count, then this function will track the requested read bytes against the limit. If a read command does not violate the total read bytes outstanding limit then the read is allowed to the VBUSM.C, otherwise it is stalled. When read data arrives from the VBUSM.C the outstanding count is reduced, allowing more read commands to be sent.

10.2.9.2.9 Ordering

Ordering becomes a concern due to the fact that the VBUSM commands are fragmented and not guaranteed to be returned in order by the VBUSM.C interface. This violates the CBA ordering rules for a single slave endpoint. So the bridge will force read data ordering based on the orderid signal across all masters, as a balance between cost and performance. This means that each read command received from the VBUSM interface with a particular orderid value will have their read data returned in exactly the same order. This means that even if the reads are from different masters, the data will still be returned in order, to reduce the amount of tracking the bridge has to perform. But, if the reads use different orderid values then that read data can be returned in any order, whichever is received first on the VBUSM.C interface.

10.2.9.2.10 Quality of Service

To support quality of service, QoS, the north bridge allows for configuring multiple VBUSM source interfaces. This not only allows defining particular sources to be realtime to achieve better qos, but also to load balance and effectively utilize any extra bandwidth provided by the VBUSM.C interface. There are registers (NB_THREADMAP) allowing programming of which source interfaces map to which of the two VBUSM.C threads, normal or realtime traffic. All traffic on the source will always map to the defined thread.

Any sources mapped to the realtime thread will be arbitrated first, before any sources mapped to the normal thread, to provide the QoS. If there are multiple sources mapped to the same thread then they are arbitrated based on priority and if they are the same priority then by round robin.

To route return traffic from the VBUSM.C back to the correct VBUSM source, the orderid is used. As such, each source mapped to each thread must use a different orderid value in the SoC. This would mean that if there are 8 sources total, with 4 mapped to each thread, then each group of 4 should not share the same orderid for any traffic routed to it in the SoC to keep their pathid values unique. The bridge is configured to identify which VBUSM source uses which orderid value(s).

10.2.9.2.11 IDLE Behavior

The north bridge IDLE output is a combination of all the IDLE outputs from the components. These are combined and registered as the NB IDLE on the Destination VBUSM bus clock.

10.2.9.2.12 Clock Power Management

The north bridge provides internal clock power management for all major components: bridges and register modules. Each component will track its own activity and shut off the clock tree when there has been no activity for 12 cycles. There is a 1 cycle latency for starting up the clock once off, so bus transactions may be initially stalled. The bus early wakeup signals can be used to wakeup the clocks before the transactions arrives to remove some of the latency impact.

10.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

10.3.1 PDMA Controller

10.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

The PDMA is linked to the UDMA-P (NAVSS) either through a direct PSI-L connection, or through a PSI-L switch (PSILSS).

10.3.1.1.1 PDMA Features

10.3.1.1.1.1 MCU_PDMA0 (MCU_PDMA_MISC_G0) Features

The MCU_PDMA0 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access units (write unit 0)
  - Provides a 32-bit wide VBUSP write only master interface for peripheral accesses
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0):
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 7 simultaneous destination (Tx) channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.2 MCU_PDMA1 (MCU_PDMA_MISC_G1) Features

The MCU_PDMA1 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.

Copyright © 2023 Texas Instruments Incorporated

  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 8 simultaneous destination (Tx) channels
- Supports up to 8 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.3 MCU_PDMA2 (MCU_PDMA_MISC_G2) Features

The MCU_PDMA2 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 4 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.4 MCU_PDMA3 (MCU_PDMA_ADC) Features

The MCU_PDMA3 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.5 PDMA5 (PDMA_MCAN) Features

The PDMA5 module supports the following features:

Copyright © 2023 Texas Instruments Incorporated

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 54 simultaneous destination (Tx) channels
- Supports up to 54 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports MCAN transfer mode only (does not support X-Y and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.6 PDMA6 (PDMA_MCASP_G0) Features

The PDMA6 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to simultaneous destination (Tx) channels
- Supports up to simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.7 PDMA9 (PDMA_SPI_G0) Features

The PDMA9 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel

Copyright © 2023 Texas Instruments Incorporated

  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.8 PDMA10 (PDMA_SPI_G1) Features

The PDMA10 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.9 PDMA13 (PDMA_USART_G0) Features

The PDMA13 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.10 PDMA14 (PDMA_USART_G1) Features

The PDMA14 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses

Copyright © 2023 Texas Instruments Incorporated

  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.11 PDMA15 (PDMA_USART_G2) Features

The PDMA15 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 6 simultaneous destination (Tx) channels
- Supports up to 6 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.2 PDMA Functional Description

10.3.1.2.1 PDMA Functional Blocks

Figure 10-26 shows the PDMA block diagram.

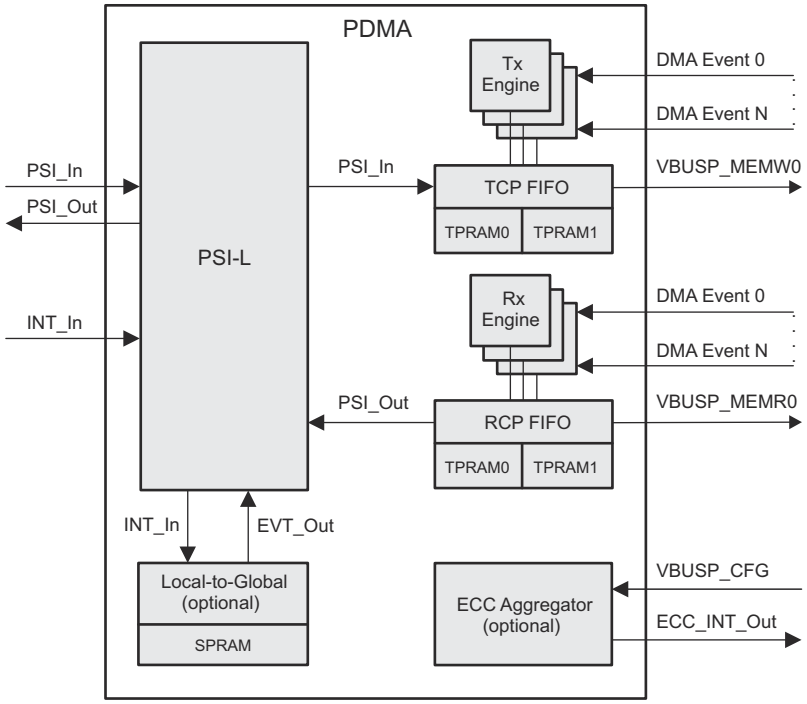

Figure 10-26. PDMA Block Diagram

Note

For detailed description of the PSI-L interface, see *Packet Streaming Interface Link (PSI-L)*.

10.3.1.2.1.1 Scheduler

The scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low-level read or write operation.

10.3.1.2.1.2 Tx Per-Channel Buffers (TCP FIFO)

The Tx per-channel buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx per-channel buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

10.3.1.2.1.3 Tx DMA Unit (Tx Engine)

The Tx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming DMA event and then writes data from the Tx per-channel data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

10.3.1.2.1.4 Rx Per-Channel Buffers (RCP FIFO)

The Rx per-channel buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte-oriented on write so that the data from the Rx DMA units, which may not be full words, can be packed properly. The buffers are word-oriented on read in accordance with the transport mechanism outlined in the PSI-L interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface.

Copyright © 2023 Texas Instruments Incorporated

The Rx per-channel buffers block outputs queue fullness information to the scheduler block, which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx per-channel buffers will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round-robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

10.3.1.2.1.5 Rx DMA Unit (Rx Engine)

The Rx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx per-channel data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

10.3.1.2.2 PDMA General Functionality

10.3.1.2.2.1 Operational States

At any given time the PDMA can be in one of three different states as follows:

- INIT: This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the INIT state, the DMA will de-assert all 'ready' signals on all applicable target interfaces and will de-assert all 'request' signals on all applicable controller interfaces. The PDMA will automatically transition out of the INIT state into the IDLE state when all of the RAM initialization has been completed.
- IDLE: Once the PDMA leaves the INIT state, it enters the IDLE state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The IDLE state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the PDMA transitions to the ACTIVE state. When no more work is pending, or when the host pauses/disables active channels, or when the power management complex on the SoC desires to shut down the PDMA and asserts 'clock stop request', the PDMA will account for any outstanding transactions and will re-enter the IDLE state. The PDMA leaves the IDLE state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
- ACTIVE: The PDMA enters the ACTIVE state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent), the PDMA transitions to the IDLE state.

10.3.1.2.2.2 Clock Stop

The clock stop interface is a request/acknowledge interface used to coordinate the handshaking of properly stopping the main clock to the IP. Before attempting to perform a clock stop operation, software is required to teardown all active channels (via 'real time' registers in the BCDMA/PKTDMA, or PSIL register 0x408 in PSIL based peripherals), and after this is complete, also clear the global enable bit for all channels (via PSIL register 0x2 in BCDMA/PKTDMA and PSIL based peripherals). Attempting a clock stop on the IP without first performing the channel teardowns or clearing of global enable bits will result in IP specific behavior that may be UNDEFINED.

The PDMA will not drive clock stop IDLE or clock stop ACK while the global enable (PSIL register 0x2) is set for any channel.

10.3.1.2.2.3 Emulation Control

The emulation control input (EMUSUSP) and the per-channel emulation control FREE bit allow PDMA operation to be suspended on a per-channel basis. When the emulation suspend state is entered, the PDMA will stop processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR.

Copyright © 2023 Texas Instruments Incorporated

Emulation control is implemented for compatibility with other peripherals. Each source and desintaion channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is conrolled via the PDMA_PSILCFG_TX_RT_ENABLE / PDMA_PSILCFG_RX_RT_ENABLE[0] FREE bit.

10.3.1.2.3 PDMA Events and Flow Control

The following sections describe the simplified mechanism that is provided on the PDMA for triggering and completion event generation.

10.3.1.2.3.1 Channel Types

Each channel in the PDMA is configured at design time (and cannot be changed by software) to be either standard X-Y FIFO mode or MCAN channel or AASRC channel. Either of these two sections provide information about the channel type support in the device: *PDMA Features* and *PDMA Sources*.

When reading the sections below, ignore any information that concerns unsupported channel type.

10.3.1.2.3.1.1 X-Y FIFO Mode

Most peripherals which are serviced by the PDMA follow the pattern of transferring 'X' bytes from a fixed, non-changing address in a burst 'Y' times for each triggering event that is received. The 'X' parameter is typically 1-16 bytes and the 'Y' parameter can be any integer up to 2048.

10.3.1.2.3.1.2 MCAN Mode

The MCAN module is found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the PDMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, there is an MCAN packet fragmentation requirement to place an 8-byte header on each 64-byte chunk that is transmitted and to remove the header from each 64-byte chunk (other than the first block) that is received.

10.3.1.2.3.1.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOS to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels to not share the same PDMA as do XY and MCAN channels.

The following addition details apply to the PDMA in AASRC mode:

- Main features:
  - Up to 16 independent RX channels and 16 TX channels
    - Each channel represents a different data stream to either the paired-DMA or a McASP PDMA
  - Each channel can be configured to read or write any of the AASRC FIFOs in any order
  - Packing support for 1, 2, 3, and 4 byte samples
    - Can directly talk to a McASP using any McASP data format
    - Packing sample size is fixed for a given channel
  - Supports both 'group' and 'stream' AASRC signaling and FIFO memory maps
    - There is a single stream/group mode setting for each PDMA channel
- Additional details:
  - Each channel has a 'mask' of which DMA requests must fire to activate the channel
    - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
    - In group mode, the mask specifies the one group DMA request that must fire
  - Each channel specifies an ordered list of how FIFOs should be accessed
    - All channels use a common list, specifying a range of entry indices within that list
      - This allow each channel to use a varying number of list elements
    - The order list can be processed multiple times per DMA request
      - The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC
  - All FIFOs are specified by index only

Copyright © 2023 Texas Instruments Incorporated

- In the TX ordering table, the indices are assumed to be TX FIFOs
- In the RX ordering table, the indices are assumed to be RX FIFOs
- If a DMA channel is in group mode, the PDMA assumes the indices referenced by that channel represent group mode FIFOs; otherwise, it assumes stream mode FIFOs

– The PDMA has configured base addressed and inter-FIFO spans such that is can always convert from a FIFO index to the proper Stream or Group mode FIFO address

10.3.1.2.3.2 Channel Triggering

Channels must be triggered in order for them to perform work. A local event input bus is provided on the PDMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.).

The PDMA provides a 2-bit counter per event input to accommodate startup latency in the channel.

10.3.1.2.3.3 Completion Events

All transfers on PDMA are split TRs in that they have a paired-DMA half and a (static) PDMA half. Completion events are designed to be triggered from the paired-DMA half of the split TR.

10.3.1.2.4 PDMA Transmit Operation

10.3.1.2.4.1 Destination (Tx) Channel Allocation

A total of *N* destination channels are provided within the PDMA for concurrent transfers from Tx per-channel buffers to the various attached peripherals, where *N* is a design-time configurable paramater. Each Tx channel requires a single PSI-L thread. See *PDMA Sources* for Tx channel allocation for each PDMA.

10.3.1.2.4.2 Destination (Tx) Channel Out-of-Band Signals

Table 10-123 shows how PSIL signals are handled for destination channels.

Table 10-123. Tx Channel Out-of-Band Signals

PSI-L Signal	XY/AASRC Mode	MCAN Mode
SOP	Ignored	Ignored
EOP	Ignored	Closes current MCAN packet
SOL	Ignored	Ignored
EOL	Ignored	Ignored
DROP	Ignored	Ignored
PKT_ERROR	Ignored	Ignored
PAUSE	Ignored	Ignored
TDOWN	Reflect in status; teardown when data marker reached	Reflect in status; teardown when data marker reached

10.3.1.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

10.3.1.2.4.3.1 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each destination PDMA channel with (typically) a corresponding source channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the paired-DMA will send all their data to the destination channel in the PDMA and the destination channel in the PDMA will never see any data other than data from the source channel in the paired-DMA.

The following PSI-L registers are related to destination thread pairing:

- PDMA_PSILCFG_TX_ENABLE
- PDMA_PSILCFG_TX_CAPABILITIES
- PDMA_PSILCFG_TX_BYTE_COUNT
- PDMA_PSILCFG_TX_RT_ENABLE

Copyright © 2023 Texas Instruments Incorporated

Refer to their descriptions for further details.

10.3.1.2.4.3.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will send configuration transactions across PSI-L and will setup the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X' and 'Y' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA_PSILCFG_TX_STATIC_TR[26-24] X
- PDMA_PSILCFG_TX_STATIC_TR[11-0] Y

Refer to their descriptions for further details.

10.3.1.2.4.3.3 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the ENABLE bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

10.3.1.2.4.4 Data Transfer

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx per-channel FIFOs which were filled via the transmit PSI-L interface to specified memory mapped address ranges via the VBUSP controller interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static transfer request.

The sequences of logical transactions that are performed by the PDMA on the memory interface during transmit is dependent on the channel type. The following sections describe what will happen for the two different channel types.

10.3.1.2.4.4.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter writes of 'X' parameter bytes to the data FIFO address specified for the channel. Each write that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the Tx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting the PDMA_PSILCFG_TX_STATIC_TR[31] BURST bit enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2×32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

Copyright © 2023 Texas Instruments Incorporated

10.3.1.2.4.4.2 MCAN Mode Channel

The PDMA channel will remain idle until data is received from the paired-DMA over the PSIL interface. At this time, the PDMA will imediately start copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA will transfer ownership of the buffer to MCAN by performing an MCAN register write. The PDMA will then wait to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA will continue with refilling the TX buffer for the next packet fragment. On subsequent fills (until the end of packet is reached), the PDMA will skip over the 8-byte MCAN header, leaving the original contents from the intial fragment copy in place.

10.3.1.2.4.4.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

10.3.1.2.4.4.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA_PSILCFG_TX_AASRC_TX_FIFO_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA_PSILCFG_TX_AASRC_TX_FIFO_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from TX order table (PDMA_PSILCFG_TX_AASRC_TX_ORDER_TABLE0, PDMA_PSILCFG_TX_AASRC_TX_ORDER_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.4.5 Tx Pause

The host initiates a channel pause by setting the PDMA_PSILCFG_TX_RT_ENABLE[9] PAUSE bit. The paused channel can be resumed by clearing the register bit.

10.3.1.2.4.6 Tx Teardown

The host initiates a channel teardown by setting the TDOWN bit in the paired-DMA (BCDMA/PKTDMA) channel that is paired with the PDMA. The paired-DMA communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous paired-DMA data for the channel has been flushed. At this time, the teardown state will be reflected in the PDMA_PSILCFG_TX_RT_ENABLE[30] TDOWN bit. Note that a non-synchronized teardown can also be initiated by directly clearing the PDMA_PSILCFG_TX_RT_ENABLE[31] ENABLE.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PDMA_PSILCFG_TX_RT_ENABLE register, but the teardown bit will remain high. Upon completion, no further packet processing will occur until the host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the paired-DMA transmission stops on a data boundary that is not compatible with the static TR configuration, the PDMA_PSILCFG_TX_RT_ENABLE[28] FLUSH bit can be set to guarantee that all data can be properly flushed from the internal pipe.

Copyright © 2023 Texas Instruments Incorporated

10.3.1.2.4.7 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the PDMA_PSILCFG_TX_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

10.3.1.2.4.8 Tx Debug/State Registers

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as follows:

- PDMA_PSILCFG_TX_DEBUG_1
- PDMA_PSILCFG_TX_DEBUG_2

Refer to their descriptions for further details.

10.3.1.2.5 PDMA Receive Operation

10.3.1.2.5.1 Source (Rx) Channel Allocation

A total of *M* destination channels are provided within the PDMA for concurrent transfers from the various attached peripherals into the Rx per-channel buffers and on to the PSI-L Rx Interface, where *M* is a design-time configurable paramater. Each Rx channel requires a single PSI-L thread. See *PDMA Sources* for Rx channel allocation for each PDMA.

10.3.1.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

10.3.1.2.5.2.1 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each source PDMA channel with (typically) a corresponding destination channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired-DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the paired-DMA and the destination channel in the paired-DMA will never see any data other than data from the source channel in the PDMA.

Refer to their descriptions for further details.

10.3.1.2.5.2.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X', 'Y', and 'Z' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA_PSILCFG_RX_STATIC_TR[26-24] X
- PDMA_PSILCFG_RX_STATIC_TR[11-0] Y
- PDMA_PSILCFG_RX_STATIC_TR_Z[11-0] Z

Refer to their descriptions for further details.

10.3.1.2.5.2.3 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

Copyright © 2023 Texas Instruments Incorporated

10.3.1.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the receive PSI-L interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx per-channel buffer for that channel. At a later time, the data is moved from the Rx per-channel FIFO to a remote peer DMA entity via the Rx PSI-L interface.

The sequences of logical transactions that are performed by the PDMA on the memory interface during receive is dependent on the channel type. The following sections describe what will happen for the two different channel types.

10.3.1.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data FIFO address specified for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

10.3.1.2.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as shown in Table 10-124.

Table 10-124. Mapping of MCAN Filter Events to MCAN Channels

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping-pong buffer for a particular RX packet ID. For example, the following two filter entries will setup a ping-pong using RX buffers 0 and 1 for packet ID = 5 on CAN RX channel 0 (Table 10-125).

Table 10-125. Ping-Pong Buffer Example in MCAN Mode

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

Copyright © 2023 Texas Instruments Incorporated

10.3.1.2.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

10.3.1.2.5.3.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA_PSILCFG_RX_AASRC_RX_FIFO_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA_PSILCFG_RX_AASRC_RX_FIFO_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from RX order table (PDMA_PSILCFG_RX_AASRC_RX_ORDER_TABLE0, PDMA_PSILCFG_RX_AASRC_RX_ORDER_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.5.4 Rx Pause

The host initiates a channel pause by setting the PDMA_PSILCFG_RX_RT_ENABLE[29] PAUSE bit. The paused channel can be resumed by clearing the register bit.

10.3.1.2.5.5 Rx Teardown

The host initiates a RX channel teardown by setting the PDMA_PSILCFG_RX_RT_ENABLE[30] TDOWN bit for the target RX channel. The PDMA communicates the teardown state to the paired-DMA through the PSI-L data channel, to ensure that the teardown is not seen by the paired-DMA until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the ENABLE bit in the pairing register, however the TDOWN bit will remain set. No further packet processing will occur until the host re-configures the channel. The teardown process will propagate to the paired-DMA and its final status can be checked there.

10.3.1.2.5.6 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the PDMA_PSILCFG_RX_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

10.3.1.2.5.7 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular opteration, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows:

Refer to their descriptions for further details.

Copyright © 2023 Texas Instruments Incorporated

10.3.1.2.6 PDMA ECC Support

The PDMA optionally integrates an ECC aggregator module that consolidates the ECC configuration and status bits for all the ECC-supported memories within the PDMA. The ECC aggregator provides a single end-of-interrupt (EOI) handshake based interrupt to the host (for both single and double error detections), and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their respective register set.

In this device, only PDMA5, PDMA9 and PDMA10 include an ECC aggregator.

For detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of PDMA ECC aggregators, see *PDMA Registers*.

10.4 Data Routing Unit (DRU)

This section describes the SoC level Data Routing Units (DRUs) for the device.

Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section. For the differences between all DRUs, see Section 10.4.3.8.

10.4.1 DRU Overview

The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CPU frequency.

The DRU supports the following features:

- Programmable configuration registers for direct transfer request submission
  - A dedicated atomic register set that requires entire TR sent in a single burst
  - Three nonatomic register sets that allow TR to be written in separate burst and a write to the SUBMIT_WORD0 register triggers the TR
- Read and write command queues
  - Five different queues with a split arbitration between fixed priority and round robin arbitration
  - Each channel can be configured to go to one of these queues
- Programmable priority for each queue
  - Allows setting priority for commands relative to other masters in the system
- One dedicated read port and one dedicated write port to generate independent read and write commands
  - Generates one read command every cycle
  - Generates one write data phase every cycle
  - Moves the data at CPU frequency
  - Optimizes transfers up to 128 byte boundaries
- Support for triggers to gate levels of the DMA loop
  - Supports one dedicated local trigger
  - Supports two dedicated external global triggers from the PSI-L
  - All triggers can be overwritten and controlled by software instead of hardware based event
- Support for region based and channelized firewall
  - Region based firewall intended to protect DRU configuration registers within a programmatically specified range
  - Channelized firewall that protects:
    - The real time configuration registers for each channel
    - The TR submission registers for each channel
    - The data transfers for each channel
- Data formatting networks
  - Circular addressing support for one side of the transfer
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
  - Has independent source and destination index for up to four dimensional transfers
- Error Handling
  - Debug support through memory mapped registers
  - Data transfer error reports
- Error detection and Correction
  - Full SEC/DED support for the incoming data
  - Full SEC/DED protection each entry in the TR queues
  - Single bit parity support for each 32-bit word in the data buffer
  - Parity protection for the address
- PSI-L Interface

Copyright © 2023 Texas Instruments Incorporated

  - Receive requests for pre-warm of L2 or L3 Cache
  - Receive TR requests from the UDMA
  - Send response TRs
  - Receive data from a remote UTC
  - Send data to a remote UTC
  - Maintains 2D formatting across PSI-L if requested in TR
- Feature enhancements for DRU R30:
  - IO memory management unit and micro-TLB
    - Features integrated uTLB (Translation Look aside Buffer)
    - Supports virtual addresses and physical addresses in TR requests
    - A read and write uTLB with 2 entries per uTLB
    - Communicates through PSI-L to IOMMU
  - Compression and Decompression

Unsupported features:

- Transpose data between source and destination memory to memory transfers

10.4.2 DRU Integration

This section describes the SoC level DRUs integration in the device, including information about clocks, resets, and hardware requests.

Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as the SoC level DRUs. For the differences between all DRUs, see Section 10.4.3.8. For integration details about the VPAC0 and DMPAC0 DRUs, see Section 6.7 *Vision Pre-processing Accelerator (VPAC)* and Section 6.8 *Depth and Motion Perception Accelerator (DMPAC)*.

10.4.3 DRU Functional Description

Note

This section describes the SoC level Data Routing Units (DRUs) for the device. There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section and its subsections. For the differences between all DRUs, see Section 10.4.3.8.

10.4.3.1 DRU Basic Functionality

Figure 10-27 shows the DRU functional diagram.

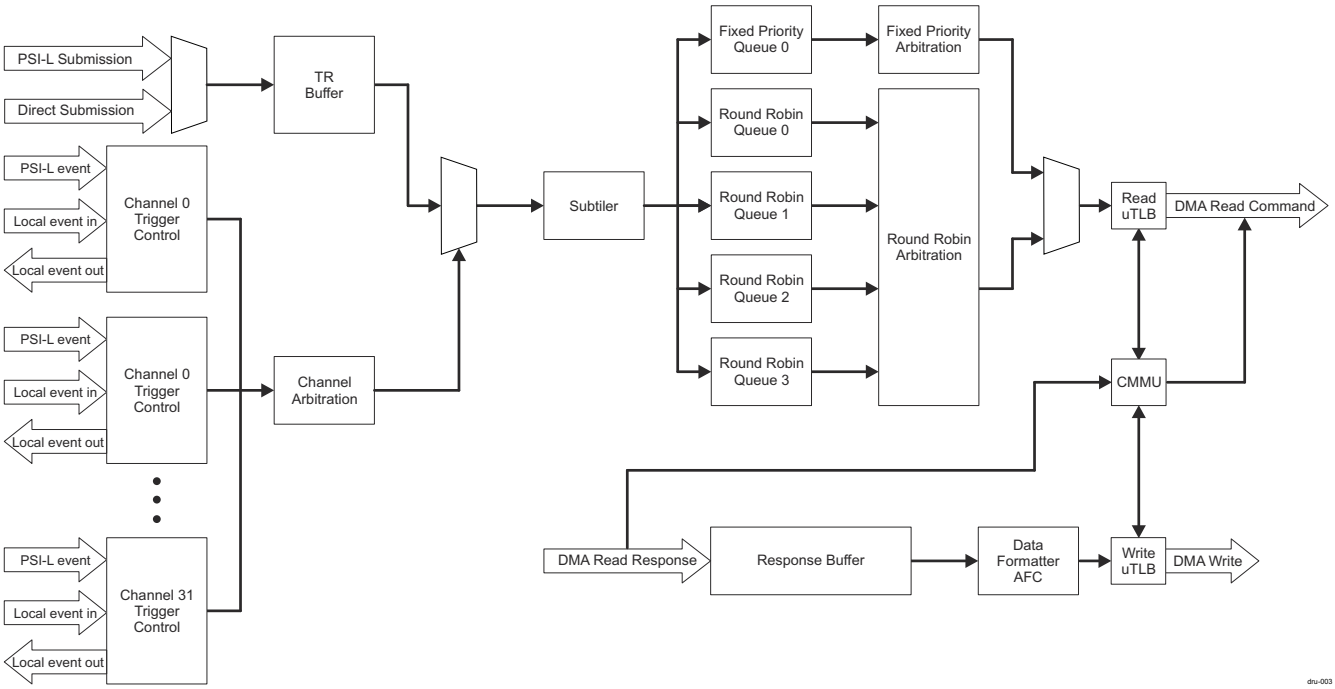

Figure 10-27. DRU Functional Diagram

The DRU receives commands to transfer data from one location to another called Transfer Requests (TRs) or to send messages to CPUs or MMUs to pre-warm logic called Cache Requests (CRs). The DRU can receive these commands through the following mechanisms:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The previously described mechanisms of receiving TRs and CRs are also referred to as TR submission (see, Section 10.4.3.1.3). In other words, the DRU memory-to-memory transfers work by receiving TR or CR through TR submission. Then the corresponding request (TR or CR) is placed in a queue to be processed.

Once the TR has been received the Channel Trigger Control block detects if the triggers specified in the TR have been received. If the trigger is not specified (value of 0x0 in the TRIGGER0 or TRIGGER1 fields of the TR FLAGS field), the treatment is as it is always received. Once received the channel is considered active. All active channels are involved in arbitration process for using the subtiler. The channel arbitration is based on the channel queue. There are queues using a fixed priority arbitration - the lowest channel has the highest priority. There are also round robin queues that use the same algorithm as in the fixed priority queue arbitration (lowest channel - highest priority) but on a round robin basis.

The subtiler takes the winning channel (that is, channel with highest priority) and generates the next 1D or 2D transfer (called also sub-TR) based on the trigger size, transfer type and event size specified in the TR. Then the subtiler places that sub-TR into the queue specified for the channel. Once the sub-TR is generated an event control is notified and any active triggers are cleared if the sub-TR crosses the boundary of one of the triggers.

Copyright © 2023 Texas Instruments Incorporated

For example, if a TR has a trigger size for a 3D block and the ICNT2 value is 16, then the active triggers are cleared after 16 sub-TRs are sent to the queue. ICNT2 can be specified through one of the following:

- DRU_ATOMIC_SUBMIT_CURR_TR_WORD4_5_j[47-32] ICNT2 field
- DRU_SUBMIT_WORD4_5_j_k[47-32] ICNT2 field
- ICNT2 field of the UDMA-C TR received over PSI-L

Upon reaching the top of the queue the TR is processed. Based on the information in the TR a read of the specified location and size is performed followed by writing the data to the specified destination. Upon sending the last write of the entire TR loop a completion event is generated. The completion event output also places a TR response in the PSI-L response FIFO in case of UDMA-C TR. For information about the TR response format, see *Transfer Response Record* in *DMA Architecture*.

Note

The channel is an independent data flow that can be given requests for data movement. Each channel operates independently of the others but they all share common resources.

The queue is a shared unit between several channels. It holds the order of the channel data movement requests until the shared data engine can perform the actual data move. A channel is assigned a queue where its data movement requests are placed.

Note

The CHRT_SWTRIG register can only be accessed directly through the DRU configuration interface and is used if software wants to control the triggers for the TR.

Figure 10-28 shows the interaction between software and hardware to setup DRU, submit TRs and then release the channel to be used by a different resource. Section 10.4.3.1.1 through Section 10.4.3.1.5 explain in more detail what occurs in each process or decision.

Copyright © 2023 Texas Instruments Incorporated

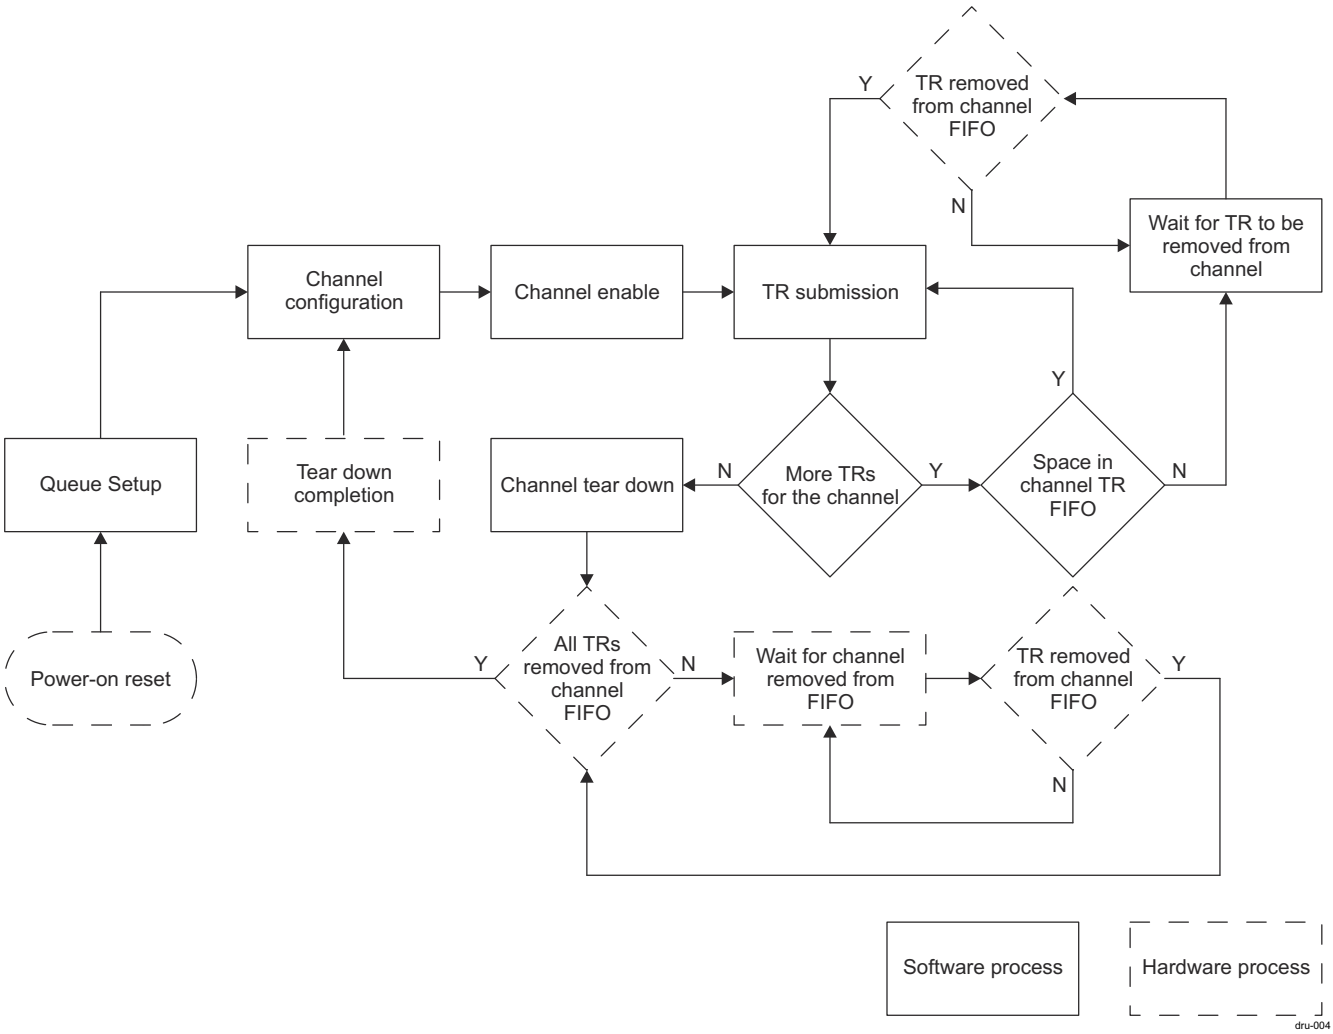

Figure 10-28. DRU Software Managed Flow Diagram

10.4.3.1.1 Queues

Every TR that is active is placed in one of the DRU queues. Each queue operates independently of the others. In a given queue the TRs complete in the order they are placed by the subtiler. Only one read and one write queue may exist at a time. The queues use same resources and need arbitration which is performed based on fixed priority or round robin scheme. In both cases the highest priority queue is the one with the lowest number. The queue priority is specified through the DRU_CFG_y[2-0] PRI field.

Whenever arbitration occurs if there is a TR in a fixed priority queue that TR always goes and the round robin queues are held off. If the fixed priority queues are empty then the round robin queues are arbitrated on a round robin basis, that is, each queue sends its specified number of transactions and then arbitration starts again. On the write side an arbitration ends if the read response has not been received for the next command when the current one completes.

The arbitration happens the last phase of a transfer chunk. A transfer chunk is defined as sending the number of read transactions specified by the DRU_CFG_y[23-16] CONSECUTIVE_TRANS field. After CONSECUTIVE_TRANS number of commands elapse the queue releases the bus and waits for the number of commands specified by the DRU_CFG_y[31-24] REARB_WAIT field before trying to request the bus and involve in arbitration again. Thus software can tune the data flow from each queue to prevent starvation.

If a queue is running and no other queues have a TR then the running one starts its next chunk without stopping. Each time arbitration is performed for round robin queues the queue with the next priority becomes the highest priority and the current one the lowest priority queue. If a fixed priority queue is active then the current round robin queue remains the highest priority one until the CONSECUTIVE_TRANS count expires or queue is empty.

Copyright © 2023 Texas Instruments Incorporated

The DMA bus QoS and order ID attributes for each queue can also be configured through the DRU_CFG_y[10-8] QOS and DRU_CFG_y[7-4] ORDERID fields.

Note

Queue configuration must be done before setting up any channel as queue changes while channels are active can cause unknown behavior.

10.4.3.1.2 Channel Configuration

The DRU operates on having multiple channels that can run in parallel on the shared hardware but are independently triggered by events as needed. Each channel must be configured before it is used. The channel configuration has the following parts:

- Non-realtime configuration intended to be controlled by a single master in the system for all software processes and processors
- Real time configuration controlled by the software process that owns the channel

10.4.3.1.2.1 Non-realtime Channel Configuration

The non-realtime configuration consists of the following:

- Assigning the channel to a submission mechanism via the DRU_CFG_j[19] CHAN_TYPE_OWNER bit
- Assigning the channel via the DRU_CHST_SCHED_j[2-0] QUEUE field to a hardware queue to be used for channel transactions
- Assigning the channel via the DRU_CHOES0_j[15-0] EVT_NUM field to an event to be used for channel notifications

The DRU_CFG_j[31] PAUSE_ON_ERR bit can be used to control the channel behavior in case of error or exception.

The DRU_CFG_j registers must be written to before the channel is enabled via the DRU_CHRT_CTL_j[31] ENABLE bit as once a channel is enabled any write to the DRU_CFG_j, DRU_CHST_SCHED_j and DRU_CHOES0_j registers will result in write failure and an address error. If a channel does not exist an address error is generated upon write too.

10.4.3.1.2.2 Realtime Channel Configuration

Once the non-realtime channel configuration has been done the DRU_CHRT_CTL_j[31] ENABLE bit should be written. It must be written before any TRs can be written. The mechanism to write this bit is based on the ownership of the channel as specified via the DRU_CFG_j[19] CHAN_TYPE_OWNER bit. If the owner is a CPU, than this bit must be written directly through the DRU configuration interface. If the owner is UDMA, than the PSI-L interface must be used to write the ENABLE bit through the PSI-L register configuration write process as described in *PSI-L*.

Note

Once a channel has been enabled the channel configuration registers cannot be modified. The channel can only be disabled through writing 0x1 to the DRU_CHRT_CTL_j[30] TEARDOWN bit.

10.4.3.1.3 TR Submission

The DRU supports the following TR methods:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The TR submission checks the following:

- If a legal TR has been submitted
- If the correct submission method has been used
- If there is space in the channel TR FIFO for the new TR

Copyright © 2023 Texas Instruments Incorporated

10.4.3.1.3.1 Direct TR Submission

The direct TR submission can be atomic or nonatomic. There is one atomic register set that allows for a TR to be submitted with a single burst write. There are also three nonatomic register sets for nonatomic direct TR submission. Each of these three sets allows direct TR submission without requiring submission in a single burst.

The direct atomic TR submission is handled through DRU register writes to the DRU_ATOMIC_SUBMIT_CURR_TR_WORD0_1_j to DRU_ATOMIC_SUBMIT_CURR_TR_WORD14_15_j registers which require write in a single 64-byte burst. Any write other than this size returns an address error. All burst values are checked if they are legal values and space in the channel FIFO is checked too. Then the TR is pushed into the FIFO and the write status is returned with success. If any of the legal TR format checks or FIFO space check fails or if the channel is not owned and enabled the result is an address error returned.

The direct nonatomic TR submission is handled through DRU register writes to the DRU_SUBMIT_WORD0_1_j_k to DRU_SUBMIT_WORD14_15_j_k registers which are intended to be used for cores not being able to perform a large burst write in a single cycle. There is a single set for each core regardless of the channel number. A write to the DRU_SUBMIT_WORD0_1_j_k register triggers the TR.

Note

The following should be taken into account:

- If a channel is full any write to the DRU_SUBMIT_WORD0_1_j_k register results in an address error.
- The DRU does not check anything to ensure that the same core writes to the same nonatomic register set. Software should perform the check procedure.

10.4.3.1.3.2 PSI-L TR Submission

The DRU PSI-L TR submission is used for TR submissions from an external UDMA-C. The DRU has a single submission thread for each channel. The channel must be configured as UDMA-C type channel before PSI-L pairing.

The PSI-L pairing, TR submission and response follow the mechanisms as described in *PSI-L*. For every TR a TR response is sent. If the TR fails a legal check or channel ownership or FIFO fullness check, an immediate TR response is sent back with the cause of the submission error provided in the response.

10.4.3.1.4 TR Removal from Channel

After all requested write responses are received from a TR the DRU sends completion event for the channel that completed the TR. Software can use this event to determine when a TR can be added to a channel FIFO. Each channel has a small FIFO allowing multiple TRs to be preloaded into a channel thus maximizing the channel throughput. The completion event signifies that an entry has become available in the FIFO.

10.4.3.1.5 Channel Tear Down

A channel must be torn down through setting the DRU_CHRT_CTL_j[30] TEARDOWN bit to 0x1. This allows for channel reconfiguration. Setting the TEARDOWN bit to 0x1 forces the channel to stop sending any new requests not already in the pipeline and when all outstanding requests have been received all other bits in the DRU_CHRT_CTL_j register are cleared. If the DRU_CFG_j[31] PAUSE_ON_ERR bit is set and an error occurs the tear down mechanism can be used to restart the channel. The TEARDOWN bit being set to 0x1 also makes the TR STATIC field in any future reads from the TR memory to be set to 0x0 no matter the value when the TR was submitted. This is the mechanism used to stop a static TR.

10.4.3.1.5.1 Tear Down Completion

The tear down completion process is when software has set the DRU_CHRT_CTL_j[30] TEARDOWN bit to 0x1 so no new TRs can be added to the channel but when previous TRs that had been added to the channel are still running. Once the TR FIFO for the channel is empty hardware clears the DRU_CHRT_CTL_j[30] TEARDOWN and DRU_CHRT_CTL_j[31] ENABLE bits. The channel is now back at the channel configuration process as described in Section 10.4.3.1.2.1 and can be reused as needed by the system.

Copyright © 2023 Texas Instruments Incorporated

10.4.3.2 DRU Virtualization

The DRU supports virtual addressing through integrated CMMU along with two uTLBs one for read commands and another for write commands. The CMMU is same as the one associated with C71SS.

The channel configuration adds a bit for ATYPE to choose if the addresses are virtual or physical. If a channel is configured to have virtual addresses the queue sends a request to the uTLB and waits for the status response before it sends the command. If the uTLB returns with a page fault then the TR will fail and all future commands for the TR will be flushed. If the pause on error option is set for the channel then no further TRs will be sent for the channel until it is torn down and setup again. All the attributes for the command are selected based on those returned from the uTLB.

10.4.3.3 DRU Compression and Decompression

The DRU supports compression and decompression of data in line by integrating the Accelerator Framework Compression (AFC) module inside the response buffer path.

The compression logic places the AFC module between the Read Response Buffer and a dedicated write engine for compression and a dedicated write engine of decompression. The read response buffer handles any out of order responses and then the data is pushed into FIFOs inside the AFC module. The AFC module pulls the data out of the FIFOs as 128-bit elements for compression or 128 CDBs for decompression.

Once the 128-bit entry is removed from the FIFO the symbol size specified for the compression is used to split the 128-bit element into the corresponding number of symbols. If the 128-bit does not divide into an even number of symbols then the remain bits are used with the next 128-bit element to create the first symbol. Once each symbol is determined then they are passed into the compression pipeline. The first stage of the compression pipeline is the difference phase. If it is a non-differential compression algorithm then a fixed bias value is subtracted from the symbol. If it is a differential compression algorithm then the symbol is subtracted from a symbol that is from a previous slot. If there was not data at the previous slot selected it will be zero until actual data is present.

The AFC module packs a byte stream into a set of 128-bit CDB that is defined as a super block. At the end of each super block the compression engine will generate a 8-byte write of the CDB information block. These CDB information blocks can then be read back in when decompressing the data to know the size location and decompression information to recreate the original data.

Table 10-147 through Table 10-151 show the templates used to setup the compression and decompression.

Table 10-147. Compression Secondary Transfer Request Template 64 Byte Secondary TR

word 15	word 14	word 13	word 12

Table 10-148. Compression Secondary TR Field Descriptions

Word	Field	Description
0-1	ADDR of Compressed Data	The Location of where the compressed data starts.
2	Secondary TR FLAGS	The Secondary TR Flags that are common for all secondary TRs
3	Compression Flags	The Compression Flags used for the compression
4	SBICNT0 & SBICNT1	The size of the super block for the compression
5	DSTDIM0	The dimension to use for DICNT0 in the original TR after each super block
6	SRCDIM0	The dimension to use for ICNT0 in the original TR after each super block is complete

Copyright © 2023 Texas Instruments Incorporated

Table 10-148. Compression Secondary TR Field Descriptions (continued)

Word	Field	Description
7	Max Offset CDB Table Start Offset	For a compression TR this is the maximum offset value that can be written in the CDB table. This means that compressed data will not be written beyond ADDR + Max Offset. For a decompression TR this is the offset from the secondary TR that the first CDB entry should be read from in bytes. It is a signed value.
8	CDB0 Format	This is the format data for the first CDB table value written after the first super block. It will never be used in an initial fetch.
9	CDB0 Offset	This is where the CDB data for this entry begins relative to the ADDR of Compressed data and is always a positive number.

Table 10-149. Multiple Buffer Interleave FLAGS Field Descriptions

Bit	Field	Description
0-3	SEC_TR_TYPE	0: Multiple Buffer Interleave 1: CDB INFO Block and Decompression/Compression Configuration
4-31	SB_DIM0	The dimension to use between lines of the super block. Lower 4 bits are always 0 since minimum element size is 16 byte element.

Table 10-150. Compression FLAGS Field for Non-Differential Algorithms Descriptions

Bit	Field	Description
0-3	Compression Algorithm	0: Zero Based Algorithm 1: Unsigned Golumb 2: Signed Golumb 3-7: Reserved for Future Use 8-15: Differential Type see the Differential Compression Flags Definition
5-4	SB_AM0	The addressing mode to use for the super block during ICNT0 is decrementing. This is only used if the TR is using circular addressing for the direction of the compression engine.
6-7	SB_AM1	The addressing mode to use for the super block when SB_ICNT1 is decremented. This is only used if the TR is using circular addressing for the direction of the compression engine.
8-15	Bias	The constant value subtracted from the symbol before the compression algorithm is applied
16-31	RSVD	Reserved for future use

Table 10-151. Compression FLAGS Field for Differential Algorithms Descriptions

Bit	Field	Description

10.4.3.4 DRU Output Events

The DRU generates the following events:

- Local output events
- PSI-L global events
- Protocol violation event
- Completion events
- Error completion events

The EVENT_SIZE field of each TR specifies how often a TR generates an output event. That event is provided on the local output event interface as shown in Figure 10-27 and as global event on the PSI-L interface. There is one event per channel. The global event number used by a PSI-L event transport lane can be configured for each channel through the DRU_CHOES0_j[15-0] EVT_NUM field.

As shown in Table 10-152, if the EVENT_SIZE value is in range from 1 to 3, then the output event is generated when the write command for the given loop level (ICNT1, ICNT2 or ICNT3 decremented) has been sent. If EVENT_SIZE = 0, then the output event is generated when all responses have been received.

Table 10-152. EVENT_SIZE Encoding

EVENT_SIZE Value	Event Encoding	Description
0	TR complete	The TR has completed and all responses have been received
1	ICNT1 loop is decremented	The last write command of a row has been sent
2	ICNT2 loop is decremented	The last write command of an array has been sent
3	ICNT3 loop is decremented	The last write command of an array of an array has been sent

For more information about PSI-L interface and its event transport lane, see *PSI-L*.

For more information about the TR EVENT_SIZE field, see *Transfer Request Record* of *DMA Architecture*.

The protocol violation event is not channel associated.

The completion events are defined for each channel. The completion event fires whenever a channel completes a TR successfully. It is only generated when all responses are received from the write portion of the block copy. A single write completion event can occur in a given cycle since it is based on the write responses being received to generate the response.

The error completion events are defined for each channel. The error completion event fires whenever a channel completes a TR with an error and it has flushed out all data related to that TR in the response buffer. Upon determining that a TR is not able to complete successfully, the DRU enters a flush mode to remove all read data received after the error is determined as well as make sure all write responses are received. Once all of this criteria has been matched the write engine fires a completion event. If multiple error completions occur at the same time the DRU will still send them out one at a time using an arbitration scheme used for the original arbitration for the queue, either fixed priority or round robin based on the queue that has the error.

Copyright © 2023 Texas Instruments Incorporated

10.4.3.5 DRU Address Fetch Algorithm, TR and CR Formats

The address fetch algorithm, TR and CR formats are defined in *Transfer Request Record* in *DMA Architecture*. It documents all features that can be supported by a Universal Transfer Controller (UTC) like the DRU but it may not support all of them. The DRU_CAPABILITIES register must be read to check what features of the TR are supported by the DRU.

The TR format allows to perform some kinds of data reformatting or to alter from the standard addressing formats. The DRU supports the transpose data reformatting function and the circular buffering alternate addressing algorithm.

10.4.3.5.1 Transpose

Linear streams work for large classes of algorithms, but not all. In some cases it is desired to transpose rows to columns and columns to rows in the data structure. To help in these cases the DRU supports a transpose function.

The transpose type works on element sizes of 32, 64 or 128 bits by sending sub-TRs in the size of 32 elements by 32 lines for 32-bit, 16 elements by 16 lines for 64-bit and 8 elements by 8 lines for 128-bit element. The sub-TR that is being sent always results in the maximum transfer size. For the write requests the data in the response buffer always looks as a buffer aligned to the zeroth offset in the address.

10.4.3.5.2 Circular Buffering

Circular addressing modifies how the DRU performs address arithmetic so that addresses remain within a power-of-two sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default linear addressing which allows all of the address bits to vary.

The TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

If circular addressing mode is selected in the AMODE field of the TR, the definition of the upper 16 bits of the FMTFLAGS field of the TR select the type of addressing for each entry in the loop and define two unique masks that can be used for the circular buffering. Additionally, the DIR field in the TR determines if the circular addressing flags apply for the source or the destination of the block move. The other direction always follows the standard linear addressing that is used if AMODE is not set.

For more information about circular buffering and the associated TR fields, see *Circular Address Mode Specific Flags* of *DMA Architecture*.

10.4.3.6 DRU Firewalls

Unlike most of the device modules whose associated firewalls reside on system interconnect (CBASS) level the DRU has its own embedded firewalls. They are the following:

- Region based firewall intended to protect DRU configuration registers within a programmatically specified range.
- Channelized firewall that protects:
  - The real time configuration registers for each channel:
    - DRU_CHRT_CTL_j
    - DRU_CHRT_SWTRIG_j
  - The TR submission registers for each channel:
    - DRU_ATOMIC_SUBMIT_CURR_TR_WORD0_1_j to DRU_ATOMIC_SUBMIT_CURR_TR_WORD14_15_j
    - DRU_SUBMIT_WORD0_1_j_k to DRU_SUBMIT_WORD14_15_j_k
  - The data transfers for each channel

The region based firewall should be configured to cover the range from 0x6D00 4000 to 0x6D0C FFFF. This allows for a single master to control the memory attribute channels and channel ownership. If the region based firewall is configured to overlap the channelized firewall then both firewall checks have to pass for the register update to occur. If the firewall check fails the DRU returns protection error status to the requestor.

Copyright © 2023 Texas Instruments Incorporated

Note

Protection error takes precedence over address error. If the address falls into the firewall protected range then a protection error is returned.

Note

Each SoC DRU (DRU0 and DRU1) has both the region based and channelized firewall.

The DRU region based and channelized firewalls are same as the other device firewalls. For more information about their functionality, see *Interconnect Firewalls* in *System Interconnect*. The DRU firewall associated registers are described in the *DRU Registers* sections.

10.4.3.7 DRU Errors

In all error cases the DRU reports the error to the system, ensures that all outstanding commands for the TR have completed and proceeds with the next TR in the queue as if the previous one has finished normally. In most error cases the read transaction completes as normal but the responses are flushed. This ensures that both the read and the write start fresh on the next TR. The error details are logged in the DRU_CHRT_STATUS_DET_j and DRU_CHRT_STATUS_CNT_j registers. The DRU_CAUSE_y registers can be read to check if an error for the corresponding channel has occurred.

10.4.3.8 DRU Configurations

Table 10-153 shows the differences between the SoC level DRUs and the rest DRUs in the device. The rest of the features and functionality is same as described in Section 10.4.1 and Section 10.4.3.

Table 10-153. Differences between DRU Configurations

Feature	SoC Level DRUs	DMPAC_UTC_DRU	VPAC_UTC0_RT_DRU, VPAC_UTC1_NRT_DRU
Cache warm support	Y	Y	N
Atomic direct TR submission	Y	N	N
Nonatomic TR submission register sets	3	0	0
Data reformat functions	Transpose	None	None
Minimum transpose size	32 bits	N/A	N/A
Embedded firewall	Y	Y	N
Event generation	Encoded	Bit vector	Bit vector

11 Time Sync

This chapter describes the time sync modules in the device.

11.1 Time Sync Module (CPTS) 1246
11.2 Timer Manager 1252
11.3 Time Sync and Compare Events 1257

Copyright © 2023 Texas Instruments Incorporated

11.1 Time Sync Module (CPTS)

This chapter describes the Time Synchronization (CPTS) module.

11.1.1 CPTS Overview

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations.

11.1.1.1 CPTS Features

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports 8 hardware timestamp push inputs
- Supports timestamp counter compare output
- Supports timestamp counter bit output
- Supports 6 timestamp Generator function outputs
- 32-bit and 64-bit timestamp modes.

11.1.2 CPTS Functional Description

11.1.2.1 CPTS Architecture

Figure 11-1 shows the architecture of the CPTS module.

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. The types of time sync events are as follows:

- Host Transmit Event
- Ethernet receive event
- Ethernet transmit event
- Time stamp push event
- Time stamp counter rollover event (32-bit mode only)
- Time stamp counter half-rollover event (32-bit mode only)
- Hardware Time Stamp Push Event
- Time Stamp Compare Event

The reference clock used for the time stamp (RCLK) can be derived from several sources.

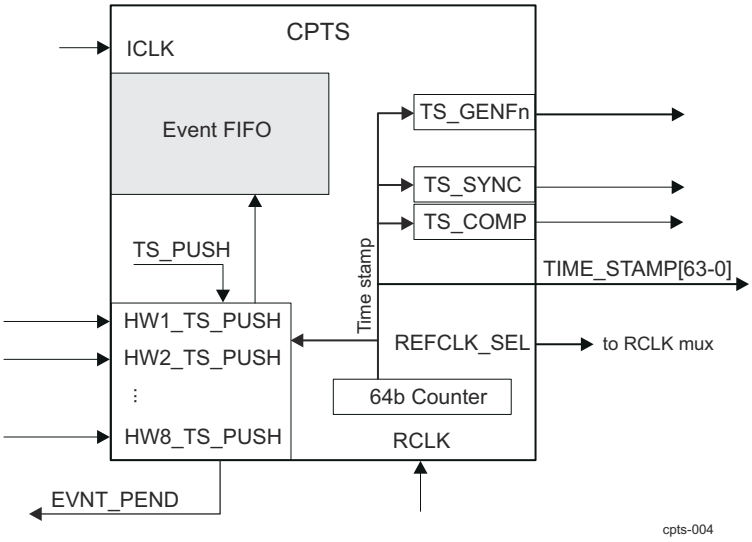

Figure 11-1. CPTS Block Diagram

11.1.2.2 CPTS Initialization

The CPTS module must be configured as follows:

1. Reset the CPTS module

Copyright © 2023 Texas Instruments Incorporated

2. Clear the CPTS_EN bit in the CPTS_CONTROL_REG
3. Write the RFTCLK_SEL value in the CPTS_RFTCLK_SEL_REG with the desired reference clock selection
4. Set the CPTS_EN bit in the CPTS_CONTROL_REG
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE_REG

11.1.2.3 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL_REG and CPTS_TS_LOAD_EN_REG).

The TS_INC_VAL[2:0] value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

11.1.2.4 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

64-bit mode is selected via CPTS_CONTROL_REG[5] MODE_64BIT bit set to 1.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL_REG, CPTS_TS_LOAD_HIGH_VAL_REG, and CPTS_TS_LOAD_EN_REG).

The TS_ADD_VAL feature is included to allow 1-ns timestamp operations with an RCLK rate less than 1 GHz. Table 11-1 shows the RCLK and TS_ADD_VAL values for 1-ns operations. The highest RCLK frequency possible should be used as allowed by the silicon technology.

Table 11-1. TS_ADD_VAL

RCLK (MHz)	TS_ADD_VAL
1000	0
500	1
333.33	2
250	3
200	4
166.66	5
142.85714	6
125	7

11.1.2.4.1 64-Bit Timestamp Nudge

The 64-bit TIME_STAMP value can be adjusted by writing the CPTS_TS_NUDGE_VAL_REG[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the next incremented TIME_STAMP[63:0] value. A nudge value of 0x01 will add one RCLK clock to the next incremented TIME_STAMP[63:0] value. For example, if the current TIME_STAMP value is 0x0F06, and TS_ADD_VAL[2:0]=3, the next incremented timestamp value would be 0x0F0A without a nudge and 0x0F0A +/- TS_NUDGE[7:0] with a nudge. The TS_NUDGE value is cleared to zero when the nudge has occurred.

11.1.2.4.2 64-bit Timestamp PPM

The 64-bit TIME_STAMP can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero value to the TS_PPM[41:0] value enables PPM operations. The adjustment is up or down depending on the TS_PPM_DIR bit. The TIME_STAMP value is increased by the PPM value when TS_PPM_DIR is cleared and decreased by the PPM value when TS_PPM_DIR is set.

- To adjust for 100 parts per million the configured value for TS_PPM[41:0] is:

Copyright © 2023 Texas Instruments Incorporated

1 000 000/100 = 10 000 (DEC)

- To adjust for 1 part per hour at 1 GHz RCLK, the configured value for TS_PPM[41:0] is:
  (1 000 000 000Hz/1pph) × (3600 seconds/hour) = 346 30B8 A000 (HEX)

11.1.2.5 Event FIFO

All time sync events are push onto the Event FIFO. No overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

11.1.2.6 Timestamp Compare Output

CPTS features one Time Stamp Compare (TS_COMP) output.

Note

64-bit mode operation is identical to 32-bit mode except that all 64 bits of the TIME_STAMP[63-0] are used instead of only the lower 32 bits.

11.1.2.6.1 Non-Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN_REG[23-0] RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_VAL_REG[31-0] and the length value is non-zero. The TS_COMP rising edge occurs three RCLK periods after the values compare. A timestamp compare event is pushed into the event FIFO when TS_COMP is asserted. The polarity of the TS_COMP output is determined by the CPTS_CONTROL_REG[2] TS_POLARITY bit. The output is asserted low when the polarity bit is 0.

11.1.2.6.2 Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN_REG RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_VAL_REG[31-0] and the length value is non-zero. The TS_COMP toggles thereafter on CPTS_TS_COMP_LEN_REG[23-0] RCLK periods. The length high or low can be adjusted by writing the CPTS_TS_COMP_NUDGE_REG[7-0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK from the CPTS_TS_COMP_LEN_REG value. A value of 0x01 will add one RCLK to the CPTS_TS_COMP_LEN_REG value. Only a single high or low time is adjusted (nudged) and the CPTS_TS_COMP_NUDGE_REG value is cleared to zero when the nudge has occurred. The TS_COMP output is asserted low when the CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is 0.

No compare events and no CPTS_EVNT interrupts are generated in toggle mode.

The CPTS_CONTROL_REG[6] TS_COMP_TOG bit must be set for toggle mode, and must be set before writing a non-zero value to CPTS_TS_COMP_LEN_REG.

11.1.2.7 Timestamp Sync Output

The TS_SYNC output is a selected bit of the TIME_STAMP counter value. One of the counter bits 17-31 can be selected in CPTS_CONTROL_REG[31-28] TS_SYNC_SEL. The TS_SYNC output is disabled when CPTS_CONTROL_REG[31-28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the TS_SYNC output. A rising edge will occur on the TS_SYNC output upon the next transition-to-1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the TS_SYNC operation. The TS_SYNC output is two RCLK periods after the actual count value.

11.1.2.8 Timestamp GENF Output

There are six TS Generate Function (TS_GENFn) outputs (n = 0 to 5). The TS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and a software nudge feature. The TS_GENFn output cycle is CPTS_LENGTH_REG_j[31:0] RCLK periods (which is different than TS_COMP operation).

The TS_GENFn output cycle is CPTS_LENGTH_REG_j[31:0] RCLK periods beginning when the TIME_STAMP[63:0] value compares with the CPTS_COMP_LOW_REG_j[63:0] and the length value is non-zero. The TS_GENFn output cycle repeats thereafter every CPTS_LENGTH_REG_j[31:0] RCLK periods. The

Copyright © 2023 Texas Instruments Incorporated

upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the TS_GENFn_POLARITY bit is low. No compare events and no CPTS_EVNT interrupts are generated.

11.1.2.8.1 GENFn Nudge

The cycle length can be adjusted by writing the CPTS_NUDGE_REG_j[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the CPTS_LENGTH_REG_j[31:0] value. A value of 0x01 will add one RCLK clock to the CPTS_LENGTH_REG_j value. The CPTS_NUDGE_REG_j value is cleared to zero when the nudge has occurred.

11.1.2.8.2 GENFn PPM

The TS_GENFn output cycle can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero CPTS_PPM_LOW_REG_j/CPTS_PPM_HIGH_REG_j value enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single RCLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPTS_CONTROL_REG_j[0] PPM_DIR bit. When PPM_DIR is set a single RCLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR is clear a single RCLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

- To adjust for 100 parts per million the configured value for TS_GENFn_PPM[41:0] is:
  1 000 000/100 = 10 000 (DEC)
- To adjust for 1 part per hour at 1 GHz RCLK the configured value for TS_GENFn_PPM[41:0] is:
  (1 000 000 000Hz/1pph) × (3600 seconds/hour) = 346 30B8 A000 (HEX)

11.1.2.9 Time Sync Events

Time Sync events are 96-bit or 128-bit (for 32-bit and 64-bit time stamp respectively) values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPTS_EVENT_0_REG throught CPTS_EVENT_3_REG hold the data of a time sync event.

11.1.2.9.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH_REG. The time stamp value is returned in the event, along with a time stamp push event code.

11.1.2.9.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented.

11.1.2.9.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 11-2 shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

Copyright © 2023 Texas Instruments Incorporated

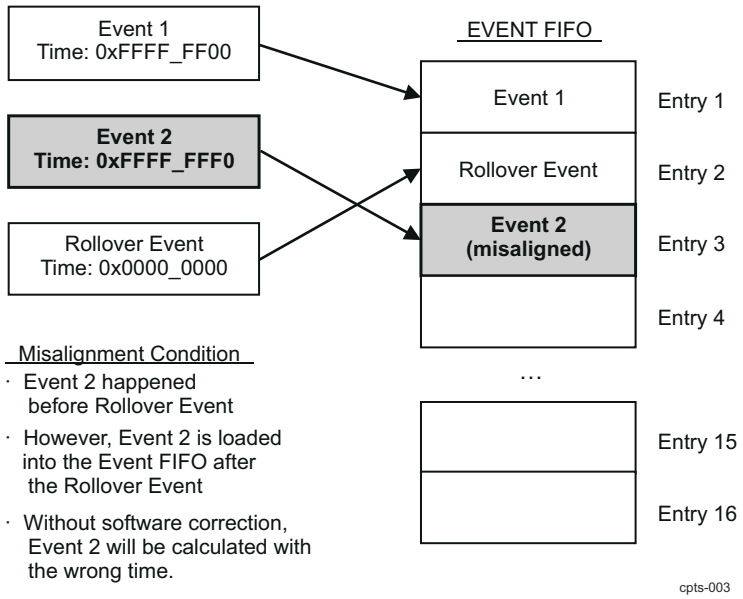

Figure 11-2. Event FIFO Misalignment Condition

11.1.2.9.4 Hardware Time Stamp Push Event

There are eight hardware time stamp inputs (HW[1-8]_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPTS Integration*.

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_1_REG register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

11.1.2.10 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode. The TS_COMP output is also asserted when the event is generated. The event is generated when the TIME_STAMP value compares with the CPTS_TS_COMP_VAL_REG/CPTS_TS_COMP_HIGH_VAL_REG and the CPTS_TS_COMP_LEN_REG value is non-zero. The CPTS_TS_COMP_LEN_REG value should be written by software after the CPTS_TS_COMP_VAL_REG/CPTS_TS_COMP_HIGH_VAL_REG is written and should be zero when the comparison value is written.

11.1.2.11 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE_REG.
2. Upon interrupt, read the CPTS_EVENT_0_REG through CPTS_EVENT_3_REG register values.
3. Set the CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1 to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

Copyright © 2023 Texas Instruments Incorporated

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE_REG.
2. Upon interrupt, read the CPTS_EVENT_0_REG through CPTS_EVENT_3_REG register values.
3. Set the CPTS_EVENT_POP_REG[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four ICLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW_REG register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, proceed to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW_REG to determine if a valid event is on the event FIFO.

11.2 Timer Manager

This chapter describes the Timer Manager module of the device.

11.2.1 Timer Manager Overview

The Timer Manager module provides timers for timing operations for the processes running on multiple processors in the device.

11.2.1.1 Timer Manager Features

Timer Manager has the following features:

- 1024 × 32-bit RAM-based independent timers
- Host access to determine which timer(s) expired
- 32 registers with individual timeout status (one bit per timer)
- A pair of quick-read registers with the number of timers that have expired and the ids of the first timers to expire
- A bank timeout register with the banks that have expired timers – to avoid having to read all timeout status registers when only a few timers have expired
- Groups of 16 timers separated into pages of 4-K address space
- Timer bits within each page to read expiration status for each timer when software only has access to that page
- 10 µs time to cycle through all of the timers
- Host access to reset individual timers
  - Reset values are preprogramed for each timer
  - Timers may all be programmed before the timer manager is enabled, or programmed after enabled.

11.2.2 Timer Manager Functional Description

11.2.2.1 Timer Manager Function Overview

Figure 11-3 shows the Timer Manager diagram.

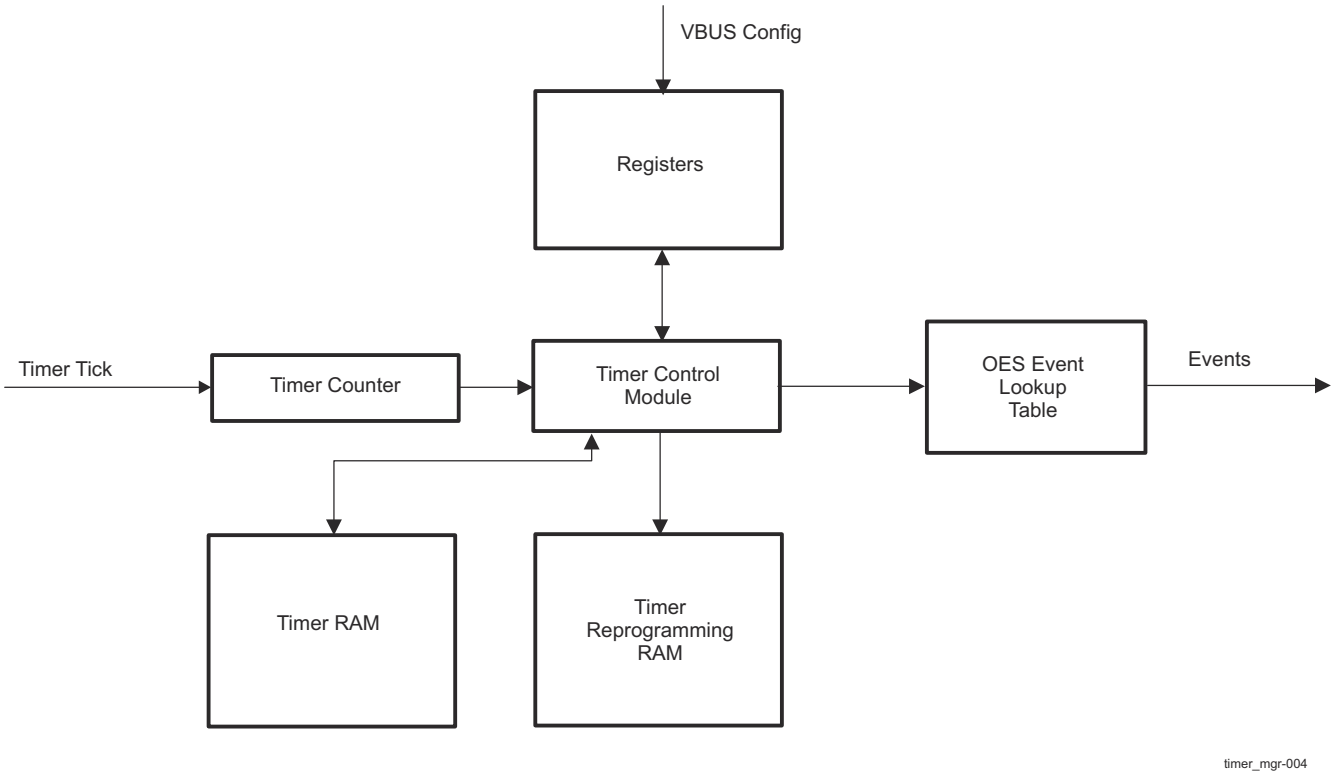

Figure 11-3. Timer Manager Block Diagram

Copyright © 2023 Texas Instruments Incorporated

The 1024 timers in the timer manager are organized as the Timer RAM in Figure 11-3. When the timer manager is enabled, the timer counter will increment with the input timer tick, and the control module continuously loops over the Timer RAM, comparing the values against this timer count. When the timer count is greater than a timer value, the timer control module will generate a timer expiration event.

Based on software writes, the timer control module will update the values in the Timer RAM to setup or cancel active timers. Whenever a new value is written to a TIMERMGR_SETUP_j_k memory address, the corresponding timer is touched/setup with the current sum of the timer count and the written value; written values are relative to the current timer count. These values are stored in the Timer Reprogramming RAM, so the software may also write to the TIMERMGR_CONTROL_j_k registers to flag a timer for reprogramming, using the previously stored reprogramming value. The latter method is preferred when the timer setup value is not changing, as it does not interrupt the RAM state machine.

11.2.2.2 Timer Counter

The Timer Manager takes an input timer tick to control the timer rate. All timers share a time base. On each rising edge of this tick event, the timer counter increments. The value of the timer counter may be read by software via the TIMERMGR_COUNTER register.

11.2.2.2.1 Timer Counter Rollover

A rollover bit is maintained for each timer, such that when reprogrammed, it is the carry bit from the sum of the current time (counter) and the relative reprogramming value for that timer. This has the effect that any timer whose rollover bit is currently set to a 1 will not expire in the current epoch.

When the counter transitions from 0xFFFF FFFF to 0x0000 0000, the timer control module changes the rollover bit for all timers from a 1 to a 0. All timers that previously did not have the rollover bit set, will expire when they are next visited by the state machine, as their timeout value was for the previous epoch.

The overall effect is that the timers continue to expire as expected, regardless of when the counter rollover occurs relative to the state machine.

11.2.2.3 Timer Control Module (FSM)

The timer control module controls the RAM accesses for reading and writing. It controls the loops over the timer RAM, checks the values in the RAM to observe expiring timers, flagging timeouts so that events may be triggered and reported. It also takes as input any software-written updates to setup, clear, and touch the timers.

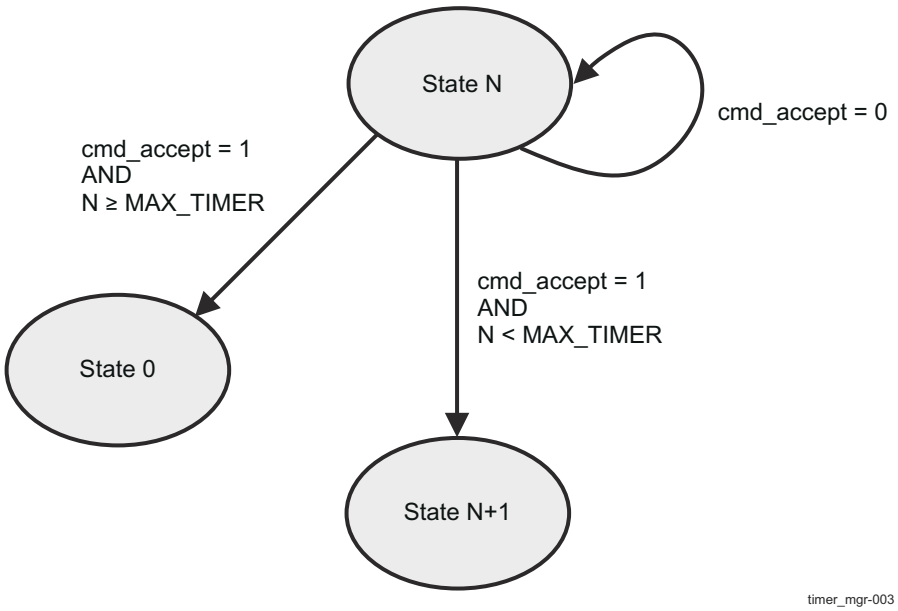

Figure 11-4. Timer State Machine

Copyright © 2023 Texas Instruments Incorporated

The timer states are sequential, that is, Timer 0 is checked, then Timer 1 is checked, then Timer 2, and so on. The Timer Control FSM will stall in a given state if the cmd_accept signal from the ksdw_spram_ecc module goes low, and will remain there until the ECC RAM will accept a command.

The timer state always transitions from N to N+1, unless N meets or exceeds the programmed MAX_TIMER value, in which case the system will start over at state 0.

11.2.2.4 Timer Reprogramming

There is a reprogramming module that runs in lock step with the FSM, always one state ahead – the FSM exports its next_state for use by the reprogramming RAM.

This RAM keeps track of the setup values for the timers as programmed by the TIMERMGR_SETUP_j_k memory mapped locations. There is a SET flag for each timer outside of the RAM – if this SET flag is true for the next_state timer, the VBUS ready signals are deasserted; if there is a pending timer setup, there cannot be a read or write to the memory, as this would interrupt the Timer FSM state machine and, with enough accesses, potentially cause the system to exceed the 10-µs window for timer accuracy.

11.2.2.5 Event FIFO

As the subsystem event aggregator requires more than one cycle to process events, there is an internal FIFO to store the generated events. Events may be generated by expiring timers or by activity on the CBA interface, as disabled timers or reset timers must send an event deactivation if the timer was previously expired.

This has an impact on performance, as if there are too many timer expirations in a given window, it potentially violates the 10-µs requirement (this is true without the event FIFO as well, given that the system cannot keep up with a timer expiring every cycle, in the worst case).

11.2.2.6 Output Event Lookup (OES RAM)

The expiring timers must be assigned corresponding event numbers for use in the instantiating system. These lookup values correspond to the 16-bit event number that is output on the event interface when a given timer expires.

The lookup table for timer to event number mapping defaults all timers to the invalid event number (0xFFFF), and any invalid event numbers observed upon lookup for an expiring timer will result in no events being generated by the timer manager – invalid (0xFFFF) events are suppressed and will not result in an event on the event interface.

It is expected that the output event assignments will be programmed once per module reset, and that they are static during operation of the timer manager.

11.2.3 Timer Manager Programming Guide

11.2.3.1 Timer Manager Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

11.2.3.1.1 Initialization Sequence

Initialization of the Timer Manager must include the following steps:

1. Set the number of timers to be used. TIMERMGR_CNTL[10-1] MAX_TIMER
   - This controls the loop over the timer RAM and is the highest ID timer that will be used in the operation of the Timer Manager (MAX_TIMER + 1 is the total number of timers in use)
   - This number must not change during the course of operation; it can only be changed when TIMERMGR_CNTL[0] ENABLE = 0. It is assumed that the user will set the MAX_TIMER value as required.
   - This step can be skipped if using all timers. MAX_TIMER defaults to 1024 (that is, all timers in use).
2. Write output event mapping for all timers to the OES output event lookup table. This must be done before enabling timer manager and must not be done again once the timer manager has been enabled.
3. Write initial setup values to the TIMERMGR_SETUP_j_k registers. All timers that will be used initially must have a setup value before the Timer Manager is enabled.
4. Enable individual timers. There are two ways to do this.
   - To enable all timers, use the TIMERMGR_CNTL[12] MASS_ENABLE bit. This will enable all timers from 0 to MAX_TIMER.
     - Note that MAX_TIMER and MASS_ENABLE should be set in successive writes, or the previous value of MAX_TIMER will be used for MASS_ENABLE
     - MASS_ENABLE must only be used during initialization.
   - Alternately, individual timers can be enabled or disabled with TIMERMGR_CONTROL_j_k
     - It is therefore faster to set the individual TIMERMGR_CONTROL_j_k bits if more than half of the in-use timers are to be enabled initially. If more than half of the in-use timers are to be enabled initially, it is faster to use MASS_ENABLE and then disable specific timers with the TIMERMGR_CONTROL_j_k bits.
5. Enable the timer manager. Set TIMERMGR_CNTL[0] ENABLE to 1.

11.2.3.1.2 Real-time Operating Requirements

While running, a CPU can take the following actions to enable, disable, or touch the timers:

11.2.3.1.2.1 Timer Touch

When a timer needs to be updated – indicating that an interface or function is still alive and timeout should be delayed – there are two means of touching a timer:

- If the timer's respective TIMERMGR_SETUP_j_k has the appropriate value for its function, the timer can be set again by writing a 1 to the SET bit of the TIMERMGR_CONTROL_j_k register.
  - As the timer should remain enabled, this effectively means writing a 3 to the TIMERMGR_CONTROL_j_k register for the timer to be touched
- If the timer's respective TIMERMGR_SETUP_j_k needs a new value, writing this value has the side effect of also setting the timer – there is no need to also write to the SET bit of TIMERMGR_CONTROL_j_k. This should be relatively infrequent during operation, as the setup values for all timers must be written during initialization.

The preferred method for touching timers is using the SET bit of TIMERMGR_CONTROL_j_k. It is considerably more efficient. The reprogramming RAM is a single port RAM, and repeated writes to the TIMERMGR_SETUP_j_k registers will impact overall timer performance and may result in longer periods before a valid timeout is observed.

11.2.3.1.2.2 Timer Disable

When a timer is no longer in use, the timer should be disabled with the respective TIMERMGR_CONTROL_j_k enable bit.

Copyright © 2023 Texas Instruments Incorporated

A disabled timer does not stop the time for that timer relative to the counter, and its current value is considered invalid once disabled. A timer should not be disabled and then subsequently re-enabled without reprogramming/re-setting, as it may timeout unexpectedly.

11.2.3.1.2.3 Timer Enable

To enable a timer while the Timer Manager is running, the timer must first be setup again.

- If the current TIMERMGR_SETUP_j_k is appropriate for the timer's intended use, the timer can be re-enabled by writing a 3 to the TIMERMGR_CONTROL_j_k register. (ENABLE = 1, SET = 1)
- If the current TIMERMGR_SETUP_j_k needs to be changed, write to the TIMERMGR_SETUP_j_k before re-enabling the timer. After this value is changed, the timer can be re-enabled by writing 0x3 to the TIMERMGR_CONTROL_j_k register (ENABLE = 1, SET = 1)
  - While TIMERMGR_SETUP_j_k implies SET, it must still be set as the timer is enabled.

11.2.3.1.3 Power Up/Power Down Sequence

The timer manager must be disabled (clear TIMERMGR_CNTL[0] ENABLE to 0) before the timer manager is powered down. The timer manager will only be idle if it is not enabled and the event FIFO is empty – an enabled Timer Manager means the state machine is running and the timer manager is waiting for expired timers.

To power up the Timer Manager if it has been powered down but not reset, the timer values in the timer RAM must be assumed to be invalid. Any timers must either be reprogrammed (TIMER_SET) before the timer is re-enabled. If this is not done, the Timer Manager may report timeouts as soon as it is enabled.

Additionally, all timers that have expired must be cleared before disabling the Timer Manager, otherwise there will be no Event Down generated on the event interface to clear the expired timers from the interrupt aggregator. This effectively means that software must disable all timers before writing a 0 to TIMERMGR_CNTL[0] ENABLE.

The event FIFO will continue to drive pending events even if the Timer Manager is disabled, so the remaining Event Down actions will still occur – software only needs to disable the timers to ensure that the Event Down commands are pushed into the event FIFO but does not need to wait for the event FIFO to flush before disabling the timer manager.

11.3 Time Sync and Compare Events

11.3.1 Time Sync Architecture

This section provides a high-level overview of the SoC time synchronization architecture.

11.3.1.1 Time Sync Architecture Overview

Table 11-2 shows the network time synchronization functions supported by the device.

Table 11-2. Network Time Synchronization Functions in the SoC

Interface	Time Sync Functions	Supported by
1×PCIE	Precision time measurement (PTM)	PCIe controller hardware
2×CPSW	IEEE 1588-2008 (2-step), 802.1AS	CPTS in CPSW
External input reference clock	External time/clock reference	CPTS

Note

These time sync functions are described in detail in their respective chapters.

Any of these functions can be a time sync master in the system. A sync router (TIMESYNC_INTRTR0) provides flexibility for each time domain to choose its synch master independently. In addition, there is also a router (CMPEVT_INTRTR0) that provides selection of active counter compare events for routing as CPU or DMA events.

Copyright © 2023 Texas Instruments Incorporated

11.3.2 Time Sync Routers

11.3.2.1 Time Sync Routers Overview

The timesync event router (TIMESYNC_INTRTR0) and compare event router (CMPEVT_INTRTR0) are instantiations of the generic interrupt router module in the device.

The TIMESYNC_INTRTR0 implements a set of multiplexers to provide selection of active CPTS time sync events for routing to CPTS capable modules. There is one register per output that controls the selection (TIMESYNC_INTRTR0_MUXCNTL_y).

The CMPEVT_INTRTR0 implements a set of multiplexers to provide selection of active CPTS counter compare events for routing as CPU or DMA events. There is one register per output that controls the selection (CMPEVT_INTRTR0_MUXCNTL_y).

Table 11-3 summarizes the configuration details for TIMESYNC_INTRTR0 and CMPEVT_INTRTR0.

Table 11-3. TIMESYNC_INTRTR0 and CMPEVT_INTRTR0 Configuration

Module	Input Interrupt Type
TIMESYNC_INTRTR0	Level
CMPEVT_INTRTR0	Pulse

Refer to *INTRTR Overview* for the general programming sequence that is recommended to be followed for all interrupt routers in the device.

11.3.3 Time Sync Event Sources

See *Interrupt Sources* for Time Sync event mapping.

12.1 General Connectivity Peripherals

This section describes the general connectivity peripherals in the device.

12.1.1 Analog-to-Digital Converter (ADC)

This chapter describes the Analog-to-Digital Converter (ADC) in the device.

12.1.1.1 ADC Overview

The Analog-to-Digital Converter (ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels).

Figure 12-1 presents an overview of the ADC modules.

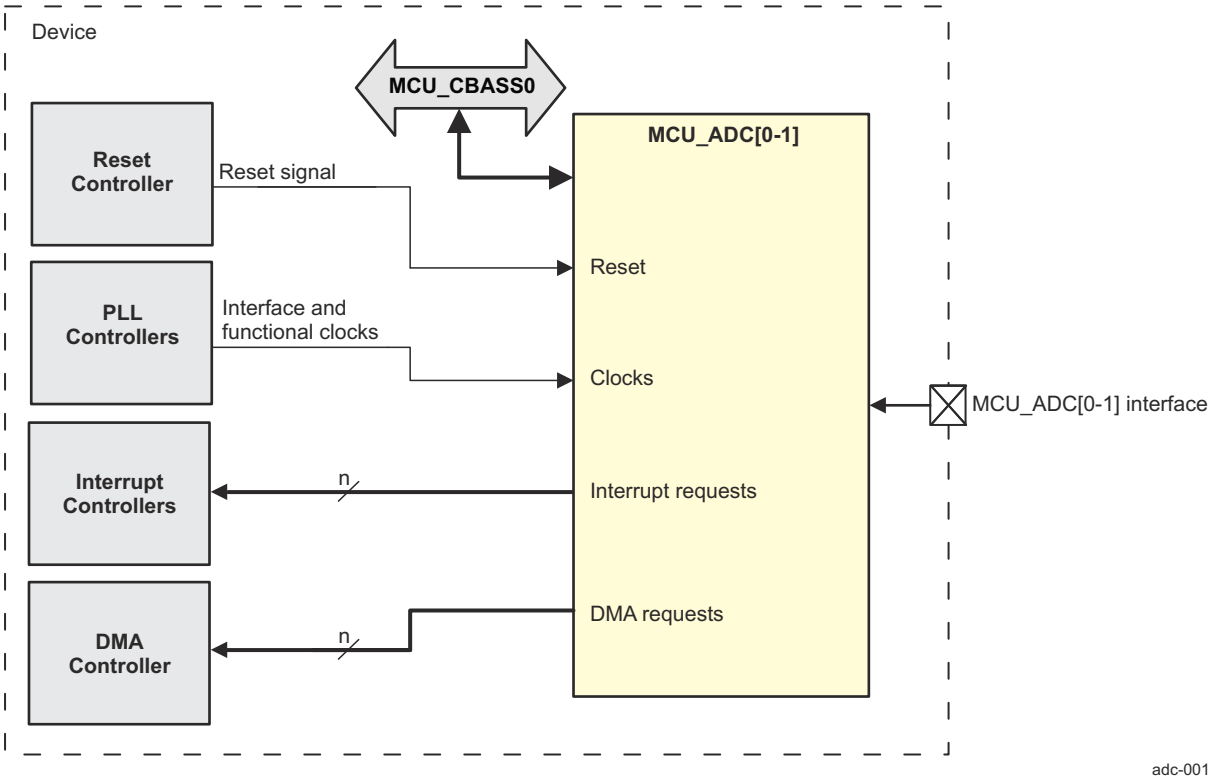

Figure 12-1. ADC Modules Overview

12.1.1.1.1 ADC Features

Each ADC module has the following features:

- 4 MSPS rate with a 60 MHz SMPL_CLK
- Single-ended or differential input options
- Programmable Finite State Machine (FSM) sequencer that supports the following:
  - Software initiated start of conversion
  - Optional hardware start of conversion (SOC), synchronized to external hardware event
  - Single conversion (one-shot mode)
  - Continuous conversions (continuous mode)
  - Sequence through all enabled steps based on a mask
  - Programmable open delay before executing each step
  - Programmable sampling delay for each step
  - Programmable averaging (16, 8, 4, 2, or 1) of input samples for each step
  - Store data in either of two FIFOs – 256-word × 16-bit
  - Option to encode input (channel) number with data
  - Support for servicing FIFOs via DMA or processor
  - Programmable DMA request event (for each FIFO)

Copyright © 2023 Texas Instruments Incorporated

- Support for the following interrupts and status, with masking:
  - Interrupt if AFE fails to return end of conversion (EOC)
  - Interrupt after a sequence of conversions (all non-masked steps)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.1.1.2 ADC Ports

Table 12-1. MCU_ADC[0-1] Clocks and Resets

Clocks	
Module Clock Input	**Description**
MCU_ADC_VBUS_CLK	MCU_ADC interface clock
MCU_ADC_SYS_CLK	MCU_ADC system clock
MCU_ADC_CLK	MCU_ADC clock. Output of multiplexer, see *ADC Integration*. Multiplexer control is provided via CTRLMMR_MCU_ADC_CLKSEL[1-0] CLK_SEL bit field. Default state is HFOSC_CLKOUT.
Resets	
Module Reset Input	**Description**
MCU_ADC_RST	MCU_ADC reset

12.1.1.3 ADC Functional Description

12.1.1.3.1 ADC FSM Sequencer Functional Description

The FSM sequencer supports up to 16 steps that can be configured to perform analog-to-digital conversions. Each of the 16 steps can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each step has its own programmable step configuration (ADC_CONFIG_j) and step delay (ADC_DELAY_j) registers that allow users to configure the ADC operation on a per-step basis.

The FSM sequencer enters Idle immediately after the ADC is enabled and remains in Idle while waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to Idle or immediately begin repeating steps configured for continuous mode.

An ENDOFEQUENCE interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

Figure 12-2 illustrates how the FSM sequencer works. Each shaded box represents a FSM state.

Note

Figure 12-2 does not represent the number of SMPL_CLK cycles required by each state since some states implement user programmable delays that may require more than one SMPL_CLK cycle to complete.

(1) MODE[N] = 10b or 11b, STEPENABLE[N] = 1b, and HW Event = 1
(2) MODE[N] = 00b or 01b and STEPENABLE[N] = 1b

Figure 12-2. Sequencer FSM

12.1.1.3.1.1 Step Enable

A step is enabled or disabled via the ADC_STEPENABLE register. The system software should only write to the ADC_STEPENABLE register when the ADC is disabled or the FSM sequencer is idle. Therefore, it may be necessary to disable the ADC before updating the ADC_STEPENABLE register if the FSM sequencer is executing back-to-back steps where it never enters idle.

Copyright © 2023 Texas Instruments Incorporated

12.1.1.3.1.2 Step Configuration

12.1.1.3.1.2.1 One-Shot (Single) or Continuous Mode

Each step can be configured to operate in one-shot or continuous mode via the least significant bit of the MODE bit-field of the respective ADC_CONFIG_j register. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

12.1.1.3.1.2.2 Software- or Hardware-Enabled Steps

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective ADC_CONFIG_j register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the ADC_CONTROL register.

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled).

The EXT_TRIGGER input signal is used by HW Enabled steps. The trigger input has the option of being sourced from a device input pin or several on-device peripherals via a multiplexer controlled by TRIG_SEL of the respective CTRLMMR_MCU_ADC0_CTRL or CTRLMMR_MCU_ADC1_CTRL register. When this option is selected, the hardware event will be triggered after the EXT_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of SYS_CLK. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

SW Enabled steps can be preempted by HW Enabled steps when the HW_PREEMPT bit in the ADC_CONTROL register is set.

12.1.1.3.1.2.3 Averaging of Samples

Each step can be configured, via the respective ADC_CONFIG_j register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, open delay is only applied to the first sample while sample delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO.

12.1.1.3.1.2.4 Analog Multiplexer Input Select

The AFE contains two 9-to-1 analog multiplexers which are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. Each step can be configured, via the respective ADC_CONFIG_j register, to select the appropriate input sources. For more information, refer to Figure 6 and the ADC_CONFIG_j register field descriptions.

12.1.1.3.1.2.5 Differential Control

The ADC supports differential inputs and each step can be configured, via the respective ADC_CONFIG_j register, to select single-ended input mode or differential input mode.

Note

The ADC INM input must be sourced from REFN for any steps configured to operate in single-ended mode.

12.1.1.3.1.2.6 FIFO Select

The ADC contains two FIFOs and each step can be configured, via the respective ADC_CONFIG_j register, to store its ADC data into either FIFO.

12.1.1.3.1.2.7 Range Check Interrupt Enable

Each step can be configured, via the respective ADC_CONFIG_j register, to compare the value of ADC data to high and low limits programmed in the ADC_RANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of HIRANGE or less than the value of LOWRANGE. Refer to the ADC_RANGE register field descriptions for information related to setting the high and low limits that trigger an out-of-range interrupt.

Copyright © 2023 Texas Instruments Incorporated

12.1.1.3.1.3 Open Delay and Sample Delay

The FSM sequencer provides two programmable delays for each step. The value of OPENDELAY is used to control when the acquisition begins after the step starts and the value of SAMPLEDELAY is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective ADC_DELAY_j register.

12.1.1.3.1.3.1 Open Delay

OPENDELAY defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one SMPL_CLK clock period for each incremental value of OPENDELAY.

12.1.1.3.1.3.2 Sample Delay

SAMPLEDELAY defaults to a value of zero which causes the acquisition period to be equal to two SMPL_CLK clock periods. The acquisition period can be extended one SMPL_CLK clock for each incremental value of SAMPLEDELAY.

The value of SAMPLEDELAY should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

12.1.1.3.1.4 Interrupts

The ADC has 9 internal events that can trigger an interrupt to the processor. These events are logically or'ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the ADC_ENABLE_SET and ADC_ENABLE_CLR registers. Once an interrupt is generated, the ADC_STATUS register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a ‘1’ to the corresponding bit of the ADC_STATUS register.

The following interrupts are supported by the device ADC:

- An ENDOFEQUENCE interrupt is generated after the FSM sequencer completes the last enabled step.
- FIFO0UNFL/FIFO1UNFL or FIFO0OVFL/FIFO1OVFL interrupts. Each FIFO also has the ability to generate overrun and underflow interrupts. The ADC does not recover from overrun or underflow conditions automatically. Therefore, software will need to disable and re-enable the ADC after this occurs. The FSM sequencer must be Idle before turning the ADC module back on. This can be confirmed by reading the ADC_SEQUENCER_STAT register, when FSM_BUSY = 0x0 and STEP_IDLE = 0x10000.
- FIFO0THRS and FIFO1THRS interrupts. Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The FIFO0THRS and FIFO1THRS interrupt is generated when the value of NUMWDS in the respective ADC_FIFO0WC or ADC_FIFO1WC register equals the word count threshold value programmed in THRESHOLD of the respective ADC_FIFO0THRESHOLD or ADC_FIFO1THRESHOLD register.
- OUTOFRANGE interrupt. This interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global ADC_RANGE register. The OUTOFRANGE interrupt is generated if the ADC data value is greater than the value programmed in HIRANGE or less than the value programmed in LOWRANGE.
- AFE_EOC_MISSING interrupt. This interrupt is generated when the FSM sequencer does not receive an expected EOC from the AFE.

12.1.1.3.1.5 Power Management

The software also has the option to turn off the AFE power by writing to the ADC_CONTROL[4] PD bit. By default, after the initial power on the AFE is powered down and software is responsible for turning it on. Software must wait minimum 4 µs after a AFE power up and before starting a conversion (must be followed every time the AFE is powered up). It is the software’s responsibility to empty the FIFO before requesting the ADC to enter sleep state.

12.1.1.3.1.6 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the ADC_DMAENABLE_SET and ADC_DMAENABLE_CLR registers.

12.1.1.3.2 ADC AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of SMPL_CLK after the falling edge of SOC. The SOC pulse width will be the value of SAMPLEDELAY plus one SMPL_CLK periods, so the total ADC acquisition time will be the value of SAMPLEDELAY plus two SMPL_CLK periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen SMPL_CLK periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

The ADC output is positive binary weighted data ranging from 0 to (2^{12} - 1). When configured for single-ended mode, ADC output data values 0 to (2^{12} - 1) represents a corresponding input voltage that ranges from the ADC negative reference (REFN) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to ((2^{12}/2) - 1) represents a corresponding negative differential input voltage that ranges from the REFP voltage to the REFN voltage and output data values (2^{12}/2) to (2^{12} - 1) represents a corresponding positive differential input voltage that ranges from the REFN voltage to the REFP voltage.

Using the minimum values of OPENDELAY and SAMPLEDELAY, the ADC can sample an analog input every 15 SMPL_CLK periods.

Figure 12-3 illustrates the operation of the FSM sequencer and ADC AFE, with indicators showing when the hardware configuration defined by ADC_CONFIG_j and ADC_DELAY_j registers are applied.

Note

Figure 12-3 assumes both steps shown are software enabled with averaging turned off, an OPENDELAY value of 1, and SAMPLEDELAY value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the SMPL_CLK. If the value of OPENDELAY were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

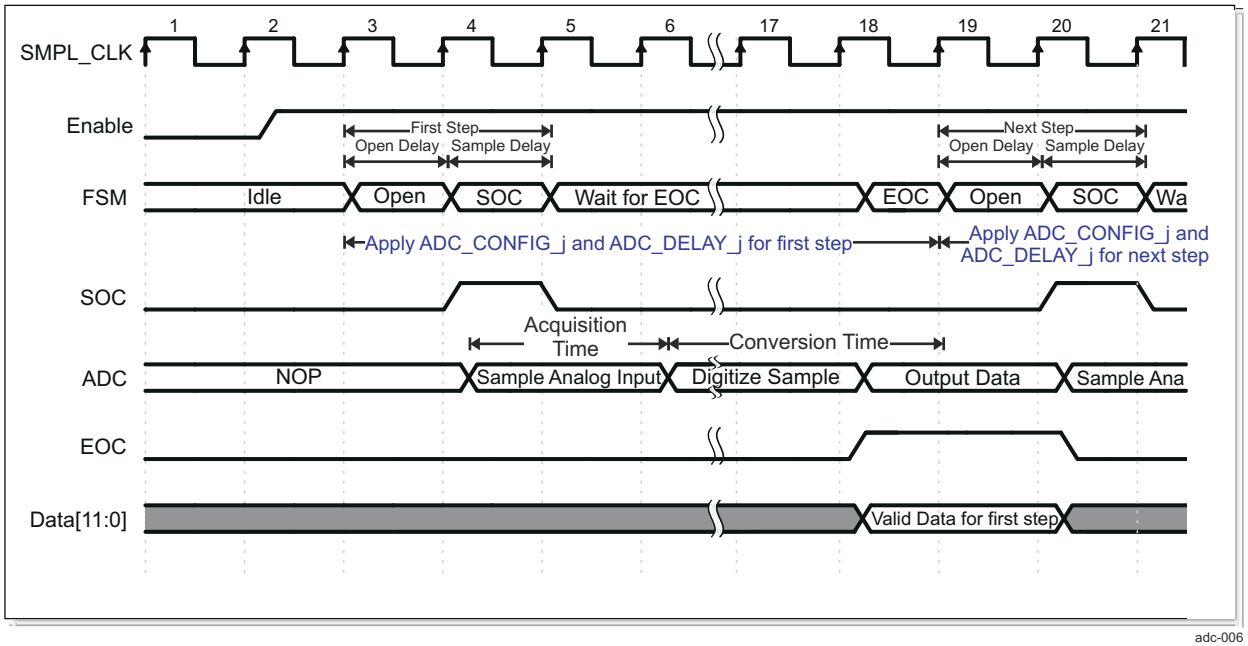

Figure 12-3. Example Timing Diagram for Sequencer

Copyright © 2023 Texas Instruments Incorporated

12.1.1.3.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. The user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. For more information, refer to Figure 12-4 and the ADC_CONFIG_j register field descriptions.

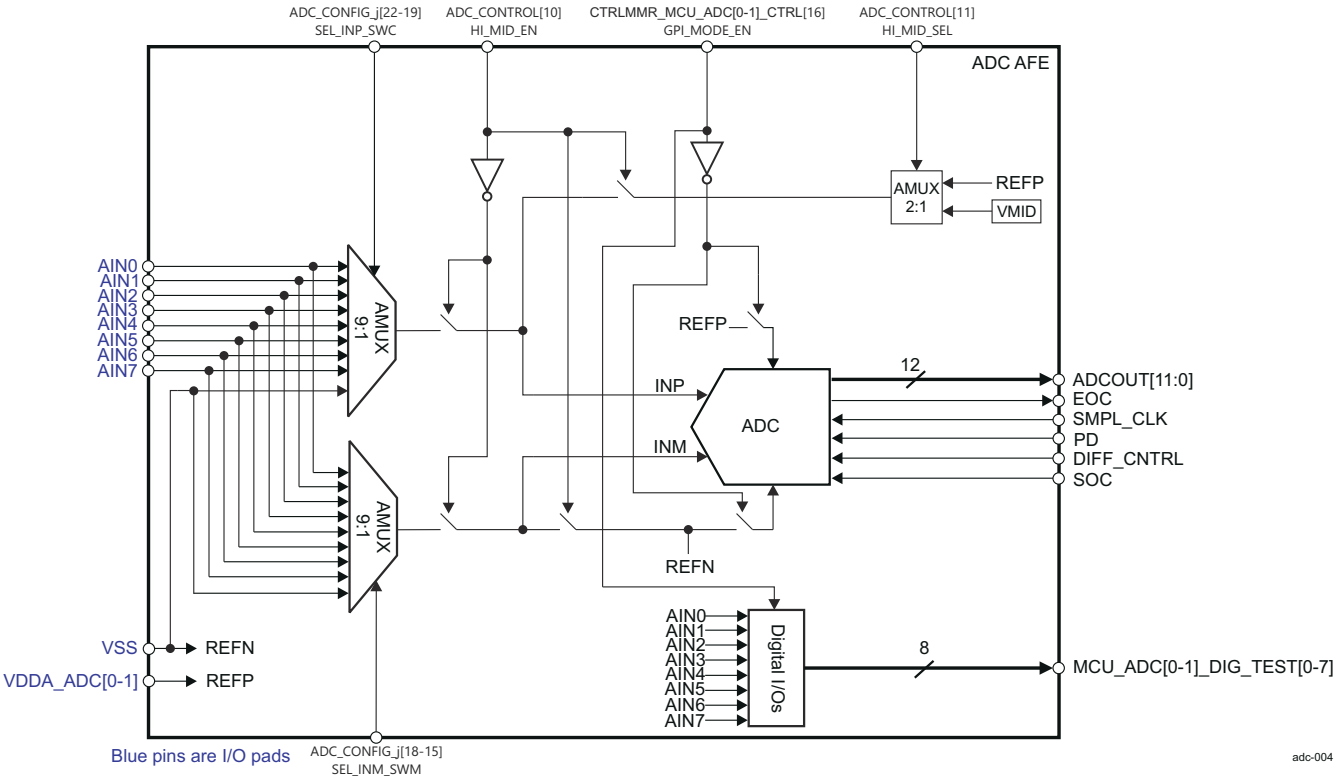

Figure 12-4. Functional Block Diagram

12.1.1.3 ADC FIFOs and DMA

12.1.1.3.1 FIFOs

There are two sample FIFOs (ADC_FIFO0 and ADC_FIFO1), which store sample data from the AFE. Can be configured, via the respective ADC_CONFIG_j register.

The processor can read ADC data directly from the FIFO by using the respective ADC_FIFO0DATA or ADC_FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after the ADC is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling the ADC.

12.1.1.3.2 DMA

The ADC has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the ADC_DMAENABLE_SET register and disabled via the ADC_DMAENABLE_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in DMAREQLEVEL of the respective ADC_FIFO0DMAREQ or ADC_FIFO1DMAREQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

Copyright © 2023 Texas Instruments Incorporated

12.1.1.3.4 ADC Error Correcting Code (ECC)

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC Aggregator provides a single EOI-handshake based interrupt to the host (for both single and double error detections).

The ECC Aggregator will write 0's to all of memory after reset is released. The ADC_SEQUENCER_STAT[6] MEM_INIT_DONE bit will be 0 during this period and will be set to 1 upon completion.

For more information about the ECC Aggregator, see *ECC Aggregator* and *ADC ECC Registers*.

See also *Testing ECC Error Injection* and *ADC ECC Registers*.

12.1.1.3.4.1 Testing ECC Error Injection

The read enable (REN) input to the RAMs instantiated in this module are constantly tied to 1'b1. As a result, read is continuously in progress.

In order to test ECC single error injection on a particular RAM row, the following conditions have to be maintained before setting the ADC_ECC_CTRL[3] FORCE_SEC bit:

- ADC_ECC_CTRL[5] FORCE_N_ROW bit has to be clear. This is required in order to configure required row in
- ADC_ECC_CTRL[6] ERROR_ONCE bit has to be clear. If this bit is set, the ECC error occurs immediately after setting ADC_ECC_CTRL[3] FORCE_SEC bit since REN is always set
- ADC_ECC_ERR_CTRL1[31-0] ECC_ROW bit field has to be point to the required row address

12.1.1.3.5 ADC Functional Debug Mode

The ADC function can be validated by measuring known reference voltage sources. This feature provides register control that connects the AFE to known reference voltage sources. However, it does not automatically configure the FSM to perform conversions to measure these sources. Software will need to configure the FSM to perform a measurement after selecting this mode of operation.

ADC_CONTROL[10] HI_MID_EN is used to disconnect the AFE from all analog inputs and connect it to one of two known reference voltage sources. ADC_CONTROL[11] HI_MID_SEL is used to select REFP or VMID as the known reference voltage source.

The conversion results is expected to produce a full scale value when the AFE is connected to REFP and approximate half scale value when the AFE is connected to VMID.

The steps are:

- Disable the ADC if previously enabled and wait until the FSM is not busy.
- Put the AFE in a functional debug mode by setting the ADC_CONTROL[10] HI_MID_EN bit to 1.
- Select one of the two reference voltage sources by setting the ADC_CONTROL[11] HI_MID_SEL bit.
  - 0 selects VMID
  - 1 selects REFP
- Configure the FSM to measure the selected reference voltage source.
- Enable the ADC and evaluate the results.
- When debug is complete, disable the ADC and wait until the FSM is not busy, re-program the FSM for functional operation, then re-enable the ADC.

12.1.2 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Input/Output (GPIO) for the device.

12.1.2.1 GPIO Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, the user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce host CPU interrupts and DMA synchronization events in different interrupt/event generation modes.

12.1.2.1.1 GPIO Features

Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:
  - Can enable interrupts for each bank of 16 GPIO signals
  - Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO signal
- Set/clear functionality:
  - Firmware writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple firmware processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
  - If preferred by firmware, some GPIO output signals can be toggled by direct write to the output register(s) in addition to set/clear.
  - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status this allows wired logic to be implemented.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

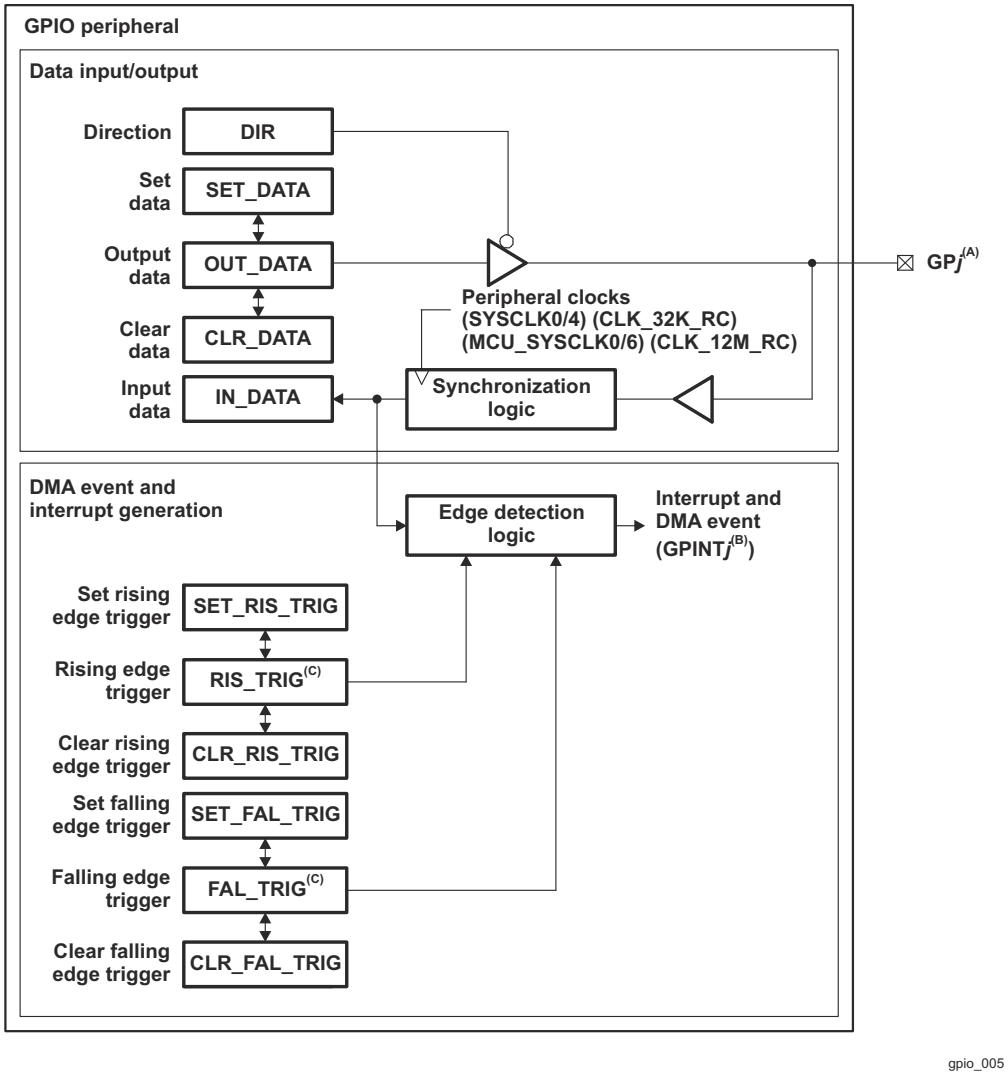
12.1.2.3 GPIO Functional Description

12.1.2.3.1 GPIO Block Diagram

Figure 12-5 shows the general-purpose interface block diagram.



A. Some of the GPj pins are muxed with other device signals. For details, see the device-specific Datasheet.
B. All GPINTj can be used as host CPU interrupts and synchronization events to the DMA.
C. The RIS_TRIG and FAL_TRIG registers are internal to the GPIO module and are not visible to the host CPU.

Figure 12-5. GPIO Block Diagram

12.1.2.3.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 0x1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 0x1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO_SET_DATA01 register.
- Write 0h to the GPIO_DIR01 register to configure as output pin.

Copyright © 2023 Texas Instruments Incorporated

- Read in GPIO_OUT_DATA01 register, change bit 8 to 0x1, and write the new value back to GPIO_OUT_DATA01.

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO_CLR_DATA01 register.
- Write 0h to the GPIO_DIR01 register to configure as output pin.
- Read in GPIO_OUT_DATA01 register, change bit 8 to 0x0, and write the new value back to GPIO_OUT_DATA01.

Note that writing a 0x0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN_DATA) will return the pin state. Reading the SET_DATA register or the CLR_DATA data register will return the value in OUT_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

12.1.2.3.3 GPIO Interrupt and Event Generation

Each GPIO pin (GPj) can be configured to generate a host CPU interrupt (GPINTj) or a synchronization event to the DMA (GPINTj). Configuration is on per-bank basis. Each bit of the BINT_EN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt and DMA event can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt or DMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts or DMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt or DMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPINT pin is configured as input, transitions on the pin trigger interrupts. When the GPINT pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPINT signal are available at the module boundary. Each group of 16 GPINT signals also has their masked interrupt outputs ORed together to generate a per bank interrupt, available at the module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

12.1.2.3.3.1 Interrupt Enable (per Bank)

The GPIO_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

12.1.2.3.3.2 Trigger Configuration (per Bit)

Two internal registers, RIS_TRIG and FAL_TRIG, specify which edge of the GPj signal generates an interrupt or DMA event. Each bit in these two registers corresponds to a GPj pin. Table 12-9 describes the host CPU interrupt and DMA event generation of GPj pin based on the bit settings of the RIS_TRIG and FAL_TRIG registers.

Table 12-9. GPIO Interrupt and DMA Event Configuration Options

RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
0	0	GPINTj interrupt and DMA event is disabled
0	1	GPINTj interrupt and DMA event is triggered on falling edge of GPj signal
1	0	GPINTj interrupt and DMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and DMA event is triggered on both rising and falling edge of GPj signal

Copyright © 2023 Texas Instruments Incorporated

The RIS_TRIG and FAL_TRIG registers are not directly accessible or visible to the host CPU. These registers are accessed indirectly through four registers: SET_RIS_TRIG, CLR_RIS_TRIG, SET_FAL_TRIG, and CLR_FAL_TRIG. Writing 1 to a bit on the SET_RIS_TRIG register sets the corresponding bit on the RIS_TRIG register. Writing 1 to a bit of the CLR_RIS_TRIG register clears the corresponding bit on the RIS_TRIG register. Writing to the SET_FAL_TRIG and CLR_FAL_TRIG registers works the same way on the FAL_TRIG register.

Reading the SET_RIS_TRIG or CLR_RIS_TRIG register returns the value of the RIS_TRIG register. Reading from the SET_FAL_TRIG and CLR_FAL_TRIG register returns the value of the FAL_TRIG register.

To use the GPIO pins as sources for host CPU interrupts and DMA events, bit 0 in the bank interrupt enable register (GPIO_BINTEN) must be set to 1.

12.1.2.3.3.3 Interrupt Status and Clear (per Bit)

The INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note

The GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

12.1.2.3.4 GPIO Emulation Halt Operation

The GPIO peripheral is not affected by emulation halts.

12.1.3 Inter-Integrated Circuit (I2C) Interface

This section describes the Inter-Integrated Circuit (I2C) module in the device.

12.1.3.1 I2C Overview

The device contains Inter-Integrated Circuit (I2C) controllers each of which provides an interface between a local host (LH), such as an Arm or a Digital Signal Processor (DSP), and any I^2C-bus-compatible device that connects via the I^2C serial bus. External components attached to the I^2C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I^2C interface.

Each multimaster I2C module can be configured to act like a slave or master I^2C-compatible device.

Some controllers have dedicated I^2C compliant open drain buffers and support high speed mode (up to 3.4 Mbps in 1.8 V mode and up to 400 Kbps in 3.3 V mode). Other controllers are multiplexed with standard LVCMOS I/O, connected to emulate open drain, and support fast mode (up to 400 Kbps in 1.8 V/3.3 V mode). The I^2C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1.

For the specific I/O buffer and timing characteristics of the different I2C instances, see the device-specific data sheet.

12.1.3.1.1 I2C Features

Each multicontroller I2C module has the following features:

- Compliant with Philips I^2C-bus specification version 2.1
- Supports a standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode (up to 3.4 Mbps) on some instances. See the the device-specific Data Manual for details.
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multicontroller transmitter/target receiver mode
- Multicontroller receiver/target transmitter mode
- Combined controller transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read
- Module enable/disable capability
- Programmable multitarget channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Low power consumption
- Support Auto Idle mechanism
- Support Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Wide interrupt capability

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

The ten multimaster I2C controllers can be configured in F/S I^2C mode or HS I^2C mode. The operation mode is selected by configuring the I2C_CON[13-12] OPMODE bit field.

Table 12-16 lists the available operation modes.

Table 12-16. I^2C Operation Mode Selection

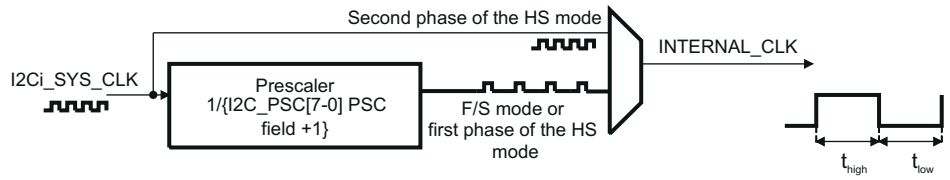
Operation Mode	Value of I2C_CON[13-12] OPMODE
F/S I^2C	0x0
HS I^2C	0x1
SCCB	0x2
Reserved (not used)	0x3

12.1.3.3.2 I2C Clocks

12.1.3.3.2.1 I2C Clocking

Figure 12-7 shows the I^2C clock generation of the I2C controllers.

Copyright © 2023 Texas Instruments Incorporated



(1) i = 0 for WKUP domain
(2) i = 0 to 1 for MCU domain
(3) i = 0 to 6 for MAIN domain

Figure 12-7. I2C Clock Generation

Each multimaster I2C controller uses the SYS_CLK functional clock in the Device Configuration section. The internal sampling clock INTERNAL_CLK is generated by dividing the functional clock by the I2C_PSC[7-0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the SCLL signal is determined by the I2C_SCLL[7-0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C_SCLL[15-8] HSSCLL bit field in the second phase of HS mode.

The high time of the SCLH signal is determined by the I2C_SCLH[7-0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C_SCLH[15-8] HSSCLH bit field in the second phase of HS mode.

Table 12-17 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I2C controller does not generate the I^2C clock).

Table 12-17. I^2C t_{LOW} and t_{high}Values of the I^2C Clock

Mode	Clock	t_{LOW}	t_{high}
F/S or HS first phase	INTERNAL_CLK = SYS_CLK / (I2C_PSC[7-0] PSC bit field + 1)	(I2C_SCLL[7-0] SCLL bit field value + 7) × INTERNAL_CLK period	(I2C_SCLH [7-0] SCLH bit field value + 5) × I2Ci_INTERNAL_CLK period
HS second phase	SYS_CLK	(I2C_SCLL[15-8] HSSCLL bit field value + 7) × SYS_CLK period	(I2CSCLL [15-8] HSSCLH bit field value + 5) × I2Ci_SYS_CLK period

Note

For HS mode, the I2C_SCLL[15-8] HSSCLL and I2C_SCLL[7-0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C_SCLH[15-8] HSSCLH and I2C_SCLH[7-0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

Note

The equations in Table 12-17 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I2C controller outputs. Actual t_{low} and thigh periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2C_SCLL and I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 12-18 lists the register values for obtaining the maximum I^2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Copyright © 2023 Texas Instruments Incorporated

Table 12-18. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes

	I²C Mode for			Description
	Standard Mode	**Fast Mode**	**High-Speed Mode**	
SYS_CLK frequency (MHz)	96			
OCP_CLK frequency (MHz)	133			
I2C_PSC[7-0] PSC	**23**	**9**	**1**	Prescaler value for F/S and HS modes
INTERNAL_CLK frequency (MHz)	4	9.6	96	
I2C_SCLL[7-0] SCLL	**13**	**7**	**115**	Value for F/S mode and first phase of HS mode
I2C_SCLH[7-0] SCLH	**15**	**5**	**113**	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
I2C_SCLL[15-8] HSSCLL			**12**	Values for second phase of HS mode
I2C_SCLH[15-8] HSSCLH			**5**	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

Note

This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

Note

For WKUP_I2C0

For MCU_I2C[0-1]

For I2C[0-6]

I2Ci_INTERNAL_CLK freq = I2Ci_SYS_CLK / (PSC +1)

F/S filter period = 1 / I2Ci_INTERNAL_CLK

HS filter period = 1 / I2Ci_SYS_CLK freq

HS bit rate = I2Ci_SYS_CLK freq / (HSSCLL+ 7 + HSSCLH + 5)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL+ 7 + SCLH + 5)

12.1.3.3.2.2 I2C Automatic Blocking of the I2C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the target addressing phase, when the I2C controller is addressed by an external controller device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2C_OA, and I2C_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2C_SBLOCK register.

12.1.3.3.3 I2C Software Reset

Each multicontroller I2C supports the software reset by accessing the I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

Copyright © 2023 Texas Instruments Incorporated

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C_CON[15] I2C_EN bit to 0).
2. Set the I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C_CON[15] I2C_EN bit to 1.
4. Check the I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

Note

The I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multicontroller I2C in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I2C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I2C controller.

The I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C_CON[15] I2C_EN bit to 1.

12.1.3.3.4 I2C Power Management

Table 12-19 describes power-management features available for the multimaster I2C controllers.

Note

For information about source clock gating, see *Power*, in the *Device Configuration*.

Note

Some of the I2C features described in this section may not be supported on this family of devices. For more information, see *I2C Not Supported Features*.

Table 12-19. I2C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C_SYSC[9-8] CLOCKACTIVITY	For configuration details, see Table 12-20.
Global wake-up enable	I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

Table 12-20. I2C Clock Activity Settings

I2C_SYSC[9-8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	OCP_CLK	SYS_CLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; Functional clock is enabled
01	ON	OFF	Functional clock is disabled; Interface clock is enabled
11	ON	ON	Both clocks are enabled.

12.1.3.3.5 I2C Interrupt Requests

The I2C controller must allocate a minimum of five registers for interrupts.

- Interrupt Raw Status (I2C_IRQSTATUS_RAW)
- Interrupt Enabled Status (I2C_IRQSTATUS)
- Interrupt Enable Set (I2C_IRQENABLE_SET)
- Interrupt enable Clear (I2C_IRQENABLE_CLR)
- End of interrupt (I2C_EOI)

End of Interrupt (I2C_EOI) is used by software to trigger an interrupt service completion.

Table 12-21 lists the event flags, and their mask, that can cause module interrupts.

Copyright © 2023 Texas Instruments Incorporated

Table 12-21. I2C Events

Event Flag	Event Unmask	Event Mask	Description
I2C_IRQSTATUS[0] AL	I2C_IRQENABLE_SET[0] AL_IE	I2C_IRQENABLE_CLR[0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in controller transmit mode, an interrupt is signaled to the host.
I2C_IRQSTATUS[1] NACK	I2C_IRQENABLE_SET[1] NACK_IE	I2C_IRQENABLE_CLR[1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C_IRQSTATUS[2] ARDY	I2C_IRQENABLE_SET[2] ARDY_IE	I2C_IRQENABLE_CLR[2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C_IRQSTATUS[3] RRDY	I2C_IRQENABLE_SET[3] RRDY_IE	I2C_IRQENABLE_CLR[3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C_IRQSTATUS[4] XRDY	I2C_IRQENABLE_SET[4] XRDY_IE	I2C_IRQENABLE_CLR[4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C_IRQSTATUS[5] GC	I2C_IRQENABLE_SET[5] GC_IE	I2C_IRQENABLE_CLR[5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[6] STC	I2C_IRQENABLE_SET[6] STC_IE	I2C_IRQENABLE_CLR[6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[7] AERR	I2C_IRQENABLE_SET[7] AERR_IE	I2C_IRQENABLE_CLR[7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C_IRQSTATUS[8] BF	I2C_IRQENABLE_SET[8] BF_IE	I2C_IRQENABLE_CLR[8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C_IRQSTATUS[9] AAS	I2C_IRQENABLE_SET[9] AAS_IE	I2C_IRQENABLE_CLR[9] AAS_IE	Address recognized as target. An interrupt is signaled to the host.
I2C_IRQSTATUS[10] XUDF	I2C_IRQENABLE_SET [10] XUDF_IE	I2C_IRQENABLE_CLR[10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C_IRQSTATUS[11] ROVR	I2C_IRQENABLE_SET [11] ROVR_IE	I2C_IRQENABLE_CLR[11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C_IRQSTATUS[13] RDR	I2C_IRQENABLE_SET [13] RDR_IE	I2C_IRQENABLE_CLR[13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C_IRQSTATUS[14] XDR	I2C_IRQENABLE_SET [14] XDR_IE	I2C_IRQENABLE_CLR[14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

12.1.3.3.6 I2C Programmable Multitarget Channel Feature

This feature allows each multicontroller I2C to be addressed using four separate Own Addresses configured in the I2C_OA and I2C_OAx registers (where x = 1, 2, 3). An additional register (I2C_ACTOA) is used to indicate to the LH which address is used by the external controller to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C_CON[7] XOA0, I2C_CON[6] XOA1, I2C_CON[5] XOA2, or I2C_CON[4] XOA3).

12.1.3.3.7 I2C FIFO Management

Each multicontroller I2C implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2C_BUFSTAT[15-14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

Copyright © 2023 Texas Instruments Incorporated

12.1.3.3.7.1 I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX FIFO or the I2C_BUF[5-0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I2C controller in receive mode and/or from any source to the I2C controller FIFO in transmit mode).

Figure 12-8 and Figure 12-9 show receive and transmit operations, respectively, from a FIFO management point of view.

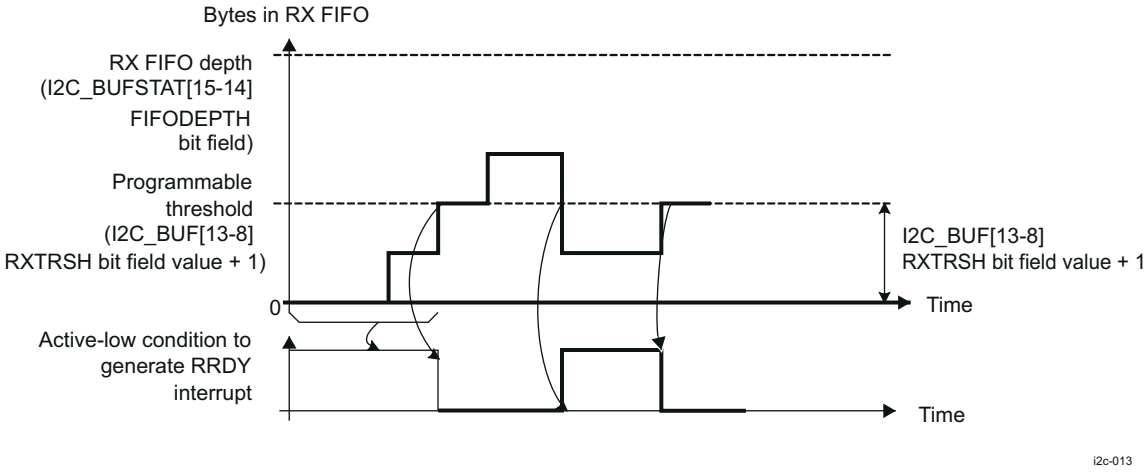


Figure 12-8. I2C Receive FIFO Interrupt Request Generation

In Figure 12-8 , the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C_BUF[13-8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

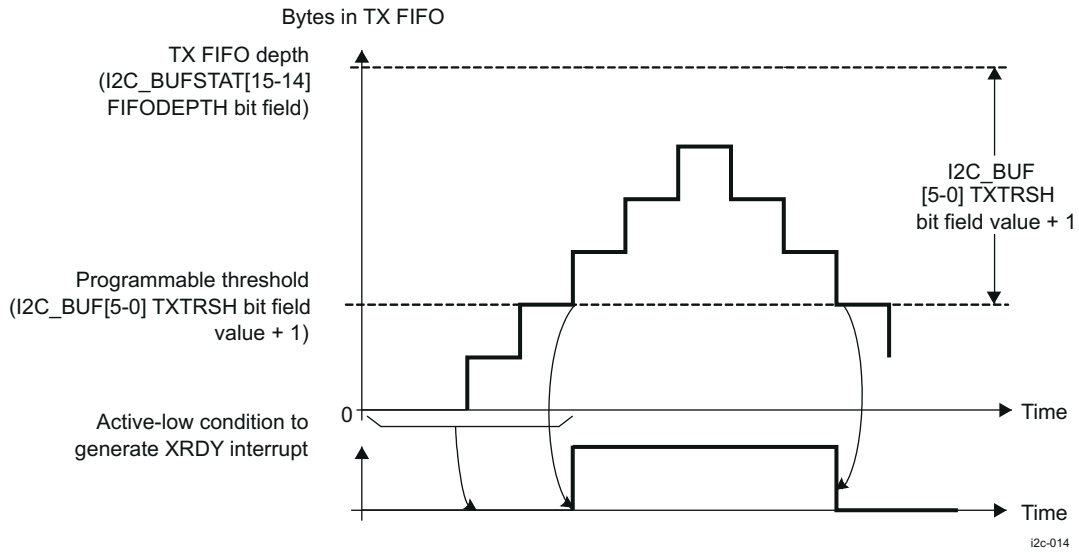

Figure 12-9. I2C Transmit FIFO Interrupt Request Generation

Copyright © 2023 Texas Instruments Incorporated

In Figure 12-9 , the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5-0] TXTRSH + 1 or I2C_BUF[5-0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 12.1.3.3.7.3, *Draining Feature [I2C Mode Only]*).

Note

In target transmit mode (the I2C_CON[10] MST bit is cleared and the I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external controller can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in target transmit mode, data can remain in the TX FIFO without being transmitted over the I^2C bus. In this case, the TX FIFO must be cleared by setting the I2C_BUF[6] TXFIFO_CLR bit.

12.1.3.3.7.2 I2C FIFO Polling Mode

In FIFO polling mode (the I2C_IRQENABLE_SET[4] XRDY_IE and I2C_IRQENABLE_SET[3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C_IRQSTATUS_RAW[4] XRDY and the I2C_IRQSTATUS_RAW[3] RRDY bits (the I2C_IRQSTATUS_RAW[13] RDR and I2C_IRQSTATUS_RAW[14] XDR bits can also be polled if the draining feature is enabled). The I2C_IRQSTATUS_RAW[4] XRDY and I2C_IRQSTATUS_RAW[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

12.1.3.3.7.3 I2C Draining Feature

Note

DMA mode and SCCB Protocol are not supported on this family of devices.

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold and the I2C_BUF[5-0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C_IRQSTATUS_RAW[7] AERR bit.

The draining mechanism generates an interrupt using the I2C_IRQSTATUS_RAW[13] RDR or I2C_IRQSTATUS_RAW[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C_BUFSTAT[13-8] RXSTAT or I2C_BUFSTAT[5-0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

Copyright © 2023 Texas Instruments Incorporated

In receive mode (controller or target), if the RX FIFO threshold (the I2C_BUF[13-8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I^2C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C_IRQSTATUS_RAW[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C_BUFSTAT[13-8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C_BUFSTAT[13-8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In controller transmit mode, if the TX FIFO threshold (the I2C_BUF[5-0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C_IRQSTATUS_RAW[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C_BUFSTAT[5-0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C_BUFSTAT[5-0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In controller mode, the LH can alternately not check the values of the I2C_BUFSTAT[5-0] TXSTAT and I2C_BUFSTAT[13-8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C_CNT[15-0] DATACOUNT bit field value modulo I2C_BUF[13-8] RXTRSH or I2C_BUF[5-0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C_IRQENABLE_SET[14] XDR_IE or I2C_IRQENABLE_SET[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C_BUF[5-0] TXTRSH bit field value + 1 for the TX threshold or the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold).

12.1.3.3.8 I2C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C_PSC[7-0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2C*i*.I2C_PSC[7-0] PSC bit field.

12.1.3.3.9 I2C System Test Mode

A system test mode is available for multicontroller I2C module testing. This mode is enabled by setting the I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I2C controller is configured in normal operation mode.

In system test mode, the I2C_SYSTEST[13-12] TMODE bit field selects the type of test. Table 12-22 lists the tests available for the multicontroller HS I2C controllers.

Table 12-22. I2C List of Tests

I2C_SYSTEST[13-12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of SCL serial clock line	The SCL line is driven with a permanent clock as if controlled with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
11	Loop-back mode + SCL/SDA I/O	In controller transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register through an internal path through the FIFO buffers. The interrupt request is normally generated if it is enabled. Moreover, the SCL and SDA are controlled with the I2C_SYSTEST[3-0] bits.

Copyright © 2023 Texas Instruments Incorporated

Note

When the I2C_SYSTEST[13-12] TMODE bit field is set to 11, the I2C controller must be configured in I^2C F/S (I2C_CON[13-12] OPMODE set to 00) or I^2C HS mode (I2C_CON[13-12] OPMODE set to 01).

Note

In normal operation mode (the I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2C_SYSTEST[3-0] bits that control the SCL, SDA lines in system test mode are read-only bits.

In system test mode (the I2C_SYSTEST[15] ST_EN bit set to 1), the I2C_IRQSTATUS_RAW[4] XRDY, I2C_IRQSTATUS_RAW[3] RRDY, I2C_IRQSTATUS_RAW[10] XUDF, I2C_IRQSTATUS_RAW[11] ROVR, I2C_IRQSTATUS_RAW[2] ARDY and I2C_IRQSTATUS_RAW[1] NACK status bits can be set to 1 when the I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C_IRQSTATUS_RAW bits to 0. The I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

12.1.3.4 I2C Programming Guide

12.1.3.4.1 I2C Low-Level Programming Models

12.1.3.4.1.1 I2C Programming Model

This section describes the programming model of the multimaster I2C controllers configured in I^2C mode.

12.1.3.4.1.1.1 Main Program

12.1.3.4.1.1.1.1 Configure the Module Before Enabling the I2C Controller

Before enabling the I2C controller, perform the following steps:

1. Enable the functional and interface clocks (see *WKUP I2C Clocks and Resets*, *MCU_I2C Clocks and Resets*, and *I2C Clocks and Resets*).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C_PSC[7-0] PSC bit field. This value depends on the frequency of the functional clock (SYS_CLK).
3. Program the I2C_SCLL[7-0] SCLL and I2C_SCLH[7-0] SCLH bit fields to obtain a bit rate of 100 Kbps or 400 Kbps. These values depend on the internal sampling clock frequency (see Table 12-17).
4. (Optional) Program the I2C_SCLL[15-8] HSSCLL and I2C_SCLH[15-8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see Table 12-17).
5. Configure the Own Address of the I2C controller by storing it in the I2C_OA register. Up to four Own Addresses can be programmed in the I2C_OA and I2C_OAx registers (where x = 1, 2, 3) for each I2C controller.

Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C_BUF[5-0] TXTRSH bit field to (TX threshold – 1) and the I2C_BUF[13-8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I2C controller out of reset by setting the I2C_CON[15] I2C_EN bit to 1.

12.1.3.4.1.1.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2C_CON register:
   - For controller or target mode, set the I2C_CON[10] MST bit (0: target; 1: controller).
   - For transmitter or receiver mode, set the I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C_IRQENABLE_SET register to 1 (the I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).

12.1.3.4.1.1.1.3 Configure Target Address and the Data Control Register

In controller mode, configure the target address register by programming the I2C_SA[9-0] SA bit field and the number of data bytes (I^2C data payload) associated with the transfer by programming the I2C_CNT[15-0] DCOUNT bit field.

Note

For a 10-bit address, set the I2C_CON[8] XSA bit to 1.

12.1.3.4.1.1.1.4 Initiate a Transfer

Poll the I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C_CON[0] STT and I2C_CON[1] STP bits. To initiate a transfer, the I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C_CON[1] STP bit to 1.

Copyright © 2023 Texas Instruments Incorporated

12.1.3.4.1.1.1.5 Receive Data

Poll the I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) to read the receive data in the I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C_BUF[13-8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

Note

In receive mode only, the I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I2C controller simply holds SCL to low to prevent other bytes from being received.

The I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

12.1.3.4.1.1.1.6 Transmit Data

Poll the I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) to write data to the I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C_BUF[5-0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

Note

In transmit mode only, the I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In controller transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C_CNT[15-0] DCOUNT bit field is not 0).

In target transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I^2C controller device still requests data bytes to be read.

The I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

12.1.3.4.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

12.1.3.4.1.1.3 Programming Flow-Diagrams

Figure 12-10 through Figure 12-16 are procedure flow charts for programming the F/S and HS I^2C modes.

Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

A. The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C_IRQSTATUS register.

B. Reprogram registers means: I2C_CON[11] STB and/or I2C_CON[10] MST bit and/or I2C_SA[9-0] SA register and/or I2C_CNT[15-0] DCOUNT register and/or I2C_CON[0] STT bit and/or I2C_CON[1] STP bit.

12.1.4 Improved Inter-Integrated Circuit (I3C) Interface

This section describes the Improved Inter-Integrated Circuit (I3C) module in the device.

12.1.4.1 I3C Overview

The device contains Improved Inter-Integrated Circuit (I3C) an interface between a local host (LH), such as an Arm, and any I3C-bus-compatible device that connects via the I3C serial bus.

For the specific I/O timing characteristics of the I3C , see the device-specific data sheet.

12.1.4.1.1 I3C Features

I3C module has the following features:

- Communication Modes:
  - Single Data Rate (SDR) mode
  - High Data Rate – Dual Data Rate (HD-DDR) mode
- Bus Modes:
  - Pure Bus Mode (supports only I3C devices). Maximum supported frequency is 10.375 MHz
- Master and Multi-Master modes
- Common Command Codes (CCC)
- Bus Enumeration and Discovery:
  - Slaves implement standardized characteristics registers that can be queried by the master after power up to enumerate the devices attached to the bus.
- Hot-Join capability:
  - A slave device can be powered on and join the bus after initial enumeration.
- In Band Interrupts (IBI):
  - Slave devices request interrupts through the I3C bus rather than with separate side-band signals. This reduces the total IO count of the SoC as well as PCB routing.
- Dynamic Address Assignment (DAA):
  - The master can assign each slave device an address during configuration. This supports IBI because interrupt priority among slaves is arbitrated with the same address arbitration scheme that is used for all communication.
- Static Addressing (SA)
- FIFO Buffers:
  - CMD Queueing out going commands:
    - CMD0_FIFO stores the least significant half-word of the command
    - CMD1_FIFO stores the most significant half-word of the command
  - TXFIFO stores data transmitted with each command
  - RXFIFO stores data received as command response
  - IBI_DATA_FIFO stores data received as part of the in-band-interrupt transfer (IBI can transfer 0, 1, or N bytes of data payload depending on the slave)
- Immediate high priority command queue
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves:
  - Each register holds the slave address and appropriate response type and payload length information for two different slaves, so that the controller can process in band interrupts without CPU intervention.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.4.3 I3C Functional Description

12.1.4.3.1 I3C Block Diagram

Figure 12-17 presents the I3C controller block diagram.

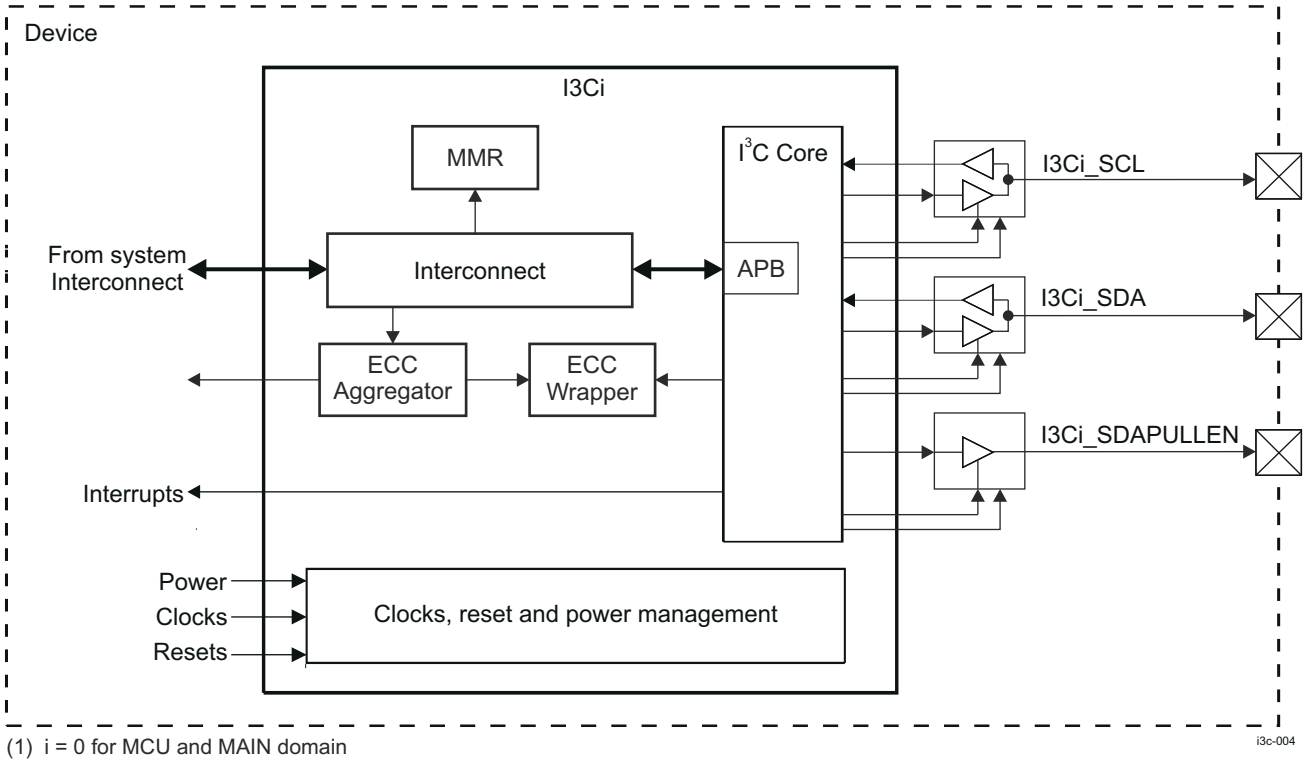

Figure 12-17. I3C Block Diagram

The two I3C controllers can be configured in SDR I^{3}C mode or HD-DDR I^{3}C mode. Default operation mode is SDR mode.

Table 12-26 lists the available operation modes.

Table 12-26. I^{3}C Operation Mode Selection

Operation Mode	Value of I3C_CMD0_FIFO[31] IS_DDR
SDR I^{3}C	0x0
HD-DDR I^{3}C	0x1

12.1.4.3.2 I3C Clock Configuration

The I3C controller allows to program time base for SCL clock generation. Programmable frequency dividers are provided for I^{3}C messaging modes independently. Based on type of messaging that is processed, one of the fields placed in I3C_PRESCL_CTRL0 register is used to establish constant ratio between the clocks and SCL clock for all messaging modes. I3C messaging uses the value of I3C field in I3C_PRESCL_CTRL0 register, and is combined with the frequency of inputs. In order to handle timing requirements specified for I^{3}C slaves I3C_PRESCL_CTRL1 register is provided.

Programming the prescalers should be performed prior to enabling I3C controller with I3C_CTRL[31] DEV_EN bit.

12.1.4.3.2.1 Setting Base Frequencies

To obtain desired base frequency of SCL signal for SDR/HDR I^{3}C messaging (I3C_FREQ) the I3C_PRESCL_CTRL0[9-0] I3C bit-field should be programmed with value defined by the following equation:

Figure 12-18. I3C Base Frequency

Copyright © 2023 Texas Instruments Incorporated

Programming the prescalers must be performed prior to enabling I3C Master controller with I3C_CTRL[31] DEV_EN bit in the control register.

In all timing schemes, the base frequency resulting from prescalers corresponds directly to the duration of the high level of the SCL line which takes always 50% of the base period. Depending on various conditions, the duration of low level is extended beyond the base period as necessary.

There is a specific relationship between SCL frequency and system clock frequency, which requires system clock to have a multiple of four cycles per each SCL period. Thus the selection of system clock frequency must be done with caution, since only specific frequencies will allow configuring SCL to fit into desired bandwidth.

Table 12-27 presents achievable SCL frequencies for exemplary set of system clock frequency values.

Table 12-27. Achievable SCL Frequencies

frequency	I3C_PRESCL_CTRL0[9-0] I3C	Actual frequencies
100 MHz	0x2	8.33 MHz
133 MHz	0x3	8.313 MHz
166 MHz	0x3	10.375 MHz
200 MHz	0x4	10 MHz

12.1.4.3.2.2 Asymmetric Push-Pull SCL Timing

In case of I^3C messaging, asymmetric generation pattern for driving SCL can be enabled. The main purpose for this feature is supporting I3C slaves that are not capable to use maximal SCL frequency during private read/write data transfers. Host can recognize limited speed device by examining value of I3C_DEV_IDn_RR2[15-8] bit-field for n = 0 to 11. Maximum frequency supported by slave can be retrieved by GETMSCL command. The low period of SCL is extended by the value programmed in I3C_PRESCL_CTRL1[15-8] PP_LOW bit-field, which can be calculated using the following equation:

Figure 12-19. SCL Asymmetric Push-Pull

The I3C_PRESCL_CTRL1[15-8] PP_LOW resolution is set to ¼ of SCL period. The high period of the SCL remains unchanged and is equal to half period of I^3C frequency.

The low period used in push-pull mode for slaves with limited SCL capability results from following equation:

$$SCL_LOW = I3C_PRESCL_CTRL1[15\text{-}8]\ PP_LOW \times \frac{T}{4}$$

i3c_014

Where:

SCL_LOW: SCL low period.
T: base SCL period.

Figure 12-20. SCL Asymmetric Push-Pull Actual Low Period

12.1.4.3.2.3 Open-Drain SCL Timing

In open-drain mode, due to protocol requirement, low period cannot be shorter than 160ns to support slowly rising SDA line. To fulfill this constrain in I^3C SDR mode, the low period must be always extended beyond the value resulting from the base I^3C frequency. The low period of SCL is extended by the value programmed in I3C_PRESCL_CTRL1[7-0] OD_LOW bit-field, which can be calculated using the following equation:

Figure 12-21. SCL Open-Drain Low Period

The I3C_PRESCL_CTRL1[7-0] OD_LOW bit-field resolution is set to ¼ of SCL period. The high period remains unchanged and is equal to half-period of I^3C frequency.

The actual SCL low period used in open drain mode results from the following equation:

Copyright © 2023 Texas Instruments Incorporated

$$SCL_LOW = I3C_PRESCL_CTRL1[7\text{-}0]\ OD_LOW \times \frac{T}{4}$$

i3c_015

Where:

SCL_LOW: SCL low period.
T: base SCL period.

Figure 12-22. SCL Open-Drain Actual Low Period

12.1.4.3.2.4 Changing Programmed Frequencies

Since SCL clock is derived, in order to change the SCL timing for any mode or to keep current I^3C bus timing, the following procedure should be used:

1. Disable the I3C controller by setting the I3C_CTRL[31] DEV_EN bit to 0.
2. Adjust to the new frequency if necessary, avoiding any glitches during change.
3. Reprogram the prescaler registers to achieve desired I^3C timing.
4. Enable the core by setting the I3C_CTRL[31] DEV_EN bit to 1.

12.1.4.3.3 I3C Interrupt Requests

The I3C controller has two sets of five interrupt registers:

- Interrupt Enable Register (I3C_MST_IER)
- Interrupt Disable Register (I3C_MST_IDR)
- Interrupt Mask Register (I3C_MST_IMR)
- Interrupt Clear Register (I3C_MST_ICR)
- Interrupt Status Register (I3C_MST_ISR)

After reset, status (I3C_MST_ISR) and mask (I3C_MST_IMR) registers both read zeroes, so all interrupts are disabled. CPU handles interrupts by several typical operations:

- To activate an interrupt, interrupt enable register (I3C_MST_IER) should be programmed with 0x1 on bit positions corresponding to interrupts sources which should be signaled to CPU. This interrupt mask is written to I3C_MST_IMR and defines which sources will be propagated.
- After receiving interrupt, I3C_MST_ISR should be read to identify the interrupt source. Since I3C_MST_ISR is always updated by all interrupt sources regardless of I3C_MST_IMR, the I3C_MST_ISR value should be compared to the programmed mask (stored in software or read from I3C_MST_IMR) as it can contain other flags which were not propagated. Interrupt handler should clear flag which triggered interrupt in I3C_MST_ISR by writing 0x1 to corresponding bits of I3C_MST_ICR. It is crucial for correct interrupt source identification to read status, apply mask and clear current interrupt flag before another (from the same or different source) interrupt can occur, so these actions should be executed at the beginning of the interrupt handler routine.
- If during operation additional interrupt sources need to be enabled, clearing their flags prior to enabling is necessary to avoid false signaling of events which occurred earlier.
- To disable interrupt source anytime during operation, corresponding bit in interrupt disable register (I3C_MST_IDR) should be programmed with 0x1, which in turn clears corresponding bit in I3C_MST_IMR, disabling interrupt source.

12.1.4.3.4 I3C Power Configuration

Before I3C controller is put into operation, several settings need to be adjusted after cycling the power on. The general settings collected in I3C_CTRL register. For most common usage scheme, two fields are the most important:

1. I3C_CTRL[31] DEV_EN bit allows enabling and disabling the I^3C bus controller. It must be enabled before any I^3C bus message is initiated, however following settings need to be programmed prior to enabling controller:
   a. Bus Mode (Only Pure Bus Mode is supported)
   b. SCL Divider prescalers (See *I3C Clock Configuration*)
   c. Devices Retaining Registers (See *I3C Retaining Registers Space*)

   During normal operation the controller should stay enabled. Before disabling, the I3C_MST_STATUS0[18] IDLE should be examined to confirm that no bus operation is pending.

Copyright © 2023 Texas Instruments Incorporated

2. I3C_CTRL[1-0] BUS_MODE bit-field is set to Pure Bus Mode by default. The I3C controller supports only I^3C compatible devices on I^3C bus and if changed bit-field has no effect. For more information see *I3C Not Supported Features*.

12.1.4.3.5 I3C Dynamic Address Management

Enumeration of I3C devices involves Dynamic Address Assignment procedure. At power up of the I^3C bus, the I^3C Master should provide dynamic address for all I^3C devices under the following conditions:

- If I^3C Slave devices with Static Address are available (not supported for this device), firmware may choose to assign Dynamic Address using SETDASA CCC to shorten bus initialization time; such devices are called Static I^3C Devices.
- For the devices that are enumerated using SETDASA CCC command the Provisional ID, BCR and DCR information should be manually acquired, using GETPID / GETBCR / GETDCR CCC commands. This step is not mandatory if the values are known prior to bus initialization and programmed into I^3C Master by host application.
- Devices with no Static Address and these with Static Address not enumerated receive Dynamic Address using the DAA procedure initiated by issuing the ENTDAA CCC command.
- For the devices that are enumerated using ENTDAA CCC command the Provisional ID, BCR and DCR information are automatically received during DAA procedure.

During I^3C bus operation, current master can disable one or all I3C devices by sending Direct or Broadcast RSTDAA CCC command. In such case, corresponding *_CLR bits in I3C_DEVS_CTRL should be set by firmware to clean retaining registers. In order to re-enable these devices, DAA procedure must be performed (initiated by master or by Hot-Join requests sent by slave devices).

Depending on I^3C slave implementation, the slave that received RSTDAA CCC command may restore its static address. In order to perform private transfers to such slave or assign dynamic address using SETDASA CCC command rather than DAA procedure, the corresponding I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit field (n = 0 to 11) should be updated with static address. Clearing Retaining Registers by setting corresponding I3C_DEVS_CTRL register is not mandatory in this scenario.

Current master can also assign new Dynamic Address to device which already has one by sending SETNEWDA command. After sending this command with new Dynamic Address in the data field, the I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit field (n = 0 to 11) must be also updated with this address in order to perform subsequent transaction to this device.

12.1.4.3.6 I3C Retaining Registers Space

The information on configuration, Provisional ID, BCR and DCR of each device connected to the I^3C bus is stored by the I^3C master in a set of retaining registers divided into Device ID sections associated with each device. Application host take any action to guarantee maintaining this information anytime the bus topology changes.

The retaining register space is divided to up to 12 sections (depending on selected configuration), from I3C_DEV_ID0 to I3C_DEV_ID11. Each containing three 32-bit registers to hold whole necessary information on I3C devices connected to the bus (e.g. hot-join device is attached, some of DA are reset to new value, etc.).

The AMBA APB interface address space for retaining registers starts at 0x080 and is divided into 12 quadruplets.

The map organization is presented in Table 12-28 below.

Table 12-28. Retaining Registers Map Organization

Register	Address	Contents
I3C_DEV_ID0_RR0	0x080	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID0_RR1	0x084	Register stores MSB of Provisional ID (1)
I3C_DEV_ID0_RR2	0x088	Register stores LSB of Provisional ID, DCR, BCR (1)
I3C_DEV_ID1_RR0	0x090	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID1_RR1	0x094	Register stores MSB of Provisional ID (1)
I3C_DEV_ID1_RR2	0x098	Register stores LSB of Provisional ID, DCR, BCR (1)

Copyright © 2023 Texas Instruments Incorporated

Table 12-28. Retaining Registers Map Organization (continued)

Register	Address	Contents
I3C_DEV_ID2_RR0	0x0A0	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID2_RR1	0x0A4	Register stores MSB of Provisional ID (1)
I3C_DEV_ID2_RR2	0x0A8	Register stores LSB of Provisional ID, DCR, BCR (1)
...	...	...
I3C_DEV_ID11_RR0	0x130	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID11_RR1	0x134	Register stores MSB of Provisional ID (1)
I3C_DEV_ID11_RR2	0x138	Register stores LSB of Provisional ID, DCR, BCR (1)

(1) The information is relevant only for I^3C devices and is automatically filled by hardware during DAA procedure. Application host needs to fill the information for all devices with Dynamic Addresses Assignment with SETDASA CCC command.

A special device control register (I3C_DEVS_CTRL) is provided to store information on devices currently connected to the bus. Each DeviceID section contains configuration register and two registers holding Provisional ID, BCR and DCR of the corresponding device. The active state bit is set automatically by hardware after Dynamic Address is assigned to given device. Firmware shall set it for devices enumerated with SETDASA CCC command after their Retaining Registers are configured and before any transaction to these devices is initiated.

The clearing bits need to be set by firmware every time RSTDAA CCC is send to corresponding devices (firmware should clear all of them for broadcast RSTDAA) or controller constantly receives NACK response and application recognizes device as no longer connected to the bus.

12.1.4.3.7 I3C Dynamic Address Assignment Procedure

The I3C bus initialization procedure can be decomposed into three main stages, described below:

- **Stage 1:** On startup, the I3C master does not have any information about I^3C slave devices and all Retaining Registers are set to the default reset vector table;
- **Stage 2:** Is fully maintained by application host. The first register section (Device ID0) is reserved for I3C master self-description. The following registers starting from Device ID1 will be filled by DAA procedure in Stage 3. This implies rules firmware should follow:
  - I^3C devices with Static Address which firmware assume to enumerate with SETDASA CCC command shall be localized in Retaining Registers table (see Figure 12-23) after address space that reserved for I^3C devices intended to be enumerated with ENTDAA;
  - Corresponding I3C_DEVS_CTRL bits for active should be set;
- **Stage 3:** Before attempting DAA procedure, firmware should take following actions:
  - For Static I3C Devices intended to be enumerated with SETDASA CCC command:
    - Configuration registers should be programmed with Static Addresses and other settings relevant for I3C device;
    - Corresponding I3C_DEVS_CTRL bits for active should be set;
    - Dynamic Addresses should be assigned using SETDASA CCC command;
    - Configuration registers should be programmed with just assigned Dynamic Addresses;
    - Provisional ID / BCR / DCR Registers (I3C_DEV_IDn_RR1 and I3C_DEV_IDn_RR1, n = 0 to 11) should be programmed with data either predefined by application or obtained by reading PID / BCR / DCR with related CCC;
  - For I^3C Devices intended to be enumerated with ENTDAA CCC command:
    - Configuration registers should be programmed with Dynamic Addresses and other settings relevant for I3C Device;

Once all above conditions are satisfied the firmware can issue the ENTDAA CCC command, which is considered as start condition for Stage 3.

Figure 12-23 presents the I3C bus initialization for DAA procedure.

Copyright © 2023 Texas Instruments Incorporated

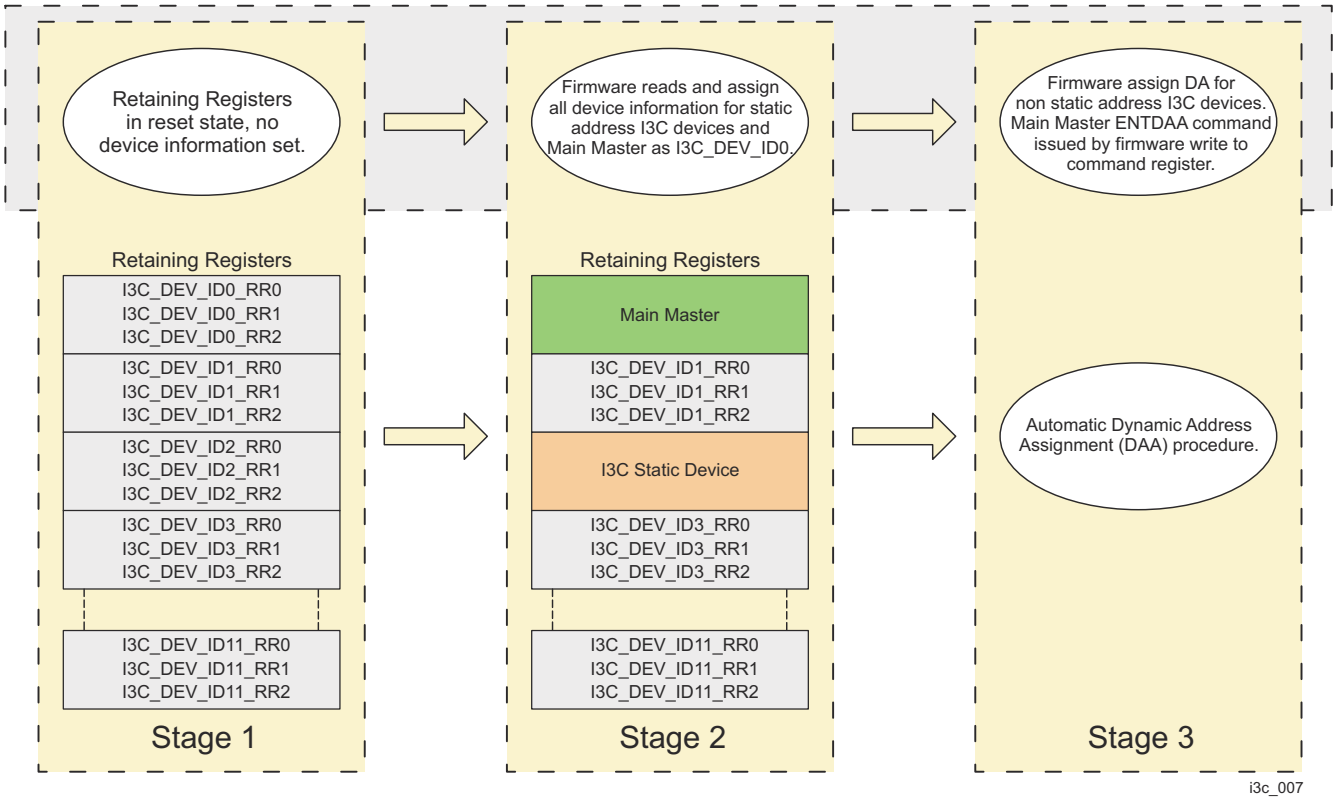

Figure 12-23. Power-up I3C Bus Initialization

During automatic Dynamic Address Assignment procedure, the I^{3}C devices send their Provisional ID, BCR and DCR using open-drain class driver. The Device ID sections are assigned to the I3C Devices based on the Provisional ID arbitration. As a result, the lower value of the Provisional ID the device has, the lower position in retaining registers map it gets. Once device gets Dynamic Address and its Retaining Registers are filled, corresponding I3C_DEVS_CTRL bit for active is set automatically.

Figure 12-24 presents the I^{3}C flow diagram for DAA procedure.

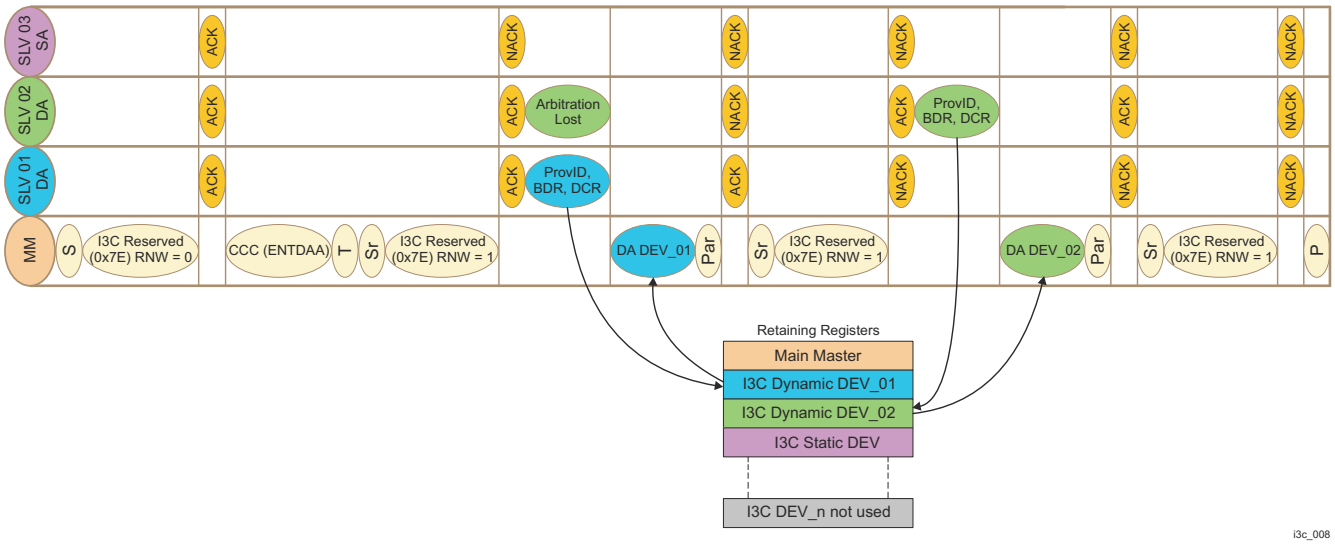

Figure 12-24. Flow Diagram for DAA Procedure

Copyright © 2023 Texas Instruments Incorporated

Note

Static I^3C devices have already assigned Dynamic Address with SETDASA CCC command and stay quiet during DAA procedure.

Note

Although arbitration continues over BCR and DCR values, it is not guaranteed to be resolved in this phase, if not resolved during Provisional ID period.

12.1.4.3.8 I3C Sending CCC Messages

To send a CCC message, I3C controller uses Host Command Format.

Following are the only relevant Command Word fields for CCC message:

- I3C_CMD0_FIFO[30] IS_CCC – should be set to 1;
- I3C_IMD_CMD1[7-0] CCC – specifies the Common Command Code to be sent;
- I3C_CMD0_FIFO[7-1] DEV_ADDR – should address slave device in case of Direct CCC command;
- I3C_CMD0_FIFO[23-12] PL_LEN – specifies the length of the Data field for commands (the number of bytes to be sent for particular CCC);
- I3C_CMD0_FIFO[0] RNW – defines the direction of the Data field: 0 for writing data to slave(s) and 1 for reading data from slaves;
- I3C_CMD0_FIFO[29] BCH – when two sequential directed CCC messages of the same type are sent; this bit determines whether the broadcast address and message code should be issued before the second address and command code;
- I3C_CMD0_FIFO[25] RSBC – use in conjunction with BCH when issuing short CCC messages;

The payload for CCC commands writing data to the slaves needs to be written to the TX FIFO prior to sending the two Command Words. The payload received by reading CCC commands can be read after receiving the COMP interrupt corresponding to the command. Note that ENTDAA command uses payload of 0, since the data it receives is not stored in RX FIFO; the amount of data depends on the number of slave responding to the command.

When sending a sequence of two identical directed CCC messages to different slaves, the I3C_CMD0_FIFO[29] BCH and I3C_CMD0_FIFO[25] RSBC Command Word fields can be used to send the second message as short CCC. I3C_CMD0_FIFO[29] BCH should be set to 0 for the second CCC message. Instead of sending the broadcast address, waiting for it to be acknowledged and then sending the message code, this will issue restart pattern and immediately transfer the address and payload afterwards. If I3C_CMD0_FIFO[29] BCH is set to 1 the second CCC message is sent with broadcast address and command code in the beginning. In all other CCC message cases the I3C_CMD0_FIFO[29] BCH field is disregarded. Because the short CCC is preceded by restart pattern in order for this to work the I3C_CMD0_FIFO[25] RSBC field for the first command should also be set to 1.

Table 12-29 below summarizes available CCC set along with their payload layout in data FIFOs and Command Word settings.

Table 12-29. CCC Commands

CCC[1]	Description	Payload Layout[2]	PL	RNW
ENEC_BC (0x00) ENEC_DC (0x80)	Enables slave event driven interrupts	TX FIFO: {28'b0, 1'b**HJ**, 1'b0, 1'b**MR**, 1'b**INT**} (**HJ** – Hot-Join, **MR** – Mastership Request IBI, **INT** – regular IBI)	1	0
DISEC_BC (0x01) DISEC_DC (0x81)	Disables slave event driven interrupts	TX FIFO: {28'b0, 1'b**HJ**, 1'b0, 1'b**MR**, 1'b**INT**} (**HJ** – Hot-Join, **MR** – Mastership Request IBI, **INT** – regular IBI)	1	0
ENTAS0_BC (0x02) ENTAS0_DC (0x82)	Set activity to State 0 (normal operation)	No payload	0	0
RSTDAA_BC (0x06) RSTDAA_DC (0x86)	Forget current Dynamic Address and wait for new one	No payload	0	0

Table 12-29. CCC Commands (continued)

CCC[1]	Description	Payload Layout[2]	PL	RNW
ENTDAA_BC (0x07)	Enter DAA procedure to assign Dynamic Addresses to unassigned devices	See Section 12.1.4.4.3, *Initiate DAA Procedure*	0	0
SETMWL_BC (0x09) SETMWL_DC (0x89)	Set maximum write length of a single private transfer	TX FIFO: {16'b0, **LSB**, **MSB**} (**LSB** and **MSB** of 16-bit Max Write Length value)	2	0
SETMRL_BC (0x0A) SETMRL_DC (0x8A)	Set maximum read length of a single private transfer	TX FIFO: {16'b0, **LSB**, **MSB**} (**LSB** and **MSB** of 16-bit Max Write Length value)	2	0
DEFSLVS_BC (0x08)	Broadcast triples of DA, DCR and SA (or 0) for each slave	No payload	0	0
ENTHDR_BC (0x20)	Switch to HD-DDR mode	No payload	0	0
SETDASA_DC (0x87)	Set Dynamic Address to slave with Static Address	TX FIFO: {24'b0, 7'b**DA**, 1'b**P**} (**DA** – new Dynamic Address, **P** – XNOR of DA bits)	1	0
SETNEWDA_DC (0x88)	Assign new Dynamic Address	TX FIFO: {24'b0, 7'b**DA**, 1'b**P**} (**DA** – new Dynamic Address, **P** – XNOR of DA bits)	1	0
GETMWL_DC (0x8B)	Get maximum write length of a single private transfer	RX FIFO: {16'b0, **LSB**, **MSB**} (**LSB** and **MSB** of 16-bit Max Write Length value)	2	1
GETMRL_DC (0x8C)	Get maximum read length of a single private transfer	RX FIFO: {16'b0, **LSB**, **MSB**} (**LSB** and **MSB** of 16-bit Max Read Length value)	2	1
GETPID_DC (0x8D)	Get Slave's Provisional ID value	RX FIFO[n+1]: {16'b0, **PID0**, **PID1**} RX FIFO[n]: {**PID2**, **PID3**, **PID4**, **PID5**}	6	1
GETBCR_DC (0x8E)	Get Device's Bus Characteristic Register value	RX FIFO: {24'b0, **BCR**}	1	1
GETDCR_DC (0x8F)	Get Device's Characteristic Register value	RX FIFO: {24'b0, **DCR**}	1	1
GETSTATUS_DC (0x90)	Read Device's operating status	RX FIFO: {16'b0, 2'b**AM**, 1'b**PE**, 1'b0, 4'b**INT**, 8'b0} (**AM** – Activity Mode, **PE** – Protocol Error, **INT** – Pending Interrupt number)		
GETACCMST_DC (0x91)	Get accept mastership	RX FIFO: {24'b0, **SlaveAddr**}	1	1
GETMXDS_DC (0x94)	Read Maximum SCL Frequency of the slave	RX FIFO: {16'b0, **MaxRd**, **MaxWr**} (**MaxRd** – Clock to Data Turnaround Time and Maximum Sustained Read Data Rate, **MaxWr** – Maximum Sustained Write Data Rate)	1	1
GETHDRCAP (0x96)	Ask slave for HDR modes it supports (can be sent only if BCR identifies HDR support)	RX FIFO: {24'b0, **HDRCAP**} (**HDRCAP** – HDR capability modes)	1	1

(1) CCC column displays:
- The name of the Common Command Code, suffixed with _BC for Broadcast CCC and _DC for Direct CCC;
- In parentheses is value of CCC field to be used in Command Word 1;

(2) Payload Layout column displays:
- {<...>,<field1>,<field0>} - concatenation of 8-bit CCC data fields within 32-bit FIFO cell;
- <width>'b<field_name> - field <field_name> takes <width> bits (8 bits if not specified);
- The payload fields are denoted in bold;

12.1.4.3.9 I3C In-Band Interrupt

In order to handle an incoming In-Band Interrupt from particular slave device, the address and configuration of IBI handling for this device needs to be stored in the I3C_SIR_MAP0 through I3C_SIR_MAP5 registers.

Copyright © 2023 Texas Instruments Incorporated

This register map holds information on device address, length of payload, device role and response. The map organization is presented in the Table 12-30 below.

Table 12-30. SIR Map Organization

Register	[31-16] bit fields	[15-0] bit fields
I3C_SIR_MAP0	Device 1	Device 0
I3C_SIR_MAP1	Device 3	Device 2
I3C_SIR_MAP2	Device 5	Device 4
I3C_SIR_MAP3	Device 7	Device 6
I3C_SIR_MAP4	Device 9	Device 8
I3C_SIR_MAP5	Reserved	Device 10

All devices requesting IBI, but not added to the SIR Map, will receive the NACK response from I3C master device.

Example for IBI Map configuration looks as follows:

1. Write 0x80470445 which is translated to the following configurations for first two devices:
   a. Regular slave with DA = 0x22 to be ACKed and receive 4 bytes of payload (Device 0)
   b. Secondary master with DA = 0x23 to be ACKed and receive no payload (Device 1)
2. Write 0x004A0749 which is translated to the following configurations for the third and fourth device:
   a. Regular slave with DA = 0x24 to be ACKed and receive 7 bytes of payload (Device 2)
   b. Regular slave with DA = 0x25 to be NACKed (Device 3)
3. Write 0x0000034D which configures the last fifth device as follows:
   a. Regular slave with DA = 0x26 to be ACKed and receive 3 bytes of payload (Device 4)

After receiving regular or mastership request IBI interrupt, firmware needs to read the I3C_IBIR register to determine which device requested IBI. The ordering of bits in the I3C_IBIR register corresponds to ordering of devices stored in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. Note that the IBI capable devices are enumerated and ordered independently from device ordering in the retaining registers used during DAA procedure.

12.1.4.3.9.1 Regular I3C Slave In-Band Interrupt

When regular IBI request appears on the I^3C bus, I^3C master hardware automatically handles whole IBI procedure based on settings in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. As the IBI procedure acknowledged by I3C master finishes (including payload reception), host is informed by the IBI interrupt that such event occurred and was successfully processed. At this point, firmware should:

1. Read I3C_IBIR register to determine requesting device
2. Read related payload from IBI RX FIFO
3. Execute related action (application/system dependent), if any designed for particular IBI/device.

12.1.4.3.9.2 Current Master Takeover In-Band Interrupt

When mastership takeover IBI request appears on the I^3C bus, I^3C master hardware automatically sends the response based on settings in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. After this host is informed by the I3C_MST_ISR interrupt that handoff procedure should be executed. At this point, firmware should:

1. Read I3C_IBIR register to determine requesting device (optionally, if such information is useful for application host)
2. Send the GETACCMST CCC to confirm mastership handover
3. Wait for the completion of pending I3C master command signaled by I3C_MST_ISR interrupt – at this moment I3C master switches to the slave mode
4. Write 0x001FXXXX to FLUSH_CTRL register to flush the FIFOs as the slave mode reuses TX and RX FIFOs (bits marked X hold RX_FIFO threshold so should be set/maintained as needed)
5. Depending on application/system, prepare for slave operation

Note that it is firmware and/or system responsibility to provide bus information to Secondary Masters before mastership handover is granted. It can be achieved in several ways:

- Secondary Masters listen to the bus during DAA and store necessary data

Copyright © 2023 Texas Instruments Incorporated

- Main Master sends DEFSLVS CCC after each ENTDAA / RSTDAA / SETNEWDA / SETDASA sequence that modifies bus

12.1.4.3.10 I3C Hot-Join Request

In order to accept any Hot-Join (HJ) request from slave device, application needs to set the I3C_CTRL[6] HJ_ACK and I3C_CTRL[8] HJ_DISEC control bits that define its response for Hot-Join request. Based on I3C_CTRL[6] HJ_ACK value the I3C master accepts or refuses the Hot-Join request by providing respectively ACK or NACK bit right after I3C_CMD0_FIFO[0] RNW bit. I3C_CTRL[8] HJ_DISEC bit controls whether master starts DAA procedure or sends broadcast DISEC command to disable HJ requests.

If Hot-Join request occurs, the application processor is notified by the I3C_MST_ISR interrupt. The application processor is aware how this particular Hot-Join request should be handled by checking current setting (can read the control bits or the stored previously used setting). In case of acknowledged request with subsequent DAA, the application processor is notified of automatically completed enumeration of hot-joined device by subsequent I3C_MST_ISR interrupt and simultaneously set I3C_MST_STATUS0 flag. In case of DISEC command, only I3C_MST_ISR interrupt will be set.

It is recommended to keep the I3C_CTRL[6] HJ_ACK bit disabled until the bus initialization procedure is completed in order to prevent slaves from indirect DAA enforcement.

12.1.4.3.11 I3C Immediate Commands

Immediate Command Register is implemented in order to allow the application processor to issue immediate command which has a higher priority over the ordinary command. The immediate commands are supposed to be used in exceptional cases and only CCC commands are applicable. The I3C supports only one immediate command at a time and it is accessed by the host through two APB registers: I3C_IMD_CMD0 and I3C_IMD_CMD1. If a normal command is currently being executed and new immediate command is loaded, then controller waits to finish the current command and after that starts executing the higher priority command regardless of the content of the ordinary command FIFO. Immediate command can be used only for CCC commands and the corresponding payload must not exceed 4 bytes. As a result the GETPID and DEVSLVS CCC commands cannot be executed using immediate commands. The format for the immediate command words is the same as for the ordinary commands, although some fields are reserved since not used or fixed for CCC commands (writing to these fields has no effect).

12.1.4.3.12 I3C Host Commands

The normal operation of the controller allows the firmware to build a message and then issue the transaction to the I^3C controller. The command queue is provided in order to allow the host to load a request for multiple messages. Single message consists of two 32-bit words (Command Word0 and Command Word1). In order to issue the transaction the following procedure should be followed:

- Write the payload to the TX FIFO (applicable for write transfers only);
- Write Command Word1;
- Write Command Word0;

If controller is enabled (I3C_CTRL[31] DEV_EN bit is set to 0x01), writing Command Word0 triggers the execution of the command, resulting in start condition on the I3C bus.

12.1.4.3.13 I3C Sending Private Data in SDR Messages

The I3C controller supports private data transfers in Single Data Rate with SCL frequencies up to 10.375 MHz. It supports all types of SDR transfers and provides hardware built-in features for transfers to I3C slave devices with limited maximum SCL frequency. Before any private transfer to the slave devices occurs, bus mode and SCL prescalers shall be programmed properly. Controller also provides vendor extension to the basic transfers which simplifies addressing internal registers of slave devices. To take advantage of this extension, the I3C controller must communicate with the slave devices supporting such transmission scheme.

The extension, called XMIT modes, combines standard private write and read frames to pass the slave register sub-address in addition to the actual payload. Four transmit modes are designed for specific usage:

- XMIT00 – burst (byte-by-byte) transfer with static register sub-address. Sends static sub-address followed by data bytes only. Expecting slave will make self-increment of the address for each data byte or will have payload buffer implemented.

Copyright © 2023 Texas Instruments Incorporated

- XMIT01 – single transfer with incremented register sub-address. Each data byte followed by repeated start condition and the slave's internal register address are incremented explicitly.
- XMIT10 – single transfer with static register sub-address. Each data byte followed by repeated start condition, register sub-address remains intact.
- XMIT11 – burst (byte-by-byte) transfer without register sub-address (first data byte after the slave address is a payload byte).

In addition to the multiple transmit modes, I3C controller has an option to provide 16-bit address of the internal register in slave device to support slaves with more than 256 internal addresses.

For arbitration priorities management, private SDR commands may use Broadcast Command Header or not. This is controlled by BCH field of command descriptor.

12.1.4.3.13.1 SDR Private Write Message

The Private Write message transmitted over I3C bus in all supported transmit modes is presented in Figure 12-25, *Master Write Transaction for Single and Multi Address Sequences*. The provided transmit modes use additional I3C write frame that utilizes the data field to pass slave register address ahead of payload byte(s). As writing command word triggers start condition immediately, it shall be guaranteed by firmware that the data payload is written to the Tx FIFO in advance before it is going to be transmitted.

The completion of the message frame on the I3C bus is signaled by the I3C_MST_ISR[16] IMM_COMP interrupt.

In case of transfers with data payload greater than the TX FIFO size, firmware can use I3C_MST_ISR[15] TX_THR interrupt to fill the FIFO on time. The system design should prevent the TX FIFO from underflow. During the time elapsed between reading the last four bytes from almost empty TX FIFO and reading the subsequent one, firmware is required to refill the TX FIFO.

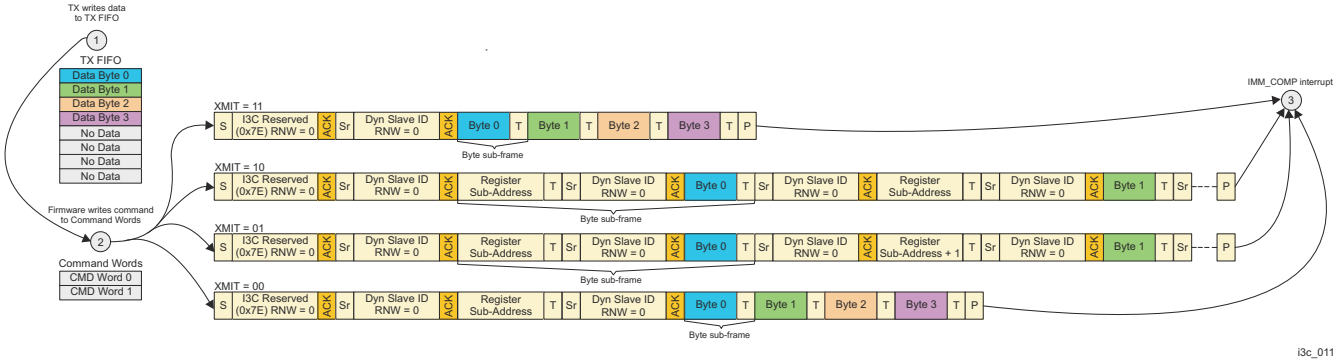

Figure 12-25. Master Write Transaction for Single and Multi Address Sequences

12.1.4.3.13.2 SDR Private Read Message

The Private Read message transmitted over I3C bus in all supported transmit modes is presented in Figure 12-26, *Master Read Transaction for Single and Multi Address Sequences*

Similarly to Private Write message, each I3C read frame is preceded by I3C write frame which sends slave register address to be read. After sending the command, firmware should wait for I3C_MST_ISR[16] IMM_COMP interrupt which signals the end of message and RX FIFO content ready to read.

In case of payload lengths exceeding RX FIFO size, firmware should utilize I3C_MST_ISR[7] TX_THR interrupt to read RX FIFO before it gets filled and prevent from data corruption. For easier management of long FIFO and/or long host read intervals, the amount of data available in FIFO that triggers the interrupt can be programmed according to actual conditions in given system.

Copyright © 2023 Texas Instruments Incorporated

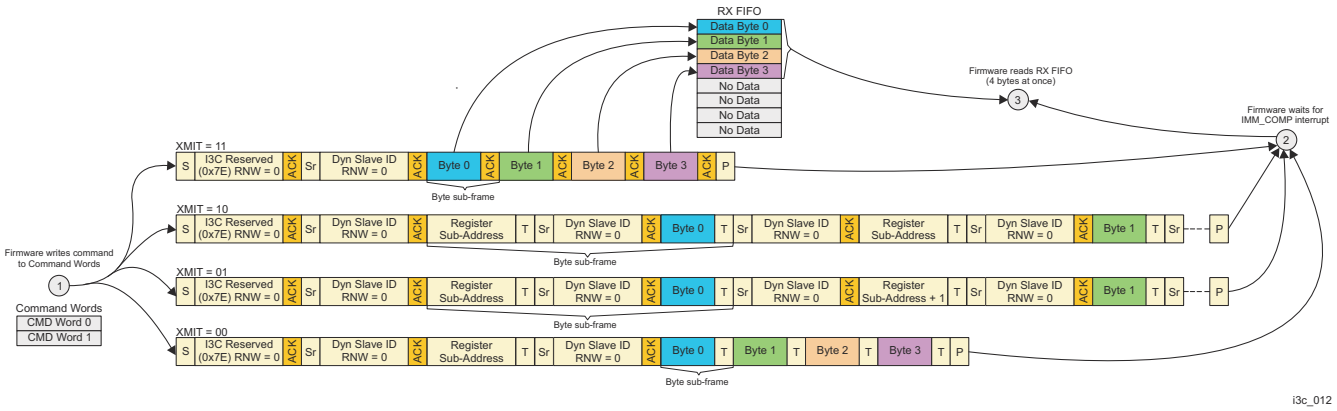

Figure 12-26. Master Read Transaction for Single and Multi Address Sequences

12.1.4.3.13.3 SDR Payload Length Adjustment

In case of Private Write SDR commands, the payload length that needs to be specified is always equal to the number of data bytes sent to slave in Private Write transmission. If the payload specified is greater than slave's capability, the data are simply ignored by slave.

In case of Private Read SDR commands slave is the device which normally decides how many bytes it is able to send and when the read transfer is terminated. This can also result from hardware architecture or from SETMRL CCC command sent earlier to the slave.

For simplified handling I3C design triggers the read abort procedure after receiving specified number of payload bytes. This matters in these transfer modes which send data bytes after one another. If one of these modes is used, the I3C_CMD0_FIFO[23-12] PL_LEN bit-field is interpreted as payload size that should not be reached during transfer rather than the actual number of bytes to be received. This applies only to read transfer from I3C devices.

Table 12-31. Payload Setting in SDR Mode

Transmission	I3C_CMD0_FIFO[28-27] XMIT_MODE	I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11)	I3C_CMD0_FIFO[23-12] PL_LEN
I3C, NCA	11	1	Abort limit(1)
I3C, Single	00	1	Abort limit(1)
I3C, Multi-Static	10	1	Number of bytes to receive
I3C, Multi-Incremental	01	1	Number of bytes to receive

(1) If payload size is known, it can be set to one more than the known size; otherwise it should be set to MRL+1 where MRL is value programmed with SETMRL CCC in particular slave or its hardware payload size limit, if known.

12.1.4.4 I3C Programming Guide

12.1.4.4.1 I3C Power-On Programming Model

Typical power-on programming sequence is as follows:

1. Program bus description into Retaining Registers according Section 12.1.4.3.6 and I3C_DEVS_CTRL.
2. If default values of SCL prescalers do not fit applied clock frequencies, program PRESCL_CTRL0 and PRESCL_CTRL1 according Section 12.1.4.3.2.
3. If any of following applies:
   a. Address Header Optimization is to be enabled.
   b. Halt mechanism should be enabled.

   then alter values of I3C_CTRL[1-0] BUS_MODE, I3C_CTRL[3] AHDR_OPT and I3C_CTRL[30] HALT_EN fields, respectively:
   a. Program I3C_CTRL register with value 0x80000000 to enable the controller.

12.1.4.4.2 I3C Static Devices Programming

I3C devices shipped with Static Address can be enumerated prior to DAA procedure using SETDASA CCC command. In order to enumerate I3C device firmware needs to follow procedure:

1. Prepare device's retaining register:
   a. Write corresponding I3C_DEV_IDn_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11:
      i. I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11): 0x01
      ii. I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit-field (n = 0 to 11): set to device's Static Address for [7-1] bits and set to Static Address parity for bit 0
2. Issue SETDASA CCC:
   a. Make sure that controller is enabled.
   b. Write new Dynamic Address to TX FIFO.
   c. Write Command Word1 with SETDASA CCC value:
      i. I3C_IMD_CMD1[7-0] CCC bit-field: 0x87
   d. Write Command Word0 with following field values:
      i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
      ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01
      iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Static Address
      iv. I3C_CMD0_FIFO[0] RNW bit: 0x00
3. Enable at least COMP, NACK and INVALID_DA interrupts by writing 0h to IER register.
4. Wait for COMP interrupt (read I3C_MST_ISR).
5. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation.
6. Fill Dynamic Address into device configuration register:
   a. Modify I3C_DEV_IDn_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11 register by writing Dynamic Address to DEV_ADDR field and its parity to ADDR_PAR field (keep values of other fields)
7. If not already known to application host, retrieve BCR with GETBCR CCC:
   a. Write Command Word1 with GETBCR CCC value:
      i. I3C_IMD_CMD1[7-0] CCC bit-field: 0x8E
   b. Write Command Word0 with following field values:
      i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
      ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01
      iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
      iv. I3C_CMD0_FIFO[0] RNW bit: 0x01
   c. Wait for COMP interrupt
   d. Read RX FIFO register - BCR is stored in bits [7:0]
8. Optionally retrieve Provisional ID and DCR with corresponding CCCs:
   a. Write Command Word1 with GETDCR CCC value:
      i. I3C_IMD_CMD1[7-0] CCC bit-field: 0x8F
   b. Write Command Word0 with following field values:
      i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
      ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01

Copyright © 2023 Texas Instruments Incorporated

iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
iv. I3C_CMD0_FIFO[0] RNW bit: 0x01

c. Wait for COMP interrupt
d. Read RX FIFO register - DCR is stored in bits [7:0]
e. Write Command Word1 with GETPID CCC value:
   i. I3C_IMD_CMD1[7-0] CCC bit-field: 0x8D
f. Write Command Word0 with following field values:
   i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
   ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x06
   iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
   iv. I3C_CMD0_FIFO[0] RNW bit: 0x01
g. Wait for COMP interrupt
h. Read RX FIFO register twice – PID bytes are stored in two FIFO locations. See Table 12-29

9. Write retrieved device configuration data to retaining registers:
   a. Write four MSB of obtained PID value into I3C_DEV_IDn_RR1 (offset 0x084 + (n × 0x010)) for n = 0 to 11:
   b. Write two LSB of obtained PID value as well as BCR and DCR values into I3C_DEV_IDn_RR2 (offset 0x088 + (n × 0x010)) for n = 0 to 11:

Note

SETDASA CCC command has advantage over DAA in shorter time spent on device configuration as retrieving PID and DCR (6 + 1 bytes transmitted over I3C bus) is optional and can be skipped if not used.

12.1.4.4.3 I3C DAA Procedure Initiation

To initiate the DAA procedure I3C needs to issue ENTDAA CCC command following the below procedure:

1. Enable at least COMP and NACK interrupts.
2. Issue ENTDAA CCC command:
   a. Make sure controller is enabled.
   b. Write Command Word1 with ENTDAA CCC command value:
      i. I3C_IMD_CMD1[7-0] CCC bit-field: 0x07
   c. Write Command Word0 with following field values:
      i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
      ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x00
      iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: 0x00
      iv. I3C_CMD0_FIFO[0] RNW bit: 0x00
3. Wait for COMP interrupt (read I3C_MST_ISR)
4. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation. NACK interrupt indicates no slave devices available on bus.
5. Read I3C_MST_STATUS0[25] DAA_COMP bit. It is asserted simultaneously with I3C_MST_ISR interrupt flag.

Note

DAA procedure takes significant amount of time since there are always 9 bytes of data transmitted for each device (PID, BCR, DCR from device and DA to device), so for maximum bus size it will take 99 bytes.

12.1.4.4.4 I3C SDR Write Message Programming Model

To accomplish the SDR write transfer, the host must perform the following steps:

1. Write all payload data bytes into TX FIFO buffer:
   a. Write first four or less bytes to be sent, with first byte stored at LSB position.
   b. Repeat writes until whole payload is written.
2. Write Private Write command to command queue:

Copyright © 2023 Texas Instruments Incorporated

a. Write the Command Word 1 (I3C_CMD1_FIFO) with slave CSR address:
   i. CSR (bits [15:0] or [7:0]): Slave register address
b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
   i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
   ii. I3C_CMD0_FIFO[30] IS_CCC: 0x0
   iii. I3C_CMD0_FIFO[28-27] XMIT_MODE: Transmit Mode
   iv. I3C_CMD0_FIFO[26] SBCA: 0x1 for 16-bit CSR address, 0x0 otherwise
   v. I3C_CMD0_FIFO[23-12] PL_LEN: Number of bytes to send
   vi. I3C_CMD0_FIFO[7-1] DEV_ADDR: Slave Address
   vii. I3C_CMD0_FIFO[0] RNW: 0x0

3. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

12.1.4.4.5 I3C SDR Read Message Programming Model

To accomplish the SDR read transfer, the host must perform the following steps:

1. Write Private Write command to command queue:
   a. Write the Command Word1 (I3C_CMD1_FIFO) with slave CSR address:
      i. CSR (bits [15:0] or [7:0]): Slave register address
   b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
      i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
      ii. I3C_CMD0_FIFO[30] IS_CCC: 0x0
      iii. I3C_CMD0_FIFO[28-27] XMIT_MODE: Transmit Mode
      iv. I3C_CMD0_FIFO[23-12] PL_LEN: See Section 12.1.4.3.13.3
      v. I3C_CMD0_FIFO[7-1] DEV_ADDR: Slave Address
      vi. I3C_CMD0_FIFO[0] RNW: 0x1
2. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
3. Read all payload data bytes from RX FIFO buffer:
   a. Read first four or less received bytes, with first received byte stored at LSB position.
   b. Repeat reads until whole payload is read.

12.1.4.4.6 I3C DDR Write Message Programming Model

To accomplish the DDR write transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB aligned in TX FIFO cell; set bits unspecified below to 0):
   a. Write command word for write HDR-DDR command to TX FIFO using following field values:
      i. Preamble (bits [19:18]): 0x01
      ii. CMD (bits[17:10]): Write Command Code (from 0x00 to 0x7F)
      iii. DA (bits[9:3]): Slave Dynamic Address
      iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
   b. Write first data word to TX FIFO using following field values:
      i. Preamble (bits [19:18]): 0x10
      ii. Data (bits[17:2]): 16-bit data
      iii. Parity (bits[1:0]): Parity
   c. Write zero or more subsequent data words to TX FIFO using following field values:
      i. Preamble (bits [19:18]): 0x11
      ii. Data (bits[17:2]): 16-bit data
      iii. Parity (bits[1:0]): Parity
   d. Write CRC word to TX FIFO:
      i. Preamble (bits [19:18]): 0x01
      ii. Token (bits[17:14]): Ch
      iii. CRC (bits[13:9]): CRC5
   e. Repeat steps 1(a) to 1(d) as many write commands are to be sent.
2. Write ENTHDR CCC command to command queue:

Copyright © 2023 Texas Instruments Incorporated

a. Write the Command Word1 (I3C_CMD1_FIFO) of ENTHDR CCC.
b. Write the Command Word0 (I3C_CMD0_FIFO) of ENTHDR CCC with following data fields:
   i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
   ii. I3C_CMD0_FIFO[30] IS_CCC: 0x1
   iii. I3C_CMD0_FIFO[0] RNW: 0x0

3. Write HDR-DDR command(s) to command queue:
   a. Write the Command Word1 (I3C_CMD1_FIFO).
   b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
      i. I3C_CMD0_FIFO[31] IS_DDR: 0x1
      ii. I3C_CMD0_FIFO[23-12] PL_LEN: Number of TX FIFO words
   c. Repeat steps 2(a) and 2(b) as many write commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

If I3C_MST_ISR[16] IMM_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C_MST_ISR[5] CMDD_EMP interrupt may be utilized instead. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C_MST_ISR[5] CMDD_EMP interrupt corresponding to the last command in the queue.

12.1.4.4.7 I3C DDR Read Message Programming Model

To accomplish the DDR read transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB-aligned in TX FIFO cell, set bits unspecified below to 0):
   a. Write Command Word for Read HDR-DDR command to TX FIFO using following field values:
      i. Preamble (bits [19:18]): 2'b01
      ii. CMD (bits[17:10]): Read Command Code (0x80..0xBF)
      iii. DA (bits[9:3]): Slave Dynamic Address
      iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
   b. Repeat step 1(a) as many read commands are to be sent.
2. Write ENTHDR CCC command to command queue:
   a. Write the Command Word1 (I3C_CMD1_FIFO) of ENTHDR CCC.
   b. Write the Command Word0 (I3C_CMD0_FIFO) of ENTHDR CCC with following data fields:
      i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
      ii. I3C_CMD0_FIFO[30] IS_CCC: 0x1
      iii. I3C_CMD0_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
   a. Write the Command Word1 (I3C_CMD1_FIFO)
   b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
      i. I3C_CMD0_FIFO[31] IS_DDR: 0x1
      ii. I3C_CMD0_FIFO[23-12] PL_LEN: 0x1
   c. Repeat steps 2(a) and 2(b) as many read commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit in interrupt status register, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
5. Read received payload:
   a. Read first data word from RX FIFO extracting field values:
      i. Preamble (bits [19:18]): 0x10
      ii. Data (bits[17:2]): 16-bit data
      iii. Parity (bits[1:0]): Parity
   b. Read zero or more subsequent data words from RX FIFO extracting field values as long as the read preamble matches following value:
      i. Preamble (bits [19:18]): 0x11
      ii. Data (bits[17:2]): 16-bit data

Copyright © 2023 Texas Instruments Incorporated

iii. Parity (bits[1:0]): Parity

c. As read preamble changes, read CRC Word:
   i. Preamble (bits [19:18]): 0x01
   ii. Token (bits[17:14]): Ch
   iii. CRC (bits[13:9]): CRC5
d. Confirm (by firmware) that CRC5 value matches data payload received.

If I3C_MST_ISR[16] IMM_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C_MST_ISR[5] CMDD_EMP interrupt may be utilized instead of I3C_MST_ISR[16] IMM_COMP. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C_MST_ISR[16] IMM_COMP interrupt corresponding to the last command in the queue.

12.1.5 Multichannel Serial Peripheral Interface (MCSPI)

This section describes the Multichannel Serial Peripheral Interface (MCSPI) modules for the device.

12.1.5.1 MCSPI Overview

The MCSPI module is a multichannel transmit/receive, master/slave synchronous serial bus.

There are MCSPI modules in the device.

12.1.5.1.1 SPI Features

The SPI module includes the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receive mode
- Controller multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - Per channel configuration for clock definition, polarity enabling, and word width
- Single interrupt line for multiple interrupt source events
- Enable the addition of a programmable start-bit for MCSPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable shift operations (1-32 bits)
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

Table 12-33. MCSPI Hardware Requests

Interrupt Requests		
Module Interrupt Signal	**Description**	**Type**
MCSPI_INTR_SPI_0	MCSPI Interrupt Request	Level
DMA Events		
Module DMA Event	**Description**	**Type**
MCSPI_DMA_WRITE_EVENT0	MCSPI Channel 0 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT0	MCSPI Channel 0 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT1	MCSPI Channel 1 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT1	MCSPI Channel 1 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT2	MCSPI Channel 2 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT2	MCSPI Channel 2 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT3	MCSPI Channel 3 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT3	MCSPI Channel 3 Receive (Read) Request Line	Pulse

12.1.5.2 MCSPI Environment

This section describes the MCSPI external connections (environment).

Table 12-34 describes the MCSPI I/O signals in master mode.

Table 12-34. MCSPI I/O Signals (Master Mode)

Module Pin	I/O(1)	Description
SPICLK	O	MCSPI Serial clock output for master mode.
SPIDAT[0]	O(2)	MCSPI Data I/O for master mode.
SPIDAT[1]	I(3)	MCSPI Data I/O for master mode.
SPIEN[i]	O	MCSPI Chip-select i output for master mode

(1) I = Input; O = Output
(2) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[16] DPE0.
(3) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[17] DPE1.

Table 12-35 describes the MCSPI I/O signals in slave mode.

Table 12-35. MCSPI I/O Signals (Slave Mode)

Module Pin	I/O(1)	Description
SPICLK	I	MCSPI serial clock input for slave mode.
SPIDAT[0]	I(2)	MCSPI Data I/O for slave mode.
SPIDAT[1]	O(3)	MCSPI Data I/O for slave mode.
SPIEN[i]	I(4)	MCSPI chip-select i input for slave mode.

(1) I = Input; O = Output
(2) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[16] DPE0.
(3) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[17] DPE1.
(4) The chip-select input in slave mode can be selected through the MCSPI_CHCONF_0/1/2/3[22-21] SPIENSLV bit field.

12.1.5.3 MCSPI Functional Description

12.1.5.3.1 SPI Block Diagram

Figure 12-27 shows the SPI module.

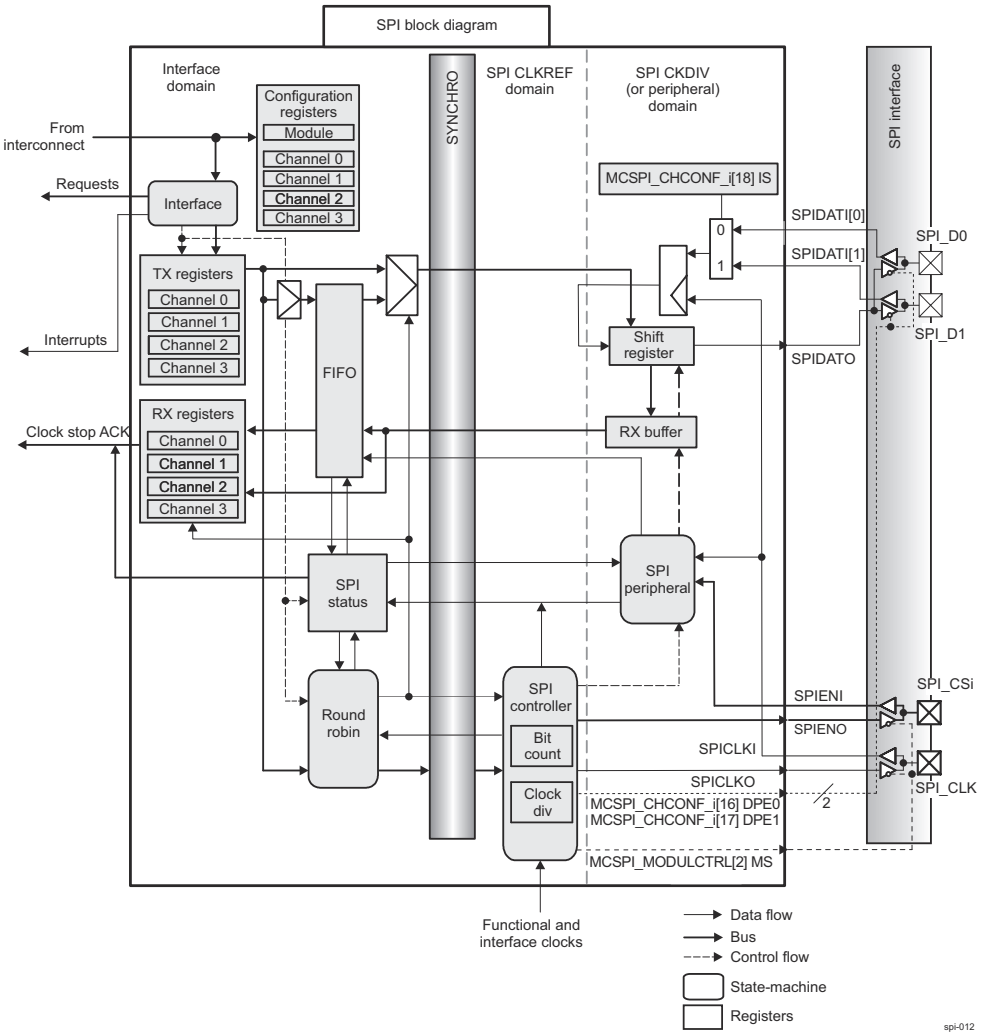

Figure 12-27. SPI Block Diagram

12.1.5.3.2 MCSPI Reset

The MCSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI_RST). MCSPI can be reset by software through the MCSPI_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI_SYSCONFIG register is not affected by that software reset.

12.1.5.3.3 MCSPI Controller Mode

12.1.5.3.3.1 Controller Mode Features

The MCSPI controller mode supports multichannel communication with up to four independent MCSPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN[i]) signals.

Connected to multiple external devices, the MCSPI exchanges data with one MCSPI device at a time through two main modes (available in peripheral mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Copyright © 2023 Texas Instruments Incorporated

Note

There is a fixed chip select line allocation in multichannel controller mode. Channel i is mapped to SPIEN[i].

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in controller mode (for more information about interrupts, see Section 12.1.5.3.7.1, *Interrupt Events in Controller Mode*).

12.1.5.3.3.2 Controller Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The controller transmit-and-receive mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TX_0/1/2/3 transmitter register state, the MCSPI_RX_0/1/2/3 receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the MCSPI_CHCTRL_0/1/2/3[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TX_0/1/2/3 transmitter register is not empty (the MCSPI_CHSTAT_0/1/2/3[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TX_0/1/2/3 register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the MCSPI_CHSTAT_0/1/2/3[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RX_0/1/2/3 register cannot be overwritten. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When MCSPI word transfer completes (the MCSPI_CHSTAT_0/1/2/3[2] EOT bit is set), the updated MCSPI_TX_0/1/2/3 register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral.

Figure 12-28 shows an example of a full-duplex system with a controller device on the left and a peripheral device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral. At the same time, WordB transfers from the peripheral to the controller.

Copyright © 2023 Texas Instruments Incorporated

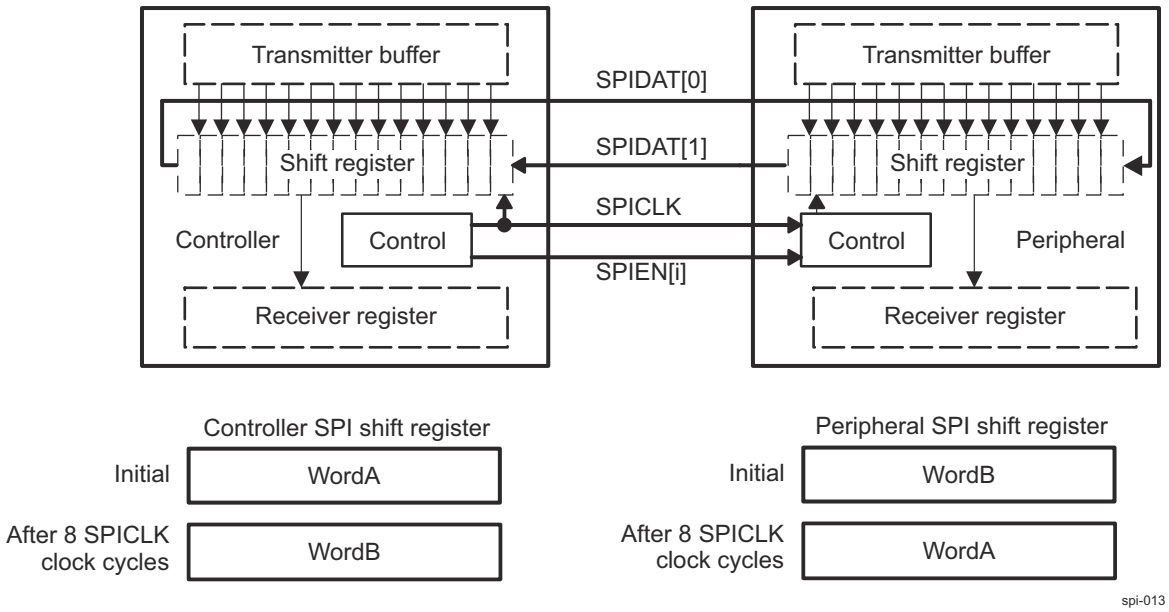

Figure 12-28. MCSPI Full-Duplex Transmission (Example)

12.1.5.3.3.3 Controller Transmit-Only Mode (Half Duplex)

The controller transmit-only mode prevents the processor from reading the MCSPI_RX_0/1/2/3 register (minimizing data movement) when only transmission is meaningful.

The controller transmit-only mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field). Transmission starts only after data is loaded into the MCSPI_TX_0/1/2/3 register.

Rule 1 and Rule 2, defined in Section 12.1.5.3.3.2, apply in this mode.

Rule 3, defined in Section 12.1.5.3.3.2, does not apply.

In controller transmit-only mode, the MCSPI_RX_0/1/2/3 register state FULL does not prevent transmission and the MCSPI_RX_0/1/2/3 register is always overwritten with the new MCSPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI_CHSTAT_0/1/2/3[2] EOT bit.

12.1.5.3.3.4 Controller Receive-Only Mode (Half Duplex)

The controller receive mode prevents the processor from refilling the MCSPI_TX_0/1/2/3 register (minimizing data movement) when only reception is meaningful.

The controller receive mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field).

The controller receive-only mode enables channel scheduling only on the empty state of the MCSPI_RX_0/1/2/3 register.

Rule 1 and Rule 3, defined in Section 12.1.5.3.3.2, apply in this mode.

Rule 2, defined in Section 12.1.5.3.3.2, does not apply.

In the controller receive-only mode, software must write dummy data to the MCSPI_TX_0/1/2/3 register. Only one dummy write is enough to receive any number of words from the peripheral. Software must ensure that the MCSPI_TX_0/1/2/3 register is always full (the TXx_EMPTY bits of MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TX_0/1/2/3 register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TX_0/1/2/3 register, the TXx_EMPTY and TXx_UNDERFLOW bits in the MCSPI_IRQSTATUS register are never set in receive-only mode.

Copyright © 2023 Texas Instruments Incorporated

The MCSPI_CHSTAT_0/1/2/3[2] EOT bit gives the status of serialization. The RXx_FULL bits of the MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RX_0/1/2/3 register. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

12.1.5.3.3.5 Single-Channel Controller Mode

When the MCSPI is configured as a controller device with a single enabled channel (MCSPI_MODULCTRL[2] MS = 0 and MCSPI_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[i] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI_TX_0/1/2/3 register or the FIFO is performed. In 4-pin mode (MCSPI_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[i] is controlled by software using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit.

12.1.5.3.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the MCSPI word transfer to complete (wait until the MCSPI_CHSTAT_0/1/2/3[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

12.1.5.3.3.5.2 Force SPIEN[i] Mode

Continuous transfers are allowed manually by keeping the SPIEN[i] signal active for successive MCSPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[i] line. This mode is supported by all channels and any controller sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[i] active mode is supported when:

- A single channel is used (with the MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI_CHCONF_0/1/2/3).

  The state of the SPIEN[i] signal is programmable:
  - Writing 1 to the MCSPI_CHCONF_0/1/2/3[20] FORCE bit drives the SPIEN[i] line high when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven low when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 1.
  - Writing 0 to the MCSPI_CHCONF_0/1/2/3[20] FORCE bit drives the SPIEN[i] line low when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven high when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI_CHCTRL_0/1/2/3[0] EN bit is set to 1). The first enabled channel activates the SPIEN[i] line.

When the channel is enabled, the SPIEN[i] signal activates with the programmed polarity. As in the multichannel controller mode, the transfer start depends on the status of the MCSPI_TX_0/1/2/3 register (the MCSPI_CHSTAT_0/1/2/3[1] TXS bit), the status of the MCSPI_RX_0/1/2/3 register (the MCSPI_CHSTAT_0/1/2/3[1] RXS bit), and the defined mode (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field) of the channel enabled.

The MCSPI_CHSTAT_0/1/2/3[2] EOT bit gives the transfer status of each MCSPI word. The RXx_FULL bit in the MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RX_0/1/2/3 register.

A change in the configuration parameters is propagated directly on the MCSPI interface. If the SPIEN[i] signal is activated, ensure that the configuration is changed only between MCSPI words to avoid corrupting the current transfer.

Note

To avoid data corruption, SPIEN[i] polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[i] signal is activated.

Copyright © 2023 Texas Instruments Incorporated

A delay between MCSPI words that requires the connected MCSPI peripheral device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last MCSPI word, the channel must be deactivated (the MCSPI_CHCTRL_0/1/2/3[0] EN bit set to 0) and SPIEN[i] can be forced to its INACTIVE state using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit.

Figure 12-29 and Figure 12-30 show successive transfers with SPIEN[i] maintained active low with a different configuration for each MCSPI word in single-data-pin and dual-data-pin interface modes, respectively.

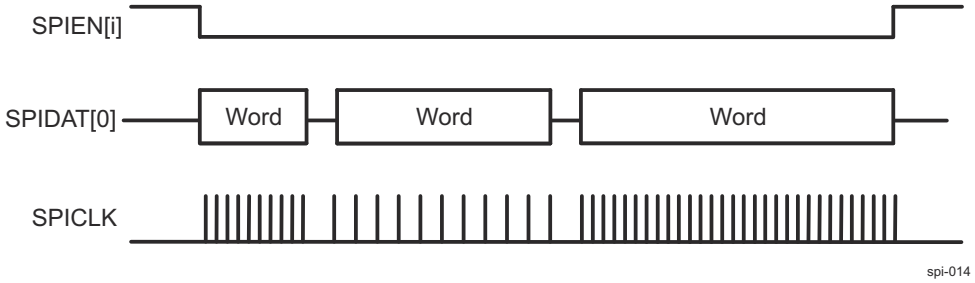

Figure 12-29. Continuous Transfers With SPIEN[i] Maintained Active (Single-Data-Pin Interface Mode)

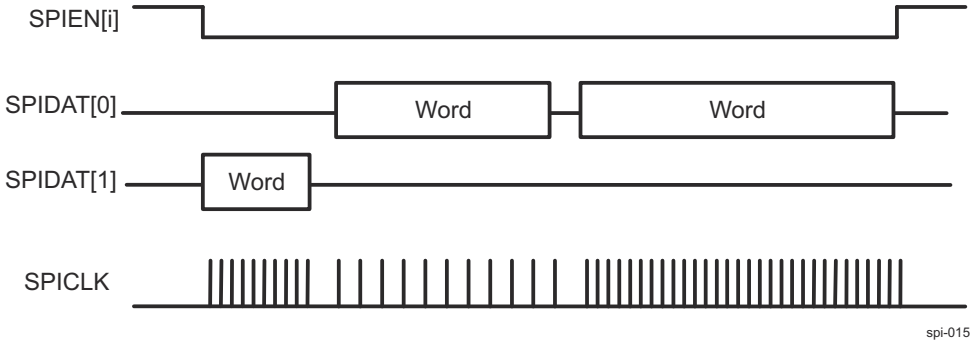

Figure 12-30. Continuous Transfers With SPIEN[i] Maintained Active (Dual-Data-Pin Interface Mode)

Note

The SPIEN[i] signal can be maintained active via software using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit only when the MCSPI_MODULCTRL[0] SINGLE bit is set to 0x1.

12.1.5.3.3.5.3 Turbo Mode

Turbo mode improves the throughput of the MCSPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RX_0/1/2/3 register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the MCSPI_CHCONF_0/1/2/3[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 12.1.5.3.3.2, *Controller Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the MCSPI_CHSTAT_0/1/2/3[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI_RX_0/1/2/3 register cannot be overwritten in turbo mode. Consequently, the MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

12.1.5.3.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the MCSPI word to indicate whether the next MCSPI word must be handled as a command or as data. This feature is available only in controller mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[i] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

Copyright © 2023 Texas Instruments Incorporated

This mode is programmable per channel by setting the MCSPI_CHCONF_0/1/2/3[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit is set to 0, the MCSPI word must be handled as a command. When the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit is set to 1, the MCSPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit before writing the MCSPI word to be transmitted to the TX register.

12.1.5.3.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in controller mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI_CHCONF_0/1/2/3[26-25] TCS0 bit field.

Figure 12-31 shows the CS SPIEN timing controls.

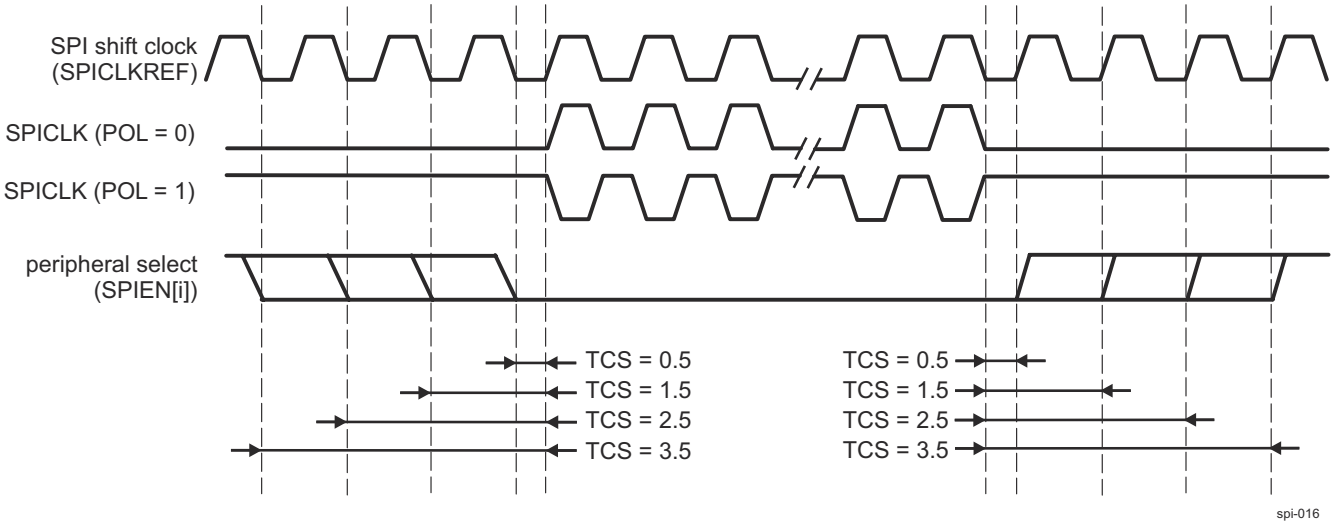

Figure 12-31. CS SPIEN Timing Controls

Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

12.1.5.3.3.8 Programmable MCSPI Clock (SPICLK)

In controller mode, the baud rate of the MCSPI serial clock is programmable.

An internal reference clock, SPICLKREF, is used as input of a programmable divider (the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. Table 12-36 summarizes the supported divisor values.

Table 12-36. MCSPI Controller Clock Rates

Divider	Clock Rate
1	50 MHz(1)
2	25 MHz(1)
4	12.5 MHz
8	6.25 MHz
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz

Copyright © 2023 Texas Instruments Incorporated

Table 12-36. MCSPI Controller Clock Rates (continued)

Divider	Clock Rate
128	390 kHz(2)
256	195 kHz(2)
512	97.7 kHz(2)
1024	48.8 kHz(2)
2048	24.4 kHz(2)
4096	12.2 kHz(2)
8192 and higher: Division not supported	–

(1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Data sheet.
(2) Approximate Frequency

12.1.5.3.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI_CHCONF_0/1/2/3[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI_CHCTRL_0/1/2/3[15-8] EXTCLK bit field is concatenated with the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI_CHCONF_0/1/2/3[1] POL and MCSPI_CHCONF_0/1/2/3[0] PHA bits (see Table 12-37).

Table 12-37. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even >= 2	T_ref * (F_{RATIO}/2)	T_ref * (F_{RATIO}/2)
Odd >= (POL = PHA)	T_ref * (F_{RATIO}– 1)/2	T_ref * (F_{RATIO} + 1)/2
Odd >= (POL =! PHA)	T_ref * (F_{RATIO}+ 1)/2	T_ref * (F_{RATIO} – 1)/2

Note

F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
T_{HIGH} = SPICLK high time period
T_{LOW} = SPICLK low time period
T_ref = MCSPI_FCLK period
T_{HIGH_REF} = MCSPI_FCLK high time period
T_{LOW_REF} = MCSPI_FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

Copyright © 2023 Texas Instruments Incorporated

For odd ratio values, the duty cycle is calculated as follows:

Duty_cycle = $(1 – 1/F_{RATIO})/2$

Table 12-38 shows examples of clock granularity with a clock source frequency of 50 MHz.

Table 12-38. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F_{RATIO}	PHA	POL	T_{HIGH} (ns)	T_{LOW} (ns)	T_{PERIOD} (ns)	Duty Cycle	F_{OUT} (MHz)
X	0	0	1	X	X	10.0	10.0	20.0	50–50	50
X	1	0	2	X	X	20.0	20.0	40.0	50–50	25
X	2	0	4	X	X	40.0	40.0	80.0	50–50	12.5
X	3	0	8	X	X	80.0	80.0	160.0	50–50	6.2
0	0	1	1	X	X	10.0	10.0	20.0	50–50	50
0	1	1	2	X	X	20.0	20.0	40.0	50–50	25
0	2	1	3	1	0	40.0	20.0	60.0	66–33	16.6
0	2	1	3	1	1	20.0	40.0	60.0	33–66	16.6
0	3	1	4	X	X	40.0	40.0	80.0	50–50	12.5
5	0	1	81	1	0	820.0	800.0	1620.0	50.6–49.4	0.617
5	7	1	88	X	X	880.0	880.0	1760.0	50–50	0.568

12.1.5.3.4 MCSPI Peripheral Mode

To select the MCSPI peripheral mode, set the MCSPI_MODULCTRL[2] MS bit.

A MCSPI peripheral device can be connected to up to four external MCSPI controller devices but handles transactions with one MCSPI controller device at a time.

In peripheral mode, the MCSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[i]) and receives an MCSPI clock (SPICLK) from the external MCSPI controller device. Only channel 0 can be configured as a peripheral but through the MCSPI_CHCONF_0[22-21] SPIENSLV bit field any of the SPIEN[i] signals can be used to select the MCSPI module. In peripheral mode and when the MCSPI_MODULCTRL[1] PIN34 is set to 0x0 (default behaviour), the MCSPI uses the edge of SPIEN[i] to detect word length. For this reason, SPIEN[i] must become inactive between each word.

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x0, the MCSPI does not support SPIEN[i] active between MCSPI words. In this case, the MCSPI uses the edge to detect word length.

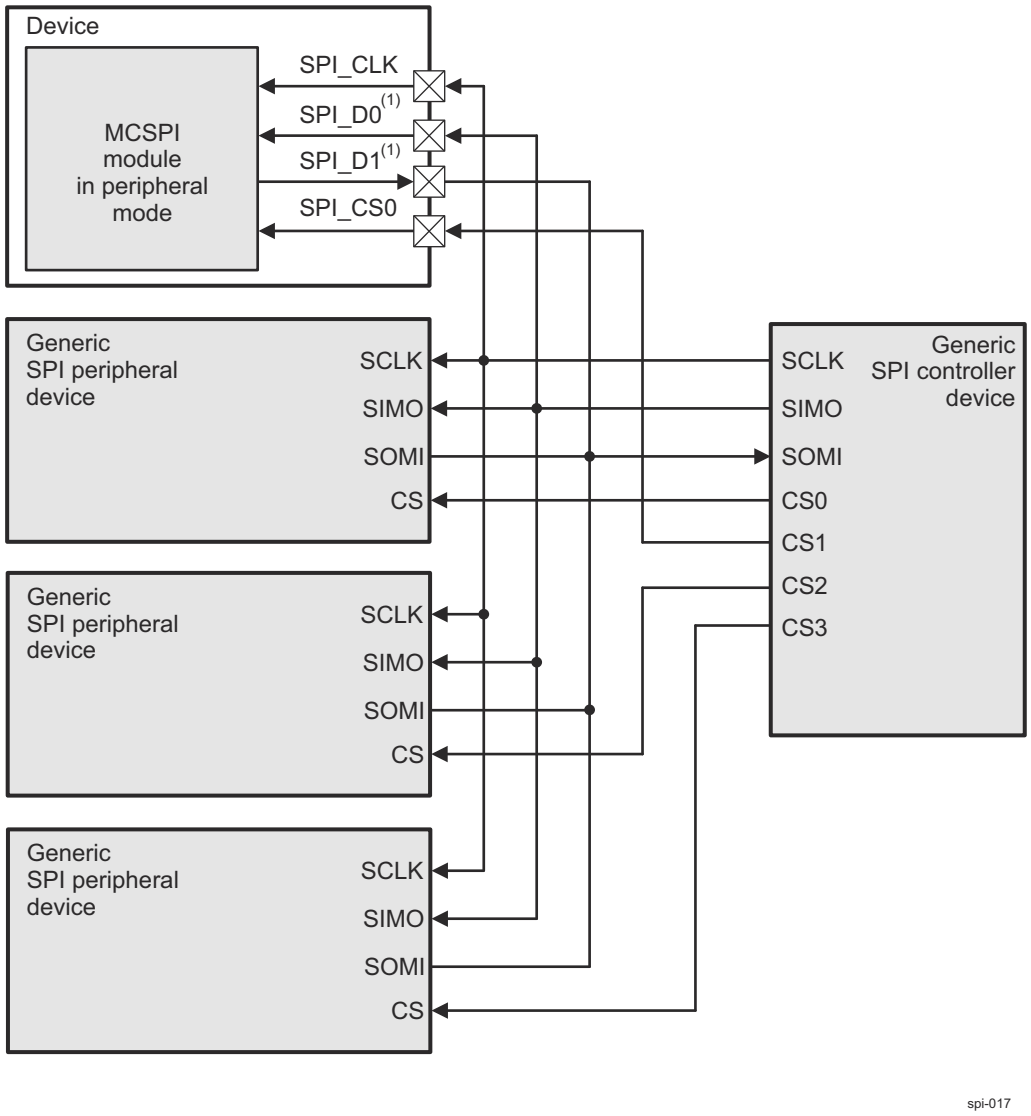
When the MCSPI_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external MCSPI controller to deactivate SPIEN[i] between each word as in this case the MCSPI module works in 3-pin peripheral mode and SPIEN[i] is not needed.

12.1.5.3.4.1 Dedicated Resources

Only channel 0 can be enabled in peripheral mode.

Figure 12-32 shows an example of four peripherals wired on a single controller device.

Copyright © 2023 Texas Instruments Incorporated



A. Direction depends on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-32. Example of MCSPI Peripheral With One Controller and Multiple Peripheral Devices on Channel 0

Channel 0 in peripheral mode has the following resources:

- Its own channel enable, programmable with the MCSPI_CHCTRL_0[0] EN bit. This channel must be enabled before transmission and reception.
- For this mode, the peripheral-select signal can be detected on any of the SPIEN[i] ports. This is programmable with the MCSPI_CHCONF_0[22-21] SPIENSLV bit field.
- Its own transmitter register, MCSPI_TX_0, on top of the common transmit shift register. If the MCSPI_TX_0 register is empty, the MCSPI_CHSTAT_0[1] TXS bit is set. If MCSPI is selected by an external controller (the active signal on the SPIEN[i] port assigned to channel 0), the MCSPI_TX_0 register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TX_0 register must be loaded before MCSPI is selected by a controller.
- Its own receiver register, MCSPI_RX_0, on top of the common receive shift register. If the MCSPI_RX_0 register is full, the MCSPI_CHSTAT_0[0] RXS bit is set.

Copyright © 2023 Texas Instruments Incorporated

Note

The MCSPI_TX_1/2/3 and MCSPI_RX_1/2/3 registers are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI_CHCONF_0:
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The MCSPI modules are in peripheral mode after reset and must be properly configured for the modules to act in controller mode.)
  - MCSPI word length, programmable with the WL bit
  - SPIEN[i] polarity, programmable with the EPOL bit
  - SPICLK polarity, programmable with the POL bit
  - SPICLK phase, programmable with the PHA bit

  The SPICLK frequency of a transfer is controlled by the external MCSPI controller connected to the MCSPI peripheral device. The MCSPI_CHCONF_0[5-2] CLKD bit field is not used in peripheral mode.

Note

The configuration of the channel can be loaded in the MCSPI_CHCONF_0 only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the MCSPI_CHCONF_0[15] DMAR bit for reading and the MCSPI_CHCONF_0[14] DMAW bit for writing.
- Four interrupt events (see Section 12.1.5.3.7.2, *Interrupt Events in Peripheral Mode*).

12.1.5.3.4.2 Peripheral Transmit-and-Receive Mode

The peripheral receive mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x0).

In peripheral transmit-and-receive mode, the MCSPI_TX_0 register must be loaded before MCSPI is selected by an external MCSPI controller device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TX_0 register content is always loaded in the shift register whether it is updated or not. The event TX0_UNDERFLOW is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI_CHSTAT_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a peripheral transmit-only device, the RX0_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RX_0 register (see Section 12.1.5.3.7.2, *Interrupt Events in Peripheral Mode*).

12.1.5.3.4.3 Peripheral Transmit-Only Mode

The peripheral transmit-only mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x2) and avoids the requirement for the processor to read the MCSPI_RX_0 register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a peripheral transmit-only device, the RX0_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RX_0 register.

When the MCSPI word transfer completes, the MCSPI_CHSTAT_0[2] EOT bit is set.

Figure 12-33 shows a half-duplex system with a controller device on the left and a transmit-only peripheral device on the right. Each time a bit transfers out from the peripheral, 1 bit transfers in the controller. After eight cycles of the serial clock SPICLK, WordB transfers from the peripheral to the controller.

k = 0 or 1 depending on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-33. MCSPI Half-Duplex Transmission (Transmit-Only peripheral)

12.1.5.3.4.4 Peripheral Receive-Only Mode

The peripheral receive mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x1).

In receive-only mode, the MCSPI_TX_0 register must be loaded before the MCSPI is selected by an external MCSPI controller device. The MCSPI_TX_0 register content is always loaded into the shift register whether it is updated or not. The TX0_UNDERFLOW event is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI_CHSTAT_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a peripheral receive-only device, the TX0_EMPTY and TX0_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI_TX_0 register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 12-34 shows a half-duplex system with a controller device on the left and a receive-only peripheral device on the right. Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral.

k = 0 or 1 depending on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-34. MCSPI Half-Duplex Transmission (Receive-Only Peripheral)

12.1.5.3.5 MCSPI 3-Pin or 4-Pin Mode

Depending on targeted application the MCSPI interface can be configured to use 3 or 4 pins through the MCSPI_MODULCTRL[1] PIN34 bit. If this bit is set to 0, MCSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[i] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[i] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI_CHCONF_0/1/2/3). 3-pin and 4-pin operation applies to both controller and peripheral modes.

12.1.5.3.6 MCSPI FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI_CHCONF_0/1/2/3[28] FFER or MCSPI_CHCONF_0/1/2/3[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Controller or peripheral mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI_CHCONF_0/1/2/3[11-7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see Figure 12-35) or receive (see Figure 12-36) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see Figure 12-37).

Copyright © 2023 Texas Instruments Incorporated

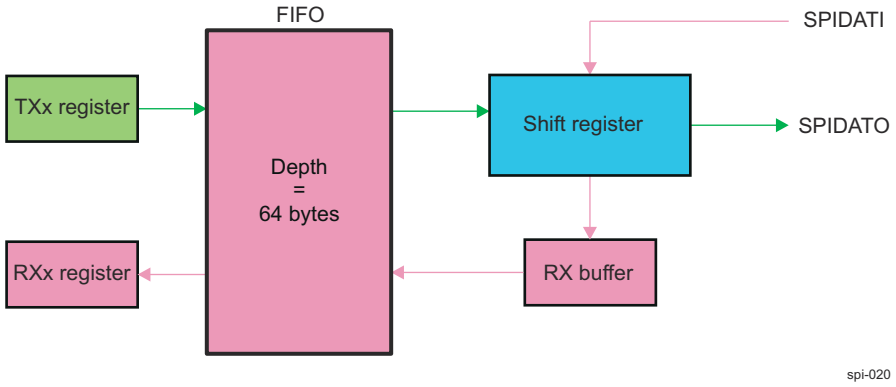

Figure 12-35. Buffer Used in Transmit Direction Only

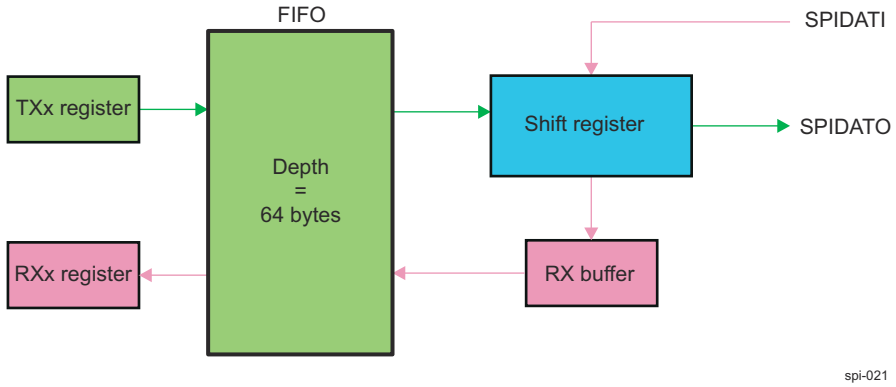

Figure 12-36. Buffer Used in Receive Direction Only

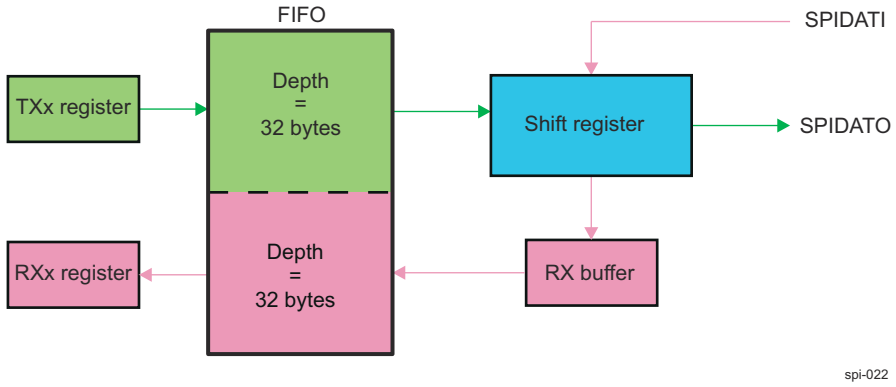

Figure 12-37. Buffer Used for Transmit and Receive Directions

Two levels (MCSPI_XFERLEVEL[5-0] AEL and MCSPI_XFERLEVEL[13-8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the MCSPI word length. The driver must set these values as a multiple of the MCSPI word length defined in WL. Table 12-39 lists the number of bytes written in the FIFO, depending on the word length.

Table 12-39. FIFO Writes, Word Length Relationship

	MCSPI Word Length (WL)		
	3 ≤ WL≤ 7	**8 ≤ WL ≤ 15**	**16 ≤ WL ≤ 31**
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

Copyright © 2023 Texas Instruments Incorporated

12.1.5.3.6.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15-8] AFL bit field is needed when the buffer is used to receive an MCSPI word from a peripheral (the MCSPI_CHCONF_0/1/2/3[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 12-38.

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the processor to enable the system to read AFL + 1 bytes from the receive register.

Note

AFL + 1 must correspond to a multiple value of the MCSPI_CHCONF_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

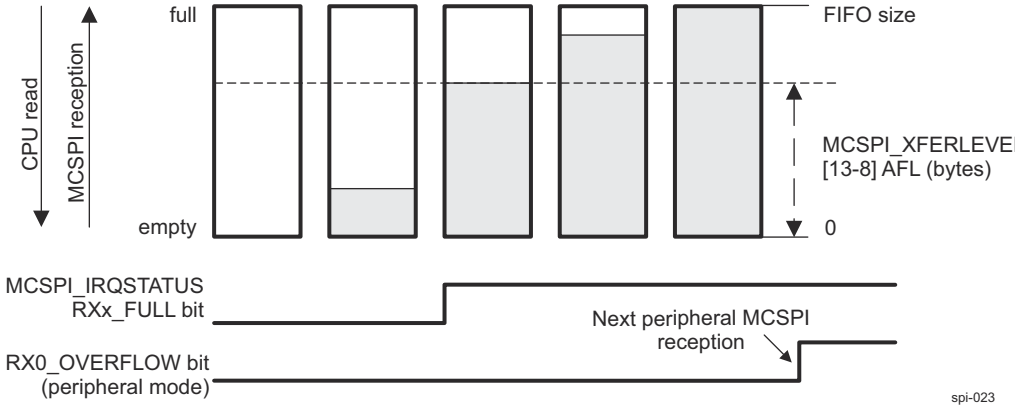

Figure 12-38. Buffer Almost Full Level (AFL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

12.1.5.3.6.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7-0] AEL bit field is needed when the buffer is used to transmit an MCSPI word to a peripheral (the MCSPI_CHCONF_0/1/2/3[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 12-39.

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the processor to enable the system to write AEL + 1 bytes to the transmit register.

Note

AEL + 1 must correspond to a multiple value of the MCSPI_CHCONF_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

Copyright © 2023 Texas Instruments Incorporated

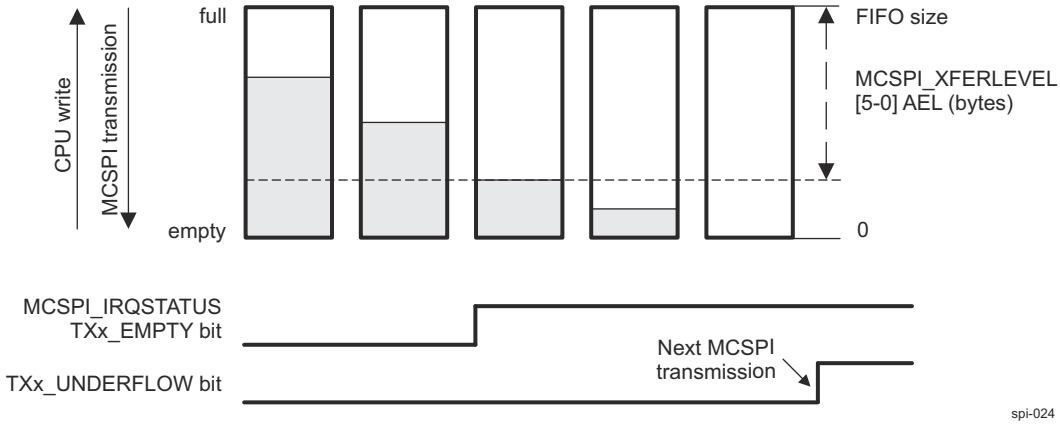

Figure 12-39. Buffer Almost Empty Level (AEL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

12.1.5.3.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31-16] WCNT bit field to define the number of MCSPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of MCSPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many MCSPI transfers have been done. For received words, software must poll the MCSPI_CHSTAT_i[5] RXFFE bit and read the MCSPI_RX_0/1/2/3 receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHSTAT_0/1/2/3[5] RXFFE bit to know the last MCSPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

12.1.5.3.6.4 Multiple MCSPI Word Access

The processor has the ability to perform multiple MCSPI word access to the receive or transmit registers within a single 32-bit interface access by setting the MCSPI_MODULCTRL[7] MOA to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- MCSPI_MODULCTRL[7] MOA is set to 1.
- Only 32-bit interface access and data width can be performed to receive or transmit registers, for other kind of access the processor must de-assert MCSPI_MODULCTRL[7] MOA bit.
- The level MCSPI_XFERLEVEL[7-0] AEL and MCSPI_XFERLEVEL[15-8] AFL must be 32-bit aligned, it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI_XFERLEVEL[31-16] WCNT is used it must be configured according to MCSPI word length.
- The word length of MCSPI words allows to perform multiple MCSPI access, that means that MCSPI_CHCONF_0/1/2/3[11-7] WL is <16.

The number of MCSPI word access depends on MCSPI word length:

- 3 ≤ WL ≤ 7, MCSPI word length smaller or equal to byte length, 4 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = WCNT[1] = 0.

Copyright © 2023 Texas Instruments Incorporated

- 8 ≤ WL ≤ 15, MCSPI word length greater than byte or equal to 16-bit length, 2 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI_XFERLEVEL[31-16] WCNT]), set the bit field to WCNT[0] = 0.
- 16 ≤ WL Multiple MCSPI word access is not applicable.

12.1.5.3.6.5 First MCSPI Word Delay

Figure 12-40 shows the MCSPI controller ability to delay the first MCSPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first MCSPI word after MCSPI channel enabled and first write in transmit register. It is based on output clock frequency.

This option is meaningful in controller mode and single channel mode asserted through MCSPI_MODULCTRL[0] SINGLE.

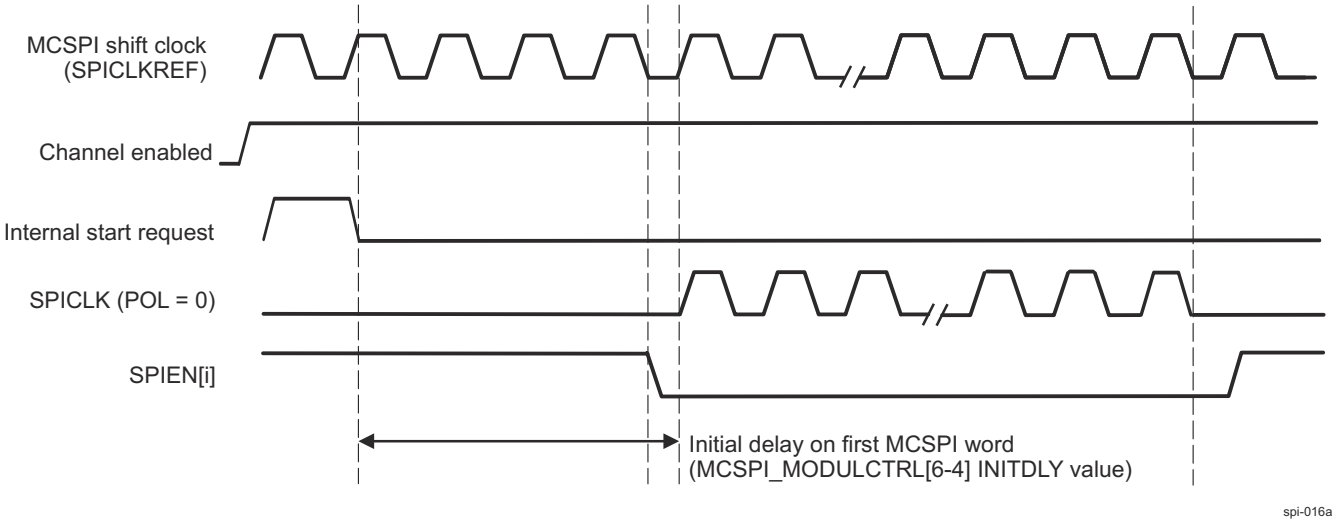

Figure 12-40. Controller Single Channel Initial Delay

Few delay values are available: No delay, 4/8/16/32 MCSPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

12.1.5.3.7 MCSPI Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

12.1.5.3.7.1 Interrupt Events in Controller Mode

In controller mode, the interrupt events related to the state of the MCSPI_TX_0/1/2/3 register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the state of the MCSPI_RX_0/1/2/3 register is RXx_FULL.

12.1.5.3.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TX_0/1/2/3 register is empty (transient event). Enabling a channel automatically triggers this event, except in controller receive-only mode (see Section 12.1.5.3.3.4, *Controller Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHCONF_0/1/2/3[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as

Copyright © 2023 Texas Instruments Incorporated

there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5-0] AEL bit field.

The MCSPI_TX_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI_TX_0/1/2/3 register defined by the MCSPI_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

12.1.5.3.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TX_0/1/2/3 register or the FIFO is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in controller mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TX_0/1/2/3 register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TX_0/1/2/3 register must seldom be loaded.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.1.3 RXx_ FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RX_0/1/2/3 register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHCONF_0/1/2/3[28] FFER bit is set to 1), RXx_ FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13-8] AFL threshold.

The MCSPI_RX_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI_RX_0/1/2/3. The processor must perform the correct number of reads.

12.1.5.3.7.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31-16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2 Interrupt Events in Peripheral Mode

In peripheral mode, the interrupt events related to the state of the MCSPI_TX_0/1/2/3 register are TX0_EMPTY and TX0_UNDERFLOW. The interrupt events related to the state of the MCSPI_RX_0/1/2/3 are RX0_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

12.1.5.3.7.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TX_0/1/2/3 register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI_CHCONF_0/1/2/3[27] FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5-0] AEL bit field.

Copyright © 2023 Texas Instruments Incorporated

The MCSPI_TX_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI_TX_0/1/2/3 register defined by MCSPI_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

12.1.5.3.7.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TX_0/1/2/3 register is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in peripheral mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TX_0/1/2/3 register because the channel is enabled.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RX_0/1/2/3 register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHCONF_0/1/2/3[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI_XFERLEVEL[13-8] AFL bit field.

The MCSPI_RX_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI_RX_0/1/2/3. The processor must perform the correct number of reads.

12.1.5.3.7.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in peripheral mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI_RX_0/1/2/3 register or FIFO is full when a new MCSPI word is received. The MCSPI_RX_0/1/2/3 register is always overwritten with the new MCSPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in peripheral mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in peripheral mode.

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

Copyright © 2023 Texas Instruments Incorporated

12.1.5.3.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the processor must:

1. Read the MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RX_0/1/2/3 register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TX_0/1/2/3 register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the TXx_ UNDERFLOW and RX0_OVERFLOW events.
3. Set the corresponding bit of the MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

12.1.5.3.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the processor must read the corresponding MCSPI_RX_0/1/2/3 register.
- TXx_EMPTY: To remove the source of the event, the processor must write into the corresponding MCSPI_TX_0/1/2/3 register.
- TXx_UNDERFLOW and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

12.1.5.3.8 MCSPI DMA Requests

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the MCSPI_CHCONF_0/1/2/3[15] DMAR bit. The DMA read request line is de-asserted when reading of the MCSPI_RX_0/1/2/3 register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI_TX_0/1/2/3 register of the MCSPI channel is empty. A DMA write request can be individually masked with the MCSPI_CHCONF_0/1/2/3[14] DMAW bit. The DMA write request line is de-asserted when loading of the MCSPI_TX_0/1/2/3 register of the channel completes.

12.1.5.3.9 MCSPI Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity.

12.1.5.3.9.1 Normal Mode

In normal mode, internal MCSPI module clocks are automatically switched off (autogated) when there is no activity in peripheral or controller mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In controller mode, there is no data to transmit or receive in all channels.
- In peripheral mode, the MCSPI is not selected by the external controller and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

Copyright © 2023 Texas Instruments Incorporated

- In controller mode, an internal access occurs.
- In peripheral mode, an internal access occurs or the MCSPI is selected by the external controller.

12.1.5.3.9.2 Idle Mode

Note

Some of the MCSPI features described in this section may not be supported on this family of devices. For more information, see *MCSPI Not Supported Features*.

At the power management level, when all conditions to shut off the MCSPI_FCLK or MCSPI_ICLK clocks are met, the corresponding LPSC asserts a clock stop request to the MCSPI. Although this procedure is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the clock stop request can be configured through the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgement modes are:

- Force-idle mode (the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the clock stop request, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges the clock stop request and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow shut off of MCSPI_FCLK and MCSPI_ICLK.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the clock stop request, depending on its internal activity. MCSPI acknowledges the shut off of MCSPI_FCLK and MCSPI_ICLK only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional feature to control gating of MCSPI_FCLK or MCSPI_ICLK. The MCSPI_SYSCONFIG[9-8] CLOCKACTIVITY bit field determines which clock shuts down (MCSPI_FCLK, MCSPI_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the clock stop request are tested. For example, if MCSPI_FCLK is not shut off on clock stop request, the MCSPI considers only MCSPI_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with MCSPI_ICLK and others with MCSPI_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPI acknowledges the clock stop request.

12.1.5.3.9.2.1 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the clock stop request by de-asserting unconditionally the interrupt and DMA request lines, if asserted.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely de-asserted. The interface clock and MCSPI clock provided to the MCSPI can be switched off.
  - A clock stop request during an MCSPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

12.1.5.4 MCSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

12.1.5.4.1 MCSPI Operational Mode Configuration

12.1.5.4.1.1 MCSPI Operational Modes

The selection of the working mode is done with the MCSPI_CHCONF_0/1/2/3 register.

Table 12-40. MCSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 12-41. MCSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 12-42. MCSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

12.1.5.4.1.1.1 Common Transfer Sequence

MCSPI module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[i] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

Table 12-43 represents the main sequence which is common to all transfers.

In multi-channel controller mode, the sequences of different channels can be run simultaneously.

Table 12-43. Common Transfer Sequence (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHCONF_0/1/2/3 to configure the channel	MCSPI_CHCONF_0/1/2/3	0x-
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
Wait for the host event for end of transfer		

Copyright © 2023 Texas Instruments Incorporated

Table 12-43. Common Transfer Sequence (Main Process) (continued)

Step	Register/Bit Field/Programming Model	Value
Stop the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	0

12.1.5.4.1.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. Table 12-44 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 12-44. End of Transfer Sequences

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
CONTROLLER Normal	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.5.1	See Section 12.1.5.4.1.1.5.2
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
CONTROLLER Turbo	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.6.1	See Section 12.1.5.4.1.1.6.2
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
PERIPHERAL	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.7	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

12.1.5.4.1.1.3 Transmit-and-Receive (Controller and Peripheral)

If the requests are configured in DMA, write_count and read_count are assigned with 'N' when the DMA handlers have completed their 'N' CBASS0 accesses.

Table 12-45. Transmit-and-Receive (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait for write_count = N **AND** read_count = N		
Stop the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	0

Table 12-46. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111

Copyright © 2023 Texas Instruments Incorporated

Table 12-46. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine) (continued)

Step	Register/Bit Field/Programming Model	Value
IF: TXx_EMPTY		
Write the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
Increment write_count +1		
IF: RXx_FULL		
Read the receiver register	MCSPI_RX_0/1/2/3	
Increment read_count +1		
ENDIF		

12.1.5.4.1.1.4 Transmit-Only (Controller and Peripheral)

12.1.5.4.1.1.4.1 Based on Interrupt Requests

Table 12-47. Transmit-Only With Interrupts (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait until last transfer = TRUE		
Wait for end of transfer	MCSPI_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	0

Table 12-48. Transmit-Only With Interrupts (Controller and Peripheral) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
IF: TXx_EMPTY **AND** write_count < N		
Write the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
Increment write_count +1		
ELSEIF: write_count ≥ N		
last_transfer = TRUE		
ENDIF		

12.1.5.4.1.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its ‘N’ CBASS0 accesses, write_count is assigned with ‘N’.

Table 12-49. Transmit-Only With DMA (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPI_CHCONF_0/1/2/3[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	0

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
IF: RXx_FULL		
Read the receiver register	MCSPI_RX_0/1/2/3	0x-
Increment read_count +1		
ENDIF		

12.1.5.4.1.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The MCSPI module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see Section 12.1.5.3.6, *MCSPI FIFO Buffer Management*.

Table 12-61. FIFO Mode Common Sequence (Controller) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS	1
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	1
Write MCSPI_CHCONF_0/1/2/3 to configure the channel	MCSPI_CHCONF_0/1/2/3	0x-
Write MCSPI_XFERLEVEL	MCSPI_XFERLEVEL	0x-
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	0

12.1.5.4.1.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in Section 12.1.5.4.1.1.8, *Transfer Procedures With FIFO*.

In multi-channel, only one channel can use the FIFO.

Copyright © 2023 Texas Instruments Incorporated

Before enabling the FIFO for a channel (MCSPI_CHCONF_0/1/2/3[28] FFER and MCSPI_CHCONF_0/1/2/3[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Peripheral mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI_CHCONF_0[22-21] SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request has been released by writing the MCSPI_TX_0/1/2/3 register, even in receive-only mode (only one write request occurs in this case).

12.1.5.4.1.1.8.2 End of Transfer Sequences in FIFO Mode

Table 12-62 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 12-62. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 12-41	See Figure 12-43	See Figure 12-44
No	See Figure 12-42	See Figure 12-43	See Figure 12-45

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

12.1.5.4.1.1.8.3 Transmit-and-Receive With Word Count

12.1.6 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART)/RS-485/Infrared Data Association (IrDA)/Consumer Infrared (CIR) module in the device.

Note

UART and USART acronyms are used interchangeably in this section.

12.1.6.1 UART Overview

The UART is a slave peripheral that utilizes the DMA for data transfer or interrupt polling via host CPU. There are UART modules in the device. All UART modules support IrDA and CIR modes when 48 MHz function clock is used. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

12.1.6.1.1 UART Features

The UART includes the following features:

- 16C750-compatible
- RS-485 external transceiver auto flow control support
- 64-byte FIFO buffer for receiver and 64-byte FIFO buffer for transmitter
- Programmable interrupt trigger levels for FIFOs
- Programmable sleep mode
- The 48 MHz functional clock is default option and allows baud rates up to 3.6 Mbps
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Optional multi-drop transmission
- Configurable time-guard feature
- Configurable data format:
  - Parity bit: Even, Odd, None
  - Stop-bit: 1, 1.5, 2 bit
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions (CTS, RTS)
- module instance in MAIN domain has extended modem control signals (DCD, RI, DTR, DSR)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.6.1.2 IrDA Features

The IrDA includes the following features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
  - Frame formatting: addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  -
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection
- IrDA mode when 48 MHz function clock is used

Copyright © 2023 Texas Instruments Incorporated

12.1.6.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following features to provide CIR support for remote-control applications:

- Transmit and receive mode
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle
- CIR mode when 48 MHz function clock is used

12.1.6.1.4 UART Ports

Table 12-67. UART Clocks and Resets

Clocks	
Module Clock Input	**Description**
UART_ICLK	UART interface clock
UART_FCLK	UART functional clock
Resets

12.1.6.2 UART Environment

This section describes the UART/RS-485/IrDA/CIR external connections (environment).

Table 12-69 lists the UART interface input/output (I/O) signals.

Table 12-69. UART I/O Signals

Module Pin Name	I/O(1)	Description
RX	I	Serial data input
TX	O	Serial data output(2)
CTS	I	Clear to send(3)
RTS	O	Request to send(4)
DCD	I	Data Carrier Detect(5)
DSR	I	Data Set Ready(6)
DTR	O	Data Terminal Ready(7)
RIN	I	Ring Indicator(8)

(1) I = Input; O = Output
(2) Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UART_MDR1[2-0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).
(3) Active-low modem status signal. Reading the UART_MSR[4] NCTS_STS bit checks the condition of CTS. Reading the UART_MSR[0] CTS_STS bit checks a change of state of CTS since the last read of the modem status register. The auto-CTS mode uses CTS to control the transmitter.

Copyright © 2023 Texas Instruments Incorporated

(4) When active (low), the module is ready to receive data. Setting the UART_MCR[1] RTS bit activates RTS signal, which becomes inactive as the result of a module reset, loopback mode, or clearing the UART_MCR[1] RTS bit. In auto-RTS mode, RTS signal becomes inactive as a result of the receiver threshold logic.
(5) Active-low modem status signal. The condition of DCD can be checked by reading the UART_MSR[7] NCD_STS bit. Any change in its state can be detected by reading the UART_MSR[3] DCD_STS bit.
(6) Active-low modem status signal. Reading the UART_MSR[5] NDSR_STS bit checks the condition of DSR. Reading the UART_MSR[1] DSR_STS bit checks a change of state of DSR since the last read of the UART_MSR register.
(7) When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting the UART_MCR[0] DTR bit.
(8) Active-low modem status signal. The condition of RIN can be checked by reading the UART_MSR[6] NRI_STS bit. Any change in its state can be detected by reading the UART_MSR[2] RI_STS bit.

Table 12-70 lists the RS-485 interface input/output (I/O) signals.

Table 12-70. UART I/O Signals (RS-485 Mode)

Module Pin	I/O(1)	Description
RX	I	Serial data input
TX	O	Serial data output
DIR	O	RS-485 Direction

(1) I = Input; O = Output

Table 12-71 lists the IrDA interface I/O signals.

Table 12-71. UART I/O Signals (IrDA Mode)

Module Pin	I/O(1)	Description
RX	I	Serial data input
TX	O	Serial data output in CIR and IrDA modes (SIR, MIR, and FIR).(2)
SD	O	SD mode is used to configure the transceivers.(3)

(1) I = Input; O = Output
(2) In other modes, this pin is set to the reset value (inactive state).
(3) The SD pinout (see UART_ACREG[6] SD_MOD bit).

12.1.6.3 UART Functional Description

12.1.6.3.1 UART Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, RS-485, IrDA, or CIR) and enables the mechanism corresponding to the chosen function.
- Register mode: Enables conditional access to registers.

For more information about mode configuration, see *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses a dedicated state-machine that is responsible for the transition between FIFO data and the associated frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART_IIR_UART register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

The UART block diagram is shown below.

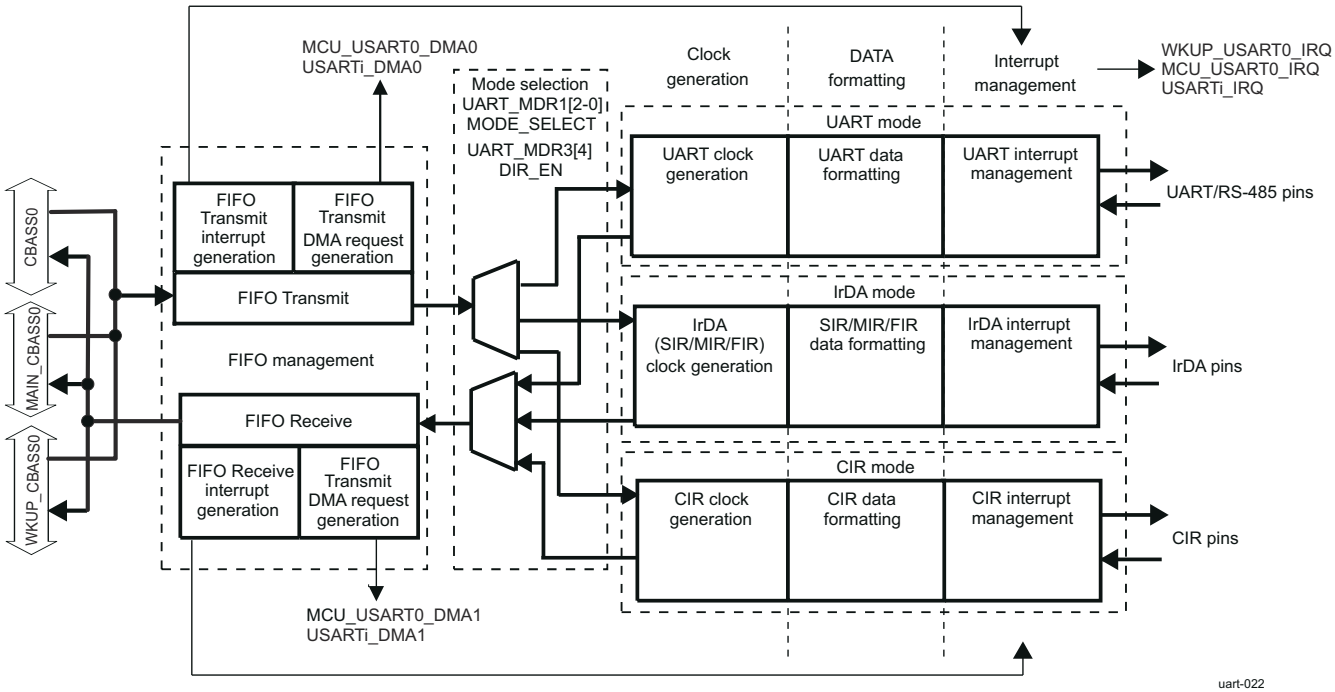

Figure 12-46. UART Functional Block Diagram

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.2 UART Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses.

12.1.6.3.3 UART Software Reset

The UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

12.1.6.3.3.1 Independent TX/RX

The receiver and transmitter are enabled by default after reset. Software can choose to disable, re-enable or to reset either the RX or the TX side independently of the other through the UART_ECR register.

12.1.6.3.4 UART Power Management

12.1.6.3.4.1 UART Mode Power Management

12.1.6.3.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UART_IER_UART[4] SLEEP_MODE bit to 1 (when the UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RX, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the RX line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 12.1.6.3.5.1.2, *Wake-Up Interrupt*.

Note

There must be no writing to the divisor latches, UART_DLL and UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UART_IER_UART[4] SLEEP_MODE bit before writing to the UART_DLL or UART_DLH register.

12.1.6.3.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

For more information, see *Power*, in the *Device Configuration*.

12.1.6.3.4.2 IrDA Mode Power Management

12.1.6.3.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART_MDR1[3] IR_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Copyright © 2023 Texas Instruments Incorporated

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

12.1.6.3.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see Section 12.1.6.3.4.1.2, *System Power Saving*).

12.1.6.3.4.3 CIR Mode Power Management

12.1.6.3.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see Section 12.1.6.3.4.2.1, *Module Power Saving*).

12.1.6.3.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see Section 12.1.6.3.4.1.2, *System Power Saving*).

12.1.6.3.4.4 Local Power Management

Table 12-72 describes power-management features available for the UART.

Note

For information about source clock gating and the sleep/wake-up transitions description, see *Power*, in the *Device Configuration*.

Table 12-72. UART Local Power-Management Features

Feature	Registers	Description
Clock autogating		
Peripheral idle modes		
Clock activity	N/A	Feature not available
Controller standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

12.1.6.3.5 UART Interrupt Requests

12.1.6.3.5.1 UART Mode Interrupt Management

12.1.6.3.5.1.1 UART Interrupts

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART_IIR_UART) sets the UART_IIR_UART[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART_IIR_UART[5-1] bit field. Table 12-73 summarizes the interrupt control functions.

Table 12-73. UART Mode Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR_UART register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears

Copyright © 2023 Texas Instruments Incorporated

Table 12-73. UART Mode Interrupts (continued)

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR_UART register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR_UART register

For the receiver-line status interrupt, the UART_LSR_UART[7] RX_FIFO_STS bit generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART_IIR_UART register.

12.1.6.3.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UART_IIR_UART register is not modified when this occurs; the UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

12.1.6.3.5.2 IrDA Mode Interrupt Management

12.1.6.3.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART_IER_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART_IIR_IRDA).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART_IER_IRDA and UART_IIR_IRDA mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see Table 12-74). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 12-74. IrDA Mode Interrupts

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the UART_RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see Section 12.1.6.3.5.1.2, *Wake-Up Interrupt*).

12.1.6.3.5.3 CIR Mode Interrupt Management

12.1.6.3.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART_IER_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART_IIR_CIR).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART_IER_CIR and UART_IIR_CIR mappings, depending on the selected mode.

Table 12-75 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART_IIR_CIR[5] TX_STATUS_IT bit is to indicate that the last bit of infrared data was passed to the TX pin.

Table 12-75. CIR Mode Interrupts

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0			
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR register until the interrupt condition disappears
2			
3			
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the UART_IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

12.1.6.3.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see Section 12.1.6.3.5.1.2, *Wake-Up Interrupt*).

12.1.6.3.6 UART FIFO Management

The FIFO is accessed by reading and writing the UART_RHR and UART_THR registers. Parameters are controlled using the FIFO control register (UART_FCR) and supplementary control register (UART_SCR). Reading the UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 12-47 shows the FIFO management registers.

Note

Data in the UART_RHR register is not overwritten when an overflow occurs.

Note

The UART_SFLSR, UART_SFREGL, and UART_SFREGH status registers are used in IrDA mode only. For information about their use, see Section 12.1.6.3.8.3.3, *IrDA Data Formatting*.

Note

Bits UART_FCR[2] TX_FIFO_CLEAR and UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after 4 × + 5 × UARTi_FCLK clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

Copyright © 2023 Texas Instruments Incorporated

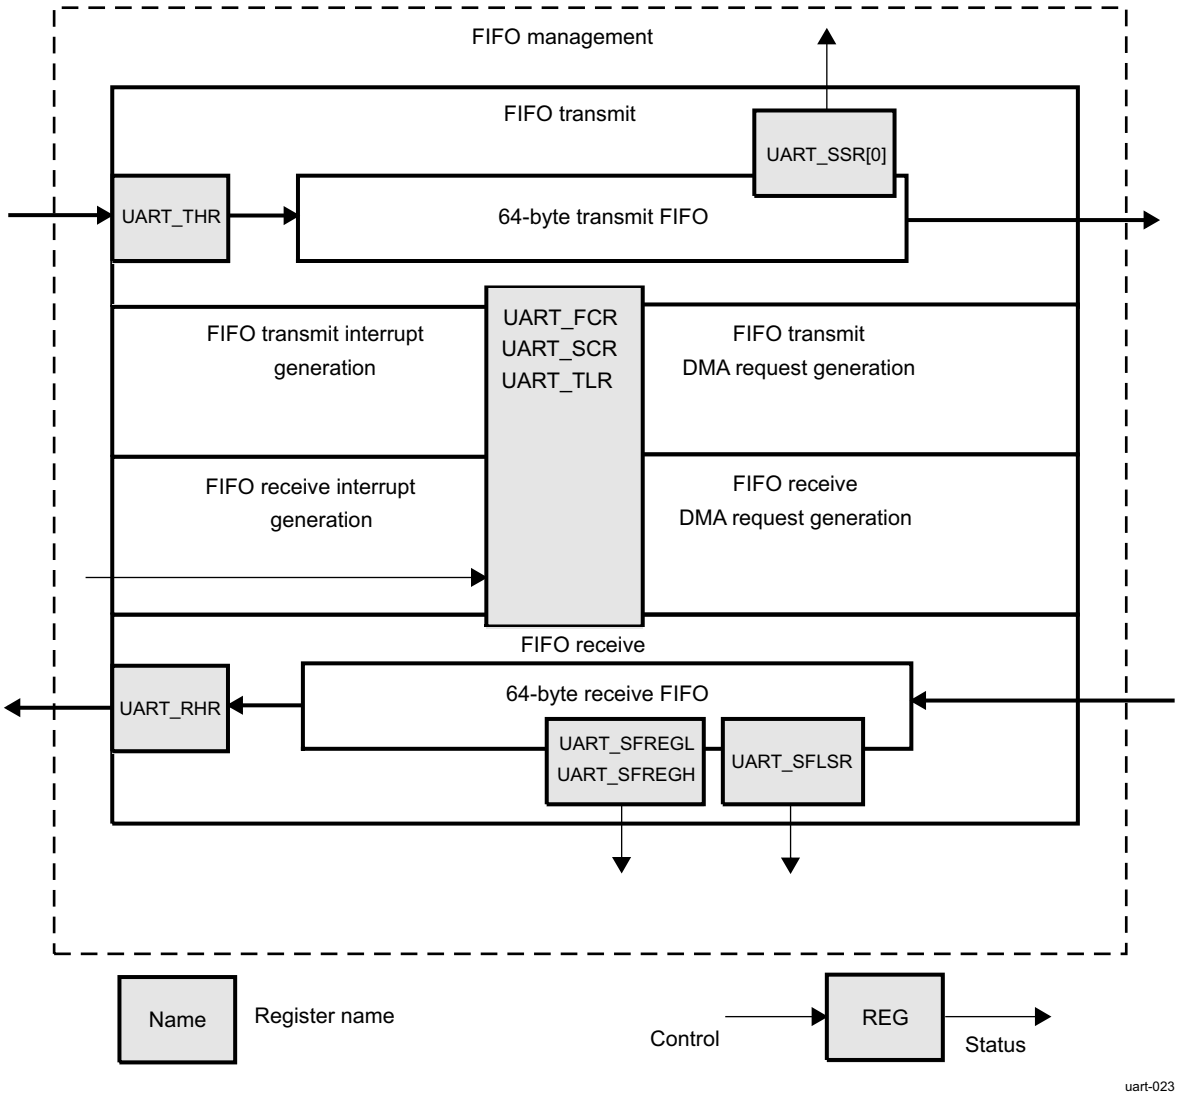

Figure 12-47. UART FIFO Management Registers

12.1.6.3.6.1 FIFO Trigger

12.1.6.3.6.1.1 Transmit FIFO Trigger

Table 12-76 lists the TX FIFO trigger level settings.

Table 12-76. UART TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[5-4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UART_TLR[3-0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

12.1.6.3.6.1.2 Receive FIFO Trigger

Table 12-77 lists the RX FIFO trigger-level settings.

Copyright © 2023 Texas Instruments Incorporated

Table 12-77. UART RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[7-6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UART_TLR[7-4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UART_TCR[7-4] RX_FIFO_TRIG_START and UART_TCR[3-0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 × (1 + CHAR_LENGTH + Parity + Stop – 0.5)] × Baud_rate + 4 × FCLK

  Note

  The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UART_TCR[7-4] RX_FIFO_TRIG_START bit field or the UART_FCR[7-6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

12.1.6.3.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UART_IER_UART register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UART_TLR[7-4] RX_FIFO_TRIG_DMA and UART_TLR[3-0] TX_FIFO_TRIG_DMA bit fields or the UART_FCR[7-6] RX_FIFO_TRIG and UART_FCR[5-4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the Host CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UART_TCR[3-0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 12-48 shows the generation of the RX FIFO interrupt request.

Copyright © 2023 Texas Instruments Incorporated

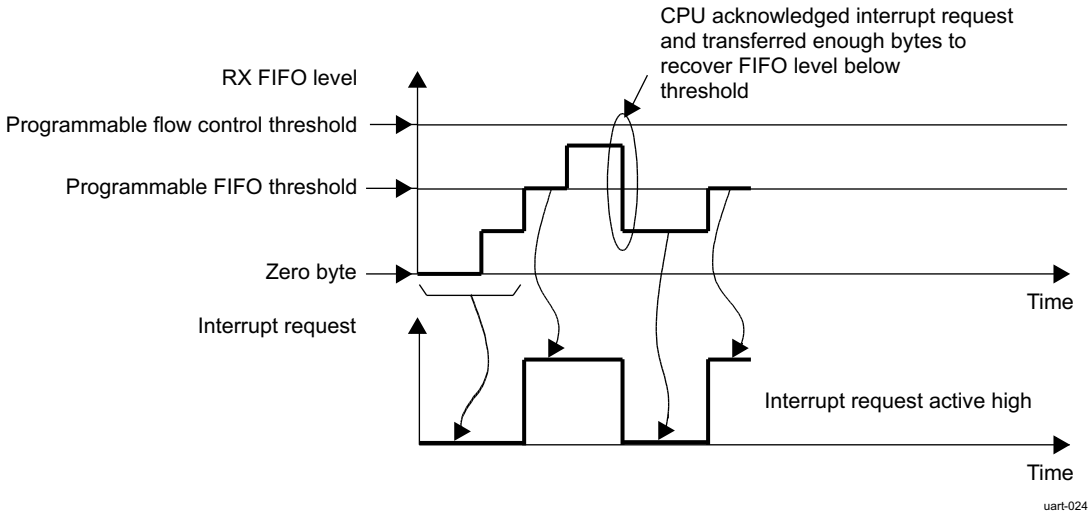

Figure 12-48. UART RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the Host CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 12-49 shows the generation of the TX FIFO interrupt request.

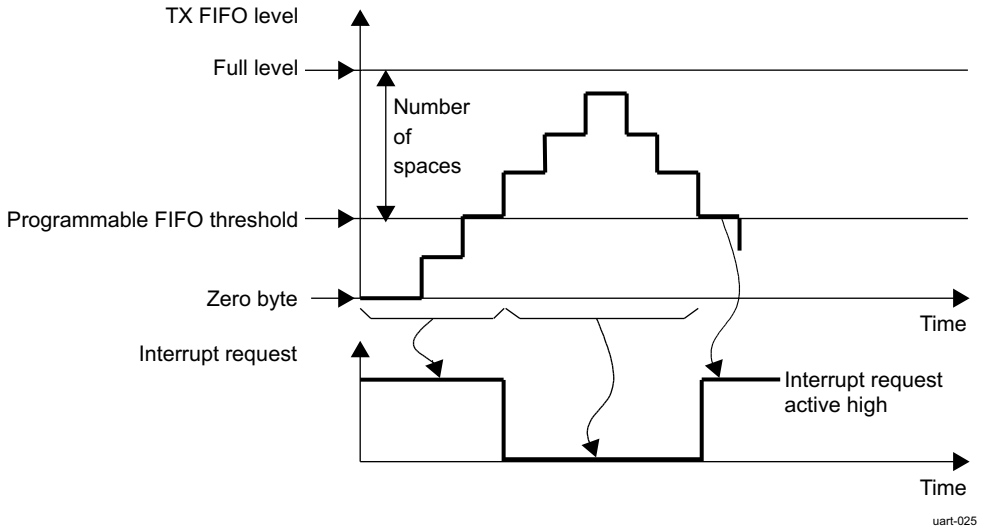

Figure 12-49. UART TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

12.1.6.3.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UART_IER_UART register), the status of the receiver and transmitter can be checked by polling the line status register (UART_LSR_UART).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the Host CPU.

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in *UART Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the signals (where i = 0 to).

signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UART_FCR[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the UART_FCR[3] DMA_MODE bit to 1 enables DMA mode 1.
- When the UART_SCR[0] DMA_MODE_CTL bit is set to 1, the UART_SCR[2-1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the UART_SCR[0] DMA_MODE_CTL bit to 1 and the UART_SCR[2-1] DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the UART_SCR[0] DMA_MODE_CTL bit to 0 and the UART_FCR[3] DMA_MODE bit to 1, or set the UART_SCR[0] DMA_MODE_CTL bit to 1 and the UART_SCR[2-1] DMA_MODE_2 bit field to 01. (The UART_FCR[3] DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

  The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

12.1.6.3.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UART_SCR[0] DMA_MODE_CTL = 0 and UART_FCR[3] DMA_MODE = 1:
   a. Set the UART_SCR[2-1] DMA_MODE_2 bit fields to 01 (DMA mode 1)
   b. Set the UART_SCR[0] DMA_MODE_CTL bit to1 (this setting of UART_SCR[0] DMA_MODE-CTL will ignores UART_FCR[3] DMA_MODE_CTL bit)

   Note

   It is strongly suggested to do steps ‘a’ and ‘b’ in two separate write in order to avoid malfunction of the device.

   c. Set the UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART_ACREG[5] DIS_IR_RX bit

Copyright © 2023 Texas Instruments Incorporated

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
f. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
g. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

2. DMA mode 1 is set (both TX/RX DMA) by registers UART_FCR[3] DMA_MODE = 0 and UART_SCR[0] DMA_MODE_CTL = 1, UART_SCR[2-1] DMA_MODE_2 = 01. It is almost the same as above, but steps ‘a’, and ‘b’ can be skipped:
   a. Set the UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART_ACREG[5] DIS_IR_RX bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   b. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
   c. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
   d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
   e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

3. DMA mode 3 is set (TX DMA only) by registers UART_FCR[3] DMA_MODE = 0 and UART_SCR[0] DMA_MODE_CTL = 1, UART_SCR[2-1] DMA_MODE_2 = 11. It is the same as above:
   a. Set the UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART_ACREG[5] DIS_IR_RX bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   b. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
   c. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
   d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
   e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

12.1.6.3.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 12-50 through Figure 12-53 show the supported DMA operations.

Copyright © 2023 Texas Instruments Incorporated

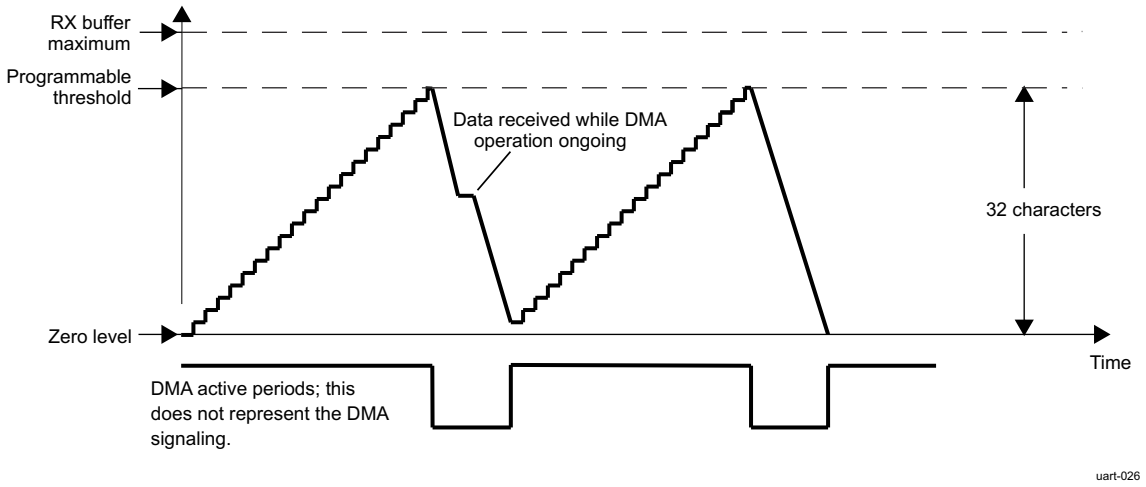

Figure 12-50. UART Receive FIFO DMA Request Generation (32 Characters)

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

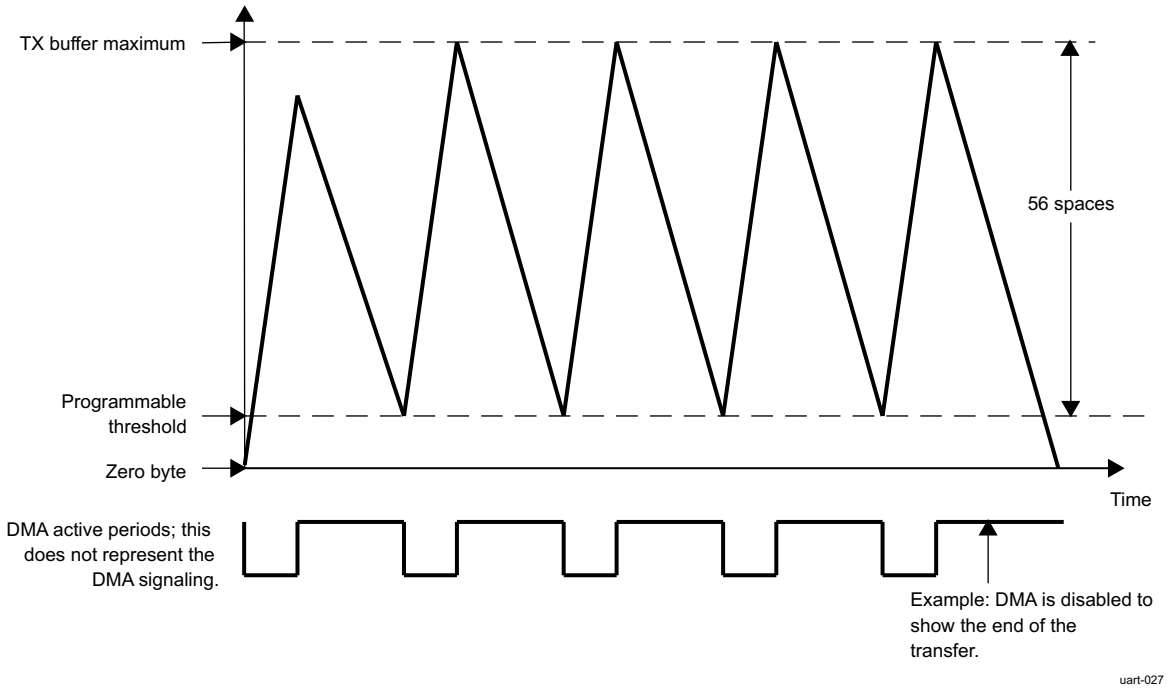

Figure 12-51. UART Transmit FIFO DMA Request Generation (56 Spaces)

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UART_TLR register.

The threshold can be programmed in a number of ways. Figure 12-51 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UART_FCR[5-4] TX_FIFO_TRIG bit field or the UART_TLR[3-0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

Copyright © 2023 Texas Instruments Incorporated

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

Figure 12-52 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

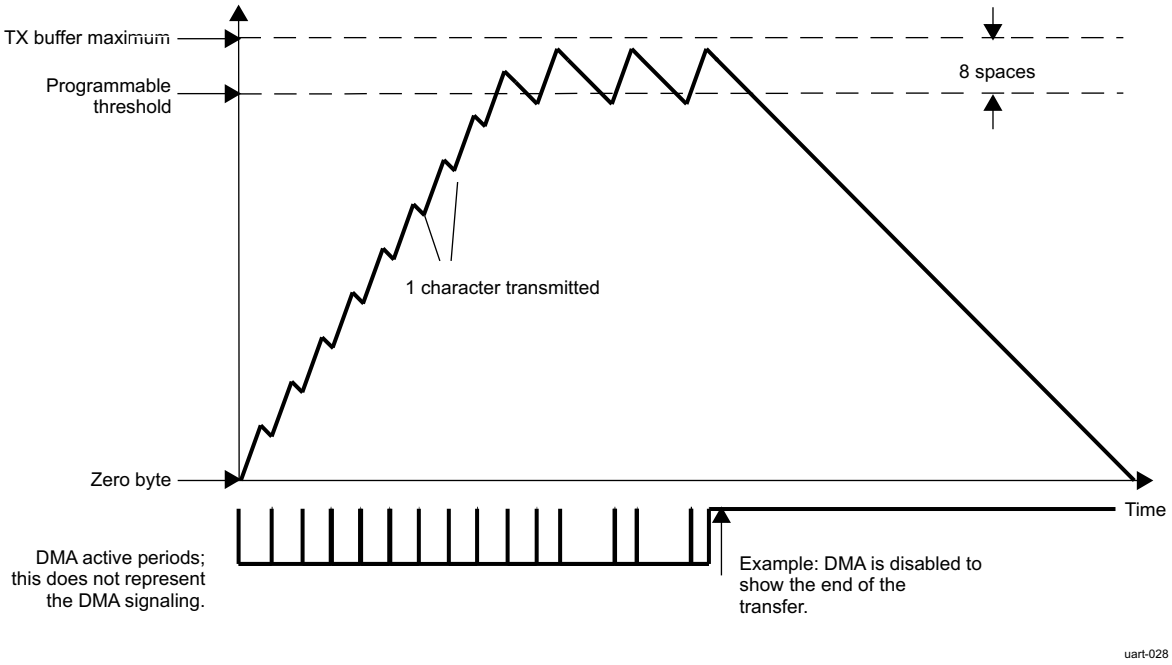

Figure 12-52. UART Transmit FIFO DMA Request Generation (8 Spaces)

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 12-53). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART_DLL and UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Copyright © 2023 Texas Instruments Incorporated

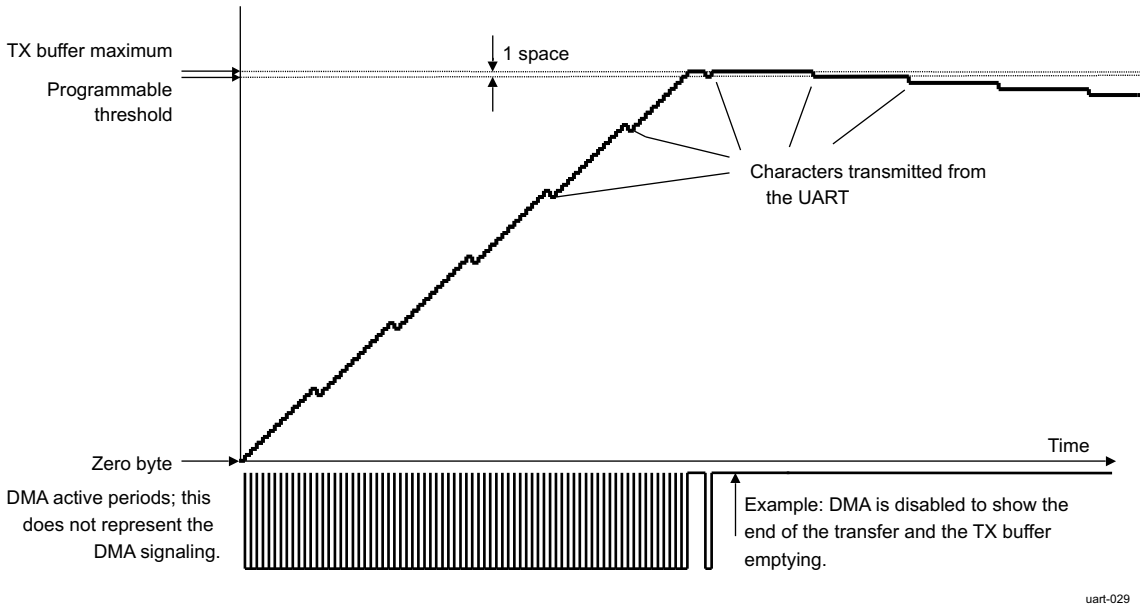

Figure 12-53. UART Transmit FIFO DMA Request Generation (1 Space)

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART_MDR3[1] NONDEFAULT_FREQ bit and UART_TX_DMA_THRESHOLD register (see Figure 12-54). In the example, the UART_TX_DMA_THRESHOLD[5-0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART_MDR3[1] NONDEFAULT_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

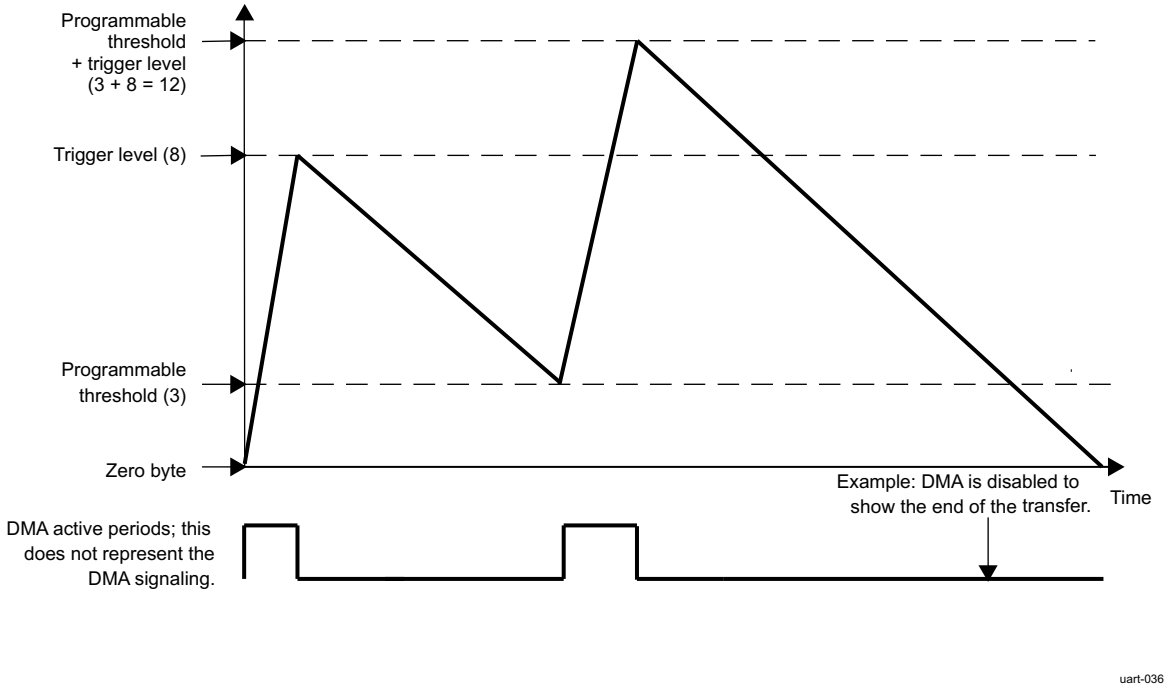

Figure 12-54. UART Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)

12.1.6.3.6.4.3 DMA Transmission

Figure 12-55 shows DMA transmission.

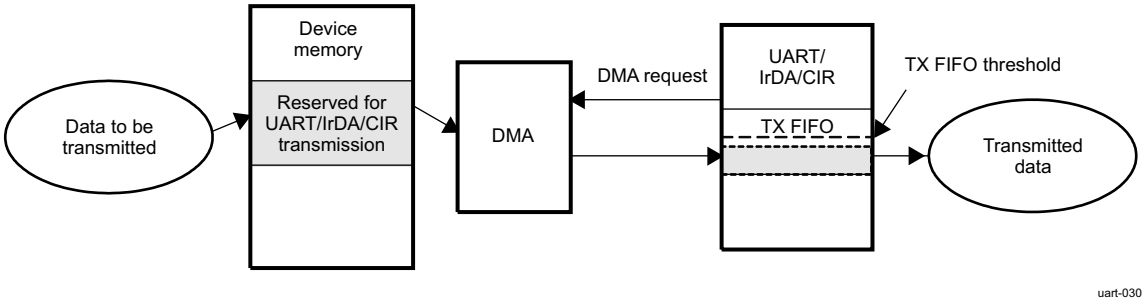

Figure 12-55. DMA Transmission

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:
   a. Until the TX FIFO trigger level is not reached, a DMA request is generated
   b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UART_THR empty (TX FIFO empty).

Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UART_THR register empties.

12.1.6.3.6.4.4 DMA Reception

Figure 12-56 shows DMA reception.

Copyright © 2023 Texas Instruments Incorporated

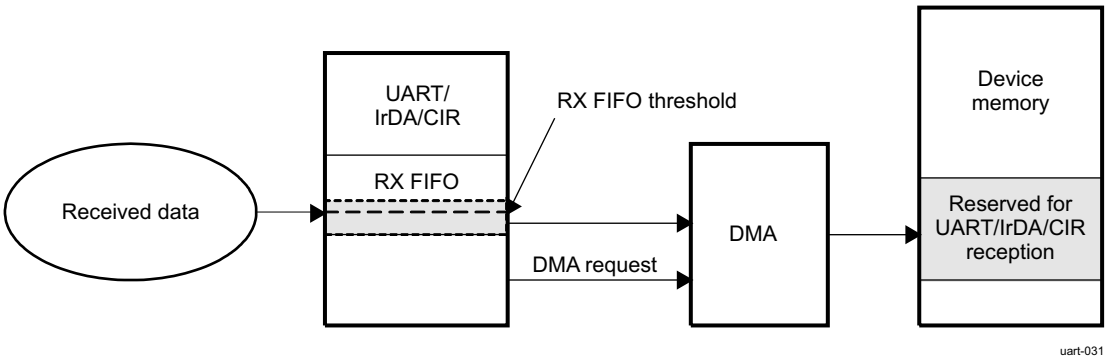

Figure 12-56. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

12.1.6.3.7 UART Mode Selection

12.1.6.3.7.1 Register Access Modes

12.1.6.3.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UART_LCR register determines the register access mode (see Table 12-78).

Table 12-78. UART Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7-0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7-0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

12.1.6.3.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Table 12-100, *UART Load FIFO Triggers Defined by the Concatenated Value*.

Table 12-79 through Table 12-81 summarize the register access submodes.

Table 12-79. UART Subconfiguration Mode A Summary

Mode	Condition

12.1.6.3.7.2 UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UART_MDR1[2:0] MODE_SELECT bit field (see Table 12-83).

Table 12-83. UART Mode Selection

Value	Mode
0x0:	UART 16× mode
0x1:	SIR mode
0x2:	UART 16× auto-baud
0x3:	UART 13× mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode
0x7:	Disable (default state)

MODE_SELECT is effective when the module is in operational mode (see Section 12.1.6.3.7.1, *Register Access Modes*).

To select a RS-485 mode, set the UART_MDR3[4] DIR_EN bit field to 0x1.

12.1.6.3.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 12-84 are used for the UART function.

0x084	UART_TX_DMA_THRESHOLD	UART_TX_DMA_THRESHOLD	UART_TX_DMA_THRESHOLD	UART_TX_DMA_THRESHOLD	UART_TX_DMA_THRESHOLD	UART_TX_DMA_THRESHOLD

(1) REGISTER_NAME(CIR) notation indicates that the register exists for other functions (IrDA or UART), but fields have different meanings for other functions (described separately in *UART Registers*).
(2) REGISTER_NAME[m:n] notation indicates that only register bits numbered m to n apply to the CIR function.

12.1.6.3.8 UART Protocol Formatting

12.1.6.3.8.1 UART Mode

12.1.6.3.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-57 shows the baud rate generator and associated controls.

Copyright © 2023 Texas Instruments Incorporated

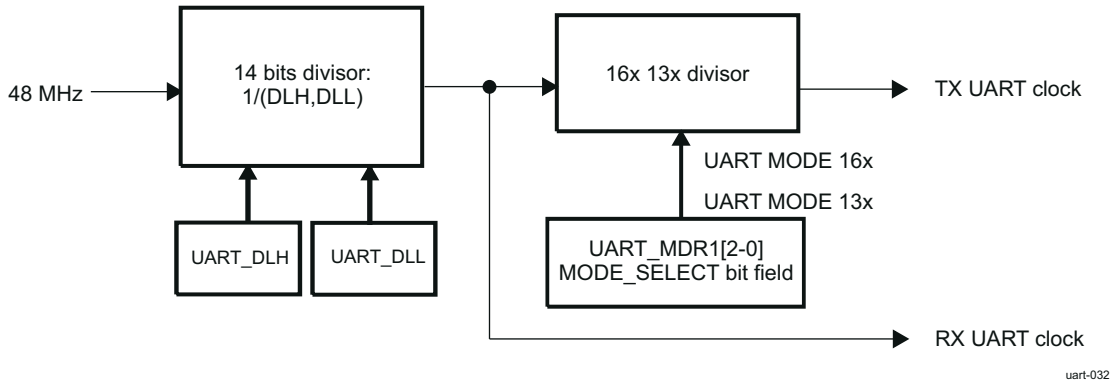

Figure 12-57. UART Baud Rate Generation

CAUTION

Before initializing or modifying clock parameter controls (UART_DLH, UART_DLL), UART_MDR1[2-0] MODE_SELECT = DISABLE must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

12.1.6.3.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16× mode: Divisor value = Operating frequency / (16× baud rate)
- UART 13× mode: Divisor value = Operating frequency / (13× baud rate)

Table 12-87. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)

12.1.6.3.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UART_LCR register.

Character length is specified using the UART_LCR[1-0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UART_LCR[5-3] PARITY_EN, UART_LCR[5-3] PARITY_TYPE_1, and UART_LCR[5-3] PARITY_TYPE_2 bit fields (see Table 12-88).

Table 12-88. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

12.1.6.3.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UART_EFR[7] AUTO_CTS_EN and UART_EFR[6] AUTO_RTS_EN bit fields, respectively.

With auto-CTS, CTS signal must be active before the module can transmit data.

Auto-RTS activates the RTS output only when there is enough room in the RX FIFO to receive data. It deactivates the RTS output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UART_TCR register determine the levels at which RTS is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UART_TCR register. RTS is active if the RX FIFO level is below the HALT trigger level in the UART_TCR[3-0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, RTS is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  RTS is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UART_TCR[7-4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, RTS is an active-low signal.
- Auto-CTS:

  The transmitter circuitry checks CTS before sending the next data byte. When CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, CTS must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the CTS state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, CTS is an active-low signal.

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UART_EFR) and the modem control register (UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UART_EFR[3-0] bit field (see Table 12-89).

Two other enhanced features relate to software flow control:

- XON-any function (UART_MCR[5] XON_EN): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

Note

The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UART_EFR[5] SPECIAL_CHAR_DETEC T): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UART_IIR_UART) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UART_IIR_UART. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 12-89. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UART_XON1_ADDR1[7-0] XON_WORD1 bit field. XON2 is defined in the UART_XON2_ADDR2[7-0] XON_WORD2 bit field.
XOFF1 is defined in the UART_XOFF1[7-0] XOFF_WORD1 bit field. XOFF2 is defined in the UART_XOFF2[7-0] XOFF_WORD2 bit field.

1.6.3.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UART_IIR_UART[4] bit (if enabled by UART_IER_UART[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UART_IIR_UART[4] bit is cleared and the XOFF interrupt disappears.

Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UART_EFR[1-0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UART_EFR[1-0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

Copyright © 2023 Texas Instruments Incorporated

1.6.3.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UART_TCR[3-0] RX_FIFO_TRIG_HALT. As soon as the RX FIFO reaches the trigger level programmed by UART_TCR[7-4] RX_FIFO_TRIG_START, two XON1 characters are sent, so the data transfer recovers.

Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

12.1.6.3.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

Copyright © 2023 Texas Instruments Incorporated

Note

The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UART_MDR1[2-0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UART_DLL, UART_DLH, and UART_LCR[5-0] bit field settings are not used; instead, the UART_UASR register is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UART_LCR, UART_DLL, and UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UART_MDR1[2-0] MODE_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115.2 bps (10 possibilities)

12.1.6.3.8.1.3.5 Error Detection

When the UART_LSR_UART register is read, the UART_LSR_UART[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UART_LSR_UART register and then reading the UART_RHR register identifies errors in a character.

Reading the UART_RHR register updates the BI, FE, and PE bits (see Table 12-73 for the UART mode interrupts).

The UART_LSR_UART[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

Note

Reading the UART_LSR_UART register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UART_RHR register.

Reading the UART_LSR_UART register clears the OE bit if it is set (see Table 12-73 for the UART mode interrupts).

12.1.6.3.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the Host CPU with the UART_IIR_UART[5-1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the Host CPU must:

- Reset the RX FIFO.
- Read the UART_RESUME register, which clears the internal flag.

12.1.6.3.8.1.3.7 Time-Out and Break Conditions

1.6.3.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (RX) is high for a time that equals 4x the programmed word length + 12 bits or manually configured amount of baud clocks, if a value other zero is set in the timeout register. RX is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on RX.

There are two modes of operation:

Copyright © 2023 Texas Instruments Incorporated

- In default operation on the UART_EFR2[6] TIMEOUT_BEHAVE is set to 0. For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on RX or when the UART_RHR register is read.
- Optionally, for choose to enable the timeout counter even if no character has been received by setting UART_EFR2[6] TIMEOUT_BEHAVE bit. This will generate periodic interrupts if the RX line remains idle. In this mode the counter will auto-reset when a timeout has been reached. Reading the UART_IIR_UART will clear the interrupt, but not the counter.

1.6.3.8.1.3.7.2 Break Condition

When a break condition occurs, TX is pulled low. A break condition is activated by setting the UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UART_LSR_UART[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

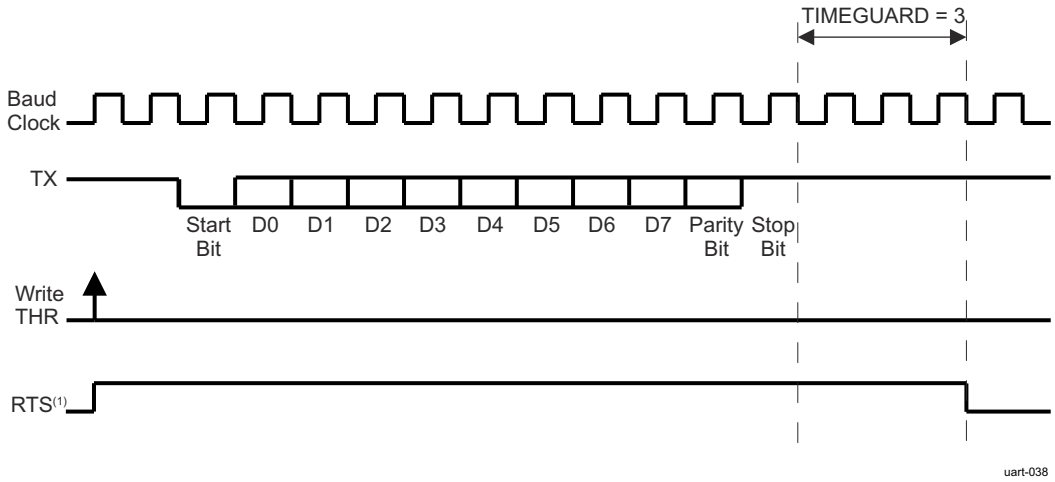
The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

12.1.6.3.8.2 RS-485 Mode

12.1.6.3.8.2.1 RS-485 External Transceiver Direction Control

The UART_MDR3[4] DIR_EN bit enables hardware control over an external transceiver to support RS-485. The direction signal comes across the DIR port. The direction polarity is controlled by the UART_MDR3[3] DIR_POL bit. The direction is determined by the hardware monitoring the TX FIFO and the TX shift register. When both are empty the transceiver is set to RX. There is a guard band delay counter of 3 bit clock cycles after the TX shift register is going empty to allow time for the stop bit to transition through the transceiver before a direction change to receive might be applied.

Figure 12-58 shows the direction control.



(1) Assumes DIR_POL = 1

Figure 12-58. RS-485 External Transceiver Direction Control

12.1.6.3.8.3 IrDA Mode

12.1.6.3.8.3.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-59 shows the baud rate generator and associated controls.

Copyright © 2023 Texas Instruments Incorporated

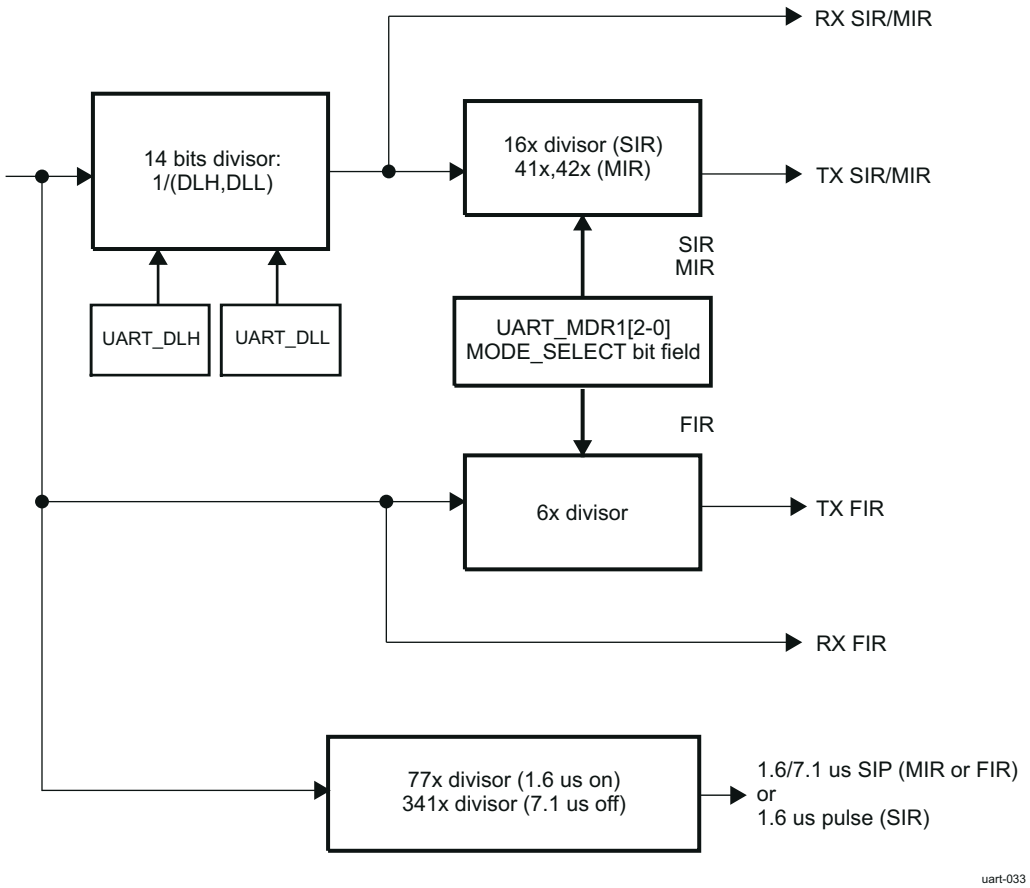


Figure 12-59. IrDA Baud Rate Generator

CAUTION

Before initializing or modifying clock parameter controls (UART_DLH, UART_DLL), MODE_SELECT=DISABLE (UART_MDR1[2-0] MODE_SELECT) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

12.1.6.3.8.3.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16× baud rate)
- MIR mode: Divisor value = Operating frequency/(41×/42× baud rate)
- FIR mode: Divisor value = None

Table 12-90 lists the IrDA baud rate settings.

Table 12-90. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs

(1) Average value

Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

12.1.6.3.8.3.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

12.1.6.3.8.3.3.1 IR RX Polarity Control

The UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the RX pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.

12.1.6.3.8.3.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the RX input can be disabled by the UART_ACREG[5] DIS_IR_RX bit.

12.1.6.3.8.3.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART_XON1_ADDR1[7-0] XON_WORD1 and UART_XON2_ADDR2[7-0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1-0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

12.1.6.3.8.3.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART_MDR1[7] FRAME_END_MODE bit to 0. The Host CPU writes the value of the frame length to the UART_TXFLH and UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the UART_MDR1[7] FRAME_END_MODE bit to 1. The Host CPU writes 1 to the UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the Host CPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

12.1.6.3.8.3.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the Host CPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the Host CPU writes 1 to the UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

Copyright © 2023 Texas Instruments Incorporated

12.1.6.3.8.3.3.6 Error Detection

When the UART_LSR_UART register is read, the UART_LSR_UART[4-2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 12-74). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

12.1.6.3.8.3.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the Host CPU must:

- Reset the TX FIFO.
- Read the UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

12.1.6.3.8.3.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 12.1.6.3.8.1.3.6, *Overrun During Receive*).

12.1.6.3.8.3.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART_SFREGH[3-0] MSB and UART_SFREGL[3-0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART_SFLSR register. Reading the UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The Host CPU uses the frame-length information to locate the frame boundary in the received frame data. The Host CPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the Host CPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

12.1.6.3.8.3.3.10 Multi-drop Parity Mode with Address Match

Multi-drop mode is enabled in the UART_EFR2 register.

Address matching mode is only available with 8 bit character length setting. UART_LCR[1-0] CHAR_LENGTH bit fields should always be set to 0x11 (8 bits) prior to enabling the feature.

This mode allows the transmitter to send data on a line where multiple receivers are connected, when supported. In this mode, a set parity bit is used to mark an address, and a parity of 0 denotes data.

This setting affects how the parity is generated. Writing a 0x1 into the UART_ECR[0] A_MULTIDROP bit will set the parity bit for the next byte to be sent, which will then be considered an address, for sending a data frame, the UART_ECR[0] A_MULTIDROP bit has to be cleared.

On reception if the feature is enabled by setting the UART_EFR2[2] MULTIDROP bit to 0x1 incoming frames with parity set to 0x1 are treated as address frames and with parity set to 0x0 as data frames. The receiver will drop all data frames until a matching address frame was found.

The matching address is determined by the values set in UART_MAR, UART_MMR and UART_MBR registers and the value set in UART_EFR2[7] BROADCAST bit.

Table 12-91 summarizes the operation of address matching based on the mentioned values.

Copyright © 2023 Texas Instruments Incorporated

Table 12-91. Details of address matching

Received frame	Received parity	Frame type	UART_MAR	UART_MMR	UART_MBR	UART_EFR2[7] BROADCAST	Operation of receiver	Address matching
0xXX(2)	0	DATA	X(1)	X(1)	0xXX(2)	X(1)	Drops data until matching address found	N/A
0xXX(2)	1	ADDRESS	0xXX(2)	0x00	0xXX(2)	0	Matches any address	Yes
0xEF	1	ADDRESS	0xXX(2)	0xXX(2)	0xEF	1	Matches broadcast address	Yes
0x1A	1	ADDRESS	0x1A	0xFF	0xXX(2)	0	Single address match	Yes
0xF5	1	ADDRESS	0xF3	0xF9	0xXX(2)	0	Group address match	Yes

(1) X indicates a do not care bit value
(2) 0xXX indicates a do not care 8 bit hexadecimal value

The possible values for matching address can be calculated in the following way:

- Single and Group addresses can be formed by masking the UART_MAR registers value with the value set in the UART_MMR register, bits set to 0x0 in the UART_MMR register result in do not care values.
- Broadcast addresses can be set in the UART_MBR register if broadcast address is enabled in the UART_EFR2[7] BROADCAST bit, the module will match on received address frames containing the broadcast address.
- For more details, see example below:
  - UART_MAR: 0xF3, UART_MMR: 0xF9, UART_MBR: 0xFF
  - Single and Group addresses: 0xF1, 0xF3, 0xF5, 0xF7
  - Broadcast addresses: 0xFF

If an address match occurred the matching address value can be obtained from the UART_RHR register in the following way:

- If the FIFO is disabled or the threshold is set to 0x1, the matching address can be directly read from UART_RHR as the FIFO will not be overwritten.
- If the FIFO is enabled or the threshold is greater than 0x1, the matching address will be the latest frame in the FIFO with a parity error bit set.

For received data, the parity error bit in the UART_LSR_UART register is set when a bit with a parity of 0x1 is received indicating an address frame and the received address matches based on the values of UART_MAR, UART_MMR, UART_MBR and UART_EFR2[2] MULTIDROP bit.

In Multi-drop mode no parity is used, as the parity bit is used to differentiate address and data frames. The parity error bit is used for indicating an address match.

For enabling the interrupt generation for address matching UART_IER_UART[2] LINE_STS_IT bit has to be set to 0x1.

An interrupt for the matching address can be identified by reading the UART_IIR_UART[5-1] IT_TYPE bit fields, a value of 0x00011 indicates a receiver line status error. After the UART_LSR_UART[2] RX_PE bit has to be read, a value of 0x1 indicates that an address match occurred. The reception of a frame is indicated with a value of 0x1 in the UART_LSR_UART[0] RX_FIFO_E bit as the matching value is written into the FIFO regardless of the frame type (data or address). UART_LSR_UART[7] RX_FIFO_STS bit will also be set to 0x1 as the parity error bit is used to indicate a matching address.

Note that the operation of the UART_LSR_UART[2] RX_PE bit depends on the value set in UART_EFR2[2] MULTIDROP bit. If UART_EFR2[2] MULTIDROP bit is set to 0x0, UART_LSR_UART[2] RX_PE bit is used to

Copyright © 2023 Texas Instruments Incorporated

indicate a received parity error. If UART_EFR2[2] MULTIDROP bit is set to 0x1, the receiver is in Multi-drop Address Match mode, thus the value in UART_LSR_UART[2] RX_PE bit is used to indicate an address match.

The interrupt is cleared the same way in both operation modes: reading the UART_LSR_UART register updates the values.

12.1.6.3.8.3.3.11 Time-guard

The time-guard feature enables the UART interface to operate with slow remote devices.

When set, it will insert a number of idle states between transmitting two characters, the length of which can be set in the UART_TIMEGUARD register. The value in the register defines the number of baud clocks of idle period to insert.

This idle state essentially acts like a long stop bit.

12.1.6.3.8.3.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

12.1.6.3.8.3.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

12.1.6.3.8.3.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-µs pulse duration methods. The UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

12.1.6.3.8.3.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART_MDR1[2-0] MODE_SELECT = 0x0) and the UART_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART_LCR[1-0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

12.1.6.3.8.3.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the CPU reads the line status register (UART_LSR_UART) to detect errors in the received frame.

When the UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART_ACREG[3] SEND_SIP bit.

Copyright © 2023 Texas Instruments Incorporated

The CPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

12.1.6.3.8.4 CIR Mode

12.1.6.3.8.4.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the Host CPU must develop a data structure that combines 1 and 0 with a *t* period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 12-60.

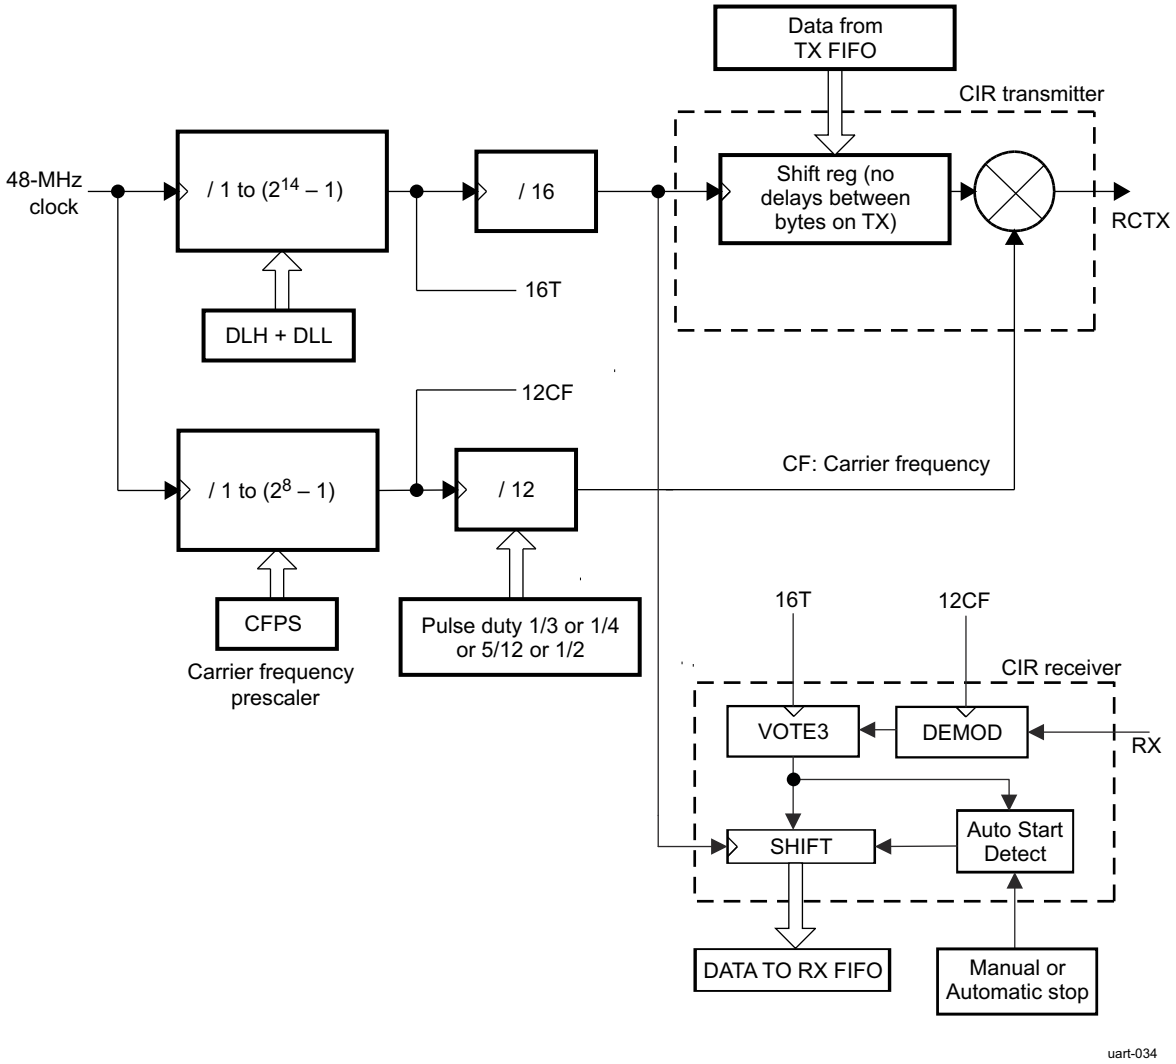

Figure 12-60. CIR Mode Block Components

Based on the requested modulation frequency, the UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

Dividing value = (FCLK / 12) / MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

Copyright © 2023 Texas Instruments Incorporated

Note

The UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART_MDR2 register. Table 12-92 shows the duty cycle.

Table 12-92. CIR Duty Cycle

UART_MDR2[5-4] CIR_PULSE_MODE	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

12.1.6.3.8.4.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

12.1.6.3.8.4.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see Section 12.1.6.3.8.3.3.1, *IR RX Polarity Control*).

12.1.6.3.8.4.2.2 CIR Transmission

In transmission, the Host CPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a *t* period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART_MDR1[5] SCT bit and the UART_ACREG[2] SCTX_EN bit, depending on the timer status
  - Using the UART_IIR_UART[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

12.1.6.3.8.4.2.3 CIR Reception

There are 2 ways to stop a CIR reception:

- The Host CPU can disable the reception by setting the UART_ACREG[5] DIS_IR_RX bit to 1. When it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the UART_ACREG[5] DIS_IR_RX bit must be set to 0.
- An automatic stop mechanism can configured by setting a value in the BOF length register (UART_EBLR). If the value set in the UART_EBLR register is different than 0, this features is enabled and the number of bits received will begin counting from 0. When the counter reaches the value defined in the UART_EBLR register, reception is automatically disabled and UART_IIR_CIR[2] RX_STOP_IT bit is set. When a 1 is detected on the RX pin, reception is automatically re-enabled.

There is a limitation when receiving data in UART CIR mode. Certain IrDA transceivers on the market have a characteristic that causes shrinking of the received modulation pulse hold-time. The UART receive filtering schema is based on the same encoding mechanism used for transmission.

For the following scenario:

- Shift register period: 0.9µs
- Modulation frequency: 36kHz
- Duty cycle: 1/4 of a modulation frequency period

Copyright © 2023 Texas Instruments Incorporated

Data sent with these conditions would contains 7µs pulses within a 28µs period. The UART expects to receive similar incoming data on receive, but various transceiver timing characteristics typically only send 2µs modulated pulses. These 2µs pulses will be filtered out and RX FIFO will not receive data. This does not affect UART CIR mode in transmission.

CIR RX demodulation can be bypassed by setting the UART_MDR3[0] DISABLE_CIR_RX_DEMOD bit.

12.1.6.4 UART Programming Guide

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 12.1.6.3.7.1, *Register Access Modes*.

12.1.6.4.1 UART Mode selection

Table 12-93 describes how to set different register access mode.

Table 12-93. UART Configure Register Access Mode

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7-0]	≠0xBF
Set the register access mode B	UART_LCR[7-0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

12.1.6.4.2 UART Submode selection

This section describes how to set different register access submode.

Table 12-94. UART Configure Register Access Submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see Table 12-93	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see Table 12-93	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

Table 12-95. UART Configure Register Access Submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option: configure the submode MSR_SPR		
Configure mode B	see Table 12-93	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option: configure the submode MSR_SPR		
Configure mode B	see Table 12-93	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

Table 12-96. UART Configure Register Access Submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF		
Configure B	see Table 12-93

Table 12-96. UART Configure Register Access Submode XOFF (continued)

Step	Register/Bit Field/Programming Model	Value
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

12.1.6.4.3 UART Load FIFO trigger and DMA mode settings

12.1.6.4.3.1 DMA mode Settings

To enable and configure program the DMA mode, perform the following steps:

Table 12-97. DMA Mode Settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see Section 12.1.6.3.6.4	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see Section 12.1.6.3.6.4	UART_SCR[2-1] DMA_MODE_2	-

12.1.6.4.3.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 12-98. Load FIFO Triggers Defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the desire RX FIFO trigger level	UART_FCR[5-4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7-6] RX_FIFO_TRIG	0x-

Table 12-99. Load FIFO Triggers Defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA	0x-

Table 12-100. Load FIFO Triggers Defined by the Concatenated Value

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA UART_FCR[7-6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA UART_FCR[5-4] TX_FIFO_TRIG	0x-

12.1.6.4.4 UART Protocol, Baud rate and interrupt settings

12.1.6.4.4.1 Baud rate settings

Table 12-101. UART Baud Rate Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 12-93	
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 12-93	

Copyright © 2023 Texas Instruments Incorporated

Table 12-101. UART Baud Rate Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Disable sleep mode	UART_IER_UART[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see Table 12-93	
Set the appropriate divisor value	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x-

12.1.6.4.4.2 Interrupt settings

Table 12-102. UART Interrupt Settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 12-93	0x7
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 12-93	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER_UART[7] CTS_IT UART_IER_UART[6] RTS_IT UART_IER_UART[5] XOFF_IT UART_IER_UART[4] SLEEP_MODE UART_IER_UART[3] MODEM_STS_IT UART_IER_UART[2] LINE_STS_IT UART_IER_UART[1] THR_IT UART_IER_UART[0] RHR_IT	0x-

12.1.6.4.4.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 12-103. UART Protocol Settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 12.1.6.3.8.1.3.1 , *Frame Formatting*	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1-0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0

12.1.6.4.4.4 UART/RS-485/IrDA(SIR/MIR/FIR)/CIR

Table 12-104. UART Mode Selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART/IrDA (SIR, MIR, FIR)/CIR modes, see Section 12.1.6.3.7.2, *UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection*	UART_MDR1[2-0] MODE_SELECT	0x-
Load the desire RS-485 mode, see Section 12.1.6.3.7.2, *UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection*	UART_MDR3[4] DIR_EN	0x1

12.1.6.4.4.5 UART Multi-drop Parity Address Match Mode Configuration

Table 12-105. UART Multi-drop Parity Address Match Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Disable receive mode	UART_ECR[3] RX_EN	0
Enable Multi-drop parity Address match mode	UART_EFR2[2] MULTIDROP	1
Set the matching device address	UART_MAR[7-0] ADDRESS	0x-
Set the address match masking	UART_MMR[7-0] MASK	0x-

Table 12-105. UART Multi-drop Parity Address Match Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Set the broadcast address match	UART_MBR[7-0] BROADCAST_ADDRESS	0x-
Enable broadcast address matching if needed	UART_EFR2[7] BROADCAST	1
Enable receive mode	UART_ECR[3] RX_EN	1

12.1.6.4.5 UART Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

12.1.6.4.5.1 Hardware Flow Control Configuration

Table 12-106. UART Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x7
Load the start and halt trigger value.	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

12.1.6.4.5.2 Software Flow Control Configuration

Table 12-107. UART Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 12-96	
Load the software control characters	UART_XON1_ADDR1[7-0] XON_WORD1 UART_XON2_ADDR2[7-0] XON_WORD2 UART_XOFF1[7-0] XOFF_WORD1 UART_XOFF2[7-0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see Table 12-94	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--
Load start and halt trigger value for software flow control	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3-0] SW_FLOW_CONTROL	0x-

12.1.6.4.6 IrDA Programming Model

12.1.6.4.6.1 SIR mode

12.1.6.4.6.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

Table 12-108. SIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x1A 0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

Copyright © 2023 Texas Instruments Incorporated

Table 12-108. SIR Mode Receive Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

Table 12-109. SIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB	0x1A
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7-0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
Set SIR pulse width to be 1.6 µs	UART_ACREG[7] PULSE_TYPE	1

12.1.6.4.6.2 MIR mode

12.1.6.4.6.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

Table 12-110. MIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (1.152 bps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force outputs DTR and RTS to active	UART_MCR[1-0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

Table 12-111. MIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

Table 12-111. MIR Mode Transmit Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7-0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

12.1.6.4.6.3 FIR mode

12.1.6.4.6.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

Table 12-112. FIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[7-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see Section 12.1.6.4.3, *Load FIFO trigger and DMA mode settings*	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7-0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

Table 12-113. FIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see Section 12.1.6.4.3, *Load FIFO trigger and DMA mode settings*	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7-0]	0x45
Set frame length	UART_TXFLL[7-0] TXFLL UART_TXFLH[7-0] TXFLH	0x4 0x0
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

12.2 High-speed Serial Interfaces

This section describes the high-speed serial interfaces in the device.

Copyright © 2023 Texas Instruments Incorporated

12.2.1 Gigabit Ethernet MAC (CPSW)

This chapter describes the Gigabit Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

12.2.1.1 CPSW Programming Guide

12.2.1.1.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, or RGMII) Mode. See the CTRLMMR_MCU_ENET_CTRL[1-0] MODE_SEL register.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW_CONTROL_REG register
6. Configure the Ethernet Port Source Address registers (CPSW_PN_SA_L_REG and CPSW_PN_SA_H_REG)
7. Configure the CPSW statistic port enable register CPSW_STAT_PORT_EN_REG
8. Configure the ALE (*Address Lookup Engine*)
9. Configure the MDIO (*Initializing the MDIO Module*)
10. Configure Ethernet port, as per the desired mode of operations

12.2.1.1.2 CPSW Reset

To reset the Ethernet port, the host must perform the following:

1. Set CMD_IDLE bit to 1h in the Ethernet port control register: CPSW_PN_MAC_CONTROL_REG.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status register: CPSW_PN_MAC_STATUS_REG.
3. Set SOFT_RESET bit to 1h in the Ethernet port software reset register: CPSW_PN_MAC_SOFT_RESET_REG.
4. Wait for SOFT_RESET bit in the CPSW_PN_MAC_SOFT_RESET_REG registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.
6. Re-configure registers reset to default value by CPSW_PN_MAC_SOFT_RESET_REG.

12.2.1.1.3 MDIO Software Interface

12.2.1.1.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW_MDIO_CONTROL_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW_MDIO_CONTROL_REG.
3. The MDIO PHY alive status register (MDIO CPSW_MDIO_ALIVE_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW_MDIO_LINK_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW_MDIO_USER_PHY_SEL_REG_k, where k = 0 or 1), and set the LINKINT_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW_MDIO_USER_INT_MASK_SET_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW_MDIO_USER_INT_MASK_SET_REG) to use the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1).

Copyright © 2023 Texas Instruments Incorporated

12.2.1.1.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW_MDIO_USER_ACCESS_REG_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW_MDIO_USER_ACCESS_REG_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.1.1.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW_MDIO_USER_ACCESS_REG_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW_MDIO_USER_ACCESS_REG_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW_MDIO_USER_ACCESS_REG_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.2 Peripheral Component Interconnect Express (PCIe) Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) subsystem.

12.2.2.1 PCIe Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) subsystem is built around a multi-lane dual-mode PCIe controller that provides low pin-count, high reliability, and high-speed data transfers at rates of up to 8.0 Gbps per lane for serial links on backplanes and printed wiring boards.

Figure 12-61 provides PCIe subsystem overview.

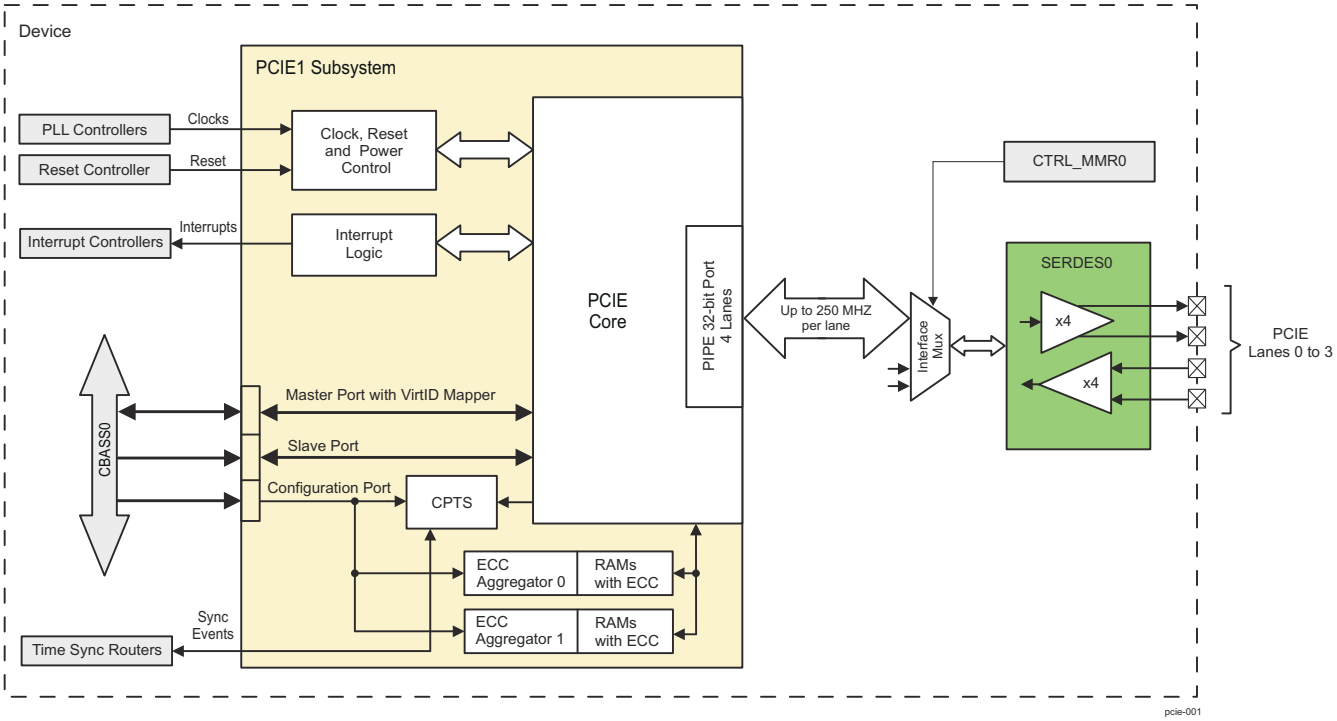

Figure 12-61. PCIe Subsystem Overview

12.2.2.1.1 PCIe Subsystem Features

Each PCIe subsystem supports the following main features:

- Compliance to PCIe® Base Specification, Revision 4.0 (Version 0.7)
- 4-lane configuration with up to 8.0 Gbps/lane (Gen3). Can be used in 1x4, 1x2, 1x1 modes.
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- 62.5/125/250MHz operation on PIPE interface for Gen1/Gen2/Gen3, respectively
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Dual mode: Root Port (RP) or End Point (EP) operation modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4K bytes
- Four virtual channels (VC)
- Four traffic classes (TC)
- PCI Power Management states are:
  - L1 Active State Power Management
  - L1 Power Management substates support
  - D1 Device Power Management state
- Maximum number of non-posted outstanding transactions: 32
- Resizable BAR capability

Copyright © 2023 Texas Instruments Incorporated

- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.2.2.1.2 PCIe Subsystem Ports

This section describes PCIe subsystem ports related to clocks, resets, and hardware requests.

Table 12-114. PCIe Subsystem Clocks and Resets

Clocks	
Module Clock Input	**Description**
PCIE_FICLK	PCIE interface bus clock (CBA_CLK).
PCIE_PM_CLK	PCIE core free-running clock used for low power state transitions and clock control generation.
PCIE_CPTS_RCLK	PCIE CPTS reference clock (RCLK). The CPTS RCLK clock frequency should be greater than or equal to the PCIE CBA_CLK clock frequency. Otherwise, the software will have to add some wait cycles before a correct event is generated by the CPTS module. Additionally, the CPTS RCLK should be set to same frequency as the PCIe core clock.
PCIE_LANE0_TXMCLK	PCIE core clock (CORE_CLK) driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_TXMCLK is used as the core clock input for all lanes. The TXMCLKs for the rest of the lanes are left unconnected
PCIE_LANE0_RXCLK	PCIE PIPE interface clock driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_RXCLK is used as the PIPE interface clock for all lanes. The RXCLKs for the rest of the lanes are left unconnected.
SERDES0_IP2_LN0_TXCLK	PCIE lane 0 PIPE/RAW TX return clock.
SERDES0_IP2_LN1_TXCLK	PCIE lane 1 PIPE/RAW TX return clock.
SERDES0_IP2_LN2_TXCLK	PCIE lane 2 PIPE/RAW TX return clock.
SERDES0_IP2_LN3_TXCLK	PCIE lane 3 PIPE/RAW TX return clock.
Resets	
Module Reset Input	**Description**
PCIE_RST	PCIE reset

Table 12-115. PCIe Subsystem Hardware Requests

Interrupt Requests		
Module Interrupt Signal	**Description**	**Type**
PCIE_DOWNSTREAM_PULSE_0	PCIE downstream interrupt	Pulse
PCIE_ERROR_PULSE_0	PCIE error interrupt	Pulse
PCIE_FLR_PULSE_0	PCIE function level interrupt	Pulse
PCIE_HOT_RESET_PULSE_0	PCIE hot reset interrupt	Pulse
PCIE_LEGACY_PULSE_0	PCIE legacy interrupt	Pulse
PCIE_LINK_STATE_PULSE_0	PCIE link state interrupt	Pulse
PCIE_LOCAL_LEVEL_0	PCIE local interrupt	Level
PCIE_PWR_STATE_PULSE_0	PCIE power state interrupt	Pulse
PCIE_PHY_LEVEL_0	PCIE PHY interrupt	Level
PCIE_PTM_VALID_PULSE_0	PCIE PTM valid interrupt	Pulse
PCIE_ECC0_CORR_LEVEL_0	PCIE ECC AGGR 0 correctable error interrupt	Level
PCIE_ECC0_UNCORR_LEVEL_0	PCIE ECC AGGR 0 uncorrectable error interrupt	Level
PCIE_ECC1_UNCORR_LEVEL_0	PCIE ECC AGGR 1 uncorrectable error interrupt	Level
PCIE_ASF_NONFATAL_LEVEL_0	PCIE active internal diagnostics interrupt	Level
PCIE_ASF_FATAL_LEVEL_0	PCIE active internal diagnostics interrupt	Level
PCIE_CPTS_PEND_0	PCIE timesync interrupt	Level
PCIE_DPA_PULSE_0	PCIE dynamic power allocation interrupt	Pulse
DMA Events		
Module DMA Event	**Description**	**Type**
-	The PCIe subsystem does not provide built-in DMA capabilities	-

Table 12-115. PCIe Subsystem Hardware Requests (continued)

Time Sync and Compare Events (Output)		
Module Event	**Description**	**Type**
PCIE_CPTS_HW1_PUSH_0	PCIE CPTS hardware push event (HW1_TS_PUSH)	Edge
PCIE_CPTS_COMP_0	PCIE CPTS compare output interrupt	Edge
PCIE_CPTS_SYNC_0	PCIE CPTS sync output interrupt	Edge
PCIE_CPTS_GENF_0	PCIE CPTS GENF0 output interrupt	Edge
Time Sync Events (Input)		
Module Event	**Description**	**Type**
PCIE_CPTS_HW2_PUSH_0	PCIE CPTS hardware time stamp push event (HW2_TS_PUSH)	Edge

12.2.2.2 PCIe Environment

This section describes the PCIe subsystem application fields from an environment point of view (external connections).

Table 12-116 describes the SERDES signal names at device level related to PCIe subsystem and specifies their functions.

Copyright © 2023 Texas Instruments Incorporated

Table 12-116. PCIe Subsystem I/O Signals

Device Level Signal	I/O[1]	Description
PCIE1_RXN0	I	PCIe Lane 0 Receive Differential Data (-)
PCIE1_RXP0	I	PCIe Lane 0 Receive Differential Data (+)
PCIE1_TXN0	O	PCIe Lane 0 Transmit Differential Data (-)
PCIE1_TXP0	O	PCIe Lane 0 Transmit Differential Data (+)
PCIE1_RXN1	I	PCIe Lane 1 Receive Differential Data (-)
PCIE1_RXP1	I	PCIe Lane 1 Receive Differential Data (+)
PCIE1_TXN1	O	PCIe Lane 1 Transmit Differential Data (-)
PCIE1_TXP1	O	PCIe Lane 1 Transmit Differential Data (+)
PCIE1_RXN2	I	PCIe Lane 2 Receive Differential Data (-)
PCIE1_RXP2	I	PCIe Lane 2 Receive Differential Data (+)
PCIE1_TXN2	O	PCIe Lane 2 Transmit Differential Data (-)
PCIE1_TXP2	O	PCIe Lane 2 Transmit Differential Data (+)
PCIE1_RXN3	I	PCIe Lane 3 Receive Differential Data (-)
PCIE1_RXP3	I	PCIe Lane 3 Receive Differential Data (+)
PCIE1_TXN3	O	PCIe Lane 3 Transmit Differential Data (-)
PCIE1_TXP3	O	PCIe Lane 3 Transmit Differential Data (+)
PCIE1_CLKREQn	I/O	PCIe sideband signal for negotiation of L1 Substate entry/exit. The PCIE1_CLKREQn pin operates as an active low open-drain bidirection reference clock request pin. 1 = no request for clock; 0 = request for clock

(1) I = Input; O = Output.

12.2.2.3 PCIe Subsystem Functional Description

12.2.2.3.1 PCIe Subsystem Block Diagram

The block diagram of PCIe subsystem is shown in Figure 12-62. The subsystem comprises of these major components – the PCIe Core with AXI interfaces, bridges to connect to the system CBASS0 interconnect master and slave interfaces, bridges to connect the system CBASS0 configuration interfaces, additional logic to implement the Precision Time Measurement (PTM), user configuration and interrupt, and RAMs to support the controller FIFOs.

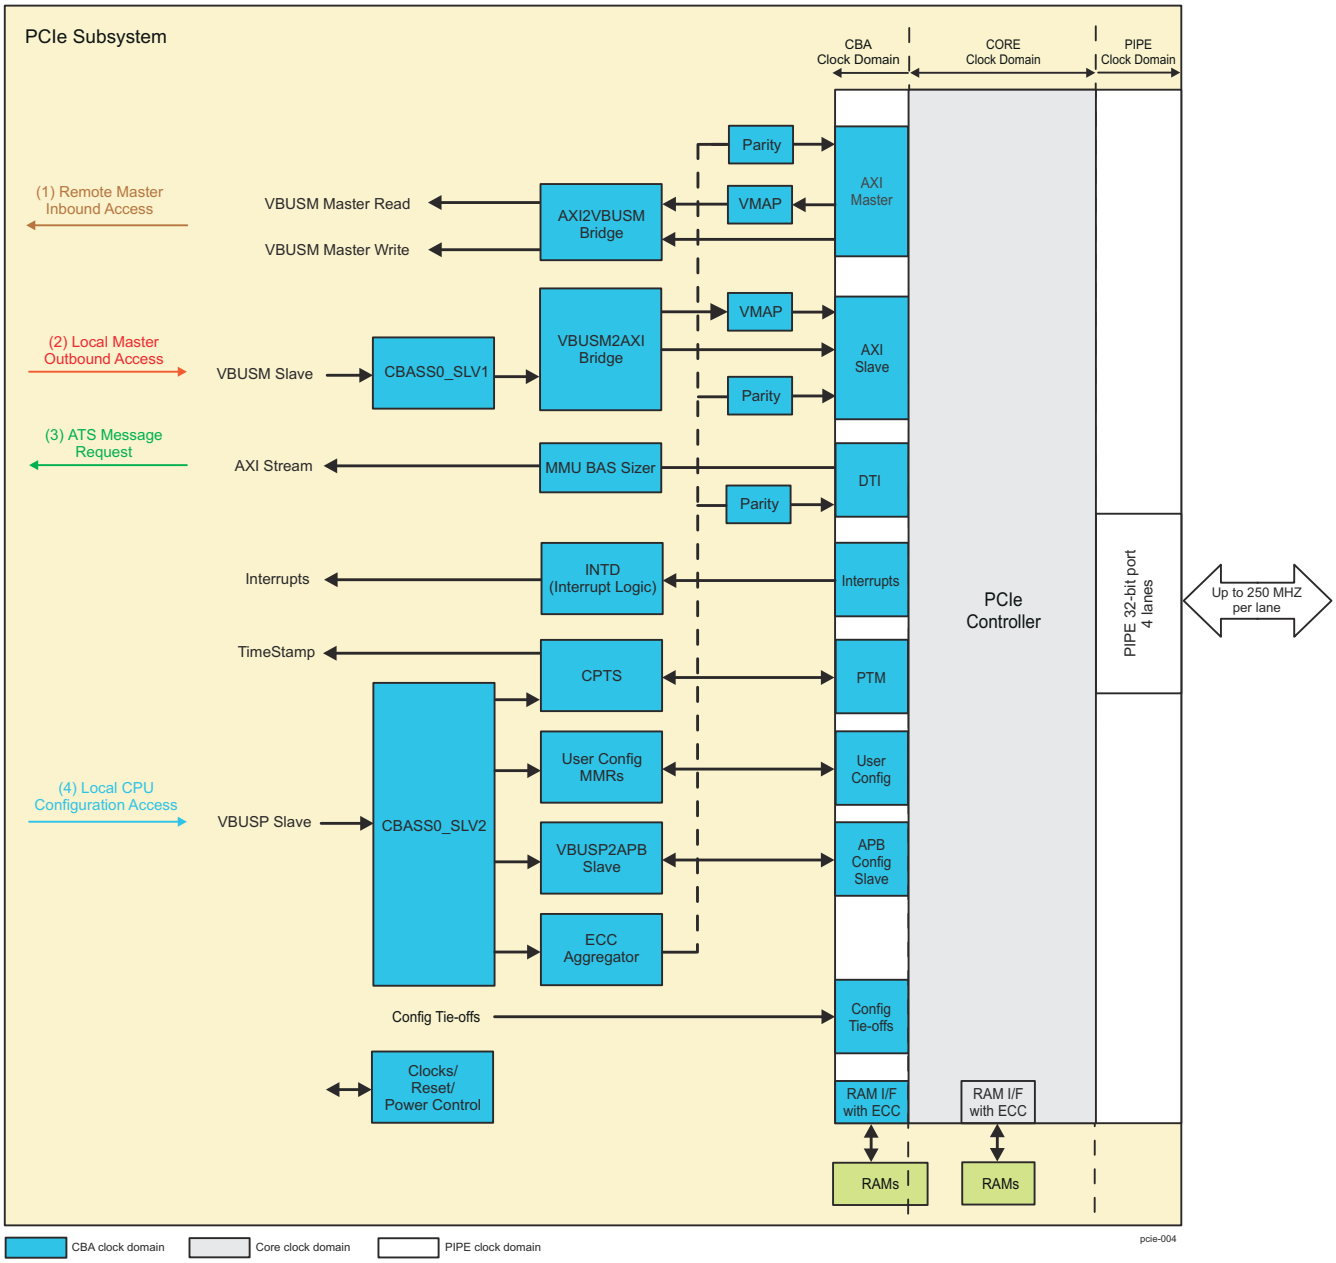

Figure 12-62. PCIe Subsystem Block Diagram

Figure 12-62 also shows some example data flows in the PCIe subsystem, such as:

1. A remote master issues a read or write access over PCIe to the local device. This will create a command to be issued on the PCIe VBUSM master read or write interface.
2. A master in the local device issues a read or write access over PCIe to the remote device. This will create a command to be issued on the PCIe VBUSM slave read or write interface.

Copyright © 2023 Texas Instruments Incorporated

3. A remote endpoint issues an Address Translation Request (ATS). This will create an inbound transaction on the AXI DTI interface.
4. A master in the local device wants to access the local PCIe configuration registers, the ECC aggregator registers or the CPTS registers. This will create a transaction over the PCIe VBUSP slave interface.

12.2.2.3.1.1 PCIe Core Module

The PCIe Core module supports dual mode of operation - it can be configured as an End Point (EP) and also as a Root Port (RP). The operational mode is selected with the CTRLMMR_PCIE1_CTRL[7] MODE_SEL register bit within the device Control Module (CTRL_MMR0). It is expected that the MODE_SEL bit is programmed during initial power up based on settings in the SoC boot configuration or a non-volatile storage such as eFuse or Flash memory.

It is not expected that the MODE_SEL setting would have to change during a full power cycle of the device. It is more likely that the operational mode of a SoC will stay as EP or RP for a particular end product's life cycle. It is not expected to switch back and forth during operation without a reset cycle.

The PCIe core module supports four virtual channels (VC) and four transfer classes (TC). The VCs can be used to implement Quality-of-Service (QoS) mechanism by enabling priority or round-robin arbitration. Typically, the highest numbered enabled VC is assigned the highest priority.

The PCIe core module is configured to support Single Root I/O virtualization (SR-IOV). It supports 6 Physical Functions (PF) and 16 Virtual Functions (VF).

There is one AXI master port and one AXI slave port in the PCIe core. All ingress data traffic regardless of the VC assigned will be delivered on the AXI master port. Similarly, all egress data that is presented on AXI slave port of the PCIe core will be assigned VCs through the outbound address translation registers.

12.2.2.3.1.2 PCIe PHY Interface

The PCIe subsystem incorporates a 4-lane PCIe compliant PHY (PIPE) interface to connect to a SERDES-based PHY. The PCIe PHY module consist of a SERDES module and a PCIe PCS (Physical Coding Sub-block) module. The SERDES module converts parallel data into PCIe serial signals and the PCIe PCS module provides an industry standard PIPE Interface to PCIe MAC. The frequency of the PIPE interface can be 62.5MHz, 125MHz or 250MHz depending on whether the system is operating in Gen1, Gen2 or Gen3 mode. The width of the PIPE interface remains constant at 32-bits for all modes of operation. The PCIe controller Lane 0 will always be the master lane for any lane width. For more information on the SERDES module, see *Serializer/Deserializer (SerDes)*.

12.2.2.3.1.3 CBA Infrastructure

The PCIe subsystem includes two CBASS modules (CBASS_SLV1 and CBASS_SLV2) to provide access to the various sub-components.

The CBASS_SLV1 is used to access the PCIe egress data region through the VBUSM2AXI bridge and the AXI slave port of the PCIe controller. There are three data regions implemented in the CBASS_SLV1. The PCIE_DAT0 region provides a region with 27 bits of address and PCIE_DAT1 region provides a region with 32 bits of address. These regions are provided to ensure separate memory spaces for 32-bit and 64-bit maps at the SoC level. The PCIE_DAT2 region provides a region with 48 bits of address. This is used to route all requests with *casel* not equal to zero to the PCIe controller slave port. The destination for all these three regions is the AXI slave port of the PCIe controller.

The CBASS_SLV2 provides multiple regions to access the VBUSP configuration ports of the sub-components of the PCIe sub-system like the PCIe controller configuration port, USER_CFG, VMAP, CPTS and the ECC aggregators. Having multiple regions on the VBUSP configuration port enables the SoC infrastructure to have hardware firewalls that can provide secure access to configuration registers.

The SERDES PLL should be initialized prior to accessing the PCIe core and ECC_AGGR1 configuration registers. Any accesses to these two regions prior to initializing the SERDES PLL will complete with a read/write status error in CBASS_SLV2.

12.2.2.3.1.4 VBUSM to AXI Bridges

A VBUSM2AXI protocol conversion bridge is attached to the each AXI slave port. This bridge translates all incoming data requests and sends them to the AXI slave port of the PCIe controller core. Wherever required, it

Copyright © 2023 Texas Instruments Incorporated

also generates side band signals that the AXI bridge needs based upon the address and the address space of the transaction on the device's native bus.

12.2.2.3.1.5 AXI to VBUSM Bridges

The AXI master port of the PCIe core has an AXI2VBUSM bridge that is used for high speed data transfer during data read/write transactions originated by remote devices over the PCIe link. This bridge provides the protocol translation between the AXI master interface of the PCIe controller core and the VBUSM interface used in the device.

12.2.2.3.1.6 VBUSP to APB Bridge

A VBUSP2APB bridge is used to convert the device VBUSP configuration access to the APB protocol supported by the PCIe controller core.

12.2.2.3.1.7 Custom Logic

The PCIe subsystem includes custom logic to implement Precision Time Management (PTM), interrupts and user configuration registers.

12.2.2.3.2 PCIe Subsystem Reset Schemes

This section describes the reset schemes supported by PCIe Base Specification and the way these resets are supported by the PCIe Subsystem. PCIe Base Specification specifies two mechanisms for performing reset – Conventional Reset mechanism and Functional Level Reset mechanism.

12.2.2.3.2.1 PCIe Conventional Reset

There are three distinct types of Conventional Reset and each of these causes the hardware state machines, hardware logic, port states and configuration registers to be initialized to their default values.

1. Cold Reset – The reset occurring at power-up of the device is referred to as Cold Reset. Cold Reset is triggered by the PERSTn signal being asserted. PERSTn signal is an auxiliary signal in PCIe Specification and can be used at power on reset for the device that has PCIe as its primary bus interface to rest of the system. The device is allowed to generate its own power-on reset as long as the PCIe requirements for PERSTn are met. See PCIe Base Specifications for details.
2. Warm Reset – A reset can be triggered by the hardware without the removal of power from the device. This reset is referred to as Warm Reset. The hardware implementation is not specified by the PCIe Specification.
3. Hot Reset – The PCIe Specifications provides an in-band mechanism to propagate a Conventional Reset across a Link. This reset, called the Hot Reset, propagates via the transmission of TS1 Ordered Sets. In general, Hot Reset is software controlled procedure and can only be issued by Root Port in a PCIe network as the propagation is downstream only. PCIe subsystem translates the received in-band hot reset into an interrupt that can then be used by software to reset the PCIe subsystem.

After a conventional reset, the software must wait at least 100 ms before attempting any PCIe transaction on the device that has been reset. If the downstream device does not respond to transaction packets, it must not give up until 1 second plus an additional 50% (0.5 second) time is lapsed.

12.2.2.3.2.2 PCIe Function Level Reset

The Function Level Reset (FLR) is an optional in-band reset mechanism that is used to reset one particular function in a PCIe device. The PCIe core will initate the appropriate function level reset process when it receives the FLR message. The PCIe subsystem will raise an interrupt to the SoC, based on the FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core. Software can update the PCIE_USER_FLR_DONE[5-0] FLR_DONE and/or PCIE_USER_VF_FLR_DONE[15-0] VF_FLR_DONE register bits to signal to the PCIe core that the application layer FLR processing is complete.

12.2.2.3.2.3 PCIe Reset Isolation

It can be important to isolate reset of PCIe subsystem from reset of the rest of the device. The procedure to implement this depends upon what functionality the PCIe subsystem is providing – Root Port or End Point.

12.2.2.3.2.3.1 Root Port Reset with Device Not Reset

When PCIe subsystem is operating as a Root Port, it is the master controller on the PCIe subsystem. When PCIe subsystem is to be reset in this operating mode, the link to the downstream device will get disconnected. To accomplish this reset, the PCIe subsystem RP should issue a hot reset to End Point or Switch downstream.

Copyright © 2023 Texas Instruments Incorporated

It should also stop any ongoing transactions. Then, a PCIe subsystem reset can be issued. The sequence of events is outlined below:

1. Stop transactions at system and application level. This is recommended for graceful suspension of activity at system level. It is not required by PCIe subsystem though. Not choosing to gracefully stop transaction would cause some of the outstanding transactions to complete in error and it may be harmful from software stability standpoint.
2. Disable “Bus Master Enable” for End Points (see Section 12.2.2.3.6.2, *PCIe Transaction Limitations*). Note that a hand shake with EP Software may be required as not all End Point application software will automatically become aware of this disable action from RP.
3. Optionally, issue Hot Reset to End Point devices via PCIE_USER_RSTCMD[0] INIT_HOT_RESET bit . Note that the link will be getting disconnected. So, a reset may be happening regardless of the Hot Reset command from RP. It depends on the architecture of the other (external) device. In devices with PCIe subsystem, link disconnection automatically results in a reset request interrupt. A PCIe subsystem reset is required to get the memory buffers out of internal flush modes.
4. Initiate Clock Stop sequence and wait for Acknowledgement. For more information, see Section 12.2.2.3.3.1, *CBA Power Management.*
5. Issue reset to PCIe subsystem (local reset).
6. Reinitialize PCIe subsystem and downstream devices. PCIe bus enumeration must be performed again.

Note that it is possible for Root Port to occasionally see the downstream device going down for some reason and disconnecting. Such events typically occur due to an internal error condition in the End Point. When such an event occurs, the sequence of events for the Root Port will be as follows:

1. The PCIe subsystem in RP mode will issue the “Reset Request” interrupt when it detects link getting disconnected unexpectedly.
2. The PCIe subsystem will flush all master transactions and any completion data from pending transactions. It will also start completing slave transactions with error completions.
3. After servicing the interrupt and disabling further interrupts, the system software must reset PCIe subsystem Root Port (see steps #4 and later specified previously in this section).

12.2.2.3.2.3.2 Device Reset with Root Port Not Reset

As a Root Port, PCIe core is the master of PCIe subsystem. If the device hardware and the software is reset and re-initialized, the system does not get additional benefit of keeping the PCIe subsystem alive as all context information is lost. So, this mode is not supported.

12.2.2.3.2.3.3 End Point Device Reset with Root Port Not Reset

It may be desirable to isolate the reset only to PCIe subsystem when it is operating as an End Point. Such resets may be implemented when a Hot Reset command is received from upstream device (Root Port or Switch). The sequence to be followed is as outlined below.

1. Hot Reset is received. The “Request Reset” interrupt is triggered.
2. The PCIe subsystem will automatically enter Flush Mode. The PCIe Link Training and Status State Machine (LTSSM) will be disabled automatically.
3. PCIe subsystem will complete all master transactions and any completion data from pending transactions will be accepted and discarded. It will also start issuing error response for new slave transactions.
4. Upon receipt of the reset interrupt from PCIe subsystem, the system software must immediately start preparing for shut down of PCIe subsystem. The DMA or software process accessing PCIe subsystem should gracefully suspend operations. Otherwise, step #3 may continue for unduly long time and Root Port may assume that the EP is non-responsive to its link re-training attempts.
5. Read the Reset Command register (PCIE_USER_RSTCMD) to check if the bridge activity flush bit is zero. This indicates that it is safe to issue warm reset to PCIe subsystem.
6. Initiate Clock Stop sequence. This will ensure no outstanding transactions exist.
7. Issue a PCIe subsystem Reset.
8. Resume initialization sequence.

12.2.2.3.2.3.4 Device Reset with End Point Device Not Reset

As an End Point, the PCIe subsystem does not need to stay operational when the device reset is happening. Upon detecting the link disconnection, the upstream port will re-train the link when Root Port issues a link retrain command to itself or to a switch port next to the EP.

Copyright © 2023 Texas Instruments Incorporated

If it is required that the PCIe subsystem be operational (without any transactions though), the End Point must negotiate with the other devices (primarily Root Port) to stop activity. Otherwise, if the End Point goes into force idle/standby or clock stop modes without properly managing the process, there will be timeouts or errors on incoming read transactions and writes will be completely lost. In such situation, the Root Port will encounter excessive errors and may issue a hot reset to the End Point anyway.

12.2.2.3.2.4 PCIe Reset Limitations

Once a reset situation occurs, the PCIe subsystem prepares for reset assertion from the device level reset controller. In this mode, all outbound write transactions are discarded and all outbound reads are returned with error. Similarly, all inbound reads/writes are discarded and any pending reads are completed but data is discarded. Additionally, any register reads on local or remote registers regions are returned in error even through data may be correct. Register writes on local registers are executed correctly.

Whenever the reset interrupt is asserted by PCIe subsystem, the host controller should clear the interrupt, perform a clock stop request/ack sequence and issue a local reset to PCIe subsystem.

12.2.2.3.2.5 PCIe Reset Requirements

Whenever link goes from connected to disconnected state, the PCIe subsystem requires re-initialization based on the events occurring in PCIe core. A request for reset is typically going to be issued and will manifest as a link down interrupt. Since loopback requires transitions through link connect and disconnect, it will generate a link down interrupts. Typically, issuing the warm reset (module reset for CBA) would be sufficient.

12.2.2.3.3 PCIe Subsystem Power Management

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

The PCIe core supports D0, D1 and D3-Hot power states.

Link power states L0, L0s, L1, L1s are supported.

L0s entry and exit is managed by the PCIe core if ASPM L0s is enabled.

L1 entry and exit is also managed by the PCIe core if ASPM L1 is enabled. Software can force the exit from L1 by writing to the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 bit in the PCIe subsystem. Entry into L1 can also be blocked by setting the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 bit.

L1s support requires that the CLKREQ pin be connected to the remote peer. L1s power state is entered when the link is in L1 and CLKREQ pin is de-asserted. Software can force the exit from L1s by writing to either the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 or PCIE_USER_PMCMD[1] CLIENT_REQ_EXIT_L1_SUBSTATE bits in the PCIe subsystem.

12.2.2.3.3.1 CBA Power Management

The power management for PCIe subsystem with CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe subsystem will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe subsystem will guarantee that in the event there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA subsystem power management logic.

Note

The PCIe subsystem does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe subsystem.

Copyright © 2023 Texas Instruments Incorporated

12.2.2.3.4 PCIe Subsystem Interrupts

The PCIe subsystem provides a mix of interrupts from the PCIe controller interrupt, CPTS interrupts, and interrupts generated in the subsystem using the internal Interrupt Distributor (CP_INTD) module.

The CP_INTD module is used to generate and aggregate interrupts from various status signals of the PCIe core. Interrupts from the PCIe core and CPTS module are ported out directly to the PCIe subsystem boundary without any aggregation. Table 12-117 shows the details on the PCIe subsystem interrupt outputs.

Table 12-117. PCIe Subsystem Interrupt Events

Interrupt Name	Clock Dependency	Description
PCIE_LEGACY_PULSE	CBA_CLK	PCIe legacy interrupt. INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT status outputs from the PCIe core are aggregated. Note: Valid in RP mode only.
PCIE_ERROR_PULSE	CBA_CLK	PCIe error interrupt. FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT status outputs from the PCIe core are aggregated. Note: Valid in both RP and EP modes.
PCIE_ASF_FATAL_LEVEL	CBA_CLK	PCIe internal diagnostics fatal interrupt. The ASF_INT_FATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_ASF_NONFATAL_LEVEL	CBA_CLK	PCIe internal diagnostics nonfatal interrupt. The ASF_INT_NONFATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_FLR_PULSE	CBA_CLK	PCIe Function Level interrupt. FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core are aggregated. Note: Valid in EP mode only.
PCIE_DOWNSTREAM_PULSE	CBA_CLK	PCIe downstream interrupt. • F0_VSEC_INTERRUPT_OUT, • F1_VSEC_INTERRUPT_OUT, • F2_VSEC_INTERRUPT_OUT, • F3_VSEC_INTERRUPT_OUT, • F4_VSEC_INTERRUPT_OUT and • F5_VSEC_INTERRUPT_OUT status outputs from the PCIe controller are aggregated. Note: Valid in EP mode only
PCIE_HOT_RESET_PULSE	CBA_CLK	PCIe hot reset interrupt. HOT_RESET_OUT status output from the PCIe controller is aggregated. Note: Valid in EP mode only.
PCIE_LINK_STATE_PULSE	CBA_CLK	PCIe link state interrupt. LINK_DOWN_RESET_OUT status from the PCIe core is aggregated. Note: Valid in both RP and EP modes.
PCIE_PWR_STATE_PULSE	CBA_CLK	PCIe power state interrupt. POWER_STATE_CHANGE status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.
PCIE_DPA_PULSE	CBA_CLK	PCIe dynamic power allocation interrupt. DPA_INTERRUPT[5:0] status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.
PCIE_LOCAL_LEVEL	CBA_CLK	PCIe local interrupt. The LOCAL_INTERRUPT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.

Copyright © 2023 Texas Instruments Incorporated

Table 12-117. PCIe Subsystem Interrupt Events (continued)

Interrupt Name	Clock Dependency	Description
PCIE_PHY_LEVEL	CBA_CLK	PCIe PHY interrupt. The PHY_INTERRUPT_OUT from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_PTM_VALID_PULSE	CBA_CLK	PCIe PTM valid interrupt. PTM_LOCAL_TIMER_OUT_VALID status output from the PCIe controller is aggregated. Note: Valid only in EP mode.
PCIE_ECC0_UNCORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 uncorrected pulse interrupt.
PCIE_ECC0_UNCORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 uncorrected level interrupt.
PCIE_ECC0_CORR_PULSE	CBA_CLK	PCIe ECC Aggregator0 corrected pulse interrupt.
PCIE_ECC0_CORR_LEVEL	CBA_CLK	PCIe ECC Aggregator0 corrected level interrupt.
PCIE_ECC1_UNCORR_PULSE	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected pulse interrupt.
PCIE_ECC1_UNCORR_LEVEL	LANE0_TXMCLK	PCIe ECC Aggregator1 uncorrected level interrupt.
PCIE_CPTS_PEND_INTR	CBA_CLK	PCIe CPTS level interrupt.

12.2.2.3.4.1 Interrupts Aggregation

The PCIe subsystem includes the CP_INTD module to aggregate some of the PCIe controller signals into the subsystem interrupts indicated in Table 12-117. The interrupt aggregator takes both level and pulse signals from the PCIe core and produces the aggregated pulse interrupt outputs.

The aggregator also supports the End of Interrupt (EOI) feature. EOI can be used to re-trigger a pulse interrupt output, if a PCIe controller level signal is still asserted at the end of interrupt processing. The re-triggering of the the pulse interrupt can be achieved by writing the specified EOI vector value to the PCIE_USER_EOI_VECTOR register.

Table 12-118. PCIe Controller Interrupts Aggregation - 1

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description
	PCIE_INTD_ENABLE_REG_SYS_0 PCIE_INTD_ENABLE_CLR_REG_SYS_0 PCIE_INTD_STATUS_REG_SYS_0(1)				
PCIE_DOWNSTREAM_PULSE	0	pcie_downstream_0	0	down_pf0_intr	Downstream PF0 interrupt (EP mode only)
	1	pcie_downstream_1		down_pf1_intr	Downstream PF1 interrupt (EP mode only)
	2	pcie_downstream_2		down_pf2_intr	Downstream PF2 interrupt (EP mode only)
	3	pcie_downstream_3		down_pf3_intr	Downstream PF3 interrupt (EP mode only)

12.2.2.3.4.2 Interrupt Generation in EP Mode

When PCIe subsystem is operating as an End Point (EP), either the legacy interrupts, MSI or MSI-X interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RP device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

12.2.2.3.4.2.1 Legacy Interrupt Generation in EP Mode

The End Point (EP) can trigger generation of a PCI Legacy Interrupt at the Root Port via an in-band Assert_INTx / Deassert_INTx messages (where x = A, B, C, or D). Software can write to the PCIE_USER_LEGACY_INTR_SET register to trigger the required INTx (where x = A, B, C, or D) assert and de-assert message from the PCIe core. Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

Note

The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

12.2.2.3.4.2.2 MSI and MSI-X Interrupt Generation

In the case of MSI interrupts signaling, the interrupt conditions are communicated from the EP to the RP via messages. Thus, upon the occurrence of an interrupt condition, a message is sent by the EP with information that identifies the origin of the interrupt. Each message is in the form of a memory write request, containing an address and a data value to be written. Each PCI function supported by a device can be assigned a separate memory address, thus providing separate virtual channels for signaling interrupts generated by each function. In addition, the MSI mechanism allows a maximum of 32 distinct data patterns in the messages generated by each PCI function, and each pattern can be assigned to an interrupt condition within the function.

In the case of MSI-X interrupts signaling, the operation is similar to the MSI mode, except that the mechanism allows a much larger number of distinct interrupt conditions as many as 2048 per function to be communicated, and enables a distinct address to be defined for each of these conditions. This mechanism requires two tables to be stored in the EP memory. The MSI-X table contains the address/data patterns to be used for each interrupt condition (as many as 2048 per function) as well as individual enable/mask bits, and the Pending Bit Array (PBA) stores the status of each interrupt condition. Interrupt conditions are communicated from the EP to the RP via messages (write requests), as in the case of the MSI mode.

12.2.2.3.4.3 Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts.

12.2.2.3.4.3.1 PCIe Core Downstream Interrupts

The Vendor Specific Capability signals of the PCIe core
- F0_VSEC_INTERRUPT_OUT, F1_VSEC_INTERRUPT_OUT, F2_VSEC_INTERRUPT_OUT, F3_VSEC_INTERRUPT_OUT, F4_VSEC_INTERRUPT_OUT and F5_VSEC_INTERRUPT_OUT, are used to generate interrupts to the EP from the RP. The F0_VSEC_INTERRUPT_OUT represents the interrupt for the EP Physical Function 0, the F1_VSEC_INTERRUPT_OUT is the interrupt output for EP Physical Function 1 and so on. These signals are aggregated into the PCIE_DOWNSTREAM_PULSE interrupt to the local host.

The RP can write to the Vendor Specific Control registers (PCIE_CORE_PFn_I_VENDOR_SPECIFIC_CONTROL_REG) to assert these signals at the EP and this will trigger the PCIE_DOWNSTREAM_PULSE interrupt to the EP host.

12.2.2.3.4.3.2 PCIe Core Function Level Reset Interrupts

The PCIE_FLR_PULSE interrupt is asserted to indicate to the host that the PCIe controller has received a function-level reset request from the remote side. The PCIE_FLR_PULSE interrupt is an aggregation of the FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] signals from the PCIe

Copyright © 2023 Texas Instruments Incorporated

core. Each bit of FLR_IN_PROGRESS[5:0] represents Physical Function0 through 5 and each bit of the VF_FLR_IN_PROGRESS[15:0] represents Virtual Function0 through 15.

Upon assertion of the function level reset interrupt, software will need to write to the PCIE_USER_FLR_DONE[5-0] FLR_DONE bit field within 100ms to acknowledge to the PCIe core that all the application level processing related to the function level reset is complete. Similarly, software will need to acknowledge virtual function level reset completion by writing to the PCIE_USER_VF_FLR_DONE[15-0] VF_FLR_DONE bit field within 100ms of the virtual function level reset being asserted.

12.2.2.3.4.3.3 PCIe Core Power Management Event Interrupts

The PCIE_PWR_STATE_PULSE interrupt is generated to let the software know of the power management events. The PCIE_PWR_STATE_PULSE interrupt is generated by the POWER_STATE_CHANGE_INTERRUPT output of the PCIe core. This interrupt is asserted when the power state of a physical or virtual function is being changed to D1 or D3 state by writing into their Power Management Control register (PCIE_CORE_PFn_I_PWR_MGMT_CTRL_STAT_REP or PCIE_CORE_VFm_I_PWR_MGMT_CTRL_STAT_REP, respectively).

Software can check the PCIE_USER_LINKSTATUS[23-16] POWER_STATE_CHANGE_FUNCTION_NUM register field to determine the physical function for which power state change occurred. The PCIE_USER_PMCMD[2] POWER_STATE_CHANGE_ACK register bit can be used to acknowledge the POWER_STATE_CHANGE_INTERRUPT.

The PCIE_DPA_PULSE interrupt is generated by aggregating the PCIe controller DPA_INTRs interrupt status outputs. This interrupt is asserted in EP mode when there is a configuration write to the dynamic power allocation control register (PCIE_CORE_PFn_I_DPA_CTRL_STATUS_REG) to modify the DPA power state of the device. The DPA_INTR0 is asserted for such an event for PF0, the DPA_INTR1 for PF1 and so on.

12.2.2.3.4.3.4 PCIe Core Hot Reset Request Interrupt

When the link is down, the Root Port may request reset of the End Point. This request is terminated as an PCIE_HOT_RESET_PULSE interrupt to the End Point host software. All outstanding transactions are completed in error on slave port and further transactions are not generated on the master port. Once the transactions are completely stopped, the software should issue a local reset to PCIe subsystem. The re-initialization process may then be started.

The PCIE_HOT_RESET_PULSE interrupt is generated from the HOT_RESET_OUT output of the PCIe core.

12.2.2.3.4.3.5 PTM Valid Interrupt

In EP mode, the PCIe subsystem will generate the PCIE_PTM_VALID_PULSE interrupt to the local CPU after a PTM dialog between the PTM requester (EP) and the PTM responser (RP). The PTM valid interrupt indicates to the CPU in the EP that the local timers have been updated with the timestamp data obtained from the RP. The CPU can read the timer registers inside the EP to determine the current timebase.

The PCIE_PTM_VALID_PULSE interrupt is generated from the PTM_LOCAL_TIMER_OUT_VALID signal from the PCIe core.

12.2.2.3.4.4 Interrupt Generation in RP Mode

As per PCIe Base Specifications, Root Port ports only receive interrupts. There is no mechanism to generate interrupts from RP port to EP mode as per PCIe specification.

However, PCIe subsystem does support generation of interrupts from RP to EP. The downstream interrupts described in Section 12.2.2.3.4.3.1, *PCIe Core Downstream Interrupts* provides a mechanism for the RP to generate software triggered interrupts to the EP.

12.2.2.3.4.5 Interrupt Reception in RP Mode

12.2.2.3.4.5.1 PCIe Legacy Interrupt Reception in RP Mode

The RP can receive any of the four legacy INTx interrupts from the EP. These will trigger the PCIE_LEGACY_PULSE interrupt to the host CPU.

The PCIE_LEGACY_PULSE interrupt is an aggregation INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT signals from the PCIe core.

Copyright © 2023 Texas Instruments Incorporated

12.2.2.3.4.5.2 MSI/MSI-X Interrupt Reception in RP Mode

The PCIe core decodes all MSI and MSI-X messages received from the link and forwards them on the low-priority AXI master interface. These messages must then be routed to the system interrupt controller by the SoC interconnect (CBASS0).

12.2.2.3.4.5.3 Advanced Error Reporting Interrupt

If enabled by software at the time of enumeration, PCIe subsystem will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable Advanced Error Reporting but if it enables, it must process the interrupt as per PCIe Specifications.

The advanced error reporting interrupt is signaled by the PCIE_ERROR_PULSE interrupt. The PCIE_ERROR_PULSE is an aggregation of the FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT from the PCIe core.

12.2.2.3.4.6 Common Interrupt Reception in RP and EP Modes

These interrupts are common to both RP and EP modes of operation.

12.2.2.3.4.6.1 PCIe Local Interrupt

The LOCAL_INTERRUPT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

12.2.2.3.4.6.2 PHY Interrupt

The PHY_INTERRUPT_OUT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

12.2.2.3.4.6.3 Link down Interrupt

If the PHY link is disconnected, the PCIE_LINK_STATE_PULSE interrupt will be generated. The expected course of action is to reset the entire PCIe subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

The PCIE_LINK_STATE_PULSE interrupt is generated from the LINK_DOWN_RESET_OUT output of the PCIe core.

12.2.2.3.4.6.4 Transaction Error Interrupts

If there is a timeout on PCIe or an abort, PCIE_PHY_LOCAL_LEVEL interrupt will be issued. The PCIE_PHY_LOCAL_LEVEL interrupt is generated by the aggregation of the LOCAL_INTERRUPT and PHY_INTERRUPT_OUT signals from the PCIe core. For more details, see the PCIe specification.

12.2.2.3.4.6.5 Power Management Event Interrupt

This PCIE_PWR_STATE_PULSE interrupt is generated to let the software know of the power management events.The PCIE_PWR_STATE_PULSE interrupt is generated by aggregating the POWER_STATE_CHANGE_INTERRUPT and DPA_INTERRUPT outputs of the PCIe core.

In EP mode, software can check the PCIE_USER_LINKSTATUS[23-16] POWER_STATE_CHANGE_FUNCTION_NUM bit field to determine the physical function for which power state change occurred.

The PCIE_USER_PMCMD[2] POWER_STATE_CHANGE_ACK bit can be used to acknowledge the POWER_STATE_CHANGE_INTERRUPT.

12.2.2.3.4.6.6 Active Internal Diagnostics Interrupts

The active internal diagnostics interrupt is signaled by the PCIE_ASF_PULSE interrupt. This is an aggregation of the ASF_CSR_ERR, ASF_DAP_ERR, ASF_INTEGRITY_ERR, ASF_INT_FATAL, ASF_INT_NONFATAL, ASF_PROTOCOL_ERR, ASF_SRAM_CORR_ERR, ASF_SRAM_UNCORR_ERR, and ASF_TRANS_TO_ERR signals from the PCIe core.

12.2.2.3.4.7 ECC Aggregator Interrupts

The PCIE_ECC0_UNCORR_PULSE/PCIE_ECC0_UNCORR_LEVEL and PCIE_ECC0_CORR_PULSE/ PCIE_ECC0_CORR_LEVEL interrupts are asserted by the CBA clock domain ECC Aggregator. The

Copyright © 2023 Texas Instruments Incorporated

PCIE_ECC1_UNCORR_PULSE/PCIE_ECC1_UNCORR_LEVEL interrupts are asserted by the Core clock domain ECC Aggregator. The Core clock domain ECC Aggregator correctable interrupts are not exported since this aggregator is only connected to the parity injection logic and the correctable interrupts for this module will never fire.

12.2.2.3.4.8 CPTS Interrupt

The PCIE CPTS_PEND_INT interrupt is asserted by the CPTS module in the PCIe subsystem to signal a TimeStamp event.

12.2.2.3.5 PCIe Subsystem DMA Support

The PCIe Subsystem has different requirements based upon whether it is operated in Root Port (RP) or End Point (EP) mode. The PCIe subsystem does not have DMA capabilities built into it. It has internal slave and master ports connected to the device-level interconnect.

An external DMA engine can make burst data read/writes on the slave port and the master port on PCIe subsystem can initiate reads/writes to memory on behalf of a remote PCIe device.

The PCIe subsystem does not specify the DMA protocol that is used for data transfers. The software implementations on the two ends of the PCIe link implement a data transfer protocol that is compatible with each other.

As a result, there will be several software drivers required – one driver that will manage the PCIe subsystem in RP mode and another set of drivers that will run on the RP side and will manage each of the End Points connected to the PCIe subsystem RP.

Similarly, when PCIe subsystem is operating as an End Point, there are two drivers – one to manage the PCIe subsystem from the device side and another driver that will run on the device operating as the Root Port.

12.2.2.3.5.1 PCIe DMA Support in RP Mode

When operating in Root Port mode, a DMA controller internal to the device (outside PCIe subsystem) can perform DMA to and from any remote device located on the PCIe subsystem. The memory address of such devices is available to the software via the PCIe bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

12.2.2.3.5.2 PCIe DMA Support in EP Mode

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. Any PCIe transactions destined for the device from the upstream ports will get transferred to the master port on the PCIe subsystem. Similarly, any transactions originating from the software will be sent over to PCIe link.

In End Point mode, the PCIe subsystem provides address translation functionality. It is possible to map memory accesses originating on PCIe side to memory accesses with different address on the CBA bus side. These address ranges are configurable through application registers.

12.2.2.3.6 PCIe Subsystem Transactions

12.2.2.3.6.1 PCIe Supported Transactions

PCIe subsystem supports the following transactions:

1. Memory Read/Write in inbound/outbound direction in Root Port (RP) and End Point (EP) modes.
2. I/O Read/Write in outbound direction in RP mode.
3. Configuration Read/Write in outbound direction in RP mode.
4. Configuration Read/Write in inbound direction in EP mode.
5. Message Transactions for interrupts and power management in RP and EP modes.

The following transactions are not supported:

1. Locked Read transactions and associated messages.
2. Inbound I/O Transaction Layer Packets (TLPs).
3. User defined messages.

Copyright © 2023 Texas Instruments Incorporated

12.2.2.3.6.2 PCIe Transaction Limitations

Added

There are some limitations that must be adhered to while issuing transactions to PCIe subsystem internal bus interface.

- System Initialization

> **CAUTION**
>
> The PCIe subsystem operation is completely dependent upon the availability of the SERDES module for PCIe transactions. The SERDES module must be configured and corresponding PLLs must be locked before the PCIe subsystem is able to process any data transactions. Any data accesses to the PCIe subsystem prior to this initialization may result in an internal bus hang condition.

- Remote Configuration and I/O Requests

Since the remote configuration and I/O transaction windows are directly mapped to internal bus space, the software must care to not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

- Byte Strobe Limitations

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater that 32-bit, the TLP (Transaction Layer Packets) size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

- Burst Type Limitations

The PCIe core and respectively the PCIe subsystem does not support 'fixed' or 'wrap' burst types on its Slave or Master port. Transactions that require any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

- Transaction Address Alignment

The PCIe subsystem imposes a limitation of a maximum of 128-byte outbound read/write command. However, if the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. This limitation is placed to avoid arithmetic overflow in computing transaction length from CBA to AXI. Unspecified behavior will occur, if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

- Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). The PCIe core will not interleave read responses, if the outbound read command/transaction size does not exceed the maximum transaction size configured in the PCIe core.

12.2.2.3.7 PCIe Subsystem Address Translation

The PCIe subsystem uses the address translation registers in the PCIe core to translate outbound system addresses to PCIe space and inbound PCIe address to a valid system address. Note that internal address translation is different from the Address Translation Services (ATS).

12.2.2.3.7.1 PCIe Inbound Address Translation

12.2.2.3.7.1.1 Root Port Inbound PCIe to AXI Address Translation

The Root Port inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the BAR match of the incoming TLP. In Root Port mode there are 2 bars, so BAR 0 and BAR1 registers are implemented. There is

Copyright © 2023 Texas Instruments Incorporated

a BAR7 register which is used as a no match BAR address translation register. In Root Port mode there are 2 bars but a BAR value of 7 will be indicated by HAL2AXI when BAR matching is disabled. Any address that does not match the Root Port BARs will be sent out as a BAR7 TLP. Each BAR register is implemented as two 32-bit registers which are named addr0 and addr1. The "Root Port Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "Root Port Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the inbound PCIe address to form the AXI address. An addr0 [5:0] + 1 number of lower bits are passed from the inbound PCIe address to AXI address. In other words, the number of bits taken from anbound PCIe address is given by the addr0[5:0] + 1 value.

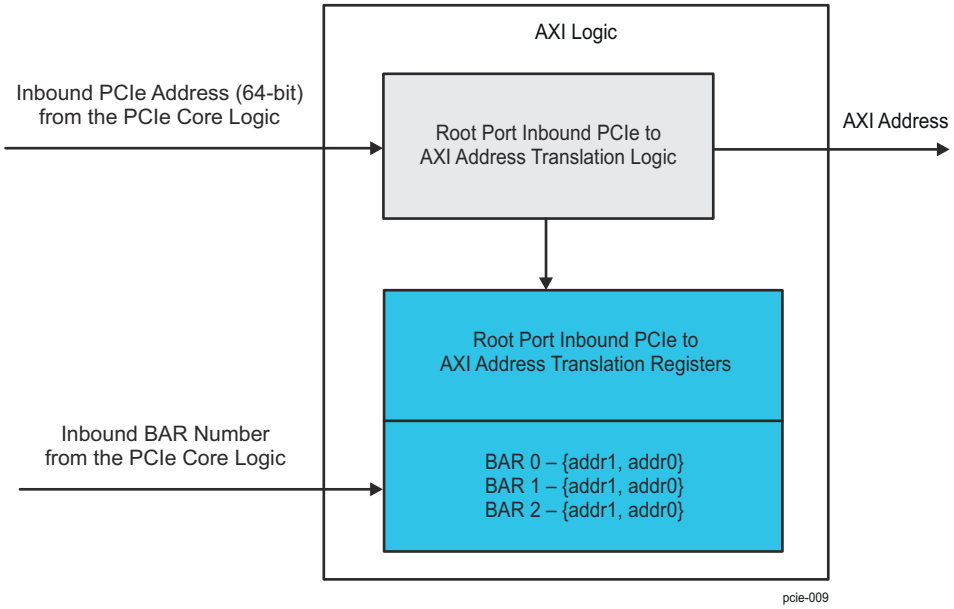

Figure 12-63. PCIE Root Port Inbound PCIe to AXI Address Translation

A set of registers corresponding to one Root Port BAR is shown in Table 12-121.

Table 12-121. PCIE Root Port Inbound PCIe to AXI Address Translation Registers for one BAR

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1 or bar7)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1 or bar7)	31:8	Lower [31:8] bits of the AXI address.	24'd0
	7:6	Reserved	2'd0
	5:0	Number of address bits passed through from PCIe to AXI. The PCIe controller passes the programmed value + 1 bits from PCIe to AXI. Minimum value to be programmed into this field is 7 as the lower 8 bits of the base address programmed in these registers (AXI) are replaced by zeros by the Root Port Inbound PCIe to AXI Address Translation Logic.	6'd0

12.2.2.3.7.1.2 End Point Inbound PCIe to AXI Address Translation

The End Point Inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the function number and BAR match of the incoming TLP. In End Point mode there are 7 bars per function, so 7 sets of registers are implemented per function, each BAR having two 32-bit registers (addr0 and addr1). The "End Point Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "End Point Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the Inbound PCIe Address to form the AXI address. The number of bits to pass from Inbound PCIe Address to AXI is decided by the Inbound BAR aperture.

Copyright © 2023 Texas Instruments Incorporated

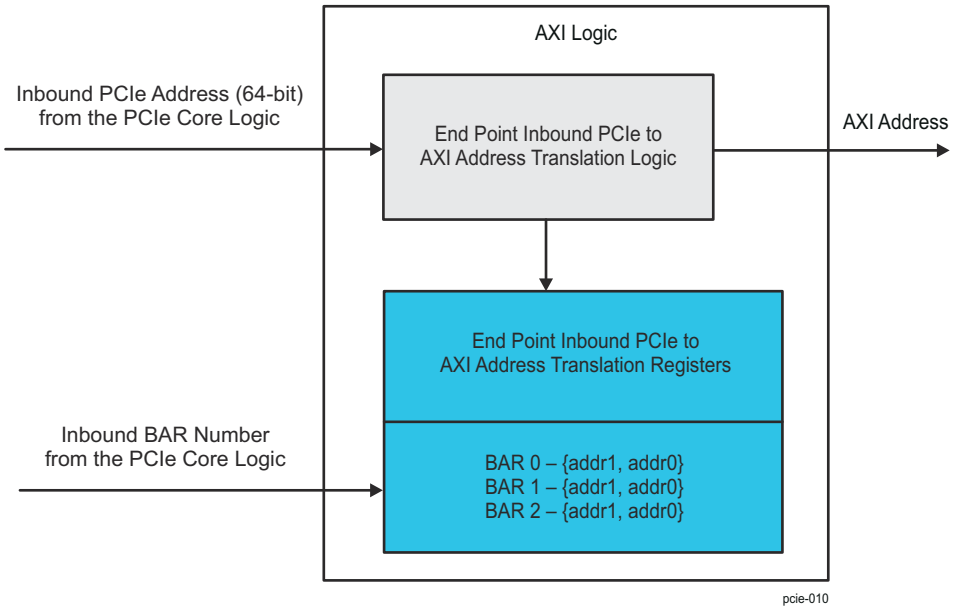

Figure 12-64. PCIE End Point Inbound PCIe to AXI Address Translation

A set of registers corresponding to one End Point BAR is shown in Table 12-122.

Table 12-122. PCIE End Point Inbound PCIe to AXI Address Translation Registers for one BAR

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Lower [31:0] bits of the AXI address.	32'd0

12.2.2.3.7.2 PCIe Outbound Address Translation

The PCIe Subsystem allows mapping of PCIe addresses to/from the internal bus addresses of the device. This is accomplished by using internal address translation unit (iATU) in the PCIe core. For each outbound read/write request, the address translation module within PCIe subsystem can convert a VBUSM address to a PCIe address of memory Read/Write type.

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation only works at the time a command is issued. So, a memory write, for example, will not automatically go to next translation region, if it starts in the previous one and is bigger than the remaining size in the starting translation region.

The “Dynamic Method: Sideband Descriptor Based” outbound address translation mechanism is used to bypass the outbound address translation unit under certain conditions. For more details on the bypass operation, see Section 12.2.2.3.7.2.1, *PCIe Outbound Address Translation Bypass*.

12.2.2.3.7.2.1 PCIe Outbound Address Translation Bypass

The PCIe subsystem supports bypassing the outbound address translation in the PCIe controller when the *casel* value on the VBUSM slave interface is non-zero.

The device UDMA has the ability to send transactions to alternate address maps which are external to the local device. This is achieved by using casel identifier in the DMA descriptors. There are three requirements that need to be met in the PCIe subsystem when using this mode in the DMA, namely:

- Block transactions based on initiator credentials to support FFI (Freedom from Interference)

Copyright © 2023 Texas Instruments Incorporated

- Bypass the Address Translation Unit (ATU) inside the PCIe controller since the transaction address is external to the local device
- Assign the correct Bus, Device, Function (BDF) and Traffic Class (TC) values to the transaction

To meet these requirements, the PCIe subsystem uses the *cvirtid* values on the VBUSM slave interface to filter transactions based on initiator credentials. The VMAP block in the PCIe subsystem has a *virtid* match register (PCIE_VMAP_OB_VIRTID_MATCH) and a set of 32 registers that can be used to program the descriptor fields when the ATU logic in the PCIe controller is bypassed.

The PCIe subsystem will filter outbound VBUSM slave transactions that have a non-zero casel value. If the *cvirtid[11:5]* attribute of the VBUSM slave transaction matches the value programmed in the PCIE_VMAP_OB_VIRTID_MATCH register, the credentials of the transaction initiator are verified. The *cvirtid[11:5]* value should also be non-zero for a successful match.

When the credentials match, the ATU of the PCIe controller is bypassed . The *cvirtid[4:0]* is used to select one of the 32 PCIE_VMAP_DESC_j descriptor registers. These registers can be programmed to assign the BDF and TC values to the outbound PCIe transaction. If the PCIE_VMAP_DESC_j[16] BD_EN0 register bit is set, then the bus, device and function numbers are all set from the external descriptor registers. If the BD_EN bit is not set, then the bus and device numbers are assigned by the PCIe controller using the values captured during enumeration. If ARI mode is enabled (in the PCIE_CORE_PFn_I_SRIOV_CTRL_STATUS_REG register), the function number uses the PCIE_VMAP_DESC_j[7:0] DEV_FUNC_NUM register field. If ARI mode is not enabled, the device number uses PCIE_VMAP_DESC_j[7:4] DEV_FUNC_NUM field and the function number uses the [3:0] DEV_FUNC_NUM field. The ARI mode is a PCIe controller hardware configuration option that is enabled for PCIe endpoints that support SR-IOV.

If the credentials of the initiator fail to match the programmed value in the PCIE_VMAP_OB_VIRTID_MATCH register, the VBUSM slave transaction is then flushed by the bridge and is not submitted to the PCIe controller. The VBUSM2AXI2 bridge will return a protection error status for both read and write transactions. In addition, the write data is discarded and the correct number of read data phases with data value of zero are returned.

12.2.2.3.8 PCIe Subsystem Virtualization Support

The PCIe subsystem supports Address Translation Request (ATS) messages in Root Port mode. All PCIe ATS requests are forwarded to the SMMU. The ATS response sent back by the SMMU is forwarded to the remote PCIe requestor.

In End Point mode, the PCIe subsystem supports SR-IOV with 6 physical functions (PF), and 4 virtual functions (VF) per physical function for PF0-PF3 only (6PF/16VF).

12.2.2.3.8.1 End Point SR-IOV Support

In End Point (EP) mode, the PCIe subsystem supports Single Root I/O Virtualization (SR-IOV) with four physical functions (PF) and four virtual functions (VF) per physical function for PF0-PF3 only.

12.2.2.3.8.2 Root Port ATS Support

In Root Port (RP) mode, the PCIe subsystem has an AXI streaming interface (DTI) to connect to the system level SMMU. The Address Translation Messages (ATS) from the End Point is routed to the SMMU over the DTI interface. The translated address and any invalidation requests from the SMMU, sent to the PCIe over the DTI interface, is converted to ATS messages and sent to the End Point.

12.2.2.3.8.3 VirtID Mapping

The PCIe subsystem includes the VMAP module that can be programed to map (convert) the incoming 16-bit PCIe requestID + 2-bit PCIe AT bits to the 16-bit CBA virtID + 2-bit CBA atype attributes.

Figure 12-65 shows the block diagram of the VMAP module. The blocks shown in the diagram are replicated for the read and write AXI channels. However, there is only one set of configuration registers in the VMAP module and these are shared by both the read and write channel logic.

Copyright © 2023 Texas Instruments Incorporated

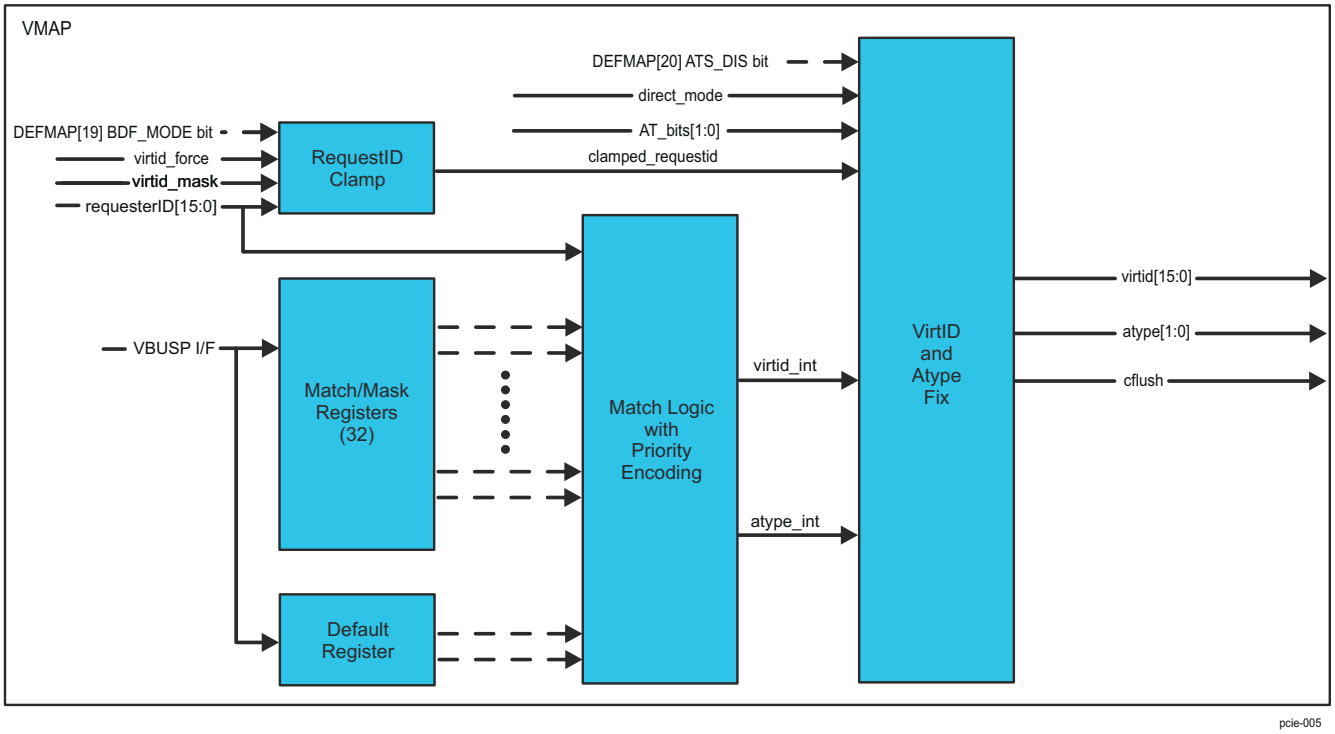

Figure 12-65. PCIe Subsystem VirtID Mapper

The RequestID Clamp block is used to clamp the incoming requestID to a maximum value. This block compares the incoming PCIe requestID[15:12] masked with the virtid_mask[3:0] to an expected value. Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP is used to set the value to virtid_force[3:0] or 4'h0. The clamped_requestid is set to the maximum value of FFFFh if the comparison is false. The clamped_requestid value is later used downstream by the PVU or SMMU in the SoC.

Each of the VMAP modules includes a set of 32 match and mask registers. Software can enable the registers to be used for the mapping by setting the [0] EN bit in PCIE_VMAP_CTRL_j registers. Software can also program the [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers to indicate the incoming PCIe requestid that needs to be matched. The [11-0] VID and [17-16] ATYPE bit fields in PCIE_VMAP_VIRTID_j registers are used to program the required CBA virtID and Atype fields in case of a match. In order to prevent a spurious match, the [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers should be set up before the [0] EN bit in PCIE_VMAP_CTRL_j registers is set. The same sets of registers are used for both read and write transactions.

The Match logic with Priority Encoding block compares the incoming PCIe requestID with the values programmed in the VMAP control registers and sets the value of the virtid_int and atype_int variables. For every incoming PCIe transaction, the incoming PCIe requestID[11:0] bits are masked with the PCIE_VMAP_REQID_j[31-16] MASK bit field and compared against each of the thirty two values indicated by PCIE_VMAP_REQID_j[15-0] RID that are enabled. The location of the first match of this comparison operation is used to select the [11-0] VID and [17-16] ATYPE bit fields in PCIE_VMAP_VIRTID_j registers. This is used as the virtid_int and atype_int values for the downstream logic. In case none of the enabled [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers pairs match the incoming requestID, the value in [11-0] DEF_VID and [17-16] DEF_ATYPE bit fields in PCIE_VMAP_DEFMAP registers is used.

The VirtID and Atype Fix block uses the incoming PCIe AT_bits along with the matched and clamped values of the requestID from the downstream blocks to set the final values of the virtID, catype and cflush attributes for the particular CBA transaction. The values of the virtID, catype and cflush are determined based on the following criteria:

1. If the incoming PCIe TLP has a translated address, as indicated by the PCIe AT_bits equal to 2 and if the match operation results in an expected atype value of 2 and Address Translation Services (ATS) is enabled in the system, as indicated by the PCIE_VMAP_DEFMAP[20] ATS_DIS register bit, the virtID is set to the *clamped_requestid* and the *catype* value is set to 2. This enables the PCIe subsystem to pass along the

Copyright © 2023 Texas Instruments Incorporated

full incoming requestID[15:0] to the upstream SMMU/PVU. The incoming transaction is flushed if it fails this criteria by setting the cflush attribute to 1. The PCIe EP initiating this transaction will be sent a Completion Abort (CA) response for a read request, if the transaction is flushed.

2. If the incoming PCIe TLP does not have a translated address, as indicated by the PCIe AT_bits equal to 0, the virtID can be set to the output of the mask/match registers or the *clamped_requestid*. The *catype* attribute for this transaction can be set to the value from the mask/match registers.

Note

The PCIE implementation in the device uses the *direct_mode* workaround. This forces the *cvirtID* and *catype* to 0 when the incoming transaction matches the criteria outlined in (1) above.

The system Interconnect only supports 12-bits of *virtid*. As a result, only *virtid[11:0]* from the PCIe VMAP module will be used in the system and *virtid[15:12]* is not connected.

The pseudo-code for the virtID mapping algorithm implemented is described below.

```
// Requestid Clamp
// Note: only the low 4 bits of virtid_force & virtid_mask are used in the current PCIe wrapper
// virtid_mask[7:4] should always be 1
// virtid_mask[n] of 1 means use the virtid_force value for this bit
// virtid_mask[n] of 0 means use the requestID value for this bit, virtid_force[n] should be 0
// Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP specifies if we are using
// 0 based bus numbers (0) or offset bus numbers (1)
expected_value[3:0] = PCIE_VMAP_DEFMAP[19] BDF_MODE ? virtid_force[3:0] : 4'h0;
if (requestID[15:12] & virtid_mask[3:0] == expected_value[3:0] )
{
clamped_requestID[15:0] = requestID[15:0];
}
else
{
clamped_requestID[15:0] = FFFFh];
}
// Match Logic with Priority Encoding
for n in 0 to 31 do
if (PCIE_VMAP_CTRL_j[0] EN == 1h &&
(requestID & PCIE_VMAP_REQID_j[31-16] MASK) == PCIE_VMAP_REQID_j[15-0] RID )
{
found[n] = true;
}
else

virtid[15:12] = 4’h0;
}
}
```

12.2.2.3.9 PCIe Subsystem Quality-of-Service (QoS)

The Virtual Channel/Transfer Class (VC/TC) feature in the PCIe core, in conjunction with the device system CBASS Quality-of-Service (QOS) capabilities, provide a mechanism for supporting differentiated QOS within the PCIe subsystem. The policy for traffic differentiation is determined by the Transfer Class (TC) and Virtual Channel (VC) mapping and VC-based arbitration mechanism.

Copyright © 2023 Texas Instruments Incorporated

A Virtual Channel is established when one or more TCs are associated with a physical resource designated by a VC ID. Every Traffic Class that is supported on a given path within the subsystem must be mapped to one of the enabled Virtual Channels. Every Port must support the default TC0/VC0 pair – this is “hardwired.” Any additional TC mapping or additional VC resource enablement is optional. The number of VC resources provisioned within a component or enabled within a given subsystem may vary due to implementation and usage model requirements.

The PCIe core in the PCIe subsystem is configured to support four virtual channels (4VC/4TC). For both ingress and egress traffic, VC3, the highest numbered virtual channel, has the highest priority.

For ingress traffic, the TC information from each transaction on the AXI master information is mapped to the CCHANID signal of the VBUSM master interface. The system level interconnect can use the CCHANID along with the ORDERID for QoS purposes. Table 12-123 shows the TC mapping to the 12-bit CCHANID of each VBUSM master interface.

Table 12-123. PCIe Subsystem QoS Ingress CCHANID Mapping

TC Value	CCHANID[11:0]
0	{9’d0, 3’b000}
1	{9’d0, 3’b001}
2	{9’d0, 3’b010}
3	{9’d0, 3’b011}
4	{9’d0, 3’b110}
5	{9’d0, 3’b101}
6	{9’d0, 3’b110}
7	{9’d0, 3’b111}

For egress traffic requiring the highest priority it should be mapped to VC=3 in the PCIe controller. The VC mapping is done using the AXI outbound descriptor registers in the PCIe controller.

12.2.2.3.10 PCIe Subsystem Precision Time Measurement (PTM)

The Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

The PTM defines the following components:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint.
- PTM Responder - A Function capable of using PTM to supply PTM Master Time associated with a RP.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root – The source of PTM Master Time for a PTM hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

When using PTM between two components on a Link, the EP sends PTM requests to the RP on the same link. During each dialog, the RP populates the PTM Response message based on timestamps stored during previous PTM dialogs. Once each component has historical timestamps from the preceding dialog, the EP can combine its timestamps with those passed in the PTM Response message to calculate the PTM Master Time.

The PCIe core implements all of the features required to handle the PTM conversation between the requestor and responder in hardware. In addition, an internal TimeStamp module (CPTS) is connected to the timestamp interface of the PCIe core so that events can be logged.

The Precision Time Measurement (PTM) support in the PCIe subsystem is handled by the combination of the PCIe core and the CPTS module.

The PCIe core controller handles the PCIe conversation to exchange timestamps between the RP and EP. It also includes logic to calculate the timestamp differences as specified in the PCIe standard.
A 64-bit timer that is the master clock is included in the PCIe core. The PCIe controller can be

Copyright © 2023 Texas Instruments Incorporated

programmed to initiate the PTM conversation automatically by setting the [0] PTMRQM bit in the PCIE_CORE_LM_I_PTM_LOCAL_CONTROL_REG register.

In EP mode, there are two methods to register a CPTS HW1 push timestamp that is needed to transfer the PCIe PTM timebase to the local system time base.

1. The first method involves the PTM_LOCAL_TIMER_OUT_VALID and PTM_EP_TIMER. The PTM_LOCAL_TIMER_OUT_VALID output from the PCIe controller will be asserted when the PTM conversation is complete and the EP local timer has been updated. The adjusted value of the EP 64-bit timer is available in the PTM_LOCAL_TIMER_OUT output of the controller. A second 64-bit free running timer, PTM_EP_TIMER, is used to shadow the value of the EP timebase. The PTM_EP_TIMER is loaded with the value of the PTM_LOCAL_TIMER_OUT[63:0] when PTM_LOCAL_TIMER_OUT_VALID is high. When PTM_LOCAL_TIMER_OUT_VALID is low, PTM_EP_TIMER will be free running based on the same PCIE CORE_CLK that drives the PTM_LOCAL_TIMER_OUT. The increment value of PTM_EP_TIMER can be adjusted by writing to the PCIE_USER_PTM_CFG[10-8] PTM_EP_TIMER_ADJ register field. The increment value is one by default. The value of the PTM_EP_TIMER will not be updated to the RP timebase until the first PTM dialog has occurred. Software can set the PCIE_USER_PTM_CFG[6-0] PTM_CLK_SEL register field value between 0 and 63 to choose a particular bit of the PTM_EP_TIMER as the source for the CPTS HW1 time stamp push event.
2. The second method to register the CPTS HW1 push timestamp involves only the PTM_LOCAL_TIMER_OUT_VALID output from the PCIe controller. Software can set the PCIE_USER_PTM_CFG[6-0] PTM_CLK_SEL register field value to 64 to select the PTM_LOCAL_TIMER_OUT_VALID as the source of the CPTS HW1 time stamp push event. This will create a CPTS HW1 timestamp when there is a PTM dialog between the PCIe End Point and Root Port. The actual value of the EP PTM local timer can be read from the PCIE_USER_PTM_TIMER_LOW and PCIE_USER_PTM_TIMER_HIGH registers.

In RP mode, the CPTS can take control of the PTM master time. The 64-bit CTPS timer is continuously loaded into the PCIe PTM master clock by tying high the PTM_TIMER_IN_VALID input of the PCIe controller. This allows for software to adjust the PCIe PTM master clock as necessary using the CTPS module and maintain the PTM master time by monotonically increasing it as required by the PCIe standard. The CPTS HW1_PUSH timestamp input is driven by the particular bit of the PTM_LOCAL_TIMER_IN counter, as selected by the value in the PCIE_USER_PTM_CFG[6-0] PTM_CLK_SEL register field.

The reference clock (RCLK) for the CPTS can be controlled via the CTRLMMR_PCIE1_CLKSEL[3-0] CPTS_CLKSEL register field in the device Control Module. This enables the SoC flexibility in choosing the CPTS reference clock input. In RP mode, the RCLK needs to be connected to the SERDES PIPE clock since the CPTS will be driving the PTM master clock. For more information on the RCLK source clock selection, see *PCIe Subsystem Integration*.

Figure 12-66 shows the PTM support logic in the PCIe subsystem.

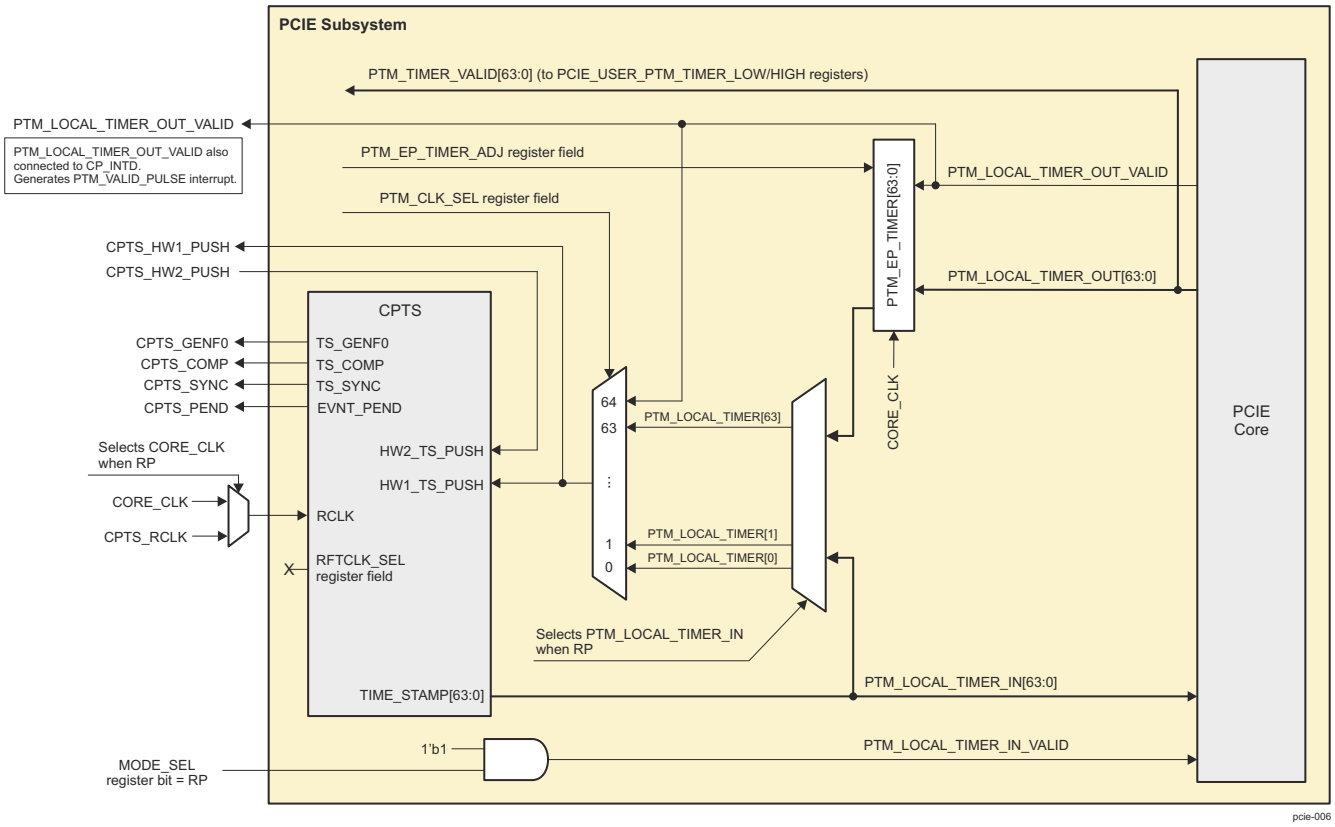

Figure 12-66. PCIe Subsystem PTM Implementation

12.2.2.3.11 PCIe Subsystem Loopback

The PCIe subsystem provides loopback support through PIPE interface (Link Layer).

12.2.2.3.11.1 PCIe PIPE Loopback

The procedure depends upon whether the device is operating in RP or EP Mode. In either case, the PCIe subsystem can be loopback master or loopback slave as outlined in PCIe specifications. A loopback master is the component requesting loopback and transmitting the data. A loopback slave is the component looping back the data.

Note

The PIPE loopback mode cannot be used for looping back transactions.

12.2.2.3.11.1.1 PIPE Loopback Master Mode

The loopback path when PCIe subsystem is loopback master is:

PCIe subsystem (loopback master) -> PIPE (TX) -> PCIe Link -> Loopback -> PCIe Link -> PIPE (RX) -> PCIe subsystem

12.2.2.3.11.1.2 PIPE Loopback Slave Mode

The loopback path when PCIe subsystem is loopback slave is:

Remote device -> PCIe Link -> PIPE (RX) -> Loopback -> PIPE (TX) -> PCIe Link -> Remote device

If the PCIe subsystem is a loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition PCIe subsystem into loopback slave state following which the inbound transactions will be loopback to the test equipment. There is no programming required on PCIe subsystem to enter loopback in slave mode. PHY support is not required to use this loopback mode.

Copyright © 2023 Texas Instruments Incorporated

12.2.2.3.12 PCIe Subsystem Error Handling

As an End Point, PCIe subsystem reports errors to root complex so that corrective action may be taken. These messages become error interrupts on the Root Port side. In addition, the errors that are detected by the PCIe subsystem locally are also reported to software via interrupts.

Note that for several errors of the same type that are detected in close succession, the PCIe subsystem will not necessarily send as many error messages to Root Port. It is guaranteed to send at least one such error message.

12.2.2.3.12.1 PCIe AXI to/from VBUSM Bus Error Mapping

Table 12-124 and Table 12-125 show the bus error mapping to/from the AXI interface on the PCIe controller to the system VBUSM interfaces.

The AXI2VBUSM bridge maps the bus errors on the ingress AXI interface to the VBUSM master interface as shown in the table below.

Table 12-124. AXI to VBUSM Bus Error Mapping

VBUSM		AXI	
Code	**Error**	**Code**	**Error**
0 (decimal)	Success	0h	OKAY
1 (decimal)	N/A	3h	N/A
2-3 (decimal) 7 (decimal)	All Others	2h	SLVERR

The VBUSM2AXI bridge maps the bus errors on the eggress VBUSM slave interface to the AXI interface as shown in the table below.

Table 12-125. VBUSM to AXI Bus Error Mapping

AXI		VBUSM	
Code	**Error**	**Code**	**Error**

12.2.2.3.13 PCIe Subsystem Internal Diagnostics Features

12.2.2.3.13.1 PCIe Parity

All the parity inputs on the PCIe controller core are driven by the EDC_INV module. This allows the parity input to the PCIe controller to be inverted and thus inject an error. Figure 12-67 shows the parity logic on the AXI AWADDR port as an example. The parity of the AWADDR inputs to the PCIe controller are calculated as an XOR and this is fed into the PCIe controller using the EDC_INV block. The input AWADDR_par can be inverted using commands from the ECC Aggregator to enable error injection. Similar logic is present on all other parity inputs to the PCIe controller.

Checking input parity and output parity are handled inside the PCIe controller. Any errors in parity are signaled using the PCIe active internal diagnostics interrupt (PCIE_ASF_PEND).

Copyright © 2023 Texas Instruments Incorporated

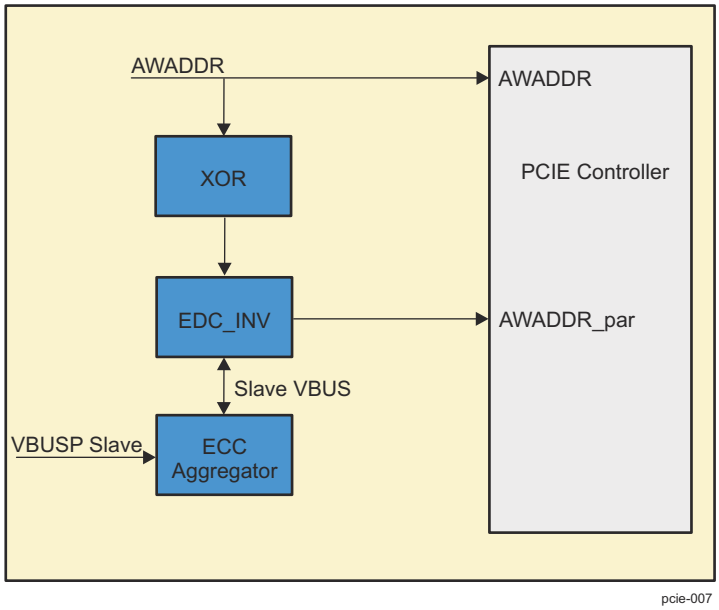

Figure 12-67. Parity Logic on AXI AWADDR Input

12.2.2.3.13.2 ECC Aggregators

The PCIe subsystem instantiates two ECC Aggregators: AXI_ECC_AGGR and CORE_ECC_AGGR.

AXI_ECC_AGGR is connected to the RAMs in PCIe CBA Clock Domain and CORE_ECC_AGGR is connected to the RAMs in the PIPE Clock Domain.

The ECC Aggregator modules integrated within the PCIe subsystem provide a mechanism to control and monitor the ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. Each ECC Aggregator module gathers level pending status from the ECC RAMs into two interrupts to system level. One interrupt is for correactable errors (SEC) and the other one for uncorrectable errors (DED). The ECC Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error. Write back correction for async read RAMs is not supported.

For more information on the ECC Aggregator operation, see Section 12.10.4, *ECC Aggregator*.

12.2.2.3.13.3 RAM ECC Inversion

The RAM ECC logic inside the PCIe controller can be tested using the ECC inversion logic.

12.2.2.3.14 LTSSM State Encoding

Table 12-126 is used when the PCIe/M-PCIe core is configured to be operating in PCIe mode.

Table 12-126 provides the encoding of the LTSSM states on the LTSSM_STATE output of the core, as well the state read from the Physical Layer Configuration Register 0.

12.2.3 Universal Serial Bus (USB) Subsystem

This section describes the USB 3.0 Dual-Role-Device (DRD) interface subsystem of the device.

Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

12.2.3.1 USB Overview

Similar to earlier versions of USB bus, USB 3.0 is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals.

The device supports these USB subsystems:

- USB3SS0 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS [1](USB2.0) PHY

[1] LowSpeed (LS) is supported only in host mode.

Copyright © 2023 Texas Instruments Incorporated

Figure 12-68 shows the USB subsystem highlights.

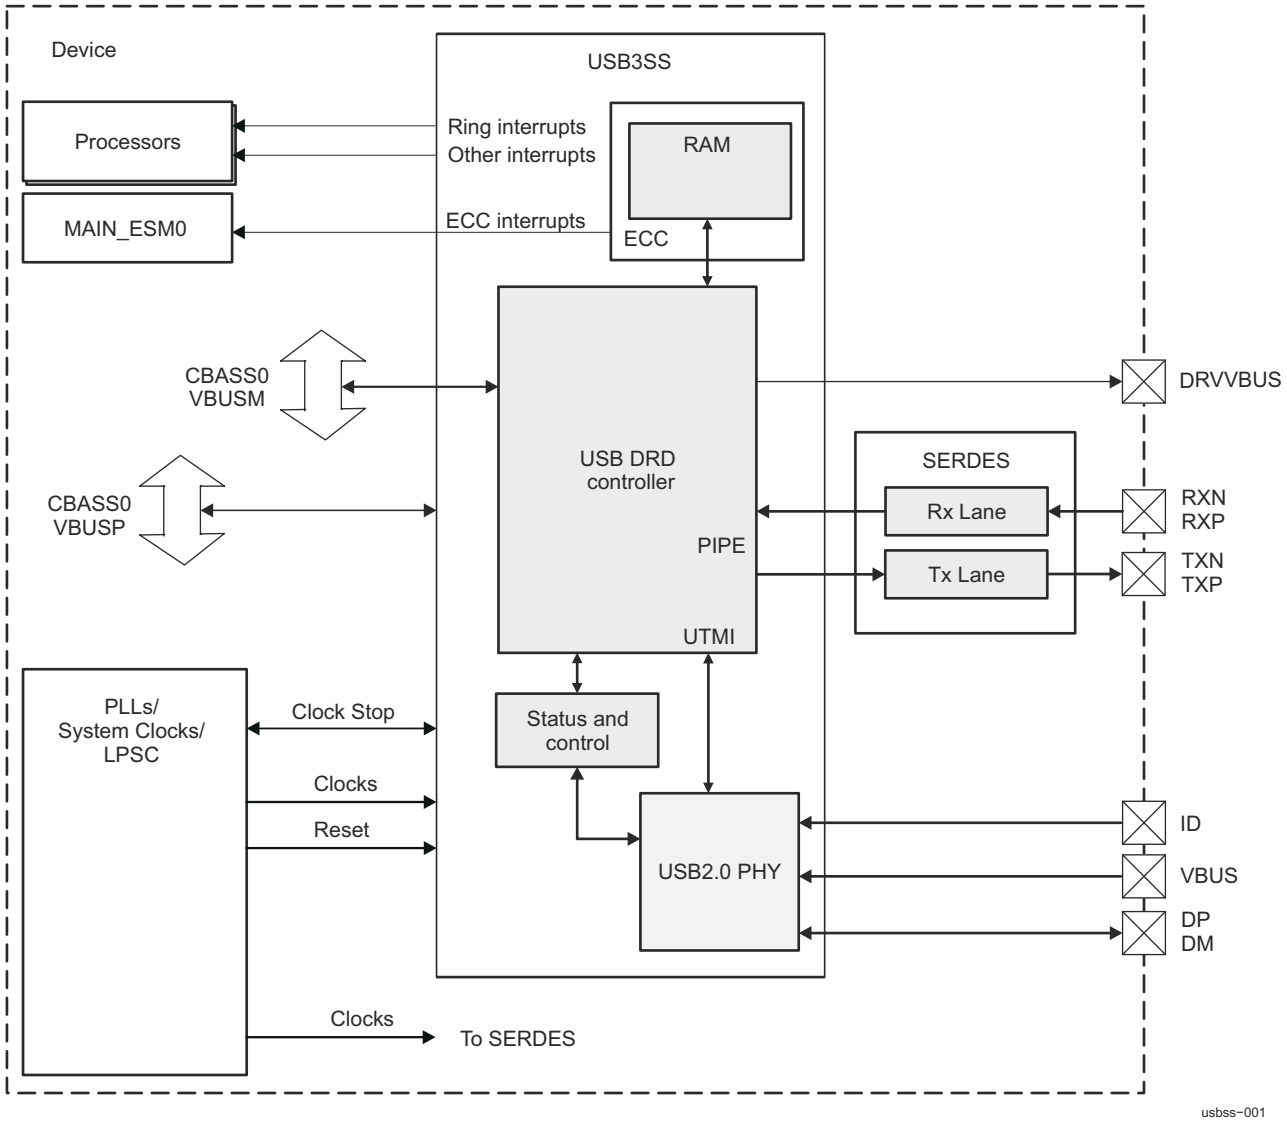

Figure 12-68. USB Subsystem Overview

12.2.3.1.1 USB Features

The USB Dual-Role-Device (DRD) subsystem, supports the following USB features:

- General features:
  - Supports Peripheral (aka Device) mode at Superspeed (5 Gbps), Highspeed (480 Mbps), and Fullspeed (12 Mbps)
  - Supports Host mode at Superspeed (5 Gbps), Highspeed (480 Mbps), Fullspeed (12 Mbps), and Lowspeed (1.5 Mbps)
  - Static peripheral operation
  - Static host operation
  - Compliant with USB 3.1 Gen1 Specification
  - Limited OTG 2.0 functionality
  - Supports VBUS and ID detection
  - Host Negotiation Protocol (HNP) support
  - Charger Downstream Port (CDP) as per Battery Charging Specification, Revision 1.2
- Each controller instance contains single xHCI with the following features:
  - Compatible to the xHCI specification (revision 1.0)

Copyright © 2023 Texas Instruments Incorporated

  - Supports 15 Transmit (TX), 15 Receive (RX) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal scatter-gather DMA controller
  - Dynamic data buffering
  - USB3 power saving states (U1, U2, and U3) and USB2 L1/L2
  - 64 slots supported with 32 endpoints per slot, for host operation
- Operation flexibility:
  - Uniform programming model for SS, HS, FS, and LS operation
  - Multiple interrupt lines:
    - 8 interrupts associated with 8 programmable Event Rings for multi-core support
    - Interrupt for OTG events
- Functional safety:
  - Internal RAM with ECC
  - Hardware transaction timeout monitor
- Supports VBUS and ID detection in the USB2.0 PHY
- External requirements and I/O features:
  - Requires an external charge pump or power switch for VBUS 5-V generation
  - Requires an external circuitry or PMIC to start the battery charging upon Battery Charger (BC) detected event
  - Requires external high-precision resistors for USB2.0 PHY and SERDES termination calibration
  - Supports internal data lane swapping for Type C connector. All other Type C features, like cable detection and CC configuration, have to be implemented using external circuitry
  - Supports short circuit protection to GND and short-term short circuit protection to VBUS on data pins

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.2.3.1.2 USB Ports

This section describes USB module ports related to clocks, resets, and hardware requests.

Table 12-127. USB Clocks and Resets

Clocks	
Module Clock Input	**Description**
ACLK	VBUSM interface clock
PCLK	VBUSP interface clock
BUFCLK	VBUSM bridge clock
CLK_LPM	Low power clock (24 MHz). This clock has to be free running when USB is enabled.
USB2_REFCLOCK	USB2PHY reference clock. HFOSC selected via CTRLMMR_USB0_CLKSEL. Frequency value must be indicated to PHY via USB3P0SS_STATIC_CONFIG.
USB2_APB_PCLK	USB2PHY VBUSP interface clock
Resets	
Module Reset Input	**Description**
USB_RST	USB3SS0 hardware reset

Table 12-128. USB Hardware Requests

Interrupt Requests		
Module Interrupt	**Description**	**Type**
IRQ_[0:7]	8 event ring interrupts in host mode. In device mode, IRQ[6] is device USB interrupt and IRQ[7] is device wakeup request.	Level
HOST_SYSTEM_ERROR	USB host system error	Level
OTGIRQ	USB OTG events	Level
ASF_INT_NONFATAL	USB safety features nonfatal interrupt	Level
ASF_INT_FATAL	USB safety features fatal interrupt	Level
A_ECC_AGGR_CORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level

Copyright © 2023 Texas Instruments Incorporated

Table 12-128. USB Hardware Requests (continued)

A_ECC_AGGR_UNCORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level
DMA Events		
Module DMA Event	**Description**	**Type**
-	No PDMA channels to external DMA engines. USB has an internal DMA controller.	-

12.2.3.1.3 USB Terminology

The following acronyms and abbreviations are related to USB.

Term	Definition
ADP	Attach Detection Protocol: detects USB OTG attach/detach events.
DRD	Dual Role Device: USB Host and Peripheral capable.
DS	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
EP	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
FS	Full-Speed USB data rate (12 Mbps).
HNP	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
HS	High-Speed USB data rate (480 Mbps).
ITP	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
LMP	Link Management Packet.
LS	Low-Speed USB data rate (1.5 Mbps).
OTG	On-The-Go extension to USB protocol.
PHY	Physical Layer Device.
SS	Super-Speed USB data rate. 5 Gbps (USB3.0 or USB3.1 Gen1)
US	Upstream facing from a device (or hub) to the host (or a hub).
USB IF	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. http://www.usb.org
xHC	Host Controller, designates the USB hardware that implements the xHCI specification.
xHCI	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

12.2.3.2 USB Environment

This chapter details the USB subsystem environment.

Table 12-129 describes the external signals of the USB3SS0 subsystem.

Table 12-129. USB3SS0 Input/Output Description

Device Pin	I/O(1)	Description
USB0_DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)
USB0_DM	I/O	
USB0_RX1_P (USB0_RX0_P) or(2) USB3_RX1_P (USB3_RX0_P)	I	USB3.0 differential data receive lane (RX+ pin)
USB0_RX1_N (USB0_RX0_N) or(2) USB3_RX1_N (USB3_RX0_N)	I	USB3.0 differential data receive lane (RX- pin)
USB0_TX1_P (USB0_TX0_P) or(2) USB3_TX1_P (USB3_TX0_P)	O	USB3.0 differential data transmit lane (TX+ pin)

Copyright © 2023 Texas Instruments Incorporated

Table 12-129. USB3SS0 Input/Output Description (continued)

Device Pin	I/O[1]	Description
USB0_TX1_N (USB0_TX0_N) or[2] USB3_TX1_N (USB3_TX0_N)	O	USB3.0 differential data transmit lane (TX- pin)
USB0_REXT or[2] USB3_REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm ±1% accurate off-chip resistor connected from this pin to ground.
USB0_ID	A/I	USB cable identifier (A/B-device). Analog ID pin sense with internal pull-up
USB0_VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm
USB0_DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate
USB0_RCALIB	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm ±1% off-chip resistor connected from this pin to ground

(1) I = Input; O = Output; A = Analog
(2) USB3SS0 Superspeed can go to either SERDES0 or SERDES3. Refer to *2-L Serializer/Deserializer (SerDes)* for more details.

Table 12-130 describes the external signals of the USB3SS1 subsystem.

Table 12-130. USB3SS1 Input/Output Description

Device Pin	I/O[1]	Description
USB1_DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)
USB1_DM	I/O	
USB1_RX1_P (USB1_RX0_P) or[2] USB2_RX1_P (USB2_RX0_P)	I	USB3.0 differential data receive lane (RX+ pin)
USB1_RX1_N (USB1_RX0_N) or[2] USB2_RX1_N (USB2_RX0_N)	I	USB3.0 differential data receive lane (RX- pin)
USB1_TX1_P (USB1_TX0_P) or[2] USB2_TX1_P (USB2_TX0_P)	O	USB3.0 differential data transmit lane (TX+ pin)
USB1_TX1_N (USB1_TX0_N) or[2] USB2_TX1_N (USB2_TX0_N)	O	USB3.0 differential data transmit lane (TX- pin)
USB1_REXT or[2] USB2_REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm ±1% accurate off-chip resistor connected from this pin to ground.
USB1_ID	A/I	USB cable identifier (host/device). Analog ID pin sense with internal pull-up
USB1_VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm
USB1_DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate
USB1_RCALIB	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm ±1% off-chip resistor connected from this pin to ground

(1) I = Input; O = Output; A = Analog

12.2.3.3 USB Functional Description

Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

The USB3SS subsystem contains the USB3.0 Dual Role Device (DRD) controller module and a USB2.0 PHY module. A wrapper module is controlling some top-level functions like Host and Device role switch and reset release.

The USB controller uses USB2PHY for USB2.0 operation and one of the device SERDESes for USB3.0 speeds. The SERDES also contains lane swap feature for USB Type-C plug flipping support.

12.2.3.3.1 USB Type-C Connector Support

Lane swapping for Type-C connector support is performed within the SERDES wrapper module. Type-C CC detection and configuration has to be performed by external ICs. Type-C device attachment/detachment and cable orientation have to be communicated using I2C, GPIO, or a similar method.

For USB Type-C support, the SERDES wrapper and SERDES must be programmed for USB protocol on lane 0, lane 1, and/or lane2, and lane 3. Software must hold PHY in reset and then write to the LN10_SWAP and/or LN23_SWAP bit of the to mux the PIPE interface to the other lane. Also the SuperSpeed port in the controller has to be in disabled state when programming LN10_SWAP or LN23_SWAP.

12.2.3.3.2 USB Controller Reset

USB controller has three resets going in, called preset_n, pwrup_rst_n, and aresetn.

- preset_n comes from the mod_g_rst_n input coming from LPSC
- pwrup_rst_n is PWRUP_RST_N register bit in the USB wrapper module (USB3P0SS_W1). This reset has to be deasserted before accessing controller registers. The default value for pwrup_rst_n is 0 (reset asserted). This reset goes to the default asserted state when mod_g_rst_n reset is asserted.
- areset_n comes from PWRUP_RST_N register bit, but the deassertion is synchronized to ACLK.

12.2.3.3.3 Overcurrent Detection

The overcurrent detection circuit is external to the device. Software must specify an overcurrent condition to the controller whenever the overcurrent signal is received from the detection circuit. Software must set the OVERCURRENT_N bit to 0 in the USB3P0SS_W1 register when overcurrent was detected.

12.2.3.3.4 Top-Level Initialization Sequence

The following initialization sequence has to be followed before configuring the controller for USB operation:

1. Software must select and configure the SERDES for USB operation. Some of the registers are shown in . Refer to , *Serializer/Deserializer (SerDes)* for more details. USB2.0 PHY contains default configuration that normally does not need change.
2. Software must configure the pseudo-static settings in USB3P0SS_W1 register
3. Software must set PWRUP_RST_N to 1 in order to deassert controller reset

After the above sequence, software can access controller registers.

Copyright © 2023 Texas Instruments Incorporated

12.2.4 Serializer/Deserializer (SerDes)

This section describes the Serializer/Deserializer (SerDes) in the device.

12.2.4.1 SerDes Overview

SerDes' goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
  - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
  - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.

12.2.4.1.1 SerDes Features

The SERDES module features include:

- Quad lane PHY containing:
  - Transmit and Receive I/Os
  - Serializer
  - Deserializer
  - Clock and data recovery (CDR) unit
- Common Module (CMN)
  - PLLs
  - Master bias
  - Automatic calibration of pin termination resistors
  - Reference clock input buffers
  - Reset and startup management
- Physical Coding Sub-block (PCS)
  - USB3.1 Gen 1 (5 Gbps)
  - PCIe Gen 1 (2.5 Gbps), Gen 2 (5 Gbps), Gen 3 (8 Gbps)
  - Hyperlink (10 Gbps)
  - Display Port / Embedded Display port v1.4
  - Symbol alignment
  - Selectable serial pin polarity reversal for both transmit and receive paths
  - Bit stream reordering
- Physical Media Attachment (PMA) layer
  - Transmit equalization
  - Receive equalization
  - Data path BIST with programmable pattern generation and error detection
  - Serial bit stream and parallel word loopback for both line and parallel side
  - 8-bit ADC provides digitized ATB measurement results
  - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (Tx and Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock
- Rx comma align block
  - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate

Copyright © 2023 Texas Instruments Incorporated

– Supports comma detection that is not sensitive to false commas using all 8B/10B character combinations

Copyright © 2023 Texas Instruments Incorporated

12.2.4.1.2 SerDes Ports

This section describes SerDes module ports related to clocks, resets, and hardware requests.

Table 12-131. SerDes Clocks and Resets

Clocks	
Module Clock Input	**Description**
SERDES_ICLK	VBUS interface clock
CMN_REFCLK_INT	Internal reference clock from device sources. Software selectable.
Resets	
Module Reset Input	**Description**
SERDES_RST	Serdes LPSC reset

Table 12-132. SerDes Hardware Requests

Interrupt Requests		
Module Interrupt Signal	**Description**	**Type**
PHY_PWR_TIMEOUT_LVL_0	Lane power timeout interrupt	Level
DMA Events		
Module DMA Event	**Description**	**Type**
-	No PDMA channels to external DMA engines	-

12.2.4.1.3 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance [2], see the device-specific Datasheet.

- PCIe: This is electrically compliant with Base specification revision 4.0.
- USB: This is electrically compliant with USB 3.1.
- Hyperlink: Electrically compliant to OIF-CEI-11G-SR.
- Display Port/ Embedded Display Port VESA Standard v1.4

Table 12-133. SerDes Supported Standards

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)	Bus Width (bits)
PCI Express 4.0 Gen1	2.5	19.2, 24, 25, 26, 100	32
PCI Express 4.0 Gen2	5.0	19.2, 24, 25, 26, 100	32
PCI Express 4.0 Gen3	8.0	19.2, 24, 25, 26, 100	32
Hyperlink	10.0	19.2, 24, 25, 26, 100, 125	20
DP/eDP	1.62-8.1	19.2, 24, 25, 26	10
USB 3.1 Gen1 SuperSpeed	5.0	19.2, 24, 25, 26, 100	32

[2] Electrical compatibility does not guarantee interoperability with devices

12.2.4.3 SerDes Integration

This section describes SerDes module integration in the device, including information about clocks, resets, and hardware requests.

Table 12-135 summarize the integration of SerDes in device MAIN domain.

Table 12-135. SerDes Hardware Requests

Interrupt Requests			
Module Instance	**Module Interrupt Signal**	**Description**	**Type**
SERDES0	PHY_PWR_TIMEOUT_LVL_0	Lane power timeout interrupt	Level
DMA Events			
Module Instance	**Module DMA Event**	**Description**	**Type**
SERDES0	-	No PDMA channels to external DMA engines	-

Note

For more information on the interconnects, see *System Interconnect*.

For more information on the power, reset and clock management, see the corresponding sections within *Device Configuration*.

Copyright © 2023 Texas Instruments Incorporated

12.2.4.3.1 WIZ Settings

This section describes the quasi-static settings that software must perform after global resets. These settings are made via registers in the CTRL_MMR0 module. For CTRL_MMR0 description, please refer to *Control Module (CTRL_MMR)*.

12.2.4.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- DP/eDP
- PCIe1 (one- to four-lane)
- Hyperlink
- USB3.0 on lane 1 or 3. Lane 0 or 2 used for Type-C plug reversal feature.

Table 12-136 describes the interface combinations supported by SERDES0.

Table 12-136. SERDES0 Supported Configurations

Interface Alias	CTRLMMR_SERDES0_LN0_CTRL [1:0]		CTRLMMR_SERDES0_LN1_CTRL [1:0]		CTRLMMR_SERDES0_LN2_CTRL [1:0]		CTRLMMR_SERDES0_LN3_CTRL [1:0]	
	LANE_FUNC_SEL	Interface on Lane 0	LANE_FUNC_SEL	Interface on Lane 1	LANE_FUNC_SEL	Interface on Lane 2	LANE_FUNC_SEL	Interface on Lane 3
IP1	0x0	eDP0 Lane0	0x0	eDP0 Lane 1	0x0	eDP0 Lane 2/0	0x0	eDP0 Lane3/1
IP2	0x1	PCIe Lane0	0x1	PCIe Lane 1	0x1	PCIe Lane 2	0x1	PCIe Lane 3
IP3	0x2	-(1)	0x2	USB3_0	0x2	-(1)	0x2	USB3_0
IP4	0x3	Hyperlink Lane0	0x3	Hyperlink Lane 1	0x3	Hyperlink Lane 2	0x3	Hyperlink Lane 3

(1) Reserved for USB0 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See Section 12.2.3, *USB*.

As seen in Table 12-136, USB0 can be routed to two different lanes. To avoid routing to two lanes at the same time, an additional muxing exists.

Table 12-137 describes the additional muxing for USB0 to lane 1 or to lane 3.

Note

Settings in Table 12-137 must be aligned with the settings made in Table 12-136.

Table 12-137. USB0 Muxing to Serdes Lanes

CTRLMMR_USB0_CTRL	
[27] SERDES_SEL	Lane Selected
0	Lane 1 (Lane 0 for Type-C)
1	Lane 3 (Lane 2 for Type-C)

12.2.4.3.1.2 ACSPCIe Reference Clock Selection

Table 12-138 describes the SERDES ACSPCIe reference clock selection. ACSPCIe buffer clk selection: Needs PCIE_REFCLK1_CLKSEL_OUT_CLK_EN to be enabled for driving the clk out onto the ref clk pins.

Table 12-138. SerDes ACSPCIe Reference Clock Selection

[1:0] CLK_SEL	ACSPCIe Clk Source

12.2.4.4 SerDes Functional Description

12.2.4.4.1 SerDes Block Diagram

Figure 12-70 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one (Tx + Rx) lane is shown.

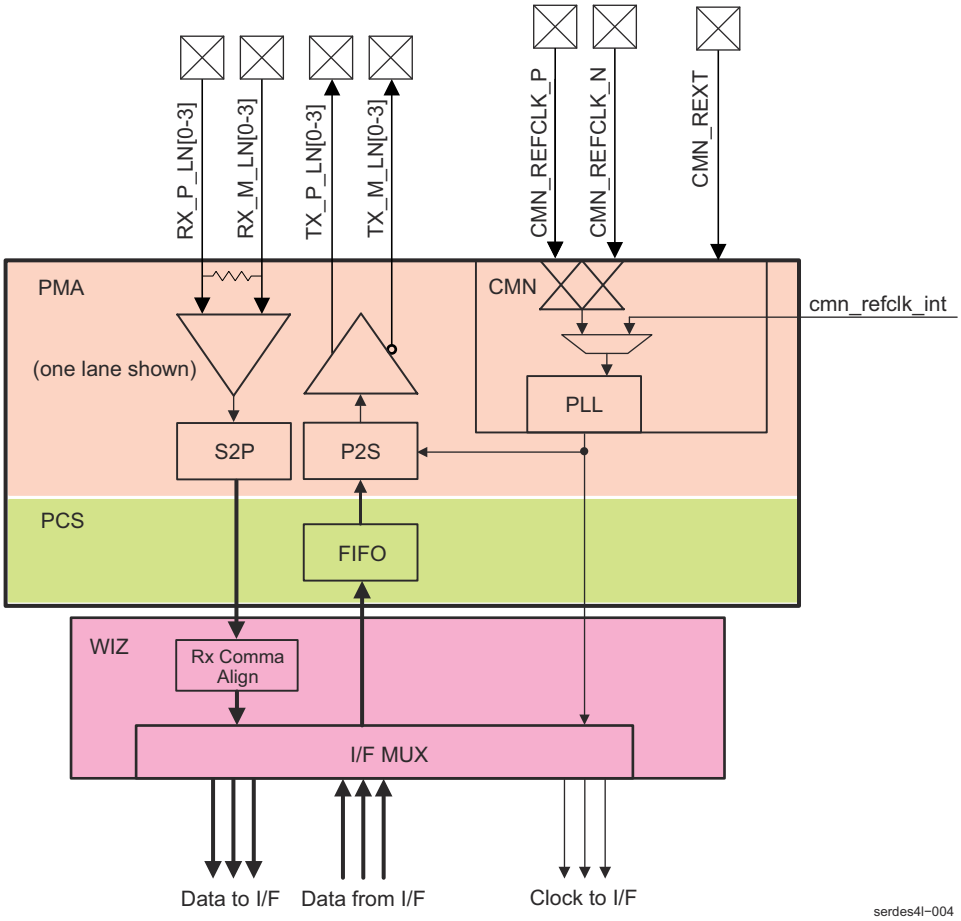

Figure 12-70. SerDes and WIZ Block Diagram

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (USB, PCIe, and others).

12.3 Memory Interfaces

This section describes the memory interfaces in the device.

Copyright © 2023 Texas Instruments Incorporated

12.3.1 Flash Subsystem (FSS)

This section describes the Flash Subsystem (FSS) in the device.

12.3.1.1 FSS Overview

The Flash Subsystem (FSS) provides access to external flash devices via Octal SPI (OSPI) andHyperBus™ interface along with encryption/decryption, authentication, and in-line ECC protection.

The FSS includes two OSPI and one HyperBus interface. For more information, see *Octal Serial Peripheral Interface (OSPI)* and *HyperBus Interface*.

Table 12-139. FSS Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0	-	✓	-

The first FSS path (FSS0) has access to either OSPI0 or HyperBus interface and can be configured for ECC, authentication, or both. The second FSS path (FSS1) has access only to OSPI1 and can be configured with or without ECC.

Figure 12-71. FSS Overview

12.3.1.1.1 FSS Features

The FSS has the following features:

- Two simultaneous flash interfaces:
  - Two OSPIs (OSPI0 and OSPI1) OR
  - One HyperBus interface and one OSPI (OSPI1)
- Primary OSPI0/HyperBus interface supports:
  - Execute in place (XIP) operation
  - 32-byte block copy (BC) operation
  - Prefetch for two XIP flows to improve performance from external flash device
- Secondary OSPI1 interface supports:
  - 32-byte block copy (BC) operation
  - ECC
- OSPIs support single, dual, quad, or octal SPI devices
- OSPIs support up to 4 devices
- HyperBus interface supports up to 2 devices
- The OSPIs and HyperBus interface have independent power management for low power operations

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.1.3 FSS Functional Description

12.3.1.3.1 FSS Block Diagram

The FSS provides access to external Flash and RAM devices. It supports XIP (Execute-in-Place) and BC (Block Copy) operations.

The FSS consists of two OSPIs and one HyperBus interface. There are two FSS paths - FSS0 and FSS1 (see). The first path (FSS0) includes OSPI0 and HyperBus interface. The second path (FSS1) includes OSPI1. These two FSS paths can be used simultaneously (see *FSS Typical Application*).

Table 12-143 shows the FSS allowed interface combinations.

Table 12-143. FSS Allowed Interface Combinations

Combination	Primary Interface (FSS0)	Secondary Interface (FSS1)
1.	OSPI0 (MCU_FSS0_OSPI0)	Not Used
2.	HyperBus Interface (MCU_FSS0_HPB0)	Not Used
3.	OSPI0 (MCU_FSS0_OSPI0)	OSPI1 (MCU_FSS0_OSPI1)
4.	HyperBus Interface (MCU_FSS0_HPB0)	OSPI1 (MCU_FSS0_OSPI1)
5.	Not Used	OSPI1 (MCU_FSS0_OSPI1)

Figure 12-72 shows the FSS block diagram.

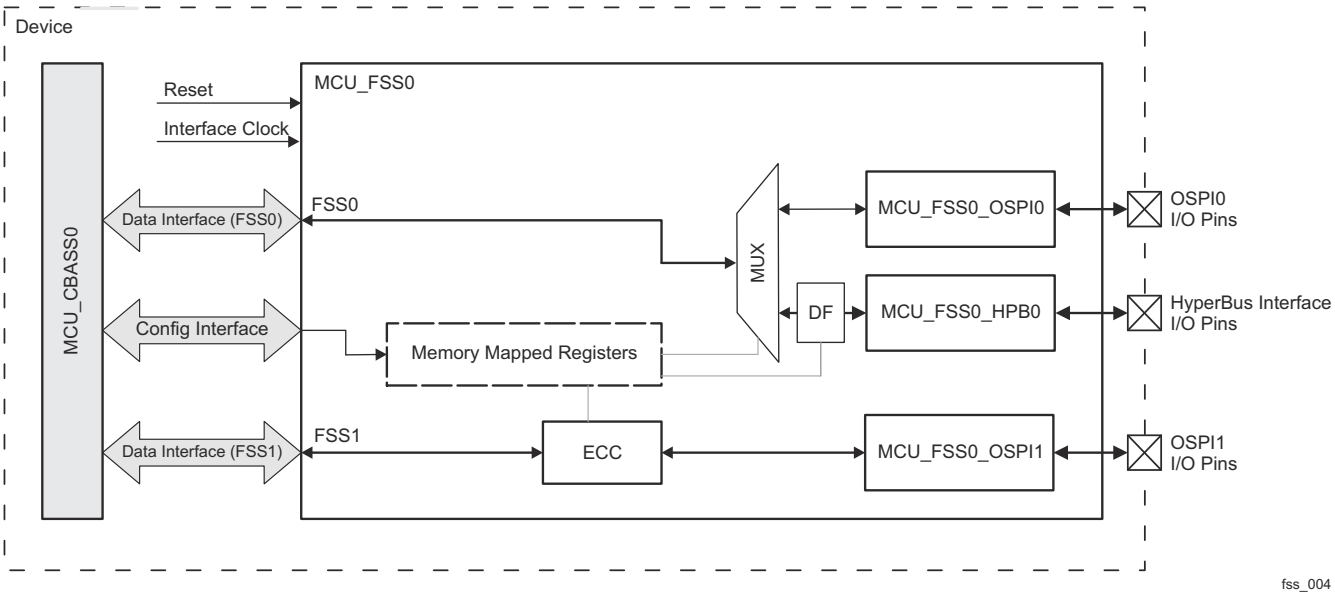

Figure 12-72. FSS Block Diagram

FSS Blocks:

- MCU_CBASS0: The MCU_CBASS0 interconnect allows FSS to communicate with the device modules and subsystems.
- Data Interface (FSS0): It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to either the OSPI0 or HyperBus interface.
- Data Interface (FSS1): It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to the OSPI1.
- Config Interface: It is used for configuration of the memory mapped registers within the FSS.
- Interface Clock and Reset:
  - For more information, see *MCU_FSS0 Clocks and Resets*.
  - For more information, see *MCU_FSS0_OSPI Clocks and Resets*.
  - For more information, see *MCU_FSS0_HPB0 Clocks and Resets*.
- Memory Mapped Registers: This block conditionally includes registers from the following blocks: FSS, ECC, MUX, and DF. The configuration of these registers defines which combination of FSS interfaces is selected

Copyright © 2023 Texas Instruments Incorporated

(see Table 12-143) and also which FSS features and operation modes are used. For more information, see MCU_FSS0_SYSCONFIG.

- MUX: The Muxing (MUX) block is used as a software controlled switch in the primary FSS (FSS0) interface. It defines which interface to be used (OSPI0 or HyperBus interface). The MUX block can switch only when the traffic is idle. The software has responsibility to cause the traffic to be stopped.
- DF: The Dynamic Fragmenter (DF) module is responsible for fragmenting write data to the flash region so that all writes to the flash region are done in 16-bits chunks (a requirement for HyperFlash). It passes all other transaction through unaffected.
- FSS Interfaces:
  - MCU_FSS0_OSPI0: The OSPI0 is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFA module.
  - MCU_FSS0_OSPI1: The OSPI1 is part of the secondary FSS interface (FSS1). It can be configured with or without ECC.
  - MCU_FSS0_HPB0: The HyperBus interface is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFA module.
- FSS I/O Pins:
  - OSPI1 I/O Pins: All used MCU_FSS0_OSPI1 interface pins (for more information, see *OSPI I/O Signals*).
  - HyperBus I/O Pins: All used MCU_FSS0_HPB0 interface pins (for more information, see *HyperBus I/O Signals*).

12.3.1.3.2 FSS ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

For more information about ECC, refer to *ECC Aggregator*.

For FSS1 path when the stand-alone ECC module is used:

- The input for the ECC module is 32-byte data block.
- The ECC module generates ECC codes for the 32-byte data block.
- The ECC module packs data + ECC, reformats the address and sends this to the flash controller (OSPI1 flash controller).

For more information, see *ECC Calculation*.

12.3.1.3.3 FSS Modes of Operation

Table 12-143 presents the possible combinations of FSS interfaces.

Both paths (FSS0 and FSS1) support XIP and BC modes.

12.3.1.3.4 FSS Memory Regions

Table 12-144 shows the FSS memory regions.

Table 12-144. FSS Memory Regions

Address Range		Size	Description
FSS0 (HyperBus interface or OSPI0)	FSS1 (OSPI1)		
0x04 0000 0000 to 0x04 FFFF FFFF	0x06 0000 0000 to 0x06 FFFF FFFF	4 GB	External Memory Space (Region 0)
0x00 5000 0000 to 0x00 57FF FFFF	0x00 5800 0000 to 0x00 5FFF FFFF	128 MB	Boot Space (Region 1)
0x05 0000 0000 to 0x05 FFFF FFFF	0x07 0000 0000 to 0x07 FFFF FFFF	4 GB	External Memory Space (Region 3)

12.3.1.4 FSS Programming Guide

12.3.1.4.1 FSS Initialization Sequence

Initialization steps:

- Configure the main boot parameters for FSS0 or FSS1):
  - Select the boot block to be used.
  - Select the size of the boot block to be used.

Copyright © 2023 Texas Instruments Incorporated

- Enable FSS in PSC.
- Configure the FSS interface which will be used:
  - For FSS0 - OSPI0 or HyperBus interface.
  - For FSS1 - OSPI1.
- Enable the selected FSS interface in PSC.
- Configure the FSS interface:
  - For more information about OSPI configuration, please see *Octal Serial Peripheral Interface (OSPI)*.
  - For more information about HyperBus interface configuration, please see *HyperBus Interface*.
- Configure the ECC region start address and size:
  - MCU_FSS0_ECC_RGSTRT_j
  - MCU_FSS0_ECC_RGSIZ_j
- Enable the ECC option if the target flash device has ECC encoded within.
- If the target device is HyperFlash/SRAM configure fragmentation address boundary:
  - Flash device requires fragmentation.
  - SRAM device does not require fragmentation.
- Enable error interrupts (see MCU_FSS0_ENABLE_SET).

12.3.1.4.2 FSS Real-Time Operation

In the event of an ECC single error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If a single error occurs, the CPU can scrub the flash block to determine if the error is permanent and requires reprogramming.

In the event of an ECC double error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If the double error detect is within the flash, the region is corrupt and have to be treated as unused.

12.3.1.4.3 FSS Power Up/Down Sequence

There are four PSC controls for the FSS: the FSS itself, OSPI0, HyperBus interface, and OSPI1. The CPU enables the appropriate interfaces before using FSS0 or FSS1 of the FSS.

The FSS0 can be used for HyperBus interface or OSPI0 and only the interface in use has to be enabled. Software should ensure the selected interface is enabled prior to FSS0 transactions.

Copyright © 2023 Texas Instruments Incorporated

The FSS1 can only be used to access OSPI1. The FSS1 transaction may be blocked depending on the power state of the OSPI1.

Normal Power Down Sequence:

- Block any new transaction to the particular interface - FSS0 or FSS1.
- Power down the target FSS interface.
- In the event when all targets are powered down, the FSS can then be powered down.

12.3.2 Octal Serial Peripheral Interface (OSPI)

This section describes the Octal Serial Peripheral Interface (OSPI) module for the device.

12.3.2.1 OSPI Overview

The Octal Serial Peripheral Interface (OSPI) module is a kind of Serial Peripheral Interface (SPI) module which allows single, dual, quad or octal read and write access to external flash devices.

The OSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling its completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device master at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM should be accessed using user programmable configuration registers.

12.3.2.1.1 OSPI Features

The OSPI modules have the following features:

- Support for single, dual, quad (QSPI mode) or octal (on MCU_FSS0_OSPI0 only) I/O instructions.
- Support dual Quad-SPI mode for fast boot applications.
- Memory mapped ‘direct’ mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM of configurable size to reduce advanced high-performance bus overhead and buffer flash data during indirect transfers.
- Set of software advanced peripheral bus accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Additional addressable memory bank to accommodate more than 8-bytes at a time.
- Support for XIP, sometimes referred to as continuous mode.
- Support for DDR Mode and DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.
- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs, bypassing the higher layer processes.
- An independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Programmable baud rate generator to generate OSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks or DQS to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external device selects - OSPI and QSPI devices can be mixed:
  - MCU_FSS0_OSPI0 has four chip-selects
  - MCU_FSS0_OSPI1 has two chip-selects.
- Programmable data decoder, enables continuous addressing mode for each of the connected devices and auto-detection of boundaries between devices.
- Support BOOT mode.
- Bidirectional CRC on Multiple-SPI interface.
- Handling ECC errors for flash devices with embedded correction engine.
- Full integration with PHY module dedicated to more flexible and power efficient transfers.
- MCU_FSS0_OSPI0 supports RESET_OUT[1-0] and ECC_FAIL pins for external flash devices where ECC is checked on the flash.
- Automatic Flash device status polling for programming operation (Auto HW Polling)

Table 12-147. OSPI I/O Signals (continued)

Module Pin	I/O[1]	Description
DQS	I[2]	MCU_FSS0_OSPI1 data strobe / external loopback input

(1) I = Input; O = Output
(2) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR_MCU_OSPIn_CLKSEL[4] LOOPCLK_SEL bit in *Control Module (CTRL_MMR)*.

Copyright © 2023 Texas Instruments Incorporated

12.3.2.3 OSPI Functional Description

12.3.2.3.1 OSPI Block Diagram

Figure 12-73 shows the OSPI module block diagram.

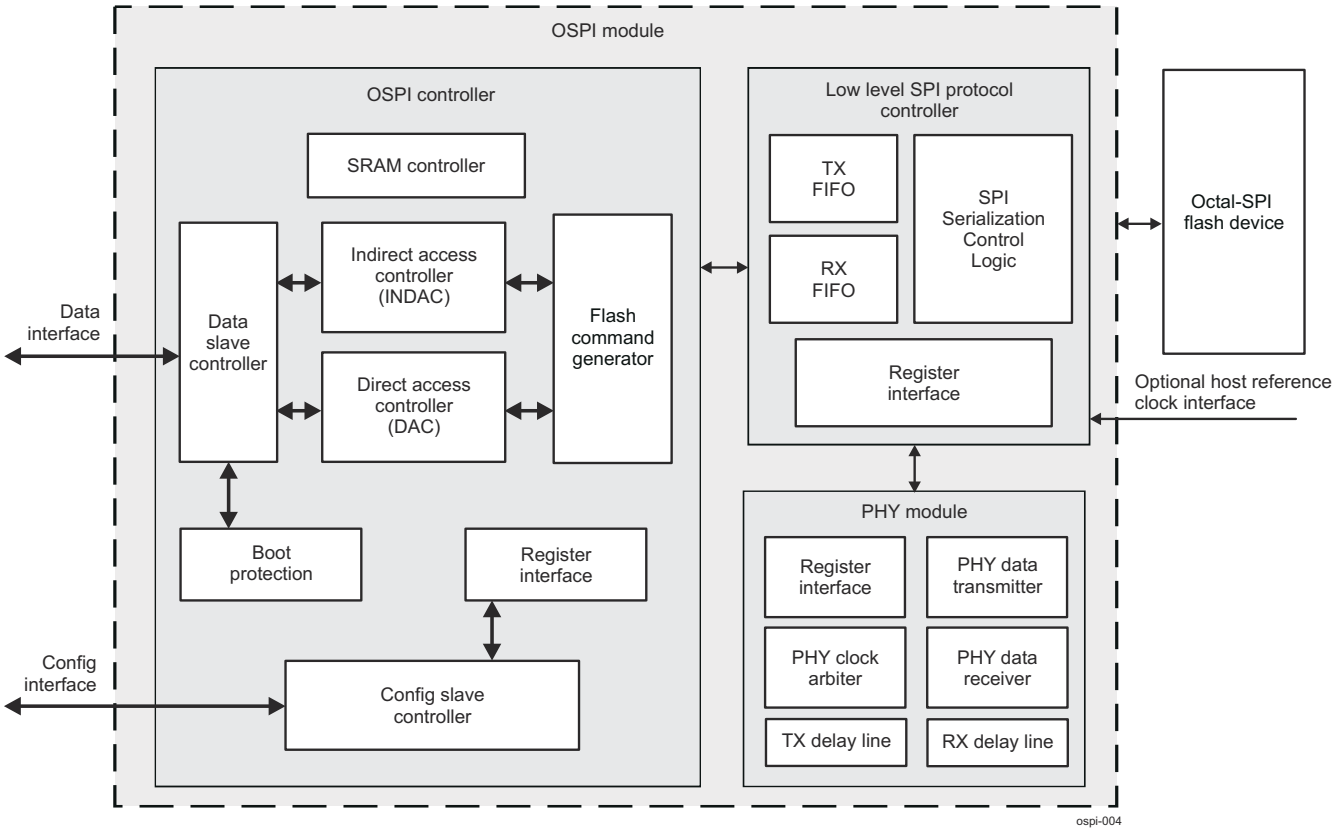

Figure 12-73. OSPI Block Diagram

The OSPI module is composed of three main blocks. The first one is the OSPI controller, the second one is the low level SPI protocol controller, and the third one is the integrated PHY.

The OSPI module has the following two slave interfaces:

- Data slave interface intended for data transfer.
- Configuration slave interface intended for accessing the programmable set of registers.

12.3.2.3.1.1 Data Slave Interface

The data interface is used for data transfer to external flash devices in direct and indirect mode of operation. The data slave controller validates incoming data accesses, responds to invalid requests, performs any required byte and halfword reordering, blocks writes that violate the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC).

The data interface bus is 32-bits wide. Therefore only byte, halfword and word accesses are permitted. When the controller is configured to work in SPI Octal DDR Mode or Octal DDR Protocol (where 2 bytes are collected within single SPI clock cycle what exceeds the size of 1 byte transfer request), 8 bit transfer size is not allowed.

Copyright © 2023 Texas Instruments Incorporated

Note

Cache line wrap accesses over the data slave port should be word aligned.

Data slave port doesn't support cache line wrap bursts of 128 bytes.

12.3.2.3.1.2 Configuration Slave Interface

The configuration interface is used to configure the OSPI module and perform software controlled flash accesses using the OSPI_FLASH_CMD_CTRL_REG register (for more information refer to Section 12.3.2.3.11, *Software Triggered Instruction Generator (STIG)*). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the OSPI configuration and SRAM ECC registers.

Note

The configuration interface supports only 32-bit accesses. For single byte or halfword manipulations software should perform read-modify-write operations.

12.3.2.3.1.3 OSPI Clock Domains

The OSPI module has two main clock sources for the Octal-SPI controller.

- For interface clocks
- For reference clock

The source for the interface clocks corresponds to the configuration and data buses. The data bus clock (OSPI_HCLK) is the main system clock used to transfer data over the data bus between a master on the system interconnect and the OSPI module. The data bus clock also drives the internal OSPI SRAM. The configuration bus clock (OSPI_PCLK) is used to access the OSPI configuration register and perform basic configuration and for interrupt handling. The OSPI reference clock (OSPI_RCLK) drives the SPI transmit and receive logic in the OSPI module. It is also used to generate the output SPI protocol clock (OSPI_OCLK) and for oversampling of the input data. Using the reference clock (OSPI_RCLK) allows the OSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

Note

There is no particular clock ratio requirement between configuration (OSPI_PCLK) and data bus (OSPI_HCLK) clocks.

12.3.2.3.2 OSPI Modes

Note

Some of the OSPI features described in this section may not be supported on this family of devices. For more information, see *OSPI Not Supported Features*.

The OSPI module supports four SPI modes. These modes are defined through the OSPI_CONFIG_REG[1] SEL_CLK_POL_FLD and OSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD bits. The SEL_CLK_POL_FLD bit defines the clock polarity and the SEL_CLK_PHASE_FLD bit defines the data launch and data capture relation to the OSPI clock edges. Table 12-148 gives a brief description of these modes.

Table 12-148. OSPI Modes

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state: low
			Data launch edge: clock falling edge
			Data capture edge: clock rising edge
1	0	1	Clock inactive state: low
			Data launch edge: clock rising edge
			Data capture edge: clock falling edge

Copyright © 2023 Texas Instruments Incorporated

Table 12-148. OSPI Modes (continued)

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
2	1	0	Clock inactive state: high
			Data launch edge: clock rising edge
			Data capture edge: clock falling edge
3	1	1	Clock inactive state: high
			Data launch edge: clock falling edge
			Data capture edge: clock rising edge

Octal flash devices provide DQS signal which allows source synchronous capture, but for Quad flash devices the OSPI module has a loopback mode. In this loopback mode the clock, looped back at board level, is used for registering the input data, and the edge used is same as the launch edge, thus giving a full cycle path (for more information, see *Read Data Capture*).

12.3.2.3.2.1 Read Data Capture

Figure 12-74 shows the Read Data Capture Logic in the OSPI module.

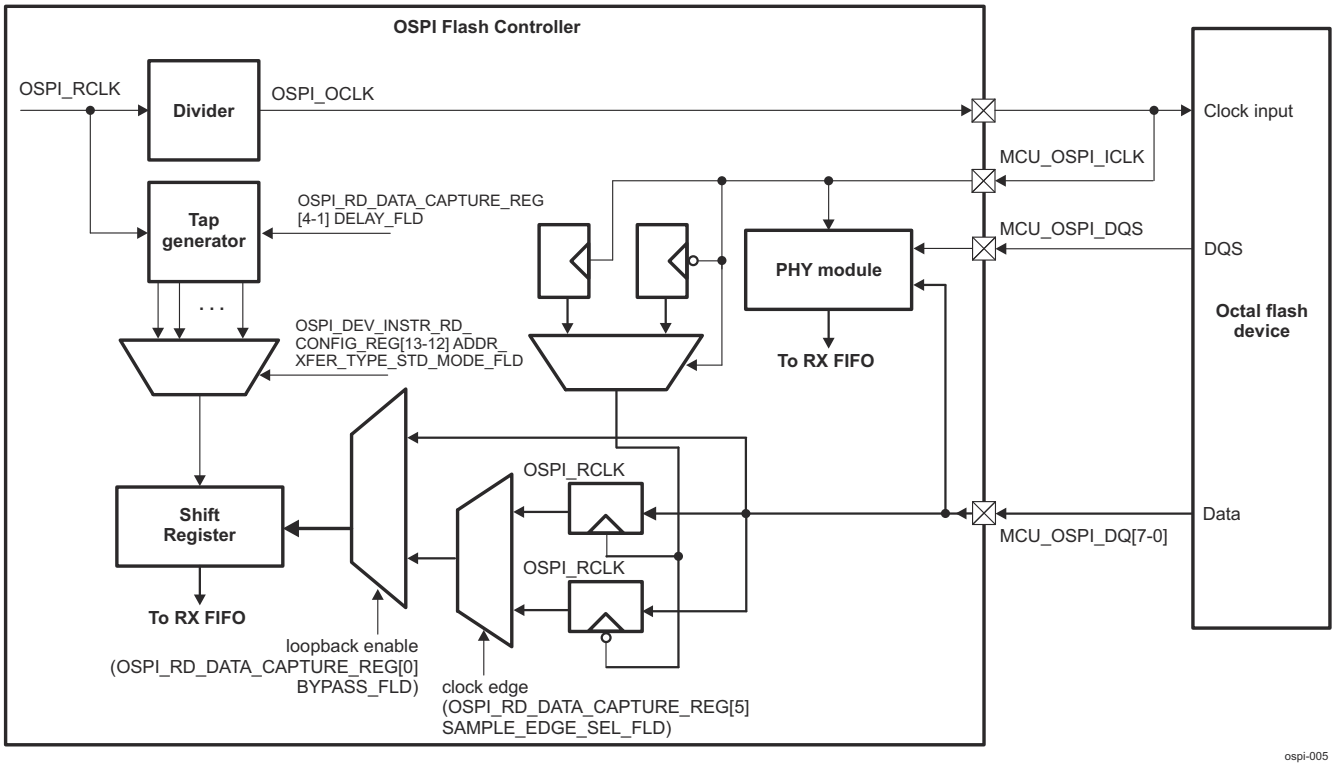

Figure 12-74. Read Data Capture Logic

The PHY module includes a DLL which allows adjustment of the sampling edge with respect to the incoming data to achieve maximum frequency. There are three sources for the sampling signal:

- The reference clock
- Output SPI clock external loopback
- The DQS (only available in Octal Flash devices)

The loopback mode (only for Quad flash devices) can work in two cases. The first one is when OSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD=0. When SEL_CLK_PHASE_FLD=1 there aren't enough clock falling edges for the register pipeline to catch the last data driven, thus causing a functional failure. Additionally, since the capture edge is falling edge, it gives a full cycle input path only in SPI mode 0, that is when SEL_CLK_POL_FLD=0 and SEL_CLK_PHASE_FLD=0. Thus SPI mode 0 is the first of two modes that support high MHz operation (greater than 50 MHz). The second mode is when SEL_CLK_PHASE_FLD=1 and

Copyright © 2023 Texas Instruments Incorporated

SEL_CLK_PHASE_FLD=1 (SPI mode 3). In this case the missing clock falling edge is compensated inside the OSPI controller when using the incorporated PHY module by inverting the loopback clock.

The loopback mode is enabled by writing 0x0 to OSPI_RD_DATA_CAPTURE_REG[0] BYPASS_FLD. The taps are selected by programming OSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD field. The taps delay the read data capturing logic by the programmed number of OSPI_RCLK cycles.

12.3.2.3.2.1.1 Mechanisms of Data Capturing

There are two mechanisms of data capturing in the OSPI module. They can be combined in some parts to ensure reliable sampling solution independent on the system requirements and the controller configuration. The mechanisms are as follows:

- Data capturing mechanism using taps
- Data capturing mechanism using PHY module.

12.3.2.3.2.1.2 Data Capturing Mechanism Using Taps

This section describes the data capturing mechanism where sampling point is adjusted for one of the reference clock edges inside divided OSPI clock.

After POR, the adapted loopback clock circuit and the OSPI_RCLK delay register line both wake in a disabled state. The OSPI_RD_DATA_CAPTURE_REG register provides the control for the mechanism using taps.

OSPI_RD_DATA_CAPTURE_REG[5] SAMPLE_EDGE_SEL_FLD bit selects the edge of the reference clock, on which data outputs from flash memory are sampled.

OSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD bit field controls the additional number of read data capture cycles (this is the fast reference clock, running at least x4 of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less than the flash memory device itself can operate at. To compensate, software shall set this register to a value that guarantees robust data captures.

12.3.2.3.2.1.3 Data Capturing Mechanism Using PHY Module

PHY module is responsible for data capturing. More detailed description of all internal PHY sampling mechanisms is included in Section 12.3.2.3.16.2, *Read Data Capturing by the PHY Module*.

12.3.2.3.2.2 External Pull Down on DQS

Per the OSPI protocol, the FLASH device drives DQS while CS is asserted. When CS is not asserted the FLASH device presents HiZ on DQS. When configured to use DQS, the controller uses the DQS as a clock, which samples the incoming data into a FIFO. Noise on the DQS when it is HiZ can cause spurious false triggering of the FIFO and filling it with invalid data. There is no way to clear this data except to reset the OSPI module.

To avoid this issue, it is recommended to add a pull down on the DQS line.

During device wakeup, before the IO ring is configured properly, the CS to the FLASH device is HiZ. Depending on the actual level of the CS line the FLASH device might drive the DQS High, Low or HiZ. A pull down on DQS forces the DQS input to Low, but the DQS might still be High or in the presence of noise there might be transitions between Low and High. This again can cause the same issue of capturing garbage data in the Controller FIFO.

To avoid this issue it is recommended to release the OSPI from reset only after the IO ring is configured properly.

12.3.2.3.3 OSPI Power Management

Note

The OSPI module does not provide any hardware signal for busy or idle status. Software need to ensure that the OSPI module is idle before clocks can be shut off by reading the OSPI_CONFIG_REG[31] IDLE_FLD bit.

OSPI_PCLK and OSPI_HCLK share the same clock stop request/acknowledge and clock enable/acknowledge interface.

Copyright © 2023 Texas Instruments Incorporated

12.3.2.3.4 Auto HW Polling

The OSPI controller is capable of automatically testing the Flash device busy bit to guarantee no reads or writes are ignored by the flash when it is busy burning in programmed data.

At the end of a programming transaction, the Flash device goes into a burn-in state and becomes busy.

When Auto HW Polling is enabled, the OSPI controller keeps track of programming transactions and will initiate a Flash status read polling transactions automatically, until Flash indicates it is not busy, before any additional data read or programming operations are sent to the flash device. See OSPI_WRITE_COMPLETION_CTRL_REG register and the associated registers.

The OSPI controller requires that the OSPI_WRITE_COMPLETION_CTRL_REG[23-16] POLL_COUNT_FLD field should always be set with values greater or equal to 3 (>=3).

12.3.2.3.5 Flash Reset

OSPI provides Flash reset out ports. These ports are active low and controlled thru OSPI_CONFIG_REG register.

12.3.2.3.6 OSPI Memory Regions

Table 12-149 shows the OSPI memory map in MCU domain.

Table 12-149. OSPI Memory Map

Address Range		Size	Description
MCU_FSS0_OSPI0	MCU_FSS0_OSPI1		
0x00 4704 0000 to 0x00 4704 0100	0x00 4705 0000 to 0x00 4705 0100	256 B	Configuration registers space
0x00 4704 4000 to 0x00 4704 4200	0x00 4705 4000 to 0x00 4705 4200	512 B	Global control registers space
0x00 4706 8000 to 0x00 4706 8400	0x00 4706 4000 to 0x00 4706 4400	1 KB	OSPI_ECC_AGGR registers space

Note

For more information about the memory space, see Section 12.3.1.3.4, *FSS Memory Regions*.

12.3.2.3.7 OSPI Interrupt Requests

The OSPI module generates three interrupts per instance. The ECC interrupts (MCU_FSS0_OSPI_0_OSPI_ECC_CORR_LVL_INTR_0 and MCU_FSS0_OSPI_0_OSPI_ECC_UNCORR_LVL_INTR_0 for MCU_FSS0_OSPI0; MCU_FSS0_OSPI_1_OSPI_ECC_CORR_LVL_INTR_0 and MCU_FSS0_OSPI_1_OSPI_ECC_UNCORR_LVL_INTR_0 for MCU_FSS0_OSPI1) are generated by the ECC aggregator.

The other interrupts (MCU_FSS0_OSPI0_LVL_INTR_0 for MCU_FSS0_OSPI0 and MCU_FSS0_OSPI1_LVL_INTR_0 for MCU_FSS0_OSPI1) are generated by the OSPI module.

Table 12-150 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

12.3.2.3.8 OSPI Data Interface

12.3.2.3.8.1 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address is forwarded. A remap feature is available to remap all incoming data addresses to ADDRESS + N, where N is the value stored in the OSPI_REMAP_ADDR_REG[31-0] VALUE_FLD bit field. It is enabled via the OSPI_CONFIG_REG[16] ENB_AHB_ADDR_REMAP_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

12.3.2.3.8.2 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, is not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first OSPI_LOWER_WR_PROT_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second OSPI_UPPER_WR_PROT_REG register defines the FLASH block that is located at the top of the region to be protected. The third OSPI_WR_PROT_CTRL_REG register is a control register consisting of 2 bits. The OSPI_WR_PROT_CTRL_REG[0] INV_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The OSPI_WR_PROT_CTRL_REG[1] ENB_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the OSPI_DEV_SIZE_CONFIG_REG register.

12.3.2.3.8.3 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTRL_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in Section 12.3.2.3.10, *Indirect Controller (INDAC)*. If DAC is disabled, any incoming access that cannot be forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

Copyright © 2023 Texas Instruments Incorporated

12.3.2.3.9 OSPI Direct Access Controller (DAC)

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see OSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD and OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD bits).

12.3.2.3.10 OSPI Indirect Access Controller (INDAC)

12.3.2.3.10.1 Indirect Read Controller

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (OSPI_INDIRECT_READ_XFER_CTRL_REG, OSPI_INDIRECT_READ_XFER_WATERMARK_REG, OSPI_INDIRECT_READ_XFER_START_REG, and OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG). This block will communicate with an embedded low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external master.

By default, the Indirect Read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in OSPI_INDIRECT_READ_XFER_START_REG and OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to Section 12.3.2.3.10.3, *Indirect Access Queuing*.

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external master will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the OSPI module. The address of the incoming read access must be in the range of indirect trigger address programmed via the OSPI_IND_AHB_ADDR_TRIGGER_REG register to indirect trigger address + 2**(indirect trigger address range) - 1. Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the indirect range to grant SRAM as source. Each valid Indirect Read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the OSPI_INDIRECT_READ_XFER_START_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the OSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with minimum latency. Once the data has been read from the SRAM, the OSPI module will free up the associated resource in the SRAM.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

Copyright © 2023 Texas Instruments Incorporated

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external master may issue a 16-bit (Halfword) or byte access to complete the transfer. It is also permitted for the external master to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the OSPI_SRAM_FILL_REG register.

An indirect operation may be cancelled at any time by setting 1 to OSPI_INDIRECT_READ_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see OSPI_INDIRECT_READ_XFER_WATERMARK_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the OSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an Indirect Read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit starts an indirect read operation. OSPI_INDIRECT_READ_XFER_CTRL_REG[2] RD_STATUS_FLD bit is available to check the status.

12.3.2.3.10.1.1 Indirect Read Transfer Process

The following sequence can be followed:

1. Setup OSPI_CONFIG_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI_INDIRECT_READ_XFER_START_REG register.
3. Setup the number of bytes to be transferred in the OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG register.
4. Setup the indirect transfer's trigger address in the OSPI_IND_AHB_ADDR_TRIGGER_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI_INDIRECT_TRIGGER_ADDR_RANGE_REG register.
6. If the watermark interrupt feature is to be used, set the OSPI_INDIRECT_READ_XFER_WATERMARK_REG register which will cause an interrupt to be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.
7. Trigger Indirect Read access by setting the OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit to 1.
8. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the OSPI_SRAM_FILL_REG register to decide when sufficient data is in the SRAM to trigger data fetches.
9. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 8. Otherwise continue to step 10.
10. The completion status of the Indirect Read operation can be polled via the OSPI_INDIRECT_READ_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD bit.
11. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

Copyright © 2023 Texas Instruments Incorporated

12.3.2.3.10.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more information see the following registers: OSPI_INDIRECT_WRITE_XFER_CTRL_REG, OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG, OSPI_INDIRECT_WRITE_XFER_START_REG, and OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG). This block will await delivery of the write data via the external data interface master, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in OSPI_INDIRECT_WRITE_XFER_START_REG and OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to Section 12.3.2.3.10.3, *Indirect Access Queuing*.

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external master. In the case of an SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable OSPI_SRAM_FILL_REG register and this can be used to avoid this situation.

An external master will provide the write data and will transfer this to the OSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the OSPI_IND_AHB_ADDR_TRIGGER_REG register to Indirect trigger address + 2**(Indirect trigger address range) - 1. Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be pushed, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the OSPI_INDIRECT_WRITE_XFER_START_REG register. Assuming the SRAM is not full at the point the data interface access is received by the OSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external master may issue a 32-bit word, 16-bit (halfword) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the master is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the OSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the OSPI module will initiate a write burst to the flash command generator.

Copyright © 2023 Texas Instruments Incorporated

An indirect operation may be cancelled at any time by setting 1 to the OSPI_INDIRECT_WRITE_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit starts an indirect write operation. The OSPI_INDIRECT_WRITE_XFER_CTRL_REG[2] WR_STATUS_FLD bit is available to check the status.

12.3.2.3.10.2.1 Indirect Write Transfer Process

The following sequence can be followed:

1. Setup OSPI_CONFIG_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI_INDIRECT_WRITE_XFER_START_REG register.
3. Setup the number of bytes to be transferred in the OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register.
4. Setup the indirect transfer's trigger address in the OSPI_IND_AHB_ADDR_TRIGGER_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI_INDIRECT_TRIGGER_ADDR_RANGE_REG register.
6. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the OSPI to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write data in one block transfer, software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a judgment as to when the most practical time to send the next part of the transfer.
7. If the watermark interrupt feature is to be used, set the OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG register which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. That is if the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
8. Trigger Indirect Write access by setting OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit.
9. If the remaining number of bytes still to be transferred into the SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to SRAM.
10. If all the data in the indirect transfer has now been sent to the SRAM, then go to 12 and await indirect complete status. Otherwise if there is more data still to be transferred then either:
    - If the watermark interrupt feature is being used, then wait for watermark interrupt.
    - Alternatively the SRAM fill level can be interrogated to identify a convenient time to send more data.
11. Loop back to 9.
12. Optional: The completion status of the Indirect write operation can be polled via OSPI_INDIRECT_WRITE_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD.
13. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

12.3.2.3.10.3 Indirect Access Queuing

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of

Copyright © 2023 Texas Instruments Incorporated

one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit or OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit) twice in short succession. The indirect number of bytes register (OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG or OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register) and the indirect FLASH start address register (OSPI_INDIRECT_READ_XFER_START_REG or OSPI_INDIRECT_WRITE_XFER_START_REG register) must be setup with the relevant transfer data before START_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG and OSPI_INDIRECT_READ_XFER_START_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

12.3.2.3.10.4 Consecutive Writes and Reads Using Indirect Transfers

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

12.3.2.3.10.5 Accessing the SRAM

The SRAM depth is separated in two segmets. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the OSPI_SRAM_PARTITION_CFG_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x00, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x01, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x02, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFD, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFE, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFF, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

Copyright © 2023 Texas Instruments Incorporated

Note

A value of 0xFF or 0x00 in the OSPI_SRAM_PARTITION_CFG_REG register should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the OSPI_SRAM_FILL_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. Table 12-151 shows priority allocated to these sources.

Table 12-151. SRAM Access Priority

SRAM Access Priority		
Indirect Write	Write to SRAM (from System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (from OSPI Module)	2nd
Indirect Read	Write to SRAM (from OSPI Module)	1st
	Read from SRAM (from System Data Bus)	3rd (exclusive with Data Bus Write Request)

Note

With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

12.3.2.3.11 OSPI Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the OSPI_FLASH_CMD_CTRL_REG register by setting up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH devices could cause unpredicted behavior of the controller. OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD bits should be set different than OSPI_DEV_INSTR_RD_CONFIG_REG[7-0] RD_OPCODE_NON_XIP_FLD and OSPI_DEV_INSTR_WR_CONFIG_REG[7-0] WR_OPCODE_FLD. The OSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit is used to trigger the command. The OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG registers. For writes, the write data should be placed in the OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG registers.

The completion of the STIG request could be also checked by the corresponding interrupt. The occurrence of the interrupt indicates that the controller is ready for accepting a new STIG request. It is important to notice that completion of the STIG request is not equivalent to completion it on SPI side. For example, if STIG is configured to the command composed of data to transmit only, the data is taken from the corresponding STIG register fields and put into TX FIFO. Since all bytes to write are known, another STIG can be queued before serialization of the current one is completed.

Copyright © 2023 Texas Instruments Incorporated

There are some commands which require more data to read than 8 bytes (for example READ ID command). The additional STIG Memory Bank is implemented in order to accommodate these data if needed. The STIG Memory Bank (internal component of the controller) is controlled by the OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD bit. If enabled, the number of bytes to read in the STIG is extended to the value ranging from 16 to 512 as defined in OSPI_FLASH_COMMAND_CTRL_MEM_REG[18-16] NB_OF_STIG_READ_BYTES_FLD bit field. It should be noticed that there are very few commands (excluding Read Array ones which are not intended to handle effectively in STIG Mode but in Direct/Indirect Modes) which return more than 8 bytes to the controller. If the maximum number of bytes to Read using STIG in target application is less than 512, the depth of the STIG Memory Bank can be set smaller what will result in saving noticeable part of the area.

If number of bytes to Read in the STIG as defined in OSPI_FLASH_COMMAND_CTRL_MEM_REG[18-16] NB_OF_STIG_READ_BYTES_FLD bit field exceeds the Memory Bank Depth, remaining data will overwrite the STIG Memory Bank locations starting from its first address. OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG keep the last 8 bytes read from the Flash Device by STIG when Memory Bank is enabled. Therefore, for example if the user wants to get just a single byte from the last eight bytes from long continuous read SPI data chain, there is no need to access the STIG Memory Bank since data can be taken from suitable Flash Command Read Data register. In order to access more data, STIG Memory Bank data request should be triggered. It is controlled by the OSPI_FLASH_COMMAND_CTRL_MEM_REG and works analogously for triggering STIG from the functional standpoint.

OSPI_FLASH_COMMAND_CTRL_MEM_REG[0] TRIGGER_MEM_BANK_REQ_FLD bit is used to trigger the command, bit OSPI_FLASH_COMMAND_CTRL_MEM_REG[1] MEM_BANK_REQ_IN_PROGRESS_FLD is used by software to poll the status of the command execution. When MEM_BANK_REQ_IN_PROGRESS_FLD bit toggles from "1" to "0", the byte of data (OSPI_FLASH_COMMAND_CTRL_MEM_REG[15-8] MEM_BANK_READ_DATA_FLD) from corresponding address (OSPI_FLASH_COMMAND_CTRL_MEM_REG[28-20] MEM_BANK_ADDR_FLD bit field) is valid. The address should be set before triggering the STIG Memory Bank access. Each consecutive STIG access overwrites the previous one so that the data in the Bank always fit into byte index fetched by the last STIG access configured to use the Memory Bank (first incoming byte equals first address of the Memory Bank, second one equals the second address and so on).

12.3.2.3.11.1 Servicing a STIG Request

A STIG request will cause the OSPI Flash controller to interrogate the OSPI_FLASH_CMD_CTRL_REG register to determine what and how many bytes it should send to the FLASH device. The OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size of which is also programmed in the same register) is sent next. The address itself is stored in the OSPI_FLASH_CMD_ADDR_REG register. If Mode bits are enabled by OSPI_FLASH_CMD_CTRL_REG[18] ENB_MODE_BIT_FLD bit. OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field are being sent right after address. If OSPI_FLASH_CMD_CTRL_REG[18] ENB_MODE_BIT_FLD and OSPI_CONFIG_REG[29] CRC_ENABLE_FLD are both enabled, STIG will replace XIP Mode bits (not applicable for CRC aware SPI interface) for automatically calculated address CRC byte. Therefore, to execute CRC aware STIGs (meaning the commands requiring sending address CRC byte), ENB_MODE_BIT_FLD bit should always be set. If there are any dummy cycles to send (the size of which is also programmed in OSPI_FLASH_CMD_CTRL_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in OSPI_FLASH_CMD_CTRL_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers, OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the OSPI Flash Controller stores that in the Flash Command Read Data Registers (OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG registers). Up to 8 bytes can be get if OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD bit is disabled or up to 512 when enabled. When the OSPI Flash controller starts to service a STIG request, it sets the OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit to indicate a command execution is in progress. When the OSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the OSPI_POLLING_FLASH_STATUS_REG[8] DEVICE_STATUS_VALID_FLD bit, which indicate active auto-

Copyright © 2023 Texas Instruments Incorporated

polling phase. After requesting a STIG, the OSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by OSPI_WRITE_COMPLETION_CTRL_REG[31-24] POLL_REP_DELAY_FLD bit field). This feature is implemented to free up SPI bandwidth if needed.

Note

The OSPI data is sent LSB first, while address is sent MSB first.

Note

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

12.3.2.3.11.2

Note

The OSPI data is sent LSB first, while address is sent MSB first.

Note

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

12.3.2.3.12 OSPI Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write
- The STIG
- The Direct Access Read
- The Indirect Access Read

12.3.2.3.13 OSPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

When PHY mode is enabled and consequently no clock divider is configured, latency caused by multi domain synchronization may make an extra byte insufficient to avoid the transfer gap. To ensure the sequential access non-interrupted and keep the maximum performance of the controller, PHY Pipeline Mode is implemented. When enabled, number of don't care bytes is calculated based on the configuration.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG).

For writes, the write enable latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The OSPI Flash Controller will automatically issue the write enable latch command before

Copyright © 2023 Texas Instruments Incorporated

triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by setting the OSPI_DEV_INSTR_WR_CONFIG_REG[8] WEL_DIS_FLD bit. The opcode for WREN is typically 0x06 and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The OSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit has cleared to zero and the write enable latch bit has also cleared to zero or device is ready bit has set to one). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

There is an option to trigger HOLD or RESET feature on I/Os of the Flash Device. The HOLD one is generally common across the devices and takes an alternative function of DQ3 pin (applicable when device operates neither in Quad SPI mode nor DDR). The transfer can be hold and then resumed by dedicated software trigger field (OSPI_CONFIG_REG[4] HOLD_PIN_FLD). The devices which have the HOLD feature on DQ3 usually need another dedicated pin for hardware reset and ones without HOLD feature usually have alternative reset on DQ3 what makes the additional reset pin being redundant. The controller supports both variants and reset selection register field (OSPI_CONFIG_REG[6] RESET_CFG_FLD) allows the user to configure which hardware reset solution is implemented in the device under usage.

After configuration is done, it is possible to trigger HOLD or RESET features using I/Os (OSPI_CONFIG_REG[4] HOLD_PIN_FLD or OSPI_CONFIG_REG[5] RESET_PIN_FLD bits). After HOLD activation the controller is introduced into waiting state and any other operations should not be requested before de-asserting of HOLD configuration bit. The HOLD feature is useful when any SPI transaction needs to be prolonged in order to adjust it into specific point in time. Note that any HOLD trigger issued during active SPI transaction may be synchronized into reference clock domain at the time the SPI transfer turns to be finished. In this case, there is nothing to hold so the low level SPI logic will not activate HOLD on DQ3. To check if HOLD request suspended the transfer OSPI_CONFIG_REG[31] IDLE_FLD bit can be polled for. If SPI is not in the IDLE state, the transfer was successfully suspended. It is important for the software to take care of resetting OSPI_CONFIG_REG[4] HOLD_PIN_FLD bit before newly triggered SPI transaction. In case HOLD request is set before the beginning of the transfer it will be HOLD right after it starts what may not always be a goal. The hardware RESET needs to be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling of OSPI_CONFIG_REG[31]. If the controller is in the IDLE state and no other transfer requests are queued to perform, the hardware RESET can be triggered. The RESET feature is useful when any write, program or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to being inactive. Triggering HOLD or RESET on DQ3 at the time the device is configured to work in Quad SPI mode or DDR will overwrite transfer data on DQ3 with '0'. This behavior is considered as a software error so it is advisable for the system to make sure that the flash device was introduced to suitable SPI mode (that is by polling its configuration register) before triggering alternative DQ3 function. There are four independent reset outputs implemented to separate between multiple devices connected to the controller (up to 4 are supported). The decision which reset output is to be activated after triggering OSPI_CONFIG_REG[5] RESET_PIN_FLD bit is made based on OSPI_CONFIG_REG[9] PERIPH_SEL_DEC_FLD and OSPI_CONFIG_REG[13-10] PERIPH_CS_LINES_FLD bits. Reset output OSPI_ECC_VECTOR is to be directly driven into corresponding dedicated RESET pins of the devices with separated RESET pin and alternatively, Reset output OSPI_ECC_VECTOR is to be control OSPI_ECC_VECTOR of the DQ3 RESET devices enabling separating of DQ3 Master Outputs on SoC integration level.

The controller supports all combinations of CPHA and CPOL for Serial Clock. It allows the controller to support any SPI slave devices not limited to Flash Memories. Multiple-SPI flash devices use just a subset of these combinations depending on the Transfer Mode as defined in Table 12-152.

Table 12-152. Flash SPI Modes

0x00 (SPI MODE 0)	SDR	Yes
0x01 (SPI MODE 1)	SDR	No
0x10 (SPI MODE 2)	SDR	No
0x11 (SPI MODE 3)	SDR	No
0x00 (SPI MODE 0)	DDR	Yes
0x01 (SPI MODE 1)	DDR	No
0x10 (SPI MODE 2)	DDR	No
0x11 (SPI MODE 3)	DDR	No

12.3.2.3.14 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the OSPI_DEV_INSTR_RD_CONFIG_REG and the OSPI_DEV_INSTR_WR_CONFIG_REG registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad or octal pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the controller can operate from a reset state, the registers will be reset to an opcode compatible with SIO devices what can be modified using BOOT feature.

Despite being applicable for both READs and WRITEs, the OSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD field only appears once – it is not included in the OSPI_DEV_INSTR_WR_CONFIG_REG register. If software sets this to anything other than '0', then the address transfer type and the data transfer type bits of both OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions).

There are devices capable to handling Read Operations in Dual Data Rate Mode (DDR) (it is also called Dual Transfer Rate Mode (DTR)). That means they can issue and capture the data on both rising and falling edges during working with dedicated command type. This enables the controller to maintain throughput at twice lower frequency of OSPI clock. The Device Read Instruction Register has DDR enable bit which informs Octal-SPI Flash Controller that opcode written into Read Opcode field is capable with DDR command type. The other field defined in OSPI_RD_DATA_CAPTURE_REG[19-16] DDR_READ_DELAY_FLD which enables the controller to shift the transmitted data in DDR mode. By default, data are shifted by 1 clock cycle to ensure hold timing greater than 0 during DDR transactions. It may not be sufficient for high reference clock frequency in accordance with the high dividers.

Table 12-153 shows how software should configure the OSPI module for selected specific READ and WRITE instruction supported by the abovementioned device.

Table 12-153. READ and WRITE Instruction Configuration

READ							
OPCODE	OPCODE sent over how many lanes / edge mode?	ADDRESS / DUMMY / MODE sent over how many lanes / edge mode?	DATA bytes sent over how many lanes / edge mode? OCPP (Octal Command Fast Program)	8	8	8	3	Don't care	Don't care

Note

This data are applicable for both 3-byte or 4-byte address variants of the commands if did not indicate otherwise.

Note

In DTR protocol all transfer phases (including opcode) take DDR edge mode independently on the command under execution. DTR protocol is to be enabled by OSPI_CONFIG_REG[24] ENABLE_DTR_PROTOCOL_FLD bit. It has higher priority than DDR Mode enable bit from OSPI_DEV_INSTR_RD_CONFIG_REG[10] DDR_EN_FLD.

12.3.2.3.15 OSPI Data Integrity

The CRC aware SPI transfer can be performed when both controller and device are configured to work in the Octal DDR Protocol.

For write transactions (the controller transmits data throughout all transfer), the controller is responsible for sending address CRC byte (XOR of all address bytes) following address bytes and TX data CRC byte (XOR of all data bytes to write) following data chunk with size as defined in OSPI_MODE_BIT_CONFIG_REG[10-8] CHUNK_SIZE_FLD bit field. All CRC data are being calculated and sent automatically by the controller and the external device is responsible for reacting accordingly on any possible interpolation on the Flash interface. For read transactions, the controller is also responsible for sending address CRC byte (like for write) and for getting and progressing RX data CRC byte returning by the Flash Device after each chunk with size as defined in OSPI_MODE_BIT_CONFIG_REG[10-8] CHUNK_SIZE_FLD bit field. At the time when the Flash Device is returning data back to the controller, the controller dynamically calculates checksum byte by byte. Once the chunk is completed, CRC returned from Flash Device should fit to dynamically calculated CRC by the controller. In case of any deviation, controller reports CRC error to the system by corresponding interrupt (CRC error interrupt). The controller also provides the last captured CRC data in RX data chunk (defined in OSPI_MODE_BIT_CONFIG_REG[31-24] RX_CRC_DATA_LOW_FLD and OSPI_MODE_BIT_CONFIG_REG[23-16] RX_CRC_DATA_UP_FLD bit fields) to give the software driver the opportunity to further detecting any data corruption on system interfaces. The CRC data valid interrupt informs the system about the accessibility of the new RX CRC data in the registers. Once the system gets the full data word, it can calculate CRC by itself. At the time it collects all data words in chunk and then gets the CRC data valid interrupt, it can compare these data and react accordingly.

Some devices also have embedded ECC mechanism allowing them to report data abnormal conditions on their ECC Correction Signal output. At the time this output turns low, the device expect the OSPI controller to read status register of the device in order to get more details about the source of detected abnormal situation. The

Copyright © 2023 Texas Instruments Incorporated

OSPI controller investigates ECC status on its ECC_FAIL input and generates an interrupt when detecting this signal being low.

12.3.2.3.16 OSPI PHY Module

OSPI module fully integrates PHY module dedicated to more flexible and power efficient transfers.

The PHY module communicates with the OSPI Flash controller via the aforementioned PHY Interface and handles data transfer on low-level stage of design hierarchy. However, when the OSPI_RCLK is configured to be equal to the SPI clock instead of alternative approach using clock divider, there is just one OSPI_RCLK cycle (not 4 or more) within single SPI period or half period for DDR Mode (SPI Control Module works on reference clock). Given that OSPI_RCLK is the input clock for RX FIFO and the output one for TX FIFO, the PHY solution incurs more restrictive requirement for value of system clock in order to synchronize data without SPI transfer interruption. For example, when the controller operates in DDR 1× octal Mode, 2 bytes of data (equivalent to one RX FIFO location) is gathered within just single OSPI_RCLK cycle. The controller cannot predict next data access while operating in the Direct Mode (meaning its size or whether it is sequential to the previous one or not). As a result, if the OSPI_HCLK is not significantly greater than OSPI_RCLK, the SPI transfer has to be suspended until the Flash Command Generator forwards new data to TX FIFO.

An optional PHY Pipeline Mode is implemented to avoid the necessity of stable clocking of the system clock for the Direct Mode when the PHY mode is enabled and to keep maximum performance while ensuring correct operation of the OSPI controller with the PHY using low frequencies from all its domains. This mode is a trade-off between large software overhead when operating in the Indirect Mode and the described limitations present in the Direct Mode. For more information about PHY Pipeline Mode, see Section 12.3.2.3.16.1, *PHY Pipeline Mode*.

When DDR 2× Mode is granted based on configuration – SPI transfer is automatically performed using the PHY module even if the OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD is de-asserted. SDR 2× commands are handled with PHY module paths being bypassed. Nevertheless, dividers of 2, 4 or 6 for DDR and divider of 2 for SDR should not be configured based on controller requirements and these configurations are perceived as a software error.

The following steps are an example of software algorithm of adapting the OSPI controller with the PHY module incorporated to work in octal 1× clock DDR Protocol. Note that all necessary configuration steps described in Section 12.3.2.4.2, *Configuring the OSPI Controller for Optimal Use* shall be completed before the algorithm.

1. Set PHY mode enable (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD bit) and DDR protocol (OSPI_CONFIG_REG[24] ENABLE_DTR_PROTOCOL_FLD bit). It is assumed that device is configured to work in DDR Protocol.
2. Before setting the DLL parameters, software calibration could be needed.
   OSPI_PHY_MASTER_CONTROL_REG[23] PHY_MASTER_BYPASS_MODE_FLD bit controls the bypass mode of the master and slave DLLs. If this bit is set, the DLL bypass mode is enabled. This mode is intended to be used only for debug. When set to 0, a Master operational mode is selected, when set to 1 the Bypass mode is selected.
   DLL works in normal mode of operation where the slave delay line settings are used as fractional delay of the master delay line encoder reading of the number of delays in one cycle.
   Master DLL is disabled with only 1 delay element in its delay line. The slave delay lines decode delays in absolute delay elements rather than as fractional delays.
   - DLL Bypass Mode (follow only if operating in this mode):
     - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD bit field.
     - Re-synchronize DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set PHY bypass mode enable through OSPI_PHY_MASTER_CONTROL_REG[23] PHY_MASTER_BYPASS_MODE_FLD bit.
   - DLL Master Mode (follow only if operating in this mode):
     - Drive DLL reset bit OSPI_PHY_CONFIGURATION_REG[30] PHY_CONFIG_RESET_FLD into low.

Copyright © 2023 Texas Instruments Incorporated

  - Calculate initial delay value for the Master DLL according to the OSPI_PHY_MASTER_CONTROL_REG[6-0] PHY_MASTER_INITIAL_DELAY_FLD bit field.
  - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD bit field.
  - Re-synchronize DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set DLL reset bit back to high (since both bits are within the same register, it is acceptable to set both bits simultaneously).
  - Poll OSPI_DLL_OBSERVABLE_LOWER_REG[15] DLL_OBSERVABLE_LOWER_LOOPBACK_LOCK_FLD bit. When set – lock is done.
  - Re-synchronize Slave DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set TX DLL Delay (OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD) and RX DLL Delay (OSPI_PHY_CONFIGURATION_REG[6-0] PHY_CONFIG_RX_DLL_DELAY_FLD) fields which are equivalent to percentage clock offsets now. It is recommended to wait for the new configuration being propagated by 20 reference clock cycles before triggering the next SPI transfer.
- Consider Read Data from location where its value is predictable. This step can be performed in different ways, depending on the device. Parameter Page, ID, Status, Data from OTP region or Data from location of Flash Array the value of which is known can act as the pattern.
- Trigger Read request chosen from above options.
- Check correctness of data and store that information:
  - Increment value of RX clock delay – it is configurable in the OSPI_PHY_CONFIGURATION_REG[6-0] PHY_CONFIG_RX_DLL_DELAY_FLD bit field.
  - Re-synchronize DLLs.
  - Trigger valid Read request.
  - Check correctness of data and store information.
  - If range boundary of RX clock delay is achieved, go to step 3. Otherwise go back to step "Increment value of RX clock delay".

3. Set RX clock delay value for one from the middle of valid range based on information in storage.
4. Re-synchronize DLLs.
5. Set OSPI_DEV_INSTR_RD_CONFIG_REG for Octal Read DDR Configuration (each transfer phase should be configured to work in Octal mode, Number of Dummy cycles should be set as specified in the documentation of the device or more when because of additional read paths delays of actual systems data is predicted to be flopped by PHY module with delay excesses actual cycle of SPI clock generated by the controller).
6. Enable Pipeline mode in the OSPI_CONFIG_REG[25] PIPELINE_PHY_FLD bit.
7. Perform Sequential Read of Data consistent with conditions indicated within Section 12.3.2.3.16.1, *PHY Pipeline Mode*.
8. After de-asserting the data slave select signal by software – poll OSPI_CONFIG_REG[31] IDLE_FLD bit.
9. When it is asserted to high – next transfer request can be triggered.

12.3.2.3.16.1 PHY Pipeline Mode

This mode is used for Direct Read Mode of operation. If any other operations are intended to be executed, it is recommended to disable PHY Pipeline Mode and re-enable for subsequent Direct Reads in PHY mode. Since there is comprehensive software mechanism controlling Read data transfers in Indirect Mode, pipeline of data interface accesses is not effective for this mode. Enable PHY Pipeline feature when at least four 4-byte-sized data words are predicted to be read in sequentially. The Flash Command Generator pipelines and puts them into TX FIFO which causes CS to remain active because low level SPI protocol controller controls TX FIFO fill level. In order to correctly trigger Direct Read in Pipeline Mode TX FIFO must be empty. Therefore first polling of OSPI_CONFIG_REG[31] IDLE_FLD bit needs to be done. The sequential data transfer will be interrupted when the data slave select signal of the data interface is asserted to low. This information is also detected by Data Slave Module which informs the Flash Command Generator that the next access is invalid and a TX FIFO locations can be flushed transparently for the system.

Copyright © 2023 Texas Instruments Incorporated

In PHY Pipeline Mode it is recommended for Data Master not to introduce wait states in between consecutive occurrences of the data interface signal that indicates transfer has finished. It will ensure regular transfer rate on data side. Introducing wait states gradually slows data transfer rate down and may finally cause SPI transfer interruption because of TX FIFO data starvation. The system, however, may need to introduce some number of wait states after completion of sequential transfer (composed of 4-byte sized data words) for progressing the data. The dedicated buffer is implemented in Data Slave Controller which collects all incoming data during wait states injection. In order to keep SPI transfer uninterrupted, number of wait states should be as little as possible. The higher the OSPI_HCLK/ OSPI_RCLK ratio the more wait states can be introduced without SPI transfer interruption. In case the system is able to launch a new transfer before wait states overflow, buffered data transfer to the host will continue. It compensates slowed down transfer by introducing wait states. In case the system is not able to launch a new transfer before wait states overflow, next incoming transfer is considered non-sequential and is executed after all pipelined data is flushed.

This mode can be enabled when following conditions are met:

- OSPI_HCLK > OSPI_RCLK (Comparing the slow data clock with the fast reference one makes Pipeline Mode ineffective – Suspend of SPI Transfer would be possible. Consequently, this condition has to be met to operate in this mode.)
- Only 4-byte sized Data Words are permitted (This ensures more data clock cycles for synchronization of FIFOs between consecutive pulses of the signal indicating transfer has finished.)
- The transfer with introduced wait states or non-sequential transfers can only be triggered in between at least four 4-byte sized Data Bursts sequential accesses (16 Bytes) to be sure that Data Master can trust buffered incoming data during wait states injection.
- Do not use Pipeline Mode along with Continuous Mode (XIP). Benefit of XIP is limited for bulk data transfers intended to execute in Pipeline Mode.

12.3.2.3.16.2 Read Data Capturing by the PHY Module

Read Data Capturing by the PHY module is useful, as the user is not responsible for the design dedicated DLL being compatible with the Octal-SPI Flash Controller. Another benefit is an option to adjust both SPI clock and sampling clock in a very wide range to fit them into individual requirements of any system. If loopback clock (OSPI_RD_DATA_CAPTURE_REG[0] BYPASS_FLD) and PHY mode (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD) are both enabled, the loopback clock is driven into RX DLL instead of gated reference clock. Because of the architecture of DLL, loopback clock needs to be provided in SPI Mode 0.
If DQS (OSPI_RD_DATA_CAPTURE_REG[8] DQS_ENABLE_FLD) and PHY mode (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD) are both enabled, the DQS is driven into RX DLL instead of gated reference clock.

12.3.2.4 OSPI Programming Guide

12.3.2.4.1 Configuring the OSPI Controller for Use After Reset

The OSPI controller has been designed to wake up in a state that is suitable for performing basic reads and writes using the direct access controller. The BASIC read (opcode 0x03) and BASIC write (opcode 0x02) instructions are operations supported by all target devices. The controller also wakes up with a baud rate divider setting of divide-by-32. Assuming the reference clock is operating at 400 MHz after reset, then this means the effective SPI clock is just 12.5 MHz. This should be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the device size configuration register must be modified to the appropriate size.

If software plans to write to the device, and the number of bytes per device page is not equal to 256, then the device size configuration register must also be modified.

While not a requirement, it is prudent for software to enable the write protect feature prior to enabling the OSPI controller. This will block any data writes from taking effect. To do so, the protection registers (OSPI_LOWER_WR_PROT_REG, OSPI_UPPER_WR_PROT_REG and OSPI_WR_PROT_CTRL_REG) should be setup and the number of bytes per device block in the device size configuration register should also be setup.

After Power-on Reset (POR), software can read from and write to the FLASH device (albeit slowly). Enabling/Disabling the controller and DAC is achieved with just one write to corresponding fields of the OSPI_CONFIG_REG register. User shall take note to maintain the default values of the baud rate divisor and the default state of SEL_CLK_POL_FLD/ SEL_CLK_PHASE_FLD bits of this register. A write data value of 0x00780081 is recommended.

12.3.2.4.2 Configuring the OSPI Controller for Optimal Use

Note

When using the OSPI Controller, the opcodes in OSPI_DEV_INSTR_RD_CONFIG_REG[7-0] RD_OPCODE_NON_XIP_FLD, OSPI_DEV_INSTR_WR_CONFIG_REG[7-0] WR_OPCODE_FLD and OSPI_WRITE_COMPLETION_CTRL_REG[7-0] OPCODE_FLD bit fields shall not match the opcode in the OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD bit field.

For high speed transfers PHY mode can be enabled and for optimal configuration PHY Pipeline mode is recommended. For more information, see Section 12.3.2.3.16.1, *PHY Pipeline Mode*.

To access the flash optimally, software must configure the controller accurately:

1. Wait until any pending STIG or INDAC operation has completed or poll OSPI_CONFIG_REG[31] IDLE_FLD bit.
2. Disable the DAC through OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTLR_FLD bit. It is permitted, but not necessary to also disable the OSPI controller completely via OSPI_CONFIG_REG[0] ENB_SPI_FLD bit.
3. Update the OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG registers for the instruction type you wish to use for indirect and direct writes and reads.
4. Update the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field if mode bits have been enabled in the OSPI_DEV_INSTR_RD_CONFIG_REG[20] MODE_BIT_ENABLE_FLD bit.
5. Update the OSPI_DEV_SIZE_CONFIG_REG if the contents are incorrect. Note parts or all of this register may have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used. If the default values are correct for the target device, or if some of the values (not including the number address bytes) were incorrect but device writes were not permitted.
6. Update the OSPI_DEV_DELAY_REG. This register allows the user to tweak how the chip select is driven after each FLASH access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become more important. Note the numbers programmed in this register are based on the period of reference clock. Example: A device needs 50ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the

Copyright © 2023 Texas Instruments Incorporated

controller will only provide a minimum of 1 SCLK period. When the device is operating at 100 MHz, the SCLK period is only 10ns, so 40ns extra is required. Since the register defines the number of reference clock cycles to add, and reference clock is running at 400 MHz (2.5ns period), then the user should program a value of at least 16 to the OSPI_DEV_DELAY_REG[31-24] D_NSS_FLD. This delay can be extended during auto-polling phase. There is possibility to define the polling repetition delay in the OSPI_WRITE_COMPLETION_CTRL_REG[31-24] POLL_REP_DELAY_FLD bit field.

7. Update the OSPI_REMAP_ADDR_REG register, if required. Affects DAC path only.
8. Setup and enable write protection registers (OSPI_LOWER_WR_PROT_REG, OSPI_UPPER_WR_PROT_REG and OSPI_WR_PROT_CTRL_REG) if they are required and if they have not already been setup from post initialization.
9. Enable required interrupts via the OSPI_IRQ_MASK_REG register.
10. Setup the baud rate divisor in the OSPI_CONFIG_REG[22-19] MSTR_BAUD_DIV_FLD to define the required clock frequency of the target device.
11. Update the OSPI_RD_DATA_CAPTURE_REG register. This register will delay when the read data is captured and can help when the read data path from the device to the controller is long and the device clock frequency is high. An update to this register may not be necessary.
12. Enable the OSPI controller and the DAC via the OSPI_CONFIG_REG.

12.3.2.4.3 Using the Flash Command Control Register (STIG Operation)

The OSPI_FLASH_CMD_CTRL_REG register provides software means to access the FLASH device in a flexible and programmable manner. This is known as a STIG operation (Software Triggered Instruction Generator). The instruction opcode, number of address bytes (if any), the address itself, number of dummy cycles (if any), number of write data bytes (if any), the write data itself and the number of read data bytes (if any) can be programmed. Once these have been programmed, software can trigger the command via OSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit and wait for its acceptance by polling OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit. When CMD_EXEC_STATUS_FLD bit turns de-asserted, another STIG can be triggered. This method of accessing the FLASH is the typical mechanism that software would use to access the FLASH device's registers, as well as for performing ERASE operations. It can also be used to access the FLASH array itself, although the maximum of 8 data bytes may be read or written at any one time, defined in the Flash Command Write and Read Data registers (OSPI_FLASH_RD_DATA_LOWER_REG, OSPI_FLASH_RD_DATA_UPPER_REG, OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG). This number of bytes can be extended for Read Data commands using additional STIG Memory Bank controlled by OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD and OSPI_FLASH_COMMAND_CTRL_MEM_REG.

Commands issued using this interface have a higher priority than all other READ accesses coming from data interface, and will therefore interrupt any READ commands being requested by the indirect or direct controllers.

12.3.2.4.4 Using SPI Legacy Mode

SPI legacy mode allows software to access the internal TX-FIFO and RX-FIFO directly, thus bypassing the direct, indirect and STIG controllers.

Legacy mode allows the user to issue any FLASH instruction to the device, but does place a heavy software overhead in order to manage the fill levels of the FIFO's effectively. This is because the legacy SPI core is bi-directional in nature, with data continuously being transferred in either direction while the chip select is enabled. Even if the driver only wishes to read data from the FLASH device, dummy data must be written out to ensure the chip select stays active, and vice versa for write transactions.

Since the TX-FIFO and RX-FIFO are of limited depth, software has a responsibility to maintain the FIFO levels to ensure the TX-FIFO does not become exhausted during the instruction execution and the RX-FIFO doesn't overflow. This can place a lot of overhead on software. Interrupts are provided to indicate when the fill levels pass programmable watermarks, which are themselves programmable registers OSPI_TX_THRESH_REG and OSPI_RX_THRESH_REG.

The limited depth may impose the limitation over execution of some specific SPI commands in legacy mode. Note that the controller interprets all transmitted bytes as valid. For example, if the Flash Device was configured to return valid data after many dummy cycles, the TX FIFO could become full before the controller sends all of dummy data.

Copyright © 2023 Texas Instruments Incorporated

12.3.2.4.5 Entering XIP Mode from POR

XIP is a mode that can be entered in a non-volatile way if the device has XIP enabled as a non-volatile configuration setting. Software will not be able to discover the state of XIP from POR via FLASH status register reads as the only operation a FLASH device will recognize when XIP mode is enabled is an XIP read operation.

If it is already known that the device will enter XIP from POR, then the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD and OSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD bits should be set in initial boot.

If it is not already known that the device will enter XIP from POR, and XIP from POR may be supported by the attached FLASH device, then software can attempt to exit XIP mode by issuing an XIP exit command using a STIG command (via the OSPI_FLASH_CMD_CTRL_REG register). To do this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

12.3.2.4.6 Entering XIP Mode Otherwise

XIP mode is supported in most FLASH devices. Some of them use signature bits that are sent to the device immediately following the address bytes, other use signature bits and also require a FLASH device configuration register write to enable XIP. For the FLASH devices that must be compliant to the OSPI controller, the following steps can be taken by software to enter XIP mode:

1. Disable the DAC and INDAC (OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTLR_FLD) to ensure no new data read accesses will be sent to the FLASH device.
2. (Optional) Configure the OSPI_FLASH_CMD_CTRL_REG to issue a VCR write to FLASH memory, because XIP mode must first be enabled for some devices.
3. Configure the XIP mode bits in the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field.
4. Enable the local controllers XIP mode by setting OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD bit.
5. Re-enable the DAC and, if required, the INDAC.

12.3.2.4.7 Exiting XIP Mode

To exit XIP mode, software should first disable the DAC and INDAC to ensure no new data read accesses will be sent to the FLASH device. It should then set mode bits to other than the established in the corresponding Flash Device specifications. These are dependent on the FLASH device and manufacturer. Software should then reset OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD.

Note the FLASH device must see a READ instruction before it can disable its internal XIP mode state, so this means XIP mode will internally stay active until the next READ instruction is serviced. User must take care to ensure that XIP mode is disabled before the end of any READ sequence.

12.3.3 HyperBus Interface

This section describes the HyperBus module in the device.

12.3.3.1 HyperBus Overview

The HyperBus module is a part of the device Flash Subsystem (FSS). For more information about FSS, see Section 12.3.1, *Flash Subsystem (FSS)*.

The HyperBus module is a low pin count memory interface that provides high read/write performance. The HyperBus module connects to HyperBus memory (HyperFlash or HyperRAM) and uses simple HyperBus protocol for read and write transactions.

There is one HyperBus™ module inside the device. The HyperBus module includes one HyperBus Memory Controller (HBMC).

12.3.3.1.1 HyperBus Features

- Support for Cypress® HyperFlash and HyperRAM
- Up to 166 MHz maximum memory bus operation for reads
  - Supports up to 166 MHz dual data rate (333 MBps) flash devices for system requiring rapid boot or instant-on displays
  - Supports up to 333 MBps external pseudo-RAM (HyperRAM) for systems

  Note: For more information, see section Timing and Switching Characteristics in the device-specific Datasheet.
- Low pin count interface with LVCMOS I/O pins (can be muxed with other FSS interfaces (OSPIs))
- Two memory chip selects
- Linear incrementing mode for reads and writes
- Up to 16 outstanding read transactions (see Section 12.3.3.3.5, *HyperBus True Continuous Read (TCR) Mode*)
- Asynchronous bus clock

12.3.3.1.2 Hyperbus Ports

12.3.3.3 HyperBus Functional Description

The HyperBus module is a high throughput memory interface. It is a part of the device FSS and provides execute in place (XIP) operation and block copy access to HyperBus memory devices (HyperRAM and HyperFlash). The FSS enables in-line ECC protection and authentication features for the HyperBus module.

For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is compliant to the *Cypress HyperBus™ Specification v1.2*.

Figure 12-75 shows the HyperBus module block diagram.

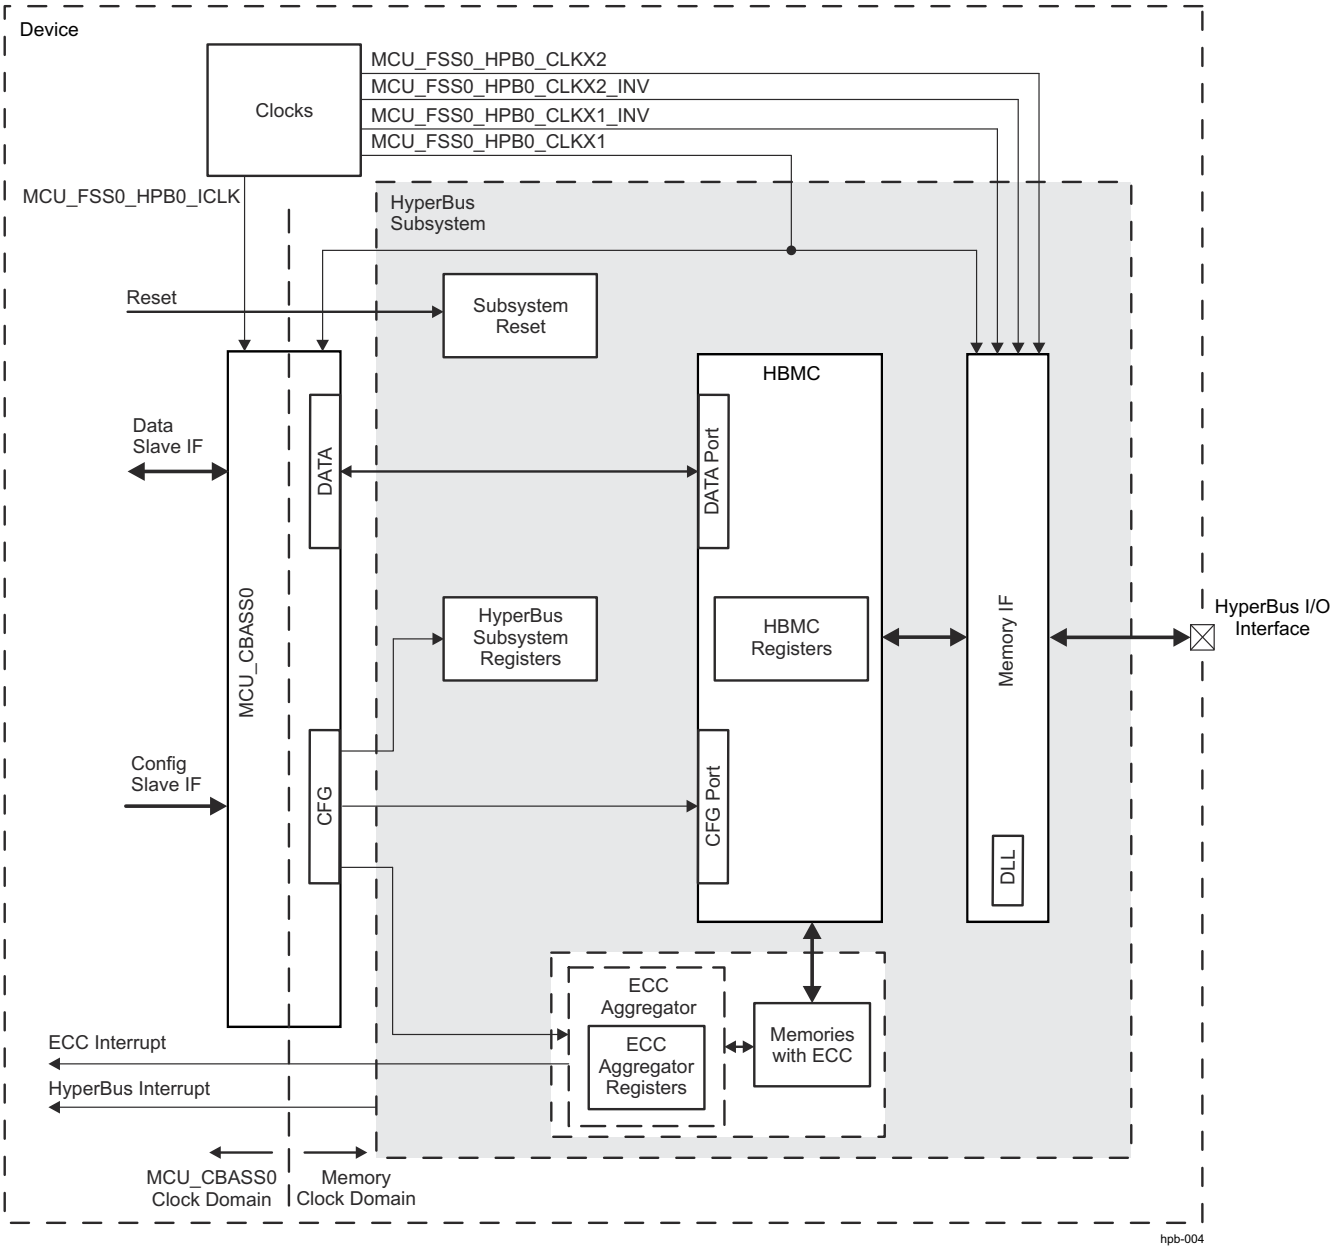

Figure 12-75. HyperBus Module Block Diagram

Basic Blocks:

- HBMC: The HyperBus Memory Controller (HBMC) is the main part (the core) of the HyperBus Subsystem and provides accessibility to external HyperBus memory (HyperFlash or HyperRAM) using simple HyperBus protocol for data read and write transfers.

Copyright © 2023 Texas Instruments Incorporated

  - The Data Port on the HBMC is used for CBASS data slave interface to access the external HyperBus memory.
  - The CFG Port on the HBMC is used for configuration of the HBMC registers.
- HyperBus I/O Interface: The HyperBus I/O Interface includes all used interface pins (for more information, see *HyperBus I/O Signals*).
- Memory IF: The Memory IF block implements the following functionality:
  - Convert single-rate command and data output from the HBMC to double-rate (DDR)
  - Use DLL to delay the incoming read data strobe from the memory
- FIFO Memories with ECC: There are internal HyperBus FIFOs implemented with memories that are used during read and write transactions. These FIFO memories are ECC protected (for more information about the FIFOs, see Section 12.3.3.3.3, *HyperBus Internal FIFOs*).
- ECC Aggregator: The ECC Aggregator facilitates aggregating and reporting internal HyperBus FIFO memory errors (for more information, see Section 12.3.3.3.2, *HyperBus ECC Support*).
- HBMC Registers: This block includes set of all used HBMC registers.
- HyperBus Subsystem Registers: This block implements memory-mapped registers at the HyperBus Subsystem level.
- ECC Aggregator Registers: This block includes all used ECC Aggregator registers.

  For more information about all HyperBus registers, see *HyperBus Registers*.
- MCU_CBASS0: The MCU_CBASS0 interconnect implements the clock domain crossing bridges needed to separate the two main clock domains: MCU_CBASS0 clock domain and Memory clock domain.
- Data Slave IF: The Data Slave IF on the interconnect is a 32-bit wide interface and is used to access an external HyperBus memory via the Data Port on the HBMC. The data interface supports linear incrementing addresses only. Cache-line wrap and fixed addressing modes are not supported.
- Config Slave IF: The Config Slave IF on the interconnect is a 32-bit wide interface and is used to access the HBMC registers (via the CFG Port on the HBMC), HyperBus Subsystem registers, and ECC Aggregator registers. The config interface also supports linear incrementing address mode only.

  For more information about supported and not supported HyperBus features, see *HyperBus Overview*.
- Clocks: For more information about HyperBus Clocks, see *MCU_FSS0_HBP0 Clocks and Resets*.
- Subsystem Reset: The reset signal to the Subsystem Reset block provides reset to the all HyperBus Subsystem parts (for more information about HyperBus Resets, see *MCU_FSS0_HBP0 Clocks and Resets*).
- Interrupts: For more information, see *MCU_FSS0_HBP0 Clocks and Resets* and *HyperBus Interrupts*.

12.3.3.3.1 HyperBus Interrupts

The HyperBus module sources one active high level HyperBus interrupt and two active high level ECC Aggregator interrupts (see *MCU_FSS0_HPB0 Hardware Requests*).

The HyperBus interrupt is generated based on the HyperBus memory's active low level interrupt. In the HyperBus Subsystem this active low level interrupt is converted to active high level HyperBus interrupt (see RESETO**n** pin in *Hyperbus I/O Signals*).

The ECC Aggregator interrupts are generated based on the ECC errors (single (correctable) and double (uncorrectable) bit errors) in the embedded HyperBus memories (for more information, see *HyperBus ECC Support*).

12.3.3.3.2 HyperBus ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

The embedded HyperBus memories are ECC protected.

Copyright © 2023 Texas Instruments Incorporated

12.3.3.3.2.1 ECC Aggregator

Note

For more information about ECC Aggregator, refer to Section 12.10.4, *ECC Aggregator*.

For more information about ECC Aggregator Registers, refer to *HyperBus Registers*.

12.3.3.3.3 HyperBus Internal FIFOs

There are 10 FIFO buffers in the module that help improve performance. Table 12-157 shows the HyperBus FIFOs details.

Table 12-157. HyperBus FIFOs

Buffer Name	Size (Width x Depth)
Address (ADR) FIFO	Two port RAM – 16 x 46-bit
Write data (WDAT) FIFO	Two port RAM – 256 x 40-bit
Write status (BDAT) FIFO	Two port RAM – 16 x 2-bit
Read data (RDAT) FIFO	Two port RAM – 128 x 40-bit
Receive (RX) FIFO	Two port RAM – 256 x 20-bit
Address write (AW) FIFO	Two port RAM – 16 x 44-bit
Write ID (WID) FIFO	Two port RAM – 16 x 2-bit
Address write ID (AWID) FIFO	Two port RAM – 16 x 14-bit
Address read (AR) FIFO	Two port RAM – 16 x 44-bit
Address read ID (ARID) FIFO	Two port RAM – 16 x 18-bit

12.3.3.3.4 HyperBus Data Regions

For more information about HyperBus data regions, refer to Section 12.3.1.3.4, *FSS Memory Regions*.

12.3.3.3.5 HyperBus True Continuous Read (TCR) Mode

The HBMC supports True Continuous Read (TCR) operation for HyperFlash. This feature is able to improve HyperFlash read performance.

When this feature is enabled, the HBMC can merge multiple up to 16 max burst read commands that are present in its command FIFO into a single memory read transaction to the HyperFlash memory. As a result, the command input and initial latency for the latter burst read commands are saved, which leads to improved throughput.

Copyright © 2023 Texas Instruments Incorporated

12.3.3.4 HyperBus Programming Guide

12.3.3.4.1 HyperBus Initialization Sequence

The HBMC provides two sets of Memory Base Address, Memory Configuration and Memory Timing registers to access devices connected to the two external chip selects. The following programming guidelines need to use the correct set of registers depending on which chip select is accessed.

The HBMC compares the input address bits [31-24] to the value programmed in the MCU_FSS0_HPB0_MC_MBAR_y registers to determine the external chip select that is accessed.

12.3.3.4.1.1 HyperFlash Access

Table 12-158. HyperFlash Access Sequence

Step	Description
1.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit .
2.	Lock MDLL:
	- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see *MCU_FSS0_HPB0 Clocks and Resets*). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.
	- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of Flash data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal Flash access .
	- The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .
3.	Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y):
	- MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.
	- MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 1h, to enable HBMC to merge multiple accesses with sequential addresses into a single memory access. This will improve memory throughput.
	- MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.
	- MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h, to set 'Memory space' instead 'CR space'.
	- MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 0h, to set 'HyperFlash' instead 'HyperRAM'.
	- MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.
4.	Initialize Memory Timing register (MCU_FSS0_HPB0_MC_MTR_y) based on timing of the memory device being used.
5.	Initialize Memory Base Address register (MCU_FSS0_HPB0_MC_MBAR_y):
	- MCU_FSS0_HPB0_MC_MBAR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperFlash can be accesed. The HBMC will initiate HyperFlash access to any memory mapped access in this range.
6.	Check the MCU_FSS0_HPB0_MC_CSR[10] RRSTOERR bit in Controller Status register to ensure that the HyperFlash is out of reset.
7.	Normal HyperFlash access can be performed after this.
8.	The HyperFlash device registers and CFI (Common Flash Interface) region can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table.
9.	The HyperFlash memory data array can be read as memory mapped access.
10.	The HyperFlash write sequence needs to be followed to update contents of the memory array.

Copyright © 2023 Texas Instruments Incorporated

12.3.3.4.1.2 HyperRAM Access

Table 12-159. HyperRAM Access Sequence

Step	Description
1.	Wait 150 µs for RAM to power up after reset. The HyperRAM does not provide any feedback on reset/ready state to the HBMC .
2.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit .
3.	Lock MDLL:
	- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see *MCU_FSS0_HPB0 Clocks and Resets*). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.
	- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of RAM data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal RAM access .
	- The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .
4.	Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y):
	- MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.
	- MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 0h, since HBMC does not support command merging for HyperRAM accesses.
	- MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.
	- MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h or 1h, depending on what needs to be accessed (memory or register space).
	- MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 1h, to set 'HyperRAM' instead 'HyperFlash'.
	- MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.
5.	Initialize MCU_FSS0_HPB0_MC_MTR_y register based on timing of the memory device being used.
6.	Initialize MCU_FSS0_HPB0_MC_MCR_y register:
	- MCU_FSS0_HPB0_MC_MCR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperRAM can be accesed. The controller will initiate HyperRAM access to any memory mapped access in this range.
7.	Check the MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK bit to ensure the Master DLL is locked.
8.	Normal HyperRAM access can be performed after this.
9.	The HyperRAM device registers can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to register space.
10.	The HyperRAM memory data array can be read/written to as memory mapped access with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to memory space.

Note

HyperRAM devices have a 150 µs startup time. Software needs to wait this duration after reset to initiate transactions to a HyperRAM device.

12.3.3.4.2 HyperBus Real-time Operating Requirements

The HBMC may assert the memory interrupt based on the status of the memory transaction. Software needs to handle this interrupt using the MCU_FSS0_HPB0_MC_ISR register. The MCU_FSS0_HPB0_MC_ISR register can provide the status information to determine the cause of the interrupt.

12.3.3.4.3 HyperBus Power Up/Down Sequence

Software needs to ensure that there are no pending transactions before stopping clock and/or power to the HBMC.

12.3.4 General-Purpose Memory Controller (GPMC)

This section describes the General-Purpose Memory Controller (GPMC) for the device.

12.3.4.1 GPMC Overview

The General-Purpose Memory Controller is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

12.3.4.1.1 GPMC Features

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports on-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity of one GPMC_FCLK clock cycle.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write-posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit interconnect slave interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

Note

Page mode is available only in non-multiplexed mode.

Unsupported Features:

12.3.4.2 GPMC Environment

This section describes the GPMC0 external connections (environment).

Table 12-162 lists the GPMC subsystem input/output (I/O) pins.

Table 12-162. GPMC I/O Signals (Master Mode)

Module Pin	I/O(1)	Description
A[27-0]	O	28-bit output address bus
A[16-1]/D[15-0]	I/O	Multiplexed address/data
nCS[3-0]	O	Chip-selects (active low)
CLK	O	Clock generated for the external memory or device. For more information, see *GPMC Integration*.
RET_CLK		
N/A	O	Free running clock. GPMC functional clock (GPMC0_FCLK) propagated on a device pad. For more information on the GPMC0_FCLK_MUX integration, see *GPMC Integration*.
nADV/ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	O	Write enable (active low)
nBE0/CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	O	Upper-byte enable (active low)
WAIT[3-0]	I	External wait signal for NOR and NAND protocol memories. Can be mapped on any of the chip-selects.
nWP	O	Write protect (active low)
DIR	O	This signal can be used to control an external buffer direction. Also controls the signal direction of D[15-0]. Low during transmit (for write access: data OUT from GPMC0 to memory). High during receive (for read access: data IN from memory to GPMC0).

(1) I = Input; O = Output; I/O - Bidirectional

Copyright © 2023 Texas Instruments Incorporated

12.3.4.3 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

12.3.4.3.1 GPMC Block Diagram

Figure 12-76 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Copyright © 2023 Texas Instruments Incorporated

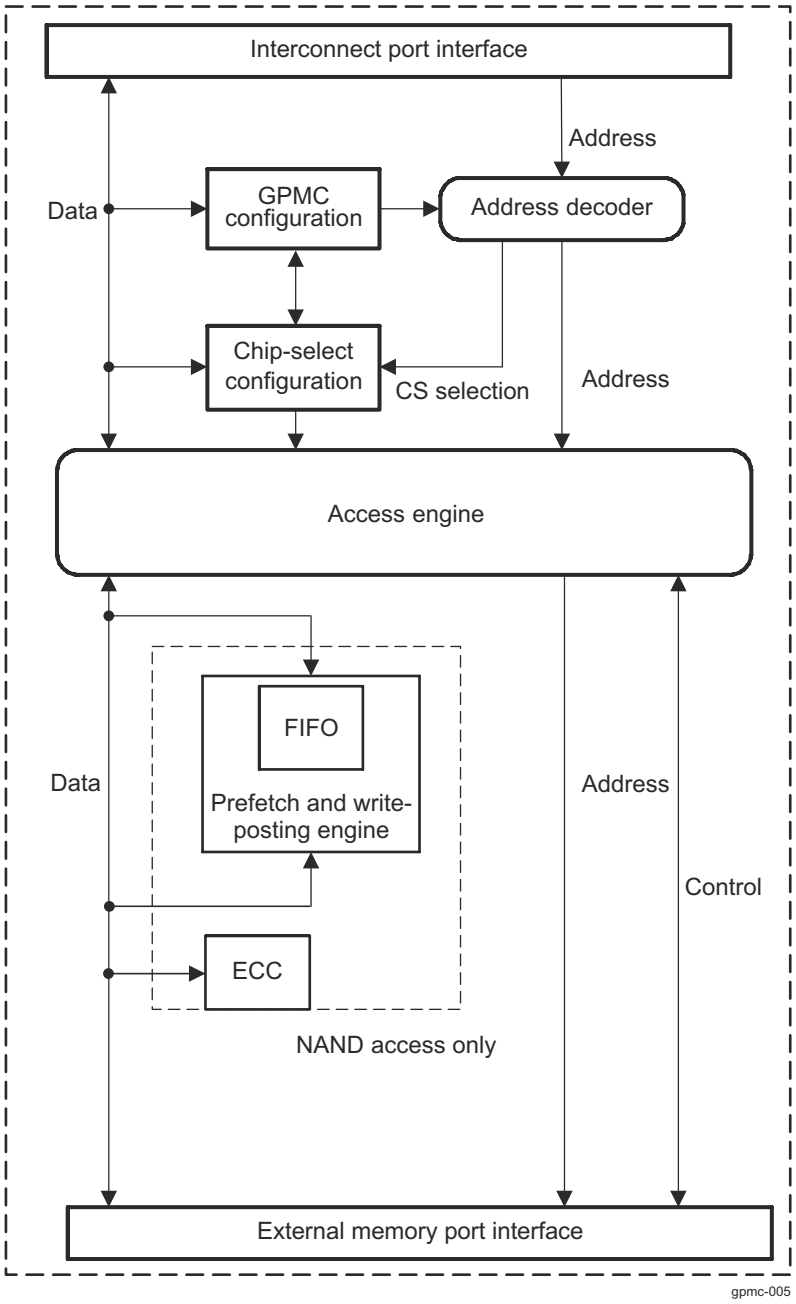

Figure 12-76. GPMC Block Diagram

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

12.3.4.3.2 GPMC Clock Configuration

Table 12-163 describes the GPMC clocks.

Table 12-163. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional clock

Copyright © 2023 Texas Instruments Incorporated

Table 12-163. GPMC Clocks (continued)

Signal	I/O(1)	Description
GPMC_ICLK	I	Interface clock
CLK (GPMC_CLKOUT pin)	O	External clock provided to synchronous external memory devices.

(1) I = Input; O = Output; I/O - Bidirectional

The GPMC output clock (CLK) is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in *GPMC0 Clocks and Resets*. The GPMC output clock is configured using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in Table 12-164.

Table 12-164. GPMC Output Clock Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC Output Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

When using synchronous interface protocols, the GPMC output clock (CLK), toggles only during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from the GPMC functional clock input (GPMC_FCLK) to the GPMC_FCLK_MUX pin. This output clock, to GPMC_FCLK_MUX pin, can be selected through the standard MUXMODE selection of the GPMC_FCLK_MUX pin PADCONFIG control register.

Note that when using such synchronous interface protocols with the continuous clock option, user should ensure that the GPMC outputs are timed to the same frequency (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0).

12.3.4.3.3 GPMC Power Management

Table 12-165 describes the local power-management features available for the GPMC module.

Table 12-165. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_ICLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle and smart-idle modes are available.

12.3.4.3.4 GPMC Interrupt Requests

The GPMC generates one interrupt request (see *GPMC0 Hardware Requests*).

Table 12-166 lists the event flags, and their mask, that can cause module interrupts.

Table 12-166. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[11] WAIT3EDGE DETECTIONSTATUS	GPMC_IRQENABLE[11] WAIT3EDGE DETECTIONENABLE	Edge	Wait3 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT3 signal. The rising or falling edge detection of Wait3 is selected through the GPMC_CONFIG[11] WAIT3PINPOLARITY bit.
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT2 signal. The rising or falling edge detection of Wait2 is selected through the GPMC_CONFIG[10] WAIT2PINPOLARITY bit.

Copyright © 2023 Texas Instruments Incorporated

Table 12-166. GPMC Interrupt Events (continued)

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

12.3.4.3.5 GPMC Interconnect Port Interface

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

12.3.4.3.6 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with an address range of 256MB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

Copyright © 2023 Texas Instruments Incorporated

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: GPMC_AD[15-8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: .
- 8-bit-wide NAND devices do not use GPMC I/O: and GPMC I/O: GPMC_AD[15-8].

12.3.4.3.6.1 GPMC I/O Configuration Setting

Note

In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 3.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

12.3.4.3.7 GPMC Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

12.3.4.3.7.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 128MB address space. For more information, see *Memory Map*.

Note

Even though GPMC supports total address space of 1GB, only 128MB are physically available in this device.

The GPMC 128MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MB to 256MB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

Copyright © 2023 Texas Instruments Incorporated

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 12-77 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

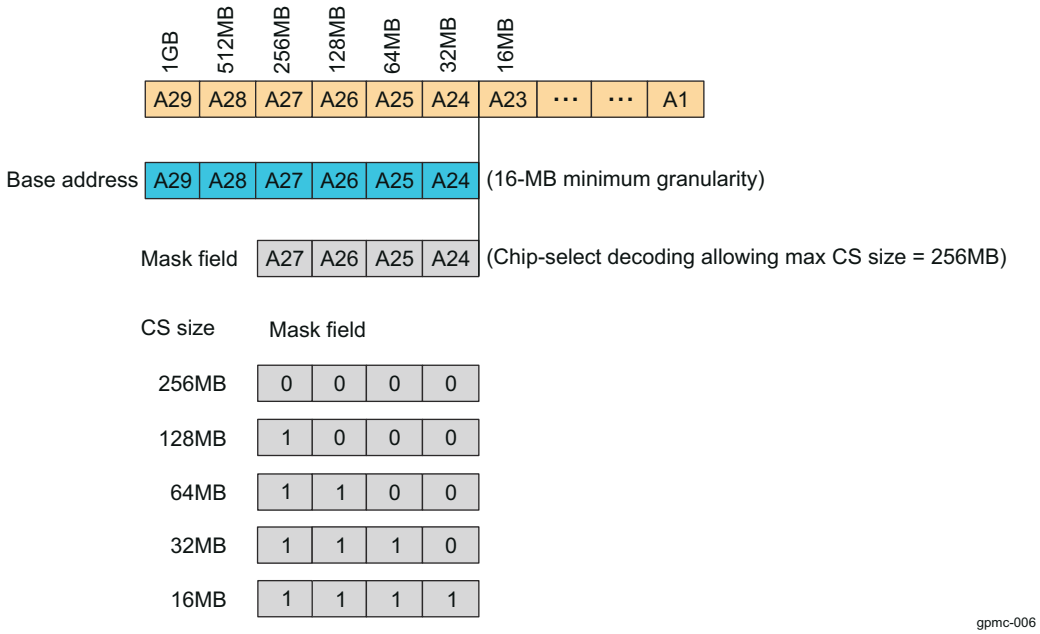

Figure 12-77. Chip-Select Address Mapping and Decoding Mask

For example, to map the 128MB address space (from 2000 0000h to 27FF FFFFh), the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field should be set to 20h.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device-specific Datasheet.

Copyright © 2023 Texas Instruments Incorporated

12.3.4.3.7.2 Access Protocol

12.3.4.3.7.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

Note

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 12.3.4.3.11, *GPMC NAND Device Basic Programming Model*, and Section 12.3.4.3.11.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

12.3.4.3.7.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE bit field (where i = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

12.3.4.3.7.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (where i = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See *GPMC Integration*.

Note

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 12.3.4.3.11, *NAND Device Basic Programming Model*.

12.3.4.3.7.3 External Signals

12.3.4.3.7.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external GPMC_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features four input WAIT pins: GPMC_WAIT0 through GPMC_WAIT3. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit field (where i = 0 to 3) selects which input GPMC_WAIT pin is used for the device attached to the corresponding chip-select.
- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

Copyright © 2023 Texas Instruments Incorporated

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC output clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

12.3.4.3.7.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and no GPMC output clock is provided to the external device. Still, because GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 12-78 shows wait behavior during an asynchronous single read access.

Figure 12-78. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

Note

The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

12.3.4.3.7.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

Copyright © 2023 Texas Instruments Incorporated

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

12.3.4.3.7.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC output clock cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3), and is expressed as a number of GPMC output clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 12-79 shows wait behavior during a synchronous read burst access.

Figure 12-79. Wait Behavior During a Synchronous Read Burst Access

Copyright © 2023 Texas Instruments Incorporated

Note

The WAIT signal is active low. WAITMONITORINGTIME = 0b00, 0b01.

12.3.4.3.7.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with WAIT pin monitoring enabled (the GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC output clock capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Note

WAIT monitoring is supported for all configurations except GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

12.3.4.3.7.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see Section 12.3.4.3.11.2, *NAND Device-Ready Pin*.

12.3.4.3.7.3.1.6 Idle Cycle Control Between Successive Accesses

3.4.3.7.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

Copyright © 2023 Texas Instruments Incorporated

Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see the following figures).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

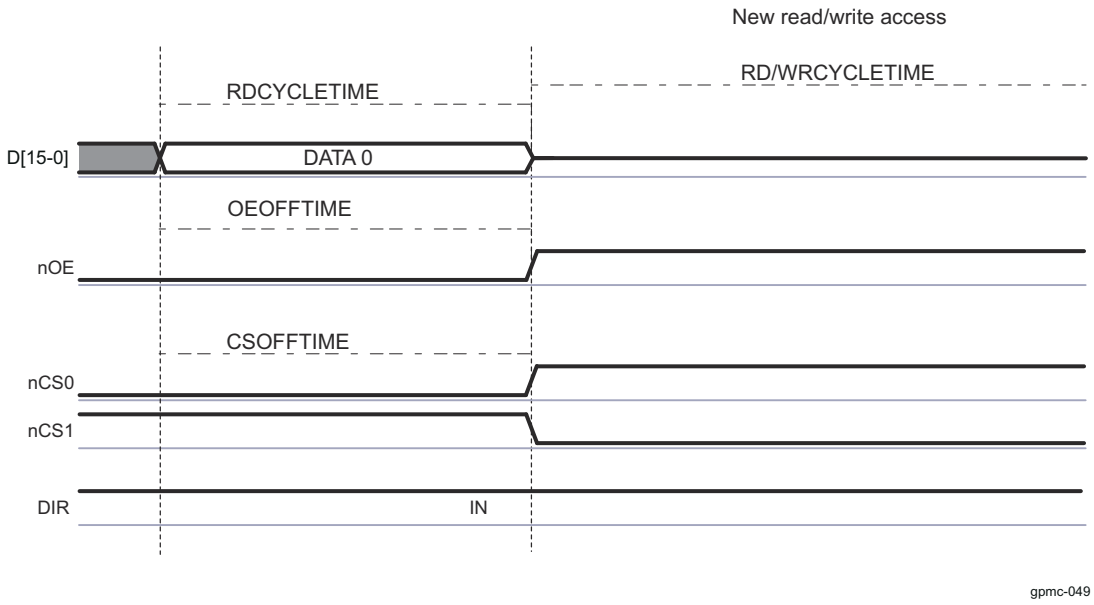

Figure 12-80. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

3.4.3.7.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 3) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock (CLK)) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

Copyright © 2023 Texas Instruments Incorporated

3.4.3.7.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 3.4.3.7.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 12-167 describes the configuration required for idle cycle insertion.

Table 12-167. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.

Table 12-167. Idle Cycle Insertion Configuration (continued)

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

12.3.4.3.7.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select i, where i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

12.3.4.3.7.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15-0]. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see Section 12.3.4.3.8.10, *Bus Keeping Support*). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

12.3.4.3.7.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

GPMC_RST is the reset signal for the GPMC module. It is connected and controlled by LPSC8 in VD_CORE. That reset signal initializes the internal state-machine and the internal configuration registers.

12.3.4.3.7.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The nWP output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit which is common for all chip selects.

12.3.4.3.7.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

Copyright © 2023 Texas Instruments Incorporated

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

12.3.4.3.7.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

12.3.4.3.8 GPMC Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLKOUT and GPMC_FCLK, see *GPMC_CLKOUT*.

Note

In the following sections, the start access time refers to the time at which the access begins.

12.3.4.3.8.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME bit fields (where i = 0 to 3) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC output clock between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC output clock cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

Copyright © 2023 Texas Instruments Incorporated

Note

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC_FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

12.3.4.3.8.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. CSEXTRADELAY is especially useful in configurations where GPMC output clock and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

12.3.4.3.8.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/ Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC output clock and GPMC_FCLK have the same frequency, but

Copyright © 2023 Texas Instruments Incorporated

can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 12.3.4.3.11, *GPMC NAND Access Description*.

12.3.4.3.8.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Note

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

12.3.4.3.8.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME bit field defines the nWE signal-

Copyright © 2023 Texas Instruments Incorporated

deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

12.3.4.3.8.6 GPMC_CLKOUT

The GPMC output clock generated for external synchronous memory or device is GPMC_CLKOUT.

- The GPMC_CLKOUT clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device-specific Datasheet.
- The GPMC_CLKOUT clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLKOUT activation.
- The GPMC_CLKOUT clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLKOUT clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLKOUT may be high because of the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLKOUT clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

12.3.4.3.8.7 GPMC Output Clock and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC output clock edge can be controlled in the following ways:

- For the GPMC output clock signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC output clock allows setup and hold control of the control-signal assertion and deassertion times.
- When the GPMC output clock runs at the GPMC_FCLK frequency so that GPMC output clock edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

Copyright © 2023 Texas Instruments Incorporated

12.3.4.3.8.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

12.3.4.3.8.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC output clock rising edge used for the first data capture.

GPMC output clock, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC output clock.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 12.3.4.3.7.3.1, *WAIT Pin Monitoring Control*.

12.3.4.3.8.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC_WAIT pin is at a valid state two GPMC output clock cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 12.3.4.3.7.3.1, *WAIT Pin Monitoring Control*.

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC output clock rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC output clock edge for a synchronous write access. For more information about wait monitoring, see Section 12.3.4.3.7.3.1, *WAIT Pin Monitoring Control*.

12.3.4.3.8.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

12.3.4.3.8.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 12.3.4.3.7.3.1, *WAIT Pin Monitoring Control*.

12.3.4.3.8.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

Copyright © 2023 Texas Instruments Incorporated

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC output clock edge in synchronous write mode. For more information about wait monitoring, see Section 12.3.4.3.7.3.1, *WAIT Pin Monitoring Control*.

12.3.4.3.8.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

12.3.4.3.9 GPMC NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC output clock (CLK), RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

Note

The address bus and nBE[1-0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

12.3.4.3.9.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC output clock is not provided outside the GPMC and is kept low.

12.3.4.3.9.1.1 Access on Address/Data Multiplexed Devices

12.3.4.3.9.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

For formulas to calculate timing parameters, see Section 12.3.4.4.6.1, *GPMC Timing Parameters Formulas*.

Table 12-208 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 12.3.4.3.7.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16-1] from a GPMC perspective, A[15-0] from an external device perspective) are placed on the address/data bus, and the remaining address bits are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field. It controls the address setup time to nCS assertion.

Copyright © 2023 Texas Instruments Incorporated

  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 12.3.4.3.9.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

12.3.4.3.9.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 12.3.4.4.6.1, *GPMC Timing Parameters Formulas*.

Table 12-208 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 12.3.4.3.7.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16-1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Note

Multiple write access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 12.3.4.3.8.10, *Bus Keeping Support*.

12.3.4.3.9.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

Copyright © 2023 Texas Instruments Incorporated

For accesses on non-multiplexed devices, see Section 12.3.4.3.9.3, *Asynchronous and Synchronous Accesses in non-multiplexed Mode*.

12.3.4.3.9.1.2 Access on Address/Address/Data-Multiplexed Devices

12.3.4.3.9.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 12.3.4.4.6.1, *GPMC Timing Parameters Formulas*.

Table 12-208 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

12.3.4.3.9.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 12.3.4.4.6.1, *GPMC Timing Parameters Formulas*.

Table 12-208 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 12-199, *NAND Memory Type*.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

12.3.4.3.9.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

Copyright © 2023 Texas Instruments Incorporated

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 12.3.4.3.9.3, *Asynchronous and Synchronous Accessed in non-multiplexed Mode*.

12.3.4.3.9.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see Section 12.3.4.3.9.3, *Asynchronous and Synchronous Accessed in non-multiplexed Mode*.

In synchronous operations:

- The GPMC_CLKOUT clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLKOUT clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLKOUT is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

12.3.4.3.9.2.1 Synchronous Single Read

For formulas to calculate timing parameters, see Section 12.3.4.4.6.1, *GPMC Timing Parameters Formulas*.

Table 12-208 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 12.3.4.3.7.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.

Copyright © 2023 Texas Instruments Incorporated

- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 12.3.4.3.8.10, *Bus Keeping Support*.

12.3.4.3.9.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 12-81 and Figure 12-82 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

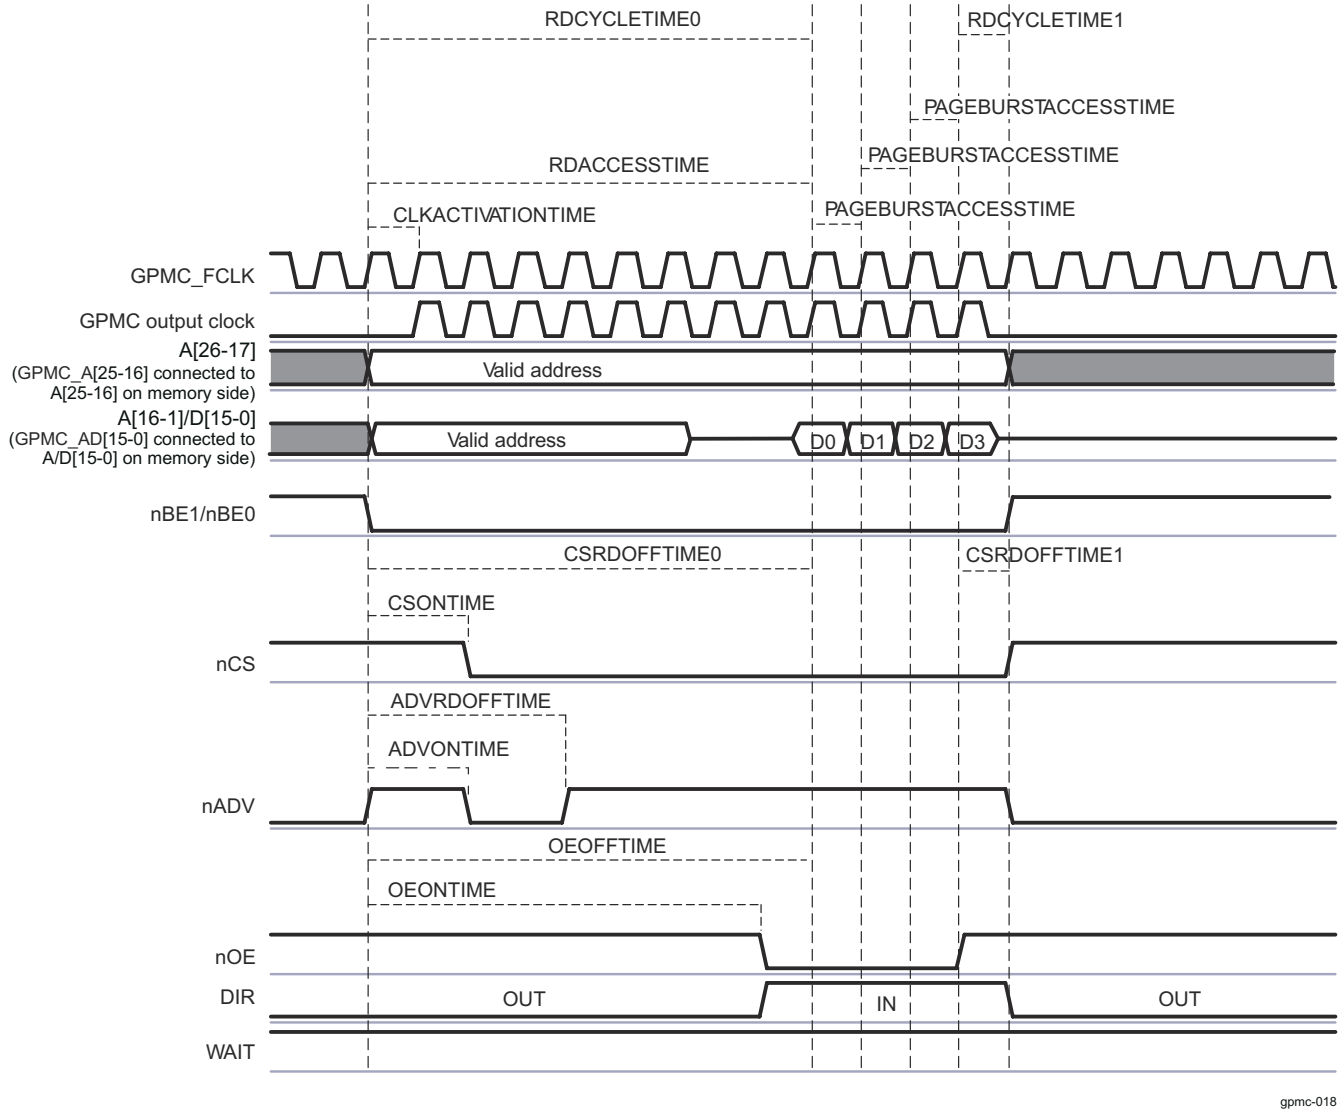

Figure 12-81. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

Copyright © 2023 Texas Instruments Incorporated

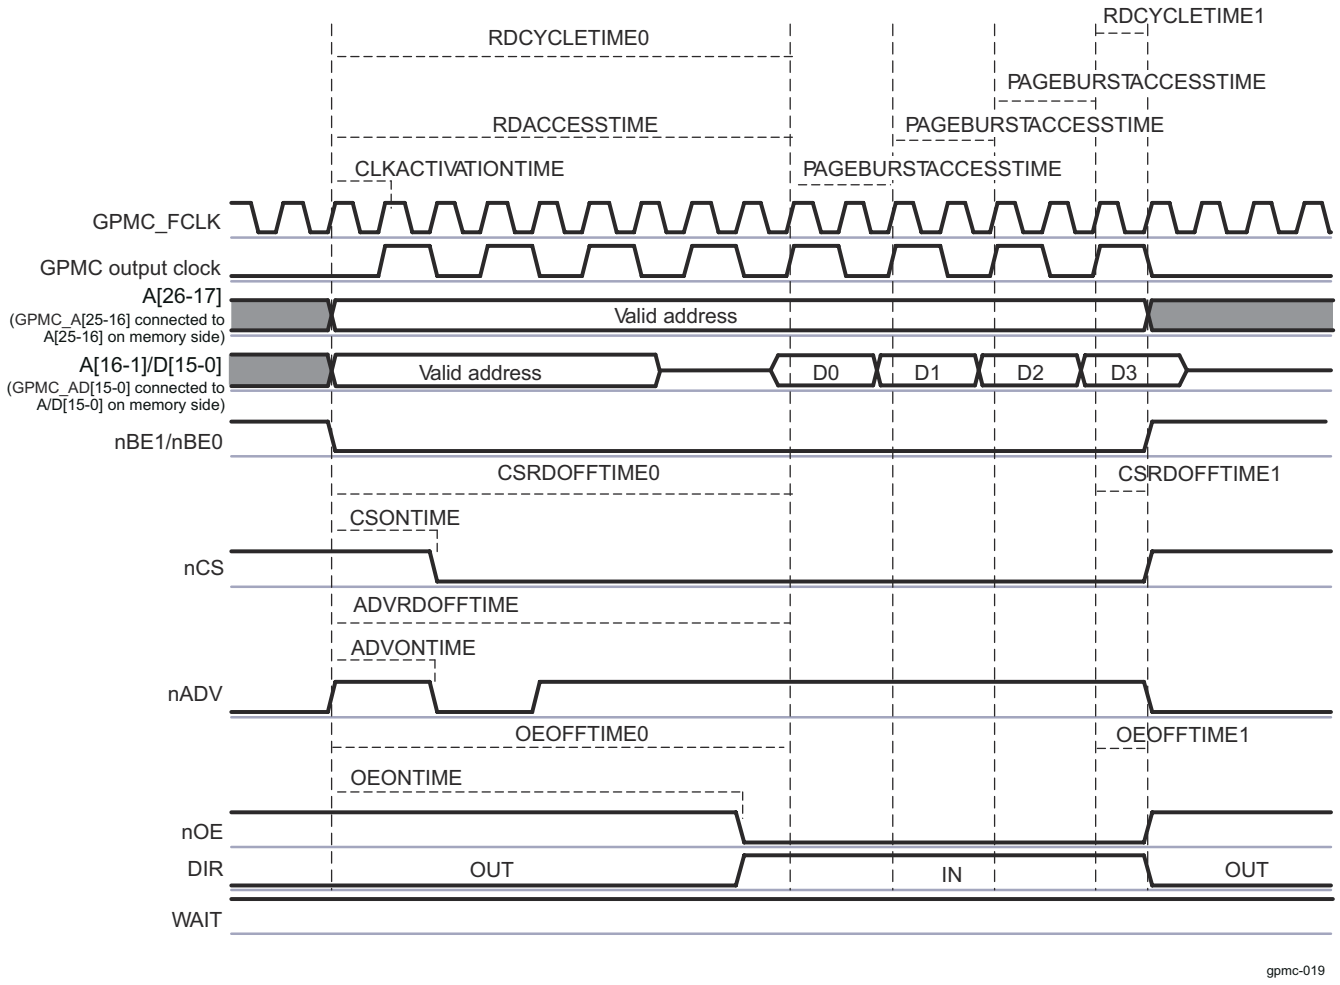

Figure 12-82. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 12-194, *NOR Memory Type*.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLKOUT cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 12-82, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 12.3.4.3.8.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

12.3.4.3.9.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16-1]) until the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

12.3.4.3.9.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 12-83 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

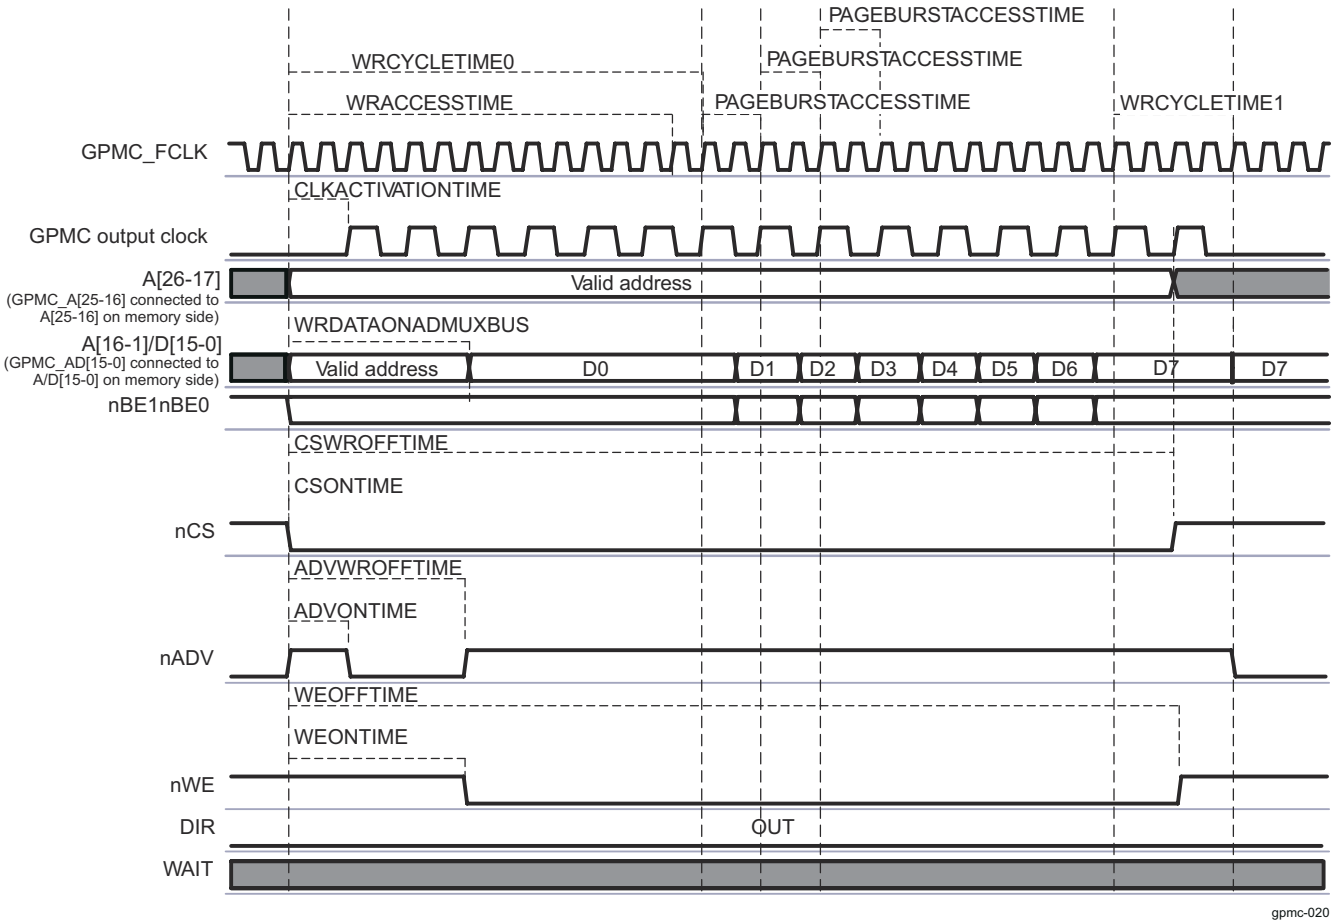

Figure 12-83. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

Figure 12-84 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Copyright © 2023 Texas Instruments Incorporated

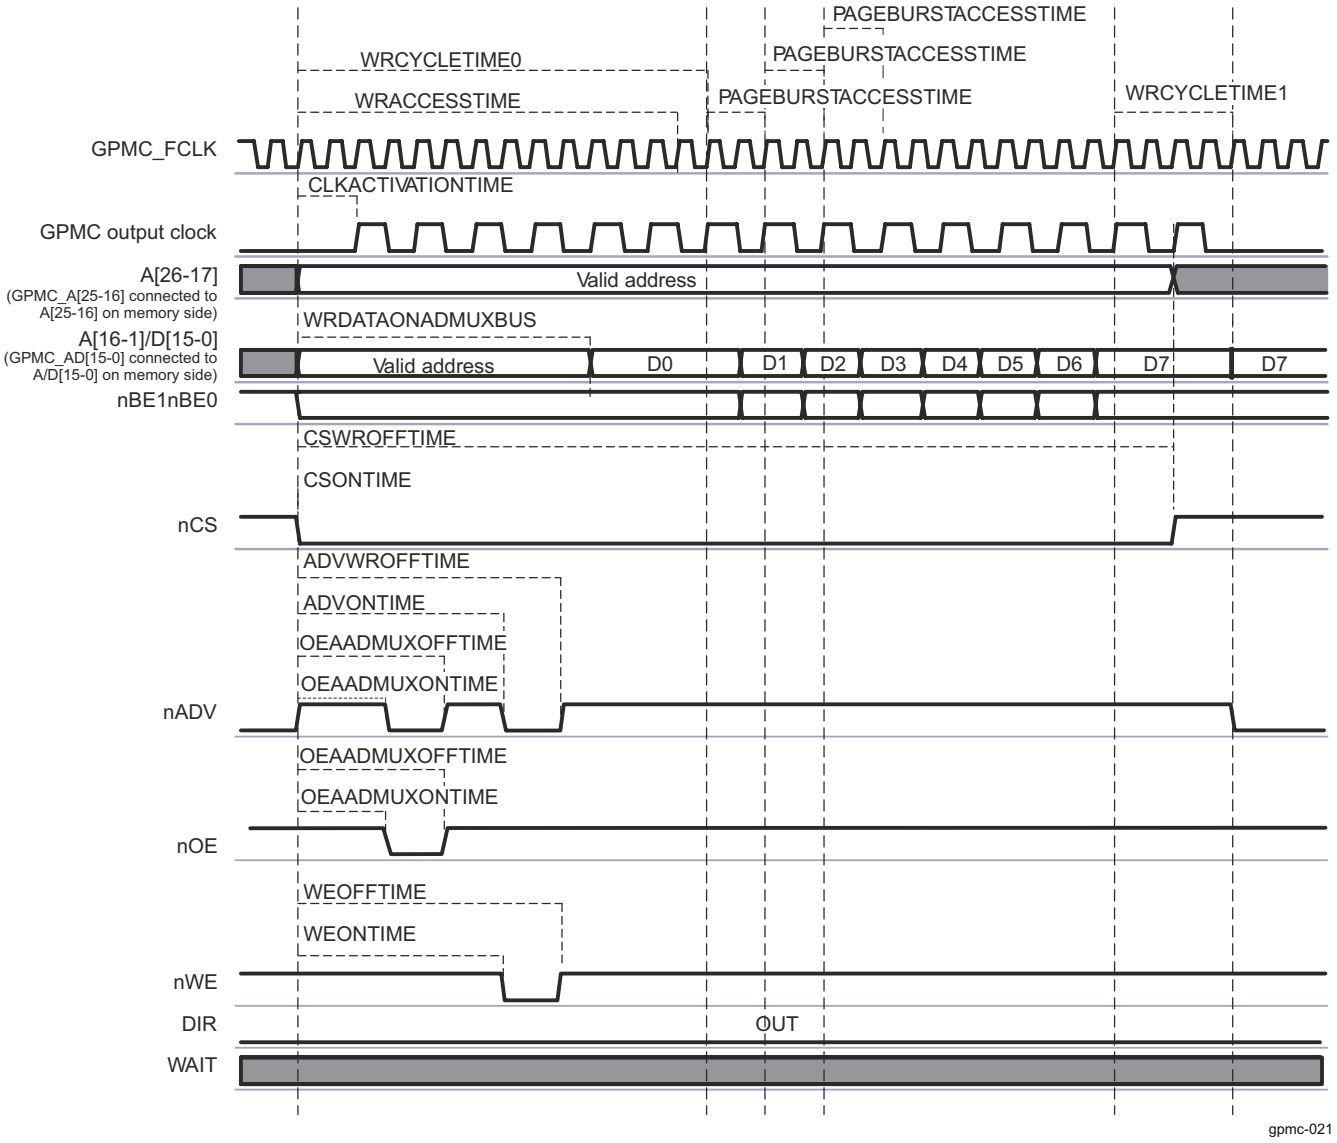

Figure 12-84. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 12.3.4.3.7.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.

Copyright © 2023 Texas Instruments Incorporated

  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.

Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 12-83, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 12.3.4.3.8.10, *Bus Keeping Support*.

12.3.4.3.9.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device
- Synchronous operations on a non-multiplexed device

12.3.4.3.9.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

The address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus and the 16-bit data is driven onto the data bus D[15-0].

Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

Copyright © 2023 Texas Instruments Incorporated

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-199, *NAND Memory Type*).

12.3.4.3.9.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-199).

12.3.4.3.9.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

Figure 12-85 shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

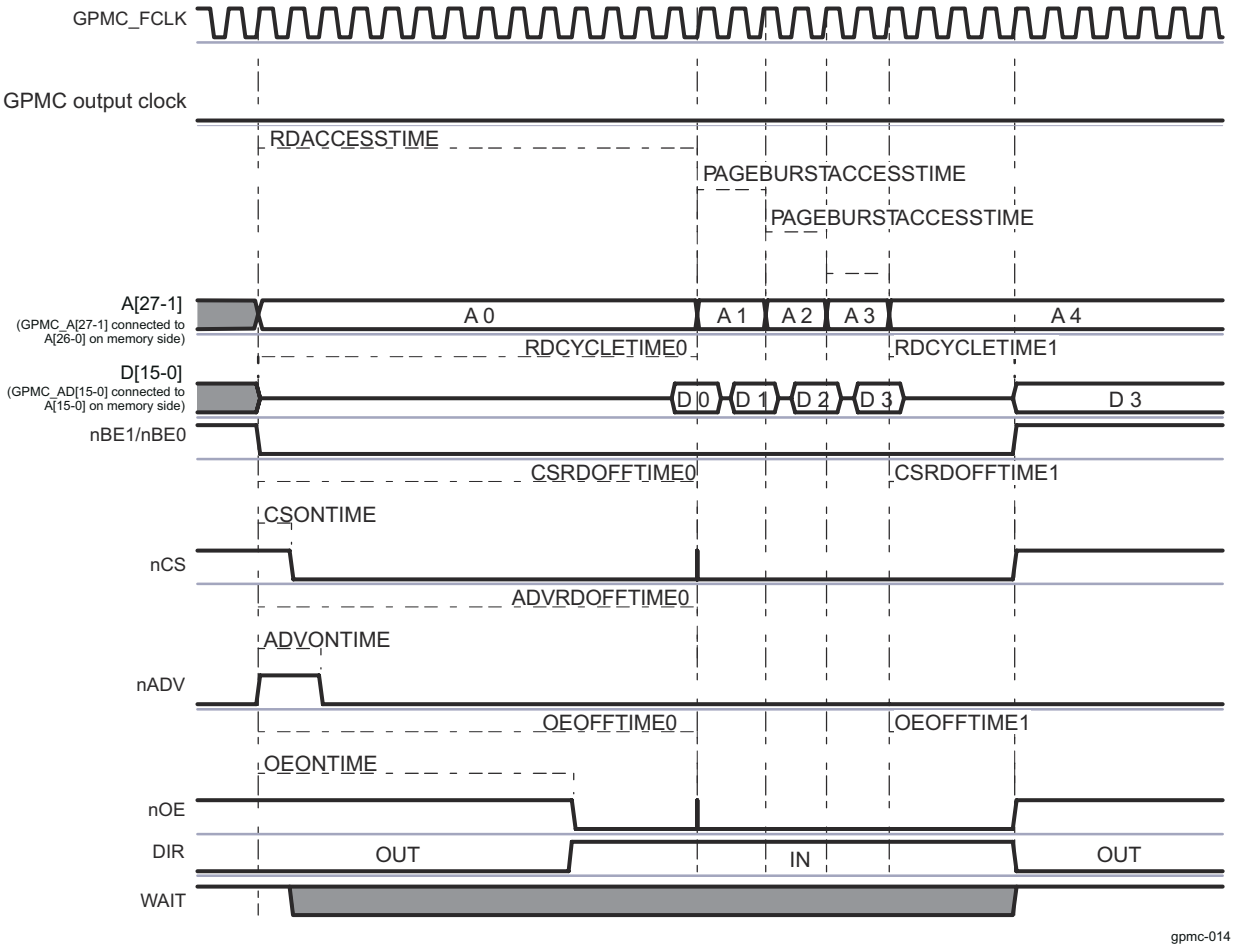

Figure 12-85. Asynchronous Multiple (Page Mode) Read

Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 12-199).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (where i = 0 to 3). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Copyright © 2023 Texas Instruments Incorporated

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field.
- In Figure 12-85, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

12.3.4.3.9.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 12.3.4.4.3, *GPMC Configuration in NOR Mode*.

12.3.4.3.9.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

12.3.4.3.9.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

Copyright © 2023 Texas Instruments Incorporated

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), WAIT pin monitoring must be enabled to dynamically control data access completion within the burst.

Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

12.3.4.3.10 GPMC pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11-10] DEVICETYPE bit field (where i = 0 to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

12.3.4.3.11 GPMC NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

Copyright © 2023 Texas Instruments Incorporated

12.3.4.3.11.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

12.3.4.3.11.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 12-168. Failure to comply with these settings corrupts the NAND interface protocol.

Table 12-168. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode

Copyright © 2023 Texas Instruments Incorporated

Table 12-168. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

(1) i = 0 to 3

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

12.3.4.3.11.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 3). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 3) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

12.3.4.3.11.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Copyright © 2023 Texas Instruments Incorporated

Figure 12-86 shows the NAND command latch cycle.

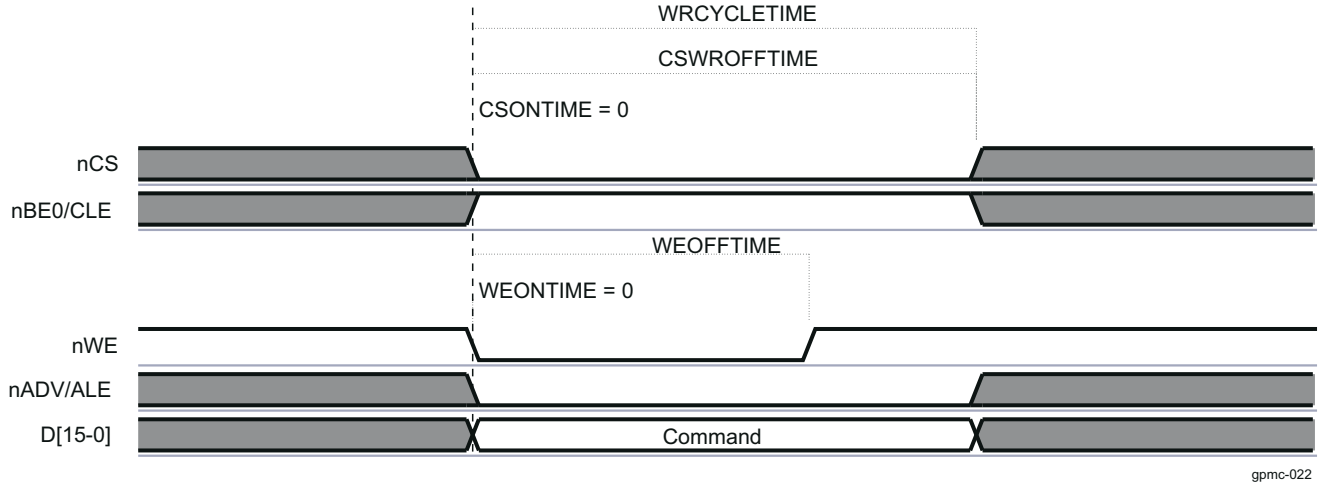

Figure 12-86. NAND Command Latch Cycle

Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

12.3.4.3.11.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 12-87 shows the NAND address latch cycle.

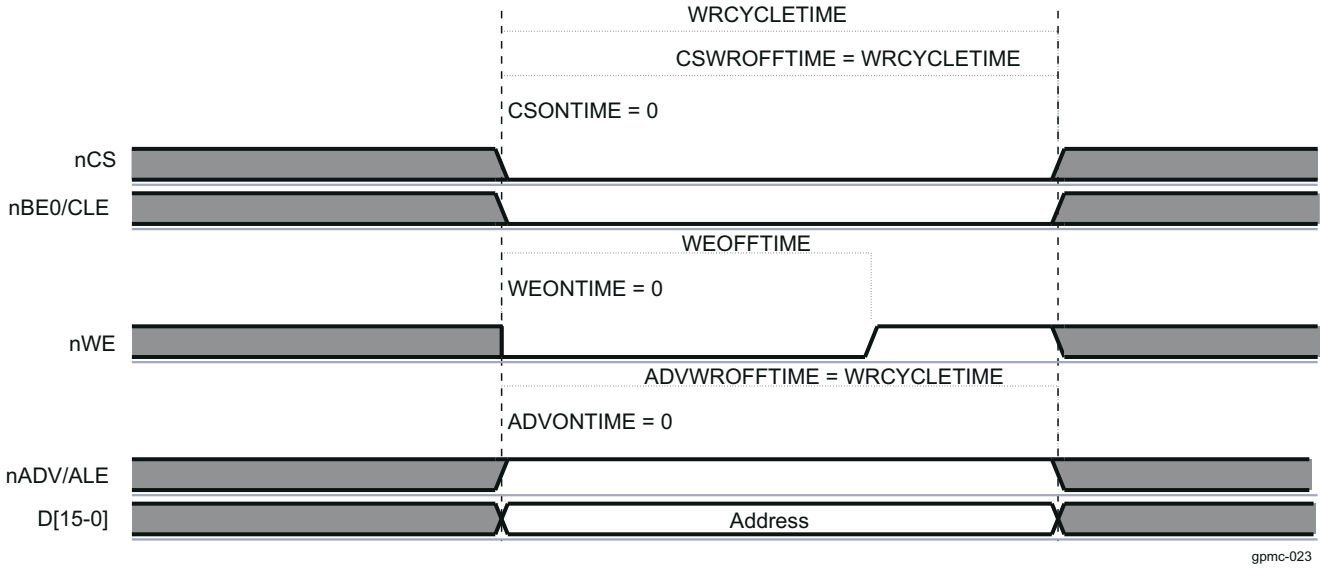

Figure 12-87. NAND Address Latch Cycle

Copyright © 2023 Texas Instruments Incorporated

Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

12.3.4.3.11.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 3) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 12-88 shows the NAND data read cycle.

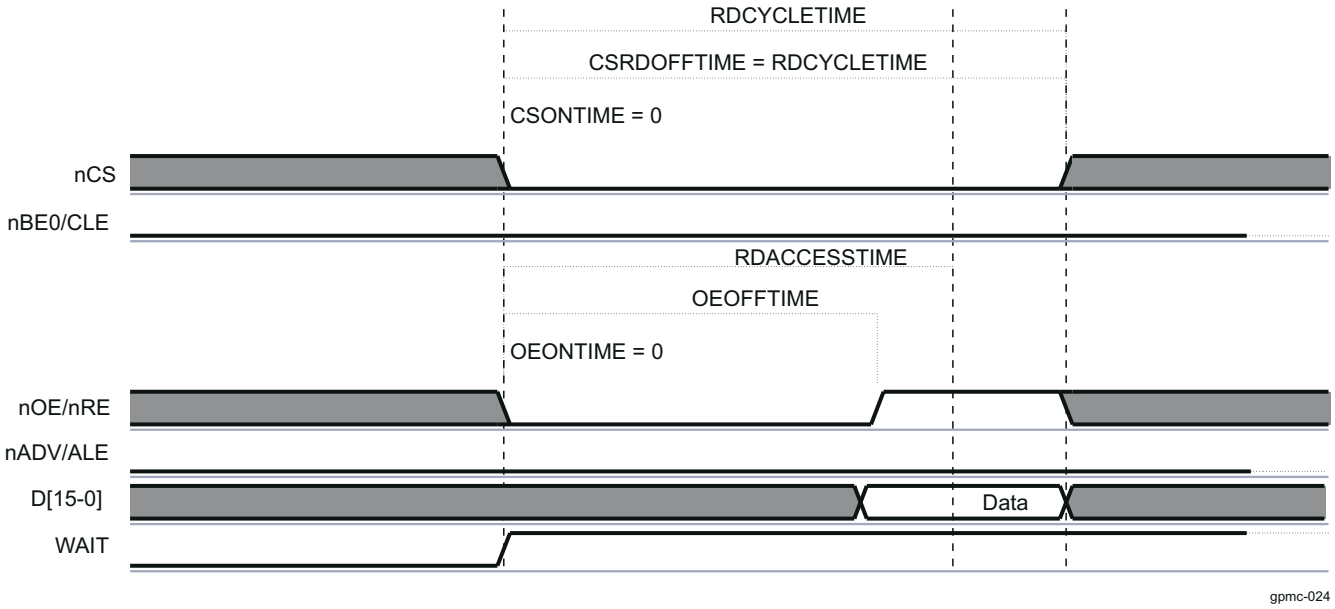

Figure 12-88. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 12-89 shows the NAND data write cycle.

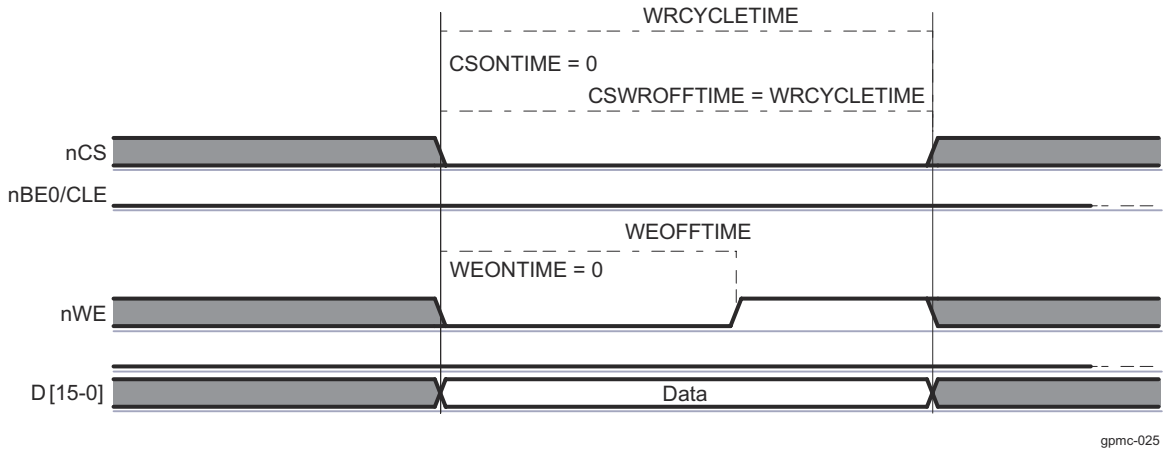

Figure 12-89. NAND Data Write Cycle

12.3.4.3.11.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 12.3.4.3.11.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

12.3.4.3.11.1.7 Read and Write Access Size Adaptation

12.3.4.3.11.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7

Copyright © 2023 Texas Instruments Incorporated

interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

12.3.4.3.11.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

12.3.4.3.11.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Note

If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 3) of the GPMC_STATUS.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

12.3.4.3.11.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 3). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

Copyright © 2023 Texas Instruments Incorporated

12.3.4.3.11.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 3) of the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for NAND device ready signal monitoring.

12.3.4.3.11.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

12.3.4.3.11.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write

Copyright © 2023 Texas Instruments Incorporated

accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

12.3.4.3.11.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

12.3.4.3.11.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

Copyright © 2023 Texas Instruments Incorporated

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 12-169 describes the ECC enable settings.

Table 12-169. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

12.3.4.3.11.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 12-90 and Figure 12-91. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

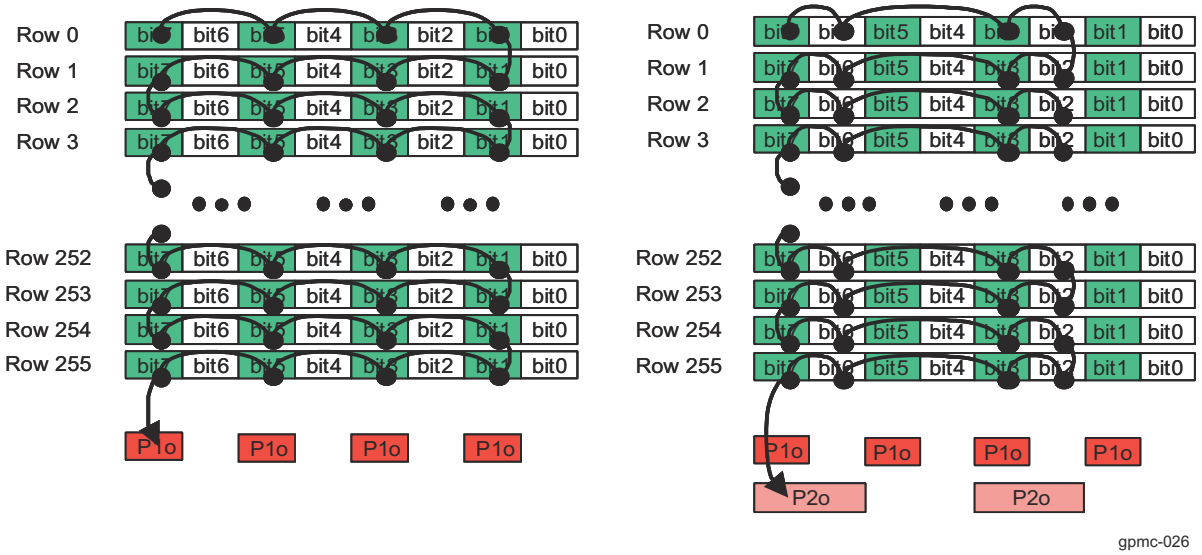

Figure 12-90. Hamming Code Accumulation Algorithm (1/2)

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

Copyright © 2023 Texas Instruments Incorporated

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

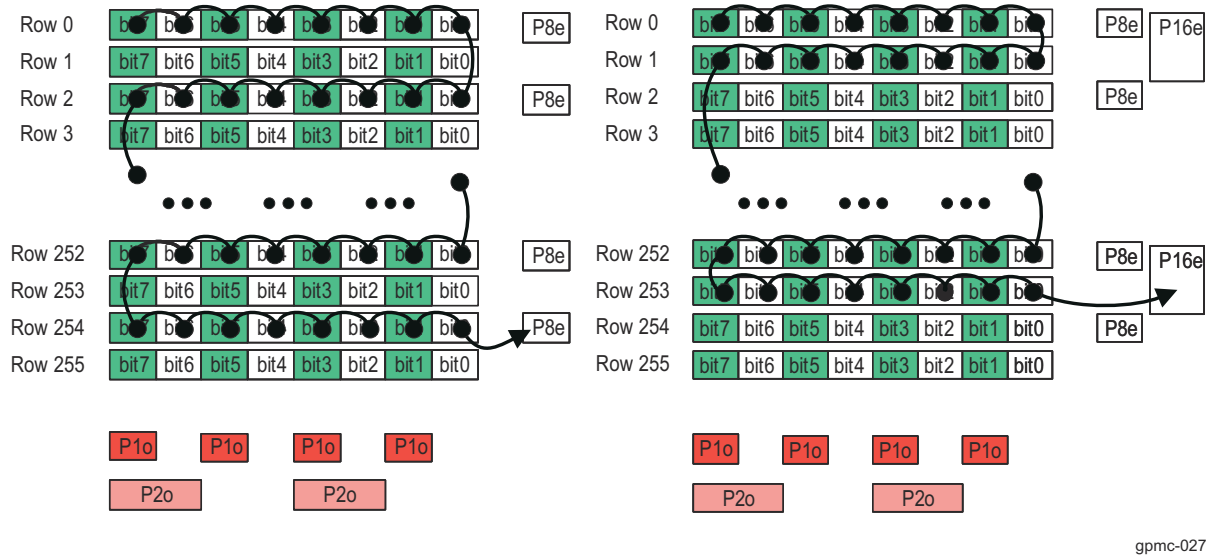

Figure 12-91. Hamming Code Accumulation Algorithm (2/2)

Unused parity bits in the result registers are set to 0.

Figure 12-92 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

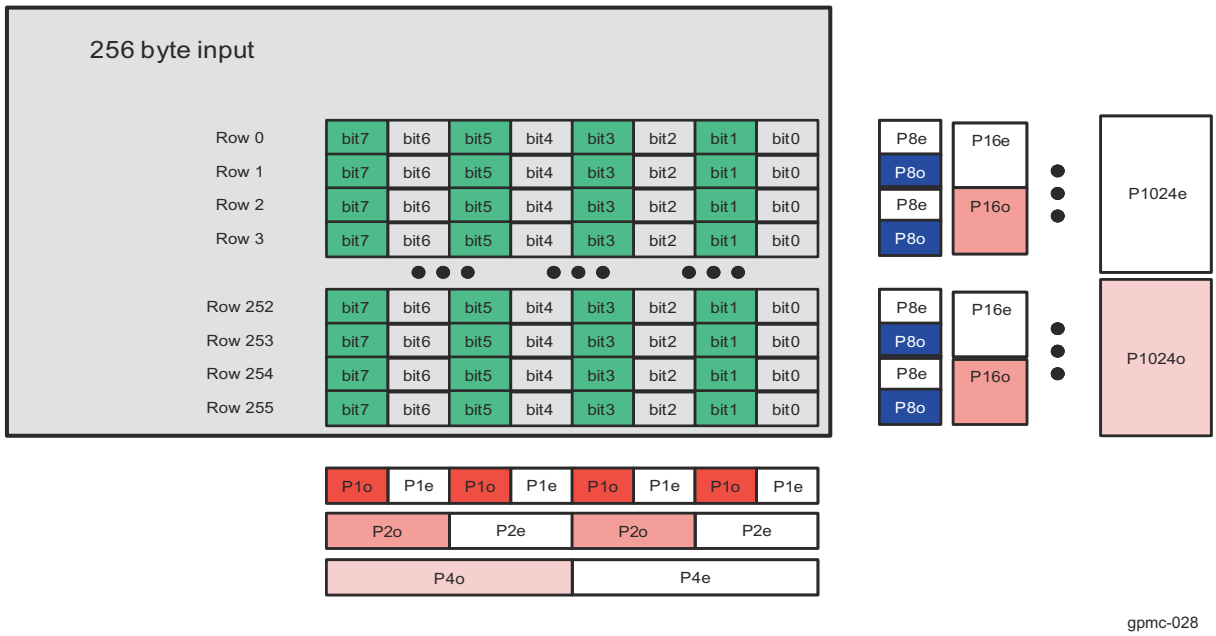

Figure 12-92. ECC Computation for a 256-Byte Data Stream (Read or Write)

Figure 12-93 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Copyright © 2023 Texas Instruments Incorporated

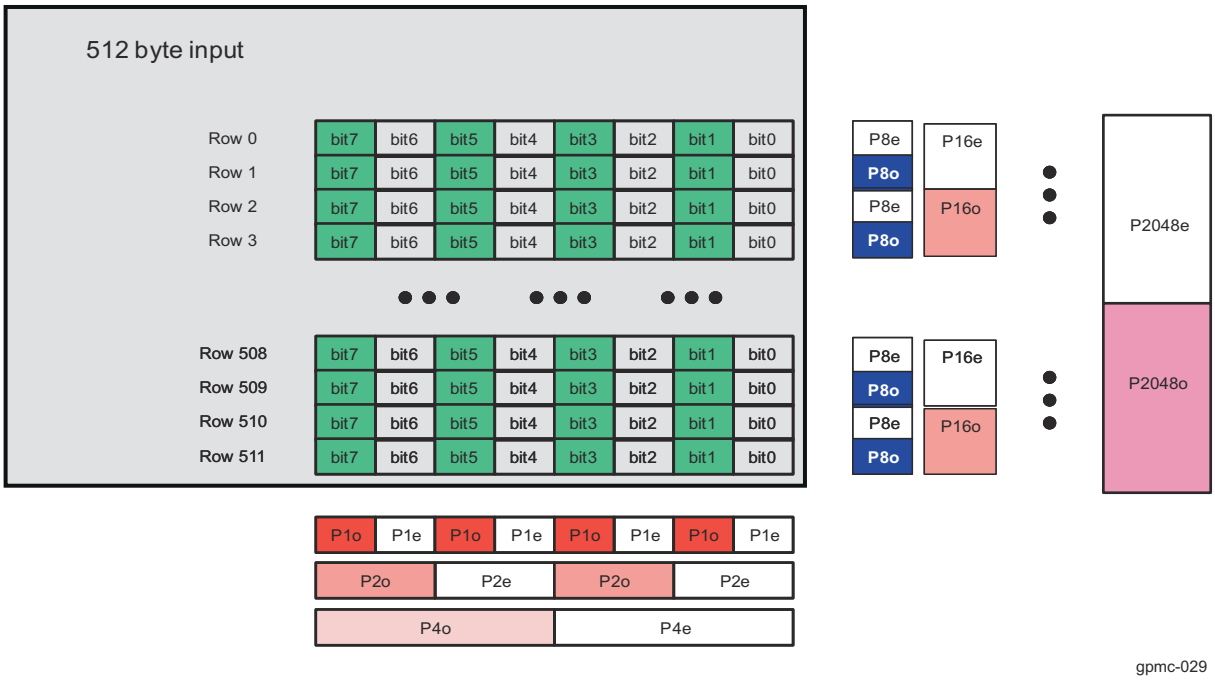

Figure 12-93. ECC Computation for a 512-Byte Data Stream (Read or Write)

For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

12.3.4.3.11.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

12.3.4.3.11.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

12.3.4.3.11.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 12-94 and Figure 12-95 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

12.3.4.3.11.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

12.3.4.3.11.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.
     - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
     - NAND writes its cache line (page) to the array.

Copyright © 2023 Texas Instruments Incorporated

- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

12.3.4.3.11.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 12-170.

Table 12-170. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 3):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

3.4.3.11.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + ... + b0 * x^{i}$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

Copyright © 2023 Texas Instruments Incorporated

Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 12-171 and Table 12-172 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset module 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2^{12}–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 12-171. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 12-172. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 12-173 through Table 12-178 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

3.4.3.11.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.

Copyright © 2023 Texas Instruments Incorporated

- The completed line buffer is then written to the NAND array.

3.4.3.11.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 12.3.4.3.11.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

4.3.11.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[31-22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[31-22] ECCSIZE1 = 0x3

Note

In the following figures, size and size0 are the same parameter.

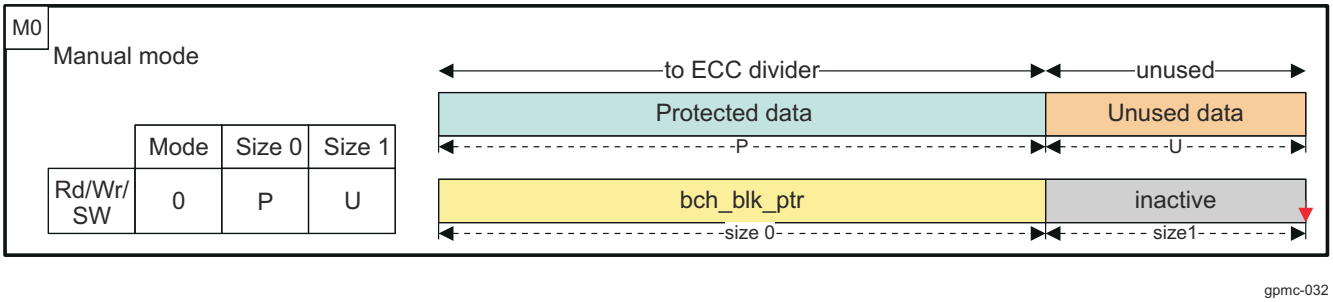

Figure 12-96. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

Checksum: Spare area size (nibbles) = S – (size0 + size1)

12.3.4.3.11.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 3.4.3.11.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 12-97 through Figure 12-99, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

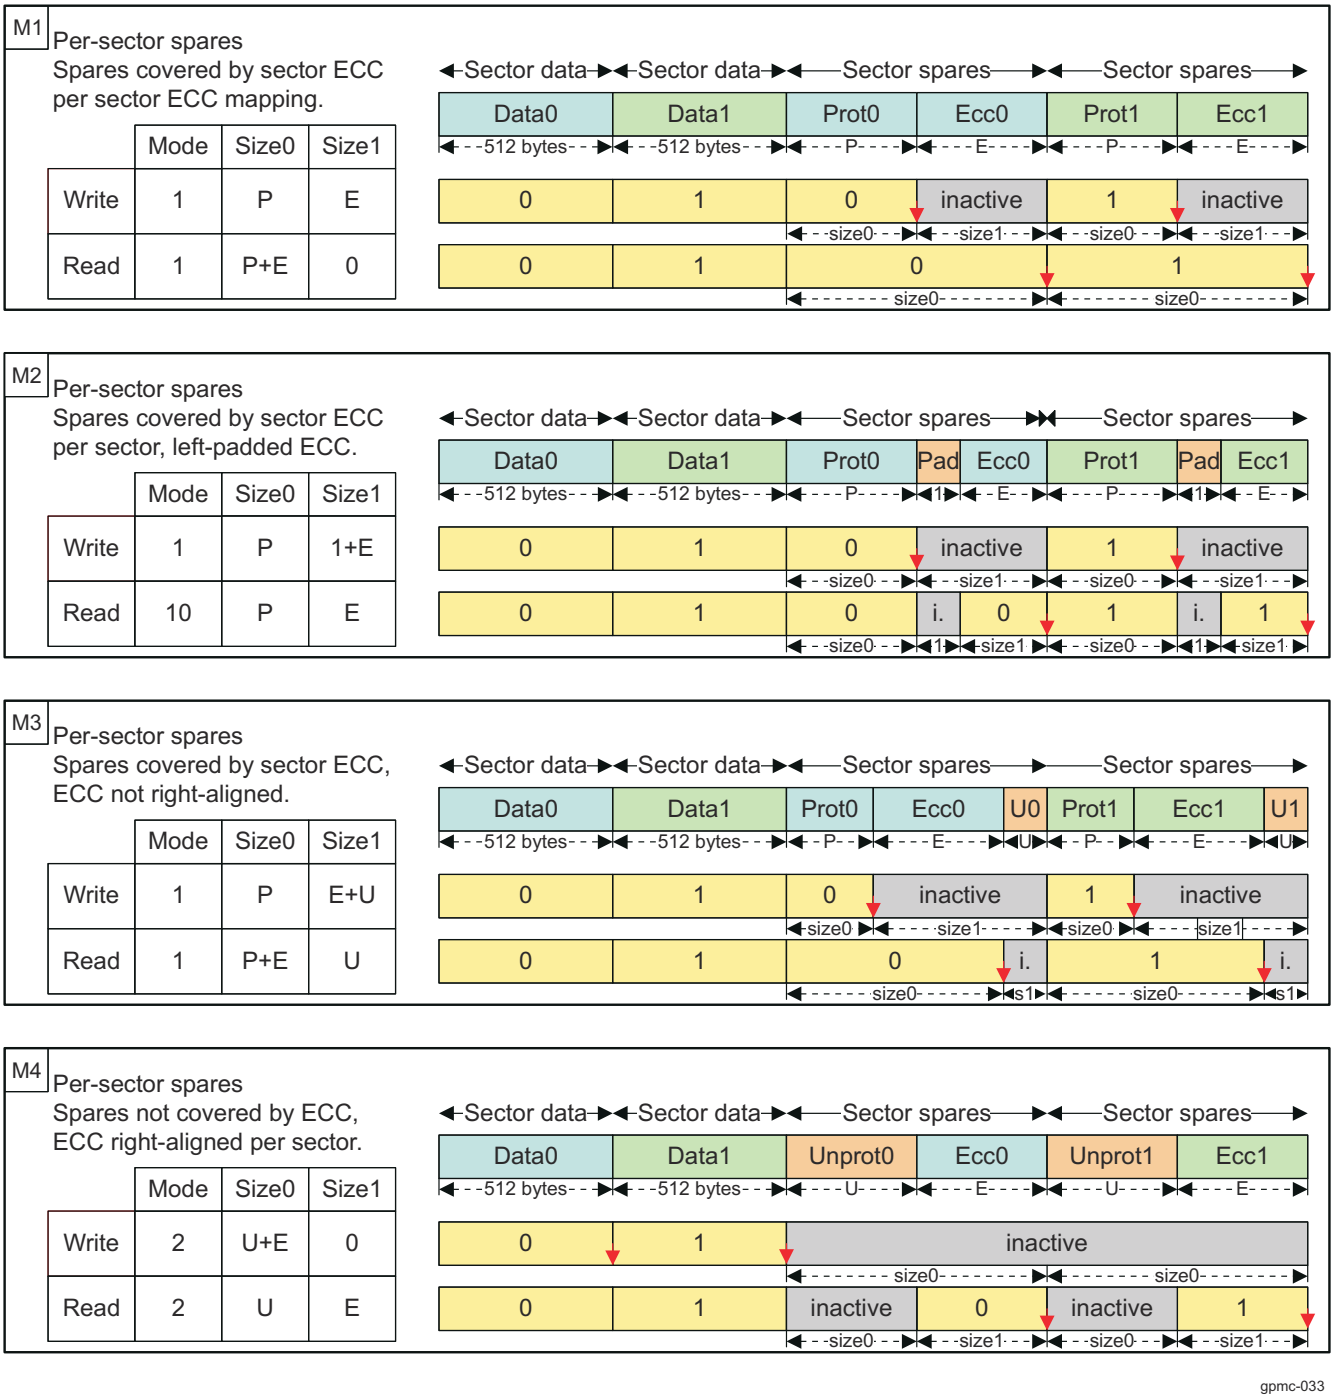
3.4.3.11.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.



gpmc-033

Figure 12-97. NAND Page Mapping and ECC: Per-Sector Schemes

3.4.3.11.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.

Copyright © 2023 Texas Instruments Incorporated

- The non-ECC spare data may or may not be covered by the ECC of sector 0.

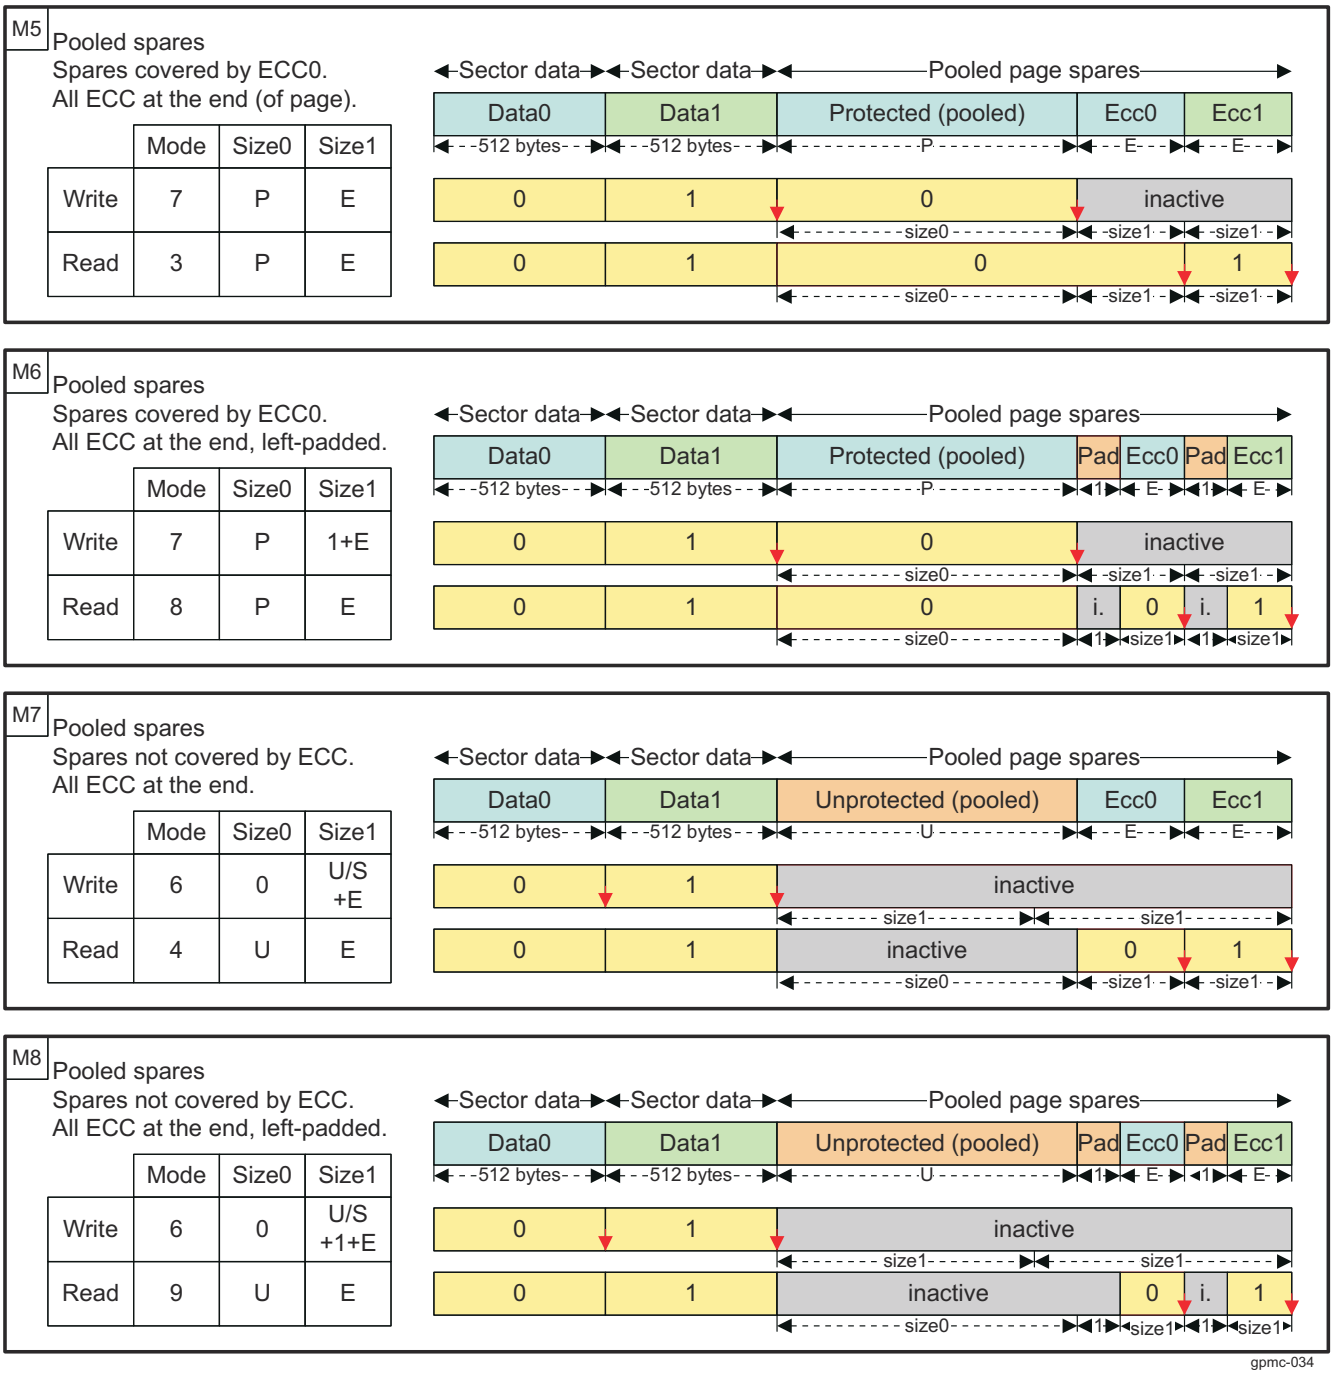


Figure 12-98. NAND Page Mapping and ECC: Pooled Spare Schemes

3.4.3.11.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

12.3.4.3.11.4 Prefetch and Write-Posting Engine

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system

Copyright © 2023 Texas Instruments Incorporated

performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write-posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

12.3.4.3.11.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

Copyright © 2023 Texas Instruments Incorporated

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

12.3.4.3.11.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 12.3.4.3.11.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT bit field.

Table 12-179 describes the prefetch mode configuration.

Table 12-179. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.

Table 12-179. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 12.3.4.3.11.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

12.3.4.3.11.4.3 FIFO Control in Prefetch Mode

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Copyright © 2023 Texas Instruments Incorporated

Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

12.3.4.3.11.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 12-180 describes the write-posting configuration.

Copyright © 2023 Texas Instruments Incorporated

Table 12-180. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 12.3.4.3.11.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

12.3.4.3.11.4.5 FIFO Control in Write-Posting Mode

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are

Copyright © 2023 Texas Instruments Incorporated

available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

12.3.4.3.11.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 3) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 12-100 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

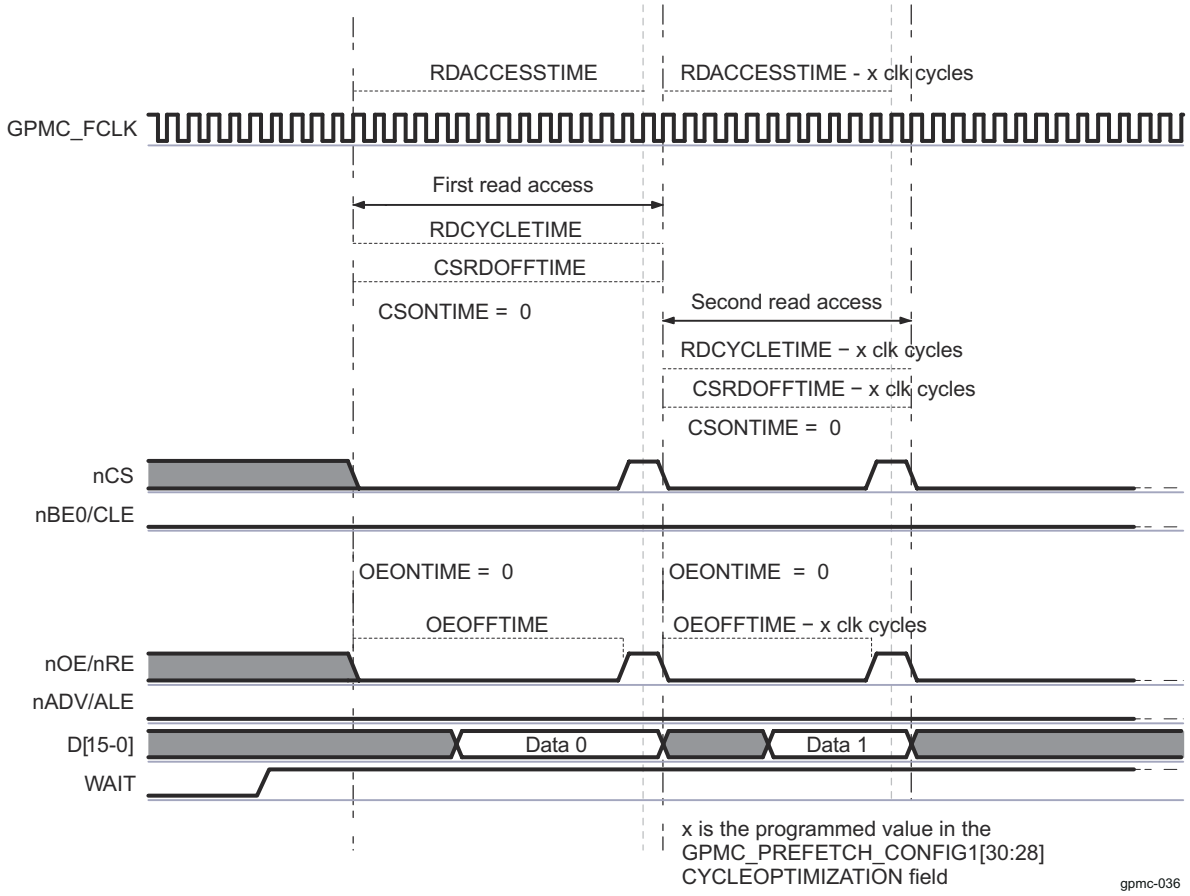

Figure 12-100. NAND Read Cycle Optimization Timing Description

12.3.4.3.11.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

12.3.4.3.12 GPMC Memory Regions

Table 12-181 shows the GPMC memory regions.

Copyright © 2023 Texas Instruments Incorporated

Table 12-181. GPMC Memory Map

Region Name	Address Range	Size	Description
GPMC0			
GPMC0_CFG	0x00 0539 0000 to 0x00 0539 03FF	1 KB	Configuration registers space
GPMC0_DATA	0x00 2000 0000 to 0x00 27FF FFFF	128 MB	External memory space region

12.3.4.3.13 GPMC Use Cases and Tips

12.3.4.3.13.1 How to Set GPMC Timing Parameters for Typical Accesses

12.3.4.3.13.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or non-multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

12.3.4.3.13.1.2 Typical GPMC Setup

Table 12-182 lists some of the I/Os of the GPMC module.

Table 12-182. Typical GPMC Setup Signals

Module Pin	I/O(1)	Description
GPMC0_FCLK	Internal	Functional clock. Acts as the time reference.
GPMC0_ICLK	Internal	Interface clock. Acts as the time reference.
GPMC0_CLKOUT	O	External clock provided to the external device for synchronous operations
	O	Address
GPMC0_AD[15-0]	I/O	Data-multiplexed with addresses A[16-1] on memory side
GPMC0_CSn[3-0]	O	Chip-selects
GPMC0_ADVn_ALE	O	Address valid enable
GPMC0_OEn_REn	O	Output enable (read access only)
GPMC0_WEn	O	Write enable (write access only)
GPMC0_WAIT[3-0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) I = Input; O = Output

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

12.3.4.3.13.1.2.1 GPMC Configuration for Synchronous Burst Read Access

Note

The examples in Section 12.3.4.3.13.1.2.1 through Section 12.3.4.3.13.1.2.3 are based on a clock rate of 104 MHz. See the device-specific Datasheet for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

Copyright © 2023 Texas Instruments Incorporated

The clock runs at 104 MHz (f = 104 MHz; T = 9.615 ns).

Table 12-183 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-184 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-101 shows the synchronous burst read access.

Table 12-183. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5.2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9.615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4.415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 12-184. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9.615 + 80 + 4.415)	10: roundmax (94.03 / 9.615)	RDACCESSTIME = 0xA
PageBurst RdAccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	RdAccess time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0xB
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0xB
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x2
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0xB

(1) The external clock provided to the NOR flash is not yet available.

Copyright © 2023 Texas Instruments Incorporated

(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

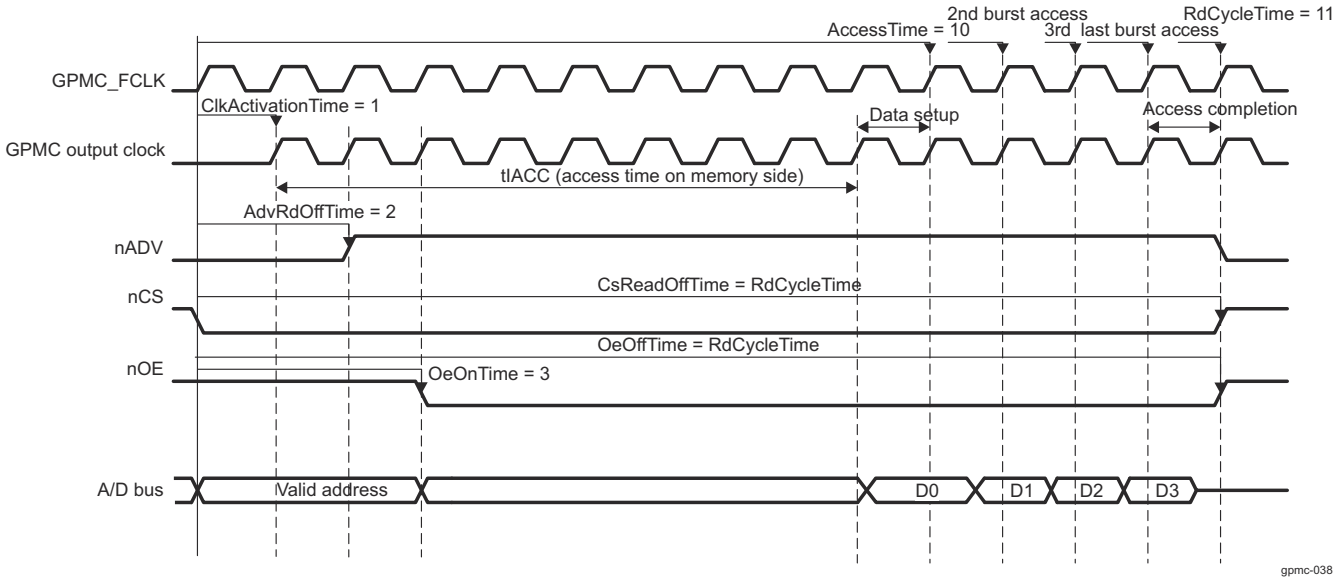

Figure 12-101. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

12.3.4.3.13.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9.615 ns).

Table 12-185 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-186 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-102 shows the asynchronous read access.

Table 12-185. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 12-185: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).
4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.

Copyright © 2023 Texas Instruments Incorporated

5. Addresses can now be relatched and a new read cycle begun.

Table 12-186. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0xA
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96.615	12	RDCYCLETIME = 0xC
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89.615	11	CSRDOFFTIME = 0xB
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x1
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89.615	11	OEOFFTIME = 0xB

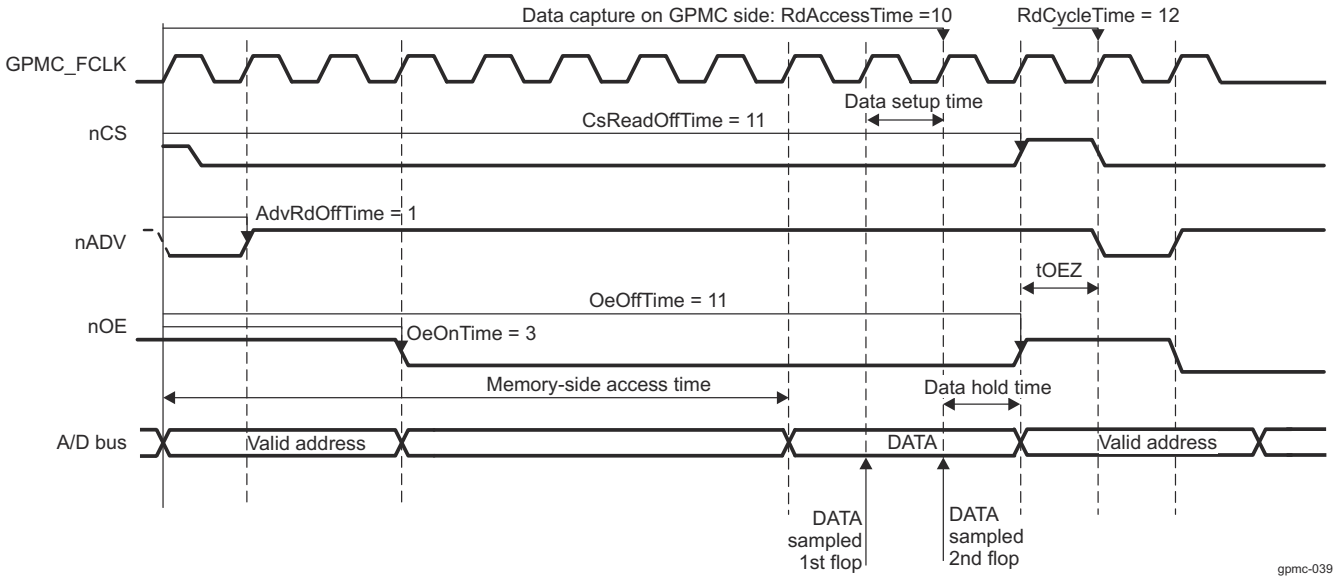

Figure 12-102. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

12.3.4.3.13.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9.615 ns).

Table 12-188 shows how to calculate timings for the GPMC using the memory parameters.

Table 12-187 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 12-103 shows the synchronous burst write access.

Table 12-187. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0

Copyright © 2023 Texas Instruments Incorporated

Table 12-187. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device-specific Datasheet.

Table 12-188. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57.615	6	WRCYCLETIME = 0x6
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57.615	6	CSWROFFTIME = 0x6
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x1
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x5

12.3.4.3.13.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

12.3.4.3.13.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, and so on)
- 8- and 16-bit NAND flash devices

12.3.4.3.13.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 12-190 summarizes the NAND interface signals level applied to external device or memories.

Table 12-190. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE (1)	nRE (1)	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H (2)	H (2)	H (2)	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

(1) RE stands for rising edge; FE stands for falling edge
(2) Can be nCE high, or WE and nRE high.

12.3.4.3.13.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 12-191 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 12-191. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15-0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

12.3.4.3.13.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

FPGA (Field-Programmable Gate Array) is a low-power integrated circuit based on an array of programmable logic blocks.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It has synchronous write capability.

12.3.4.4 GPMC Basic Programming Model

12.3.4.4.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 12-104 and Table 12-192 through Table 12-193 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

12.3.4.4.2 GPMC Initialization

GPMC can be reset via software bit in LPSC. For more information, see Section 5.3, *Reset*.

12.3.4.4.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 12-194. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency (1).	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time (1).	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations (1).	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

Table 12-195. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 12-196. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 12.3.4.4.6, *GPMC Timing Parameters*

Table 12-197. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable WAIT pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable WAIT pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a WAIT pin monitoring time.	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input WAIT pin for the chip-select.	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

Table 12-198. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

12.3.4.4.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

Table 12-199. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 12.3.4.4.5, *Set Memory Access*.	x

Table 12-200. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 12-201. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 12.3.4.4.6, *GPMC Timing Parameters*.	

Table 12-202. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x (2)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 and [31-22] ECCSIZE1	x (1)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_CONFIG[6-4] ECCTOPSECTOR	x

Copyright © 2023 Texas Instruments Incorporated

Table 12-202. ECC Engine (continued)

Subprocess Name	Register/Bit Field	Value
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) Depends on the size of each sector in the NAND page
(2) This parameter depends on the numbers of sectors in a page.

Table 12-203. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue an interrupt request.	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select interrupt synchronization mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 12-204. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

Table 12-205. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

12.3.4.4.5 Set Memory Access

Note

Some of the GMPC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

This section describes the bit field to configure to set the GPMC in various memory modes. Table 12-206 and Table 12-207 provide check lists for mode parameters and access type parameters, respectively.

Table 12-206. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	Don't care	0x1 (1)	Not Supported	0x0	Don't care	0x1	Don't care
GPMC_CONFIG1_i	29	READTYPE	0x0	Don't care	0x0 (1)	Not Supported	0x1	Don't care	0x1	Don't care

Copyright © 2023 Texas Instruments Incorporated

Table 12-206. Mode Parameters Check List (continued)

Register	Bit	Name	Asynchronous				Synchronous			
GPMC_CONFIG1_i	28	WRITEMULTIPLE	Don't care	0x0	- (1)	Not Supported	Don't care	0x0	Don't care	0x1
GPMC_CONFIG1_i	27	WRITETYPE	Don't care	0x0	- (1)	Not Supported	Don't care	0x1	Don't care	0x1

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

Table 12-207. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	0x0	0x2	0x1

12.3.4.4.6 GPMC Timing Parameters

Figure 12-105 shows a programming model diagram for the NOR interfacing timing parameters.

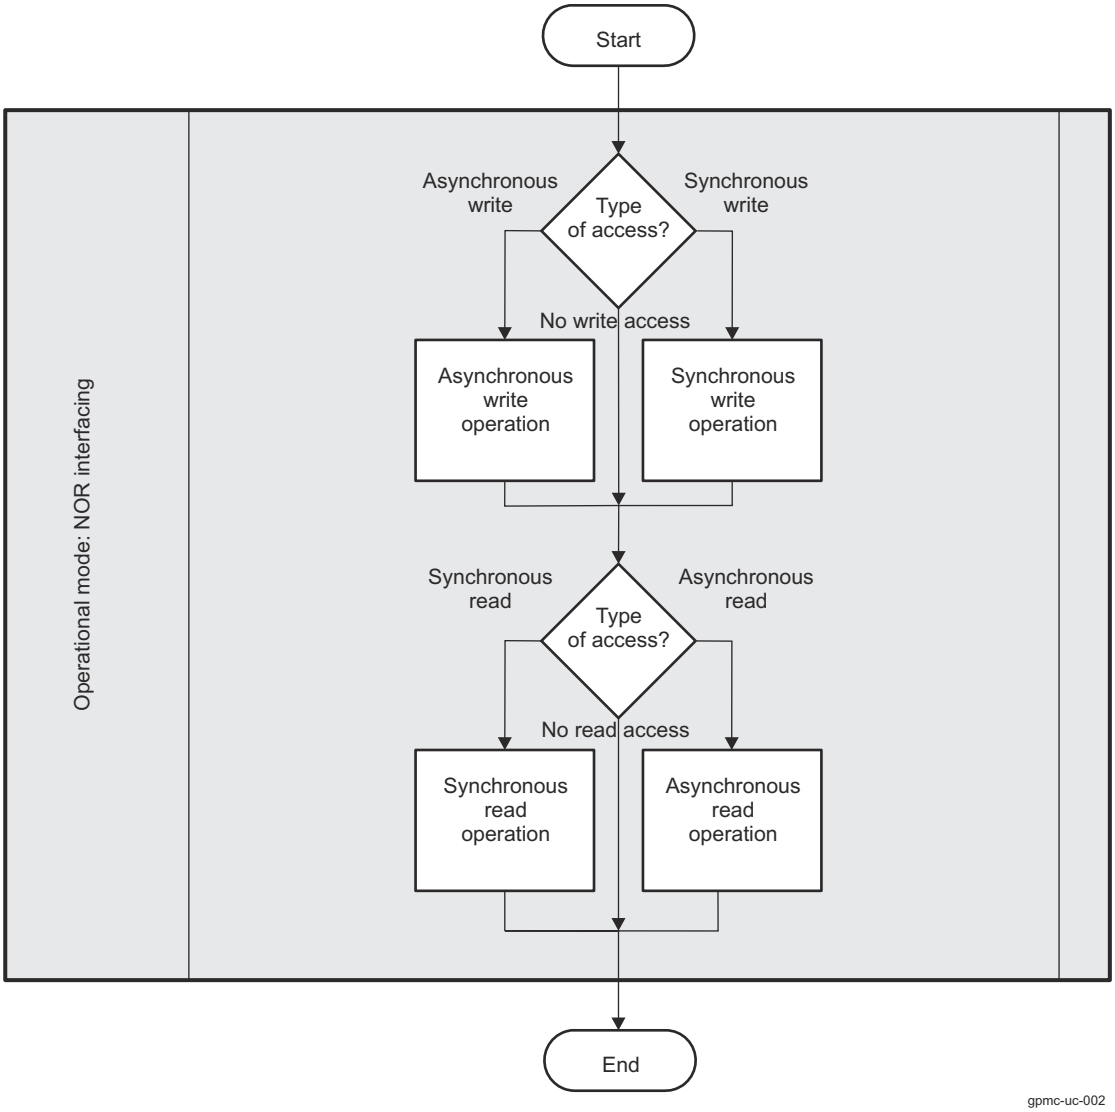

Figure 12-105. NOR Interfacing Timing Parameters Diagram

Table 12-208 lists the bit fields to configure adequate timing parameters in various memory modes.

12.3.4.4.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device-specific Datasheet.

12.3.4.4.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0x2. Table 12-209 describes the NAND timing parameters.

Table 12-209. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15-0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15-0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15-0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

Copyright © 2023 Texas Instruments Incorporated

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((RdAccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 12-106 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

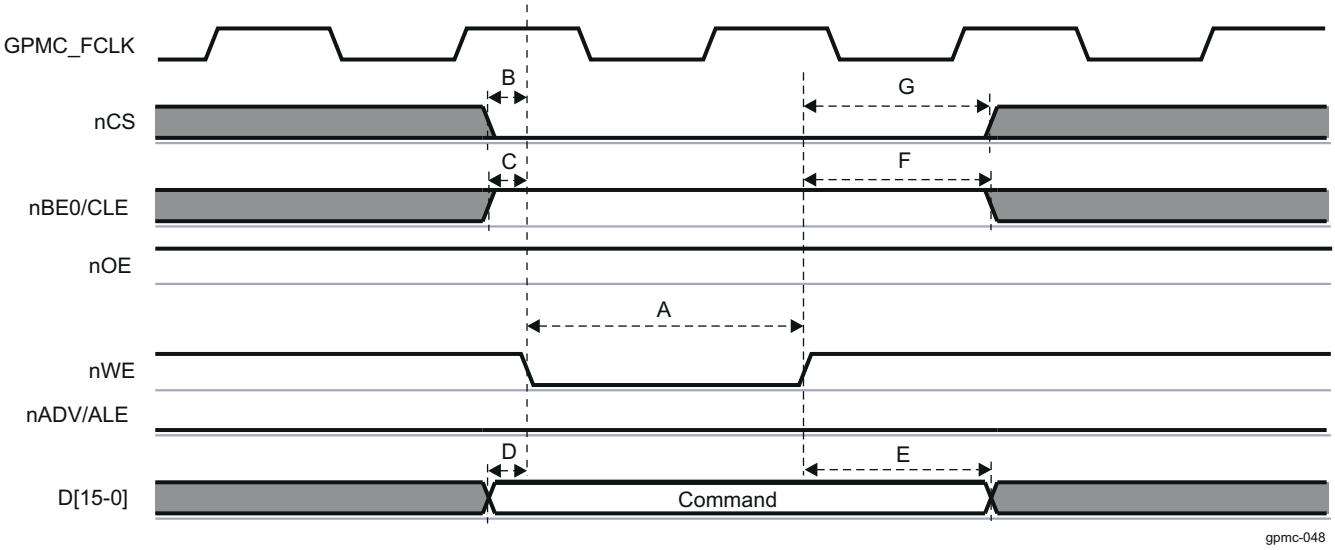

Figure 12-106. NAND Command Latch Cycle Timing Simplified Example

12.3.4.4.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 12-210 describes the synchronous NOR formulas.

Table 12-210. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – address bus valid to CLK first edge
		Delay time – nBE0 / nBE1 valid to CLK first edge
C	ns	Pulse duration – nBE0 / nBE1 low
D	ns	Delay time – CLK rising edge to nBE0 / nBE1 invalid
		Delay time – CLK rising edge to nADV/ALE invalid
E	ns	Delay time – CLK rising edge to nCS invalid
		Delay time – CLK rising edge to nOE/nRE invalid
F	ns	Delay time – CLK rising edge to nCS transition
G	ns	Delay time – CLK rising edge to nADV/ALE transition
H	ns	Delay time – CLK rising edge to nOE/nRE transition
I	ns	Delay time – CLK rising edge to nWE transition
J	ns	Delay time – CLK rising edge to A[16-1/]D[15-0] data bus transition
		Delay time – CLK rising edge to nBE0 / nBE1 transition
K	ns	Pulse duration – nADV/ALE low
L	ns	Delay time – WAIT invalid to first data latching CLK edge

Copyright © 2023 Texas Instruments Incorporated

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

1. For single read accesses:
   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – RDACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – RDACCESSTIME) * GPMC_FCLK period
2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSRDOFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSWROFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (chip-select activated):
   - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in writing mode:
   - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:

Copyright © 2023 Texas Instruments Incorporated

F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:

Copyright © 2023 Texas Instruments Incorporated

H = 0.5 * OEEXTRADELAY * GPMC_FCLK period

- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV low pulse duration:

- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For WAIT invalid to first data latching GPMC output clock edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC output clock period

Figure 12-107 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

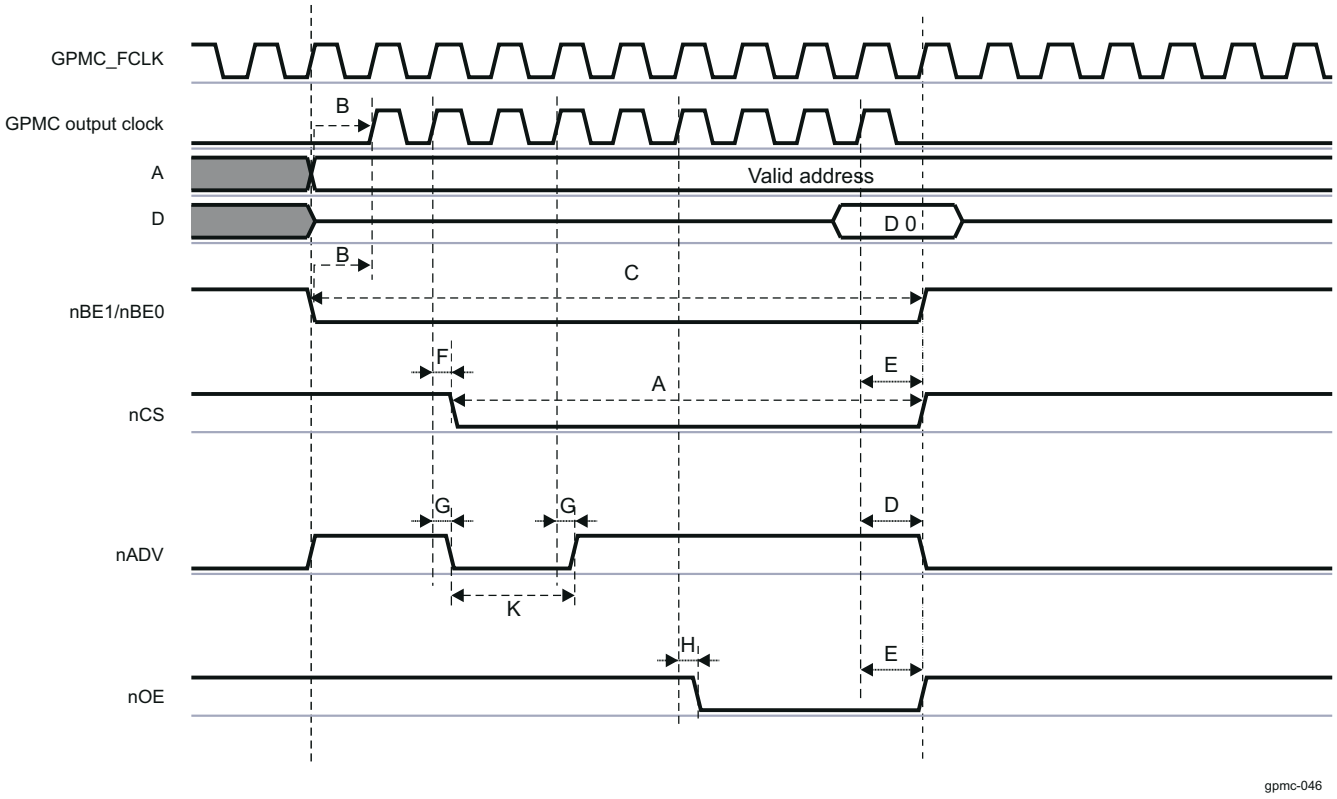

Figure 12-107. Synchronous NOR Single Read Simplified Example

12.3.4.4.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 12-211 describes the asynchronous NOR formulas.

Table 12-211. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – nCS valid to nADV/ALE invalid
C	ns	Delay time – nCS valid to nOE/nRE invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – nCS valid to nWE valid
F	ns	Delay time – nCS valid to nWE invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before nOE/nRE high

Copyright © 2023 Texas Instruments Incorporated

Table 12-211. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
I	ns	Delay time – nCS valid to nOE/nRE invalid (burst read)
J	ns	Delay time – address bus valid to nCS valid
		Delay time – data bus valid to nCS valid
		Delay time – nBE0 / nBE1 valid to nCS valid
K	ns	Delay time – nCS valid to nADV/ALE valid
L	ns	Delay time – nCS valid to nOE/nRE valid
M	ns	Delay time – nCS valid to first data latching edge
N	ns	Pulse duration – nBE0 / nBE1 valid time
O	ns	Delay time – nCS valid to nADV/ALE valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device-specific Datasheet.

- nCS low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- nCS valid to nADV/ALE invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- nBE0 /nBE1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

Copyright © 2023 Texas Instruments Incorporated

For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 12-108 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

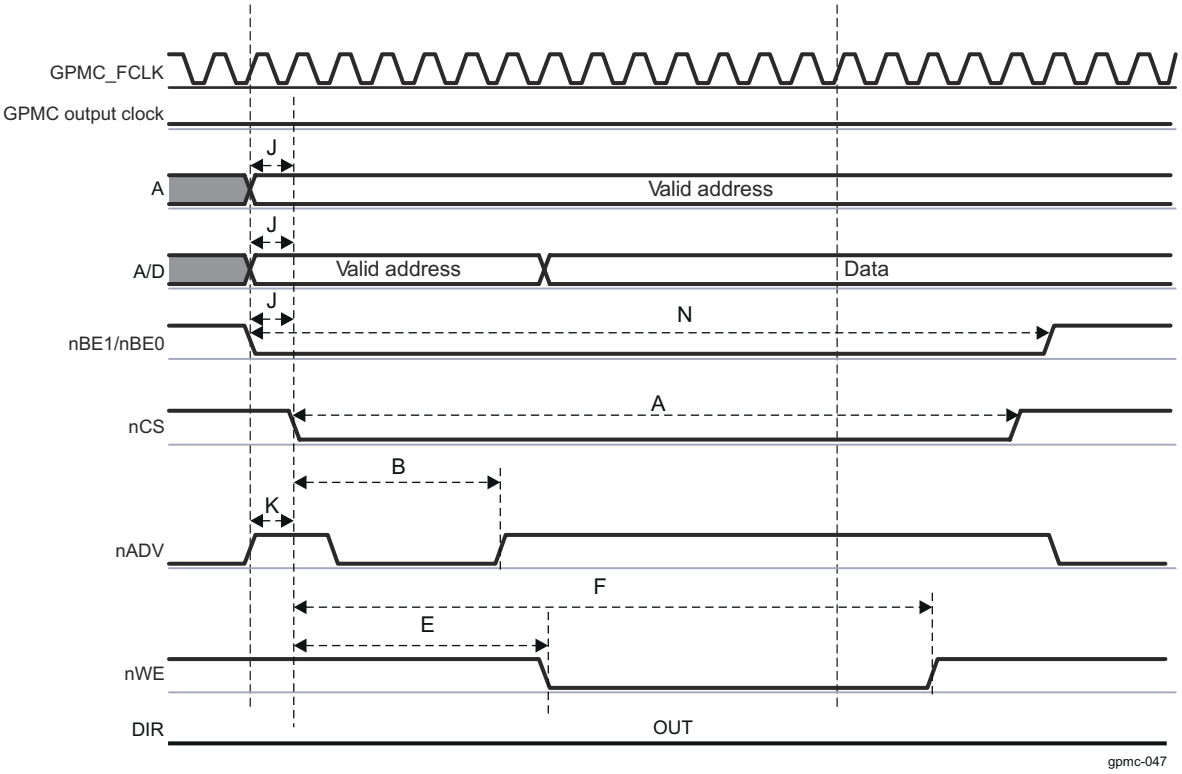

Figure 12-108. Asynchronous NOR Single Write Simplified Example

Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

12.3.5 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

12.3.5.1 ELM Overview

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller. ELM can be also used to support parallel NOR flash or NAND flash.

The General-Purpose Memory Controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

12.3.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode.

12.3.5.1.2 ELM Ports

12.3.5.2 ELM Functional Description

The ELM0 module is hereinafter referred to as ELM.

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

12.3.5.2.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

12.3.5.2.2 ELM Power Management

Note

Some of the ELM features described in this section may not be supported on this family of devices. For more information, see *ELM Not Supported Features*.

Table 12-214 describes the power-management features available to the ELM.

Table 12-214. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FICLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

12.3.5.2.3 ELM Interrupt Requests

Table 12-215 lists the event flags, and their masks, that can cause module interrupts asserting the signal.

Table 12-215. ELM Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

12.3.5.2.4 ELM Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26-16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Copyright © 2023 Texas Instruments Incorporated

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

12.3.5.2.5 ELM Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION bit field, and so on.

Table 12-216 describes the ELM_LOCATION_STATUS_i value decoding.

Table 12-216. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

Copyright © 2023 Texas Instruments Incorporated

12.3.5.2.6 ELM Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

Note

Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

12.3.5.3 ELM Basic Programming Model

12.3.5.3.1 ELM Low-Level Programming Model

12.3.5.3.1.1 Processing Initialization

Table 12-217. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
IF continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enable interrupt for syndrome polynomial i.	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
ELSE (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
ENDIF		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

12.3.5.3.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 12-218 and Table 12-219 describe the processing completion for continuous and page modes, respectively.

Table 12-218. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
IF the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Copyright © 2023 Texas Instruments Incorporated

Table 12-219. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
IF the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

12.3.5.3.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

12.3.5.3.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 12-220). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980.

Table 12-220. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x1
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiate the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1

Table 12-220. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0: is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 12-221 are given in decimal format.

Table 12-221. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464

49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

12.3.5.3.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see Table 12-222). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface,

Copyright © 2023 Texas Instruments Incorporated

four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

12.3.6 Multi-Media Card Secure Digital (MMCSD) Interface

This section describes the MMCSD modules in the device.

12.3.6.1 MMCSD Overview

There are two MMCSD modules inside the device - MMCSD0 and MMCSD1. Each MMCSD module includes one MMCSD Host Controller.

Each controller has the following data bus width:

- MMCSD0 - 8-bit wide data bus
- MMCSD1 - 4-bit wide data bus

The MMCSD Host Controller provides an interface to eMMC 5.1 (embedded Multi-Media Card), SD 4.10 (Secure Digital), and SDIO 4.0 (Secure Digital IO) devices. The MMCSD Host Controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The MMCSD Host Controller provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method. In programmed IO method, the device CPU transfers data using the Buffer Data Port register (MMCSD0_DATA_PORT / MMCSD1_DATA_PORT). In DMA data transfer method, the MMCSD Host Controller can read or write memory without device CPU intervention.

Copyright © 2023 Texas Instruments Incorporated

12.3.6.1.1 MMCSD Features

Each MMCSD Host Controller supports:

- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3 (for more information about ADMA support, see Section 12.3.6.3.5, *Advanced DMA*)
- System Bus Interface:
  - 64-bit data width (master interface)
  - 64-bit address
  - Clock asynchronous to MMCSD clock (MMCi_CLK)
  - Little endian only
- Configuration Bus Interface:
  - 32-bit data width (slave interface)
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
- Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level (MMCSD1 only)

MMCSD0 Host Controller (eMMC interface):

- MultiMedia Card Support:
  - eMMC Electrical Standard 5.1 (JESD84-B51)
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR:
    - 1.8 V, 8-bit bus width, 0-25 MHz, 25 MBps
    - 1.8 V, 4-bit bus width, 0-25 MHz, 12.5 MBps
    - 1.8 V, 1-bit bus width, 0-25 MHz, 3.125 MBps
  - High Speed SDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 50 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 25 MBps
    - 1.8 V, 1-bit bus width, 0-50 MHz, 6.25 MBps
  - High Speed DDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 100 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 50 MBps
  - HS200 SDR:
    - 1.8 V, 0-200 MHz, 8-bit bus width, 200 MBps
    - 1.8 V, 0-200 MHz, 4-bit bus width, 100 MBps
  - HS400 DDR:
    - 1.8 V, 0-200 MHz, 8-bit bus width, 400 MBps

MMCSD1 Host Controller (SD/SDIO interface):

-
- Secure Digital Card Support:
  - Backward compatible with earlier SD card specifications
  - SD Host Controller Standard Specification 4.10 and SD Physical Layer Specification v3.01
  - SDIO Specification v3.00
  - Default Speed mode: 3.3 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - High Speed mode: 3.3 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR12: UHS-I 1.8 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - SDR25: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR50: UHS-I 1.8 V signaling, frequency up to 100 MHz, up to 50 MBps
  - DDR50: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 50 MBps
  - SDR104: UHS-I 1.8 V signaling, frequency up to 200 MHz, up to 100 MBps

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.6.3 MMCSD Functional Description

12.3.6.3.1 Block Diagram

Figure 12-109 shows the MMCSDi module block diagram (where i = 0 to 1).

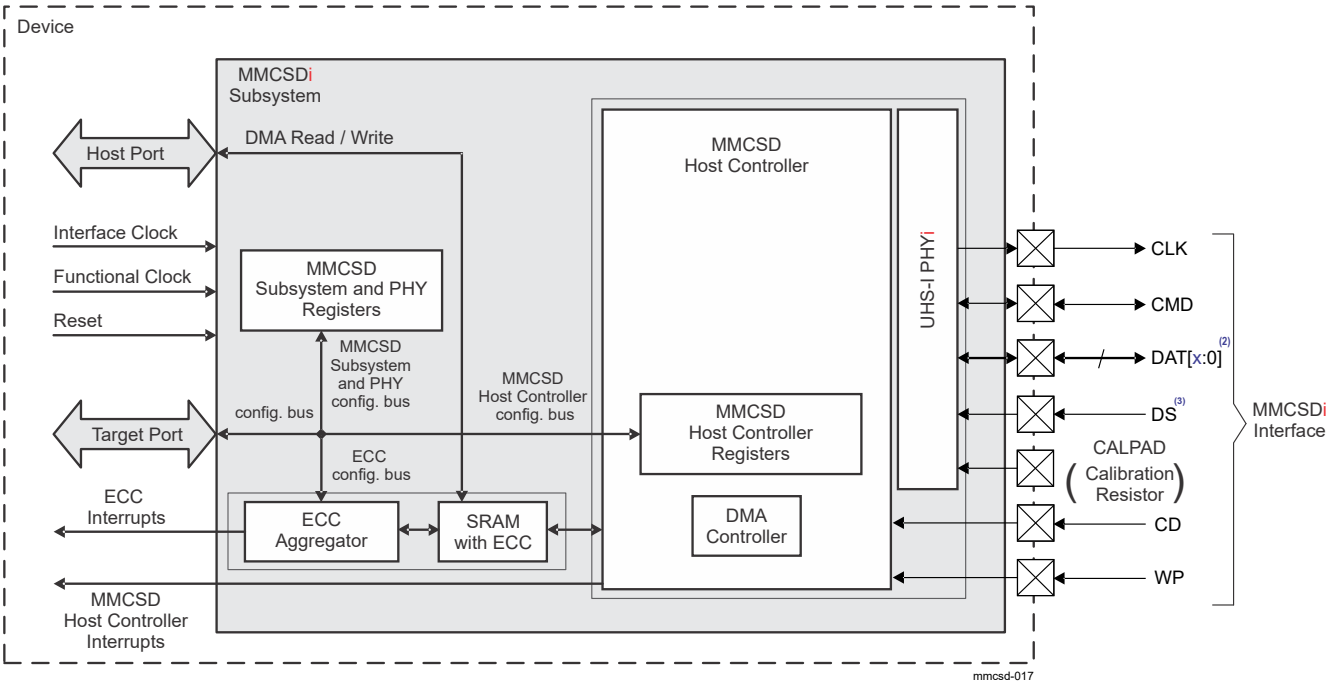

Figure 12-109. MMCSDi Module Block Diagram

Basic Blocks:

- MMCSD Host Controller: The MMCSD Host Controller is situated in the MMCSD Subsystem and provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method.
- UHS-I PHY: The integrated UHS-I PHY provides an interface between the MMCSD Host Controller and external MMC/SD/SDIO devices.
- MMCSDi Interface: The MMCSDi Interface includes all used interface pins (for more information, see *MMCSDi I/O Signals*).
- Host Port: Provides a 64-bit wide read/write interface between the device and the MMCSD Subsystem internal SRAM.
- Target Port: Provides a 32-bit wide interface between the device and the MMCSD Subsystem and MMCSD Host Controller parts.
- MMCSD Host Controller Registers: This block includes set of all MMCSD Host Controller registers.
- MMCSD Subsystem and PHY Registers: This block implements memory-mapped registers at the MMCSD Subsystem level and memory-mapped registers to control and program the MMCSD PHY.
- ECC Aggregator: The ECC Aggregator block facilitates aggregating and reporting internal SRAM ECC errors (for more information, see Section 12.3.6.3.4, *ECC Support*).
- Internal SRAM with ECC: The internal SRAM block is used for data storage during read/write transactions.
- DMA Controller: Manages the data transfer between the device memory and the MMCSD Subsystem internal SRAM.
- System Clocks: There are asynchronous relationship between the interface (system) clock and functional clock (for more information, see *MMCSD Clocks*).
- System Reset: The reset to the MMCSD Subsystem provides reset to the all MMCSD Subsystem parts (for more information, see *MMCSD Clocks*).
- Interrupts: The MMCSD Subsystem sources one MMCSD Host Controller interrupt and four ECC Aggregator interrupts (for more information, see *MMCSD Hardware Requests* and *Interrupt Requests*).

For more information about all MMCSD registers, see *MMCSD Registers*.

Copyright © 2023 Texas Instruments Incorporated

The MMCSD Host Controller can use a Programmed IO method (PIO) or DMA data transfer method to access external MMC/SD/SDIO devices.

The target port is used for device CPU access to the MMCSD Host Controller register set. The MMCSD Host Controller register set provides the communication between the device CPU and the MMCSD Host Controller. In PIO method the device CPU transfers data using the MMCSD0_DATA_PORT / MMCSD1_DATA_PORT register. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the target port, the MMCSD0_DATA_PORT / MMCSD1_DATA_PORT register in the MMCSD Host Controller, and the PHY.

The host port is used for connection to the DMA controller (for more information about ADMA support, see Section 12.3.6.3.5, *Advanced DMA* and MMCSD0_CAPABILITIES / MMCSD1_CAPABILITIES register). In DMA data transfer method the DMA controller uses the host port to transfer data between the device memory and the MMCSD Subsystem internal SRAM. The other side of the internal SRAM is connected to the MMCSD Host Controller. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the host port, internal SRAM, MMCSD Host Controller, and the PHY. The DMA controller manages the read/write operations from/to the internal SRAM without device CPU intervention.

12.3.6.3.2 Memory Regions

shows MMCSDi module memory map.

12.3.6.3.3 Interrupt Requests

Each MMCSD instance sources one active high level MMCSD Host Controller interrupt and four active high level ECC Aggregator interrupts (see *MMCSD Hardware Requests*). The MMCSD Host Controller interrupt is generated based on the bit values in the MMCSD0_NORMAL_INTR_STS / MMCSD1_NORMAL_INTR_STS and MMCSD0_NORMAL_INTR_STS_ENA / MMCSD1_NORMAL_INTR_STS_ENA registers. The ECC Aggregator interrupts are generated based on the ECC errors - single and double bit errors (for more information about ECC Aggregator interrupts, see Section 12.3.6.3.4, *ECC Support*).

12.3.6.3.4 ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

There are two SRAM memories (transmit SRAM and receive SRAM) within each MMCSD instance. These two memories are ECC protected.

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

12.3.6.3.4.1 ECC Aggregator

There are two SRAMs (each with size 4 KB - 512 words × 64-bit) in each MMCSD Subsystem. One SRAM dedicated for transmit and one SRAM dedicated for receive operations.

Figure 12-110 shows the ECC Aggregator block diagram.

Copyright © 2023 Texas Instruments Incorporated

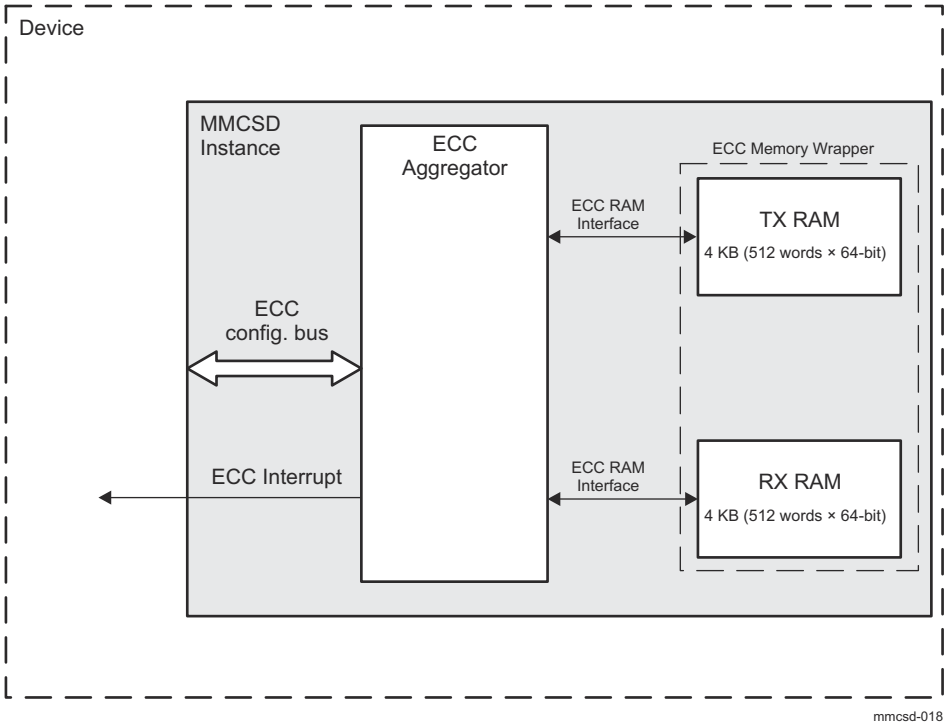

Figure 12-110. ECC Aggregator Block Diagram

Note

For more information about ECC Aggregator Registers, refer to *MMCSD Registers*.

12.3.6.3.5 Advanced DMA

The MMCSD modules support SD Advanced DMA – ADMA2 and ADMA3.

Note

For more information, refer to the SD Association specification titled *"SD Host Controller Simplified Specification, Part A2, Version 4.10"*.

12.3.6.4 MMCSD Programming Guide

12.3.6.4.1 Sequences

This section defines basic sequence flow chart divided into several sub sequences.

Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

Note

UHSII is not supported. For more information, see *Not Supported Features*.

"Wait for interrupts" is used in the flow chart. This means the Host Driver waits until specified interrupts are asserted. If already asserted, then fall through that step in the flow chart. Timeout checking shall be always required to detect no interrupt generated but this is not described in the flow chart.

This specification uses the double box like Figure 12-111, (the step (1) in Figure 12-115), it means that the other flows, which already are shown, shall be performed. Therefore, the interrupt may be included in the other flows.

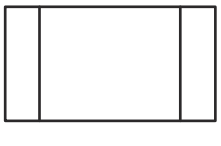

Figure 12-111. Double Box Notation

12.3.6.4.1.1 SD Card Detection

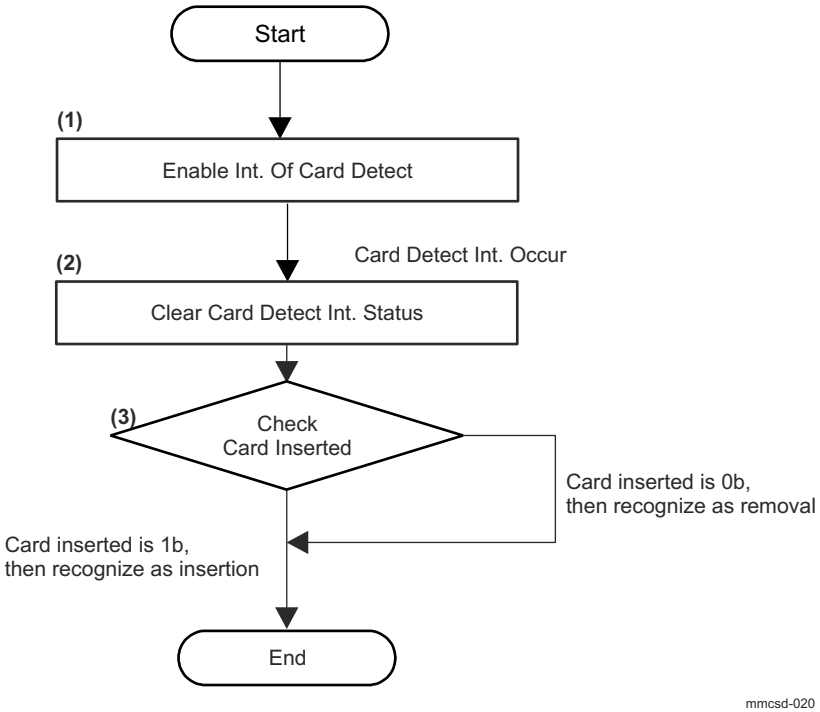

Figure 12-112. SD Card Detect Sequence

The flow chart for detecting a SD card is shown in Figure 12-112.

Each step is executed as follows:

To enable interrupt for card detection, write 1 to the following bits:

Copyright © 2023 Texas Instruments Incorporated

- MMCSD0_NORMAL_INTR_STS_ENA[6] CARD_INSERTION
- MMCSD0_NORMAL_INTR_SIG_ENA[6] CARD_INSERTION
- MMCSD0_NORMAL_INTR_STS_ENA[7] CARD_REMOVAL
- MMCSD0_NORMAL_INTR_SIG_ENA[7] CARD_REMOVAL

(1) When the Host Driver detects the card insertion or removal, clear its interrupt statuses. If Card Insertion interrupt is generated, write 1 to MMCSD0_NORMAL_INTR_STS_ENA[6] CARD_INSERTION bit. If Card Removal interrupt is generated, write 1 to MMCSD0_NORMAL_INTR_STS_ENA[7] CARD_REMOVAL bit.

(2) Check MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit. In the case where MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit is 1, the Host Driver can supply the power and the clock to the SD card. In the case where MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit is 0, the other executing processes of the Host Driver shall be immediately closed.

If miniSD adaptor is used for standard SD slot and miniSD card is inserted or extracted from the adaptor, card detect interrupt may not be generated. When host does not receive response to any commands, miniSD card is extracted or in idle state, the host should try to re-initialize the card. In this case, all card information shall be re-loaded.

12.3.6.4.1.2 SD Clock Control

12.3.6.4.1.2.1 Internal Clock Setup Sequence

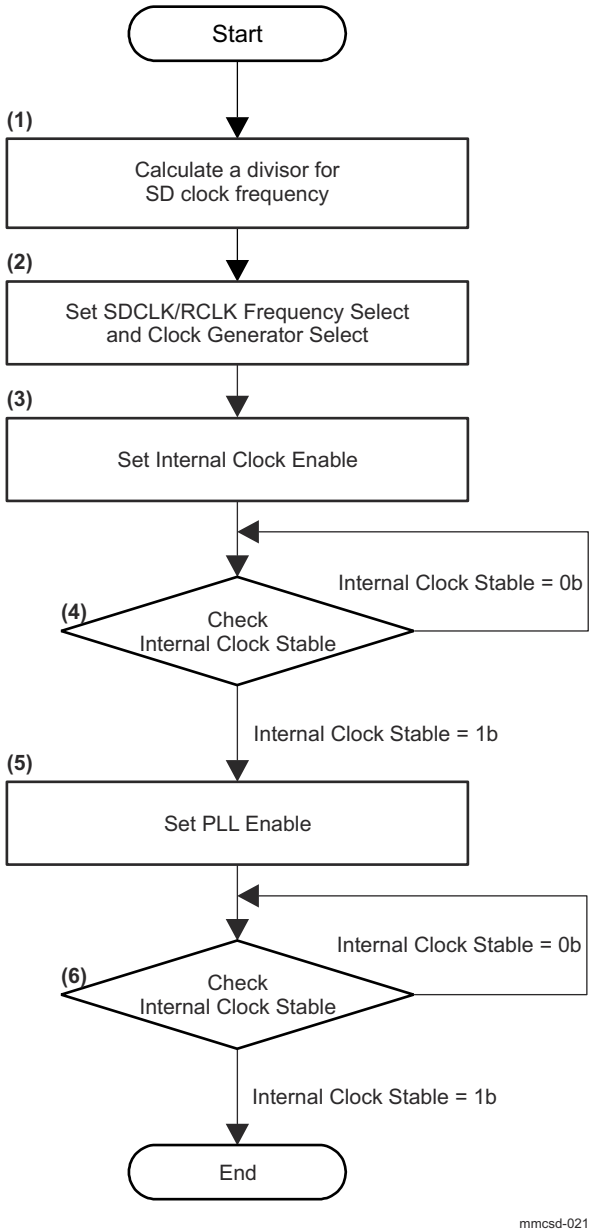

Figure 12-113. Internal Clock Setup Sequence

The sequence for supplying SD Clock to a SD card is described in Figure 12-113. From Version 4.10, MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is added. This sequence is also applicable to prior versions which do not support MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit.

(1) Calculate a divisor to determine SD Clock frequency for legacy IF or RCLK frequency for UHS-II IF by reading MMCSD0_CAPABILITIES[15-8] BASE_CLK_FREQ and MMCSD0_CAPABILITIES[55-48] CLOCK_MULTIPLIER bit fields. If non-zero value is set to MMCSD0_CAPABILITIES[55-48] CLOCK_MULTIPLIER bit field, Programmable Clock Mode can be used (for more information, see MMCSD0_CLOCK_CONTROL[5] CLKGEN_SEL bit). If MMCSD0_CAPABILITIES[15-8] BASE_CLK_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0_CLOCK_CONTROL[15-8] SDCLK_FRQSEL bit field and MMCSD0_CLOCK_CONTROL[5] CLKGEN_SEL bit in accordance with the calculated result of step (1).

Copyright © 2023 Texas Instruments Incorporated

If MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set, these bits are set by Host Controller automatically as specified in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10).

(3) Set MMCSD0_CLOCK_CONTROL[0] INT_CLK_ENA bit.

(4) Check MMCSD0_CLOCK_CONTROL[1] INT_CLK_STABLE bit. Repeat this step until this status is 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

(5) Set MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit. This step does not affect Host Controllers which do not support MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit.

(6) If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is supported, PLL locked may be checked by this status (if MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this status is supposed to indicate 1 by step (3)). Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

12.3.6.4.1.2.2 SD Clock Supply and Stop Sequence

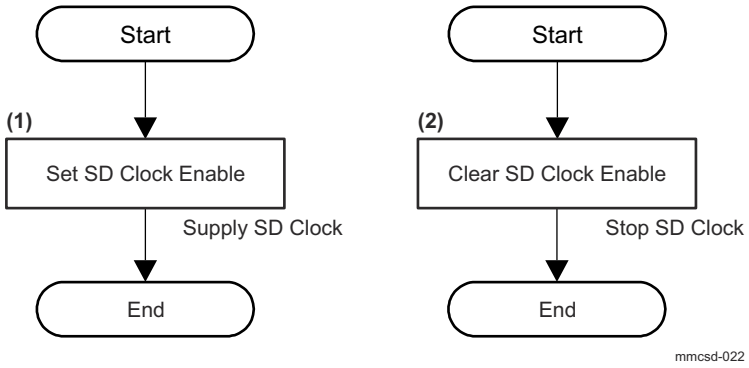

Figure 12-114. SD Clock Supply and Stop Sequence

The flow chart for stopping the SD Clock is shown in Figure 12-114. The Host Driver shall not stop the SD Clock when a SD transaction is occurring on the SD Bus -- namely, when either MMCSD0_PRESENTSTATE[1] INHIBIT_DAT or MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is set to 1.

(1) Setup Internal Clock (see Figure 12-113). Then set MMCSD0_CLOCK_CONTROL[2] SD_CLK_ENA bit to 1. Then, the Host Controller starts supplying the SD Clock.

(2) Set MMCSD0_CLOCK_CONTROL[2] SD_CLK_ENA bit to 0. Then, the Host Controller stops supplying the SD Clock. Internal Clock is still oscillating.

Copyright © 2023 Texas Instruments Incorporated

12.3.6.4.1.2.3 SD Clock Frequency Change Sequence

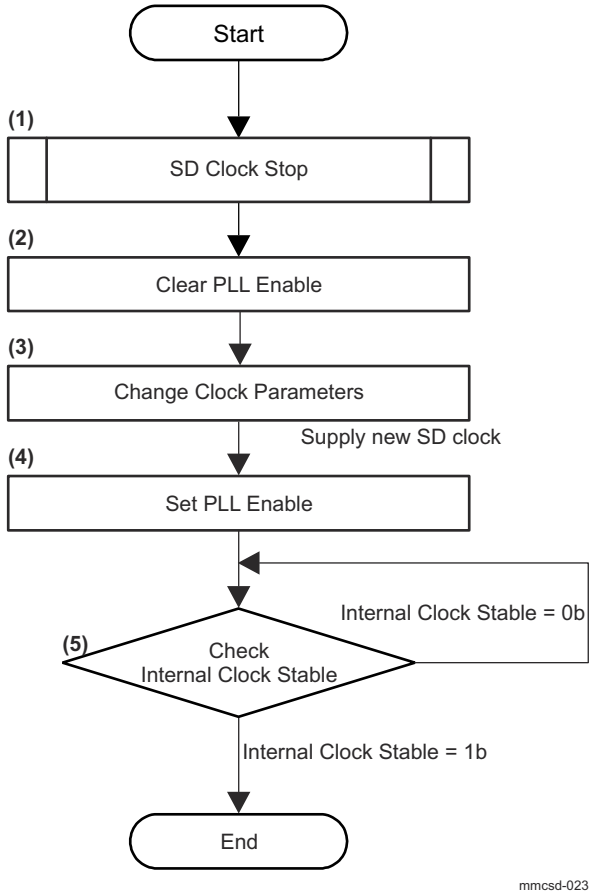

Figure 12-115. SD Clock Change Sequence

The sequence for changing SD Clock frequency is shown in Figure 12-115.

(1) Execute the SD Clock Stop Sequence (see Figure 12-114). If SD Clock supply to card is already stopped, skip this step.

(2) Clear MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit to 0. If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this step has no effect and may be skipped.

(3) When MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set to 0, change clock parameters in the MMCSD0_CLOCK_CONTROL register. When MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set to 1, select Bus Speed Mode as described.

(4) Set MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit to 1. If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this step this step has no effect and may be skipped.

(5) Wait until MMCSD0_CLOCK_CONTROL[1] INT_CLK_STABLE bit is set to 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms. SD Clock Supply Sequence is required to provide clock to device (see Figure 12-114).

12.3.6.4.1.3 SD Bus Power Control

The sequence for controlling the SD Bus Power is described in Figure 12-116.

Copyright © 2023 Texas Instruments Incorporated

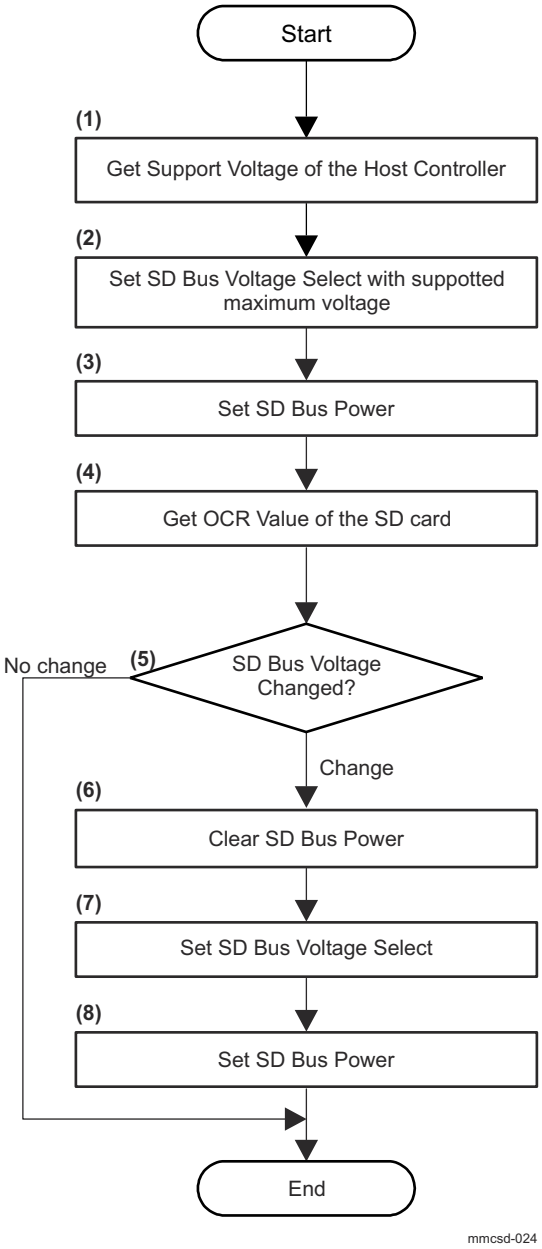

Figure 12-116. SD Bus Power Control Sequence

(1) By reading the MMCSD0_CAPABILITIES register, get the support voltage of the Host Controller.

(2) Set MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field with maximum voltage that the Host Controller supports.

(3) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit to 1.

(4) Get the OCR value of all function internal of SD card.

(5) Judge whether SD Bus voltage needs to be changed or not. In case where SD Bus voltage needs to be changed, go to step (6). In case where SD Bus voltage does not need to be changed, go to "End".

(6) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit to 0 for clearing this bit. The card requires voltage rising from 0 volt to detect it correctly. The Host Driver shall clear MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit before changing voltage by setting MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field.

(7) Set MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field.

Copyright © 2023 Texas Instruments Incorporated

(8) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER to 1.

Note: Step (2) and step (3) can be executed at same time. And also, step (7) and step (8) can be executed at same time.

12.3.6.4.1.4 Changing Bus Width

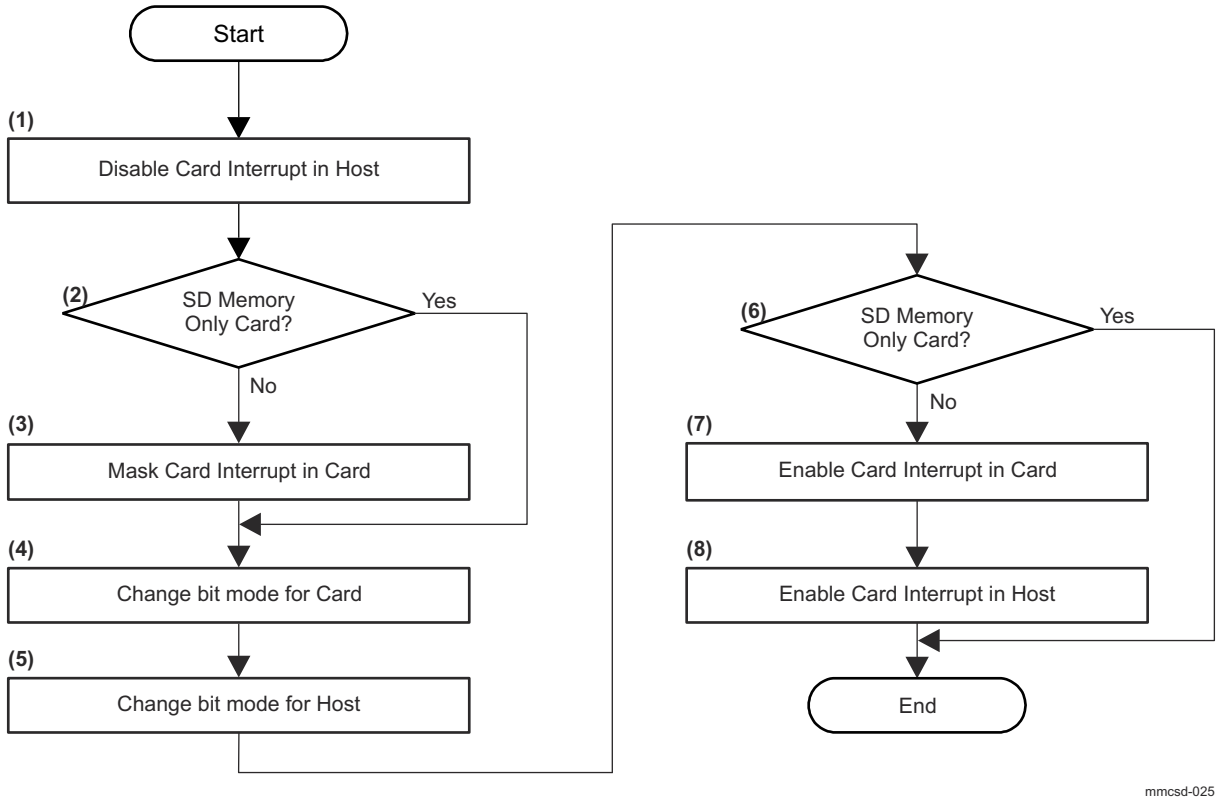

Figure 12-117. Change Bus Width Sequence

The sequence for changing bit mode on SD Bus is shown in Figure 12-117.

(1) Set MMCSD0_NORMAL_INTR_STS_ENA[8] CARD_INTERRUPT bit to 0 for masking incorrect interrupts that may occur while changing the bus width.

(2) In case of SD memory only card, go to step (4). In case of other card, go to step (3).

(3) Set "IENM" of the CCCR in a SDIO or SD combo card to 0 by CMD52.

(4) Change the bus width mode for a SD card. SD Memory Card bus width is changed by ACMD6 and SDIO card bus width is changed by setting Bus Width of Bus Interface Control register in CCCR.

(5) In case of changing to 4-bit mode, set MMCSD0_HOST_CONTROL1[1] DATA_WIDTH bit to 1. In another case (1-bit mode), set this bit to 0.

(6) In case of SD memory only card, go to the "End". In case of other card, go to step (7).

(7) Set "IENM" of the CCCR in a SDIO or SD combo card to 1 by CMD52.

(8) Set MMCSD0_NORMAL_INTR_STS_ENA[8] CARD_INTERRUPT bit to 1.

Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

Copyright © 2023 Texas Instruments Incorporated

12.3.6.4.1.5 Timeout Setting on DAT Line

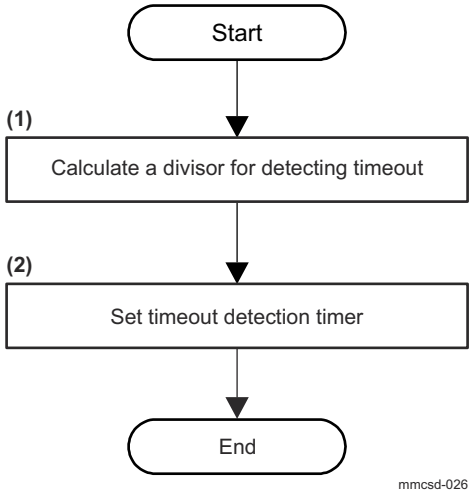

Figure 12-118. Timeout Setting Sequence

In order to detect timeout errors on DAT line, the Host Driver shall execute the following two steps before any SD transaction. For more information regarding SD transactions:

(1) Calculate a divisor to detect timeout errors by reading MMCSD0_CAPABILITIES[5-0] TIMEOUT_CLK_FREQ bit field and MMCSD0_CAPABILITIES[7] TIMEOUT_CLK_UNIT bit. If MMCSD0_CAPABILITIES[5-0] TIMEOUT_CLK_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit field in accordance with the value from step (1) above.

12.3.6.4.1.6 Card Initialization and Identification (for SD I/F)

Figure 12-119 and Figure 12-120 shows initialization and card identification sequence for the Standard Capacity SD Memory Card (SDSC), the High Capacity SD Memory Card (SDHC) and the Extended Capacity SD Memory Card (SDXC) that was based on the Physical Layer Version 3.01. Refer to the latest sequence.

Copyright © 2023 Texas Instruments Incorporated

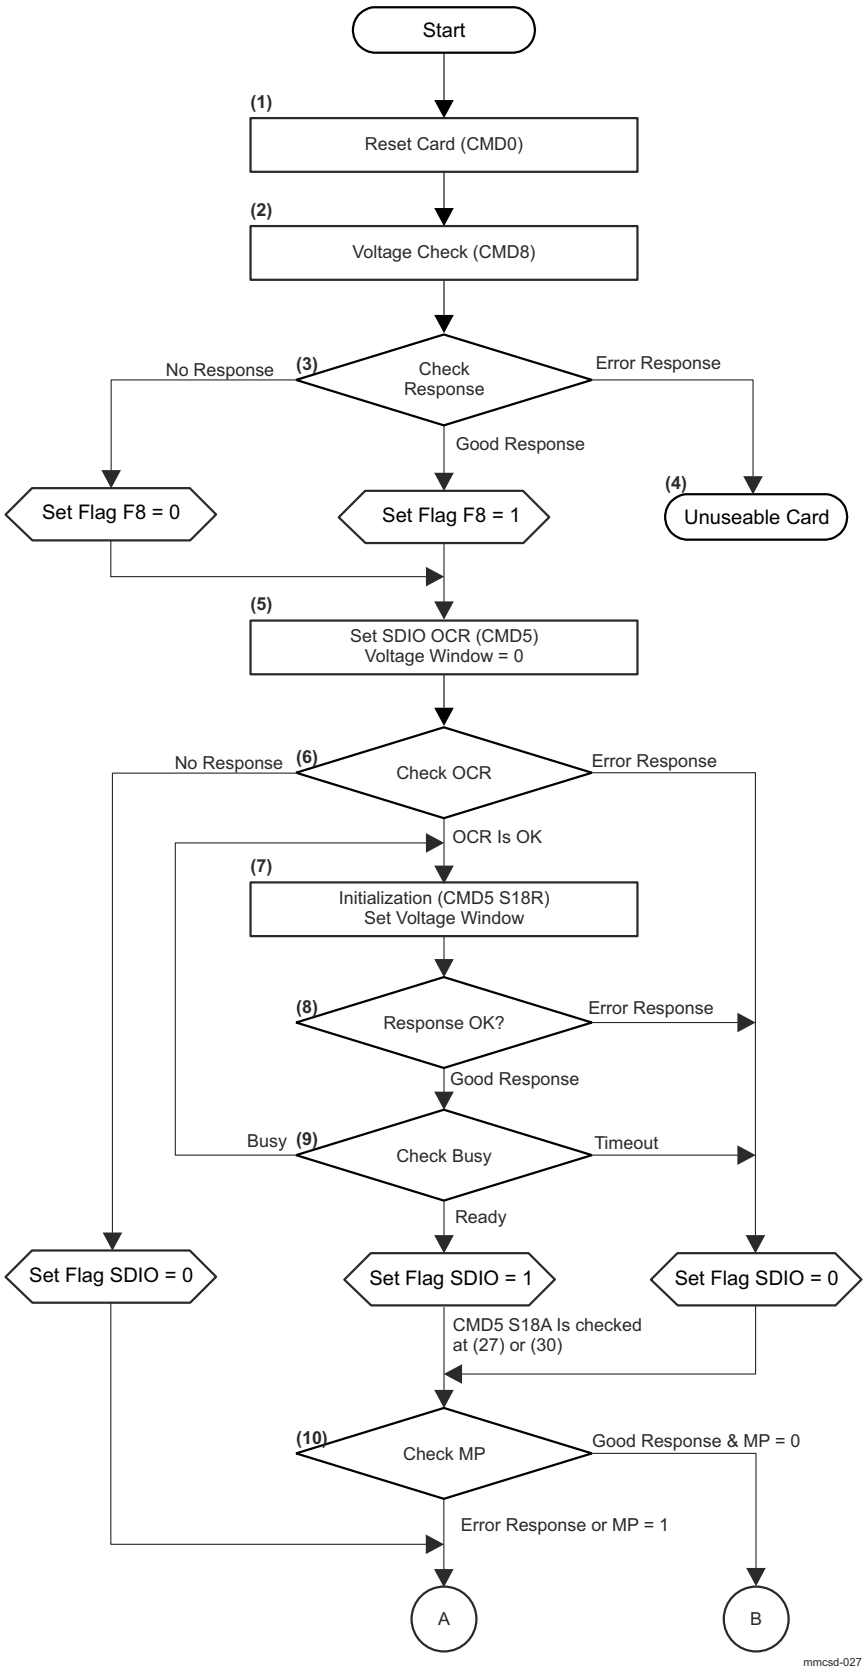

Figure 12-119. Card Initialization and Identification (1)

Copyright © 2023 Texas Instruments Incorporated

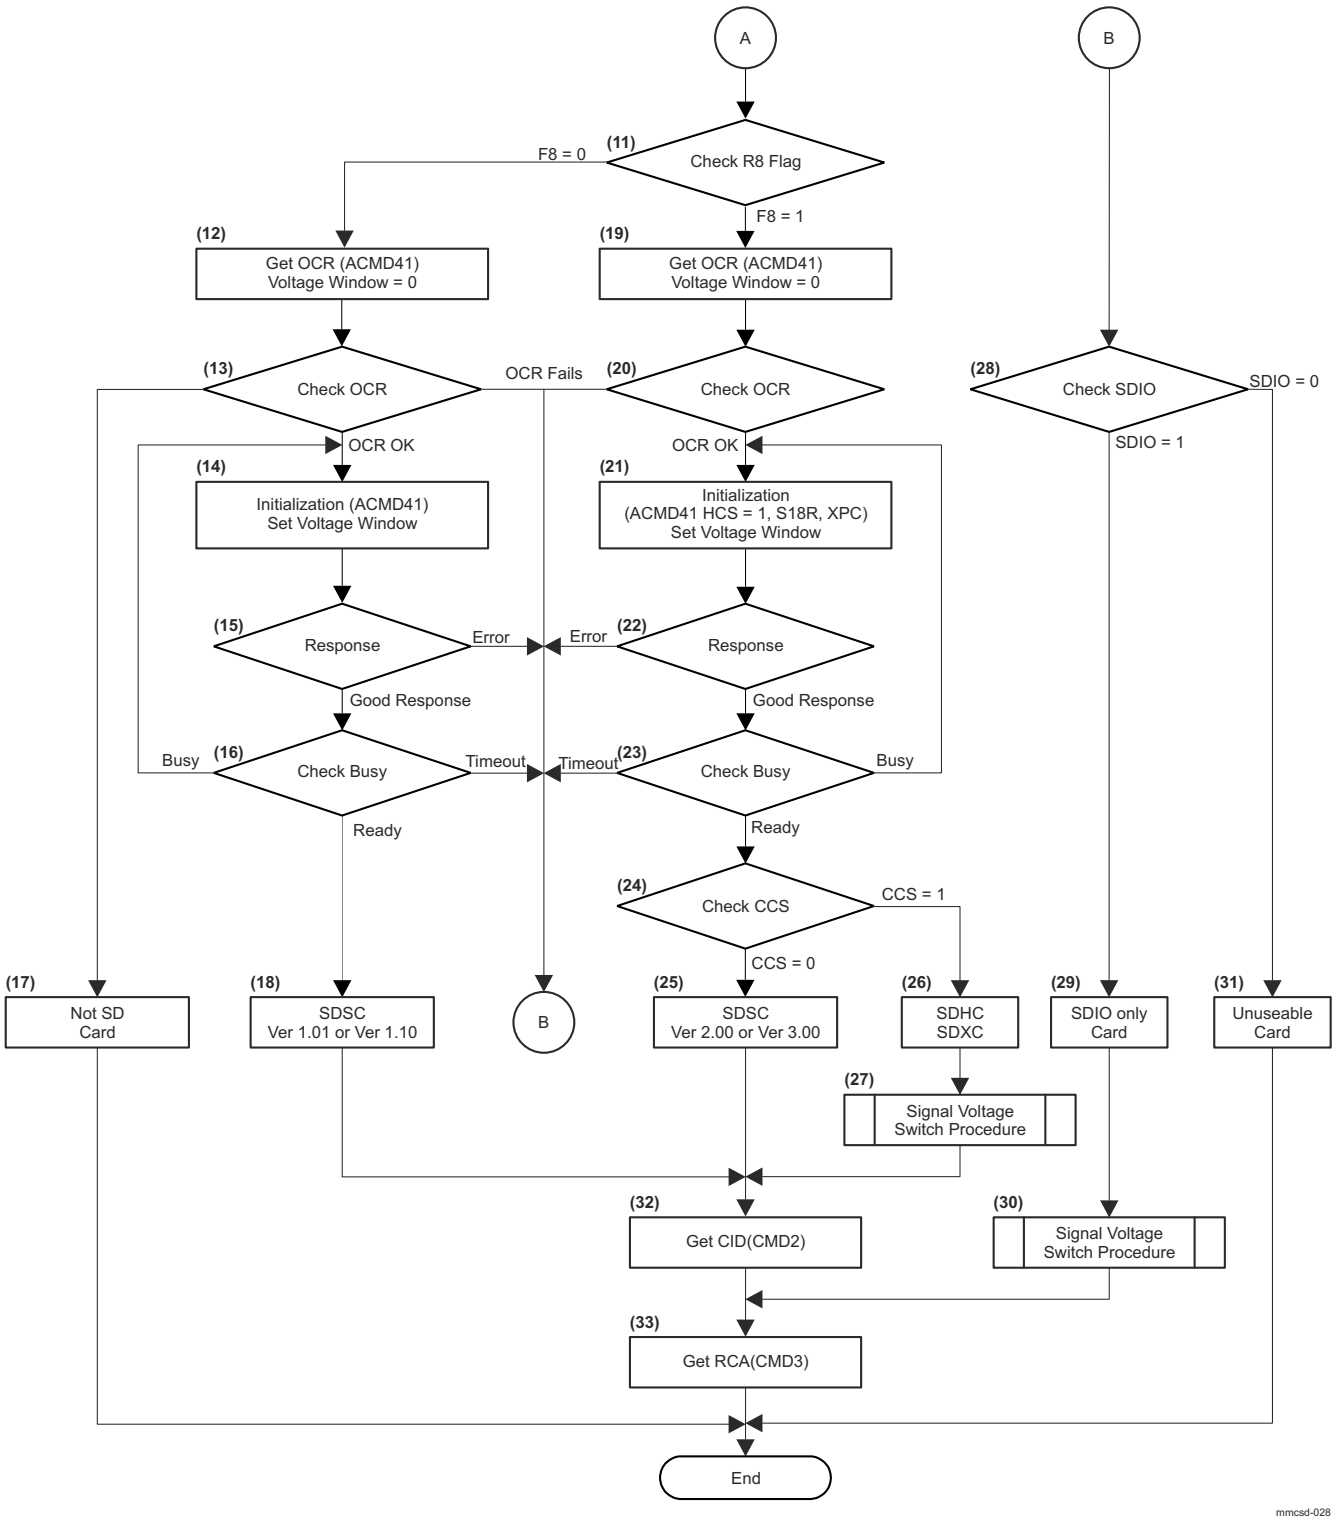

Figure 12-120. Card Initialization and Identification (2)

(1) SD Bus mode is selected by CMD0 (Keep Pin 1 to high during CMD0 execution).

(2) New CMD8 shall be issued after CMD0 to support High Capacity SD Memory Card.

(3) Voltage check command enables the Hosts to support future low voltage specification. However, at this time, only one voltage is defined. Legacy cards and Not SD cards do not respond to CMD8. In this case, set F8 to 0 (F8 is CMD8 valid flag used in step (11)) and go to Step (5). Only Version 2.00 or higher cards can respond to CMD8. The host needs to check whether CRC of the response is valid and whether VHS and check pattern in

Copyright © 2023 Texas Instruments Incorporated

the argument are equal to VCA and check pattern in the response. Passing all these checks results in CMD8 response OK. In this case, set F8 to 1 and go to step (5). If one of the checks is failed, go to step (4).

(4) Initialization is stopped by CMD8 fails. The Host Driver should retry step (1) to (3) one more time (this is not described in the figure).

(5) SDIO OCR is available by issuing CMD5 with setting voltage window (bit 23 to 0) in the argument to 0. SDIO initialization is not started.

(6) No response means the card does not have SDIO function. Set SDIO flag to 0 and go to step (11). If the card responds to CMD5 and the response is OK, go to step (7). If the response is error, set SDIO flag to 0 and go to step (10). SDIO flag indicates whether SDIO functions are initialized or not.

(7) The SDIO portion starts initialization by CMD5 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(8) If no response or error response is receive, set SDIO flag to 0 and go to step (10). If good response is received, go to step (9).

(9) Check busy status in the response. If busy is released, set SDIO flag to 1 and go to step (10). Repeat from step (7) while busy is indicated. Detecting timeout of 1 second exits the loop. In this case, set SDIO flag to 0 and go to step (10).

(10) Good response in this step means that all responses received at (6) and (8) are valid. When response is good, MP (memory present) flag in the response can be checked. If the response valid and MP = 0, go to step (28). Otherwise, go to step (11).

(11) Check F8 flag set in step (3). If CMD8 is executed correctly (F8 = 1), go to step (19). Otherwise, go to step (12).

(12) OCR is available by issuing ACMD41 with the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. The response of CMD55 (ACMD41) may indicate illegal command error due to some SD cards do not recognized CMD8. The Host Driver should ignore this error or issue CMD0 before ACMD41 to clear this error status.

(13) If response of CMD55 is not received, the card is not SD cards and goes to (17). If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (14). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(14) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(15) If no response or error response is received, go to step (28). If good response is received, go to step (16).

(16) Check busy status in the response. If busy is released, go to step (18). Repeat from step (14) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(17) The host recognizes that the card is not SD memory card and quits SD card initialization.

(18) The host recognizes that the card is Version 1.xx Standard Capacity SD Memory Card. Go to Step (30).

(19) OCR is available by issuing ACMD41 with setting the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. Setting of HCS does not affect this operation.

(20) If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (21). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(21) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to1. If the host can supply more than 150mA, XPC is set to 1. HCS in the argument is set to 1, which indicates supporting High Capacity Memory Card. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

Copyright © 2023 Texas Instruments Incorporated

(22) If no response or error response is received, go to step (28). If good response is received, go to step (23).

(23) Check busy status in the response. If busy is released, go to step (24). Repeat from step (21) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(24) CCS in the response is valid after busy is released. If CCS = 0, it indicates the Standard Capacity SD Memory Card and go to step (25). If CCS = 1, it indicates the High Capacity SD Memory Card or Extended Capacity Memory Card and go to Step (26).

(25) The host recognizes that the card is Ver2.00 or Ver3.00 Standard Capacity SD Memory Card. Optimal functions defined in Version 2.00 or higher are available. Go to Step (32).

(26) The host recognizes that the card is the High Capacity SD Memory Card or Extended Capacity Memory Card.

(27) Perform the signal voltage switch procedure and go to step (32).

(28) Check SDIO flag. If SDIO = 1, go to step (28). Otherwise, go to step (31).

(29) The host recognizes that the card is SDIO only card and go to step (30).

(30) Perform the signal voltage switch procedure and go to step (33).

(31) The host recognizes that the card is unusable.

(32) In case of memory card, CMD2 is issued to get CID and Go to Step (31).

(33) CMD3 is issued to get RCA. If the RCA number is 0, the Host should issue CMD3 again.

Copyright © 2023 Texas Instruments Incorporated

12.3.6.4.1.6.1 Signal Voltage Switch Procedure (for UHS-I)

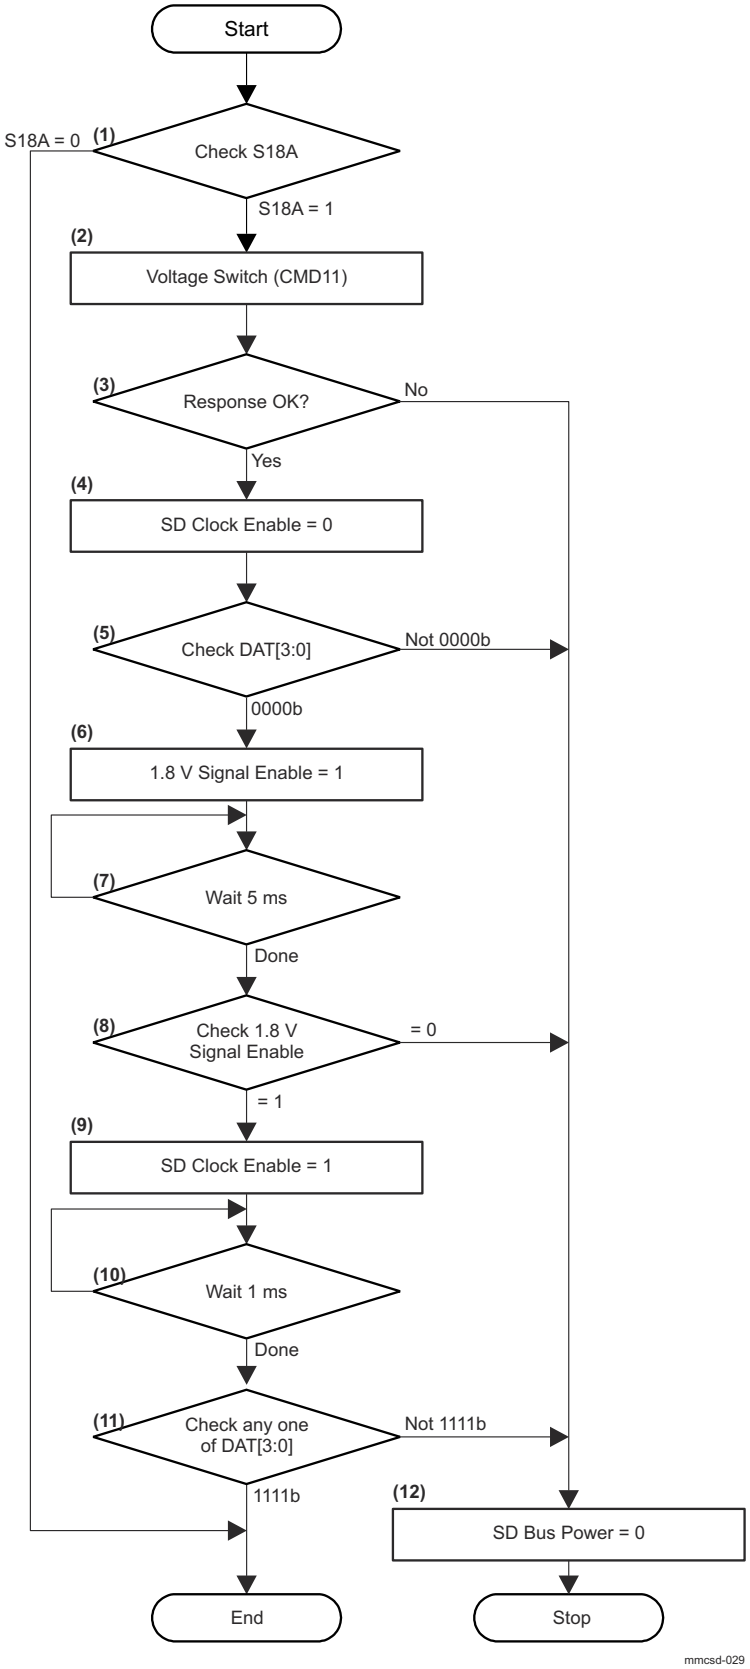

Figure 12-121. Signal Voltage Switch Procedure

Copyright © 2023 Texas Instruments Incorporated

(1) If S18A of CMD5 or S18A of ACMD41 is set to 1, signal voltage switch is performed according to the following steps. Otherwise, exits from this procedure.

(2) Issue CMD11.

(3) Check response and if an error is detected, go to step (12).

(4) Stop providing SD clock to the card.

(5) Check DAT[3:0] level. If the level is 0000b, the card is ready to start voltage switch sequence. Otherwise, go to (12) to quit the sequence.

(6) Set MMCSD0_HOST_CONTROL2[3] V1P8_SIGNAL_ENA bit.

(7) Wait 5 ms. 1.8 V voltage regulator shall be stable within this period.

(8) If MMCSD0_HOST_CONTROL2[3] V1P8_SIGNAL_ENA bit is cleared by Host Controller, go to step (12).

(9) Provide SD Clock to the card again.

(10) Wait 1 ms.

(11) Check DAT[3:0] level. If the level is 1111b, switch to 1.8 V signal level is completed successfully. Otherwise, go to (12).

(12) If an error occurs during voltage switch procedure, stop providing the power to the card. In this case, Host Driver should retry initialization procedure by setting S18R to 0 at step (7) and (21) in Figure 12-119 and Figure 12-120.

12.3.6.4.1.7 SD Transaction Generation

This section describes the sequences how to generate and control various kinds of SD transactions. SD transactions are classified into three cases:

(1) Transactions that do not use the DAT line.

(2) Transactions that use the DAT line only for the busy signal.

(3) Transactions that use the DAT line for transferring data.

In this specification the first and the second case's transactions are classified as "Transaction Control without Data Transfer using DAT Line", the third case's transaction is classified as "Transaction Control with Data Transfer using DAT Line". Refer to the latest SD Physical Layer Specification and SDIO Specification for more detail about SD commands specification.

12.3.6.4.1.7.1 Transaction Control without Data Transfer Using DAT Line

In this section, the sequence for how to issue SD Command and how to complete SD Command is explained. Figure 12-122 shows the sequence to issue a SD Command and Figure 12-123 shows the sequence to finalize a SD Command.

12.3.6.4.1.7.1.1 The Sequence to Issue a SD Command

The sequence to issue the SD Command is detailed in Figure 12-122.

Copyright © 2023 Texas Instruments Incorporated

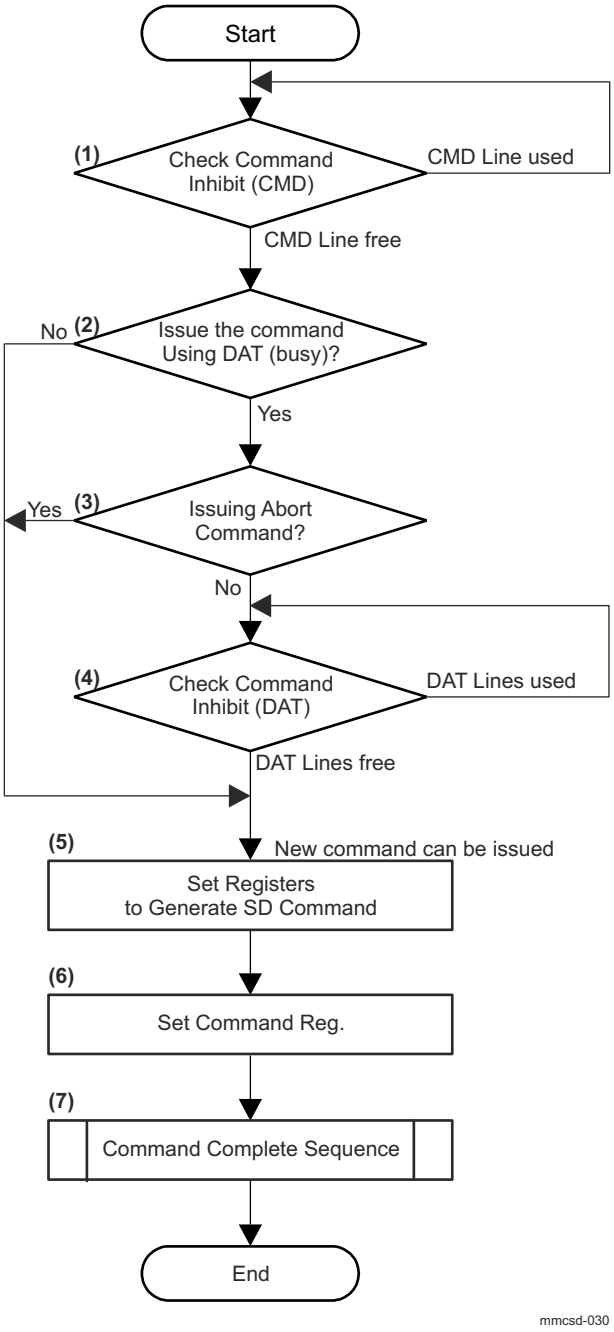

Figure 12-122. SD Command Issue Sequence

(1) Check MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit. Repeat this step until MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is 0. That is, when MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is 1, the Host Driver shall not issue a SD Command.

(2) If the Host Driver issues a SD Command using DAT lines including busy signal, go to step (3). If without using DAT lines including busy signal, go to step (5).

(3) If the Host Driver is issuing an abort command, go to step (5). In the case of nonabort command, go to step (4).

(4) Check MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit. Repeat this step until MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit is set to 0.

(5) Set registers except the MMCSD0_COMMAND register.

Copyright © 2023 Texas Instruments Incorporated

(6) Set the MMCSD0_COMMAND register.

Note: Writing the upper byte [3] in the MMCSD0_COMMAND register causes the Host Controller to issue a SD command to the SD card.

(7) Perform Command Completion Sequence in accordance.

12.3.6.4.1.7.1.2 The Sequence to Finalize a Command

Figure 12-123 shows the sequence to finalize a SD Command when response check is disabled. There is a possibility that some errors (Command Index/End bit/CRC/Timeout Error) occur during this sequence. If response check is enabled, error is indicated by Response Error Interrupt.

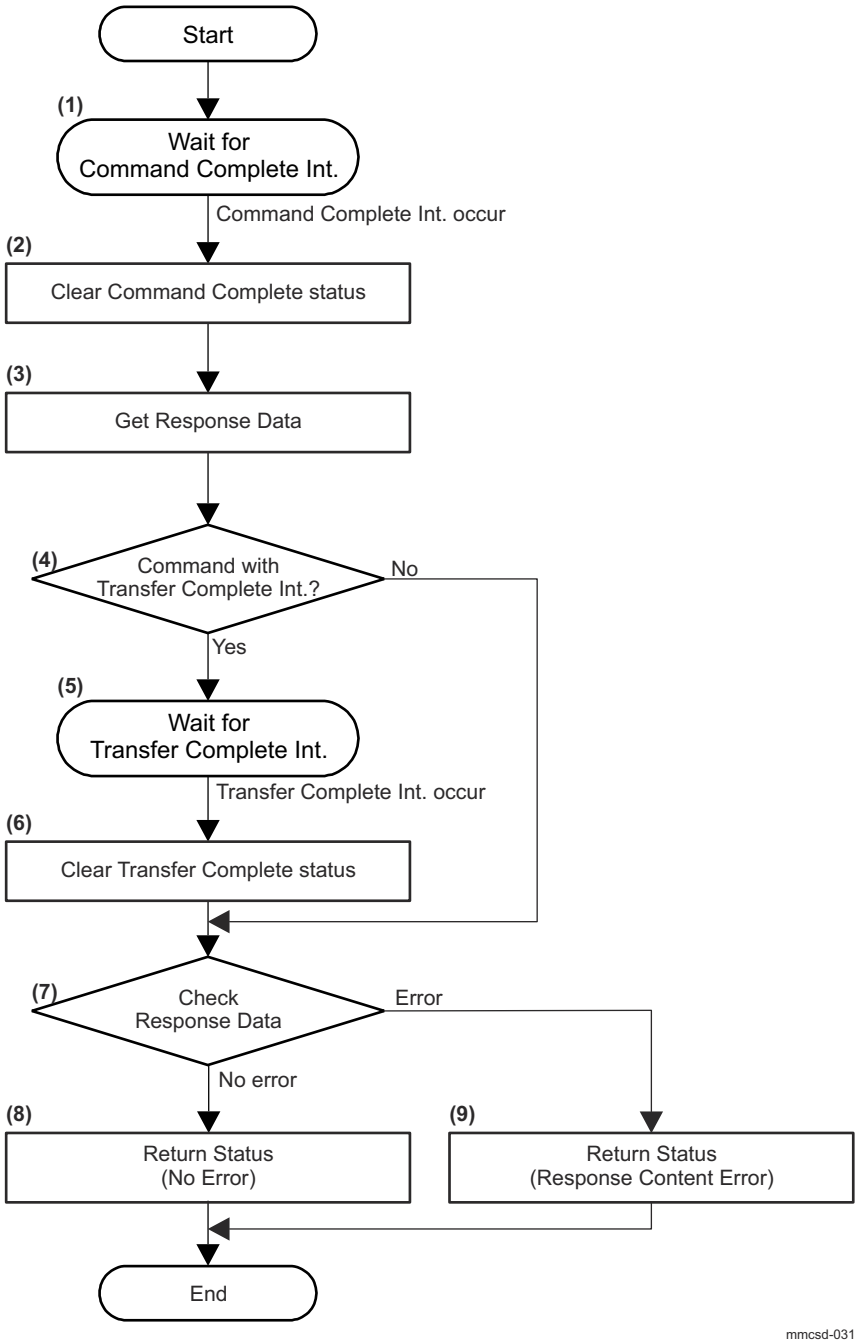

Figure 12-123. Command Complete Sequence

Copyright © 2023 Texas Instruments Incorporated

(1) If MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit is set to 1 (response check is enabled), go to stop (4) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE). If the Command Complete Interrupt has occurred, go to step (2).

(2) Write 1 to MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(3) Read the Response register (see MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(4) Judge whether the command uses the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) or not. If it uses Transfer Complete, go to step (5). If not, go to step (7).

(5) Wait for the Transfer Complete Interrupt. If the Transfer Complete Interrupt has occurred, go to step (6).

(6) Write 1 to MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to clear this bit.

(7) Check for errors in Response Data (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7). If there is no error, go to step (8). If there is an error, go to step (9).

(8) Return Status of "No Error".

(9) Return Status of "Response Contents Error".

Note1: While waiting for the Transfer Complete interrupt, the Host Driver shall only issue commands that do not use the busy signal.

Note2: The Host Driver shall judge the Auto CMD12 complete by monitoring Transfer Complete.

Note3: When the last block of un-protected area is read using memory multiple block read command (CMD18), OUT_OF_RANGE error may occur even if the sequence is correct. The Host Driver should ignore it. This error will appear in the response of Auto CMD12 or in the response of the next memory command.

12.3.6.4.1.7.2 Transaction Control with Data Transfer Using DAT Line

Depending on whether DMA (optional) is used or not, there are two execution methods.

In addition, the sequences for SD transfers are classified into following three kinds according to how the number of blocks is specified:

(1) Single Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified is always one.

(2) Multiple Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified shall be one or more.

(3) Infinite Block Transfer: The number of blocks is not specified to the Host Controller before the transfer. This transfer is continued until an abort transaction is executed. This abort transaction is performed by CMD12 in the case of a SD memory card and by CMD52 in the case of a SDIO card.

12.3.6.4.1.7.2.1 Not using DMA

The sequence for not using DMA is shown in Figure 12-124.

Copyright © 2023 Texas Instruments Incorporated

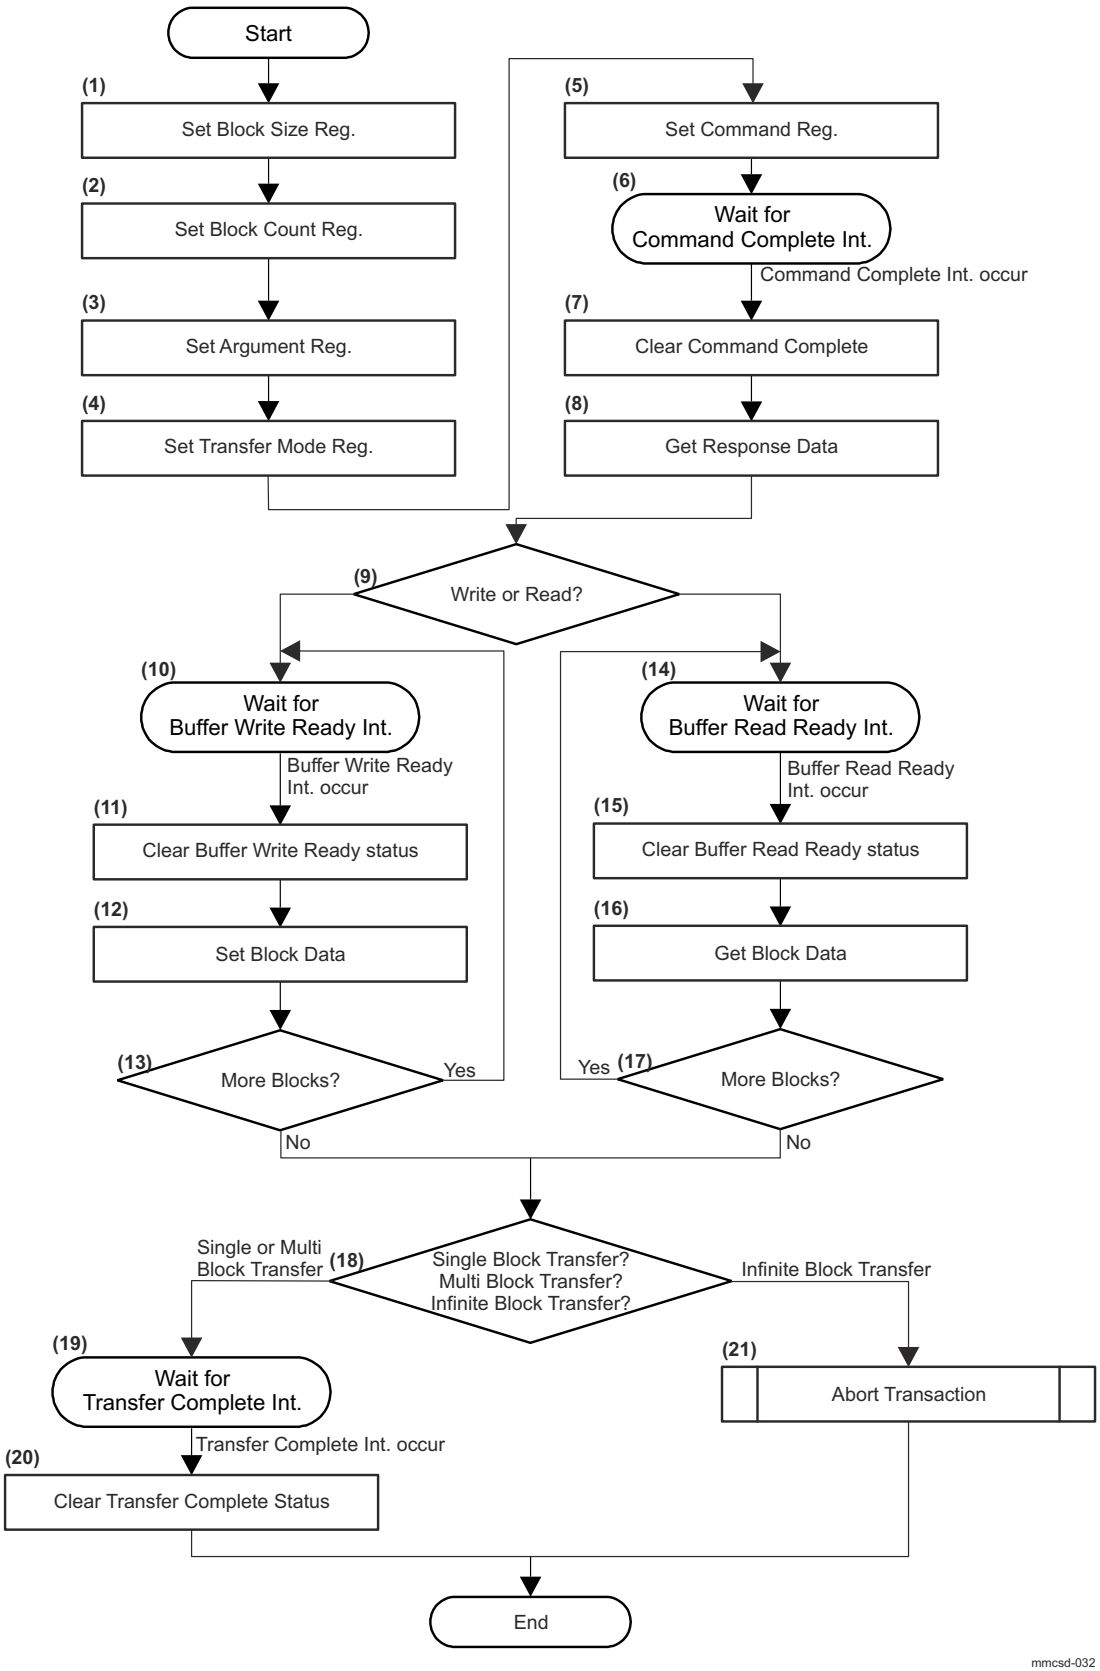

Figure 12-124. Transaction Control with Data Transfer Using DAT Line Sequence (Not using DMA)

(1) Set the value corresponding to the executed data byte length of one block to the MMCSD0_BLOCK_SIZE register.

Copyright © 2023 Texas Instruments Incorporated

(2) Set the value corresponding to the executed data block count to the MMCSD0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.

(3) Set the argument value to Argument register (MMCSD0_ARGUMENT1_LO and MMCSD0_ARGUMENT1_HI).

(4) Set the value to the MMCSD0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*.

If response check is enabled (MMCSD0_TRANSFER_MODE[7] RESP_ERR_CHK_ENA = 1), set MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5 (MMCSD0_TRANSFER_MODE[6] RESP_TYPE).

(5) Set the value to MMCSD0_COMMAND register.

Note: When writing the upper byte [3] of MMCSD0_COMMAND register, SD command is issued.

(6) If response check is enabled, go to stop (9) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).

(7) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit for clearing this bit.

(8) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(9) In the case where this sequence is for write to a card, go to step (10). In case of read from a card, go to step (14).

(10) Then wait for Buffer Write Ready Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[4] BUF_WR_READY).

(11) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[4] BUF_WR_READY bit for clearing this bit.

(12) Write block data (in according to the number of bytes specified at the step (1)) to MMCSD0_DATA_PORT register.

(13) Repeat until all blocks are sent and then go to step (18).

(14) Then wait for the Buffer Read Ready Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[5] BUF_RD_READY).

(15) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[5] BUF_RD_READY bit for clearing this bit.

(16) Read block data (in according to the number of bytes specified at the step (1)) from the MMCSD0_DATA_PORT register.

(17) Repeat until all blocks are received and then go to step (18).

(18) If this sequence is for Single or Multiple Block Transfer, go to step (19). In case of Infinite Block Transfer, go to step (21).

(19) Wait for Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).

(20) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit for clearing this bit.

(21) Perform the sequence for Abort Transaction in accordance with Section 12.3.6.4.1.8, *Abort Transaction*.

Note: Step (1) and Step (2) can be executed at same time. Step (4) and Step (5) can be executed at same time.

12.3.6.4.1.7.2.2 Using SDMA

The sequence for using SDMA is shown in Figure 12-125.

Copyright © 2023 Texas Instruments Incorporated

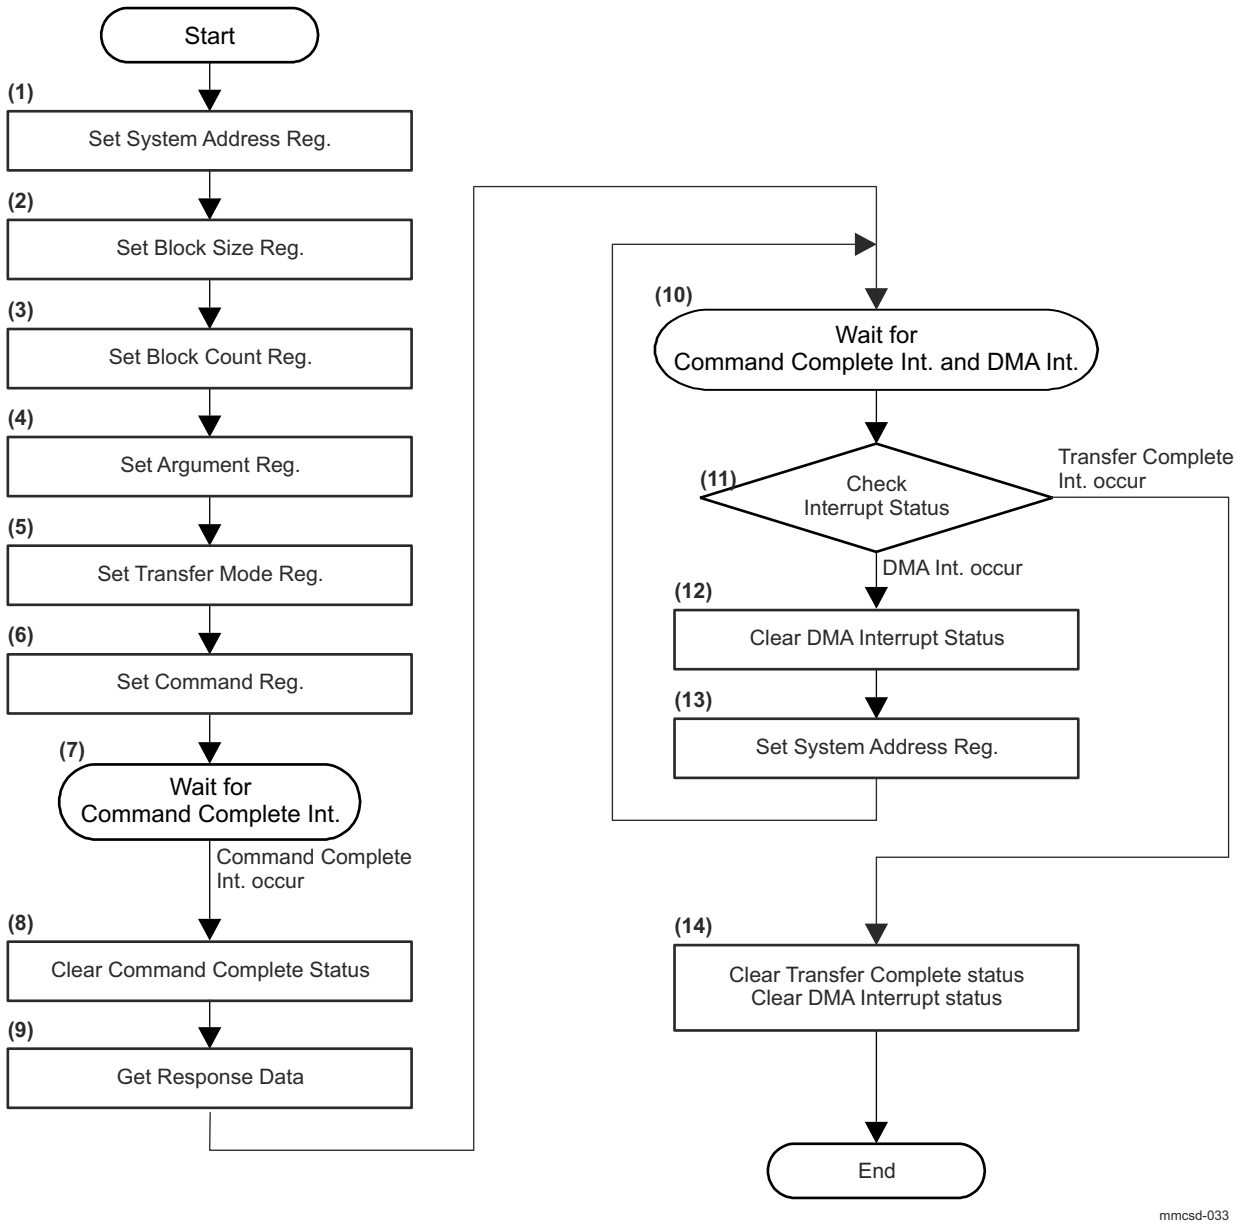

Figure 12-125. Transaction Control with Data Transfer Using DAT Line Sequence (Using SDMA)

(1) Data location of system memory is set to the SDMA System Address register if MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA = 0 or set to the MMCSD0_ADMA_SYS_ADDRESS register if MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA = 1.

(2) Set the value corresponding to the executed data byte length of one block in the MMCSD0_BLOCK_SIZE register.

(3) Set the value corresponding to the executed data block count in the MMCSD0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.

(4) Set the argument value to the Argument register (MMCSD0_ARGUMENT1_LO and MMCSD0_ARGUMENT1_HI).

(5) Set the value to the MMCSD0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCSD0_TRANSFER_MODE[7]

Copyright © 2023 Texas Instruments Incorporated

RESP_ERR_CHK_ENA = 1), set MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5.

(6) Set the value to the MMCSD0_COMMAND register.

Note: When writing to the upper byte [3] of the MMCSD0_COMMAND register, the SD command is issued and SDMA is started.

(7) If response check is enabled, go to stop (10) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).

(8) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(9) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(10) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) and DMA Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT).

(11) If MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is set to 1, go to Step (14) else if MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit is set to 1, go to Step (12). The MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is higher priority than the MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit.

(12) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit to clear this bit.

(13) Set the next system address of the next data position to the System Address register (MMCSD0_ADMA_SYS_ADDRESS) and go to Step (10).

(14) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit and MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit to clear this bit.

Note: Step (2) and Step (3) can be executed simultaneously. Step (5) and Step (6) can also be executed simultaneously.

12.3.6.4.1.7.2.3 Using ADMA

The sequence for using ADMA is shown in Figure 12-126.

Copyright © 2023 Texas Instruments Incorporated

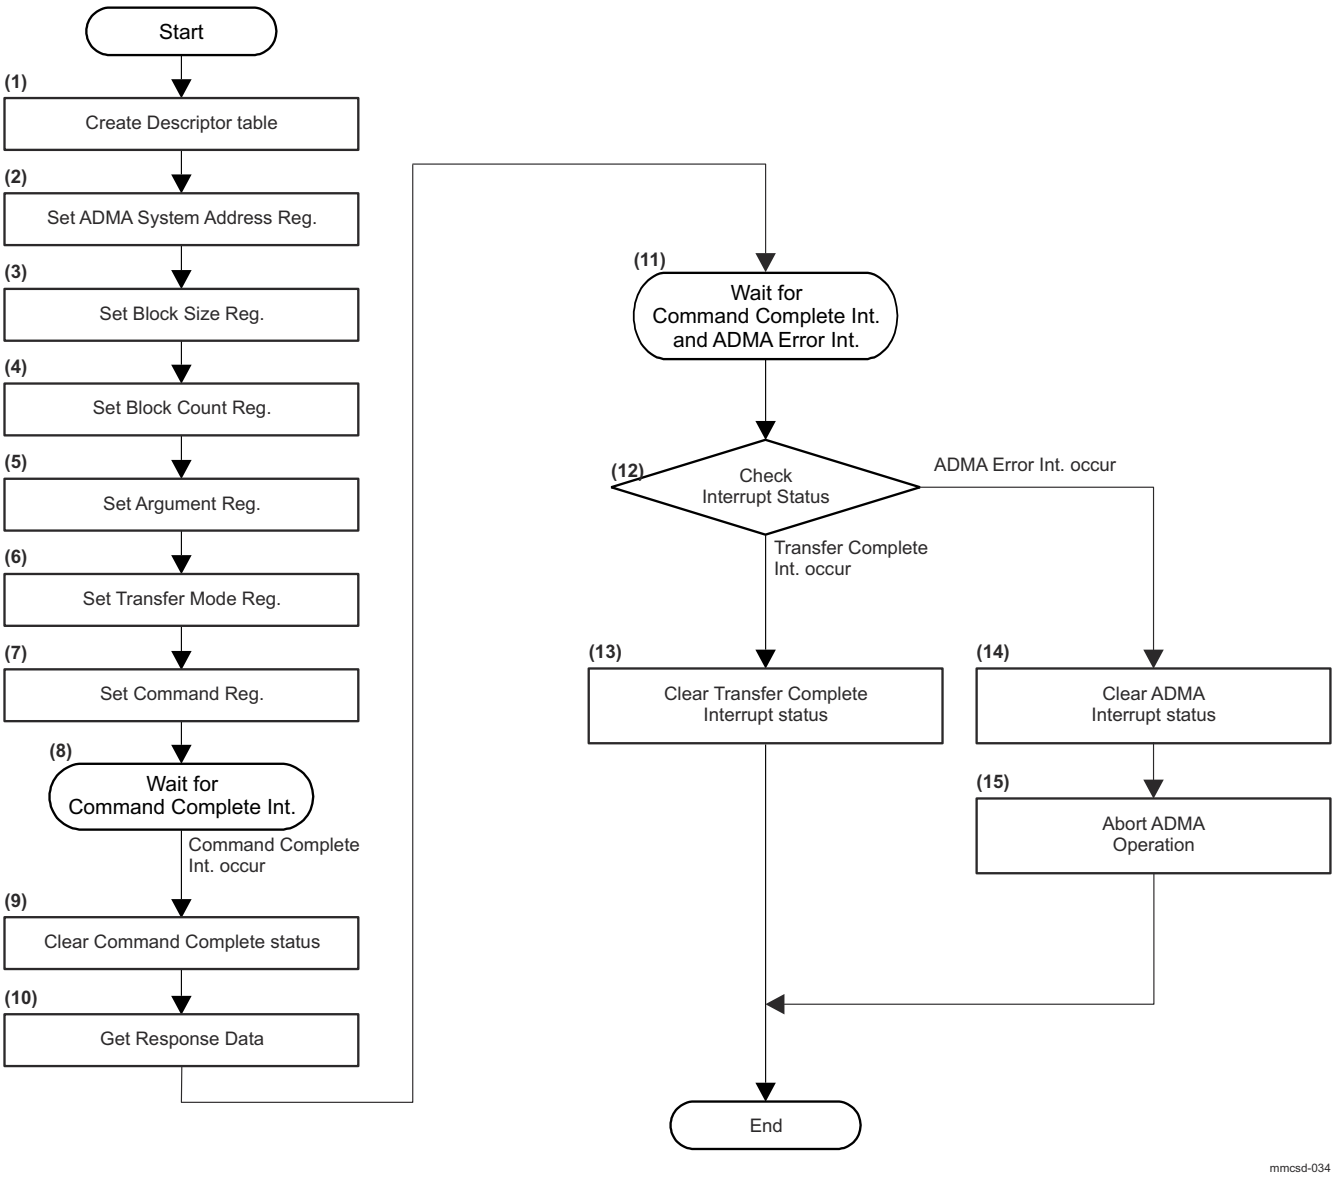

Figure 12-126. Transaction Control with Data Transfer Using DAT Line Sequence (Using ADMA)

(1) Create Descriptor table for ADMA in the system memory.

(2) Set the Descriptor address for ADMA in the MMCSD0_ADMA_SYS_ADDRESS register.

(3) Set the value corresponding to the executed data byte length of one block in the MMCSD0_BLOCK_SIZE register.

(4) Set the value corresponding to the executed data block count in the MMCSD0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.

(5) Set the argument value to the Argument register (MMCSD0_ARGUMENT1_LO and MMCSD0_ARGUMENT1_HI).

(6) Set the value to the MMCSD0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCSD0_TRANSFER_MODE[7] RESP_ERR_CHK_ENA = 1), set MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5 (MMCSD0_TRANSFER_MODE[6] RESP_TYPE).

(7) Set the value to the MMCSD0_COMMAND register.

Copyright © 2023 Texas Instruments Incorporated

Note: When writing to the upper byte [3] of the MMCSD0_COMMAND register, the SD command is issued and DMA is started.

(8) If response check is enabled, go to stop (11) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).

(9) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(10) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(11) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) and ADMA Error Interrupt (MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE).

(12) If MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is set to 1, go to Step (13) else if MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE bit field is set to 1, go to Step (14).

(13) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to clear this bit.

(14) Write 1 to the MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE bit field to clear this bit.

(15) Abort ADMA operation. SD card operation should be stopped by issuing abort command. If necessary, the Host Driver checks MMCSD0_ADMA_ERR_STATUS register to detect why ADMA error is generated.

Note: Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

12.3.6.4.1.8 Abort Transaction

An abort transaction is performed by issuing CMD12 for a SD memory card and by issuing CMD52 for a SDIO card. There are two cases where the Host Driver needs to do an Abort Transaction. The first case is when the Host Driver stops Infinite Block Transfers. The second case is when the Host Driver stops transfers while a Multiple Block Transfer is executing.

There are two ways to issue an Abort Command. The first is an asynchronous abort. The second is a synchronous abort. In an asynchronous abort sequence, the Host Driver can issue an Abort Command at any time unless MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is set to 1. In a synchronous abort, the Host Driver shall issue an Abort Command after the data transfer stopped by using MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

12.3.6.4.1.8.1 Asynchronous Abort

The sequence for Asynchronous Abort is shown in Figure 12-127.

Copyright © 2023 Texas Instruments Incorporated

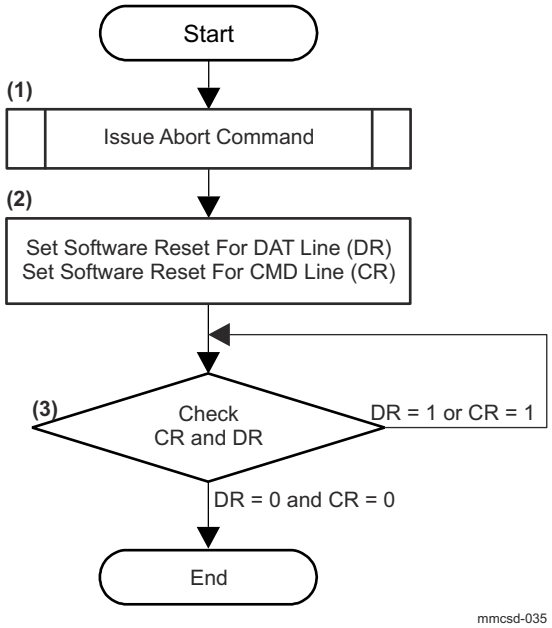

Figure 12-127. Asynchronous Abort Sequence

(1) Issue Abort Command in accordance.

(2) Set both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 to do software reset.

(3) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit are 0, go to "End". If either MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit or MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 1, go to step (3).

12.3.6.4.1.8.2 Synchronous Abort

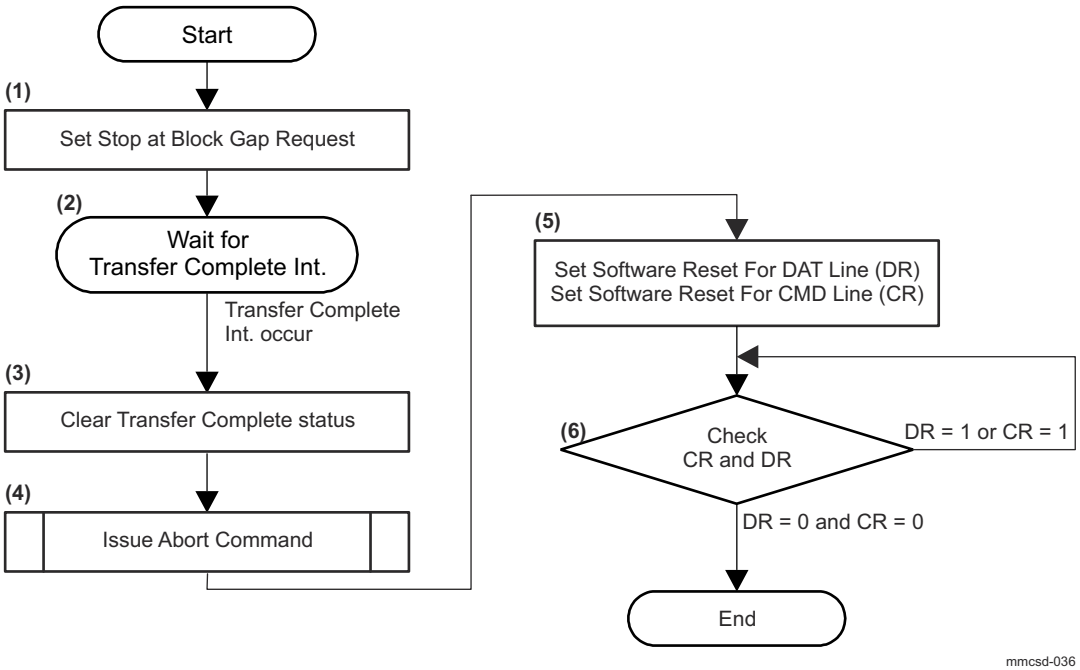

Figure 12-128. Synchronous Abort Sequence

Copyright © 2023 Texas Instruments Incorporated

(1) Set the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 1 to stop SD transactions.

(2) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).

(3) Set the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to 1 to clear this bit.

(4) Issue the Abort Command

(5) Set both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 to do software reset.

(6) Check both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit are 0, go to "End". If either MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit or MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 1, go to step (6).

12.3.6.4.1.9 Changing Bus Speed Mode

This section describes the sequence for switching the bus speed mode: Default Speed, High Speed mode and UHS-I mode. The switch command (CMD6) is used to change memory card bus speed mode. The EHS bit (SDIO Version 2.00) or BSS[2-0] bits (SDIO Version 3.00) in the CCCR register is used to change the bus speed mode for SDIO card. In case of Combo card, either of the switch method changes both memory and IO bus speed mode. This means the first switch is effective. Refer to the Physical Layer Specification Version 3.0x and the SDIO Specification Version 3.00 for more information about switching bus speed. Figure 12-129 shows the sequence for switching bus speed mode for Combo Card. Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

Copyright © 2023 Texas Instruments Incorporated

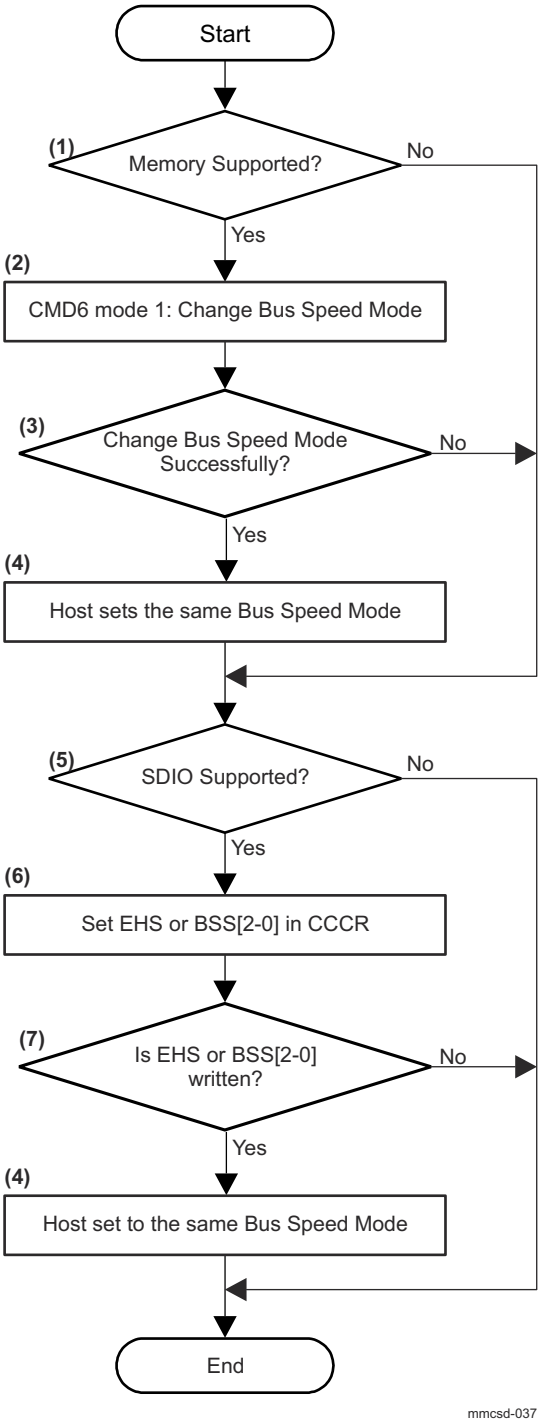

Figure 12-129. Changing Bus Speed Mode

(1) The Host Driver checks if the card supports memory. If not supported, go to (5).

(2) Issue CMD6 with mode 1 to change bus speed mode (Default, High Speed mode or UHS-I mode).

(3) Check the response of CMD6. If the card does not supports CMD6 (no response) or bus speed is not changed successfully, go to step (5). In this case, the card is in Default Speed mode.

(4) The Host Driver changes the Host Controller bus speed mode to the same mode.

(5) The Host Driver checks if the card supports SDIO. If not supported, go to the end.

Copyright © 2023 Texas Instruments Incorporated

(6) Issue CMD52 to write EHS bit or BSS[2-0] bits in CCCR to change bus speed mode (the same bus speed mode of (2) shall be set).

(7) If EHS or BSS[2-0] are not changed successfully, go to the end.

(8) The Host Driver changes the Host Controller bus speed to the same mode. In case of Combo card, bus speed is already changed at step (4) and this step does not affect changing bus speed.

12.3.6.4.1.10 Error Recovery

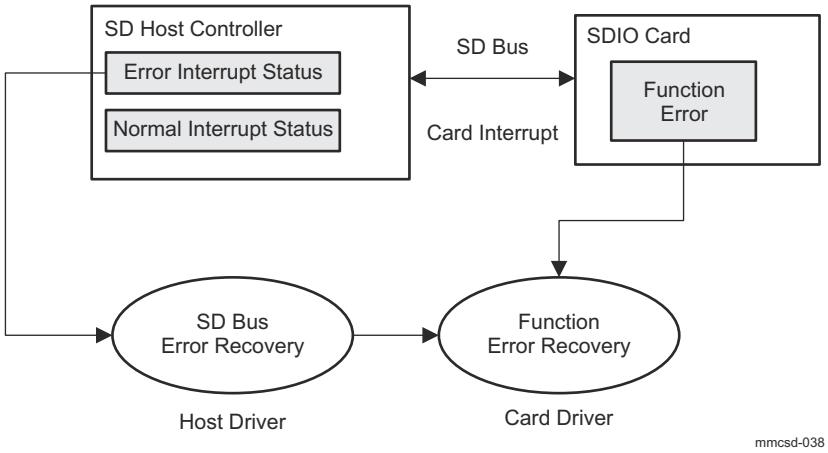

Figure 12-130. Error Report and Recovery

Figure 12-130 shows concept of error report and its recovery. The Host Controller has 2 interrupt status registers. If an error occurs in the SD Bus transaction, one of the bits is set in the MMCSD0_ERROR_INTR_STS register. If the function errors occur in the SDIO card, the card interrupt informs these function errors and the Card interrupt is set in the MMCSD0_NORMAL_INTR_STS_ENA register (the Card Interrupt is used to inform not only error statuses but also normal information. For example, to inform function ready). The Card Driver shall do function error recovery because the Host Driver does not know how to control the function. In the case that function error occurs due to SD Bus error, SD Bus error recovery is required before function error recovery. Abort command is used to recover SD Bus, and then the Host Driver should save error statuses related to SD Bus errors before issuing abort command and transfer these statuses to the Card Driver. These statuses may be used to recover function error. Following explanations are related to SD Bus error recovery. This specification does not specify the function error recovery.

When an error occurs during data transfer in 2L-HD UHS-II mode, there will be the case that Host Controller cannot drive D0 lane in input mode due to DIR LSS for retrieving lane direction is not detected. In this case, Host Driver cannot issue abort command for recovery. Then if DIR LSS is not detected, Host Controller sets MMCSD0_UHS2_ERR_INTR_STS[17] DEADLOCK_TIMEOUT bit. Host Driver should execute power cycle if MMCSD0_UHS2_ERR_INTR_STS[17] DEADLOCK_TIMEOUT bit is detected to recover from this error. Furthermore, if this type of error is detected several times in 2L-HD, Host Driver should use FD mode rather than using 2L-HD.

Implementation Note:

If the Card Driver cannot recover the function errors, the Host Driver should try following methods.

(9) Using IOEx for SDIO card

IOEx may be used as the reset per function basis. Sequence is as follows:

Clear IOEx = 0 and wait until IORx = 0 and then set IOEx = 1 again. SDIO may be recovered when IORx = 1.

(10) Using reset command for memory and SDIO card Re-initialization sequence is required.

(11) Off and on power supply for the SD Bus.

The card may be recovered by the power on reset. Re-initialization sequence is required.

The two cases where the Host Driver needs the "Error Recovery" sequence are classified as follows:

Copyright © 2023 Texas Instruments Incorporated

(1) Error Interrupt Recovery:

If error interrupt is indicated by the MMCSD0_ERROR_INTR_STS register, the Host Driver shall apply this sequence.

(2) Auto CMD12 Error Recovery:

If there are errors in Auto CMD12, the Host Driver shall apply this sequence. In terms of Return Status, Auto CMD12 Error Recovery is classified into 4 cases. It is shown in Figure 12-131. If error occurs during memory write transfer, strongly recommend using ACMD22 and then in the following recovery sequence, retry to send remaining blocks not written.

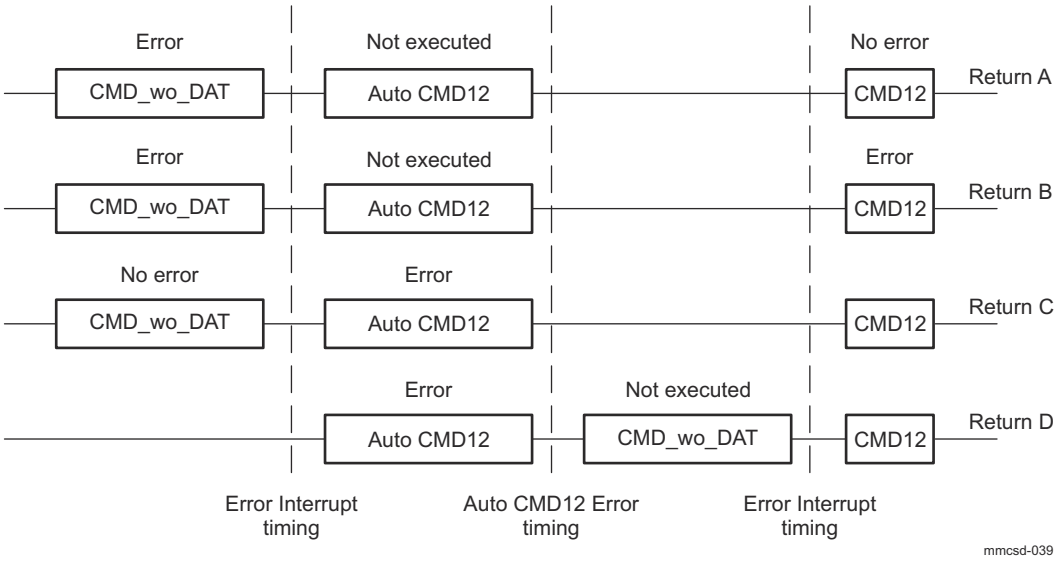

Figure 12-131. Return Status of Auto CMD12 Error Recovery

Implementation Note:

Abort command is used to recover from SD Bus error. SDIO transaction abort using CMD52 returns response but in the case of memory transaction abort using CMD12, response returns depending on the memory card state. If no response returns after issue CMD12, the Host Driver should check card state using CMD13. If the state is "tran" in the CURRENT_STATE, consider CMD12 is successful.

Implementation Note:

The following sequence is one possible error recovery flow. There may be another methods, sometimes using interrupts or polling. It can be possible to use another flows, based on Host System requirements.

In these error recovery sequences, return statuses for the next sequence. When the Host Controller cannot issue the next command due to SD Bus error, the error recovery sequences return "Non-recoverable" status. In this case, the Host System may cut off power to the SD Bus and then power on SD Bus and initialize both the Host Controller and the SD card again.

12.3.6.4.1.10.1 Error Interrupt Recovery

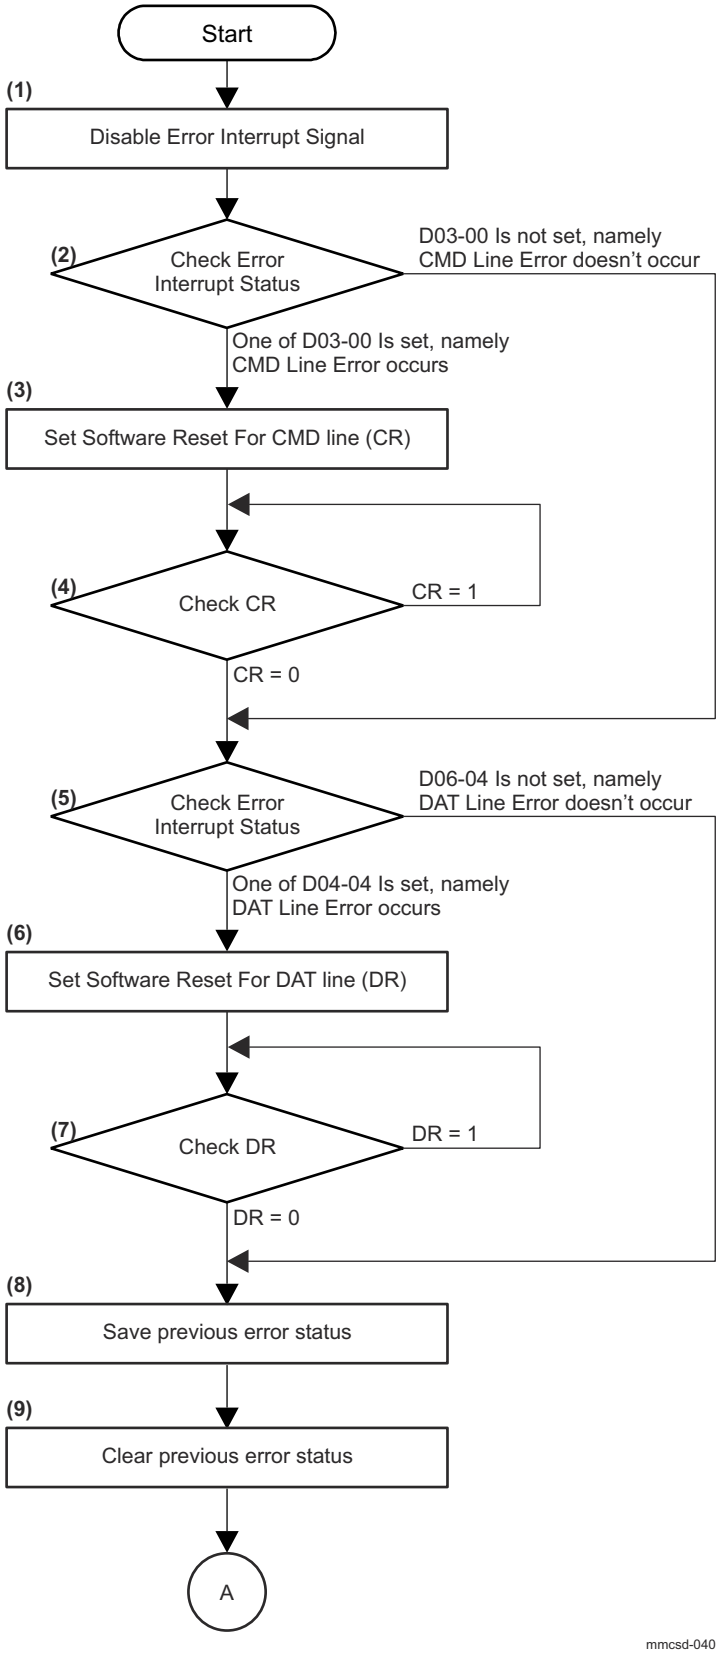

Figure 12-132. Error Interrupt Recovery Sequence (1)

Copyright © 2023 Texas Instruments Incorporated

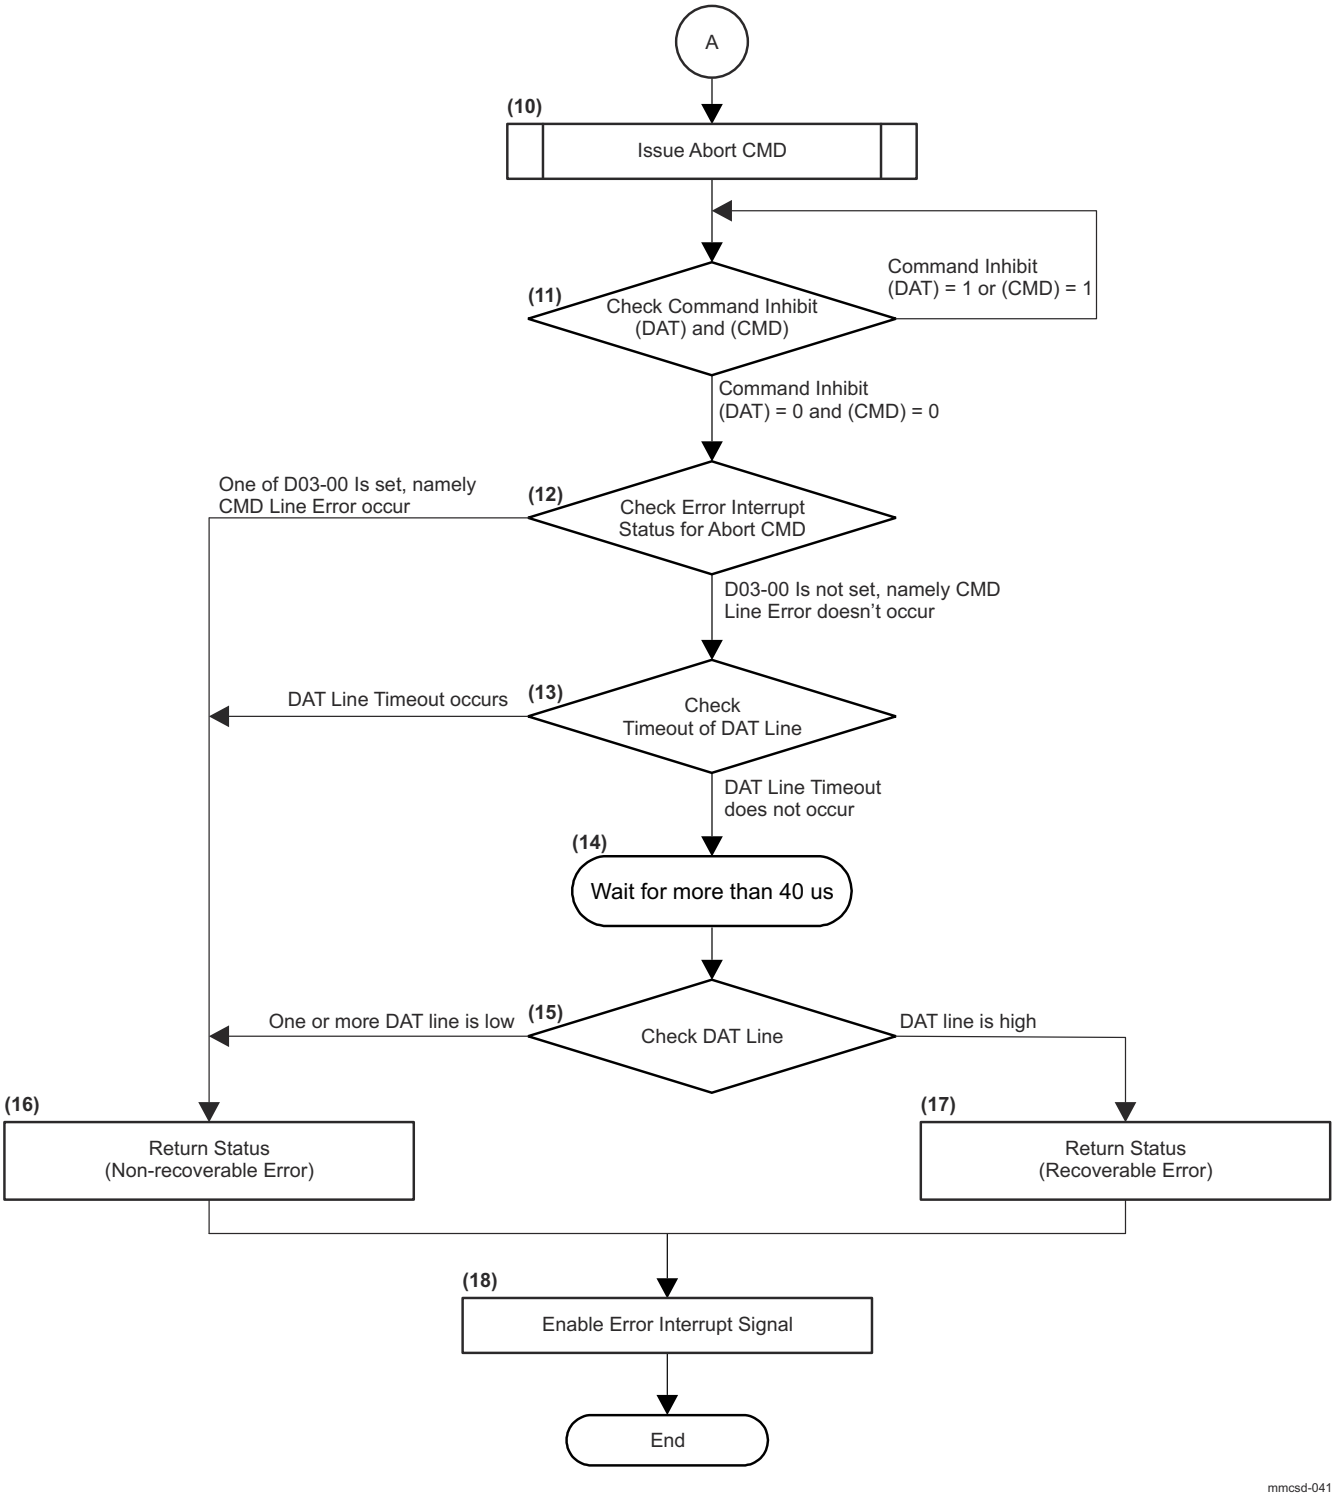

Figure 12-133. Error Interrupt Recovery Sequence (2)

(1) Disable the Error Interrupt Signal (MMCSD0_ERROR_INTR_SIG_ENA).

(2) Check bits D03-00 in the MMCSD0_ERROR_INTR_STS register. If one of these bits (D03-00) is set to 1, go to step (3). If none are set to 1 (all are 0), go to step (5).

(3) Set MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1.

(4) Check MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 0, go to step (5). If it is 1, go to step (4).

Copyright © 2023 Texas Instruments Incorporated

(5) Check bits D06-04 in the MMCSD0_ERROR_INTR_STS register. If one of these bits (D06-04) is set to 1, go to step (6). If none are set to 1 (all are 0), go to step (8).

(6) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.

(7) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (8). If it is 1, go to step (7).

(8) Save previous error status.

(9) Clear previous error status with setting them to 1.

(10) Issue Abort Command.

(11) MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit and MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit. Repeat this step until both MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit and MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit are set to 0.

(12) Check bits D03-00 in the MMCSD0_ERROR_INTR_STS register for Abort Command. If one of these bits is set to 1, go to step (16). If none of these bits are set to 1 (all are 0), go to step (13).

(13) Check MMCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT bit. If this bit is set to 1, go to step (16). If it is 0, go to step (14).

(14) Wait for more than 40 us.

(15) By monitoring the DAT [3:0] Line Signal Level in the MMCSD0_PRESENTSTATE register, judge whether the level of the DAT line is low or not. If one or more DAT lines are low, go to step (16). If the DAT lines are high, go to step (17).

(16) Return Status of "Non-recoverable Error".

(17) Return Status of "Recoverable Error".

(18) Enable the Error Interrupt Signal (MMCSD0_ERROR_INTR_SIG_ENA).

Copyright © 2023 Texas Instruments Incorporated

12.3.6.4.1.10.2 Auto CMD12 Error Recovery

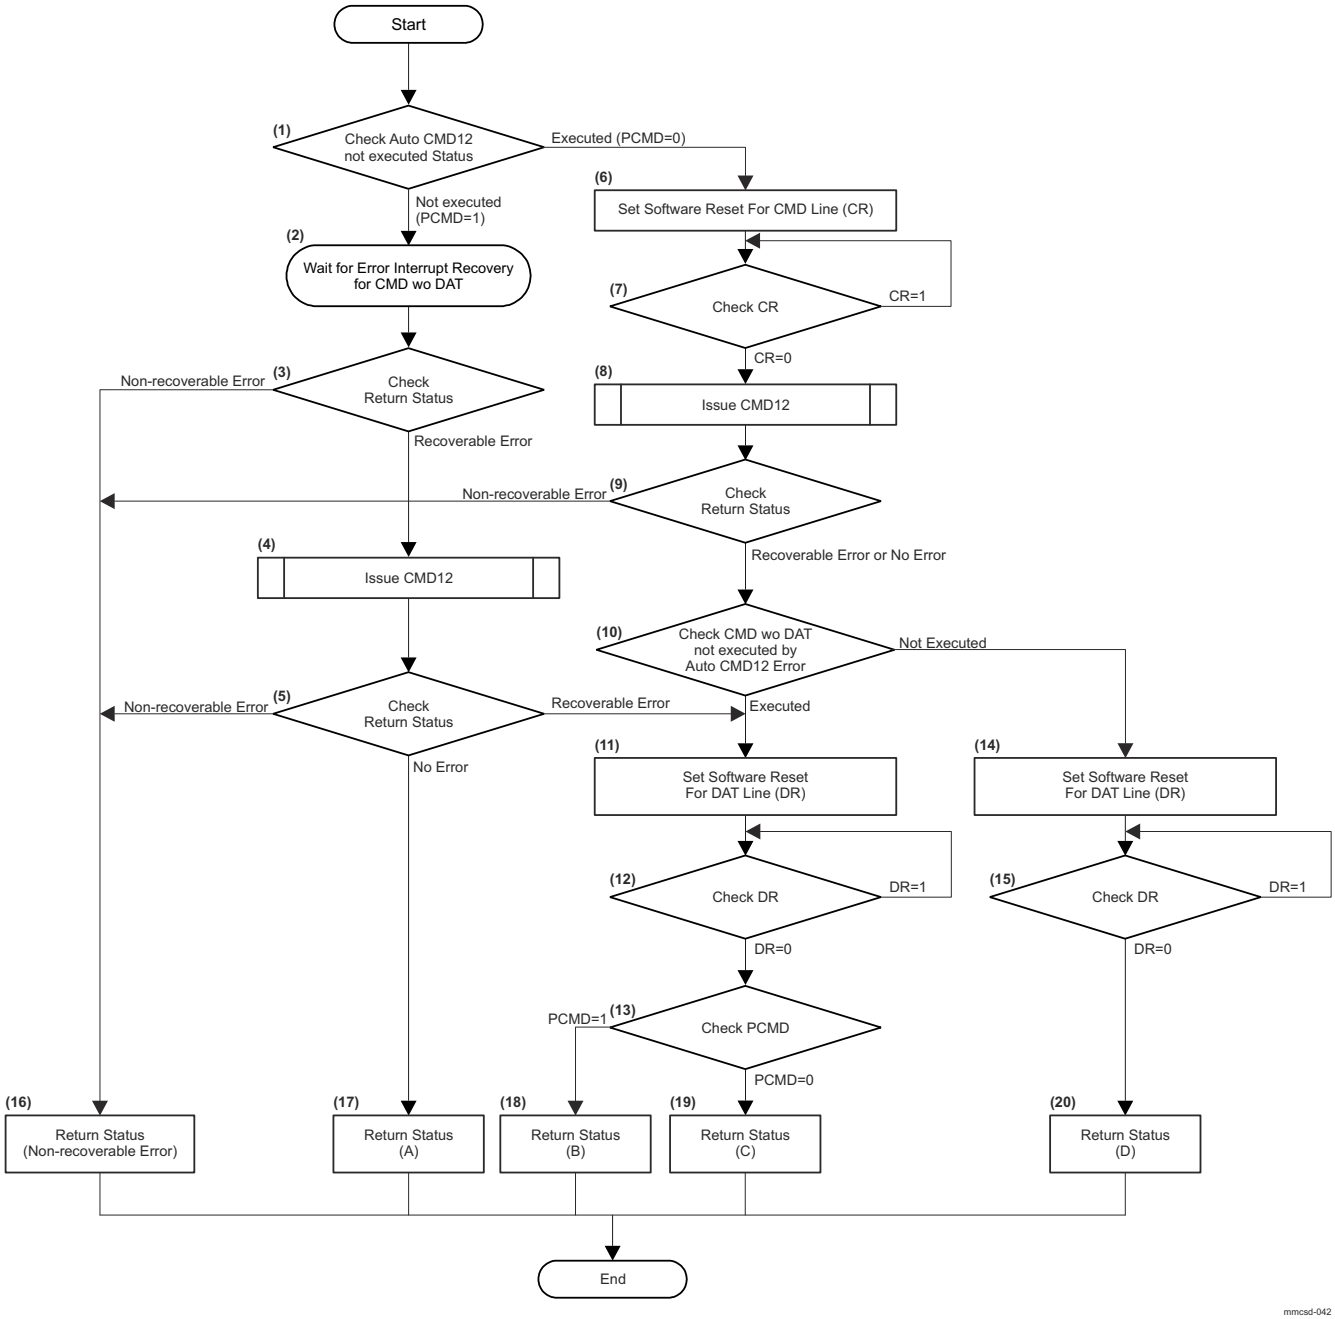

Figure 12-134. Auto CMD12 Error Recovery

The sequence for Auto CMD12 Error Recovery is shown in Figure 12-134. Following four cases A-D shall be covered.

A: An error occurred in CMD_wo_DAT, but not in the SD memory transfer.

B: An error occurred in CMD_wo_DAT, and also occurred in the SD memory transfer.

C: An error did not occur in CMD_wo_DAT, but an error occurred in the SD memory transfer.

D: CMD_wo_DAT was not issued, and an error occurred in the SD memory transfer.

(1) Check MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit. If this bit is set to 1, go to step (2). If this bit is set to 0, go to step (6). In addition, the Host Driver shall define PCMD flag, which changes to 1 if MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit is set to 1.

Copyright © 2023 Texas Instruments Incorporated

(2) Wait for Error Interrupt Recovery for CMD_wo_DAT.

(3) Check "Return Status". In the case of "Non-recoverable Error", go to step (16). In the case of "Recoverable Error", go to step (4).

(4) Issue CMD12 .

(5) If the CMD line errors occur for the CMD12 (one of D03-00 is set in the MMCSD0_ERROR_INTR_STS register), "Return Status" is "Non-recoverable Error" and go to step (16). If not CMD line error and busy timeout error occur (D04 is set in the MMCSD0_ERROR_INTR_STS register), "Return Status" is "Recoverable Error" and go to step (11). Otherwise, "Return Status" is "No error" and go to step (17).

(6) Set MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 for software reset of the CMD line.

(7) Check MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 0, go to step (8). If it is 1, go to step (7).

(8) Issue CMD12 . Acceptance of CMD12 depends on the state of the card. CMD12 may make the card to return to tran state. If the card is already in tran state, the card does not response to CMD12.

(9) Check "Return Status" for CMD12. If "Return Status" returns "Non-recoverable Error", go to step (16). In the case of "Recoverable Error" or "No error", go to step (10).

(10) Check the MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit. If this bit is 0, go to step (11). If it is 1, go to step (14).

(11) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.

(12) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (13). If it is 1, go to step (12).

(13) Check the PCMD flag. If PCMD is 1, go to step (18). If it is 0, go to step (19).

(14) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.

(15) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (20). If it is 1, go to step (15).

(16) Return Status of "Non-recoverable Error".

(17) Return Status that an error has occurred in CMD_wo_DAT, but not in the SD memory transfer.

(18) Return Status that an error has occurred in both CMD_wo_DAT, and the SD memory transfer.

(19) Return Status that an error has not occurred in CMD_wo_DAT, but has occurred in the SD memory transfer.

(20) Return Status that CMD_wo_DAT has not been issued, and an error has occurred in the SD memory transfer.

12.3.6.4.1.11 Wakeup Control (Optional)

After the Host System goes into standby mode, the Host System can resume from standby via a wakeup event initiated by one of the following three events:

(1) Interrupt from a SD card: If an SD card interrupt occurs, the Host System can resume from standby mode. If the Host System uses this wakeup factor, SD Bus power shall be kept on.

(2) Insertion of SD card: If a SD card is inserted, the Host System can resume from standby mode.

(3) Removal of SD card: If a SD card is removed, the Host System can resume from standby mode.

The sequence for preparing wakeup before the Host System goes into standby mode is shown in Figure 12-135.

Copyright © 2023 Texas Instruments Incorporated

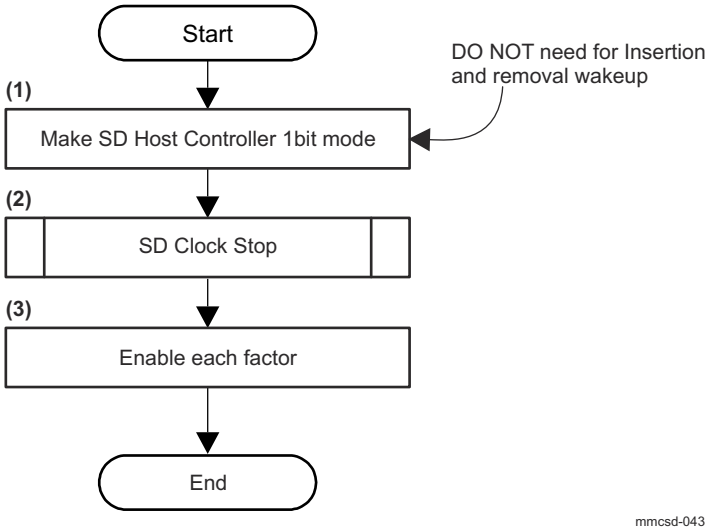

Figure 12-135. Wakeup Control before Standby Mode

(1) Set MMCSD0_HOST_CONTROL1[1] DATA_WIDTH bit to 0.

(2) Execute SD Clock Stop Sequence as described in Section 12.3.6.4.1.2.2, *SD Clock Supply and Stop Sequence*.

(3) Clear the MMCSD0_NORMAL_INTR_STS register and the MMCSD0_NORMAL_INTR_SIG_ENA register, and then set the enable bits of each wakeup event factor to 1 in the MMCSD0_WAKEUP_CONTROL register and set the bits of MMCSD0_ERROR_INTR_STS_ENA register to use wakeup.

The sequence for wakeup once in standby mode is shown in Figure 12-136.

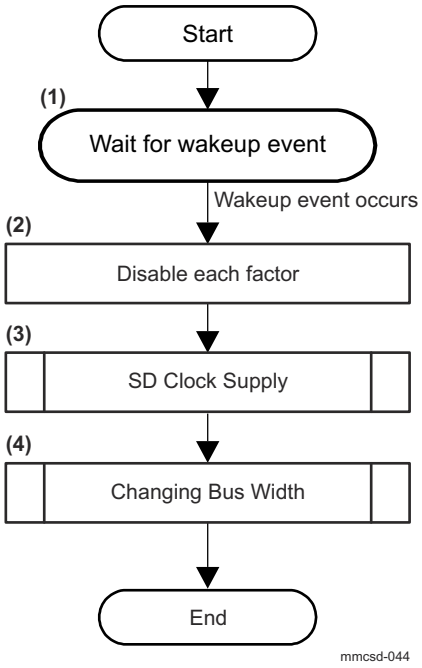

Figure 12-136. Wakeup from Standby

(1) Wait for wakeup event.

(2) Set the enable bits of each wakeup event factor to 0 in the MMCSD0_WAKEUP_CONTROL register and then clear event statuses in the MMCSD0_NORMAL_INTR_STS register. If necessary, set the MMCSD0_NORMAL_INTR_SIG_ENA register.

Copyright © 2023 Texas Instruments Incorporated

(3) Execute SD Clock Supply Sequence (see Section 12.3.6.4.1.2.2, *SD Clock Supply and Stop Sequence*).

(4) Set the SD Bus width (see Section 12.3.6.4.1.4, *Changing Bus Width*).

12.3.6.4.1.12 Suspend/Resume (Optional, Not Supported from Version 4.00)

If a SD card supports suspend and resume functionality, then the Host Controller can initiate suspend and resume. It is necessary for both the Host Controller and the SD card to support the function of "Read Wait". ADMA operation does not support this function.

12.3.6.4.1.12.1 Suspend Sequence

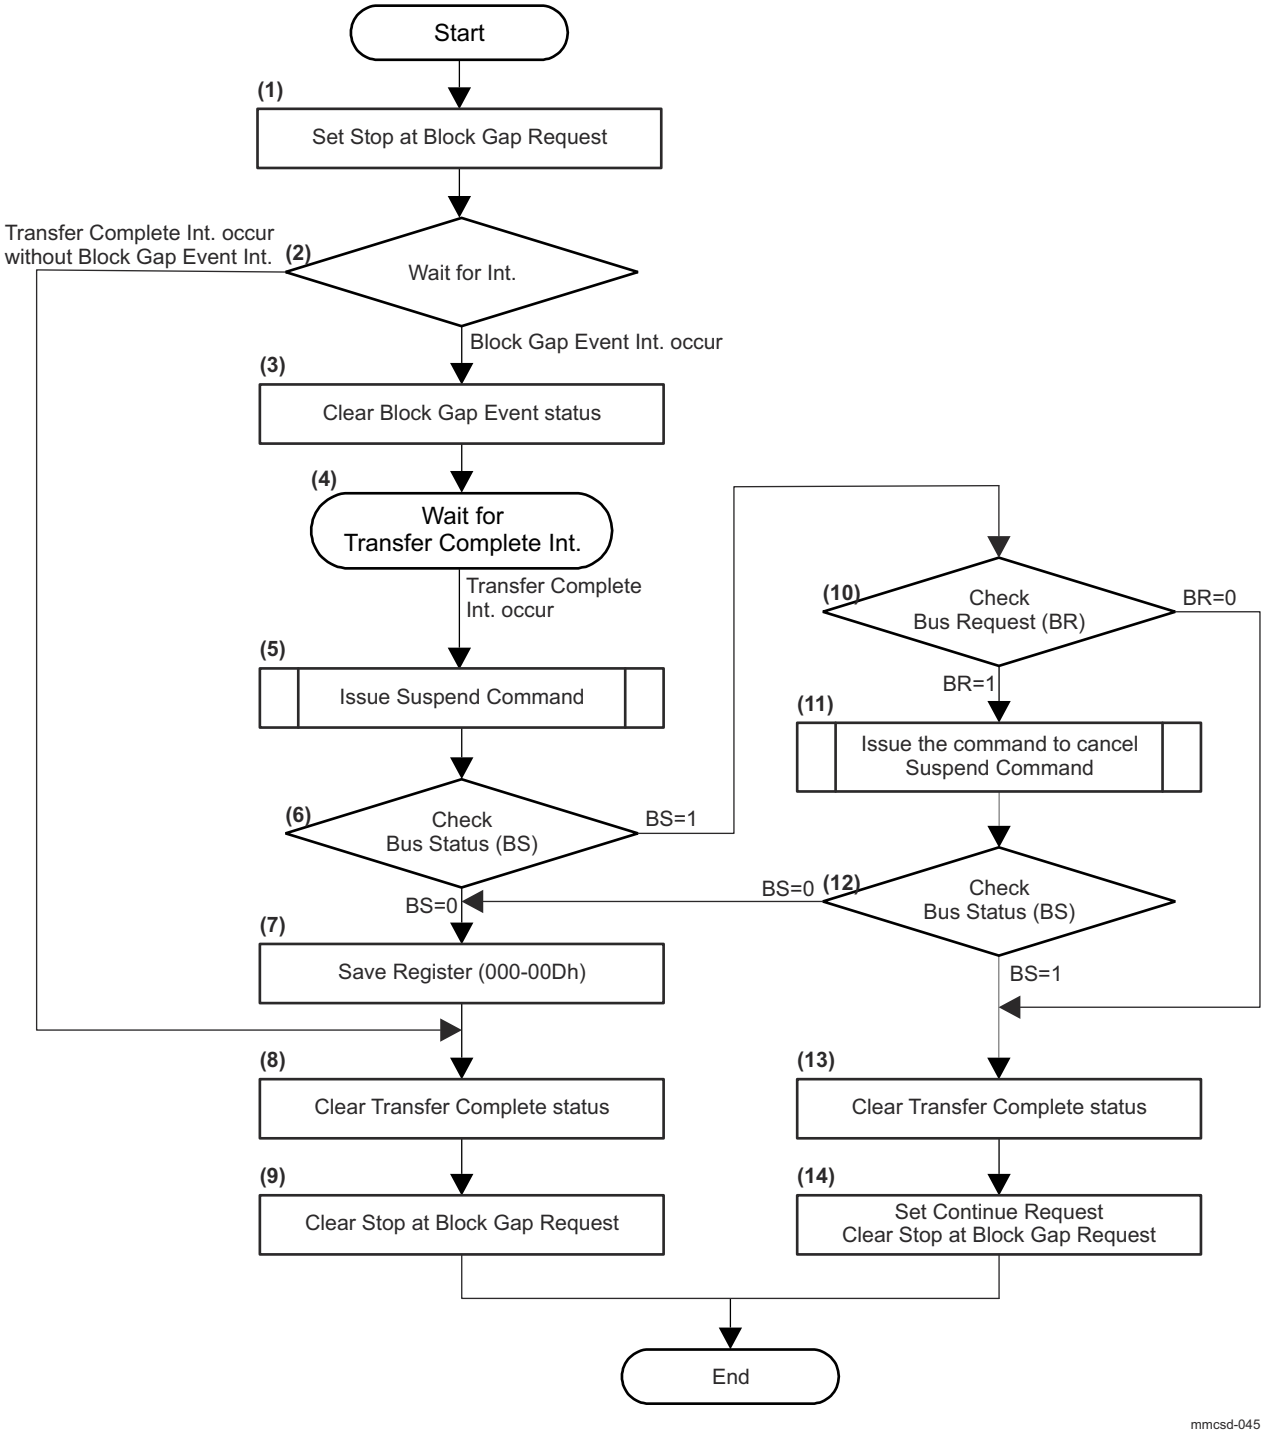

Figure 12-137. The Sequence for Suspend

Copyright © 2023 Texas Instruments Incorporated

(1) Set MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 1 to stop the SD transaction.

(2) Wait for an Interrupt. If MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit is set to 0 and MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit is set to 1, go to step (8). If MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit is set to 1, go to step (3).

(3) Set MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit to 1 to clear this bit.

(4) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).

(5) Issue the Suspend Command in accordance with Section 12.3.6.4.1.7.1, *Transaction Control without Data Transfer Using DAT Line*.

(6) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (10).

(7) Save the register .

(8) Set MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit to 1 to clear this bit.

(9) Set MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 0 to clear this bit.

(10) Check the BR value of the response data. If BR is 1, go to step (11). If BR is 0, go to step (13).

(11) Issues the command to cancel the previous suspend command in accordance with Section 12.3.6.4.1.7.1, *Transaction Control without Data Transfer Using DAT Line*.

(12) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (13).

(13) Set MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit to 1 to clear this bit.

(14) Set MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 to continue the transaction. At the same time, write 0 to MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to clear this bit.

Conditions			Suspend/Resume Function

Figure 12-138. Suspend/Resume Condition

Copyright © 2023 Texas Instruments Incorporated

12.3.6.4.1.12.2 Resume Sequence

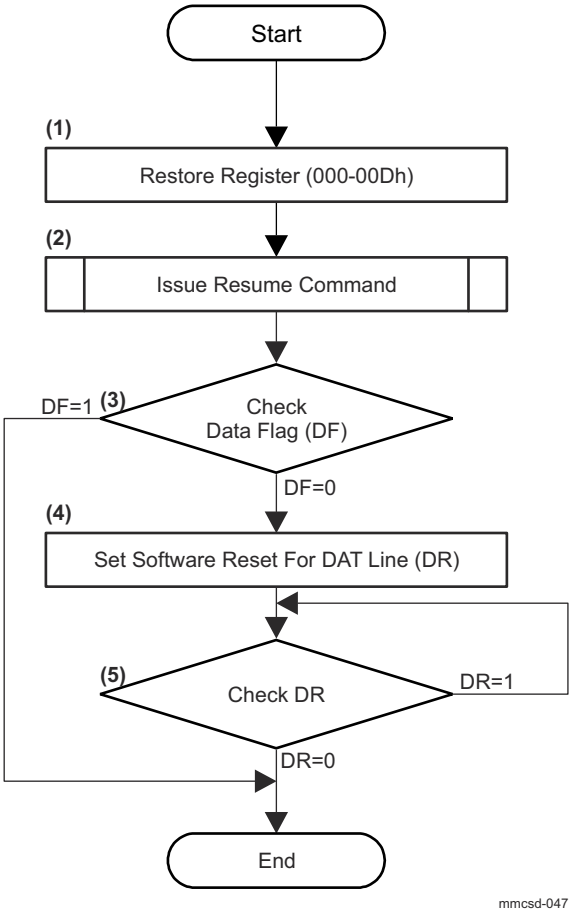

Figure 12-139. The Sequence for Resume

(1) Restore the register .

(2) Issue the Resume Command .

(3) Check the DF value of the response data. If DF is 0, go to step (4). If DF is 1, go to "End".

(4) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.

(5) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to "End". If it is 1, go to step (5).

12.3.6.4.1.12.3 Stop At Block Gap/Continue Timing for Read Transaction

The timing of Stop At Block Gap Request and Continue Request. The Transfer Complete interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE) is always generated by setting MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit where data transfer is stopped. However, generation of the Block Gap Event interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT) is dependent on whether the last data block is sent or not. Block Gap Event is not generated If all data blocks are transferred (the last block is transferred). It is not necessary to enable Block Gap Event interrupt. The status can be checked when transfer complete interrupt is detected. It is not necessary to use Continue Request (MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE) if Block Gap Event status is not set because there is no further data to be transferred. If Read Wait is not supported, Host Controller stops SD Clock at the block gap.

Implementation Note:

The MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL, MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE, MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bits shall be set and cleared by the Host Controller.

Copyright © 2023 Texas Instruments Incorporated

The MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set and cleared by the Host Driver. The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit shall be set by the Host Driver and be cleared by the Host Controller. The MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit and MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit shall be set by the Host Controller and be cleared by the Host Driver.

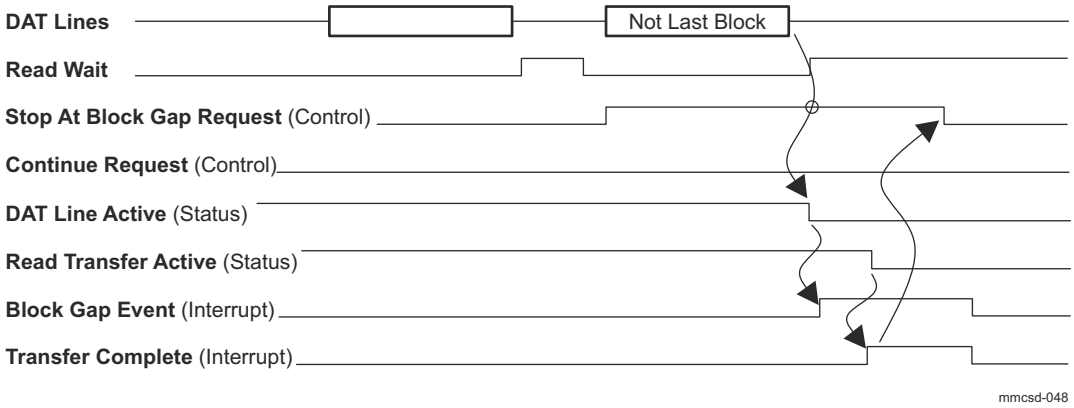

Figure 12-140. Wait Read Transfer by Stop At Block Gap Request

The Host Controller can accept a Stop At Block Gap Request (MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP) when all the following conditions are met.

(1) It is at the block gap.

(2) The Host Controller can assert read wait or it is already asserted.

(3) The MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL bit is set to 1.

After accepting the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit:

(1) Clear MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT).

(2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE).

(3) After accepting MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit, clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

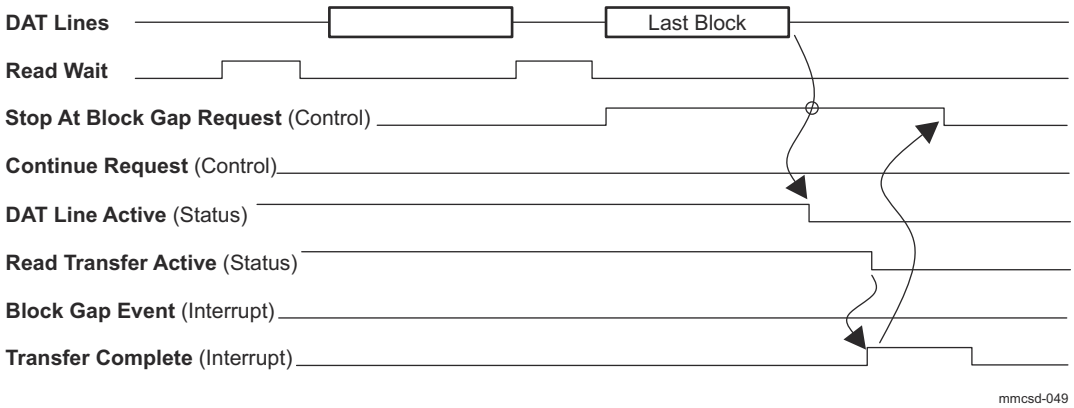

Figure 12-141. Stop At Block Gap Request is Not Accepted at the Last Block of the Read Transfer

If the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit and stops the transaction normally. The Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT) is not generated. When the Transfer

Copyright © 2023 Texas Instruments Incorporated

Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE) is generated, and if the MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit status is not set to 1, the driver shall clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

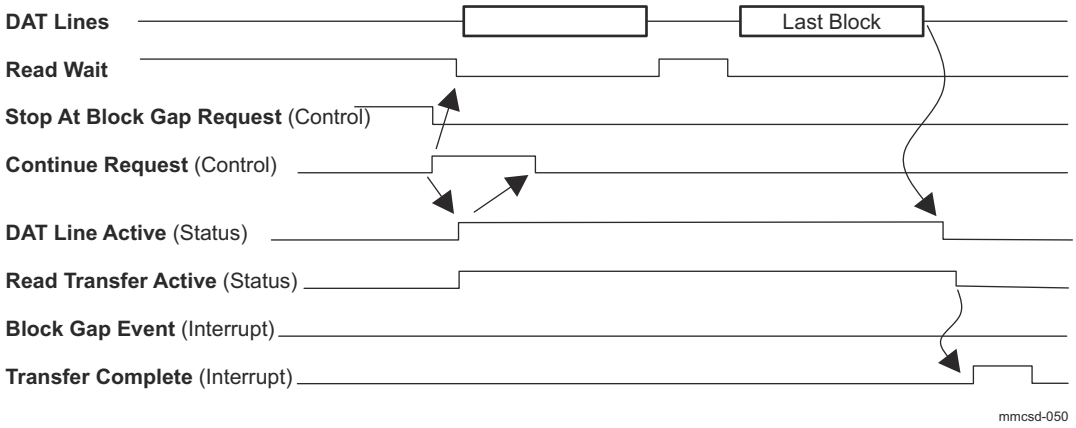

Figure 12-142. Continue Read Transfer by Continue Request

To restart a stopped data transfer, set the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 (the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set to 0).

After accepting the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit:

(1) Release MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL bit (if the data block can accept the next data).

(2) Set the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit.

(3) The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit is automatically cleared by (2).

The end of the read transfer is specified by data length.

(1) Clear the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and do not generate the Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit).

(2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit).

12.3.6.4.1.12.4 Stop At Block Gap/Continue Timing for Write Transaction

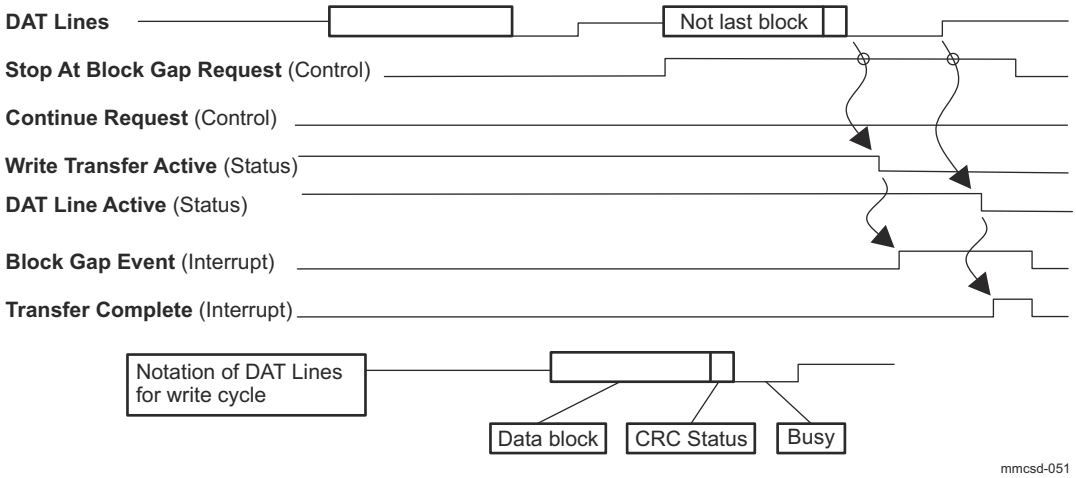

Figure 12-143. Wait Write Transfer by Stop At Block Gap Request

Copyright © 2023 Texas Instruments Incorporated

The Host Controller can accept the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit when matches all following conditions:

(1) It is at the block gap.

(2) No valid write data remains in the Host Controller.

After accepting the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

(1) Clear the MMCSD0_PRESENTSTATE[8] WR_XFER_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit).

(2) After the busy signal is released, clear the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit).

(3) After accepting the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit), clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

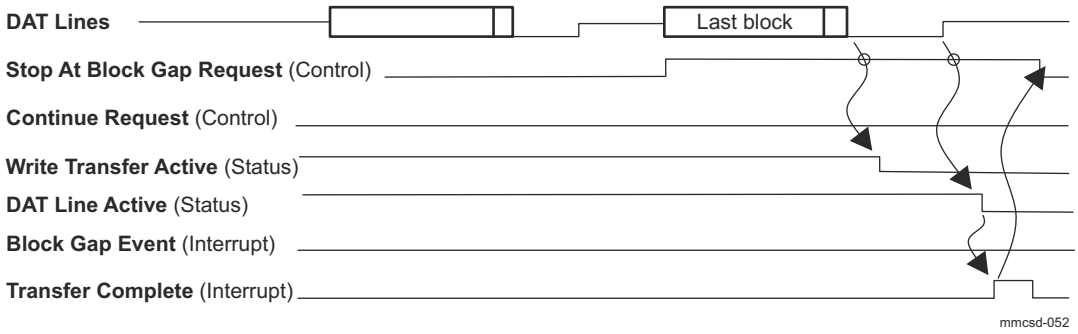

Figure 12-144. Stop At Block Gap Request is Not Accepted at the Last Block of the Write Transfer

If the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit and terminates the transaction normally. The Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE) is generated, and if the MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVEN bit is not set to 1, the driver shall clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

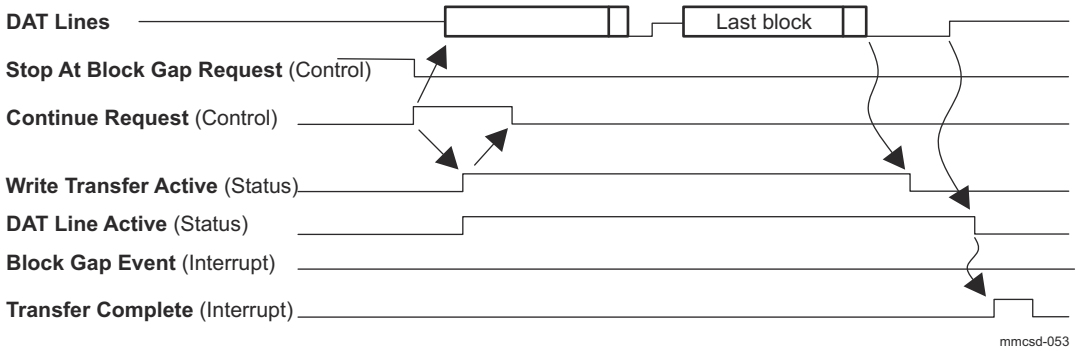

Figure 12-145. Continue Write Transfer by Continue Request

To restart a stopped data transfer, set the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 (the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set to 0).

After accepting the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit:

(1) Set the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and MMCSD0_PRESENTSTATE[8] WR_XFER_ACTIVE bit.

(2) The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit is automatically cleared by (1).

The end of transfer is specified by data length.

Copyright © 2023 Texas Instruments Incorporated

(1) Clear the MMCSD0_PRESENTSTATE[8] WR_XFER_ACTIVE bit, and do not generate the (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVEN).

(2) After the busy signal is released, clear the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and generates the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit).

12.3.6.4.2 Driver Flow Sequence

Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

Note

UHSII is not supported. For more information, see *MMCSD Not Supported Features*.

12.3.6.4.2.1 Host Controller Setup and Card Detection

12.3.6.4.2.1.1 Host Controller Setup Sequence

Figure 12-146 and Table 12-226 show a Host Controller setup sequence.

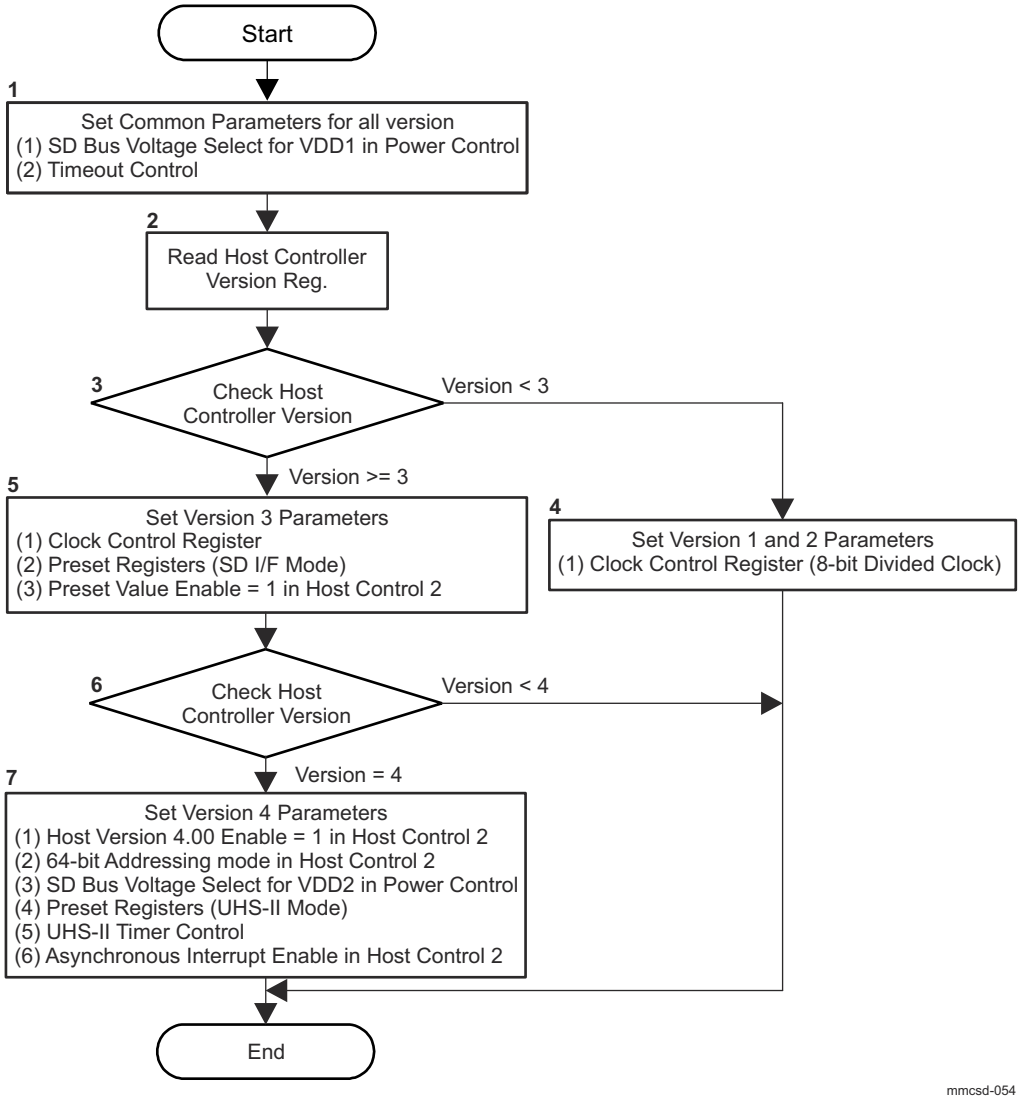

Figure 12-146. Host Controller Setup Sequence

Table 12-226. Host Controller Setup Sequence

Step	Description
1	Set parameters for all Host Controller version. Set the MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE and MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit fields.
2	Read the MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM bit field.

Copyright © 2023 Texas Instruments Incorporated

Table 12-226. Host Controller Setup Sequence (continued)

Step	Description
3	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is less than version 3, go to step (4), if it is version 3 or later go to step (5).
4	Set the MMCSD0_CLOCK_CONTROL register using 8-bit Divided Clock mode.
5	Set Version 3 parameters. The MMCSD0_CLOCK_CONTROL register is sets in 10-bit Divided Clock Mode or Programmable Clock Mode. If Clock Multiplier in the MMCSD0_CAPABILITIES register is not zero, Programmable Clock Mode should be used. If Preset Value is used, set Preset Values of SD I/F Modes in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set the MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit to 1.
6	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is version 4, go to step (7), if it is less than version 4, exits.
7	Set Version 4 parameters. Set the MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA bit to 1. If the MMCSD0_CAPABILITIES[27] ADDR_64BIT_SUPPORT_V4 bit is set to 1, set the MMCSD0_HOST_CONTROL2[13] BIT64_ADDRESSING bit to 1. If UHS-II Support is set to 1 and 1.8 V VDD2 Support is set to 1 in the MMCSD0_CAPABILITIES register, set SD Bus Voltage Select for VDD2 to 1.8 V mode in the MMCSD0_POWER_CONTROL register, set preset value for UHS-II Mode to Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set Timeout Counter Value for CMD_RES and Timeout Counter Value for Deadlock in the MMCSD0_UHS2_TIMER_CONTROL register based on Timeout Clock Frequency and Timeout Clock Unit in the MMCSD0_CAPABILITIES register. If Asynchronous Interrupt Support in the MMCSD0_CAPABILITIES register is set to 1, set Asynchronous Interrupt Enable to 1 in the MMCSD0_HOST_CONTROL2 register.

12.3.6.4.2.1.2 Card Interface Detection Sequence

This procedure is invoked by the Card Insertion interrupt. Figure 12-147 and Table 12-227 show a card interface detection sequence.

Copyright © 2023 Texas Instruments Incorporated

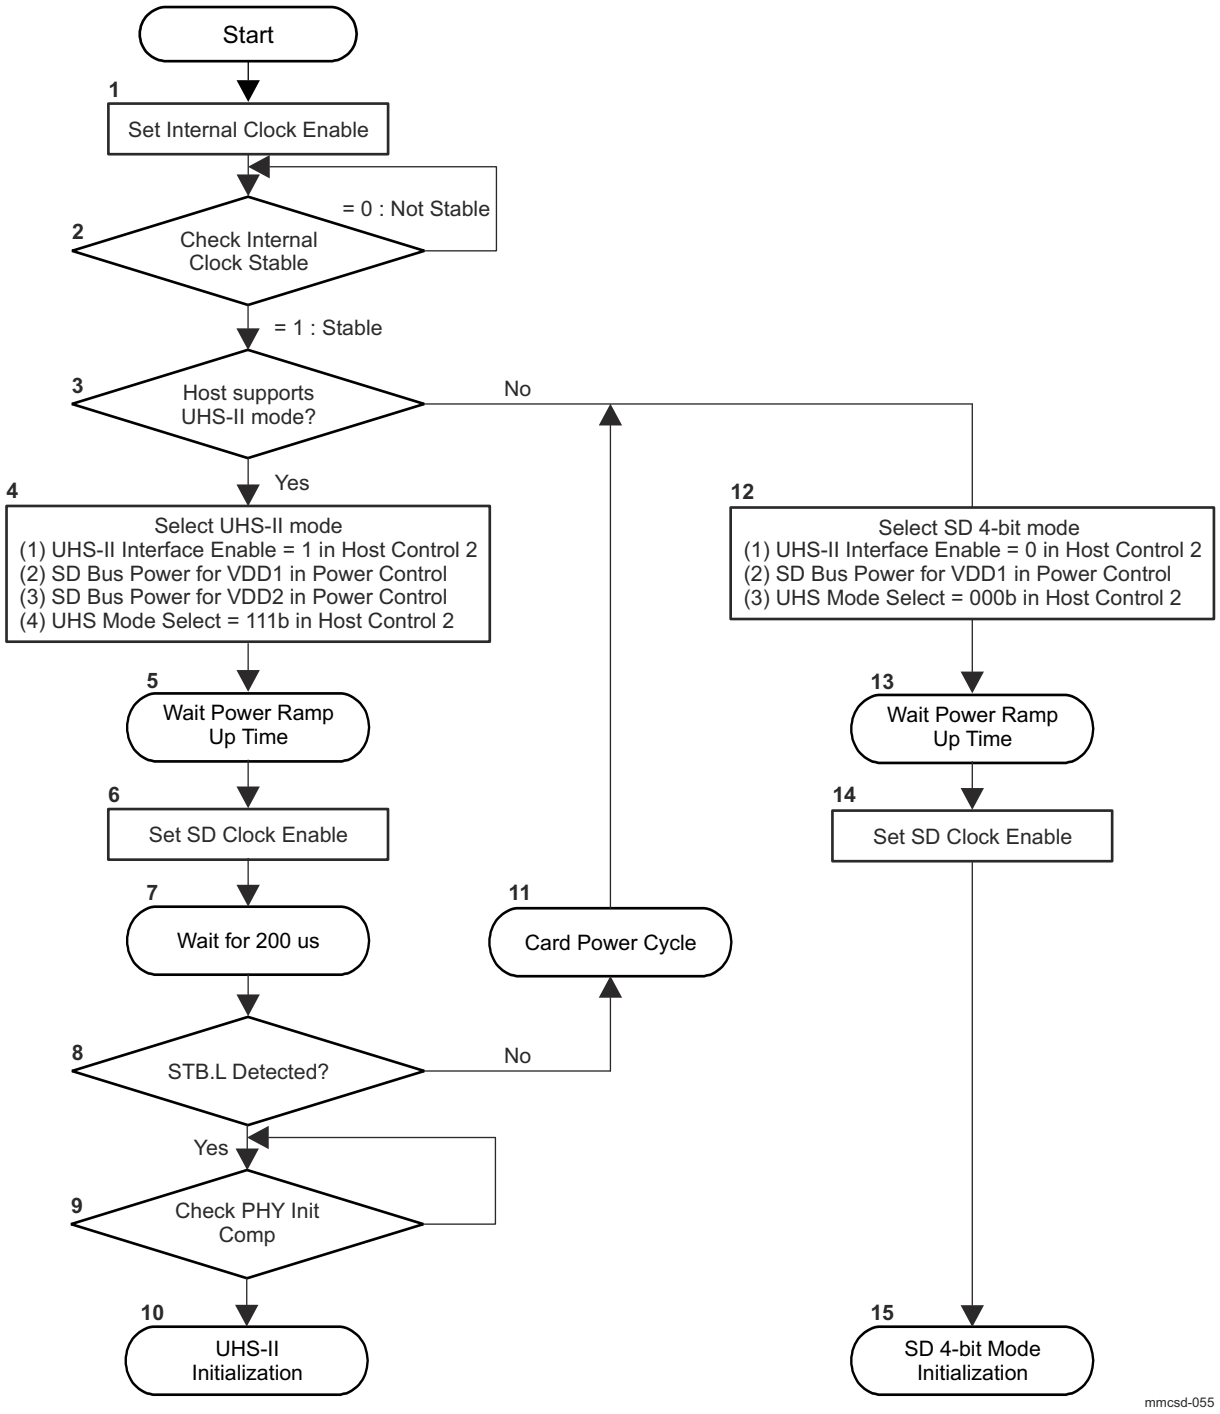

Figure 12-147. Card Interface Detection Sequence

Table 12-227. Card Interface Detection Sequence

Step	Description
1	Set Internal Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
2	Wait until Internal Clock Stable is set to 1 in the MMCSD0_CLOCK_CONTROL register.
3	If Host Supports UHS-II, go to step (4) else go to step (12).
4	Try to initialize a card to UHS-II mode. Set UHS-II Interface Enable to 1 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 and SD Bus Power for VDD2 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 111b in the MMCSD0_HOST_CONTROL2 register.
5	Wait power ramp up time. It is dependent on a Host System.
6	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.

Copyright © 2023 Texas Instruments Incorporated

Table 12-227. Card Interface Detection Sequence (continued)

Step	Description
7	Wait 200 µs to check a card supports UHS-II mode.
8	Check STB.L Detection in the MMCSD0_PRESENTSTATE register. If UHS-II IF is detected, go to step (9). If UHS-II IF is not detected, go to step (11).
9	Wait until Lane Synchronization in the MMCSD0_PRESENTSTATE register is set to 1 (PHY Initialization is completed).
10	Perform UHS-II initialization.
11	Perform card power cycle.
12	Try to initialize a card to SD 4-bit mode. Set UHS-II Interface Enable to 0 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 000b in the MMCSD0_HOST_CONTROL2 register.
13	Wait power ramp up time. It is dependent on a Host System.
14	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
15	Perform SD 4-bit mode initialization. Refer to Section 12.3.6.4.1.6, *Card Initialization and Identification (for SD I/F)*.

12.3.6.4.2.2 Boot Operation

The boot operation sequence is shown in Figure 12-148.

Copyright © 2023 Texas Instruments Incorporated

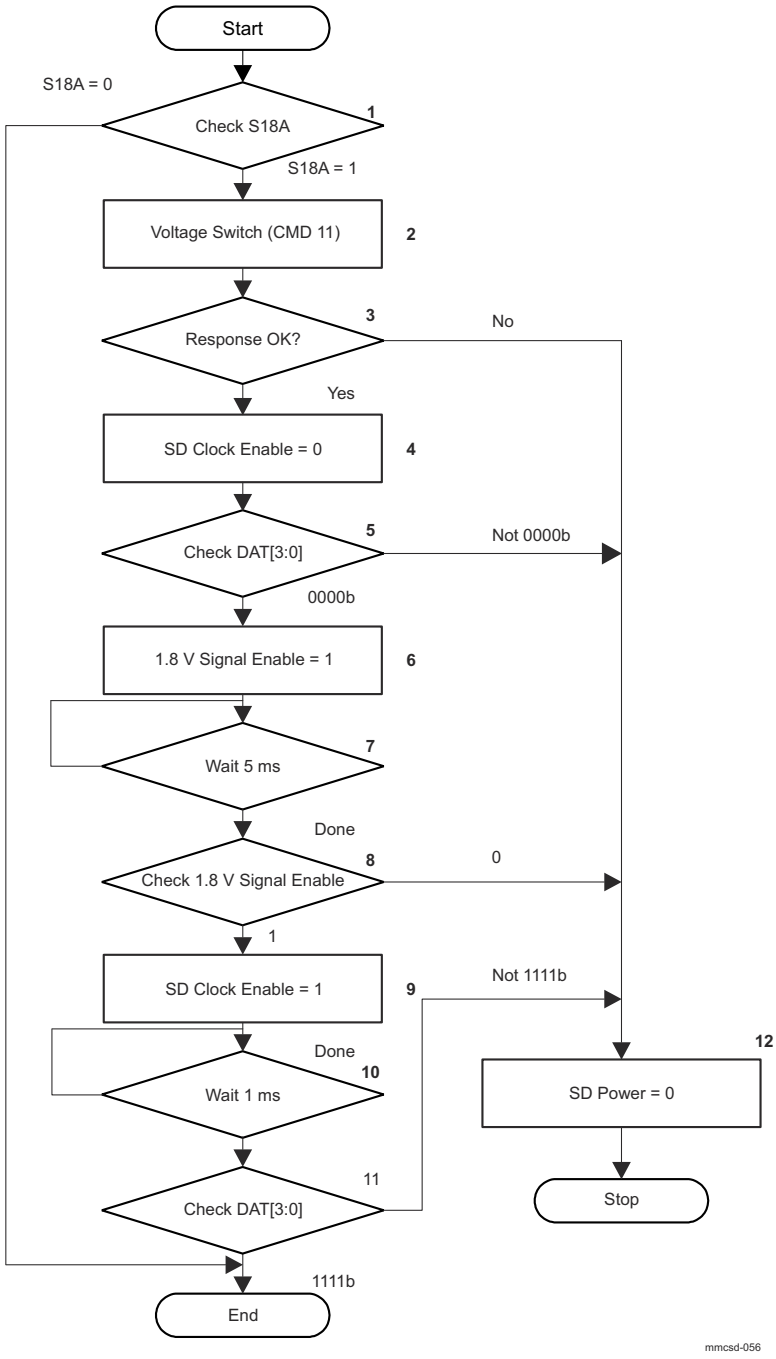

Figure 12-148. Boot Operation Sequence

12.3.6.4.2.2.1 Normal Boot Operation: (For Legacy eMMC 5.0)

The Host driver writes the boot timeout value into MMCSD0_BOOT_TIMEOUT_CONTROL register as per the eMMC4.3+ spec.

When the Host driver sets the "BOOT_ENABLE" to 1 in MMCSD0_BLOCK_GAP_CONTROL register and "DATA_XFER_DIR" bit to "1" in MMCSD0_TRANSFER_MODE register, the Host controller drives the CMD line to "0" for boot operation.

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV_BOOT_ACK" interrupt to the driver (MMCSD0_NORMAL_INTR_STS[13] RCV_BOOT_ACK). If the Host controller doesn't receive the boot acknowledgement from the device within the timeout value, the Host controller will assert the data timeout error interrupt (MMCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT).

Copyright © 2023 Texas Instruments Incorporated

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the MMCSD0_BOOT_TIMEOUT_CONTROL register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The Host controller terminates the boot operation when the programmed number of blocks is transferred to the System. The Driver can writes "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register.

The boot operation can also be terminated in between the boot transfer (the Driver can set the "BOOT_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, the Host controller asserts soft reset for CMD line and DATA line internally once the driver clears the BOOT_COMPLETE interrupt (MMCSD0_NORMAL_INTR_STS[14] BOOT_COMPLETE), to reset all the state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (ignore sending abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgement to the Host, the Host controller will assert Data CRC Error interrupt (MMCSD0_ERROR_INTR_STS[5] DATA_CRC) on the Driver. In this case, the Host driver has to stop the boot mode operation by setting "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller will assert Data End Bit Error interrupt (MMCSD0_ERROR_INTR_STS[6] DATA_ENDBIT) on the Driver.

The Host driver stops the boot mode operation by setting "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

Note: Enable the MMCSD0_BLOCK_GAP_CONTROL[7] BOOT_ACK_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

12.3.6.4.2.2.2 Alternate Boot Operation (For Legacy eMMC 5.0):

The Host driver writes the boot timeout value as per the eMMC4.3+ spec into MMCSD0_BOOT_TIMEOUT_CONTROL register.

If the "ALT_BOOT_MODE" and "BOOT_ENABLE" is set to 1 in MMCSD0_BLOCK_GAP_CONTROL register and "DATA_XFER_DIR" bit is set to 1 in MMCSD0_TRANSFER_MODE register, the host controller drives the CMD0 (0xFFFFFFFA) on the CMD line.

The system shall wait for command complete interrupt before "RCV_BOOT_ACK" interrupt (MMCSD0_NORMAL_INTR_STS[13] RCV_BOOT_ACK).

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV_BOOT_ACK" interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The System needs to send CMD0 to inform the device about the boot operation complete. The system shall program MMCSD0_COMMAND register with argument "00000000h" for the CMD0 and waits for command complete.

The Host controller terminates the boot operation when the programmed number of blocks are transferred to the System and the Driver shall send CMD0 to eMMC card and then program "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register.

The boot operation can be terminated at any time (the Driver can send CMD0 and set the "BOOT_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, all state machines in the Host controller need to move to IDLE state. The Host controller asserts the soft reset for CMD and data line internally when the driver clears the BOOT_COMPLETE interrupt (MMCSD0_NORMAL_INTR_STS[14] BOOT_COMPLETE) and all the state machine goes to the idle state.

If the Host controller doesn't receive the acknowledgement from the device with in timeout value the Host controller will assert the data timeout error interrupt (MCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT).

The driver programs the MMCSD0_BOOT_TIMEOUT_CONTROL register with boot data timeout value.

Copyright © 2023 Texas Instruments Incorporated

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above. If the device sends wrong acknowledgement to the Host, then Host controller will assert Data CRC Error interrupt to the Driver (MCSD0_ERROR_INTR_STS[5] DATA_CRC). The Host driver has to stop the boot mode operation by setting "ALT_BOOT_MODE" and "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller asserts Data End Bit Error interrupt (MCSD0_ERROR_INTR_STS[6] DATA_ENDBIT) on the Driver. The Host driver stops the boot mode operation by setting "ALT_BOOT_MODE" and "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

Note: Enable the MMCSD0_BLOCK_GAP_CONTROL[7] BOOT_ACK_ENA bit during boot operation . If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

12.3.6.4.2.2.3 Boot Code Chunk Read Operation (For Legacy eMMC 5.0):

The following figure explains the boot code read done as chunks of data (the Driver can read the boot data as 2K, 4K, 1K and 8K etc. instead of 128K at a time

Copyright © 2023 Texas Instruments Incorporated

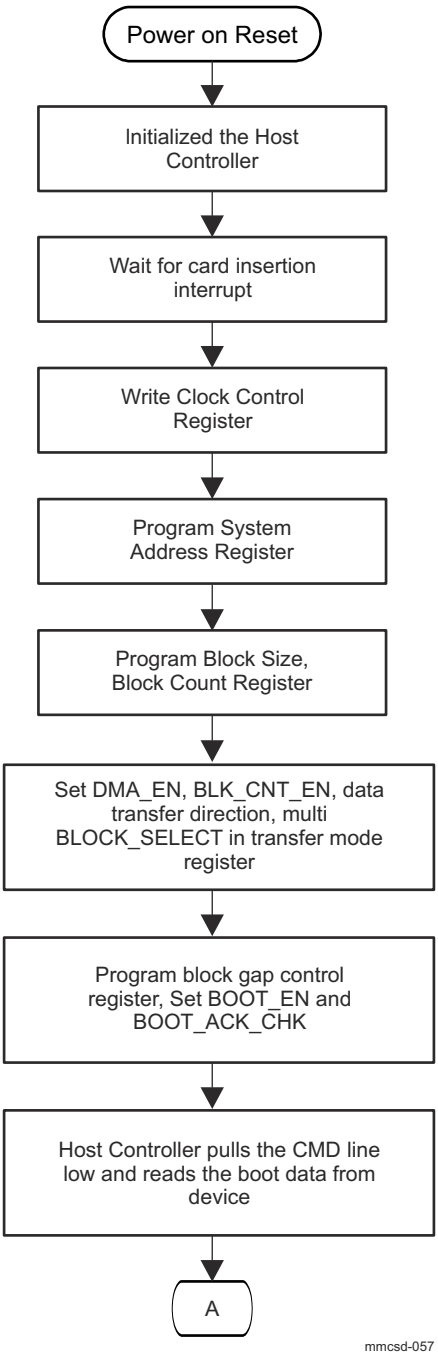

Figure 12-149. Boot Code Access Flow Diagram (1)

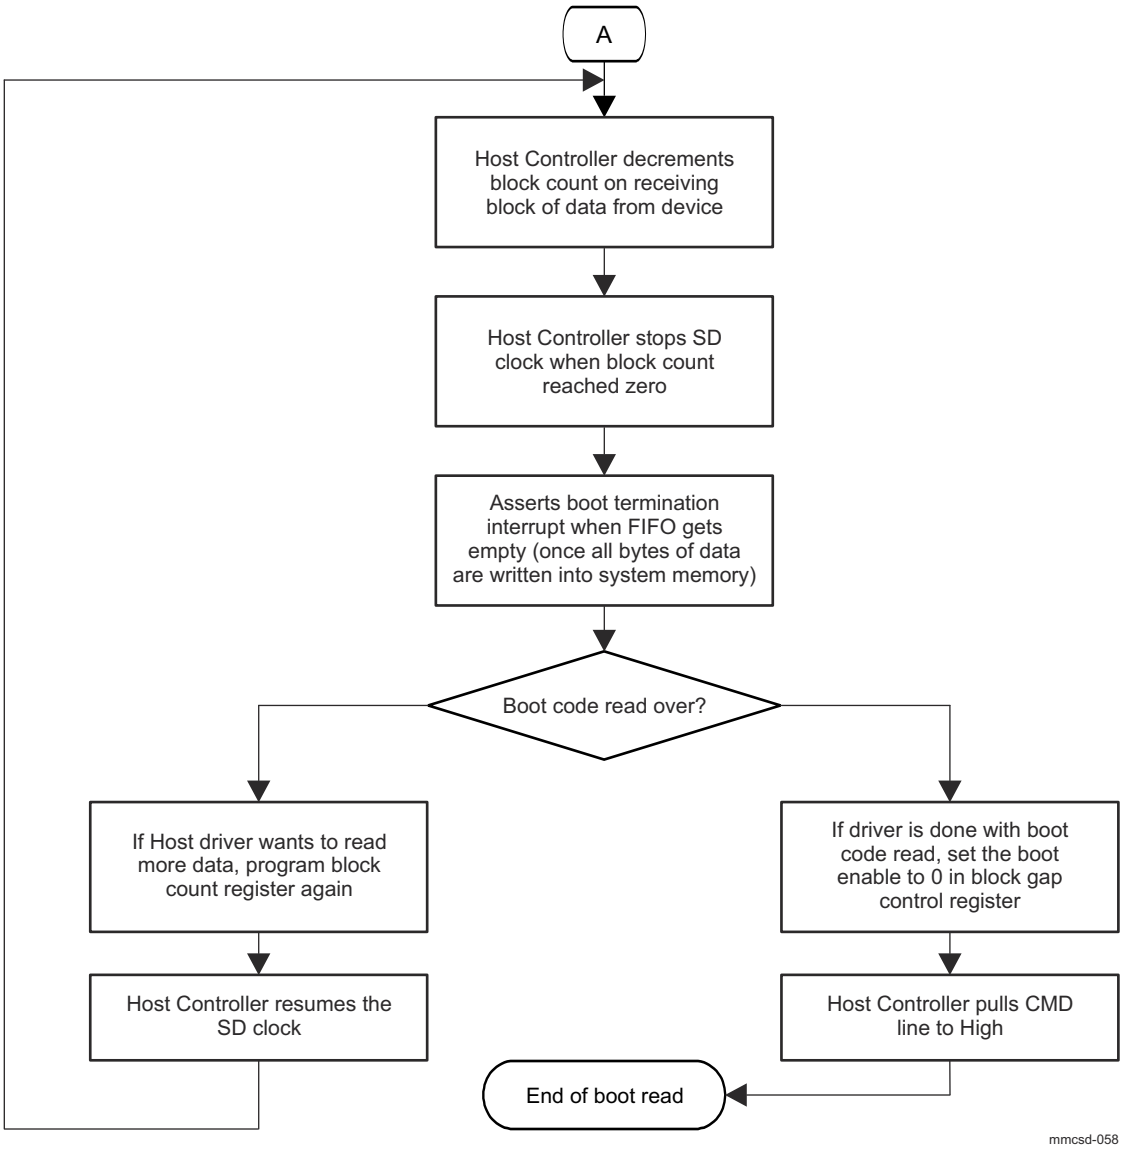

Figure 12-150. Boot Code Access Flow Diagram (2)

12.3.6.4.2.3 Retuning procedure (For Legacy Interface)

12.3.6.4.2.3.1 Sampling Clock Tuning

The SD bus can be operating in high clock frequency mode and then the data window from the card on CMD and DAT[3:0] lines gets smaller. The position of the data window will vary depending on the card and host system implementation. Therefore, the Host Controller shall support a tuning circuit when SDR104 or SDR50.
